## ABSTRACT

Leguminosae is an economically important family that contains a large number of medicinal plants, many of which are widely used in African traditional medicine. Angola holds a great socio-cultural diversity and is one of the richest floristic regions of the world, with over 900 native Leguminosae species. This study is the first to assess the medicinal uses of the legumes in Angola and provides new data to promote the conservation and the sustainable use of these unique resources. We document the ethnobotanical knowledge on Angola by reviewing the most important herbarium collections and literature, complemented by recent field surveys. Our results revealed that 127 native legume species have medicinal uses and 65% of them have other important uses by local populations. The species with most medicinal applications are *Erythrina abyssinica*, *Bauhinia thonningii* and *Pterocarpus angolensis*. The rich flora found in Angola suggests an enormous potential for discovery of new drugs with therapeutic value. However, the overexploitation and the indiscriminate collection of legumes for multiple uses such as forage, food, timber and medical uses, increases the threats upon the native vegetation. Efforts to assess the conservation status of these species are urgently needed, and future actions should promote the sustainable use of medicinal plants in Angola together with the implementation of conservation strategies.

## INTRODUCTION

Over the past decades, following the United Nations Conference on Environment and Development (UNCED) held in Rio de Janeiro in 1992, the conservation of biodiversity has come to be understood as an essential aspect of sustainable development worldwide (*Najam & Cleveland, 2005*). In particular, Africa's growing population, which is set to nearly double by 2050, and the implications for food production and provision for a

growing population while maintaining healthy ecosystems and habitats, have become one of the most pressing issues of the 21st century (*Thorn et al., 2015*).

Two-thirds of all angiosperm species are found within the tropics (*Pimm & Joppa, 2015*). It is now well-established that plants support critical ecosystem services, which includes: (i) supporting services (e.g., nutrient cycling, and primary production); (ii) regulating services (e.g., climate regulation, and pollination services); (iii) provisioning services (e.g., fuel wood, edible, medicinal, and aromatic plants); and (iv) cultural services (e.g., education, recreational, tourism, bequest or aesthetic value) (*Millennium Ecosystem Assessment, 2005*). In sub-Saharan Africa, the majority of people depend mainly on natural resources for subsistence and income generation and urgent actions are required to achieve the global goals to reduce the rate of biodiversity loss, degradation of ecosystems and subsequent reduction in goods and services that can be obtained from it (*Mertz et al., 2007*). In this region, medicinal plants are one of the most important elements of biodiversity, because of their role in ecosystem services such as healthcare, cultural value and heritage, local economics and human well-being (*Okigbo, Eme & Ogbogu, 2008*). Indigenous knowledge about the use of plants in traditional medicine constitutes a strategic resource and several studies have highlighted the great potential of native medicinal plants for therapeutic purposes (for reviews see: *Van Wyk, 2008; Moyo, Aremu & Van Staden, 2015; Máthé, Neffati & Najjaa, 2017*). Moreover, much of our understanding is still anchored in indigenous knowledge rather than in scientific studies. Hence, preserving this traditional knowledge is a critical aspect of conservation efforts focusing on useful plant species, especially given the risk that this knowledge could be lost in future generations. Furthermore, the medicinal plants are being overexploited in sub-Saharan Africa, and the high rates of destruction of their natural habitat is harmful not only to single species, but also to whole communities and ecosystems (*Okigbo, Eme & Ogbogu, 2008*). The consequences of these threats are such that they demand our urgent attention to conserve wild plant species used in African traditional medicine. In order to achieve this objective, reliable data are needed on their distribution and level of use, especially in understudied regions.

Angola is the largest country in southern Africa (1,246,700 km<sup>2</sup>) with an estimated population of over 26 million, according to the 2014 population census (*INE, 2014*). The country is divided into eighteen provinces (*Data S1*) and presents a great ethnical diversity with about 90 different groups, each with its own culture, beliefs and ways of appropriating nature (*Schubert, 2017*). The largest ethnic groups are the Ovimbundu and Ambundu, with ca. 37% and 25% of the total population respectively. Other representative groups are Bakongo, Chokwe, Ovambo, Ganguela and Xindonga (*Gosoni, Veta & Vounatsou, 2010*).

Angola encompasses a very wide range of ecosystems and habitats, and according to the World Wildlife Fund (WWF) (*Olson et al., 2001; Burgess et al., 2004*) there are seven major terrestrial biomes: (1) tropical and subtropical moist broadleaf forests; (2) tropical and subtropical dry broadleaf forests; (3) tropical and subtropical grasslands, savannas, and shrublands; (4) flooded grasslands and savannas; (5) montane grasslands and shrublands; (6) deserts and xeric shrublands; and (7) mangroves (more details are provided in *Data S2*). Although there is a wide-range of biomes, substantial habitat loss is confirmed by recent studies, above all with regard to the dry forests that are currently

experiencing the consequences of human exploitation on an unprecedented scale (see for more details: [Hansen et al., 2013](#); [Romeiras et al., 2014](#)). Without a clear involvement of local organizations to halt the risks associated with the threat to the country's biodiversity, progressive ecological disturbance may lead to the extinction of species with an inherent value and potential for agriculture, forestry or medicinal purposes.

