CATALOGUE OF X-RAY DIFFRACTION PATTERNS AND SPECIMEN MOUNTS
ON FILE AT THE GEOLOGICAL SURVEY OF CANADA

The reference collection of X-ray powder diffraction patterns of minerals on film, and the specimen mounts used to prepare the patterns, is maintained at the Geological Survey of Canada. The present catalogue lists 901 patterns which were on file as of September 1, 1973. Data given for each pattern include: reference number; mineral name; reference to published X-ray powder diffraction data, most commonly to the Joint Committee on Powder Diffraction Standards (JCPDS); and d-spacings and relative intensities of five strongest lines on the film, measured in our laboratory. Specimen mounts are available for all patterns, unless otherwise stated, and may be issued on loan to other laboratories where a reference film library is maintained. Persons wishing to borrow specimen mounts should write to:

Director,
Geological Survey of Canada
601 Booth Street
Ottawa, Ontario
K1A 0E8

Most of the reference patterns were made from mineral specimens that constitute the Systematic Reference Series of the National Mineral Collection of Canada. Fragments of the minerals were selected under a microscope to ensure purity, then ground to a fine powder and mounted on the tip of a thin, vaseline-coated glass rod. The glass rods are attached with wax to metal pins which fit the holder of a Philips (Netherlands) Debye Scherrer powder camera. Unless otherwise noted, the reference films were prepared in a 57.54 mm diameter camera using copper radiation and a nickel filter. The listed d-spacings have not generally been corrected for film shrinkage or expansion and are, therefore, not in complete agreement with more precise data published elsewhere.

An index of the measured data for the five strongest lines, which we have found useful for identification purposes, follows the catalogue listing. The d-spacing of the "strongest" line is listed in the first column, followed by its intensity, and the d-spacings and intensities of the other four lines in order of decreasing d-spacings. The final column gives the reference number of the mineral pattern in the catalogue. To allow for variations in estimating intensities the five lines have been permuted so that each is listed as "strongest". Identification of an unknown pattern is made by listing the measured data for five strongest lines in order of decreasing d-spacings, then searching the index in the vicinity of the d-spacing of the strongest line for an approximate match of the d-spacings of the other strong lines. The reference numbers of possible matching patterns (final column in the table) are consulted in the main catalogue to obtain mineral names and references to detailed data with which to confirm the identification.

In our laboratory we have automated the search process by placing all of the numerical data from the catalogue on a magnetic tape file used in conjunction with a small (8K memory) Hewlett-Packard computer. A program has been written in HP Fortran IV (Appendix I) to enable us to input measured data for an unknown pattern and carry out a search of the reference data for matching patterns. We obtain a printout of all reference patterns for which a pre-selected number (e.g. 3) of d-spacing values agree within pre-selected limits (e.g. $\pm 0.02\text{\AA}$) with the data measured on the unknown pattern. The final identification is made by visual comparison with the standard reference films from our collection.

COLLECTIONS DE LA COMMISSION GEOLOGIQUE DU CANADA,
CATALOGUE DES DIAGRAMMES DE DIFFRACTION DES
RAYONS X ET DE SPECIMENS MONTES

La Commission géologique du Canada tient une collection de référence sur film des diagrammes de diffraction des rayons X (méthode des poudres) des minéraux et des spécimens montés utilisés à la préparation des diagrammes. Le catalogue comprend les 901 diagrammes au fichier le 1^{er} septembre 1973. Les données de chaque diagramme comportent le numéro de référence, le nom du minéral, la référence des données publiées de diffraction des rayons X (méthode des poudres), en général par Joint Committee on Powder Diffraction Standards (JCPDS) (Comité mixte des modèles de diffraction par la méthode des poudres), les distances interréticulaires et les intensités relatives des cinq raies les plus intenses du film, mesurées à notre laboratoire. Les spécimens

montés ayant servi à établir les diagrammes, sauf indication contraire, ont été conservés et peuvent être prêtés aux laboratoires qui tiennent une collection de référence de ces diagrammes. Les personnes désireuses d'mprunter de ces spécimens montés doivent écrire au:

Directeur
Commission géologique du Canada
601, rue Booth
Ottawa (Ontario)
K1A 0E8

La plupart des diagrammes de référence ont été obtenus à partir de spécimens sélectionés de la Série de

référence systématique de la Collection canadienne des minéraux. Les fragments des minéraux on fait l'objet d'une analyse au microscope pour s'assurer de leur pureté, puis d'un broyage en fine poudre déposée sur l'extrémité vaselinée d'un mince tige de verre. La tige de verre est collée à la cire sur une aiguille de métal qui s'adapte au porte-objet d'une caméra Debye Sherrer de fabrication Philips (Pays-Bas). Sauf indication contraire, les diagrammes de référence on été filmés en 57, 54 mm de diamètre et les rayons X provenaient d'une anticathode de cuivre à travers un filtre de nickel. Les distances interréticulaires données ne sont généralement pas corrigées pour les erreurs dues à la contraction ou à l'allongement de la pellicule; elles ne sont donc pas tout à fait conformes aux données plus précises publiées ailleurs.

Pour faciliter le travail d'identification, nous avons jugé utile d'ajouter au catalogue un index des données mesurées pour les cinq raies les plus intenses. La distance interréticulaire correspondant à la raie «d'intensité maximale» se trouve dans la première colonne, suivie de son intensité et des distances interréticulaires et intensités respectives des quatre autres raies, en ordre de distances interréticulaires décroissantes. La dernière colonne donne le numéro de référence dans le catalogue du diagramme du minéral. Pour tenir compte de l'erreur d'appreciation dans l'estimation des intensités, nous avons permuted les cinq raies de sorte que chacune apparaît une fois dans la colonne

des raies «d'intensité maximale». Pour identifier un diagramme donné, on dresse la liste des données mesurées pour cinq raies les plus intenses, dans l'ordre de distances interréticulaires décroissantes, puis on cherche dans l'index, au voisinage de la distance interréticulaire de la raie «d'intensité maximale» une corrélation approximative avec les quatre autres raies les plus intenses. Il ne reste qu'à consulter le catalogue, aux numéros de référence des diagrammes présentant des corrélations possibles, pour obtenir les noms des minéraux et des données plus détaillées qui permettront de confirmer leur identité.

Au laboratoire, nous avons automatisé le processus de recherche en faisant entrer les données numériques du catalogue dans un fichier sur bande magnétique, qu'on peut consulter à l'aide d'un petit ordinateur (mémoir de 8K) Hewlett-Packard. Un programme en langage HP Fortran IV Appendice I) nous permet, en introduisant les données mesurées d'un diagramme donné, de rechercher dans le fichier les données de référence des diagrammes en corrélation. Nous obtenons à la sortie, la liste des diagrammes de référence pour lesquels un nombre choisi à l'avance (par exemple, 3) de distances interréticulaires sont conformes, dans certaines limites pré-établies (par exemple, $\pm 0,02A$), aux données mesurées du diagramme à identifier. L'identification finale est fait par comparaison visuelle avec les diagrammes types de référence de notre collection.
