### Re-evaluating the Upper Guinean species of *Triclisia* (*Menispermaceae*)

Version of record first published online on 9 November 2017 ahead of inclusion in December 2017 issue.

**Abstract:** In Upper Guinea in Africa three species of *Triclisia* Benth. (*Menispermaceae*) are recognized: *T. dictyophylla* Diels, *T. patens* Oliv. and *T. subcordata* Oliv. *Triclisia dictyophylla* and *T. subcordata*, as delimited in the revision of this genus by Troupin (1962), each include more than one distinct species. On the basis of a comparative morphological analysis, *T. dictyophylla* is split here into *T. dictyophylla* s.s. and *T. gilletii* (De Wild.) Staner and *T. subcordata* is split into *T. angolensis* Exell, *T. hypochrysea* Diels and *T. subcordata* s.s. No new names have to be published. Illustrations are provided along with distribution maps.

**Key words:** Africa, *Menispermaceae*, taxonomy, *Triclisia*, tropical forest, Upper Guinea

**Article history:** Received 12 April 2017; peer-review completed 14 August 2017; received in revised form 19 August 2017; accepted for publication 23 August 2017.

## Introduction

*Triclisia* Benth. is a genus of *Menispermaceae* with c. 16 liana species endemic to Africa including Madagascar; all species are dioecious. In Upper Guinea (sensu White 1979), three species are recognized: *T. dictyophylla* Diels, *T. patens* Oliv. and *T. subcordata* Oliv. (Hawthorne & Jongkind 2006). Only *T. patens* is endemic to Upper Guinea. In Upper Guinea the male flowers and fruits of *T. dictyophylla*, *T. patens* and *T. subcordata* are clearly different from each other. *Triclisia dictyophylla* has male flowers with six stamens (Fig. 1A–E) and almost glabrous fruit carpels of 3–4.5 × 2.5–3.5 cm, while *T. patens* has male flowers with only three stamens (Fig. 1H–M, Fig. 2) and pubescent fruits 1–2 cm in diameter. The third species, *T. subcordata*, has male flowers with six stamens (Fig. 3) and is

smaller than the other two in habit, leaf, inflorescence, flower and fruit (Table 1).

Part of the herbarium specimens from outside Upper Guinea, included in *Triclisia dictyophylla* and *T. subcordata* in the last revision of the African *Menispermaceae* (Troupin 1962), have flower and fruit characters that are clearly different from those in Upper Guinea. Because of that, these two species are re-evaluated here. Three species, *T. angolensis* Exell, *T. gilletii* (De Wild.) Staner and *T. hypochrysea* Diels, which were earlier made synonym by Troupin, are resurrected here as a result.

This paper is a first step to a new revision of *Triclisia* for continental Africa. More problems have to be solved before a complete revision can be published. Several more *Triclisia* species, in the way they are used by Troupin (1962) in his revision of the *Menispermaceae* for Africa, are clearly a mixture. Solving the complete *Tri-*

Table 1. Summary of diagnostic characters for the species of *Triclisia* treated here.

<i>Triclisia</i>	<i>dictyophylla</i>	<i>gilletii</i>	<i>patens</i>	<i>angolensis</i>	<i>hypochrysea</i>	<i>subcordata</i>
Leaf blade size	to 36 cm wide	to 32 × 27 cm	10–18 × 6–12 cm	7–9.5 × 3–5.5 cm	7–9 × 6–6.5 cm	5–11 × 3.5–8 cm
Petiole length	5–20 cm	5–22 cm	5–12 cm	3–4 cm	2.5–3 cm	1.6–3.2 cm
Male flower innermost sepal length	3–4 mm	c. 6 mm	c. 3 mm	c. 7 mm	—	3–4 mm
Stamens number	6	6	3	6	—	6
Stamens length	c. 2 mm	4–5 mm	2–2.5 mm	c. 4 mm	—	2.5–3 mm
Fruit carpel size	3–4.5 × 2.5–3.5 cm (excluding beak)	2–2.5 × c. 2 cm	1.5–2 cm in diam.	c. 1 cm in diam.	—	1–1.5 cm in diam.
Fruit carpel indumentum	glabrous	hairy	hairy	hairy	—	hairy

*clisia* puzzle is hampered by several accepted names that are only represented by incomplete collections.

