Abstract

This paper reviews and determines the fungi growing on seeds and fruits of wild plants in various habitats. Such fungi colonise a wide range of substrates with most reported from cones, cupules, and leguminous pods that are high in cellulose and lignin content. There are 1348 fungal species (belonging to 230 families and 609 genera) reported from wild seeds and fruits in 84 countries, listed in this paper. Of these, 300 fungi were described from wild seeds and fruit substrates. Members of the Fabaceae support the highest number of taxa, namely 19% of the novel wild fruit fungi. Twenty-eight genera, including 5 fossil fungal genera have been described from wild seeds and fruits: *Agarwalomyces*, *Amorocoelophoma*, *Anisogenispora*, *Archephoma*, *Centrolepidosporium*, *Cylindroaseptospora*, *Cylindromyces*, *Davidhawksworthia*, *Delonicicola*, *Discotubeufia*, *Glaxoa*, *Kionocephala*, *Leucaenicola*, *Naranus*, *Neolindgomycetes*, *Pleohelicoon*, *Quercicola*, *Remotididymella*, *Repetoblastiella*, *Restilago*, *Soloacrosporiella*, *Strobiloscypha* and *Tainosphaeria*. *Archephoma*, *Meniscoideisporites*, *Palaeodiplodites*, *Palaeopericonia* and

Xylohyphites are the new fossil fungal genera. Fungal asexual morphs predominate on wild seeds and fruits rather than the sexual morphs. The dominant fungal genera on wild seeds and fruits include *Alternaria*, *Aspergillus*, *Candida*, *Chaetomium*, *Cladosporium*, *Colletotrichum*, *Curvularia*, *Diaporthe*, *Drechslera*, *Fusarium*, *Mucor*, *Penicillium*, *Pestalotiopsis*, *Restiosporium*, *Rhizopus*, *Talaromyces*, *Trichoderma* and *Xylaria*. Certain assemblages of fungi have specific and distinct relationships with their hosts, especially *Xylaria* species (e.g., *Xylaria magnoliae* on *Magnolia* fruits; *X. xanthinovelutina* (= *X. ianthino-velutina*) on Fabaceae pods; *X. carpophila* on *Fagus* cupules; *X. persicaria* on liquidambar fruits). Whether these species occur as endophytes and become saprobes following fruit fall requires further investigation. In this study, we also made several sexual morph collections of sordariomycetous taxa from different seed and fruit substrates mainly from Thailand, with a few from the UK. These include 15 new species, 13 new host records and 1 new geographical record. The new species are described and illustrated.

Keywords – 15 new taxa – forest floor – fructicolous – pathogens – saprobes – seminicolous

Ascomycota

Sordariomycetes O.E. Erikss. & Winka

Amphisphaerales D. Hawksw. & O.E. Erikss.

Beltraniaceae Nann.

Beltraniella fertilis Heredia, R.M. Arias, M. Reyes & R.F. Castañeda, new host record

Chaetosphaerales Huhndorf et al.

Chaetosphaeriaceae Locq.

Dictyochaeta coryli R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Dictyochaeta lithocarpi R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Menisporopsis theobromae S. Hughes, new host record

Diaporthales Nannf.

Cytosporaceae Fr.

Cytospora diopuiensis Q.J. Shang, K.D. Hyde & J.K. Liu, new host record

Diaporthaceae Höhn. ex Wehm.

Diaporthe delonicis R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Hypocreales Lindau

Bionectriaceae Samuels & Rossman

Clonostachys rogersoniana Schroers, new host record

Clonostachys rosea (Link) Schroers, Samuels, Seifert & W. Gams, new host record

Clonostachys swieteniae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Myrotheciomycetaceae Crous

Trichothecium roseum (Pers.) Link, Mag. Gesell. naturf. Freunde, new host record

Nectriaceae Tul. & C. Tul.

Fusarium cassiae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fusarium magnoliae-champaca R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fusarium salinense Sand.-Den., Guarnaccia & Polizzi, new host and new geographical record

Fusarium sp.

Fusicolla siamensis R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Gliocladiopsis aquaticus Y.Z. Lu, R.H. Perera & K.D. Hyde, new host record

Gliocladiopsis tenuis (Bugnic.) Crous & M.J. Wingf., new host record
Gliocladiopsis swieteniae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.
Macronectria jungneri (Henn.) Salgado & P. Chaverri, new host record
Murinectria pseudotrichia (Schwein) M. Niranjan and V.V. Sarma, new host record
Neocosmospora magnoliae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.
Sarcopodium durantae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.
Sarcopodium flocculentum (Henn. & E. Nyman) Pennycook & P.M. Kirk, new host record
Volutella delonicis R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Xylariales Nannf.

Diatrypaceae Nitschke

Allodiatriype thailandica (R.H. Perera, Jian K. Liu & K.D. Hyde) Konta & K.D. Hyde, new host record

Hypoxylaceae DC.

Hypoxylon delonicis R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Xylariaceae Tul. & C. Tul.

Xylaria arbuscula Sacc.

Xylaria fabacearum R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Xylaria fabaceicola R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Leotiomycetes O.E. Erikss. & Winka

Helotiales Nannf. ex Korf & Lizoń

Helotiales sp.

Lachnaceae Raity.

Lachnum sp.

Introduction

Seeds are produced by spermatophytes of both angiosperms and gymnosperms. Angiosperm seeds originate from a hard or fleshy structure known as a fruit which also encloses the seeds. However, in gymnosperms, there is no specific biological structure developed to enclose the seeds (<http://pediaa.com/difference-between-fruit-and-seed/>). Plants have evolved various mechanisms for the dispersal of mature seeds, which have the potential to produce new individuals (Bewle & Black 1994).

There is a great diversity in the form and structure of seed and fruits, such as, grains, cones, acorns, berries, drupes, capsules, seed pods, nuts, nut cupules, caryopses, and nutlets (fruits of restiads or sedges). Fruit cases, such as nut cupules are considered as fruits in this paper. Cupules of beech (*Fagus* spp.) are a woody substrate, containing lignocellulose and similar to lignocellulose composition of coarse woody debris (Fukasawa et al. 2012). Leguminous pods also are rich in cellulose, hemicelluloses and lignin (Paula et al. 2011). Cones, which protect the seeds during development, are the reproductive organs of coniferous plants (Kilic et al. 2010). They consist of an axis with surrounding scales, which are rich in cellulose, hemicellulose (mannose, galactose, xylose) and lignin (Fogel & Cromack 1977, Kilic et al. 2010). Nuts, kernels of chestnut, hazelnut, walnut and oak are diverse in their protein, carbohydrate and fat content, while some are rich in phosphorus (eg. hazelnut, hickory nut, and black walnut) (Wainio & Forbes 1941). Nut shells are rich in lignin, cellulose and hemicelluloses (Vellingiri et al. 2014, Zhai et al. 2015). Fruits (achenes, pomes, berries and drupes) comprise mostly carbohydrates, some are high in lignin and cellulose, and others are rich in protein and fat, mainly because of their seeds (Wainio & Forbes 1941). Acorns such as red oak, rock chestnut oak, and scrub oak and, some edible wild fruits (eg.

chokeberries, sumac berries, blackhaw and mountain ash berries) are high in tannin content (Wainio & Forbes 1941). Moreover, seeds such as those of legumes and cereals are major food sources and contain storage reserves of protein, starch and oil (Bewle & Black 1994, Shimada 2001, Ragaee et al. 2006).

History of studies of wild seed/fruit fungi

Around the world the forest floor is seasonally covered by a carpet of native seeds and fruits, which are colonised by a wide range of endophytic, saprobic and pathogenic fungi (Rogerson & Samuels 1992, Morais et al. 1995, Rogers et al. 2002, Somrithipol et al. 2002a, b, Udayanga et al. 2013, Perera et al. 2018a).

Figure 1 – Fabaceae fruits on the forest floor in Thailand (a–g) and Taiwan (h). a *Cassia fistula*. b Fabaceae sp. c *Delonix regia*. d *Samanea saman*. e *Adenocalymma pterocarpus*. f *Cassia grandis*. g *Entada* sp. h *Mucuna macrocarpa*.

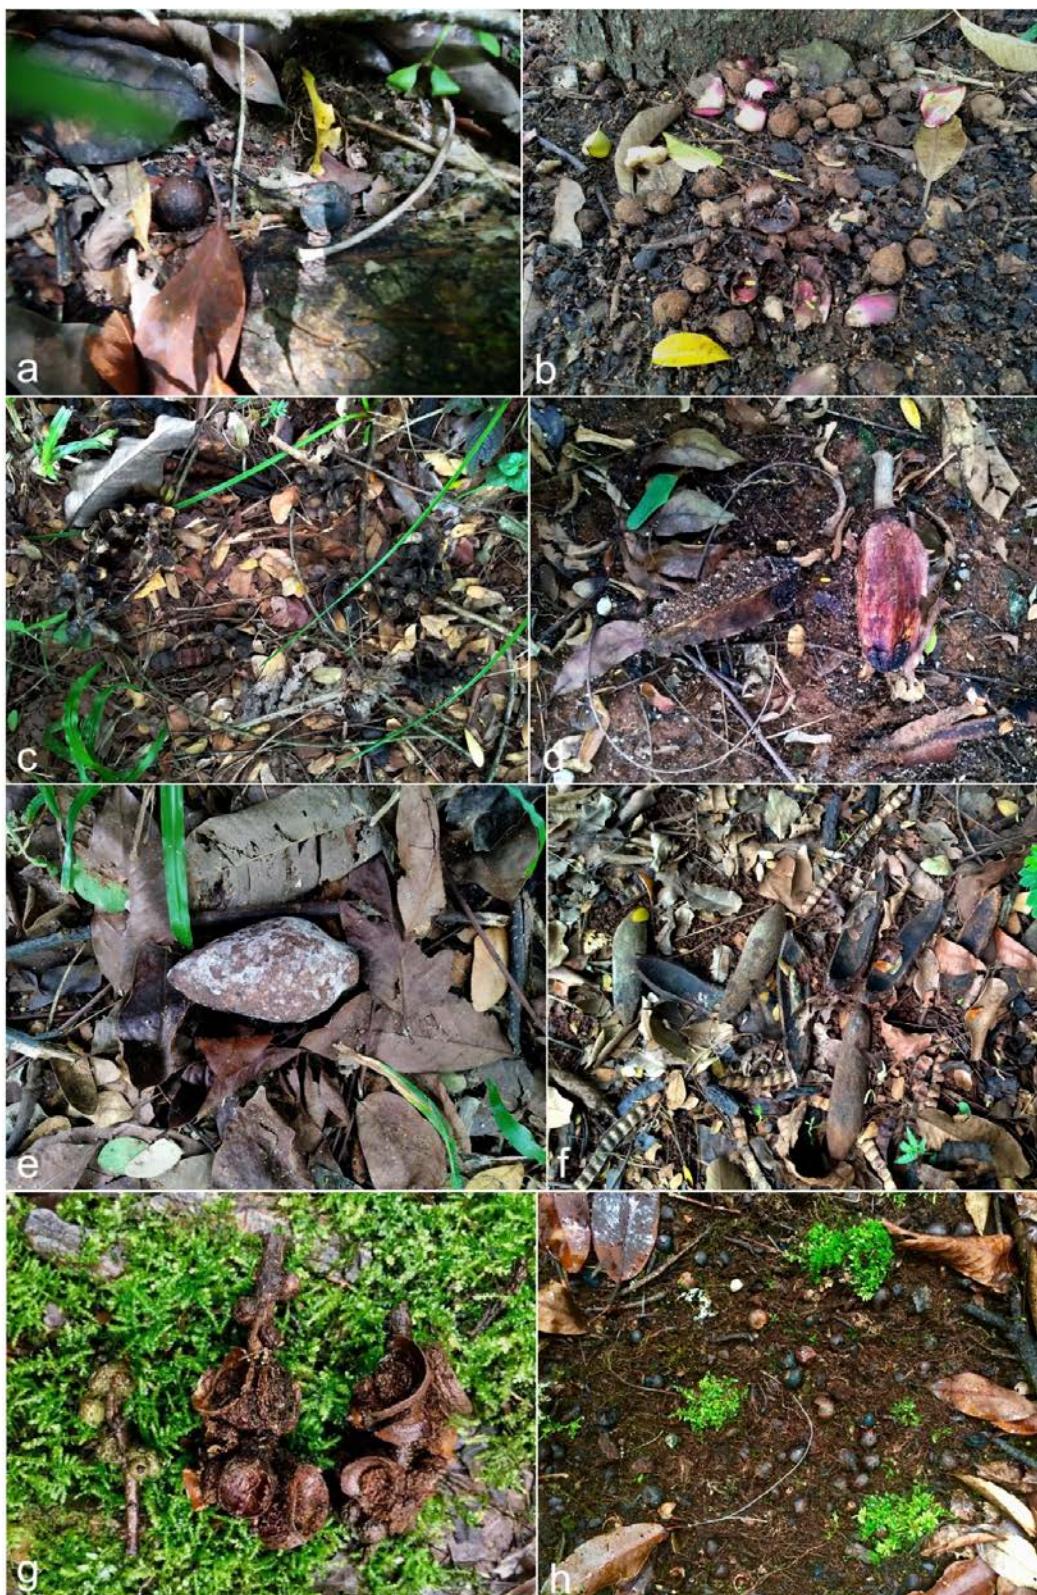

Figure 2 – Seeds and fruits on the forest floor in Thailand (a–f) and China (g, h). a Seed of *Lithocarpus* sp. b Immature fruits of *Couroupita guianensis* (cannonball tree). c Fruits of *Magnolia champaca*. d–f *Swietenia mahagoni* (d placenta with seeds, e fruit, f fruit outer carpels). g Unidentified fruits. h Unidentified seeds.

Few studies have been undertaken to document fungal groups from wild seeds and fruits, when compared to other plant substrates, e.g. wood, culms, leaves and commercial seeds and fruits (Kasai et al. 1995, Nirenberg & Aoki 1997, Vujanovic et al. 2000, Yli-Mattila et al. 2009, Weir et

al. 2012, Udayanga et al. 2013, Rashmi et al. 2019). Hyde et al. (2015) acknowledged that the taxonomy, ecology, and distribution of fruit and seed inhabiting fungi are poorly studied in both temperate and tropical areas. Previous research has mainly targeted postharvest fungi, those responsible for economic losses of cereals and edible fruits (Tang et al. 2003a, Neergaard 2017). However, seed and fruit inhabiting fungi of conifers and eucalyptus species has been investigated broadly as they have been widely introduced as exotic timber trees in plantations (Kasai et al. 1995, Vujanovic et al. 2000, Lupo et al. 2001, Palm 2001, Wingfield et al. 2001, Desprez-Loustau 2009). Most of the early research focused on endophytic isolations and identification of seed-borne pathogens (Anderson 1986, Mittal et al. 1990). Hence, wild seed and fruit fungi are not a well-studied group.

An extensive study of dothideomycetous fungi associated with wild seeds and fruits in selected areas of Thailand, UK and China was carried out by Jayasiri et al. (2019), who introduced 58 new taxa. Fukasawa et al. (2012) and Carré (1964) surveyed fungi on beech cupule litter in Japan and the UK. Tang et al. (2003a) examined fruit samples from 18 native plant species yielding 101 fungal taxa in Hong Kong. Another survey in Thailand by Somrithipol et al. (2002b) investigated fungi on tropical forest fruit of *Delonix regia* and identified 70 fungi. Ten fungal species belonging to Ascomycota were isolated from cone scales and seeds of 28 *Pinus* hosts in East Asia, Europe and North America, and Canada (Vujanovic et al. 2000). In their study, *Sphaeropsis sapinea*, *Herpotrichia juniperi*, ‘*Phomopsis*’ *conorum*, *Truncatella hartigii*, *Tubercularia* sp. and *Valsa* spp. were recognised as dominant pathogens of *Pinus* (Vujanovic et al. 2000). A fungal succession study on *Pinus densiflora* cones on a forest floor investigated the early decomposition process in Japan, and identified 31 taxa (Kasai et al. 1995). Pandey & Nimmi (1990) isolated 48 fungal species from *Pinus roxburghii* seeds collected from a forest in India and observed that the predominant species in ungerminated seeds are *Alternaria* and *Fusarium* spp. Anita et al. (1999) and Anita & Sridhar (1999) reported a number of endophytic fungi from seeds and pods of mangrove wild legumes (*Canavalia cathartica* and *Sesbania bispinosa*) in Southwest coast of India. Lupo et al. (2001) studied endophytic fungi in capsules and seeds of *Eucalyptus globulus* in Uruguay and found 18 taxa from unopened capsules (cut off from the tree) and ten from seeds. Seed-borne fungi associated with *Podocarpus falcatus* and *Prunus africana* in Afromontane rain forests of Ethiopia were investigated by Gure (2004), and identified four Botryosphaeriaceae taxa with one new species, *Diplodia rosulata*. Yeasts (*Candida* spp., *Debaryomyces* spp., *Kloeckera* spp., *Pichia* spp.) colonizing the fallen ripe fruits of Amapa (*Parahancornia amapa*) and *Clusia grandiflora* in tropical forests were examined by Morais et al. (1995). They found 44 yeasts including one new species. Rogers (1979a) described a new saprobic *Xylaria* species, *X. magnolia* on decaying fruits of *Magnolia* sp. and discussed several other fruit inhabiting *Xylaria* species. Ju et al. (2018) studied 25 *Xylaria* species inhabiting fallen seeds and fruits and introduced three new species namely: *Xylaria reevesiae*, *X. rossmanae* and *X. vivantii*. Jankowiak (2008) investigated fungi occurring on acorns of *Quercus robur*, which were infested by insects in Poland. He identified 45 fungi with *Alternaria alternata* and yeasts as the most frequently isolated fungi (Jankowiak 2008). Although there is great diversity in fruit and seed-bearing plants, few studies have been carried out especially in temperate regions (Table 2). Accordingly, the present work on fungal diversity found on seeds and fruits was undertaken.

Anderson (1986) and Mittal et al. (1990) provided checklists of micro-organisms associated with tree seeds and primarily focused on forestry trees. Seed-borne diseases of 12 host tree species namely: *Acer* spp., *Alnus* spp., *Araucaria excelsa*, *Betula* spp., *Chamaecyparis* sp., *Fraxinus* spp., *Larix* spp., *Picea sitchensis*, *Pinus* spp., *Quercus* spp., *Thuja* spp., *Ulmus americana* and *U. pumila* were listed by Noble et al. (1958). Watanabe (2010) listed a number of culturable seed fungi with illustrations and provided a key to species in wild and crop plants in Japan. Previous studies and check lists revealed that the fungi colonising seeds and fruits are dominated by asexual morphic fungi (Carré 1964, Anderson 1986, Mittal et al. 1990, Kasai et al. 1995, Amusa et al. 2002, Somrithipol et al. 2002b, Tang et al. 2003a, Fukasawa et al. 2012). However, a comprehensive literature review or a checklist on fungi that occur on wild seeds and fruits is lacking.

Our approach is to provide a checklist of fungi described from seeds and fruits of non-commercial trees, shrubs and weedy plants or grasses. However, there are no details of substrates such as wood, leaves, seeds, fruits provided in most of the previous fungal lists. In Petrak's lists, fungi were listed under host names but did not mention the substrates. We also looked in the USDA host database for search by substrates, but it lists only host details. It supports for fungal host-search but not for other substrate details. Since 1981, Index of Fungi series and the website provided substrate details, such as wood, leaves, seeds and fruits. Our list of new fungi therefore was mainly based on Index of Fungi. Here we also list fungi reported from wild seeds and fruits based on available literature. The aim of the present study is to give an idea of the different groups of fungi occurring on wild seeds and fruits, document, discuss their role and importance, and illustrate some Sordariomycetes taxa. We also provide a brief account on fossil fungi described from seed fruit substrates.

Importance of studying wild seed/fruit fungi

Diverse fungal groups can be found generally on every part of a single plant host (Hyde 1995). Domesticated, genetically modified commercial seeds (cereals) and fruits are different from wild fruits/seeds in size, nutrient content and chemical defenses (Tang et al. 2003a, Hernández-Terán et al. 2017). Disease development of those post-harvest fruits and cereals occur during transportation and storage, which is different to that in nature (Tang et al. 2003a). The few studies that have been conducted on fungi on non-commercial seeds and fruits indicate the occurrence of fungi belonging to diverse taxonomic groups such as, Ascomycota, Basidiomycota, Chytridiomycota, Mucoromycota and Blastocladiomycota (Desjardin 2000, Vujanovic et al. 2000, Somrithipol et al. 2002a, b, Nelson & Abad 2010, Fukasawa et al. 2012, Jayasiri et al. 2019). The significance of studying wild seed/fruit fungi is further discussed below.

Where do these seed/fruit fungi come from?

There are three different ways fungi can infect or colonise wild seeds or fruits: 1) seeds become infected with endophytic fungi while in the canopy during fruit development, 2) within the soil after dispersal, and 3) by animal vectors such as fruit flies (Gallery 2007, Morais et al. 1995, Somrithipol et al. 2002b). Plant seeds carry spores of different fungi on the seed surface or inside tissues of the seed (Anderson 1986). Seed surfaces are mostly contaminated with fungal spores as they easily stick to the outer seed coat, while fungi mostly occur as mycelia inside the seed (Anderson 1986). Seeds/fruits inhabiting fungi may include endophytic, saprophytic, and pathogenic fungal species (Gallery et al. 2007). *Diaporthe*, *Fusarium*, *Penicillium*, *Trichoderma* and *Xylaria*-like fungi initially can occur as endophytes, but become pathogenic or saprobic under favorable conditions (Somrithipol et al. 2002b, Udayanga et al. 2013, Fukasawa et al. 2012). However, pathogenicity of most fungi associated with wild seeds/fruits has been much debated (Mittal et al. 1990). Somrithipol et al. (2002b) studied pods of *Delonix regia* and observed *Aspergillus*, *Chaetomium*, *Penicillium*, and *Rhizopus* species mainly occurring on the dry fruits when still attached to the tree. A different fungal community developed once seeds and fruits had been shed from the host plant (Somrithipol et al. 2002b). Lupo et al. (2001) observed *Eucalyptus globulus* capsules attached to the tree and shared the same endophytic fungal species with flowers, but in higher numbers. Clavicipitaceous fungi are parasitic on Poaceae hosts, and can also occur as endophytes (Rodriguez et al. 2009). During flowering of grasses, endophytic species such as *Acremonium* species grow into ovules and become incorporated into the seeds (Neill 1941, Clay 1990). Endophytes can be transmitted horizontally (among individuals of the same generation) or vertically (from maternal plants to offspring through seed infections) to other plants/ generations (Chung & Schardl 1997, Saikkonen et al. 2002). Animal vectors such as common flies and fruit flies are partially responsible for fungal contamination of fruits (Morais et al. 1995), for example, *Drosophila* spp. are known to be the major vectors of yeasts (Morais et al. 1995). Morais et al. (1995) and Miller & Phaff (1962) observed the coexistence of different *Drosophila* species in different stages of deterioration of *Parahancornia amapa* fruits and *Ficus* figs. Some studies reveal

seeds infected by endophytic fungi contain higher concentrations of alkaloids than the normal seeds, thus they may protect seeds from vertebrate and invertebrate predators (Cheplick & Clay 1988, Clay 1990).

Fossil fungi records of seeds and fruits

The origin of fungi is aged to the Paleoproterozoic–Mesoproterozoic eras (2500–1000 million years ago; Mya). The phylum Chytridiomycota is the earliest known group of fungi which diverged during the Mesoproterozoic (1600–1000 Mya) before the divergence of terrestrial plants (Lücking et al. 2009, Padovan et al. 2005, Torruella et al. 2012). The divergence of the phyla Ascomycota, Basidiomycota and Glomeromycota has been dated to the Neoproterozoic to Early Paleozoic (1000–485 Mya) with interaction with different groups of plants (Schüßler et al. 2001, Berney & Pawłowski 2006, Lücking et al. 2009, Taylor et al. 2009, Beimforde et al. 2014). Selosse et al. (2015) suggested that the highly diversified plant-fungal interactions are the backbone of land ecosystems and biogeochemical cycles from the Palaeozoic era (<541 Mya). Several remarkable studies revealed well-preserved fungal associations with plants mainly on leaves and different woody substrates (e.g. Cookson 1947, Dilcher 1965, Taylor et al. 1999, Mindell et al. 2007, Taylor et al. 2014, Vishnu et al. 2017). However, few fungal remains associated with fossil ovules, seeds and fruits have been described to date (Taylor 2009, Krings et al. 2012).

Renault & Bertrand (1895) described *Grilletia sphaerospermii* as a chytrid fossil inhabiting the nucleus of a Carboniferous gymnosperm *Sphaerospermum* and dated to the upper Pennsylvanian (307–298 Mya) in France. *Grilletia sphaerospermii*-like organisms have been described by Oliver (1903) from seeds of *Polylophospermum* and *Conostoma* from the lower Carboniferous (358.9–323.2 Mya) in France and Scotland. Pirozynski & Dalpé (1989) suggest that the *Grilletia* is close to extant *Glomus*, but this hypothesis needs further study. Batra et al. (1964) reported *Protoascon missouriensis* from a cluster of fossil fungi in a *Nucellangium glabrum* seed. It was preserved in Carboniferous permineralization (coal ball) collected from Tebo Coal of the Cabaniss Formation, Missouri, North America (middle Pennsylvanian, ~315–307 Mya). Taylor et al. (2005) re-examined the *Polylophospermum missouriensis* fossil and suggested it was comparable to modern members of the Mucorales (Mucromycota).

There are several Ascomycota fossil fungi described from seeds, fruits and ovules. Two fossil fungal species were described from India (upper Cretaceous; Maastrichtian, 72–66 Mya) associated with permineralized fruits of *Viracarpon* (monocotyledons). *Diplodites sweetii*, which is morphologically similar to extant *Sphaeropsis* in Botryosphaeriaceae, was described by Kalgutkar et al. (1993). *Xylohyphites verrucosa*, which is characterized by having verrucose conidia in chains, hence shows morphological affinities to *Cladosporium* (Kalgutkar & Sigler 1995). Watanabe et al. (1999) described three fossil fungal genera: *Archephoma*, *Meniscoideisporites* and *Palaeodiplodites* in Japan (middle Turonian, 93.9–89.8 Mya), all associated with a bisexual cone of *Cycadeoidella japonica*. They suggested that the *Archephoma* and *Palaeodiplodites* are comparable to the modern phoma-like taxa and *Diplodia*, while *Meniscoideisporites* is not assignable to any extant taxon based on reliable taxonomic characters (Fig. 3). Two fossil fungal genera *Palaeopericonia* and *Xylohyphites* were described from permineralized fruit of *Viracarpon* sp. and fossilised cones of *Araucaria mirabilis* in Argentina and Canada (Kalgutkar & Sigler 1995, Ibáñez & Zamuner 1996).

In addition, LePage et al. (1994) described several asexual morphic fossil fungi associated with seeds and fruits from Princeton chert, British Columbia, Canada (middle Eocene, 50 Mya) and suggested that the fossils represent extant species from Dothideales, *Alternaria* and some coelomycetous asexual morphs. Stakhov et al. (2008) described the most recent fossil fungus associated with seeds of undetermined higher plants from Russia (Pleistocene 30,000 years ago).

These few fungal fossils described from seeds, fruits, pods, ovules or any other reproductive plant materials (Table 2) might be due to less attention given to microorganisms associated with reproductive structures of plants.

Materials & methods

Sample collection, specimen examination and isolation

Specimens were collected from seeds and fruits in Northern Thailand and United Kingdom (UK) during 2014 to 2018. Fungal fruiting structures were observed, photomicrographed and measurements were made in the laboratory as designated in Perera et al. (2016b). Fungal colonies were obtained from single spore isolation technique described in Chommunti et al. (2014). Pure cultures were grown on potato dextrose agar (PDA) or malt extract agar (MEA) media and incubated at 25°C or 28°C.

Herbarium material was preserved in the Mae Fah Luang University (MFLU) herbarium, Chiang Rai, Thailand. Living cultures were stored in the Culture Collection at Mae Fah Luang University (MFLUCC). Facesoffungi and Index Fungorum numbers were registered as outlined in Jayasiri et al. (2015) and Index Fungorum (2020). Species are delineated based on recommendations outlined by Jeewon & Hyde (2016).

DNA isolation, amplification and analyses

Genomic DNA was extracted from fungal colonies growing on PDA or MEA or directly from the fruiting bodies as designated in Perera et al. (2016b). DNA amplifications were performed by polymerase chain reaction (PCR). Part of the large subunit nuclear rRNA gene (LSU) was amplified with primer pairs LROR (Rehner & Samuels 1994) and LR5 (Vilgalys & Hester 1990). The small subunit nuclear rRNA gene (SSU) was amplified with primer pairs NS1 and NS4 (White et al. 1990). Primer pairs ITS4 and ITS5 were used to amplify the 5.8S rDNA region and flanking internal transcribed spacers (ITS) (White et al. 1990). The translation elongation factor 1-alpha gene (TEF1) was amplified by using primers EF1-983F and EF1-2218R (Rehner 2001, Currie et al. 2003) or the primers EF1-728F and EF1-986R (Carbone & Kohn 1999) or EF2 (O'Donnell et al. 1998). The RNA polymerase II second largest subunit (RPB2) gene was amplified with primers fRPB2 and fRPB2-7cR (Liu et al. 1999). The beta-tubulin (TUB2) gene was amplified by using primers T1 (O'Donnell & Cigelnik 1997), Bt2b (Glass & Donaldson 1995), CYLTUB1R (Crous et al. 2004) or T22 (Cigelnik 1997). Histone H3 (HIS3) region was amplified with the primers CYLH3F and CYLH3R (Lombard et al. 2012). PCR was performed following the protocols in Perera et al. (2016b). Assemblage of consensus sequences were done in ContigExpress (Vector NTI Suite 6.0). Newly generated sequences were deposited in NCBI GenBank and accession numbers are given at the end of the protologue.

Phylogenetic analyses

The sequences obtained in this study were supplemented with the additional sequences retrieved from GenBank. The sequences were aligned using MAFFT v. 7 online server (<http://mafft.cbrc.jp/alignment/server/>) and, rechecked visually and improved manually using BioEdit v. 7.0.5.2 (Hall 1999). Ambiguous regions were excluded from the analyses and gaps were treated as missing data. Phylogenetic analyses were carried out with maximum likelihood analysis

(ML), which was performed at the CIPRES web portal (Miller et al. 2010) using RAxML v. 8.2.12 as part of the “RAxML-HPC2 on TG” tool (Stamatakis 2006). Bayesian inference analysis (BI) was performed in MrBayes v. 3.2.0 (Ronquist & Huelsenbeck 2003). Phylogenetic trees were viewed in FigTree v1.4 and modified using Microsoft PowerPoint 2016.

Before combining, single gene phylogenetic analyses were conducted for each locus to compare the tree topology and clade stability. The names of the isolates obtained in this study are printed in **blue** font and names of ex-type and ex-epitype taxa are printed in **black bold** font in the trees. Maximum likelihood bootstrap support values $\geq 75\%$ (BT) and Bayesian posterior probabilities ≥ 0.99 (PP) are given at the nodes respectively.

Results

Taxonomy

The classification of Sordariomycetes has been detailed in Hyde et al. (2020) and provided in the *Outline of fungi and fungus-like taxa* by Wijayawardene et al. (2020) and is followed here.

Amphisphaerales D. Hawksw. & O.E. Erikss.

Beltraniaceae Nann.

Beltraniella Subram.

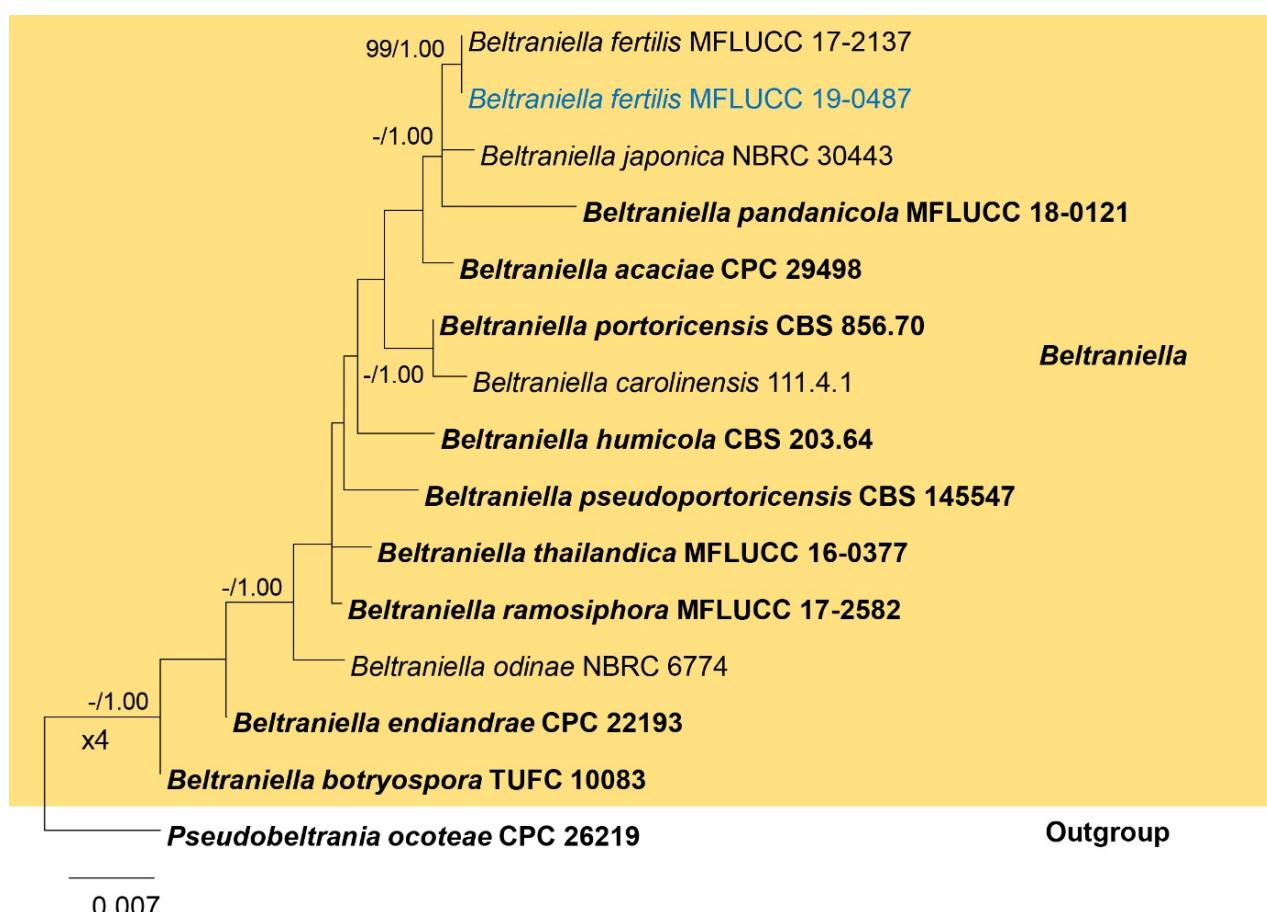

Figure 6 – Phylogram generated from RAxML analysis based on combined ITS and LSU sequence data of *Beltraniella* isolates. Sequences from fifteen taxa, which comprise 1311 characters including gaps, are included in the analyses. The tree was rooted to *Pseudobeltrania ocoteae* (CPC 26219). The scale bar indicates 0.007 nucleotide changes per site.

Saprobic on dried fruit of *Lithocarpus* sp. Sexual morph: Undetermined. Asexual morph: Hyphomycetous. Colony on the host greenish. *Setae* 115–185 × 3.5–4.5 µm (n = 10), erect, dark brown, thick-walled, indistinctly septate, with prominent warts, straight or flexuous, unbranched, tapering to an acute apex, arising from radially lobed basal foot cell. *Long setiform conidiophores* not observed. *Short conidiophores* 33–50 × 3.5–5 µm ($\bar{x} = 41.8 \times 4.1$ µm, n = 15), macronematous, mononematous, single or arranged in groups around the setae, erect, straight or slightly curved, simple or branched, septate, subhyaline to pale brown, thin-walled, smooth-walled. *Conidiogenous cells* 6–20 × 4–6 µm ($\bar{x} = 10.4 \times 3.5$ µm, n = 15), terminal and intercalary, subcylindrical, polyblastic, apex with several flat-tipped denticles, pale brown, smooth-walled. *Separating cells* 7.5–10 × 3–4.1 µm ($\bar{x} = 8.6 \times 3.5$ µm, n = 10), ovoid or obovoid, fusiform, hyaline to subhyaline, thin-walled, smooth-walled, with a single flat-tipped denticle. *Conidia* 20–22 × 4.3–5.5 µm ($\bar{x} = 20.8 \times 4.8$ µm, n = 20), solitary, turbinate to pyriform, distal end truncate, subhyaline, smooth, aseptate, with median transverse band of lighter pigment, base tapering to an acutely rounded tip.

Culture characteristics – Conidia germinating on PDA within 12 hours. Colonies on PDA reaching 7.5 cm within 14 days at 28°C, medium dense, circular, flat, even margin, with sparse aerial mycelium, white from above, reverse dark brown.

Material examined – THAILAND, Chiang Mai Province, on dried fruit of *Lithocarpus* sp. (Fagaceae), 22 December 2017, R.H. Perera, Seed 06 (MFLU 19-0982), living culture MFLUCC 19-0487.

GenBank numbers – ITS: MT215489, LSU: MT215539.

Notes – In the phylogenetic analysis our new isolate clustered with *Beltraniella fertilis* (MFLUCC 17-2137) with high statistical support (99% MLBT, 1.00 BIPP; Fig. 6). A comparison of nucleotides shows ITS and LSU loci of our isolate are identical to *B. fertilis* (MFLUCC 17-2137). Our collection is similar to *B. fertilis* by its setae, conidiophore and conidial morphology and dimensions (Heredia et al. 2002, Lin et al. 2017). Therefore, our collection is a new host record for *B. fertilis*.

Chaetosphaerales Huhndorf, A.N. Mill. & F.A. Fernández
Chaetosphaeriaceae Locq.

Dictyochaeta Speg. 1923

Dictyochaeta coryli R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Index Fungorum number: IF556867; Facesoffungi number: FoF07752

Etymology – Named after the host genus *Corylus*.

Holotype – MFLU 19-1387

Saprobic on dried *Corylus avellana* fruits. Sexual morph: Undetermined. Asexual morph: Hyphomycetous. Colonies on natural substrate, effuse, hairy, pale brown, with glistering white conidial masses. *Setae* 115–135 × 3.5–4.8 µm, straight or flexuous, septate, unbranched, pale brown to brown, paler towards the apex, apex fertile with persistent collarettes, smooth-walled. *Conidiophores* 55–70 × 3.3–4 µm ($\bar{x} = 62.3 \times 3.8$ µm, n = 15), macronematous, mononematous, solitary or in small groups often associated with setae, straight or flexuous, cylindrical, unbranched, septate, smooth, brown to pale brown, almost hyaline at apex, smooth-walled. *Conidiogenous cells* 10–22 × 2.7–3.8 µm ($\bar{x} = 15.7 \times 3.3$ µm, n = 15), monopodial, integrated, terminal, sympodially proliferating, determinate, sub-cylindrical, pale brown, with distinct, funnel-shaped collarettes, 1.2–1.6 µm high, 2.2–3 µm wide. *Conidia* 12–19.5 × 2.3–3.5 µm ($\bar{x} = 17.4 \times 3$ µm, n = 30), solitary, aseptate, fusiform, curved, sometimes guttulate, hyaline, smooth-walled, in slimy mass, single setula at each end, 4.7–8.4 µm long, 0.5–0.8 µm wide, filiform, hyaline.

Culture characteristics – Conidia germinating on PDA within 12 hours. Colonies on PDA reaching up to 30 cm diameter after 21 days at 28°C, circular or irregularly circular, medium dense,

effuse, aerial mycelium forming concentric rings with cottony texture, edge entire, white from above, reverse brown.

Material examined – UK, Hampshire, Bishop Waltham, standing water, on dried fruits of *Corylus avellana* L. (Betulaceae), 8 December 2017, E.B.G. Jones, GJ 406 (MFLU 19-1387, holotype).

GenBank numbers – ITS: MT215494, LSU: MT215545.

Figure 7 – *Beltraniella fertilis* (MFLU 19-0982). a Herbarium material. b Colony on natural substrate. c, d Setae with conidiogenous apparatus. e Conidiophores, conidiogenous cells with conidia. f–j Conidia. k Germinating conidium. Scale bars: b = 500 µm, c, d = 50 µm, e = 20 µm, f–j = 10 µm, k = 20 µm.

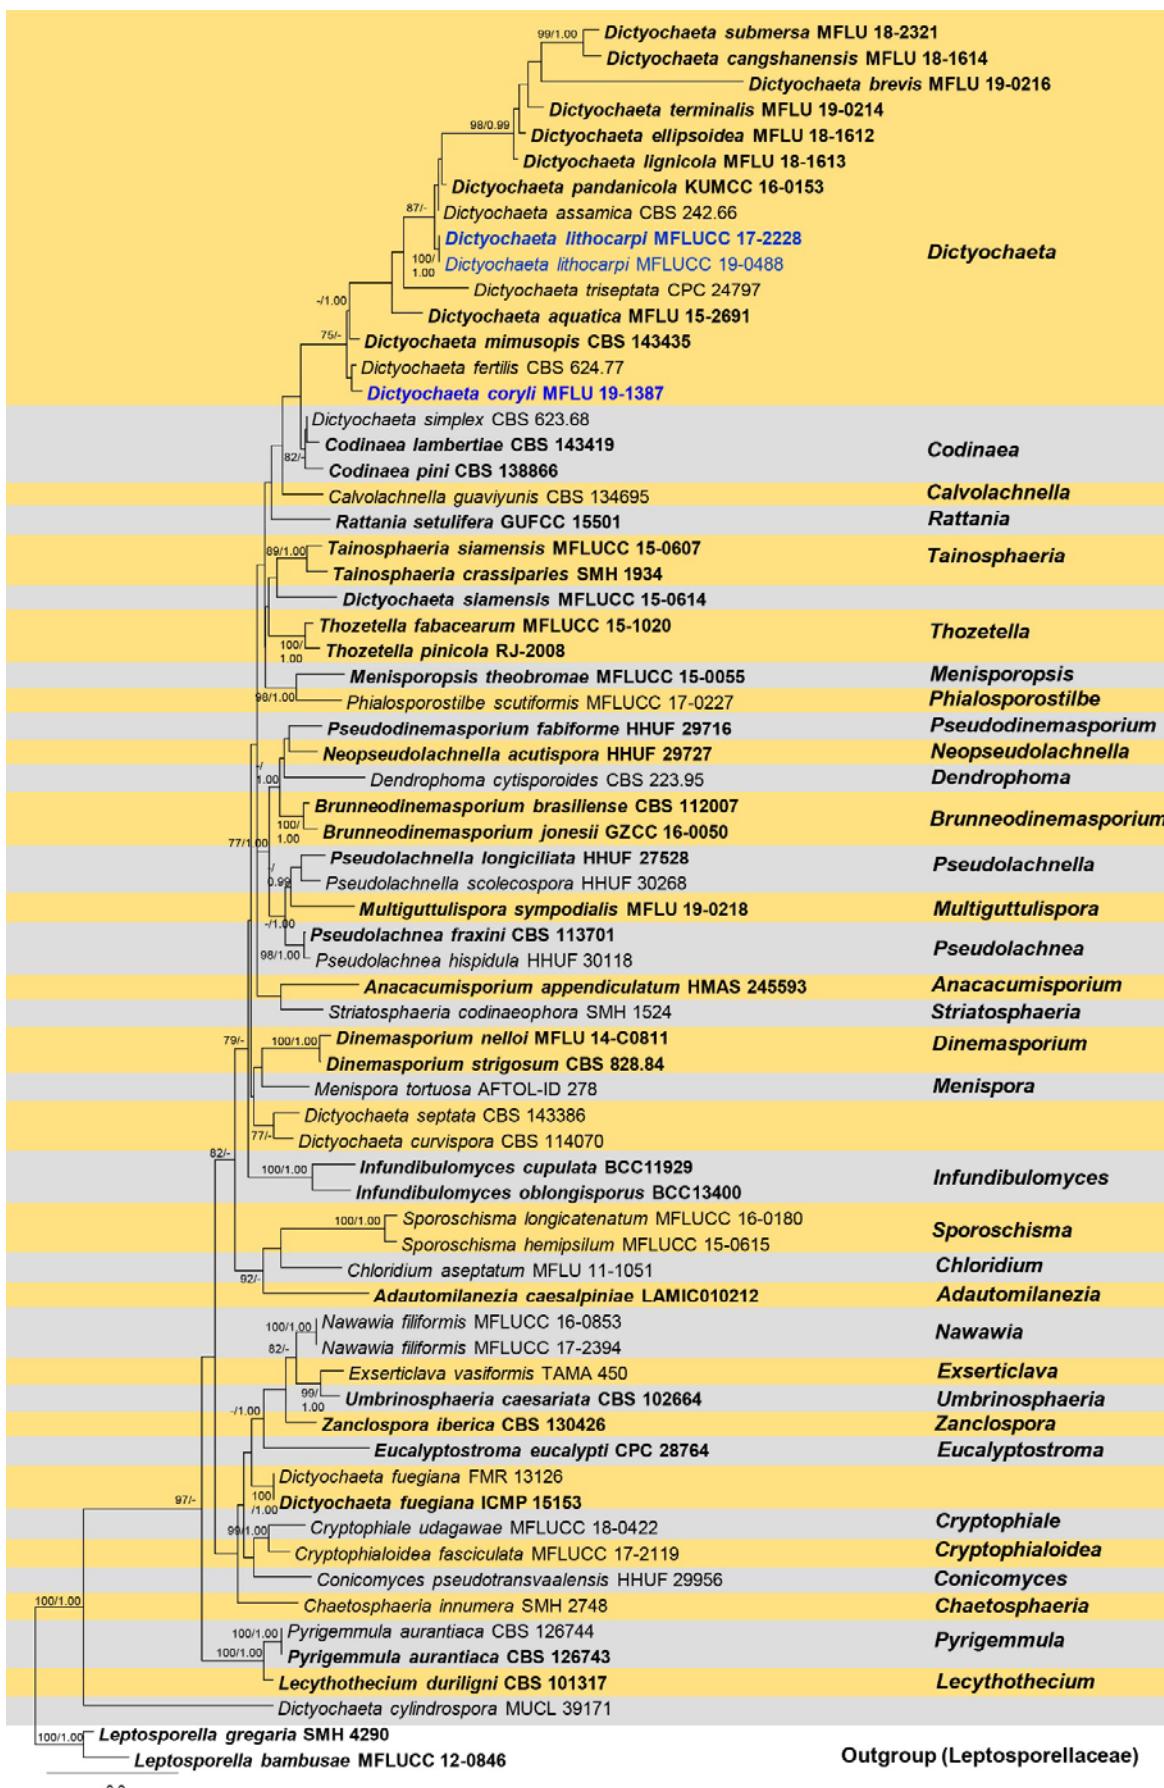

Figure 8 – Phylogram generated from RAxML analysis based on combined ITS and LSU sequence data of selected *Chaetosphaeriaceae* isolates. Sequences from sixty-eight taxa, which comprise

1438 characters including gaps, are included in the analyses. The tree was rooted to *Leptospora bambusae* (MFLUCC 12-846) and *L. gregaria* (SMH 4290). The scale bar indicates 0.2 nucleotide changes per site.

Figure 9 – *Dictyochaeta coryli* (MFLU 19-1387, holotype). a Herbarium material. b Colony on fruit. c Seta. d, e Conidiophores and conidiogenous cells. f–k Conidia l Germinating conidium. m, n Colony on MEA. Scale bars: b = 200 µm, c–e = 100 µm, f–l = 10 µm.

