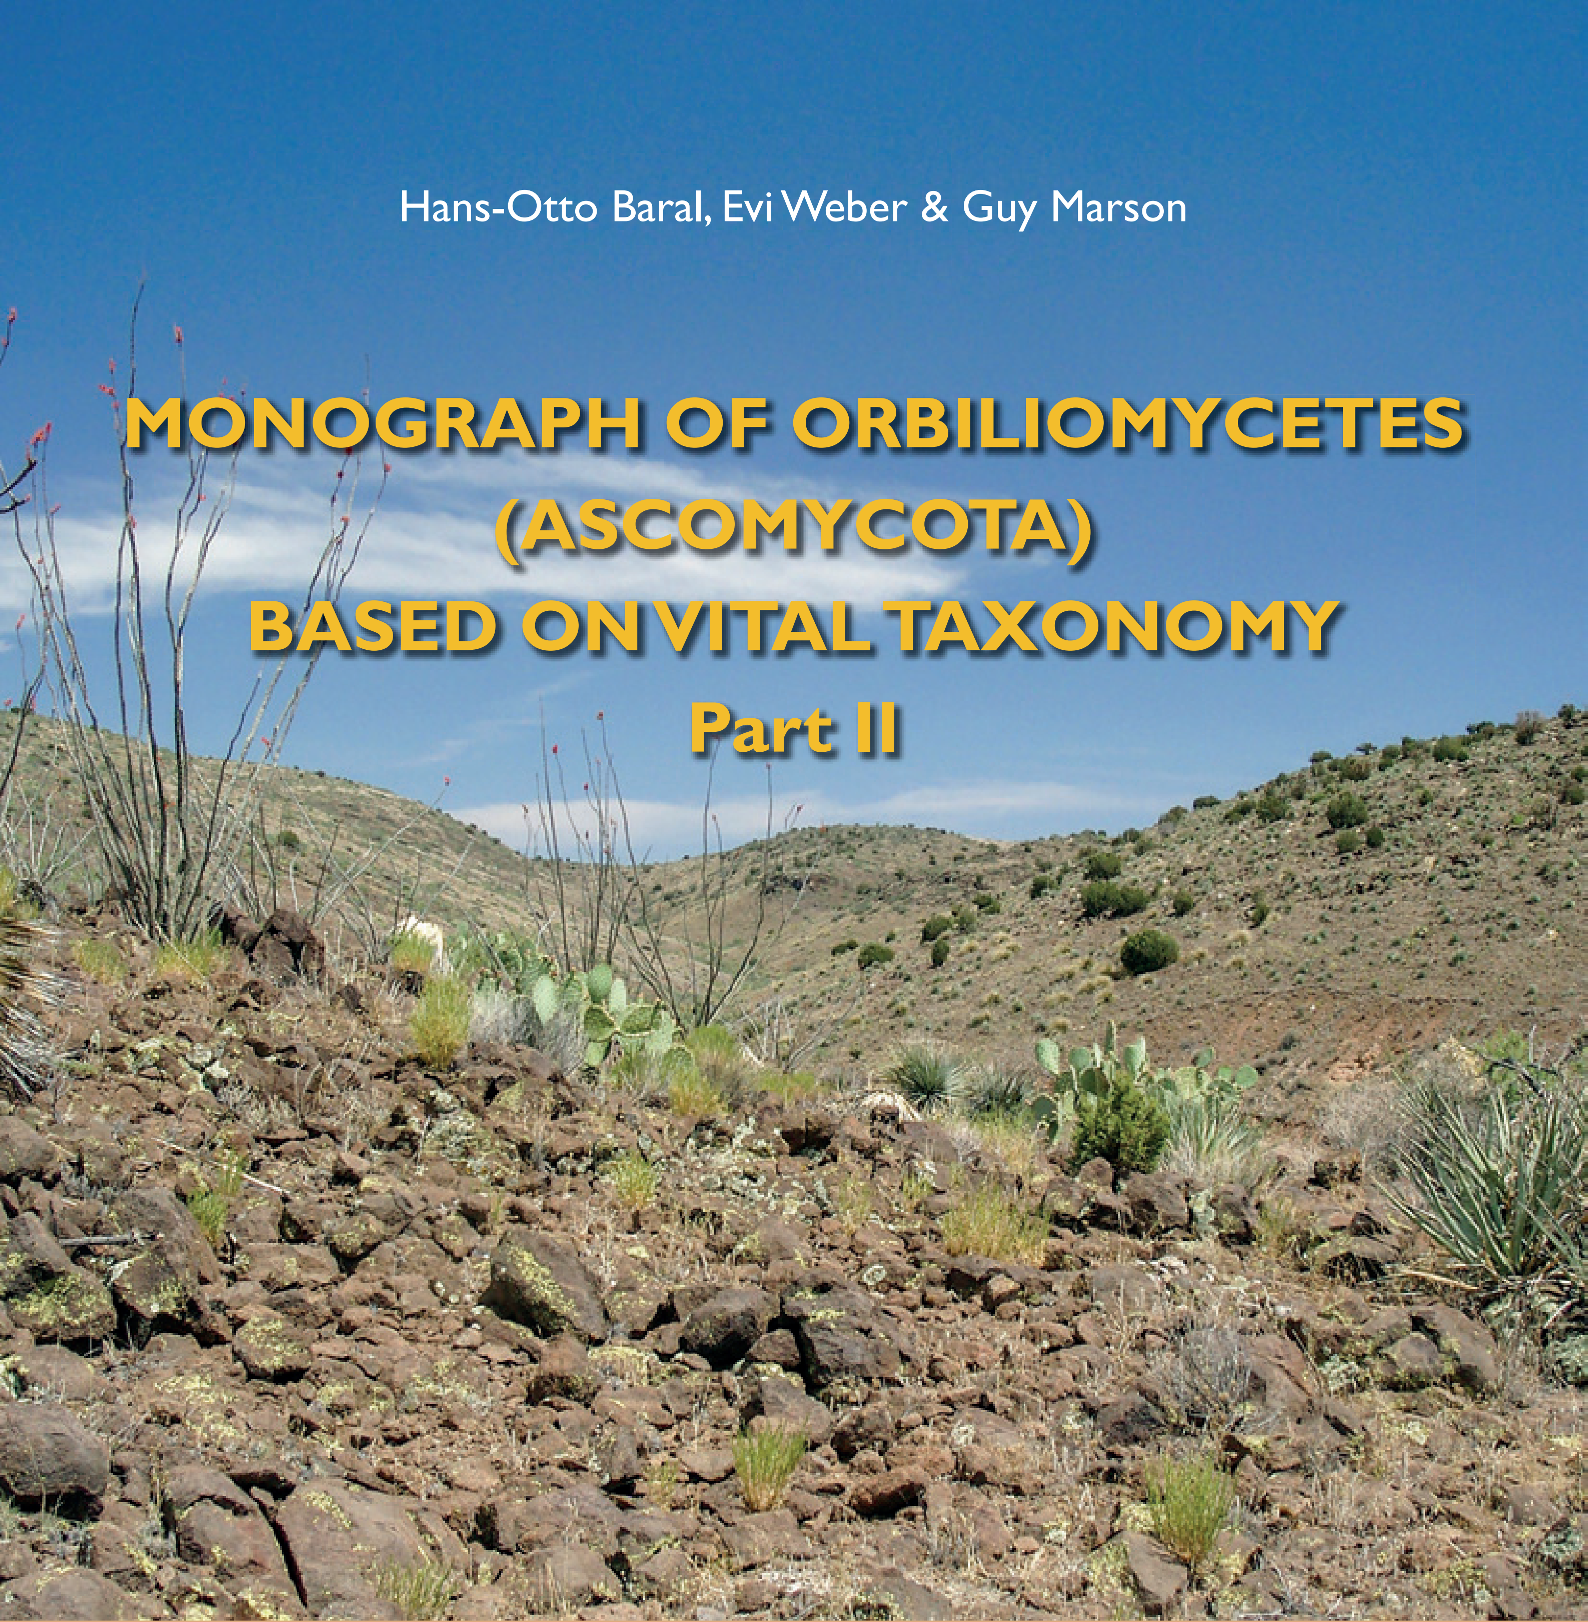
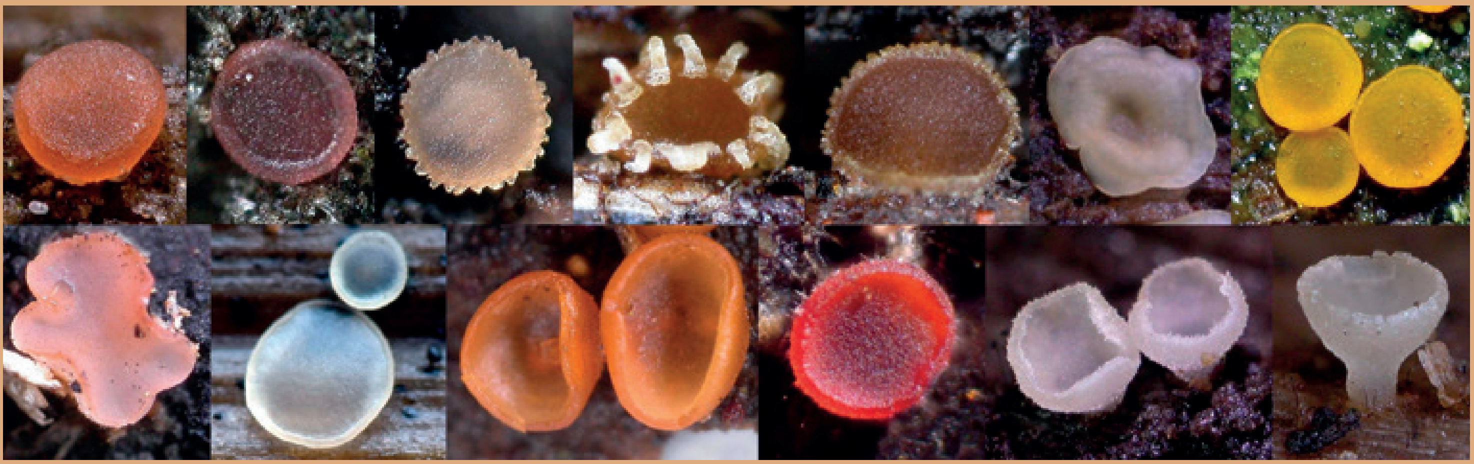
MONOGRAPH OF ORBILIOMYCETES (ASCOMYCOTA) BASED ON VITAL TAXONOMY

Part II





MONOGRAPH OF ORBILIOMYCETES (ASCOMYCOTA) BASED ON VITAL TAXONOMY

Orbilia xanthostigma drawn by the famous French mycologist Émile Boudier (Icones fungorum 1904–10, pl. 460). Note that Boudier correctly recognized the shape of the tiny ascospores, which resemble a cashew nut, but could not clearly see the warts on their surface and overlooked the small globose spore body contained in one of their ends.

Section *Helicoon*

Orbilia subgenus ***Habrostictis*** section ***Helicoon*** (Morgan) Baral & E. Weber, **comb. & stat. nov.**, MB 815017 – Lectotype species: *Helicoon sessile* Morgan [= *Orbilia luteorubella* (Nyl.) P. Karst.], designated by Linder (1929)

Basionym: *Helicoon* Morgan, J. Cincinnati Soc. Nat. Hist. 15: 49 (1892).

Emended diagnosis: **TELEOMORPH**: Apothecia with smooth, rarely crenulate margin, desiccation-sensitive, partially semiaquatic. Asci 8-spored, apex (†) truncate, thin-walled, furcate base almost never H-shaped. Ascospores cylindrical to ± fusiform, rarely lacrimiform, straight, rarely strongly curved; spore bodies filiform to subulate or tear-shaped. — **Anamorph**: Conidia either phragmosporous, straight to strongly curved, or non-septate and then usually with terminal protuberances. Trapping organs absent.

Description: — **TELEOMORPH**: **Apothecia** fresh (0.2–)0.3–1.5(–4) mm diam., whitish or pale to bright rosaceous-lilaceous, yellowish-cream or yellow-orange, margin not or slightly protruding, smooth, rarely with small teeth; sessile or with a ± distinct short stipe, superficial. **Asci** *30–60(–68) × 3.5–5.5 µm, 8-spored, (1–)2–6(–7) lower or upper spores inverted; **apex** (†) medium to strongly truncate, not or slightly to sometimes strongly indented and laterally inflated, hemispherical in profile view, thin-walled; **base** T- to L-, sometimes Y-, exceptionally H-shaped. **Ascospores** *(3.8–)5–14(–17) × (0.8–)1–1.8(–2.2) µm, cylindrical to fusiform or limoniform to obclavate, rarely lacrimiform-ovoid, apex rounded to acuminate, straight to strongly curved, **SBs** attached to apical spore wall, (1–)2–6(–8) × (0.1–)0.2–0.7(–0.9) µm, filiform to subulate or tear-shaped, apically narrowed to a small point. **Paraphyses** slightly to strongly clavate-capitate at the apex, terminal cells 2.5–6× longer than lower cells, unbranched near apex. **Ectal excipulum** of vertically or indistinctly oriented textura globulosa-angularis(-prismatica) from base to margin, thin-walled to slightly gelatinized (common walls †0.3–1 µm), inner region rarely strongly gelatinized (common walls 1–3 µm), cells near base *(9–)15–30(–40)((–45)) × (6–)10–25(–35) µm; **glassy processes** absent, rarely 1–30 µm long (*O. martinicensis*). **SCBs** globose or absent, exceptionally ring-shaped; **VBs** usually present, hyaline, sometimes turning yellow in dead state; **LBs** with carotenoids rarely observed (*O. sarraziniana*). **Exudate** 0.2–2 µm thick, granular to cloddy, rarely cap-like (then up to 5 µm thick), scattered to abundant, loosely or firmly attached, hyaline to bright yellow. — **ANAMORPH**: anguillospora-like, dactylella/vermispora-like, helicoon-like, pseudotripoconidium-like. **Conidiophores** unbranched or branched, 10–165 µm long. **Conidiogenous cells** mono- or polyblastic (?sympodial) and then with denticles. **Conidia** unbranched, either phragmo- to scolecosporous, or amerosporous (clavate to inversely tear-shaped or pyramidal, smooth or with ± distinct protuberances). **Trapping organs**: none observed.

Habitat: on semiaquatic to hygric, rarely mesic wood and bark, exceptionally caulicolous, always desiccation-sensitive.

Recognized series: *Helicoon* and *Pseudotripoconidium*, with 15 recognized, 3 unnamed ('affinis'), and 2 unassigned species.

Taxonomic remarks. Members of section *Helicoon* are characterized by small to medium-sized, mainly elongate, narrow, cylindric-fusoid to fusiform or clavate, rarely lacrimiform-ovoid (*O. martinicensis*), straight or sometimes strongly curved ascospores which are usually without a tail (only in *O. falciformis* the spores are basally sometimes tail-like). The spore bodies are often long and narrow, filiform to subulate, straight or sometimes ± flexuous, but also rather short and comparatively wide, ± tear-shaped.

Similar ascospores and SBs also occur in the two other sections of subgenus *Habrostictis*, and in section *Hemiorbilia* of subgenus *Hemiorbilia*. Members of all these sections differ from section *Helicoon* in a high desiccation tolerance of their apothecia, also in the consistent absence of VBs in the living paraphyses, the frequent presence of crystalloid SCBs, polysporous asci in many taxa (but in section *Aurantiorubrae* mainly 8-spored), and mostly staurosporous or vermispora-like anamorphs. Only taxa of series *Hyalinia* and *Xanthoguttulatae* p.p. break this rule.

Concerning their teleomorph, members of section *Hemiorbilia* are easily distinguished from section *Helicoon* by hemispherical, thick-walled ascus apices and usually not or only slightly inflated paraphysis apices, which are often covered by abundant exudate. Delimitation against the other two sections of subgenus *Habrostictis* is problematic, however, since the three sections do not differ in ascus and paraphysis features. For this reason, a few species are difficult to assign at the sectional level, particularly *O. martinicensis*, *O. aethiopica*, and *O. bannaensis*. The latter two species were at first thought by us to belong to section *Helicoon* until sequences became available which positioned them in section *Aurantiorubrae*, and here with high support in series *Abutilones* and *Piliferae*, respectively.

Several taxa of section *Helicoon* are characterized by an unusual spore orientation (i. e., upper spores with SBs directed downwards, lower spores upwards). In such a case the SB-containing spore end is often the narrower, more tapered end, and the widest part of the obclavate spore is often closer to the spore base (similar cases of spore orientation and/or heteropolar spores occur in sections *Aurantiorubrae* and *Habrostictis*, see also Fig. 62). More or less homopolar, fusoid or sometimes subcylindrical spores are also frequent.

Some of the examined ± subtropical collections possess a more or less bright golden-yellow exudate in the outer parts of the hymenium and ectal excipulum, at least in an advanced stage of development. A similar pigment is found in the dead cytoplasm of some of the paraphyses. The living paraphyses of these species frequently contained hyaline, low- to high-refractive VBs but no yellow pigment. Specimens with a yellow exudate mainly derived from Asia, whereas from temperate zones no such pigment came to our notice.

Series delimitation, **anamorph**. Two series can be distinguished within section *Helicoon*, which sharply differ in their anamorphs: (1) series *Helicoon* with ± curved, vermiform, phragmo- to scolecosporous conidia (dactylella/vermispora-, anguillospora-, helicoon-like), and (2) series *Pseudotripoconidium* with aseptate, inversely pyramidal conidia with several nipple-shaped protuberances (pseudotripoconidium-like). The striking morphological difference between these two types of conidia is difficult to explain in terms of their phylogenetic relationship. As a hypothesis, the latter conidial type might have been derived from microconidia of the former group by suppression of the macroconidial state. A somewhat intermediate species, *O. tianmushanensis*, is placed in series *Helicoon* because its rather unique, straight, fusiform phragmoconidia fit better in that group.

In their teleomorph features the two series are so similar that recognition of the group is virtually impossible. As a tendency, filiform to vermiform SBs which are not or only hardly inflated at their base are typical of species with a pseudotripoconidium-like anamorph, whereas SBs with a more or less tear-shaped basal inflation are so far exclusively found in species with a phragmo- to scolecosporous anamorph. Species with a yellow exudate occur in both sections, and species without this pigment and sometimes also without VBs in the living paraphyses also occur in both groups.

In several species of section *Helicoon* the anamorph is unknown or could not be ascertained in pure culture. When also molecular data were unavailable, these species could not with certainty be assigned to one of the two series. Conidia on the natural substrate have very rarely been seen. In some cases, flooding of apothecia on the natural substrate in an empty Petri dish provoked formation of conidia.

Species delimitation in series *Helicoon* is highly problematic. Some collections assigned to a given taxon appear rather well-defined, based on an extraordinary shape and size of ascospores or spore bodies, or unusual spore orientation. Yet, intermediate collections are frequent and suggest a continuum between some of the taxa. As a further complication, mixed populations of two closely related species were sometimes observed. Such intermingled growth easily causes confusion, e. g., when taking a sequence or when preparing a culture.

Although spore orientation is easily seen in fresh living specimens, herbarium material is very difficult to study in this respect. Even when applying various staining techniques, SBs are generally hardly or not at all to be seen. Sometimes it is necessary to break the asci by strong pressure on the cover slip, so that some spore ends project from the broken lower part of the ascus. In the types of *O. luteorubella* (Pl. 534: 1b), *O. sarraziniana* (Pl. 537: 1b), and *O. juruensis* (Pl. 543: 1b left ascus) the SBs could be discerned in some asci as a faint region but, for instance, in most of Velenovský's type specimens spore orientation could not clearly be seen.

As an example, we were unable to find any convincing features of the teleomorph to permit clear distinction between *O. luteorubella* and *O. rosea*, apart from a tendency in adaptation to stagnant vs. running water and in different apothecial colours (yellowish-orange vs. rose, respectively). Some variation in macro- and microscopical features within each of these species and *O. sarraziniana* complicates identification of most of the examined specimens in which culture and DNA studies were not undertaken. A more comprehensive molecular investigation would be desirable in order to clarify how sharp the molecular limits between the here accepted species are.

Phylogeny. Sequences which include the ITS region and partly also LSU and SSU were available for five species of series *Helicoon* (*O. luteorubella*, *O. rosea*, *O. sarraziniana*, *O. tianmushanensis*, *O. yuanensis*) and six of series *Pseudotripoconidium* (*O.* aff. *fusiformis*, *O. sinensis*, *O. tenuispora*, three unidentified). Although the two series can sharply be distinguished by their anamorph, distinction is less clear in their molecular data, which might reflect the strong morphological similarities in their teleomorphs. The distance in the ITS region between the two series lies in the range of 12.5–18 %, which is hardly higher than between species of series *Helicoon* (12–15 %), though much higher than within series *Pseudotripoconidium* (3–8 %).

When analysing SSU+ITS+LSU, section *Helicoon* formed a highly supported monophyletic clade which clustered unresolved in the genus *Orbilia* (Baral et al. 2017b, Phyl. 7). Within this section, series *Pseudotripoconidium* clustered as a highly supported monophyletic clade, but series *Helicoon* formed a paraphyletic group. Also in the present analyses (Phyls 17–18, S19) only series *Pseudotripoconidium* formed a monophyletic clade with strong (ITS) or medium (ITS+LSU, LSU) bootstrap support. *O. tianmushanensis* (with phragmoconidia) and a strain for which no illustration was available (B.L. X079) clustered intermediate between the two series when analysing ITS, but when analysing LSU *O. tianmushanensis* clustered in the *Pseudotripoconidium* clade (no LSU was available for B.L. X079). Another strain without available documentation (B.L. 730) comprises only LSU and shows, like the other two strains, intermediate combinations of nucleotides (Tabs 70–71). This unsharp delimitation between the two series confirms Yu et al.'s (2011) result of a close molecular relationship between them.

Also the S1506 intron permits to recognize paraphyly of series *Helicoon* (Phyl. S18). It occurs in most species with available SSU though often only in some of the sequences (see also Tab. 26): in four species of series *Helicoon*: *O. sarraziniana* (2 of 6 strains), *O. luteorubella* (2 of 3 strains), *O. rosea* (1 of 8 strains), *O. yuanensis* (2 strains), and in two of series *Pseudotripoconidium*: *O. tenuispora* (1 strain), *O.* aff. *fusiformis* (1 strain). Also here, the latter series forms a strongly supported clade while the other taxa cluster paraphyletically (S18).

Based on the available phylogenetic analyses we may conclude that series *Helicoon* represents the ancestral group of section *Helicoon*, which means that the amerosporous, obpyramidal conidia of series *Pseudotripoconidium* developed from phragmoconidia, a conidial type that is common also in various other groups of subgenus *Habrostictis* and the *Orbiliomycetes* as a whole.

Specific nucleotide positions. No molecular motifs that unequivocally characterize section *Helicoon* have been found. A common characteristic of the entire section is that the ITS2 starts at its 5'-end with ATTT, except for *O. tianmushanensis* which has ATTA. The motif ATTT is also typical of section *Lentiformes* and several series of section *Aurantiorubrae*, and occurs also in *O. carpoboloides* of section *Habrostictis* and a

Table 70. Four nucleotide positions in the ITS1, two in the 5.8S region, and three in the ITS2 which more or less characterize the two series of section *Helicoon*, showing intermediate character combinations for *O. yuanensis*, B.L. X079, and *O. tianmushanensis*. Position numbers evaluated by inclusion of all inserts. A similar table is given in Zhang et al. (2016: tab. 1). D = AGT, R = G (rarely A). At pos. 22–27 the alignment is not unequivocal.

Taxon	ITS1				5.8S		ITS2	
	4–6	22–27	150–155	161–162	298–302	320–323	377–382	441–452

Pseudotripoconidium p.p.maj.	ACA	CT--TT	AGTCTT	ATT	GCACC	GGTA	TTGGGC	ACCCAGCC-AAC
O. tenuispora (p.p.)	ACA	CT--TT	AGTCTT	ATT	GCACC	GGTA	TTGAGC	ACTCTGCC-AAC
O. aff. *sinensis* (CBS 917.72)	ACA	CT--TT	AGTCTT	ATT	GCACC	GGTA	TTGGGC	ACCCTGCC-AAC

few members of series *Drechslerella* (see Tab. 20).

In the LSU D1–D2 domain, pos. 252 is consistently GTG**A**A, whereas it is GTG**T**A in most other groups of subgenus *Habrostictis*, but GTG**A**A also in *O. albovinosa* and *O. ficicola* (and in most members of section *Arthrobotrys*). Pos. 516 is GGA**T**AAA in series *Pseudotripoconidium* and in *O. sarraziniana* and *O. rosea*, but GGA**C**AAA in *O. luteorubella*, *O. tianmushanensis*, and *O. tenuispora* B.L. 6228, as in most other *Orbilia* spp. However, pos. 516 is also GGA**T**AAA in series *Aurantiorubrae*, *O.* (aff.) *farnesianae*, *O. paracaudata*, and *O. amarilla* of series *Piliferae*, and a few *Arthrobotrys* spp. Pos. 500 is consistently ATC**A**GTT in section *Helicoon* while ATC**G**GTT in many other *Orbilia* spp., yet it is also ATC**A**GTT in series *Aurantiorubrae*, *Rubellae*, and *Commatoideae*, series *Piliferae* p.p. and *Albovinosae* pp., and some members of series *Lentiformes* and most of section *Arthrobotrys*.

About a dozen of informative positions in the ITS region (Tab. 70) and 3 in the LSU D1–D2 (Tab. 71) permit distinction between the two series. The 5.8S region is almost identical in series *Pseudotripoconidium* and *Helicoon*, except for pos. 300 and 322 (Tab. 70). Two species are problematic: based on their phragmoconidia, *O. yuanensis* and *O. tianmushanensis* clearly belong to series *Helicoon*. Yet, *O. yuanensis* coincides at these two positions and at pos. 445 (ITS2) with series *Pseudotripoconidium*, but at 6 positions of ITS1 and 1 of ITS2 (449) it concurs with series *Helicoon*. *O. tianmushanensis* matches series *Pseudotripoconidium* at pos. 380, 443, and 449 (ITS2), but concurs with series *Helicoon* at pos. 300 and 322 (5.8S). Also strain B.L. X079 shares some characteristic positions with series *Helicoon* and others with series *Pseudotripoconidium*.

At the 3 diagnostic positions in the LSU (176, 577, 582), series *Pseudotripoconidium* has **T**+**A**+**G**, whereas series *Helicoon* has **C**/**A**+**T**+**A**/**C** (Tab. 71). At all 3 position, *O. tianmushanensis* concurs with series *Pseudotripoconidium*, whereas two strains of unknown morphology have intermediate combinations (B.L. 730: **C**+**A**+**T**, CBS 917.72: **C**+**A**+**G**), although the latter is a clear member of series *Pseudotripoconidium* in Phyls 17 and 18.

Table 71. Three nucleotide positions in the LSU D1–D2 (in bold) which characterize the two series of section *Helicoon*, showing intermediate nucelotide combinations for B.L. 730 and CBS 917.72 (Benedict's strain). Position numbers starting with TGACCT by omitting predominant gaps in alignment of all groups of *Orbiliomycetes*.

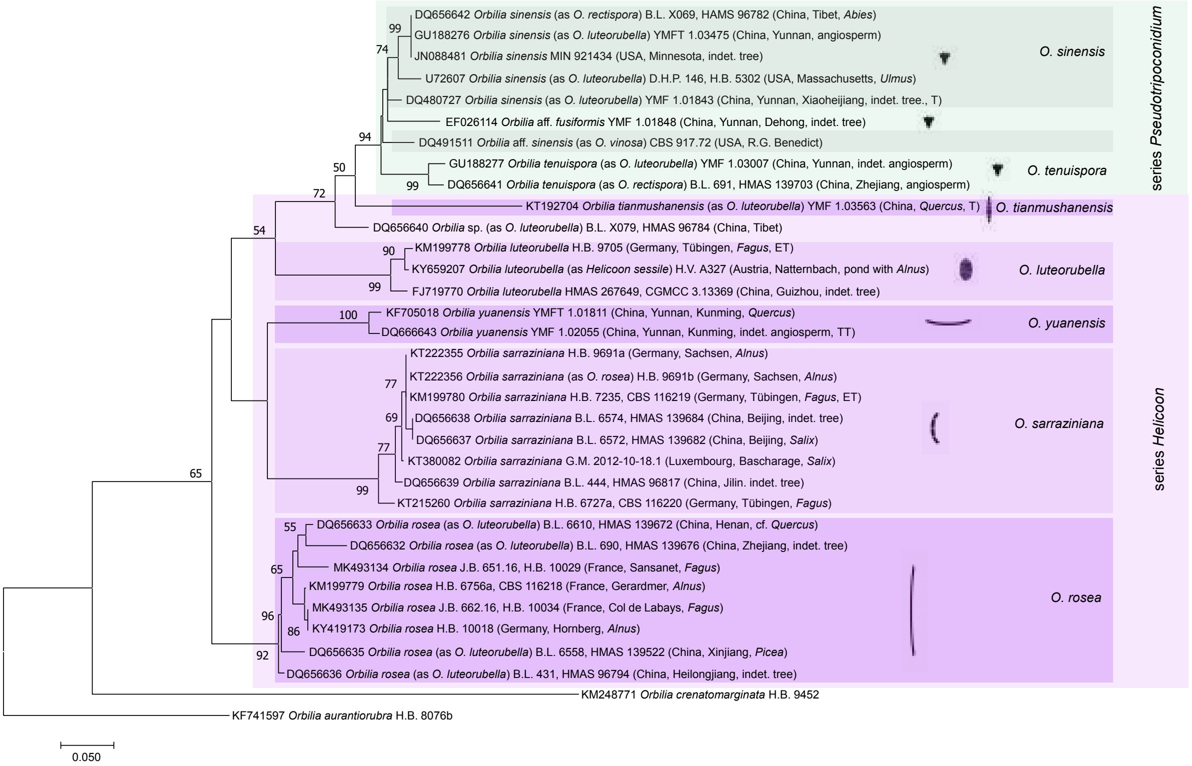
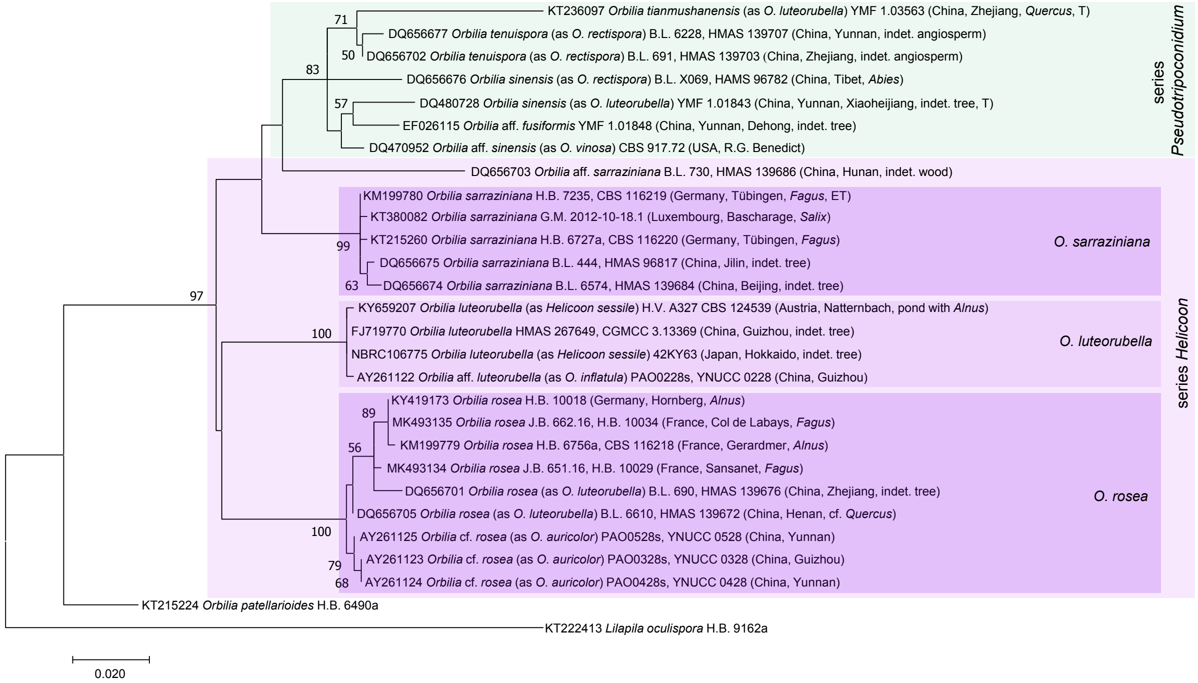
Ecology. Six species are known at present in the temperate to montane-boreal zone of the northern hemisphere: four of series *Helicoon* (*O. rosea*, *O. luteorubella*, *O. sarraziniana*, *O. juruensis*) and two of series *Pseudotripoconidium* (*O. sinensis*, *O. tenuispora*). The three first species of series *Helicoon* are very common in Europe and show a strong preference for semiaquatic habitats very close to running or stagnant water. They form comparatively large apothecia growing almost exclusively on woody substrates, often in large numbers. Their mycelia and apothecia not only withstand but apparently require periodical flooding which induces the formation of conidia. According to the available molecular data it is evident that these three species also occur in eastern Asia, and based on their morphological traits they seem to be also present in North America. *O. sinensis*,



Phylogenetic analysis 17. Phylogram of section *Helicoon* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (34 sequences, 620 positions, aligned with MUSCLE) using the T2+G model in MEGA7 (500 replicates). The tree is rooted with *O. aurantiorubra* and *O. crenatomarginata*. Asci 8-spored in all taxa; T = type, ET = epitype.

