Abstract: Members of *Dodonaea* are broadly distributed across subtropical and tropical areas of southwest and southern China. This host provides multiple substrates that can be richly colonized by numerous undescribed fungal species. There is a severe lack of microfungal studies on *Dodonaea* in China, and consequently, the diversity, phylogeny and taxonomy of these microorganisms are all largely unknown. This paper presents two new genera and four new species in three orders of Dothideomycetes gathered from dead twigs of *Dodonaea viscosa* in Honghe, China. All new collections were made within a selected area in Honghe from a single *Dodonaea* sp. This suggests high fungal diversity in the region and the existence of numerous species awaiting discovery. Multiple gene sequences (non-translated loci and protein-coding regions) were analysed with maximum likelihood and Bayesian analyses. Results from the phylogenetic analyses supported placing *Haniomyces dodonaeae* gen. et sp. in the Teratosphaeriaceae family. Analysis of *Rhytidhysterion* sequences resulted in *Rhytidhysterion hongheense* sp. nov., while analysed Lophiostomataceae sequences revealed *Lophiomurisporea hongheensis* gen. et sp. nov. Finally, phylogeny based on a combined dataset of pyrenochaeta-like sequences demonstrates strong statistical support for placing *Quixadomyces hongheensis* sp. nov. in Parapyrenochaetaceae. Morphological and updated phylogenetic circumscriptions of the new discoveries are also discussed.

Keywords: Ascomycota; Asexual morph; Capnodiales; Greater Mekong Subregion; Hysteriales; Pleosporales; Sexual morph; Yunnan

1. Introduction

Fungi are cosmopolitan, featuring a broad geographic distribution and high level of diversity compared to plants and other organisms [1]. 140,000 fungal species have been listed in Kirk [2], and one recent overview of global fungi and fungus-like taxa by Wijayawardene et al. [3] listed approximately 100,000 known taxa. However, both numbers represent less than 5% of global fungal estimates [4,5]. There is a need to bridge the gap between our understanding of these missing fungi and their diversity. Numerous diverse habitats and substrates remain unexplored. It has also been observed that several countries and regions are bountiful repositories of many missing fungi, such as northern Thailand [6]. Despite this, fungi in Asia are relatively understudied [5]. Even though the Greater Mekong Subregion (GMS) hosts a high level of biodiversity and forms an integral part of the Indo-Burma Biodiversity Hotspot, fungi from this region largely remain a mystery. Yunnan Province, China, as part of the GMS, is home to an extremely wide variety of ecosystems. Mycologists working in Yunnan have recently focused their attention on abundant “less-researched habitats” for fungal occurrences, including caves, forests, grasslands, lakes, karst landscapes and mountains; accordingly, there is a rich body of literature documenting novel discoveries across the region [7–19].

The Honghe Hani and Yi Autonomous Prefecture is in south-eastern Yunnan Province. The region features a mountainous topography, numerous limestone deposits and a south-eastward decreasing elevation gradient. Owing to its abundant precipitation and heat as well as its dramatic altitudinal range and varied flora, this region harbours a rich diversity of plant species [20,21]. Along the altitudinal gradient, vegetation from lower to higher elevations range from tropical and montane rain forests to monsoon evergreen, montane mossy evergreen and summit mossy evergreen broad-leaved forests [22]. This complex topography and climatic diversity are both significant contributors to local biodiversity richness [23]. Among publications documenting fungal encounters across Yunnan Province, ascomycetes are critically neglected when compared to the amount of research on basidiomycetes [24]. Regrettably, studies on microfungi in Honghe are virtually non-existent. Except Marasinghe et al. [25], we could not find a single detailed account of microfungi in Honghe based on both morphological and phylogenetic analyses.

Dodonaea viscosa is a perennial evergreen woody shrub belonging to the family Sapindaceae. It is drought- and pollution-resistant as well as capable of growing on poor soils and rocky sites. The plant can also easily inhabit open areas and secondary forests [26,27]. A fast-growing plant, it typically grows 1 to 3 m in height but on rare occasions can reach up to 8 m [28]. *Dodonaea viscosa* is believed to have originated from Australia [29], though it grows throughout tropical and subtropical countries, including the African, Asian, Northern American and Southern American continents [30–32]. *Dodonaea viscosa* is effective at performing sand dune fixation and controlling coastal erosion since its roots function as excellent soil binders [33]. It can also be used to reclaim marshes. It is also grown as an ornamental plant owing to its shiny foliage and pink–red winged fruit [33]. Moreover, it is a well-known topic in environmental impact studies to determine the growth and yield of crops based on the presence of *D. viscosa* [27,34] as well as study its capacity to increase resilience to pollution [35,36] and drought [37]. In traditional medicine systems, plant parts such as the stem, leaves, seeds, roots, bark and aerial parts are used for various treatments [38]. Hossain [39] reported that extract obtained from *D. viscosa* has shown significant antidiabetic, antimicrobial, insecticidal, antioxidant, cytotoxic, antifertility, anti-inflammatory, analgesic, anti-ulcer, antispasmodic, anti-diarrheal and detoxification properties [27].

This study is the second in a series comprising an exhaustive taxonomic effort to document the microfungi of Yunnan Province [24]. In this study, we collected fresh fungal specimens from dead woody twigs of *Dodonaea* species at the Centre for Mountain Futures (CMF), an applied research centre jointly managed by World Agroforestry (ICRAF) and the Kunming Institute of Botany, Chinese Academy of Sciences (CAS), in Honghe County of the Honghe Hani and Yi Autonomous Prefecture. Using morphology and multi-gene phylogenetic evidence retrieved from the gathered ascomycetes, we characterized two new genera and four new species in the orders Capnodiales, Hysteriales and Pleosporales from dead twigs of *Dodonaea viscosa* in Honghe.