Notes – *Dictyochaeta coryli* groups with *D. fertilis* (S. Hughes & W.B. Kendr.) Hol.-Jech. (CBS 624.77) in our phylogenetic analysis, with low statistical support (Fig. 8). *Dictyochaeta coryli* differs from *D. fertilis* in having aseptate conidia, while those of *D. fertilis* are 6–11 septate (Whitton et al. 2000). *Dictyochaeta coryli* can be distinguished from *D. mimusopis* Crous & M.J. Wingf by having fertile setae, while *D. assamica* (Agnihothr.) Aramb., Cabello & Mengasc. does not have setae (Arambarri et al. 1987). *Dictyochaeta coryli* resembles *D. intermedia* Gusmão & S.M. Leão, but differs in having shorter and wider conidia (12–19.5 × 2.3–3.5 vs. 18–21 × 1.5–2.5) and fertile setae, while *D. intermedia* forms non-fertile setae (Cruz et al. 2009). *Dictyochaeta coryli*

also cannot be assigned to any known *Dictyochaeta* species which lack sequence data (Kuthubutheen & Nawawi 1991, Whitton et al. 2000, Cruz et al. 2009). We therefore identify *D. coryli* as a new species of *Dictyochaeta*.

***Dictyochaeta lithocarpi* R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.**

Fig. 10

Index Fungorum number: IF556868; Facesoffungi number: FoF07753

Etymology – Named after the host genus *Lithocarpus*.

Holotype – MFLU 19-1173

Saprobic on decaying *Lithocarpus* fruits. Sexual morph: Undetermined. Asexual morph: Hyphomycetous. *Colonies* on natural substrate, effuse, hairy, brown, with white conidial masses. *Setae* 170–275 × 4–5 µm ($\bar{x} = 209 \times 4.3$ µm, n = 10), solitary or in groups of 2–3, straight or flexuous, septate, unbranched, apex fertile with persistent collarettes, dark brown and robust at the base, paler towards the apex, smooth-walled. *Conidiophores* 55–110 × 3.2–4 µm ($\bar{x} = 86 \times 3.7$ µm, n = 20), macronematous, mononematous, aggregated, in small groups often associated with setae, rarely solitary, straight or flexuous, cylindrical, unbranched, septate, smooth, dark brown to pale brown, paler at apex, smooth-walled. *Conidiogenous cells* 12–22 × 3.5–5.3 µm ($\bar{x} = 16.6 \times 4.2$ µm, n = 20), monopodialic, integrated, terminal, determinate, hyaline or pale brown, with distinct, sub-cylindrical, funnel-shaped collarettes, 1.8–2.1 µm high, 2.8–3.6 µm wide. *Conidia* 14–17 × 1.5–2.8 µm ($\bar{x} = 15.2 \times 2.3$ µm, n = 30), solitary, aseptate, fusiform, curved, in slimy mass, hyaline, smooth-walled, single setula at each end, 6.8–10.5 µm long, 0.4–0.6 µm wide, filiform, hyaline.

Culture characteristics – Conidia germinated on PDA within 12 hours. Colonies on PDA reaching up to 35 cm diameter after 15 days at 28°C, circular or irregularly circular, medium dense, flat or effuse, edge entire, white from above, reverse yellow brown.

Material examined – THAILAND, Chiang Mai Province, on dried fruits of *Lithocarpus* sp. (Fagaceae), 20 July 2017, R.H. Perera, Doi 05 (MFLU 19-1173, holotype), ex-type living culture MFLUCC 17-2228; *ibid.*, 22 December 2017, Seed 08 (MFLU 18-2772), living culture MFLUCC 19-0488.

GenBank numbers – ITS: MT215492, LSU: MT215543 (MFLUCC 17-2228); ITS: MT215493, LSU: MT215544 (MFLUCC 19-0488).

Notes – *Dictyochaeta lithocarpi* is well separated from other *Dictyochaeta* species in the phylogenetic analysis (Fig. 8). Our isolate is related to *D. pandanicola* (KUMCC 16-0153) and *D. assamica* (CBS 242.66) (87% MLBT). *Dictyochaeta lithocarpi* differs from *D. pandanicola* by having smaller conidia (14–17 × 1.5–2.8 vs. 16–26 × 4–6 µm) and presence of setae (Tibpromma et al. 2018). *Dictyochaeta lithocarpi* can be distinguished from *D. assamica* by having monopodialic conidiogenous cells, while *D. assamica* has polyphialidic conidiogenous cells (Arambarri et al. 1987). *Dictyochaeta lithocarpi* also cannot be assigned to any known *Dictyochaeta* species, which lack sequence data (Kuthubutheen & Nawawi 1991, Whitton et al. 2000, Cruz et al. 2009). Therefore, we identify *D. lithocarpi* as a novel species of *Dictyochaeta*.

***Menisporopsis* S. Hughes**

***Menisporopsis theobromae* S. Hughes, Mycol. Pap. 48: 59 (1952)**

Fig. 11

Colonies on decaying Fabaceae seed pod, scattered, superficial, effuse, white. Sexual morph: Undetermined. Asexual morph: *Setae* 230–280 × 5.1–6.2 µm, central, solitary, erect, septate, thick-walled, lower part encased tightly by compact conidiophores and obviously wider than each conidiophore, brown. *Conidiophores* up to 128 µm long, synnematous, macronematous, brown, cylindrical, septate, unbranched, lower part narrow, upper part wider, erect, straight or slightly flexuous, smooth, thin to thick-walled. *Conidiogenous cells* terminal, monopodialic, integrated, pale brown, with visible collarettes. *Conidia* (11–)15.7–21.6 × 2.1–3.8 µm ($\bar{x} = 18.6 \times 2.6$ µm, n = 30), aggregated in slimy masses at the apex of the synnemata, acrogenous, lunate to falcate, gently

curved or straight, aseptate, hyaline, thin- and smooth-walled; with a single, unbranched, flexuous, tubular, hyaline setula at each end, 7.3–9.4 µm long.

Material examined – THAILAND, Chiang Mai Province, on decaying seed pods of Fabaceae plant, 5 July 2015, R.H. Perera, RHP 128 (MFLU 16-1055).

Figure 10 – *Dictyochaeta lithocarpi* (MFLU 19-1173, holotype). a Herbarium material. b Colony on natural substrate. c–e Setae, conidiophores and conidiogenous cells. f–k Conidia. l Germinating conidium. Scale bars: b = 200 µm, c, d = 100 µm, e = 50 µm, f–l = 20 µm.

Notes – We were unable to get a culture of this fungus. However, our collection resembles the genus *Menisporopsis* by its synnematosus conidiophores, central, simple, dark brown setae, phialidic conidiogenous cells and lunate to falcate, 0–1-septate conidia, with setulae at ends (Cruz et al. 2014). The newly collected fungus is morphologically similar to *M. theobromae*, which was collected in Ghana and Thailand (Hughes 1952, Liu et al. 2016). Based on morphological features we regard our fungus as *M. theobromae* (Hughes 1952, Cruz et al. 2014, Liu et al. 2016).

Menisporopsis theobromae was previously reported from *Theobroma cacao* and submerged wood, and this is the first record of the fungus from seed pods of a Fabaceae plant (Hughes 1952, Liu et al. 2016).

Figure 11 – *Menisporopsis theobromae* (MFLU 16-1055). a Herbarium material. b, c Colony on natural substrate. d, e Conidiophores and seta. f Conidiogenous cells with conidia in Congo red. g Conidia. Scale bars: b = 1 mm, c = 500 µm, d, e = 100 µm, f = 50 µm, g = 30 µm.

**Diaporthales Nannf.
Cytosporaceae Fr.**

***Cytospora* Ehrenb.**

***Cytospora diopuiensis* Q.J. Shang, K.D. Hyde & J.K. Liu, in Shang et al., Mycosphere 11: 203 (2020)**
Figs 15, 16

Associated with dried seed pods of *Cassia fistula*. Sexual morph: Undetermined. Asexual morph: Stromata 125–470 µm high, 130–465 µm wide (n = 10), with poorly developed interior, solitary to gregarious, immersed, becoming raised or erumpent through the host tissue, discoid, circular to irregular in shape, dark brown to black, glabrous. Conidiomata (excluding necks) 110–210 × 95–325 µm diam. (n = 15), immersed in host tissue, scattered, erumpent, circular, with 1–2

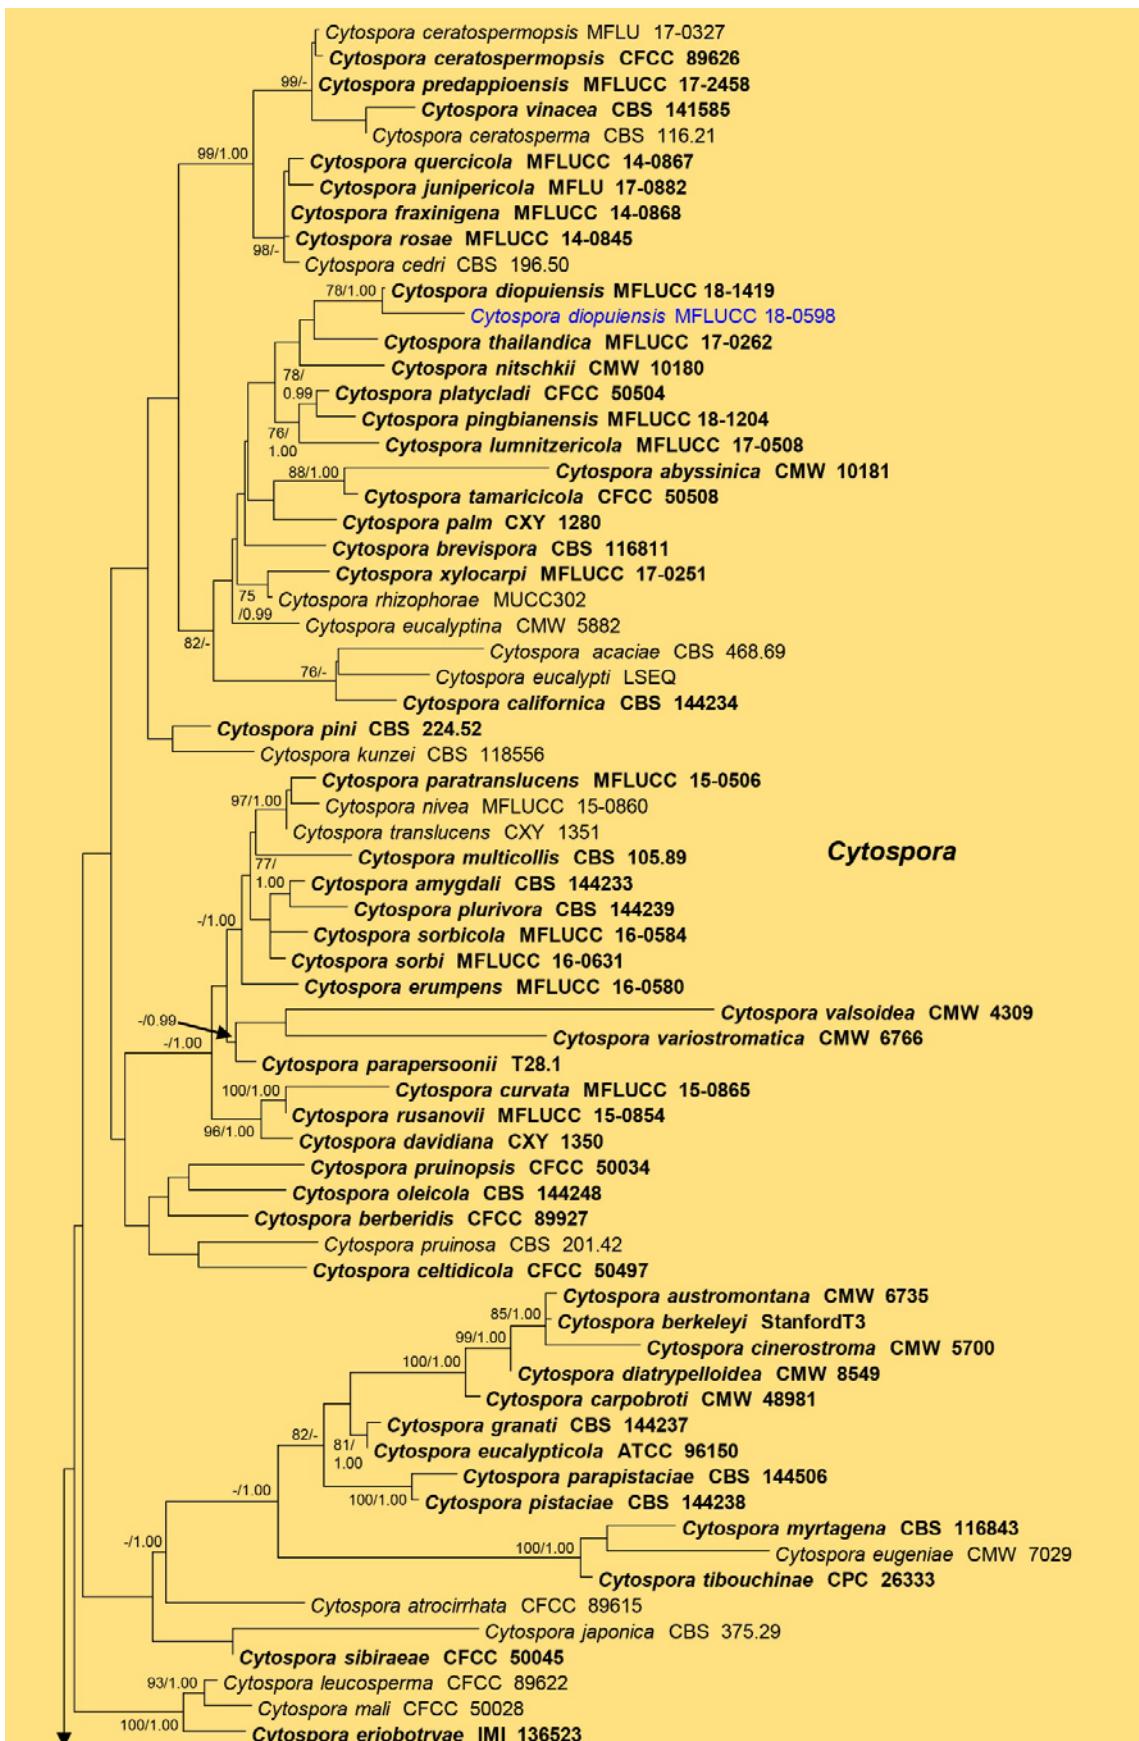

Figure 14 – Phylogram generated from RAxML analysis based on combined ITS, LSU, RPB2 and ACT sequence data of *Cytospora* isolates. Sequences from one hundred thirty taxa, which comprise 3352 characters including gaps, are included in the analyses. The tree was rooted to *Cytospora punicae* CBS 144244. The scale bar indicates 0.04 nucleotide changes per site.

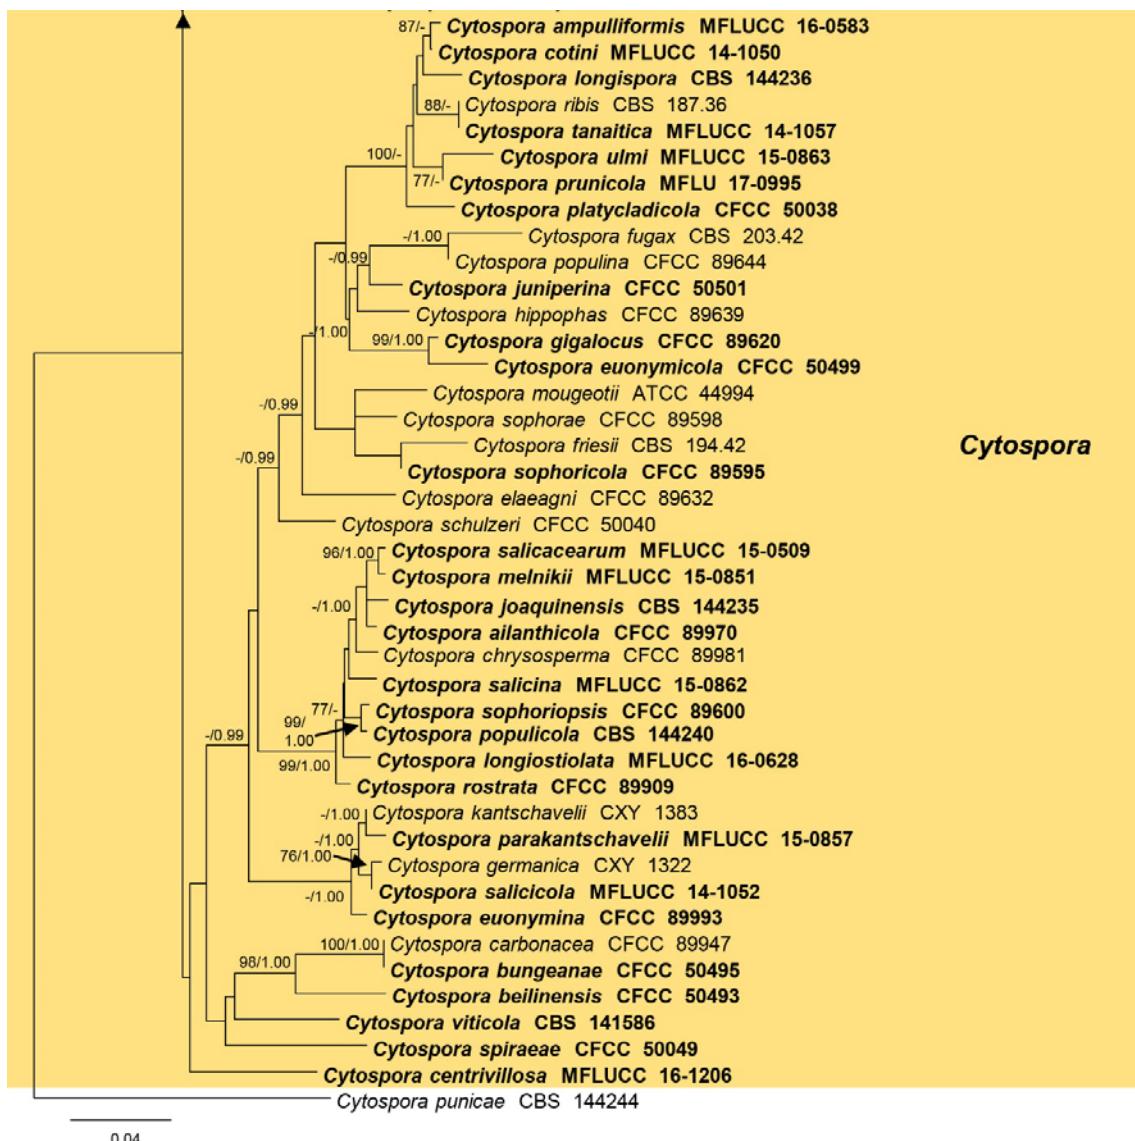

Figure 14 – Continued.

locules, ostiolate, occasionally with yellow conidial exudate. *Ostioles* 120–150 µm diam. *Peridium* comprising a few to several layers of cells of *textura angularis*, inner layer thick, brown, outer later dark brown. *Conidiophores* branched, reduced to conidiogenous cells. *Conidiogenous cells* 8.4–14 × 1.5–2.4 µm ($\bar{x} = 11 \times 1.9$ µm, n = 20), enteroblastic, phialidic, formed from the inner most layer of pycnidial wall, hyaline, smooth-walled. *Conidia* 4.3–6.7 × 1.4–2.3 µm ($\bar{x} = 5.3 \times 1.9$ µm, n = 50), unicellular, allantoid, sometimes ovoid, guttulate, hyaline, smooth-walled. *Chlamydospores* produced on PDA, hyaline, in chains.

Culture characteristics – Conidia germinated on PDA within 12 hours. Colonies on PDA reaching 40–45 mm diameter after 7 days at 28°C, colonies circular to irregular, medium dense, flat or effuse, with edge fimbriate, white from above and below, pale brown with time, sporulating on PDA within 60 days.

Material examined – Thailand, Phayao Province, dried seed pod of *Cassia fistula* L. (Fabaceae), 4 August 2017, R.H. Perera, PH-CAS 01 (MFLU 18-2749), dry culture MFLU 18-0620, living culture: MFLUCC 18-0598.

GenBank numbers – ITS: MT215491, LSU: MT215540, RPB2: MT212203.

Notes – A modern treatment of *Cytospora* was provided by Norphanphoun et al. (2017) and is followed here. Our new isolate MFLUCC 18-0598 groups with ex-type of *Cytospora diopuiensis* (MFLUCC 18-1419) in our phylogenetic analysis with low statistical support (Fig. 14). In the

combined gene analysis of ITS and LSU, our isolate grouped with *C. diopuiensis* (MFLUCC 18-1419) with high statistical support (99% MLBT) (data not shown). ITS and LSU data of two isolates are identical and, there is no RPB2 gene available for *C. diopuiensis* for comparison. However, only the sexual morph is reported for *C. diopuiensis* (Shang et al. 2020). By considering the similarities in the ITS and LSU loci, we identify our isolate as the first asexual morph record for *C. diopuiensis* and a new host record. *Cytospora diopuiensis* can be distinguished from *C. thailandica* in having larger allantoid conidia ($4.3\text{--}6.7 \times 1.4\text{--}2.3$ vs. $3.8\text{--}4 \times 1\text{--}1.3 \mu\text{m}$) and larger conidiogenous cells ($8.4\text{--}14 \times 1.5\text{--}2.4$ vs. $6\text{--}9.1 \times 1\text{--}1.3 \mu\text{m}$), while conidia of *C. thailandica* are subcylindrical (Shang et al. 2020).

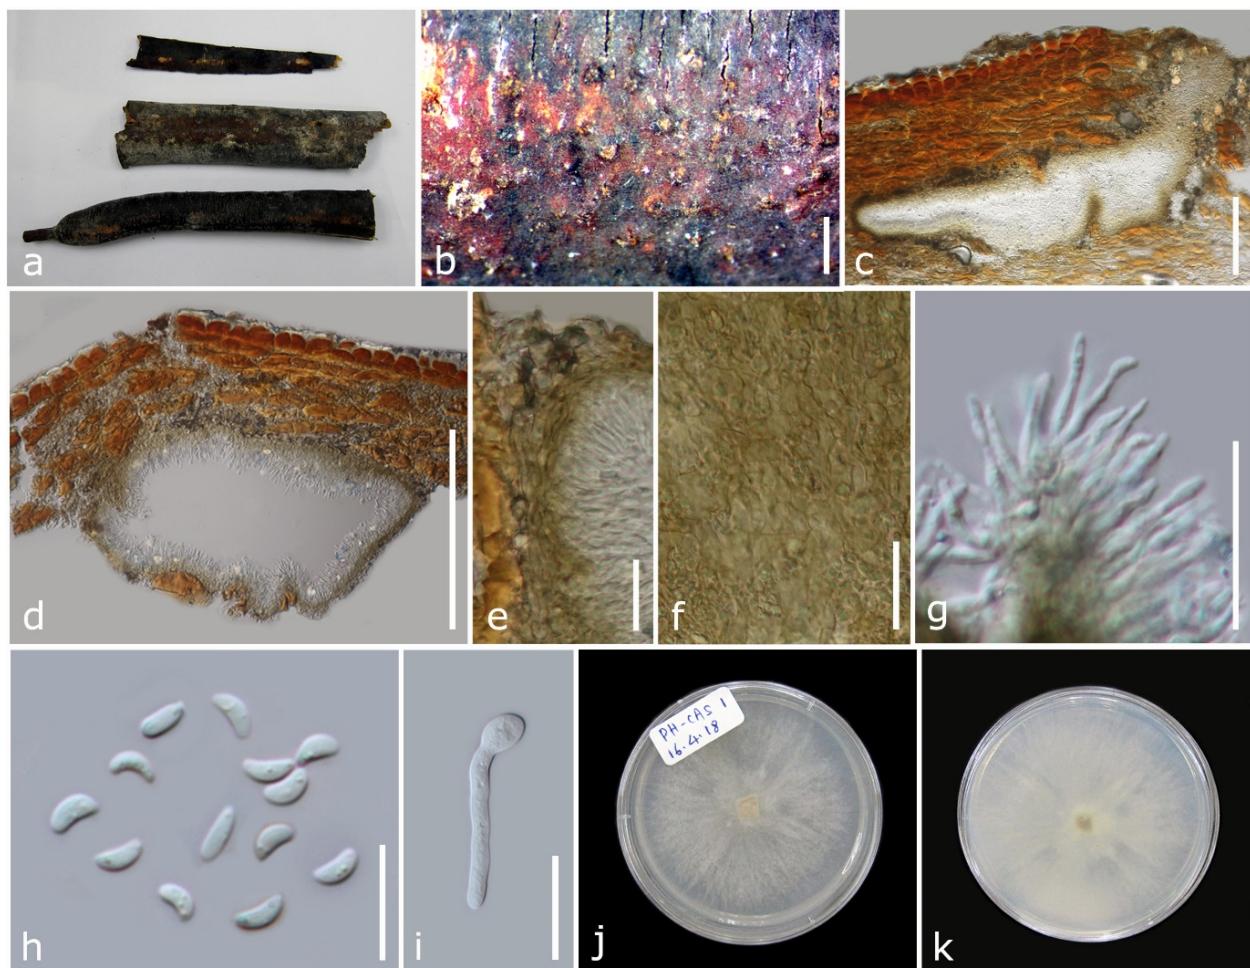

Figure 15 – *Cytospora diopuiensis* (MFLU 18-2749). a Herbarium material. b Conidiomata on host surface. c, d Cross section of the stroma showing conidiomata. e Peridium. f Peridium in face view. g Conidia attached to conidiogenous cells. h Conidia. i Germinating conidium. j, k Colony on PDA. Scale bars: b = 500 μm , c = 100 μm , d = 200 μm , e–g = 20 μm , h = 10 μm , i = 20 μm .

Diaporthaceae Höhn. ex Wehm.

Diaporthe Nitschke

Diaporthe delonidis R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 13

Index Fungorum number: IF556855; Facesoffungi number: FoF07754

Etymology – Named after the host genus *Delonix*.

Holotype – MFLU 16-1059

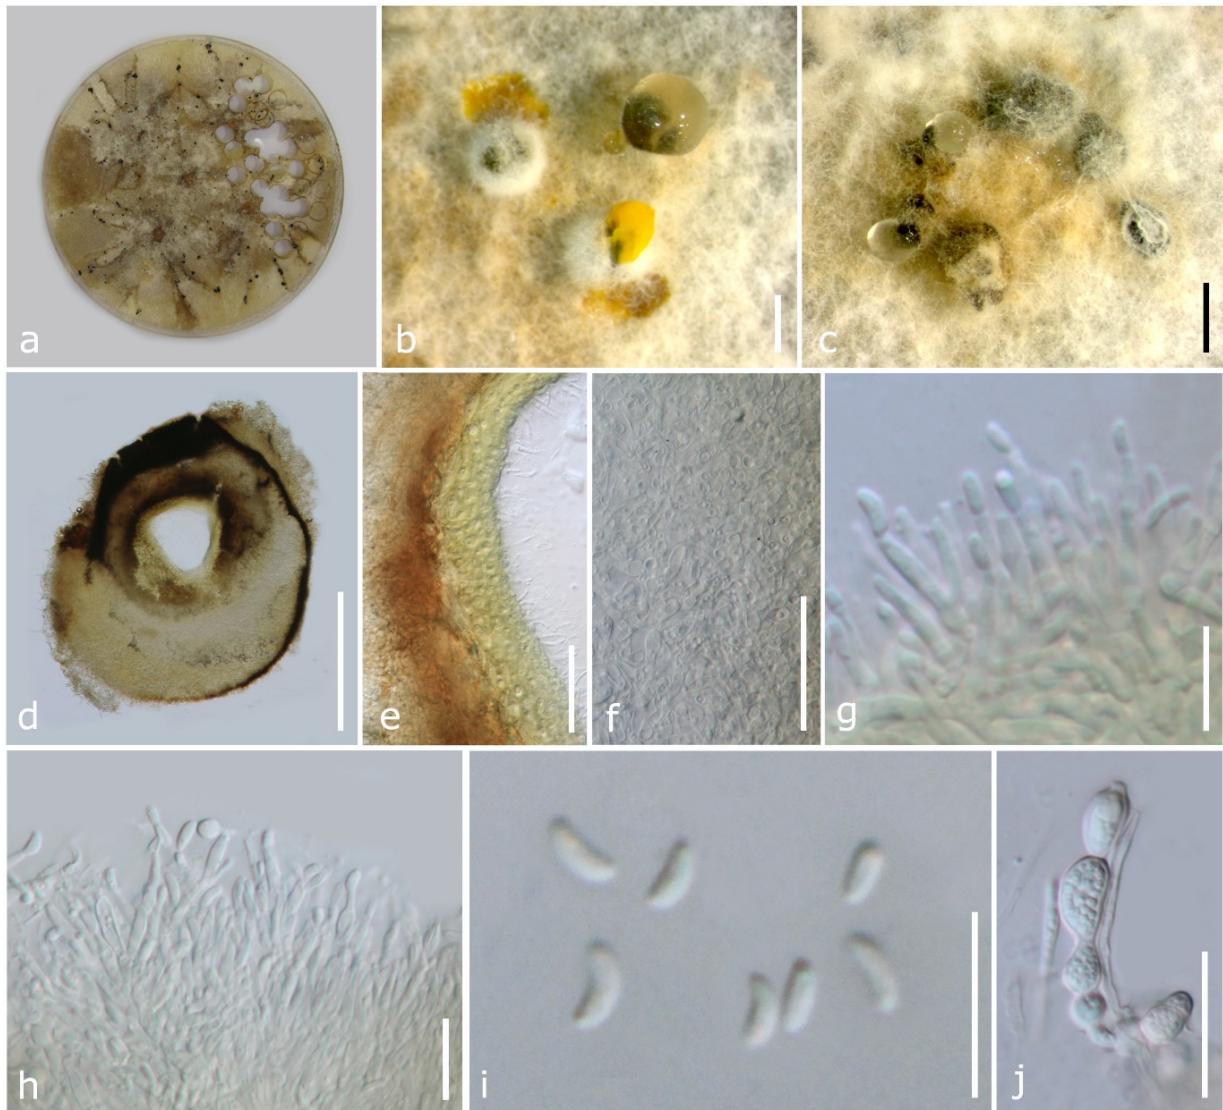

Figure 16 – *Cytospora diopuiensis* (MFLU 18-0620). a–c Conidiomata on PDA. d Conidioma. e Wall of the ostiolar canal. f Stromatal tissue. g, h Conidia attached to conidiogenous cells. i Conidia. j Chlamydospores. Scale bars: b, c = 1 mm, d = 500 µm, e, f = 50 µm, g–j = 10 µm, j = 20 µm.

Saprobic on seed pods of *Delonix regia*. Sexual morph: Undetermined. Asexual morph: Conidiomata 78–190 µm ($\bar{x} = 120$ µm) in diam., appearing as black raised spots on the host, scattered, globose or near-globose, brown to dark brown, conidia exuded from conidiomata in white creamy drops. Peridium 20 µm thick, composed of 5–8 rows of hyaline to light brown cells of *textura angularis*. Conidiophores 6.4–15.2 × 1.4–2.2 µm ($\bar{x} = 11.6 \times 1.9$ µm), sub-cylindrical, hyaline. Conidiogenous cells 5.3–10.5 × 1.3–2.5 µm ($\bar{x} = 7.9 \times 1.9$ µm), phialidic, tapering to the apex, collarette prominent. Alpha conidia 4.4–9 × 1.3–2.2 µm ($\bar{x} = 7.7 \times 1.8$ µm), aseptate, fusoid with obtuse ends, 4-guttulate, hyaline, smooth-walled. Beta conidia 16–23 × 1–1.7 µm ($\bar{x} = 19.4 \times 1.2$ µm), aseptate, filiform, slightly curved at one end and both ends rounded, hyaline, smooth-walled.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University premises, on dried seed pods of *Delonix regia* (Boj. ex Hook.) Raf. (Fabaceae), 7 May 2015, R.H. Perera, RHP 99 (MFLU 16-1059, holotype).

GenBank numbers – ITS: MT215490, TUB2: MT212209.

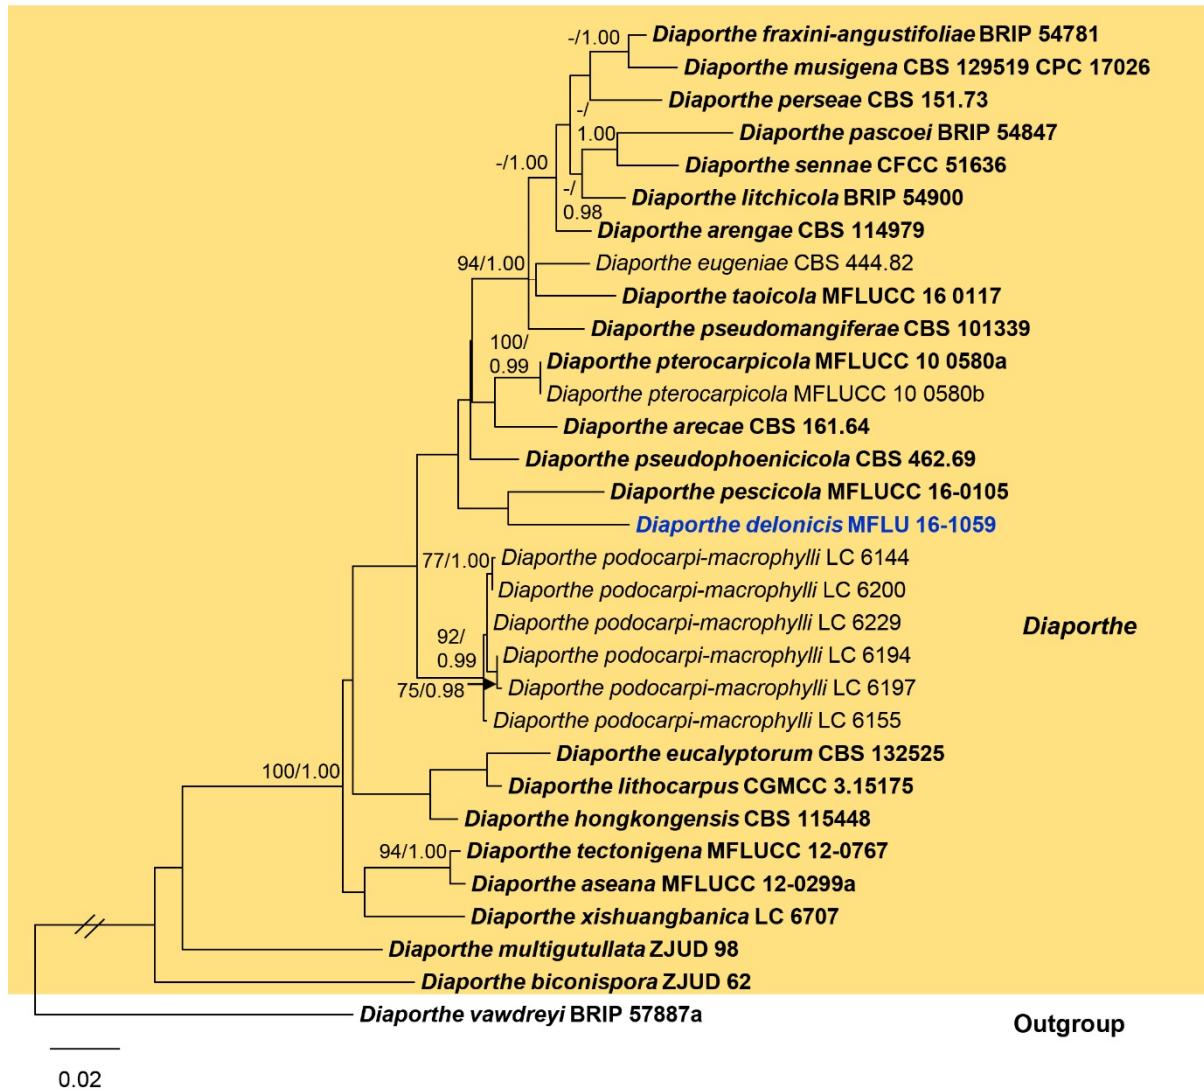

Figure 12 – Phylogram generated from RAxML analysis based on combined ITS, TEF1 and TUB2 sequence data of *Diaporthe* isolates. Sequences from thirty-one taxa, which comprise 1578 characters including gaps, are included in the analyses. The tree was rooted to *Diaporthe vawdreyi* (BRIP 57887a). The scale bar indicates 0.02 nucleotide changes per site.

Notes – The genus has been well-studied and requires ITS, TEF1 and TUB2 sequence data to resolve species (Udayanga et al. 2014, 2015, Dissanayake et al. 2017a). DNA was directly extracted from the fruiting bodies of this fungus. *Diaporthe delonicis* (MFLU 16-1059) groups with *D. pescicola* (MFLUCC 16-0105), but is unsupported within *Diaporthe* (Fig. 12). *Diaporthe pescicola* was identified as a pathogen on *Prunus persica* shoots in China by Dissanayake et al. (2017b). *Diaporthe delonicis* differs from *D. pescicola* by producing smaller conidiomata (78–190 vs. 300 µm) and conidiophores (6.4–15.2 × 1.4–2.2 vs. 21–35 × 1.5–2.5 µm) (Dissanayake et al. 2017b). *Diaporthe delonicis* can also be distinguished from *D. pescicola* by smaller beta conidia (16–23 × 1–1.7 vs. 18–37 × 1–1.5 µm) (Dissanayake et al. 2017b). Furthermore, *D. delonicis* produces alpha conidia with 4-guttules, while *D. pescicola* forms bi-guttulate alpha conidia (Dissanayake et al. 2017b). We also observed prominent collarettes in conidiophores of *D. delonicis*, and this character was not reported from *D. pescicola* (Dissanayake et al. 2017b). We therefore identified *D. delonicis* as a new species.

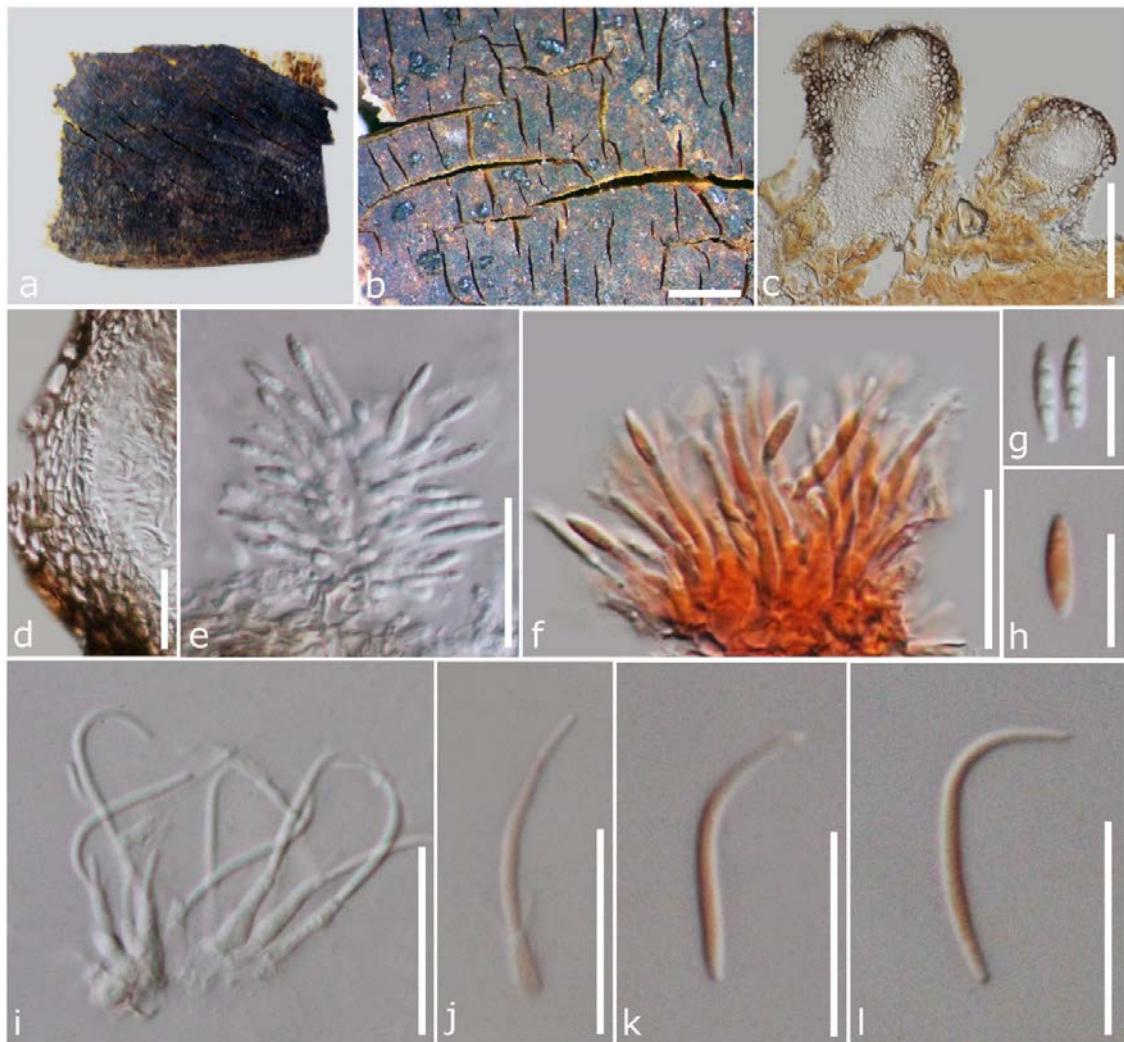

Figure 13 – *Diaporthe delonicis* (MFLU 16-1059, holotype). a Herbarium material. b Conidiomata on natural substrate. c Section through conidiomata. d Peridium. e, f Conidiogenous cells with alpha conidia (f in Lugol's solution). g, h Alpha conidia (h in Lugol's solution). i Conidiogenous cells giving rise to beta conidia. j–l Beta conidia in Lugol's solution. Scale bars: b = 1 mm, c = 100 μm , d–f = 20 μm , g, h = 10 μm , i–l = 20 μm .

Hypocreales Lindau

Bionectriaceae Samuels & Rossman

Clonostachys Corda

Clonostachys rogersoniana Schroers, Stud. Mycol. 46: 109 (2001)

Fig. 18

Facesoffungi number: FoF07755

Saprobic on decaying seed pods of *Delonix regia*. Sexual morph: Undetermined. Asexual morph: Hyphomycetous, colonies appearing as white patches on both inner and outer epidermis of the seed pod. *Conidiophores* arising from stroma, monomorphic, hyaline, smooth-walled, penicillate, stipes 70–100 μm long, 4.2–6.8 μm wide at base. *Penicilli* 58–80 μm high, \times 50–100 μm diam. at widest point; solitary to gregarious, not sporodochial, bi- to quaterverticillate; branches of the penicillus divergent, each branch terminating in metulae and adpressed phialides. *Phialides* 7–12.4 μm ($\bar{x} = 10 \mu\text{m}$) long, 1.8–2.9 μm ($\bar{x} = 2.4 \mu\text{m}$) wide at widest point, in whorls of up to 6, narrowly flask-shaped, slightly tapering toward the apex. *Intercalary phialides* not observed. *Conidial masses* white. *Conidia* 4.9–9.1 \times 1.6–2.3 μm ($\bar{x} = 7.2 \times 2 \mu\text{m}$, n = 30), broadly ellipsoidal to oval, rarely minutely curved, ends broadly rounded, bi-guttulate, hilum laterally displaced, almost median or invisible, hyaline, smooth-walled.

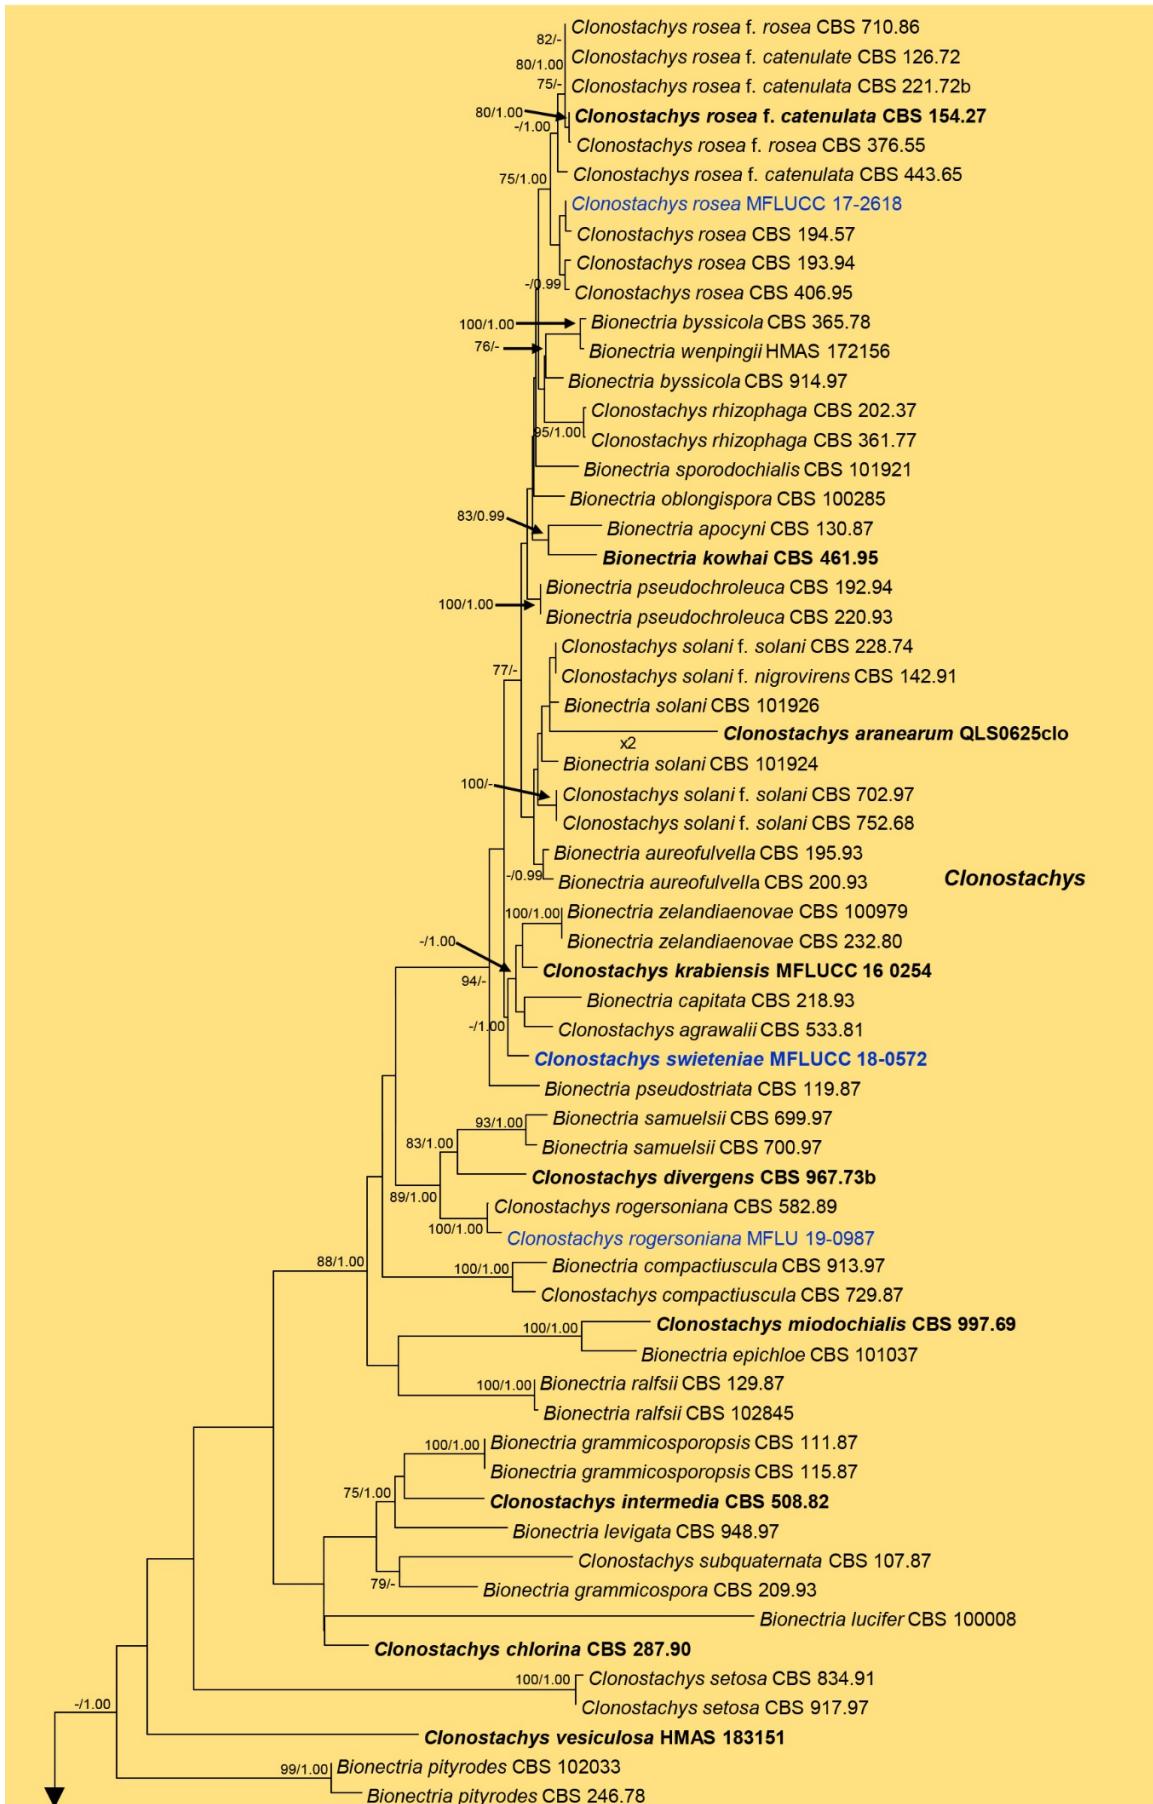

Figure 17 – Phylogram generated from RAxML analysis based on combined ITS and TUB2 sequence data of *Clonostachys* isolates. Sequences from seventy-two taxa, which comprise 1087

characters including gaps, are included in the analyses. The tree was rooted to *Nectria cinnabarin* NRRL 20484 and *Fusarium acutatum* CBS 402.97. The scale bar indicates 0.07 nucleotide changes per site.

