ALBERT PILÁT:

Hymenomycetes novi vel minus cogniti Čechoslovakiae, II.

(Allatum 19. I. 1952)

In tractatu meo praesenti seriem secundam adnotationum* ad fungos quos ipse annis 1951—52 legi vel quos ab amicis meis e diversis regionibus Čechoslovakiae obtinui.

Anni 1951 et 1952 siccii erant, qua de causa mycologis parum fecundi. Attamen species novas vel rarissimas vel mance compertas observavi, eas descripsi et iconibus arte photographica depictis illustravi.

In supplemento diagnoses latinae specierum novarum Polyporacearum, quarum descriptiones in opere meo „Polyporaceae“ in Atlas des Champignons de l'Europe, vol. III., annis 1936—1942 edito, solum in lingua čechica et gallica publicavi, versantur.

Amanita Vittadinii (MORETTI, 1826) VITTADINI, Cf. GILBERT in BRESADOLA, Icon. Mycol. vol. XXVII, p. 374—377, t. 59—60, 1941, — *Lepidella Vittadinii* (MORETTI) GILBERT. (Fig. 1.)

Species in Europa media et australi et Africa boreali (Algeria) distributa, sed rara, in Europa media rarissima. In Čechoslovakia rarissime prope Pragam invenitur cf. specimina in Krombholz, Naturgetreue Abbildungen und Beschreibungen der Schwämme, 1836, IV:17, t. 27.). Anno 1938 unum exemplar Pragae (Vyšehrad) Jar. Petrbok legit. In. Moravia meridionali et Slovakia meridionali probabiliter locis plurioribus adest. M. Deyl in Slovakia meridionali 10. X. 1951 in collibus stepposis solo andesitico prope Kováčov haud procul Šturovo, specimina legit et mihi donavit. Teste collectore haec species ibi haud rara sit et quotannis obvia. Incolae huius districti in magna multitudine carposomata huius fungi colligunt et in foris olitorii, praecipue in Šturovo vendunt. Sporas in specimibus, quas amicus M. Deyl collegerat, subglobosas, laeves, subhyalinas 9—11, 5×8—9,5 μ magnas observavi.

Limacella guttata (FR.) SINGER. (Fig. 2.)

Hanc speciem, in Čechoslovakia sat raram, in montibus Carpaticis, Slovakiae centralis, in monte Polana, ca 1800 m s. m. solo andesitico in Pi-

Kováčov prope Šturovo, Slovakiae merid., 10. X. 1951, loco stepposo, leg. M. Deyl.

ceto virgineo 26. VIII. 1951 observavi. Specimen pulchrum, sed unicum et optime evolutum, quod legi, arte photographica depinxi. Pileus huius speciminis 55 mm diam., viscidus, levis glaberque, pallide ochraceus, cacumine obscurior, huc illuc paulum albopruinosus, late conicus, margine haud rimoso, anguste sterili et lamellas paulisper superanti et huc illuc paulum subinvoluto. Lamellae confertae, humiles, liberae. Stipes cylindraceus, solidus, basi vix incrassatus, praecipue dimidio superiori paulum subtiliter griseo- vel luteo-griseo-squamulosus. Annulus membranaceus, subitus laevis et fuscidulus, supra albus vel griseo-maculatus, non striatus. Caro alba, in stipite fibrillosa, sapore paulum adstringenti et odore debili, farinaceo.

Lepiota Wichanskýi PILÁT sp. n. (Fig. 3—11. Tab. I.)

Pileo 4—5 cm diam., e semigloboso convexo, dein plano, adulto saepe margine elevato, exumbonato vel umbone parvo et humili ornato, ex albido mox pallide ochraceo tinctu carneo, cacumine plerumque fragmanto uno et sat magno albo et arachnoideo, cuti pilei agglutinato pra-

Agaricus chionodermus PILÁT. (Fig. 22. Tab. IV. a—b.)

Speciem commemoratam in tractatu meo "The Bohemian Species of the Genus Agaricus", Acta Musei Nationalis Pragae, VII B: No. 1, pp. 101, t. III, XIV, XV, XVI, fig. 60, 1951, descripsi et illustravi.

In localitate originali prope Karlštejn Bohemiae centralis in Picetis solo calcareo iterum 2. VII. 1951 et 16. VIII. 1951 specimina pulchra huius speciei collegi et viva arte photographica depinxi.

Agaricus Annae PILÁT. (Fig. 25—27. Tab. V.)

Hanc speciem in tractatu meo "The Bohemian Species of the Genus Agaricus", Acta Musei Nationalis Pragae VII B: No. 1, p. 73, 1951 descripsi. Iterum hunc fungum (3 specimina) in Picetis solo calcareo prope Karlštejn, haud procul domum venatoriae „Amerika“, Bohemiae centralis, 27. VI. 1951 inveni. Specimina commemorata a typo paulum discrepant. Probabiliter *Agaricus Annae* PILÁT et *Agaricus silvaticus* var. *pallens* PILÁT (l. c., p. 67 speciem unam representant.

Descriptio et icones speciminum anno 1951 collectorum sequuntur: Pileus angulato-semiglobosus, convexus, 6 cm diam., dein convexo-explanatus et ca 10 cm diam. metiens, ad fundamentum albido vel album squamis subtiliter fibrillosis, ochraceo-fuscis tinctu rubeolo, cacumine confluentibus, parte tertia hemidiametri maximis, ad marginem minutioribus tectus. Lamellae primum roseae, dein obscurae. Stipes cylindraceus, 50—60 × 20—24 mm, albus tinctu debili rosaceo, subtiliter (magis parte inferiori) squamulosus, basi haud bulbosus, rotundatus. Annulus membranaceus, albus, iuventute (dum pileus clausus est) subitus ad pilei marginem verrucis floccoso-squamosis et rubro-fuscidulis ornatus. Caro pilei sat crassa, rubescens. Sporae $8,5-9,2 \times 5,5 \mu$, ellipsoideae et apiculatae. Cheilocystidia in acie lamellarum copiosa, clavato-piriformia, hyalina et tenuiter tunicata, $45-55 \times 18-28 \mu$. Basidia tetraspora.

Fungus Agarico silvatico similis, sed colore conspecte pallidiori, sporis majoribus et squamis subtilioribus ad fundamentum fere album dispositis in pilei superficie ornatus.

Agaricus edulis VITT. (Fig. 28—29. Tab. VI.)

Specimina pulcherrima huius speciei in Bohemia rarae anno 1951 e localitatibus sequentibus perscrutavi:

1. Praha-Dejvice, in horto publico e via asphalto tecta erumpens, 20. V. 1951 legit Ivan Charvát.
2. In urbe Brno, Moraviae, 1. VII. 1951, legit Bohuslav Nevěčný.
3. Moravia: Skalní Mlýn prope Blansko, 3. VI. 1951, legit Ing. Landkammer.

Nonnulla specimina collecta iconibus arte photographica depictis illustrata sunt.

Agaricus perdicinus PILÁT sp. n. (Fig. 24, 30—34. Tab. VII.—X.)

Synonymia:

Psalliota meleagris J. Schaeffer f. „Rebhuhnchampignon“ in Michael-Hennig-Schaeffer, Führer für Pilzfreunde, Leipzig 1939.

Agaricus meleagris J. Schaeff. var. *perdicinus* Pilát, in Actis Musei Nationalis Pragae, vol. VII. B. No. 1, p. 108, 1951.

Pileus iuvenilis subcampanulatus, pallide brunneus, haud squamosus, sed mox, centro excluso, in squamas sat magnas, adpressas, pallide brunneas fundamento albido insidentes diffractus; pileus semiadultus 9—10 cm diam., regulariter convexus, solum centro applanatus usque paulisper depresso, maturus subplanus et centro subplanus vel depresso, squamis sat magnis, pallide brunneis tinctu debili purpurino (cacao et coffea cum lacte combinatae) modo Agarici silvatici obtectus. Squamae adpressae, subtiliter fibrillosae, parte media pilei hemidiametri usque 5 mm latae, marginem versus minores, magis fibrilosae; cacumen pilei haud in squamas diffractus, squamis concolor. Margo pilei lamellas paulum membranaceo-superans.

Lamellae iuveniles pallidae, dein roseo-cacaina, chocolateae, maturitate subnigrae, sed numquam conspecte roseae, subconfertae, liberae. Stipes sat crassus et subbrevis, maturus anguste cavus, 12—15 cm longus, 6—7 mm crassus, basi incrassatus, saepe subbulbosus et ibi usque 25 mm crassus, albus vel albidus, sericeo-fibrillosus, tritus vel sectus parum lutescens, saepe fere immutabilis, aetate vel tactu vulneratus dimidio inferiore superficie paulisper lutescens (et mox color luteus brunnescens). Bulbus minime lutescit.

Annulus magnus, membranaceus, mollis, superus, superficie sublaevis vel minime irregulariter rimosus, subtus irregulariter squamosus, tenuis, mox collapsus et stipiti agglutinatus.

Caro alba, sat mollis, in pileo subcrassa (usque 11 mm), secta minime lutescens, maxime in parte stipitis inferiori (bulbo excluso, ubi fere alba). Color luteus mox in colorem pallide fuscum vel brunneum mutatur. Odor debilis, terreus, sed haud innamoenus, sapor subacidus, haud inamoenus. Cheilocystidia in acide lamellarum numerosa, globoso-piriformia, 12—20 μ crassa et 20—27 μ longa.

Basidia tetraspora, 15—20 \times 5—6 μ .

Sporae breviter ellipsoideae, basi oblique in apiculum contractae, uniguttulatae, 5,5—6 \times 3,5—3,6 μ .

Hab. Bohemia, Praga, in horto publico „Kinského sady“, 3 exemplaria, 28. V. 1951, Ing. Benda legit. Iam anno 1950 ex eadem localitate specimina huius speciei 15. IX. 1950 lecta a collectore citato obtinui.

Fungus hic in localitate citata teste Ing. Benda quotannis crescit. Specimina bene evoluta in tractatu meo “The Bohemian Species of the Genus *Agaricus*”, Acta Musei Nationalis Pragae, vol. VII. B. p. 109—111, fig. 63—65, 1951, arte photographica depinxi. Fungus noster in localitate citata Pragensi semper constans est, numquam mutatur et haud variat, habitu valde insignis, qua de causa semper facile determinabilis. Non dubito, quin species bona sit! Ab *Agarico meleagri* J. Schaeffer squamis multo majoribus, pallide brunneis, stipite crassiori relativiterque breviori et carne minime lutescenti facile dignoscitur.

Fig. 35. *Agaricus macrosporus* (M. et S.) PILÁT.
Modřany u Prahy, 28. IX. 1952.

Fungus noster *Agarico placomyces* Peck, speciei americanae, affinis est, sed non identicus. Comparavi iconem bonam photographicam in tractatu A. H. Smith, The Genus *Agaricus*, Pap. Michig. Acad. 25 : 125, t. IX, 1940 cum fungo nostro vivo. Species americana citata squamas pilei multo parviores habet et carposomata etiam habitu paulum discrepant.

***Agaricus macrosporus* (MOELLER et SCHAEFFER) PILÁT.** Cf. Pilát, The Bohemian species of the genus *Agaricus*, Acta Musei Nationalis Pragae, vol. VII B, No. 1 1951, pp. 78—80. (Fig. 35—41.)

Syn. *Psalliota arvensis* subsp. *macrospora* Moell. et Schaeff. 1938, — *Psalliota augusta* sensu Ricken non Fr. 1914. *Psalliota villatica* sensu Lange non alliorum 1939. — *Psalliota collina* Velenovský, Novitates Mycologicae p. 152, 1939. — ? *Agaricus crocodilinus* Murrill, Mycologia 4 : 300, t. 77, 1912.

Anno 1952 tria collecta huius speciei, in Bohemia haud rarae, per-scrutavi:

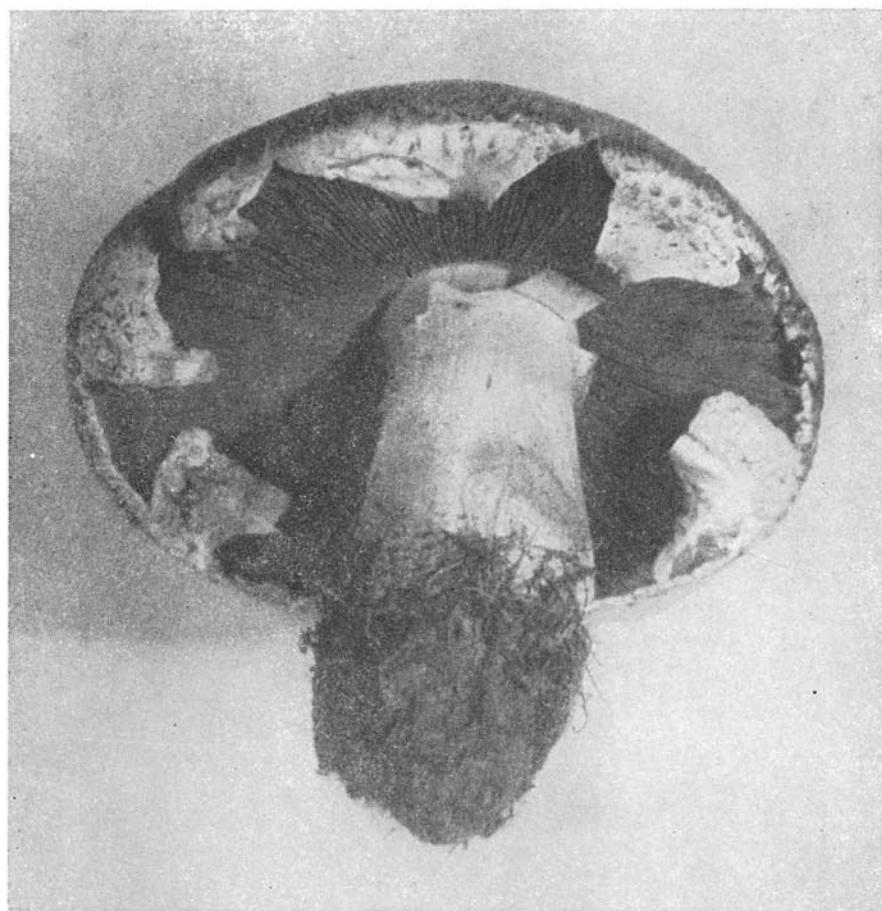

Photo A. Pilát.

