

Generally the fructifications of *Monochaezia* and *Pestalotia* are acervuli. Sometimes they show more or less stroma, or none of it, and the 6-celled conidial forms show the least stroma, or none of it, and the 6-celled conidial forms the most. The stroma in the 6-celled conidial forms can be extensive, forms the most. The stroma in the 6-celled conidial forms can be extensive, and enveloping the base and sides of the sporogenous layer as to resemble an apothecial structure. There is considerable uniformity among the fructifications in vitro and considerable variable variation in vivo. The fructifications show variable variation in vivo and considerable variable variation in vitro. The fructifications in vitro and some other plant materials. Their distribution is usually irregular and without order. A punctiform arrangement in leaf spots appears somewhat swollen; later at the summit of the conidium the developing pustules are not singularly arranged, number, distribution, and even size of the fruitifications aids in the removal of the conidia without the loss of their cellular structure, and they appear in spots or dead areas on leaves, bark, stems or biornocular, and they are better with a naked eye, or better with a hand. The black pustules can be observed with the naked eye, or better with a hand than in black coils or masses, leaving a black sooty deposit over the area. The contents are scattered or conchuent, and sometimes densely aggregated. They are black, carbonaceous, impure or the epidemics or covering tissue. The conidial forms are numerous, numerous of the conidiospores like setae, and some other plant materials. Their distribution is usually borne in the matrix and are freed by the fruitings. There are exceptions.

EXAMINATION OF SPECIMENS AND USE OF KEYS

A.E.

Cordia (Lcenes Fung., 1931, Pl. 52, Fungi, 1931) has aroused interest tips like setae, pointed tips like setae, early as 1856 by developing the spore to the development of the conidium, later somewhat swollen; at the summit of the conidium parallel aggregates remain parallel to the arrangement of the conidiospores peristome. *Diplopeltozizria* (Bull., 1878; VI, 7: 55-60, 1878; Cite (Bull., 1878; VI, 7: 55-60, 1878; reported that the specimens are multisetulate and seutulate and considerate He considered that the specimen is either the *Monochaezia* or *Pestalotia* species. The position of the specimen in the author's scheme of classification should be grossly recognized. Are the conidia provided with one, or more than two conidia? The exterior or extreme hyaline cells added to the number of the conidia? [Fig. 1a,c; Fig. 2e,f]. Does the specimen belong to *Monochaezia* or *Pestalotia*? [Fig. 1b,c; Fig. 2b,c].

From here on, the color of the conidial cells, number and peculiarities of the *Monochaezia*, *Quinque-*, or *Sexloculata* section of the genus [Fig. 1b,c; Fig. 2b,c]. The conidial cells will total 4, 5, or 6 cells, thus placing the specimen in either the *Monochaezia*, *Quinque-*, or *Sexloculata*. The exterior or extreme hyaline cells comprising the conidia. The position of the specimen in the author's scheme of classification should be grossly recognized. Are the conidia provided with one, or more than two conidia? The exterior or extreme hyaline cells added to the number of the conidia? [Fig. 1a,c; Fig. 2e,f]. Then determine the number of cells comprising the conidia. The specimen in the author's scheme of classification should be grossly recognized. Are the conidia provided with one, or more than two conidia? The exterior or extreme hyaline cells added to the number of the conidia? [Fig. 1a,c; Fig. 2e,f].

Wear on a glass slide and covered for examination under the microscope.

The fruiting area is treated with a specck of water which is allowed to soak

into the matrix. The pedicels, exterior hyaline cells, and crest of setulae are

removed to the identification of the species, and a smear of setulae are

placed on a glass slide and covered for examination under the microscope.