O. tenuispora, and *O. juruensis* occur from cold-temperate to subtropical or tropical regions, being recorded from southeastern Europe (Caucasus), North America, and eastern Asia, but a possible preference for semiaquatic habitats is only known for *O. sinensis*. Because of their adaptation to permanent moisture, the apothecia generally do not survive complete desiccation.

A majority of taxa in the two series of section *Helicoon* emanate from the subtropics or tropics, particularly from southeastern Asia but also middle America. They do not seem to exhibit any preference for running or stagnant water, and in



Phylogenetic analysis 18. Phylogram of section *Helicoon* inferred from ML analysis of LSU (D1–D2) rDNA dataset (28 sequences, 584 positions, aligned with MUSCLE) using the T2+G model in MEGA7 (500 replicates). The tree is rooted with *Lilapila oculispora* and *O. patellarioides*. Asci 8-spored in all taxa; T = type, ET = epitype.

Key to species of section *Helicoon*, based mainly on the teleomorph

1. Spores medium to strongly curved; anamorph unknown; angiosperm bark, subtropical humid eastern Asia 2
1. Spores ± straight or only sometimes slightly curved 3

2. Spores *8–13 × 1.1–1.3 µm .... ***O. arcospora*** (?series *Pseudotripoconidium*), p. 1011
2. Spores *5.5–7.5 × (1.3–)1.5–1.6(–1.8) µm .... ***O. falciformis*** (inc. sed.), p. 994

3. Spores predominantly *1.2–1.3 (†1.1–1.2) µm wide or narrower 4
3. Spores predominantly wider 10

4. Spores *(9–)10–12(–13.5) × 0.9–1.3 µm, apex (sub-)acute; conidia obpyramidal, non-septate, with prominent protuberances; angiosperm wood, cold-temperate to subtropical humid eastern North America & eastern Asia.... ***O. tenuispora*** (series *Pseudotripoconidium*), p. 1007
4. Spores predominantly less than *10 µm long 5

5. Upper spores predominantly inverted; spores †5.5–6.5 × 0.8–1 µm, ± straight, usually subulate; anamorph unknown; angiosperm bark, tropical humid Middle America .... ***O. subuliformis*** (?series *Pseudotripoconidium*), p. 1001
5. Lower spores predominantly inverted; spores *5–7.5 up to 8–11 µm long, straight to slightly curved 6

6. SBs 1.5–3 × 0.3–0.8 µm, ± tear-shaped; conidia elongate, septate; (sub)tropical humid eastern Asia 7
6. SBs (2–)2.5–3 up to 4(–5) × (0.1–)0.2–0.4(–0.5) µm, filiform; conidia obpyramidal, non-septate, with inconspicuous protuberances, cold-temperate to subtropical humid northern hemisphere .... (series *Pseudotripoconidium*) 8

7. Spores *(5–)6–7(–7.3) × 1.2–1.4 µm, subcylindrical or slightly fusoid; living paraphyses containing many globose to shortly elongate VBs, in more aged apothecia with yellow pigment; conidia scolecosporous, multiseptate, containing rather small LBs; bark of angiosperms........ ***O. yuanensis*** (series *Helicoon*), p. 991
7. Spores *7–8.5 × 1–1.3 µm, narrowly clavate, with or without basal tail; VBs unknown; anamorph uncertain; bark of *Broussonetia* .... ***O. bannaensis*** (section *Aurantiorubrae*), p. 930

8. SBs *(2–)2.5–3 × 0.2–0.3 µm; spores *(5–)6–7.5(–8) × 1.2–1.4 µm; bark of angiosperms, warm-temperate to subtropical eastern Asia & southern Africa........ ***O. jinguangsiensis***, p. 1002
8. SBs *(2.3–)3–4.5(–5) × 0.1–0.5 µm; spores *(7–)8–10(–11) µm long; wood & bark of angiosperms, rarely gymnosperms 9

9. Spores with subacute to acute apex, *(7–)7.5–10(–11) × 0.8–1.3 µm, SBs 3–4(–5) µm long; cold-temperate to subtropical eastern Asia, eastern North America, southern Europe .... ***O. sinensis***, p. 1003
9. Spores with obtuse apex, *8–9.5 × 1.2–1.3 µm, SBs 4.5–5.5 µm long; subtropical eastern Asia .... ***O.* cf. *sinensis***, p. 1004

10. Spores *2.6–6.3 µm × (1.6–)1.8–2.2(–2.5) µm wide, length/width ratio 1.5–3; SBs ± flexuous 11
10. Spores min. *(4.5–)5–7 µm long, max. *1.8(–2) µm wide, length/width ratio min. 3–4 13

11. Paraphyses often (sub)lanceolate; spores cylindric-clavate with a broadly subacute tip, *4.8–6.3 × 1.8–2.5 µm; SBs about half as long as spores; apothecia urceolate, with short marginal hairs; angiosperm bark, warm-temperate humid northeastern Africa .... ***O. aethiopica*** (section *Aurantiorubrae*), p. 912
11. Paraphyses consistently capitate or clavate-spathulate; SBs about as long as spores; apothecia ± flat 12

12. Spores broadly lacrimiform, *2.6–3 µm long; SBs filiform, with a strongly inflated basal part; margin with glassy processes; angiosperm bark, tropical humid Middle America .... ***O. martinicensis*** (inc. sed.), p. 995
12. Spores limoniform to fusiform, *3.8–6 µm long; SBs filiform-subulate; margin without glassy processes; wood of *Pinus*, subtropical humid eastern Asia .... ***O. limoniformis*** (?series *Pseudotripoconidium*), p. 998

13. Spores *11.5–17 × 1.4–1.7 µm, cylindric-fusoid; SBs filiform; conidia obpyramidal, non-septate, with ± distinct protuberances; bark & wood of angiosperms, subtropical humid eastern Asia .... ***O. acicularis*** (series *Pseudotripoconidium*), p. 1009
13. Spores *4.5–11 µm long 14

14. Upper spores predominantly inverted (with SB pointing downwards); spores obclavate to fusoid, often basally only slightly to medium tapered, widest part often in the middle of spore or more near base, *(5.5–)6–8.5(–10) × 1.3–1.8(–2) µm 15
14. Lower spores predominantly inverted (with SB pointing downwards); spores usually fusoid, medium to strongly tapered at base, widest part in the middle of spore or often more near apex 17
Compare also *O. tianmushanensis* in which spore orientation is unknown (p. 986).

15. SBs tear-shaped within living asci, *(2–)2.5–3(–3.8) × 0.6–0.8(–1) µm; anamorph unknown; wood of angiosperms, (sub)tropical to cold-continental humid South America, eastern Asia .... ***O. juruensis*** (series *Helicoon*), p. 989
15. SBs predominantly filiform to subulate within living asci, 3–5(–5.5) × (0.2–)0.3–0.5(–0.7) µm, turning tear-shaped only when overmature..16

16. Conidia cylindric-fusoid, falcate to helicoid, 1–3-septate, *~30–50 × 4–7 µm; wood & bark of angiosperms, rarely gymnosperms, oroboreal to submediterranean (semi)humid Europe, Asia, Australasia, North America .... ***O. sarraziniana*** (series *Helicoon*), p. 978
16. Conidia obpyramidal, non-septate, with distinct protuberances; angiosperm bark, subtropical humid eastern Asia (Pl. 556: 3) .... ***O*. aff. *fusiformis*** (series *Pseudotripoconidium*), p. 1000

17. Spores subcylindrical or only slightly fusoid, *5–7.3 × 1.2–1.4 µm; SBs *1.5–2.8 × 0.3–0.6 µm, predominantly straight, usually with distinct filum .... see under 7 (*O. yuanensis*)
17. Spores fusoid to fusiform, mostly larger; SBs mostly longer and/or wider, partly flexuous 18

18. SBs tear-shaped within living asci, (1.8–)2.3–3(–4) × 0.5–0.9 µm; spores often fusiform, *(4.5–)5–8(–9.3) × 1.3–1.8 µm; conidia scolecosporous, multiseptate, with 1 large LB in each cell; wood of angiosperms, subtropical humid eastern Asia .... ***O. hoana*** (series *Helicoon*), p. 987
18. SBs filiform to subulate within living asci, (2.5–)3–4.5(–5.2) × 0.2–0.6 µm 19

19. Spores *(4.5–)5–7(–7.5) × 1.3–1.6(–1.7) µm; SBs narrowly subulate, 3–4.5 × 0.2–0.4(–0.5) µm; conidia obpyramidal (tear-shaped to clavate), non-septate, without protuberances; wood & bark of angio- and gymnosperms, subtropical humid eastern Asia .... ***O. fusiformis*** (series *Pseudotripoconidium*), p. 998
Two collections from southern China and Australia differ in shorter and wider SBs (Pls 555; 556: 1–2).
19. Spores *(5.5–)6.5–10.5(–11) × (1.2–)1.3–1.8(–2) µm; macroconidia scolecosporous, multiseptate, microconidia 1–4(–8)-septate; temperate to subalpine-boreal humid Europe, Asia, North America .... (series *Helicoon*) 20

20. Apothecia whitish to light rose-lilaceous(-cream), sometimes yellow-orange; macroconidia curved under a wide arch; wood and bark of angiosperms, also gymnosperms, semiaquatic at streams, oroboreal to (oro)temperate/orosubmediterranean humid Europe & North America, hemiboreal to subtropical eastern Asia .... ***O. rosea***, p. 959
20. Apothecia pale to light (yellow-)orange(-ochraceous), sometimes with rose component; macroconidia densely coiled by forming a barrel-shaped body; wood and bark of angiosperms, rarely gymnosperms, semiaquatic, mainly at lakes, thermoboreal to cold- or warm-temperate or subtropical Europe, eastern Asia, eastern North America .... ***O. luteorubella***, p. 970

Key to species of section *Helicoon*, based on the anamorph

1. Conidia 4.7–9 × 3–6.5 µm, clavate to inversely tear-shaped or obpyramidal, non-septate, with or without protuberances, containing 1 or a few large LBs .... (series *Pseudotripoconidium*) 2
1. Conidia ~40–450 × 2–10 µm (actual length), vermiform with tapered ends, septate .... (series *Helicoon*) 4

2. Conidia entirely without protuberances .... ***O. fusiformis***, p. 998
2. Conidia with ± conspicuous protuberances 3

3. Conidia with 2–4 inconspicuous to distinct protuberances . ***O. sinensis*** (p. 1003), ***O. jinguangsiensis***, (p. 1002), ***O. acicularis*** (p. 1009)
3. Conidia with 5–8 prominent protuberances .... ***O. tenuispora***, p. 1007

4. Conidia coiled to form a barrel-shaped body of *26–42 × 19–29 µm with 6–8 coils (in a Chinese collection only about †10–20 × 18–22 µm with 1–4 coils); conidia up to 30–45-septate .... ***O. luteorubella***, p. 970
4. Conidia straight or falcate to helicoid but not coiled like a barrel; conidia max. 21-septate 5

5. Conidia *42–74 × 7.7–10.2 µm, fusiform, straight, (1–)3 septate, 2 central cells much wider than terminal cells, with obtuse apex and tail-like base, lipid content low .... ***O. tianmushanensis***, p. 986

5. Conidia cylindric-fusoid (vermiform), ± falcate to helicoid, max. 7.5(–9) µm wide, often multiseptate 6

6. Conidia containing a single, 2–4 µm large LB in the centre of each cell (living state), †(29.5–)39–80(–111) × (4–)4.5–7.5(–9) µm, (3–)5–10(–12)-septate .... ***O. hoana***, p. 987

6. Conidia containing several smaller LBs (max. 1–2 µm diam.), especially near the septa 7

7. Conidia with low to rather high lipid content, macroconidia *80–127 × (5–)6–6.8(–7.3) µm, (10–)11–13(–14)-septate .... ***O. yuanensis***, p. 991

7. Conidia with very low to low lipid content, *(3–)4–5.5(–7) µm wide 8

8. Conidia mainly falcate, sometimes helicoid; macroconidia 9–21-septate, actual length *110–210(–285) µm; microconidia (0–)2–4(–6)-septate, (23–)30–60(–115) µm long .... ***O. rosea***, p. 959

8. Conidia (1–)3-septate, strongly helicoid, actual length *30–50 µm .... ***O. sarraziniana***, p. 978

some collections a distinct desiccation tolerance of apothecial tissues was noted. It would, however, be premature to see an evolutionary centre of section *Helicoon* in these Asian evergreen rainforests, since other parts of the world with similar forests have not or only insufficiently been investigated.

Series *Helicoon*

Orbilia subgenus ***Habrostictis*** section ***Helicoon*** series ***Helicoon*** – Lectotype: *Helicoon sessile* Morgan [= *Orbilia luteorubella* (Nyl.) P. Karst.]

Etymology: referring to the helicoid conidia.

Description: — **TELEOMORPH**: **Apothecia** fresh (0.2–)0.3–1.5(–4) mm diam. **Asci** *(33–)37–60(–68) × 3.5–5.5 µm, (1–)3–6(–7) lower or upper spores inverted. **Ascospores** *(3.8–)4.5–10(–11) × (1–)1.2–1.8(–2) µm, cylindrical to fusiform(-clavate), also obclavate or broadly tear-shaped, apex (rounded to) obtuse to acute (to acuminate), straight or only slightly curved near base; **SBs** (1–)1.5–4.5(–5.5) × (0.2–)0.3–0.8(–0.9) µm, filiform to subulate or tear-shaped. **Ectal excipulum** cells near base *(10–)15–30(–40) × (6–)10–25(–35) µm. — **ANAMORPH**: anguillospora-like, dactylella-like, helicoon-like, vermispora-like. **Conidiophores** 10–65(–100) µm, unbranched or branched below. **Conidiogenous cells** monoblastic. **Conidia** unbranched, vermiform (scolecosporous), 42–210 µm long (actual length), slightly to strongly curved under a wide arch; or up to 300–450 µm long, strongly coiled to form barrel-shaped bodies; (2–)3–7.5(–10) µm wide, (3–)5–17(–21)-septate; rarely fusiform, straight, 3-septate, with two inflated central cells; containing a few to many small LBs or one large LB; **microconidia** often present, sharply delimited or not, (0–)1–6(–8)-septate, straight to strongly curved.

Habitat: on hygric to semiaquatic, also mesic wood and bark, exceptionally caulicolous, desiccation-sensitive or slightly -tolerant, humid, temperate-boreal to (sub)tropical.

Recognized species: 7, plus 1 unnamed species ('affinis'), and 2 species with uncertain affinity.

Taxonomic remarks. Series *Helicoon* is circumscribed here to include taxa with anamorphs forming vermiform, differently curved phragmoconidia. *O. tianmushanensis* with its straight, fusiform conidia stands genetically somewhat intermediate to series *Pseudotripoconidium*. For two species no anamorph and sequence data were available: *O. falciformis* with its falcate conidia could as well belong to series *Pseudotripoconidium*, and *O. martinicensis* with its short, tear-shaped ascospores and long glassy processes might even belong to another section of subgenus *Habrostictis* (the associated conidia are possibly not orbiliaceous). Therefore, we have treated both species as 'incertae sedis'. *O. juruensis* closely resembles *O. hoana* which has anguillospora-like conidia, therefore, both seem well-placed here.

Species delimitation. Very late we have made the necessary split of the obviously heterogeneous taxon *O. luteorubella* in separating *O. rosea* from it, based on the connection to two very distinctive anamorphs (*Helicoon* vs. *Anguillospora*). Problematic is also the delimitation between *O. sarraziniana* and collections of *O. rosea* with short asci and spores. In one of our sequence analyses it came out that *O. sarraziniana* may also occur with the regular spore orientation of *O. rosea*. Further molecular studies are necessary to clarify the meaning of this result which would make our morphological concept rather unfounded. Similar as with *O. sarraziniana*, we propose distinction between *O. hoana* and *O. juruensis* merely because of the deviating spore orientation, but for these taxa molecular data are so far wanting.

Anamorph. The anamorphs of series *Helicoon* form phragmo- to scolecosporous, i.e., unbranched, usually multiseptate conidia. The conidia differ among the species especially in their length and width, number of septa, strength of curvature, and lipid content, but the available data are too scarce to decide whether all of the here accepted species with a known anamorph can be recognized by their conidial morphology.

At least some of the species (*O. rosea*, *O. luteorubella*, *O. yuanensis*, ?*O. sarraziniana*) form two types of vegetative propagules, micro- and macroconidia, that differ in size and number of septa. This rises the question whether differences in conidial characters between two samples are substantial or only a result of absence of one of the two conidial types in a given strain.

Two anamorphs with a published name are known in the literature: *Anguillospora rosea* has very long (scolecosporous) macroconidia that are curved under a wide arch, and much shorter microconidia (Pls 526; 527: 2h). *Helicoon sessile* has similar but strongly coiled macroconidia that form barrel-shaped bodies which function as air traps (Pl. 534) but may also form short, microconidia-like propagules (Pl. 534: 1a, upper left) which resemble microconidia of *A. rosea*.

In *O. martinicensis*, condylospora-like conidia were observed on the natural substrate. They resemble anguillospora-like anamorphs but differ in being sharply bent for ~ 180° in the middle. However, their connection to the associated teleomorph appears to be improbable.

Phylogeny. Series *Helicoon* forms a paraphyletic clade within section *Helicoon*. When analysing the ITS region (Phyl. 17), the five sequenced species clustered in five distant clades by showing comparatively low intraspecific variation. *O. sarraziniana* and *O. rosea* are represented by rather numerous sequences, while only three were available for *O. luteorubella*, two for *O. yuanensis*, and one for *O. tianmushanensis*.

Two of the anamorph-teleomorph connections previously reported from pure culture are confirmed here by molecular data: (1) a conidial isolate of *Anguillospora rosea* (paratype) from GenBank fully agrees in the SSU with our ascospore isolate of *O. rosea* (H.B. 6756a), (2) a conidial isolate of *Helicoon sessile* shows a high similarity in the ITS with a collection of *O. luteorubella* (H.B. 9705). Two earlier isolates of *O. luteorubella* and *H. sessile* (D.H.P. 125, 129) represent contaminations with a hypocrealean species (see under *O. luteorubella*, p. 976).

Specific nucleotide positions. Nucleotides being characteristic of series *Helicoon* are listed in Tab. 70 (ITS) and Tab. 71 (LSU D1–D2). Several dozens of positions in the ITS as well as LSU D1–D2 region permit unequivocal distinction among the four species (for *O. yuanensis* no LSU was available). At the 3'-end of ITS1 *O. luteorubella* coincides with *O. rosea* (C) and *O. sarraziniana* with all remaining sequences of section *Helicoon* including *O. yuanensis* (T), and also in the LSU such more or less consistent concordance exists, while in the remaining ITS1 and ITS2 no such cases could be seen. In the D1–D2 a relationship between *O. luteorubella* and *O. rosea* is supported at 13 positions, between *O. luteorubella* and *O. sarraziniana* at 11 positions, and between *O. rosea* and *O. sarraziniana* at 10 positions. Only at pos. 234 and 235 all three species differ from each other: *O. luteorubella* TT**CA**GGCT, *O. rosea* TG**TG**GGCC, *O. sarraziniana* TG**GT**GGCT.

Ecology. Series *Helicoon* comprises two ecological groups: (1) species growing in a temperate to montane-boreal, humid climate on substrates exposed to an only slightly varying moisture, being periodically flooded, always on banks of stagnant (lentic) or running (lotic) water; (2) species growing in a (sub)tropical, often humid (winter-dry) climate on substrates lying on the moist ground, rarely exposed some 1–2 m above the ground by getting dry after prolonged moisture. In the first group the exudate is sparse and hyaline, whereas in the second group it is more abundant and often turns more or less golden-yellow. According to the hypothesis that desiccation tolerance is a plesiomorphic feature in *Orbilia* (see phylogenetic part), group (2) might form a basal assemblage of hygric taxa within series *Helicoon*, from which those semiaquatic species of group (1) have evolved.

Species with a temperate-boreal distribution

Orbilia rosea (J. Webster & Descals) Baral & E. Weber, **comb. nov.**, MB 813627 — Pls 528–533, Map 88

Basionym: *Anguillospora rosea* J. Webster & Descals, in Descals et al., Can. J. Bot. 76(9): 1651 (1999) ['1998']
≡ *Anguillospora rosea* Descals, in Descals & Chauvet, Nova Hedwigia 54(1–2): 87 (1992), nom. inval., ICN Arts 36.1, 37.1
(?)= *Orbilia spinosae* Velen., Monogr. Discom. Bohem.: 93, pl. 11 fig. 46 (1934)
(?)= *Orbilia juniperi* Velen., Monogr. Discom. Bohem.: 94, pl. 11 fig. 21 (1934)

Taxonomic remarks. *Orbilia rosea* is distinguished from *O. luteorubella* mainly because of strong differences in conidial shape (anguillospora- vs. helicoon-like). The two species appear to differ also in apothecial colour (rose-lilaceous vs. yellowish-orange) and ecology (preference for streams vs. stagnant waterbodies). Although apothecial colour may show some variability within species of series *Helicoon*, *O. rosea* had quite consistently rosaceous-lilaceous or sometimes whitish or cream to rose(-amber), but never distinctly yellowish-orange colours, except for the orange colour reported for collections from China (but note that the epithet *rosea* refers to the colony colour on MEA agar, not that of the apothecia). In contrast to the similar *O. sarraziniana* which likewise often exhibits rosaceous-lilaceous apothecia, the spores of *O. rosea* and *O. luteorubella* are predominantly fusoid to fusiform with also the basal end ± tapered, and the lower spores are rather consistently inversely oriented within the asci, while the upper spores mostly point with their SBs upwards. A clear difference in spore characters between samples with anguillospora-like and those with helicoon-like anamorph could not be found, though the asci and spores of *O. rosea* were sometimes a bit larger than in *O. luteorubella*. Besides spore shape and orientation, *O. sarraziniana* differs from these two species in its anamorph (see below).

Some more subtropical, extra-European taxa with a spore orientation as in *O. rosea* and *O. luteorubella* distinctly deviate from these in spore characteristics, sometimes also in apothecial pigmentation or in the anamorph. *O. hoana* differs in shorter and much wider SBs and may possess a more or less striking golden-yellow exudate. *O. sinensis*, *O. tenuispora*, and *O. acicularis* sharply differ in the pseudotripoconidium-like anamorph, *O. sinensis* and *O. tenuispora* also in distinctly narrower and *O. acicularis* in longer spores.

Macroscopic variation. Though typically showing a pale rosaceous-lilaceous tint in the fresh state (Pl. 531: 1–4), some collections here assigned to *O. rosea* were colourless (including the type of *O. rosea*) while others showed rose-cream(-yellowish) or rose-amber to salmon colours, sometimes intermingled with rosaceous-lilaceous apothecia within a population (5a–b), apparently as a result of the age of the fruitbodies. The lilaceous component nearly disappears in the dry state in which the apothecia are more yellowish-cream to orange-rose. In older herbarium material they appear whitish-cream to yellowish-ochraceous, even when rehydrated.

Overall 12 records were reported by Liu (2006) under the name *O. luteorubella* from different parts of China. Their apothecial colour was given as 'fresh orange, dry orange-red' (see Pl. 532: 1). This latter collection was here examined 1.5 years later (Pl. 529: 6). The apothecia had a pale cream-orange-ochraceous colour when rehydrated, and a few spores were still alive. Based on anamorph and molecular data, this strain belongs to *O. rosea*. In its teleomorph features it agrees in most respects with European *O. rosea* except for the deviating apothecial colour and an apparent tendency to wider SBs in the mature living spores.

Apothecia of *O. rosea* considerably vary in size. In a collection from Gérardmer (IVV: H.B. 6257) the largest (up to 3 mm) and thickest (up to 0.8 mm) were found. Very small and thin apothecia were noted, e. g., in the type of *O. juniperi* (see below).

Microscopic variation. As in many other species of *Orbilia*, rather high variation in the number of inverted spores within a given apothecium was observed in quite a few collections here referred to *O. rosea*. Also asci with a mixed orientation, or asci with inverted upper spores occurred. For instance, in H.B. 6756a (from Vosges) around 7% of the asci showed an orientation as in *O. sarraziniana*, with most or all lower spores being upwards oriented and some or all upper spores showing inverse orientation. Also in H.B. 6366b (from Luxembourg), H.B. 7109b (from Bretagne), H.B. 7776 (from Denmark), H.B. 9691b (from Sachsen) and some other specimens the asci rarely or infrequently showed an orientation that strongly deviates from the typical case. An ascus with the lower spores pointing with its SBs upwards is figured for H.B. 6366b on p. 151 (under *Helicogonium*, Fig. 123). However, in some

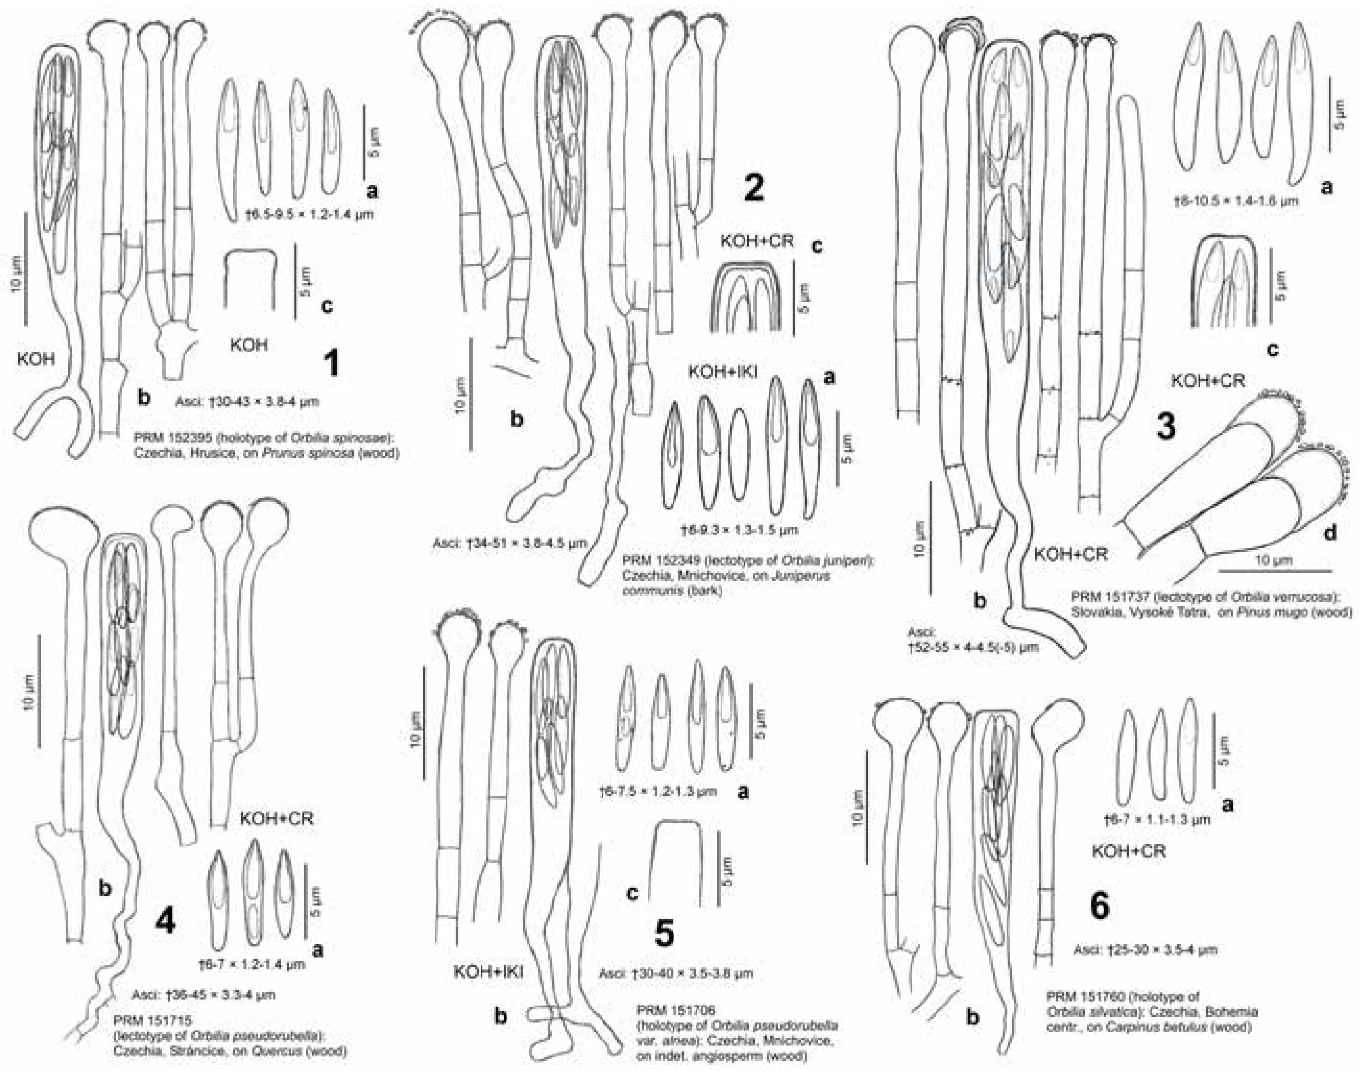

Plate 530. **1–6**: *Orbilia* cf. *rosea*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section.

collections from different geographical origin (e.g. H.B. 4892, 5077, 5573, 8892) virtually all asci of an apothecium showed the typical orientation.