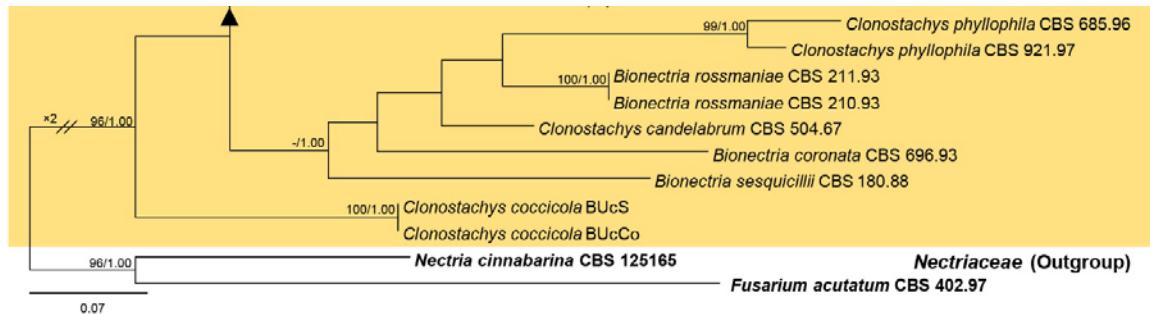

Figure 17 – Continued.

Material examined – Thailand, Chiang Mai Province, on decaying seed pods of *Delonix regia* (Fabaceae), 20 December 2016, R.H. Perera, Delo 01 (MFLU 19-0987).

GenBank numbers – ITS: MT215572, LSU: MT215538, TUB2: MT212208.

Notes – Our new strain clusters with *Clonostachys rogersoniana* (CBS 582.89) with high statistical support (100% MLBT, 1.0 BIPP; Fig. 17) in phylogenetic analysis of ITS sequence data, and they are morphologically similar in having the same conidiophore characters and conidial dimensions (Schroers 2001). However, verticillate conidiophores were not observed in our collection (Schroers 2001). With morphological and DNA molecular analysis support, we report a new host record of *Clonostachys rogersoniana* from *Delonix regia*.

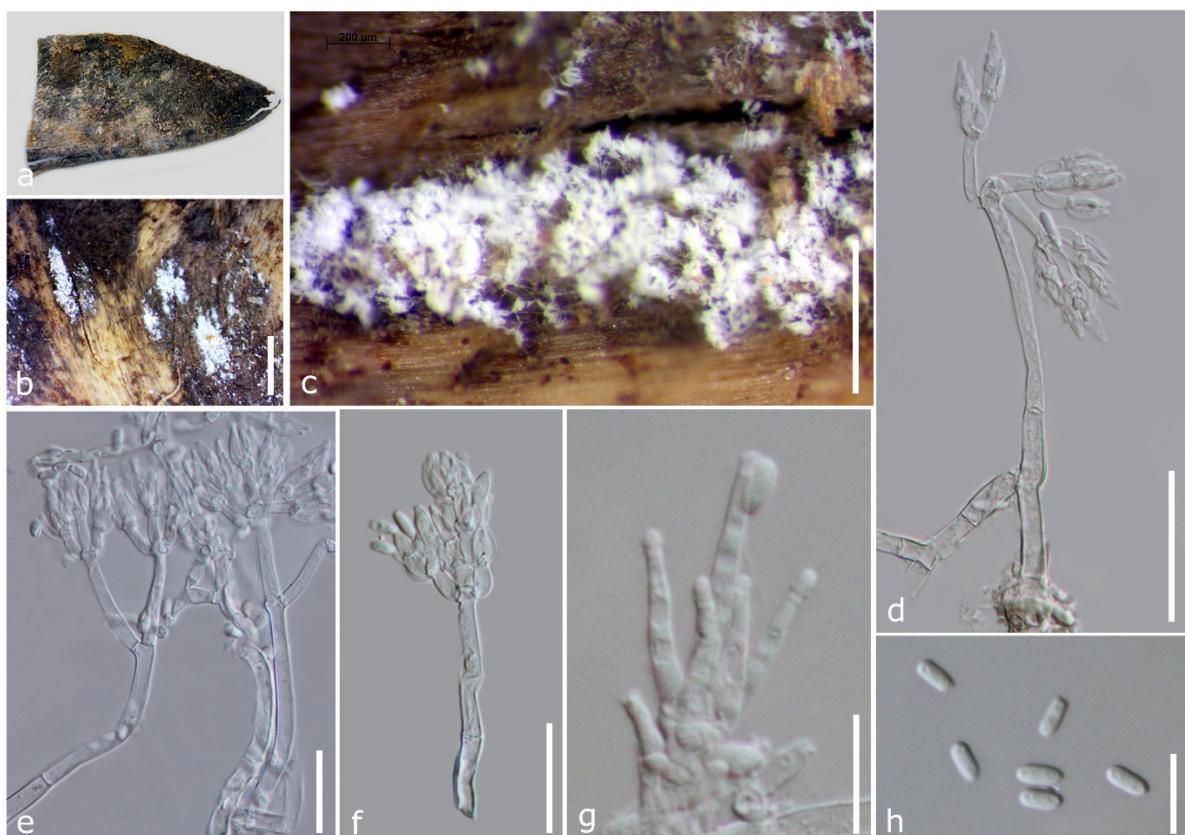

Figure 18 – *Clonostachys rogersoniana* (MFLU 19-0987). a Herbarium material. b, c Colonies on host. d-f Conidiophores with phialides. g Phialides with conidia. h Conidia. Scale bars: b = 2 mm, c = 1 mm, d-f = 20 μ m, g, h = 10 μ m.

Facesoffungi number: FoF06012

Saprobic on decaying fruits of *Swietenia mahagoni*. Sexual morph: *Stromata* well developed, erumpent. *Ascomata* 170–215 × 160–218 µm ($\bar{x} = 185 \times 186$ µm, n = 7), perithecial, densely crowded in groups, globose to subglobose to oval, not collapsing or sometimes slightly laterally pinched when dry, light orange to yellowish orange, KOH-, not papillate, surface smooth to slightly roughened, but not distinctly warted. *Ostiole* periphysate. *Peridium* 21–46 µm wide, wider around the ostiole, two strata: outer layer 21–30 µm wide, comprising unevenly thickened brownish yellow cells of *textura angularis* to *textura globosa*, becoming larger towards the periphery, most cells containing a vacuole; inner layer 8–14 µm wide, consists of flat, hyaline cells of *textura angularis*. *Asci* 50.6–62.2 × 6–7.2 µm ($\bar{x} = 55.4 \times 6.6$ µm, n = 18), 8-spored, unitunicate, narrowly clavate, apex flat with somewhat rounded edges, short stalked, apical ring J-. *Ascospores* 8.9–11.9 × 2.9–3.4 µm ($\bar{x} = 10.7 \times 3.1$ µm, n = 25), bi-seriate above and uni-seriate below, 1-septate, equilateral, not constricted at the septum or slightly constricted in mature ascospores, ellipsoidal to oblong ellipsoidal, 4-guttulate, hyaline, spinulose. Asexual morph: See Schroers (2001).

Culture characteristics – Ascospores germinating on PDA within 12 hours. Colonies growing on PDA, reaching up to 4.5 cm in 7 days at 25°C, surface effused, smooth, margin entire to undulate, aerial mycelium rare, initially white, becoming yellowish, reverse yellowish.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University Garden, on decaying fruits of *Swietenia mahagoni* (L.) Jacq. (Meliaceae), 06 September 2017, R.H. Perera, Maho 04 (MFLU 18-2770), living culture MFLUCC 17-2618.

GenBank numbers – ITS: MT215574, LSU: MT396165, TEF: MT415234.

Notes – Our new isolate (MFLUCC 17-2618) groups with *Clonostachys rosea* isolates of CBS 194.57, CBS 193.94 and CBS 406.95. (Fig. 17). A comparison of nucleotides shows ITS loci of our isolate identical to *C. rosea* (CBS 194.57, CBS 193.94 and CBS 406.95). Our collection morphologically resembles *C. rosea* in ascromatal colour, size, ascii and ascospore dimensions (Rossman et al. 1999, Schroers et al. 1999). This collection represents a new host record for *C. rosea*.

Index Fungorum number: IF556856; Facesoffungi number: FoF07756

Etymology – Named after the host genus *Swietenia*.

Holotype – MFLU 18-2769

Saprobic on decaying fruits of *Swietenia mahagoni*. Sexual morph: Undetermined. Asexual morph: Hyphomycetous, colonies appearing as white patches on the host. *Conidiophores* arising from stroma, mononematous, monomorphic, hyaline, smooth-walled, penicillate, stipes 130–200 µm long, 5–8 µm wide at base. *Penicilli* 28–66 µm high, × 20–60 µm diam. at widest point; solitary to gregarious, not sporodochial, bi- or quater-verticillate; branches of the penicillus divergent, each branch terminating in metulae and adpressed phialides. *Phialides* 9–14.1(–17) × 2.1–3.2 µm ($\bar{x} = 11.4 \times 2.6$ µm, n = 40), in whorls of 2–6, narrowly flask-shaped, slightly tapering toward the apex, with visible periclinal thickening, collarettes inconspicuous, hyaline, smooth-walled. *Intercalary phialides* not observed. *Conidial masses* white. *Conidia* (4.5–)5.1–6.7 × 1.9–2.6 µm ($\bar{x} = 6 \times 2.2$ µm, n = 40), broadly ellipsoidal to oval, rarely minutely curved, ends broadly rounded, straight, bi-guttulate, hilum laterally displaced, almost median or invisible, hyaline, smooth-walled.

Culture characteristics – Conidia germinating on PDA within 12 hours. Colonies growing on PDA, reaching up to 3.8 cm within 7 days at 25°C, surface slightly raised, smooth, margin entire to undulate, aerial mycelium dense, initially white, becoming yellowish, reverse yellow.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University Garden, on decaying fruits of *Swietenia mahagoni* (Meliaceae), 6 September 2017, R.H. Perera, Maho 02 (MFLU 18-2769, holotype), ex-type living culture MFLUCC 18-0572.

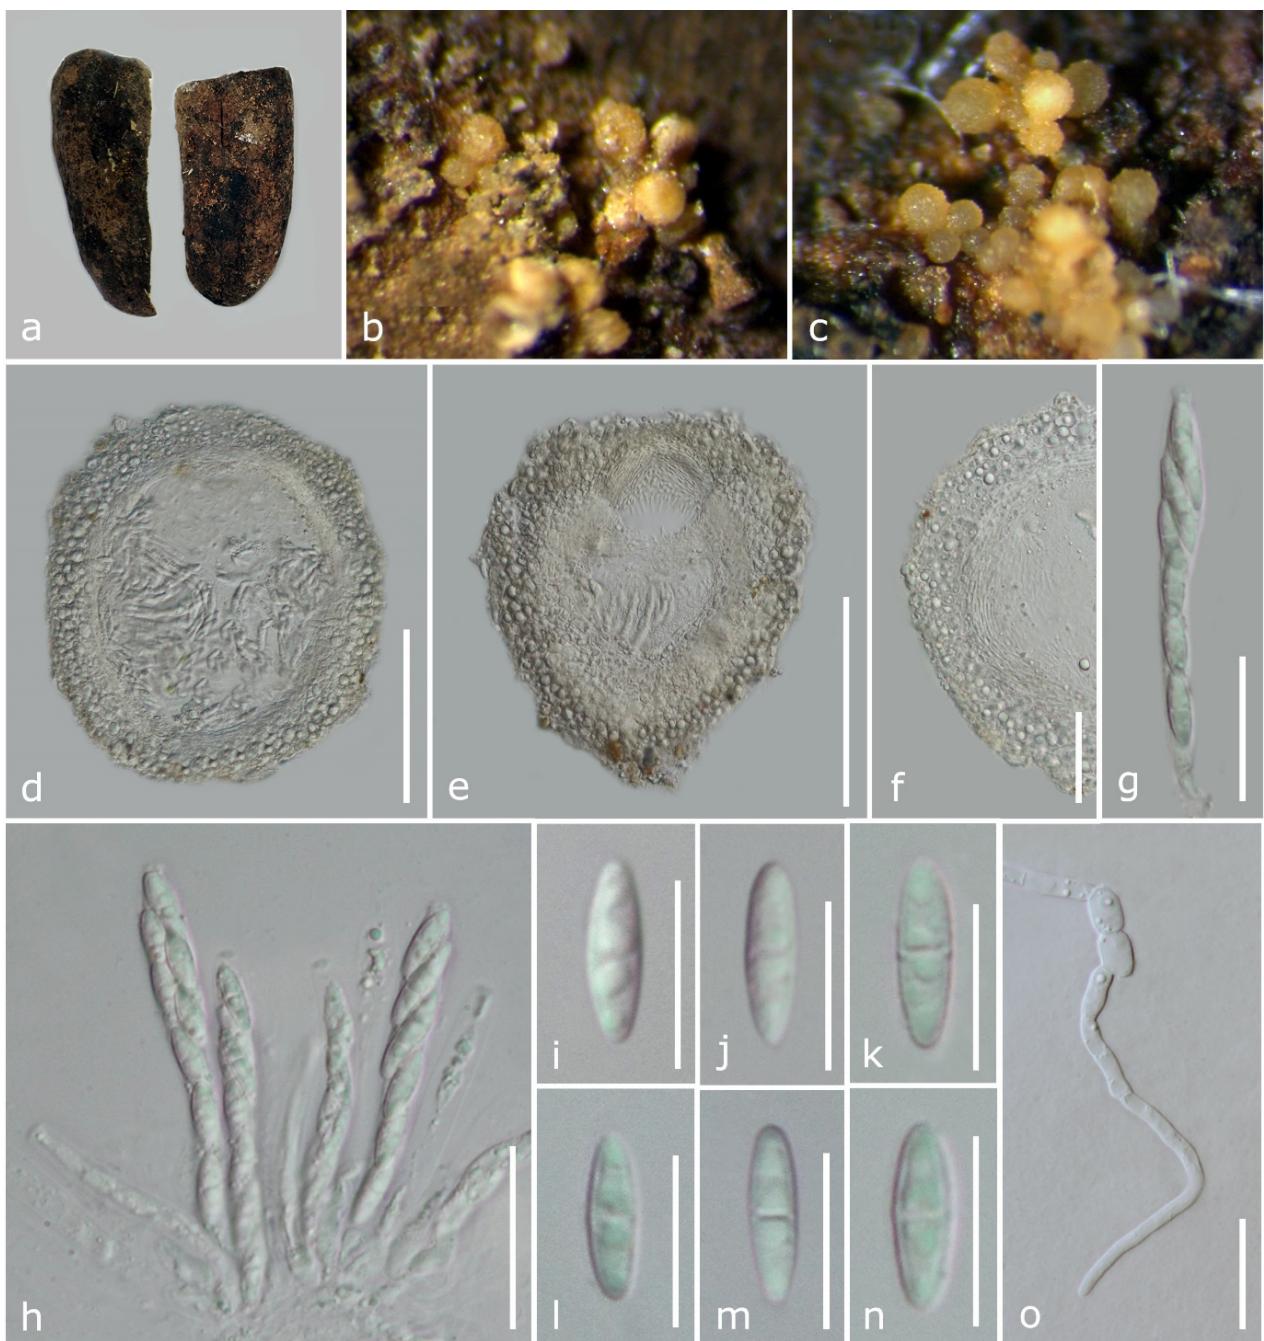

Figure 19 – *Clonostachys rosea* (MFLU 18-2770). a Herbarium material. b, c Ascomata on host. d, e Section of ascomata. f Section of peridium. g, h Ascii. i–n Ascospores. o Germinating ascospore. Scale bars: d, e = 100 µm, f = 50 µm, g, h = 20 µm, i–n = 10 µm, o = 20 µm.

GenBank numbers – ITS: MT215573, LSU: MT396164, TEF1: MT212204.

Notes – *Clonostachys swieteniae* constitutes a distinct lineage within *Clonostachys* (Fig. 17). A comparison of the ITS regions of *C. swieteniae* reveals 11 (2.1%), 10 (2.1%), 7 (1.5%) and 8 (1.7%) nucleotide differences with *C. capitata*, *C. zelandiaenovae*, *C. agrawalii* and *C. krabiensis*, respectively. *Clonostachys swieteniae* can be discriminated from *C. capitata* by its longer and wider conidiophore stipe (130–200 × 5–8 vs. 100 × 3.5 µm) and straight, smaller conidia (5.1–6.7 × 1.9–2.6 vs. 6–7.2 × 2.8–3.4 µm), which are curved in *C. capitata* (Schroers 2001). *Clonostachys swieteniae* is different from *C. krabiensis*, which was also collected from Thailand, by the absence of setae and not forming sporodochial conidiophores (Tibpromma et al. 2018). We therefore identified *Clonostachys swieteniae* as a new taxon.

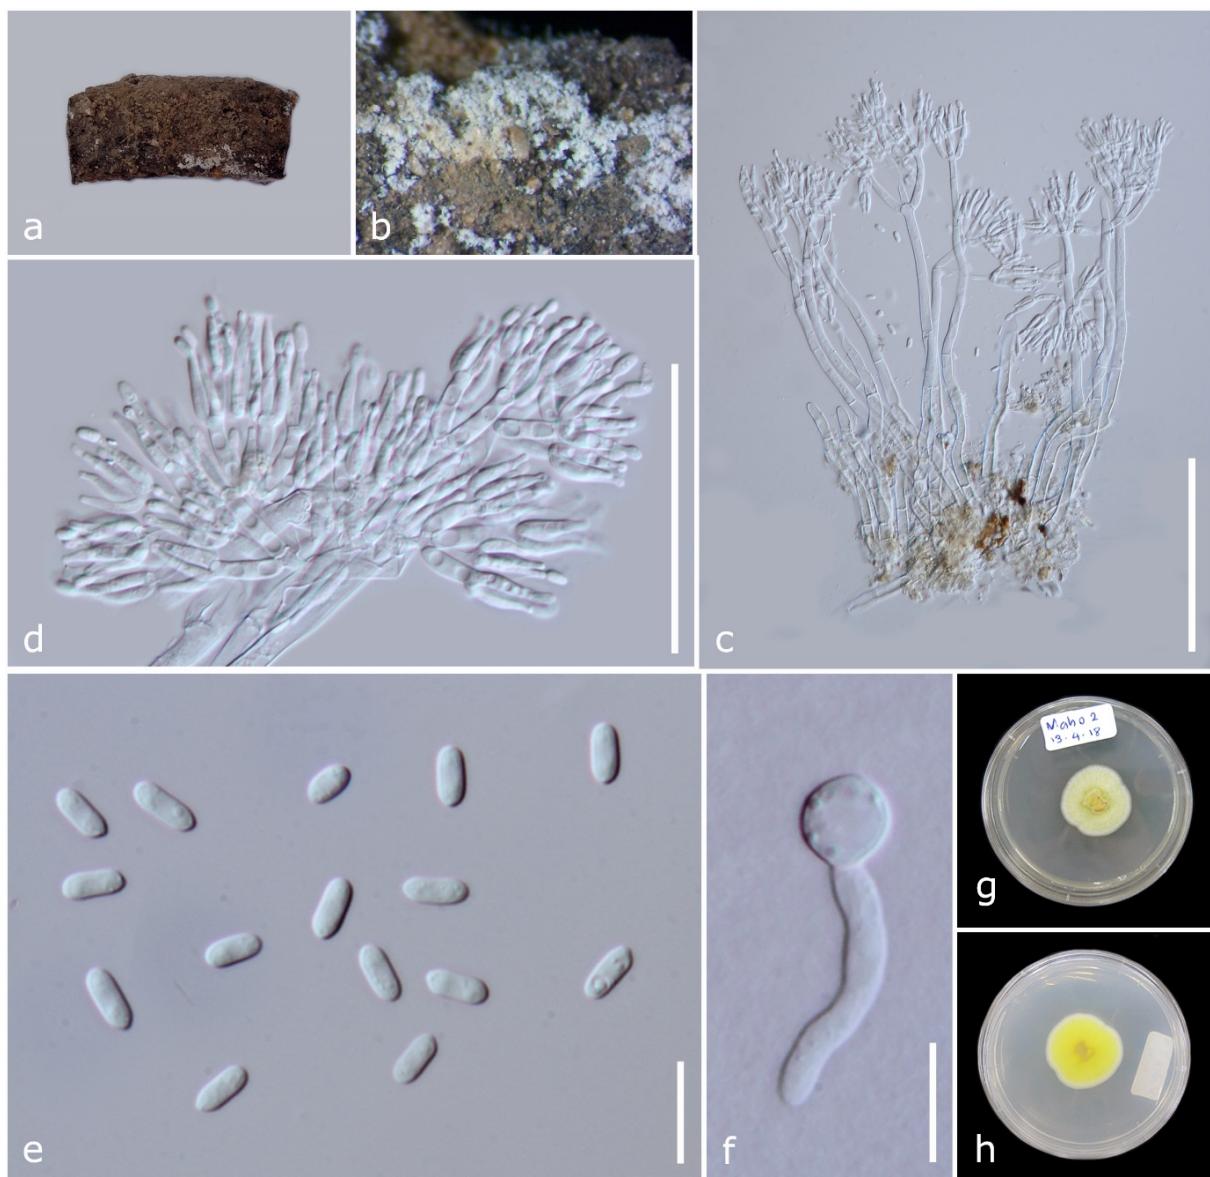

Figure 20 – *Clonostachys swieteniae* (MFLU 19-0987). a Herbarium material. b Colony on host. c Conidiophores. d Conidiogenous apparatus. e Conidia. f Germinating conidium. g, h Colony on PDA. Scale bars: c = 100 µm, d = 50 µm, e, f = 10 µm.

Myrotheciomyctaceae Crous
***Trichothecium* Link**

***Trichothecium roseum* (Pers.) Link**, Mag. Gesell. naturf. Freunde, Berlin 3(1-2): 18 (1809)

Figs 22, 23

Facesoffungi number: FoF07768

On dried pods of *Delonix regia*. Sexual morph: Undetermined. Asexual morph: Hyphomycetous. *Conidiophores* 215 × 360 µm long, 3.3–5 µm wide ($\bar{x} = 270 \times 4$ µm, n = 20), simple, long, slender, rarely branched, septate, often slightly swollen at the tip, hyaline, smooth-walled. *Conidia* 11.5–25.5 × 8–14.6 µm ($\bar{x} = 20 \times 11$ µm, n = 30), borne apically and singly, attached in groups or chains, pink in mass, 1-septate, ovate, hyaline, thick-walled, each with a decurved, abruptly narrowed basal hilum terminating in a distinct truncate end, often clustered. *Conidiophores* on MEA retrogressive, with each conidial base subsuming a portion of conidiophore apex. *Conidia* arise from the side of the conidiophore apex. *Chlamydospores* present, 7–8.8 µm wide (n = 10), in intercalary chains, hyaline, smooth-walled.

Culture characteristics – Conidia germinating on PDA within 12 hours. Colonies growing on PDA, reaching up to 4.5 cm within 7 days at 28°C, surface effused, smooth, margin entire, aerial mycelium rare, initially white, turning salmon pink, reverse salmon pink. Colony on MEA reaching up to 3.3 cm in 7 days at 28°C, sporulating within 30 days.

Materials examined – THAILAND, Chiang Rai Province, Mae Fah Luang University garden, on dried pods of *Delonix regia* (Fabaceae) on the ground, 1 December 2017, R.H. Perera, Delo 24 (MFLU 18-2773), living culture: MFLUCC 17-1036; *ibid.*, on dried pods of *Tamarindus indica* L. (Fabaceae) on the ground, 6 December 2016, R.H. Perera, Tam 4 (MFLU 18-2735), sporulated dry culture: MFLU 18-0624, living culture: MFLUCC 17-0141.

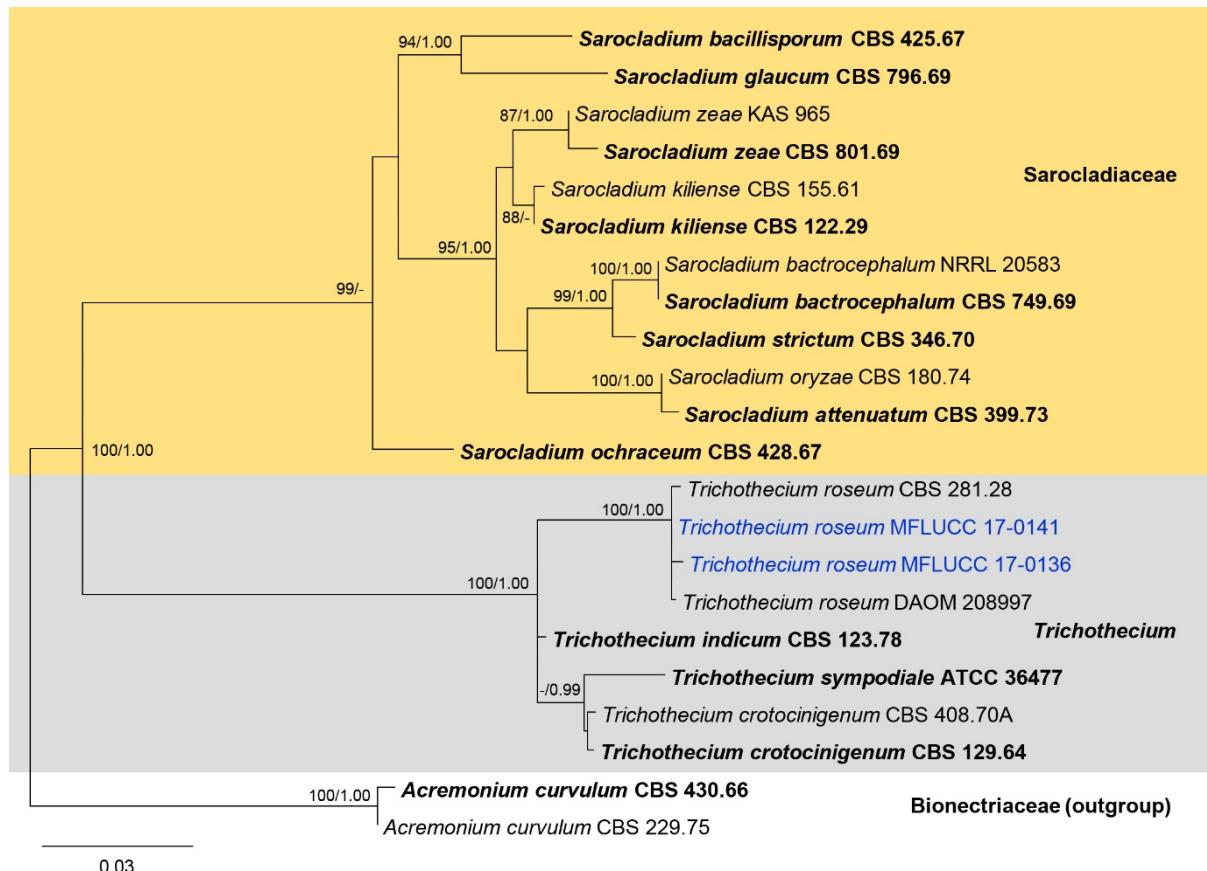

Figure 21 – Phylogram generated from RAxML analysis based on combined LSU and ITS, sequence data of *Trichothecium* isolates. Sequences from twenty-two taxa, which comprise 1390 characters including gaps, are included in the analyses. The tree was rooted to *Acremonium curvulum* CBS 430.66 and *Acremonium curvulum* CBS 229.75. The scale bar indicates 0.03 nucleotide changes per site.

GenBank numbers – ITS: MT215509, LSU: MT215558 (MFLUCC 17-1036); ITS: MT215510, LSU: MT215559 (MFLUCC 17-0141).

Notes – In the phylogenetic analysis our two isolates grouped within *Trichothecium roseum* isolates CBS 281.28 and DAOM 208997 (Fig. 21). Based on the phylogenetic analysis and morphological similarities the fungus was identified as *Trichothecium roseum* (Petrak 1953, Bello 2008), and is a new host record.

Nectriaceae Tul. & C. Tul.

Fusarium Link

Fusarium cassiae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 25

Index Fungorum number: IF556857; Facesoffungi number: FoF07757

Etymology – Name reflects the host genus *Cassia fistula*.

Holotype – MFLU 18-2751

Saprobic on decaying pods of *Cassia fistula*. Sexual morph: Ascomata 110–180 µm high × 110–155 µm diam. ($\bar{x} = 132 \times 128$ µm), superficial, solitary to gregarious, blue-black to dark purple, subglobose to ampulliform, or obpyriform, collapsing laterally when dry, with a slightly papillate ostiole. Peridium 16–30 µm wide, comprising dark purple to hyaline, thick-walled cells of *textura angularis*. Catenophyses absent. Ascii 59–83 × 9–16 µm ($\bar{x} = 70.2 \times 11.8$ µm, n = 20), 4–8-spored, unitunicate, clavate, with a short pedicel, truncate at the apex, apical ring J-. Ascospores 10.3–21.2 × 5.6–8.8 µm ($\bar{x} = 15.9 \times 7$ µm, n = 37), 1–2-seriate, varied in shape, ellipsoidal to oblong, or subglobose to ovoid, or fusiform, with both ends rounded, (0–)1-septate, not or slightly constricted at the septum, hyaline, pale brown when mature, guttulate, smooth-walled. Asexual morph: Undetermined.

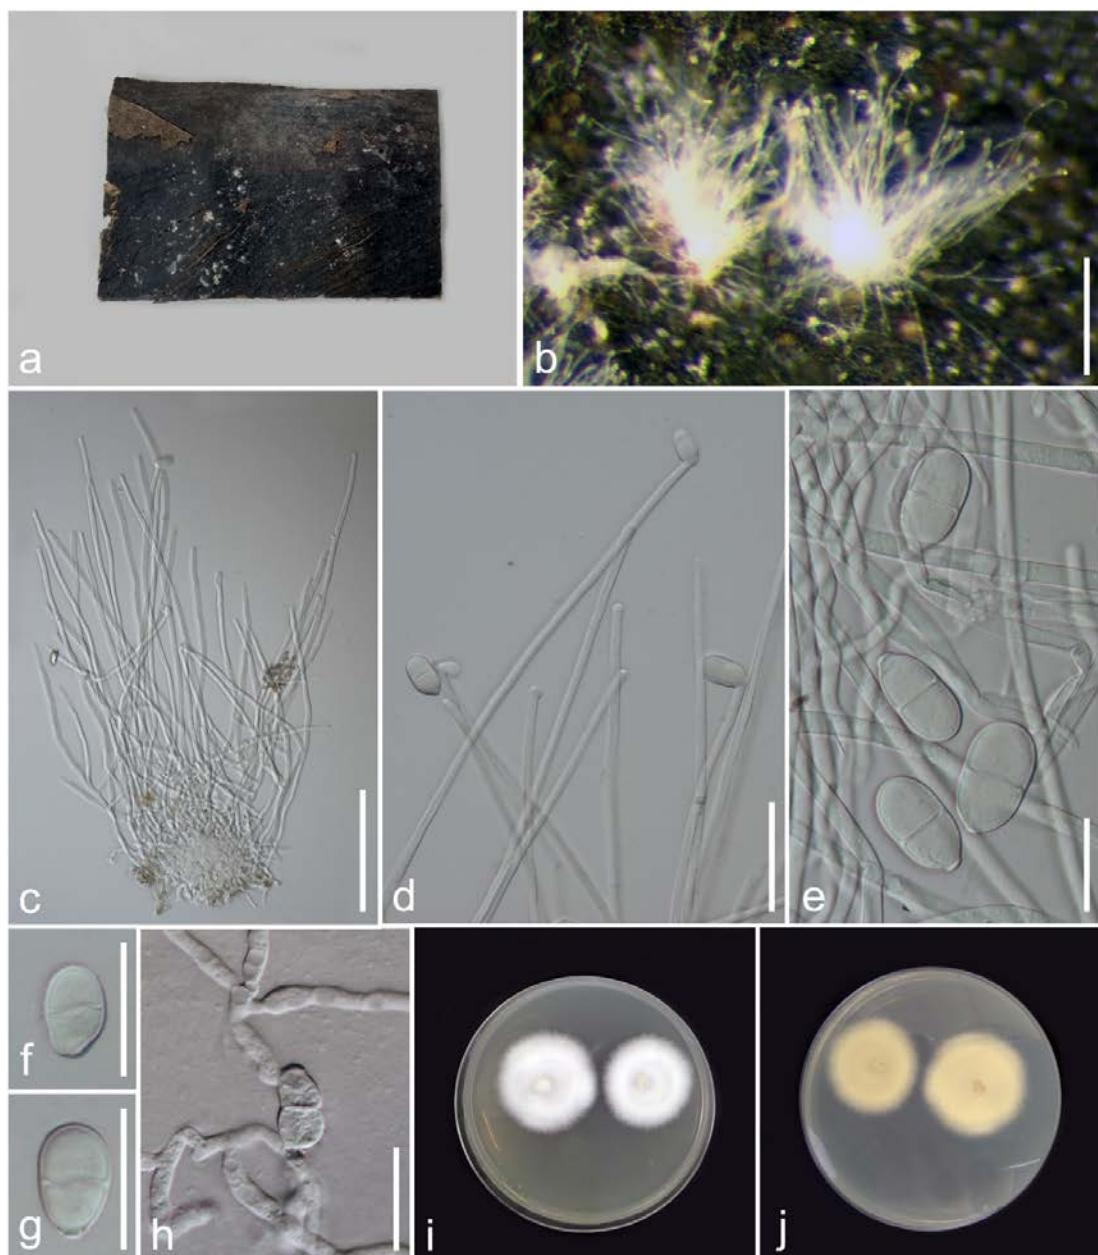

Figure 22 – *Trichothecium roseum* (MFLU 18-2773). a Herbarium material. b Conidiomata on host. c, d Conidiophores with conidia. e–g Conidia. h Germinating conidium. i, j Colony on PDA. Scale bars: b = 200 µm, c = 100 µm, d = 50 µm, e–h = 20 µm.

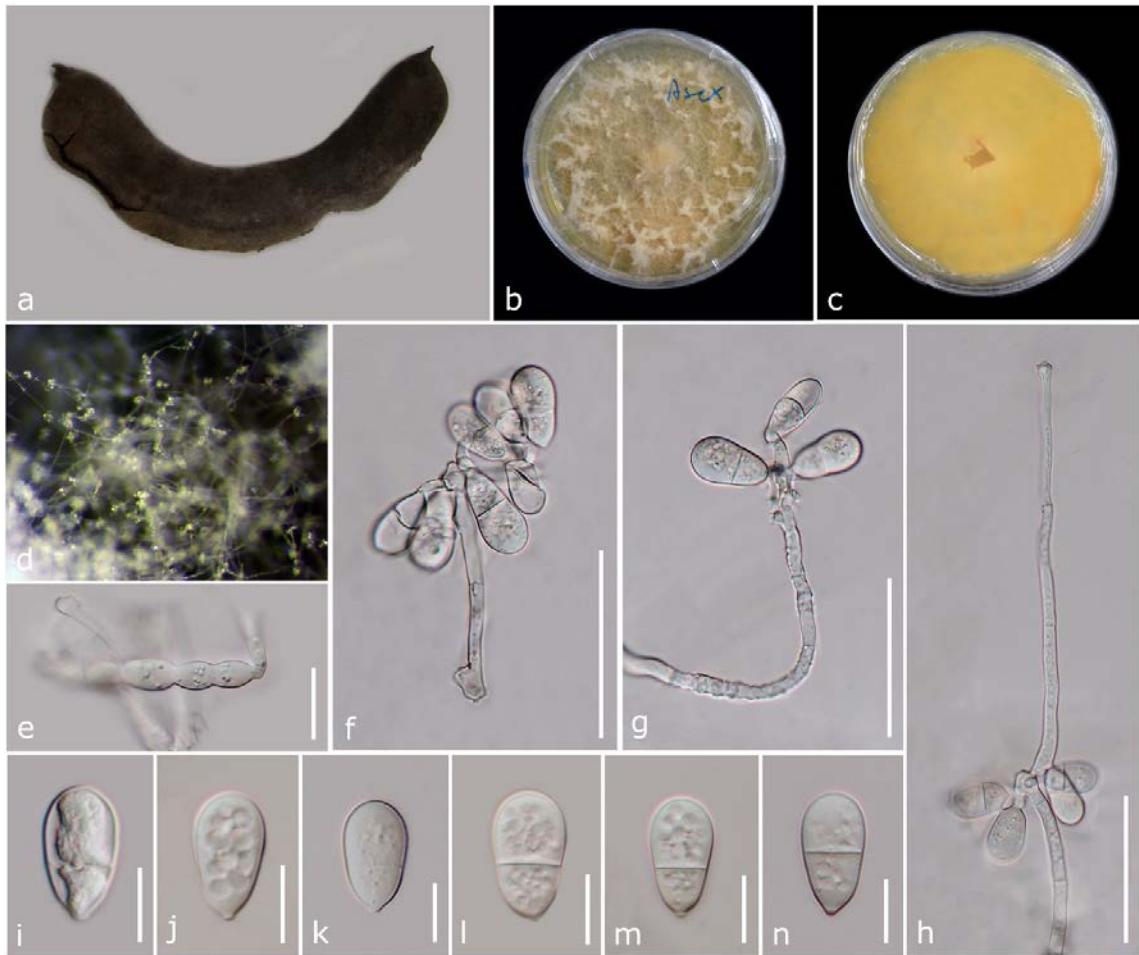

Figure 23 – *Trichothecium roseum* (MFLU 18-0624). a Herbarium material. b, c Sprouting colony on MEA. d Conidiomata on MEA. e Chlamydospores. f–h Conidiophores with conidia. i–n Conidia. Scale bars: e–h = 20 µm, i–n = 10 µm.

Culture characteristics – Colonies on PDA reach 3–4.5 cm diameter within 7 days at 25°C, circular, flat, smooth, edges crenate, zonate, whitish above, reddish at the center, reverse white.

Material examined – THAILAND, Phayao Province, decaying pods of *Cassia fistula* (Fabaceae) on the ground, R.H. Perera, 4 August 2017, PH-CAS 05 (MFLU 18-2751, holotype), ex-type living culture MFLUCC 18-0573.

GenBank numbers – ITS: MT215495, LSU: MT215546, RPB2: MT212197, TEF1: MT212205.

Notes – In the phylogenetic tree, *Fusarium cassiae* is closely related to *F. stilboides* (NRRL 20429) with low support (70% ML, 0.99 BIPP; Fig. 24). A comparison of RPB2 gene region of new fungus and *F. stilboides* (NRRL 20429) indicates 53 (5.9%) different nucleotides. *F. cassiae* also can be discriminated from *F. stilboides* in having variously shaped, (0–)1-septate ascospores vs. elliptical, 1–3 septate ascospores in *F. stilboides* (Booth 1971). The NCBI megablast search of ITS and TEF1 sequences show 99% similarity (476/477) with *F. lateritium* (CF6), and 97% similarity (659/682) with *F. lateritium* (YT2-7), respectively. However, the highest similarity (93%, 801/858) obtained in the megablast search of RPB2 sequences is with *F. lateritium* strain (NRRL 13622). We therefore recognize *F. cassiae* as a novel species.

Fusarium magnoliae-champaca R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 26

Index Fungorum number: IF556920; Facesoffungi number: FoF07758

Etymology – Name reflects the host plant *Magnolia champaca*.

Holotype – MFLU 18-2736

Saprobic on dried fruits of *Magnolia champaca*. Sexual morph: Ascomata 75–215 µm high × 70–210 µm diam. ($\bar{x} = 147 \times 143$ µm, n = 10), superficial, solitary to gregarious, blue-black to dark purple, subglobose to ampulliform, or obpyriform, collapsing laterally when dry. *Ostioles* periphysate. *Peridium* 30–40 µm wide, composed of two layers, inner 3–5 layers, comprising hyaline cells of *textura angularis*, outer 3–5 layers, comprising brown to dark purple, thick-walled cells of *textura angularis*. *Hamathecium* comprising hyaline, distinctly septate catenophyses, each cell 12.7–17.5 µm long × 14.2–22.5 µm wide. *Asci* (70–)90–100(–109) × (7–)9–13(–16) µm ($\bar{x} = 96.5 \times 11$ µm, n = 40), 8-spored, unitunicate, clavate, with short pedicel, slightly rounded to truncate at the apex. *Ascospores* (8–)16–20(–25) × (4.5–)6–7.5(–9) µm ($\bar{x} = 18 \times 6.6$ µm, n = 165), 1–2-seriate, pale brown, varied in shape, ellipsoidal to oblong, or subglobose to obovoid, or fusiform, with both ends rounded, (0–)1-septate, not constricted at the septum, smooth-walled. Asexual morph: Undetermined.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University garden, on ground, dried fruits of *Magnolia champaca* (L.) Baill. ex Pierre, (Magnoliaceae), 7 August 2017, S. Boonmee, Fruit 1 (MFLU 18-2736, holotype), ex-type living culture MFLUCC 18-0580.

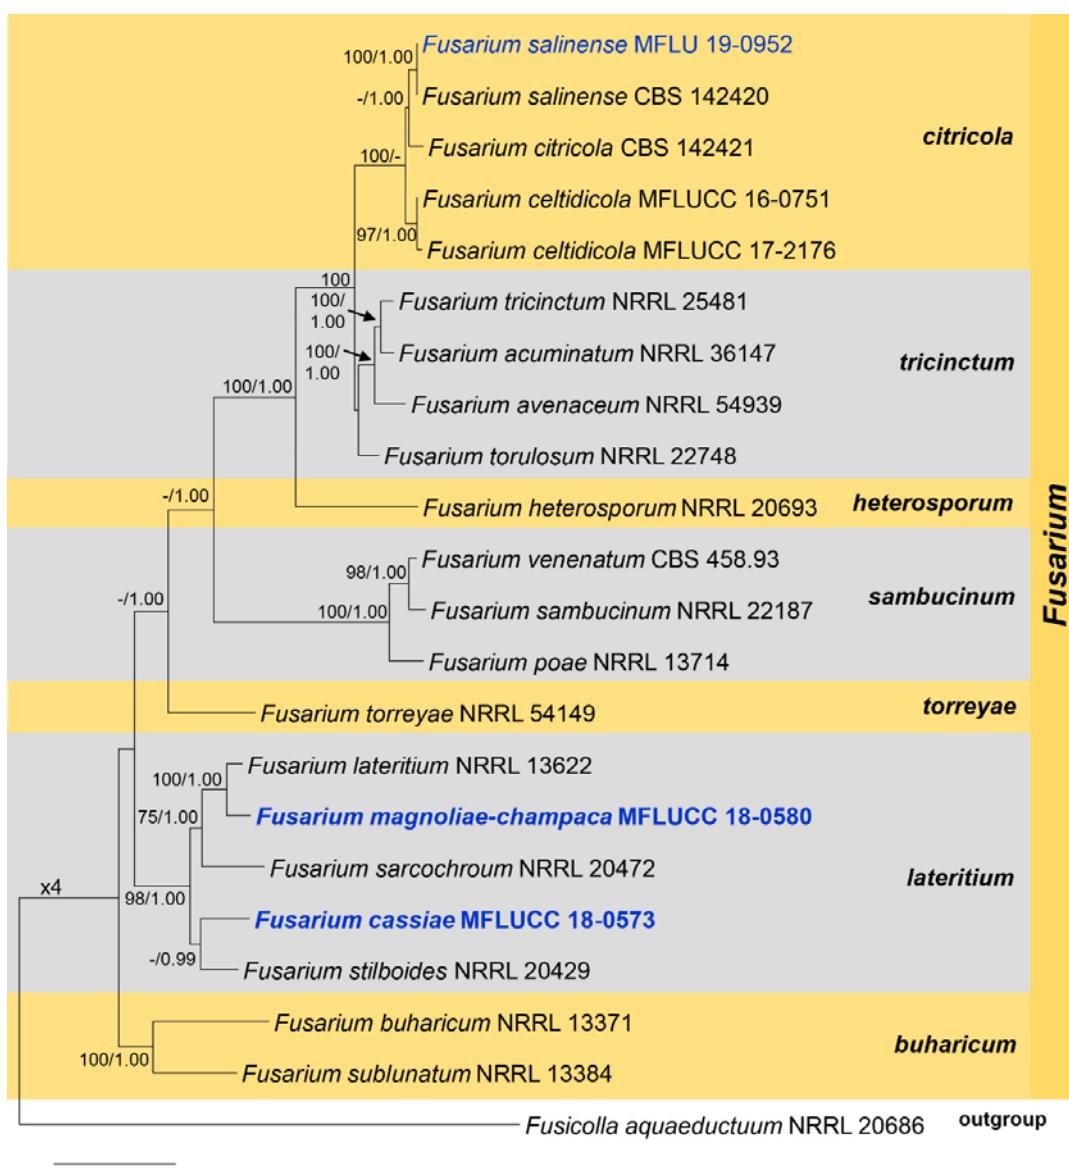

Figure 24 – Phylogram generated from RAxML analysis based on combined RPB2 and RPB1 sequence data of selected *Fusarium* isolates. Sequences from twenty-two taxa, which comprise

3349 characters including gaps, are included in the analyses. The tree was rooted to *Fusicolla aquaeductuum* (NRRL 20696). The scale bar indicates 0.08 nucleotide changes per site.