2. Materials and Methods

2.1. Herbarium Material and Fungal Strains

Fresh fungal materials were gathered from dead twigs of *Dodonaea viscosa* at CMF in Honghe County (Yunnan Province, China UTM/WGS84: 48 Q 216849–217075 E, 2592645–2592856 N, 600–750 m above sea level) during the dry season (April 2020). The local environment is characterized by poor eroded soils, steep valleys and a subtropical monsoon climate. Specimens were transported to the laboratory in Ziploc bags. Single spore isolation was conducted in accordance with methods described in Wanasinghe et al. [40]. Germinated spores were individually placed on potato dextrose agar (PDA) plates and grown at 20 °C in daylight. Dry herbarium materials were stored in the herbarium of Cryptogams Kunming Institute of Botany, Academia Sinica (KUN-HKAS). Living cultures were deposited at the Kunming Institute of Botany Culture Collection (KUMCC), Kunming, China and duplicated at China General Microbiological Culture Collection Centre (CGMCC). MycoBank numbers

were registered as outlined in MycoBank (<http://www.MycoBank.org> accessed on 11 November 2020).

2.2. Morphological Observations

The morphology of external and internal macro-/micro-structures were observed as described in Wanasinghe et al. [24]. Images were captured with a Canon EOS 600D digital camera fitted to a Nikon ECLIPSE Ni compound microscope. Measurements were made with the Tarosoft (R) Image Frame Work program, and images used for figures were processed with Adobe Photoshop CS5 Extended version 10.0 software (Adobe Systems, San José, CA, USA).

2.3. DNA Extraction, PCR Amplifications and Sequencing

The extraction of genomic DNA was performed in accordance with the methods of Wanasinghe et al. [24], using the Biospin Fungus Genomic DNA Extraction Kit-BSC14S1 (BioFlux, P.R. China) following the instructions of the manufacturer. The reference DNA for the polymerase chain reaction (PCR) was stored at 4 °C for regular use and duplicated at −20 °C for long-term storage. The primers and protocols used for the amplification are summarized in Table 1. The amplified PCR fragments were then sent to a private company for sequencing (BGI, Ltd. Shenzhen, P.R. China).

Table 1. Genes/loci used in the study with PCR primers, references and protocols.

^a *act*: actin; *btub*: β-tubulin; *cal*: calmodulin; ITS: part of rDNA 18S (3' end), the first internal transcribed spacer (ITS1), the 5.8S rRNA gene, the second ITS region (ITS2), and part of the 28S rRNA (5' end); LSU: large subunit (28S); *rpb2*: RNA polymerase II second largest subunit; SSU: small subunit rDNA (18S); *tef1*: translation elongation factor 1-alpha gene. ^b fRPB2-5f and fRPB2-414R were used only for Teratosphaeriaceae analysis. ^c All the PCR thermal cycles include initiation step of 95 °C: 5 min, and final elongation step of 72 °C: 10 min and final hold at 4 °C.

2.4. Molecular Phylogenetic Analyses

2.4.1. Sequence Alignment

Sequences featuring a high degree of similarity were determined from a BLAST search to identify the closest matches with taxa in Dothideomycetes and recently published data [49,53–56]. Initial alignments of the acquired sequence data were first completed using MAFFT v. 7 (<http://mafft.cbrc.jp/alignment/server/index.html> accessed on 18 January 2021) [57,58] and manually clarified in BioEdit v. 7.0.5.2 when indicated [59].

2.4.2. Phylogenetic Analyses

Single-locus data sets were scanned for topological incongruences between loci for members of the analyses. Conflict-free alignments were concatenated into a multi-locus alignment that underwent maximum-likelihood (ML) and Bayesian (BI) phylogenetic analyses. Evolutionary models for BI and ML were selected independently for every locus using MrModeltest v. 2.3 [60] under the Akaike Information Criterion (AIC) implemented in PAUP v. 4.0b10.

The CIPRES Science Gateway platform [61] was used to perform RAxML and Bayesian analyses. ML analyses were made with RAxML-HPC2 on XSEDE v. 8.2.10 [62] employing the GTR+GAMMA swap model with 1000 bootstrap repetitions.

MrBayes analyses were performed setting GTR+I+GAMMA for 2–5 million generations, sampling every 100 generations and ending the run automatically when standard deviation of split frequencies dropped below 0.01 with a burnin fraction of 0.25. ML bootstrap values equal or greater than 60% and Bayesian posterior probabilities (BYPPs) greater than 0.95 were placed above each node of every tree.

Phylograms were visualized with FigTree v1.4.0 program [63] and reassembled in Microsoft PowerPoint (2007) and Adobe Illustrator® CS5 (Version 15.0.0, Adobe®, San Jose, CA, USA). Finalized alignments and trees were deposited in TreeBASE, submission ID: S27699 (<http://purl.org/phylo/treebase/phyloids/study/TB2:S27699>).

3. Results

3.1. Global Checklist of Fungi on *Dodonaea viscosa*

Information for the global checklist (Table 2) was retrieved from the Agriculture Research Service Database generated by the United States Department of Agriculture (USDA) [64], related books and research papers. This checklist includes fungal species associated with *Dodonaea viscosa* and the countries from which they were recorded.

Table 2. Checklist of fungi recorded from *Dodonaea viscosa* in worldwide.

3.2. Phylogenetic Analyses

Four phylogenetic analyses were performed using the acquired sequences from GenBank (Table 3). The first is a phylogenetic overview of the genera treated in Teratosphaeriaceae (Figure 1), while the remaining three alignments represent the species in *Rhytidhysterion* (Figure 2), an overview of the phylogeny of the genera treated in Lophiostomataceae (Figure 3) and *Parapyrenochaeta*, and allied genera in Pleosporineae (Figure 4). Other details related to ML and BI analyses from different datasets are presented in Table 4. The acquired phylogenetic results are discussed where applicable in the notes below.

Table 3. Taxa used in the phylogenetic analyses and their corresponding GenBank numbers.

GenBank accession numbers with * are resulting from EF1-728F and EF-2 primers and – means missing data or not used in the phylogenetic analyses. The newly generated sequences are indicated in bold.

Figure 1. RAxML tree based on a combined dataset of partial LSU, ITS, *rpb2*, *act*, *cal* and *tef1* DNA sequence analysis in Teratosphaeriaceae. The tree is rooted to *Staninwardia suttonii* (CPC 13055). Bootstrap support values for ML equal to or greater than 60%, Bayesian posterior probabilities (BYPP) equal to or greater than 0.95 are presented as ML/BI above nodes. Known genera are indicated with coloured blocks. Blue represents new isolates. The ex-type strains are indicated in **bold**. The scale bar presents the expected number of nucleotide substitutions per site.