Traditional medicine plays an important role in health care in Angola ([Costa & Pedro, 2013](#)), and since the middle of the 20th century some documents were published containing ethnobotanical information (e.g., [Gossweiler, 1953](#); [Peres, 1959](#); [Santos, 1967](#); [Santos, 1989](#)). At the end of the 20th century, [Bossard \(1996\)](#) published the most comprehensive study, and a total of 780 species used in traditional medicine were recorded. Over the last decade, the study of Angola's medicinal flora has been the subject of more research, namely by [Costa & Pedro \(2013\)](#), [Urso, Signorini & Bruschi \(2013\)](#), [Göhre et al. \(2016\)](#), [Bruschi et al. \(2017\)](#) and [Heinze et al. \(2017\)](#).

Angola is one of the richest floristic regions of Africa, with over 6,700 native plant species, with ca. 15% Leguminosae species which thus form the richest family in this country ([Figueiredo & Smith, 2008](#)). This family encompasses key-crops, medicinal plants and important African timber species ([Soares et al., 2007](#)) thus making it an important family of flowering plants with economic and medicinal applications. The uses of legumes as a source of drugs have been extensively reported in several studies (e.g., [Graham & Vance, 2003](#); [Howieson et al., 2008](#)). For instance, *Acacia senegal* (L.) Willd., also known as gum Arabic, is native in arid regions of sub-Saharan Africa, and is widely used as a food additive (e.g., in commercial emulsification for the production of beverages and flavor concentrates) and in the pharmaceutical industry, namely to treat bacterial and fungal infections of the skin and mouth ([Mahomoodally, 2013](#)). Current evidence suggests that medicines derived from several Leguminosae species have important therapeutic effects in cancer treatments. The methanol extract of the bark of *Guibourtia tessmannii* (Harms) J. Leonard (from Cameroon) has shown antiproliferative activity against cervical cancer cells ([Kuete et al., 2013](#)), while serine protease inhibitors from *Cajanus cajan* (L.) Millsp. seeds (also known as the pigeon pea) demonstrated anticancer potential ([Shamsi et al., 2017](#)).

As stated above, Angola hosts high levels in terms of the species richness and endemism, but threats to this rich flora and their habitats are emerging. Therefore, it is imperative to conserve and study its biodiversity, also with regard to useful plant species. In particular, legumes are a highly appropriate *proxy* group for an understanding of the diversity and conservation issues of useful plants as a whole, in view of the fact that it (a) forms the largest plant family in Angola ([Figueiredo & Smith, 2008](#)), (b) has diversified in almost all biomes and ecoregions and is often a dominant component of the major habitats ([Olson et al., 2001](#)), (c) is also of ecological importance in maintaining soil fertility through fixation of atmospheric nitrogen by bacteria in nodules on their roots ([LPWG, 2017](#)) and (d) is known to contain a wide range of uses including many commercially important species ([Soares et al., 2007](#)).

Therefore, this study focuses on the knowledge and use of the flora as a major Angolan socio-cultural heritage, and particularly the diverse Leguminosae family, aiming to identify the species used in traditional medicine. A better understanding of the multiple uses of

these medicinal plants, including food and timber, will provide key knowledge to conserve plant diversity in Angola and tackle the potential threats that are endangering these species' survival. In particular, this study seeks to respond to two central questions: (i) which Leguminosae species are used in traditional medicine, and (ii) what can be done to ensure the conservation and sustainable use of these medicinal species in Angola?

## MATERIALS & METHODS

### Data collection

Data on the Leguminosae plant species used in the traditional medicine in Angola was obtained by means of a comprehensive review conducted through the study of numerous herbarium specimens, and of published works and online databases. To provide a critical and updated review of Angola's medicinal plants, interviews with indigenous healers were conducted over the last two decades in some regions of Angola.

Therefore, this study was made using four main sources:

1. The Angolan collections held in the Herbarium of the Instituto de Investigação Científica Tropical, University of Lisbon (LISC). This is the most comprehensive and representative collection of the Angolan flora comprising over 80,000 specimens that have been collected since the 19th century. Information recorded on the labels allowed us to get data on the medicinal and other uses (e.g., food, timber, fibers and forage), plant parts used, diseases treated, as well as growth form and distribution of each species within Angola.
2. A thorough investigation of the medicinal plant data described in literature. We review data available from the past (e.g., *Ficalho, 1947*; *Gosswailer, 1953*; *Peres, 1959*; *Santos, 1967*; *Santos, 1989*; *Van-Dúnem, 1994*; *Bossard, 1996*) and also more contemporary sources (e.g., *Costa, Dombo & Paula, 2009*; *Leyens & Lobin, 2009*; *Costa & Pedro, 2013*; *Göhre et al., 2016*; *Bruschi et al., 2017*; *Heinze et al., 2017*). Furthermore, species occurrences were compiled from specialized bibliography, namely in *Conspectus Florae Angolensis* (e.g., *Exell & Mendonça, 1956*; *Exell & Fernandes, 1962*; *Exell & Fernandes, 1966*).
3. Online databases, namely: (i) PROTA - The Plant Resources of Tropical Africa (<https://www.prota4u.org/>), which has detailed information on the taxonomy and uses of many African plants; (ii) IUCN - Red List of Threatened Species (<http://www.iucnredlist.org>) that provides useful information on each species assessed, threats and conservation actions; and (iii) Global Biodiversity Information Facility (GBIF) to get distribution data.
4. Field research carried out by one of the authors (E. Costa), which substantially contributed to updating and complementing the inventory of Angola's medical flora. Field surveys were conducted in four provinces of Angola: Luanda, Bengo, Zaire and in the exclave province of Cabinda, located in the north of Angola (more information is provided in [Data S1](#)). In each rural community, a first meeting was held with the village chief (Soba –Portuguese name) and his advisors to inform them about the purposes of our work and get their support for the choice of the best skilled traditional healers in