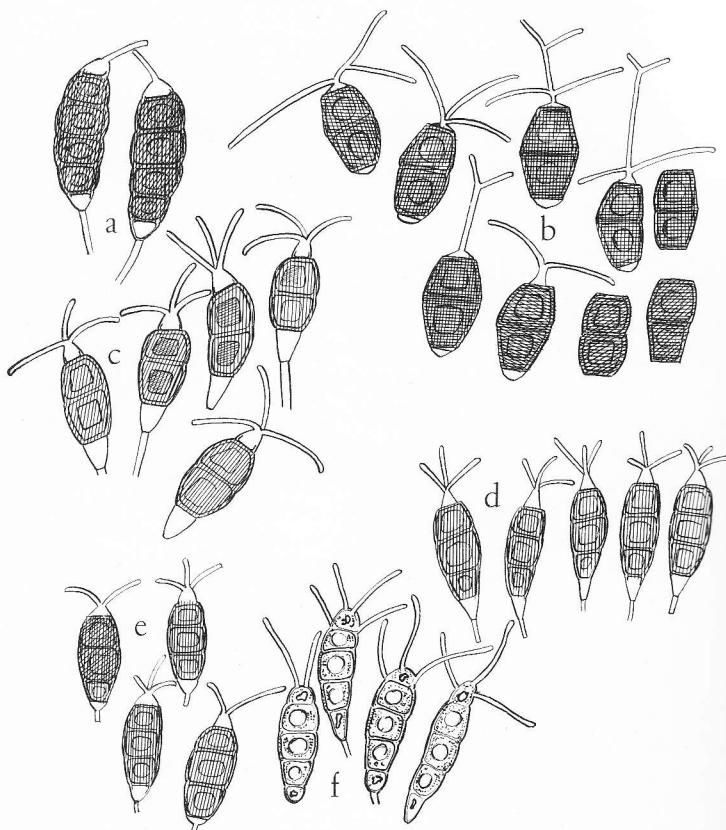

FIG. 1. Conidia of (a) *Monochaetia unicornis*, (b) *Pestalotia hartigii*, (c) *P. stevensoni*, (d) *P. micheneri* (=*P. microspora*), (e) *P. cryptomeriae*, (f) *Pestalozzina unicolor*.

rant conidia and characters should be disregarded. Figures 1-4 will serve to illustrate the variation in number, form, and color of conidial cells and variations of the setulae.

The exterior or terminal cells of the conidia are hyaline or usually so. Rarely are they dilute yellow or faintly colored. The coloration of the intermediate cells is an important diagnostic character. These cells may be faintly colored, brown or yellow-brown, and equally colored (concolorous) [Fig. 1c,d,e]. They may be of two colors or versicolored and slightly or strongly contrasted. The upper two colored cells may be brown or umber in contrast to the pale or yellow-brown color of the lowest of the three colored cells [Fig. 3b,f,g]. These color contrasts appear only among the 5-celled conidial forms with three intermediate colored cells. The upper two colored cells may be dark brown or nearly black and opaque (fuliginous) and most

difficilis or

If the specimen remains in the section *Concolorae*, *Olivace-Pallidæ*, and should the specimen be assigned to the species in that category.

If there is a distinct and consistent color difference between the upper two specimens or yellow-brown, then the specimen belongs in the section *Versicolorae*.