Fig. 36. *Agaricus macrosporus* (M. et S.) PILÁT.
Modřany u Prahy, 28. IX. 1952.

1. In prato prope Dobříš carposomata optime evoluta 15. VI. 1952
V. Nejedlo legit.

2. In prato silvatico prope Příbram 10. X. 1952 carposomata senilia
in magna multitudine (circulos magicos formantia) observavi.

3. Modřany prope Pragam, 28. IX. 1952.

Fungus conspectus, magnus et crasse carnosus.

Pileus iuvenilis subglobosus, dein plus quam semiglobosus, cacumine
paululum applanatus, statu semiclauso ca 13 cm diam., expansus usque
25 cm, albus, dein pallide ochraceus, siccus parte marginali squamulis
subtilibus adpressis, pallide ochraceis fundamento albo ornatus, cacumine
levis, cute continua pallide ochracea tinctu viridulo tectus, haud lucidus
vel solum minime sericeus.

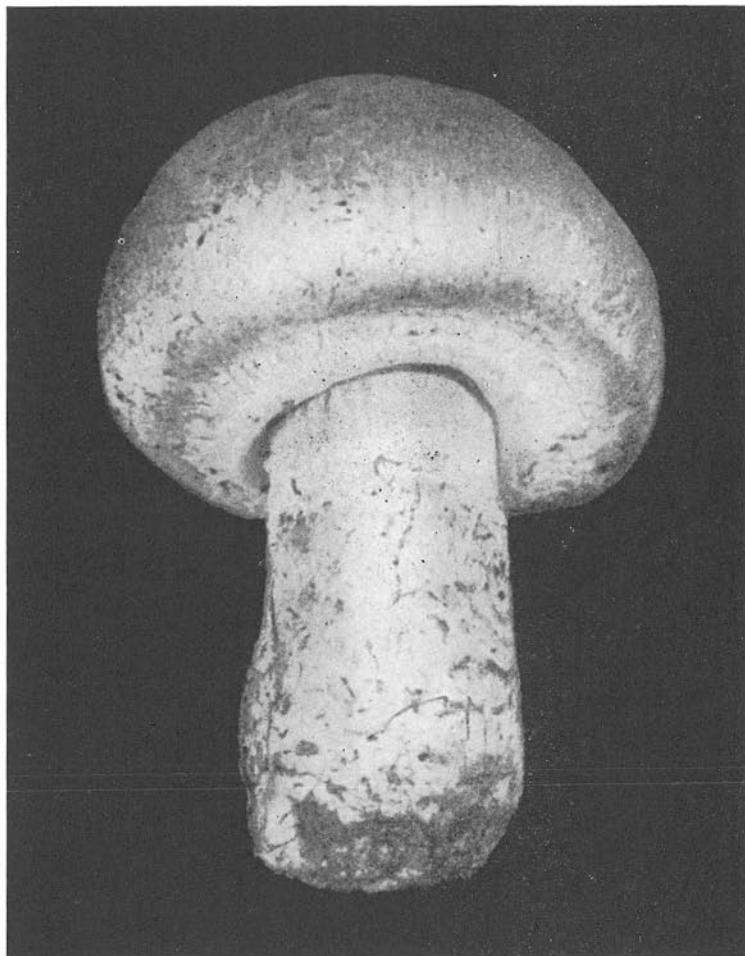

Photo A. Pilát.

Fig. 37. *Agaricus macrosporus* (M. et S.) PILÁT.
Modřany u Prahy, 28. IX. 1952.

Lamellae diu pallide griseo-rubeolae, dein griseo-chocolateae, confertae et relativiter angustae.

Stipes albus, dein basi pallide ochraceo-fuscescens, ca diametri pilei aequilongus, usque 45 mm crassus, basi paululum angustatus, sericeo-fibrillosus, solidus, demum cavus, parte tertia superiore annulo instrutus. Annulus magnus conspectusque, crassé membranaceus, subtus grosse radialiter fibrilloso-diffractus, subtus marginem paululum ferrugineo-fuscidulus, superne levis, sed paululum confragoso-rugosus. Pars stipitis supraannularis alba.

Caro stipites firma, pilei mollior, alba, locis vulneratis paulum ferrugineo-fuscidula (haud conspecte lutescens ut in *Agarico arvensi*), odore

Agaricus Deylpii PILÁT, Acta Musei Nationalis Pragae vol. VII. B. (1951)
No. 1, p. 53. (Fig. 42—44.)

Tria carposomata adulta huius speciei rarae in Piceto solo calcareo supra „Vodopády“ prope Karlštejn Bohemiae centralis solo calcareo 29. VI. 1952 Ing. Landkammer et Z. Pouzar legerunt.

Haec species *Agarico Benešii* Pilát proxime affinis videtur, sed sporis majoribus, carposomatibus robustioribus, magis carnosis, stipite relativiter breviori et crassiori discrepat. Etiam squamulae in pilei superficie serius tincto sordide subochraceo colorantur, contra in *Agarico Benešii* Pilát pileus fere stabiliter albus est.

Pileus 6—10 cm diam., semiglobosus, candidus, in squamulas minutissimas, agglutinatas, apice subtilime fibrilosas et sparsas praecipue

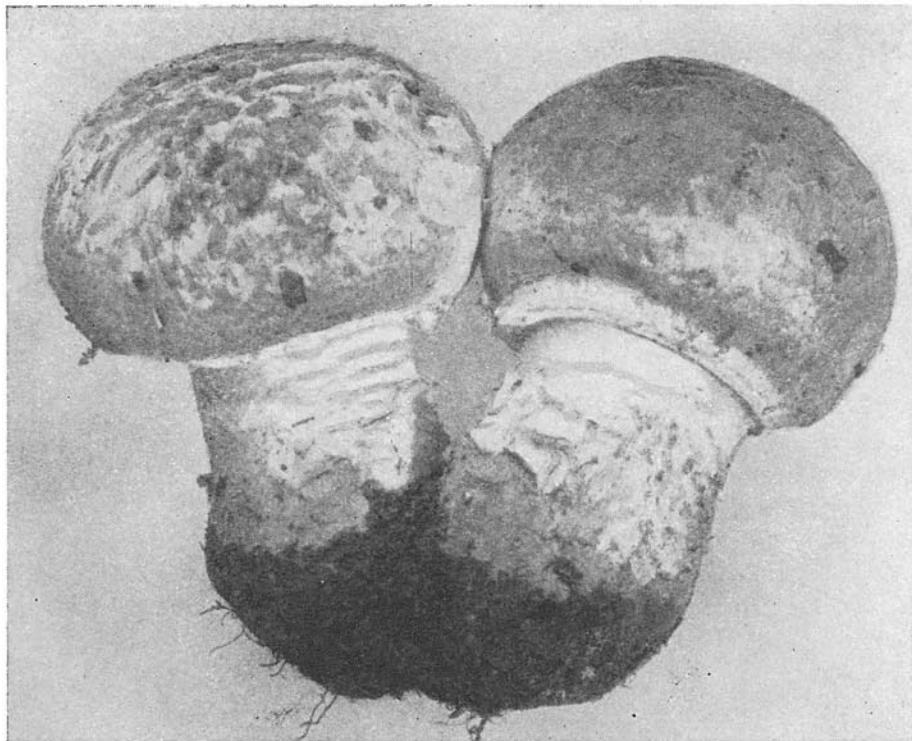

Photo A. Pilát.

Fig. 41. *Agaricus macrosporus* (M. et S.) PILÁT.
Modřany prope Praga, 28. IX. 1952.

parte marginali solutus, cacumine haud umbonatus, levis, serius tinctu ochraceo fuscescenti et eodem tempore etiam squamulae colore pallide ochraceo inhalatae sunt.

Lamellae primum pallide rosaceae, dein griseo-roseae, denique cholateae. Stipes 10—11 × 2—2,5 cm, cylindraceus, demidio inferiori paululum crassior, sed basi haud tuberosus, potius angustato-rotundatus, albus, subtiliter fibrilloso-squamulosus, solidus, dein centro paululum cavus, profunde in terra (ca 1/3 totius longitudinis) submersus, parte quarta superiore annulo membranaceo, albo, sat magno, subtus levi, superne paululum rugoso et solum margine, denticulato-squamuloso instructus (solum stratum eius inferius denticulatum est, stratum eius superiorius margine rotundatum).

Caro secta praecipue parte superiore stipitis modo intensivo tinctu salmoneo rubescit, caro pilei solum parum, dein potius tinctu salmoneo-ferrugineo coloratur.

Basidia tetraspora. Cheilocystidia in acie lamellarum late clavata, subpiriformia, tenuiter tunicata, 9—18 μ crassa.

Sporae ellipsoideae, 9—9,5 × 4,5 μ .

Agaricus Benešii PILÁT. (Fig. 45.)

Specimen unum huius speciei rarissimae uxor mea Anna in Piceto prope „Fontem regis“ haud procul Karlštejn, Bohemiae centralis, substrato calcareo, 16. X. 1952 legit.

Pileus huius speciminis 5 cm diam., semigloboso-convexus, albus, squamulis parvis albidoisque, apice paulisper griseolo-fuscidulis ornatus est. Haec squamulae parte pilei marginali magis conspicuae et majores sunt, quam in pilei cacumine. Margo pilei membranaceo-involutus est.

Stipes adultus cavus, conspecte longus et curvulatus, 10 cm longus et 13 mm crassus, basi paulum incrassatus et ibi solum 15 mm crassus et rotundatus, tota superficie albus et sericeo-sublucidus, parte inferiore tactu paululum luteo-rufescens et minime fibrilloso-squamulosus, apice albus tinctu debili rosaceo et parte superiori ($\frac{1}{5}$ — $\frac{1}{6}$ totius longitudinis)

Photo A. Pilát.

Fig. 45. *Agaricus Benešii* PILÁT.
Karlštejn, 15. X. 1952 in Picetis solo calcareo, 15. X. 1952, leg. Anna Pilátová.

annulo membranaceo, parte superiori substriato et margine dentato ornatus.

Caro stipitis parte superiori, tramae lamellarum et tramae pilei supralamellaris aëre cito et conspecte vinoso-rubescit, partis stipitis inferioris paulum et ibi potius tincto luteo-rufescenti coloratur. Caro secta sat fibrillosa et lucida. Color ruber carnis aëre sat cito expallescit. Odor amoene fungineus, sapor mitis.

Lamellae liberae, confertae, iuveniles roseae, tum griseo-salmoneae, dein obscurae.

Cheilocystidia in acie lamellarum sat crebra et parva, hyalina, $30 \times 10-14 \mu$. Basidia tetraspora.

In turfosis Blata prope Soběslav, Bohemiae merid.,
19. XI. 1951, leg. Fr. Kotlaba.

Coprinus velatus QUÉL., Ass. fr. 1883, p. 4, t. 6, f. 9.! Flore Mycol. p. 50, 1888.! SACCARDO, Syll. Fung. 5:1087, 1887. — JUILLARD-HARTMANN, Icon. 4:t. 153 f. 6. — LANGE Fl. Ag. Dan. 4:111, t. 158A (f. *substerilis* Lange). (Fig. 47.)

Pileus e glandiformi cylindraceo-campanulatus, dein magis expansus, 15—20 mm altus et 12—15 mm latus, plumbeo-griseus, hygrophanus, lamellis translucescentibus, siccus albidus, tota superficie velo albo, facillime detersibili, primum tomentoso, dein in squamulas fibrilloosas soluto iuventute totus obtectus.

Lameliae ex albo pallide roseae, maturae nigrae.

Stipes niveus, sericeo-lucidus, minime fibrilloso-squamulosus, levis, cylindraceus, 40—70 mm longus et ca 5 mm crassus.

Basidia hyalina, ca 9 μ crassa.

Sporae in cumulo nigrae, sub microscopio nigro-brunneae, breviter ovoideae vel globoso-ovoideae usque subcordiformes, basi apiculo paululum oblique posito munitae et apice poro germinativo lato instructae, 8,5—9,5 \times 6—6,5 μ .

Hab. ad ligna putridissima *Fagi silvaticae* L. in monte andesitico Połana prope Detva, Slovakiae (Slovenské Krušnohoří), ca 1250 m s. m., duo carposomata 25. VI. 1952 A. Pilát legit.

Species rarissima Queletiana anno 1883 e Gallia descripta. Serius eam Lange in Dania legit. Specimina danica e descriptione et icona Langei fere sterilia, qua de causa paululum atypica sunt. Fungus noster optime fertilis est et stipitem fere laevem et glabrum habet. In ceteris cum descriptione Langei concordat.

Quoque *Coprinus extinctorius* (Bull.) Fr., qui raro ad ligna putrida vere fructificat, affinis est. Pileum album, plus minusve pilosum, cacumine fasciculis parvis fibrillarum nigrobrunnearum ornatum habet. Sporae eius breviter amygdaliformes vel subnaviculares, 8,2—11 \times 5,7—7,5 μ sunt. Cf. Romagnesi in Revue Mycologique, 6:112, 1941. *Coprinus extinctorius* sensu Ricken t. 23/3, teste Romagnesi, cum *Copriño glo-bisporo* sensu Romagnesi identicus est.

Psathyra corrugis (PERS.) QUÉL. [*Psathyra gracilis* var. *corrugis* (PERS.) LANGE.] (Fig. 48.)

