Barreto GG, Gusmão LFP, Dianese JC 2022 – Checklist of ascomycetes recorded on eucalypts in Brazil (1976–2022). Asian Journal of Mycology 5(1), 107–129, Doi 10.5943/ajom/5/1/9

Abstract

The fungi associated with eucalypts (*Eucalyptus* and *Corymbia* species) have been widely studied. Starting in the 70's, many ascomycetes were described mainly in the State of São Paulo, Brazil. As planted forests spread throughout the country, an increasing number of new fungal species were detected resulting in the checklist here shown. Ascomycete species on eucalypts were listed and distributed in class, order, and family with indications of host species, substrate, locality, and geographical distribution among Brazilian states. This checklist includes 236 ascomycetes, belonging to 32 orders, and 61 families associated with 30 species, 5 interspecific hybrids of *Eucalyptus* and 4 species of *Corymbia*. Species were distributed among four classes, 32 orders, and 62 families, most of them in Dothideomycetes (28 species in Mycosphaerellales), Sordariomycetes (55 species in Hypocreales, 22 in Diaporthales, 19 in Xylariales), and Eurotiomycetes (10 species in Eurotiales). Most species were found in the states of São Paulo and Minas Gerais, with a total of 101 and 28 species, respectively.

Keywords – Ascomycota – *Corymbia* – *Eucalyptus* – leaf litter – mycodiversity – Neotropica

Introduction

Eucalypt is a group of plant species belonging to the family Myrtaceae (Rejmánek & Richardson 2011), embodying three phylogenetically close genera, viz. *Eucalyptus* L'Her. with more than 700 species, *Corymbia* K.D. Hill over 100 species, and *Angophora* Cav. around 12 species (Nicolle 2018, Thornhill et al. 2019). Historically, eucalypt was introduced as a forest crop by Edmundo Navarro de Andrade in 1914 in Brazil and was initially used in the production of railroad sleepers and charcoal for steam engines belonging to the São Paulo Railway Company (Wilcken et al. 2008).

Nowadays, eucalypts are used for reforestation in a wide range of climatic conditions and countries due to fast growth, wood quality and easy acclimatization (Sankaran & Hussain 2019). Eucalypt, represented by *Eucalyptus* and *Corymbia* species, is grown globally. The largest eucalypt plantations are found in Brazil covering almost 7 million hectares, mostly in the South-eastern region of the country, involving a work force of 3.7 million people in plantations, and facilitates wood product manufacturing, cellulose/paper mills, and paper products, accounting for 1.2 % of the Brazilian GDP (gross domestic product) (IBÁ 2020).

The eucalypt-associated microfungal community has diversified with the expansion of the plantations. There are saprotrophic-epiphytes, endophytic and pathogenic species (Crous et al. 2019a), reaching 10,000 records in association with 300 species of eucalypts worldwide (Sankaran & Hussain 2019).

The taxonomic studies on eucalypts-associated micro-fungi in Brazil started in 1975, involving samples from different regions of the country, resulting in 20 new species and six new genera described (Sutton 1975, Sutton & Hodges 1975a, b), and other taxonomic novelties were published later (Crous et al. 1994, Alfenas et al. 2015, Lacerda et al. 2018, Crous et al. 2019b).

The first worldwide checklist of fungi on *Eucalyptus* compiled 172 species, including saprobic and pathogenic species, with 36 species introduced from Brazil (Crous et al. 1989). A major contribution by Sankaran & Hussain (2019) registered a global list of 10,000 fungal records on *Eucalyptus*, revealing 2,360 species from 84 countries, including mycorrhizal, saprotrophic, or pathogenic fungi with 116 ascomycetes species recorded from Brazil.

Therefore, our aim is to list the occurrence and distribution of ascomycetes associated with *Eucalyptus* and *Corymbia* species in Brazil, also revealing their geographical distribution in the country.

Material & Methods

The data herein shown includes our publications, new records, and results from a review of the available literature and online databases (Mendes et al. 1998, 2019, Sankaran & Hussain 2019, Farr & Rossman 2022). Our new records, shown in Table 1, are all hyphomycetes isolated in pure cultures and preserved in our fungal collection at the Laboratory of Mycology of the State University of Feira de Santana. Their identification was based on the literature available, and on our long experience in dealing with hyphomycetes (Lacerda et al. 2018, 2019). The identification started with observations under a stereomicroscope, followed by the preparation of semi-permanent slides to be studied in a light microscope. A manual frequently used to begin the identifications was The Genera of Hyphomycetes by Seifert et al. (2011). Once identified the genus, we moved to species identification consulting the specific literature indicated in the list of species of the genus shown in Index Fungorum (Available at: <https://www.indexfungorum.org>). All identifications were based on morphological analyses. The literature was analyzed and documented with the occurrence, host species, symptoms, and locality, when the data was available. The graphics (Figs 1, 2, 3) were produced using Microsoft Office Excel 2019. The geographical distribution map was produced using Datum/Sirgas 2000 geographic coordinates, and territorial meshes provided by the Brazilian Institute of Geography and Statistics (IBGE). The checklist was organized following the current classification of the Ascomycota by Mycobank (Available at: <https://www.mycobank.org>. Accessed on May 2, 2022).