each community. The ethnobotanical surveys were conducted using semi-structured questionnaires, previously prepared and tested (*Albuquerque et al., 2014*). During the interviews each healer was previously informed about the objectives of the study and asked to get his informed consent to participate.

In the course of fieldwork, botanical samples were collected for herbarium vouchers. These specimens were preserved for later identification and are kept in the LISC Herbarium and LUA Herbarium (University of Agostinho Neto, Luanda Angola).

### **Database construction and calculation of pharmacological importance**

Based on the best currently available knowledge, we combined ethnobotanical data to complete a database with all the Leguminosae medicinal species known from Angola. This database includes for each species the scientific name and subfamily; distribution in Angola; ethnobotanical data (e.g., plant part(s) used; group of diseases; and other uses such as food, timber, fibers and forage); and their conservation status and main threats, using the Threats Classification Scheme version 3.2 proposed by IUCN (*Data S3*) (<http://www.iucnredlist.org/technical-documents/classification-schemes/threats-classification-scheme>). Moreover, for each species it is indicated the number of different sources (e.g., herbarium specimens, published sources, and fieldwork) that refers to its medicinal uses, as a measure to provide more confidence in the legitimacy of usage data, and estimate the ethnobotanical importance of the species.

After compiling the database of the medicinal legumes of Angola, we calculated the pharmacological importance (PI) of each medicinal species by dividing the number of pharmacological properties attributed to the species by the maximum number of properties attributed to the most resourceful species (i.e., the species with the greatest number of pharmacological properties referred). The value of 1 is the highest possible value for PI, indicating the most versatile species with the greatest number of medicinal properties. Pharmacological importance was adapted from *Bennett & Prance (2000)* where is designated as “normalized pharmacological properties”. It is a widely used method to measure the species importance in traditional medicine and was previously applied in other studies (e.g., *Albuquerque et al., 2007*; *Giday, Asfaw & Woldu, 2009*; *Oliveira et al., 2010*).

Plant names have been checked and updated according to The Plant List (<http://www.theplantlist.org>) and the African Plant Database (<http://www.ville-ge.ch/musinfo/bd/cjb/africa>). The Leguminosae subfamilies were updated following the recent proposed classification of the “Legume Phylogeny Working Group”, which presently recognized six subfamilies: Caesalpinioideae (which also includes the former subfamily Mimosoideae), Cercidoideae, Detarioideae, Dialioideae, Duparquetioideae and Papilionoideae (*LPWG, 2017*).

## **RESULTS**

Our results reveal that 127 Leguminosae species and subspecies are recognized as medicinal plants used in Angolan traditional medicine (*Table 1*). The geographic distribution in

Notes.

<sup>a</sup>**Main distribution in Angola:** Distribution in Angola. Provinces: BE, Benguela; BI, Bié; BO, Bengo; CA, Cabinda; CC, Cuando-Cubango; CN, Cuanza Norte; CS, Cuanza Sul; CU, Cunene; HA, Huambo; HI, Huíla; LA, Luanda; LN, Lunda Norte; LS, Lunda Sul; MA, Malanje; MO, Moxico; NA, Namibe; UI, Uíge; ZA, Zaire.

<sup>b</sup>**Main Groups of Diseases:** A, pains; B, intestinal problems; C, stomach problems; D, skin inflammations, wounds and burns; E, cough, and respiratory diseases; F, fever, malaria (species indicated specifically for malaria are with F\*); G, stings, bites and poisoning; H, mental and neurological disorders; I, anemia and blood disorders; J, diseases of the eyes; K, diseases of the liver and gallbladder; L, diseases of the kidney; M, hearth diseases; N, rheumatism and arthritis; O, bones and joints; P, headaches; Q, tooth and mouth diseases; R, hair problems; S, hemorrhoids; T, internal parasites; U, sexually transmitted diseases; V, infertility; W, bladder and urinary problems; X, pregnancy, childbirth, breastfeeding and diseases of the new-born; Y, menstrual problems and uterine disorders; Z, male impotence; **Others** (i.e., other diseases includes sore throat, gout, nasal bleeding, scurvy, leprosy, earache, appetite disorders, obesity, hydrops, coma, rickets, anaesthetic, smallpox, polio, cancer, syncope and paralysis).