Figure 3. RAxML tree based on a combined dataset of partial SSU, LSU, ITS, *tef1* and *rpb2* DNA sequence analysis in Lophiostomataceae. The tree is rooted to *Gloniopsis praelonga* (CBS 112415) and *Hysterium angustatum* (MFLUCC 16-0623). Bootstrap support values for ML equal to or greater than 60% and BYPP equal to or greater than 0.95 are shown as ML/BI above the nodes. Known families and selected genera are indicated with coloured blocks. Blue represents new isolates. The ex-type strains are indicated in **bold**. The scale bar represents the expected number of nucleotide substitutions per site.

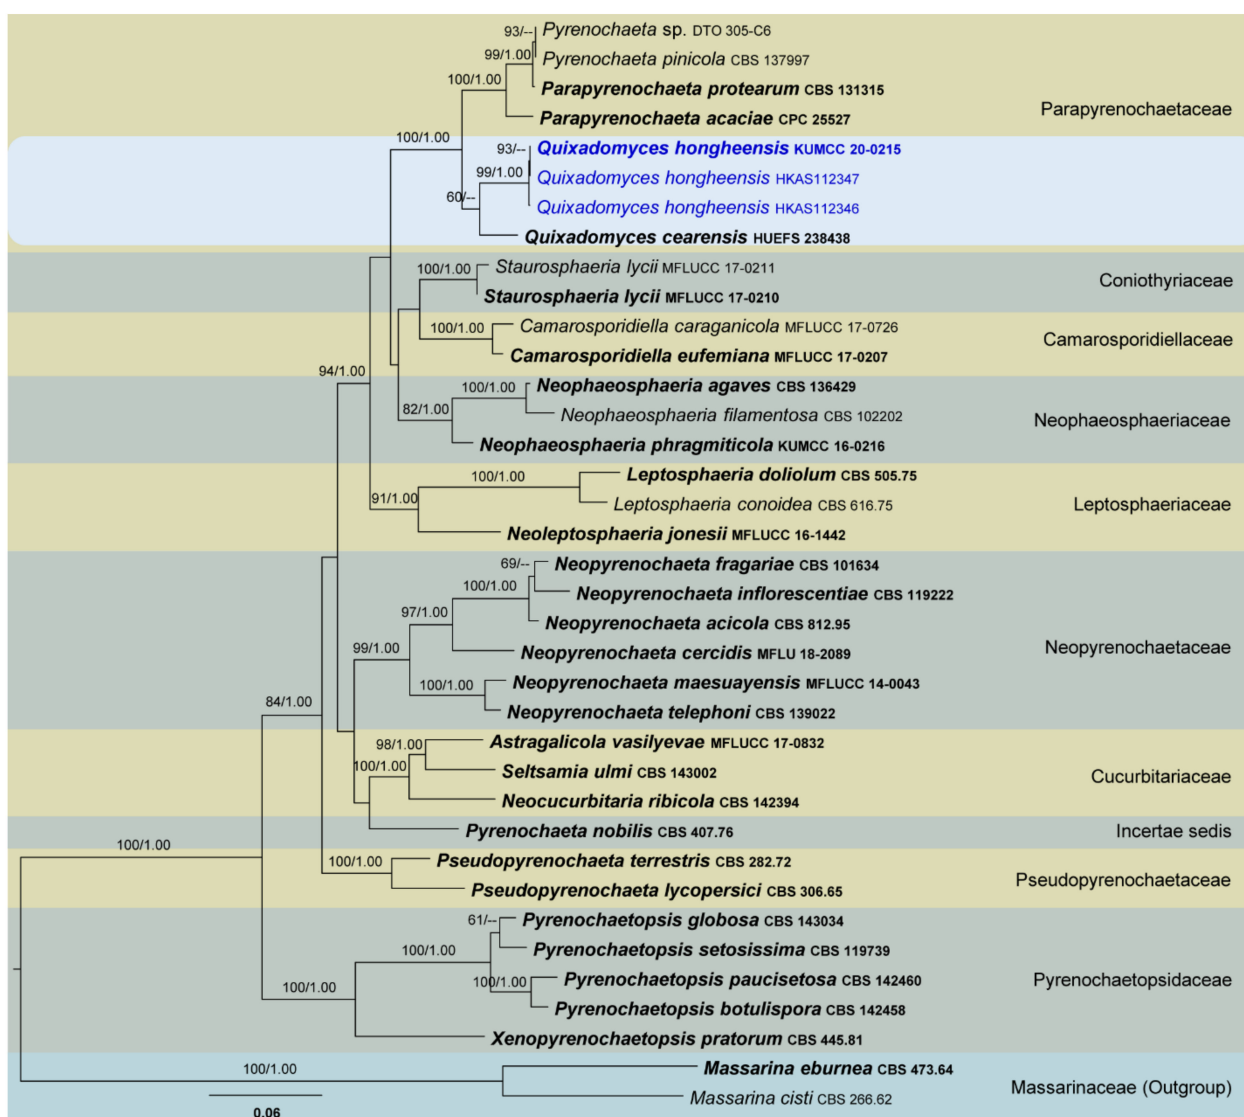

Figure 4. RAxML tree based on a combined dataset of partial LSU, SSU, ITS, *rpb2*, *tef1* and *btub* DNA sequence analysis in Pleosporineae. The tree is rooted to *Massarina cisti* (CBS 266.62) and *M. eburnea* (CBS 473.64). Bootstrap support values for ML equal to or greater than 60% and BYPP equal to or greater than 0.95 are shown as ML/BYPP above the nodes. Known families and the genus *Quixadomyces* are indicated with coloured blocks. Blue represents new isolates. The ex-type strains are indicated in **bold**. The scale bar represents the expected number of nucleotide substitutions per site.

3.3. Taxonomy of Fungi Colonising *Dodonaea Viscosa* Twigs

In the current study, two new genera and four novel species were found. These taxa are subsequently described below.

Class Dothideomycetes O.E. Erikss. and Winka, Myconet 1: 5 (1997)

Capnodiales Woron., Annales Mycologici 23: 177 (1925)

Teratosphaeriaceae Crous and U. Braun, Studies in Mycology 58: 8 (2007)

***Haniomyces* J.C. Xu gen. nov.**

MycoBank: MB837991

Etymology: The generic epithet refers to the “Hani” ethnic group in Honghe County, Yunnan Province, China.

