Senanayake IC, Lian TT, Mai XM, Jeewon R, Maharachchikumbura SSN, Hyde KD, Zeng YJ, Tian SL, Xie N 2020 – New geographical records of *Neopestalotiopsis* and *Pestalotiopsis* species in Guangdong Province, China. Asian Journal of Mycology 3(1), 510–530, Doi 10.5943/ajom/3/1/19

Abstract

A study of monocotyledon inhabiting fungi in Guangdong Province, China resulted in the collection of several pestaloid taxa. Evidence from multi-locus phylogenies using ITS, BT and *tef* 1– α , together with morphology revealed *Neopestalotiopsis alpapicalis*, *Pestalotiopsis diploclisiae* and *P. parva* from living leaves of *Phoenix roebelenii*. *Pestalotiopsis parva* was also found on a dead petiole of *Phoenix* sp. and *P. diploclisiae* on dead leaves of *Butia* sp. *Pestalotiopsis foedans*, *P. lawsoniae*, *P. macadamia* and *P. virgatula* have been reported in Guangdong Province, and *Pestalotiopsis parva* and *P. diploclisiae* reported for the first time. This *Neopestalotiopsis alpapicalis* collection is the first species of the genus collected from this province. We provide descriptions and illustrations for these three isolates. Additionally, we provide a list of *Pestalotiopsis* and *Neopestalotiopsis* species recorded from China.

Key words – Appendage bearing conidia – Coelomycetes – Monocotyledons – Saprobes – Sporocadaceae

Introduction

Pestalotiopsis Steyaert was introduced to accommodate pestaloid species with 5-celled conidia (Steyaert 1949). Maharachchikumbura et al. (2014) re-examined *Pestalotiopsis* at the morphological and molecular levels and introduced two new genera, *Neopestalotiopsis* and *Pseudopestalotiopsis*. Currently, these three genera placed in Sporocadaceae (Amphisphaeriales) (Wijayawardene et al. 2018, Hyde et al. 2020). *Neopestalotiopsis* typified by *N. protearum* (Crous & L. Swart) Maharachch., K.D. Hyde & Crous, is morphologically distinguished from other pestaloid genera by its varicolored median cells and indistinct conidiophores which are often reduced to conidiogenous cells. *Pestalotiopsis* typified by *P. guepinii* (Desm.) Steyaert and is easily

distinguished from other pestaloid genera as its conidia have concolourous median cells (Maharachchikumbura et al. 2014).

Species in both *Pestalotiopsis* and *Neopestalotiopsis* commonly occur as endophytes in leaves (Hu et al. 2007, Liu et al. 2010, Maharachchikumbura et al. 2012a, Debbab et al. 2013, Chen et al. 2018, Norphanphoun et al. 2019), saprobes on dead leaves (Ariyawansa & Hyde 2018, Tsai et al. 2018), bark and twigs (Ellis & Ellis 1997) or human and animal pathogens (Monden et al. 2013). Some species found from soil, fabrics, wools and some are in the extreme environments (Guba 1961, Strobel et al. 1996, Tejesvi et al. 2007). Some *Pestalotiopsis* species can degrade plastics (Russell et al. 2011). Pestaloid endophytes produce chemical compounds, which use in therapeutic applications and agriculture (Aly et al. 2010, Xu et al. 2010, 2014). Therefore, investigation of novel pestaloid taxa and their chemical properties are of importance.

In this study, we collected three pestaloid taxa from Shenzhen, Guangdong Province, China, and their identifications, and phylogenetic relationships are investigated based on morphology and DNA sequence data of the internal transcribed spacer (ITS), β -tubulin (BT) and partial translation elongation factor 1- α gene (*tef 1- α*). Additionally, a list of *Pestalotiopsis* and *Neopestalotiopsis* species recorded from China is provided.

Materials & Methods

Sample collection and fungal isolation

Samples were collected in a survey of monocotyledon inhabiting fungi during 2018–2019 in Guangdong Province, China. The samples were brought to the laboratory in paper bags. They were examined and photographed using a Carl Zeiss Discovery V8 stereomicroscope fitted with Axiocam. The morphological characters were photographed using a Nikon Eclipse 80i compound microscope fitted with a Canon 450D digital camera. All microscopic measurements were made with Tarosoft image framework (v. 0.9.0.7). Colony characters were recorded from cultures grown on potato dextrose agar (PDA).

Single conidia isolation was carried out following the method described by Senanayake et al. (2018). Germinated conidia were aseptically transferred into fresh PDA plates, and incubated at 16°C to obtain pure cultures. Cultures were later transferred to PDA slants and stored at 4°C for further studies. All the voucher specimens are deposited in the fungaria of Mae Fah Luang University (MFLU), and living cultures are deposited at the Culture Collection of Kunming Institute of Botany (KUMCC).

DNA extraction, PCR amplification and DNA sequencing

Fungal mycelium grown on PDA for two weeks at 16°C in the dark and fruit bodies directly picked from the specimens were used for DNA extraction using M5 fungal Genomic DNA extraction kit. PCR reactions were carried out using ITS1/ITS4 for internal transcribed spacer nrDNA (ITS) (White et al. 1990), BT2a/BT2b for β -tubulin (BT) (Glass & Donaldson 1995), and EF1-728F/EF2 for translation elongation factor 1- α (*tef 1- α*) (Rehner 2001, Liu et al. 2017) genes according to the same protocol of Maharachchikumbura et al. (2014).

The amplification reactions were carried out with the following protocol: 25 μ L reaction volume containing 1 μ L of DNA template, 1 μ L of each forward and reverse primers, 12.5 μ L of 2 \times PCR Master Mix and 9.5 μ L of double-distilled sterilized water (ddH₂O). The PCR products were observed on 1% agarose electrophoresis gel stained with ethidium bromide. Purification and sequencing of PCR products were carried out at the Sunbiotech Company, Beijing, China. Sequence quality was checked and sequences were concatenated with DNASTAR Lasergene v.7.1. Sequences derived in this study were deposited in the GenBank, and accession numbers were obtained (Table 1).

Sequence alignment and phylogenetic analyses

BLASTn searches were made using the newly generated sequences to assist taxon sampling

for phylogenetic analyses. All sequences obtained from GenBank and used by Maharachchikumbura et al. (2014, 2016), Liu et al. (2017), Nozawa et al. (2017), Ariyawansa & Hyde (2018), Chen et al. (2018), Tibpromma et al. (2018), Tsai et al. (2018), Watanabe et al. (2018), Norphanphoun et al. (2019), are listed in Table 1. DNA sequence data of the ITS, BT and *tef 1- α* sequence alignments were done using default settings of MAFFT v.7 (Katoh et al. 2017) and manually adjusted using BioEdit 7.1.3 (Hall 1999) to allow maximum alignment and minimum gaps. The evolutionary models for phylogenetic analyses were determined by MrModeltest v. 2.3 under the Akaike Information Criterion (AIC) was implemented in PAUP v. 4.0b10 (Nylander 2004).

Maximum likelihood analysis was performed by RAXML (Stamatakis & Alachiotis 2010) implemented in raxmlGUIv.1.3 (Silvestro & Michalak 2012). The search strategy was set to rapid bootstrapping, and the analysis carried out using the GTRGAMMAI model of nucleotide substitution with 1,000 replicates.

For the Bayesian inference (BI) analyses of the individual loci and concatenated ITS, BT and *tef 1- α* alignment, the above-mentioned model test was used to determine the best fitting nucleotide substitution model settings for MrBayes v. 3.0b4. Dirichlet base frequencies and the GTR+I+G model with inverse gamma-distributed rate were predicted by the MrModeltest analysis for all three data partitions and used in the Bayesian analysis.