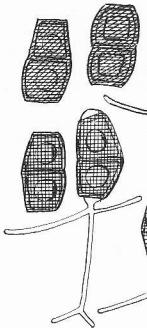

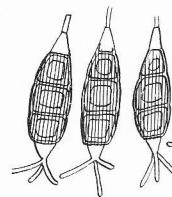

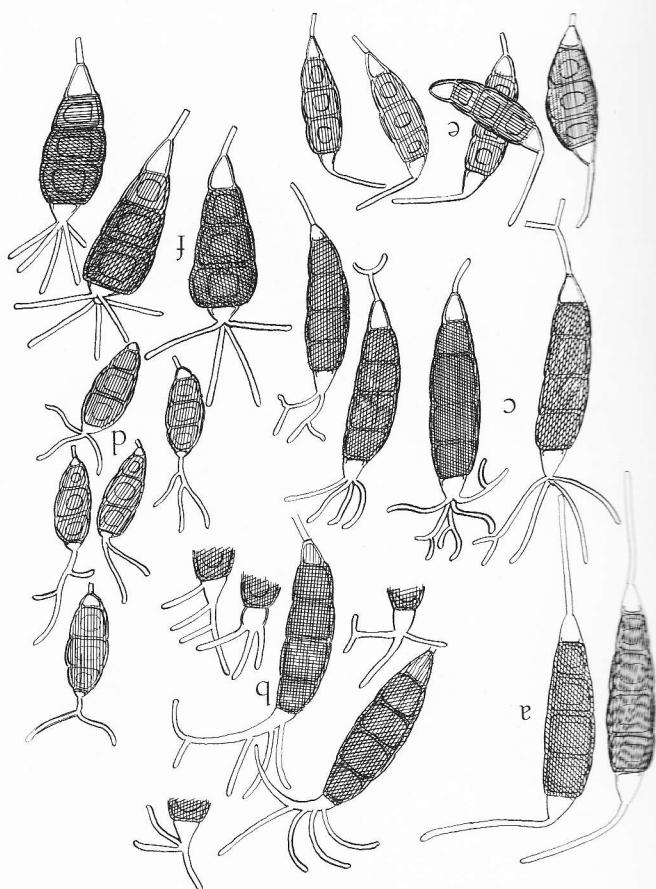

If the lowest colored cells of the conidia throughout the mass of conidia in the microscope mount, the specimen remains in the section *Concolorae*. If the color contrast is not striking enough to be assigned to the species in that category.

If the conidia of a given specimen have concolorous or pale brown cells the specimen belongs in the section *Concolorae*, *Olivace-Pallidæ*.

If the conidia from the upper two and the lowest colored cells differ in color between the upper two and the lowest colored cells. This is the extreme case from the specimen belonging to the genus *Pestalotia*.

If the color can obscure the septum dividing the two upper colored cells.

FIG. 2. Conidia of (a) *Monochaetia setridioides*, (b) *Pestalotia cornu-cervæ*, (c) *P. streevensonii*, (d) *P. guapinii*, (e) *Monochaetia lichenæ* (= *M. monochetaria*), (f) *Pestalotia juncea*.

among the 5-celled brown and slightly or barely colored (concolorous) These cells may be colored (concolorous) of the three colored red (concolorous) among the two colored among the upper two colored red and slightly or barely colored (concolorous) of usually so.

of conidial cells and figures 1-4 will serve *P. streevensonii* until *P. streevensonii*.

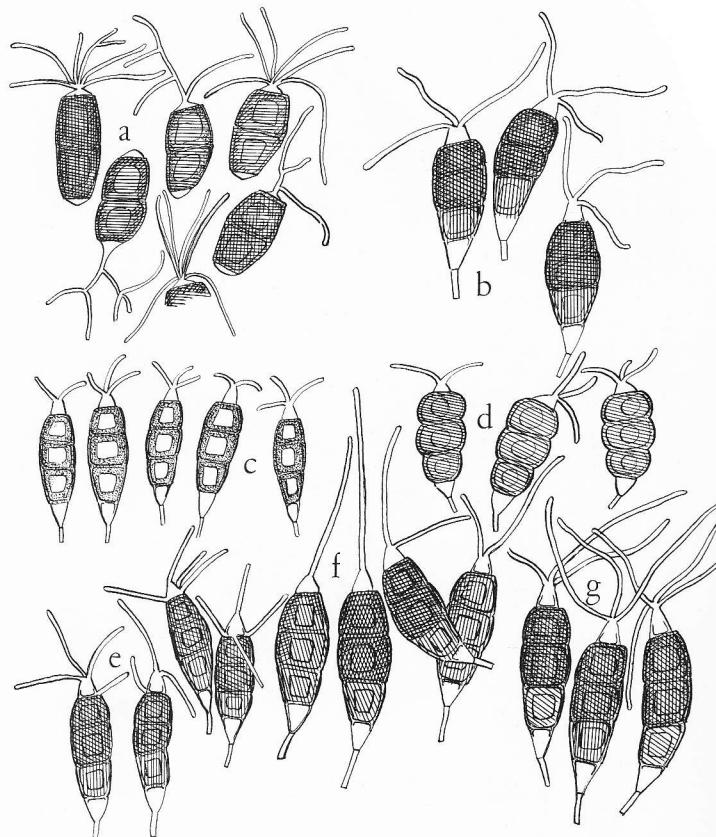

FIG. 3. Conidia of (a) *Pestalotia caulincola*, (b) *P. oleandri*, (c) *P. podocarpi*, (d) *P. torulosa*, (e) *P. gravesii*, (f) *P. monochaetoides*, (g) *P. conigena*.