## Material and methods

The morphological characters of all continental African *Triclisia* species in the BM, BR, K, P and WAG herbaria were studied and the three Upper Guinean species were also studied in the field. The herbaria are indicated by the international code registered in Index Herbariorum (Thiers 2017+). The African Plant Database (2015+) was checked for more information on the species and the genus. The distribution maps are based only on herbarium specimens.

## Results

When specimens of *Triclisia dictyophylla* from all over its distribution area are compared, conspicuous differences in the shape and size of flowers and fruit carpels can be seen. The exceptionally large, for *Triclisia*, fruit carpels from the specimens west of Cameroon were already described by Keay & Troupin (1954: 71, as *T. gilletii*). In publications on Central Africa the fruit carpels of the same species were described by Troupin (1951: 216, fig. 17; 1962: 91) as being about half that size and ending in a conspicuous beak. Both descriptions are correct for the specimens of that area. It is clear that Troupin included two species in *T. dictyophylla* with conspicuously different fruits and flowers. The species involved are *T. dictyophylla* s.s., from Guinea to Angola, with small flowers (Fig. 1A–E) and large fruit carpels (Fig. 5), and *T. gilletii*, from Cameroon, Central African Republic, Gabon, Congo Kinshasa and Angola, with large flowers (Fig. 1F, G) and relatively small fruit carpels (Fig. 6) (see also Table 1). The fruits of *T. dictyophylla* are usually found on the bigger stems closer to the forest floor while the fruits of *T. gilletii* are often found on the smaller branches. *Triclisia gilletii* is the only *Triclisia* species with fruit carpels that are conspicuously

beaked. This beak was also mentioned by Exell (1935: 8) for *T. flava* Exell, here a synonym of *T. gilletii*.

Another name presented by Troupin as synonym of *Triclisia dictyophylla*, *T. trichantha* Diels from Cameroon, cannot be placed yet with certainty; it might not be a *Triclisia* species.

In the *Flora of West Tropical Africa* (Keay & Troupin 1954: 72), *Triclisia subcordata* was still restricted to Ghana, Togo, Benin and Nigeria, but was later united by Troupin with *T. angolensis* Exell from Angola and *T. hypochrysea* Diels from Gabon (Troupin 1962: 86). This lumping does not seem correct because the flowers and fruits from *T. subcordata* s.s. and *T. angolensis* are clearly different. The type and only known specimen of *T. hypochrysea*, the third species included by Troupin in *T. subcordata*, is sterile.

*Triclisia angolensis* and *T. subcordata* s.s. (Table 1) are in fact distinct species. The innermost sepals in the male flower of *T. angolensis* are more than twice as long as wide (Exell 1926: 13), while these sepals in *T. subcordata* s.s. (Fig. 3C–G) are almost equal in length and width (Keay & Troupin 1954: 71). The fruit carpel and endocarp of *T. subcordata* s.s. are also conspicuously different from those of *T. angolensis* and from all other species in the genus. To show this, these fruit characters are illustrated here for five different *Triclisia* species, including four *T. subcordata* s.s. examples from different countries (Fig. 4). The shape of the fruit carpel and endocarp of *T. angolensis* is more or less equal to that of most other species of the genus, with the style relatively close to the stipe (Fig. 4A1–3). The orientation of the endocarp in the fruit carpel of *T. subcordata* s.s. is different from that in all the other *Triclisia* species, resulting in a style that is situated almost opposite to the stipe (Fig. 4B–E, Fig. 7).

