

Vollstadt, M. G. R., Ferger, S. W., Hemp, A., Howell, K. M., Bohnig-Gaese, K. and Schleuning, M. 2017. Seed-dispersal networks respond differently to resource effects in open and forest habitats. – Oikos doi: 10.1111/oik.04703

Appendix 1

List of all variables included in the analysis. Given are means, standard deviation as well as minimum and maximum values for each variable. Habitat structure is the mean value of canopy height, canopy closure and vegetation heterogeneity, each scaled to zero mean and unit variance. The number of available fruits was log-transformed prior to analyses. Fruit diversity was calculated as the Shannon index of fruits per species for each plot. We also provide the number of plots on which we were able to collect data or calculate the specific metric.

	Mean	SD	Minimum	Maximum	n plot
Temperature [°C]	15.6	4.1	9	21.6	50
Precipitation [mm]	1611.6	527.8	609	2653	50
Habitat structure	0	0.9	-1.8	1.9	50
Fruit availability [log N fruits]	4.27	1.14	1.84	7.08	50
Fruit diversity	0.69	0.54	0	1.94	50
Frugivore species	10.1	5.5	2	24	50
Plant species	5.8	3.5	1	15	50
Shannon interaction diversity	2.1	0.9	0.5	3.6	45
Interaction evenness	0.6	0.1	0.3	0.9	45
Network specialization	0.5	0.2	0.1	1	37

Appendix 2

List of all study plots and the predictor and response variables used in the linear models. For every study plot, we show the elevation above sea level (m asl), mean annual precipitation (prec [mm]), mean annual temperature (temp [$^{\circ}$ C]), habitat complexity (hab, mean of canopy height, canopy closure and vegetation heterogeneity per plot), fruit availability (N fruit [log]), fruit diversity (H fruit), species richness of plants (N plant) and birds (N bird), Shannon interaction diversity (H), interaction evenness (E_H) and network specialization (H_2'); H_2' could not be calculated for all plots. Abbreviations of study plots refer to the corresponding habitat type: Sav = savanna, Mai = maize field, Flm = lower montane forest, Hom = Chagga homegarden, Cof = coffee plantation, Gra = grassland, Foc = *Ocotea* forest, Fod = disturbed *Ocotea* forest, Fpo = *Podocarpus* forest, Fpd = disturbed *Podocarpus* forest.

Plot	m	Prec	Temp	Hab	N	H	N	N	H	E_H	H_2'

Appendix 3

List of models contained in the set of best linear models with $\Delta\text{AICc} < 2$ for (a) Shannon interaction diversity (H), (b) interaction evenness (E_H) and (c) network specialization (H_2'). In all cases, the full model included main and two-way interaction effects of temperature, precipitation, habitat complexity, fruit diversity (H fruits) and fruit availability (N fruits). All predictor variables were scaled to zero mean and unit variance before analysis. Shown are the standardized full model estimates for each predictor in the respective model.

(a)	Intercept	H fruits	Habitat	N fruits	Precipitation	Temperature	Habitat × N fruits	N fruits × Temperature	ΔAICc
(b)	2.06	0.64	-	0.47	-	0.14	-	-	0.00
	2.06	0.65	-	0.46	-	-	-	-	0.17

	0.49	-	0.11	-0.03	-	0.11	-0.12	-	0.00

Appendix 4

List of fleshy-fruited plant species recorded on 50 study plots between November 2013 and October 2015. Given is the frequency the respective species interacted with frugivores, pooled over all plots. Range gives the lowest elevation and the highest elevation a plant species was observed. Plants are ordered alphabetically within the respective taxonomic division.

Scientific name	Family	N interactions	Range [m a.s.l.]

Appendix 5

List of the fruit-eating bird and mammal species observed on 50 study plots during the study period (November 2013–October 2015). Given is the number of individual visits from the respective species that have been observed legitimately dispersing seeds, pooled over all study plots. The range gives the lowest elevation and the highest elevation a species has been observed at. Birds are named and ordered taxonomically following Zimmerman et al. (1999), mammals following Kingdon et al. (1997).