It is *saprobic* on dead twigs and branches in terrestrial habitats. Sexual morph: the *ascomata* is a scattered, immersed to semi-immersed, subglobose to conical or shaped irregularly, glabrous, brown to dark brown ostiolate. The *ostiole* is a short papillate, black, smooth periphysate. The *peridium* comprises cells of *textura angularis*. The *hamathecium*

comprises numerous, filamentous, branched, septate, pseudoparaphyses. The *asci* are eight-spored, bitunicate, fissitunicate, clavate, with a pedicel, apically rounded with or without an ocular chamber. The *ascospores* overlap the biseriata, are ellipsoidal to sub-fusiform, hyaline, one-septate, with small to large guttules in each cell, with the ends remaining rounded, surrounded by a distinct mucilaginous sheath. Asexual morph: Coelomycetous. The *conidiomata* are sporodochial on PDA, globose, solitary or aggregated, semi-immersed, black, exuding yellow conidial masses. *Conidiophores* and conidiogenous cells were not observed in vitro. The *conidia* are solitary, aseptate, globose to ellipsoid, with the hyaline becoming medium to golden brown, and finely verruculose.

Type species: *Haniomyces dodonaeae*

Haniomyces dodonaeae Wanas. and Mortimer sp. nov. (Figure 5)

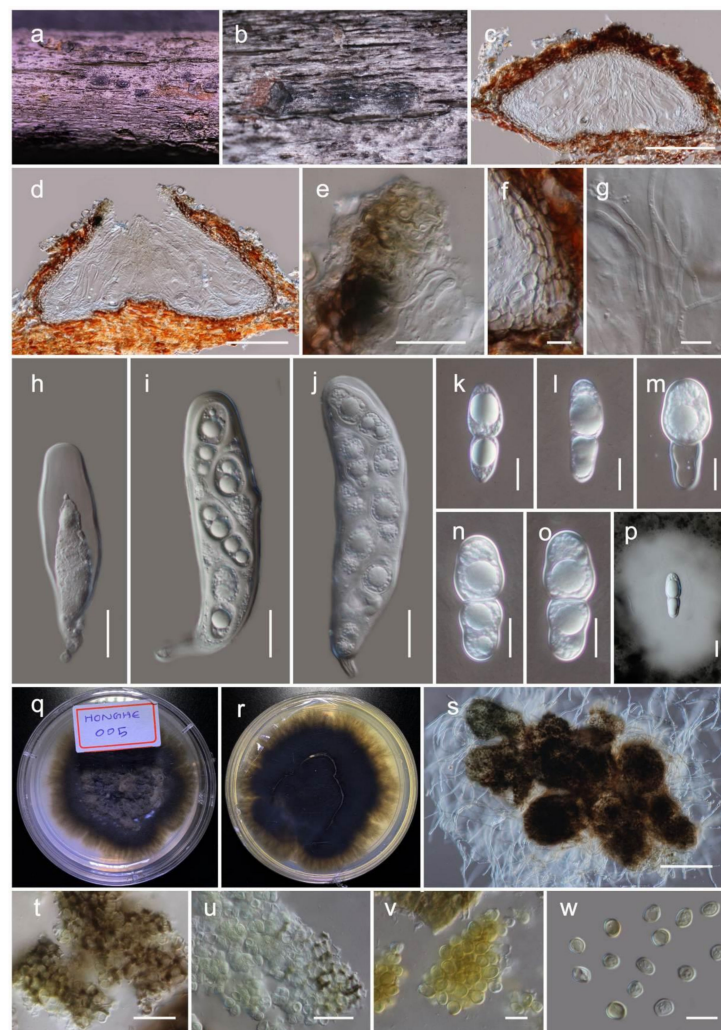

Figure 5. The sexual (HKAS110128, holotype) and asexual (KUMCC 20-0220, ex-type) morphs of *Haniomyces dodonaeae*. (a,b) ascomata on the dead woody twigs of *Dodonaea viscosa*; (c,d) vertical section of ascoma; (e) periphyses; (f) peridium; (g) pseudoparaphyses; (h–j) asci; (k–p) ascospores (p in Indian Ink); (q,r) colony on potato dextrose agar (PDA) (r from the bottom); (s) squashed pycnidia which were produced on PDA; (t) pycnidia wall; (u–w) conidia. Scale bars, (c,d) 100 μ m; (e,h–j,t,u) 20 μ m; (f,k–p,v,w) 10 μ m; (s) 200 μ m.

Mycobank: MB837997

Etymology: The specific epithet reflects the host genus *Dodonaea*.

Holotype: HKAS110128

It is *saprobic* on dead twigs of *Dodonaea viscosa* Jacq. (Sapindaceae). Sexual morph: the *ascomata* is a 150–200 μ m high, 350–450 μ m diam. ($M = 165.4 \times 390.3 \mu\text{m}$, $n = 5$), scattered,

semi-immersed to erumpent, subglobose to conical or shaped irregularly, flattened base, glabrous, brown to dark brown ostiolate, fused with host tissues. The *ostiole* is a short papillate, black and smooth, with hyaline periphyses (15–25 µm long, 1.5–2 µm wide). The *peridium* 5–10 µm wide at the base, 10–20 µm wide at sides, comprising 2–4 layers, outer layer pigmented, comprising reddish brown to dark brown, with thin-walled cells of *textura angularis*, and an inner layer composed of hyaline, loosen, cells of *textura angularis*. The *hamathecium* comprises numerous, 2–3 µm wide, filamentous, branched, septate, pseudoparaphyses. The *asci* are 110–130 × 25–35 µm (M = 118.5 × 31.2 µm, n = 20), eight-spored, bitunicate, fissitunicate, clavate, with a short pedicel (10–15 µm long), apically rounded with an ocular chamber. The *ascospores* 25–35 × 12–15 µm (M = 32.2 × 14.3 µm, n = 30), overlap the biseriate, are ellipsoidal to sub-fusiform, hyaline, one-septate, with the septum almost median, deeply constricted at the middle septum, with the upper cell wider than the lower cell, and are smooth-walled with small to large guttules in each cell, rounded at both ends and covered by a distinct mucilaginous sheath (30–50 µm, diam.). Asexual morph: Coelomycetous. The *conidiomata* are up to 250 µm diam., sporodochial on PDA, globose, solitary or aggregated, semi-immersed, black, exuding yellow conidial masses. *Conidiophores* and conidiogenous cells were not observed in vitro. The *conidia* are 5.5–7.5 × 4.5–5.5 µm (M = 6.4 × 5.4 µm, n = 30), solitary, aseptate, globose or ellipsoid, with the hyaline becoming medium to golden brown, and finely verruculose.