In foliis deiectis ad terram in colle „Studený vrch“ prope Stříbrná Skalice, Bohemiae centralis, 11. XI. 1951, leg. Dr. Kubička et Z. Pouzar.

Fungus bohemicus cum icona et descriptione Langei bene concordat. Pileus iuvenilis glandiformis, dein e conico-parabolico late conicus, cacumine obtuse umbonatus, tota superficie, praecipue maturitate, subtiliter radialiter sulcatus, primum fuscus, dein conspecte pallidior, pallide griseo-fuscus vel tinctu debili caesio vel carneo, rarius usque albide alutaceus. Lamellae subangustae, angustato-adnatae, maturae nigrogriseae tinctu debili violaceo, acie albidae. Stipes longus et tenuis, paulum undulatus, 80—140 μ longus et 2—3 mm crassus, laevis glaberque, candidus et sericeo-lucidus, basi breviter fibrilloso-hirsuto-radicatus et cum foliis deiectis coniunctus. Cystidia in acie lamellarum copiosa, lageniformia, hyalina, 25—35 \times 10—13 \times 5—6,5 μ . Sporae in cumulo fusco-

nigrae. Sporae fuscae, maturaे nigro-fuscae, ellipsoideae, apiculo vix provisae, absque poro germinativo distincto, $11-13 \times 6-7 \mu$.

Panaeolus subbalteatus B. et Br. (Fig. 50—51.)

Specimina bene evoluta in culturis Agarici hortensis in calidario in Veltrusy, Bohemiae centralis, 30. IX.—2. X. 1951, Řezník legit. Hanc speciem, in Bohemia sat raram, iam Velenovský prope Mnichovice, Radotín et Strašice locis stercoratis observavit et in opere suo „České houby“, p. 599, 1921 bene descriptis. Etiam icon Langei (Flora Agar. Dan. 4:87, t. 149 H, 1939). bona est.

Descriptio speciminum e calidario in Veltrusy:

Pileus 25—35 mm diam., sat molliter et fragiliter carnosus, margine paulum lobatus et superficie scrobiculatus, convexus et umbonatus, dein expansus et humiliiter obtuseque umbonatus, ferrugineo-fuscus tinctu

Photo A. Pilát.

Fig. 53. *Inocybe napipes* LANGE.

In turfosis Blata prope Soběslav, Bohemiae merid., 8. VII. 1951, leg. Fr. Kotlaba.

carneolo, hygrophanus, exsiccatione pallidior, argillaceo-fuscidulus, praecipue margine et centro obscurior, zona marginali saepe distincte obscuriori notatus, haud lucidus, cute e cellulis globosis, 18—27 μ diam. tectus. Lamellae subconfertae, 2—4 mm latae, late adnatae, dein ecarptae et rotundatae, primum tinctu carneo, dein griseo-carneae usque griseopapaverinae, maturae nigrae, acie albidae, sub lente puberulae. Stipes 60—120 \times 4—7(9) mm, cylindraceus, saepe paulum curvulatus, fibrillosus, sublucidus, basi haud incrassatus, potius attenuatus, maturus fistuloso-cavus, apice argillaceo-fuscidulus tinctu debili carneo, deorsum obscurior, fusco-purpureus, imma basi albo-tomentosus, apice albido-pruinosus et subrimosus. Caro subinodora, sapore haud conspecto. Basidia tetraspora, conspecte clavata, 27 \times 9—10 μ . Cheilocystidia copiosa, hyalina, irregulariter clavato-lageniformia, 30—40 \times 15 \times 6,5 μ . Sporae late ovoideo-subcitriformes, fuscae, dein nigrofuscae usque nigrae, maturae

fere haud translutescentes, apiculo parvo et poro germinativo parvo provisae, $10-12 \times 7,5-9,3 \mu$.

Stropharia albo-nitens Fr. (Fig. 49.)

In turfosis „Blata“ prope Soběslav, Bohemiae merid., in Pinetis graminosis solo turfoso, 19. XI. 1951, Fr. Kotlaba legit.

Hanc speciem, in Čechoslovakia raram, iam Velenovský prope Mnichovice in Pinetis iuvenilibus legit. (cf. České houby, p. 568, 1921.). Specimina mea cum descriptione et iconē Langei (Fl. Agar. Dan. 4:65, t. 141 B, 1939.) bene concordant.

Pileus 3—4 cm diam., subsemigloboso-convexus, plerumque umbone indistincto obtusoque provisus, candidus, rarius, praecipue centro, tinctu debili luteolo vel luteo-fusco coloratus, maximē viscidus. Lamellae pallide chocolateae, in speciminiibus siccis relativiter pallidae, sat latae, emarginatae, acie pallidiores. Stipes albus, cylindricus, basi minime incrassatus, sub anulo distinete albo-floccosus et fibrillosus, anulo plerumque bene evoluto et membranaceo, margine lacerato, albo ornatus. In basi stipitis funiculi myceliales albi inveniuntur. Sporae ellipsoideae, paulum amygdaliformes, relativiter pallidae, apiculo parum obliquo munitae, $8-9 \times 4,8-5,3 \mu$. Cheilocystidia clavata. Basidia tetraspora, $20-25 \times 5,5 \mu$.

Hebeloma testaceum (BATSCH.) QUÉL. cf. BRESADOLA t. 707, LANGE 118 E. (Fig. 52.)

Hanc speciem praecipue Bresadola (Ic. Mycol. t. 707) bene depinxit et Velenovský e Bohemia sub nomine novo „*Hebeloma velatum*“ VEL. (České houby p. 390, 1921) descriptsit et id ad exemplaria, quae mense maio in Pinetis Picetisque prope Hrusice, Bohemiae centralis legit.

Hebeloma testaceum BATSCH probabiliter fungus sero-autumnalis et hiemalis est, qui usque in verem annis faventibus occurrit.

Specimina huius speciei in magna multitudine 28. XII. 1951 Dr. Kučka et Zdeněk Pouzar in Piceto iuvenili graminoso in declivitate solo schistaceo prope Radotín Bohemiae centralis legerunt. Descriptio speciminum e localitate commemorata:

Pileus 2,5—4 cm diam., pallide rubeolo-fulvus usque sordide argillaceo-fuscus vel sordide ochraceus vel testaceo-alutaceus, ad marginem albidos usque albus, primum convexus, dein subplanus, indistincte umbo-natus, subviscidus, dein siccus, sebaceo-lucidus, laevis. Lamellae latae, late et distincte emarginatae usque subliberae, adultae usque 8 mm latae, ad pilei marginem conspecte angustatae, primum albido-argillaceae tinctu debili carneo, dein pallide ferrugineo-argillaceae, acie haud denticulatae et ibi iuventutem albidae, dein concolores. Stipes $35-50 \times 7-10$ mm, cylindraceus, parte inferiore plerumque paulum arcuatus, basi haud vel minime incrassatus, apice albus, deorsum sordide subfuscus, tactu fuscus, fibrillis cortinae crebris, albis laxisque indusiatis et apice e cortina abundantanti subanulatus, solidus, farctus, dein anguste cavus. Caro pilei sordide albida usque pallide fuscidula, in basi stipitis sordide subfusca, odore debili raphanideo et sapore miti vel amariuscule; praecipue glutaea in pilei superficie debiliter amara. Cheilocystidia cylindracea vel cylindraceo-clavata, basi paulum lageniformiter incrassata, hyalina, tenuiter tunicata,

In Picetis montis Polana prope Detva. Slovakiae centralis, ca 1200 m s. m.,
25. VIII. 1951, leg. A. Pilát.

40—50 × 6 × 4,5—5,5 μ . Sporae in cumulo argillaceo-fuscae. Sporae elongato-ellipsoideae usque subamygdaliformes, pallide argillaceo-fuscae, conspecte pallidae, membrana indistincte et subtilime verrucosa instructae et excentriciter apiculatae, 9—11 × 6,5—7,5 μ .

Inocybe dulcamara (PERS.) FR.

Ad argillam luteam nudam (loes) in fossa in Picetis prope Boubová haud procul Karlštejn, 27. VI. 1951, leg. A. Pilát (ca 30 carposomata). Cf. Pilát, Studia Botanica Čechoslovaca, 12:22—24, 1951.

Pileus 15—30 mm diam., e convexo subplanus et plane obtuse umbo-natus vel exumbonatus, velutino-tomentosus, dein dense tomentoso-squamulosus, primum ochraceus vel fusco-ochraceus, dein laete ochraceus,

centro obscurior et ad marginem melleus. Cortina distinete arachnoidea. Lamellae e luteolo albidae, luteo-fuscae usque cinnamomeae, acie albae, debiliter emarginatae et denticulo parvo decurrentes. Stipes 20—35 × 3—5 mm, floccoso-fibrillosus, e pallido dein, praecipue dimidio inferiori, tinctu ochraceo-fusco. Caro sordide luteola. Sporae in cumulo ochraceo-cinnamomeae. Basidia 9 μ crassa. Sporae ovato-phaseoliformes, 8—11 × 5—6,5 μ . Cystidia solum in acie lamellarum evoluta, tenuiter tunicata, cylindraceo-clavata vel subfusoidea, 30—50 × 9—15 μ .

Inocybe napipes LANGE. (Fig. 53.)

In turfosis „Blata“ prope Soběslav, Bohemiae merid. ad terram turfosam 8. VII. 1951, leg. Fr. Kotlaba. Specimina bohemica cum iconibus et descriptionibus Langei et Heimii optime concordant. Species haec, in Bohemia rara, in Dania, Hollandia, Helvetia, Britannia et Gallia etiam locis uidis in Pinetis et Betuletis occurrit.

Inocybe praetervisa QUÉL. (Fig. 54.)

Ad terram in Piceto claro loco graminoso in monte Poiana prope Detva, Slovakiae centralis, solo andesitico, 25. VIII. 1951, A. Pilát legit. Specimen arte photographica depictum pileum late conico-campanulatum, obtuse umbonatum, 30 mm diam., ochraceum, ad marginem paulum ex-pallescentem, radialiter subtiliterque fibrilloso-laceratum habet. Lamellae ex albido argillaceae, acie albide, emarginatae. Stipes 60 × 5—7 mm, cylindraceus, sursum paulum attenuatus, basi bulbo conspecte marginato, globoso, ca 15 mm lato provisus, albus, fibrillosus, sed laevis glaberque. Cystidia ad latera et acies lamellarum subfusoidea vel conice lageniformia, apice obtusa et ibi 7,5 μ crassa et crystallis coronata, hyalina, crasse tunicata, 45—65 × 13—16 μ . Sporae nodoso-substellatae, 9—11 × 7,5—8,5 μ , in circumscriptione gibberis 5—7 obtuse conicis ornatae.

Icon et diagnosis Inocybis praetervisae in opere Velenovský „České houby“, p. 361, fig. 62/1 hanc speciem modo diverso describunt et probabiliter erroneae sunt vel speciem aliam representant. Fungus Velenovský lamellis pallide griseolis, dein lilacinis demum fuscis, sporis aculeato-echinatis (in figura aculeis permultis ornatis) discedit.

Inocybe pusio KARSTEN sensu LANGE, Fl. Ag. Danica 3:75, t. 112 A.

Ad argillam luteam (loes) in fossa in Piceto prope Boubová haud procul Karlštejn, Bohemiae centralis, solo calcareo, 27. VI. 1951, A. Pilát legit. Tres carposomata unacum speciminiibus copiosis *Inocybis dulcamarae* (PERS.) FR. in grege. HEIM *Inocybe pusio* KARSTEN pro formam *I. obscurae* tenet. Parva species pileo 10—20 mm diam., umbone sat prominenti, conico provisa, qua de causa iuventute pileo conico, dein planiuscula expanso, umbone sat plano ornato, tabacino, radialiter rimoso et carne albida in rimis, praecipue ad marginem visibili, caeterum subtiliter fibrilloso-fusso et parum fibrilloso-tomentoso, squamuoso. Lamellis e pallido sordide fuscis, postice profunde emarginatis et dente decurrentibus. Stipite subbrevi, 20—35 × 2,5—3 mm, cylindraceo, plerumque paulum

fasciculata. Pileus 15—25 mm diam., conico-campanulatus, umbone conico, sed obtuso instructus, tenuissime carnosus, solum centro crassior, ad marginem paulo rotundato-convexus, laevis, glaber, argillaceo-fuscus vel ochraceo-mellinus, centro paulum obscurior, hygrophanus, udus obscurior et pellucide striatus. Lamellae subconfertae, argillaceo-fusco-ferrugineae,

sat late adnatae, dein ecarptae, usque 5 mm latae. Stipes 50—60 × 1,5—2 mm, apice pileo concolor, deorsum obscurior, nigro-umbinus vel obscure fuscus, apice subtiliter pulverulentus, laevis, glaber, fibrillosus, basi tomento albo cum terra argillacea coniunctus, farctus, dein in dimidio inferiore fistuloso-cavus, plerumque arcuatus. Caro pilei albida, fuscidula, sapore amariusculo, caro stipitis fusca et fibrillosa, sed pallidior quam stipitis superficies. Cheilocystidia in acie lamellarum copiosa, lageniformia, 25—35 × 10 × 3—5 μ . Cutis pilei ex hyphis radialiter dispositis, diverse crassis, subochraceis, 5,5—22 μ crassis. Basidia tetraspora vel bispora. Sporae 9—11 × 5,5—6 μ , ellipsoideae, subamygdaliformes, in aqua sublaeves, in solutione KOH subtilime verrucosae, in regione suprahilaris laeves, argillaceo-fuscae, guttis oleosis conspectis 2—3 parvioribus vel una gutta magna statu adulto instructis.

Naucoria Charvatii PILÁT sp. n. (Fig. 60.)