Ascus and spore size showed rather high variation among the collections and, therefore, much overlap between closely related taxa. For example, some records showed an ascus and spore size and partly also spore shape as in *O. sarraziniana* (e.g., Pls 529: 5; 530: 4–6). Extraordinarily long ascospores occurred in specimens from the Vosges and Pyrénées-Atlantique (Pl. 529: 3–4). In these and some other collections (e.g., Pl. 529: 2) the SBs were rather narrow and filiform, whereas in others they were often wider and more subulate and sometimes basally inflated.

The paraphyses show considerable variation in length of the terminal cells as well as in the strength of apical inflation (a similar variation is noted in *O. sarraziniana*). Usually, one or several globose SCBs occur in the apical inflation or shortly below, and these are also found in the marginal ectal excipulum (Pl. 529: 1–3, 5). Additionally, the paraphyses and cortical cells were rarely filled with large, round to elongate VBs (Pl. 529: 1). A similar variation was noted in *O. luteorubella*, and we conclude that the presence of SCBs and VBs is not species-specific.

A more or less severe asymmetry of the apical inflation was noted in some paraphyses of some specimens (see Pl. 529: 3b, 5b). Also a paratype of *O. rosea* (apothecia grown on agar) was illustrated by Descals et al. (1999: fig. 4) with strongly asymmetrical and deformed paraphysis heads (Pl. 528: 2), whereas the holotype illustration (apothecia from natural substrate) shows consistently symmetrical heads (Pl. 528: 1). Asymmetrical heads were also seen in two of Velenovský's not included type specimens (Pl. 530: 4, 6).

Type studies of teleomorph. Webster & Descals (1979) and Descals et al. (1999) provided a detailed description and illustration of the teleomorph, which they found to be connected to the anamorph ***Anguillospora rosea***. Although the epithet *rosea* suggests a rose or pinkish apothecial colour, only the mycelial colonies on agar had a pink colour (but cream-coloured on 0.1% MEA), while the apothecia formed on agar were reported as 'translucent, watery' (the colour of the apothecia on natural substrate was not mentioned). Although the authors mounted the apothecia in water, they studied only dead asci, ascospores, and paraphyses, therefore, no SBs were observed. The spores were described as eguttulate and, as a consequence, the spore orientation inside the asci remained unclear. Nevertheless, the partially (Pl. 528: 1) or consistently (528: 2) fusoid (homopolar) spores and the anguillospora-like anamorph suggest identity with our ascospore isolate and two further collections from the Vosges (Pl. 529: 1–3). Morphological features were not available for the teleomorph of Pfister's (1997) strain which he tentatively identified as *O. luteorubella*.

The differences in ascospore size and shape in the British samples between apothecia from natural substrate (Descals et al. 1999: fig. 7A–D, see Pl. 528: 1) and pure culture (Descals et al. 1999: fig. 8, see Pl. 528: 2) are mainly due to the use of a 40× dry objective in the former case. We assume that the spores in the holotype from Yorkshire were wider than can be evaluated from the scale, also the spore bases are certainly not as acute as they were drawn. The difference in symmetrical vs. asymmetrical apices of the paraphyses has probably no taxonomic weight.

The following three taxa erected by Velenovský might well represent synonyms of *O. rosea*, for which they would provide earlier names. We here refrained from adopting any of these names because of the inadequate and partly incorrect diagnoses of this author, and because no anamorph data exists.

The holotype of ***O. spinosae*** (on wood of *Prunus spinosa*) contains 3–4 minute apothecia, although Svrček thought the material to be empty. In spite of rather short asci, some of the fusoid spores attained a length of up to †9.5 µm (Pl. 530: 1). Spore orientation was only seen in a few asci, in which the upper spores were often not inverted. Because of the ascus length the taxon is somewhat intermediate between *O. rosea*/*O. luteorubella* and *O. sarraziniana*, although such short asci occurred also in some other specimens referred to *O. rosea* (Pls 529: 5; 530 5, 6). Velenovský described the fresh apothecia as 0.1–0.3 mm diam., glassy and colourless (present study: rehydrated 0.15–0.2 mm, whitish translucent), and incorrectly reported the spores as narrowly acicular, 4–5 µm long. In his 'Additamenta', Velenovský (1934: 401) added a further collection on *Prunus spinosa*, with likewise 'linear' spores 4–5 × 0.3 µm, but with rose-coloured apothecia.

In the present reexamination of the lectotype of ***O. juniperi*** (Pl. 530: 2), which derives from *Juniperus* branches lying on wet ground, only a single apothecium was found on a fragment of loose bark (rehydrated whitish, 0.25 mm diam., slightly concave). This was used up during examination. The spores are ± fusoid and the SBs clearly discernible in some spores as elongate transparent regions. This permitted to see the spore orientation in the asci which, besides spore shape and ascus length, excludes *O. sarraziniana*. Velenovský described the apothecia as 0.5–0.6 mm diam., lens-shaped, translucent, colourless, rarely with a rose tint, and the acicular spores as 4–6 µm long. He believed that the long and thin, flexuous ascus stipe, which was indistinctly branched only at the very base (L-shaped), was characteristic of this taxon.

Svrček (1954: 15), who did not make a distinction between *O. luteorubella*, *O. rosea*, and *O. sarraziniana* as circumscribed at present, believed that *O. juniperi* was a synonym of *O. luteorubella*, in spite of the reported whitish colour and the rather small asci (30 × 3.5–4 µm) and spores (6–7 × 1 µm) observed by him. Contrary to Velenovský and Svrček who stated that the paraphyses are 'without epithecium', these are found to be covered by a thin, refractive, granular exudate.

A separate decorticated, thin coniferous twig in the type packet bears two small apothecia of a whitish orbilia-like *Mollisia* with IKI-blue asci and light brown excipulum, but no *Orbilia*. Both Velenovský and Svrček stated *O. juniperi* to grow 'on wood'. Velenovský reported abundant apothecia in the lectotype, and referred a collection on *Abies* to this species. Svrček cited a second collection on *Juniperus* (topotype) which was not examined in the present study.

Velenovský (1934) described ***O. verrucosa*** on the basis of two collections on coniferous wood (Vysoké Tatry, *Pinus mugo*, VIII.1926, PRM 151737; Mnichovice, *Picea abies*, 26.VII.1926, PRM 152356). Apparently because Svrček did not find any spores in the *Pinus* specimen, he designated the *Picea* collection as lectotype. However, on Velenovský's two manuscript plates it can be seen that the protologue predominantly includes data of the collection on *Pinus*. Particularly spore length (5–8 µm) is that from the *Pinus* collection, whereas in the *Picea* collection Velenovský gave 8–12 µm long spores. The name *verrucosa* is undoubtedly derived from the thick-walled marginal cortical cells, each being terminated by a papilla. Again, this feature is only illustrated for the *Pinus* collection. Therefore, Svrček's lectotypification must be considered as being against the Code (Art. 9.19, Turland et al. 2018).

When the rich *Picea* collection was reexamined here, indeed no such wall thickenings and papillae could be observed. Svrček (1954: 22) is confirmed here when referring this specimen to *O. auricolor* (as '*O. curvatispora*', see Pl. 950: 3). Reexamination of the *Pinus* collection (Pl. 530: 3) revealed 3–5 × (4–)5–7 µm large glassy caps on the cortical cells at margin and flanks, which undoubtedly correspond to the wall thickenings reported by Velenovský, though distinctly papillate caps could not be seen. In the largest apothecium (rehydrated 0.45 mm diam.) a few mature asci were found. The included spores are fusoid with an acute apex, and only slightly inequilateral or curved, in contrast to the protologue and manuscript plate which report filiform, strongly curved (C-shaped) spores. Since the remaining features agree with Velenovský's manuscript, it is concluded that the C-shaped spores do not belong to the present *Orbilia*. As a consequence, we here designate the collection on *Pinus* (PRM 151737) as **lectotype** of *Orbilia verrucosa*.

The hymenial features of this lectotype specimen, e. g., spore orientation inside the asci, fit quite well *O. rosea*. We did not include *O. verrucosa* in our description because we never saw such prominent glassy caps in *O. rosea*. In the protologue of *O. verrucosa* the apothecia were described as 0.3–0.8 mm diam., glassy rosaceous or pale yellowish. According to Velenovský's manuscript plates, the apothecial data of the lectotype on *Pinus* read '0.3–0.5 mm, glassy translucent, pale with pink or yellow tinge' which would match more or less the present concept of *O. rosea*, while those of the *Picea* collection read '0.5–0.8 mm, translucently apricot', a colour not mentioned in the protologue.

Another collection under the name *O. verrucosa* (PRM 151769, from Vysoké Tatry, VIII.1926) was neither cited by Velenovský (1934) nor treated in his manuscript and also Svrček did not mention it. Except for the host (*Picea abies*), the collection data concur with those of PRM 151737. The apothecia are larger (rehydrated 0.4–0.8 mm diam.), and the hymenial elements appeared senescent. Three apothecia were examined, but no spores could be found. Some of the marginal cells bear small caps but a majority are without. It seems probable that this specimen is conspecific with the lectotype on *Pinus*.

The holotype of ***O. silvatica*** (on wood of *Carpinus*, Pl. 530: 6) was placed by Svrček (1954: 20) in synonymy with *O. luteorubella* var. *pellucida* (= *O. cardui* in the present monograph). This is surprising because Svrček separated that variety from typical *O. luteorubella* by a layer of exudate over the paraphyses, which could not be found in the present reexamination of the type. Yet, Svrček did not mention any observations made on this material. Velenovský's description indeed suggests identity with *O. cardui* (apothecia colourless, paraphyses non-capitate, covered by exudate). Only ± overmature apothecia referable to *O. ?rosea* could be found in the holotype (two apothecia examined), and the material does not look like a mixture. The paraphyses are strongly capitate and covered by minute scattered granules. The rather small spores are often pointed at one end, and their widest part is in the middle or closer to the pointed end. Spore orientation was very difficult to see: the upper spores are perhaps

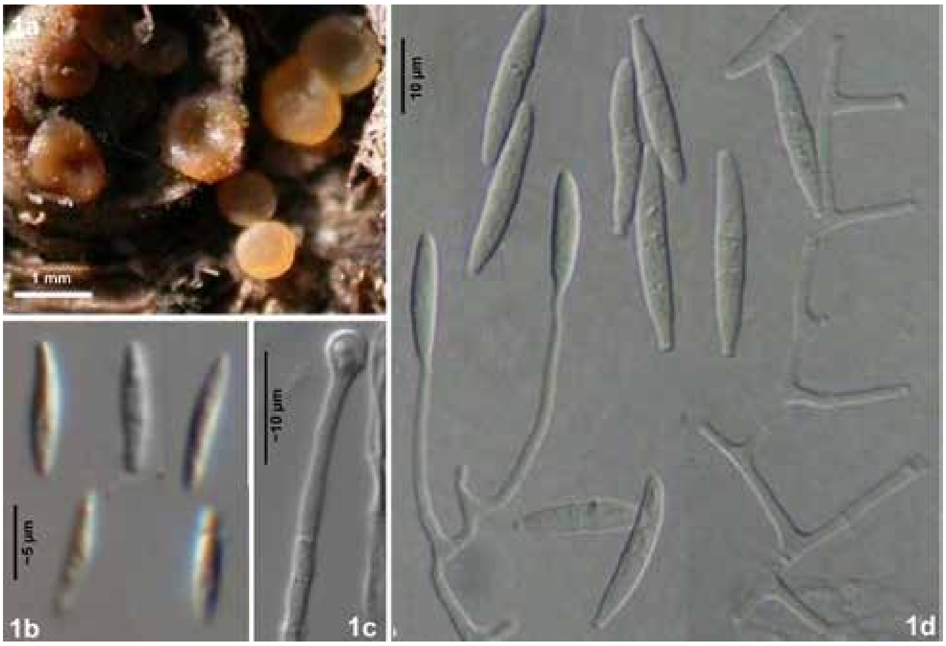

Plate 532. **1**: *Orbilia rosea*. – **1a**. fresh apothecia; **1b**. ascospores; **1c**. paraphysis; **1d**. conidiophores and microconidia (from culture). – Dead state; from Liu (2006, figs 129–130, DIC). — **1**. HMAS 139672: China, Henan, on ?*Quercus*.

predominantly oriented with their pointed ends downwards, but the lower spores sometimes also. Spore orientation better fits *O. sarraziniana*, whereas spore shape better fits *O. rosea*. About 50 scattered apothecia (rehydrated 0.2–0.5 mm diam., convex, pale cream) occur on the wood fragments. Why Velenovský gave the apothecial size as ‘smaller than 0.1 mm (!)’ remains a mystery. Also the spores were given by him much too small (3–4 µm long, very narrowly linear). A confusion of the specimen might have happened, but the wood anatomy fits the host (*Carpinus*) mentioned by Velenovský.

O*. *pseudorubella was placed in synonymy with *O. luteorubella* by Svrček (1954: 19). The examined syntype (PRM 151715, on Quercus wood, Pl. 530: 4) might fit *O. sarraziniana* because of rather small spores and very strongly capitate paraphyses. Also ascus size fits that species. However, spore shape (with the widest part often closer to the acute end) would better fit *O. luteorubella* or *O. rosea*. Svrček found the asci shorter (28–33 × 3.5 µm) and the spores narrower (6–8 × 1 µm) than evaluated here. Spore orientation could clearly be seen in some spores of the well-preserved material (in KOH+CB_L, sometimes the upper spores were inverted but often they were not inverted, and usually the orientation was rather mixed). Velenovský characterized his taxon by large (1–2 mm), carneous-rose apothecia and emphasized the absence of a yellow tint. He erroneously reported the spores as very narrow, linear, 3–5 × 0.3 µm. The protologue mentions five localities and two substrates (*Quercus* and *Carpinus*). Velenovský’s manuscript notes actually contain a lot of records, and a total of six specimens can now be found at PRM (M. Chlebická pers. comm.). The syntype examined here is among those for which Velenovský made unpublished microscopic sketches, and Svrček appears to have considered this material as ‘holotypus’ because it fits for all measurements exactly the data of the protologue. We therefore designate the collection on *Quercus* (PRM 151715) as **lectotype** of *O. pseudorubella*. Svrček mentioned one further specimen under the name *O. pseudorubella* (PRM 151702), which we did not see and which he likewise referred to *O. luteorubella*. Based on the rose apothecial colour in the protologue we tentatively place *O. pseudorubella* in synonymy with *O. rosea*.

The holotype of ***O*. *pseudorubella* var**. ***alnea*** (Pl. 530: 5) now consists of only three small apothecia which certainly did not grow on *Alnus glutinosa* as stated by the author, but perhaps *Tilia*. Svrček (l.c.) considered the taxon to be young *O. luteorubella*. The fusoid ascospores have their widest part in the middle or sometimes closer to the acute end. In some free spores liberated by strong squeezing, SBs could be discerned in the acute end, while within the asci the SBs could hardly be seen. Judging from spore shape, the spore orientation appears to be clearly variable: sometimes the lower spores are inverted and sometimes the upper. Again Velenovský reported much too small spores (3–4 × 0.2 µm) which Svrček corrected to 7–8 × 1 µm. The apothecia were described as glassy translucent, colourless, 0.3–0.6 mm diam., and perhaps this was the reason why Velenovský separated the specimen from *O. pseudorubella* at the variety level. Ascus and spore size fit *O. sarraziniana* as well as *O. rosea* or *O. luteorubella*. Because of the colourless apothecia and the fusoid spores with their widest part closer to the acute end we tentatively place the taxon in synonymy with *O. rosea*.

Misapplication. Costantin’s (1888) detailed description of samples under the name *O. vinosa* (no substrate or other collection data are mentioned) belong to a member of section *Helicoon*, probably *O. rosea*, based on the rose apothecia colour. Costantin illustrated asci with truncate apices, strongly capitate paraphyses, and fusoid-acicular spores 8–11 × 1 µm. For the other cases of misapplication see below (under Not included collections and Anamorph) or above (Type studies).

Not included collections. Due to the difficulty in recognizing *O. rosea* by the teleomorph alone, we refrained from including a number of specimens, partly because the apothecial colour was not clearly pinkish, or because the fresh colour was not documented. Also the spore orientation was sometimes very variable, or it could not clearly be seen in specimens that were studied in the dead state.

In a few specimens both types of spore orientation were rather frequent, though the inverse orientation of the lower spores prevailed. For instance, in a collection from Chemnitz (Pl. 531: 2) around 50% of the asci showed the lower spores inverted, and perhaps 40% the upper spores inversed, while a mixed orientation occurred in a further 10–20% of the asci. Spore shape was here often fusoid, which seems to exclude *O. sarraziniana*. Because of this uncertainty, the collection was not included in either description. Spore orientation was similarly variable in the types of *O. pseudorubella* and *O. pseudorubella* var. *alnea*, though here the spores and their SBs could only clearly be seen in some asci. In the types of *O. verrucosa* and *O. juniperi* exceptions of the typical orientation were not observed, but spores were only seen in a few asci. For the latter four species and the likewise not included *O. silvatica* and *O. spinosae* see also under Type studies.

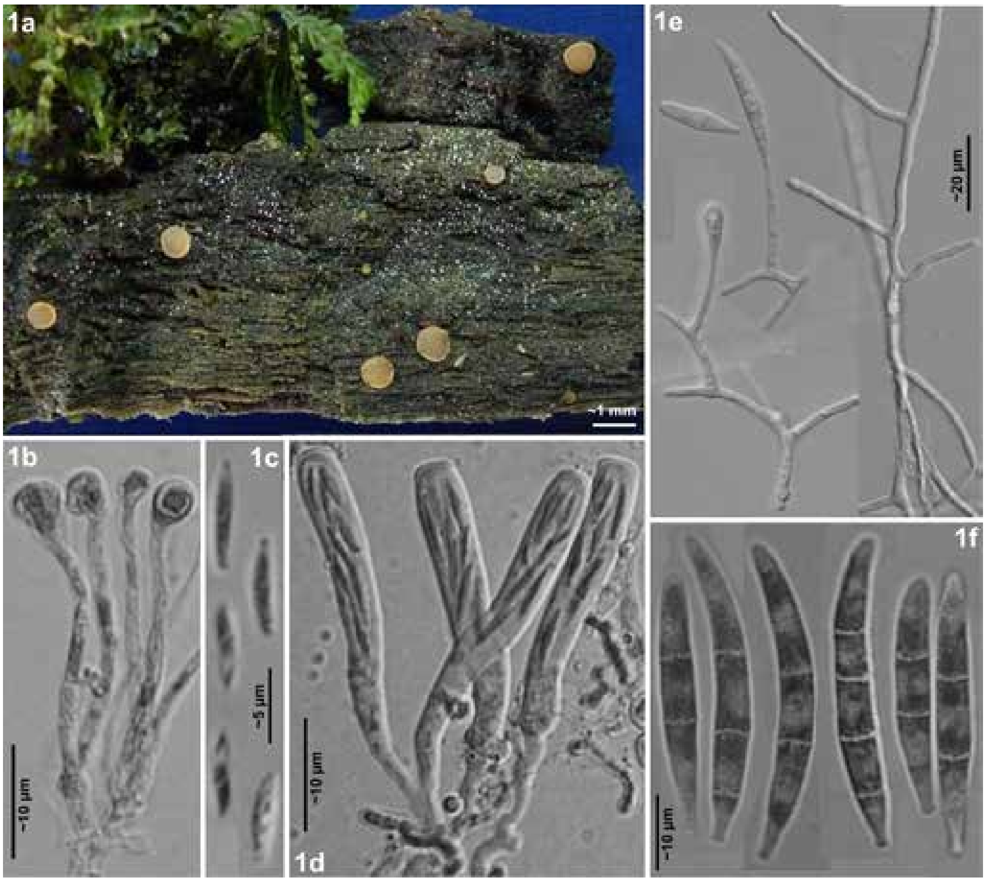

Plate 533. **1**: *Orbilia* cf. *rosea*. – **1a**. fresh apothecia; **1b**. paraphyses; **1c**. ascospores; **1d**. asci; **1e**. conidiophores with young conidia; **1f**. conidia (from culture). – Dead state (in MLZ); phot. Two collections from France (Côte-d'Or) with spores *6.5–10.5 × 1.2–1.5 µm were presented under the name *O. luteorubella* by J.P. Priou in Fournier et al. (2010, see also IVV: J.P.P. 29201). The obclavate spore shape is strongly reminiscent of *O. sarraziniana*, but spore orientation appears to exclude this species. The apothecia were grey-cream with a rose but also yellowish component. Collections from Bretagne (IVV: J.P.P. 28085) and Midi-Pyrénées (IVV: J.P.P. 26213) show similar features but deviate in distinctly smaller spores (*6–7 × 1.1–1.2 µm).

Two collections from subalpine Switzerland in an *Alnetum viridis* on calcareous soil are also not included in the description. One on *Alnus alnobetula* from Sörenberg (Luzern) was reported by Breitenbach & Kränzlin (1981: pl. 252) under the name *O. sarraziniana*. According to our reexamination, spore shape and orientation appear to exclude this species. The 'grey-pink' apothecia suggest identity with *O. rosea* while the photo shows an orange colour. The one from Sittlisalp (Uri, IVV: H.B. 8283) grew on a herbaceous stem of *Adenostyles* and concurred quite well with lignicolous specimens, except for rather short SBs (2.5–3.5 × 0.3 µm).

A collection from Guizhou, China, examined and cultured by M.H. Mo (pers. comm., M.H.M. 003) was at first glance considered to be close to *O. bannaensis* because of similar ascospores and conidia, but appears to belong to *O. rosea* s.l. (Pl. 533). Those from Hong Kong and western Russia are only known in the dead state and lack clear data on spore orientation, in the latter also apothecial colour is unknown.

Anamorph. Webster & Descals (1979) obtained various conidial isolates of *Anguillospora* sp. from foam of streams in England (Cumbria, Wales, and Devon). In one from Cumbria, mature apothecia developed which they identified as *Orbilia* sp. (Pl. 528: 2; Descals et al. 1999: fig. 8). Later, Descals et al. described the anamorph as *A. rosea*, which they obtained also in ascospore isolates of two collections of *Orbilia* sp. on submerged branches from streams in Yorkshire (Pl. 528: 1; Descals et al. 1999: fig. 7A–C) and Cumbria (Descals et al.: fig. D). Apparently the same anguillospora-like anamorph was obtained by Pfister (1997: 8) in an ascospore isolate of an *Orbilia* collected near Concord, Massachusetts (Pl. 528: 5), and by us in an ascospore isolate of a collection on an *Alnus* branch from the Vosges (Pl. 529: 2).

According to Descals et al. (1999), the characteristics of *A. rosea* include colonies with a pink colour on 2% MEA (but pale cream on 0.1% MEA), and very long scolecosporous macroconidia which are strongly curved under a wide arch (C- but also S-shaped), with ± tapered apex and truncate base, 120–185(–210) × 3–6 µm (actual length), (0–)9–17-septate. These conidial data agree quite well with ours obtained from the French specimen. We assume, however, that the 100 µm-scale in fig. 4 in Descals et al. is erroneous, while the 50 µm-scale in their fig. 6 might be valid also for fig. 4. With the 100 µm-scale the conidia would have a size of 125–255 × 6–8 µm which is distinctly beyond the above values, while with the 50 µm-scale a reasonable size of 73–150 × 4–4.7 µm is obtained. Pfister (1997) did not provide conidial measurements. According to the given scale a size of 88–108(–142) × 1.8–2.4 µm (actual length) was evaluated for the 10–17-septate macroconidia. However, we assume also here an error in the scale, for which perhaps 40 instead of 20 µm are valid: this would result in a size of about 175–215(–285) × 3.5–5 µm.

Both Descals and Pfister observed also microconidia in their cultures, while no such conidia were observed in our strain. In the strains of Webster & Descals (1979) and Descals et al. (1999: figs 6B, 9) these microconidia were usually curved, 0–2(–4)-septate, 22–43(–63) × 3–4 µm, whereas in Pfister's strain they were straight, 2-septate, ~26–32 × 3.5–5.5 µm (scale corrected as stated above). In an isolate from Cumbria, Descals et al. (l.c.: fig. 6C; Pl. 528: 4c) found intermediate, 3–6 septate conidia of about 40–115 × 3–4 µm (actual length), which resemble the multiseptate macroconidia although their length was not included in the protologue of *A. rosea*. The authors emphasized that the observed macro- and microconidia overlap in length and number of septa by showing a continuum without sharp limits between the two conidial types. However, these intermediate conidia are drawn narrower than the long conidia which are about 4.5–5 µm wide, hence we included them in the microconidial measurements. In different streams in southern France, Descals & Chauvet (1992) found conidia which they referred with hesitation to *A. rosea*. Neither a culture was obtained nor a description provided. According to the scale, the single drawn conidium has a size of ~185 × 5 µm and shows 29 septa.

In one of B. Liu's 12 Chinese strains identified as *O. luteorubella* (Henan, at rivulet, on bark of ?*Quercus*, Pl. 529: 6) an anamorph with ± straight, 1–2-septate conidia was obtained which Liu named *Dactylella* sp., but which appears to represent the microconidial stage of *O. rosea* (Pl. 532: 1d). The absence of macroconidia in this strain might be due to the fact that the culture was not flooded. Similar, but larger, straight to slightly curved, 1–4-septate microconidia were reported by M.H. Mo in his strain of *O.* cf. *rosea* (Pl. 533: 1e–f). The conidia observed in *O. sarraziniana* (Pl. 539) resemble microconidia of *O. rosea* but are partly broader and more strongly curved, comparable to the microconidia observed in the helicoon-like anamorph of *O. luteorubella*.

Dactylella stenomeces Drechsler (1963), a species with long and slender multiseptate conidia isolated from decaying leaves and parasitizing *Pythium* oospores, was transferred to *Brachyphoris* by Chen et al. (2007b). The conidia resemble macroconidia of *A. rosea* but are narrower (2.5–3.2 µm). Also *Anguillospora curvula* S.H. Iqbal (1972), isolated from grass leaves in a stream in Devon (England), has similar-sized conidia (110–187 × 2.7–3.7 µm, but 3.7–4.7 µm according to scale) which are, however, only 2–5 septate and the colonies light greyish- to reddish-brown. For both species no sequences were available in GenBank.

Anamorphs very similar to *Anguillospora rosea* are connected to members of *Phaeohelotium* or *Cudoniella* (*Helotiales*). For instance, the teleomorph of *A. furtiva* Descals, referred to *Pezoloma* by Descals et al. (1999) appears to belong to *Phaeohelotium imberbe* (Bull.) Svrček, a frequent species on dead wood at stream banks. Unlike *A. rosea*, *A. furtiva* possesses a phialidic synanamorph which forms minute, subglobose microconidia.

Since the holotype of *A. rosea* does not appear to have been preserved as living culture, and molecular data were not gained from it, we here designate the paratype isolate CCM F-18983 as **epitype** of *A. rosea*, for which an SSU sequence exists in GenBank (AY357265).

Phylogeny. Sequences of five European strains were available: two ascospore isolates (Vosges, H.B. 6756a; Schwarzwald, H.B. 10018) comprising SSU, ITS, and LSU, two from apothecia (Pyrenees, H.B. 10029, 10034) comprising ITS and LSU, and the epitype isolate of *Anguillospora rosea* (England, CCM F-18983) for which only SSU was available. Sequences were also available for five Chinese strains identified by B. Liu as *O. luteorubella*, comprising ITS, two also LSU. The S1506 intron is present in the epitype (406 nt, mentioned also by Belliveau & Bärlocher 2005), but absent in our two ascospore isolates and those from China.

The connection between teleomorph and anamorph is confirmed by a 100 % similarity in the partial SSU (352 nt, V8–V9, excluding intron) by which the isolate from Vosges overlaps with the British *A. rosea* strain (H.B. 10018 has only V9 where it concurs with H.B. 6756a). In the V9 region of these 352 nt, *O. rosea* differs at 4 nucleotide positions (**A**AG**A**TCGGCAACGA**T**CA**T**) from the available four strains of *O. sarraziniana* (China: HMAS 139684, 96817; Europe: H.B. 7235 & 6727a) and two of *O. luteorubella* (China: gz-08; Europe: H.V. A327) which have **G**AG**G**TCGGCAACGA**C**CA**C**. This paired symmetrical change of nucleotides suggests a stem-loop structure which roughly corresponds to the long loop in the V9 region of the *Escherichia coli* SSU.

The only member of series *Pseudotripoconidium* with SSU V9 (DQ471000, AFTOL-ID 905, CBS 917.72, *Orbilia* aff. *sinensis*, Benedict's strain) concurs at these 4 positions with *O. sarraziniana* and *O. luteorubella*. In fact, this motif is by far the most frequent one across the genus *Orbilia* and occurs even in *Lilapila* and *Bryorbilia*. The *O. rosea* motif, on the contrary, does not occur in any other *Orbiliomycetes* for which the V9 region was available. Further sequences of the SSU V9 within section *Helicoon* are necessary to clarify whether this motif is unique to *O. rosea*. Also it might be worth finding out whether the S1506 intron, which the British epitype strain of *O. rosea* possesses, occurs also in strains of this species from central Europe or elsewhere.