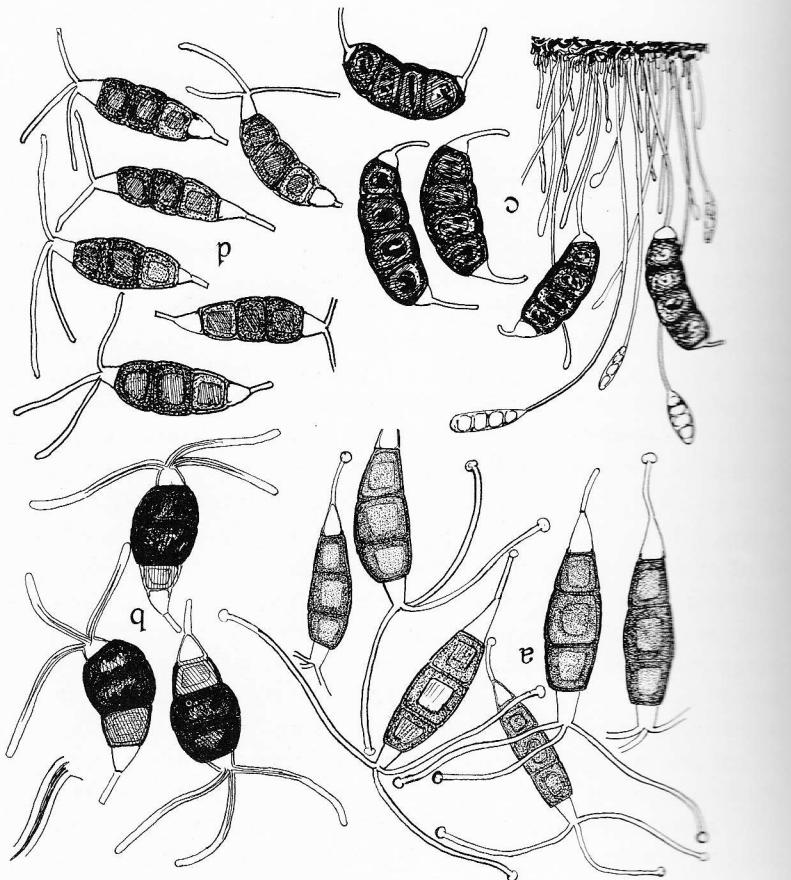

colorae, Umbrae-Olivae. If the contrast is extreme, that is, the upper two colored cells usually swollen, of an intense or chocolate brown color (fuliginous) and even opaque, the lowest colored cell olivaceous or yellow-brown, then the specimen belongs in the section *Versicolorae, Fuliginae-Olivae.* In addition, the conidia may be strongly constricted at the septa dividing the colored cells [Fig. 3d], or usually the fuliginous and the olivaceous colored cells [Fig. 4b]. These color contrasts are illustrated in the text by figures of conidia of representative species embraced within the three categories of the author's system of classification.

The conidia are of different forms. In some species they are clavate, in others narrow fusiform. The exterior hyaline cells may be acute, long or short, cylindric, turbinate, or conic. These peculiarities are useful distinguishing characters in defining species.