The Markov Chain Monte Carlo sampling (MCMC) resulted in MrBayes v. 3.0b4 (Huelsenbeck et al. 2003) was used to calculate Posterior probability values (Zhaxybayeva & Gogarten 2002). Four simultaneous Markov chains were initially run for 10,000,000 generations, and every 500th generation was sampled. The distribution of log-likelihood scores was observed to check whether sampling is in stationary phase or not and Tracer v1.5 was used to check if further runs were required to reach convergence or not (Rambaut & Drummond 2007).

The Bayesian analysis lasted 10,000,000 generations (average standard deviation of split frequencies value = 0.0098), and the consensus tree and posterior probabilities were calculated after discarding the first 20% of sampled trees as burn-in. The remaining trees were used for calculating posterior probabilities in the majority rule consensus tree. The bootstrap values equal to or greater than 0.9 are given below or above each node (Figs 1, 2). The phylogram was visualized in FigTree v. 1.2.2 (Rambaut & Drummond 2008).

Table 1 Details of the isolates used in the phylogenetic tree. Newly generated sequences are bold.

Results

Phylogenetic inferences

The first combined BT, ITS and *tef* 1- α sequence dataset comprised 102 strains of *Pestalotiopsis*, and *Neopestalotiopsis* sp. (CBS 119.75) was the outgroup taxon. The second combined BT, ITS and *tef* 1- α sequence data set comprised 72 sequences of *Neopestalotiopsis* with *Pestalotiopsis parva* (CBS 265.37) as the outgroup taxon. Both concatenated data matrixes comprised 1527 characters (ITS: 566, BT: 469 and *tef* 1- α : 490). All individual trees generated under different criteria. Single-gene datasets were essentially similar in topology and not significantly different from the tree generated from the concatenated dataset (not discussed herein).

Maximum likelihood analysis for *Pestalotiopsis* with 1,000 bootstrap replicates yielded a tree with the likelihood value of $\ln: -13138.225580$ and the following model parameters: alpha: 0.550988; $\Pi(A)$: 0.239550, $\Pi(C)$: 0.287070, $\Pi(G)$: 0.215467 and $\Pi(T)$: 0.257914. Maximum likelihood analysis for *Neopestalotiopsis* with 1,000 bootstrap replicates yielded a tree with the likelihood value of $\ln -6466.001103$ and the following model parameters: alpha: 0.731256; $\Pi(A)$: 0.234344, $\Pi(C)$: 0.266539, $\Pi(G)$: 0.216132 and $\Pi(T)$: 0.282985. The ML analyses also resulted in similar tree topologies to those obtained in the Bayesian analyses. The best scoring RAxML trees derived from the analyses of the concatenated datasets for *Pestalotiopsis* (ingroup) and *Neopestalotiopsis* (ingroup) are shown in Figs 1, 2, respectively. Maximum likelihood bootstrap values $\geq 50\%$ and Bayesian inference (BI) ≥ 0.9 are given at each node.

In our concatenated ML analyses, one *Pestalotiopsis* isolate (KUMCC 20-0035) form a distinct subclade with *P. diploclisiae* (CBS 115449) with high statistical support (Fig. 1). In addition, the other two isolates of *Pestalotiopsis* (KUMCC 20-0038 and MFLU 20-0060) form a separate, high statistical supported lineage with *Pestalotiopsis parva* (CBS 278.35 and CBS 265.37). Hence, *Pestalotiopsis* strains of KUMCC 20-0038/MFLU 20-0060 is confirmed as *Pestalotiopsis parva* (Fig. 1). In the second dataset, two strains of *Neopestalotiopsis* form a distinct subclade with *Neopestalotiopsis alpapicalis* and *N. rhizophorae* with high statistical support. Hence, this collection is proposed here as *Neopestalotiopsis alpapicalis* (Fig. 2).

Taxonomy

Pestalotiopsis diploclisiae Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 160 (2014) Fig. 3

Facesoffungi number: FoF 06982

Saprobic, associated with dead leaves of *Butia* sp. Sexual morph: Undetermined. Asexual morph: *Conidiomata* 500–900 μm diam., pycnidial, globose, blackish brown, immersed on substrate, semi-immersed in PDA, releasing conidia as a black, slimy, globose, glistening mass on culture media. *Conidiophores* indistinct or reduced to conidiogenous cells. *Conidiogenous cells* 5–20 \times 2–3 μm ($\bar{x} = 11 \times 2.8 \mu\text{m}$, $n = 20$), discrete, lageniform, hyaline, smooth-walled, annellidic, proliferating 2–3 times percurrently, collarete present, may not appears as flared. *Conidia* 18–25 \times 5–7 μm ($\bar{x} = 23 \times 6 \mu\text{m}$, $n = 20$), fusiform to clavate, straight to slightly curved, wall of one side curved than other side, 4-euseptate; basal cell obconic with a truncate base, hyaline or sometimes greenish brown, thick-and smooth-walled, 2–3.5 μm long ($\bar{x} = 2.9 \mu\text{m}$, $n = 20$); three median cells \pm equal, each 4–5 μm long ($\bar{x} = 4 \mu\text{m}$), doliiform or trapezoid, concolorous, pale brown, septa and periclinal walls darker than rest of the cell, wall smooth; apical cell 3–5 μm long ($\bar{x} = 3.9 \mu\text{m}$, $n = 20$), hyaline, conic to acute with truncate base; apical appendages 8–13 \times 0.5–1 μm ($\bar{x} = 11.5 \times 0.5 \mu\text{m}$, $n = 40$), 3–4 (mostly 3), tubular, inserted at different loci but in a crest at the apex of the apical cell, unbranched, flexuous, rough; single basal appendage, tubular, unbranched, centric, 3–6 μm long ($\bar{x} = 4.9 \mu\text{m}$, $n = 20$).

Culture characteristics – Colonies on PDA reaching 2 cm diam., after 1 week at 18°C, under dark, colonies circular, medium dense, aerial mycelium on surface raised, white from above and reverse; fruiting bodies appears as black slimy bubbles.