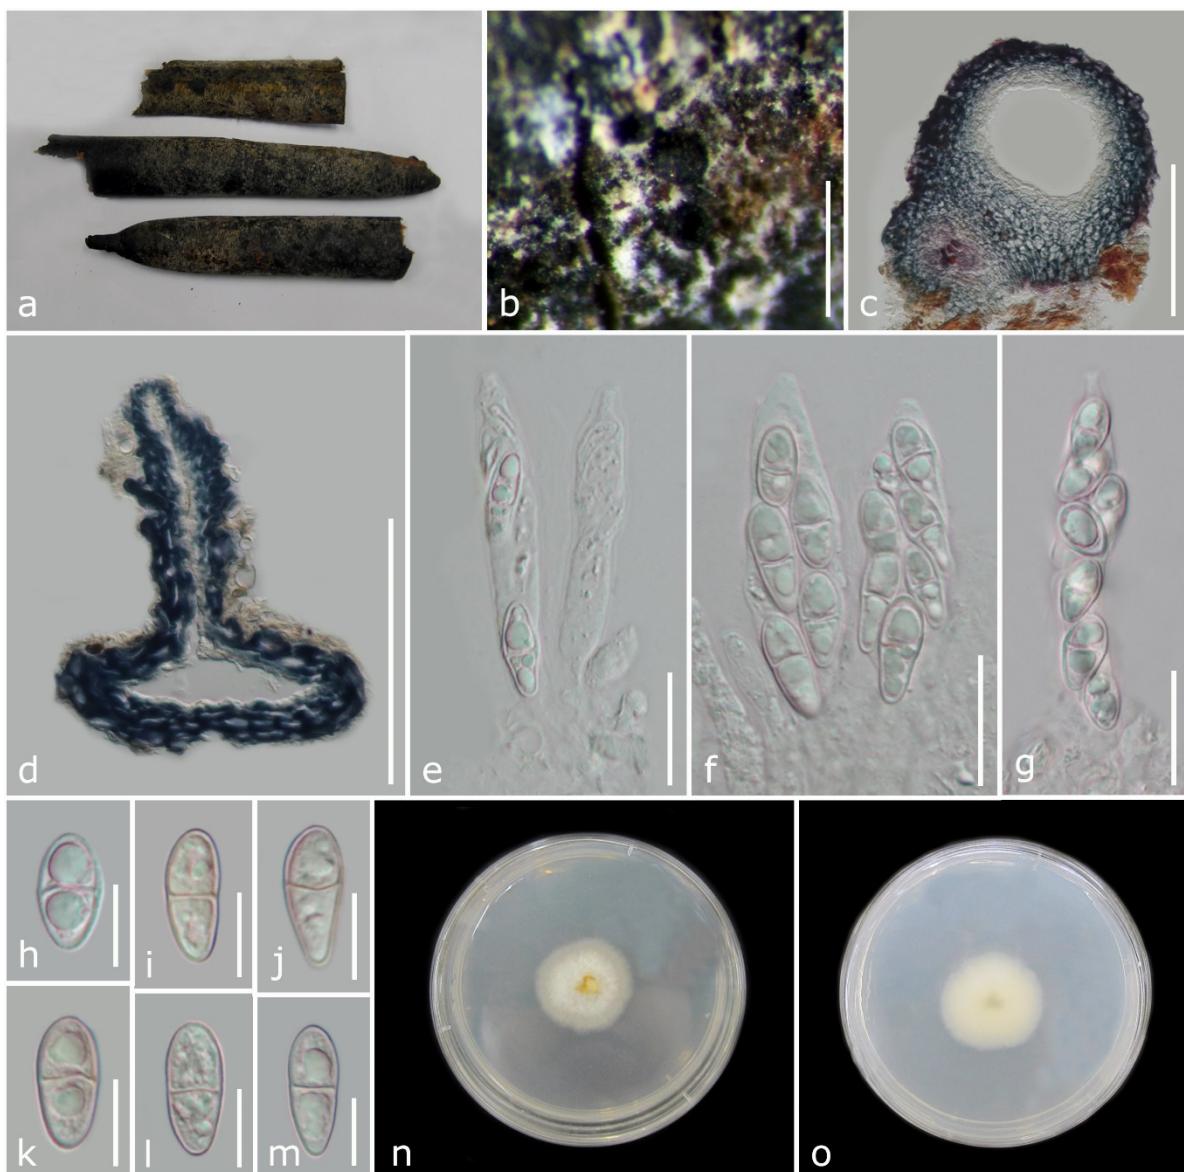

Figure 25 – *Fusarium cassiae* (MFLU 18-2751, holotype). a Herbarium material. b Ascomata on host. c, d Section of ascoma (d laterally collapsed). e–g Ascii. h–m Ascospores. n, o Colony on PDA. Scale bars: b = 500 µm, c = 100 µm, e–g = 20 µm, h–m = 10 µm.

GenBank numbers – ITS: MT215496, LSU: MT215547, RPB2: MT212198.

Culture characteristics – Ascospores germinated on PDA within 12 hours. Colonies on PDA reaching 15–17 mm diameter after 7 days at 28°C, colonies circular, medium dense, flat or effuse, with entire margin, white, becoming yellowish with time, reverse pale yellow.

Notes – In the phylogenetic analysis *Fusarium magnoliae-champaca* (MFLUCC 18-0580) clusters with *F. lateritium* strain (NRRL 13622) with high statistical support (100% MLBT, 1.00 BIPP; Fig. 24). A comparison of RPB2 gene region of the new fungus and *F. lateritium* (NRRL 13622) indicates 27 (3.1%) different nucleotides. *Fusarium magnoliae-champaca* also can be delineated from *F. lateritium* in having (0–)1 septate ascospores vs. 1–3 septate ascospores and larger asci 90–100 × 9–13 vs. 65–80 × 8–11 µm (Booth 1971).

Figure 26 – *Fusarium magnoliae-champaca* (MFLU 18-2736, holotype). a Herbarium material. b Ascomata on host. c, d Section of ascomata. e Periphyses. f–h Ascii. i–o Ascospores. p Germinating ascospore. q, r Colony on PDA. Scale bars: b = 200 µm, c, d = 100 µm, e–h = 20 µm, i–o = 10 µm, p = 20 µm.

Fusarium salinense Sand.-Den., Guarnaccia & Polizzi, in Sandoval-Denis, Guarnaccia, Polizzi & Crous, Persoonia 40: 15 (2017)

Fig. 27

Facesoffungi number: FoF07759

On dead samaras of *Fraxinus angustifolia*. Sexual morph: Undetermined. Asexual morph: *Colonies* on the host appearing as pale orange coloured masses. *Conidiomata* sporodochial, pale orange coloured. *Conidiophores* 33–48 × 5–6.6 µm, densely and irregularly branched, bi- or tri-verticillately, bearing 1–2 terminal phialides, hyaline, smooth-walled. *Phialides* 7.3–12.1 × 2.9–3.6 µm, subulate to subcylindrical, with a minute apical collarette, hyaline, smooth- and thin-walled. *Conidia* 21–42 × 3.4–4.5 µm ($\bar{x} = 40 \times 3.7$ µm, n = 20), (1–)3–4-septate, falcate, slender, curved, curvature more prominent in the upper part of the conidium, slightly tapering towards the basal end, with a foot-like basal cell, hyaline, thin- and smooth-walled.

Material examined – ITALY, Forlì-Cesena Province, Collina – Forlì, dead aerial samaras of *Fraxinus angustifolia* Vahl (Oleaceae), Erio Camporesi, 22 January 2015, IT 2345 (MFLU 19-0952).

GenBank numbers – LSU: MT215548, RPB2: MT212199, TUB2: MT212211.

Notes – Since single spore isolation was unsuccessful, DNA was isolated directly from the fruiting bodies. In the phylogenetic analysis the new isolate (MFLU 19-0952) clusters with the ex-type strain of *Fusarium salinense* (CBS 142420) with high statistical support (100% MLBT, 1.00 BIPP; Fig. 24). The morphology of the new collection is similar to the holotype of *F. salinense* (Sandoval-Denis et al. 2017). However, microconidia, obtained in the culture in holotype of *F. salinense*, were not observed in our collection. The DNA sequences of new strain (MFLU 19-0952) and *F. salinense* are similar. Hence, we identify our collection as *Fusarium salinense* with a new geographical record and new host for the fungus.

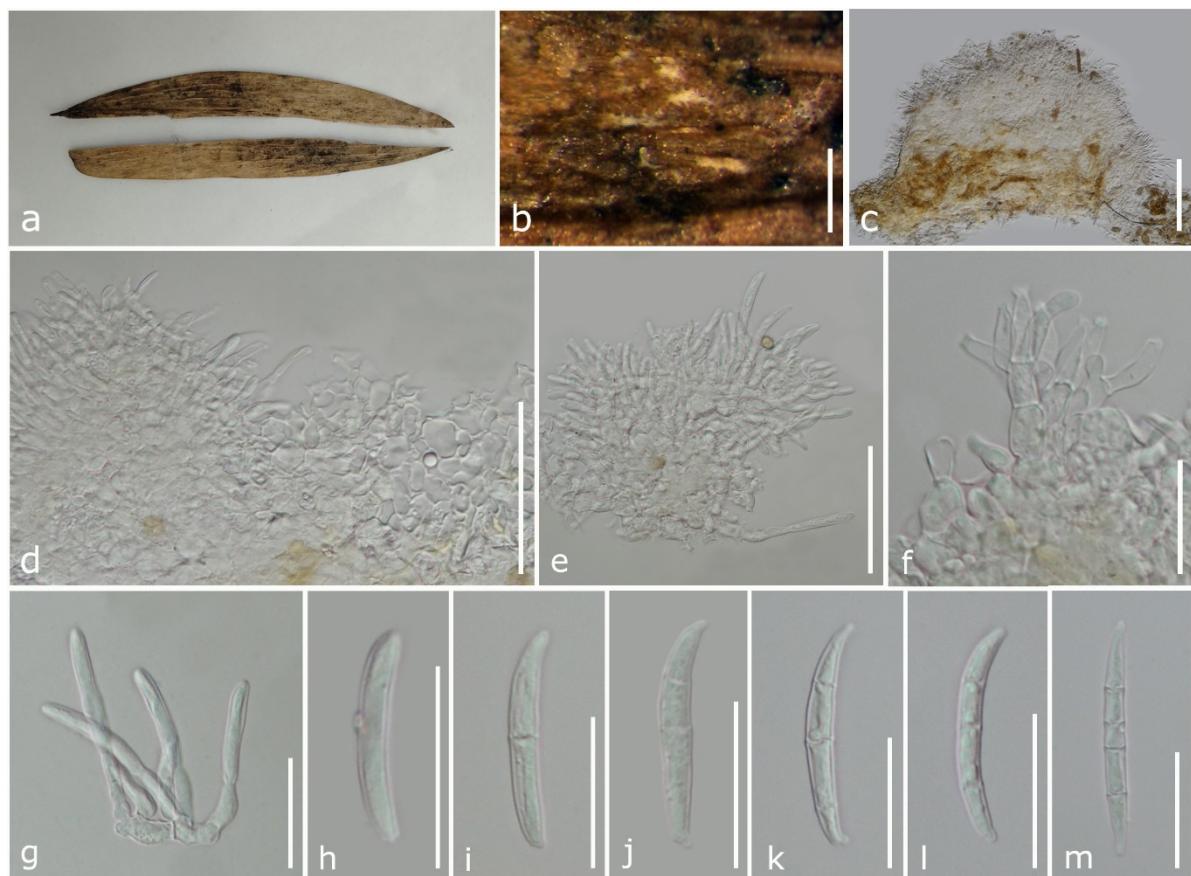

Figure 27 – *Fusarium salinense* (MFLU 19-0952). a Herbarium material. b Conidiomata on the host. c Conidioma mounted in water. d–g Conidiophores with conidia. h–m Conidia. Scale bars: b, c = 100 µm, d, e = 50 µm, f–m = 20 µm.

Fusarium sp.

Fig. 28

Saprobic on decaying seed pods of *Delonix regia*. Sexual morph: Ascomata 75–215 µm high × 70–210 µm diam. ($\bar{x} = 147 \times 143$ µm, n = 7), superficial, solitary to gregarious, blue-black to dark purple, subglobose to ampulliform, or obpyriform, collapsing laterally when dry. Ostioles slightly papillate, periphysate. Peridium 30–40 µm wide, composed of two layers, inner 3–5 layers, comprising hyaline cells of *textura angularis*, outer 3–5 layers, comprising brown to dark purple, thick-walled cells of *textura angularis*. Hamathecium comprising hyaline, distinctly septate catenophyses, each cell 12.7–17.5 µm long × 14.2–22.5 µm wide. Ascii (70–)90–100(–109) × (7–)9–13(–16) µm ($\bar{x} = 89 \times 11$ µm, n = 40), 6–8-spored, unitunicate, clavate, with a short pedicel, truncate at the apex, apical ring J-. Ascospores (8–)16–20(–25) × (4.5–)6–7.5(–9) µm ($\bar{x} = 18 \times$

6.6 μm , $n = 165$), overlapping 1–2-seriate, varied in shape, ellipsoidal to oblong, or subglobose to obovoid, or fusiform, with both ends rounded, 1-septate, slightly constricted at the septum, hyaline, smooth-walled. Asexual morph: Undetermined.

Material examined – THAILAND, Chiang Mai Province, on decaying seed pods of *Delonix regia* (Fabaceae), 6 January 2015, R.H. Perera, M-9 (MFLU 16-1075).

GenBank numbers – LSU: MT396166, SSU: MT396180, TUB2: MT415235.

Notes – We were unable to obtain cultures of this fungus using single spore isolation. DNA was extracted from the fruiting bodies. Fungal morphology of this fungus resembles *Fusarium*. Only ITS and LSU sequences are available.

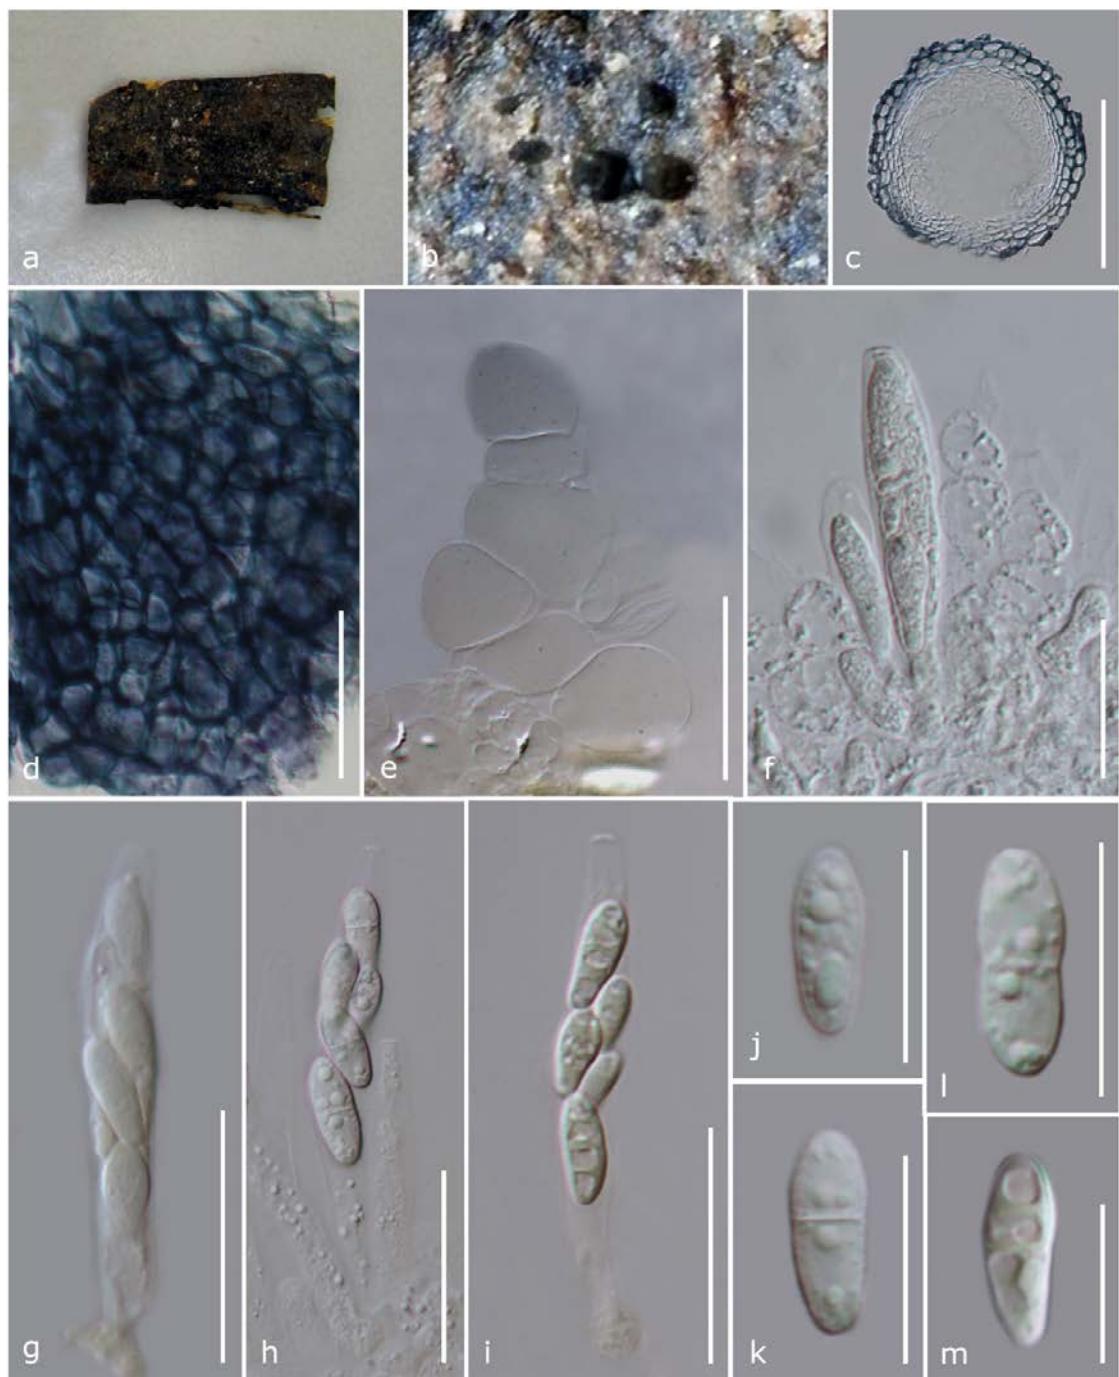

Figure 28 – *Fusarium* sp. (MFLU 16-1075). a Herbarium material. b Appearance of ascomata on host substrate. c Cross section through ascoma. d Peridium in face view. e, f Catenophyses. g–i Asci (i in Melzer's reagent). j–m Ascospores. Scale bars: c = 100 μm , d–i = 20 μm , j–m = 10 μm .

Fusicolla Bonord.

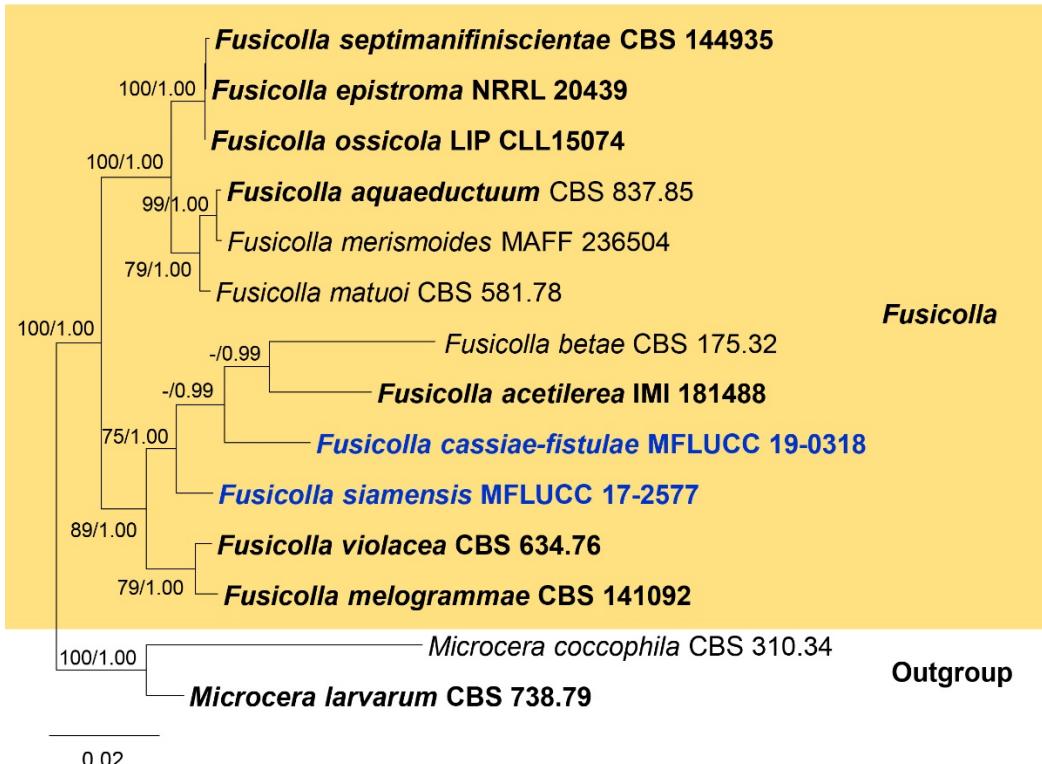

Figure 29 – Phylogram generated from RAxML analysis based on combined ITS and LSU sequence data of *Fusicolla* isolates. Sequences from fourteen taxa, which comprise 1337 characters including gaps, are included in the analyses. The tree was rooted to *Microcera larvarum* (CBS 738.79) and *M. coccophila* (CBS 310.34). The scale bar indicates 0.02 nucleotide changes per site.

Fusicolla cassiae-fistulae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 30

Index Fungorum number: IF556858; Facesoffungi number: FoF07760

Etymology – Name derived from the host plant *Cassia fistula*.

Holotype – MFLU 18-2753

Saprobic on decaying wood and seed pods of *Cassia fistula*. Sexual morph: Ascomata 150–180 µm high, 130–182 µm diam. ($\bar{x} = 173 \times 157$ µm, n = 10), perithecial, stroma erumpent, scattered or in small groups of 3–8, globose to pyriform sometimes collapsing when dry, yellow, pale yellow to pale orange, not changing colour in 5% KOH, smooth walled. Ascomatal surface cells forming a *textura angularis* in face view, with a broadly conical, rounded ostiolar neck 40–55 µm high, 70–85 µm diam. at base. Ostiole periphysate. Peridium 14–30 µm wide, two strata: outer region composed of 3–4 layers of hyaline to pale brown, thick-walled cells of *textura angularis* to *textura globosa*; inner region composed of 2–3 layers of hyaline cells of *textura angularis*. Ascii 53–65 × 5.8–8.2 µm ($\bar{x} = 57 \times 6.7$ µm, n = 20), 8-spored, unitunicate, cylindrical to narrowly clavate, short pedicellate, apex flat, apical ring J-, lying without paraphyses. Ascospores 6.9–10.2 × 3.6–4 µm ($\bar{x} = 8.8 \times 3.8$ µm, n = 35), uniseriate, 1-septate, not constricted at the septum, ellipsoidal, rounded at ends, equilateral or inequilateral, hyaline to very pale brown, thick-walled, smooth and slightly verrucose when mature. Asexual morph: Undetermined.

Culture characteristics – Colonies on PDA at 25°C attaining 15–18 mm in 7 days. Aerial mycelium rare to absent, white to cream in centre, white at margin, margin entire, reverse pale luteous.

Material examined – THAILAND, Phayao Province, on decaying seed pods of *Cassia fistula* (Fabaceae), 4 August 2017, R.H. Perera, PH-CAS 08 (MFLU 18-2753, holotype), ex-type living culture MFLUCC 19-0318.

GenBank numbers – ITS: MT215497, LSU: MT215549.

Notes – Based on phylogenetic inference of the LSU and ITS sequences *Fusicolla cassiae-fistulae* forms an unsupported lineage within genus *Fusicolla* (Fig. 29). *Fusicolla cassiae-fistulae* resembles *F. melogrammae* and *F. ossicola* in having yellow, pale yellow to pale orange ascomata (Crous et al. 2016, Lechat & Rossman 2017). However, *F. cassiae-fistulae* can be easily distinguished from *F. melogrammae* and *F. ossicola* by having smaller ascomata, ascii and ascospores (Table 1). *Fusicolla cassiae-fistulae* and ex-type of *F. melogrammae* (CBS 141092) showed 15 (2.9%, 2 gaps) different nucleotides in the ITS region and, 32 (3.8%, 0 gaps) in LSU sequences. Furthermore, ITS region of *F. cassiae-fistulae* and ex-type of *F. ossicola* (LIP CLL15074) showed 24 (4.7%, 1 gap) different nucleotides and 45 (5.3%, 3 gaps) in LSU sequences. Hence, we introduce *F. cassiae-fistulae* as a novel species.

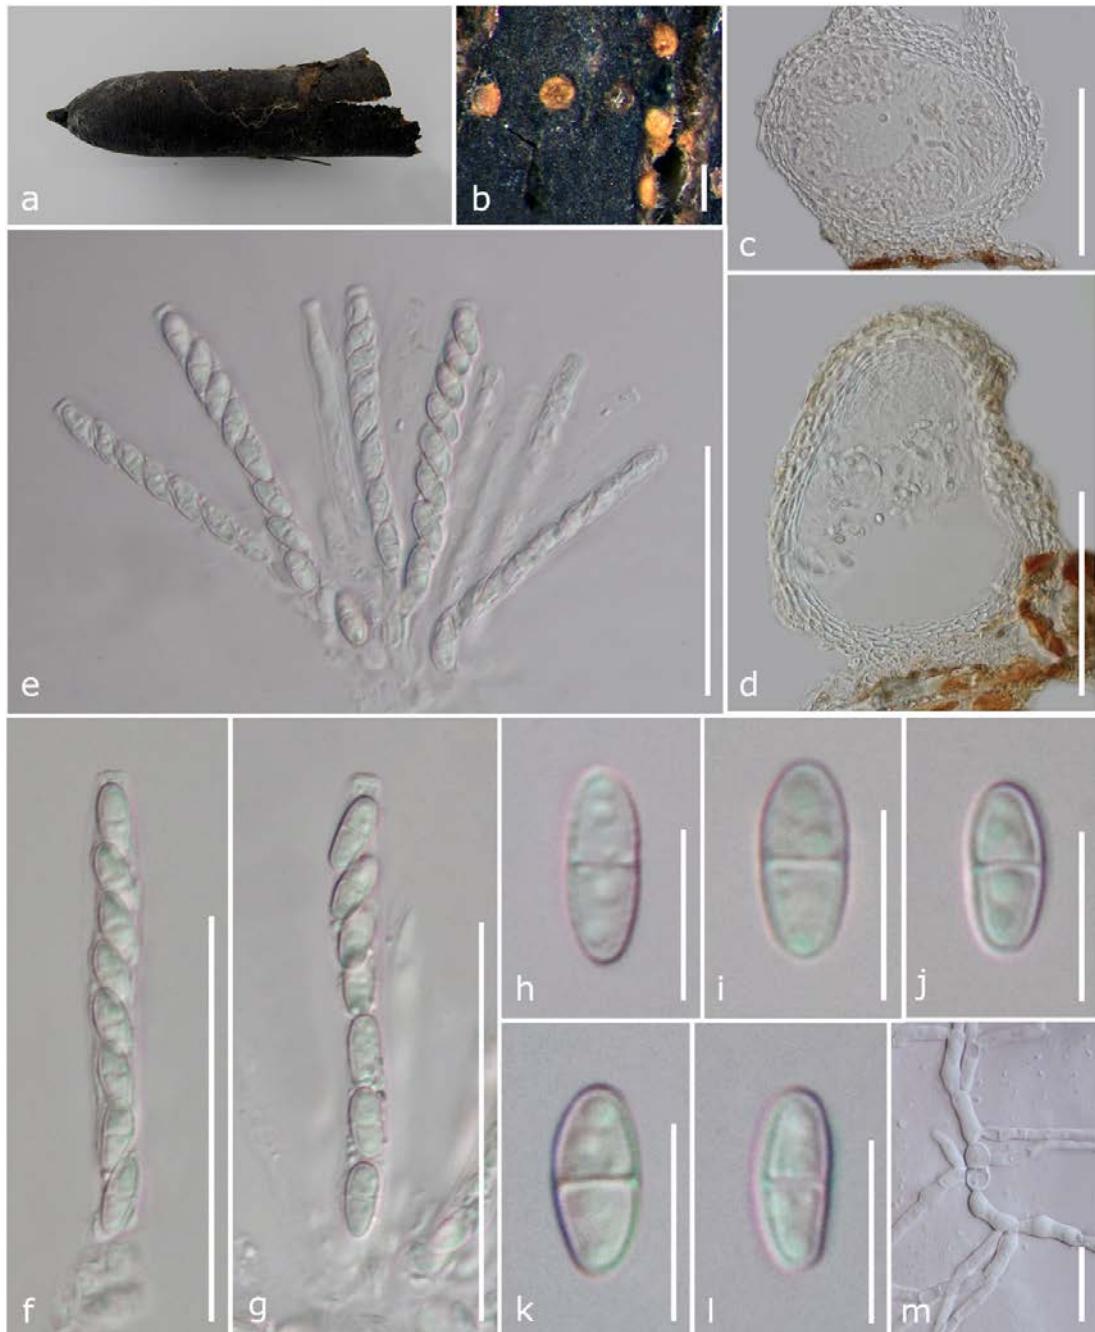

Figure 30 – *Fusicolla cassiae-fistulae* (MFLU 18-2753, holotype). a Herbarium material. b Ascomata on host. c, d Section of ascomata. e–g Ascii. h–l Ascospores. m Germinating ascospore. Scale bars: b = 200 µm, c, d = 100 µm, e–g = 50 µm, h–l = 10 µm, m = 20 µm.

Fusicolla siamensis R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 31

Index Fungorum number: IF556859; Facesoffungi number: FoF07761

Etymology – Name refers to the country Thailand, where the specimen was collected.

Holotype – MFLU 19-1385

Associated with dried seed pods of *Cassia fistula*. Sexual morph: Undetermined. Asexual morph: *Conidiomata* sporodochial, appearing as flat wart-like, orange masses on the host surface. *Conidiophores* 27–46 μm \times 3.7–5.1 μm ($n = 10$), monochasial, verticillate or penicillate, each branch terminating in one or two phialides, hyaline. *Phialides* 11.5–22.5 \times 3.1–5.1 μm ($\bar{x} = 14.8 \times 4.1 \mu\text{m}$, $n = 10$), monophialidic, cylindrical to subulate, hyaline, with periclinal thickening at the unflared tip. *Microconidia* absent. *Macroconidia* 50.5–70.5 \times 5.1–8 μm ($\bar{x} = 58.2 \times 6.8 \mu\text{m}$, $n = 25$), 3–5(7)-septate, not constricted at the septa, sub-falcate, straight to curved, narrowing towards the ends, apical cell with a flat or sometimes rounded tip, basal cell slightly hooked with a more or less pointed end, hyaline, smooth-walled.

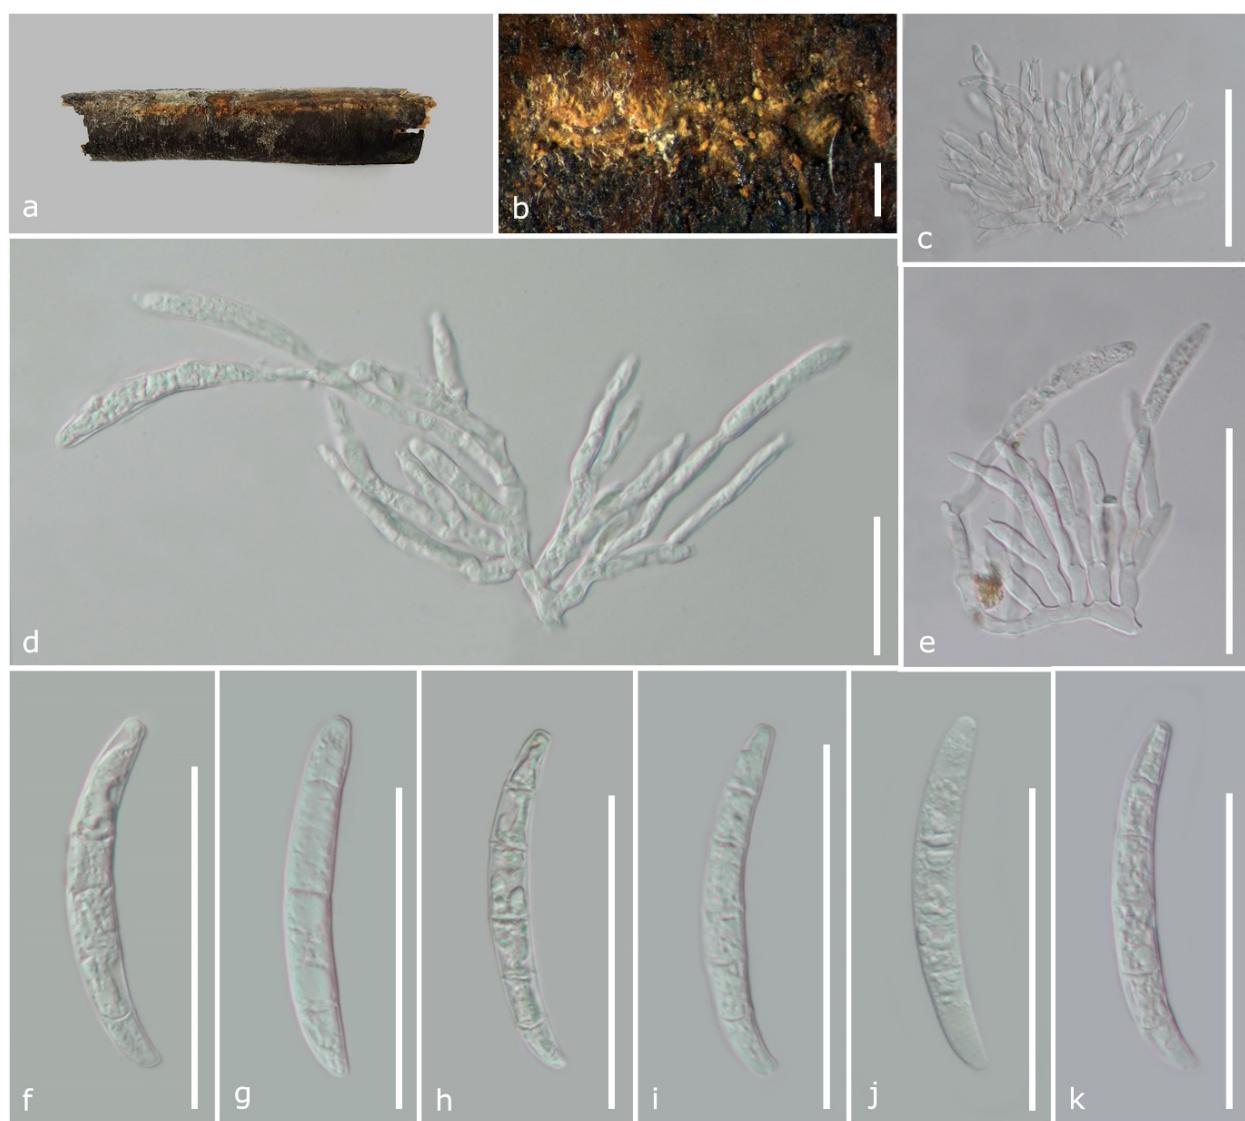

Figure 31 – *Fusicolla siamensis* (MFLU 19-1385, holotype). a Herbarium material. b Sporodochia on host. c–e Conidiogenous apparatus. f–k Conidia. Scale bars: b = 500 μm , c = 50 μm , d = 20 μm , e–k = 50 μm .

Culture characteristics – Colonies on PDA at 25°C attaining 20–25 mm in 7 days. Aerial mycelium rare to absent, white to cream in centre, white at margin, reverse pale luteous, margin entire.

Material examined – THAILAND, Phayao Province, on decaying seed pods of *Cassia fistula* (Fabaceae), 4 August 2017, R.H. Perera, PH-CAS 07 (MFLU 19-1385, holotype), ex-type living culture MFLUCC 17-2577.

GenBank numbers – ITS: MT215498, LSU: MT215550.

Notes – Based on phylogenetic inference of LSU and ITS sequence data *Fusicolla siamensis* is closely related to *F. acetilerea* (Tubaki, C. Booth & T. Harada) Gräfenhan & Seifert, *F. betae* Bonord. and *F. cassiae-fistulae* (Fig. 29). However, *F. siamensis* produced 3–5(7)-septate macroconidia, with basal cell slightly hooked ($50.3\text{--}70.4 \times 5.1\text{--}8 \mu\text{m}$), which are larger than the 3(–4) septate conidia of *F. acetilerea* ($35\text{--}40 \times 3\text{--}3.5 \mu\text{m}$; Tubaki et al. 1976). The conidia of *F. betae* are not falcate and 2–3-septate (Gräfenhan et al. 2011).

Table 1 Morphological comparison of related *Fusicolla* species.

Species	Ascomatal size (μm)	Asc size (μm)	Ascospore size (μm)	Reference
<i>Fusicolla cassiae-fistulae</i>	$150\text{--}180 \times 130\text{--}182$	$53\text{--}65 \times 5.8\text{--}8.2$	$6.9\text{--}10.2 \times 3.6\text{--}4$	This study
<i>F. melogrammae</i>	$250\text{--}290 \times 220\text{--}250$	$70\text{--}80 \times 10\text{--}12$	$12\text{--}14 \times 4.5\text{--}5$	Crous et al. (2016)
<i>F. ossicola</i>	$250\text{--}300 \times 240\text{--}280$	$80\text{--}85 \times 8\text{--}11$	$10\text{--}12 \times 5\text{--}5.5$	Lechat & Rossman (2017)

Gliocladiopsis S.B. Saksena

Gliocladiopsis aquaticus Y.Z. Lu, R.H. Perera & K.D. Hyde, in Hyde et al., Mycosphere 9(2): 387 (2018) Fig. 33

Saprobic on seed pods of *Cassia fistula*. Sexual morph: Undetermined. Asexual morph: appearing as white masses on the substrate, becoming yellowish with age. *Conidiophores* $90\text{--}120 \times 5.1\text{--}6.5 \mu\text{m}$, penicillate, lacking stipe extensions and terminal vesicles, very pale brown. *Conidiogenous apparatus* with several series of hyaline to very pale brown branches; primary branches $22\text{--}27 \times 3.1\text{--}5.6 \mu\text{m}$, aseptate or 1-septate; secondary branches $14.5\text{--}25 \times 3\text{--}4.1 \mu\text{m}$, aseptate, hyaline; tertiary branches $9.1\text{--}15 \times 2.2\text{--}3.4 \mu\text{m}$, aseptate, hyaline. *Phialides* $7.5\text{--}13.1 \times 1.6\text{--}2.6 \mu\text{m}$ ($\bar{x} = 11 \times 2.1 \mu\text{m}$, $n = 30$), doliiiform to cymbiform to cylindrical, arranged in terminal whorls of 2–5 per branch, with periclinal thickening and minute collarettes, central phialide frequently extending above the rest. *Subverticillate conidiophores* absent. *Conidia* $13.4\text{--}20.6 \times 1.7\text{--}2.6 \mu\text{m}$ ($\bar{x} = 17.3 \times 2.2 \mu\text{m}$, $n = 30 \mu\text{m}$), cylindrical, hyaline, smooth with rounded ends, straight, 0–1-septate, lacking a visible abscission scar.

Culture characteristics – Conidia germinating on PDA within 8 hours. Colonies growing on PDA reaching 35 mm within 2 weeks at 28°C , circular, with flat to effuse surface, edge entire, aerial mycelium dense, pale brown from above and below.

Material examined – THAILAND, Phayao Province, on decaying seed pods of *Cassia fistula* (Fabaceae), 4 August 2017, R.H. Perera, PH-CAS 04 (MFLU 18-2750), living culture MFLUCC 19-0317.

GenBank numbers – ITS: MT215502, LSU: MT215552, HIS3: MT212195.

Notes – The new isolate (MFLUCC 19-0317) grouped with *Gliocladiopsis aquaticus* isolates collected from Thailand with high statistical support (Fig. 32). Our collection also shares similar morphology with *G. aquaticus* in having similar sporodochial morphology, forming phialides in 2–5 terminal whorls per branch and, similar conidiophores and conidial sizes (Hyde et al. 2018). Our isolate (MFLUCC 19-0317) and two species of *G. aquaticus* (MFLUCC 17-1811, MFLUCC 17-2028) showed 6 nucleotide differences (1.2%, 1 gap) in the HIS3 region, and ITS region was identical. TUB2 gene region of *G. aquaticus* (MFLUCC 19-0317) was not available for comparison. Based on the morphological similarities and phylogenetic analysis we identify our collection as *Gliocladiopsis aquaticus* and a new host record from *Cassia fistula*.

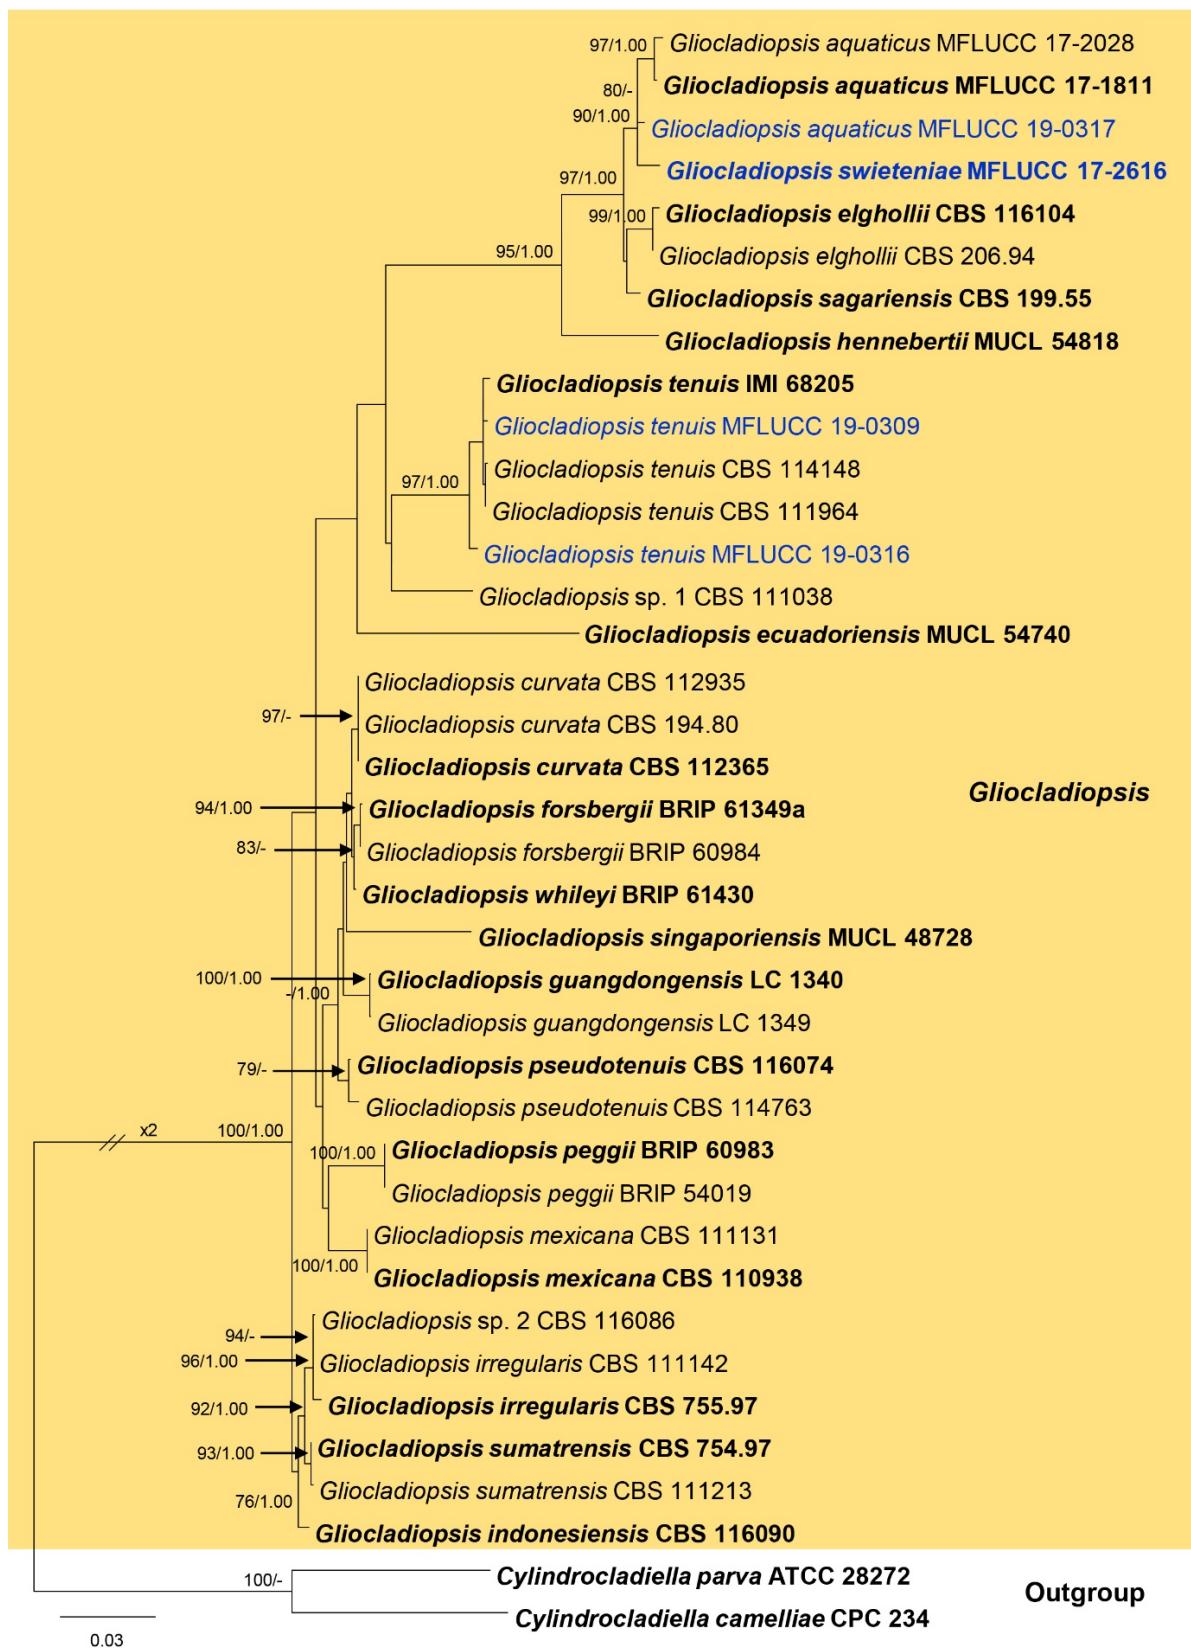

Figure 32 – Phylogram generated from RAxML analysis based on combined ITS, TUB2 and HIS3 sequence data of *Gliocladiopsis* isolates. Sequences from thirty-eight taxa, which comprise 1667 characters including gaps, are included in the analyses. The tree was rooted to *Cylindrocladiella parva* (ATCC 28272) and *C. camelliae* (CPS 234). The scale bar indicates 0.03 nucleotide changes per site.

Figure 33 – *Gliocladiopsis aquaticus* (MFLU 18-2750). a Herbarium material. b, c Conidiomata on the host. c–g Conidiophores with conidia. h Conidia. i Germinating conidium. Scale bars: d, e = 50 μm , f–i = 20 μm .