In a phylogenetic analysis of the ITS region by Liu et al. (2006a), all five Chinese strains clustered in a clade, though showing some distance among each other. In our ITS analysis they clustered strongly supported with the four European *O. rosea* strains (one of the Chinese strains, B.L. T540, is not shown), whereas strains with a helicoon-like anamorph appeared distant from those (Phyl. 17). The ITS distance among the Chinese strains lies in the range of (0.2–)2.2–3.5(–6.5) %, and between the four European strains at 0–0.4(–3) %, whereby the Chinese differ from European by (2.5–)3–3.5(–5.5) %. However, although one of the two strains from Pyrenees (H.B. 10034) fully concurs with H.B. 10018, the other deviates from it by 15 nt (3 %) and 4 gaps in the ITS and 3 nt in the LSU D1–D2 as closest match.

We assume that all five Chinese strains are able to produce anguillospora-like macroconidia and belong to *O. rosea* as a genetically variable species. It would be valuable to gain ITS from the ex-type and other cultures of *A. rosea* in order to better explore the molecular variation of *O. rosea* within Europe.

O. rosea differs from *O. luteorubella* in the ITS region by 13–15 % and from *O. sarraziniana* by 14–17 % (*O. luteorubella* differs from *O. sarraziniana* by 15–15.5 %). In the LSU D1–D2 the two *O. rosea* strains concur except for 1 nt (0.2 %), while they differ from the mentioned Chinese '*O. luteorubella*' strains (2 have LSU) and three other Chinese strains uploaded under the name *Orbilia auricolor* (AY261123–5) by 1–1.5 %, from *O. luteorubella* and *O. sarraziniana* by 5–5.5 %, and from series *Pseudotripoconidium* also only by 5–6 % (582 nt).

Ecology. Apothecia of *O. rosea* were found on ± rotten wood (more rarely bark) of periodically submerged branches and logs of various angiosperms, often on *Alnus*, but also gymnosperms. A sparse, not included record was on a herbaceous stem (*Adenostyles*).

The species is adapted to running water (streams and rivulets up to their source), by which the apothecia are sometimes flooded. The included collections are from cold- to warm-temperate humid regions but also from orotemperate and orosubmediterranean (montane to subalpine) or thermo- to oroboreal zones and comprise atlantic to subcontinental regions of Europe. In contrast, *O. luteorubella* is usually not observed in orotemperate zones. Collections are also known from continental, oroboreal and subtropical humid (partly winter-dry) eastern Asia and from cold-temperate humid eastern North America. The vegetation includes *Alnetum glutinosae*, *Alnetum viridis*, *Abieti-Fagetum*, etc.

Besides Descals et al.'s (1999) records of mainly anamorphs, which concentrate on the western part of England and Scotland, the database of the British Mycological Society (FRDBI) lists *A. rosea* also from some other counties of England: South West (Cornwall, West Gloucestershire, South Wiltshire), South East (South Hampshire), and East Midlands (Derbyshire, Leicestershire, Rutland). Apothecia which formed *Anguillospora rosea* in our pure culture were collected from a place where a small rivulet flows into a large lake (Lac de Longemer) in a montane forest of Vosges (eastern France).

The filiform shape of anguillospora-like conidia represent an adaptation to running water by which they are transported, in contrast to the air-enclosing conidia of *Helicoon sessile* which occur in stagnant water (Michaelides & Kendrick 1982), though *H. sessile* was also found at streams (Pfister 1997). Records of *O. rosea* are predominantly from streams that emerge from more or less acidic bedrock. For instance, Descals & Chauvet (1992) observed *Anguillospora* (?)*rosea* in southwest France in three of the four streams, with a pH between 5.5–6.5 and 6.7–7.8, while the species was absent in the fourth stream with a pH of 8. The holotype of *A. rosea* was collected on quite strongly acidic Upper Carboniferous Millstone Grit in West Yorkshire, and on this sandstone were also the two sites where C. Yeates (pers. comm.) detected the teleomorph.

Map 88. Known distribution of *O. rosea* in Europe (yellow = not included collections).

Specimens included (all conidial isolates from foam). **SWEDEN**: **Västerbotten**, Vilhelmina, 4.5 km SW of Saxnäs, Satsfjället, Pojken, 715 m, branch of *Betula pubescens*, on wood, 24.VII.2010, P. Perz (H.B. 9410 ø). — **FINLAND**: **Uusimaa**, 50 km ENE of Helsinki, 5.5 km ESE of Porvoo, log of *Betula*, on wood, 25.VI.2019, J. Äikäs (doc. vid.). — **DENMARK**: **Nordjylland**, 8 km NW of Brovst, 3 km W of Tranum, SSE of Naturcenter Fosdalen, Lien, 15 m, branch of *Corylus avellana*, on wood, ~14.V.2005, C. Lange (H.B. 7776 ø). – ibid., log of ?*Acer*, on wood, ~14.V.2005, C. Lange (ø). — **GREAT BRITAIN** (from foam, if not otherwise stated): **Scotland**, **Highland**, 25 km NW of Inverness, 4 km W of Strathpeffer, River Contin, Falls of Rogie, 60 m, 13. XI.1979, E. Descals (B124-1-6, -9, conid. isol., non vid.). – 34 km NNW of Inverness, Strath Rusdale, River Black Water, Creag Braigh, 180 m, 15.XI.1979, E. Description: — **TELEOMORPH**: **Apothecia** fresh (0.15–)0.3–2(–2.5) mm diam., in total (0.12–)0.2–0.5(–0.63) mm high (receptacle 0.09–0.2 mm), light to bright (yellow-)orange(-ochraceous) to orange(-rose), young pale pinkish-orange, very slightly to medium translucent, round, slightly lobed when large, subgregarious to gregarious; disc flat to medium convex, margin smooth, indistinct, not protruding (but thick and slightly rising above disc when very young), exterior glabrous; broadly sessile or with a thick and short stipe 0.1–0.3(–0.4) × 0.3–0.8(–1.2) mm, superficial; dry bright orange-red to dull orange-brownish. **Asci** *(36–)40–55 × (4–)4.3–4.8(–5) µm {4}, †(32–)43–55(–60)

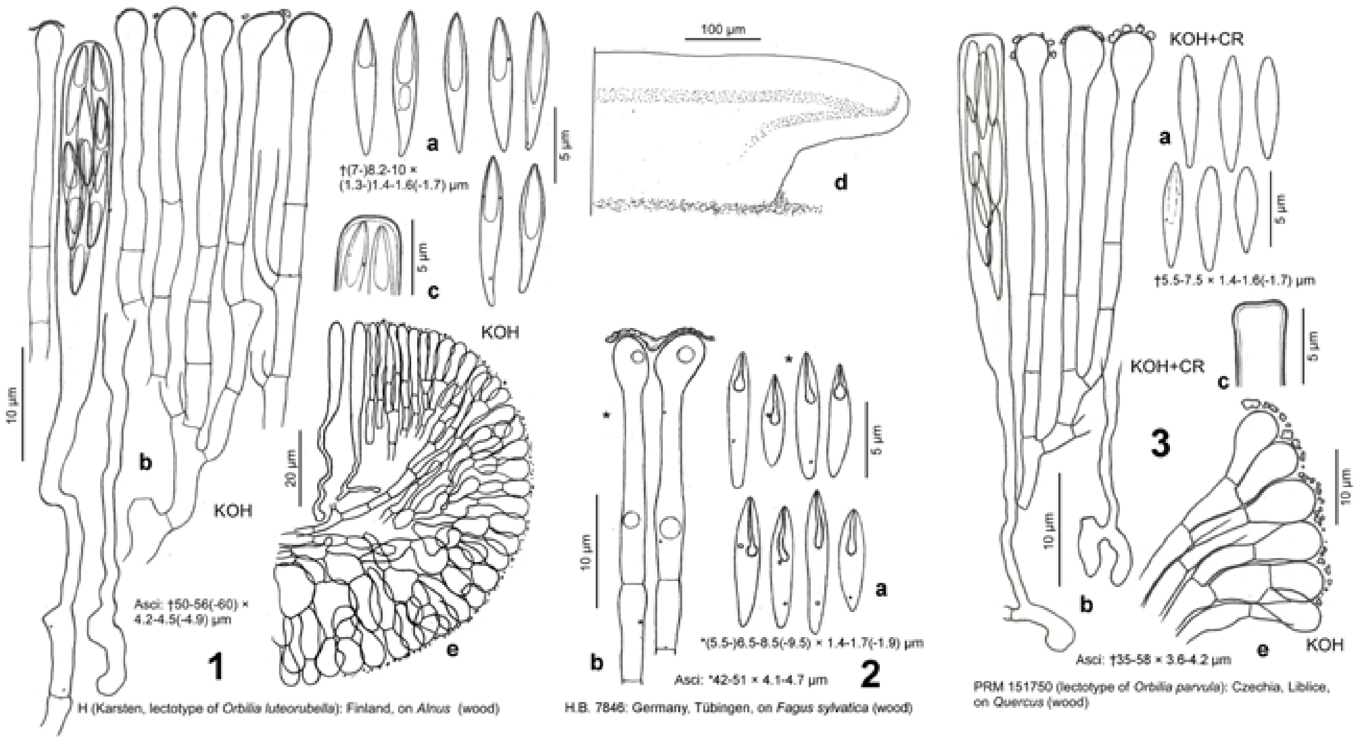

Plate 534. **1–3**: *Orbilia luteorubella*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. marginal ectal excipulum (median section).

{5} × (3.4–)3.6–4.5(–4.9) µm {5}, 8-spored, spores 2–4-seriate, pars sporifera *16–22 µm, (2–)4–5(–6) lower spores inversely oriented {12}, sometimes mixed, exceptionally upper spores inverted; **apex** (†) (medium to) strongly truncate (± not indented, laterally not or very slightly inflated); **base** with medium to very long, thin, flexuous stipe, base L- to T-shaped. **Ascospores** *(5.5–)6.5–10(–11) × (1.3–)1.4–1.8(–2) µm {14}, †(5.5–)6–9(–10.5) × (1.2–)1.3–1.6(–1.7) µm {5}, narrowly (fusoid- to) fusiform(-clavate), widest part mostly in the middle or often above, apex subacute to acute, base slightly to often strongly tapered, straight, rarely slightly curved (especially near base); **SBs** 2.5–4.2 × (0.2–)0.4–0.6 {5}, †(3.3–)4–5 × 0.7–0.9 µm {T}, vermiform to subulate, often inflated at the base, straight or slightly flexuous, overmature tear-shaped to ampulliform, 2–2.5 × 0.7–1 µm. **Paraphyses** apically slightly to medium but also very strongly (clavate-)capitate, sometimes asymmetrical, terminal cells *18–28 {4} × (2.3–)3–4.5(–5) µm {5}, †(17–)19–22(–25) × 2.3–3.5(–4) µm {2}; lower cells *(4–)5–9 × 1.7–2.5(–3) µm {3}, †4.5–10 × 1.3–2.3 µm {2}, branched only at lower septa; hymenium hyaline to pale yellow- or rosaceous-orange in lower part. **Subhymenium** hyaline to pale orange, 20–40 µm thick, medium to sharply delimited. **Medullary excipulum** subhyaline to very pale orange, (30–)100–350 µm thick in centre, of medium to very dense, non-gelatinized textura angularis-globulosa(-intricata), very indistinctly delimited from ectal excipulum but sharply so at flanks and margin (sometimes by a very thin t. porrecta), cells in central part *(10–)15–30(–60) × (8–)12–17(–21) µm {3}. **Ectal excipulum** hyaline, of thin-walled, vertically oriented t. globulosa-angularis-prismatica from base to margin, 60–80 µm thick near base, cells *10–30(–35) × 8–20 µm {2}, †(10–)13–25(–30) × (6–)10–15(–20) µm {2}; 35–60 µm thick at lower flanks, 10–35 µm at mid flanks and margin, oriented at 70–90°, marginal cortical cells *10–16 × 5–8 µm {2}, †7–18 × 3–6.5 µm {2}, clavate to pyriform, **glassy processes** absent. **Anchoring hyphae** very sparse to abundant, *2–4(–6) µm wide, walls smooth, 0.2–0.3(–0.4) µm thick {5}, forming a dense t. intricata up to 100 µm thick. **SCBs** in paraphyses globose, medium- to high-refractive, 1–2 per cell, 1–2 µm diam. {8}; in ectal excipulum only at margin (inner cells), globose, 1–1.8 µm diam. **VBs** in paraphyses absent {1} or low- to medium-refractive {5}, globose to elongate, filling entire terminal cell, also sometimes present in marginal cortical cells; not turning yellow in dead state. **Exudate** over paraphyses and margin granular-cloddy, 0.2–1(–1.5) µm thick, ± scattered, hyaline, ± loosely attached to the wall, but also absent. — **ANAMORPH**: helicoon-like (from ascospore isolate {3} or in wet box or unsterile water culture on natural substrate {3}). **Colonies** distinctively pink on malt extract-yeast extract agar (MEYE, Pfister 1997). **Conidiophores** mononematous, *35–100 × 2–2.5 µm {H.B. 9424a}, †27–60 × 2–2.2 µm {Jiang}, sometimes branched below or in middle part, multiseptate, septa ± equidistant, with a small knob-like inflation at apex, conidiogenesis terminal; conidiophores very short or virtually absent in the type of *H. sessile* and samples from Austria (Voglmayr 1994). **Macroconidia** *((21–))(26–)30–36 × (19–)20–25(–29) µm {2} (Pfister: 36–42 × 18.5–20 µm, Jiang: †~10–20 × 18–22 µm, Voglmayr: 26–42 × 20–27.5 µm), filiform, strongly helicoidally curved under a narrow arch by forming a compact, ellipsoid, barrel-shaped body, with ~6–8 coils (Pfister: ~12, Jiang: ~1–4, Voglmayr 6–8), twisted like a left-hand thread (exceptionally a few conidia like a right-hand thread), actual length ~300–450 µm (Jiang: ~60–200 µm), thread *4–5 µm wide [Pfister: 2.5–3.7 µm, Jiang: †4–5 µm, Voglmayr: 4.5–5(–7.5) µm], multiseptate (~5–7 cells per turn, each cell ~10–15 µm long, in total about 30–45-septate (Pfister: ~5–6 cells per turn, each cell ~5–9 µm long). **Microconidia** *(14–)20–40(–44) × 4.3–4.8 µm, actual length 25–50(–80) µm, slightly to very strongly curved (hook- to spiral-like), with (0–)0.2–1(–2) coils, (1–)3(–8)-septate {2} [Voglmayr: 25–40 × 4.4–6(–7.5) µm, 2–4-septate]. Macro- and microconidia containing a few minute LBs close to the septa, wall surface bright lilac in CRB.

Habitat: lying on or sticking in wet mud, periodically submerged in small ponds, decorticated or partially corticated, 15–150 mm thick branches, logs or roots of *Acer* sp. {1}, *Alnus* sp. {2}, *A. glutinosa* {1}, *Betula* sp. {1}, *Betula pendula* {2}, *Fagus sylvatica* {8/1}, *Fraxinus excelsior* {1}, *Picea abies* {1}, *Populus* sp. {1}, *Prunus padus* {1}, *Quercus* sp. {1}, *Salix* sp. {5/1}, *S. caprea* {2}, on lateral and also upperside, on min. 0.1–1 mm deep medium to strongly decayed wood {27}, rarely bark (periderm) {2}, usually grey-brown or blackened, green algae absent or present in varying abundance. **Associated**: ?*Ascitendus* sp. {1}, *A. austriacus* {2}, *Ascocoryne lilacina* {1}, *Bactridium flavum* {2}, *Bulbillomyces farinosus* {1}, *Cyanophyta* {1}, *Helicogonium orbiliarum* (parasitic in *O. luteorubella*) {2}, *Hyaloscypha* sp. {1}, *Hydropus alpinus* {1}, *Jahnula aquatica* {1}, *Jobellisia saliciluticola* {1}, *Lasiosphaeria ovina* {1}, *Marasmius* *alliaceus* {1}, *Mollisia cinerea* {1}, *Nectria* sp. {1}, *Orbilia leucostigma* {1}, *O. rubrovacuolata* {1}, *O. sarraziniana* {1}, *Pseudaegerita* sp. {1}. **Desiccation tolerance**: a few ascospores survived for 12 days. **Altitude**: 55–525 m (temperate Europe), 40–100 m (eastern North America), 130 m (northern Japan), 1420 m (southern China). **Geology**: Carboniferous greywacke & shale, Buntsandstein, Keuper (gypsum, marl, sandstone), Cretaceous clay & sand, Plio- & Pleistocene boulder till, loess; granite, granodiorite, syenite, basalt, mica schist, gneiss. **Phenology**: (V–)VI–XI (teleomorph).

Phenology of *O. luteorubella* (teleomorph/anamorph)

Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0/0	0/1	0/0	0/0	1/0	2/0	10/0	8/1	3/0	3/0	1/2	0/0

Taxonomic remarks. *Orbilia luteorubella* is characterized by light or bright yellowish-orange apothecia (Pl. 535: 1–4), spores of a predominantly fusoid to fusiform shape with both ends tapered, and by the lower spores being rather consistently inversely oriented within the asci while most of the upper spores point with their SBs upwards. However, in the here presented concept the species is mainly characterized by a helicoon-like anamorph, a character that was not available in most of the records.

O. sarraziniana differs mainly in spore shape and orientation, whereas *O. rosea* is microscopically nearly indistinguishable from *O. luteorubella* by teleomorph features. Without conidia we were, therefore, unable in many cases to identify with certainty the collections examined. However, we observed some correlation with apothecial colour in the fresh state (compare Pl. 531 with Pl. 535): in strains which were identified as *O. rosea* by conidial and/or molecular data the apothecia were watery-hyaline (Webster & Descals 1979) or very pale to light rose-lilaceous (H.B. 6756a, 9691b, 10018; Pl. 531: 3a–b, 6b), whereas strains with helicoon-like conidia showed bright yellow-ochre(-orange) (D.H. Pfister pers. comm., D.H.P. 79), bright orange-brownish (X.Z. Jiang pers. comm., Pl. 535: 4a), or light to bright yellowish-orange to rose-orange apothecia (Pl. 535: 1b–e & 2a, see also IVV: H.B. 9424a, 9705).

The yellowish-orange pigment in fresh samples of *O. luteorubella* is due to the presence of carotenoids in small LBs in the lower part of the paraphyses and in the subhymenial layer (not clearly seen in the medullary and ectal excipular cells). In larger, more aged, though still fully viable apothecia these carotenoid pigments may get more abundant.

Most literature reports under the name *O. luteorubella* actually refer to yellowish-reddish apothecia, but they probably include also populations of *O. sarraziniana* with similar pigments. Rehm (1891: 455) drew attention to the variable colour of *O. luteorubella* by possibly inlcuding also pale-coloured *O. sarraziniana* and *O. rosea* in his concept of *O. luteorubella*, besides taxa of *Hyalorbilia* and *Orbilia* section *Hemiorbilia* (see under Misapplication).

Macroscopic variation. Mature apothecia of *O. luteorubella* usually range between 0.5 and 1 mm diam., but may sometimes attain a diameter of up to 2(–2.5) mm or sometimes only 0.2–0.5 mm. Depending on the presence and height of the stipe, a maximum total thickness of up to 0.45(–0.63) mm may occur. In the type of *O. luteorubella* the apothecia are of the smaller size (rehydrated 0.3–0.95 mm diam., 0.2 mm thick; Nylander 1869: 0.5–1.2 mm). Very small and thin apothecia were noted in the type of *O. parvula* (0.15–0.45 mm diam., 0.12 mm thick). The colour of fresh adult apothecia varies somewhat in different shades of yellowish-orange, with or without some shade of rose. Young apothecia are usually paler coloured. For instance, at the site in Tübingen the young apothecia were pale pinkish-orange, while the larger ones were more intensely (rose-)orange.

Microscopic variation. Ascospore size and shape varied somewhat in the studied specimens. At the site in Tübingen spore size ranged between *6–8.5 and 9–11 µm in length and between *1.4–1.6 and 1.5–1.8(–2) µm in width, though sometimes the whole range was found within a population. Variation in the spore base between slightly and strongly attenuated regularly occurred within an apothecium. Spore orientation was rather consistent in the included specimens. For instance, in the type of *O. luteorubella* virtually all asci showed the typical orientation (Pl. 534: 1b), and this was also the case at the sites in Tübingen, Hirschau, and Würzburg.

The North-American collection from which Pfister (1997, D.H.P. 79) obtained *Helicoon sessile* was studied by the first author (H.B. 5168a, not illustrated) when it still contained some living elements a week after collecting. The noted features fit well the present concept of *O. luteorubella*, particularly the bright yellow-ochre(-orange) apothecial colour but also spore shape and size (*6.5–10 × 1.4 µm), with filiform SBs of 2.5–4 × 0.4–0.5 µm in the acute end, the lower 3–5 spores being inverted within the asci.

Globose SCBs were observed in three specimens from which a *Helicoon* was obtained (Pls 534: 2; 535: 2b, 4c), and in one of them (Pl. 535: 2b) also VBs were present in the paraphyses. SCBs and VBs were sometimes also present in other samples, but also absent (a similar variation was observed in *O. rosea* and *O. sarraziniana*, especially concerning VBs). The granular exudate varied among the collections, being abundant in the type of *O. parvula* and often also in samples from Tübingen, but sparse in the type of *O. luteorubella*. Yet, such variation was also noted in *O. rosea* and *O. sarraziniana*.

Type studies of teleomorph. The apothecia of *O. luteorubella* were described by Nylander (1869) as ‘pale yellow-reddish or yellow-brownish’ (the epithet *luteorubella* means yellow-reddish). Although the connection to an anamorph is unknown in the type collection, we suspect helicoon-like conidia here because of the observed correlation with apothecial colour. Ascus size and spore orientation in the type (Pl. 534: 1) clearly exclude *O. sarraziniana*, but not *O. rosea*. It would be desirable to isolate this anamorph also in southern Finland, or to collect apothecia there and take a culture or ITS sequence.

Two authentic specimens of ***O. luteorubella*** were received from H. One bears a red label ‘holotype’ given by a curator, and later received the number H 6003831. It contains over 50 apothecia in very good shape, whereas the other is labelled ‘isotype’ (H 6003832) and contains only five apothecia. In both the substrate could be identified as *Alnus* (the protologue says ‘*Populus*?’), and the branch fragment in the ‘isotype’ might well have been broken from that in the ‘holotype’. Both packets bear inside very similar original sketches of paraphyses, asci, and spores with measurements, together with the name *Peziza luteorubella* Nyl., drawn and written by Nylander (T. Ahti pers. comm.), with the difference that the spore size in the ‘holotype’ reads 7–11 × 1.5–2 µm, that in the ‘isotype’ 7–11 × 1–1.5 µm. Nylander obviously examined the whole collection, although only the latter spore measurement was included in the protologue. The holotype carries the name ‘*Peziza cinerea* v. *rubella*’, given by the collector P.A. Karsten, a student of Nylander, before Nylander described it as a new species.

Further data of *O. luteorubella* mentioned in the protologue but not on the sketches concern asci almost 40 µm long, 4 µm wide, and a width of the paraphysis apices of ~2 µm. The apothecia were described as pale yellow-reddish or yellow-brownish, subgelatinous, flat, 0.5–1.2 mm diam. The present reexamination (Pl. 534: 1) is based on the 'holotype', while the apothecia in the 'isotype' were not examined. The asci turned out to be distinctly longer than indicated in the protologue, which is certainly due to Nylander's omission of their long stipes, and the width of the paraphysis apices distinctly wider [2.3–3.4(–3.8) µm].

In ascus and spore size this specimen is at the upper end of the range of the present concept of *O. luteorubella*. We here adopt the epithet *luteorubella* for the taxon associated with a helicoon-like anamorph, mainly because of the apothecial colour given in the protologue. In case that apothecial colour will turn out to be unreliable in this species complex, Karsten's collection might instead be conspecific with *O. rosea*.

According to S. Stenroos (pers. comm.), the holotype specimen remained in Karsten's herbarium, while the isotype was split by Nylander from Karsten's collection for his own herbarium. When writing the protologue, Nylander obviously took the ascospore data only from his 'isotype' specimen. When these specimens came to the herbarium of Helsinki, they were designated as holo- and isotype, perhaps mainly because of their size: the rather small 'isotype' is clearly a fragment taken from the 'holotype', which represents the main specimen. Because it was unusual at Nylander's time to specify a holotype, and a published lectotypification appears to have never been made, we here designate H 6003831 (labelled 'holotype') as **lectotype** of *O. luteorubella*. A German specimen (Tübingen-Pfrondorf, on *Fagus*, IVV: H.B. 9705), from which a sequence was gained, is designated here as **epitype** of *O. luteorubella*.

The present revision of the lectotype of ***O. parvula*** (Pl. 534: 3) confirms Svrček's (1954: 18) suggestion of a probable identity with *O. luteorubella*. Svrček hesitated because of apically encrusted paraphyses and, therefore, also considered a possible identity with *O. cardui*. The abundant material appears to fit quite well the holotype of *O. luteorubella*. The rather long asci often have a very long stipe, the paraphyses are capitate and bear granules. The fusoid ascospores are not strikingly heteropolar and have their widest part a bit closer to that spore end which is slightly more obtuse than the other end. The spores are much shorter compared to the holotype and would better fit *O. sarraziniana*, but the long asci contradict this. The spore body could not be seen with certainty, even when viewed in KOH+CB_L, therefore, it was impossible to clearly recognize spore orientation in *O. parvula*. In many of the asci the lower spores were found to point with their more obtuse end downwards, but sometimes it was the more attenuated end which pointed downwards, and frequently the orientation was unclear due to quite homopolar spores; whether it was generally the more acute end which contained the SB remained unclear.

Velenovský emphasized the amber colour of the rather small apothecia (0.3–0.5 mm diam.) as characteristic to distinguish his taxon 'with certainty' from *O. luteorubella*, for which he also gave an amber apothecial colour, though with a rose tint. He misleadingly described the spores as narrowly acicular, 4–5 µm long. Svrček corrected to 7–8.5 × 1.2–1.5 µm but gave the asci with 30 × 3–4 µm much too short.

During reexamination of the holotype, some eggs of a *Daphnia* were encountered on the very rotten and eroded wood surface. This indicates that the branch was lying at the edge of stagnant water. The long asci and fusoid spores exclude *O. sarraziniana*. The abundant holotype material is in good shape and would require a molecular investigation to better understand its identity.

No material of ***O. salicina*** (Svrček 1954) exists which was said to grow on wet wood of *Salix* in a pond at Solopisky (SW of Praha). In the lack of a voucher specimen, the illustration added to the protologue must serve as holotype (Arts 8.1, 40.4 ICN). The original drawing shows narrowly fusoid ('acicular') spores which, together with the habitat (standing water), suggest synonymy with *O. luteorubella* as was also stated by Svrček. Whether the ochraceous-brown colour of the rather large apothecia (0.5–1 mm diam.) in the protologue arose from senescence is not clear, but it seems to exclude *O. rosea*. Velenovský gave the spores as 6–10 × 1/4 µm (width appearing only on manuscript plate; from the length/width ratio of the drawn spores it lies between 0.5 and 1.2 µm) and the paraphyses strongly capitate.

Misapplication. Reports of *O. luteorubella* in the literature possibly often match the species concept here presented, though some might include the similar *O. sarraziniana*. A few reports refer to desiccation-tolerant species of other sections of *Orbilia* with similar fusoid spores. For example, Rehm's (1891: 455) description comprises collections on 'rotten wood and corticated, dead and dry branches', which suggests a species of series *Hesperideae* (section *Hemiorbilia*): *O. aprilis* might have been mistaken for *O. luteorubella* by Rehm because of a similar spore shape, although species of that section differ from section *Helicoon* in hemispherical, thick-walled ascus apices, a thick exudate, and desiccation-tolerant apothecia. Also P.L. & H.M. Crouan (in sched.) figured and preserved under the name *Peziza luteorubella* a collection with a thick-walled, hemispherical ascus apex (see under *O. vinosa*, p. 607).

On the other hand, early reports under the epithet *vinosa* often appear to represent *O. rosea*, *O. luteorubella*, or *O. sarraziniana*. For instance, Feltgen (1899, 1901) identified collections as *O. vinosa*, *O. rubella*, and *O. luteorubella*, which are affiliated here as *O.* cf. *luteorubella*. In a further, apparently unpublished collection which he named *O. coccinella* (with spores 2 × 0.75–1 µm) also only *O.* cf. *luteorubella* was found. Jaap (1922: 15) reported *O. vinosa* from 'rotten twigs of *Salix*, *Populus* and *Alnus* at the water', and reexamination of the cited specimen (FSE 765, on *Salix*) revealed *O.* cf. *luteorubella*. More difficult to understand is why García Alonso (2003) identified the hairy desiccation-tolerant *O. pilifera* (section *Aurantiorubrae*), being undescribed at that time, as *O. luteorubella*. Even confusion with the genus *Hyalorbilia* ocurred (see under *H. inflatula*, p. 342, 344), and due to a similar colour also with *O. xanthostigma* and pigmented populations of *O. auricolor*. A report on *Adenostyles* by Gremmen (1966: 399) obviously refers to a member of *Helotiales*, according to the reported shape of ascus apex and base.

Not included collections. Some European samples are not included mainly because of insufficient teleomorph data: either the fresh apothecial colour was not stated, or it did not display yellowish-orange colours. In some cases the spore orientation could not be evaluated from the dead material, and *O. sarraziniana* was then excluded by a fusoid spore shape and a spore length exceeding 10 µm in some spores. A record from New Zealand (J.A. Cooper, IVV: 6.III.2010) is not included because it was documented in the dead state and has rather wide, fusiform spores (†6.8–8.7 × 1.6–2 µm).