Pileus 15—25 mm diam., hygrophanus, uodus sordide mellino-brunneus, siccus pallide ochraceus usque albide ochraceus tinctu luteo, centro haud obscurior, iuvenilis plane convexus et margine subinvolutus, mox planus, adultus centro depresso, cute uda, dein minime viscida vel sicca.

Lamellae sordide albidae, dein pallide argillaceae, subcrassae, late adnatae, serius irregulariter et parum emarginatae, adultae acie conclores, subventricosae et subcarnosae.

Stipes relativiter brevis et crassus, 15—20 × 4—5 μ magnus, albidus, pallide subochraceus, cylindraceus, basi saepe curvatus, apice paululum gossypino-floccosus, ceterum parum fibrillosus, glaber et parte tertia basali adultus paululum sordide subfuscus.

Caro albida, sordide lutescens, sat tenuis, sed crassior quam in Naucoriis ceteris, odore vix conspecto et sapore miti.

Cheilocystidia in acie lamellarum iuvenilium haud conspecta, clavata, paulisper curvulata et constricta, tenuiter tunicata et hyalina, 27—37 × 7—8 μ magna. In lamellis adultis haec cheilocystidia evanescunt, qua de causa acies lamellarum adultarum homomorpha est.

Basidia tetraspora, 25 × 5,5—6 μ .

Sporae in cumulo sordide argillaceo-brunneae, sub microscopio pallide sordide argillaceo-fuscae, ellipsoideae, paululum phaseoliformes, laeves, absque poro germinativo distincto, 9—11,3 × 5—5,5 μ .

Hab. Bohemia centralis: Dolní Břežany prope Pragam, ad terram in foliis deiectis uidis et putridis sub *Alno glutinosa*, *Fraxino excelsiore*, *Picea Abiete* etc 6. IV. 1952 cel. Ivan Charvát, cui speciem dedicavimus, legit.

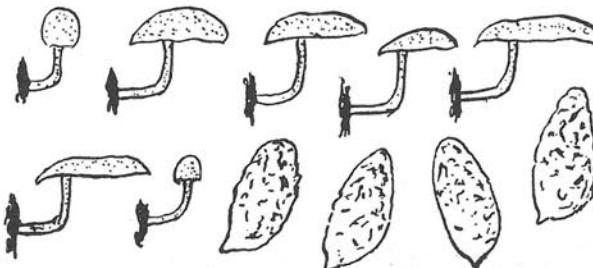

Tempestas primo vere 1952 valde frigida erat (frigi nocturni)! Species nostra nova maxime *Naucoriae vervacti* Fr. sensu Lange, Flora Agar. Danica 4 : 23, t. 126 G affinis videtur, sed vix identica. Species commemorata carposomata maiora habet (2—4 cm), et cheilocystidiis characteristicis sublageniformibus in acie lamellarum dignoscitur. Fungum Langei etiam Romagnesi in Bulletin de la Soc. Mycologique

de France 58 : 138, 1942 sub nomine *Agrocybis vervacti* bene descriptis et anatomiam eius in figura 10. illustravit.

Naucoria vervacti sensu Ricken p. 210, t. 60, f. 4 pileum 1,5—2 cm diam. habet et etiam sapore odoreque farinaceis, sporis maximis, 12—17 × 8—12 μ , sporis in cumulo olivaceo-brunneis et cystidiis in acie lamellarum fusoideis, 40—45 × 9—10 μ magnis dignoscitur. Certe species diversa. *Hylophila vervacti* sensu Quélet e descriptione pileum 2—3 cm diam. et sporas pruiniformes, 9 μ longas habet.

Naucoria intertrunca PILÁT sp. n. (Fig. 61.)

Pileo 5—8 mm diam., e subgloboso plane expanso, assymetrico, conspecte excentrico, fragillimo, sub lente subtille puberulo, ferrugineo

Fig. 63. *Nolanea chionoderma* PILÁT. In silva mixta virginea montis Połana prope Detva, Slovakiae centralis, 24. VIII. 1951, leg. A. Pilát.

***Nolanea chionoderma* sp. n. (Fig. 63.)**

Pileus 35 mm diam., conicus vel conico-campanulatus, dein margine sursum reflexus, albus, solum centro tinctu griseolo, sericeo-nitens, subfibrillosus, sed glaber, haud radiato-rimosus, tenuiter carnosus, non hygrophanus, margine irregulariter flexuoso-lobatus.

Stipes 70 mm longus et 7 mm latus, cylindricus vel sursum minime attenuatus, elatus, rectus, paulisper tortus, fibrillosus et huc illuc fissilis, tenax, albidus vel minime griseolus, basi fere non incrassatus, sed parte basali ca 3 cm longa in terram humosam immersus et ibi fragmentis terrae agglutinatis destitutus.

Lamellae pallide griseo-brunneolae, haud roseae, emarginatae, subconfertae, acie irregulariter sinuoso-dentatae.

Caro, tenuis, subtenax, alba vel albida, odore saporeque haud conspectis. Basidia tetraspora. Cystidia nulla. Sporae heterodiametricae, ambitu ovoideae, angulatae, subroseae, $10-13 \times 7,5-8,5 \mu$.

Habitat. In silva mixta virginea (*Fagus sylvatica* et *Abies alba*) sub *Fago* in monte Polana prope Detva, ca 1200 m s. m., Slovakiae centralis (Čechoslovakia) ad terram humosam profundam, 24. VIII. 1951, solum unum exemplar A. Pilát legit.

A d n o t a t i o n e s. Fungus maxime eximius, habitu externo *Nolaneis* ceteris dissimilis et potius species nonnullas non hygrophanas generis *Inocybe* in mentem revocans. Species nostra *Rhodophyllo eximio* ROMAGNESI, Bulletin de la Société Mycologique de France, 50 : 99, 1944 proxime affinis (vel solum varietas huius speciei?). Differt a specie commemorata, mihi solum e descriptione citata nota, colore pilei albo centro tinctu griseolo (non eburneo tinctu lutescenti), odore haud conspecto (non farinaceo vel odore Lactario glyceosmo simili) et cystidiorum absentia. ROMAGNESI solum specimina sub *Carpino* in silvis St. Germain prope Maisons-Laffite (S.-et-O) Galliae, 19. VIII. 1943 semel lecta examinavit et descriptis.

Pouzaryomyces fumosellus (WINT.) n. c. (Fig. 64.)

Agaricus fumosus Rabh. Handb. 504. — *Ag. fumosellus* Winter, Pilzfl. 1 : 853, 1884.

Nolanea fumosella (WINT.) SACCARDO, Syll. Fung. 5:724, 1887.

Nolanea strigosissima REA, Trans Brit. Mycol. Soc. VI, t. 7. — Brit. Basid. p. 402, 1922.

Nolanea Babingtonii (BLOX.) B. et BR. Notices 680, 903 ? Cooke Ill. no. 363, t. 477 figura superior. — DENNIS in Trans. Brit. Mycol. Soc. 31 : 206, 1948. Ad lignum putridissimum (? *Pini silvestris*) prope Srbsko, haud procul Beroun, Bohemiae centralis, solo calcareo 30. IX. 1951 unum exemplar Zdeněk Pouzar legit.

Pileus conicus, 8 mm diam. et 5 mm altus, obtuse umbonatus, habitu Mycenae similis, obscure sordide fuscus vel umbrinus tinctu purpureo vel ferrugineo, non hygrophanus, tenuissime, sed sat firme membranaceus, tota superficie, sed praecipue cacumine, pilis purpureo-fuscis vel ferrugineis, suberectis, septatis 400—600 μ longis, apice obtusis, et cellulis 4,5—15 μ crassis et 50—70 μ longis compositis vestitus. Cutis pilei ex hyphis radialiter intricatis, pallidioribus, pallide fuscis, tenuiter tunicatis, 11—18 μ crassis composita. Lamellae fuscae, cinereo-pruinosaes, acie pallidiores, subliberae et sat ventricosae. Stipes longus et tenuis, cylindraceus, 40 mm longus et ca 1 mm crassus, deorsum minime incrassatus, umbrino-fuscus, pilei obscurior, basi fere umbrinus, tota superficie, pilis erectis, patentibus, subcurvulis, obscure ferrugineofuscis, usque 700 μ longis, apice 4,5—6 μ et basi usque 15 μ crassis crinitus, subelasticus, firmus et vix frangibilis. Caro, pilei concolor, dein cinerea. In acie lamellarum cheilocystidia piriformia, copiosa, tenuiter tunicata, plasma fuscidula et granulosa provisa, 45—55 \times 20—30 μ magna. Haud raro etiam cystidia cylindriceo-fusoidea, subhyalina, tenuiter tunicata, 60—150 μ longa et 10—22 μ crassa inveniuntur. In lamellis nonnullis solum cellulas piriformes observavi. Cutis stipitis ex

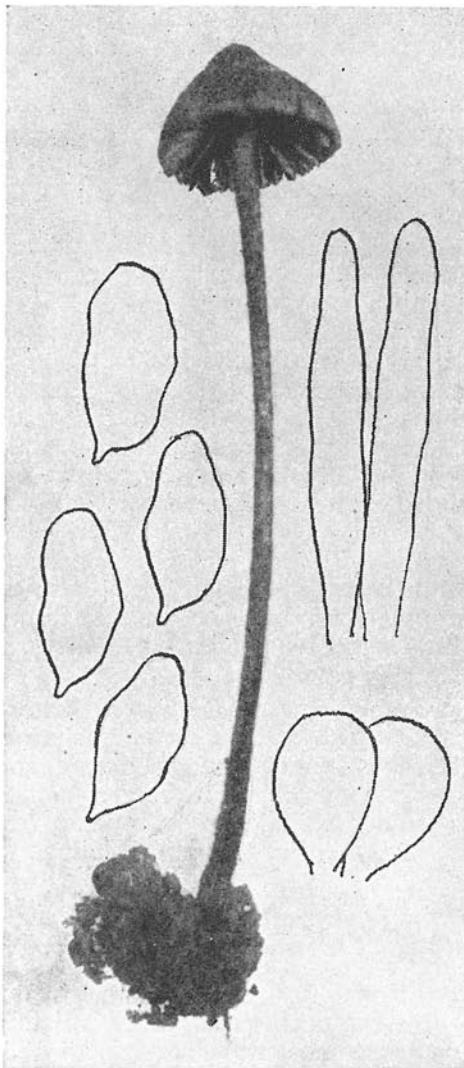

Photo A. Pilát.

sko prope Beroun, Bohemiae centralis, estris, 30. IX. 1951, Zdeněk Pouzar
ligna putridissima, probabiliter Pini legit.

hyphis conferte paralelliter intricatis, quam pili pallidioribus, 6—9 μ
crassis constat. Sporae pallide roseae, angulatae, in circumscriptione
ellipsoideae, apiculo conspecto, paulum obliquo instructae, 14—16 \times
8—9 μ . Hunc fungum Rea l. c. sub nomine *Nolanea strigosissime* REA
optime descriptis. A. A. PEARSON eam cum *Nolanea fumosella* (WINT.)
SACC. synonymisat. In fungo bohemico cellulas piriformes in cute pilei
non observavimus, solum istas cellulas in acie lamellarum, quas Rea

in diagnose sua non commemorat. Lamellae cum pileo firme concretae sunt, qua de causa putari potest. Ream in preparato microscopico positionem cellularum piriformium modo erroneo descriptissee.

Nolanea Babingtonii (BLOX.) B. et Br. = *Agaricus (Nolanea) Bloxami* BERK. e specimine originali (ex parte!) teste DENNIS (Some little-known British species of Agaricaceae, Trans. British Mycol. Soc. 31 : 206, 208, 1948) cum *Nolanea fumosella* (WINT.) SACC. = *N. strigosissima* REA identica est.

VELENOVSKÝ e Bohemia duas species novas descriptis, — quae aut identicae cum *Nolanea fumosella* sunt, vel proxime affines et in genus commune (*Pouzaromyces*) pertinent:

1. *Nolanea hirta* VELENOVSKÝ, Mykologia, 6 : 28, 1929: „Valde gracilis, pileo 5—10 mm diam., obtuse conico, dein paulisper expanso, pellucide membranaceo, sed non hygrophano, e lamellis pellucidis, margine denticulato, cinereo, vertice nigrescenti, toto patule dense hirto. Stipe longo, recto, 1 mm crasso, fragili, striato, pallido, dense floccoso-squamuloso, basi longe ciliato. Lamellis distantibus, sparsis, valde late ventricosis, cinereis, dein rubescensibus. Sporis oblongis, obtuse angulatis, 12—15 μ .

In declivibus calidis calcareis siccis formatione xerophila (Anthericum liliago, Thesium linophyllum, Pulsatilla pratensis, Muscari tenuiflorum) ornatis in dumetis nanis prope Radotín frequens (Bohemia centralis), junio 1926. Ab omnibus notis plene diversa vestimento, pileo non hygrophano, lamellis cinereis“.

Hic fungus probabiliter cum *Nolanea fumosella* identicus est, quamquam diagnosis VELENOVSKÝI in omnibus characteribus cum fungo meo non concordat. Stipes fungi Velenovskýi fragilis est contra in fungo meo sat elasticus et firmus et non „floccoso-squamulosus“, sed pilis patentibus crinitus et haud pallidior, sed obscurus, fere nigrofuscus. Icon Velenovskýi (l. c. pag. 27, fig. 7), cum *Nolanea fumosella* sat bene concordat.

2. *Nolanea setulosa* VELENOVSKÝ, Novitates Mycologicae p. 147, 1939: „Solitaria, pileo 10—16 mm, obtuse conico, dein convexo, umbo-nato, obscure cinereo, vertice subatro, hygrophano (nervis pellucidis), toto e setulis hirto. Stipite 2—3 plo longiore, stricto, pallido, pellucido, toto granuloso-paleaceo, supra obscuro. Lamellis distantibus (!), crassiusculis, cinereis, saepe anastomosantibus. Sporis 15—18 μ longis, oblongis, obtuse angulatis, basi attenuatis.