There is a large geographical gap between *Triclisia angolensis* and *T. subcordata* s.s. The type and only specimen of *T. hypochrysea*, the third species included by Troupin, was collected in between the areas of these other two species (Fig. 10). This type specimen is sterile and the leaf shape and indumentum do not link it

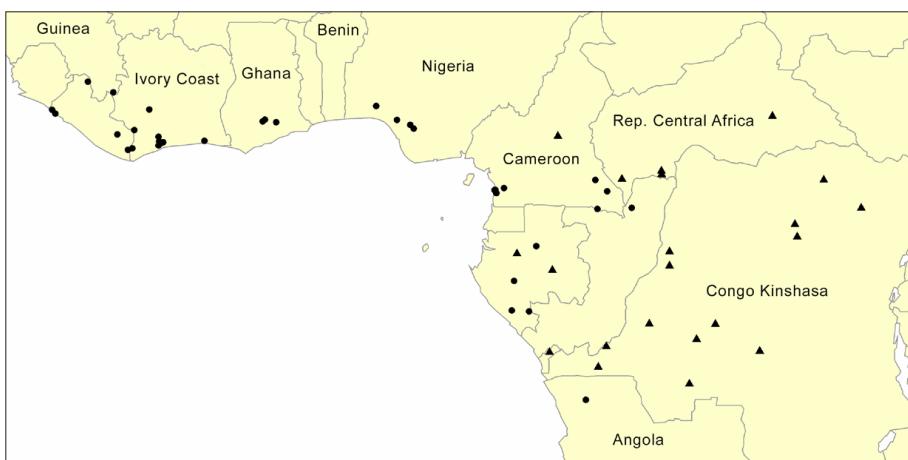

Fig. 8. Distribution map of *Triclia dictyophylla* (●) and *T. gilletii* (▲).

to *T. angolensis* or to *T. subcordata*, making it hard to place this species. In the protologue, Diels keyed out *T. hypochrysea* using the characters of the flowers (Diels 1910: 69, 71), which is surprising because in the same publication he wrote that his type and only specimen is sterile. Mildbraed 8726 from Cameroon, a specimen with flower buds also cited by Troupin under *T. subcordata*, might belong to *T. hypochrysea*. Looking at indumentum and leaf shape, there could also be a connection with *T. lucida* Exell & Mendonça from Angola.

After separating *Triclia subcordata*, *T. angolensis* and *T. hypochrysea*, *T. subcordata* is here restricted to West Africa again, it is found from Ivory Coast to Nigeria (Fig. 10). There it is found only in drier forest types such as semi-deciduous forest (Hall & Swaine 1981: 310). *Triclia angolensis* is again endemic to

the north of Angola. Only a few herbarium specimens of *T. angolensis* exist but, according to Exell (1926: 13), it was not uncommon early last century in rocky situations around Cazengo in the north of Angola.

The distribution of none of the three species from Upper Guinea goes all the way to E Africa. In the *Flora of Tropical East Africa*, Troupin (1956: 5–7) recognized three species of *Triclia* for East Africa: *T. sacleuxii* (Pierre) Diels, *T. sp. A* (based on Faulkner 769) and *T. sp. B* (based on Loveridge 244). Faulkner 769 (*T. sp. A*) became the type of *Anisocyclea blepharosepala* subsp. *tanzaniensis* Vollesen (Vollesen 1981). Loveridge 244 (*T. sp. B*) in the Kew herbarium is in the present study identified as *Syrrheonema fasciculatum* Miers. This means that *T. sacleuxii* is the only species of *Triclia* that is found in East Africa.

No new names have to be published here, all species have already published names. The number and names of the species in Upper Guinea stays the same: *Triclia dictyophylla*, *T. patens* and *T. subcordata*.

#### List of species with synonyms, types and vouchers

***Triclia angolensis*** Exell in J. Bot. 64 (Suppl. 1): 12. 1926. – Holotype: Angola, Cuanza Norte, Cazengo, Granja de S. Luis, fl., Nov 1909, Gossweiler 4892 (BM; isotypes: COI, K, LISC). – Table 1, Fig. 4A, Fig. 10.