Culture characteristics: the colonies on PDA reached a 3 cm diameter after 2 weeks at 20 °C. They were circular has a serrate margin, whitish at the beginning, becoming brown at the centre and brownish green towards the margin after 4 weeks. They were slightly raised, and reverse blackish brown. The hyphae septate were branched, hyaline, thin, and smooth-walled.

Known distribution: Yunnan, China, on *Dodonaea viscosa*.

Material examined: China, Yunnan, Honghe Hani and Yi Autonomous Prefecture, Honghe County, 23.421068 N, 102.229128 E, 735 m, on dead twigs of *Dodonaea viscosa*, 22 April 2020, D.N. Wanasinghe, Honghe 005 (HKAS110128, holotype), ex-type living culture, KUMCC 20-0220, *ibid.* 23.419206 N, 102.231375 E, 618 m, Honghe 010 (HKAS110125, paratype), ex-paratype living culture, KUMCC 20-0221.

Hysteriales Lindau, Die Natürlichen Pflanzenfamilien nebst ihren Gattungen und wichtigeren Arten 1 (1): 265 (1897)

Hysteriaceae Chevall., Flore Générale des Environs de Paris 1: 432 (1826)

Rhytidhysterion Speg., Anales de la Sociedad Científica Argentina 12 (4): 188 (1881)

***Rhytidhysterion hongheense* Wanas. sp. nov.** (Figure 6)

Mycobank: MB837992

Etymology: The specific epithet is derived from Honghe County, Yunnan Province, China.

Holotype: HKAS110133

It is *aaprobic* on dead twigs of *Dodonaea* Mill. (Sapindaceae). Sexual morph: The *hysterothecia* is 1200–2000 µm long × 350–500 high × 600–1000 µm diam. (M = 1590 × 410 × 840 µm, n = 10), arising singly or in small groups, sessile, and slightly erumpent from the substrate. The *receptacle* is cupulate, black, flat or slightly concave, with a slightly dentate margin. The *excipulum* are 70–100 µm wide, with the ectal excipulum narrow layered, deep, and thick-walled, with black cells of *textura globulosa* to *textura angularis*; the medullary excipulum is composed of narrow, long, thin-walled, hyaline to brown cells of *textura angularis*. The *hamathecium* are 2.5–4 µm wide, numerous, propoloid, pseudoparaphyses, exceeding asci in length, apically swollen, branched and reddish-orange pigmented. The branched apices form a layer on hymenium to develop pseudo-epithecium. The *asci* are 140–180 × 12–16 µm (M = 163.3 × 13.8 µm, n = 20), eight-spored, long cylindrical, short pedicellate, and is rounded at apex. The *ascospores* 20–33 × 9–13 µm (M = 28.2 × 11.2 µm, n = 30), overlap the uniseriate, are hyaline to light brown, one-septate, with wrinkled walls when young, becoming dark brown at maturity. They are ellipsoid with conical ends, regularly three-septate, and rarely muriform with one longitudinal septum, smooth walled, guttulate. Asexual morph: Undetermined.

Figure 6. *Rhytidhysteron hongheensis* (HKAS110133, holotype). (a,b) Appearance of hysterothecia on the dead woody twigs of *Dodonaea viscosa*; (c,d) horizontal section of hysterothecium; (e) vertical section of hysterothecium; (f) cells of peridium; (g,h) pseudoparaphyses; (i,j) asci; (k–p) ascospores; (q,r) colony on PDA (r from the bottom). Scale bars, (d,e) 200 μ m; (f,i,j) 50 μ m; (g,h,k–p) 10 μ m.

Culture characteristics: Colonies on PDA reached a 4 cm diameter after 2 weeks at 20 °C. The colony was dense, circular, slightly raised, and the surface was smooth, with an undulated edge, with floccose which were greenish grey at the centre and brown towards margin from the top and reverse dark brown. The hyphae septate were branched, hyaline, thin, and smooth-walled.

Known distribution: Yunnan, China, on *Dodonaea*.

Material examined: China, Yunnan, Honghe Hani and Yi Autonomous Prefecture, Honghe County, 23.421068 N, 102.229128 E, 735 m, on dead twigs of *Dodonaea*, 22 April 2020, D.N. Pleosporales Luttr. ex M.E. Barr, Prodrumus to class Loculoascomycetes: 67 (1987)

Lophiostomataceae Sacc., Sylloge Fungorum 2: 672 (1883)

Lophiomurispora Wanas. and Mortimer, gen. nov.

Mycobank: MB837993

Etymology: The generic epithet stems from the combined two words “lophio” and “murispota”, referring to muriform ascospores in Lophiostomataceae.

It is *saprobic* on woody substrates in terrestrial habitats. Sexual morph: The *ascmata* is a solitary or gregarious, semi-immersed, erumpent through the host surface, coriaceous to carbonaceous, dark brown to black, globose to subglobose or conical ostiolate. The *ostiole* is a slit-like, central papillate, with or without a crest, opening by an apical, lysigenous pore or dehiscence, comprising hyaline periphyses or hyaline to lightly pigmented, pseudoparenchymatous cells. The *peridium* is broad at the apex and thinner at the base,

comprising two strata with several layers of brown or lightly pigmented to hyaline cells of *textura angularis* to *textura prismatica*, fusing and indistinguishable from the host tissues. The *hamathecium* comprises many branched, septate, cellular pseudoparaphyses, located between and above the asci, embedded in a gelatinous matrix. The *asci* are eight-spored, bitunicate, fissitunicate, cylindric-clavate, pedicellate, and apically rounded, with an ocular chamber. The *ascospores* are uni- to bi-seriate, partially overlapping, and are hyaline when immature, becoming brown to dark brown when mature. They are ellipsoidal to fusiform, muriform, two-to-eight-transversely septate, with one-to-two-longitudinal septa, constricted at the central septum, with or without a mucilaginous sheath. Asexual morph: Coelomycetous. The *conidiomata* is pycnidial, phoma-like, solitary, gregarious, dark brown to black, immersed or slightly erumpent, coriaceous to carbonaceous, papillate or apapillate. The *conidiomata wall* is multi-layered, with three to four outer layers of brown-walled pseudoparenchymatous cells, with the inner most layer being thin and hyaline. The *conidiophores* are long, septate, and sparsely branched, which are formed from the inner most layer of the pycnidium wall. The *conidiogenous cells* are phialidic, cylindrical, hyaline, flexuous and smooth, with a short collarette. The *conidia* are hyaline, aseptate, straight to curved, ellipsoidal with rounded ends, thin-walled, smooth, and numerous.