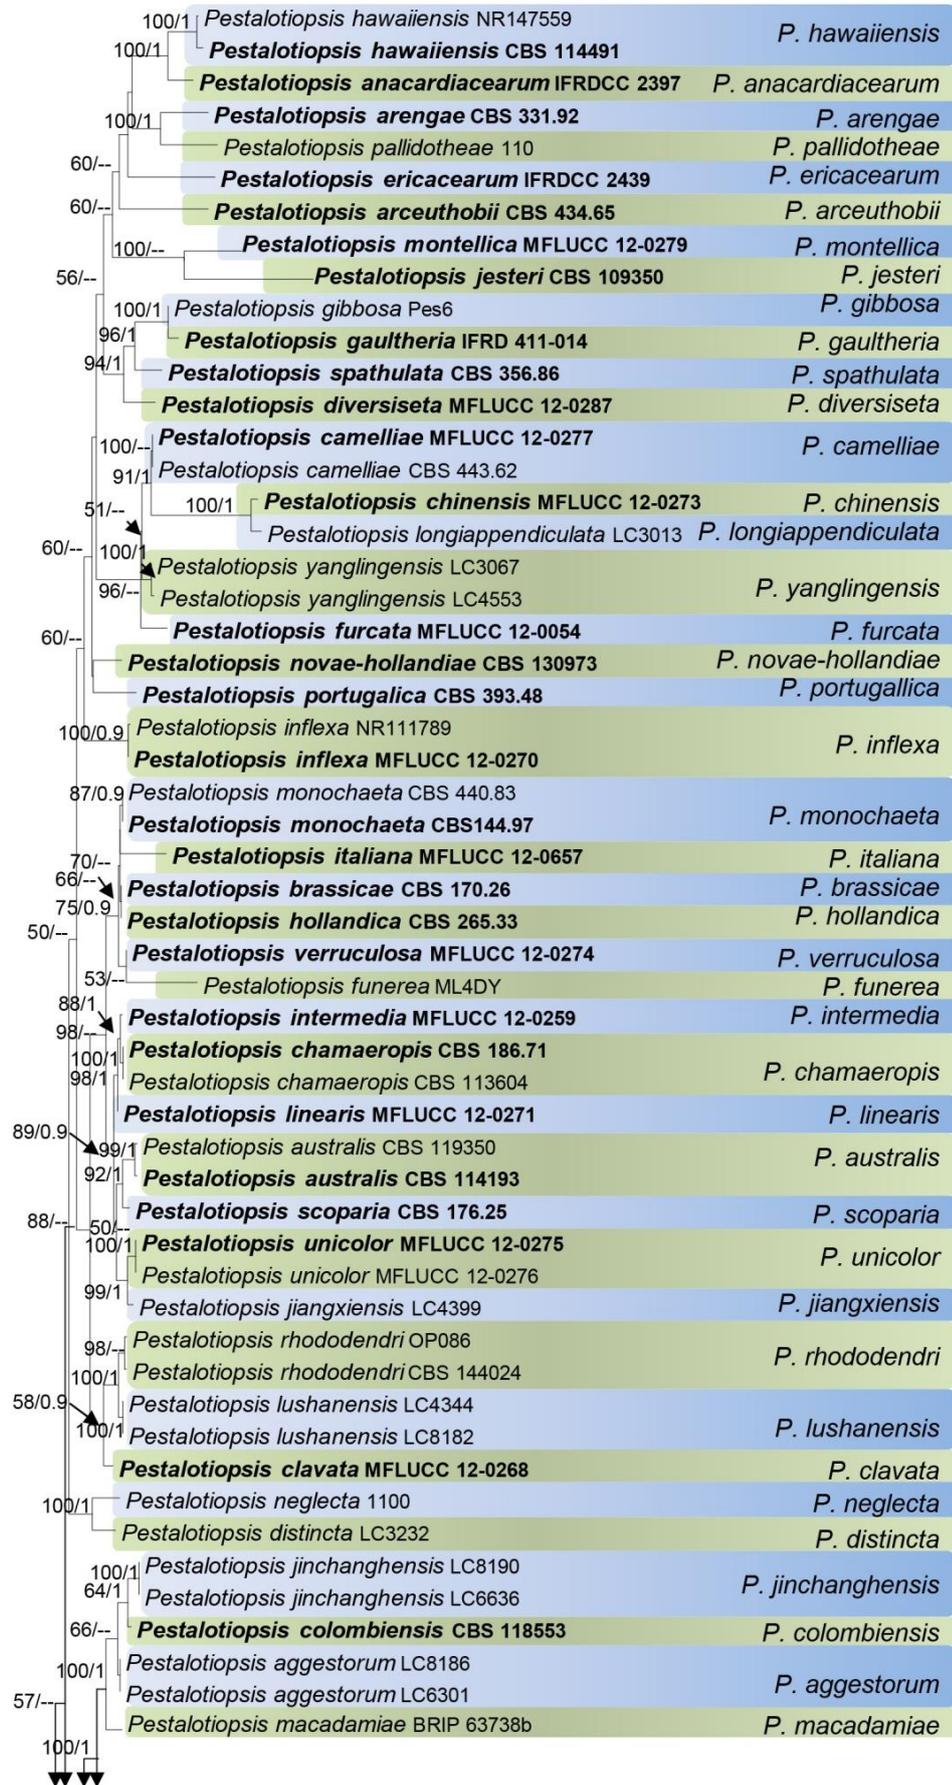

Fig. 1 – Phylogram generated from maximum likelihood analysis based on combined ITS, BT and tef 1– α sequence data. Bootstrap support values for ML greater than 50% and Bayesian posterior

probabilities greater than 0.9 are given near nodes respectively. The tree is rooted with *Neopestalotiopsis* sp (CBS 119.75). Ex-type strains are in black bold and the newly generated sequences are indicated in blue bold.