Ad verrimenta in dumeto humido, umbroso prope Mnichovice (Jidášky) junio 1939. *Nolaneae hirtae* Vel. major, non stepposa“.

Descriptio huius fungi a fungo nostro dimensionibus majoribus, stipite pallido, pellucido et pileo paulisper hygrophano discedit.

Pro dolor unum carposoma *Nolaneae fumosellae* in manu habui, qua de causa variabilitatem huius speciei nescio. Ideo quoque nescio utrum species ambae Velenovskýi species bonae, an cum *Nolanea fumosella* identicae sint.

Nolanea fumosella (WINT.) SACC. a ceteris Nolaneis valde discedit et parum affinis est. Ideo eam in genus proprium et novum insero: *Pouzaromyces* g. n.

Photo A. Pilát.

Fig. 65. *Clitopilopsis hirneola* (Fr.) KÜHNER.
In turfosis Blata prope Soběslav, Bohemiae centralis,
2. XII. 1951, leg. R. Veselý.

Fungi rhodogoniospori, habitu Mycenis similes, pileo conico non vel parum hygrophano, sat obscure colorato, pilis fuscis, septalis, longis, magnis, erectis vestito. Lamellae cinereae vel fuscae, haud albae vel roseae. Stipes tenuis, cylindraceus, pilis longis, fuscis, septatis crinitus. Cystidia adsunt. Fungi lignobiotici, rarius terrestres, silvarum et dumetorum incolae.

Clitopilopsis hirneola (Fr.) KÜHNER. Cf. FAVRE, Mater. Fl. Cryptog. Suisse 10: No. 3: 77, 1948. — SINGER, Lilloa 22: 623, 1949. (Fig. 65.)

Rhodophyllus hirneolus (Fr.) SINGER, Lloydia 5: 100, 1942.

Hirneola VELENOVSKÝ, genus novum, Novitates Mycologicae p. 73,

1939, nom Fries. — *Clitopilopsis arthrocystis* KÜHNER et MAIRE, Le genre *Clitopilopsis* (Agar.) Bull. Soc. Hist. nat. Afrique du Nord 28 : 112, 1937. — MAIRE, Fungi Catalaunici II, p. 82, 1937.

?*Clitocybe xanthophylla* VELENOVSKÝ, České houby, p. 256, 1920.

In musco et in gramine solo turfoso extra sylvam in turfosis „Blata“ prope Soběslav, Bohemiae meridionalis, 2. XII. 1951, leg. R. Veselý.

Pileus 1—3 cm diam., hygrophanus, tenuis, glaber, sub lente arachnoideo-pruinosis, uds griseo-fuscus usque fusco-alutaceus, expallens, semisiccus sordide albido, subplane convexus usque centro distinete umbilicatus vel rarius subumbonatus, e hygrophanitate haud raro indistincte circellatus, uds lamellis non vel parum translucescentibus. Caro griseo-fusca, tenuis, sed satis elastica, sapore miti, subindora. Lamellae griseo-fuscae tinctu subcarneo vel sordide fuscidulo, confertae, ad stipitem plus minusve arcuato-decurrentes vel solum adnatae, mediocriter confertae. Stipes tenuis, 25—45 μ longus et 1,5—2,5 mm crassus, griseo-fuscus, semisiccus griseolus, paulum flexuosus, subglaber, albide floccoso-prunoisus, basi paulum albido-tomentosus. Sporae in cumulo sordide griseo-fuscae. Sporae globoso-ovoideae, apiculatae, laeves, plasma subtiliter granulosa, haud absolute hyalina, tinctu griseo-fuscidulo, 7—8 \times 6—6,5 μ . Basidia tetraspora, clavata, 25—35 \times 7,5—8,5 μ . Cystidia in acie lamellarum conspecte copiosa, irregulariter fusoidea, cylindracea, nonnulla unicellularia, sed maxima ex parte septis duobus usque quaternis provisa, 45—55 \times 9—11 μ .

Species haec praecipue locis uds et turfosis invenitur. FAVRE eam etiam in turfosis duobus in montibus Jura collegit.

Clitocybe hirneola var. *ovispora* LANGE, Flora Agar. Danica 1 : 77, t. 36 C, 1935, cum sporis ovoideis, 7 \times 4 μ magnis et pileo solum 8—18 mm diam., haud hygrophano, terreo-griseo, siccо lucido, sporis in cumulo albis, certe ad speciem alliam pertinet.

Clitocybe xanthophylla VELENOVSKÝ, České houby p. 256, fig. 40/14, 1920 probabiliter ad *Cl. hirneolam* Fr. pertinent, — ut iam Maire (Publ. de Inst. Bot. de Barcelona vol. III, No 4, p. 82, 1937) commemorat, quamquam diagnosis Velenovskýi paulum discrepat. (Pileus non hygrophanus, niveus, centro umbone parvo notatus.) Clitocybem xanthophyllam Vel. in Piceto alto loco humoso in societate Asperulae odoratae collegit.

VELENOVSKÝ speciem suam novam erronee nomine „*xanthophylla*“ designavit et loco citato in diagnosi hoc nomen in linguam bohemiam „šedolupenná“, id est „griseo-lamellata“ transfert. Error simile philosophicum in opere Velenovskýi citato apud *Leptonia xanthopa* Vel. invenimus. Hoc nomen in linguam bohemiam auctor „tmavooká“ id est „obscure occulata“ transfert.

In diagnose originali *Clitocybis xanthophyllae* VELENOVSKÝ lamellas huius fungi griseas (non luteas) describit.

VELENOVSKÝ *Clitopilopidem hirneolam* in opere suo „České houby“ etiam sub nominibus „*Clitocybe hirneola* Fr.“ (p. 259) et „*Clitocybe strangulata* Vel.“ (p. 274, fig. 40/6) descriptsit. In „Novitatibus Mycologicis“ p. 73, 1939 has duas species synonymisat.

Loco citato VELENOVSKÝ etiam genus novum *Hirneola* VEL. descriptsit, sed male characterisavit (fungi pusilli, graciles, hygrophani,

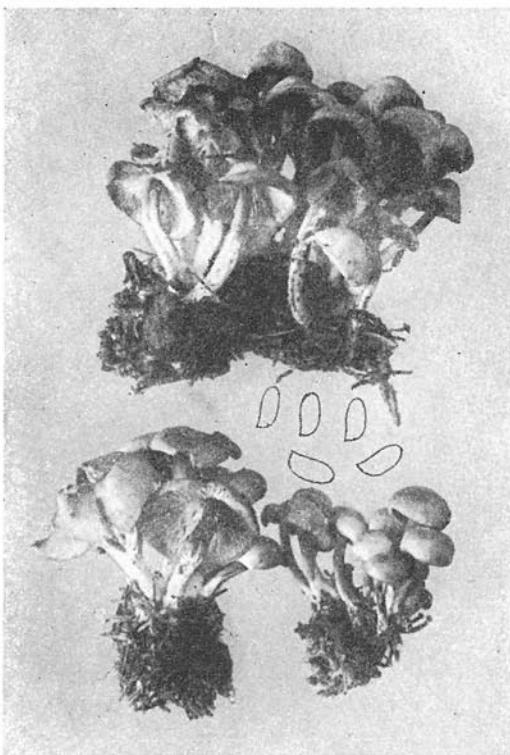

Photo A. Pilát.

Fig. 66. *Collybia acervata* (Fr.) KARSTEN.

In monte Połana prope Detva, Slovakiae centralis, ad truncum putridum Piceae excelsae. Stipites mycelio Polypori sp. indusiati. 26. VIII. 1951, leg. A. Pilát.

pileo colorato, dein convexo, haud cyathleo, stipite tenui, longissimo, subcorneo, sporis globosis vel ovatis. Omnes extra silvas nascentes. Genus hoc itaque transitum ad Marasmios praebet). Cystidia et sporas coloratas non commemorat, qua de causa genus hoc male characterisatum vix cum genere *Clitopilopsis* identicum est, quae iam e speciebus, quas Velenovský in hoc genus novum transposuit, clare apparere puto: *Clitocybe hirneola* Fr., *Cl. confusa* VEL., *Cl. anastomosica* VEL., *Cl. pelludica* VEL., *Cl. decolorans* VEL., *Cl. nigripes* VEL., *Cl. pinetorum* VEL., *Cl. cinnerea* VEL., *Cl. tenerrima* VEL., *Cl. marasmiaeformis* VEL.

SINGER in ephemeride Lilloa (22 : 623, 1949) genus *Clitopilopsis* post genus *Rhodophyllus* inter generibus incertae sedis enumerat. Non dubito — similiter ut iam KÜHNER — quin haec species genus transitorium inter genera *Clitocybe* et *Rhodophyllus* sit. Sporae in cumulo non modo typico carneo-roseo, ut in *Rhodophyllis* veris coloratae sunt, sed potius sordide argillaceae. Genus proximum etiam *Rhodocybe* est, quod cystidia habet, sed sporis verrucosis discrepat.

2. VII. 1951, leg. Dr. Wichanský.

Clitocybe gallinacea (SCOP.) GILL. sensu LANGE, Fl. Agar. Dan. 1 : 80,
t. 34 C. (Fig. 79.)

In turfosis „Blata“ prope Soběslav, Bohemiae meridionalis, ad
terrā in foliis deiectis Betulae pendulae, 18. XI. 1951, leg. Fr. Kotlaba.
Pileus orbicularis, plane convexus, adultus centro depresso, haud

umbonatus, albus et haud hygrophanus, solum centro tinctu sordide luteo-fuscidulo, glaber, sublucidus, margine tenuis et paulum involutus, tenuiter membranaceo-carnosus. Lamellae candidae, confertae, parum decurrentes, sat angustae. Stipes 20—35 × 1,5—2 mm, cylindraceus, subfibrillosus, apice albus vel sordide albus, parte inferiore tinctu luteo-fuscidulo, basi haud incrassatus, mycelio albo, tomentoso cum foliis deiectis coniunctus. Caro alba, tenuissima, sapore debili, amaro,

A. Pilát del.

Fig. 81. *Pleurotus Kotlabae* PILÁT.

inamoenus, odore haud conspectu. Basidia 18 × 5—5,6 μ . Sporae hyalinae, ellipsoideae, oblique acutatae, laeves, 7—7,5 × 3,5—4 μ .

Fungus descriptus cum diagnose et icona *Clitocybis gallinaceae* sensu LANGE l. c. bene concordat, solum sporas LANGE paulisper minores describit (5,5—6,5 × 3,5—4 μ). Sed etiam diagnoses et icones Langei *Clitocybis candicans* sensu LANGE et *Clitocybis dealbatae* sensu LANGE similes sunt et solum sapore haud amaro discrepant.

Omphalia scyphoides FR. sensu BRESADOLA, VELENOVSKÝ, RICKEN.
(Fig. 80.)

Pileus 5—10 mm diam., iam e iuventute umbilicato-depressus, adultus late et profunde infundibuliformis, haud hygrophanus, candidus, haud lucidus, solum subsericeus, subtiliter adpresso tomentosus vel subglaber, semper irregulariter rugosus, margine paululum et irregulariter rimosus, tenuiter membranaceus, subfragilis, adultus margine haud

involutus. Lamellae vix latae, arcuato-decurrentes, haud raro ad pilei marginem furcatae, acie concolores, et homomorphae, e candido sublutescentes vel pallide subochraceae, longiores cum brevioribus intermixtae. Stipes subbrevis, 5—8 mm longus, vix 1 mm crassus, cylindraceus, sub pileo latissimus, basi angustatus vel incrassatus, ad folia emortua graminum vel ad detritum insidens, pileo concolor, dein tinctu sordide pallide subochraceo, laevis, glaber, subfimus, plerumque paulum curvulatus. Sporae elongato-amygdaliformes, subfusciformes, guttulis parvis oleosis 1—3 instructae, saepe in tetradas conglomeratae, 7,5—8,3 × 4,5 μ , hyalinæ (? vel tinctu debili luteolo ?). Cystidia nulla. Basidia tetraspora.

Hab. ad folia graminum emortua in horto publico „Kinského sady“ dicto, Pragae, 4. VII. 1951, Dr. Wichanský legit.

Fungus noster pragensis bene cum descriptione iconique BRESADOLAE (Iconographia Mycologica t. 260/1) concordat, solum sporas paulum majores habet (fungus Bresadolae: 6—7,5 × 3—3,5 μ).

CEJP (Omphalia in Kavina—Pilát, Atlas des Champignons de l'Europe, vol. III, p. 89) sub hoc nomine fungum paulum majorem, pileo 10—30 mm diam., cum sporis 8—10 × 4,5 μ describit.

PECK (diagnosis apud KAUFFMAN, Agaricaceae of Michigan p. 814) sub hoc nomine fungum pileo 4—8 mm diam., stipite 8—16 mm longo et sporis 6 × 4—5 μ describit.

Fungus PATOUILLARDII, hoc nomine designatus, nostro certe similis est (Tabulae analyticae No. 415): pileus 10—20 mm diam., sporae ovoideae (absque dimensionibus indicatis), in hymenio cystidia parum conspecta. Identitaas eius incerta mihi videtur. Probabiliter sub Omphalia scyphoidi auctores nonnulli diversos fungos describunt.

Contra VELENOVSKÝ (České houby, p. 291) fungum nostrum optime describit et specimina eius cum nostris certe identica sunt (sporae teste Velenovský, ellipsoideae, 6—8 μ longae). VELENOVSKÝ fungum suum in collibus siccis, insolatis in gramine gregatim aestate post pluvias calidas pro Mnichovice, Bohemiae centralis, collegit.

Idem fungus RICKENI certe identicus est (Blätterpilze p. 394: an sonnigen moosreichen grasigen Orten besonders nach reichlichen Regen geselig V—IX. Sporae teste Saccardo 6 × 2 μ . Fries t. 75, f. 2. RICKEN adnotat fungum QUÉLETII cum Pleuroto mutilo identicum esse.