Type species: *Lophiomurispora hongheensis*

MycoBank: MB 837998

Etymology: The specific epithet is derived from Honghe County, the region of Yunnan Province in which this species was gathered.

Holotype: HKAS110127

It is *saprobic* on dead twigs of *Dodonaea viscosa* Jacq. (Sapindaceae) in terrestrial habitats. Sexual morph: The *ascmata* is a 280–360 μm high, 200–250 μm diam. ($M = 318.6 \times 232.7 \mu\text{m}$, $n = 5$), scattered to gregarious, immersed, coriaceous, dark brown to black, globose to subglobose ostiolate. The *ostiole* is a 70–100 μm long, 40–80 μm diam. ($M = 82.1 \times 64.8 \mu\text{m}$, $n = 5$), crest-like, central papillate, with a pore-like opening, comprising hyaline periphyses. The *peridium* is 20–30 μm wide at the base, 30–60 μm wide at the sides, broad at the apex, comprising two strata, with outer stratum composed of small, pale brown to brown, slightly flattened, thick-walled cells of *textura angularis*, fusing and indistinguishable from the host tissues. The inner stratum is composed of several layers with lightly pigmented to hyaline cells of *textura angularis* to *textura prismatica*. The *hamathecium* comprises 1–2 μm wide, branched, septate, cellular pseudoparaphyses, situated between and above the asci, embedded in a gelatinous matrix. The *asci* are 120–160 \times 17–22 μm ($M = 135.2 \times 18.5 \mu\text{m}$, $n = 15$), eight-spored, bitunicate, fissitunicate, cylindric-clavate, with a short pedicel, and is rounded at the apex, with an ocular chamber. The *ascospores* are 25–30 \times 11–13 μm ($M = 27.8 \times 12 \mu\text{m}$, $n = 30$), uni- to bi-seriate, overlapping, and are initially hyaline, turning brown at maturity. They are ellipsoidal to fusiform, muriform, four-to-eight-transversely septate, with one-to-two-longitudinal septa. They are slightly curved, deeply constricted at

the central septum, slightly constricted at the remaining septa, conically rounded at the ends, and smooth-walled, with a distinct mucilaginous sheath. Asexual morph: Coelomycetous. The *conidiomata* is 1–1.5 mm diam. pycnidial, phoma-like, solitary, gregarious, dark brown to black, and immersed, with a sphaerical mass of slimy conidia oozing out at ostiolar apex. The *conidiomata wall* is multi-layered, with brown-walled pseudoparenchymatous cells, with a hyaline inner most layer. The *conidiophores* are 10–15 × 1.5–2.5 µm long ($M = 12.4 \times 2.1 \mu\text{m}$, $n = 15$), septate and sparsely branched, which are formed from the inner most layer of the pycnidium wall. The *conidiogenous cells* are phialidic, cylindrical, hyaline, flexuous and smooth, with a short collarette. The *conidia* are 2.5–4 × 1.5–2 µm ($M = 3 \times 1.7 \mu\text{m}$, $n = 50$), hyaline, aseptate, straight to curved, ellipsoidal with rounded ends, and are thin-walled, smooth-walled, and numerous.

Culture characteristics: the colonies on PDA reached a 4 cm diameter after 2 weeks at 20 °C. They were circular, had a serrate margin, and were whitish at the beginning, becoming greenish-brown 4 weeks later. They were slightly raised, and reverse dark brown. The hyphae septate were branched, hyaline, thin, and smooth-walled.

Known distribution: Yunnan, China, on *Dodonaea viscosa*.

Parapyrenochaetaceae Valenz-Lopez, Crous, Stchigel, Guarro and J.F. Cano, Studies in Mycology 90: 64 (2017)

Quixadomyces Cantillo and Gusmão, Persoonia 40: 317 (2018)

Quixadomyces hongheensis Wanas. sp. nov. (Figure 9)

MycoBank: MB837994

Etymology: The specific epithet is derived from Honghe County, Yunnan Province, China.

Holotype: HKAS110126

It is *saprobic* on dead twigs of *Dodonaea viscosa* Jacq. (Sapindaceae) in terrestrial habitats. Sexual morph: Undetermined. Asexual morph: Coelomycetous. The *conidiomata* is immersed to erumpent, solitary, globose, brown, from 200–300 µm diam, with a central ostiole, exuding a hyaline conidial mass. It has a wall of two to three layers of brown *textura angularis*. The *paraphyses* are 20–100 µm long, 2–3 µm wide, cylindrical, hyaline, septate, and smooth. The *conidiophores* are mostly reduced to conidiogenous cells. The *conidiogenous cells* are 5–8 × 3.5–5 µm ($M = 6.4 \times 3.1 \mu\text{m}$, $n = 15$), lining the inner cavity, hyaline, smooth, are ampulliform to subcylindrical, and are phialidic with periclinal thickening. The *conidia* are 3–4.7 × 1.2–2 ($M = 3.7 \times 1.7 \mu\text{m}$, $n = 60$) µm, solitary, hyaline, smooth, aseptate, and allantoid with obtuse ends.

Culture characteristics: The colonies on PDA reached a 4 cm diameter after 2 weeks at 20 °C. They were circular, had a serrate margin, and were greenish brown after 4 weeks. They were slightly raised, and reverse dark brown. The hyphae septate were branched, hyaline, thin, and smooth-walled.

Known distribution: Yunnan, China, on *Dodonaea viscosa*.