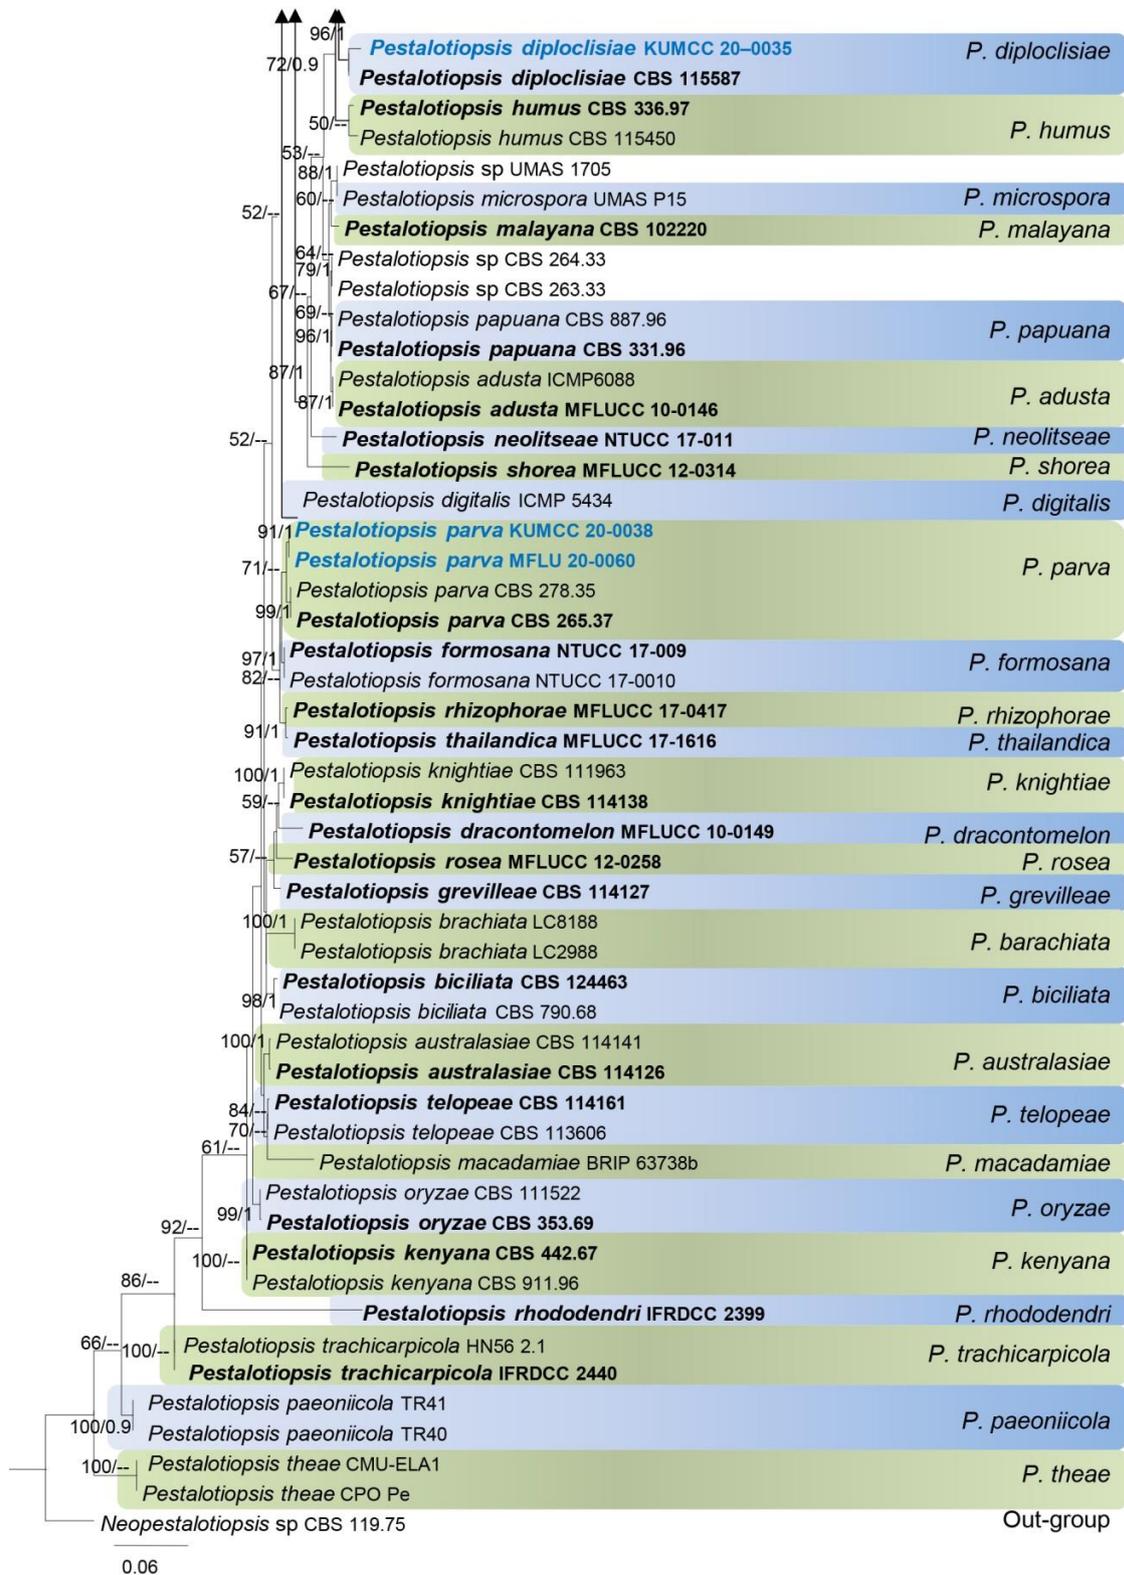

Fig. 1 – Continued.

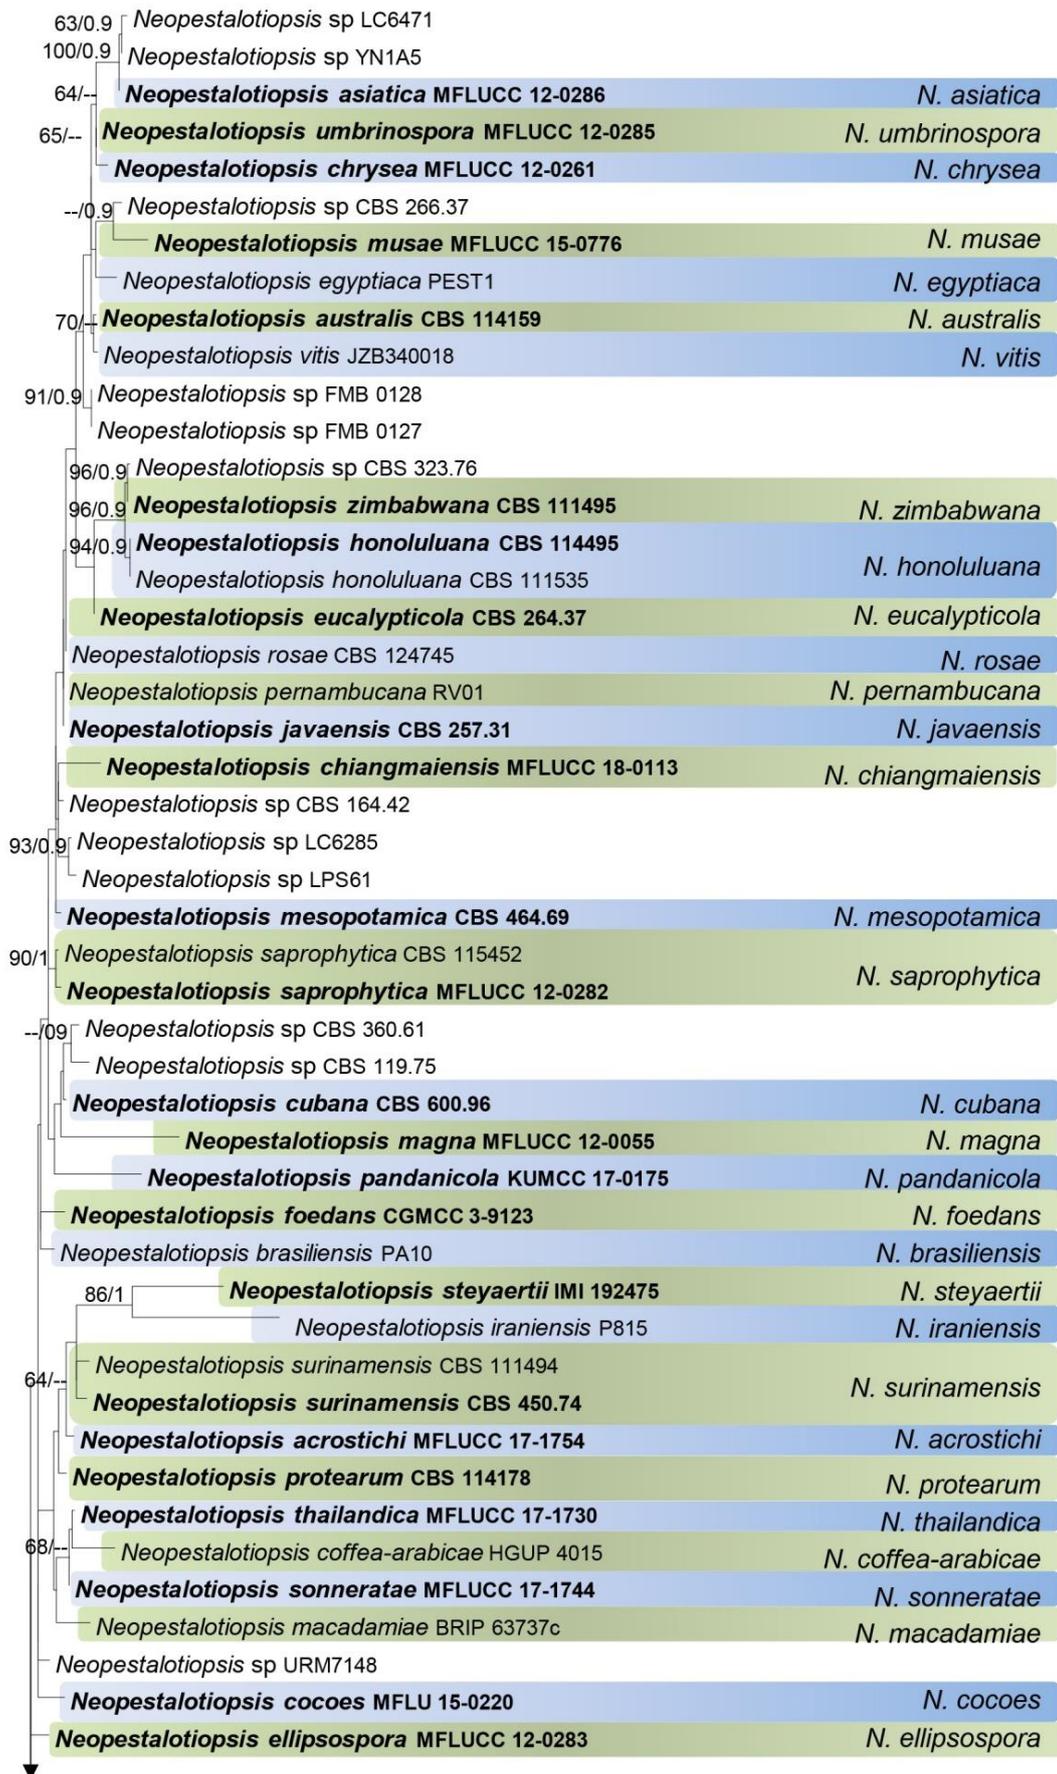

Fig. 1 – Continued.