Pleurotus (Pleurotellus) Kotlabae PILÁT sp. n. (Fig. 81.)

Pileus 6—9 mm diam., membranaceus et molliter carnosus (haud gelatinosus), conspecte hygrophanus, conchiformis, stipite vix evoluto (1—2 × 1 mm magno), fere uno puncto excentrico insidens vel etiam ex parte dorso adnatus et fibrillis albidis substrato insidens vel stipite brevissimo instructus, Jove udo griseo-fuscus, semisiccus pallidior, pallide griseo-fuscidulus usque griseo-albidus, uodus margine pilei lamellis paululum translucescentibus, subtiliter tomentosus usque subglaber, sed haud lucidus, margine tenuis et orbicularis, paulum crenulato-lobulatus. Lamellae griseo-fuscidulae, subsparcae et plerumque undulatae, acie concolores. Hyphae tenuiter tunicatae et relativiter subcrassae, laxe intricatae, 6,5—8 μ crassae (cellulae nonnullae usque 14 μ crassae). Basidia

Fig. 88. *Cyphella Lloydeana* PILÁT.
Carposemata semisicca (sinistra) et uda (dextra). A. Pilát del.

Anno 1952 (14. VIII.) specimina nova huius speciei a cel Dr. Francisco Kotlaba obtinui. Ille ea ad folia emortua *Typhae latifoliae* in turfosis „Blata“ prope Soběslav („U dubu“); Bohemiae meridionalis, unacum *Psathyra typhae* Kalchbr. legit.

Specimina nova cum typo bene concordant. Diagnosem originalem notis supplementariis completere possum:

Carposomata late conico-cupulata usque semigloboso-patelliformia, incidentia, rotundata et margine sublobata, 0,8—1,3 mm diam., latiora quam alta, extus albida, sed haud candida, non lucida, glabra, solum adpresso subtomentosa, margine iuventute parum involuta, dein recta et saepe paululum lacerata, subsicca margine irregulariter inflexa vel involuta.

Hymenium concavum, albidum tinctu ochraceo vel griseolo, leve, dein saepe subrugosum.

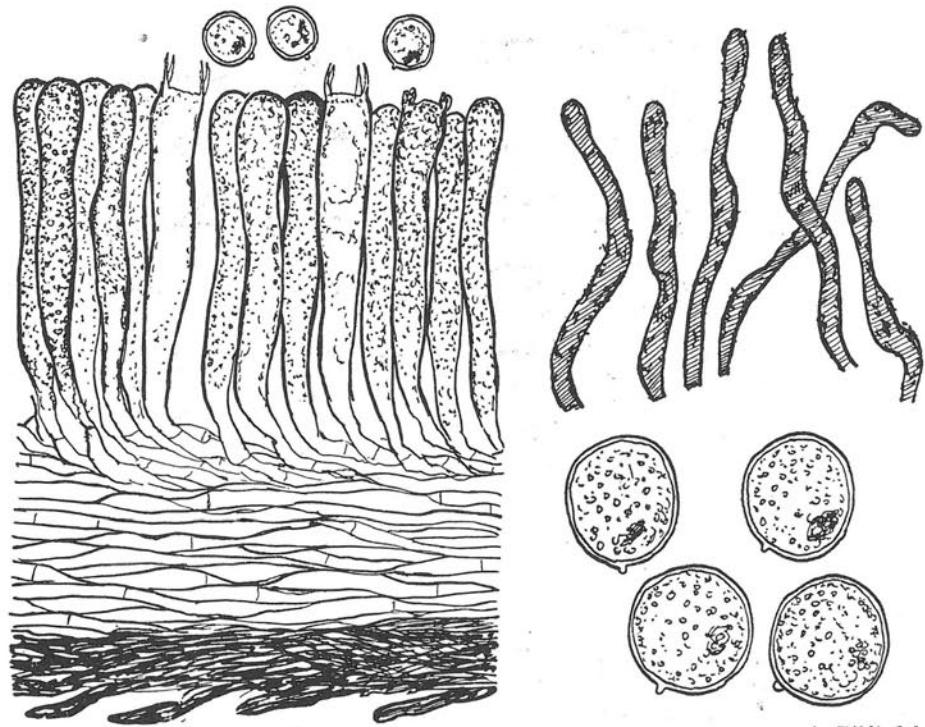

Stratum cupulae externum ex hyphis tenuiter tunicatis, levibus, haud incrustatis, sublaxe intricatis, 3,5—5,5 μ crassis constat. Pili desunt. Basidia hyalina, conspecte clavata, ca 7,5 μ crassa, tetraesterigistica. Sporae ellipsoideo-ovoideae, basim versus in apiculum distinctum contractae, hyalinae, leves, 7,5—9 \times 4—5,5 μ .

Hab. in gregibus laxis, sed numerosis, ad folia emortua *Typhae latifoliae*, aqua imbuta, in turfosis „Blata“ prope Soběslav, Bohemiae

merid., 14. VIII. 1952 cel. Dr. Kotlaba legit. Species paludosa, biologia sua *Psathyrae typhae*, cum qua eodem loco crescit, similis est.

Solenia digitalis (A. et S.) QUÉLET, Fl. Myc. p. 28, 1888.

Cupulae 8—12 mm longae et 4—8 mm latae, elasticiter membranaceae, elongato-cylindraceo oblique digitaliformes vel oblique campanulatae et nutantes, breviter sed distincae oblique et lateraliter stipitatae.

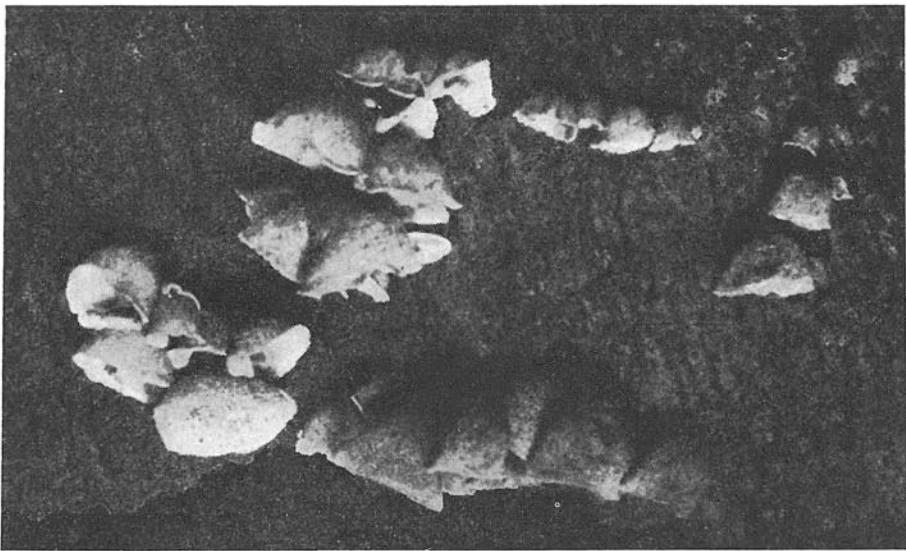

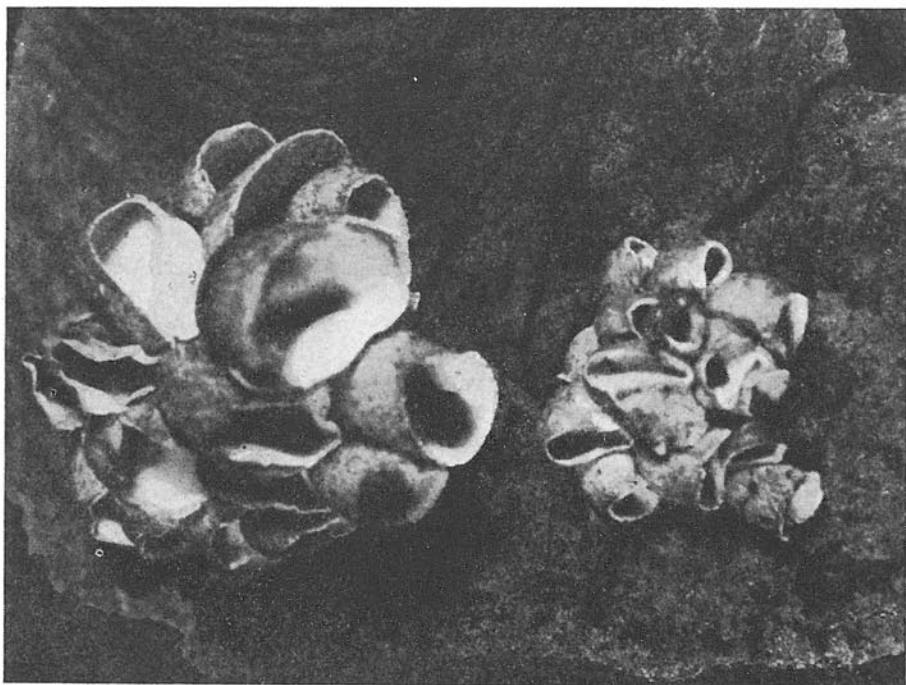

Fig. 90—91. *Cyphella digitata* (A. et S.) Fr.
Čechoslovakia: Moravia, montes Beskydy, Carpatorum occidentalium, in monte
Vsetský Cáb, ad corticem trunci emortui Abietis albae 29. I. 1951,
leg. Zdeněk Pouzar. Photo A. Pilát.

Stipes usque 4 mm longus, plerumque curvatus, brunneus usque brunneoniger. Cupula extus pallide fulva vel pallide brunnea, dein obscurior, fibrillis, obscurioribus striata et paulum floccoso-pilosula, saepe subglabrata, adulta usque nigro-brunnea, margine acuta, recta, levis.

Hymenium leve, albido-cinerellum vel subglaucinum, relatititer carnosum. Basidia conspecte magna, tetraspora vel bispora, 100—150 × 12—20 μ . Sterigmata subcrassa et arcuata, 10—15 μ longa.

Hyphae tramales hyaline, tenuiter tunicatae, 4—8 μ crassae. Hyphae strati externi cupulae brunneae, 5—6 μ crassae, confertiuscule intricatae, externae pilos irregulares in cupulae superficie parce distributos brunneos, 5,5—7,5 μ crassos, arcuatos flexuososque, apice rotundatos, extus granulis agglutinatis brunneis, sparsis incrustatos formantes.

Sporae regulariter globosae, apiculo verruciformi minimo instructae, membrana haud amyloidea, laevi, paululum sordide fusco-colorata instructae, 16—18 μ diam. Plasma hyalina granulosa.

Hab. ad corticem trunci emortui *Abietis albae*. Moravia, montes Beskydy Carpatorum occidentalium, in monte Vsacký Cáb 29. I. 1951 Zdeněk Pouzar legit. Carposomata solitaria, seriatim disposita vel fasciculata. — saepe fasciculos confertos semiglobulares, usque 20 mm diam. metientes et usque e 20 carposomatibus compositos formantia.

Adnotatio. Species rarissima, adhuc solum e Germania, Gallia et Helvetia cognita. In Gallia in montibus Vosges et Jura, in Helvetia in Aargau (Ruedertal, F. HALLER) occurrit. Speciem commemoratam ALBERTINI et SCHWEINITZ e speciminibus prope Zhořelec (Görlitz: Arnsdorfer Berge) et in Lusatia Saxonica (Sohlander Berg) lectis descripserunt. Fries in Suecia hanc speciem non invenit.

Species conspecta et magna, *Cyphellis* FR. et *Soleniis* Hoffm. intermedia. Forma carposomatum et magnitudine potius *Cyphellas* in mentem revocat, sed consistentia membranacea et colore hypharum externalium *Soleniis* (ex gr. *Soleniae ochraceae* Hoffm.) similis est.

Sporae non sunt hyalinæ, sed pallide sordide fuscae vel pallide argillaceæ, conspecte magnæ. Qua de causa species in Cyphellaceis monotypica et genere proprio digna est.

Clavulinopsis luteo-alba (REA) CORNER, A monograph of the Clavaria and allied genera p. 374, 1950. (Fig. 92.)

Syn.: *Clavaria luteoalba* REA, Trans. Brit. Mycol. Soc. 2 : 66, 1903, t. 3, f. 2 B et ibid. 3 : t. 11 C, 1907. — *Clavaria inaequalis* auctorum p. p., *Clavaria helvola* PERS. sensu COKER, Clavaris of U. S. and Canada p. 37, t. 1, f. 4, 1923.

Clavulae solitariae, simpleces vel laxe gregariae, elongatae, 30—60 × 2 mm, terricolae, cylindraceo-clavatae terretes vel subcompressae et rimis duabus haud raro provisae, aurantiaceae vel luteo-aurantiaceae, apice saepe pallidiores, subacutatae vel obtusae, saepe paululum flexuosa, basi in stipitem brevem plus minusve distinctum et pallidiorem angustatae. Caro subconcolor vel aurantiaco-lutea, sat fragilis, saepe centro subcava, odore inconspecto et sapore potius inamoeno, ex hyphis 2—9 μ crassis, hyalinis, tenuiter tunicatis composita.

Basidia tetraspora, 30—40 × 7,5 μ .

Diagnoses latinae specierum novarum Polyporacearum, quarum descriptiones in opere meo „Polyporaceae“ in Atlas des Champignons de l'Europe, vol. III., annis 1936—1942 edito, solum in lingua čechica et gallica publicavi.

Leptoporus minusculoides PILÁT in Atlas des Champignons de l'Europe, vol. III., Polyporaceae, p. 193, t. 109, 1938.