Material examined: China, Yunnan, Honghe Hani and Yi Autonomous Prefecture, Honghe County, 23.421068 N, 102.229128 E, 735 m, on dead twigs of *Dodonaea viscosa*, 22 April 2020, D.N. 4. Discussion

Teratosphaeriaceae was introduced by Crous et al. [187]. Given that it is composed of 61 genera, it is regarded as one of the largest families in Dothideomycetes [188]. Members of this family are adapted to a broad range of life modes and can be saprobic, plant and human pathogenic, rock-inhabiting and endophytic; accordingly, they are widely distributed across varied terrain [49,136,139,188,189]. We have included representative sequence data of all available genera listed in Hongsanan et al. [188] for the phylogenetic analyses (except *Davisoniella*, *Pachysacca* and *Placocrea*, which lack DNA-based sequence data). Among them, *Aulographina* was grouped in Venturiales, and *Leptomelanconium* was related to Helotiales in the initial analysis. Therefore, they were excluded from the final analysis (Figure 1). In addition, representative taxa for *Piedraia* were included in the final dataset that were phylogenetically closely related to Teratosphaeriaceae. However, this genus is still considered a member in Piedraiaceae. The phylogeny generated herein (Figure 1) is congruent with those of other published studies to resolve intergeneric relationships in Teratosphaeriaceae [49,188]. In the combined LSU, ITS, *rpb2*, *act*, *cal* and *tef1* data analysis, 58 clades are recognized from the ingroup taxa. Two strains from our new collections

constitute a distinct monophyletic lineage (subclade 17, Figure 1) within the genera in Teratosphaeriaceae, which we introduce as a new genus.

The phylogeny (Figure 1) reveals a close relationship between two strains of the newly collected fungus (*Haniomyces dodonaeae*) to *Camarosporula persooniae*, *Lapidomyces hispanicus*, *Neophaeothecoidea proteae*, Teratosphaeriaceae sp. (CCFEE 5569), *Xenoconiothyrium catenata* and *Xenophacidiella pseudocatenata*, with 87% ML and 1.00 BYPP support values. Among them, only *Camarosporula persooniae* is reported from the sexual morph, and despite the high degree of phylogenetic similarity, these two species are morphologically dissimilar [136]. *Neophaeothecoidea* is more closely related to *Haniomyces* in the phylogenetic results, but this relationship lacks statistical support. In addition, *Neophaeothecoidea* is reported as a hyphomycete [188], whereas *Haniomyces* produces a coelomycetous asexual morph.

Out of the 61 genera listed in Teratosphaeriaceae, only 24 genera are described with sexual morphs. We suggest that the sexual morphs of these genera require further examination with increased collections to verify the accurate treatment of and relationships to remaining species. During asexual stages of Teratosphaeriaceae, most members are pathogenic, whereas they are non-pathogenic during sexual stages. This is an important distinction for identifying opportunistic pathogens, as members of this family can easily spread diseases between locations. The new taxon, *Haniomyces dodonaeae*, fits morphologically well into Teratosphaeriaceae by its periphysate ostiole and hyaline ascospores with a single septum in each. However, the dimensions of the asci and ascospores are significantly larger than the existing sexual reports of this family. The golden brown, ellipsoidal conidia of *Haniomyces dodonaeae* are similar to those in *Neophaeothecoidea* and *Readeriella*. Phylogenetically, *Haniomyces dodonaeae* has a close proximity to *Neophaeothecoidea proteae*. This relationship, however, is not strongly supported in the ML and BI analyses (Figure 1). *Neophaeothecoidea proteae* was originally isolated as a coelomycete (*Phaeothecoidea proteae*) based on its yeast-like growth in culture [190]; however, it is currently accounted for in a hyphomycetous genus. Comparison of the 805 base pairs (bp) across the LSU gene region of *Haniomyces dodonaeae* shows 17 bp (2.1%) differences exist in comparison with *Neophaeothecoidea proteae*. Similarly, comparison of the 356 bp of the *rpb2* gene region shows 56 bp (15.73%) differences in comparison with *Neophaeothecoidea proteae*.

Rhytidhysterion was introduced by Spegazzini [191] to account for *R. brasiliense* and *R. viride* collected from southern Brazil in 1877 and 1880, respectively. Spegazzini [56] did not designate any type; therefore, Clements and Shear [192] designated *R. brasiliense* as the type species. Subsequently, few species were introduced to this genus based on morphological evidence [193–196]. In recent studies, more species have been introduced based on both morphology and DNA-based sequence data [55,56,172,177,178,183]. Presently, there are 23 species mentioned in *Species Fungorum* [197], including saprobic to weakly pathogenic taxa that grow on woody plants in terrestrial habitats [56,181]. Species of *Rhytidhysterion* are typically involved in wood degradation and occur primarily on the woody parts of a broad range of hosts [64,188].

We introduce a new species into *Rhytidhysterion* from a dead twig of *Dodonaea* sp. in Honghe, China, and its relationships with other species are presented based on multigene phylogenetic analyses (Figure 2). Our analysed molecular data generated phylogenies consistent with those of Mapook et al. [55] and Hyde et al. [56]. The novel species, *Rhytidhysterion hongheense*, is phylogenetically closely related to *R. camporesii* (KUN-HKAS 104277) and *Rhytidhysterion chromolaenae* (MFLUCC 17-1516), and these three constitute a strongly supported monophyletic clade. The ascospore and asci characteristics between the three species are similar, but the colour of hysterothecia in *R. chromolaenae* (green) is different from the other two (black). The pseudo-epithecium of *R. camporesii* is brown to purple, whereas it is reddish orange in *R. hongheense*. The significance of these morphological characteristics in species delineation should be further investigated in terms of phylogenetic signals. A pairwise comparison of 521 ITS (+5.8S) sequence data showed 31 (5.95%) bp differences between *R. hongheense* and *R. camporesii* as well as 28 (5.37%) bp differences between *R. hongheense* and *R. chromolaenae*. Currently, there are only two *Rhytidhysterion* species,

viz. *Rhytidhysteron magnoliae* and *Rhytidhysteron thailandicum*, reported from China [56,198], making this report the third of its kind from China and first from Honghe Prefecture.