<i>Paraxerus lucifer</i>	Sciuridae	21	1560–2120

Appendix 6

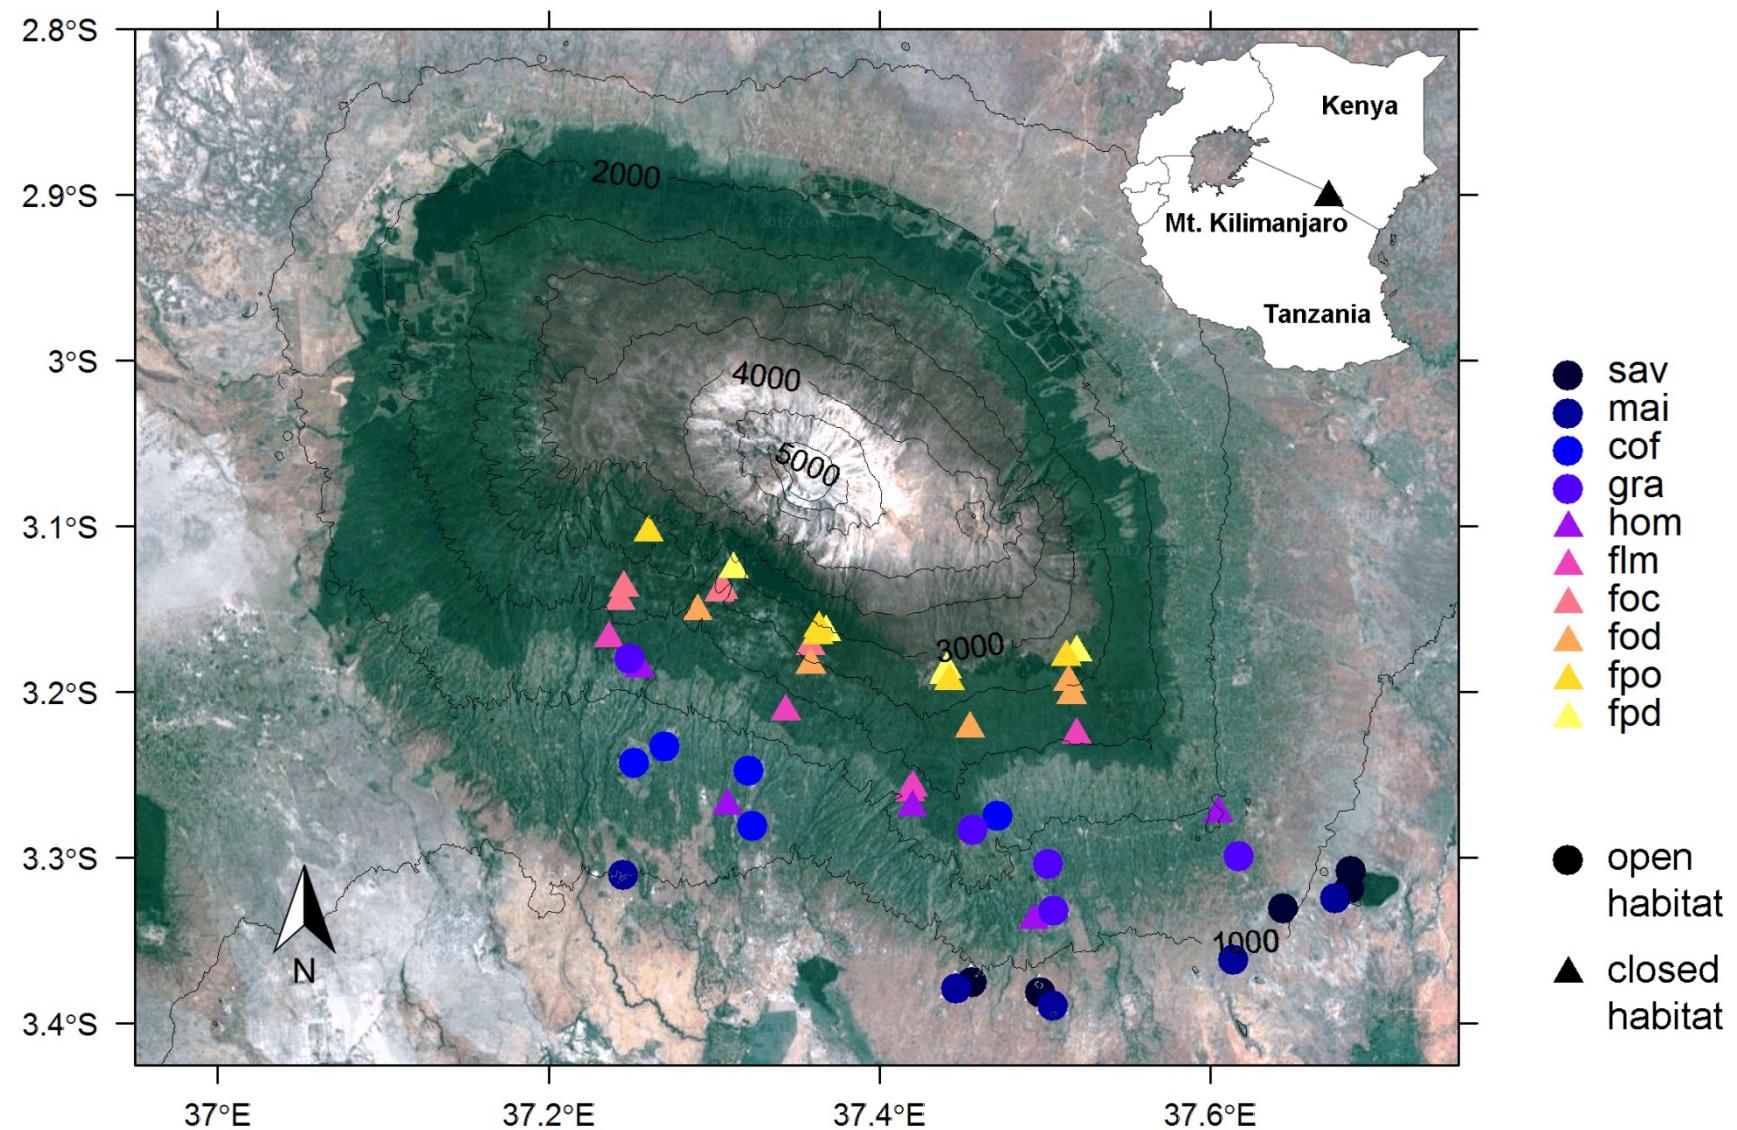

Location of the study plots on the southern slopes of Mt Kilimanjaro, Tanzania. We worked on 50 study plots, covering ten habitat types each with five replicate plots. We excluded 15 plots in the alpine zones, since no frugivore activity could be observed at these elevations. Different habitat types are indicated by different colors. Open habitats refer to study plots with 0 to – 1 standard deviation units of habitat complexity (circles), while closed habitats refer to study plots with 0 to 1 standard deviation units of habitat complexity (triangles).

Appendix 7

Accumulation curves showing the relationship between link richness and the number of observed interaction events for each plot, separately plotted for the plots of each habitat type. We used a sample-based rarefaction method to calculate plot-specific accumulation curves and computed means (points) and the corresponding standard deviations (error bars) across plots of the same habitat type. In order to account for variability in frugivore activity per plot, link richness and the number of observed interaction events were divided by the respective plot maximum. Open habitats (habitat complexity: 0 to -1 standard deviation units) are shown with points and closed habitats (habitat complexity: 0 to 1 standard deviation units) are shown with triangles. Habitat types are ordered from lower to high elevations: savanna (sav), maize field (mai), lower montane forest (flm), Chagga homegarden (hom), coffee plantation (cof), sun coffee (sun), grassland plots (gra), *Ocotea* forest (foc), disturbed *Ocotea* forest (fod), *Podocarpus* forest (fpo), disturbed *Podocarpus* forest (fpd). Sampling effort per habitat corresponds to five plots with an observation time of 25 h on each plot.