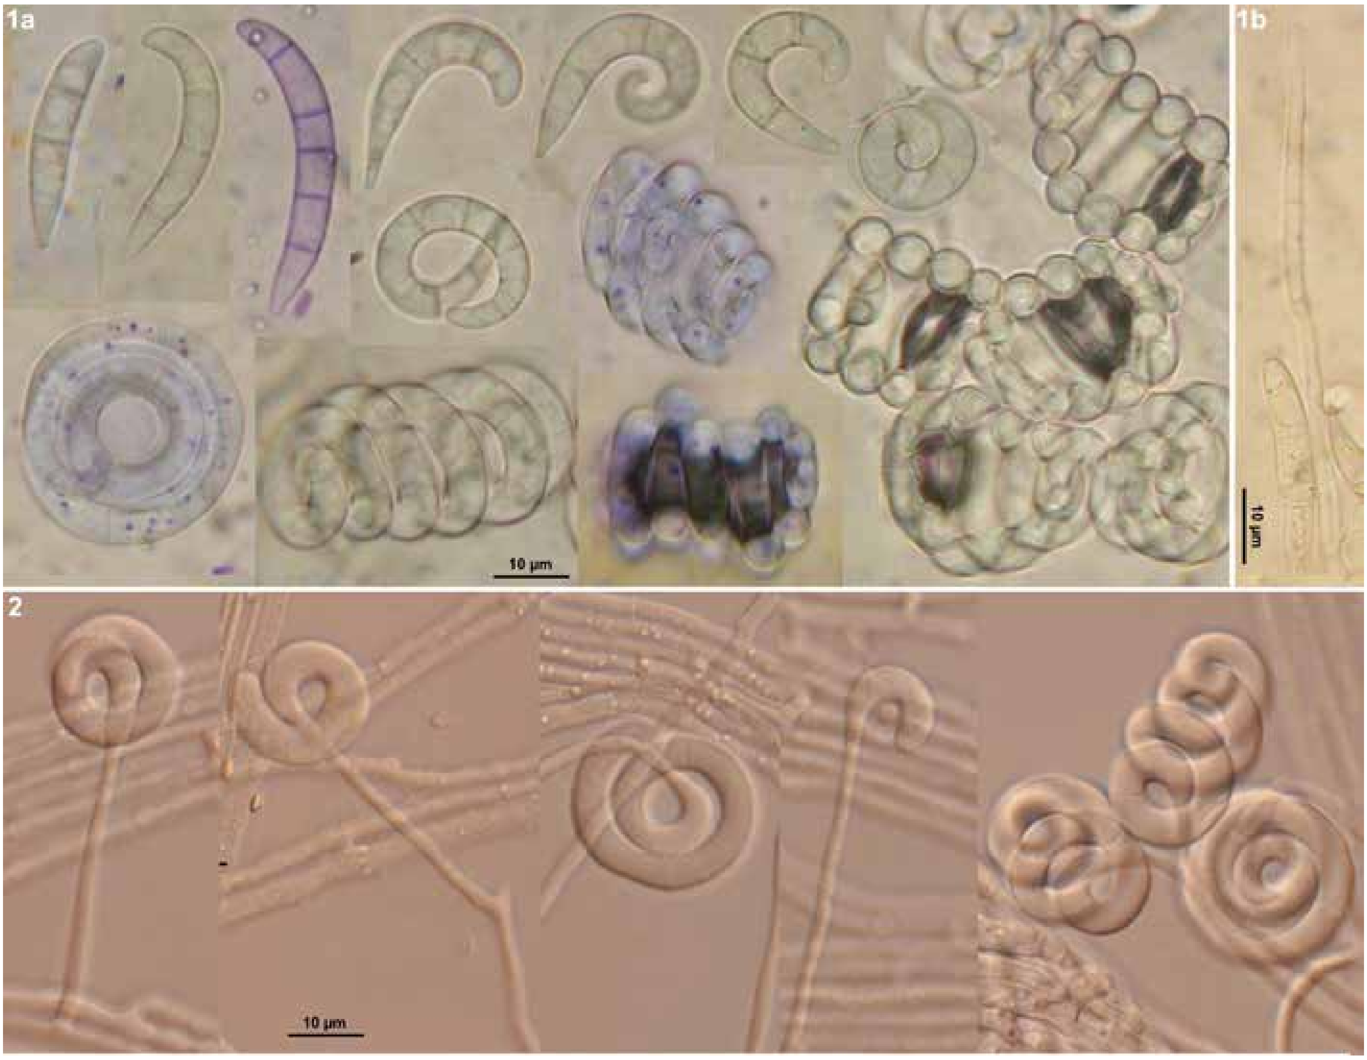

Plate 536. **1–2**: *Helicoon sessile*. – Conidiophores and conidia (from culture). – Living state (**1a–b**), dead state (**2**); **2**: phot. X.Z. Jiang (DIC), — **1a–b**. H.B. 9424a: Germany, Tübingen, on *Fagus*; **2**. HMAS 267649: China, Guizhou, on unidentified tree.

Anamorph. Morgan (1892) described *Helicoon sessile* with 40–48 × 25 µm large conidial bodies with 6–8 coils (thread 5–6 µm wide, septa not illustrated, see Pl. 15). Saccardo's (1906) unillustrated description of *H. fairmanii* with 45 × 28 µm large bodies with 6–8 coils of sparingly septate, 5 µm wide threads appears to differ merely in a pale rose colour of the conidia. Therefore, Linder (1929: 325) placed *H. fairmanii* in synonymy, which he found to differ in no respect. Together with a sample from Massachusetts he redescribed *H. sessile* by conidial bodies of 37–56 × 20–30 µm, with 4.5–6.5 µm wide threads and 5–16 coils. Goos et al. (1986) copied Linder's data but included material from Great Britain by changing the size to 30–59 × 20–30 µm. Voglmayr (2000, fig. 23, from Austria, A327) presented a drawing of *H. sessile* in which a size of 37–42 × 25–27 µm can be evaluated, with 7–8 coils of ~5–7 µm wide threads with only a few septa indicated on the drawing. With this concur data in Voglmayr (1994) which include also smaller conidia with 6 coils and narrower threads (see above).

Conidial states referable to *Helicoon sessile* were obtained in three ascospore isolates. In a collection from Massachusetts tentatively referred to *O. luteorubella*, Pfister (1997) obtained conidial bodies which have a size of 36–42 × 18.5–20 µm (evaluated from his drawing); the multiseptate threads show 12 coils and the individual cells measure 5–9 × 2.5–3.7 µm. Our German collection (Pl. 535: 1–3) formed conidial bodies of predominantly *30–36 × 20–25 µm; the threads show 6–8 coils and individual cells of *10–15 × 4–5 µm. Compared to the above strains, conidial bodies are thus distinctly shorter in the German isolate and narrower in the American isolate. A Chinese isolate by X.Z. Jiang (Pl. 535: 4) produced similar conidia in pure culture, according to photographs kindly provided by X.Z. Jiang (pers. comm., Pl. 536: 1–2), but they show only about 1–4 coils of the †4–5 µm wide threads (septa not shown), resulting in a body size of only †10–20 × 18–22 µm. We presume that these are young stages, because they are still attached to the conidiophore. However, molecular differences to European strains might support that two different species are involved.

Linder (1929) also described *H. farinosum* Linder based on a collection from Massachusetts (Cambridge, Fresh Pond, on decaying wood), which would fit quite well our isolate from Tübingen. However, this species was found to be the anamorph of *Ascotaiwania hughesii* Fallah, J.L. Crane & Shearer in the *Sordariomycetes* (Fallah et al. 1999). Also *Helicodendron tubulosum* (Riess) Linder can very easily be confused with *H. sessile* because of a similar conidial morphology. It occurs on branches and leaves in mountain streams and is the anamorph of '*Lambertella*' *tubulosa* Abdullah & Webster (1981) in the *Helotiales*, a species that belongs to the vicinity of *Cudoniella* or *Phaeohelotium* rather than *Lambertella*.

Voglmayr (1994, 2000) drew attention to the sense of rotation of the barrel-shaped conidia, which was not stressed for *H. sessile* in the literature before, and which he found to be consistent within a strain. Morgan's protologue figure of *H. sessile* shows a right-handed twist whereas Voglmayr (1994) found a left-handed twist in the type material in FH and later confirmed this also for a duplicate in NY (H. Voglmayr pers. comm.). He found conidia with left-handed twist also in the holotype of *H. fairmanii* in PAD and confirmed Linder's synonymisation with *H. sessile*. Also in various of his recent records referred to this species Voglmayr (1994) observed a left-handed twist, so he assumed that the protologue figure was mirror-inverted during reproduction.

According to Voglmayr (2000), strains referable to *H. sessile* exist which deviate in a right-handed twist, but the possibility cannot be excluded that this mirror-symmetric deviation belongs to a different species. From one of his left-handed strains he gained a sequence, while no sequence is available from a right-handed strain (Voglmayr pers. comm., see also p. 236). On Pfister's drawing the three conidia figured in side view are left-handed, whereas those in top view are right-handed, supposed that the chirality was not changed during reproduction. On Jiang's photographs (Pl. 536: 2) the sense of rotation is difficult to assess, but two conidia on the right appear to be left-handed. His culture on PDA formed colonies with distinct concentric zones (IVV: 25.VII.2008) very similar as observed by us in *O. sarraziniana* (Fig. 102: d).

Voglmayr (1994) observed also small falcate conidia with 2–4 septae which also we have twice obtained in our cultures, and he assumed that they are air-transported unlike the barrel-shaped ones. He stressed the fact that *H. sessile* has very short or almost no conidiophores. This is in strong contrast to the Asian isolate with rather long and thin conidiophores (Pl. 536: 2), but also in our German isolate we observed such conidiophores which here possibly produce only the small falcate conidia (Pl. 536: 1b) whereas the barrel-shaped ones are formed on very reduced conidiophores.

Phylogeny. In Pfister's phylogenetic analysis of ITS sequences, a non-sporulating ascospore isolate identified as *O. luteorubella* (D.H.P. 125, U72604) and a culture of *Helicoon sessile* without teleomorph (D.H.P. 129, U72605) clustered together (with a distance of 3 nt), which was also the case in Hagedorn & Scholler's (1999) neighbour joining analysis. However, Hagedorn & Scholler found that these sequences are very distant from the remaining members of *Orbiliaceae*. As a consequence, another of Pfister's ascospore isolate (D.H.P. 79), for which no sequence was available but which formed a *Helicoon sessile* anamorph, was thought by us to be also contaminated. *H. sessile* appeared to be hypocrealean rather than orbiliaceous, since a BLAST search for Pfister's two sequences in GenBank revealed only hypocrealean species (1–2 nt deviation in the complete ITS). The first 100 hits all deviated only by 1(–2) nt when testing D.H.P. 125 or D.H.P. 129, therefore, these BLAST searches do not give hits with 3 nt deviation when restricted to 100 results. Most of these hits were identified as *Sarocladium kiliense* (Grütz) Summerb. but also *S. strictum* (W. Gams) Summerb. (both were formerly placed in *Acremonium*). In a phylogenetic analysis on some members of *Hypocreales* (Collopy et al. 2002), Pfister's sequences clustered with *Acremonium strictum* W. Gams.

In contrast to this, the mentioned Austrian isolate of *Helicoon sessile* (A327, KY659207) identified and sequenced by H. Voglmayr (pers. comm.) as well as a sequence of the mentioned Chinese ascospore isolate with a helicoon-like anamorph (X.Z. Jiang pers. comm., gz-08, FJ719770) turned out to be orbiliaceous. From this we now conclude that the two cultures sequenced by Pfister contained, besides the correct helicoon-like anamorph, a contaminant of a member of *Hypocreales*.

The sequences of Voglmayr and Jiang both comprise SSU, ITS, and LSU. Voglmayr's sequence possesses the S1506 intron (1326 nt) which is absent in Jiang's sequence. The two sequences concur perfectly in the overlapping parts of SSU (119 nt, Phyl. S17). In the ITS the difference is 15 nt (3 %) and in the LSU D1–D3 4 nt (0.4 %). LSU sequences of a Japanese strain of *H. sessile* by K. Yamaguchi (NBRC106775, D1–D2) and one submitted by Li et al. to GenBank in 2003 (AY261122, D1–D3, misnamed as *O. inflatula*) are identical with Jiang's strain in the overlapping part, whereas Voglmayr's strain differs here by 1 nt (see Phyl. 18).

A further sequence comprising S1506 intron (701 nt) and ITS was taken from apothecia (H.B. 9705) later re-collected at the site in Tübingen from where our ascospore isolate with *H. sessile* was gained. This clustered quite close to the Austrian sequence, deviating in the ITS by only 5 nt (1 %) and 1 gap (Phyl. 17). The intron concurs almost perfectly in the two European strains (1 nt difference), except for a large central part which is absent in H.B. 9705.

The obvious difference between European and Chinese strains might indicate that two different species are involved, supporting the above-mentioned difference in conidial morphology. Yet, since the molecular distance between *O. luteorubella*, *O. rosea*, and *O. sarraziniana* lies in the range of 13–17 % (see under *O. rosea*, p. 968), a 3 % distance appears to be an acceptable infraspecific variation.

The name *O. luteorubella* is adopted here with hesitation to the species with a helicoon-like anamorph. It is hoped that future extraction of DNA from the holotype of *O. luteorubella* will settle its identity.

Ecology. *O. luteorubella* was found on hygric to semiaquatic branches and logs of different angiosperms, rarely gymnosperms, mainly from decorticated, rotten and darkened wood. The species occurs rather strictly confined to water (typically ponds and lakes, also swamps, ditches, and rivulets) by which the substrate is periodically flooded. Collections mainly derive from planar and colline, cold- or sometimes warm-temperate humid regions of Europe, comprising atlantic and subcontinental areas. In contrast, the holotype of *O. luteorubella* was from thermoboreal northern Europe, and a record from near Oslo is hemiboreal at the border to thermoboreal. Frequent occurrence of *O. luteorubella* in England is suggested from various collections by P. Thompson (pers. comm.) made in the West and East Midlands; documentation has not been available in most of them, but a ± orange apothecial colour and occurrence in bogs and at ponds would exclude *O. rosea*. Two eastern Asian samples are from cold-temperate humid northernmost Japan and subtropical humid (winter-dry) southern China, and a few records from cold-temperate to ?warm-continental humid eastern North America.

The geology comprises both basic and acidic soil. The area of the type locality of *O. luteorubella*, the town Alavus in Finland, shows a lot of lakes but also streams. The geological situation around Alavus is mainly granodiorite, which produces an acidic soil. To the present knowledge, both *O. luteorubella* and *O. rosea* occur on acidic bedrock. The vegetation includes alder and willow but also other types of deciduous forests.

Various samples from Navarra (Spain) were reported by R. Galán (in Pando & Hernández 2001: 124). Seaver (1951: 159) reported *O. luteorubella* from northeastern to southeastern USA and the Caribbean region, Otani (1990) from Japan, Raitviir (1991: 360) from northeastern Asia, Korf (1992) from Macaronesia, and Thind & Sharma (1980) from northwestern Himalaya. Yet, all these records are unverified to some extent. Karsten (1869: 175), Massee (1895: 149), and Massee & Crossland (1905: 301) found the species to occur also on decaying bracket fungi (*Phellinus igniarius*, *Polyporus squamosus*), but also these reports need confirmation.

Our collections from Tübingen were made in a small forest pond which lies over Knollenmergel in a *Fagus* forest and sometimes completely dries out (Pl. 535: 1a). Here the species was recorded in abundance during July–Oct. in 2005 and 2010–2012 on *Fagus* logs. However, *O. sarraziniana* was also abundantly collected on these logs during July–Sept., though in different years (2000, 2003, 2006).

The type substrate of *Helicoon sessile* was stated by Morgan (1892) to be wood of *Ulmus*. According to Linder (1929), the type was collected by J.B. Ellis, presumably in New Jersey. *H. fairmanii* was collected by C.E. Fairman in New York. Linder further examined a personal collection from Massachusetts on wood of *Acer*. Goos et al. (1986) gave a survey on the occurrence of *H. sessile* ‘on decaying leaves, twigs and wood of *Acer*, *Quercus*, *Fagus*, and coniferous wood’, recorded from Great Britain and USA (Massachusetts, Maryland, New Jersey, Iowa). Voglmayr (2000) reported the species from strains from Austria (Sauwald), but isolated it also from near Oslo (pers. comm.). The database of the British Mycological Society (FRDBI) lists three records of *H. sessile* (Scotland, Wales, Devon).

According to Voglmayr (pers. comm.), typical left-handed *Helicoon sessile* is mostly encountered in shallow, temporarily flooded ponds or marshes with *Alnus* and *Salix*, also ditches at the margin of peat bogs, though these included also conidia with right-handed threads. A record by Voglmayr (pers. comm.) from Norway (near Oslo) was on bark of *Betula* in a peaty boreal conifer forest. All his conidial strains from Europe and also USA derive from submerged leaves or mostly deciduous wood at usually medium oligotrophic water bodies, always on acidic bedrock, at altitudes up to 700–800 m.

The barrel-shaped conidia of *H. sessile* function as air traps (Pl. 536: 1a lower right). They are formed above water, and when the water level raises they float on the water surface by means of internal air bubbles (Michaelides & Kendrick 1982, Pfister 1997, Pl. 536: 1a). Fungi with air-trapping conidia are mainly encountered at stagnant water bodies without noticeable water flow (so-called aero-aquatic fungi), while the scolecosporous conidia of *O. rosea* are adapted to running water. Such elongated filiform conidia are classified as aquatic or Ingoldian (Michaelides & Kendrick l.c.), though also *H. sessile* was found at running water (Pfister l.c.). The ability to float appears to support propagation, for instance by birds.

Map 89. Known distribution of *O. luteorubella* in Europe (yellow = not included collections).

Specimens included. **GREAT BRITAIN**: **West Midlands**, **Shropshire**, 4.5 km NNE of Telford, S of Muxton, Muxton Marsh, 85 m, branch of *Salix*, on wood, 16.VII.2018, P. Thompson (doc. vid.). – **Staffordshire**, 15 km NE of Wolverhampton, 1 km SSW of Chasetown, Chasewater Country Park, 150 m, branch of *Salix*, on wood, 12.VII.2013, P. Thompson (non vid.). – **Birmingham**, 8 km NNE of Birmingham, Longmoor Pool, 130 m, branch of *Betula pendula*, on wood, 18.VIII.2016, P. Thompson (non vid.). – 17 km NNW of Birmingham, Sneyd Reservoir, 155 m, branch of *Salix caprea*, on wood, 17.VIII.2015, P. Thompson (non vid.). – **Herefordshire**, 10.5 km SW of Ludlow, 8.5 km NNW of Leominster, NE of Croft Castle Estate, Fishpool Valley, 168 m, branch of *Fraxinus excelsior*, on wood, 14.VIII.2016, P. Thompson (non vid.). – **East Midlands**, **Leicestershire**, 6 km SSE of Leicester, 1 km SSW of Oadby, Lucas’ Marsh, 92 m, branch of *S. caprea*, on wood, 17.VII.2013, P. Orbilia sarraziniana Boud., in Roumeguère, Rev. Mycol. (Toulouse) 7: 221 (1885) — Pls 537–539, Map 90

(?)= *Orbilia luteorubella* f. *microspora* (Sacc.) Sacc., Syll. Fung. 8: 624 (1889)
≡ *Calloria luteorubella* f. *microspora* Sacc., Michelia 2: 614 (1882)

Etymology: *sarraziniana*: from the collector, F. Sarrazin; *microspora*: referring to the smaller spores compared to *O. luteorubella*.

Typification: France, Oise, Senlis, log of (?)*Fraxinus excelsior*, 21.VII.1885, F. Sarrazin (PC, herb. Sarrazin, holotype of ***Orbilia sarraziniana***); Germany, Baden-Württemberg, Tübingen, Pfrondorf, branch of *Fagus sylvatica*, 29.X.2002, E. Weber (ex H.B. 7235, M-0291764, epitype, designated here, MBT385123, ex-epitype culture: CBS 116219; sq.: KM199780). — France, Seine-et-Marne, Fontainebleau, on rotten wood, undated, J. Therry (herb. Therry 6025, Fungi Gall. no. 1897, holotype of ***O. luteorubella* f. *microspora***).

Misapplied names: Benny et al. (1978), as *O. luteorubella*; Feltgen (1899: 54), as *O. rubella*, (1901: 36, 1903: 42), as *O. luteorubella*; Fuckel (1871: 57), as *O. vinosa*;

Misinterpretation of *O. sarraziniana*: Breitenbach & Kränzlin (1981, pl. 252), (?)= *O. luteorubella*; Liu (2006: 104 p.p., HMAS 96784), = *Orbilia* sp.

Description: — **TELEOMORPH**: **Apothecia** fresh 0.2–1.3(–2.5) mm diam., 0.12–0.4(–0.5) mm high (receptacle 0.1–0.2 mm), pale to light rosaceous-lilaceous {~36} or pale to bright (amber-)orange {~24}, more rarely yellowish-ochraceous {5} or whitish {8}, translucent, round, sometimes strongly undulating when large, scattered to gregarious in large numbers, sometimes in dense clusters; disc slightly concave to flat, finally slightly to distinctly convex, margin indistinct, thin, not or scarcely protruding, smooth; sessile or often with a distinct, broad, ± obconical stipe 0.02–0.3 × 0.2–0.8(–1.3) mm, superficial; dry pale cream-ochraceous to bright amber-reddish-brown or ochre-orange(-rose). **Asci** *(30–)35–45(–50)((–57)) × (3.5–)4–4.5(–5)((–5.3)) µm {16} → *4.7–5.3 µm wide, †(28–)34–45(–50)((–60)) × (3–)3.3–4(–4.5)((–5)) µm {32}, 8-spored, spores 4-seriate, (1–)3–5(–6) of the upper spores inverted {94} (not or slightly mixed, sometimes a few asci with 1(–2) upper spores not inverted, lower spores regularly not inverted but exceptionally in very few asci all lower spores inverted), pars sporifera *(15–)17–22 → 12–16 µm long; **apex** (†) strongly truncate (not or slightly indented, laterally sometimes inflated); **base** with short to very long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *(5.5–)6–8.5(–9)((–10)) × (1.2–)1.3–1.6(–1.7)((–2)) µm {43}, †(5.5–)6–8(–9)((–9.3)) × (1.1–)1.3–1.6(–1.7) µm {23}, (fusiform-)obclavate (to fusiform), widest part often below the middle, rarely above, apex acute (to acuminate), base slightly to medium attenuated (obtuse to subacute), rarely acute, straight, sometimes slightly inequilateral or curved; **SBs** *3–5(–5.5) × (0.2–)0.3–0.5(–0.7) µm {14}, filiform to subulate, mostly not inflated at base, straight to ± flexuous, in aged spores 2–3.5 × 0.6–1.1 µm, tear-shaped to ampulliform. **Paraphyses** apically (uninflated to) slightly to strongly (rarely very strongly) (clavate-)capitate, sometimes asymmetrical, terminal cells *16–24 × (2.3–)3–5.3 µm {6}, †14–21 × 1.7–2.8 µm {1}, lower cells *4–8 × (1.4–)1.8–2.7(–3) µm {4}, †3.5–7 × 1.7–2 µm {1}, near base *(2–)3–6 × 2.7–4 µm; rarely branched at upper septum. **Medullary excipulum** 30–150(–200) µm thick, of medium dense textura globulosa(-intricata), with many sometimes strongly inflated cells in centre, medium sharply delimited from ectal excipulum mainly towards margin by an indistinct 10–15 µm thick t. porrecta. **Ectal excipulum** of thin-walled, vertically oriented t. globulosa-angularis(-prismatica) from base to margin, (25–)60–100(–150) µm thick near base, cells *11–30(–40) × 9–25(–35) µm {4}, †(10–)13–25(–30) × (6–)10–15(–20) µm {1}; 15–60 µm thick at flanks, 10–20 µm near margin, oriented at a 70–90° angle to the surface, marginal cortical cells *6–18 × 4–8.5(–10.5) µm {5}, †8.5–12 × (3–)4–6 µm {1}; **glassy processes** absent. **Anchoring hyphae** sparse to abundant, */†2–3.5(–5) µm wide, walls (0.1–)0.2(–0.3) µm thick {5}, forming a dense t. intricata up to 50–100 µm thick. **SCBs** globose, in paraphyses 1.4–2.2 µm diam., 1(–2) per cell; in ectal excipulum 1.5–2.5 µm {16}. **VBs** in paraphyses often abundant, large, low- to medium refractive {16}, hyaline, not turning yellow in dead state, but also often absent {7}, inflated cells of medullary and basal ectal excipulum sometimes with small, trembling, pale golden-yellow aggregates {2}. **LBs** in lower part of paraphyses and in subhymenium hyaline or sometimes pale to light golden-orange (carotenoids), minute. **Exudate** over paraphyses 0.2–0.5 µm thick, granular, ± loosely attached, hyaline; over margin and flanks thin, granular. — **ANAMORPH**: vermispora- to helicoon-like (from ascospore isolate {3} or from non-sterile culture {1}). **Conidiophores** 15–150 × 1.6–2.5 µm {2}, septate, erect, solitary, apparently unbranched, conidiogenesis terminal. **Conidia** *19–50 × 4.8–7 µm in situ {3, Germany}, †21.5–40.5 × 3.2–4.2 µm in situ {1, China}, actual length ~30–50 µm {4}, strongly curved, helicoid, C-shaped in profile view, (1–)3-septate.

Habitat: on moist or mostly wet soil, often semi-immerged, sometimes 5–20 cm above water or soil but occasionally flooded, rarely up to 6 m above low water level, on water-soaked, decorticated or sometimes ± corticated, 4–10 mm up to 2–35 cm thick branches and logs, rarely conifer cones, of *Acer* sp. {2}, *Alnus* sp. {4/1}, *A. glutinosa* {9/2}, *Betula* sp. {3}, *B. pendula* {1}, *Carpinus betulus* {2/1}, ?*Corylus* sp. {1}, *Cupressus* sp. {1} *Fagus* ?*crenata* {1}, *F. sylvatica* {28/2}, *Fraxinus angustifolia* {1}, *F. excelsior* {6/1}, ?*Phyllostachys* sp. {1}, *Picea abies* {2}, *Pinus* sp. {2/1}, *P. uncinata* {1}, *Populus* sp. {2}, *Quercus* sp. {6/1}, *Ribes rubrum* {1}, *Rubus fruticosus* {1}, (?)*Rosaceae* {1}, *Salix* sp. {26/5}, *S. alba* {1}, *S.* (?)*atrocinerea* {1}, *S. caprea* {3}, *S. cinerea* {3/1}, *S. fragilis* {1}, *Sambucus nigra* {1}, *Tilia* sp. {2}, *Ulmus* sp. {4}, indet. angiosperms {14}, indet. gymnosperm {1}, indet. woody plant {3}, on wood {108} or bark {29} (periderm {5} and bast {11}); exceptionally on herbaceous stem of *Epilobium hirsutum* {1}, bone of *Sus scrofa* {1}, or fungicolous on old ?*Peniophora* {1}, *Nectria* sp. {1}, old pyrenomycete {1}; on upper or lateral, also on lower side of branches and logs, rarely on inner surface of bark, exceptionally on cut surface of stump, wood 0.2–1 or sometimes 2–5 mm deep (slightly) medium to strongly decayed, partially eroded, grey-brown or often blackened, inner parts usually ± undecayed, green algae absent or medium to very abundant; rarely on pores of indet. polypore {1}, on soil with organic matter {2}, e. g., among *Funaria hygrometrica*, *Bryum bicolor* & *B. argenteum*. **Associated**: *Acrogenospora sphaerocephala* {2}, *Ascocoryne cylichnium* {1}, *Bactrodesmium pallidum* {1}, *Bisporella*

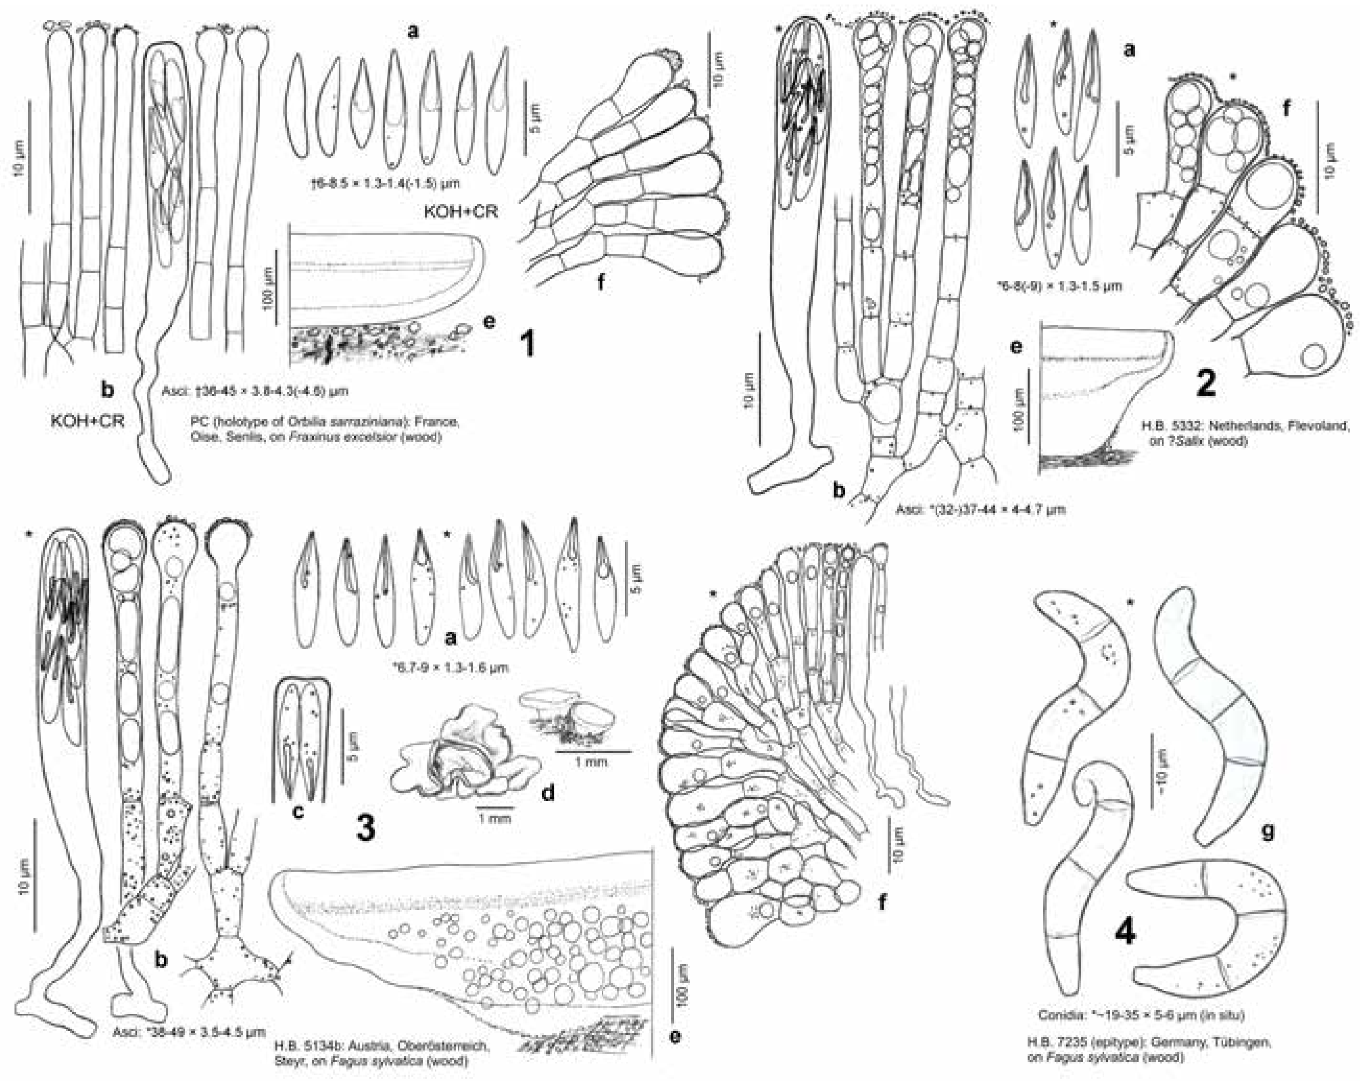

Plate 537. **1–4**: *Orbilia sarraziniana*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. fresh apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum with hymenium at margin and mid flanks; **g**. conidia (from pure culture).

subpallida {1}, *Bulbillomyces* sp. {1}, *Calycina* sp. {1}, *Chalara* sp. {1}, *Coniochaeta velutina* {1}, *Graphium calicioides* {1}, *Helicogonium orbiliarum* (parasitic in *O. sarraziniana*) {3}, *Hydropisphaera peziza* {2}, *Hyalorbilia juliae* {1}, *Hypoxylon howeanum* {1}, *Lachnum brevipilosum* {1}, *L. impudicum* {1}, *Lasiosphaeria hirsuta* {2}, *Miladina lecithina* {4}, *Mollisia albogrisea* {1}, *Nectria* sp. {5}, *Neonectria* ?*coccinea* {1}, *Olla scrupulosa* {1}, *Ombrophila* sp. {1}, *O. violacea* {1/2}, *Orbilia cardui* {1}, *O. crenatomarginata* {1}, *O. eucalypti* {1}, *O. luteorubella* {1}, *O. nemaspora* {1}, *O. rosea* {2}, *O. rubrovacuolata* {1}, *Pachyella babingtonii* {3}, *Peziza granularis* {1}, *Pseudaegerita* sp. {1}, ?*Pseudocosmospora vilior* {1}, *Sclerococcum* sp. {1}, *Stictis* ?*sarothamni* {1}, *Subulicystidium longisporum* {2}, pleurocarpous moss {3}. **Desiccation tolerance**: asci and paraphyses (except for a few excipular cells) do not survive for 5 hours; many spores still viable after up to 10 (H.B. 8483c) or even 21 months (6.VIII.1992), in other cases all spores dead after 4 months. **Altitude**: 0–825 m a.s.l. (central and western Europe), 25–2020 m (southern Europe), 10–970 m (Russia). **Geology**: Ordovician, Devonian & Carboniferous sediments, Permian (Rotliegend, Zechstein dolomite), Buntsandstein, Muschelkalk, Keuper (gypsum, marl, sandstone), Lower Jurassic sandstone & shale, Cretaceous & Tertiary sand, marl-, mud- & limestone, Pleistocene boulder till, silt, sand & gravel; granite, granulite, basalt, mica schist. **Phenology**: (III–)IV–XI(–XII).