Lophiostomataceae species are usually characterized by a slot-like ostiole on the top of the flattened neck, occurring mainly on twigs, stems or the bark of different woody and herbaceous plants in terrestrial, freshwater and marine environments as saprobes [129,140,188]. Thambugala et al. [129] undertook a comprehensive study of this family and accepted 16 genera. Subsequently, 12 new genera have been introduced by recent publications, and currently the family comprises 28 accepted genera [188]. The most recent multi-locus phylogenetic backbone tree to the family is presented in this study, including a novel genus (*Lophiomurispota*) found in Honghe County, Yunnan Province, China.

Lophiomurispota morphologically resembles *Coelodictyosporium*, *Platystomum* and *Sigarispota* with its crest-like ostiole and brown, multi-septate ascospores. However, these genera are revealed as phylogenetically distant in multi-gene phylogenetic analysis (Figure 3). *Lophiomurispota* has a close phylogenetic relationship to *Desertiserpentica* (Figure 3). However, *Desertiserpentica* is only known from its hyphomycetous asexual morph [54], whereas *Lophiomurispota* differs from *Desertiserpentica* by its coelomycetous asexual morph. Five strains of *Lophiomurispota* clustered in Lophiostomataceae as a strongly supported monophyletic clade (Figure 3) in both ML and BI of a concatenated SSU, LSU, ITS, *tef1* and *rpb2* dataset. All specimens were collected from dead twigs of *Dodonaea viscosa* at the Centre for Mountain Futures (CMF) in Honghe. There was no significant difference between morphological characteristics and DNA-based sequence comparisons between these collections. Therefore, we introduce them as different collections of *Lophiomurispota hongheensis*.

Parapyrenochaetaceae was proposed by Valenzuela-Lopez et al. [53] to accommodate three isolates which were previously recognized in *Pyrenochaeta*. They introduced the novel genus *Parapyrenochaeta* for *P. acaciae* (*Pyrenochaeta acaciae*), *P. protearum* (*Pyrenochaeta protearum*) and for the strain CBS 137997, formerly misidentified as *Pyrenochaeta pinicola* (re-identified as *Parapyrenochaeta protearum*). Later, Crous et al. [131] introduced *Quixadomyces* as another genus in Parapyrenochaetaceae to accommodate *Quixadomyces cearensis*. Therefore, there are currently two accepted genera in Parapyrenochaetaceae [3,188].

Crous et al. [131] introduced *Quixadomyces* for a fungus that was collected from Brazil on decaying bark. However, they did not observe the development of any internal structures. This fungus slightly resembles species in Pleosporales with its setose pycnidia [131,188]. In a multi-gene (concatenated LSU, SSU, ITS, *rpb2*, *tef1* and *btub*) phylogenetic analysis, the ex-type strain of *Quixadomyces cearensis* (HUEFS 238438) clustered with two of our new strains as a monophyletic clade with poor bootstrap support (Figure 4). We introduce this isolate as a novel species belonging to this genus, *Q. hongheensis*. Based on the features of conidiogenous cells and conidia of *Quixadomyces hongheensis*, no substantial morphological differences exist to warrant two generic ranks. Therefore, this genus could potentially be reclassified as a synonym of *Parapyrenochaeta* in future studies. Because we did not perform extensive taxonomic reassessment using multiple fresh collections (especially sexual morphs of both genera), we will not attempt to synonymize any extant taxa.

Owing to lack of details on the internal structures of *Quixadomyces cearensis*, it is difficult to compare morphological characteristics such as conidiogenous cells and conidia between the new collection and this species. Lacking sufficient morphological evidence to perform accurate comparisons, we analysed nucleotide differences between these two strains. Comparing the 544 ITS (+5.8S) nucleotides of the two strains (HUEFS 238438 and KUMCC 20 0215) revealed 32 (5.88%) nucleotide differences. Therefore, it would seem prudent to treat our isolate as a new species in *Quixadomyces* as *Q. hongheensis*.

Nearly a century's worth of taxonomic investigation into *Dodonaea viscosa* has yielded only 58 fungal records [Table 2]. These are mainly reported as saprobes or pathogens, but very few of these taxa are confirmed by both morphological and phylogenetic evidence. Many of these published records lack illustrations, descriptions or DNA sequence data, resulting in unclear taxonomic relationships. Even though *Dodonaea viscosa* is widely distributed across southwest and southern China, e.g., Fujian, Guangdong, Guangxi, Hainan,

Sichuan and Yunnan [199], there is only one report for the fungus *Pseudocercospora mitteriana* on this host from China [124]. Previous taxonomic studies have suggested that increased collections might lead to the discovery of many new fungal species, and we, too, believe that *Dodonaea* is likely teeming with fungal diversity. More *Dodonaea* collections across different geographic regions are urgently needed, along with accompanying work in culture isolation, morphological description, DNA sequence analyses, phylogenetic relationship investigation, and accurate identification and classification. This study provides a case study for *Dodonaea viscosa* as a worthwhile host for the further study of microfungal associations and hints that it may potentially host numerous unknown fungal species.

Author Contributions: Conceptualization, D.N.W.; resources, P.E.M. and J.X.; writing—original draft preparation, D.N.W.; writing—review and editing, P.E.M.; supervision, P.E.M. and J.X.; funding acquisition, P.E.M. and J.X. All authors have read and agreed to the published version of the manuscript.

Funding: This research was funded by the Key Research Project, Agroforestry Systems for Restoration and Bio-industry Technology Development (Grant No. 2017YFC0505101), Ministry of Sciences and Technology of China (Grant No. 2017YFC0505100), CAS President’s International Fellowship Initiative (Grant No. 2019PC0008), the 64th batch of China Postdoctoral Science Foundation (Grant No. 2018M643549), Postdoctoral Fund from Human Resources and Social Security Bureau of Yunnan Province, NSFC project codes 41761144055 and 41771063.

Data Availability Statement: The datasets generated for this study can be found in the NCBI GenBank, MycoBank and TreeBASE.

Acknowledgments: Austin G. Smith at World Agroforestry (ICRAF), Kunming Institute of Botany, China, is thanked for English editing. Lu Wen Hua and Li Qin Xian are thanked for their invaluable assistance. We acknowledge Kunming Institute of Botany, Chinese Academy of Sciences for providing the laboratories and instruments for molecular work.

Conflicts of Interest: The authors declare no conflict of interest.