Results

Eucalypts represent the most important forest crop in Brazil and are susceptible to infection mostly by ascomycetes; the checklist summarizing their incidence throughout the country is herein shown. The checklist includes around 236 ascomycetes in classes Dothideomycetes, Eurotiomycetes, Leotiomycetes and Sordariomycetes, distributed across 32 orders and 61 families, and associated with 30 species and five interspecific hybrids of *Eucalyptus* and four species of *Corymbia*. The unidentified *Eucalyptus* species were associated with 116 fungal species. *Eucalyptus microcorys* and *E. grandis* hosted the most fungal species reported, with 46 and 56 species, respectively (Fig. 1).

Most ascomycetes found on eucalypt in Brazil were allocated in the orders Hypocreales with 55 species, Mycosphaerellales 28, Diaporthales 22, Xylariales 19, and Eurotiales with 10 (Fig. 2). However, 30 species were not assigned to any order, remaining *incertae sedis*.

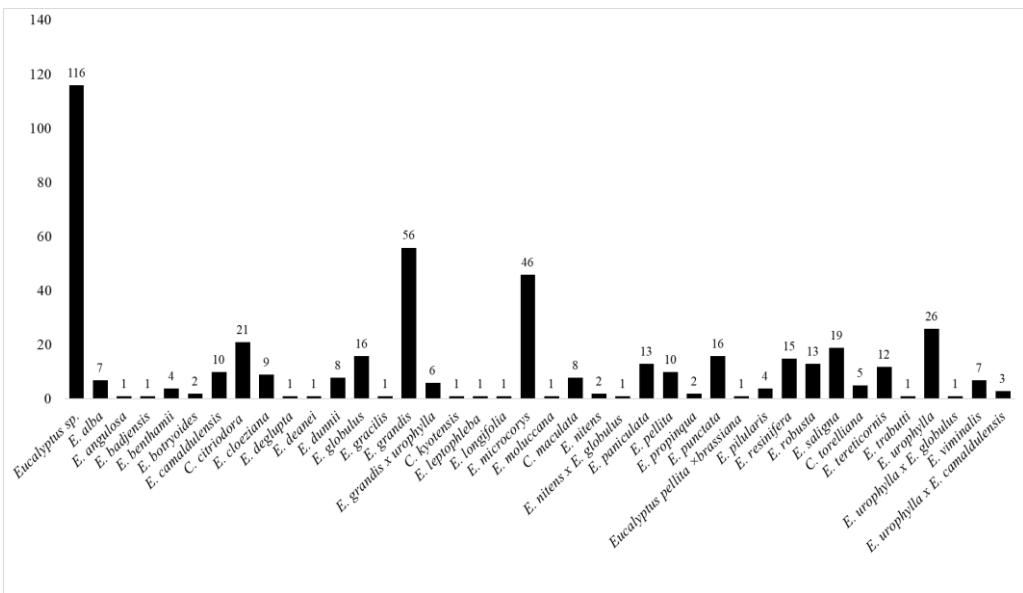

Fig. 1 – Number of ascomycetes associated with *Corymbia* and *Eucalyptus* species and interspecific hybrids in Brazil.