<sup>c</sup>**Parts used in medicine:** Ae, aerial parts of plant; Bk, bark; Br, branches; Fl, flowers; Fr, fruits; Lv, leaves; Rt, roots; Sa, sap; Se, seeds; St, stem; Wp, whole plant; Yl, young leaves.

<sup>d</sup>**PI:** relative importance of each species indicating the most versatile species (value=1) with the greatest number of medicinal properties.

<sup>e</sup>**Voucher:** Vouchers are stored in LISC Herbarium, with the exception of *D. hirtum* (in the Herbarium Dresdense).

<sup>f</sup>**References:** 1, Ficalho (1947); 2, Gosswailer (1953); 3, Peres (1959); 4, Santos (1967); 5, Van-Dúnem (1994); 6, Bossard (1996); 7, Costa, Dombó & Paula (2009); 8, Leyens & Lobin (2009); 9, Göhre et al. (2016); 10, Bruschi et al. (2017); 11, Heinze et al. (2017); 12, IUCN (2018) Red List; 13, Protá; 14, Specimens of LISC Herbarium.

<sup>g</sup>**Healers information:** Species marked with \* were mentioned by the healers during author (EC) field surveys.

More details in Data S3.

<sup>i</sup>**Number of information sources** is the number of different sources that refers to the medicinal uses, including herbarium specimens, bibliographic sources, and fieldwork references.

Angola, ethnobotanical uses; medicinal applications and plant parts used; other non-medicinal uses (e.g., timber, food and forage); and potential threats for these medicinal plants, are described in [Table 1](#).

The large majority of the species used for medicinal purposes are native non-endemic species (110 species, representing 86.6% of the total), and the endemic plants used as medicinal account for 17 species or 13.4% of the total. The genus *Acacia* have the highest number of medicinal taxa (10), followed by *Crotalaria* with 8 taxa. The most represented Leguminosae subfamilies are Papilionoideae and Caesalpinioideae, with 80 and 35 taxa respectively ([Table 1](#)). More than half of the medicinal plants listed in our study are commonly found in three provinces: Huíla (78%), Malanje (54%), and Benguela (54%) while less than 20% is found in Luanda. Overall, Huíla in the South (99 taxa), and Malanje in north-central Angola (69 taxa), boast the greatest diversity of recorded medicinal flora ([Table 1](#); [Data S1](#)).

The most frequent conditions treated by Leguminosae species are: skin infections, wounds and burns (39 species, 30.7%), intestinal problems (36 species, 28.3%) and respiratory diseases (36 species, 28.3%) ([Fig. 1](#)). These plants can be used entirely or only partially, and our study reveals that the most commonly used parts are: roots (33%), leaves (26%) and bark (18%) ([Fig. 2](#)). Furthermore, four species of Leguminosae stand out for their high number of medicinal applications: *Erythrina abyssinica* DC. ([Fig. 3A](#)) which is used for 18 of the 26 medicinal categories established (PI = 1); the species *Bauhinia thonningii* Schum. ([Fig. 3B](#)) and *Pterocarpus angolensis* DC. ([Fig. 3C](#)) have 17 applications each (PI = 0.94) followed by *Dichrostachys cinerea* (L.) Wight & Arn ([Fig. 3D](#)) with 16 applications (PI = 0.89). Our results also revealed that these species were consistently mentioned as used in traditional medicine by different sources (i.e., herbarium specimens, published sources, and fieldwork) ([Table 1](#)).

Of the 127 Leguminosae plants used by the local populations, 35% are only used medicinally, while the remaining species were reported to have other uses ([Table 1](#)). For instance as forage (63), timber (42), or food (31), and 14 medicinal species overlapping all these uses ([Fig. 4](#)). Among these species, some timber trees were identified as particularly vulnerable (e.g., *Acacia goetzei* Harms; *Albizia adianthifolia* (Schum.) W. Wight; *A. gumifera* (J.F. Gmel.) C.A. Sm.; *Brachystegia spiciformis* Benth.; *B. tamarindoides* Benth.; *Burkea africana* Hook.; *Cassia angolensis* Hiern; *Erythrina abyssinica*; *Julbernardia paniculata* (Benth.) Troupin; *Lonchocarpus sericeus* (Poir.) DC.; *Peltophorum africanum* Sond.; *Piptadeniastrum africanum* (Hook.f.) Brenan; *Pterocarpus angolensis*; *P. tinctorius* Welw.; and *Tamarindus indica* L.) due to the over-collection of their wood in the wild, which was identified as a major threatening factor. Moreover, we identify for each medicinal Leguminosae species the main threats, and our results revealed that 65% of these plants are potentially threatened, mostly as a consequence of: (i) logging & wood harvesting; (ii) increase in livestock farming & ranching; and (iii) gathering terrestrial plants, including harvesting plants, for commercial, subsistence, or cultural purposes ([Table 1](#) and [Data S3](#)). Habitat degradation and human disturbance (i.e., residential & commercial development; and natural system modifications) were also reported among the potential threats. Finally, the information available at the IUCN Red List of Threatened Species ([IUCN, 2018](#)),

**Figure 1** Principal disease groups used by traditional medicine in Angola. Disease groups with fewer than 10 species are not shown (see more details in Table 1).