Phenology of *O. sarraziniana*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0	0	1	4	9	18	32	29	20	19	6	1

Taxonomic remarks. *Orbilia sarraziniana* can easily be confused with *O. luteorubella* and *O. rosea*, to which it is closely related. It differs from both in spore orientation within the asci: in the majority of asci the upper ~3–5 spores are inversely oriented (with the SBs pointing downwards) while the lower spores are not inverted. It also differs in a tendency to obclavate spores which are tapered only at the apical end, while the widest part of the spores is either ± in the middle or closer to the lower, mostly obtuse end. When Liu (2006: 48) used our unpublished key of *Orbiliomycetes*, he confirmed the criteria of spore shape and orientation in Chinese specimens as follows: 'Ascospores clavate, upper spores inversely oriented in asci, 5.8–8.7 × 1.3–1.7 µm: *O. sarraziniana*; Ascospores fusoid, lower spores inversely oriented in asci, 7.5–10.5 × 1.3–1.8 µm: *O. luteorubella*'.

Some more tropical taxa distinctly deviate from *O. sarraziniana*. Chinese specimens here referred to *O. juruensis* differ in broader, tear-shaped SBs, a feature seen in *O. sarraziniana* only in overmature spores, also in a tendency to a ± yellow exudate. The type collection of *O. juruensis* closely resembles *O. sarraziniana* in spore size and orientation, but differs in distinctly thick-walled excipular cells and more fusiform spores, also in larger apothecia (the original shape of the SBs is unknown). A Chinese collection mentioned under *O.*

fusiformis (Pl. 556: 3) resembles *O. sarraziniana*, but sharply differs in a pseudotripoconidium-like anamorph.

Macroscopic variation. Apothecial colour varies in *O. sarraziniana* between whitish to pale or light rose-lilaceous and pale to bright yellowish-orange-ochraceous. In quite a lot of collections both colour variants occurred, though in separate populations (H.B. 5134: IVV; 5139a; 5141; 6727a; 7957a: Pl. 538: 2b–c, e; 8225: Pl. 538: 3b–d; TAAM 62408; Sheffield 16.V.2011; J.P.P. 13188/13189). The colour contrast between these populations was not always sharp, however, and the microscopical features were the very same, except for the presence of pigmented LBs in the orange populations. In some collections apothecial colour was somewhere between rose and orange. Such colour variants concern apothecia of equal maturity while, within each such population, young apothecia are often paler than mature ones. Yet, we once had the case that orange *O. sarraziniana* (H.B. 9691a) grew intermingled with rose-coloured apothecia that seemed to belong to *O. rosea* (H.B. 9691b, Fig. 14: d–e), with a sharp and constant colour difference and a clear correlation with a deviating spore orientation (but no difference appeared in the ITS-rDNA, see below). Purely orange populations of *O. sarraziniana* have repeatedly been observed in light-exposed habitats such as unshadowed banks of lakes.

Also Le Gal (1938: 137) and Liu (2006: 104) observed variable colours between different populations of *O. sarraziniana*: from vividly orange to pale greyish-orange, yellow, greyish with lilaceous tint, and pink to violet. These findings question the distinction between *O. luteorubella* and *O. sarraziniana* based on apothecial colour as reported in the literature, e.g., by Dennis (1978: 188, pl. XXV B, E; 'pallid, drying yellowish' vs. 'very pale pink and translucent'). On the other hand, we have noted mostly yellowish-orange apothecia in *O. luteorubella* in comparison to consistently pale rose apothecia in *O. rosea*. In all these species the original pigmentation gradually disappears in herbarium material. Dry or rehydrated apothecia of *O. sarraziniana* are whitish or usually cream to yellowish-ochraceous after some years, by completely obscuring differences observed in the fresh state.

Microscopic variation. Spore orientation was highly consistent in a majority of the included collections, with distinct deviations from the typical case noted in only ~1–2% of the asci, while in 5–10% a single spore at the top or base of the pars sporifera was oriented other than typical. In some collections the upper spores showed a very variable orientation, but the lower spores were mostly not inverted. A very variable orientation was observed in a recent collection (IVV: 10.XI.2018), which is assigned here to *O. sarraziniana* because of its predominantly strongly heteropolar and rather short spores, although conidia referable to *Helicoon sessile* grew abundantly in association.

O. sarraziniana shows considerable variation in ascus and spore size, spore shape, and in the strength of apical inflation of paraphyses. Asci varied among the collections from */†30–40 µm up to *40–50(–60) µm in length and from *3.5–4 µm up to *4.5–5 µm in width, ascospores from */†6–7 up to 7.5–9 µm in length and from */†1.3–1.4 up to 1.5–1.7 µm in width (surprisingly hardly any difference occurred between the living and dead state). In a collection from Caucasus (TAAM 49849a) the asci were exceptionally long (†45–60 µm), but also two specimens from Germany had an extraordinary ascus length (Tübingen, 6.VI.1993, †35–55 µm) and Austria (Leoben, H.B. 7412, *45–57 µm). A western European collection (Le Mans, 10.IV.2008) showed exceptionally wide spores of *6–8 × 1.7–1.8(–2) µm and an unusual habitat (growing inside small holes of bark of a corticated branch of *Ribes rubrum*). Spore shape is usually fusiform-obclavate with acute upper and obtuse lower end, and the widest part of the spores often more towards the base. Yet, also fusiform spores with (sub)acute lower end occurred, with the widest part in the middle or rarely closer to the acute upper end. In *O. luteorubella* and *O. rosea* distinctly obclavate spores were only exceptionally seen, though in a few records from France mentioned under *O. rosea* they prevailed. Therefore, spore orientation needs to be evaluated for identification.

Globose SCBs were quite consistently present in the cells of both paraphyses and marginal ectal excipulum. VBs were often seen in the paraphyses, but they were sometimes also completely absent or only inconsistently present within a collection.

Type studies. Boudier (1885) described ***O. sarraziniana*** without a reference to *O. luteorubella*. The brief unillustrated protologue is based on a collection from near Paris (Forêt d'Halatte – erroneously as 'Hallate'), with translucent, orange (as 'oronge') apothecia, and spores 8–8.5 × 1.2–2 µm. Later, Boudier (1904–10: 267, pl. 462) illustrated under the name *O. sarraziniana* a specimen from a different locality near Paris (bois d'Ecouen) with pale greyish-ochraecous(-rose) apothecia, spores 7–8 × 1.5–2 µm (7.2–8 × 1–1.2 µm evaluated from scale), but without commenting on the different colour in the holotype. In both records the spores are described as fusiform-acicular-acute, but no SBs are reported. In the examined holotype the bright amber red-brown apothecia still showed an orange tint when rehydrated. The spores are distinctly heteropolar in shape, with one end acute to acuminate and the other end obtuse to subacute (Pl. 537: 1). SBs could be discerned in the acute spore end, and the inverse orientation of the upper spores was seen in about 10 asci. The collection from Ecouen was not studied, but judging from Boudier's illustration it might represent *O. rosea* because of consistently fusoid spores and rose-coloured apothecia ('pale ochraceous-grey and slightly rose' in the text).

A German specimen (Tübingen, on *Fagus*, Pl. 537: 4, IVV: H.B. 7235), from which an ascospore isolate (CBS 116219) and a sequence were gained, is designated here as **epitype** of *O. sarraziniana*.

Saccardo described ***O. luteorubella* f. *microspora*** as a small-spored form of *O. luteorubella*. Type material (France, Fontainebleau, on rotten wood, J. Therry 6025, Fungi Gall. no. 1897) could not be located in PAD, PAL, and W. The taxon was considered by Rehm (1891: 456) to be a synonym of *Orbilia luteorubella*. However, the spore size (5–6 × 1–1.5 µm) indicated by Saccardo (1882b) would better fit *O. sarraziniana*.

Literature reports and misapplication. Two TEM studies on *O. sarraziniana* account for the characteristic heteropolar spore shape, the filiform to subulate SBs in the acute end, and the extraordinary orientation within the asci. Benny et al. (1978) treated a collection from Florida (USA, as *O. luteorubella*, see Fig. 71: a). A spore width of 1.3–1.6 µm (length ~6 µm) and a spore body size of 2.6–3 × 0.5–0.6 µm can be evaluated from their micrograph. The figured features fit quite well *O. sarraziniana*, which would be the only certain American record of this species known to us. The anchoring hyphae illustrated by the authors on their fig. 19 appear much too wide for that species, yet it seems that the given magnification of 875× is erroneous, i.e., much too low in comparison to figs 18 and 21.

Based on several Chinese collections, Liu (2006: 22, pl. 1 figs C-D; 48, 104, pl. 41) characterized *O. sarraziniana* by clavate

Plate 538. **1–7**: *Orbilia sarraziniana*. – **1**. Ravine in Knollenmergel where *O. sarraziniana* repeatedly was found; **2a–c**, **e**, **3a–d**, **4a–b**, **5a–c**, **6**, **7**. fresh apothecia; **3f–g**, **5d**. apothecia in median section; **3e**. id., marginal region; **2d**. asci and paraphyses; **4c**. fully turgescent ascus; **5e**. ejected ascospores. – Living state. — **1**. 12.VIII.2000/26.VII.2001/25.VII.2012 (phot. 27.V.2006): Germany, Tübingen-Pfrondorf, Tiefenbach; **2a–e**. H.B. 7957a: ibid., on *Fagus*; **3a–g**. H.B. 8225: ibid., on *Fagus*; **4a–c**. H.B. 8506: Denmark, Sjælland, on *Alnus*; **5a–e**. H.B. 8886: Germany, Chemnitz, on indet. gymnosperm; **6**. H.B. 7619: France, Pays-de-la-Loire, on *Cupressus* (bark); **7**. H.B. 7806: China, Beijing, on *Salix*.

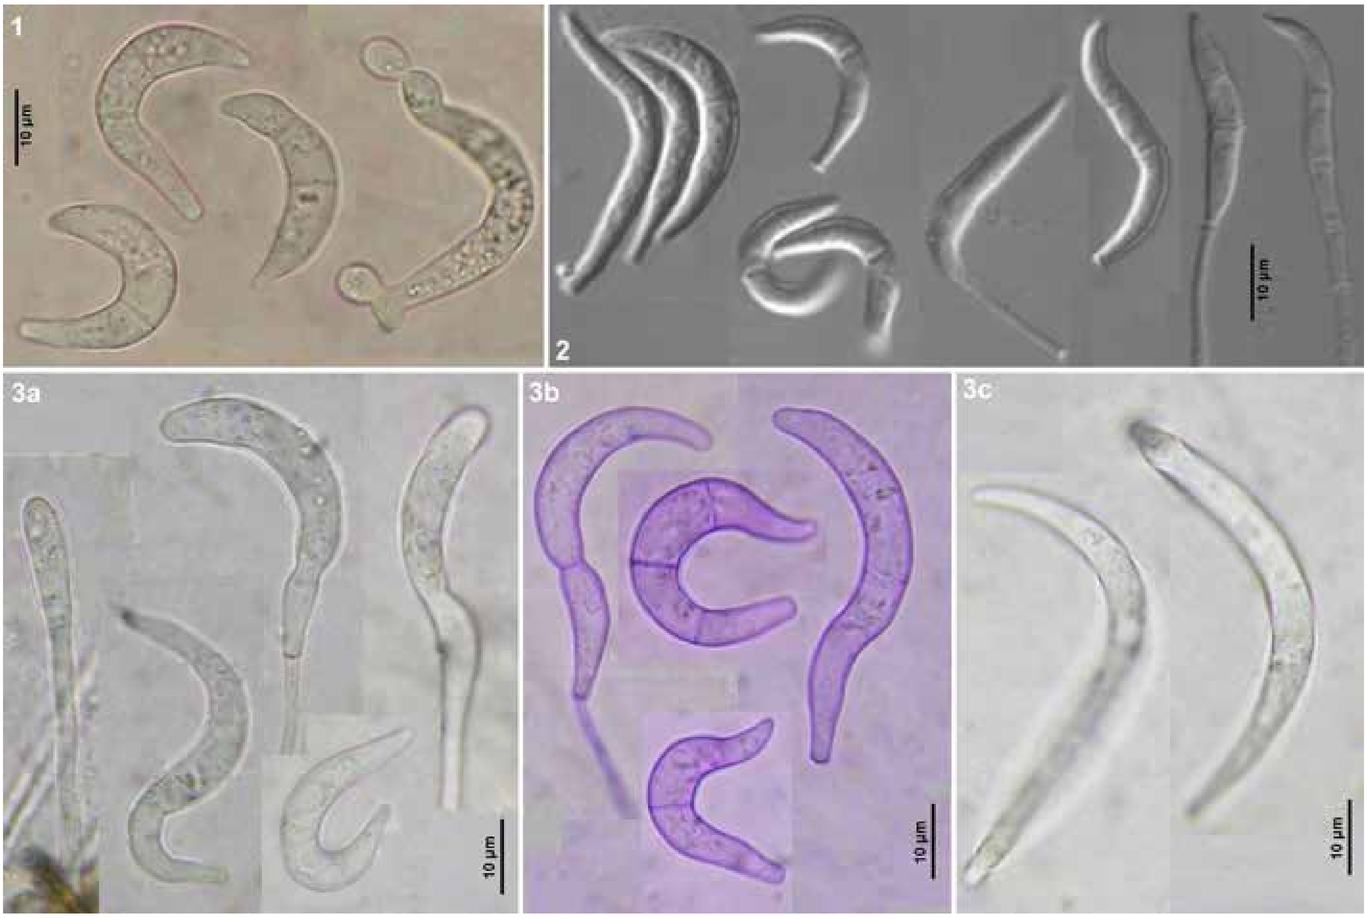

Plate 539. **1–3**: *Orbilia sarraziniana* (**3c** ?*O. rosea*). – **1–3**. microconidia, some adhering to conidiophores (**1–2** from pure culture, **3** from natural substrate flooded with water). – Living state (**3b** in CRB), except for **2** (in H_2O). – **2**: from Liu (2006, fig. 42, DIC). — **1**. H.B. 8225: Germany, Tübingen, on *Fagus*; **2**. HMAS 139684: China, Beijing, on indet. tree; **3a–c**. H.B. 9691a: Germany, Chemnitz, on *Alnus* (**3c** ?*O. rosea*).

ascospores and their extraordinary orientation (upper spores often inverted, see Fig. 71: b). On his TEM micrographs of HMAS 139680 (Beijing, Matsuyama forest) the spore bodies are rather wide (†3–6 × 1–1.2 µm), perhaps because they are artificially inflated in the dead state. In another Chinese specimen collected at the same place and date (HMAS 139684), Liu figured a much narrower spore body (*3 × 0.5 µm), which appears to exclude a possible identity with the similar *O. juruensis*. In his description Liu reported the SBs as 3 × 1 µm.

Reports of *O. sarraziniana* in the literature often give too narrow spores. For example, Dennis (1960a, 1978: 188, followed by Moser 1963, Chmiel 1982, Ellis & Ellis 1985, and Courtecuisse 1988) gave the spores as 6–8 × 0.5 µm, Breitenbach & Kränzlin (1981, pl. 252) as 7 × 0.5–1 µm, Raitviir (1991: 361) as 6–8 × 0.5–0.8 µm. On the contrary, *O. luteorubella* is generally reported with a spore width of 1–1.5 µm or up to 2 µm, although the two species actually do not differ in this detail. The single specimen treated by Breitenbach & Kränzlin (l.c.) was reexamined and found to be probably *O. rosea* (or *O. luteorubella*), showing fusoid spores of †6–7(–9) × 1–1.2 µm. Raitviir's (l.c.) records from northeastern Asia doubtfully belong to this species complex because of partly curved spores (described as 'bent'). Tewari & Pant (1966) reported *O. sarraziniana* on piled up stems of *Cajanus cajan* from Varanasi (Uttar Pradesh, northern India) with rather wide, clavate spores of 3.5–8.5 × 1.5–2.5 µm. They emphasized this as the first record of an identified *Orbilia* from India, but did not provide an illustration.

The holotype of *O. carpathica* Velen. did not contain the described fungus with long and thin spore tails, but instead *O. sarraziniana* (IVV: H.B. 6054; see also p. 1664). This discrepancy might be due to some confusion of the material, since also the substrate does not concur with the protologue. In the lectotype of *O. roseohyalina* Velen. (= *O. crenatomarginata*) two apothecia of *O.* (?)*sarraziniana* occur in association (IVV: H.B. 6265b).

Not included collections. In all those collections listed below as not included, the spore orientation is unknown: either it was neglected when the fresh specimen was studied, or the feature was impossible to see in the dead state. In these cases the identity is assumed mainly because of a clavate spore shape, but in some cases the spore shape was variable by including also fusoid spores. A record from New Zealand studied by J.A. Cooper (pers. comm., as *O. luteorubella*, IVV: 4.I.2010) showed rather small spores (†5.5–6.2 × 1.1–1.5 µm), but in Europe a spore length of †(5–)6–7 µm was also sometimes noted. Regrettably, vital characters including spore orientation were not documented. The collection from Brandenburg by H. Sydow showed a spore size of †6–8 × 1.2–1.7 µm, but is not included because of rather large, especially broad asci of †40–47(–53) × 4.6–5.2 µm.

Anamorph. An anamorph similar to the microconidial state of *O. yuanensis* (Pl. 546: 5b) or *O. rosea* (Pl. 528) was observed in culture of four different collections of *O. sarraziniana*. Liu (2006: 104, fig. 42) obtained it in pure culture of one of his Chinese strains and tentatively called it provisionally '*Anguillospora sarraziniana*'. The 1–3 septate, strongly curved conidia (helicoid, C-shaped in side view, Pl. 539: 2) show an actual length of ~30–43 µm. This type of conidia we have also obtained in three German collections of *O. sarraziniana*, mainly with 3 septa, once in a Petri dish by flooding apothecia on a wood fragment with non-sterilized tap water (Pl. 539: 3a–b), and twice by flooding an agar block from sterile cultures with sterilized water (Pls 537: 4; 539: 1).

Besides these (1–)3-septate conidia, slightly longer, 1-septate, helicoid conidia (*47–52 × 5.5 µm in situ, Pl. 539: 3c) were found in the non-sterile Petri dish. This might indicate a similar dimorphism in conidial size and shape as in the very closely related *O. rosea*. It must be mentioned, however, that the two types of conidia developed on a piece of wood, which carried only pale rose-lilaceous apothecia of what seemed to be *O. rosea* (H.B. 9691b) based on ascospore orientation, while on other pieces of wood rose-lilaceous apothecia grew in mixture with orange apothecia of *O. sarraziniana*. From the similarity with conidia obtained in pure culture (Pl. 539: 1–2) one might conclude that the shorter and wider conidia belong to *O. sarraziniana*, while those in 3c belong to *O. rosea*. However, the two colour variants were identical in their ITS rDNA (see below). A culture from Luxembourg (G.M. 2012-10-18) formed in CMA:2 a colony with distinct concentric zones (see Fig. 102: d), but did not sporulate.

Phylogeny. Molecular phylogenetic analysis of the ITS region by Liu et al. (2006a) in various Chinese strains of series *Helicoon* supports distinction between *O. rosea* (as *O. luteorubella*, 5 sequences) and *O. sarraziniana* (3 sequences). The two species form two highly supported and distant clades. For two strains of *O. sarraziniana* (HMAS 139684 and 96817) also LSU was available, and for the former also SSU.

Another strain, obviously misidentified by Liu (2006) as *O. sarraziniana* (B.L. X079, HMAS 96784, Tibet, in GenBank as *O. luteorubella*), falls intermediate between series *Helicoon* and *Pseudotripoconidium*, and also at the 6 informative positions of the ITS region (Tab. 70) it stands intermediate between both series.

Among our five sequences of *O. sarraziniana*, three were gained from ascospore isolates (H.B. 7235, 6727a, Tübingen, SSU+ITS+LSU; G.M. 2012-10-18, Luxembourg, ITS+LSU) and two from apothecia of a problematic collection (H.B. 9691a/b, Chemnitz, ITS) which consists of two populations growing intermingled by sharply differing in rose vs. orange apothecia and in spore orientation (see below).

The three Chinese strains clustered in the ITS region with our five European strains in a strongly supported clade, showing an internal variation of 0–2.5%. This variation is lower than that observed within *O. rosea* (0.2–6.5%). H.B. 7235, 9691a, and 9691b fully concur in the entire ITS region (except for 1 gap), and strain G.M. 2012-10-18 shows 0.6% distance to them, whereas H.B. 6727a shows a distance of 2.5% (11–13 nt and a few inserts). Surprisingly, one of the available Chinese sequences (HMAS 139684) deviates from H.B. 7235 and 9691 only by 2 nt (0.4%) besides 1 gap and 1 insert. The ITS distance to *O. rosea* (14–17%) and *O. luteorubella* (15–15.5%) is unexpectedly high.

Because of the unexpected result of full identity between H.B. 9691a and 9691b, these strains were resequenced by E. Kuhnert but the result was confirmed. This raises the question whether our concept of *O. sarraziniana* needs to be widened to include populations showing the normal spore orientation of *O. rosea* or *O. luteorubella*, in combination with comparatively short asci and spores. Because this result remained the only exception, we refrained from any reassessment of collections, awaiting further research. The inverse orientation of the upper spores was strongly predominant in four sequenced European collections, and we assume that also Liu (2006) observed this feature in his three sequenced samples.

Also when analysing LSU (D1–D2), the five available sequences of *O. sarraziniana* form a strongly supported clade (Phyl. 18), showing 0.2–0.5% distance among each other, while the distance to other members of section *Helicoon* lies at 4–6%. An LSU sequence from an obviously misidentified strain (B.L. 730, DQ656703, as *O. sarraziniana*) deviates from this species by ~5.5% and clustered distantly from identified clades. In the SSU, strains H.B. 6727a and 7235 fully concur in the overlapping region (V8–V9), whereas HMAS 139684 deviates by 1 nucleotide and *O. rosea* (H.B. 6756a) by 5 nt (for further details see under *O. rosea*, p. 968).

Strains H.B. 6727a and G.M. 2012-10-18 of *O. sarraziniana* include the S1506 intron of 442 and min. 432 nt, respectively, which differ by 12 nt and 3 gaps (3%), whereas the distance to other members of section *Helicoon* lies in the range of 20% in this gene region. The intron is absent in H.B. 7235 and H.B. 9691a/b and in the Chinese strain HMAS 139684. Whether it is also absent in HMAS 96817 and 139682 is uncertain.

Ecology. *O. sarraziniana* occurs on ± rotten wood and more rarely bark of hygric, usually wet (semiaquatic) branches and logs (exceptionally twigs) of various angiosperms, mainly *Salix* {~36} and *Fagus* {~31}, also *Alnus* {~15} and *Fraxinus* {~8} etc., sometimes coniferous trees, exceptionally on herbaceous stems etc. Like *O. luteorubella* and *O. rosea*, the species grows close to water (muddy depressions, ponds, lakes, rivulets and streams) by which its substrate is periodically flooded. The vegetation includes grey willow marshes and aggradation zones of lakes (*Salicetum cinereae*), riparian white willow floodplain forests, alder marsh forests, green alder bushes (*Alnetum viridis*), wet ravine forests (*Aceri-Fraxinetum*, *Pruno-Fraxinetum*), sphagnum-rich moorland forests with *Betula* and *Alnus*, lowland sedge swamps adjacent to rivulets, and ponds in *Querco-Carpinetum* or *Fagetum*.

Within Europe *O. sarraziniana* was collected at planar to montane, rarely subalpine, atlantic to continental sites, including oro- to thermotemperate, but also orosub- to mesosubmediterranean or hemi- to oroboreal, humid to semihumid climates. Extra-European collections, however, are from continental oroboreal northern (West Siberian Plain east of Ural) and orotemperate southern Russia (Sayan Mts.), and cold-temperate humid northern China and central Japan, but also from cold-temperate oceanic New Zealand and subtropical humid eastern North America (Florida).

Otani (1990) reported collections under the name *O. sarraziniana* from Japan, and López & García (2001) from Xalapa (Veracruz, Mexico, subtropical humid, 1400 m), both without data on SBs and spore orientation. A report from Michigan (North America) by Kanouse (1934: 95) is without microscopic data, as are those by R. Galán (in Pando & Hernández 2001: 125) from different parts of Spain. Also Sierra López's (1987) record on branches of *Opuntia* in Cataluña (Spain) requires reexamination. The lack of collections from most parts of Scandinavia and eastern Europe is possibly accidental. Two Norway databases (Soppdatabasen, Artsobservasjoner) contain four records under the name *O. sarraziniana* (Oppland, Sør-Trøndelag, Vestfold, K. Homble pers. comm.).

Species with a (sub)tropical distribution

Orbilia tianmushanensis Baral, Y. Zhang & Z.F. Yu, in Zhang et al., J. Microbiol. 54: 10 (2016) — Pl. 540

Etymology: named after the type locality, Tianmushan in Zhejiang province of China.

Typification: China, Zhejiang, Lin'an, Tianmushan, branch of *Quercus*, 6.IX.2009, J.W. Guo (YMFT 1.03563, holotype; sq.: KT192704, KT236097).

Description: — **TELEOMORPH**: **Apothecia** fresh 0.5–0.9 mm diam., pale yellowish-red, translucent, round or undulating, gregarious; disc flat, margin smooth; sessile, superficial; dry yellow. **Asci** †(28.3–)37–59 × (3.4–)4–4.7 µm, 8-spored, no data about spore arrangement and orientation available; **apex** (†) truncate (not indented, laterally not inflated); **base** with short to long, thin, flexuous stalk, L- to Y-shaped. **Ascospores** †7.2–8(–9.5) × 1.3–1.8 µm, fusoid, apex subacute, base ± attenuated, straight to slightly curved; **SBs** *3–4.5 × 0.5–1 µm, vermiform, straight or slightly curved. **Paraphyses** apically slightly to medium capitate, terminal cells †18.5–21 × (1.8–)2.5–3.8 µm, lower cells †4.5–8 × 1.5–2.3 µm; unbranched at upper septum. **Medullary excipulum** not examined. **Ectal excipulum** examined only near margin: marginal cortical cells †7–12 × 2.5–5.5 µm, thin-walled; without **glassy processes**. **Anchoring hyphae** not examined. **SCBs** and **VBs** not examined. **Exudate** over paraphyses absent or very thin. — **ANAMORPH**: dactylella-like (from ascospore isolate {1}). **Conidiophores** erect, occasionally branched, 114–122 um long. **Conidia** *42–74 × 7.7–10.2 µm, straight, fusiform, two central cells distinctly inflated, tapered towards obtuse apex, below ± abruptly narrowed to a tail-like base, (1–)3-septate, containing a few minute LBs. **Chlamydospores** frequently formed in older cultures, ellipsoidal to subglobose, 6–13 µm in diam., forming chains.

Habitat: branch of *Quercus* lying on moist ground away from water bodies, on rotten wood and bark. **Associated**: none noted. **Desiccation tolerance**: unknown, probably drought-intolerant. **Altitude**: 825 m a.s.l. **Geology**: felsic volcanic rock. **Phenology**: IX.