***Gliocladiopsis tenuis* (Bugnic.) Crous & M.J. Wingf., Mycol. Res. 97(4): 446 (1993)**

Fig. 34

On decaying fruits of palms and *Swietenia mahagoni*. Sexual morph: Undetermined. Asexual morph: Appearing as white masses on the substrate. *Conidiophores* penicillate, 80–105 \times 4.4–8.5 μm , septate, branched, hyaline, without stipe extensions and terminal vesicles. *Conidiogenous apparatus* with several series of hyaline branches; primary branches 15–26 \times 3.8–6 μm , aseptate; secondary branches 8.7–24.5 \times 1.9–5.2 μm , aseptate; tertiary branches 12.1–16.2 \times 2.5–4.1 μm , aseptate; quaternary branches absent. *Conidiogenous cells* phialidic. *Phialides* 10–14.7 \times 2.2–3.7 ($\bar{x} = 12.4 \times 2.8 \mu\text{m}$, $n = 25$), doliform to cymbiform to cylindrical, arranged in terminal whorls of 2–4 per branch, sometimes with a minute collarette, central phialide frequently extending above the rest. *Conidia* 11.4–18 \times 2.1–3.2 μm ($\bar{x} = 15.6 \times 2.5 \mu\text{m}$, $n = 35$), 1-septate, cylindrical, with rounded ends, straight, hyaline, smooth-walled, without appendages. *Chlamydospores* extensive, in clearly delimited chains. *Conidia* on MEA smaller, 9.4–14.2 \times 1.5–2.7 ($\bar{x} = 12 \times 2.3 \mu\text{m}$, $n = 35$).

Culture characteristics – Colonies growing on MEA, reaching 30 mm within 2 weeks at 28°C, sporulation after 8 weeks, circular, surface effused, edge entire, initially yellowish white, orange brown to golden brown with age, reverse brown, mycelium superficial and partially immersed, branched, septate, hyaline to orange-brown, smooth-walled.

Material examined – THAILAND, Chiang Rai Province, personal garden, on decaying fruits of palm tree, 18 August 2017, R.H. Perera, CR-F 12 (MFLU 18-2741), living culture MFLUCC 19-0309; *ibid.* Mae Fah Luang University Garden, on decaying fruits of *Swietenia mahagoni*

(Meliaceae), 6 September 2017, R.H. Perera, Maho 05 (MFLU 18-2771), living culture MFLUCC 19-0316.

GenBank numbers – ITS: MT215499, HIS3: MT212193, TEF1: MT212206, TUB2: MT212212 (MFLUCC 19-0309); ITS: MT215500, LSU: MT215551, TUB2: MT212213 (MFLUCC 19-0316)

Notes – Isolates MFLUCC 19-0309 and MFLUCC 19-0316 group with ex-type of *Gliocladiopsis tenuis* (IMI 68205) and other *G. tenuis* isolates. They were identified as *Gliocladiopsis tenuis* based on morphology and phylogenetic analysis (Fig. 32) (Crous & Wingfield 1993, Crous & Peeraly 1996). *Gliocladiopsis tenuis* MFLU 18-2771 is a new record on *Swietenia mahagoni*.

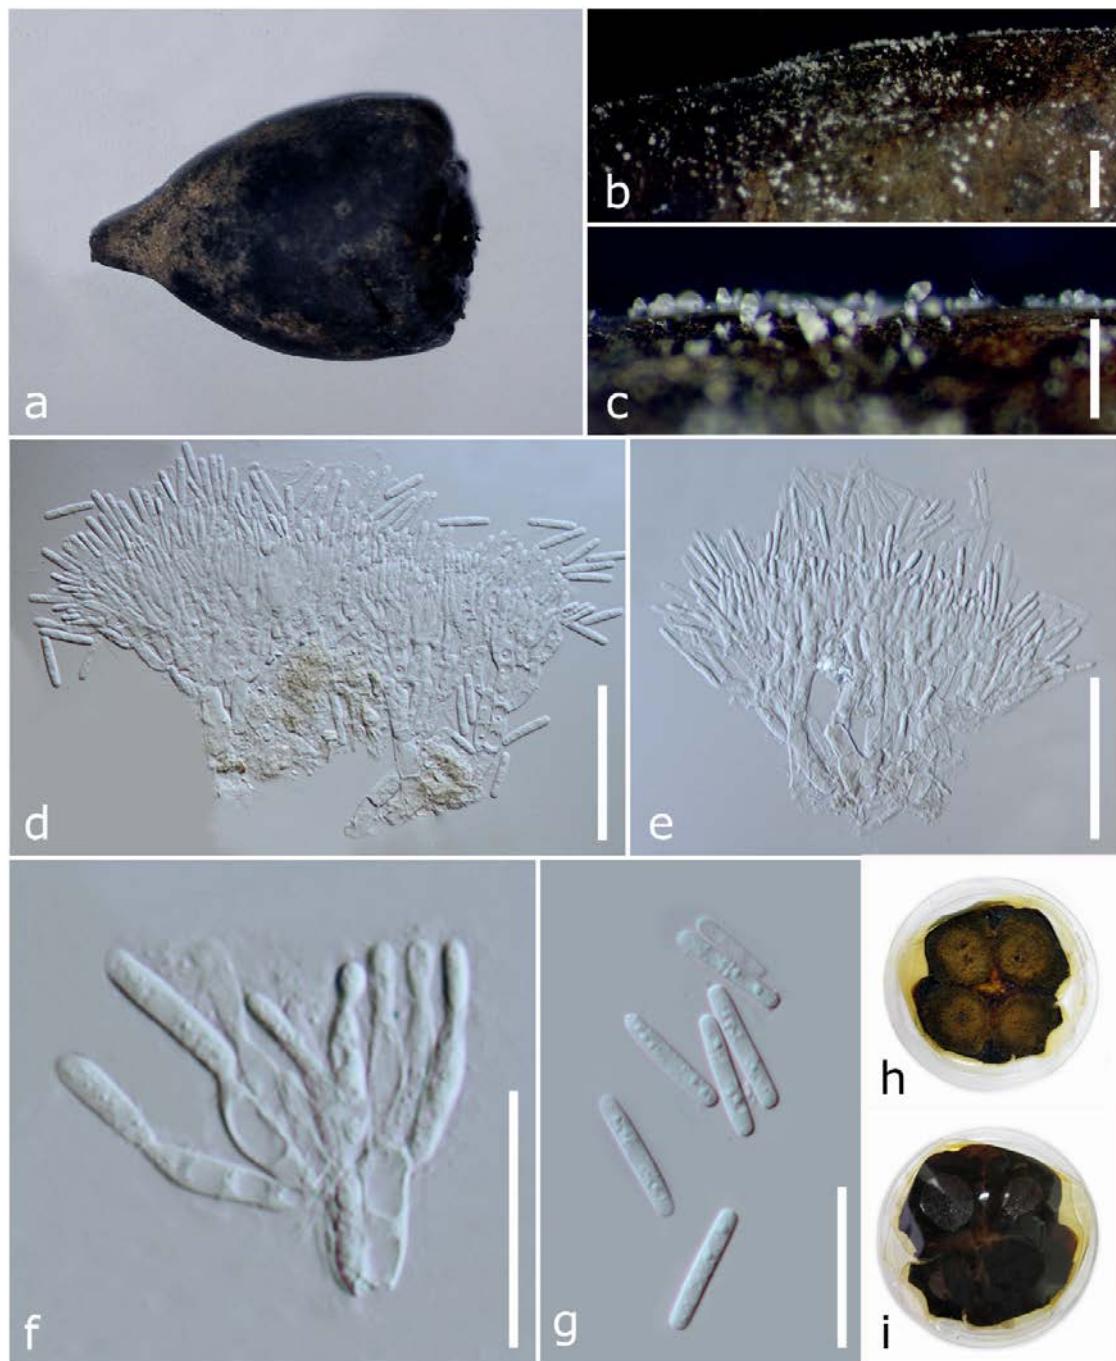

Figure 34 – *Gliocladiopsis tenuis* (MFLU 18-2741). a Herbarium material. b, c Conidiomata on the host. d–f Conidiophores with conidia. g Conidia. h, i Colony on MEA. Scale bars: b = 1 mm, c = 500 µm, d, e = 50 µm, f, g = 20 µm.

Gliocladiopsis swieteniae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 35

Index Fungorum number: IF556860; Facesoffungi number: FoF07762

Etymology – Named after the host genus *Swietenia*.

Holotype – MFLU 18-2767

Saprobic on decaying *Swietenia mahagoni* fruits. Sexual morph: Undetermined. Asexual morph: appearing as yellowish masses on the substrate. Conidiophores 70–105 × 5.2–7.6 µm, penicillate without stipe extensions and terminal vesicles, very pale brown. Conidiogenous apparatus with several series of hyaline to very pale brown branches: primary branches 16.7–32 × 4.5–7 µm, aseptate or 1-septate; secondary branches 11.2–20 × 2.7–5 µm, aseptate, hyaline; tertiary

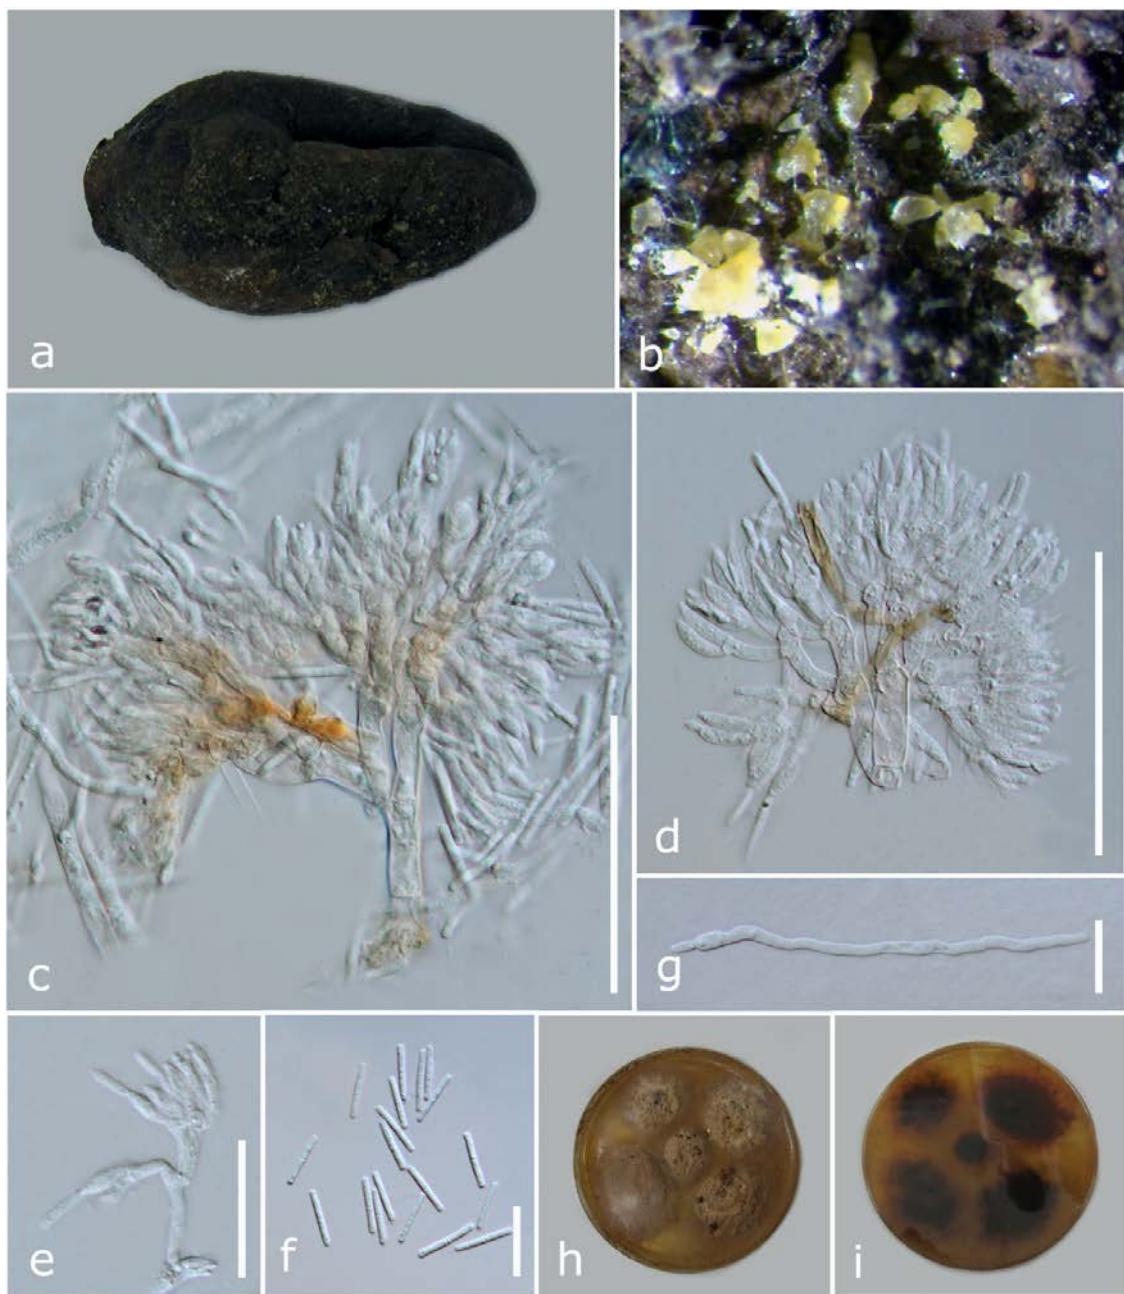

Figure 35 – *Gliocladiopsis swieteniae* (MFLU 18-2767, holotype). a Herbarium material. b Conidiomata on the host. c–e Conidiophores with conidia. f Conidia. g Germinating conidium. h, i Colony on MEA. Scale bars: c, d = 50 µm, e–g = 20 µm.

branches 10–14 × 2.3–3.8 µm, aseptate, hyaline; quaternary branches 8.5–13 × 1.7–2 µm, rare to absent, aseptate, hyaline. Phialides 10.6–17 × 1.9–3.8 µm, doliform to cymbiform, arranged in terminal whorls of 2–6 per branch, with periclinal thickening and minute collarettes. Subverticillate

conidiophores absent. *Conidia* (12.7–)14.4–17.9(–18.3) × 1.4–2 µm ($\bar{x} = 16.5 \times 1.8$, n = 40 µm), cylindrical, hyaline, smooth, with rounded ends, straight, 1-septate, lacking a visible abscission scar.

Culture characteristics – Conidia germinating on PDA within 8 hours. Colonies growing on PDA reaching 30 mm within 2 weeks at 28°C, circular, with effuse surface, edge entire, aerial mycelium dense, initially white, becoming saiyal brown to sepia (reverse).

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University Garden, on decaying fruits of *Swietenia mahagoni* (Meliaceae), 20 September 17, R.H. Perera, Maho 08 (MFLU 18-2767, holotype), ex-type living culture MFLUCC 17-2616.

GenBank numbers – ITS: MT215501, HIS3: MT212194, TUB2: MT212214.

Notes – *Gliocladiopsis swieteniae* is sister to *Gliocladiopsis aquaticus* isolates (MFLUCC 17-1811, MFLUCC 17-2028 and MFLUCC 19-0317) with high support (90% MLBT, 1.0 BIPP; Fig. 32). *Gliocladiopsis swieteniae* and *G. aquaticus* also share similar morphology in having yellowish sporodochia and similar conidiophore size (Hyde et al. 2018). However, *G. swieteniae* differs from *G. aquaticus* in having smaller conidia (14.4–17.9 × 1.4–2 vs. 16.5–21 × 2–3 µm) (Hyde et al. 2018). A comparison of the ITS, TUB2 and HIS3 gene regions of *G. swieteniae* and ex-type of *G. aquaticus* (MFLUCC 17-1811) reveals 1 (0.6%, 1 gap), 8 (1.3%, 0 gaps) and 13 (2.8%, 1 gap) nucleotide differences, respectively. *G. swieteniae* and *G. aquaticus* (MFLUCC 17-2028) showed 3 nucleotides differences (0.6%, 2 gaps) in the ITS region, 10 different nucleotides (1.6%, 0 gaps) in the TUB2 region and, 13 different nucleotides (2.8%, 1 gap) in the HIS3 region. *Gliocladiopsis swieteniae* and *G. aquaticus* (MFLUCC 19-0317) showed 2 nucleotides differences (0.4%, 0 gaps) in the ITS region, and 10 different nucleotides in the HIS3 (2.2%, 1 gap) region. TUB2 gene region of *G. aquaticus* (MFLUCC 19-0317) was not available for comparison. Even though morphological differences are not strongly supported, we introduce *G. swieteniae* as a novel species considering nucleotide differences in ITS, TUB2 and HIS3 gene regions.

***Macronectria* Salgado & P. Chaverri**

***Macronectria jungneri* (Henn.) Salgado & P. Chaverri**, in Salgado-Salazar et al., Fungal Diversity 80: 448 (2016)

Fig. 37

Facesoffungi number: FoF07763

Saprobic on various plant substrates including fruits. Sexual morph: *Ascomata* 380–533 µm diam (n = 10), perithecial, gregarious in groups of many, superficial on an erumpent stroma, subglobose to pyriform, sometimes elongated and flask shaped, ostiole papillate, 128–280 µm wide, constricted below apex, not collapsing when dry, orange to sienna, with papilla same colour as perithecium, becoming dark black red when aged, red in 5% KOH, surface smooth. *Peridium* 20–40 µm, of two intergrading regions; outer region of intertwined hyphae with cells slightly elliptical, inner region of flattened fusoids cells. *Asci* 75–96 × 13–27 µm ($\bar{x} = 83 \times 21.5$ µm, n = 15), 8-spored, unitunicate, clavate, thin-walled, short pedicellate, apex simple. *Ascospores* 26–31 × 8.7–11 µm ($\bar{x} = 29.5 \times 9.8$ µm, n = 25), bi-seriate, fusiform, sometimes inequilateral, 1-septate, not constricted at septum, hyaline, striate. Asexual morph: See Salgado-Salazar et al. (2016).

Culture characteristics – Ascospores germinating on PDA within 12 hours. Colonies growing on PDA, reaching 2.6 cm in 7 days at 25°C, surface effused, smooth, margin entire to undulate, aerial mycelium rare, initially white, becoming yellowish orange, reverse yellowish, organge at centre.

Material examined – Thailand, Chiang Rai Province, Mae Fah Luang university garden, on decaying fruits of *Swietenia mahagoni* (Meliaceae), 4 August 2014, R.H. Perera, RHP 09 (MFLU 16-1050), living culture MFLUCC 14-0568.

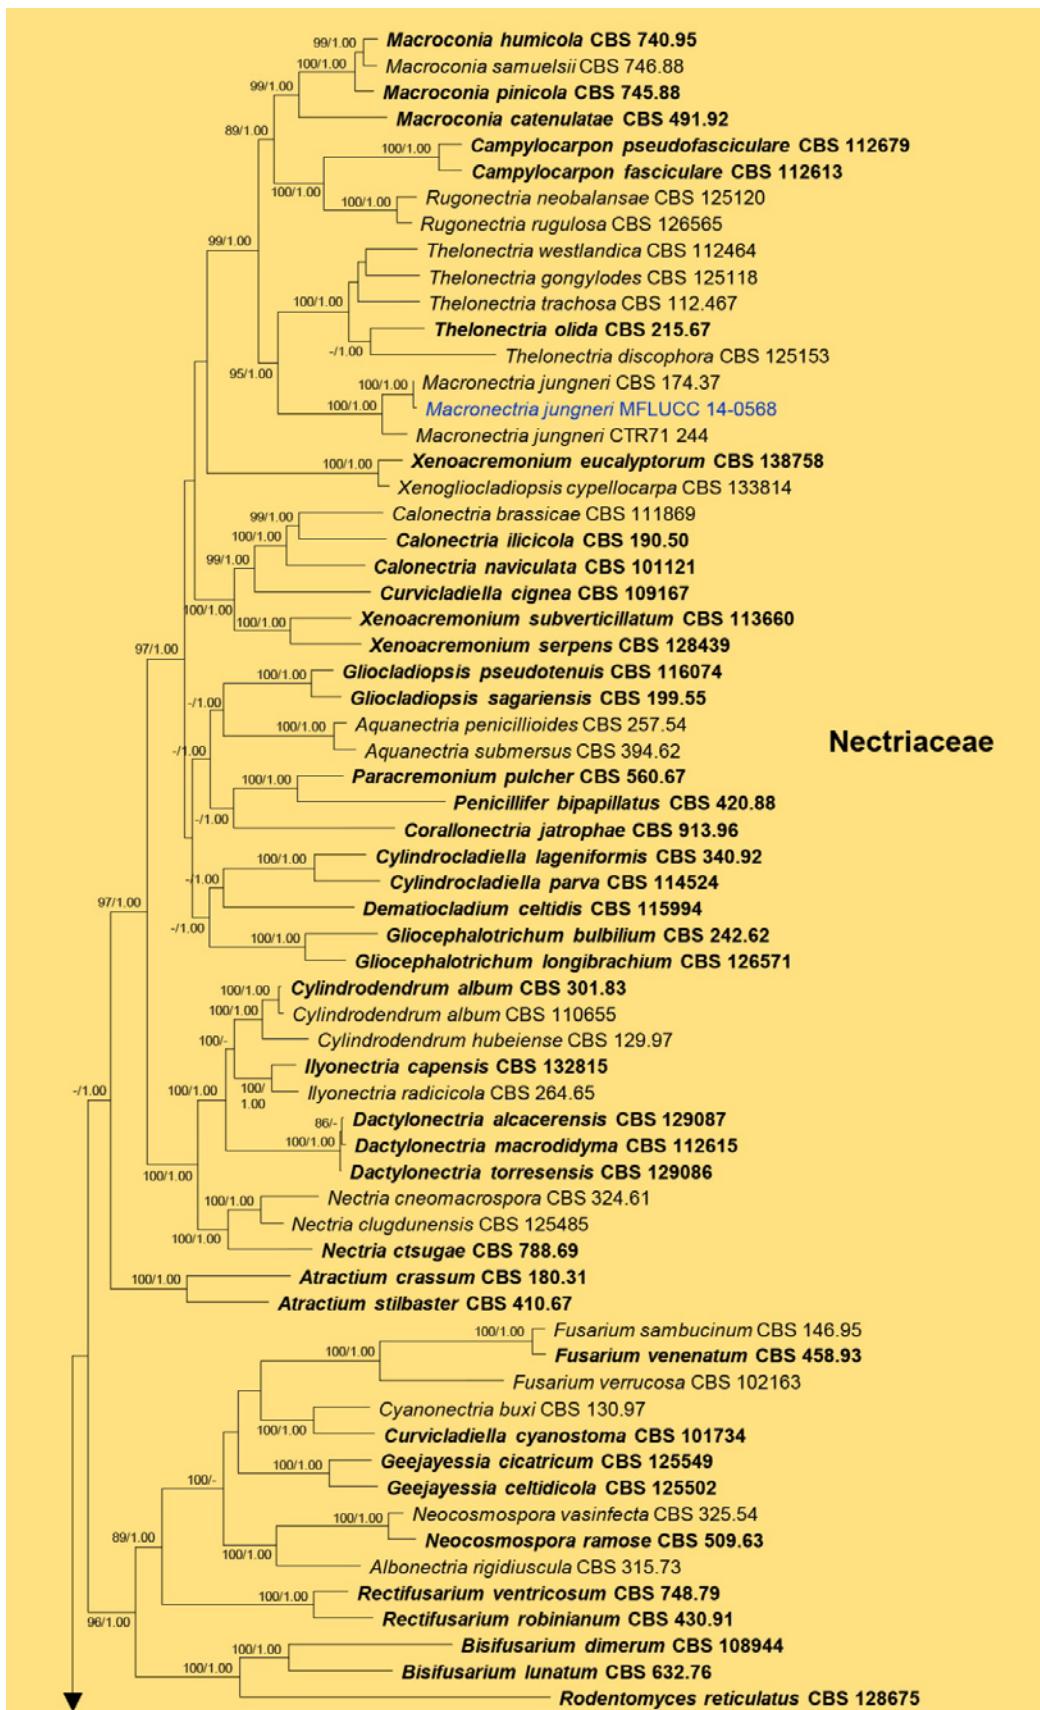

Figure 36 – Phylogram generated from RAxML analysis based on combined LSU, ITS, RPB1, RPB2, TEF1 and TUB2 sequence data of selected Nectriaceae isolates. Sequences from one hundred and twenty-nine taxa, which comprise 4456 characters including gaps, are included in the analyses. The tree was rooted to *Clonostachys buxi* CBS 696.93 and *Verrucostoma freycinetiae* MAFF 240100. The scale bar indicates 0.2 nucleotide changes per site.

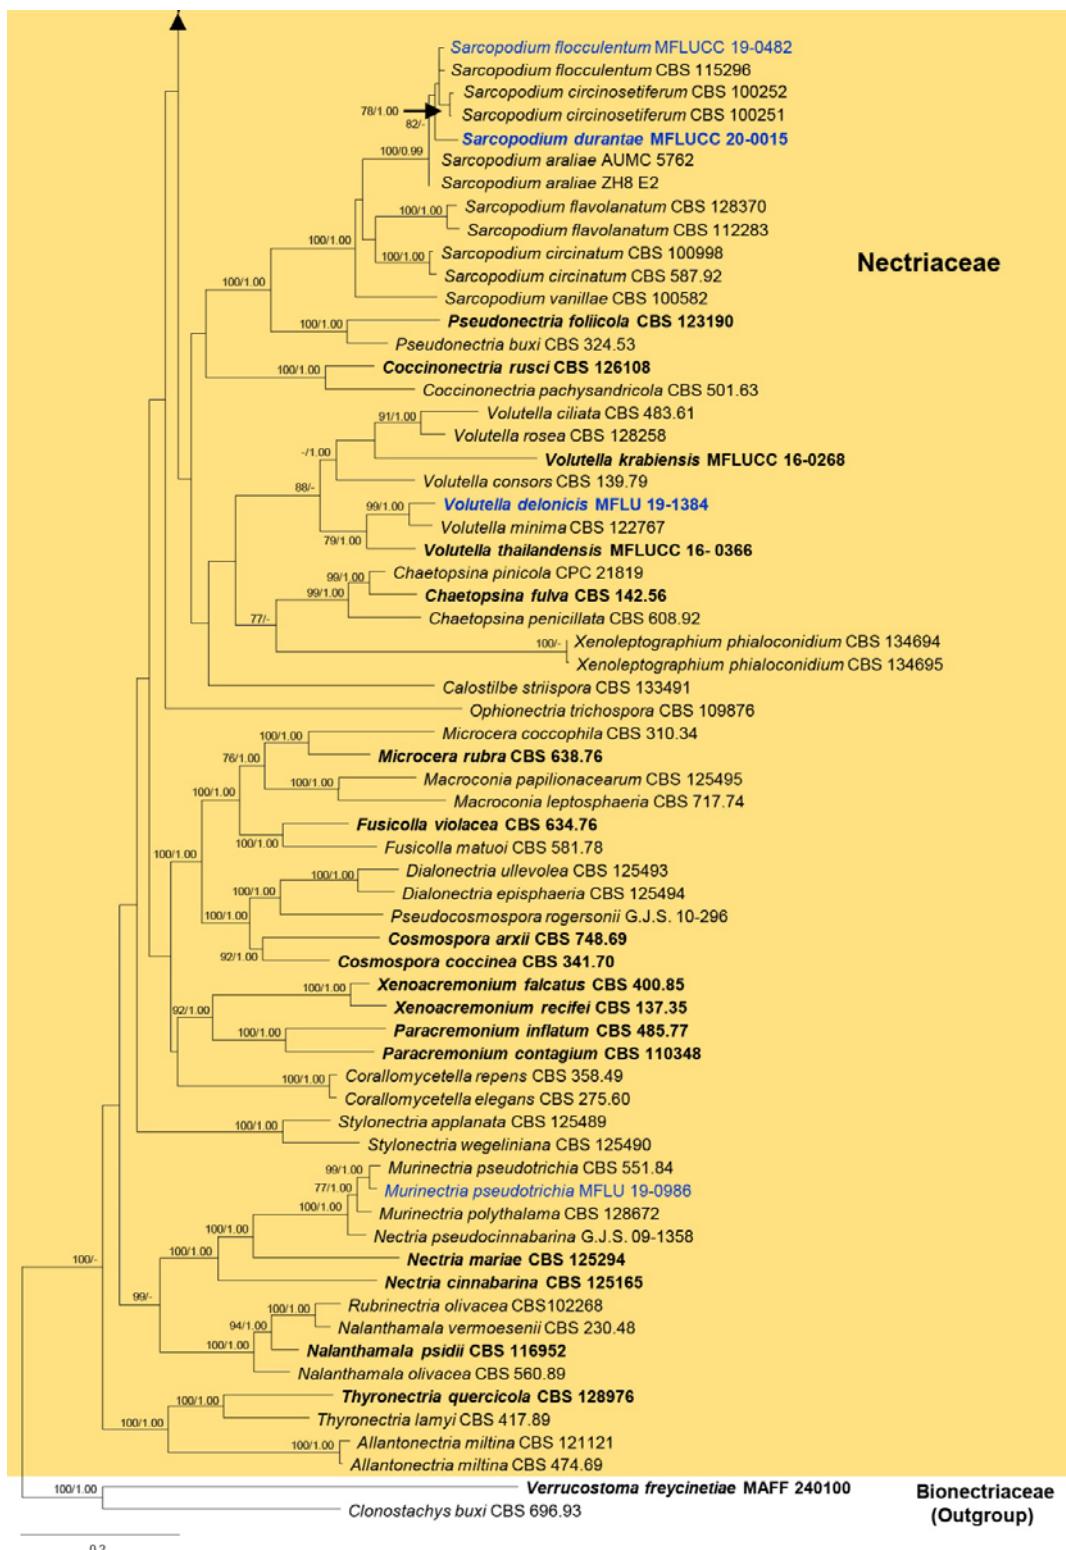

Figure 36 – Continued.

GenBank numbers – ITS: MT215505, LSU: MT215554, SSU: MT199562, TUB2: MT212217.

Notes – Our new isolate (MFLUCC 14-0568) clustered with *Macronectria jungneri* isolates (CBS 174.37, CTR71-244) with high bootstrap support (100% MLBT, 1.00 BIPP; Fig. 36) and, overlapping in morphology with *M. jungneri* (Salgado-Salazar et al. 2016). ITS and TUB2 sequences of MFLUCC 14-0568 are identical with the *Macronectria jungneri* strain CBS 174.37

with one nucleotide difference in LSU gene region. Therefore we identify our new isolate as *M. jungneri* and *Swietenia mahagoni* as a new host record for the fungus.

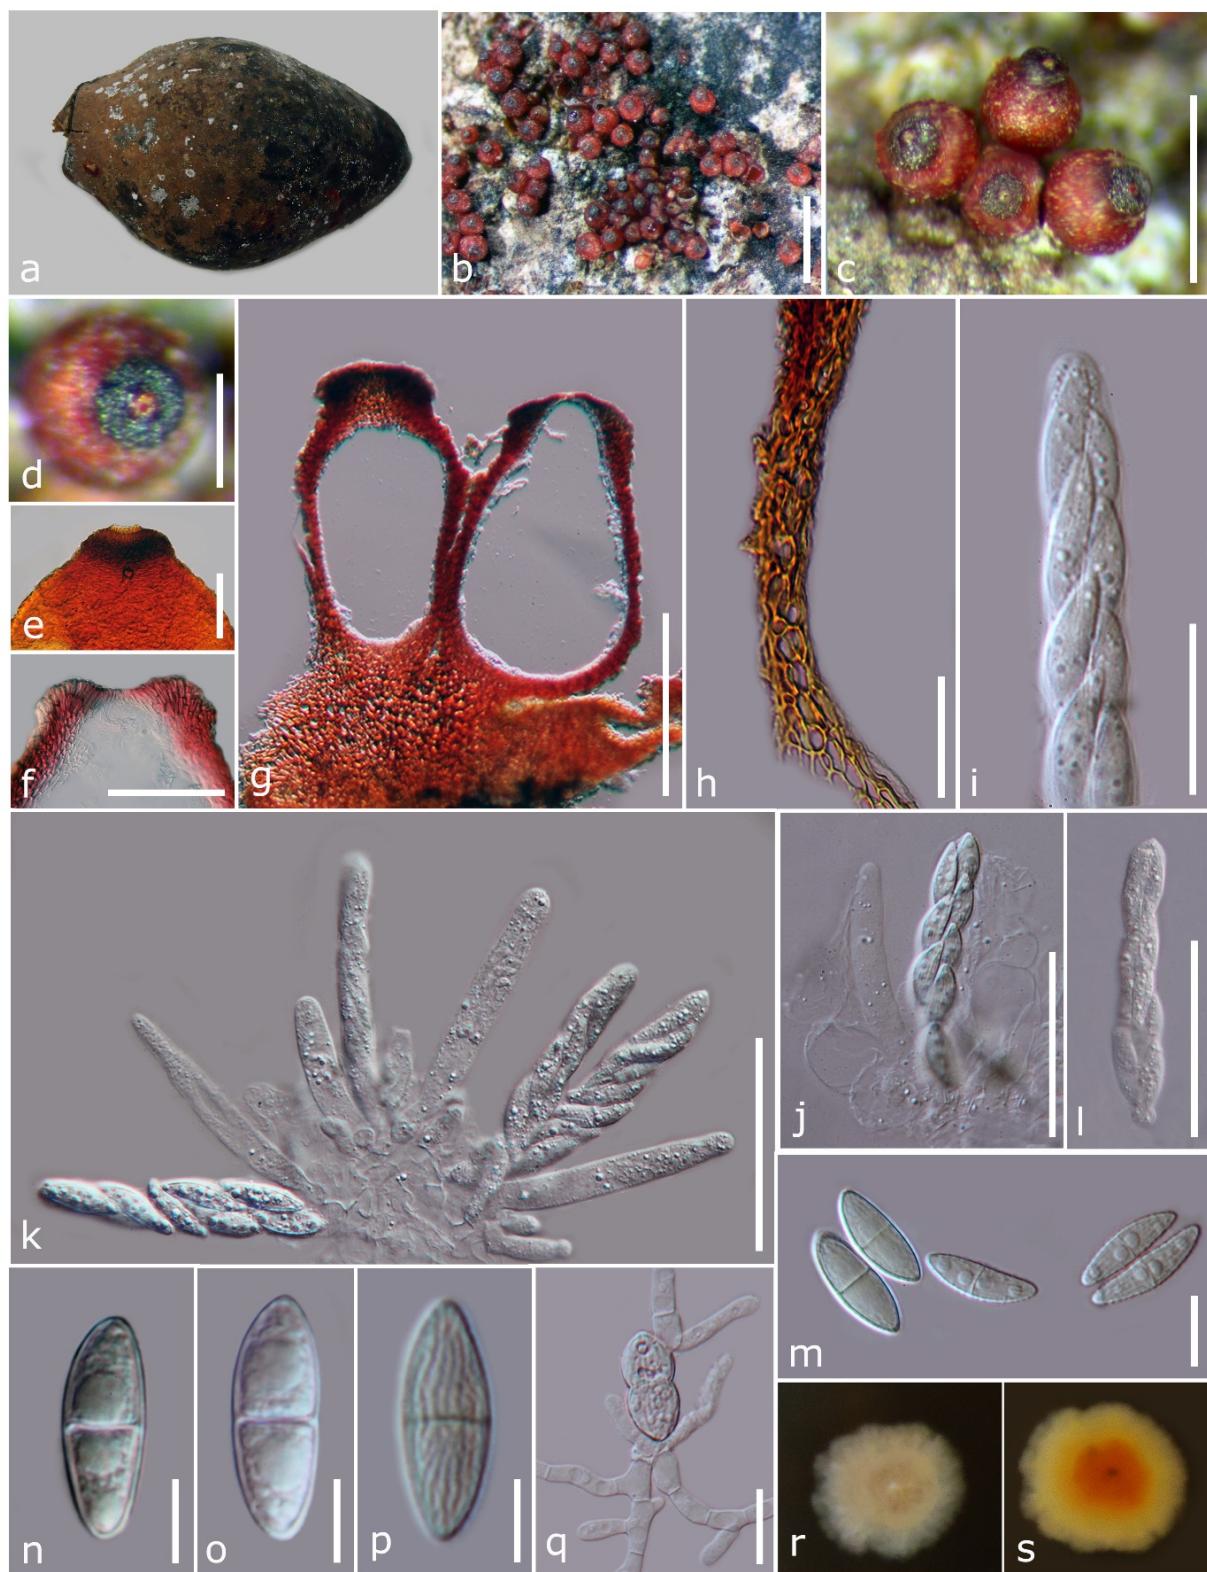

Figure 37 – *Macronectria jungneri* (MFLU 16-1050). a Herbarium material. b, c Ascomata on host. d Ostiole in face view. e Ostiole in side view. f Section of ostiole. g Section of ascocarp. h Section of peridium. j Catenophyses. i, k, l Ascii. m–p Ascospores. q Germinating ascospore. r, s Colony on PDA. Scale bars: b = 1 mm, c = 500 µm, d, e = 200 µm, f = 100 µm, g, h = 200 µm, i = 20 µm, j–l = 50 µm, n–p = 10 µm, q = 20 µm.

Murinectria M. Niranjan & V.V. Sarma

Murinectria pseudotrichia (Schwein) M. Niranjan and V.V. Sarma

Fig. 38

On decaying seed pods of *Delonix regia*. Sexual morph: See Hirooka et al. (2012). Asexual morph: Synnematosus. *Synnemata* 1000–1800 µm high including stipe, 72–115 µm wide (n = 20), erumpent through epidermis, solitary or gregarious, caespitose, cylindrical-capitate, subulate-capitate, or claviform. *Stipe* erect or nodding, usually unbranched or rarely up to 3 branched at base, medium to slender, distinctly hispid at base to mid-level, red-brown at base, turning dark red in 5% KOH. *Hyphae on stipe* 3.4–4.5 µm wide, hyphae pigmented orange brown at base, becoming less pigmented towards apex, KOH+. *Ornamental hyphae on stipe* 6–17 µm long, 2.2–4.5 µm wide (n = 16), cylindrical, straight, curved, sinuous or twisted, arising laterally at more or less right angles, distributed evenly over surface of synnemata, usually unbranched but occasionally dichotomously branched, aseptate. *Conidiophores* with sterile hyphae monoverticillate or biverticillate. *Conidiogenous cells* 16–22 × 1.4–1.8 µm (n = 20), enteroblastic, monopodialidic, cylindrical to subulate, straight or curved, with periclinal thickening, collarette not conspicuous. *Sterile hyphae* 68–88 × 1.5–1.9 µm (n = 16), mixed with phialides, acicular, usually curved or sometimes straight, unbranched or dichotomously branched, often in groups of 1–3. *Conidial masses* 140–285 µm wide, globose, hemispherical or more-or-less discoid, whitish yellow to sienna. *Conidia* 3.1–4.5 × 1.6–2.2 µm ($\bar{x} = 3.9 \times 2$ µm, n = 55), ellipsoidal, obovate or oblong, aseptate, multi-guttulate, hyaline, smooth-walled.

Material examined – THAILAND, Chiang Mai Province, on decaying seed pods of *Delonix regia* (Fabaceae), 1 September 2016, R.H. Perera, S-16 (MFLU 19-0986).

GenBank numbers – ITS: MT215506, LSU: MT215555, TUB2: MT212218.

Notes – DNA was directly extracted from fruiting bodies of this fungus. New isolate (MFLU 19-0986) grouped with *Murinectria pseudotrichia* (CBS 551.84) with good bootstrap support (96%; Fig. 36) in our phylogenetic analysis. Our fungus was identified as *Murinectria pseudotrichia* based on the phylogenetic analysis and morphological similarities (Fig. 36) (Seaver 1909, Hirooka et al. 2012). This collection represents *Delonix regia* as a new host record for *M. pseudotrichia*.

Neocosmospora E.F. Sm.

Neocosmospora magnoliae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 40

Index Fungorum number: IF556861; Facesoffungi number: FoF07764

Etymology – Named after the host genus *Magnolia*.

Holotype – MFLU 18-2748

Associated with dried fruits of *Magnolia champaca*. Sexual morph: *Ascomata* 200–250 × 180–220 µm; perithecial, astromatic, solitary or gregarious, superficial, globose to pyriform, orange to orange brown, glabrous, coarsely warted, warts 23–45 µm diam, 10–50 µm tall, ostiolate. *Ostiole* non-papillate, canal periphysate. *Peridium* 15–38 µm diam., inner region 1–2 layers of hyaline, flattened cells of *textura angularis*; outer region composed of 3–5 layers of orange brown, thick-walled cells of *textura angularis*; in face view a *textura angularis* of thick-walled, medium to dark brown cells. *Hamathecium* of hyaline, distinctly septate catenophyses, 14–20 µm wide. *Asci* 55–76 × 9.8–13 µm ($\bar{x} = 67 \times 11$ µm, n = 25), 8-spored, unitunicate, clavate, short-pedicellate, with a broad flattened apex, with a minute apical apparatus, J-. *Ascospores* (5–)8.3–11.7 × 4.5–5.8 µm ($\bar{x} = 10 \times 5$ µm, n = 30), obliquely uniseriate or irregularly biseriate, broadly ellipsoid to ovoid or subfusiform, 1-septate, not constricted at the septum, 2 or 4 guttulate, hyaline to pale yellow-brown, thick-walled, finely striate when mature. Asexual morph: Undetermined.

Culture characteristics – Ascospores germinating on PDA within 12 hours. Colonies growing on PDA, reaching up to 2.6 cm within 7 days at 28°C, surface effused, smooth, margin entire, aerial mycelium rare, initially white, turning rosy pink, reverse rosy pink.

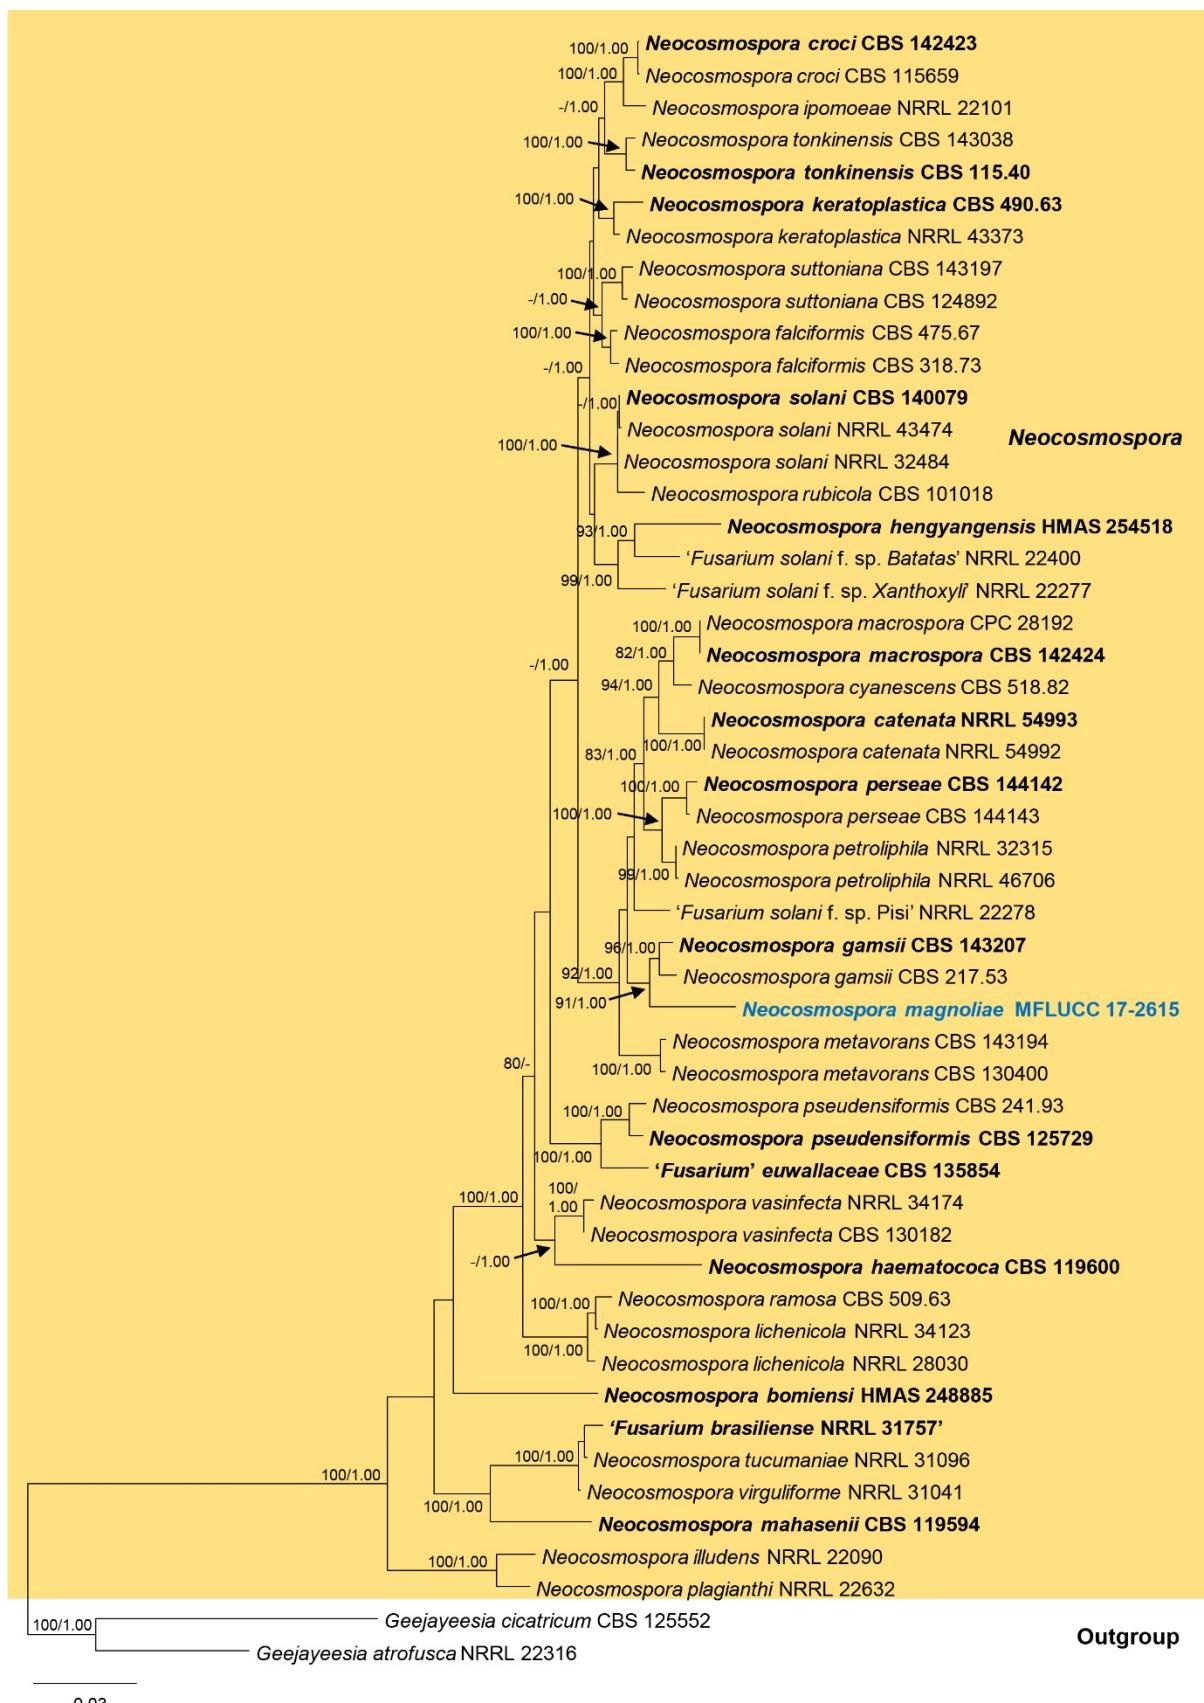

Figure 39 – Phylogram generated from RAxML analysis based on combined LSU, ITS, TEF1 and RPB2 sequence data of *Neocosmospora* isolates. Sequences from fifty-one taxa, which comprise 3425 characters including gaps, are included in the analyses. The tree was rooted to *Geejayeesia atrofusca* NRRL 22316 and *Geejayeesia cicatricum* CBS 125552. The scale bar indicates 0.03 nucleotide changes per site.