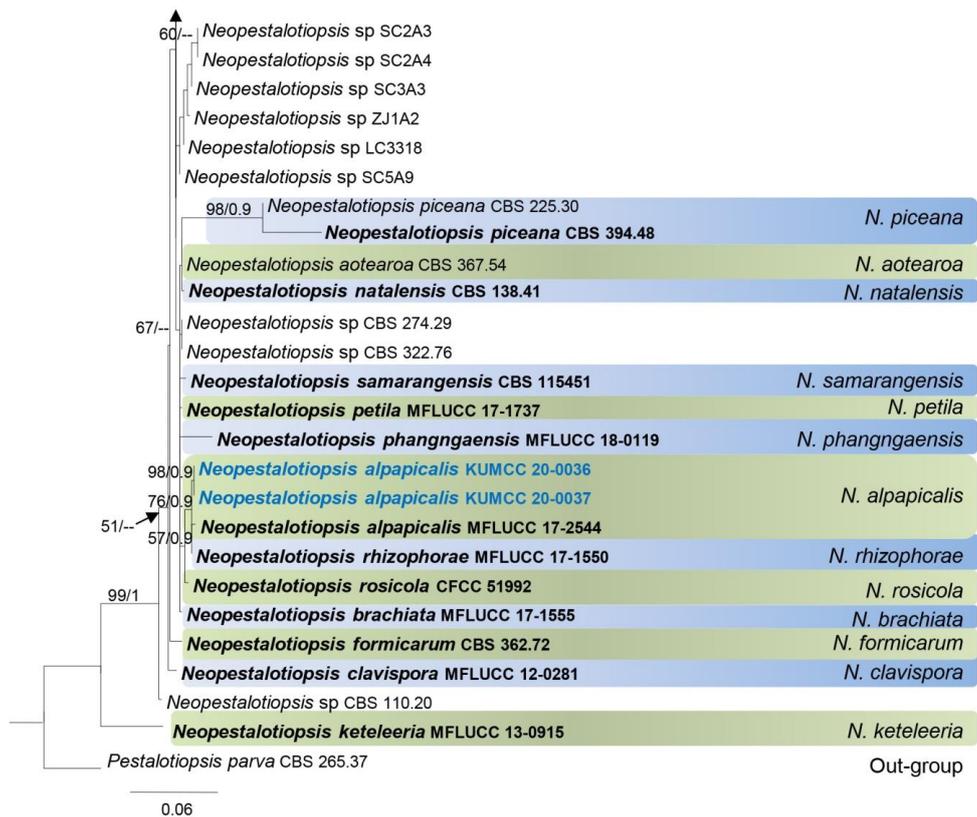

Fig. 2 – Phylogram generated from maximum likelihood analysis based on combined ITS, BT and tef 1- α sequence data. Bootstrap support values for ML greater than 50% and Bayesian posterior probabilities greater than 0.9 are given near nodes respectively. The tree is rooted with *Pestalotiopsis parva* (CBS 265.37). Ex-type strains are in black bold and the newly generated sequences are indicated in blue bold.

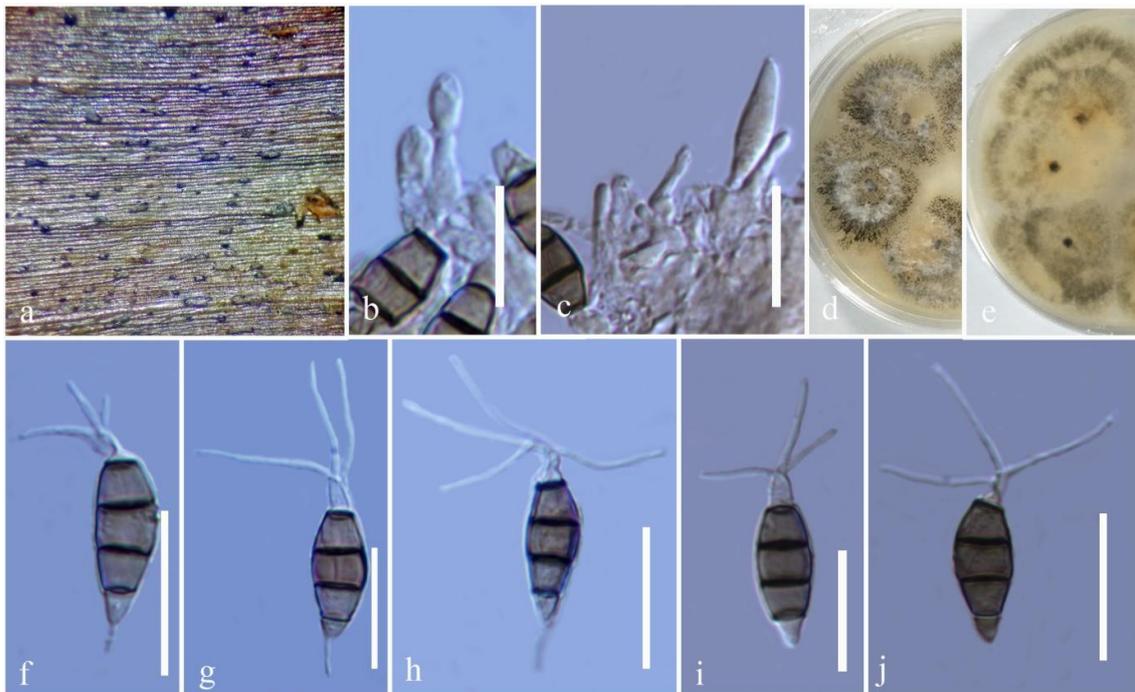

Fig. 3 – *Pestalotiopsis diploclisiae* (MFLU 20-0059). a Conidiomata on substrate. b-c Conidiogenous cells attached to conidia. d Upper surface of culture on PDA. e Lower surface of culture on PDA. f-j Conidia. Scale bars: b-c = 50 μ m, f-j = 15 μ m.

Material examined – CHINA, Guangdong Province, Shenzhen, Nanshan District, Mountain Yangtai Forest Park, 22°39'21.26"N 113°57'18.53"E, dead leaves of *Butia* sp. (Arecaceae), 5 September 2018, I. C. Senanayake, SI 66, (MFLU 20–0059; living culture KUMCC 20–0035).

Notes – Phylogenetically, our *Pestalotiopsis diploclisiae* collection (KUMCC 20–0035) is closely related to *P. diploclisiae* (CBS 115449) with high bootstrap support. Type strains of *Pestalotiopsis diploclisiae* were collected from fruits of *Diploclisia glaucescens* and *Psychotria tutcheri* in Hong Kong, while our *P. diploclisiae* strain (KUMCC 20–0035) collected from a dead leaf of *Butia* sp. in Shenzhen (China) closer to Hong Kong. The prologue provided by Maharachchikumbura et al. (2014) for *Pestalotiopsis diploclisiae* was based on the morphology derived from cultures. However, our description and illustration are based on the morphology derived from the specimen. Our strain produces smaller (5–11 × 2–3 µm), discrete, lageniform conidiogenous cells and smaller (17–24 × 6–7 µm), fusiform to clavate conidia with conic to acute apical cell and 3–4 apical appendages. Except for the size variation in conidia and conidiogenous cells, our collection of *Pestalotiopsis diploclisiae* (KUMCC 20–0035) is morphologically identical to its holotype. Comparison of the ITS regions DNA sequence of *Pestalotiopsis diploclisiae* (KUMCC 20–0035) with *P. diploclisiae* (CBS 115449) gives 0.94% base pair differences and therefore, our strain assigned as *Pestalotiopsis diploclisiae*.