Full-size DOI: 10.7717/peerj.6736/fig-1

revealed that few species were evaluated (12 species, representing 9.4% of the total), among which only *Brachystegia bakeriana* Burt Davy & Hutch. was classified in a threatened category at global scale, with the Status: Vulnerable B1+2c (Phiri, 1998).

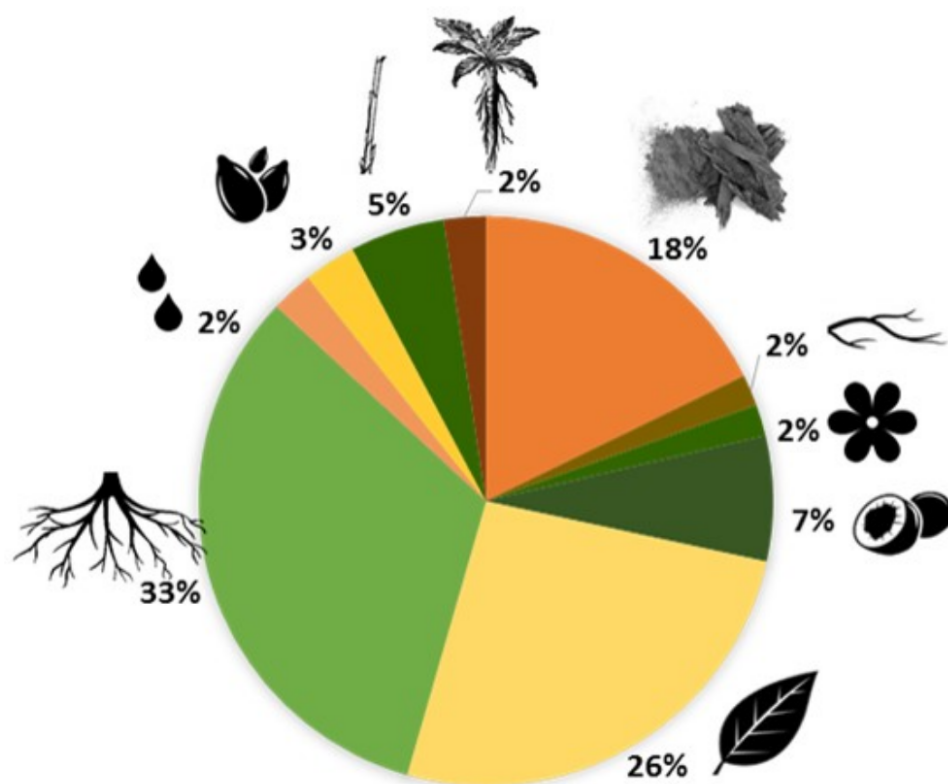

## DISCUSSION

### Leguminosae species used in traditional medicine

The present study is the first survey carried out in Angola to document all the species used in traditional medicine, of one of the biggest plant families - Leguminosae. A total of 127 medicinal plant species were documented, 110 being native non-endemic species, while 17 are endemic species from Angola. Thirty percent of the species have been recorded for the first time as having medicinal uses. Of all the endemic species reported in our study, only three (i.e., *Droogmansia gossweileri* Torre; *Eriosema albo-griseum* Baker f.; and *Philenoptera pallescens* (Welw. ex Baker) Schrire) were reported in current literature about useful plants of tropical Africa (e.g., Burkill, 1994) or in PROTA Web site (<http://www.prota.org>).

An interesting result of our study was the comparison between our field data and the historical information based on botanical collections. It demonstrated that the Leguminosae medicinal plants recorded several decades ago were also mentioned by the informants

**Figure 2** Plant parts used in traditional medicine. Chart: 33%, roots; 26%, leaves; 18%, bark; 7%, fruits; 5%, steam; 3%, seeds; 2%, whole plant; 2%, sap; 2%, flowers; 2%, branches.

during the recent ethnobotanical surveys. Furthermore, it was noted during the field surveys that the knowledge of medicinal plants in Angola is traditionally kept by local healers, but people living in rural areas also demonstrate a broad knowledge of plants and their properties. In general, they maintain a strong relationship with the surrounding environment throughout their lives, using natural resources to supply most of their needs. In fact, our study underlined that some species, which are widely distributed in Angola (e.g., *Bauhinia thonningii*; *Erythrina abyssinica*; and *Pterocarpus angolensis*), are used to treat a relatively large number of illnesses, demonstrating a wide and deep knowledge of medicinal plant properties across the country.