The setulae, in addition to number and size, may show other peculiarities. They may arise together at the summit of the apical cells or they may be disseminated. They may arise from the bases of the apical cells [Fig. 3e]. The setulae may be slope or even extended backward. If coarse and thick, they may show a lumen extending and flexuous or coarse and rigid, projecting forward and widely divergent or simple or branched, or both. The length of the setulae and their number, the shape of the base of the setulae toward their middle point [Fig. 4b]. They may be acute, long or be clavate, in

the upper two of them brown orumber, the lowest one oliveaceous or pale brown. The upper two of them brown orumber, the lowest one oliveaceous or pale brown. In the text by figures of the oligivaceous colored categories of the septa dividing the ligulae-Olivae. In brown color (full-brown, yellow-brown), the upper two of them brown and opaque; stout setulae with lumen. (c) *Monocheatia cerasi*: conidia with hyaline exterior cells and four filiginous, opaque sporogenous layer; conidia with hyaline exterior cells and four filiginous, opaque intermediate cells. (d) *Pestalotia*: conidia with dark brown and opaque; stout setulae with lumen. (e) *Pestalotia*: conidia with three intermediate cells; setulae with knobbed or spatulate extremities.

FIG. 4. Variation in form and color of conidia. (a) *Pestalotia rheae*; three concolorous

the setulae may be capitate or spatulate [Fig. 4a]. Consideration of all the features appears in the keys to the species and the species descriptions.

Units of measure can be useless if the calibration of the microscope is inaccurate or if low-power lenses are used. Measurements are changed by the culture of the fungus on different substrata and they are increased by growth on artificial nutrient media. The subject of variation of the species and the influence of substrate on the form and dimensions of the conidia have been treated by numerous investigators and recently by Tandon (Proc. Nat. Acad. Sci. India 25, 1-2, 11-14, 1956) and Gambogi (Nuovo Gior. Bot. Ital. n.s. 63, 2-3, 248-256, 1956). Therefore, latitude must be recognized in employing the measurements in the text, and small differences in width and length between descriptions and specimens are insignificant. With this approach the keys should be helpful in the identification of specimens and in discouraging the erection of superfluous species.

There are still too many species of *Pestalotia*. The specimen must be distinctly different from anything that is recognized to be considered new. To the student disposed to naming new species, let me advise caution and judgment. If the traditional system of describing new species continues, then some bolder plan of regulation and administration more effective than the present method is necessary to curb the practice. Otherwise a monographic study can be futile and virtually impossible of accomplishment in view of the magnitude of the work and the inaccessibility of type material.

Conidia 18-26 μ
e. Setulae 4-5, 15-30 μ long 74. *P. tenuicilli*
e. Setulae 4 up to 14 μ long 75. *P. watsoniae*
d. Colored cells brown to fuliginous
e. Setulae 3, 13-16 μ 76. *P. ploispora*
d. Colored cells brown to fuliginous, walls thick
dark; apical cells obscure, basal cells
cytindrical
e. Setulae 3-4, 15-29 μ long 77. *P. puvae*
c. Conidia 5.5-7.5 μ wide
e. Setulae 3, 5-7 μ 78. *P. maura*
d. Colored cells oliveaceous or pale brown
e. Setulae 2-4, usually 3, 7-25 μ long. 79. *P. camphorii*
d. Colored cells oliveaceous or pale brown
e. Setulae 3 up to 8 μ long 80. *P. stevensonii*
e. Setulae 2-4, usually 3, 7-25 μ long. 81. *P. maculicola*
c. Conidia 7.5-8.5 μ wide
d. Colored cells fuliginous, walls thick
dark; apical cells obscure, basal cells
cytindrical
e. Setulae 3-4, 15-29 μ long 82. *P. jacksoniae*
Conidia 8-10 μ wide
d. Colored cells brown to fuliginous
e. Setulae 3-4, 15-29 μ long 83. *P. hordeodestra*
e. Setulae 4-5, 20-27 μ long 84. *P. penzigi*
e. Setulae 2-6, 8-20 μ long 85. *P. insulera*
Conidia 6-10 μ wide
e. Setulae 3, 20 μ long 86. *P. hordeodestra*
e. Setulae 4-5, 20-27 μ long 87. *P. penzigi*
e. Setulae 2-6, 8-20 μ long 88. *P. insulera*
Conidia 6-8 μ wide
e. Setulae 3, 20 μ long 89. *P. hordeodestra*
e. Setulae 4-5, 20-27 μ long 90. *P. penzigi*
e. Setulae 2-6, 8-20 μ long 91. *P. insulera*