Taxonomic remarks. *Orbilia tianmushanensis* is mainly characterized by its peculiar anamorph (Zhang et al. 2016). The above description is based on the morphological study by Ying Zhang. Apart from notes on apothecial colour and size and shape of spore bodies, no detailed documentation of the living teleomorph was done, therefore, the spore orientation in the asci is unknown, because this is very difficult to assess in dead material. Also spore size and shape could only tentatively be documented by the authors from the dried specimen. Based on the available data, the teleomorph does not markedly differ from *O. luteorubella* or *O. rosea*.

Anamorph. *Orbilia tianmushanensis* forms characteristic conidia with a swollen central part and a strongly narrowed tail-like base which is rather unique within the *Orbiliomycetes* (Pl. 540: 1d–e). The conidia are reminiscent of members of series *Neodactylella* or *Dactylellina* of section *Arthrobotrys*. No trapping organs were formed when nematodes were added to the culture, and molecular data clearly refer the species to section *Helicoon*.

Phylogeny. A sequence was gained from pure culture, comprising S1506 intron, ITS, and LSU (Zhang et al. 2016). Also SSU, *TUBB*, *RPB2*, and *TEF1* were obtained (Y. Zhang pers. comm.) but so far not uploaded. When observing the alignment of the ITS region at those positions where series *Helicoon* differs from series *Pseudotripoconidium*, the somewhat intermediate *O. yuanensis* and *O. tianmushanensis* concur partially with one series and partially with the other: *O. tianmushanensis* agrees with series *Helicoon* at pos. 150, 300, and 322, and with series *Pseudotripoconidium* at pos. 162, 163, 443, and 449 (Tab. 70, see also Zhang et al. 2016, tab. 1, where, due to a deviating alignment, the position numbers slightly deviate and a match with series *Pseudotripoconidium* at pos. 23–24 was asserted).

In ML analyses of ITS or ITS+LSU, *O. tianmushanensis* nested intermediate between the two series by forming a medium supported clade with series *Pseudotripoconidium* (Phyls 17, S19), but when analysing LSU it clustered in series

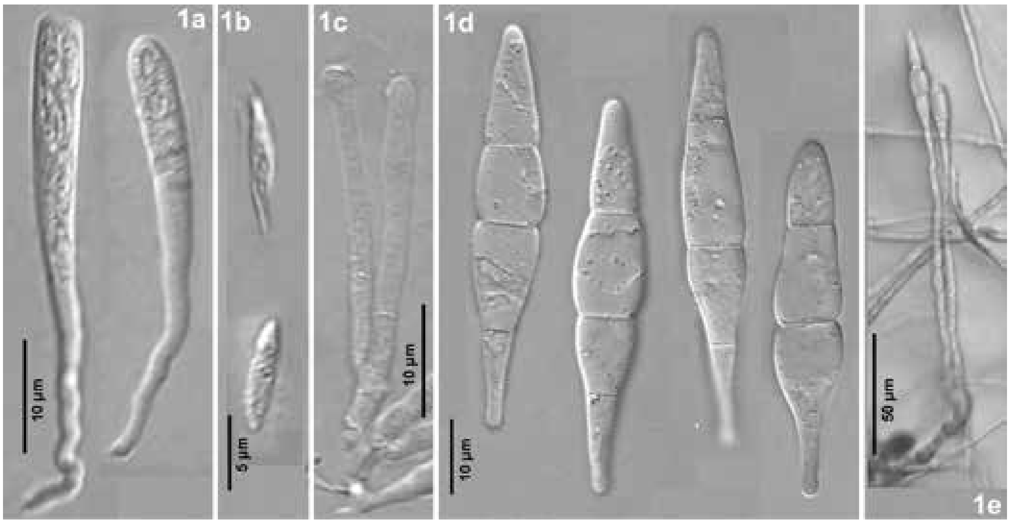

Plate 540. **1**: *Orbilia tianmushanensis*. – **1a**. asci; **1b**. ascospores; **1c**. paraphyses; **1d**. conidia (from culture): **1e**. conidiophores with conidia. – Living state (**1d–e**), dead state (**1a–c**); from Zhang et al. 2016 (DIC). — **1a–e**. YMFT 1.03563: China, Zhejiang, on *Quercus* (holotype).

Pseudotripoconidium, though with a long branch (Phyl. 18). The same result was obtained by Zhang et al. (2016) in their separate ITS and LSU analyses, though without support in the ITS tree. The molecular distance to members of series *Pseudotripoconidium* ranges in the ITS region at 12–15 % (4–7 % in LSU), and to members of series *Helicoon* at 15–18 % (6.5–9 % in LSU). Also in the intron the species shows a rather high distance to other taxa of section *Helicoon*. All these distances are lower compared to those observed between *O. tianmushanensis* and members of section *Arthrobotrys*.

Ecology. *O. tianmushanensis* is only known from the type collection, growing on wood and bark of a hygric branch of *Quercus* in a subtropical humid (winter-dry) oceanic broad-leaved mountain forest in eastern China.

Specimens included. **CHINA**: **Zhejiang**, **Hangzhou**, 30 km WNW of Lin'an, Tianmushan, 825 m, branch of *Quercus*, on bark & wood, 6.IX.2009, J.W. Guo (J.W.G. tms-18, YMFT 1.03563, **holotype**; YMF 1.03563 ex-type culture, anam. cult., doc. vid.; sq.: KT192704, KT236097, as *O.* [aff.] *luteorubella*).

Orbilia hoana Baral, Hong Y. Su & Y.C. Su, **sp. nov.**, MB 813628 — Pls 541–542

Etymology: named after the collector, WaiHong Ho.

Typification: China, Hong Kong, Lai Chi Hang, branch of indet. angiosperm, 28.IX.1997, W.H. Ho (ex H.B. 6012, M-0276493, holotype).

Latin diagnosis: *Apothecia hydratata 0.2–1.5 mm diam.*, *alba vel dilute ochraceo-lutea*, *sessilia vel substipitata*, *margine laevi. Ascosporae *4.5–9.3 × 1.3–1.8 µm*, *fusiformes*, *apice acutae*, *ad basim leniter vel valde attenuatae*, *plus minusve rectae*, *prope apicem in statu vivo corpusculum refringens elongatum lacrimiformem continentes. Paraphyses ad apicem leniter ad valde inflatae. Excipulum marginale exsudato valido pallide luteo tectum. Status anamorphicus: Generi* Anguillosporae *similis. Habitat ad lignum et corticem putridum ramorum uvidorum vel madidorum arborum angiospermarum in zona subtropica humida Asiae meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** fresh (0.2–)0.3–0.8(–1.5) mm diam., (0.11–)0.16–0.23 mm high (receptacle 0.09–0.1 mm), watery white to light dull yellowish-ochraceous, ± translucent, round to slightly irregular, medium scattered to ± gregarious; disc flat (to slightly convex), margin indistinct to distinct, thin, 0–5 µm protruding, ± smooth; sessile or with a ± distinct stipe 0.05–0.1 × 0.13–0.35 mm, superficial; dry pale yellowish-cream to orange. **Asci** *40–47 × 4–4.2(–4.8) µm {1}, †(28–)32–45(–50) × (3.3–)3.5–4(–4.2) µm {4}, 8-spored, spores *3–4-seriate, 4–5(–6) lower spores inverted {13} (rarely to often mixed), pars sporifera *18–19 → 11–15 µm long; **apex** (†) strongly truncate (not or sometimes deeply indented, laterally not inflated); **base** with medium to long, thin, scarcely flexuous stalk, L-, T-, Y- or sometimes H-shaped. **Ascospores** *(4.5–)5–8(–9.3) {13} × 1.3–1.4 {2} or (1.4–)1.5–1.7(–1.8) {10} µm, †5–8 × 1.5–1.7 µm {1}, fusoid or mostly fusiform, sometimes fusiform-clavate or -obclavate, apex acute, rarely acuminate or subacute, base slightly to often strongly attenuated, straight, sometimes slightly curved, especially in lower half; **SBs** *(1.8–)2.3–3(–4) × 0.5–0.9 µm {4}, (narrowly) tear-shaped

H.Y.S. jgs-6: ibid., on indet. angiosperm; **4a–b**. H.B. 8780 (jgs-17): ibid., on indet. angiosperm; **5a–d**. H.B. 6012 (holotype): China, Hong Kong, on indet. angiosperm.

(to ampulliform), sometimes subulate, straight or sometimes slightly flexuous. **Paraphyses** apically slightly to strongly capitate(-clavate), terminal cells *18–22 {1} or 24–28 {1} × 3–4.5(–5.5) µm {2}, lower cells *4–6 × 2–3 µm {2}; unbranched at upper septum. **Medullary excipulum** 20–40 µm thick, of ± dense, not or slightly gelatinized textura intricata, with many inflated cells with some LBs 1–2 µm diam., medium sharply delimited. **Ectal excipulum** of thin-walled († slightly gelatinized), indistinctly oriented t. globulosa-angularis from base to mid flanks or margin, 50–150 µm thick near base, cells in stipe *15–30 × 12–23 µm {T}, †(7–)12–20(–27) × (6–)8–15(–18) µm {3}, common walls †0.3–1 µm thick, hyaline, inner region sometimes of (†) strongly gelatinized t. globulosa, common walls 1–3 µm {T}, intercellular gel light amber-yellow; 20–25 µm thick at lower flanks, cells †10–13 × 6–9 µm, 10–25 µm thick near margin, of t. prismatica(-globulosa) oriented at a 50–90° angle to the surface, marginal cortical cells */†(6–)8–12(–15) × (3–)4–6.5(–8) µm {4}, ± thin-walled; **glassy processes** absent (but sometimes with conical exudate caps). **Anchoring hyphae** very sparse, *2.8–4 µm wide, walls 0.2–0.3 µm thick {1}. **SCBs** in paraphyses and ectal excipulum not observed. **VBs** in paraphyses strongly refractive, hyaline, globose to very elongate, in excipulum absent. **Exudate** over paraphyses 0.2–0.5(–1.5) µm thick, granular(-cloddy) to continuous, ± loosely attached, over margin and mid flanks 0.3–2 or rarely 1–5 µm thick, then forming individual, conical or hemispherical-truncate caps, high-refractive, pale to light golden yellowish-amber. **— ANAMORPH** (fide H.Y. Su): anguillospora-/vermispora-like (from ascospore isolate {3}). **Conidiophores** branched or not, mostly 35–68 um long, 1.5–2.7 µm wide at the base, terminally forming 1 or 2 conidia. **Conidia** (*)/†(29.5–)39–80(–111) × (4–)4.5–7.5(–9) µm, vermiform, slightly curved under a wide arch, both ends usually somewhat tapered, basal end truncate, (3–)5–10(–12)-septate {3}, with a single, 2–4 µm large LB in each cell (living state). **Chlamydospores** present (jgs-14, jgs-17), globose to ellipsoidal, or not observed (jgs-15).

Habitat: on moist or wet (submerged) ground, partially decorticated, min. 18 mm thick branches and ?logs of *Castanopsis orthacantha* {1}, indet. angiosperms {8/}, indet. ?gymnosperm {1}, on wood {3} and bark {7} (periderm), up to 1–2 mm deep medium to strongly decayed, slightly greyed, with or without green algae. **Associated**: *Orbilia juruensis* {1}, *O. latispora* {1}, *O. yuanensis* {2}. **Desiccation tolerance**: probably drought-intolerant, spores still viable after 2 months. **Altitude**: 120–2730 m a.s.l. **Geology**: Proterozoic, Jurassic & Tertiary sedimentary rock; felsic plutonic rock. **Phenology**: I–II, ?VI, VIII–IX, XI (apparently throughout the year).

Taxonomic remarks. *Orbilia hoana* is characterized by fusiform ascospores with rather broad, consistently tear-shaped SBs, also by vermispora-like conidia with a high lipid content. The presence of yellow exudate varies among the populations and possibly depends on their age. The more temperate to subalpine-boreal *O. luteorubella*, *O. rosea* and *O. sarraziniana* differ in narrower, more filiform to subulate SBs when comparing spores inside mature living asci, and in conidia with a different size and without a large central lipid body.

O. yuanensis differs from *O. hoana* in narrower, cylindric(-fusoid) ascospores and smaller SBs, also in conidia without a large central lipid body. *O. juruensis* differs in the upper instead of the lower spores being more or less consistently inverted within the asci, also in a tendency to larger apothecia. *O. fusiformis* and *O.* aff. *fusiformis* (Pls 553–556) differ in narrower, filiform to subulate SBs and a pseudotripoconidium-like anamorph. Their spore length is at the lower end of the range of *O. hoana*.

Variation within *O. hoana* was noted in apothecial size and colour (from white to yellowish-ochraceous, pigment located in the exudate), also in spore size, length of terminal cells of paraphyses, and thickness of the exudate. The type from Hong Kong differs from the remaining collections in narrower spores, a gelatinized, light yellow-amber inner ectal excipulum, and a sometimes rather thick exudate forming glassy caps on the marginal cells (whether the entire cap consists of exudate or the exudate covers glassy processes by a thin layer is not clear). In one of the specimens from Dali (Yunnan) the SBs were exceptionally long (3.3–4 µm, Pl. 542: 3), but also in the collection from Taiwan (Pl. 541: 3) they attained about this length.

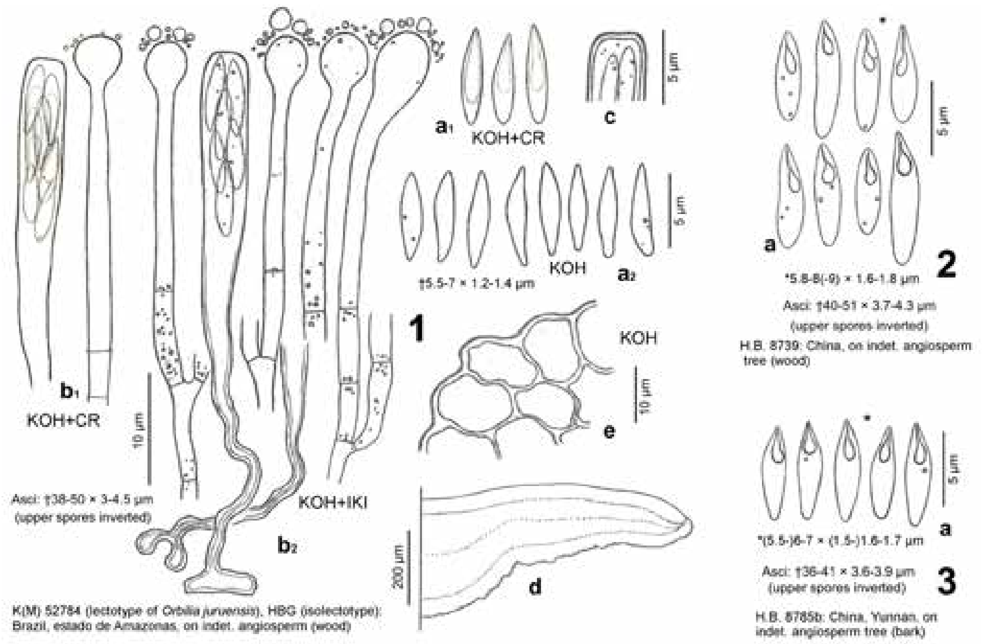

Plate 543. **1–3**. *Orbilia juruensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., ectal excipulum at margin [$\mathbf{a_1}$, $\mathbf{b_1}$ from HBG; $\mathbf{a_2}$, $\mathbf{b_2}$, **c–e** from K(M) 52784].

Not included collection. A sample from Guizhou (M.H. Mo, IVV: H.B. 9432) formed a tridentaria-like anamorph in pure culture, but otherwise it would fit *O. hoana*. Since comparable anamorphs are unknown in section *Helicoon*, some doubts remain about this strain.

Anamorph. The three ascospore isolates of *O. hoana* were all obtained from samples collected at the same site and day (H.Y. Su pers. comm.). The obtained conidia well concur in their shape and particularly their large oil drops in their cells (Pl. 542: 2e, 4b; see also IVV: jgs-14). However, in one of them (542: 4b) the conidia are distinctly longer (51–110 µm, 5–12-septate) than in the other two (29–79 µm, 4–7-septate). In a further sample of *O. hoana* (jgs-31, H.B. 8984a) an arthrobotrys-like anamorph was obtained, obviously by confusion, as a sequence from it clustered with similar anamorphs gained from a teleomorph with falcate ascospores. This isolate was used as holotype of the new species *A. latisporus* (Su et al. 2011b, as '*latispora*', YMFT 1.03168, see under *O. latispora*, p. 1571).

Ecology. *O. hoana* was found on hygric rotten bark and wood on moist soil or on the banks of streams in subtropical humid (winter-dry), high- to lowland, evergreen broad-leaved forests in southeastern Asia. In four collections, other species of *Orbilia* grew in association. In three of them the portion sent to the first author contained only the associated species (*O. juruensis* & *O. yuanensis*) which are also members of section *Helicoon*.

Specimens included. **CHINA**: **Hong Kong**, 8 km SE of Fanling, 0.3 km SE of Lai Chi Hang, Tai Po Kau, 120 m, branch of indet. angiosperm, on bark & wood, 28.IX.1997, W.H. 7.5(–9) × (1.5–)1.6–1.7(–1.8) µm {2}, †5.5–7 × (1.2–)1.3–1.4 µm {T}, fusoid to fusiform, apex acute, base slightly to strongly attenuated, obtuse to subacute or sometimes acute, straight to slightly inequilateral; **SBs** *(2–)2.5–3(–3.8) × 0.6–0.8(–1) µm {2}, tear-shaped, with an often sharply delimited, subulate to filiform upper part, straight to medium flexuous. **Paraphyses** apically (slightly to) medium to strongly (to very strongly) (clavate-)capitate, terminal cells †18–25 × (2.3–)3–4.2(–4.8) µm {T}, lower cells †4–9 × 1.6–2(–2.5) µm wide {T}; unbranched at upper septum. **Medullary excipulum** pale yellowish-ochraceous-orange, 20 {T} or 40–60 {1} µm thick, of dense, small-celled t. angularis. **Ectal excipulum** hyaline, near base 170–270 µm {T} or up to 400 µm {1} thick, hyaline, of (†) non- {1} or slightly gelatinized {T} (common walls ~1 µm thick), indistinctly vertically oriented t. angularis from base to margin, cells at base †11–14 × 6–11 {T} or †13–33 × 10–25 {1} µm, either homogeneously of t. angularis {1} or with a rather sharply delimited, 120–220 µm thick inner part of ± horizontally oriented t. prismatica-angularis {T} made up of †17–25 × 10–16 µm large, slightly gelatinized cells, medium gelatinized towards medullary excipulum, common walls 1–2 µm thick; 40 µm thick near margin {T}, pale yellowish-ochraceous, marginal cortical cells †10–13 × 5–8 {1} or 11–14 × 6–11 µm {T}, thin- {1} or thick-walled {T}. **Anchoring hyphae** medium abundant, †1.5–3 µm wide (4–5 µm at insertion), wall 0.2 µm thick {1}. **SCBs** no data available (but in dead marginal cortical cells globose ?SCBs 1.5–2.2 µm diam. seen), **VBs** in dead terminal cells of paraphyses refractive, yellow {1}. **Exudate** over paraphyses 0.2–2 µm thick, granular (in KOH), loosely attached, pale to light yellow-ochraceous, over margin and flanks thin and inconspicuous or absent. **— ANAMORPH**: unknown.

Habitat: on damp ground, on corticated branches (e.g., 13 mm thick) {2} or decorticated log of unidentified woody angiosperm {3}, *Pinus* sp. {1}, on medium rotten {1} or min. 5 mm deep {T} strongly decayed wood {3}, also on medium rotten bark (periderm) {1}. **Associated**: *Nectria* sp. {1}, *Orbilia hoana* {1}. **Desiccation tolerance**: unknown, probably intolerant. **Altitude**: 90–2730 m a.s.l. **Geology**: Paleozoic & Jurassic sedimentary rock. **Phenology**: I, VIII (northern hemisphere).

Taxonomic remarks. *Orbilia juruensis* closely resembles *O. hoana*, from which it differs in the upper spores being inversely oriented within the asci, also in rather large and thick apothecia. *O. juruensis* differs from *O. sarraziniana* in the SBs which are much wider in their lower part when compared from mature spores inside living asci, and in the more or less abundant yellowish exudate. *O.* aff. *fusiformis* (Pls 555–556, series *Pseudotripoconidium*) deviates in narrower (< 0.6 µm), more flexuous SBs.

Variation. The type of *O. juruensis* features thick-walled (gelatinized) cells in the medullary and ectal excipulum. A pale yellow-ochre pigmentation is now seen in the marginal excipulum and subhymenium. The three included Chinese collections concur with the type in the spores and their orientation, but differ in a thin-walled excipulum (examined in one of them, Pl. 544: 2), also in somewhat less inflated apices of paraphyses. With its rather large apothecia (1.2–1.5 mm) with a convex hymenium, this specimen quite closely resembles the type of *O. juruensis* also macroscopically, even in the reddish colour as reported in the protologue.

Type studies. Hennings' unillustrated protologue of *O. juruensis* describes the apothecia as 2–3 mm diam., umbilicate, incarnate-red ('incarnato-coccineis'), with crisped margin, the capitate apices of paraphyses as containing oil drops, and the spores as needle-shaped, with acute ends, 6–10 × 0.7–0.8 µm. These spore features are in conflict with Spooner's (1987: 180, fig. 24 E–F) detailed description and microscopic drawing of an 'isotype' in K, as well as to the present reexamination of two 'isotypes' (K, HBG, Pl. 543: 1), which revealed much wider, distinctly fusiform spores [Spooner: 6–8 × 1.4–1.6 µm according to scale]. This contradiction, which was not commented by Spooner, is probably due to a bad resolution of Hennings' microscope rather than a mixture of different species. The two duplicates examined here look indeed quite homogeneous. The personal specimen of Hennings in B was destroyed during the Second World War. The specimen in K is designated here as **lectotype** of *Orbilia juruensis* (Art. 9.11, Turland et al. 2018).

In a KOH mount of the specimen from HBG faint remnants of the SBs could be discerned in the more acute spore ends in many of the asci. This permits to conclude that the upper spores are mostly inversely oriented, and only rarely the orientation was in disorder within an ascus. In some asci a part of the lower spores was apparently immature.

O. juruensis was accepted by Spooner (l.c.) as a tropical species different from the north temperate *O. luteorubella*. He found the ectal excipulum to have slightly thickened walls only at the outer surface of the marginal cortical cells, and also emphasized the terminal cells of the paraphyses to differ from *O. luteorubella* in being tapered upwards and there abruptly clavate-subcapitate. However, we observed thickened walls in the type of *O. juruensis* also at the lower flanks and at the inner cells of the ectal excipulum, and subapically narrowed paraphyses partly also in *O. luteorubella*, *O. rosea*, and *O. sarraziniana*.

Dennis (1954) reported *O. juruensis* with spores of a size similar as in the protologue (5–7 × 1 µm), but with a strongly heteropolar shape: narrowly clavate (subulate), slightly curved, with rounded apex and acute base (see Fig. 159: C). The spores are somewhat reminiscent of a member of section *Arthrobotrys* rather than section *Helicoon* (4 spores are drawn inside an ascus, with the acute ends pointing downwards). Dennis also mentioned a report of *O. juruensis* by Cash (1937, without description) from Panama, but did not state on which material his drawing was based. The drawing of a specimen from Yucatán peninsula (Mexico) under the name *O. juruensis* by Guzmán (1983, in tab. 2 as *O. cruenta*) shows narrowly cylindrical spores (no size given). Medel et al.'s (2013) report from Guatemala also concerns a specimen with narrow spores (6–)7–9(–10) × 1–1.5 µm (not illustrated), which might represent *O. sinensis* rather than *O. juruensis*.

From a Chinese collection referred by us to *O. juruensis*, M. Mo (pers comm., Pl. 544: 3) obtained a pure culture but no anamorph. Instead, numerous apothecia were formed on agar.

Not included collections. A specimen from the Comoros (Pl. 544: 4) resembles *O. juruensis* in its large apothecia (~2–4 mm) with a crenulate margin and in the upper spores being inverted in the asci, but deviates in smaller spores (*5–7 × 1.1–1.5 µm). The SBs are ± filiform and shorter than half the spore length.

Spooner (1987: fig. 24 A–D) referred to *O. juruensis* a drawing (see Fig. 163) of a collection from tropical Melanesia (Solomon Islands) with up to 6 mm large apothecia and spores †6.5–8 × 1.6–1.9 µm according to scale. No information on SBs and spore orientation is provided, therefore this collection needs reinvestigation. The same applies to a collection from Taiwan referred by Wang (2002) to *O. juruensis* (spores 'fusoid, 5–7 × 1–2 µm'); the brief, unillustrated description could as well refer to, e. g., *O. sarraziniana* or *O. hoana*.

Ecology. *O. juruensis* was found on ± rotten wood, rarely bark of hygric branches and logs of unidentified angiosperm trees, but also *Pinus*, in tropical and subtropical humid (partly winter-dry) evergreen broad-leaved rainforests of South America and southern China, but also in the cold-continental, orotemperate humid Altay mountain range of western China. The not included collections are from a tropical humid oceanic rainforest on the islands of the Comoros (wet and dry) and Melanesia. The type was collected at the Juruá river in the tropical humid upper part of the Amazonas basin during investigations on the rubber tree genera *Hevea* and *Sapium* (*Euphorbiaceae*) and *Castilla* (*Moraceae*) that are all used for caoutchouc production (see Harms 1916: 158).

Specimens included. **BRAZIL**: **Amazonas**, Lower part of Rio Juruá, 165 km SW of Carauari, 35 km SSW of Marari, Bom Fim, 90 m, log of indet angiosperm, on wood, X.1900, E.H.G. Ule (Ule no. 2820, K(M) 52784, **lectotype**, H.B. 5897 ø: HBG, **isolectotype**). — **CHINA**: **Xinjiang**, **Altay**, 127 km NW of Altay, S-end of Kanas (Kanasi/Kalasi) lake, 1 km ESE of Bo Ouleke, 1390 m, branch of indet. angiosperm, on wood, VIII.2007, Z. Yu (Z.F.Y. xj-4, YMFT, H.B. 8739). – **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, Jinguangsi virgin forest, 2730 m, branch of indet. angiosperm, on bark,19.I.2008, H.Y. Su, R.X. Bi & J. Li (H.Y.S. jgs-14, CBCD, H.B. 8785b). – **Kunming**, ~35 km W of Kunming, ~8 km WNW of Yiliang, Xiaobailong Mt., ~1900 m, on wood of *Pinus*, 15.VIII. 2003, M.H. Mo et al. (M.H.M. 006, doc. vid.).

Not included. **COMOROS**: **Mayotte**, 6 km NW of Bandrele, 2.8 km NE of Poroani, Crête de Benara, 340 m, branch of indet. ?angiosperm, on wood, 20.IV.2013, M. Pélissier, vid. J.P. Priou (M.P. 13.169, doc. vid.). — **MELANESIA**: **Solomon Islands**, Kolombangara island, unlocalized, log of indet. tree, 29.VIII.1965, collector unknown ('RS') (1136, BSIP, doc. vid.). — **CHINA**: **Taiwan**, **Lanyu** (Orchid Island), 87 km SSE of Taitung, Tienchih, on indet. wood, 25.X.1999, C.H. Chung (WAN 749, TNM F10168).

Orbilia yuanensis Baral, Z.F. Yu & H.Y. Su, in Qiao et al., Mycol. Progress 14:1022: 2 (2015) — Pls 545–546

Etymology: named after the type locality, Yu'an mountain (= Qinglongxia).
Typification: China, Yunnan, Qinglongzhen, branch of indet. angiosperm, 3.XI.2004, Z.F. Yu (ex H.B. 7665, M-0257564, holotype).