Our findings reveal that 65% of the species reported in our study have their traditional uses confirmed elsewhere in Africa (e.g., *Burkill, 1994*; PROTA), showing the potential of the Angolan native plants as a source of new compounds of therapeutic interest. The traditional use most frequently noted in our study was the treatment of infectious diseases (e.g., skin infections, intestinal problems and respiratory diseases), which remain the most serious diseases in Africa (*Iwu, Duncan & Okunji, 1999*). Many of the reported Leguminosae plants have already shown to have interesting biological activity in the treatment of infectious diseases, namely: *Abrus precatorius* L. is traditionally used in Nigeria to treat tuberculosis (*Ibekwe et al., 2014*); *Albizia adianthifolia* is an important medicinal

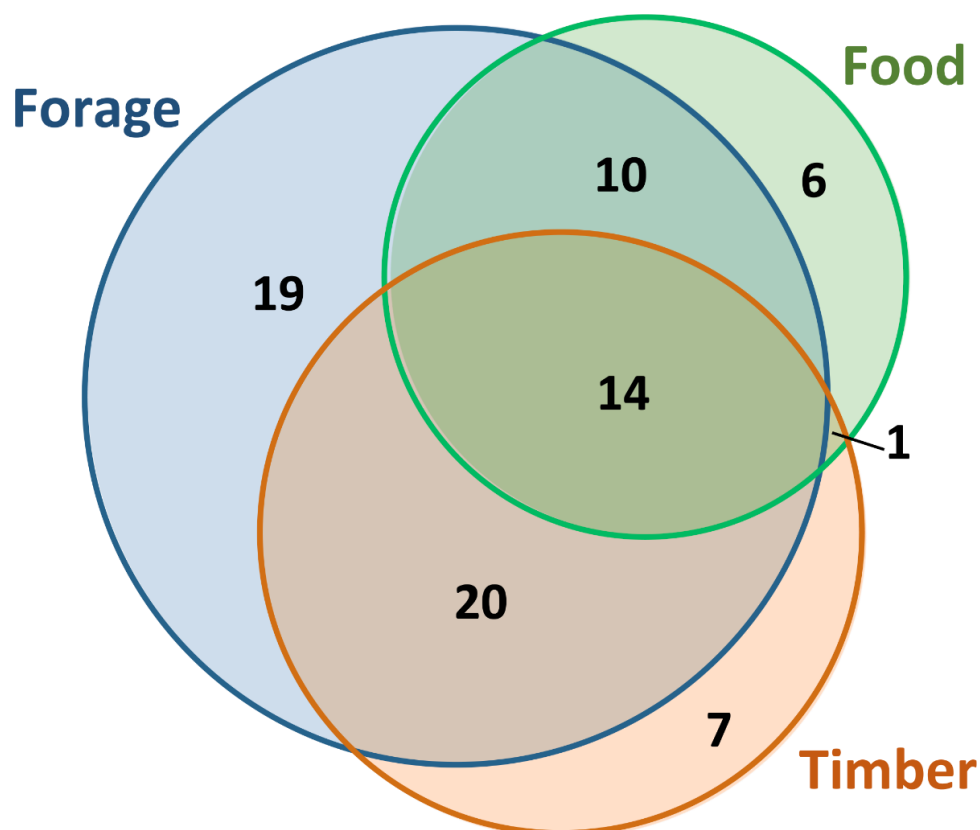

**Figure 3** Leguminosae species with more medicinal applications in Angola. *Erythrina abyssinica* (A); *Bauhinia thonningii* (B); *Pterocarpus angolensis* (C); *Dichrostachys cinerea* (D). Photos by Esperança Costa.

plant in Guinea-Bissau for alleviating intestinal pain (Catarino, Havik & Romeiras, 2016); and *Pterocarpus angolensis* is used in South Africa for the treatment of parasitic infections affecting humans (Cock, Selesho & Vuuren, 2018).

Since the last decade of the 20th century the prevalence of infectious diseases in Africa increased significantly, and the most important contributing factors are attributed to increases in tuberculosis and HIV/AIDS (Iwu, Duncan & Okunji, 1999). The spread of HIV/AIDS infection has been particularly alarming in sub-Saharan Africa and several studies have focused on plants that can be used in the treatment of this disease (e.g., Mbonu, Borne & Vries, 2009; Becerra, Bildstein & Gach, 2016). Recently, several concerns about the increase of HIV/AIDS were also reported for Angola (e.g., Bártolo et al., 2014) and some species listed in our study (e.g., *Abrus precatorius*; *Acacia goetzei*; *Azalia quanzensis* Welw.; *Dichrostachys cinerea*; *Mucuna pruriens* (L.) DC.; *Peltophorum africanum*; *Sesbania sesban* (L.) Merr.) have shown great promise in the treatment of infectious diseases including opportunistic HIV/AIDS infections (see more details in Chinsembu, 2016). These medicinal plants were highlighted as containing a broad-spectrum of antimicrobial agents used to treat: skin infections, sexually transmitted infections (STI), lung infections such as tuberculosis, pneumonia and cough, and also oral infections, revealing the potential properties of these species for the treatment of HIV/AIDS related diseases.

Similarly, there has been an increased scientific interest in the study of bioactive compounds extracted from plants in prevention and treatment of cancer (Greenwell &

**Figure 4** The main uses of medicinal plants in Angola. Euler diagram showing the number of medicinal species with other uses (timber in orange, food in green and forage in blue). The overlapping shapes represent species with two or three uses.