Minimus, 2—5 mm diam., globoso-conicus usque subgloboso-campanulatus, basim versus angustatus et uno puncto insidens, solum e tubulis 20—150 compositus, candidus, molliter gossypino-carnosus, facile putrescens et evanescens, e rhizomorpha in ligno putrido sita crinique equino brunneo simili enascens. Tubuli 2—3,5 mm longi, apice dentati, candidi, siccii sublutescentes vel minime subfuscantes, poris 0,15—0,2 mm latis, rotundato-angulosis, dissepimentisque tenuibus. Trama pilei subnulla, e hyphis tenuiter tunicatis, irregulariter intricatis, 2—3,5 μ crassis. Hyphae dissepimentorum similes, confertius intricatae. Basidia 12—18 × 4—4,5 μ , sterigmatibus quaternis, 3—3,5 μ longis instructa. Sporae copiosae, ovoideae, uni vel pluriguttulatae, laeves, hyalinae, 4—4,5 × 2 μ .

Hab. ad truncum putridum ad terram iacentem *Piceae excelsae* in montibus Carpaticis orientalibus: SSSR prope Trebušany, 3. et 20. VII. 1937 A. Pilát legit. Typus in herbario Musei Nationalis Pragae No. 488457—59.

Leptoporus Šimani PILÁT in Atlas des Champignons de l'Europe, vol. III, Polyporaceae, p. 181, 1938.

Syn. *Leptoporus caesius* (Schrad) var. *porioides* BOURDOT in Bull. Soc. Myc. de France 48:252, 1932.

Effusus, tenuis, in circumscriptione plus minusve rotundatus, primum 5—10 mm diam., dein confluens et crustam rotundatam 30—40 mm

diam., metientem formans, margine distinctus et saepe ibi elevatus cingulumque angustum sterilem, 0,25—0,5 mm latum formans, albus, mollis, etiamque exsiccatus mollis et fragilis, fere solum e tubulis constans. Trama tenuissima, gossypina, solum 50—500 μ crassa. Tubuli breves, solum 0,5—1 mm longi, rarius usque ad 2 protracti (substrato obliquo), albi, sicci cremei. Pori rotundato-subangulosi, sat regulares, 0,2—0,3 mm diam., sicci cremei, regulares, non lacerati neque dentati. Trama ex hyphis hyalinis, irregulariter intricatis, hyalinis, 2,5—3,5 μ crassis, mediocriter tunicatis, conspecte lucem frangentibus. Dissepimenta tenua, 100—140 μ crassa, ex hyphis similibus, densius intricatis, 2—3 μ crassis, tenuiter vel mediocriter tunicatis. Hymenium e basidiis et cystidiis constat. Cystidia cylindracea, subconica, apice rotundata vel obtusa, capitulo crystallinico coronata, 12—20 \times 2—4 μ magma, copiosa vel rarius sparsa. Basidia clavata, 8—10 \times 3 μ , sterigmatibus binis vel quaternis, 3—4 μ longis. Sporae cylindraceae, subcurvulae, basi paululum oblique acutatae, hyalinae laeves, plerumque biguttulatae, 4—5 \times 1 μ .

Hab. ad ligna decorticata ramorum emortuorum ad terram iacentium *Fagi silvaticae* in montibus Carpaticis orientalibus: SSSR, Kobylecká Polana (3 collecta) et prope Veliký Bočkov (2 collecta), VII. — 1934 A. Pilát legit. Typus in herbario Musei Nationalis Pragae depositus est.

Leptoporus Loweii PILÁT in Atlas des Champignons de l'Europe, vol. III, Polyporaceae, p. 205, 1938.

Effusoreflexus vel resupinatus, vivus aquose carnosus usque subfibrillosus, exsiccatus fragilis, carposomatibus plerumque seriatim dispositis, rarius imbricatis. Pileus 1—2 cm latus et 0,2—0,4 cm crassus, superficie candidus, pubescens, sparse radialiter fibrillosus, setosus, saepe glabrescens, haud zonatus, vel zonis indistinctis notatus, exsiccatus cremeo-lutescens, hue illuc fuscescens, margine saepe ferrugineo-resinoso, subtus marginem saepe anguste sterilis, subpubescens, exsiccatus a substrato ecarptus et tortus. Trama alba, viva carnosofibrillosa, aquose succosa, exsiccata fragillima, 0,25—1 mm crassa, ex hyphis parum ramosis, subcrasse tunicatis, subgelatinosis, 2,5—4 μ crassis constans. Tubuli albi, 1—3 mm longi, exsiccati tinctu sulphureo. Pori albi, angulosi vel elongati, 0,15—0,25 mm diam. (3—4 ad 1 mm), dissepimenti tenuissimis, fragillimis, dentatis vel ciliatis. Pori obliqui majores. Cystidia nulla. Sporae hyalinae, cylindraceo-ellipsoideae, basi oblique acutatae, 4—5,5 \times 1,5—2 μ .

Hab. ad trunco emortuos coniferarum ad terram iacentes. Montes Carpatici orientales: SSSR, Magura prope Berlebáš, VIII, 1937, frequens. Leptoporus Moeszii PILÁT in Atlas des Champignons de l'Europe, vol. III, Polyporaceae, p. 217, 1938.

Resupinatus, e orbiculari confluens et usque 30 cm latus, superficie nodis tubulis diverse longis instructis ornatus, ex parte effusoreflexus,

conchatus, pileos convexos, usque 3 cm latos et 4—8 cm longos, 4—8 mm crassos, marginem versus attenuatos, sed obtusos vel paululum subinvolutos et ibi steriles, coriaceo-carnosos, sicclos ligneoduros vel osseos formans. Pilei superficie conferte modo concentrico zonato-rimosi, albidi usque fusciduli, iuventute radialiter fibrillosi et breviter radialiterque pilosi, sed mox glabrescentes. Carposomata resupinata 2—4 mm crassa, plus minus secernibilia, subtus brunneo-ochracea. Nodi parte superficiali carposomatum resupinatorum fusti. Tubuli 2—5 mm longi, albidi vel griseolo-fusciduli, regulares, dissepimentis tenuibus, 20—40 μ crassis, ex hyphis conferte intricatis usque conglutinatis, 2—3 μ crassis, hyalinis vel pallide oleoso-lutescentibus. Pori parvi, plus minus angulato-rotundati, regulares, 0,1—0,15 mm diam., haud lacerati, albidi vel pallide griseo-fusti. Hyphae tramales confertissime, plus minusve paralleliter radialiterque intricatae, subcrasse tunicatae, hyaline vel oleoso-lutescentes, 3—5 μ crassae. Basidia hyalina, 8—10 \times 5—6 μ . Sporae haud copiosae, hyalinae, globosae vel subglobosae, laeves, 5—8 μ diam.

Hab. ad truncum *Robiniae pseudacaciae* in horto botanico Budapestino, Hungariae, 1918, Dr. Mágoczy-Dietz legit. Typus in herbario Musei Nationalis Pragae No. 487597 et cotypus in Museo Nationali Budapestino depositus est.

Leptoporus dalmaticus PILÁT in *Atlas des Champignons de l'Europe*, vol. III, p. 218, 1938.

Pileus lateralis vel subeffusoreflexus, 4 cm latus et ad 10—15 cm elongatus, e carnoso durus fragilisque, dissectus triangularis, 2—3 cm crassus, margine attenuatus, adultus superficie laevis, ex albo lutescens vel subochraceus, subgelificatus et cute falsa, sublucida tectus, imbricatus. Tubuli 3—6 mm longi, exsiccati fragiles, albi vel luteo-fusciduli. Pori 0,2—0,3 mm diam., plus minusve orbiculares, albi vel luteofusci, senescentes subbrunnei. Trama pilei carnosa, dein dura et fragillima, rarius paululum suberosa, ex albo ligneo-lutescens, ex hyphis sat laxe intricatis, crasse tunicatis, hue illuc fibrilla formantibus, 2—4 μ crassis, subhyalinis vel oleoso-lutescentibus, pilei superficie subgelificatis constans. Dissepimenta ex hyphis 2—4,5 μ crassis, irregularibus, fragilibus, dense intricatis, crasse tunicatis, lutescentibus. Basidia 12—18 \times 4—5 μ . Sporae amygdaliformes vel elongato-piriformes, basim versus conspecte cuneato-acutatae, laeves, pallide oleoso-fuscidulae, 4—5,5 \times 3—4 μ .

Hab. Ad. tricum Pini maritimae; Jugoslavia: Dubrovnik, VIII. 1936, leg. R. Veselý. Typus in herbario Musei Nationalis Pragae No. 33388.

Leptoporus carpatorossicus PILÁT in *Atlas des Champignons de l'Europe*, vol. III, Polyporaceae, p. 226, 1938.

Paryus, 10—15 mm diam., effusoreflexus, conchiformis, dimidio superiori pileum semiorbicularem, candidum, exsiccando subcremeum, succose carnosum, exsiccatum mollem fragilemque, superficie album vel subcremeum, laevem vel subrugosum glabrumque formans. Habitu Leptoporo lacteo similis. Tubuli 1—3 mm longi, plus minusve angulati, sicci cremei. Trama pilei tenuissima, 0,5—1 mm crassa, ex hyphis hyalinis,

tenuiter tunicatis, parum distinctis, $3-4 \mu$ crassis. Dissepimenta tenua, ex hyphis hyalinis, tenuiter tunicatis, parum distinctis, $2-3,5 \mu$ crassis. Cystidia nulla. Basidia $10-12 \times 4-5 \mu$, tetrasterigmatica. Sporae globoso-ovoideae vel breviter ellipsoideae, laeves, plerumque una gutta magna instructae, $3,5-4,5 \times 3-3,2 \mu$.

Hab. ad ramulos deiectos ad terram iacentes *Fagi silvaticae* in fagetis Carpatorum orientalium: SSSR, prope Kobylecká Polana, VIII. 1928, A. Pilát legit. Typus in herbario Musei Nationalis Pragae No. 36867.

Leptoporus epileucusin PILÁT in *Atlas des Champignons de l'Europe*, vol. III, Polyporaceae, p. 229, t. 141, Fig. 81, 1938.

Syn. *Polyporus epileucus* Fries. p. p. Epicr. 452, 1837, non Quélet, Gillet nec Lloyd.

Lateraliter adnatus, ex parte effusoreflexus, imbricatus, 5×8 cm, latere $2-3$ cm crassus, superficie glaber, solum hue illuc tomento albo, crasso vestitus, mox glabrescens, dissectus saepe subtriangularis, superficie rugoso-confragosus, albus, albidus vel subgriseus usque subfuscus, firme fibrilloso-carnosus, exsiccatus durissimus. Tubuli $6-12$ mm longi, a trama pilei distincti, albi, albidi, carnosii, exsiccati sordide luteo-fusciduli fragilesque. Pori albi, irregulariter angulosi, $0,1-2,5$ mm diam., dissepimentis tenuibus, ex hyphis conferte intricatis usque conglutinatis, $2,5-3,5 \mu$ crassis. Trama pilei ex hyphis tenuiter tunicatis, irregulariter intricatis, $3-4,5 \mu$ crassis, sat lucem frangentibus, hyalinis. Trama veta dura, sed materia sirupposa non impregnata. Basidia $10-15 \times 4-5 \mu$. Sporae late ellipsoideae, hyalinae, laeves, $4-5 \times 3,5 \mu$.

Hab. ad truncos arborum frondosarum, praecipue *Fagi silvaticae*, in fagetis Carpatorum orientalium: SSSR prope Kobylecká Polana, VII. 1929 A. Pilát legit. Leptoporus bredeceiensis PILÁT in *Atlas des Champignons de l'Europe*, vol. III. Polyporaceae, p. 240, t. 159—161, Fig. 87, 1938.

Lateraliter adnatus, succoso-carnosus, subcoriaceus, exsiccatus subdurus et subsuberous, saepe effusoreflexus, imbricatus, $4-10 \times 8-14$ cm, basi $1,5-3$ cm crassus, marginem versus attenuatus et acutus, margine $1-3$ mm sterilis, rarius usque ad marginem fertilis, superficie albus vel lignicolor, grosse radialiter rugosus et confragosus, coriaceo-tomentosus, marginem versus subglabrescens. Tubuli $1-2$ cm longi, ad marginem pilei breviores, a trama pilei distincti, coriaceo-carnosii, albi, dein cremei usque lignicolores, exsiccati ochraceo-fusciduli. Pori elongati, mox larynthici, irregulares, $0,5-5(3)$ mm diam. vel longi, adulti irpexoiditer profunde lacerati, albi, lignicolores, exsiccati ochraceo-fusciduli. Trama pilei heteromorpha, $1-1,5$ cm crassa, dimidio superiore magis gossypina, subalba vel pallide lignicolor, $4-8$ mm crassa, dimidio inferiore compactior, obscurior, lignea, subfibrillosa, viva succosa et

subcarnosa usque subfirma vel coriacea. Trama dissepimentorum pallidior. Hyphae tramales hyalinae, sublaxe intricatae, subtenuiter vel medio-criter tunicatae, septato-nodosae, $5-7 \mu$ crassae. Dissepimenta ex hyphis $4-6 \mu$ crassis, distinctis et sublaxe intricatis. Cytidia nulla. Basidia $15-25 \times 5-7 \mu$. Sporae late ovoideae, basi minime acutatae, hyalinae, plerumque uniguttulatae, copiosae, $7-8,5 \times 5-6 \mu$.

Hab. ad truncum *Fagi silvaticae* in silvia mixta Carpatorum orientalium: SSSR prope Trebušany, in valle Bredečel, VIII. 1934, A. Pilát legit. Typus in herbario Musei Nationalis Pragae.

Trametes kuzyana PILÁT in *Atlas des Champignons de l'Europe*, vol. III. Polyporaceae, p. 285, 1939.