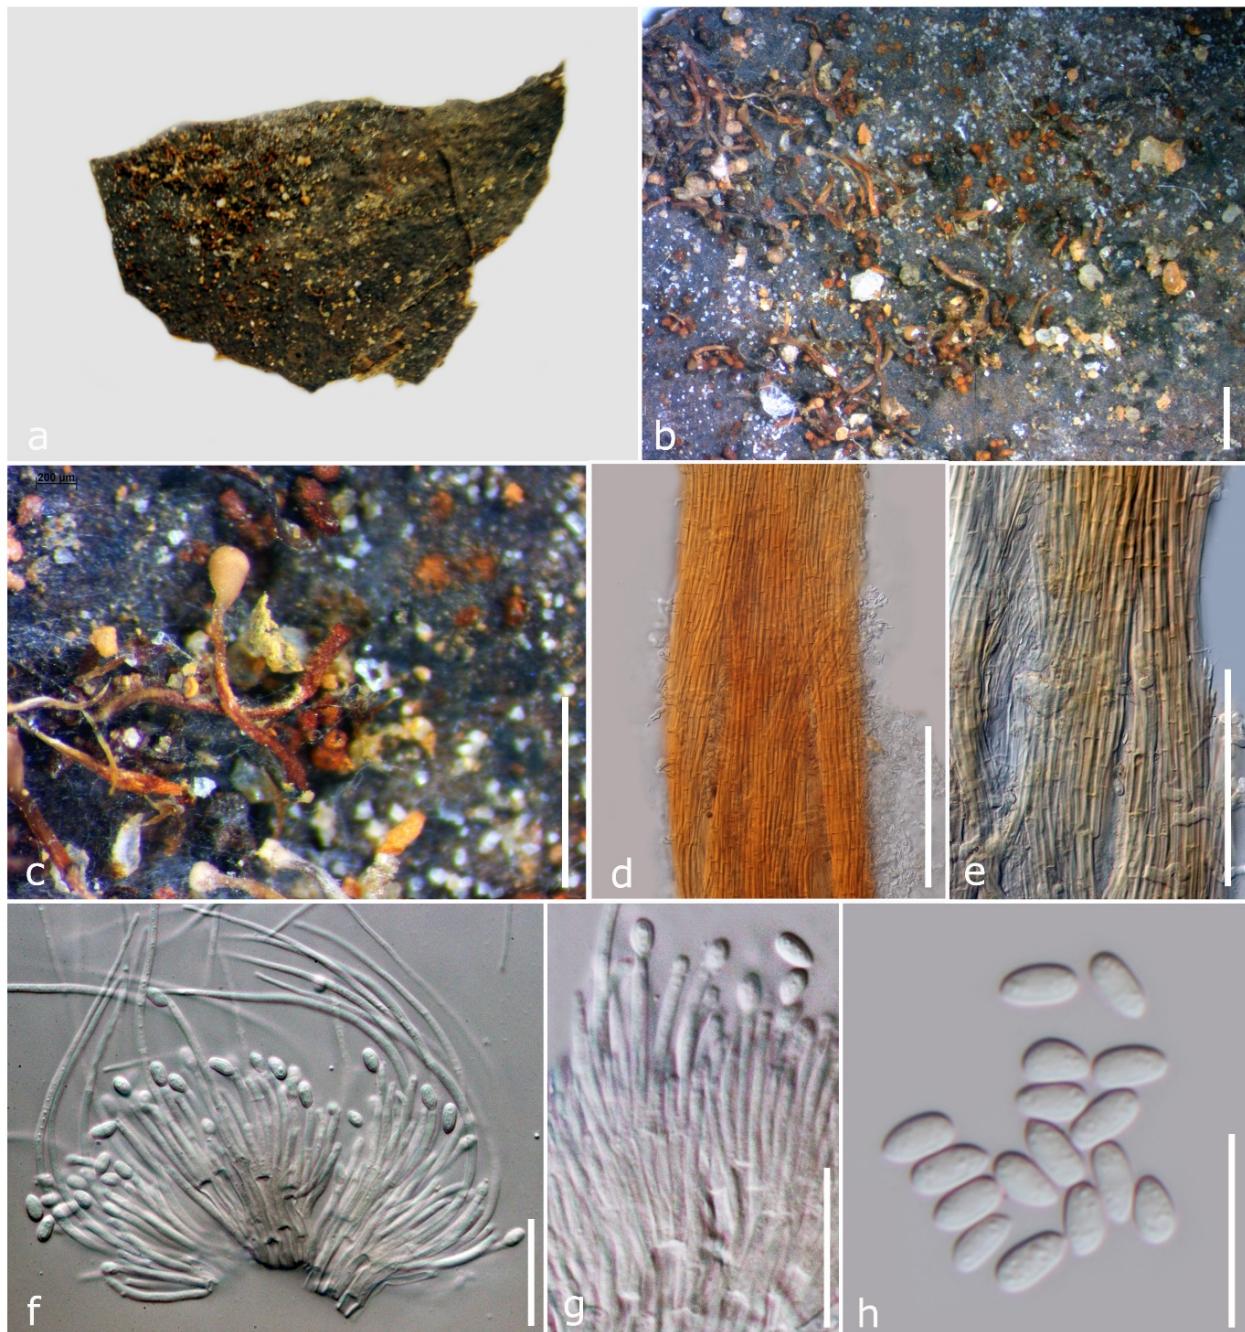

Figure 38 – *Murinectria pseudotrichia* (MFLU 19-0986). a Herbarium material. b, c Synnemata on host. d Stipe with ornamental hyphae. e Stipe hyphal strands. f Sterile hyphae and conidiophores. g Conidiophores with conidia. h Conidia. Scale bars: b, c = 1 mm, d, e = 100 µm, f, g = 20 µm, h = 10 µm.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University garden, dried fruits of *Magnolia champaca* (Magnoliaceae) on the ground, 07 September 2017, R.H. Perera, MAG 01 (MFLU 18-2748, holotype), ex-type living culture MFLUCC 17-2615.

GenBank numbers – ITS: MT215508, LSU: MT215557, RPB2: MT212200, TEF1: MT212207.

Notes – Our new isolate (MFLUCC 17-2615) grouped sister to two isolates of *Neocosmospora gamsii*, CBS 143207 and CBS 217.53 with moderate bootstrap support (91%; Fig. 39). Our isolate and ex-type *N. gamsii* (CBS 143207) showed 4 nucleotide differences (0.7%, no gaps) in the ITS region, 12 nucleotide differences (1.8%, 2 gaps) in the TEF1 region, and 36 different nucleotides (7.3%, no gaps) in the RPB2 region, while their LSU sequences were

identical. Our isolate and *N. gamsii* strain (CBS 217.53) showed 18 nucleotide differences (3.4%, 4 gaps) in the ITS region, 8 nucleotide differences (1.2%, no gaps) in the TEF1 region, and 36 different nucleotides (7.3%, no gaps) in the RPB2 region, while their LSU sequences were identical. *Neocosmospora magnoliae* can be distinguished from *N. gamsii* by its orange to orange brown ascomata and smaller ascci (55–76 vs. 70–97.5 µm), while *N. gamsii* has orange to dark brown-red ascomata (Sandoval-Denis & Crous 2018). Hence, based on the above-mentioned differences in morphology and molecular sequence data, a new species, *N. magnoliae* is introduced.

Figure 40 – *Neocosmospora magnoliae* (MFLU 18-2748, holotype). a Herbarium material. b Ascomata on host. c Section of ascoma. d Peridium in section. e Peridium in face view. f–h Ascospores. i–n Ascospores. o Germinating ascospore. p, q Colony on PDA. Scale bars: b, c = 100 µm, d = 50 µm, e = 20 µm, f–h = 50 µm, i–n = 10 µm, o = 20 µm.

Sarcopodium Ehrenb. ex Schlecht.

Sarcopodium durantae R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 41

Index Fungorum number: IF557322; Facesoffungi number: FoF07765

Etymology – Named after the host genus *Duranta*.

Holotype – MFLU 18-2719

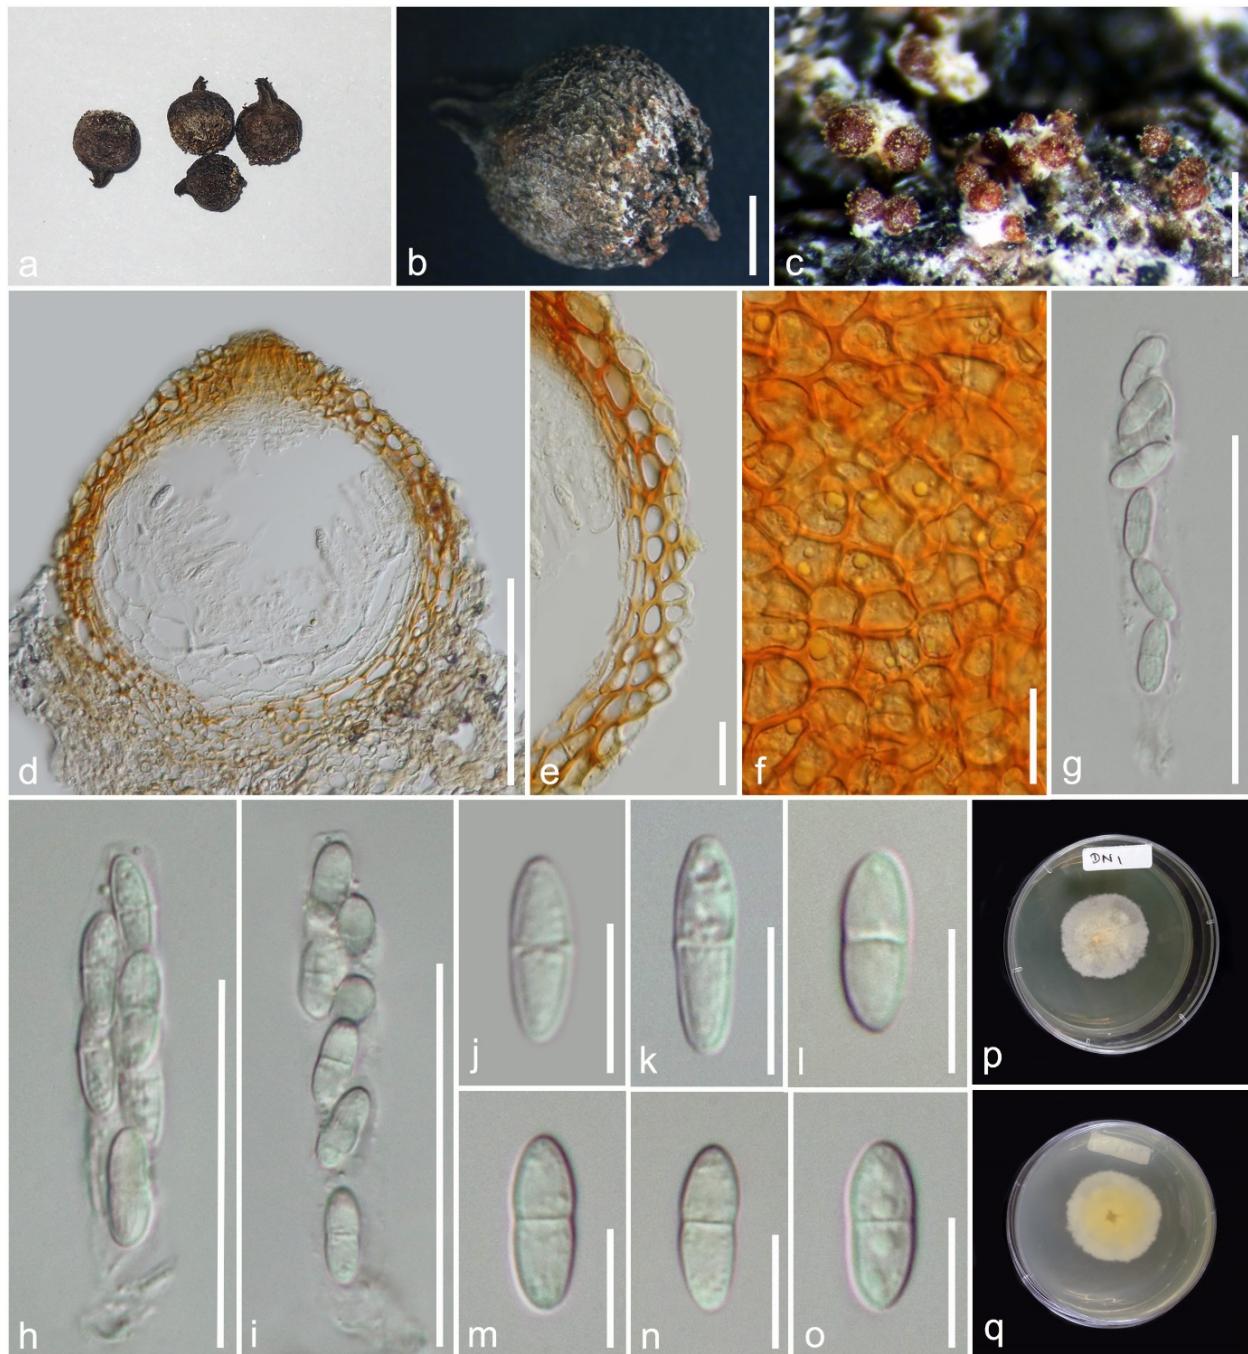

Figure 41 – *Sarcopodium durantae* (MFLU 18-2719, holotype). a Herbarium material. b, c Ascomata on host. d Section of ascoma. e Section of the peridium. f Peridium in face view. g–i Ascii. j–o Ascospores, p, q Colony on PDA. Scale bars: b = 2 mm, c = 500 µm, d = 100 µm, e, f = 20 µm, g–i = 50 µm, j–o = 10 µm.

Saprobic on dry fruits of *Duranta erecta*. Sexual morph: Ascomata 175–210 µm high, 170–210 µm wide, perithecial, solitary or in groups, superficial on a minute stroma surrounded by white mycelium, globose to broadly obpyriform, not collapsing when dry, red, turning dark red in 5% KOH, spinulose hyphal hairs arising from the surface of the ascromatal wall, ostiole slightly papillate. Peridium 17–26 µm, composed of 3–5 layers of dark orange colour cells of *textura*

angularis. *Hamathecium* comprising hyaline, distinctly septate catenophyses, each cell 16–25 µm long × 9–15 µm wide. Asci 50–75 × 7.5–10 µm ($\bar{x} = 61 \times 8.8$ µm), unitunicate, 8-spored, clavate to fusiform, short pedicellate, with an apical ring, J-. Ascospores 12–15 × 4–6 µm ($\bar{x} = 13.4 \times 5$ µm), uni-seriate to multi-seriate, ellipsoid to fusiform, 1-septate, slightly constricted at the septum, guttulate, hyaline to pale yellow-brown, striate. Asexual morph: Undetermined.

Culture characteristics – Ascospores germinating on PDA within 12 hours. Colonies growing on PDA reaching 4 cm in 7 days at 28°C, surface effused, smooth, margin entire, aerial mycelium rare, initially white, becoming pale yellowish orange, reverse yellowish, orange at centre.

Material examined – Thailand, Chiang Rai Province, on dried fruits of *Duranta erecta* L. (Verbenaceae), 25 November 2018, D. Sandaruwan, DN1 (MFLU 18-2719, holotype), ex-type living culture MFLUCC 20-0015.

GenBank numbers – ITS: MT386004, LSU: MT386007, TEF1: MT383671, TUB2: MT383672.

Notes – *Sarcopodium durantae* (MFLUCC 20-0015) groups with *Sarcopodium* species, forming an unsupported clade (Fig. 36). Our isolate and ex-type *S. flocculentum* (CBS 115296) showed 7 different nucleotides (3%, 2 gaps) in the TEF1 region, 8 different nucleotides (1%, 1 gap) in the TUB2 region. A comparison of the TUB2 and TEF1 gene regions of *S. durantae* (MFLUCC 20-0015) and *S. circinosetiferum* (CBS 100251) reveals 20 (3%, 6 gaps) and 16 (6%, 2 gaps) nucleotide differences, respectively. Our new isolate and *S. flocculentum* (CBS 115296) showed 7 different nucleotides (3%, 2 gaps) in the TEF1 region, 8 different nucleotides (1%, 1 gap) in the TUB2 region. A comparison of the TUB2 and TEF1 gene regions of *S. durantae* and *S. flocculenta* (MAFF 241413) reveals 9 (2%, 1 gap) and 14 (7%, 4 gaps) nucleotide differences, respectively. *Sarcopodium mammiforme* and *S. rariplum* do not have DNA sequence data in the GenBank for the comparison. *Sarcopodium durantae* can be distinguished from *S. flocculentum* by smaller ascocata (175–210 × 170–210 vs. 224–314 × 215–293 µm) and larger ascospores (12–15 × 4–6 vs. 10–13 × 3–4.5 µm) (Rossman et al. 1999). *Sarcopodium durantae* differs from *S. mammiforme* by having smaller ascocata (175–210 × 170–210 vs. 300–700 µm) and smaller ascospores (12–15 × 4–6 vs. 24–30 × 7–9 µm) (Rossman et al. 1999). *Sarcopodium durantae* has smaller ascospores when compared to *S. rariplum* (12–15 × 4–6 vs. 27.5–32 × 6.5–8 µm) (Rossman et al. 1999). *Sarcopodium durantae* differs from *S. oblongisporum* in having larger asci (50–75 × 7.5–10 vs. 43–59 × 6–7.6 µm) and ascospores (12–15 × 4–6 vs. 9.5–12.2 × 2.2–3.9 µm) (Nong & Zhuang 2005). Based on these morphological differences, a new species, *S. durantae* is introduced in the genus *Sarcopodium*.

Sarcopodium flocculentum (Henn. & E. Nyman) Pennycook & P.M. Kirk, Index Fungorum 418: 1 (2019) Fig. 42

Facesoffungi number: FoF07766

Associated with Fabaceae hosts and *Eucalyptus grandis*. Sexual morph: Ascomata 150–180 µm high, 135–170 µm wide, perithecial, solitary or in groups, superficial on a minute stroma, subglobose to broadly obpyriform, sometimes collapsing apically to form cups when dry, red, turning dark red in 5% KOH, spinulose hyphal hairs arising from the surface of the ascatal wall and forming around the ascatal base, ostiole papillate. Peridium 16–34 µm, composed of 2–4 layers of dark orange colour cells of *textura angularis*, thinner around ostiole, 2–12 µm wide, composed of compactly arranged, flat cells. *Hamathecium* comprising hyaline, distinctly septate catenophyses, each cell 4.1–19.4 µm long × 6.3–12 µm wide. Asci 35–63 × 6.2–8.3 µm ($\bar{x} = 50 \times 7.4$ µm), unitunicate, 8-spored, clavate to fusiform, short pedicellate, with apical ring, J-. Ascospores 7.2–12 × 3.5–4.6 µm ($\bar{x} = 9.3 \times 3.9$ µm), uni-seriate to multi-seriate, ellipsoid to fusiform, 1-septate, slightly constricted at the septum, hyaline to pale yellow-brown, striate. Asexual morph: See Sutton (1981).

Culture characteristics – Ascospores germinating on PDA within 12 hours. Colonies growing on PDA reaching 3.8 cm in 7 days at 28°C, surface effused, smooth, margin entire, aerial mycelium rare, initially white, becoming yellowish orange, reverse brownish orange.

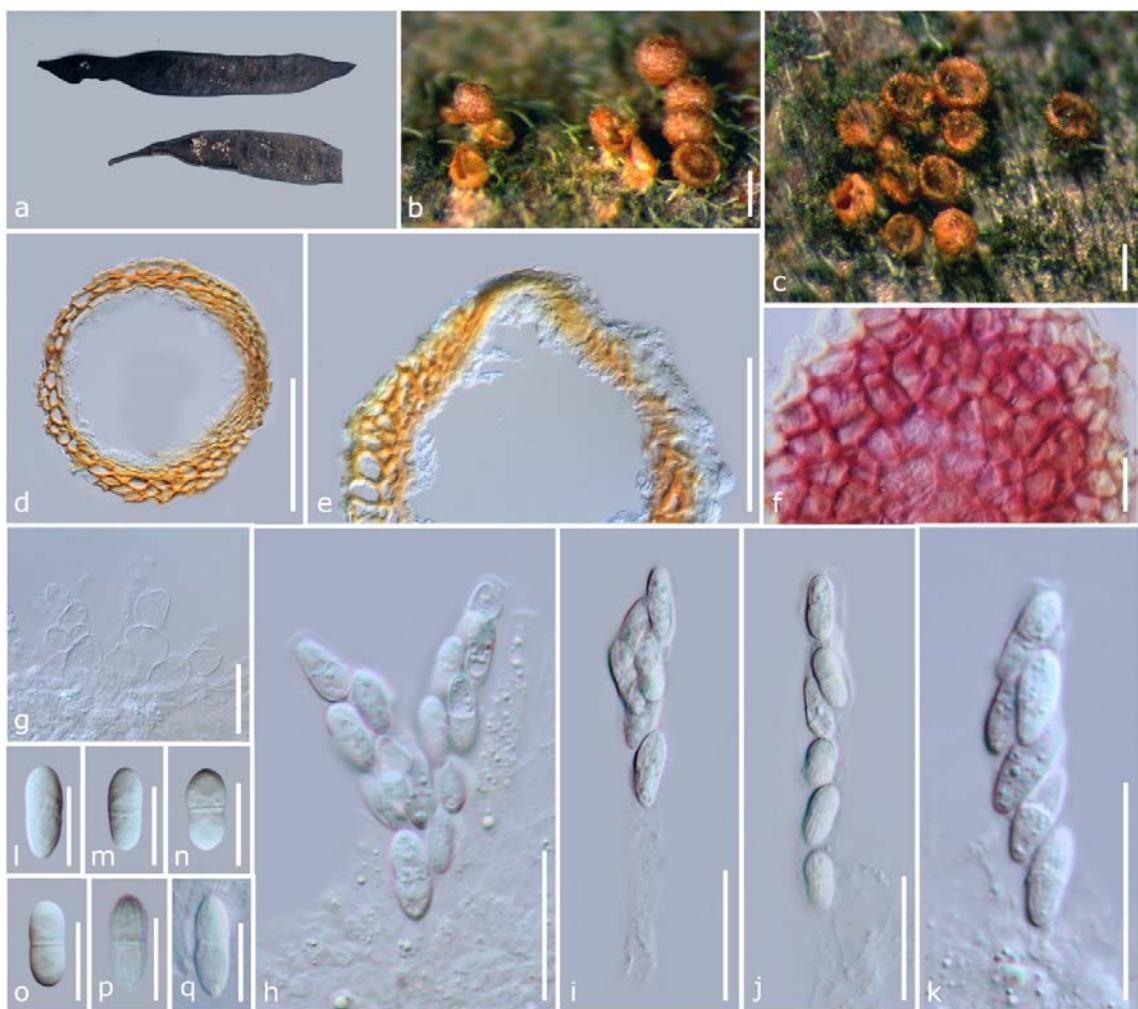

Figure 42 – *Sarcopodium flocculentum* (MFLU 19-0988). a Herbarium material. b, c Ascomata on host. d Section of ascoma. e Section of ostiole. f Peridium in face view (in 5% KOH). g Catenophyses. h–k Ascospores. Scale bars: b, c = 200 µm, d = 100 µm, e = 50 µm, f–k = 20 µm, l–q = 10 µm.

Material examined – Thailand, Chiang Rai Province, on dried seed pods of *Leucaena leucocephala* (Lam.) de Wit (Fabaceae), September 2017, I.D. Goonasekara, Ipil 01 (MFLU 19-0988), living culture MFLUCC 19-0482).

GenBank numbers – ITS: MT215507, LSU: MT215556.

Notes – Our collection resembles the genus *Sarcopodium* by having red ascomata and spinulose hyphal hairs arising from the surface of the ascromatal wall and forming around the ascromatal base (Rossman et al. 1999, Lombard et al. 2015). In our phylogenetic analysis, the new isolate (MFLUCC 19-0482) clusters with *S. flocculentum* (CBS 115296) (Fig. 36). *Sarcopodium flocculentum* previously reported from two Fabaceae hosts (*Pongamia pinnata* and *Albizia richardiana*) and *Eucalyptus grandis* in India (Sutton 1981). Our isolate and *S. flocculentum* strain (CBS 115296) showed 1 nucleotide difference (no gaps) in the ITS region while, their LSU sequences were identical, which indicates that they are same species (Jeewon & Hyde 2016). However, only the asexual morph was reported for *S. flocculentum* (Sutton 1981). We identified our collection as the sexual morph of *S. flocculentum* and *Leucaena leucocephala* as a new host record for the fungus.

Volutella Tode

Volutella delonicis R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Figs 43, 44

Index Fungorum number: IF556863; Facesoffungi number: FoF07767

Etymology – Named after the host genus *Delonix*.

Holotype – MFLU 19-1384

Saprobic on seed pods of *Delonix regia*. Sexual morph: Ascomata associated with conidiomata, 285–345 μm high, 260–280 μm wide ($n = 6$), perithecial, solitary, basal stroma inconspicuous, superficial, obpyriform to pyriform, with an acute apex, orange to red, turning dark red in 5% KOH, surface finely roughened. Peridium 45–82 wide, two strata, outer stratum composed of 5–9 layers of orange to red, thick-walled cells of *textura globosa* to *textura angularis*; inner stratum composed of 2–4 layers of orange to red, flat, thick-walled cells of *textura angularis*; thinner around ostiole, composed of elongated cells. Ascii not observed. Ascospores $10.7\text{--}13.1 \times 2.5\text{--}3.3 \mu\text{m}$ ($\bar{x} = 11.9 \times 2.9 \mu\text{m}$, $n = 20$), 1-septate, hyaline, fusiform to biconic, smooth-walled, without appendages, germinated inside the ascomata. Asexual morph: Hyphomycetous, sporodochial, stroma inconspicuous. Sporodochia sessile, yellow. Setae $197\text{--}318 \times 4.7\text{--}8 \mu\text{m}$ ($\bar{x} = 258 \times 6 \mu\text{m}$, $n = 10$), forming around the margin of conidiomata, hyaline, aseptate, stiff, cylindrical, tapering towards the apex, apex rounded. Conidiophores terverticillate, branched, septate, hyaline. Conidiogenous apparatus with subulate, conidiogenous cells, $8\text{--}9 \times 1.9\text{--}2.5 \mu\text{m}$ ($\bar{x} = 8.6 \times 2.3 \mu\text{m}$, $n = 20$), monopodial, hyaline, with periclinal thickening, collarette prominent, up to $1.7 \mu\text{m}$ long, $1.9 \mu\text{m}$ wide. Conidia $5.2\text{--}7.4 \times 1.1\text{--}1.5 \mu\text{m}$ ($\bar{x} = 6.1 \times 1.3 \mu\text{m}$, $n = 30$), slimy, aseptate, hyaline, oblong, smooth-walled, without mucilaginous sheath, forming yellow masses.

Material examined – Thailand, Chiang Mai Province, on decaying seed pods of *Delonix regia* (Fabaceae), 20 December 2016, R.H. Perera, Delo 02 (MFLU 19-1384, holotype).

GenBank numbers – ITS: MT215504, LSU: MT215553, RPB1: MT212196, TUB2: MT212216.

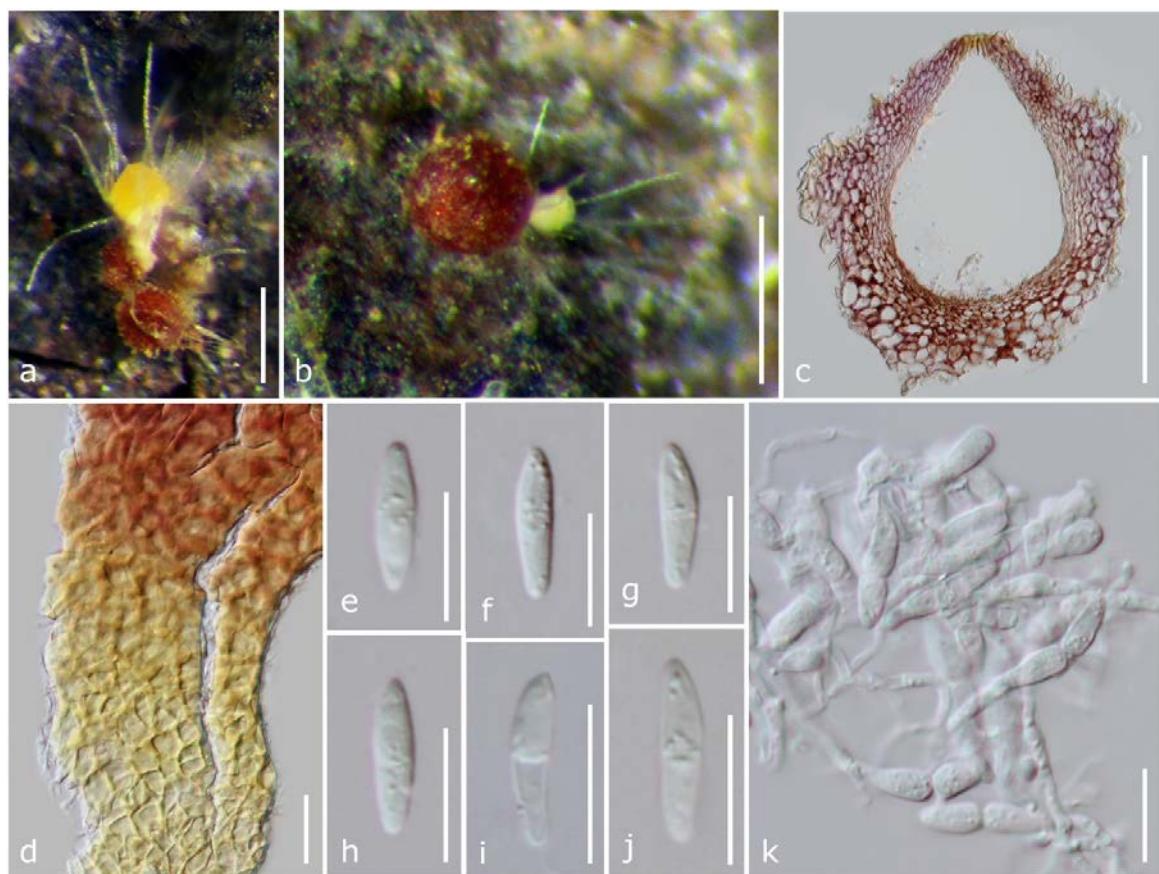

Figure 43 – *Volutella delonicis* (MFLU 19-1384, holotype) a, b Ascomata associated with conidiomata on host. c Section of ascoma. d Peridium in face view. e–j Ascospores. k Ascospores germinating inside the ascocarp. Scale bars: a–c = $200 \mu\text{m}$, d = $20 \mu\text{m}$, e–k = $10 \mu\text{m}$.

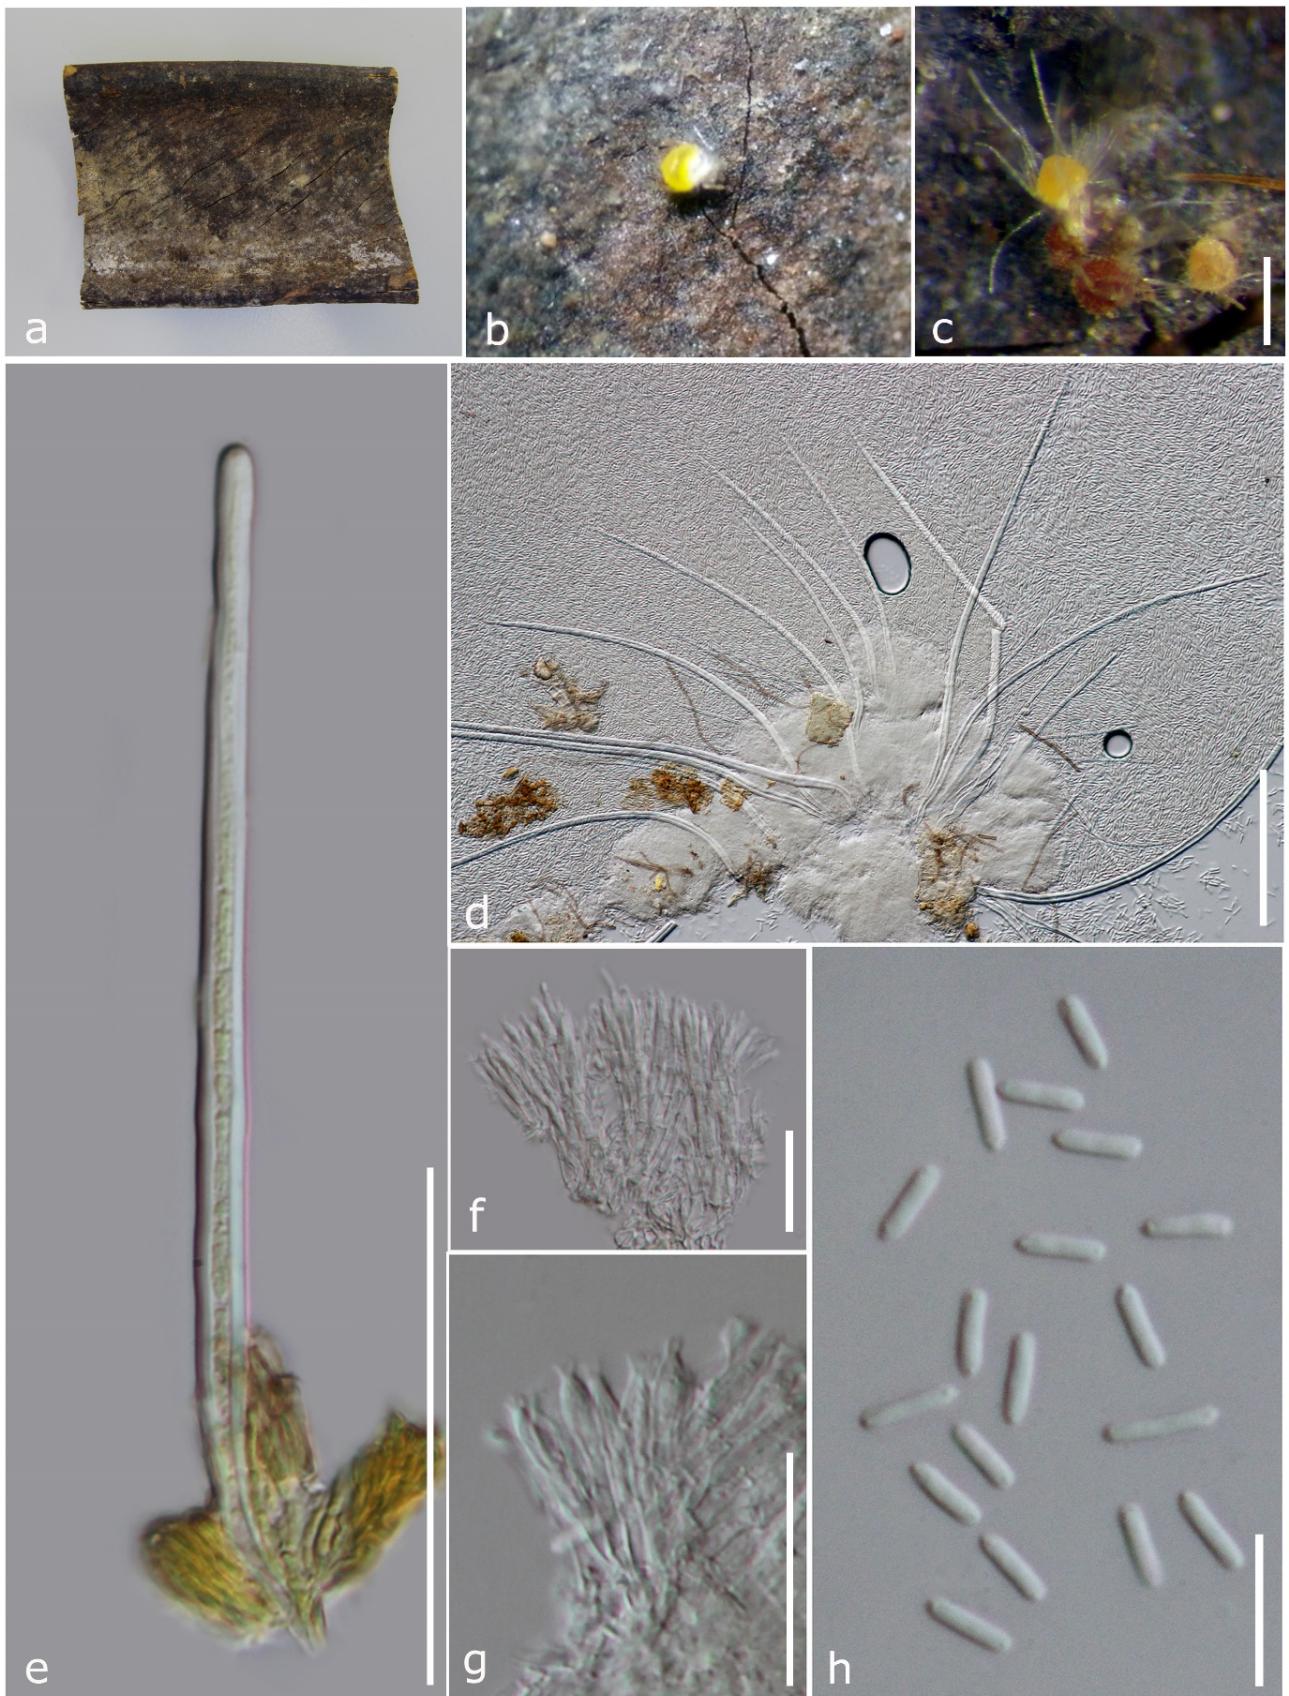

Figure 44 – *Volutella delonicis* (MFLU 19-1384, holotype). a Herbarium material. b, c Sporodochia (c associated with ascomata). d Sporodochium mounted in water. e Seta. f, g Conidiogenous apparatus. h Conidia. Scale bars: c = 200 µm, d = 100 µm, e = 50 µm, f, g = 20 µm, h = 10 µm.

Notes – Holomorph of *Volutella delonicis* was associated with decaying seed pods of *Delonix regia*. *Volutella delonicis* has a close phylogenetic affinity to *V. minima* CBS 122767 in multi-locus phylogenetic analysis (Fig. 36). *Volutella delonicis* has yellow sporodochia and aseptate setae, while *V. minima* produces white sporodochia and septate setae (Höhn 1909). Furthermore, *V. delonicis* forms larger conidia than *V. minima* (5.2–7.4 µm vs. 3–5 µm) (Höhn 1909). A comparison of the LSU, ITS, RPB2 and TUB2 nucleotides of these two strains reveals 8 (0.9%), 10 (1.8%), 15 (1.6%), 44 (6.2%) and 40 (7.1%) nucleotide differences respectively in each gene region, which indicates that they are distinct taxa (Jeewon & Hyde 2016).

Xylariales Nannf.

Diatrypaceae Nitschke

***Allodiatriype* Konta & K.D. Hyde**

***Allodiatriype thailandica* (R.H. Perera, Jian K. Liu & K.D. Hyde) Konta & K.D. Hyde 2020**

Fig. 46

Saprobic on decaying wood or seed pods of *Delonix regia*. Sexual morph: *Stromata* 540–1050 µm wide, gregarious or scattered on host, erumpent, arising through the cracks in host tissue, with 1–5 ascomata immersed in white entostroma becoming greenish yellow near the periphery, stromata outer layer black. *Ascomata* 280–370 µm high, 150–300 µm wide ($\bar{x} = 320 \times 210$ µm, n = 20), perithecial, immersed in stromatic tissues, aggregated, globose to subglobose, narrowing towards the apex and very narrow at the base of papilla, pale brown, ostiolate, papillate. *Papilla* 85–150 µm high, 80–110 µm wide, immersed in outer layer of stromata, conical, apex wider than base, periphysate, periphyses 17–28 µm long. *Peridium* 20–27 µm wide, comprising an outer, brown, thick-walled, stratum of 4–5 layers of cells of *textura angularis* and inner, hyaline, thick-walled, stratum of 7–10 layers of cells of *textura angularis*; peridium in face view a *textura angularis* of thin-walled, medium to dark brown cells. *Hamathecium* comprising long, 7.4–10.3 µm wide ($\bar{x} = 8.9$ µm, n=20), septate, paraphyses, slightly constricted at basal septa, and narrowing and tapering towards the apex. *Asci* 75–120 × 6.1–9.4 µm ($\bar{x} = 101 \times 8.2$ µm, n = 20), 4–8-spored, unitunicate, clavate, with narrow, long, thin-walled pedicel, with thick-walled, swollen upper portion, apex flat, with J- apical apparatus. *Ascospores* 6.5–10.7 × 1.6–2.7 µm ($\bar{x} = 7.8 \times 2.2$ µm, n = 50), biseriate, allantoid to cylindrical, unicellular, pale brown at maturity, thick-walled, with small, fat globules at ends, smooth-walled. Asexual morph: See Li et al. (2016).

Culture characteristics – Ascospores germinated on PDA within 12 hours. Reaching 3.5 cm within 14 days on PDA at 25°C, colonies medium dense, circular, flat, with diffuse margin, white, greenish yellow with time, below similar in colour, not zonate.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University premises, on dried seed pods of *Delonix regia* (Fabaceae), 6 January 2015, R.H. Perera, RHP 150 (MFLU 17-0735), *ibid*. Doi Mae Salong, on unidentified plant stem, 15 March 2014, R.H. Perera, M-1 (MFLU 16-1073), living culture MFLUCC 16-0459.

GenBank numbers – ITS: MT386002, LSU: MT215541, TUB2: MT212210 (MFLU 17-0735); ITS: MT386003, LSU: MT215542 (MFLUCC 16-0459).

Notes – In molecular phylogenetic analysis our new isolates clustered with putative strain of *Allodiatriype thailandica* (MFLUCC 15-3662) (Fig. 45). Our collection is similar to *A. thailandica* by greenish yellow entostroma, ascospore colour and size (Li et al. 2016, Konta et al. 2020). It is therefore reported here as a new host record of *A. thailandica* and in providing TUB2 gene region sequence for the first time.

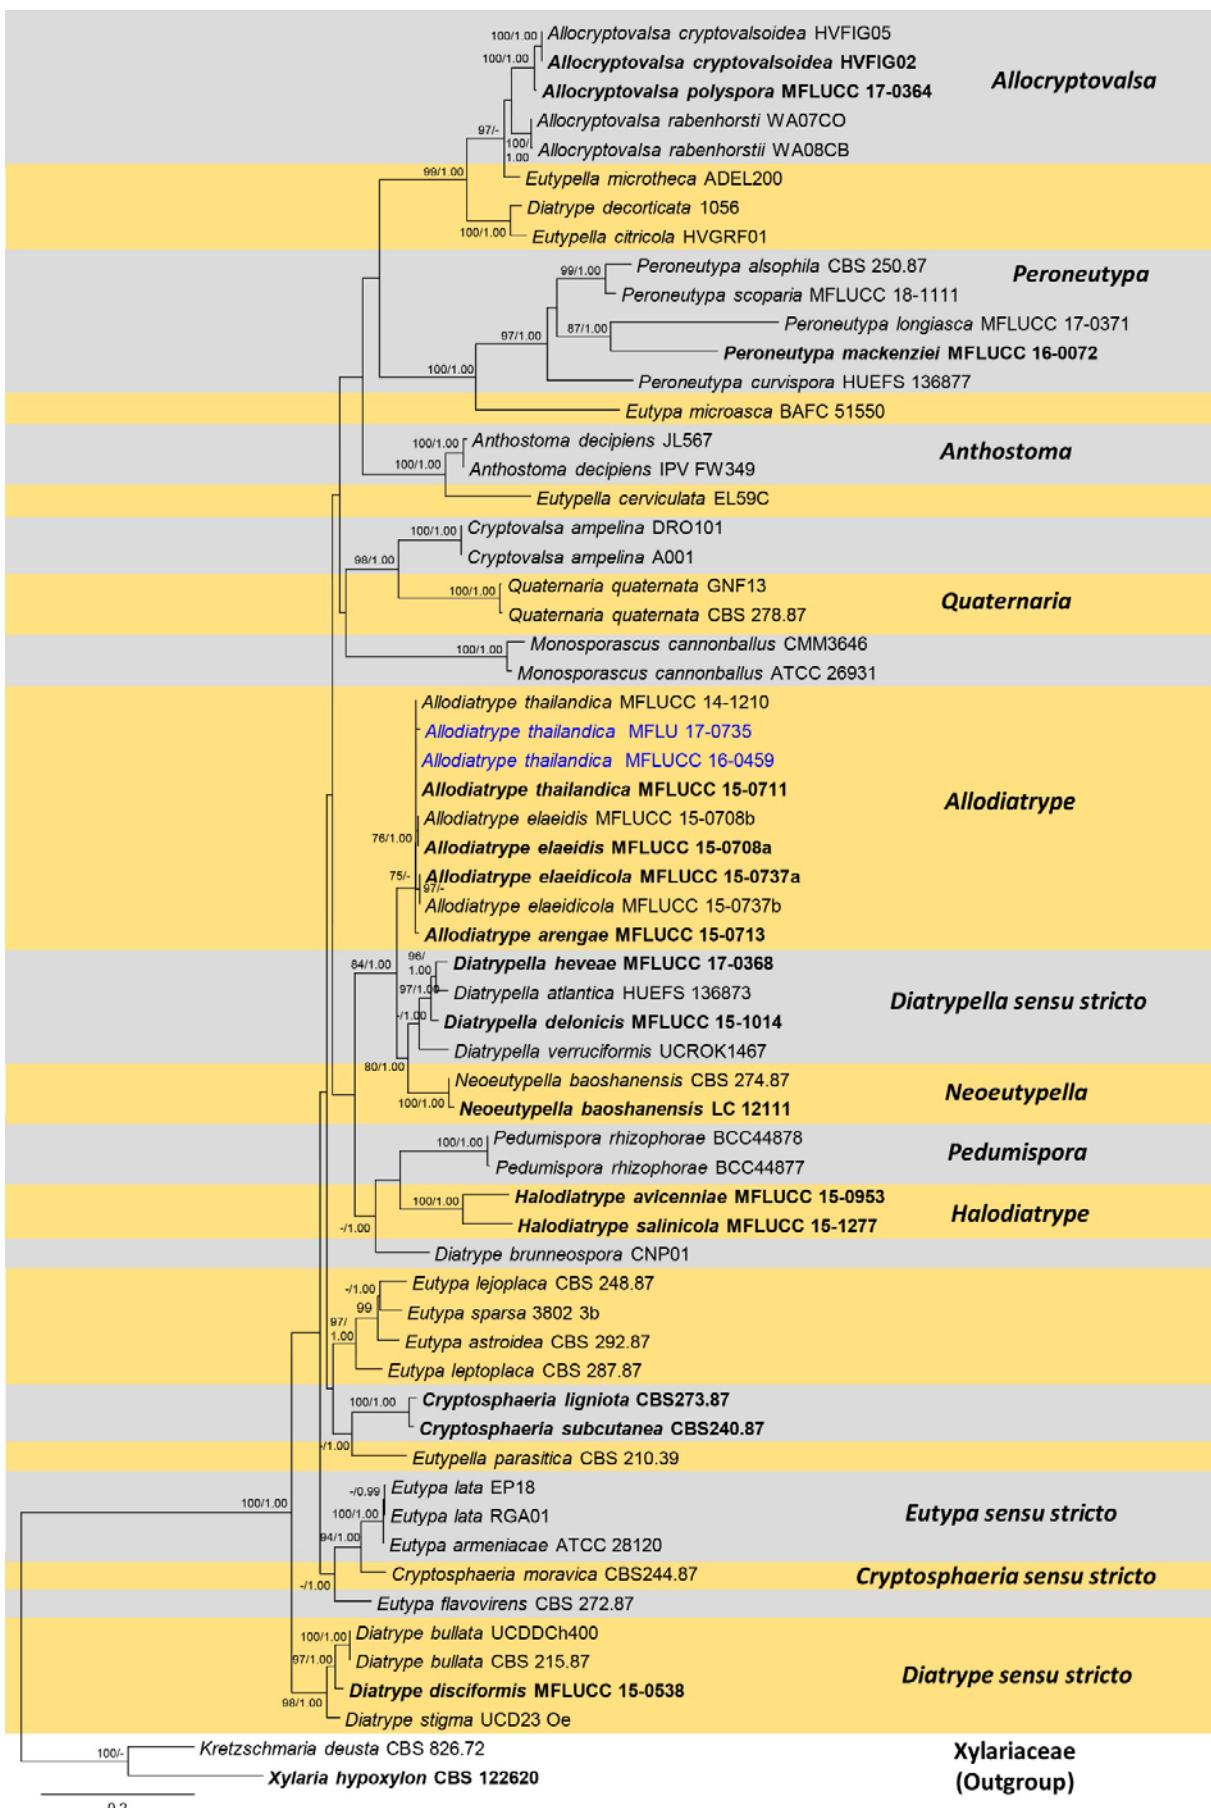

Figure 45 – Phylogram generated from RAxML analysis based on combined ITS and TUB2 sequence data of Diatrypaceae isolates. Sequences from sixty-one taxa, which comprise 993

characters including gaps, were included in the analyses. The tree was rooted to *Kretzschmaria deusta* (CBS 826.72) and *Xylaria hypoxylon* (CBS 122620). The scale bar indicates 0.2 nucleotide changes per site.