Pestalotiopsis parva Maharachch., K.D. Hyde & Crous, in Maharachchikumbura, Hyde, Groenewald, Xu & Crous, Stud. Mycol. 79: 175 (2014) Fig. 4

Facesoffungi number: FoF 07749

Saprobic, associated with dead petiole of *Phoenix* sp. Appears as black spots coming out from plant epidermis surface. Sexual morph: Undetermined. Asexual morph: *Conidiomata* pycnidial, globose, immersed in substrate, semi-immersed on PDA, brown, releasing conidia in a black, slimy, globose, glistening mass. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* 7–10 × 2–3 (\bar{x} = 8.9 × 2.4 µm, n = 20), discrete, subcylindrical to lageniform, hyaline, smooth, thin-walled, annellidic, proliferating once percurrently. *Conidia* 17–21 × 6–7 µm, (\bar{x} = 18.9 × 6.8 µm, n = 20), fusiform to mostly globose, straight, 4-septate; basal cell conic to acute with a truncate base, hyaline or sometimes pale brown, thin and smooth-walled, 2.5–4 µm long (\bar{x} = 3 µm, n = 20); three median cells ± equal, each 3–5 µm long (\bar{x} = 4 µm, n = 20), doliiform, pale brown, septa darker than rest of the cell, concolorous, wall rugose; apical cell 3–4.5 µm long (\bar{x} = 3.5 µm, n = 20), hyaline, subcylindrical to obconic, with 2–3 tubular appendages on apical cell, arising from the apical crest, unbranched, flexuous, 9–18 × 0.6–0.9 µm (\bar{x} = 13 × 1 µm, n = 20); basal appendage single, tubular, unbranched, centric, 3–4.5 µm long, (\bar{x} = 3.6 µm).

Culture characters – Colonies on PDA reaching 2.5 cm diam., within 1 week at 20°C, under dark, circular with several layers, medium dense, aerial mycelium clots concentrated along the colony margin, flat, filiform margin, white from above and reverse; fruiting bodies did not appear on cultures.

Material examined – CHINA, Guangdong Province, Shenzhen, Nanshan, Nanhai Avenue, Shenzhen University, dead petiole of *Phoenix* sp. (Arecaceae), 28 August 2018, I.C. Senanayake, SI 9, (MFLU 20–0060, living culture KUMCC 20–0038).

Notes – One of our *Pestalotiopsis* strain (KUMCC 20–0038) clusters with the type species of *P. parva* (CBS 265.37) with moderate bootstrap support in the phylogenetic analysis. *Pestalotiopsis parva* was introduced based on only two strains as CBS 265.37 and CBS 278.35 (Maharachchikumbura et al. 2014). However, the collected localities of those strains are unknown. Maharachchikumbura et al. (2014) described *Pestalotiopsis parva* based on the morphology derived from cultures. However, we obtained morphological characters of our *Pestalotiopsis* strain directly from the specimen, not from culture. Comparison of the ITS sequence of *Pestalotiopsis parva* KUMCC 20–0038 with *P. parva* CBS 265.37 and CBS 278.35 revealed that the base pair differences between them are less than 1% (0.88% and 0.88% respectively) which propose our strain as an existing species (Jeewon & Hyde 2016).

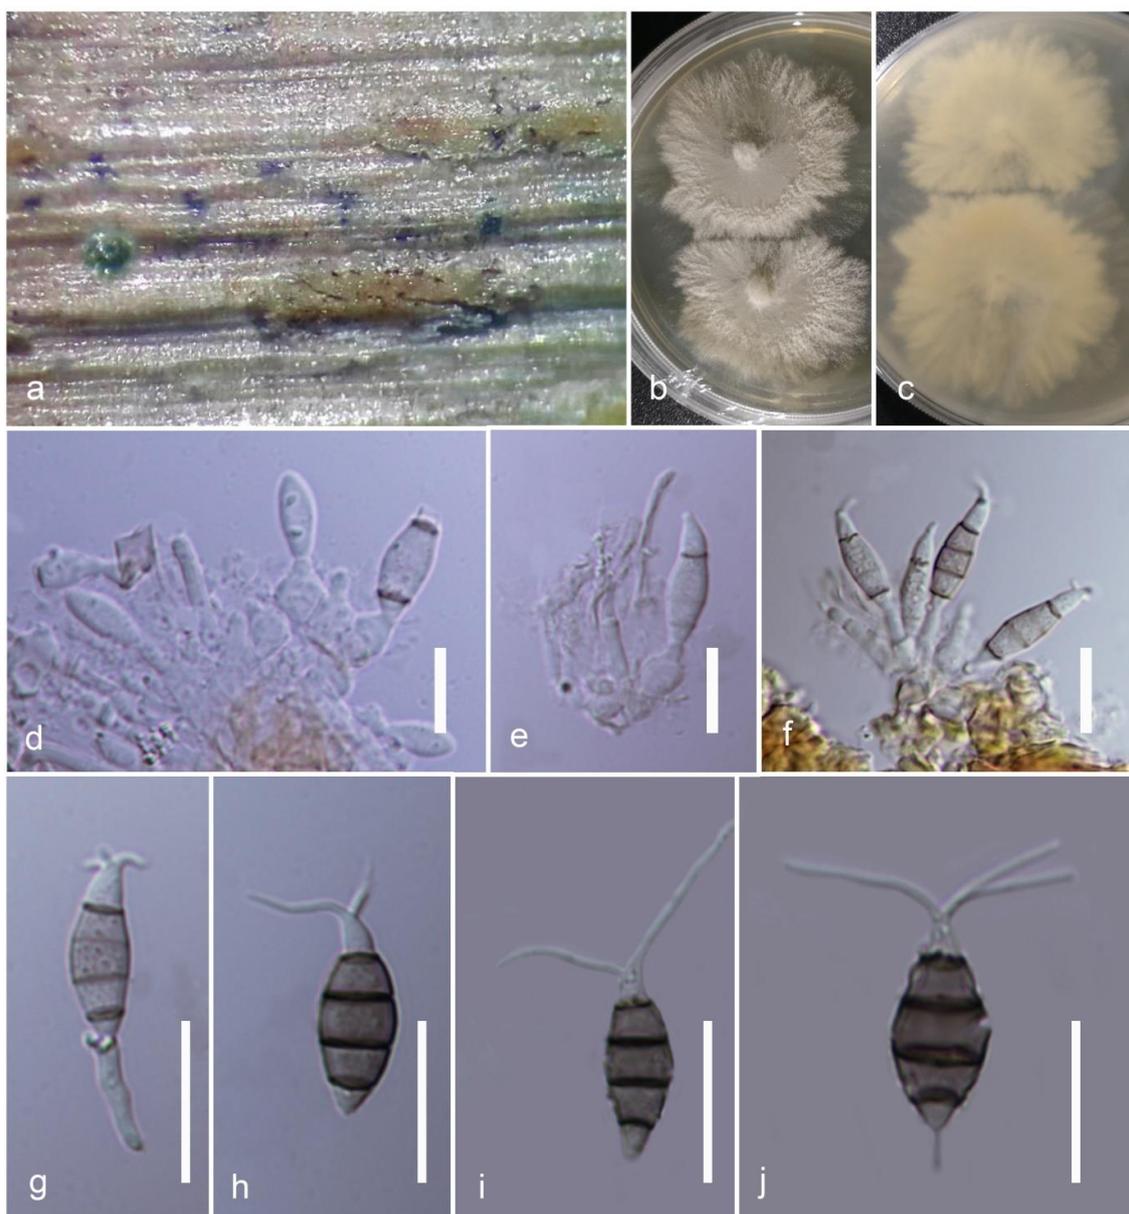

Fig. 4 – *Pestalotiopsis parva* (MFLU 20–0060). a Conidiomata on substrate. b Upper surface of culture on PDA. c Lower surface of culture on PDA. d–f Conidiogenous cells attached to conidia. g–j Conidia. Scale bars: d–j = 20 μ m.