Full-size DOI: 10.7717/peerj.6736/fig-4

*Rahman, 2015*). For example, *Albizia adianthifolia* extracts collected in Cameroon have revealed considerable cytotoxic activities to fight cancer (*Kuete et al., 2016*) and ethanol extracts obtained from the roots of *Albizia gummifera* (J.F.Gmel.) C.A.Sm. in Madagascar have shown cytotoxicity against ovarian cancer (*Cao et al., 2007*). Both species were also reported in our study and the medicinal properties of these species are well-known in Angola (*Costa & Pedro, 2013*).

With this paper we contribute to update estimations of medicinal plants from Angola and it is highlighted the enormous therapeutic potential of the Leguminosae species in particular. However, the biological activities of these plants are poorly known and require further research in the laboratory, as only few studies (see *Pompermaier et al., 2018*) have been carried out with Angolan plants to specifically examine the relationships between the activity of the extracts and their medicinal properties.

### Conservation of Leguminosae species in Angola

The preservation of local knowledge together with the conservation of biodiversity are currently regarded as being of major importance in the development of the sub-Saharan Africa (*Okigbo, Eme & Ogbogu, 2008*). However, there are still important gaps in available

data on the conservation status of most of the African medicinal plants. Presently, it is widely accepted that the Red Lists provides the most comprehensive framework to identify and prioritize threatened species (Romeiras *et al.*, 2016a) and several research initiatives were recently conducted across Africa (e.g., for Cameroon by Onana, Cheek & Pollard (2011), for Ethiopia and Eritrea by Vivero, Kelbessa & Demissew (2005), for Cabo Verde by Romeiras *et al.* (2016b) and for Morocco by Rankou *et al.* (2015); Lamrani-Alaoui & Hassikou (2018)). The IUCN Red List assessment for the flora of Angola has not yet been conducted, and only a preliminary survey was recently published (Costa, Dombó & Paula, 2009). In fact, assessing the conservation status of medicinal legumes from Angola is a key challenge, because only twelve species were globally evaluated according to the IUCN Red List Categories and Criteria, and only one species (*Brachystegia bakeriana*) was considered Vulnerable (Phiri, 1998). This assessment was published more than 20 years ago and is cleared outdated. This contrasts with some efforts made in other African countries. For example, the Red List of the Flowering Plants of Cameroon classify 815 species under threat categories, being 9% Leguminosae species (Onana, Cheek & Pollard, 2011), while the Red List of Endemic Trees and Shrubs of Ethiopia and Eritrea reports a worst scenario with 18% of the 135 endangered species, from the family Leguminosae (Vivero, Kelbessa & Demissew, 2005). Therefore, particular attention must be given to initiatives for conserving useful plant species, which corresponds to 21% of the threatening processes for vascular plant species assessed on the IUCN Red List (Bachman *et al.*, 2016).

Angola urgently needs to promote actions that will conserve its great diversity of species and also its unique ecosystems, namely: Angolan Miombo woodlands, Angolan Montane Forest-Grassland Mosaic and Angolan scarp savanna, where several medicinal plants thrive. Our results revealed that 38 of the studied taxa are trees, of which 25 are widely used for timber as well as being medicinal. Several of these tree species have a restricted distribution in Angola, namely: (i) *Brachystegia tamarindoides* Benth. has limited distribution in Africa, occurring mainly in Angola in the Miombo area (Exell & Mendonça, 1956); (ii) *Albizia gummifera* and *Pentaclethra macrophylla* Benth. are mainly distributed in the Atlantic Equatorial forests of Cabinda (Exell & Mendonça, 1956); and (iii) *Colophospermum mopane* (Benth.) occurs only in the southern provinces of Angola, mainly in the Mopane woodlands (Makhado *et al.*, 2014; Duvane *et al.*, 2017). On the other hand, *Brachystegia spiciformis*, *Burkea africana*, *Julbernardia paniculata* and *Pterocarpus angolensis* are widespread in savannas and Miombo woodlands (Moura *et al.*, 2017). However, several of these tree species are overexploited and are being cut down on a large scale because they are widely used for charcoal production and much valued as timber for furniture and construction, fetching high prices in international markets (Romeiras *et al.*, 2014).

The sustainable management of the legume species is very important as it is crucial to conserve these unique genetic resources. When roots and whole-plants are harvested is clearly more destructive to medicinal plants than collecting their leaves, flowers or fruits (Hamilton, 2004; Kurian & Sankar, 2007). Therefore, vulnerability of species depends on the parts of plants used and how they are collected. For Angola good harvesting practices

must be formulated, particularly when collecting roots, which correspond to 33% of the most frequently parts of legume plants used in traditional medicine (see Fig. 2).

For each medicinal species considered in our study, information on other uses was also compiled (i.e., forage; timber; and for human food and livestock feed), which in turn provided further inputs to identify potential threats to the Angola's medicinal species. The most serious threats identified in our study were logging and wood harvesting and gathering terrestrial plants, which were generally related to over-harvesting, partly due to the collection of plants for other purposes than medicinal. Moreover, habitat degradation and human disturbance, were reported as main threats to species occurring in the surrounding areas of Luanda (the country's capital and largest city), and in this field the potential threats are highlighted with regard to several endemic species, namely *Acacia welwitschii* Oliv. and *Philenoptera pallescens*, which occur in coastal areas from Luanda to southern parts of Angola.