Figure 46 – *Allodiatripe thailandica* (MFLU 17-0735). a Herbarium material. b Appearance of ascomata on host substrate. c Cross section through stromata with ascomata. d, e Vertical section through stromata with ascomata. f Ostiole. g Peridium. h Peridium in face view. i Paraphyses. j–l Ascii. m Ascospores. Hypoxylaceae DC. emend. M. Stadler & L. Wendt.

***Hypoxylon* Bull.**

***Hypoxylon delonicis* R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.**

Fig. 50

Index Fungorum number: IF556864; Facesoffungi number: FoF07769

Etymology – Named after the host genus *Delonix*.

Holotype – MFLU 16-1031

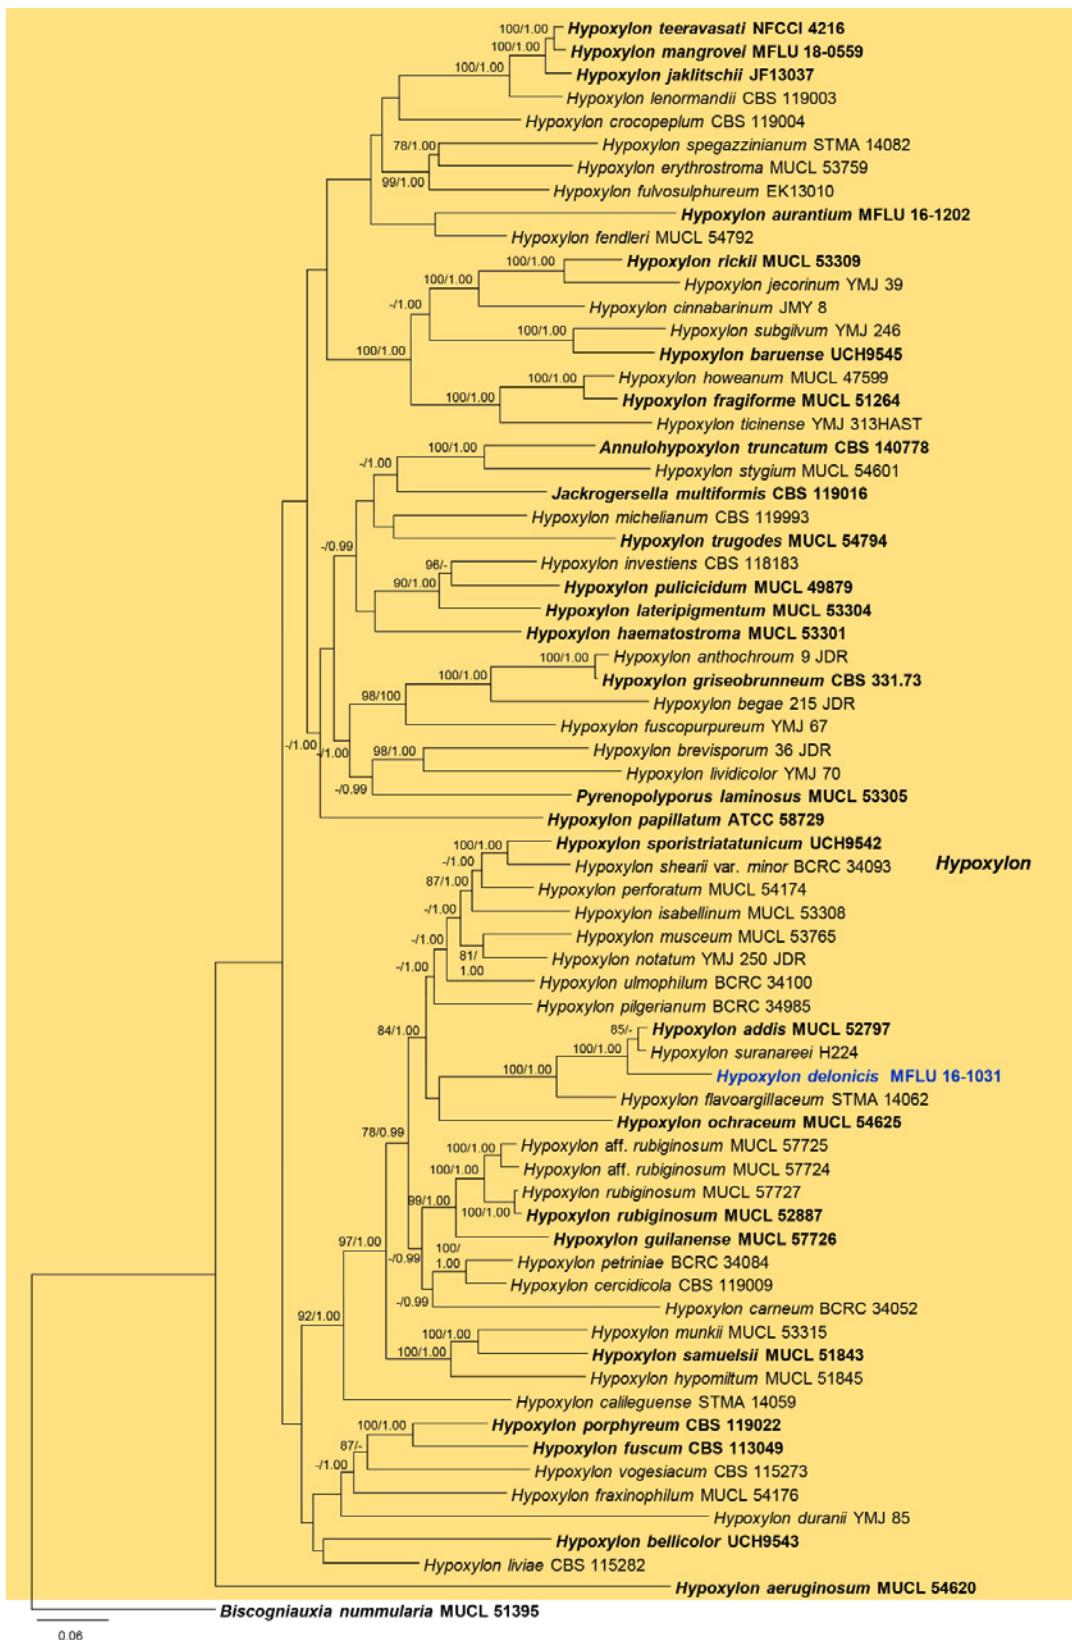

Figure 47 – Phylogram generated from RAxML analysis based on combined ITS and TUB2 sequence data of *Hypoxylon* isolates. Sequences from sixty-nine taxa, which comprise 2290 characters including gaps, are included in the analyses. The tree was rooted to *Biscogniauxia nummularia* (MUCL 51395). The scale bar indicates 0.06 nucleotide changes per site.

Notes – Colours were determined as in the previous literature of *Hypoxylon* species and the codes following Rayner (1970).

Saprobic on dried seed pods of *Delonix regia*. Sexual morph: *Ascostromata* 1.3–2.3 mm diam., glomerate, effuse-pulvinate, with conspicuous perithecial mounds, surface dark Brick (60), orange red granules immediately beneath surface and between perithecia, with KOH extractable pigments Citrine (13). *Ostioles* umbilicate, opening at the centre of a raised disc. *Ascomata* 300–635 × 200–485 µm ($\bar{x} = 423 \times 328$ µm), perithecial, obovoid. *Peridium* 20–75 µm, multilayered, inner layers composed of flattened, hyaline cells of *textura angularis*, outer layers composed of brown cells of *textura globosa*. *Paraphyses* absent. *Asci* 110–140 × 8–12 µm ($\bar{x} = 126 \times 10$ µm, n = 20), 8-spored, unitunicate, cylindrical, pedicellate, apex simple. *Ascospores* 12.4–15 × 6.3–7.4 µm ($\bar{x} = 13.4 \times 6.8$ µm, n = 40), uniseriate, one-celled, ellipsoid-inequilateral, with narrowly rounded ends, brown to dark brown, with sigmoid germ slit spore-length, guttulate, guttules aggregated in ends when mature, perispore dehiscent in 10% KOH, smooth-walled, episporous smooth. Asexual morph: Undetermined.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University premises, on dried seed pods of *Delonix regia* (Fabaceae), 6 January 2015, R.H. Perera, RHP 26 (MFLU 16-1031, holotype).

GenBank numbers – ITS: MT215503, LSU: MT386008, TUB2: MT212215.

Notes – Phylogenetically *Hypoxyylon delonicis* is related to *H. addis* and *H. suranareei* with high statistical support (100% MLBT, 1.00 BIPP; Fig. 47). However, the holotype of *H. suranareei* was not available from the herbarium where it was reported to be deposited in the protologue, and the comparison with this species can only rely on the published data. *Hypoxyylon delonicis* can be distinguished from *H. suranareei* by having larger ascocarps 300–635 × 200–485 vs. 200–400 µm, and broader asci (8–12 vs. 3.8–5 µm) and ascospores (6.3–7.4 vs. 5–6.3 µm) (fide Suwannasai et al. 2006). *Hypoxyylon delonicis* differs from *H. addis* in having shorter asci lacking an apical apparatus (110–140 vs. 170–190 µm) and by its ascospores having a smooth (vs. faintly striate) perispore (Fournier et al. 2010b). *Hypoxyylon addis* was collected from an Euphorbiaceae host in Ethiopia. *Hypoxyylon delonicis* resembles *H. shearrii* by glomerate stromata, but differs in having conspicuous raised discs around the ostioles, which are absent in *H. shearrii* (Fournier et al. 2010b). *Hypoxyylon shearrii* has been collected from *Quercus* wood (Ju & Rogers 1996, Fournier et al. 2010b). *Hypoxyylon delonicis* is also similar to *H. gibriacense* by its glomerate stromata and lack of an apical apparatus in asci (Fournier et al. 2010b). However, *H. delonicis* differs from *H. gibriacense* in having larger ascospores (12.4–15 × 6.3–7.4 vs. 11.5–13 × 6–6.8 µm) and by its ascospores having a smooth (vs. fairly conspicuous striate) perispore (Fournier et al. 2010b). Hence, we introduce *H. delonicis* as a new species based on both morphological and molecular evidence.

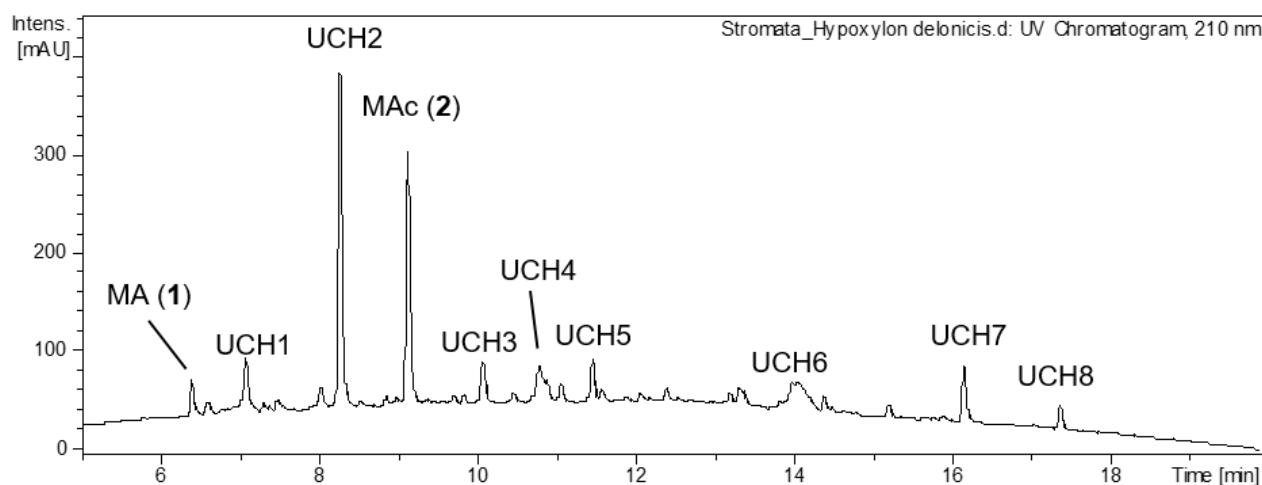

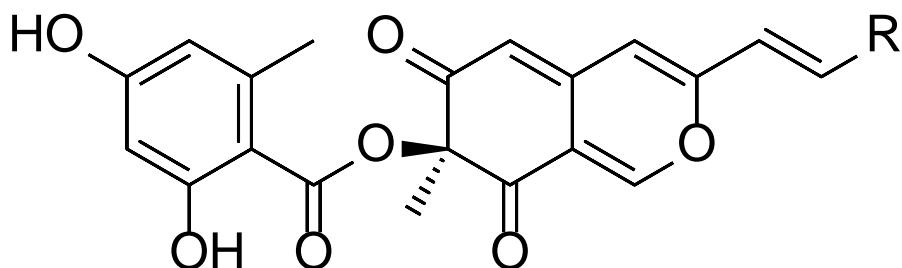

Figure 48 – HPLC-UV/VIS chromatogram of the stromatal extract of *Hypoxyylon delonicis* at 210 nm. MA = Mitorubrinic acid (1), MAc = Mitorubrinol acetate (2), UCH1–8 = unknown compounds from *H. delonicis*.

R:

1 -CH₂Ac

2 -COOH

Figure 49 – Known secondary metabolites found in stromatal extracts of *Hypoxyton delonicis*. 1 mitorubrinic acid. 2 mitorubrinol acetate.

Secondary metabolites: The stromatal extract was prepared and measured by HR-ESI-MS as described before (Kuhnert et al. 2017). The extract of *Hypoxyton delonicis* was found to contain the known azaphilone pigments mitorubrinol acetate (1) and mitorubrinic acid (2), which are widespread in *Hypoxyton* and form the core structures of more complicated metabolites (Surup et al. 2018) (Figs 48, 49). Besides, several peaks indicating probably representing yet unknown azaphilones were observed and labelled UCH1–8, with UCH2 even being the main peak within the extract and may account for the citrine color of the stromatal extract in KOH (notably, mitorubrins give an orange colour in KOH). It was of course not an option to attempt to isolate and identify these unknown components, to avoid destruction of valuable holotype specimen. However, it could be an option to watch out for the new fungus and collect more material for future mycochemical studies.

Xylariaceae Tul. & C. Tul.

Xylaria Hill ex Grev.

Xylaria arbuscula Sacc., Michelia 1(no. 2): 249 (1878)

Figs 52, 53

Facesoffungi number: FoF07770

On decaying fruits of *Swietenia mahagoni*. Sexual morph: *Stromata* gregarious to solitary, usually unbranched or rarely branched near base, stipitate, two types: longer stromata 9.5–18 mm high × 2–2.3 mm diam., abundant, with fertile head 4–8.5 mm long, cylindrical, conical to acute at the apex; stunted stromata, 1–3 mm high × 0.6–1.4 mm diam., rare, very short-stipitate, broadly conical or flattened, fertile head conical 0.7–1.1 mm long, with a conical sterile apex or apically obtuse; without visible perithecial contours, surface black, glabrous, obscurely cracked and roughened; internal tissue white, brownish grey in the stipe, solid, KOH. *Ostioles* obtusely papillate, black, often inconspicuous. *Peridium* 15–25 µm thick, composed of pale to brown cells of *textura angularis*. *Ascomata* 360–500 µm diam. ($\bar{x} = 440 \mu\text{m}$), completely immersed, perithecial, subglobose. *Paraphyses* 1.9–2.8 µm wide, hypha-like, septate, hyaline, thin-walled, embedded in gelatinous matrix. *Asci* 120–170 × 6.5–7.8 µm ($\bar{x} = 142 \times 7.2 \mu\text{m}$), 8-spored, unitunicate, cylindrical, the spore-bearing parts 75–106 µm long ($\bar{x} = 90 \mu\text{m}$), apical apparatus cylindrical, with a J+ apical ring, 3.2–3.6 × 2–2.6 µm ($\bar{x} = 3.4 \times 2.3 \mu\text{m}$). *Ascospores* 12.4–18 × 4.6–6.2 µm ($\bar{x} = 14.6 \times 5.4 \mu\text{m}$), obliquely to transversely uniseriate, fusiform, inequilateral with narrowly rounded to subacute or slightly pinched ends, 1–2(–3) guttulate, brown, with a conspicuous, straight, germ slit slightly less than spore-length; episporae smooth, not dehiscent in 5% KOH.

Asexual morph: *Stromata* 7–16 mm high × 1.3–2 mm diam., smaller than ascostroma, gregarious, unbranched, stipitate; head 5–7 mm in length, cylindrical, with a conical to acute apex; dark brown. *Conidiophores* 30–100 × 2–4 µm, forming around the stromatal head, pale brown, dichotomously branched, septate. *Conidia* 2.5–4.7(–10) × 2–4.8 µm ($\bar{x} = 4 \times 3$ µm), globose, subglobose, elliptical or sometimes angular or oblong, aseptate, with a flat basal abscission scar, hyaline, thick- and smooth-walled.

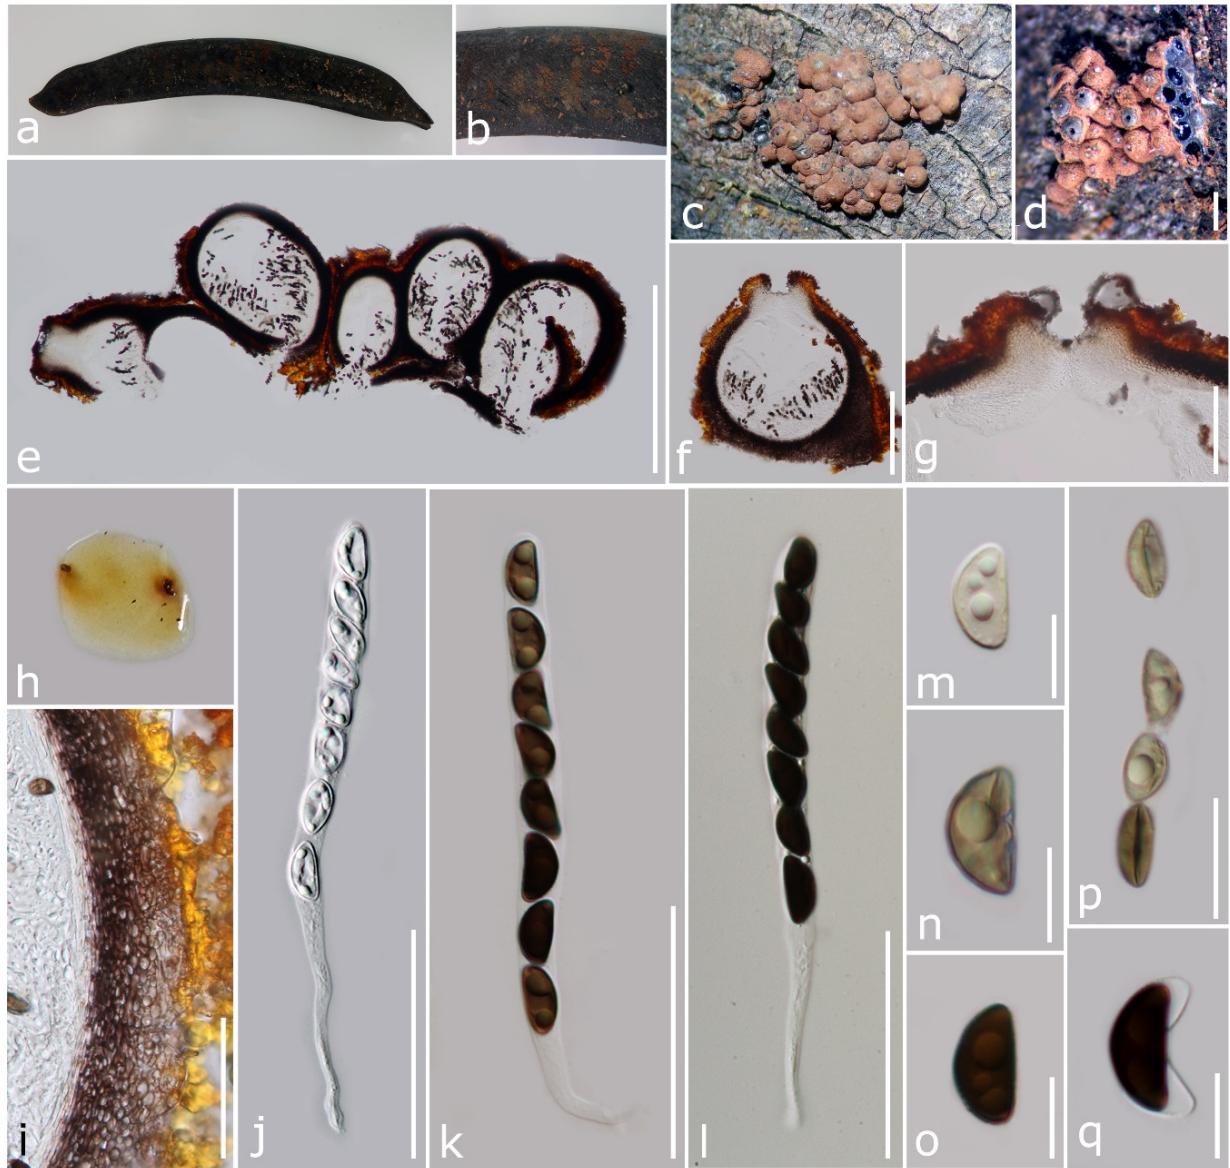

Figure 50 – *Hypoxylon delonicis* (MFLU 16-1031, holotype). a Herbarium material. b–d Appearance of ascocarps on host substrate. e, f Vertical section through stromata with ascocarps. g Ostiole. h Stromatal pigments in 10% KOH. i Close up of the peridium. j–l Immature and mature asci. m–o Immature and mature ascospores. p Ascospores with the germ slit. q Ascospore with released episporule in 5% KOH. Scale bars: d, e = 500 µm, f = 200 µm, g = 100 µm, i–l = 50 µm, m–o = 10 µm, p = 20 µm, q = 10 µm.

Material examined – THAILAND, Chiang Rai Province, Mae Fah Luang University garden, on decaying fruits of *Swietenia mahagoni* (Meliaceae), 16 August 2015, R.H. Perera, RHP 21 (MFLU 16-1022); *ibid.*, 16 December 2015, RHP 21b (MFLU 18-2721).

GenBank numbers – ITS: MT215513, LSU: MT215562 (MFLU 16-1022); ITS: MT215514, LSU: MT215563 (MFLU 18-2721).

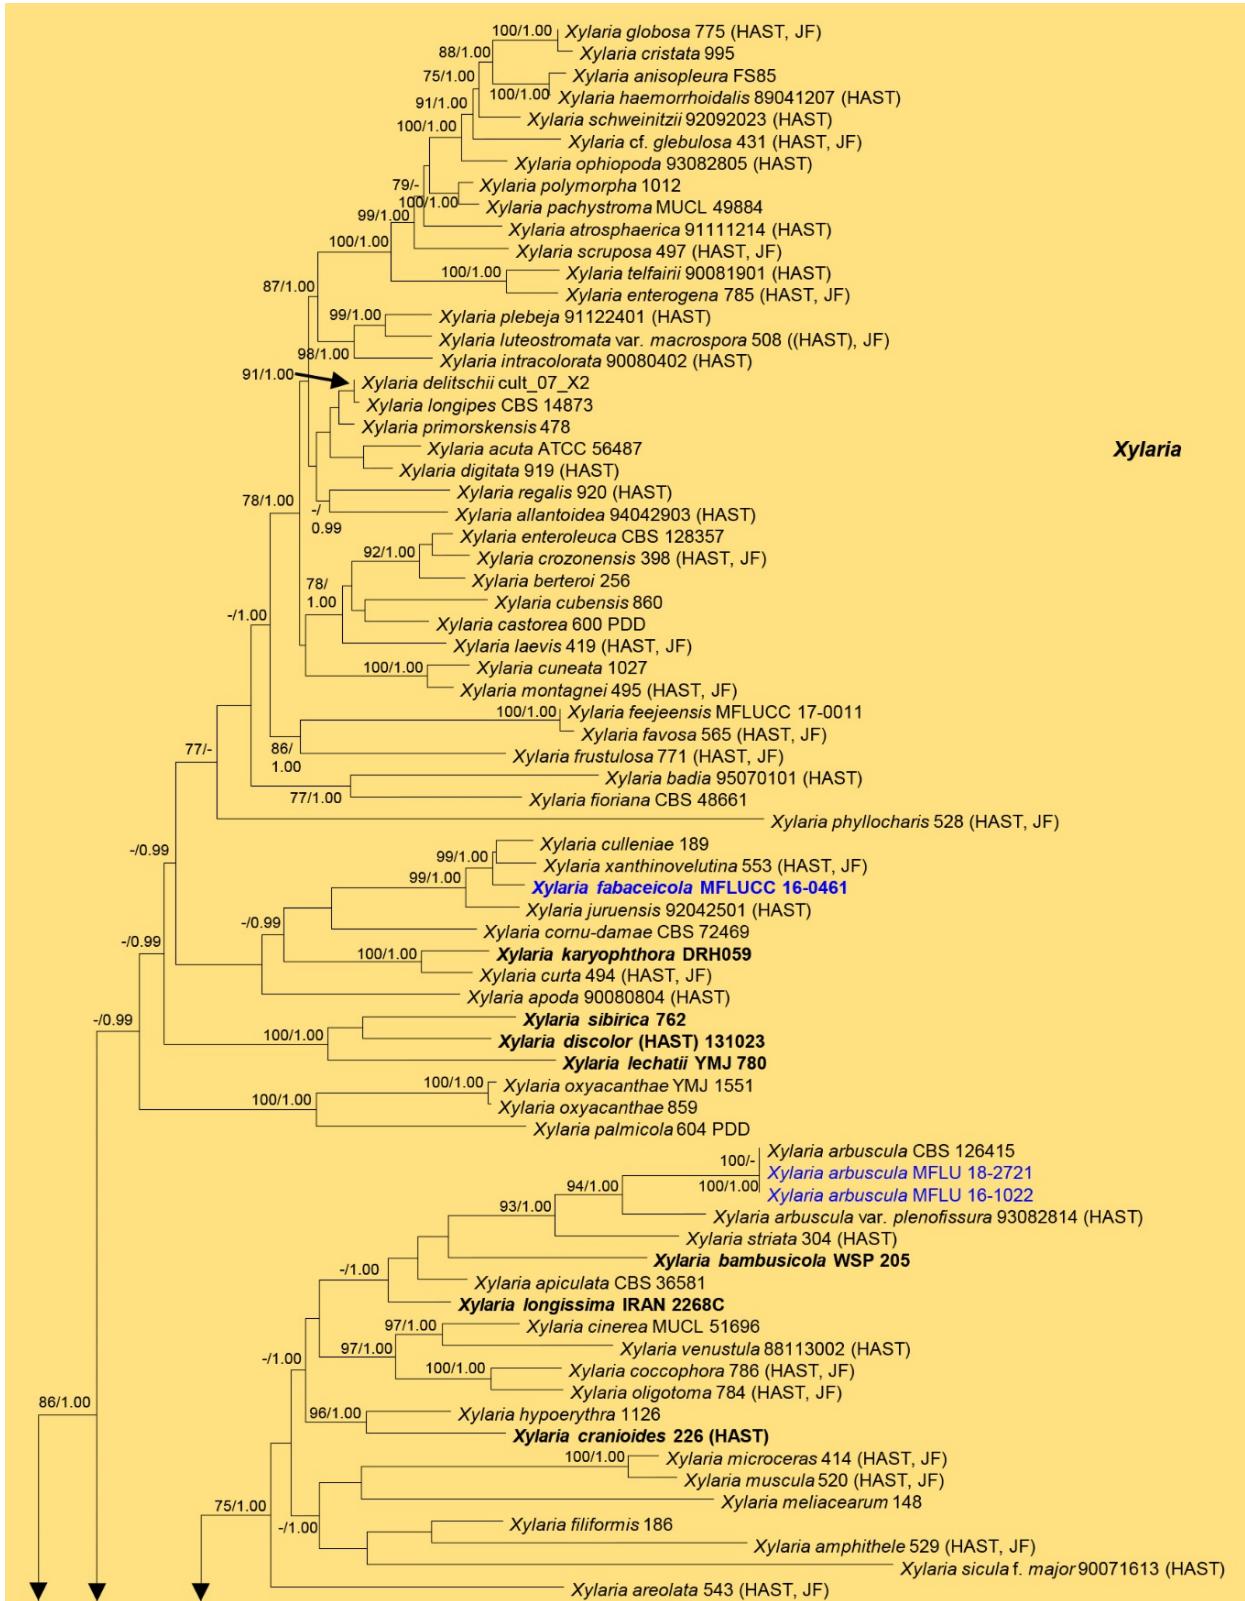

Figure 51 – Phylogram generated from RAxML analysis based on combined ITS, RPB2 and TUB2 sequence data of *Xylaria* isolates. Sequences from one hundred five taxa, which comprise 3476 characters including gaps, are included in the analyses. Tree was rooted to *Biscogniauxia nummularia* (MUCL 51395) and *Hypoxylon fragiforme* (MUCL 51264). The scale bar indicates 0.06 nucleotide changes per site.

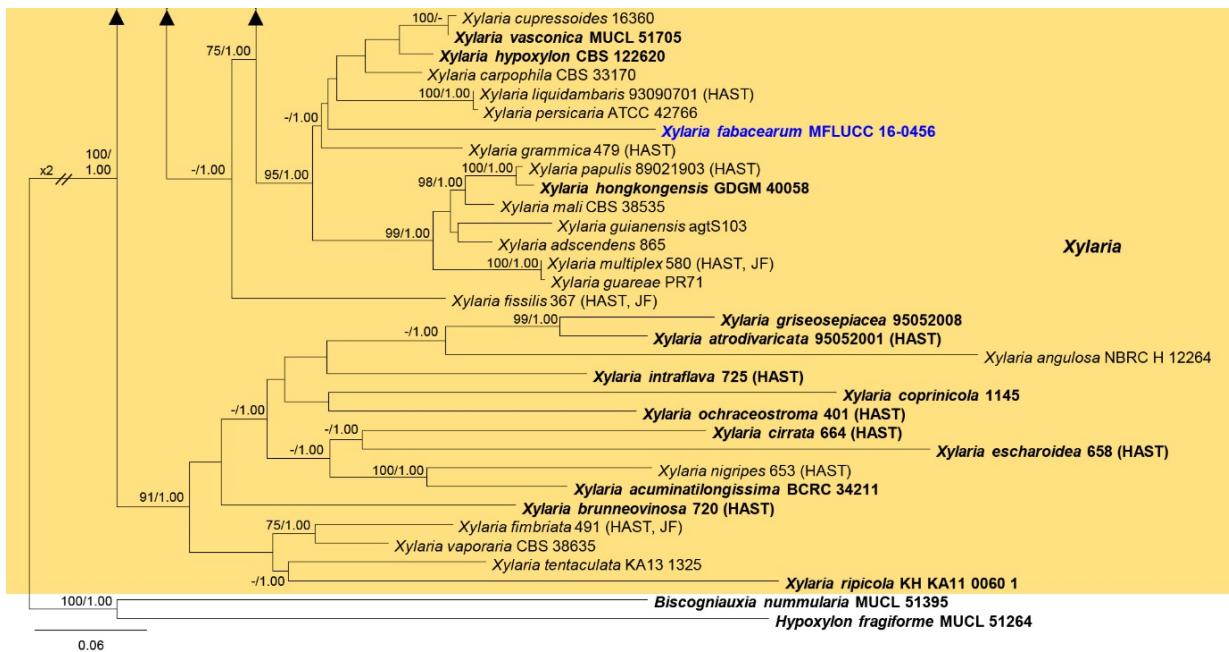

Figure 51 – Continued.

Notes – Wendt et al. (2017) and Daranagama et al. (2018) provided modern treatments of Xylariaceae which we follow here. Our new collections MFLU 16-1022 and MFLU 18-2721 grouped with *Xylaria arbuscula* (CBS 126415) with high statistical support in our phylogenetic analysis (Fig. 51). Specimens MFLU 16-1022 and MFLU 18-2721 belong to asexual morph and sexual morph stages, which were collected from *Swietenia mahagoni* fruits at the same location. The ITS and LSU gene regions of MFLU 16-1022 and MFLU 18-2721 are identical. Sexual morph of our collection was similar to *X. arbuscula* in morphology, ascospore and ascospore dimensions (Saccardo 1878, Fournier et al. 2010a). The holotype of *X. arbuscula* was collected from a greenhouse in Germany (Saccardo 1878). There was no asexual morph of the fungus reported so far (Saccardo 1878, Fournier et al. 2010a). By considering the morphological similarities, similarities in the ITS loci and phylogenetic analysis we identify our collection as *X. arbuscula* (Jeewon & Hyde 2016). This is the first record of *X. arbuscula* from *Swietenia mahagoni* and the first report of its asexual morph. Unfortunately, we were unable to amplify the RPB2 gene region of the fungus despite several attempts.

***Xylaria fabacearum* R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.**

Fig. 54

Index Fungorum number: IF556865; Facesoffungi number: FoF07771

Etymology – Named after the host family Fabaceae.

Holotype – MFLU 16-1061

Saprobic on decaying seed pods of Fabaceae. Sexual morph: *Stromata* 4.5–16 mm long × 0.9–1.8 mm diam., fertile part up to 9 mm long × 1.8 mm diam., cylindrical, branched or unbranched, solitary or clustered, stipe, tomentose, black, with sterile apices. *External surface* black, non-tomentose, roughened with ascomatal contours. *Internal tissue* white, not becoming hollow. *Ascomata* 290–480 µm high × 270–450 µm diam. ($\bar{x} = 390 \times 376 \mu\text{m}$), perithecial, globose to subglobose, mammiform, more less immersed, ostioles black, slightly papillate. *Peridium* 20–30 µm wide, composed of up to 12 layers of light brown-walled cells of *textura angularis* to *textura prismatica*, integrated with inner stroma cells. *Paraphyses* 1.4–2.4 µm wide, septate, hyaline. *Asci* 8-spored, 90–135 × 4–6 µm ($\bar{x} = 109 \times 5 \mu\text{m}$; n = 25), cylindrical, long stipitate, the spore-bearing part 56–65 µm long, with an inverted hat-shaped, J+ apical ring 2–2.5 × 1.5–2 µm ($\bar{x} = 2.3 \times 1.7 \mu\text{m}$, n = 10). *Ascospores* uniseriate to overlapping uniseriate, 9–11.2 × 3–4.3 µm ($\bar{x} = 10 \times 3.6 \mu\text{m}$, n = 35), ellipsoid-inequilateral, brown to dark brown, aseptate, guttulate;

germ slit conspicuous, straight, running full-length of the ascospore, perispore indehiscent in 10% KOH; episporae smooth, lacking a hyaline sheath. Asexual morph: Undetermined.

Figure 52 – *Xylaria arbuscula* (MFLU 18-2721). a Herbarium material. b, c Appearance of ascostromata on host substrate. d Cross section through stromata with ascomata. e Vertical section through ascomata. f Close up of the peridium. g–j Ascii. k, l Close up of apical ring (k in Melzer's iodine reagent). m–s Ascospores (q, r in 10% KOH, s arrows showing the germ slit).

Scale bars: c, d = 2 mm, d = 500 μ m, e = 200 μ m, f–j = 50 μ m, k, l = 20 μ m, m–r = 10 μ m, s = 20 μ m.

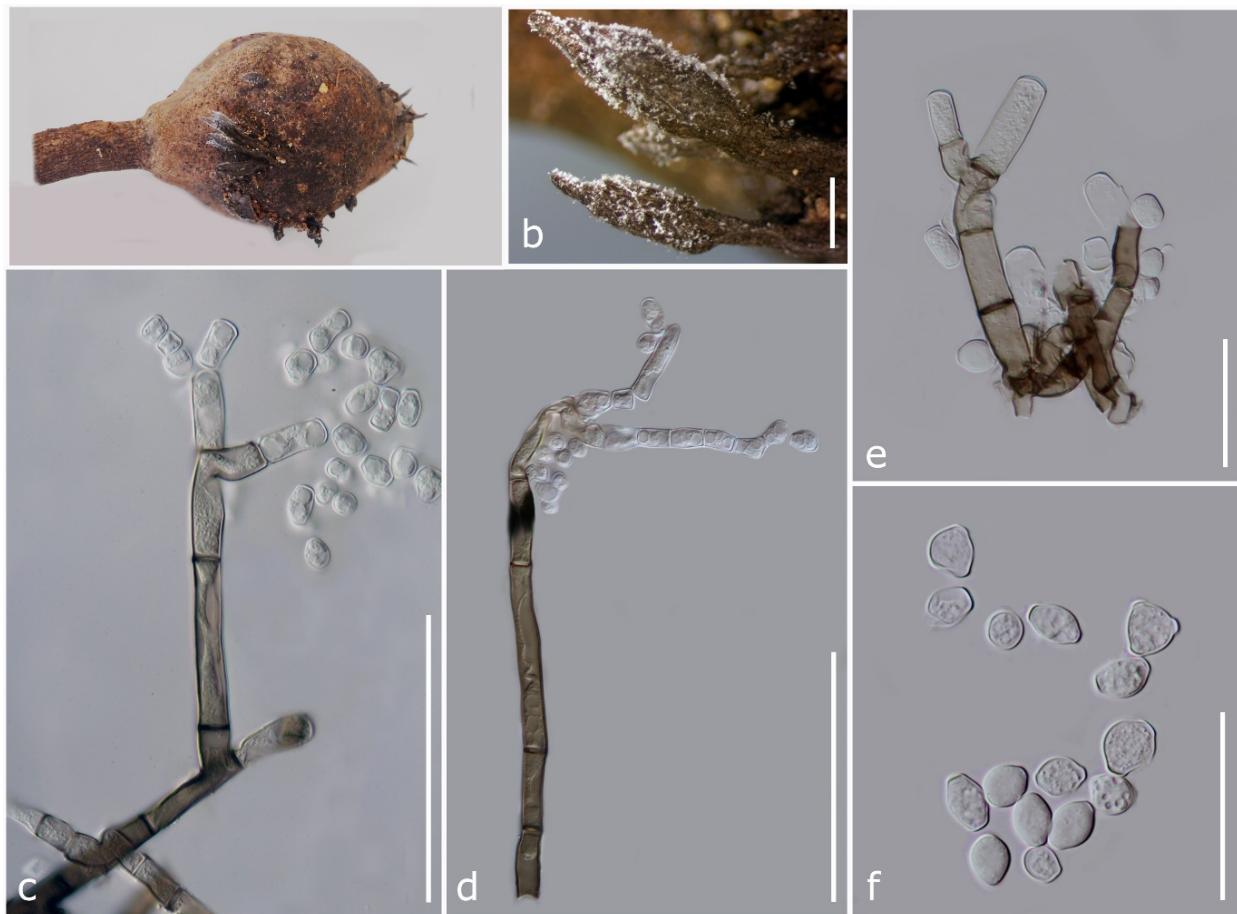

Figure 53 – *Xylaria arbuscula* (MFLU 16-1022). a Herbarium material. b Conidiophores on stromata. c–e Conidiophores with conidia. f Conidia. Scale bars: b = 200 μ m, c, d = 50 μ m, e, f = 20 μ m.

Culture characteristics – Ascospores germinating on PDA within 14 hours. Colonies growing on MEA, reaching 30 mm in 14 days at 28°C, flat, initially white, aerial mycelium forming concentric rings with cottony texture, margin undulate, white to ash or black above, reverse dark brown.

Material examined – THAILAND, Chiang Mai Province, on decaying seed pods of Fabaceae, 20 December 2015, R.H. Perera, DeloL4, (MFLU 16-1061, holotype); ex-type living culture MFLUCC 16-0456.

GenBank numbers – ITS: MT215512, LSU: MT215561, RPB2: MT212202, TUB2: MT212220.

Notes – *Xylaria fabacearum* (MFLUCC 16-0456) groups apart from other *Xylaria* species in an unsupported clade (Fig. 51). *Xylaria fabacearum* resembles *X. culleniae*, *X. fabaceicola* and *X. xanthinovelutina* (which were mostly isolated from leguminous fruits), but differs mainly by having ascospores that lack a hyaline sheath (Ju et al. 2018). *Xylaria fabacearum* can be distinguished from *X. luzonensis* (which is also isolated from leguminous pods) by its larger, brown to dark brown ascospores (9–11.2 × 3–4.3 vs. 8.5–9.5 × 3–3.5 μ m), while *X. luzonensis* has light brown ascospores (Ju et al. 2018). Hence, we identified our collection as a new species of *Xylaria*.

Figure 54 – *Xylaria fabacearum* (MFLU 16-1061, holotype). a Herbarium material. b Appearance of ascomata. c, d Vertical section through stroma with ascocarps. e Face view of the peridium.

f Section through peridium. g Paraphyses. h–l Ascii. (l in Melzer's reagent). m–o Ascospores. p Germinating ascospore. Scale bars: b = 1 mm, c, d = 200 μ m, e = 20 μ m, f–j = 50 μ m, k–l = 20 μ m, m–o = 10 μ m, p = 5 μ m.

Xylaria fabaceicola R.H. Perera, E.B.G. Jones & K.D. Hyde, sp. nov.

Fig. 55

Index Fungorum number: IF556866; Facesoffungi number: FoF07772

Etymology – Named after the host family Fabaceae.

Holotype – MFLU 16-1072

Saprobic on decaying seed pods of Fabaceae. Sexual morph: *Stromata* 13–25 mm long \times 0.6–1.5 mm diam., fertile part up to 12 mm long \times 1.2 mm diam., cylindrical, branched or unbranched, solitary or clustered, with sterile apices, stipe tomentose, black. *External surface* black, tomentose, roughened with ascomatal contours. *Internal tissue* white, not becoming hollow. *Ascomata* 360–550 μ m high \times 300–440 μ m diam. (\bar{x} = 480 \times 375 μ m), perithecial, mammiform, more or less immersed, ostioles black, slightly papillate. *Peridium* 30–45 μ m wide, two regions, outer region of 8–10 layers of hyaline to light brown, thick-walled cells of *textura prismatica*; inner region of 4–6 layers of hyaline cells of *textura angularis*. *Paraphyses* 3–4 μ m wide, septate, hyaline, tapering towards the apex. *Ascii* 100–130 \times 4.6–6.5 μ m (\bar{x} = 117 \times 5.6 μ m, n = 20) diam., unitunicate, 8-spored, cylindrical, long stipitate, the spore-bearing part 56–65 μ m, with an inverted hat-shaped, J+ apical ring 1.7–2.3 μ m \times 1.3–1.8 μ m (\bar{x} = 2 \times 1.5 μ m, n = 10) diam. *Ascospores* 7.5–10 \times 3.4–4.8 μ m (\bar{x} = 8.5 \times 4.2 μ m; n = 25) diam., uniseriate to overlapping uniseriate, ellipsoid-inequilateral, pale brown to brown, aseptate, guttulate; germ slit conspicuous, straight, slightly less than the spore length; surrounded with a hyaline sheath swelling at both ends to form non-cellular appendages, perispore indehiscent in 10% KOH, episporous smooth. Asexual morph: Undetermined.

Culture characteristics – Ascospores germinating on PDA within 12 hours. Colonies growing on MEA, reaching up to 55 mm in 14 days at 28°C, flat, initially white, aerial mycelium forming concentric rings with cottony texture, margin undulate, white to ash or black, reverse dark brown.

Material examined – THAILAND, Chiang Mai Province, Mushroom Research Center, on decaying seed pods of Fabaceae, 23 December 2015, R. H. Perera, M-8 (MFLU 16-1072, holotype); ex-type living culture MFLUCC 16-0461.

GenBank numbers – ITS: MT215511, LSU: MT215560, RPB2: MT212201, TUB2: MT212219.

Notes – *Xylaria fabaceicola* (MFLUCC 16-0461) shows close phylogenetic relationship to *X. xanthinovelutina*, *X. culleniae* (which were mostly isolated from leguminous fruits), and *X. juruensis* (Fig. 51). *Xylaria fabaceicola* can be distinguished by *X. xanthinovelutina* by smaller ascospores (7.5–10 \times 3.4–4.8 vs. 9–12 \times 3.5–5 μ m), and shorter spore-bearing parts of its asci (56–65 vs. 65–85 μ m) (Ju et al. 2018). A comparison of the ITS, RPB2 and TUB2 sequences of *X. fabaceicola* and *X. xanthinovelutina* (553 HAST, JF) revealed 13 (2.4%), 13 (1.4%) and 29 (4%) nucleotide differences, respectively, in each DNA locus. *Xylaria fabaceicola* resembles *X. culleniae*, from which it differs by having a smaller stroma (13–25 \times 0.6–1.5 mm vs. 55–70 \times 2–4 mm) (Ju et al. 2018). In considering morphological and, nucleotide differences in ITS, RPB2 and TUB2 regions, we identified our collection as a new *Xylaria* species.

There are several seed and fruit inhabiting *Xylaria* species, which lack DNA sequence data: *Xylaria duranii*, *X. euphorbiicola*, *X. guazumae*, *X. heloidea*, *X. himalayensis*, *X. jaliscoensis*, *X. patrisiae*, *X. psidii*, *X. rhizocola*, *X. rossmanae* and *X. warburgii* (Ju et al. 2018). We also compared our collections *X. fabacearum* and *X. fabaceicola* with these species based on morphological descriptions provided in Ju et al. (2018).

Helotiales Nannf. ex Korf & Lizoň

Fig. 56

Helotiales sp.

Saprobic on decaying cones of *Pseudotsuga menziesii*. Sexual morph: 275–420 \times 275–350 μ m (\bar{x} = 360 \times 300 μ m, n = 10). *Ascomata* apothecial, gregarious or in small groups, sessile,

slightly erumpent from the substrate. Disc yellow, slightly concave or flat and smooth. Receptacle subspherical, concolorous, clothed with hyaline hairs. Hairs 94–105 × 5.9–6.6 µm ($\bar{x} = 98 \times 6.2$ µm, n = 20), tapered, 5-septate, walls usually thin. Ectal excipulum 13–18 µm ($\bar{x} = 15.0$ µm, n = 10), composed of thin-walled, hyaline cells of *textura globulosa*. Medullary excipulum 76–112 µm ($\bar{x} = 89$ µm, n = 10) composed of narrow, thin-walled, hyaline cells of *textura epidomoidea*. Hymenium hyaline. Paraphyses 0.9–1.2 µm wide ($\bar{x} = 1.0$ µm, n = 20), numerous, filiform, obtuse at the apex, non-septate. Asci 91–105 × 6.6–9.6 µm ($\bar{x} = 96 \times 8.7$ µm, n = 30), 8-spored, cylindric-clavate, unitunicate, tapered, with a stipitate base, croziers present at the base of ascospores, conical at the apex, with an amyloid ring at apex, partly blue in Meltzer's reagent. Ascospores 52–58.6 × 2.3–2.9 µm ($\bar{x} = 56.5 \times 2.6$ µm, n = 40), lying parallel in a single long fascicle within the ascus, hyaline, filiform-cylindric, slightly tapered to the lower end, rounded at the poles, 7-septate. Asexual morph: Undetermined.