Effusoreflexa, plerumque dense imbricata, saepe concrescens, ligneo-dura. Pileus reflexus, plus minusve semiorbicularis vel irregularis, 1—3 cm latus et 2—8 mm crassus, superficie adpresse radialiter setoso-fibrillosus, saepe scaber, pallide luteo-fuscus, isabellinus, adultus subglaber, margine plus minusve acuto, subtus anguste sterili. Tubuli 1—6 mm longi, lignicolores vel subgrisei, pruinosi, iuventute dissepimentis subcrassis, deinde subtenuibus. Pori irregulariter angulosi, 0,3—0,5 mm diam., relativiter magni, substratu obliquo vel verticali oblique aperti, iuveniles obtusi, dein denticulati vel sublacerati, lignicolores, dein subgrisei vel isabellini. Trama coriaceo-suberosa, dura, 0,5—2 mm crassa, lignicolor, lutescens vel brunnescens, marginem versus in pileis adultis attenuata, ex hyphis oleicoloribus vel fuscidulis, conferte irregulariter intricatis, $4-5 \mu$ crassis composita. Dissepimenta ex hyphis oleicoloribus vel fuscidulis, conferte irregulariter intricatis, $3-4,5 \mu$ crassis, crasse tunicatis. Basidia $12-16 \times 4-5,5 \mu$. Sporae ellipsoideo-elongatae, basi oblique acutatae, hyalinae, $8-12 \times 4-4,5 \mu$.

Hab. ad truncos et ligna *Fagi silvaticae* in fagetis virgineis Carpatorum orientalium. SSSR: Kuzy prope Veliký Bočkov in quatuor locis, VIII. 1934. Herbarium Musei Nationalis Pragae No. 108.267—70. *Trametis gallica* proxime affinis.

Poria gilvella PILÁT in *Atlas des Champignons de l'Europe*, vol. III. Polyporaceae, p. 405, t. 256. Fig. 174, 1941.

Effusa, iuvenilis membranaceo-pergamenea, coriaceo-carnosa, tenuis, exsiccata subfragilis, iuventute Peniophorae giganteae sat similis, deinde tubulis 3—5 (10) mm longis, adulta de substratis laevibus sat bene seceribilis, subtus alutacea, modo concentrico zonata, margine fibrilosopergamenea et ibi iuventute sat late sterilis, dein solum anguste sterilis (1—3 mm), poris ad marginem humilibus, reticuliformibus. Subiculum coriaceum, album, 0,5—1,5 mm crassum, plerumque tenue, sed semper distinctum. Tubuli iuventute solum 0,5 mm longi, 150—300 μ diam., angulati, saepe denticulati, dein conspecte denticulati et pruinoso-puberuli, in speciminiibus adultis 2—5 mm longi, plerumque obliqui, sed non fissi, iuventute albi, dein luteo-fusciduli, griseo-brunnei, nam pori con-

specie pruinosi sunt. Tubulotrama ex hyphis confertissime paralelliter intricatis, oleicoloribus vel luteo-fuscidulis, 3—4 μ crassis. Subiculum ex hyphis hyalinis, subconferte irregulariter intricatis, 4—5,5 μ crassis. Dissepimenta 20—35 μ crassa. Cystidia nulla. Basidia 8—10 \times 4—5 μ . Sporae cylindraceae, subcurvulae, basi minime oblique acutatae, haud raro guttulis binis oleosis polaribus provisae, 4—5 \times 0,6—1,3 μ .

Hab. ad cortices et ligna emortua coniferarum, praecipue Piceae et Abietis in Carpatis orientalibus, huc illuc haud rara. SSSR: Pop Ivan prope Trebušany, Berlebáš, Bílý Potok, Liščenka, Kuzy, — in summa 25 collecta in herbario Musei Nationalis Pragae inveniuntur. Typus No. 20.297. Etiam in Siberia, districtus Kansk, ad ligna Laricis sibiricae, 27. VII. 1934, leg. Trotzuk; herbarium Musei Nationalis Pragae No. 34.289.

Poria mentschulensis PILÁT in *Atlas des Champignons de l'Europe*, vol. III. Polyporaceae, p. 414, t. 261b. Fig. 182, 1941.

Effusa, carnosa, adnata, exsiccatione contracta, subiculo tenuissimo 0,2—0,3 mm crasso, albo vel albido, membranaceo-gossypino, marginem angustum tomentosum, albidum et mox evanescentem formans. Etiam subiculum statu adulto evanescit. Tubuli primum breves, albidi, margine 0,5—1 mm longi, dein ad 3—7 mm elongati, carnosí, regulares, albi, albidi, exsiccati sordide lignicolores, in speciminiibus veteribus sordide fuscis. Pori albi vel albidi, sicci sordide lignicolores, rotundato-angulosi, 0,1—0,4 mm diam., saepe usque angulosi, acuti, fimbriato-denticulati, saepe fissi, exsiccatione contracti. Trama dissepimentorum ex hyphis conferte intricatis usque conglutinatis, 1—2 μ crassis, oleicoloribus, parum distinctis; huc illuc in contextu crystalla irregularia, usque 20 μ diam., versantur. Subiculum ex hyphis laxe intricatis, gossypinis, hyalinis, tenuiter tunicatis, 2—4 μ crassis. Dissepimenta tenua, 30—50 μ crassa. Cystidia nulla. Basidia parum distincta, 7—9 \times 2—3 μ . Sporae copiosae, cylindraceae, arcuatae, hyalinae, laeves, saepe guttulis binis polaribus instructae, 3—4 \times 8—1 μ .

Hab. ad ligna putridissima *Fagi silvaticae* in fagetis virgineis Carpatorum orientalium: SSSR in monte Menčul prope Trebušany, VIII. 1934, leg. A. Pilát. Typus in herbario Musei Nationalis Pragae.

Poria subpudorina PILÁT in *Atlas des Champignons de l'Europe*, vol. III. Polyporaceae, p. 426, t. 269a. Fig. 195, 1941.

Resupinata, tenuis, adnata, haud secernibilis, 0,5—1 mm crassa, fragilis, subiculo tenui, marginem sterile sat latum (1—3 mm) album, vel lignicolorem, tomentoso-byssinum, subfibrilloso-fimbriatum formans. Tubuli recti vel subobliqui, 0,5—1 mm longi, cremeo-lignicolores tinctu pudorino vel roseo-aurantiaco (ut aculei Mycoleptodontis ochracei). Pori concolores, angulosi, pallidiores, obtusi vel subtillime denticulati, 0,2—0,4 mm diam. Tubulotrama et subiculum ex hyphis tenuiter tunicatis, hyalinis, septato-nodosis, 4—5 μ crassis, plerumque granulis crystallinicas calcii oxalatī dense agglutinatis incrustatis. Cystidia nulla. Basidia

$15 \times 5 \mu$. Sporae ovato-ellipsoideae, basi plerumque paululum angustatae et oblique acutatae, tenuiter tunicatae, hyalinae, guttulis parvis oleosis provisae, $5-6 \times 3-3,5 \mu$.

Hab. ad ramos emortuos *Salicis capreae* in silvis Carpatorum orientalium: SSSR, Kosovská Polana—Jalinka, VII. 1930, leg. A. Pilát. Typus in herbario Musei Nationalis Pragae No. 498.304. Species ex affinitate *Poriae gilvescentis* Bres., sed colore alio et sporis diversis insignis.

Poria pulvinascens PILÁT in *Atlas des Champignons de l'Europe*, vol. III. Polyporaceae, p. 451, t. 289b. Fig. 213, 1941.

Poriae corticolae Fr. habitu similis, effusa, primum tenuis, adnata et plana, dein tubuli centro plerumque longiores et ad marginem breviores, que de causa carposomata pulvinata. Iuventute Poriam aneirinam in mentem revocat. Subilicum album, tomentoso-coriaceum, 0,5—1 mm crassum, marginem sterilem tomentosum vel fimbriatum album, adnatum, dein evanescentem formans. Tubuli 0,3—2 mm longi, ex albo lignicolo, exsiccatae ochraceo-fuscidulae. Pori concolores, rotundato-angulati, sat regulares, 0,2—0,3(0,4) mm diam., rarius latiores, subtiliter denticulati, albi, albidi, cremei vel sordide luteoli. Basidia parum distincta. In subhymenio et hymenio guttae copiosae excretionis oleosae et fines hypharum copiosae inveniuntur. Basidia (et cystidiola) 10—15 \times 3—5 μ . Hyphae subiculi sat laxe irregulariter intricatae, hyalinae, solidae, 2—3,5 μ crassae. Hyphae dissepimentorum similes, 2—4 μ crassae, confertius a magis paralleliter intricatae. Sporae ovato-ellipsoideae, basi oblique acutatae, $5-6 \times 3-3,3 \mu$.

Hab. ad ligna *Salicis*. Suecia: Uppland, Bondkyrka „Vardsätra skog“ prope Uppsalam, 16. X. 1936, Seth Lundell legit. Typus in herbario Musei Nationalis Pragae.

Poria subtramea PILÁT in *Atlas des Champignons de l'Europe*, vol. III. Polyporaceae, p. 453, t. 291a. Fig. 215, 1941.

Syn. *Poria medula panis* f. *prunicola* Pilát.

Effusa, plus minusve orbicularis, confluens, adnata, 2—4 mm crassa, subiculo tenui vel subnullo, albo vel albide lignicolori, margine angusto, rotundato, 0,5—1 mm lato, tomentoso-gossypino, distincto, albo vel cremeo. Consistentia coriacea vel tomentoso-coriacea, sed submollis. Tubuli 1—4 mm longi, sat regulares, pallide cremei. Pori rotundati 0,25—0,35 μ diam., ad substrata oblique majores et ellipsoidei, obtusi, non denticulati, velutini, albo-cremei vel pallide ochracei. Tubulotrama ex hyphis subtenuiter tunicatis, 2,4 μ crassis, hyalinis, mediocriter conferte et irregulariter intricatis. Dissepimenta 80—100 μ crassa. Cystidia nulla. Basidia 15—20 \times 6 μ , tetrasterigmatica. Sporae plerumque elongato-ellipsoideae vel ellipsoideo — cylindraceae, basi paululum oblique acutatae, hyalinae, subcopiosae, 9—14 \times 4,5—7,5 μ .

Hab. ad ligna *Pruni Padi*: SSSR, Sibiria, distr. Wasjunganje, leg. Krawzew. Typus in herbario Musei Nationalis Pragae.

Poria pseudoobducens PILÁT, Atlas des Champignons de l'Europe, vol. III. Polyporaceae, p. 462, t. 296b, 297a. Fig. 224, 1941.

Resupinata, adnata vel solum in fragmentis secernibilis, unistratosa, coriacea, subiculo subnullo, solum e tubulis usque ad marginem constans, margine distincto, dein subrotundato. Tubuli unistratosi, 1—4 mm longi, albi vel cremeo-lignicolores, regulares. Pori rotundato-angulati, 0,1—0,15 mm diam., albi, cremeo-lutescentes vel lignicolores, haud denticulati. Tubulotrama ex hyphis hyalinis, subcrasse tunicatis, mediocriter conferte inrrregulariterque intricatis, 3—5 μ crassis. Dissepimenta tenua, regularia. Cystidia nulla. Basidia 10—15 \times 4—5 μ . Sporae globosae vel subovoideae, basi apiculo parvo munitae et plerumque uniguttulatae, 4—4,5 μ diam. Fungus plerumque sterilis.

Hab. ad ligna arborum frondosarum, praecipue *Fagi silvatica* et probabiliter rarissime etiam ad ligna coniferarum. Montes Carpatici, Sibiria. Čechoslovakia: Turňa nad Bodvou, Slovakiae, X. 1934, leg. A. Pilát. SSSR: Bílý Potok, Tiščora, Kuzy, Veliký Bočkov, leg. A. Pilát. Sibiria: Wasjukanje, IX. 1934 leg. Krawtzew.

Habitu macroscopico *Oxyporo populino* var. *obducenti* similis, sed absque cystidiis.

Poria Stellae PILÁT in Atlas des Champignons de l'Europe, vol. III. Polyporaceae, p. 464, t. 299. Fig. 226, 1941.

Late effusa, resupinata, adnata, sed facile secernibilis, viva succose coriacea, deinde coriacea, exsiccata ossea et exsiccatione torta, qua de causa pro parte a substrato ecarpta, iuvenilis margine tomentoso, aggeriformi, adulta margine incrassata, rotundato-sterilis, 1—3 mm lata. Subiculum candidum, tomentoso-coriaceum, semper distinctum, 1—2 mm crassum. Tubuli regulares, recti, rarius subobliqui, in speciminibus perennantibus distincte pluristratosi (2—6 stratosi). Tubuli se elongunt regulariter, sed partes vetustiores colore obscuriore, brunneo, manifestae sunt. Tubuli iuveniles candidi, dein cremei usque fusco-griseoli, usque 10 mm longi. Pori albi, tactu leniter lutescentes vel pallide luteo-rufescentes, serius cremei vel subfusciduli usque griseoli, conspecte parvi, 0,07—0,1 mm lati, regulariter orbiculares vel solum minime angulosi, puberulo-pruinosi, haud denticulati. Tubulotrama gelatinosa, ex hyphis plus minusve paralelliter conglutinatis vel solidis, 4—5,5 μ crassis. Intervalla materia subtiliter granulosa, pallide fuscidula farcta, qua de causa partes tubolorum vetustiores subfuscae sunt. Dissepimenta 20—30 μ crassa. Subiculum coriaceo-tomentosum, candidum, ex hyphis crasse tunicatis vel solidis, hyalinis, crebre ramosis, 4—6 μ crassis constat. Cystidia nulla. Basidia indistincta. Sporae hyalinae, haud copiosae, cylindraceae, subcurvulae, 3—4,5(5) \times 0,5—1 μ .

Hab. ad ligna emortua coniferarum, ex. gr. Piceae, Abietis, Pini silvestris etc., praecipue in silvis montanis borealibusque distributa. Montes Carpatici orientalis: SSSR Bílý Potok prope Trebušany, ad ligna