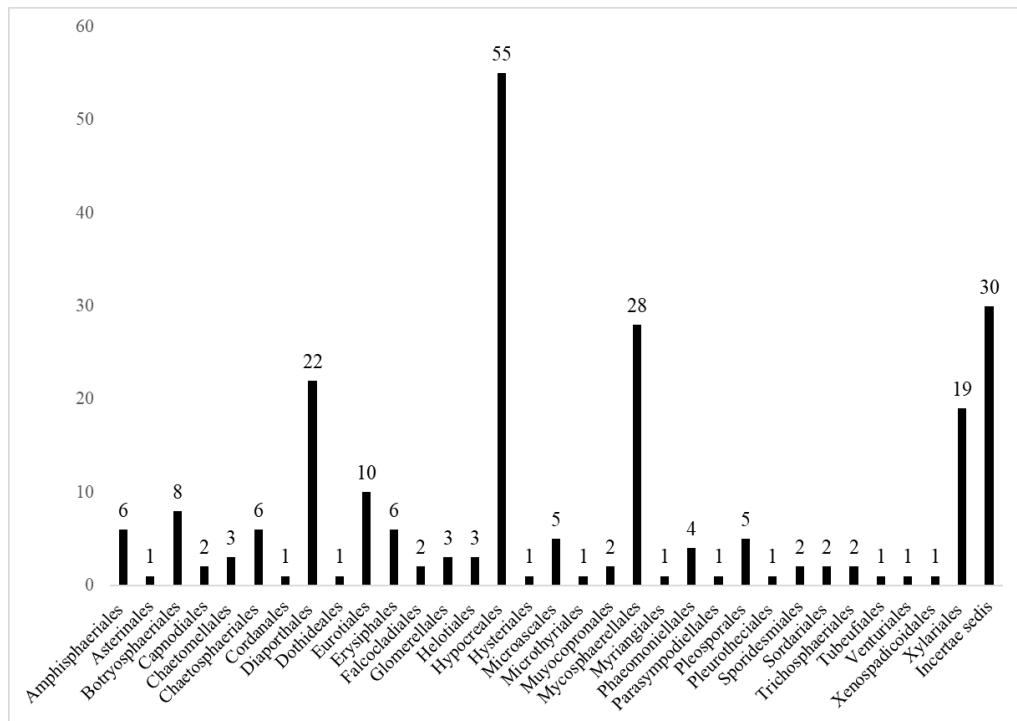

Fig. 2 – Number of ascomycete species per order, including *insertae sedis*, associated with *Corymbia*, *Eucalyptus* and interspecific hybrids in Brazil.

The family Nectriaceae with 49 taxa recorded had the highest number, followed by Teratosphaeriaceae (15), Mycosphaerellaceae (13) and Aspergillaceae (10) (Fig. 3).

The distribution of the ascomycetes by state (Fig. 4) showed significant number of species recorded in the States of São Paulo (SP) with 101, Minas Gerais (MG) 28, Pará (PA) 19, Espírito Santo (ES) 15, Maranhão (MA) and Paraná (PR) with 10 species.

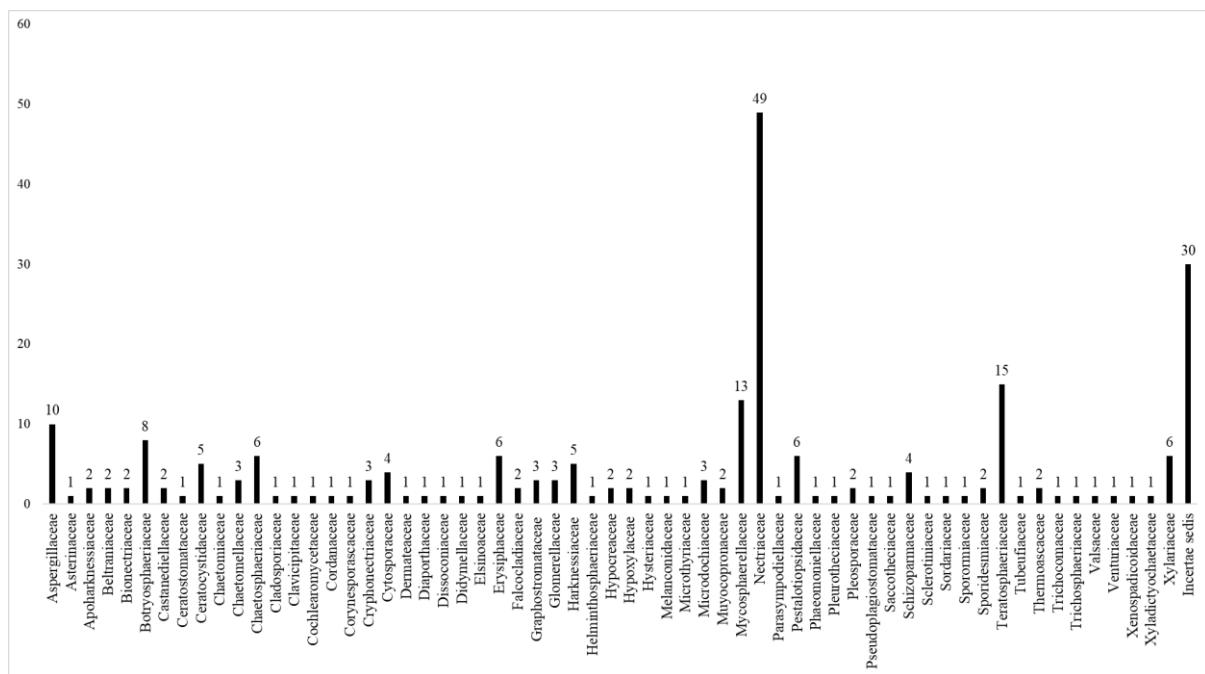

Fig. 3 – Number of ascomycete species per fungal family, including *insertae sedis*, associated with *Corymbia*, *Eucalyptus* and interspecific hybrids in Brazil.