Neopestalotiopsis alpapicalis Vin. Kumar, Gentekaki & K.D. Hyde, in Kumar, Cheewangkoon, Gentekaki, Maharachchikumbura, Brahmange & Hyde, *Phytotaxa* 393(3): 253 (2019) Fig. 5
 Facesoffungi number: FoF 05753

Saprobic or *pathogenic*, associated with living leaves of *Phoenix roebelenii*. Sexual morph: Undetermined. Asexual morph: Appears as swollen areas with split barks. *Conidiomata* 25–80 μ m diam., pycnidial, globose, black, immersed in substrate, superficial in PDA, releasing conidia as a black, slimy, globose, mass on culture media. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* 4–6 \times 3–4 μ m (\bar{x} = 5 \times 4 μ m, n = 20), discrete, annellidic, globose to umbonate, short, hyaline, smooth-walled, simple, wide at the base. *Conidia* 24–28 \times 9–11 μ m (\bar{x} = 26 \times 10 μ m, n = 20), ellipsoid, straight to slightly curved, 4–(6)-septate; basal cell conic to obconic with a truncate base, hyaline, thin- and smooth-walled, 3–4 μ m long (\bar{x} = 3.8 μ m, n = 20); 3–(5) median cells, each 4.5–7 μ m long (\bar{x} = 5.5 μ m, n = 20), 4–7 μ m long (\bar{x} = 5.6 μ m, n = 20), 4–6 μ m long (\bar{x} = 4.6 μ m, n = 20), doliiform, concolorous, pale brown, septa and periclinal walls darker than rest of the cell, wall rugose; apical cell 3–6 μ m long (\bar{x} = 4.6 μ m, n = 20), long, hyaline, conic

to obtuse with truncate base; apical appendages 7–12 μm long (\bar{x} = 10 μm , n = 20), short, 1–4, more tubular, inserted at different loci but in a crest at the apex of the apical cell, unbranched, flexuous; single basal appendage, tubular, unbranched, rarely branched, centric, 4–6 μm long (\bar{x} = 4.7 μm , n = 20).

Culture characteristics – Colonies on PDA reaching 2 cm diam., within 10 days at 18°C, under dark, circular, medium dense, aerial mycelium clots scattered on PDA, flat, filiform margin, white from above and reverse; black, globose, sporulate on cultures after 4 weeks incubate at 20°C in dark.

Material examined – CHINA, Guangdong Province, Shenzhen, Luohu District, Fairy-lake botanical garden, 22°34'43.10"N 114°09'55.98"E, living leaves of *Phoenix roebelenii* O'Brien (Arecaceae), 26 July 2018, I.C. Senanayake, SI 100, (MFLU 20–0061, living culture KUMCC 20–0037); CHINA, Guangdong, Shenzhen, Luohu District, Fairy-lake botanical garden, 22°34'43.10"N 114°09'55.98"E, living leaves of *Musa* sp. (Musaceae), 26 July 2018, I.C. Senanayake, SI 103, (MFLU 20–0058, living culture KUMCC 20–0036).

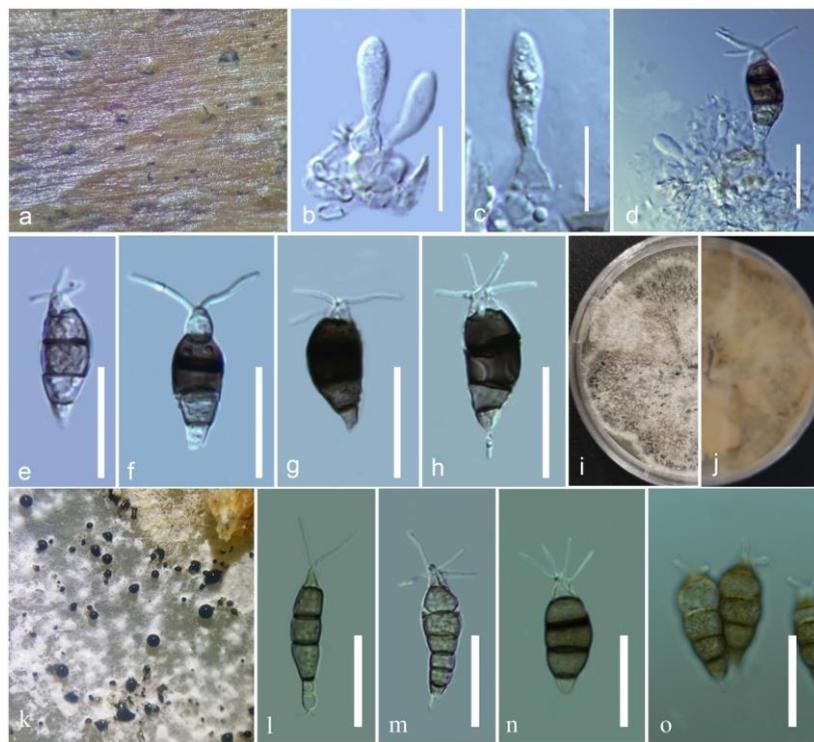

Fig. 5 – *Neopestalotiopsis alpapicalis* (MFLU 20–0058). a Conidiomata on substrate. b-d Conidiogenous cells attached to conidia. e-h Conidia from fruit bodies in substrate. i upper surface of culture on PDA. j Lower surface of culture on PDA. k Conidioma on PDA. l-o Conidia derived from culture (l; unusual basal cell, m; conidia with six cells, o; wall ornamentations). Scale bars: b-h, l-o = 25 μm .

Notes – In the phylogenetic analysis (Fig. 2), our *Neopestalotiopsis* strain forms a distinct subclade basal to *N. alpapicalis* (MFLUCC 17–2544), and *N. rhizophorae* (MFLUCC 17–1550) with moderate bootstrap support. There are 1.27%, 1.07% and 1.02% base pair differences of the ITS (566bp), BT (469bp) and *tef* 1– α (490bp) sequences of our *Neopestalotiopsis* strains with *N. alpapicalis* (MFLUCC 17–2544), and these values are 1.59%, 0.85%, and 1.02% for *N. rhizophorae* (MFLUCC 17–1550). However, multi-locus gene regions use in this study may not enough to separate *Neopestalotiopsis* species well and there are no more gene regions available in GenBank. Therefore, determination of taxonomy of *Neopestalotiopsis* strains is challenging.

However, morphologically our *Neopestalotiopsis* collection is similar to *N. alpapicalis* more than *N. rhizophorae* in having highly pigmented, conidia with shorter, tubular, apical appendages

which are attached to the tip of apical cell. It is difficult to clarify and compare the morphological characters of fungi grown in different media and different growth conditions. Our *Neopestalotiopsis* strain is a saprobe collected from a terrestrial, monocotyledon plant in China, while *Neopestalotiopsis alpapicalis* collected with leaf spots of mangrove plants in Thailand. Therefore, based on available molecular data, morphology and ecological data we named this species as *N. alpapicalis*.