Scale bars: b = 1 mm, c = 200 µm, d = 300 µm, e = 50 µm, f = 25 µm, g = 30 µm, h–l = 20 µm, m–s = 5 µm.

Saprobic on decaying cones of *Pseudotsuga menziesii*. Sexual morph: Apothecia 0.6–1 mm diam., arising singly or in small groups, stipitate, white when fresh, margins, flanks and stipe

covered with hairs. *Receptacle* cupulate, disc concave, disc and the margins are white when fresh. *Hairs* 40–65 × 2.8–3.6 µm ($\bar{x} = 51.2 \times 3.2$ µm, n = 30) cylindric, septate, hyaline, walls usually thin, surface finely granulate. *Ectal excipulum* 8–15 µm ($\bar{x} = 11$ µm, n = 10) in flanks, composed of thin-walled, long, hyaline cells of *textura prismatica*. *Medullary excipulum* in flanks, composed of thin-walled, hyaline cells of *textura porrecta*. *Hymenium* hyaline. *Paraphyses* 2–4 µm wide ($\bar{x} = 2.8$ µm, n = 20), numerous, lanceolate, septate, exceed asci in length. *Asci* 35–50 × 3.7–4.2 µm ($\bar{x} = 46.3 \times 4.1$ µm, n = 30), 8-spored, unitunicate, cylindric–clavate, conical at the apex, amyloid ring present at the ascus apex, partly blue in Meltzer's reagent, stipitate base, arising from croziers. *Ascospores* 5.5–8.2 × 1.2–2.2 µm ($\bar{x} = 6.5 \times 1.8$ µm, n = 40), 1–2-seriate, fusoid-clavate, aseptate, hyaline. Asexual morph: Undetermined.

Material examined – UK, Hampshire, New Forest, on decaying cones of *Pseudotsuga menziesii* (Pinaceae), 16 May 2015, E.B.G. Jones, GJ158 (MFLU 16-1863).

Notes – We identified our collection as a *Lachnum* species based on morphological resemblance to the genus (Ekanayaka et al. 2017).

Fungal check list

Discussion

Diversity of fungi on wild seeds and fruits

In this paper we review the fungal taxa described from wild fruit substrates until December 2019 (Table 2). Currently 300 new fungal species have been described from wild seeds/fruit substrates, from 54 countries (Index Fungorum 2020). Fungi reported from wild seeds and fruits belong to 609 fungal genera of different fungal families and included 28 novel genera (Table 2). Ascomycota and Basidiomycota are the major fungal phyla reported from wild seeds and fruits with significantly fewer Mucoromycota, Chytridiomycota, and Blastocladiomycota reported (Fig. 58). The highest number of fungi on wild seed/fruit substrates, belong to Ascomycota with 82% reported (Fig. 58). The dominant genera include: *Alternaria*, *Aspergillus*, *Candida*, *Chaetomium*, *Cladosporium*, *Colletotrichum*, *Curvularia*, *Diaporthe*, *Drechslera*, *Fusarium*, *Mucor*, *Penicillium*, *Pestalotiopsis*, *Restiosporium*, *Rhizopus*, *Talaromyces*, *Trichoderma* and *Xylaria*. (Fig. 60). Most were recorded as asexual morphic taxa, with fewer sexual morphs. Wild seed and fruit fungi belong to 27 fungal classes (Fig. 59). The number of Sordariomycetes taxa (30%) and Dothideomycetes taxa (26%) associated with forest seeds and fruits are significantly higher than other classes (Fig. 59). Lichenization is one of the major lifestyles among fungi, and are classified in the Ascomycota and Basidiomycota (Lücking et al. 2017). There are three novel lichen fungi, *Cladonia lacryma*, *Lecanora shangriensis* and *Lecanora substrobilina*, described from wild seed/fruit substrates (Table 2).

Forest tree seeds have vast diversity in their size, shape and texture (Sutherland et al. 2002). The size and texture of tree seeds ranging from small and hard to the relatively large and fleshy (Sutherland et al. 2002) may influence the fungal diversity. The highest number of new wild seed/fruit fungi are from Thailand (18%), while Australia, China, USA and India also have significant numbers of novel species (Fig. 62). Fruit diversity in tropical regions is higher than in temperate regions which may lead to an increase in the availability and variety of resources or substrates for fungal

colonisation (Hyde et al. 2005). Mittal et al. (1990) indicated that the climate conditions in the tropics also facilitate the development of seed-borne fungi in the region. Most of the new fungi have been described from wild fruits and coniferous cones (246 taxa), when compared to seeds (54 taxa).

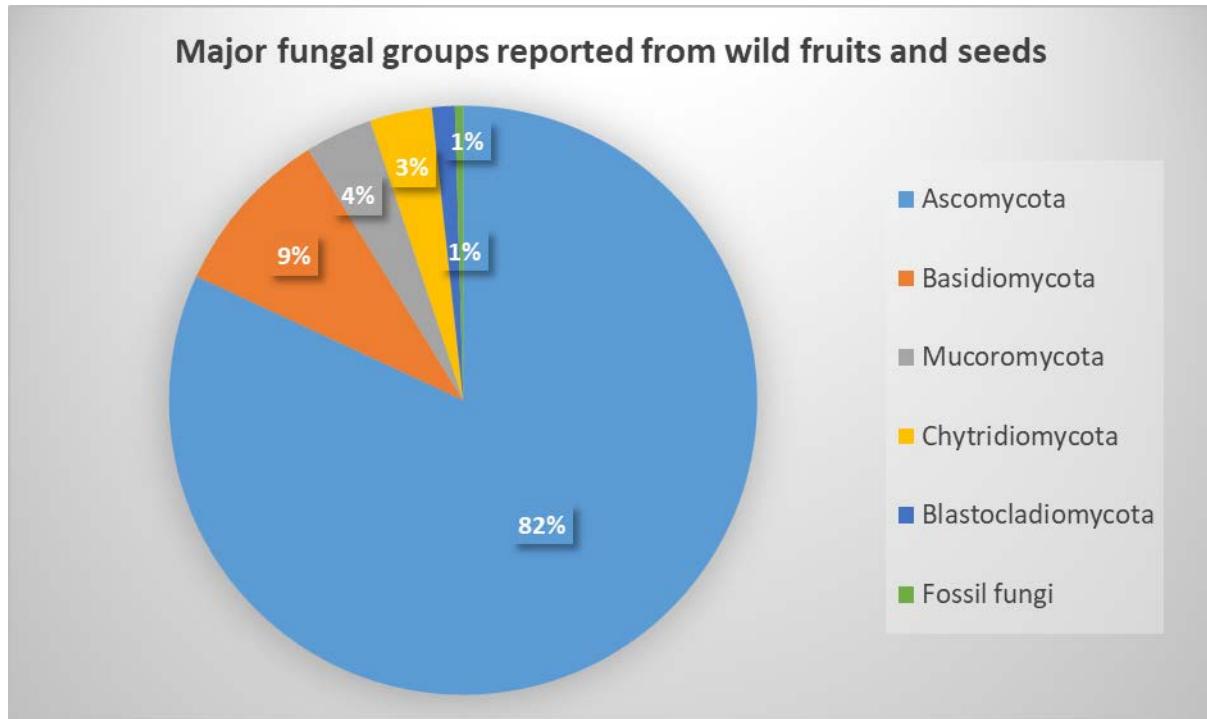

Figure 58 – Percentage of species belonging to major fungal phyla reported from wild seeds and fruits.

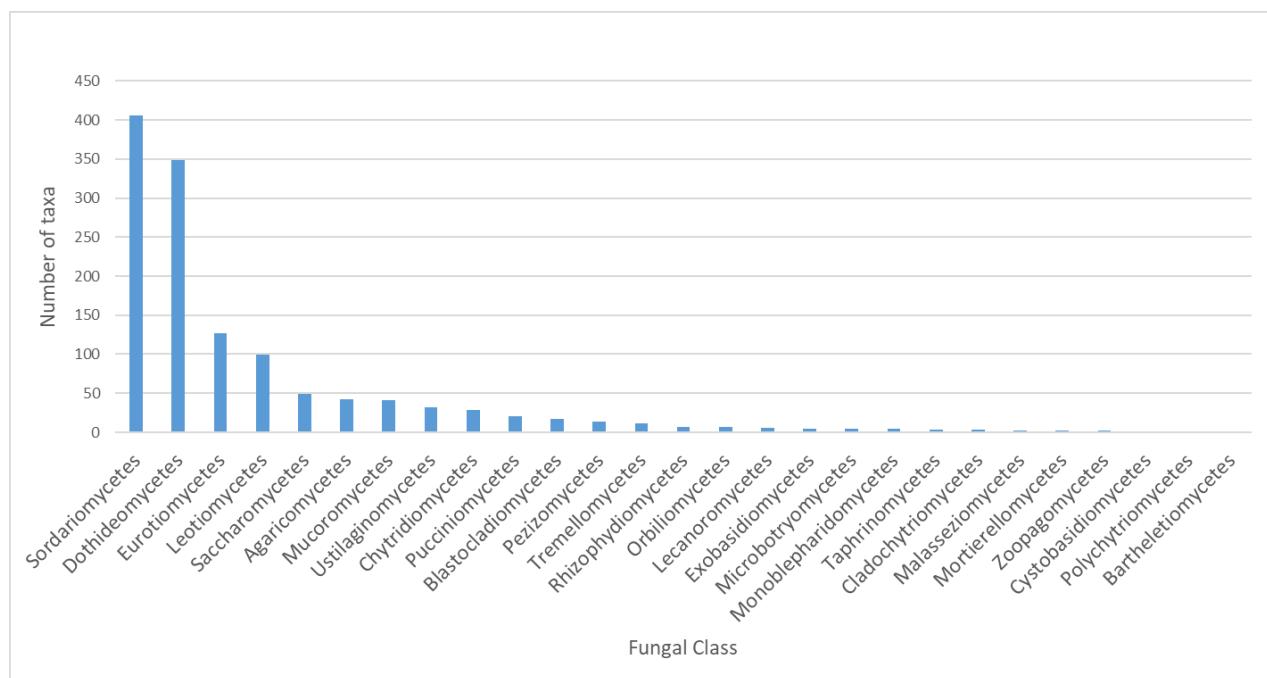

Figure 59 – Number of wild seeds/fruit inhabiting fungi belonging to different fungal classes.

Wild seed and fruit fungi have been described from 80 plant families, although most were collected from the legume family, Fabaceae (Fig. 63, Table 2). Fabaceae is the third largest

flowering plant family with worldwide distribution (Gepts et al. 2005). Pinaceae, Fagaceae, Restionaceae, and Poaceae are the other plant host families from where the novel wild seed/fruit fungi were mostly described (Fig. 63).

Fusarium species isolated from wild fruits in our study are mainly belonging to *Fusarium lateritium* species complex (Fig. 24). Species of this complex prefer seed and fruit substrates. They are commonly reported from fruits of commercially important plants, for example, *Fusarium stilbooides* associated with fruits of banana, bell pepper (*Capsicum annum*) and *Coffea arabica* (Geiser et al. 2005, Sandoval-Chávez et al. 2011, Zeng et al. 2013), while *Fusarium lateritium* was isolated from fruits of banana, *Coffea arabica*, dragon plant (*Cereus undatus*) and hazelnut (*Corylus avellana*) (Abo-El-Dahab & El-Goorani 1969, To et al. 1999, Geiser et al. 2005, Vitale et al. 2011). *Fusarium lateritium*, *F. sarcochroum* and *F. stilbooides* are also reported from seeds of various forest plants and acorns of *Quercus robur* (Table 2).

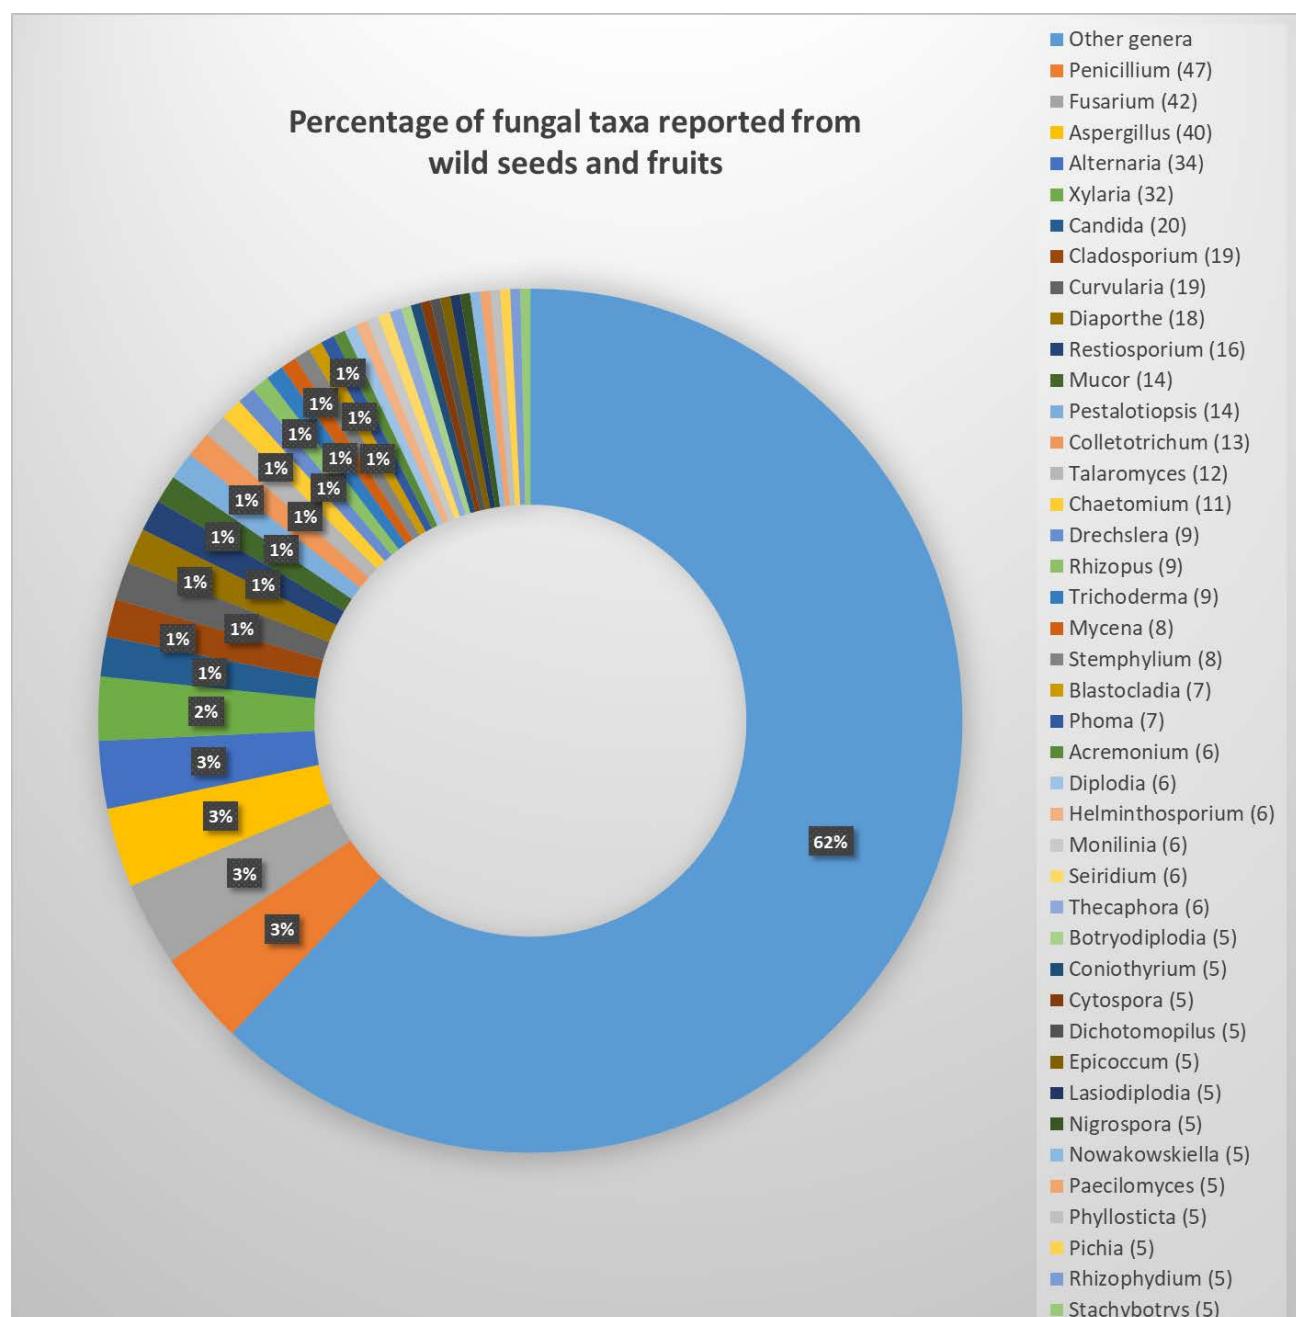

Figure 60 – Percentage of fungal species in different genera reported from wild seeds and fruits (number of species reported for each genus are given in brackets).

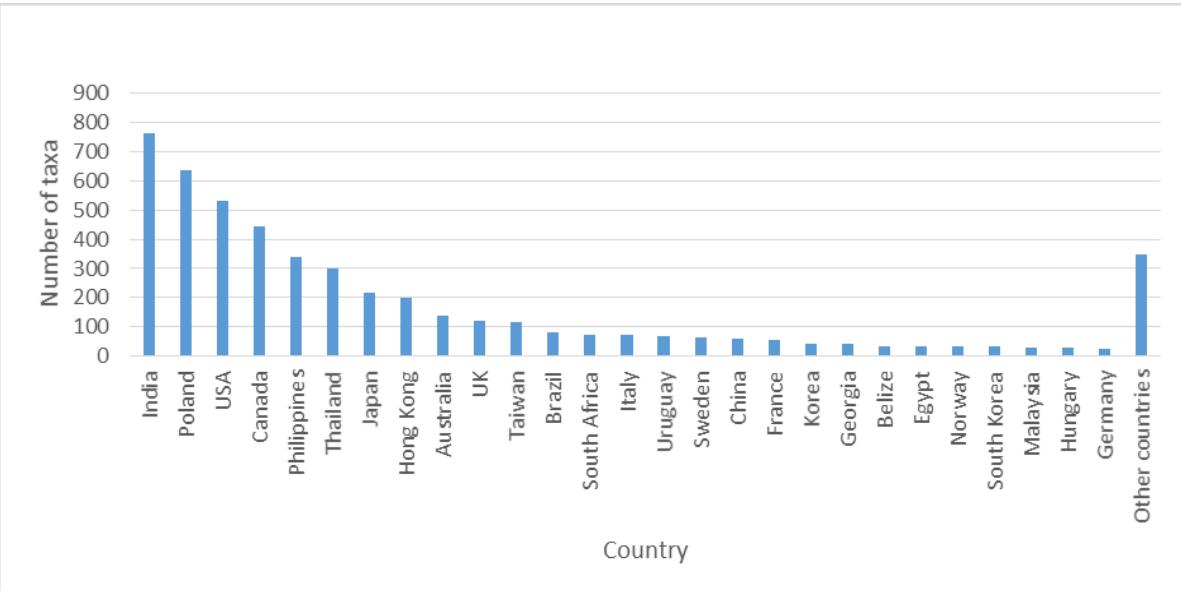

Figure 61 – Number of wild seeds/fruit inhabiting fungi reported from different countries.

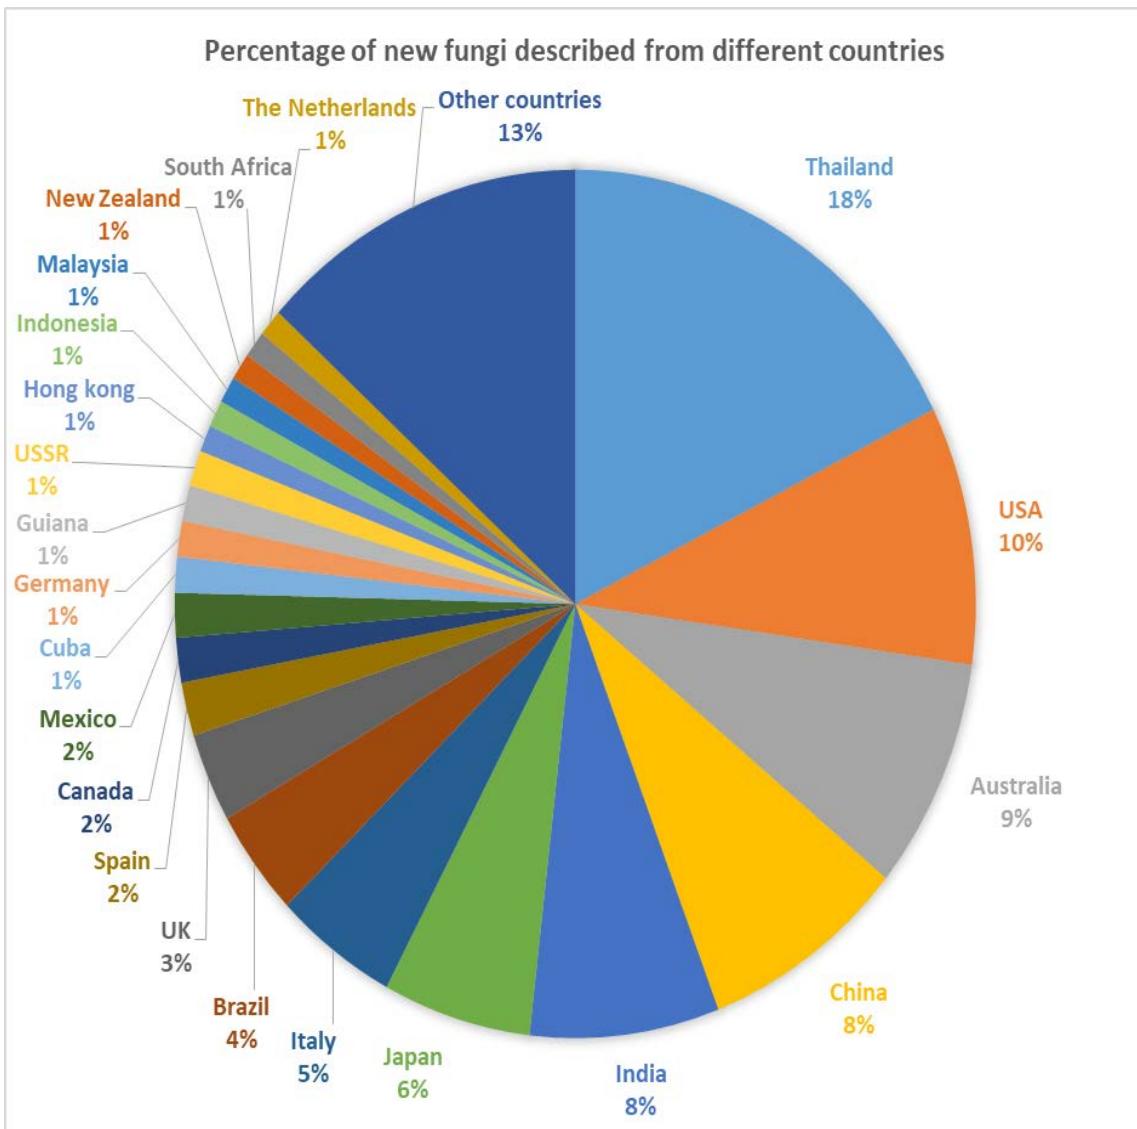

Figure 62 – Percentage of new seed and fruit fungi described from different countries.

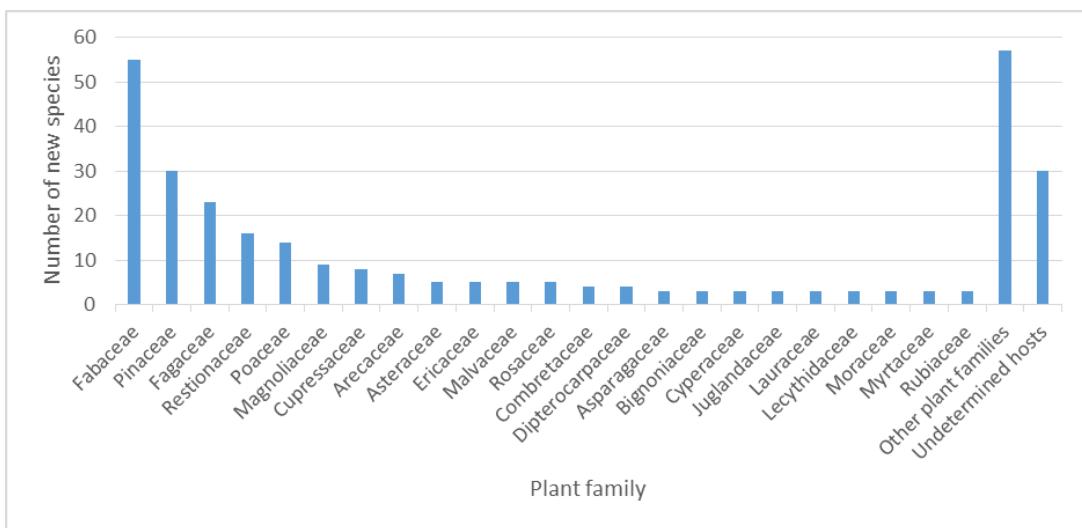

Figure 63 – Number of new wild seed and fruit fungi reported from different plant host families.

Basidiomycota

The second largest group of fungi reported from wild seeds and fruits is Basidiomycota (9%), including 65 new species (Fig. 58). This group includes several classes such as Agaricomycetes, Cystobasidiomycetes, Exobasidiomycetes, Microbotryomycetes, Pucciniomycetes and Ustilaginomycetes.

Discomycetes

Discomycetes are a group of apothecia-producing fungi, having operculate or inoperculate asci, in the phylum Ascomycota (Ekanayaka et al. 2017). There were 20 discomycete species newly introduced from wild seeds and fruits (Table 2).

Rust fungi

Rust fungi (Pucciniales, Pucciniomycetes) are biotrophic pathogenic fungi with a narrow host range (Niks 1987). They are less likely to infect seeds/fruits however, they can also be found from fruits (Walker & van der Merwe 2009, Berndt 2011). *Aecidium acanthocarpi* and *Endoraecium kauaiianum* were described from fruits of *Acanthocarpus verticillatus* and *Acacia koa*, respectively (Walker & van der Merwe 2009, Berndt 2011). We list four rust fungi described from wild seeds/fruits substrates including the above two species (Table 2).

Smut fungi

Many smuts produce spores in seeds (Table 2). We list 36 new smut fungi reported from wild seed and fruits worldwide (Table 2). They belong in Urocystidales, Ustilaginales (Ustilaginomycetes), Microbotryales (Microbotryomycetes) and Tilletiales (Exobasidiomycetes) (Table 2). *Centrolepidosporium* was described from fruits of *Centrolepis exserta* in Australia (Shivas & Vánky 2007). Restionaceae plants are the most common hosts for many seed/fruit inhabiting smut fungi, while others were found on Fabaceae, Cyperaceae, Poaceae, Araliaceae, Amaranthaceae, Primulaceae, Hypoxidaceae, Asparagaceae, Asteraceae, Droseraceae, Primulaceae and Montiaceae hosts (Fig. 60).

Clavicipitaceous fungi

Five new clavicipitaceous parasites have been described from seeds and fruits since 1981 and, three (*Claviceps bothriochloae*, *C. microspora* and *C. panicoidearum*) were from non-commercial grass seeds collected in Japan (Tanda 1985, 1991, Tanda & Harada 1989). Generally, clavicipitaceous species have a narrow host range (Rodriguez et al. 2009).

Yeast

We listed 13 new yeast species belonging to 8 genera namely *Candida*, *Cyberlindnera*, *Hanseniaspora*, *Hyphopichia*, *Kuraishia*, *Metschnikowia*, *Saccharomyopsis* and *Wickerhamiella* described from wild seeds and fruits (Table 2). The succession of yeast species colonizing the fallen ripe fruit of amapa (*Parahancornia amapa*) and *Clusia grandiflora* in tropical forests was examined by Morais et al. (1995). Fruits with sugary, soft, fleshy inner layer are prone to yeast colonisation during the first few days of fruit fall (Miller & Phaff 1962, Morais et al. 1995).

Host-specificity

It has been reported that xylariaceous taxa have specific and distinct relationships with their hosts (Rogers 1979b, 2000, Laessøe & Lodge 1994, Ju et al. 2018). Some of the seed/fruit associated species of *Xylaria* appear to be host-specific, as they are restricted to one host species, genus or family (Husbands et al. 2018, Ju et al. 2018). *Xylaria carpophila* occurs only on *Fagus sylvatica*; *X. karyophthora* on *Chlorocardium*; *X. liquidambar* on *Liquidambar*; *X. magnoliae* var. *magnolia* and var. *microspora* on *Magnolia*, and *X. warburgii* on *Sloanea* (Rogers et al. 1992, 2002, Husbands et al. 2018, Ju et al. 2018). *Xylaria palmicola* and *X. rhizocola* are probably associated only with palm seeds (Ju et al. 2018). In contrast, Ju et al. (2018) collected *X. oxyacanthalae* from fruits/seeds of plants in various families, such as *Carpinus* (Betulaceae), *Carya* (Juglandaceae), and *Cornus* (Cornaceae), *Crataegus* (Rosaceae), and *Prunus* (Rosaceae). However, whether seed and fruit fungi are host-specific is doubtful for most species associated with seeds and fruits, especially if they have been collected only once or twice (Ju et al. 2018). There are other species such as *X. clusiae*, *X. duranii*, and *X. heloidea* not only grow on fallen fruits or seeds, but also can be found on fallen leaves as well (Ju et al. 2018). *Xylaria xanthinovelutina* (= *X. ianthinovelutina*), probably the most commonly found fruit inhabiting *Xylaria* species, usually occurs on woody pods of legumes but has also been found on dead woody substrates (Martín 1970, Ju et al. 2018). Clavicipitaceous grass fungi are known to be specific at the family level (Petrini 1996, Zhou & Hyde 2001). Most *Epichloë* and *Neotyphodium* species are host-specific and show symbiotic relationships with C3 grasses (Bacon & White 2000).

Production of bioactive compounds

Shen et al. (2014) revealed that some wild seed fungi can be potential sources of bioactive compounds and plant defense activators. They screened 49 endophytic fungal strains from seeds of moso bamboo (*Phyllostachys edulis*) in China for production of bioactive substances and identified *Cladosporium* sp., *Curvularia* sp., undefined fungal genus 1, *Penicillium* sp. and *Shiraia* sp. with antimicrobial activity against clinical bacteria and yeasts. *Shiraia* sp. produced hypocrellin which has promising antileishmanial properties (Ma et al. 2004, Shen et al. 2014).

Decomposition of wild seeds and fruits and fungal succession

Decomposition and nutrient cycling play a crucial role in the balance of ecosystems. Saprobic fungi are vital for decomposition and nutrient cycling processes on the forest floor (Somrithipol et al. 2002a, Bucher et al. 2004, Fukasawa et al. 2012). Fungi secrete extracellular enzymes and play an important role in decomposition of lignocellulose substrates in forest ecosystems (Pointing et al. 2005, Fukasawa et al. 2012). In forest ecosystems the wild seed/fruit litter (especially the woody seed covering organs) is quantitatively important, since it contributes to total carbon in forest soils (Fukasawa et al. 2012). Mast-seeding (masting), the periodic synchronous production of seed crops by a plant population (Kelly 1994), can be observed in many forest tree species (Suzuki et al. 2005) (Fig. 60). Mast seeding of *Fagus crenata* (Japanese beech) occurs every 5–7 years (Hiroki & Matsubara 1995, Suzuki et al. 2005, Fukasawa et al. 2012). Cupules are the second largest component of beech litter and comprises up to 28% of total annual litter fall in mast-seeding years (Kawada & Maruyama 1986). Pine cones are one component of coniferous litter (Kasai et al. 1995). A study conducted in a coniferous forest (giant sequoia, white fir and sugar pine) in USA revealed 4–10% of the total litter fall was cones (Stohlgren 1988).

Nutrient rich substrates (cereals, fruits, berries) are usually colonised by rapidly growing asexual filamentous fungi such as *Colletotrichum* spp., *Fusarium* spp., *Diaporthe* spp. (Marasas et al. 1998, Somrithipol et al. 2002b, Torp & Nirenberg 2004, Prihastuti et al. 2009, Weir et al. 2012, Udayanga et al. 2013, Crous et al. 2015b). Woody substrates such as cupules of beech, legume pods, cones and woody seeds are rich in lignin and celluloses and provide substrates for saprobic fungi (eg. *Xylaria carpophila*, *Pseudohalonectria fagicola*, *P. hampshirensis* on cupules of *Fagus* spp.; *Thozetella nivea* on seed pods of *Delonix regia*; *Lecanora substrobilina* on cones of *Pinus*; *Xylaria magnoliae* on magnolia fruits (Rogers 1979a, Rogers et al. 1992, Printzen 2001, Somrithipol et al. 2002b, Fukasawa et al. 2012, Perera et al. 2016a). Furthermore, all Helotiales sexual morphic taxa collected from wild fruits/seeds are reported from woody substrates (Table 2).

The fungal assemblages associated with seeds/fruits, in different stages of decomposition also vary (Somrithipol et al. 2002b, Fukasawa et al. 2012). Fungi with different decay abilities successively colonise fruits/seeds and therefore enhance the decay process and is time dependent (Rayner & Boddy 1988, Somrithipol et al. 2002b, Fukasawa et al. 2012). Loss of weight as fruits/seeds are decomposed can be observed during the fungal succession process (Somrithipol et al. 2002b, Fukasawa et al. 2012). Few fungal succession studies have focused on seeds and fruits (Carré 1964, Kuthubutheen 1984, Somrithipol et al. 2002b, Fukasawa et al. 2012). Fukasawa et al. (2012) studied litter decomposition patterns by fungal colonisers on beech cupules, while Somrithipol et al. (2002b) reported succession on seed pods of *Delonix regia*.

Fukasawa et al. (2012) found that the major and early stage holocellulose decomposers in beech cupule litter are *Xylaria* spp. Xylariaceous taxa are recognised as endophytes of live beech plants (Chapela 1989, Sahashi et al. 1999, Osono & Mori 2003) including cupules (Fukasawa et al. 2012). Following the selective holocellulose decay process, acid-unhydrolyzable residues are decomposed by Basidiomycetes that replaced *Xylaria* spp. (Fukasawa et al. 2012). In contrast, fallen fruits of *Delonix regia* were dominated by litter fungi such as *Dictyochaeta*, *Helicosporium*, *Phaeoisaria*, *Phoma* and *Sporoschisma* species (Somrithipol et al. 2002b). Surprisingly, *Aspergillus*, *Chaetomium*, *Penicillium*, and *Rhizopus* species, were the main groups of fungi on *D. regia* seed pods when samples were collected directly from the tree (with no contact with soil). Similar fungi (*Aspergillus niger*, *Aspergillus flavus*, *Penicillium* sp., and *Rhizopus* sp.) were associated with decaying *Artocarpus communis* (breadfruit) kept in storage (Amusa et al. 2002). Kasai et al. (1995) observed that *Xylaria* sp. and *Phomopsis* sp. are frequently associated with *Pinus densiflora* cones when attached to the tree. Conversely *Mortierella* spp. and *Trichoderma* spp. were the early stage decomposers of cones on the ground (Kasai et al. 1995).

Resin acids, an important group of extractives found in conifers, were identified in seed cones of *Picea glauca* and *Pinus* spp. (Hafizoglu & Holmbom 1987, Eberhardt et al. 1994). Some of these resin acids can inhibit fungal decay of seed cones of *Pinus* spp. by imparting water repellency or by inhibiting white rot-fungi (Eberhardt et al. 1994). Takahashi et al. (2010) studied the effects of tannin (polyphenolic compounds) content in *Quercus serrata* acorns, on the pathogenic fungus *Ciboria batschiana*. They revealed acorns with higher tannin contents were more resistant to *Ciboria batschiana* infection (Takahashi et al. 2010). Collectively, the determining factors for the fungal community after death of fallen seed/fruit tissues include the size of the tissue, nutrients, secondary metabolites (antimicrobial compounds such as resin acids, polyphenols), contents of the tissues, moisture content, existing endophytic fungi, and also the life cycles of fungal decomposers (Rayner & Boddy 1988, Somrithipol et al. 2002b, Tang et al. 2003a, Fukasawa et al. 2012).

Sarmiento et al. (2017) mentioned that communities of fallen seed-associated fungi are structured predominantly by host plant species other than by soil type, forest characteristics, or time in the soil. Carré (1964) indicated that the occurrence pattern of fruiting bodies of fungi on fallen fruits was mostly affected by the weather rather than accumulation and availability of food materials. However, the pattern of occurrence of fruiting bodies was not considered as a proper index for fungal succession in internal tissues (Rayner & Boddy 1988, Fukasawa et al. 2012). Osono (2011) observed that decomposition rate of fungal species was higher in warmer climates than in cooler locations. Tang et al. (2003a) indicated that the surface area of the fruit does not

significantly correlate with the number of fungal species. Tang et al. (2005) also observed less diversity and different groups of fungi occurring on persistent fruits of *Ardisia* spp., *Dichroa febrifuga*, *Sarcandra glabra*, and *Wikstroemia nutans* that cling to the branches and do not drop, when compared to non-persistent fruits.

Figure 62 – Fruits on the forest floor (a, b in Sri Lanka, c, d in Thailand, e Taiwan, f–h UK). a–c *Pinus* spp. d, e Unidentified fruits. f Fir cone with a bright coloured discomycete. g, h *Fagus sylvatica* (h. with a *Xylaria* sp.).

Figure 63 – Fruits on the forest floor (a, b, e, f in UK, c, d in Singapore). a *Quercus* fruits on forest floor. b Fruits infect by a fungus while still on the palm tree. c Fallen *Terminalia catappa* (sea almond) fruits on forest floor colonised by *Schizophyllum commune*. d Close up of *Schizophyllum commune* colonising *Terminalia catappa* fruits. e *Fagus sylvatica* (beech) cupules and seeds on forest floor. f *Pseudotsuga menziesii* cone.

A study of succession of yeast species colonizing *Parahancornia amapa* fruits found that the common fruit-associated genera *Kloeckera* and *Hanseniaspora* spp., *Candida guilliermondii*, and *Candida krusei* colonised fruits during the first three days after fruit fall (Morais et al. 1995). They also reported that the succession of yeast species on fallen fruits is determined by both competitive interactions of yeast species (such as production of killer toxins) and the selective dispersion of yeast species by vectors such as *Drosophila* spp.

Effects of fungi on seed germination and survival of forest plants

Biological factors causing mortality of buried seeds in natural forest communities are not widely understood (Blaney & Kotanen 2001). Few field experiments have addressed this topic although fungi are believed to be most responsible cause of buried seed mortality (Kremer 1993, Blaney & Kotanen 2001). Soil fungi such as *Fusarium* spp., *Lasiodiplodia* spp. and *Trichoderma* spp. infect forest seeds (Gallery et al. 2007, Sarmiento et al. 2017). Knowledge of host-specific nature of fungi that infect seeds of tropical trees is limited (Gallery et al. 2007, Sarmiento et al. 2017).

Different assemblages of fungi usually colonise pine cone scales and seeds on the forest floor (Lilja et al. 1995, Vujanovic et al. 2000). Anderson et al. (1984) reported that some of these fungi destroy embryos and gametophyte tissues of the pine seeds, kill seeds, or damage cones. This damage happens in both mature and premature cones in natural forests and as well as cone collections in storage conditions (Fraedrich & Miller 1995, Vujanovic et al. 2000). *Sphaeropsis sapinea* often infects cones and seeds, and is considered one of the most destructive pathogens of *Pinus* causing die-back and canker diseases (Smith et al. 1996, Vujanovic et al. 2000). Cram & Fraedrich (2010) listed several seed-borne pathogens of coniferous forest trees in North America. *Caloscypha fulgens*, *Fusarium circinatum*, *F. oxysporum*, *F. moniliforme* var. *moniliforme*, *F. proliferatum*, *Lasiodiplodia theobromae*, *Sirococcus conigenus*, *Diplodia pinea* and *Trichothecium roseum* are reported as seed-borne pathogens of *Abies grandis*, *Picea* spp., *Pinus* spp., *Pseudotsuga menziesii*, *Tsuga heterophylla* and are responsible for seed diseases, cotyledon blight, damping-off, shoot dieback, cankers and root rot of coniferous plants in North America (Fraedrich et al. 1994, Cram & Fraedrich 2010).

Pathogenic fungi damage fruits/cones, infect seeds, destroy internal tissues, endosperm and the embryo leading to reduction in storage lifespan, seed vigour and seedling germination in forests and nurseries (Anderson et al. 1984, Cram & Fraedrich 2010). Moreover, some fungi can weaken and make seeds susceptible to a number of soil-borne pathogens (Mamatha et al. 2000, Gure 2004). Mittal & Wang (1987) indicated that saprobic fungi do not affect seed viability or vigor as they colonise dead plant material. However, saprobic fungi also can behave as seed pathogens under some conditions, following seed or seed coat injuries, favorable moisture and temperature conditions in seeds or fruits/cones (Singh & Mittal 1989, Gure 2004). These fungi can impact on the reproduction of forest trees and potentially contribute to maintaining diversity in terrestrial communities (Sarmiento et al. 2017). *In vitro* experiments found that most of the fungi associated with *Quercus* seeds inhibited their germination (Sahai & Otra 1982). The incubation time period of fungal culture filtrates and different fungal strains have different inhibitory effects on seed germination (Armolik & Dickson 1956, Sahai & Otra 1982). Sahai & Otra (1982) attributed that to the amount of toxin production by fungi in different incubation stages.

Some seed-inhabiting fungi have a positive effect on seed germination. Mittal & Wang (1993) and Gure et al. (2005b) observed a significant increase in germination in seeds of *Pinus strobus* by *Alternaria alternata*, *Cladosporium cladosporioides*, *Epicoccum purpurascens* and *Mucor hiemalis*; and seeds of *Podocarpus falcatus* by *Diaporthe* sp.

Seed/fruit fungi dispersal and quarantine aspects

Fruits play an important role in seed dispersal (Tang et al. 2003a). Various agents are involved in the dispersal of seeds and fruits, such as animals, wind, water, self-dispersal and creeping diaspores (creeping diaspores occur with variation in humidity) (Howe & Smallwood 1982). Dispersal of seeds/fruits also brings about dispersal of their inhabiting microbes. Infected plant seeds might introduce plant diseases to a new area by long distance dispersal of pathogens (Gure 2014).

Unintentional or deliberate introduction of fungi through human activities leads to extensive spread of plant diseases, sometimes causing epidemics (Blaney & Kotanen 2001, Palm 2001, Wingfield et al. 2001, Desprez-Loustau 2009). Many plant diseases often emerge during the initial stages of establishment of exotic species (Palm 2001, Wingfield et al. 2001, Desprez-Loustau

2009). Fungal pathogens are most likely introduced with planting stock, seeds, or cones (Wingfield et al. 2001). Alien fungal invasions through seeds is poorly researched, hence the need for greater future attention (Palm 2001, Wingfield et al. 2001, Desprez-Loustau 2009). Repeated introductions of *Sphaeropsis sapinea* infected seeds of different pine species from a wide range of countries, apparently explains the high genetic diversity of this fungus in South Africa (Smith et al. 2000, Wingfield et al. 2001, Burgess & Wingfield 2002). Exotic *Pinus* species were introduced to New Zealand with the implementation of afforestation projects at the end of the 19th Century (Burgess & Wingfield 2002). However, comparatively low genetic diversity of *Sphaeropsis sapinea* was observed in New Zealand as they reduced the import of pine seeds after the local seeds became abundant (Wingfield et al. 2001). The quantity of imported pine seeds to South Africa was higher and it occurred repeatedly over a longer period of time leading to a higher genotypic diversity of *Sphaeropsis sapinea* (Burgess & Wingfield 2002). Western Australia also imported pine seeds for plantations mostly from other Australian states and New Zealand. Very low genotypic diversity of *Sphaeropsis sapinea* in South and Western Australia was observed due to a small amount of exotic pine seeds importation over a shorter period (Burgess & Wingfield 2002). Wernham (1942) reported an incident of introduction of *Epichloë typhina* infected seeds of *Festuca rubra* from Hungary to Pennsylvania, USA. Dogwood anthracnose caused by *Discula destructiva* may have entered USA through imported seeds of kousa dogwood (*Cornus kousa*) from Asia (native region) (Palm 2001). Pitch canker disease of wild pines (*Pinus radiata*) caused by the seed-borne fungus *Fusarium circinatum* was first discovered in California in 1986 (Dick 1998, Gordon 2006). Infected pinus forestry seeds imported from California are one of the pathways the disease was introduced into North America, New Zealand and many other countries (Dick 1998, Gordon 2006). The seed-borne fungus *Fusarium subglutinans* f. sp. *pini*, the causative agent of pine pitch canker disease (Dick & Dobbie 2002), has the potential of becoming a serious threat to *Pinus radiata* plantations if introduced to New Zealand (Storer et al. 1998, Dick & Dobbie 2002).

Transmission of diseases through international transport of seeds is of concern and preventive measures are needed (Neergaard 1977). Hence, quarantine regulations have been introduced by governments to control or prevent the spread of pests and diseases entering through its borders via seeds (Tanner 1997, Wingfield et al. 2001, Sharma & Thakur 2007). The risk of introducing harmful pathogens through transport of seeds, and the need of take action to overcome these risks must be recognised (Cleary et al. 2013). Even though governments have introduced quarantine regulations, they need the support of the public and industry to fulfill their aims (Wingfield et al. 2001, Cleary et al. 2013). Morphological and molecular identification of wild seed/fruit fungi and knowledge of the fungal biodiversity will lead to better assessment of risks associated with seed transport and plant diseases. Such databases, as provided in this paper, will be advantageous for effective quarantine decisions and policies in trading agricultural commodities between countries, and in order to safeguard plant resources (Palm 2001, Burgess & Wingfield 2002).

Acknowledgements

The Research of Featured Microbial Resources and Diversity Investigation in Southwest Karst area (project no. 2014FY120100) is thanked for financial support. This work was also supported by the Thailand Research Fund, ‘The future of specialist fungi in a changing climate: baseline data for generalist and specialist fungi associated with ants, *Rhododendron* species and *Dracaena* species’ (grant no. DBG6080013). Kevin D. Hyde thanks the Foreign Experts Bureau of Yunnan Province, Foreign Talents Program (2018; grant no. YNZ2018002), the 2019 high-end foreign expert introduction plan to Kunming Institute of Botany (granted by the Ministry of Science and Technology of the People's Republic of China, grant number G20190139006) and, a Visiting Professorship at Chiang Mai University, Thailand. E. B. Gareth Jones acknowledges the award of a Distinguished Scientist Fellowship Program (DSFP), King Saud University, Kingdom of Saudi Arabia and a Visiting Professorship at Chiang Mai University, Thailand. Rekhani H. Perera offers her gratitude to Samantha C. Karunaratne, Rungtiwa Phookamsak and Jianchu Xu for financial support on molecular work under the National Science Foundation of China (NSFC) project no:

31750110478, The Research Fund from China Postdoctoral Science Foundation (grant no. Y71B283261) and Key Research Program of Frontier Sciences, CAS (grant no. QYZDY-SSW-SMC014). H. B. Lee acknowledges the BK21 plus program through the National Research Foundation (NRF) funded by the Ministry of Education of Korea. We are also immensely grateful to Paul Kirk for providing fungal lists of Index Fungorum. Rekhani H. Perera would like to thank Shaun Pennycook for his essential nomenclatural review. Kevin Becker is thanked for the HPLC analysis of the *Hypoxylon* species. Dhanushka N. Wanasinghe, Chamath Dinuka, Vinodhini Thiagaraja, Wei DP, Danushka S. Tennakoon, Anuruddha Karunarathna, Ishani Goonasekara, Anupama Daranagama and Diana Sandamali are thanked for their support.