Moreover, in the scope of this paper, Angola's medicinal flora has been documented in accordance with their native distribution by the 18 provinces, and notwithstanding notable regional variations, more than half of the medicinal Leguminosae plants are found in southern areas of the country, namely in the regions of Huíla and Benguela, but also in Malanje in north-central Angola. A significant number of species were reported in these 3 provinces to treat a wide range of health conditions, thereby illustrating the need for conserving these species and threatened habitats. Although Angola has established a network of nature reserves and protected areas, encompassing more than 12% of the total land area (MINUA, 2014), there are some limitations in their management structures, namely insufficient financial and staffing commitments. The need for much greater effort and investment in the conservation of threatened species beyond protected areas where most plant diversity occurs, are currently stressed and considerable efforts have been made to identify Important Plant Areas (IPAs) throughout the world (Heywood, 2018). The IPA programme is a mean of identifying and protecting the most important sites for wild plant and habitats, and also offer protection to a wide range of species including medicinal plants, and many common but declining species (Anderson, 2002). IPAs have been delimited for several countries (e.g., De Dios et al., 2017 and specifically to conserve medicinal plants (Hamilton & Radford, 2007). The identification of IPAs in Angola could be based on the presence of threatened plant species under criterion A or based in high concentration of socio-economically important wild-harvested species (including medicinal plants, food plants, timber species, etc.) under sub-criterion B(iii) (Darbyshire et al., 2017). Therefore, our study could provide data towards long term conservation of key sites for plant diversity—IPAs, namely to preserve medicinal species on Huíla, Malanje and Benguela, where the protected area system is not yet representative and comprehensive for safeguarding its botanical diversity. It must be emphasized that in Huíla the existing protected area of Bicular National Park was historically created to protect big mammals (e.g., black buffalo, antelopes, and elephants), and Cangandala National Park, in Malanje, to protect only one species—the giant sable antelope “Palanca Negra Gigante” (*Hippotragus niger variiani*). Therefore, more studies are needed to understand whether medicinal plants

are being overexploited within these protected areas in order to suggest conservation strategies for their future preservation.

## CONCLUSIONS

This study highlights the importance to proceed with new ethnobotanical studies in developing countries. In particular, the rich plant diversity of Angola suggests a tremendous potential for the discovery of new medicines with considerable therapeutic value. Thus it is essential that further research on the traditional uses of plants by local populations must be carried out, which will require: (i) systematic field surveys, including interviews with local communities; (ii) a review of medicinal data and assembling a specialized literature; and (iii) international cooperation to enable the recovery of scientific knowledge associated with botanical collections, mostly kept in European herbaria. These initiatives will facilitate the undertaking of ethnobotanical studies, particularly where recent field surveys are still lacking, as it happens in most of the Angolan provinces.

Angola is among the sub-Saharan African countries dealing with a crisis of Human Resources for Health (HRH) (*Craveiro & Dussault, 2016*). Only the populations living in large towns, such as Luanda and other provincial capitals, have access to health facilities and the medicinal plants are still widely used across the country, as they are effective, cheap, used for cultural reasons, and readily available (*Macaia & Lapão, 2017*). Thus, priority should be given to initiatives for preventing the loss of local knowledge in this country, and for identifying relevant gaps with regard to the conservation and sustainable use of the medicinal plant diversity.

## ACKNOWLEDGEMENTS

We thank the thoughtful comments of the editor and the two reviewers, which greatly improved our paper. We are grateful to many collaborators in Angola for their support during field surveys, namely Manuela Pedro and Tomásia Adão from Universidade Agostinho Neto, Luanda, Angola. We are also grateful to Philip Havik (IHMT/UNL), Dora Batista (FCUL) and Liz Taylor for very helpful discussions and assistance with English editing.

## ADDITIONAL INFORMATION AND DECLARATIONS

### Funding

The work was funded by Foundation for Science and Technology, from Portugal (FCT) through the: (i) grant to Silvia Catarino (SFRH/BD/120054/2016), and (ii) Units funding: UID/AGR/04129/2019 to Linking Landscape, Environment, Agriculture and Food (LEAF), UID/BIA/00329/2019 to Centre for Ecology, Evolution and Environmental Changes (cE3c), and UID/AGR/00239/2019 to Forest Research Centre (CEF). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

## Grant Disclosures

The following grant information was disclosed by the authors:

Foundation for Science and Technology: SFRH/BD/120054/2016.

Centre for Ecology, Evolution and Environmental Changes (cE3c): UID/BIA/00329/2019.

## Competing Interests

The authors declare there are no competing interests.

## Author Contributions

- Silvia Catarino conceived and designed the experiments, performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft.
- Maria Cristina Duarte conceived and designed the experiments, performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft.
- Esperança Costa performed the experiments, contributed reagents/materials/analysis tools, prepared figures and/or tables, approved the final draft.
- Paula Garcia Carrero performed the experiments, approved the final draft.
- Maria M. Romeiras conceived and designed the experiments, performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft.

## Data Availability

The following information was supplied regarding data availability:

All the data are available in [Table 1](#).

## Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.6736#supplemental-information>.