Discussion

Pestalotiopsis parva and *Neopestalotiopsis alpapicalis* collected from *Phoenix* are mostly dominant in northern and central Africa, Southeastern Europe, Southern Asia and east to Southern China (Chase et al. 2000). Fruits of some *Phoenix* species are edible and used as raw materials in the sugar industry. *Phoenix roebelenii* is widely grown for its ornamental value and its fruit used as food for livestock and poultry (Riffle & Craft 2003). *Phoenix* species have some resistant to pests and tolerance to soil variation and drought. Therefore, *Phoenix* species used for reforestation in swamps, deserts and mangrove coasts. *Pestalotiopsis diploclisiae* collected from dead leaves of *Butia*, which is an ornamental genus (Faria et al. 2011) and fruits of *Butia* species are used as foods, such as juices, liquor, marmalades and ice cream, while seeds are used to extract oil. *Musa* species are also important as a food source.

Even though fungal diversity associated with these plants have been studied, the micro-fungi inhabiting them are poorly known in Guangdong Province (Chobba et al. 2013, Shen et al. 2014, Wei et al. 2007, Zakaria & Aziz 2018). In this study, we collected several pestaloid taxa on *Butia*, *Phoenix* and *Musa* species and identified them through morpho-phylogenetic studies. Here, we provide taxonomic details for them.

Colonies of *Pestalotiopsis parva* grew faster on PDA than *Neopestalotiopsis alpapicalis* and *Pestalotiopsis diploclisiae* and did not sporulate in culture. *Pestalotiopsis diploclisiae* and *Neopestalotiopsis alpapicalis* sporulate in culture after four weeks of incubation at 20°C in the dark. Both *Pestalotiopsis diploclisiae* and *Neopestalotiopsis alpapicalis* initially formed copious aerial mycelia clots and those clots disappear with the formation of conidiomata on the PDA.

A checklist of *Neopestalotiopsis* and *Pestalotiopsis* fungi in China is given in Table 2. This includes seven species of *Neopestalotiopsis* and 69 species of *Pestalotiopsis*. Pestaloid fungi are common phytopathogens that cause a variety of diseases, including canker lesions, shoot dieback, leaf spots, needle blight, tip blight, grey blight, scabby canker, severe chlorosis, fruit rots and various post-harvest diseases (Crous et al. 2011, Zhang et al. 2013, Maharachchikumbura et al. 2014). *Pestalotiopsis clavispora* and *P. anacardiacearum* have been reported to cause grey leaf spots and associated with the mango tip borer by *Penicillaria jocosatrix*, respectively in China. *Pestalotiopsis camelliae* was associated with grey leaf blight of *Camellia japonica* and *Pestalotiopsis ericacearum* with leaf spots of *Rhododendron delavayi*.

Table 2 Checklist of *Neopestalotiopsis* and *Pestalotiopsis* fungi in China

| Taxon | Host/substrate | Province | References |
|-----------------------------------|--|----------|----------------------------------|
| <i>Neopestalotiopsis asiatica</i> | leaves of tree | Hunan | Maharachchikumbura et al. (2014) |
| <i>N. chrysea</i> | dead leaves | Guangxi | Maharachchikumbura et al. (2014) |
| <i>N. clavispora</i> | dead leaves of <i>Magnolia</i> sp. | Guangxi | Maharachchikumbura et al. (2014) |
| <i>N. ellipospora</i> | dead plant material | Yunnan | Maharachchikumbura et al. (2014) |
| <i>N. foedans</i> | mangrove plant leaves | Hainan | Maharachchikumbura et al. (2014) |
| <i>N. saprophytica</i> | leaves of <i>Magnolia</i> | Yunnan | Maharachchikumbura et al. (2014) |
| <i>N. umbrinospora</i> | dead leaves | Guangxi | Maharachchikumbura et al. (2014) |
| <i>Pestalotiopsis adusta</i> | leaves of <i>Podocarpus macrophyllus</i> | Guangxi | Wei et al. (2007) |
| <i>P. affinis</i> | unknown | Yunnan | Chen et al. (2002) |

Table 2 Continued.

| Taxon | Host/substrate | Province | References |
|----------------------------|--|-----------------|-----------------------------------|
| <i>P. aggestorum</i> | leaves of <i>Camellia sinensis</i> | Yunnan | Liu et al. (2017) |
| <i>P. alpiniae</i> | leaves of <i>Alpinia galanga</i> | Guangxi | Chen et al. (2002) |
| <i>P. anacardiacearum</i> | living leaf of <i>Mangifera indica</i> | Yunnan | Maharachchikumbura et al. (2013) |
| <i>P. antiaris</i> | leaves of <i>Antiaris toxicaria</i> | Guangxi | Chen et al. (2002) |
| <i>P. apiculata</i> | trunk and leaves of <i>Cunninghamia lanceolata</i> | Fujian | Huang (1983) |
| <i>P. brideliae</i> | living leaves of <i>Bridelia morcica</i> | China | Chen & Wei (1997) |
| <i>P. briosiana</i> | twigs of <i>Camellia sasanqua</i> | Yunnan | Wei et al. (2007) |
| <i>P. camelliae</i> | leaves of <i>Camellia japonica</i> | Yunnan | Zhang et al. (2012a) |
| <i>P. canarii</i> | living leaves of <i>Canarium album</i> | Guangxi | Chen et al. (2003) |
| <i>P. chinensis</i> | leaves of <i>Taxus</i> | Yunnan | Maharachchikumbura et al. (2012b) |
| <i>P. clavata</i> | leaf of <i>Buxus</i> | Yunnan | Maharachchikumbura et al. (2014) |
| <i>P. coffeae-arabicae</i> | living leaves of <i>Coffea arabica</i> | Hainan | Song et al. (2013) |
| <i>P. crassiuscula</i> | leaves of <i>Podocarpus macrophyllus</i> | Zhejiang | Wei et al. (2007) |
| <i>P. dilleniae</i> | leaves of <i>Dillenia turbinata</i> | Guangxi | Chen et al. (2002) |
| <i>P. dilucida</i> | leaves of <i>Camellia sinensis</i> | Jiangxi | Liu et al. (2017) |
| <i>P. diospyri</i> | leaves of <i>Podocarpus macrophyllus</i> | | Wei et al. (2007) |
| <i>P. disseminata</i> | leaves of <i>Podocarpus macrophyllus</i> | | Wei et al. (2007) |
| <i>P. diversiseta</i> | leaves of <i>Rhododendron</i> | | Maharachchikumbura et al. (2014) |
| <i>P. dracaenae</i> | leaves of <i>Dracaena fragrans</i> | | Ariyawansa et al. (2015) |
| <i>P. ericacearum</i> | leaves of <i>Rhododendron delaveyi</i> | | Zhang et al. (2013) |
| <i>P. foedans</i> | twigs of <i>Podocarpus massoniana</i> | Guangdong | Wei et al. (2007) |
| <i>P. gaultheriae</i> | on <i>Gaultheria</i> | Yunnan | Maharachchikumbura et al. (2014) |
| <i>P. hainanensis</i> | stem of <i>Podocarpus macrophyllus</i> | Hainan | Liu et al. (2007) |
| <i>P. heterocornis</i> | fruit and bark of <i>Podocarpus macrophyllus</i> | Zhejiang | Wei et al. (2007) |
| <i>P. inflexa</i> | leaf of tree | Hunan | Maharachchikumbura et al. (2014) |
| <i>P. intermedia</i> | dead leaf of tree | Hubei | Maharachchikumbura et al. (2014) |
| <i>P. jiangxiensis</i> | on <i>Camellia</i> | Jiangxi | Liu et al. (2017) |
| <i>P. jinchanghensis</i> | on leaves of <i>Camellia sinensis</i> | Yunnan | Liu et al. (2017) |
| <i>P. keteleeriae</i> | on leaves of <i>Keteleeria pubescens</i> | Guizhou | Song et al. (2014) |
| <i>P. kunmingensis</i> | leaves of <i>Podocarpus macrophyllus</i> | Yunnan | Wei & Xu (2004) |