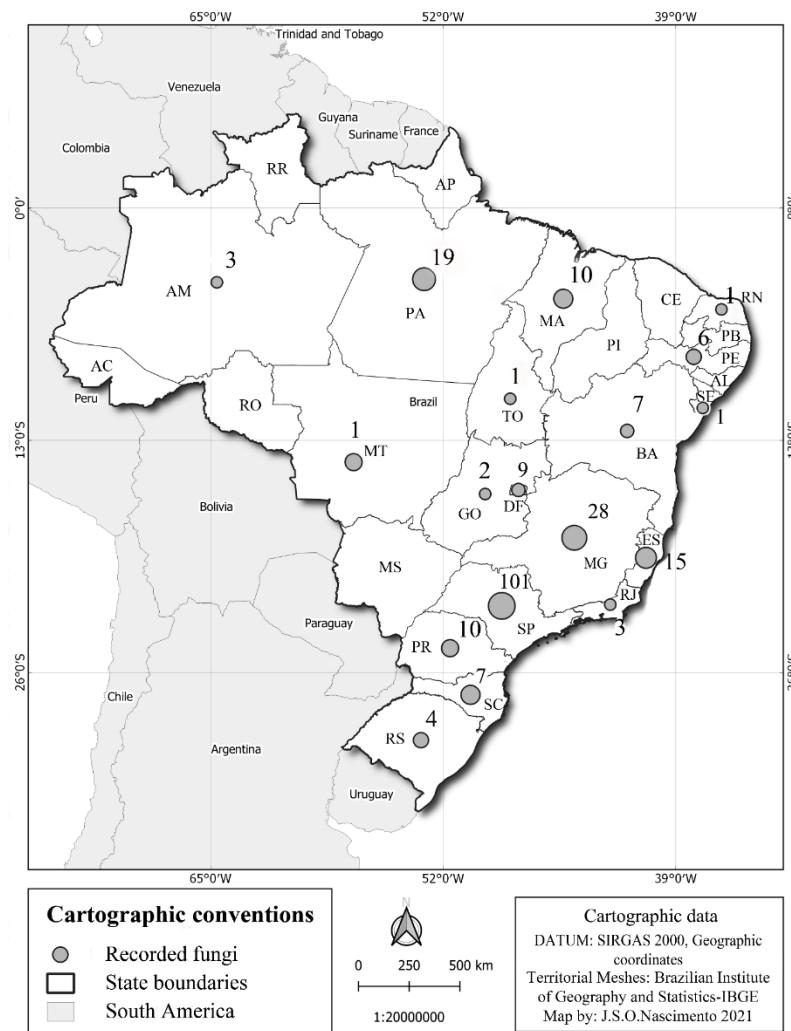

Fig. 4 – Number of ascomycetes recorded on *Corymbia*, *Eucalyptus* and interspecific hybrids per

Brazilian State (North to South: AM- Amazon, MT- Mato Grosso, PA- Pará, MA- Maranhão, RN- Rio Grande do Norte, PE- Pernambuco, SE- Sergipe, TO- Tocantins, BA- Bahia, DF- Distrito Federal, GO- Goiás, MG- Minas Gerais, ES- Espírito Santo, RJ- Rio de Janeiro, SP- São Paulo, PR- Paraná, SC- Santa Catarina, RS- Rio Grande do Sul).

Conclusion

In this checklist, 236 eucalypt-associated species were listed from Brazil. *Eucalyptus grandis* and *E. microcorys* are the host plants with the most associated ascomycetes. The largest number of species belonged to Nectriaceae, followed by those in Teratosphaeriaceae, Mycosphaerellaceae and Aspergillaceae.

The states of São Paulo and Minas Gerais in the Southwest region are the locations where most fungi occurred, coinciding with areas where most eucalypt plantations are located, and the presence of mycologists and plant pathologists is more prevalent. Most fungi recorded are leaf pathogens causing leaf spots or leaf and seedling blight, some occur on bark causing canker, and several were detected on dead leaves and bark. Submerged leaves also host several fungal species, as seen in Table 1.

Finally, it must be noted that most fungi herein listed are plant pathogenic, causing large economic losses still to be precisely estimated.