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated (0.25–)0.4–0.6(–0.7) mm diam., 0.11–0.3 mm high (receptacle 0.09–0.1 → 0.06–0.07 mm), fresh whitish, rehydrated light pure or dirty (sulphur-)yellow to chlorinaceous-cream, ± translucent, round, scattered

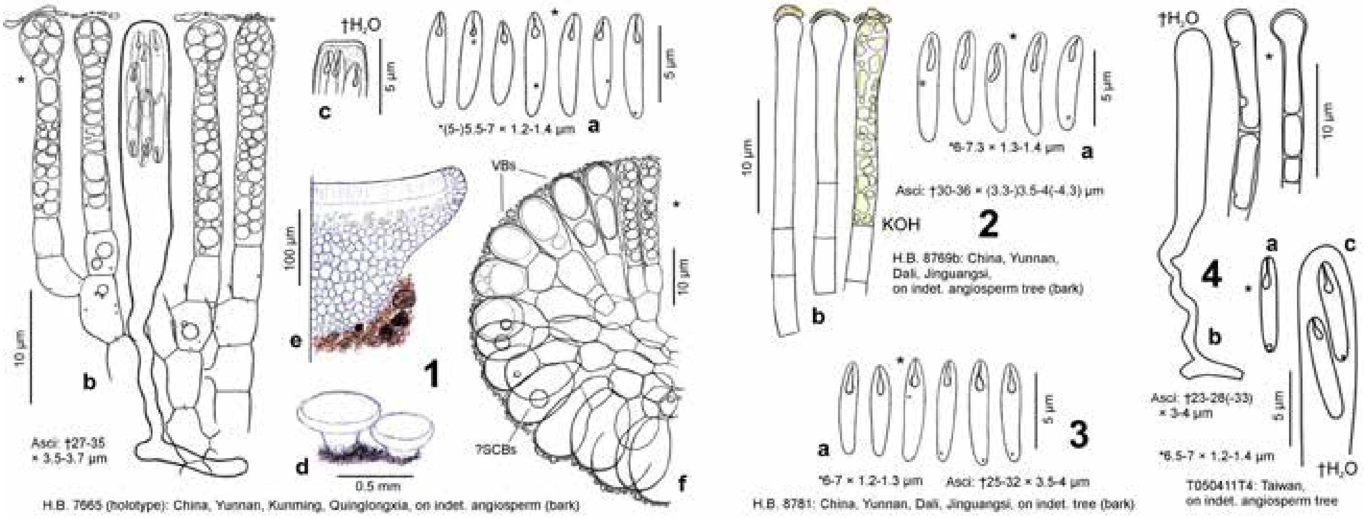

Plate 545. **1–4**: *Orbilia yuanensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum. – **4**: del. Y.C. Su.

to gregarious; disc slightly concave to slightly convex, margin distinct, 0–5 µm protruding, smooth; sessile or with obconical to cylindrical stipe 0.06–0.2 × 0.15–0.33 mm, superficial or slightly immersed in detritus, dry pale to light yellow or buff. **Asci** *33–42 × 4–4.5(–5) µm {1}, †(23–)25–36 × (3–)3.3–4(–4.3) µm {4}, 8-spored, spores *4-seriate, (3–)4 lower spores inverted {4} (not or hardly mixed), pars sporifera *13–14 µm long; **apex** (†) strongly truncate (not or slightly indented, laterally sometimes inflated); **base** with short to long, thin, flexuous stalk, L- or T-shaped. **Ascospores** *(5–)6–7(–7.5) × 1.2–1.4 µm {4}, †5.5–7 × 1.1–1.2(–1.3) µm {1}, (sub)cylindrical, rarely narrowly fusoid-ellipsoid or slightly fusoid-clavate, ± homopolar, both ends rounded to obtuse, straight to very slightly inequilateral; **SBs** *1.5–2.2 {2} or 2–2.8 {1} × 0.3–0.6 µm {3}, typically divided into a lower tear-shaped part and a ± thin filum of about the same length, also narrowly pyriform to shortly vermiform and apically narrowed to a very short filum, straight to very slightly, rarely medium flexuous. **Paraphyses** apically (uninflated to) slightly or medium (clavate-)capitate, terminal cells *17–23 × (2.5–)3–4 µm {1}, †13–20 × 2–3.2 µm {1}, lower cells *(2–)3–5(–6) × 2–3 µm {1}, †4–6.5(–8) × 1.5–2 µm {1}; unbranched at upper septum, hymenium hyaline to bright golden-yellow. **Medullary excipulum** hyaline, 15–40 µm thick, of medium dense textura intricata-globulosa, sometimes of pale yellowish t. prismatica in lower part, indistinctly to medium sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. globulosa-angularis from base to margin, 60–200 µm thick near base, cells */†(12–)15–24(–27) × (9–)10–19(–23) µm {4}; 20–25 µm thick at flanks, 10–25 µm near margin, of t. (prismatica-)globulosa oriented at a 60–90° angle to the surface, marginal cortical cells *8–12(–15) × 6–8.5(–11) µm {1}, †7–12 × (3–)4–6 µm {3}; **glassy processes** absent. **Anchoring hyphae** very sparse, */†2–4(–5) µm wide, walls 0.2–0.3(–0.5) µm thick {3}. **VBs** in paraphyses consistently present {4}, multiguttulate, finally a few large and elongate bodies, rather strongly refractive, hyaline; in marginal cortical cells low-refractive, large; in dead cells turning golden yellow {2}. **SCBs** in paraphyses not seen; in cortical cells of ectal excipulum at flanks and margin globose, (0.5–)1–4 µm diam., strongly refractive, hyaline, singly or in groups {1}. **Exudate** over paraphyses 0.2–1(–1.5) µm thick, granular to small-cloddy, at first loosely, later firmly attached; over margin and flanks 0.2–0.3 or mostly 0.5–1.5 µm thick, rough-cloddy to granular, firmly attached, hyaline to bright golden (ochraceous-)yellow(-orange). — **ANAMORPH**: anguillospora-/vermispora-like (from ascospore isolate {3}). **Macroconidiophores** 25–53 × 2–3 µm, 0–2-septate, erect, unbranched or branched. **Conidiogenous cells** monoblastic. **Macroconidia** *((70–))(80–)90–120(–127)((–135)) × (5–)6–6.8(–7.3) µm {2}, †94–110 × 4.6–5 µm {1}, slightly to medium curved under a wide arch, sometimes somewhat bent near the ends or the middle, (10–)11–13(–14)-septate {2}, with many ± small LBs and sometimes also larger ones (0.3–2 µm diam.) near the septa or in the entire cell (lipid content low to rather high). **Microconidiophores** 22–30 µm long, (0–)2-septate, erect, unbranched, conidia formed terminally, singly. **Microconidia** *(21–)25–40(–60) × (2.3–)2.6–3.5 µm {1}, slightly to strongly curved (sometimes helicoid) or bent, (0–)1–3-septate, lipid content similar as in macroconidia.

Habitat: on the moist ground, corticated, ~12–50 mm thick branches of *Quercus* sp. {1}, unidentified woody angiosperms {6/1}, on medium to strongly decayed bark (periderm) {5} or wood {1}, partially blackened, no algae. **Associated**: *Orbilia hoana* {1}, *O.* ?*rosea* {1}. **Desiccation tolerance**: probably desiccation-sensitive, spores still viable after 2–4 weeks. **Altitude**: 1325–2730 m a.s.l. **Geology**: Proterozoic, Paleozoic, Jurassic & Tertiary sedimentary & metamorphic rock. **Phenology**: XI–II, IV, VII.

Taxonomic remarks. *Orbilia yuanensis* is characterized by cylindrical to cylindric-ellipsoid ascospores with rounded to obtuse apices and comparatively short, typically tear-shaped SBs tapered above into a short filum. The living paraphyses contain abundant small or a few large, rather strongly refractive, hyaline VBs which turn yellow in the dead state.

O. yuanensis is assigned to series *Helicoon* here because of its anguillospora-like anamorph with long and slender macroconidia and much smaller microconidia, reminiscent of the anamorph of *O. rosea*. *O. yuanensis* seems to be closely related to *O. hoana* with which it also shares a similar anamorph. *O. hoana* differs in more fusiform ascospores with (sub)acute apices and longer and wider SBs, also in conidial characters (see below). *O. jinguangsiensis* differs in subacute spore apices and in a pseudotripoconidium-like anamorph. Similar spores with short SBs occur in *O. bannaensis* (series *Piliferae* of section *Aurantiorubrae*, Pls 508–509, for the differences see p. 931).

O. rectispora and *O. cardui* (section *Arthrobotrys*) resemble *O. yuanensis* in spore size and shape, also in the short SBs which are, however, wider and more globose and lack a visible attachment. The two species mainly differ in their much shorter, straight, dactylella-like conidia without microconidia. Also *O. pseudocylindrospora* (section *Aurantiorubrae*) and *O. cylindrospora* (section *Orbilia*) closely resemble *O. yuanensis* in spores and SBs, but have desiccation-tolerant apothecia, paraphyses without VBs, also the marginal excipulum is different. Likewise, *O. quercus* (section *Arthrobotrys*) may easily be confused with *O. yuanensis*, but differs in basally tapered spores and shorter SBs, and particularly in

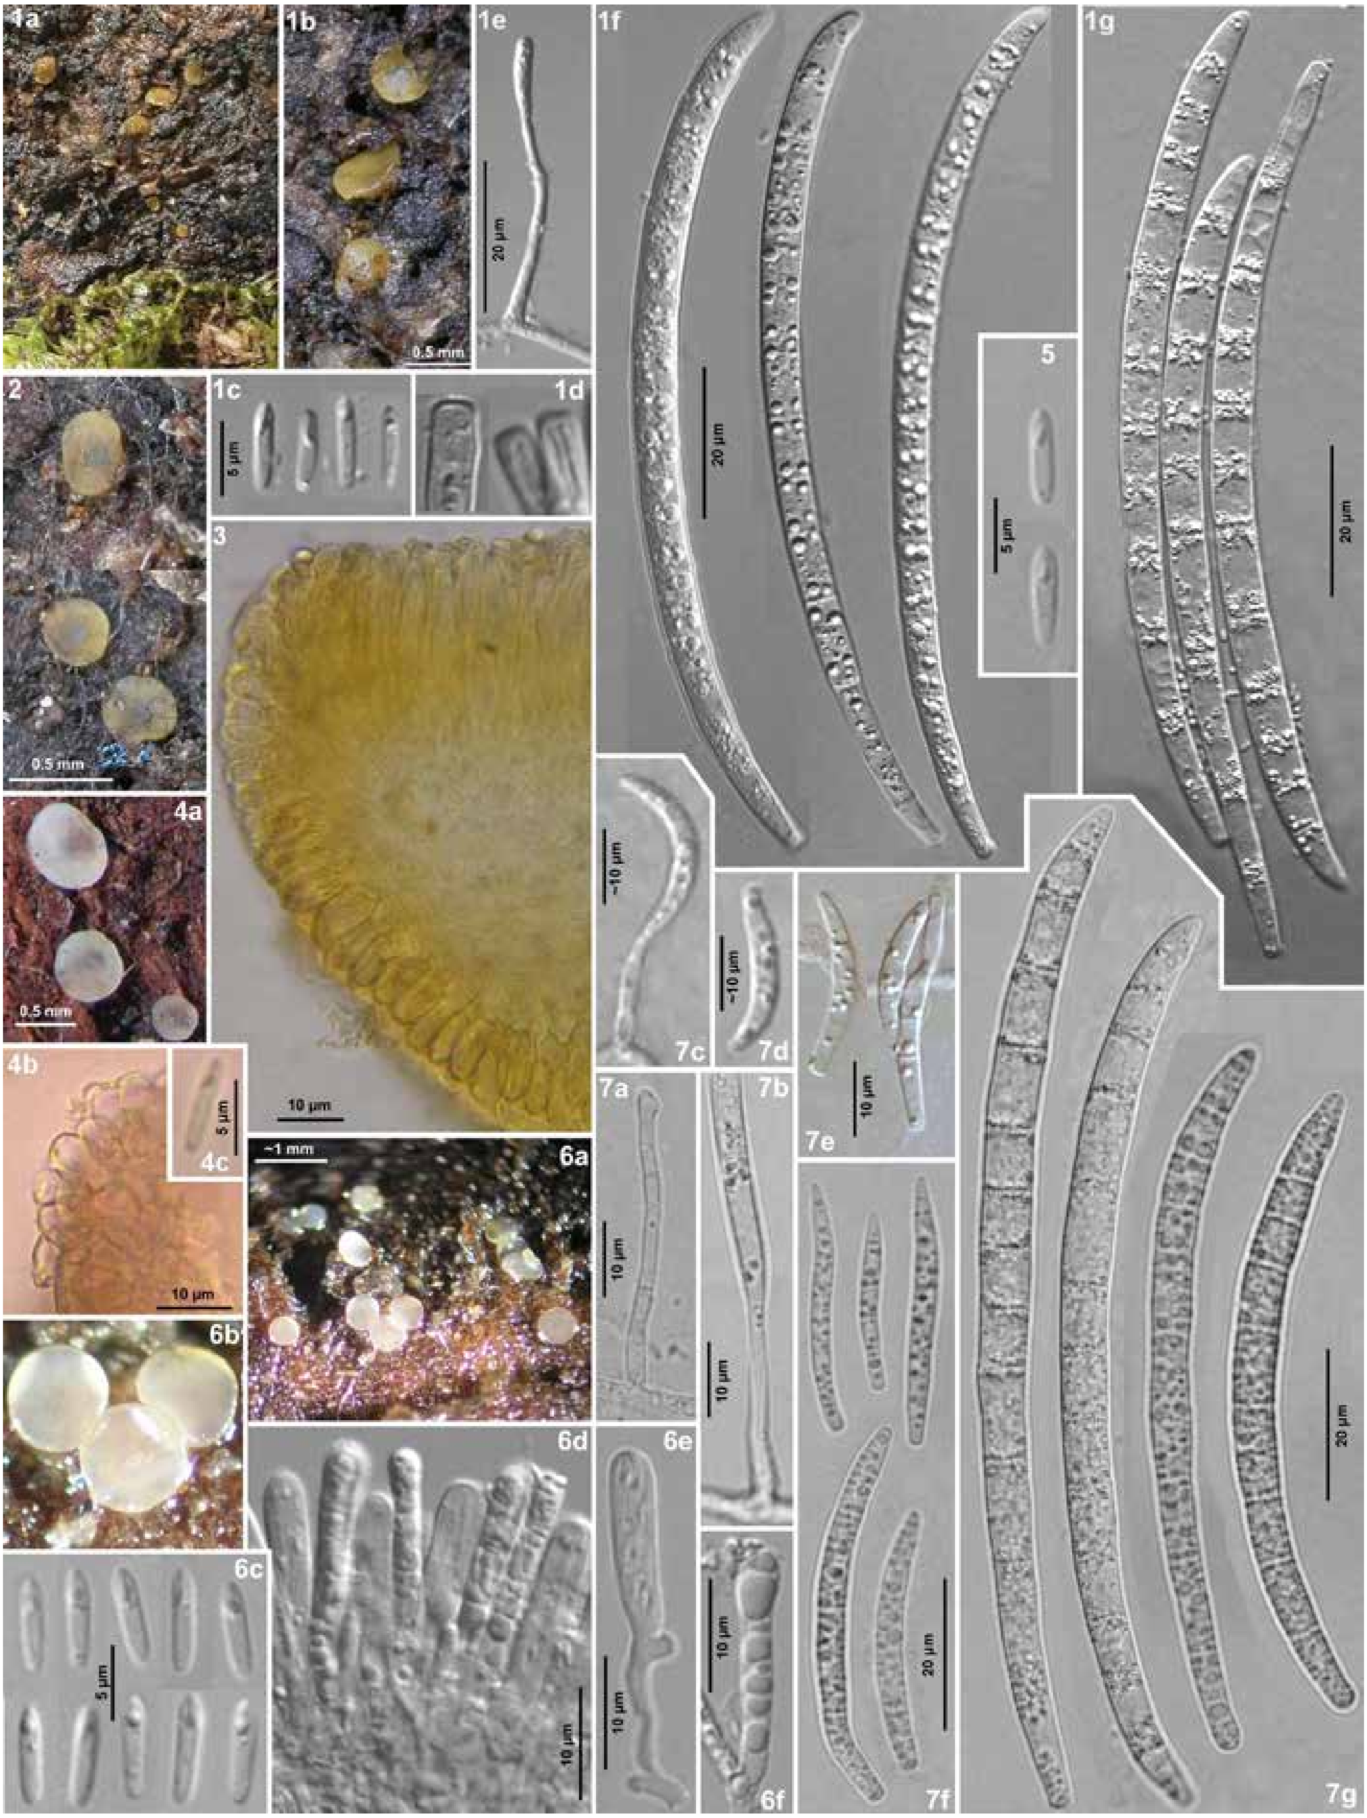

Plate 546. **1–7**: *Orbilia yuanensis*. – **4a**, **6a–b**. fresh apothecia; **1a–b**, **2**. rehydrated apothecia; **3**, **4b**. median section of ectal excipulum at margin and mid flanks; **6d–f**. asci and paraphyses (with VBs); **1d**. ascus apices; **1c**, **4c**, **5**, **6c**. ascospores; **1e**, **7a–b**. macroconidiophores: **7c**. microconidiophores; **1f–g**, **7g**. macroconidia from culture; **7c–f**. microconidia from culture. – Living state, except for **1d–e**, **7c** (in H_2O), asci in **6d–e**. – **1c–g**: phot. YMFT 1.01811 (Y.Z. ya-2): China, Yunnan, Kunming, Qiongzhushi, on *Quercus*; **6a–f**. H.B. 7665 (holotype, Z.F.Y. qlx-3/5): ibid., Qinglongxia, on indet. angiosperm; **7a–g**. YMFT 1.02055 (topotype, Y.Z. qlx-8): ibid.

a dactylellina-like anamorph with much shorter and wider, fusiform conidia.

Variation. *O. yuanensis* varies somewhat in spore shape, some spores being slightly fusoid or fusoid-clavate instead of cylindric-ellipsoid. The spore bodies are rather consistent within a specimen but among the collections they vary a bit in both shape and length. A filum was frequently present in the holotype from Kunming (Pl. 545: 1) and partly also in the paratypes from Dali (3) and Taiwan (4), whereas in other samples from Dali (Pl. 545: 2, apparently also in Pl. 546: 1c), the SBs tend to be longer, vermiform and somewhat flexuous, without distinct filum. Spores with such elongate SBs are very similar to those of *O. jinguangsiensis*.

Apothecial colour was fresh whitish in the specimens from Kunming and Taiwan, while for those from Dali only the yellow colour of the rehydrated apothecia was documented.

Anamorph. The anamorph of *O. yuanensis* (Pl. 546: 1f–g, 5c) resembles that of *O. hoana* in the long, vermiform, slightly curved conidia. In contrast to *O. hoana*, the living conidia contain a very different guttule pattern (medium- to small-sized oil drops aggregated mainly close to the septa). Together with the observed microconidia (Pl. 546: 5b), the anamorph of *O. yuanensis* resembles that of *O. rosea* but its macroconidia are distinctly shorter and wider and possess mainly 11–13 instead of 15–17 septa. Microconidia were only observed in the culture from Kunming but not in that from Dali.

Phylogeny. Sequences of two strains of *O. yuanensis* (topotype qlx-8 and a paratype ya-2) were available, comprising S1506 intron and ITS. They are identical in the entire ITS region except for 4 gaps and a few uncertain nt in the ITS2. In the intron they differ probably by error at the 5'-end by 3 nt and 2 gaps. In our phylogenetic analyses (Phyls 17, S18) the species clustered in section *Helicoon*, though with a rather high distance to other members of series *Helicoon* (ITS 12.5–14.5 %), and a very similar distance (ITS 13.5–14.5 %) to members of series *Pseudotripoconidium*. In the 5.8S region, *O. yuanensis* fully concurs with series *Pseudotripoconidium* (see also Tab. 70), while differing from the remaining members of series *Helicoon* in stem-loop B8 at pos. 117 and 138 (A-T vs. G-C, Tab. 18), whereas the 6 informative positions in the ITS1 region and 3 in the ITS2 (with exceptions in *O. tenuispora*) concur with series *Helicoon* s.str. (see Tab. 70). Possibly, *O. yuanensis* represents some kind of ancestor of both series by showing the plesiomorphic character of the phragmoconidial anamorph.

Ecology. *O. yuanensis* was found on ± rotten hygric wood of *Quercus* and bark of unidentified angiosperm trees in subtropical humid (winter-dry), evergreen broad-leaved mountain forests of southeastern Asia.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, Jinguangsi virgin forest, ~2700 m, branch of indet. angiosperm, on bark, 8.XII.2007, H.Y. Incertae sedis

Orbilia falciformis Z.F. Yu, Baral & K.Q. Zhang, in Y. Zhang et al., Fungal Diversity 36: 142 (2009) — Pls 547–548

Etymology: named after the sickle-shaped ascospores.

Typification: China, Yunnan, Xiaoheijiang, branch of indet. angiosperm, 4.V.2005, M. Qiao (ex H.B. 8696a, M-0140893, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.2 mm diam., 0.07–0.12 mm high, fresh light to bright yellow-orange, rehydrated light amber-yellow-orange, medium translucent, round, scattered to medium gregarious; disc slightly concave to flat, margin thick, not protruding, smooth; sessile, superficial. **Asci** †(25–)30–40 × 3.8–4.3(–4.8) µm, 8-spored, spores †3–4-seriate, ~3–4 lower spores inverted (often mixed), pars sporifera †13–14 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to long, ± thin, flexuous stalk, T- to L-shaped. **Ascospores** *(5.5–)6–6.7(–7.5) × (1.3–)1.5–1.6(–1.8) µm, †5.5–7.3 × (1–)1.1–1.2 µm, cylindric- to fusoid-clavate, apex obtuse to subacute, base (*) not or slightly to strongly attenuated, (†) medium to strongly attenuated (sometimes tail-like), (*/†) medium to very strongly curved; **SBs** *(1–)1.2–2.6(–3.5) × (0.4–)0.5–0.8 µm, elongate tear-shaped to subulate, straight to slightly curved, partly obliquely oriented. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells †12.5–15.5 × 2.2–3 µm, lower cells †3.5–6(–7) × 1.3–1.8 µm; never branched at upper septum, hymenium very pale yellowish-ochraceous. **Medullary excipulum** very pale yellowish-ochraceous, 10–50 µm thick, of dense textura intricata-angularis, medium sharply delimited. **Ectal excipulum** hyaline at base, of (†) thin-walled, vertically oriented t. angularis(-prismatica) from base to margin, 20–30 µm thick near base, cells †6–10 × 4–6(–7) µm; light orange-ochre at flanks and margin, 10–15 µm thick near margin, oriented at a 60–80° angle to the surface, marginal cortical cells †6–8 × 3–5 µm; **glassy processes** absent. **Anchoring hyphae** medium abundant at base, †2–3 µm wide, walls 0.2 µm thick. **SCBs** no data available. **VBs** in paraphyses large, refractive, globose to long-cylindrical, hyaline, in cortical ectal excipulum pale brown. **Exudate** over paraphyses 0.2–0.8(–1.3) µm thick, granular, hyaline, loosely attached, over margin and flanks 0.2–0.5(–1) µm thick, rough-granular, pale yellow. **— ANAMORPH**: unknown.

Habitat: on moist ground, ?15 mm thick corticated branch of unidentified woody angiosperm, on medium decayed bark (periderm), strongly blackened, green algae absent. **Associated**: ?*Tubeufia* sp. **Desiccation tolerance**: unknown (probably intolerant). **Altitude**: 1320 m a.s.l. **Geology**: Jurassic-Cretaceous sedimentary rock. **Phenology**: V.

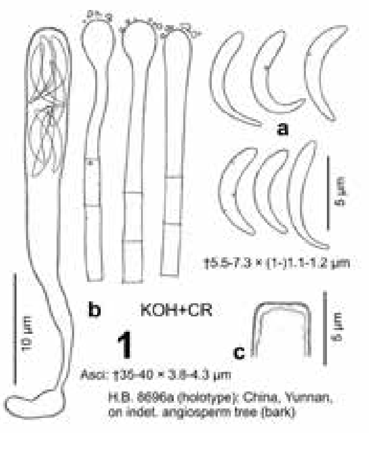

Plate 547. **1**: *Orbilia falciformis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Taxonomic remarks. *Orbilia falciformis* might be related to *O.* aff. *fusiformis* (series *Pseudotripoconidium*), or to *O. yuanensis* (series *Helicoon*) based on the yellow pigment and similar though strongly curved ascospores. The spores and SBs of *O. falciformis* resemble also those of *O. curvativitalbae* (section *Habrostictis*). However, the rather long terminal and short lower paraphysis cells, the included

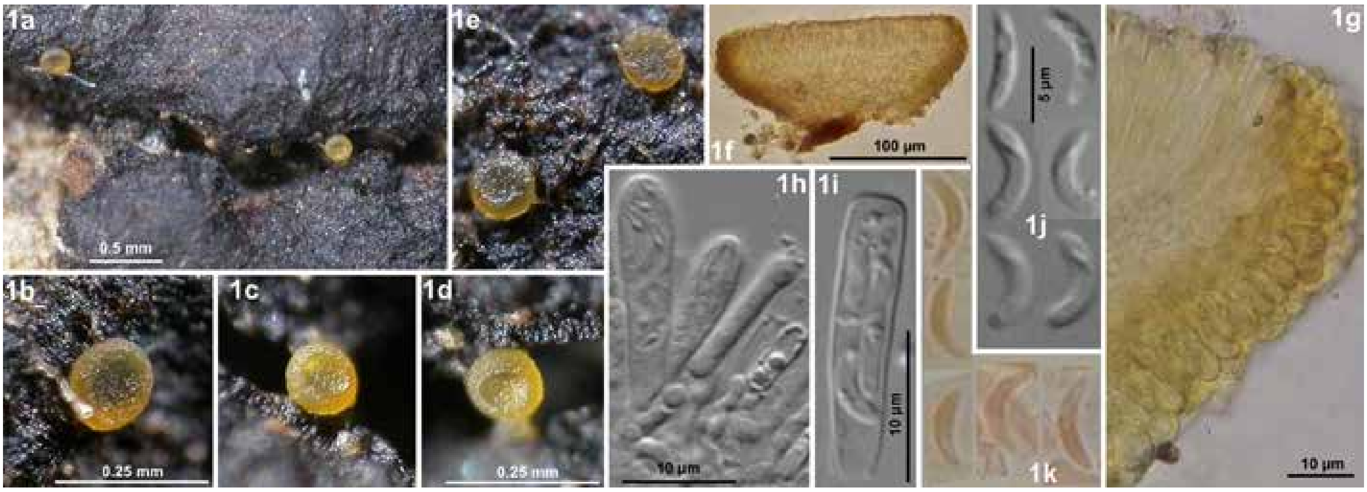

Plate 548. **1**: *Orbilia falciformis*. – **1a–e**. rehydrated apothecia; **1f**. apothecium in median section; **1g**. id., marginal ectal excipulum; **1h–i**. asci and paraphyses; **1j–k**. ascospores. – Living state, except for **1f** (in H_2O), **1g** (in KOH), asci in **1h–i**, **1j** (2 upper spores), **1k** (in KOH+CR). – **1h–j**: from Zhang et al. (2009b, DIC). — **1a–k**. YMFT 030, H.B. 8696a (iso- & holotype): China, Yunnan, on indet. angiosperm.

VBs, and also the thick ascus base from which a thin stalk emerges, are typical of section *Helicoon* but quite unknown in section *Habrostictis*. *O. arcospora* (series *Pseudotripoconidium*) differs in longer spores with longer and narrower SBs, also in a rather hyaline exudate and a rose(-cream) colour of the much larger apothecia.

In the dead state the spores of *O. falciformis* were considerably narrower, also distinctly more tapered at the base, though the curvature remained unchanged. In the fresh state the apothecia were said to have a diameter of 0.2–0.3(–0.5) mm (Zhang et al. 2009b), whereas in the here examined part of the collection (Pl. 548: 1a–d) they measured rehydrated only 0.15–0.2 mm.

Ecology. *O. falciformis* was collected on medium rotten bark of an unidentified woody angiosperm in a shady subtropical humid (winter-dry), evergreen broad-leaved mountain forests in southern China.

Specimens included. **CHINA**: **Yunnan**, **Pu'er**, Ning'er, Xiaoheijiang Forest Park, 1320 m, branch of indet. angiosperm, on bark, 4.V.2005, M. Qiao (YMFT 030, **isotype**; ex H.B. 8696a, M-0140893, **holotype**).

Orbilia martinicensis Baral, Priou & Lechat, **sp. nov.**, MB 813629 — Pls 549–550

Etymology: from the island of Martinique, where the only known collection was made.

Typification: Martinique, Case Pilot, branch of indet. angiosperm, 4.XII.2005, C. Lechat (ex C.L.L. 5525 & ex H.B. 8032, M-0276509, holotype).

Latin diagnosis: *Apothecia rehydratata 1–1.5 mm diam., vivide ochraceo-aurantiaca, subsessilia, margine minute pallide luteo-denticulatae. Ascosporae *2.6–3 × 1.6–2.2 µm, late lacrimiformes, apice acutae vel acuminatae, in statu vivo corpusculum refringens lacrimiformem, filo longo subtenui ad apicem affixum continentes. Paraphyses ad apicem modice clavato-spathulatae, pileo vitreo tectae. Excipulum marginale processis vitreis praeditum. Habitat ad corticem leniter putridum in ramo uvido arboris angiospermae in zona tropica humida Americae centralis.*

Description: — **TELEOMORPH** (mainly from holotype): **Apothecia** rehydrated 1–1.5 mm diam., 0.3–0.45 mm high (receptacle 0.2–0.27 → 0.12–0.15 mm), light ochre-orange {T} with a bright brown translucent centre, or pale cream {1}, round, medium gelatinous, subgregarious; disc flat to slightly convex, margin distinct, 25–30 µm protruding (incl. teeth), finely crenulate by small pale yellowish teeth {T} or smooth {1}; with a distinct short and broad stipe 0.1–0.25 × 0.35–0.8 mm, superficial; dry more convex, bright ochre-orange, centre dark reddish-brown. **Asci** *33–44 × 3.2–3.5 µm {1}, †42–51 × 3–3.5 µm {T}, 8-spored, spores (†) uniseriate, ~4 lower spores inverted (partly some crosswise), pars sporifera †19–21 µm long; **apex** (†) strongly truncate (very slightly indented, laterally not or scarcely inflated); **base** with medium to long, very thin, flexuous stalk, T- to L-shaped. **Ascospores** *2.6–3 × (1.6–)1.9–2.2 µm {2}, †2.5–3 × 1.8–2 µm {T}, broadly tear-shaped (lacrimiform-ovoid), apex acute to acuminate under a rather wide angle, base rounded; often slightly inequilateral, rarely slightly curved; **SBs** *1.8–2.5 × 0.5–0.8 µm in situ {2} (~2.8–3.8 µm actual length), divided into an abruptly swollen, tear- to stomach-shaped lower part and a ± filiform upper part of equal or higher length, strongly flexuous or helicoid to somewhat uncinate. **Paraphyses** apically medium (to strongly) clavate(-spathulate), terminal cells *20–28 × 3.5–4.5(–6.5) µm, †16–30 × 3–3.8 µm {T}, distinctly exceeding the dead asci, lower cells *6–7.5 × 2–2.3(–3) µm {1}, †6–10 × 1.5–2 µm {T}; branched only near base, hymenium pale rose-orange. **Medullary excipulum** hyaline, 25–30 µm thick, of dense textura intricata-angularis, medium sharply delimited. **Ectal excipulum** hyaline, pale orange towards margin, of slightly gelatinized, ambiguously oriented t. globulosa at base and flanks, 250–370 µm thick at base, cells †28–50 × (18–)25–38 µm; vertically oriented towards mid flanks, 40 µm thick at margin, oriented at an 80–90° angle to the surface, submarginal cortical cells †7–17 × 6–8 µm, those at upper margin 10–20 × 4–5 µm; **glassy**

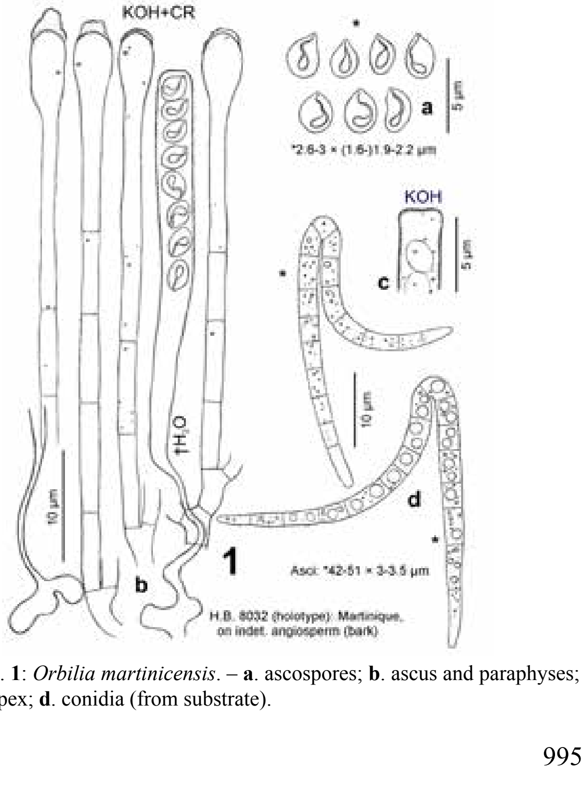

Plate 549. **1**: *Orbilia martinicensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. conidia (from substrate).

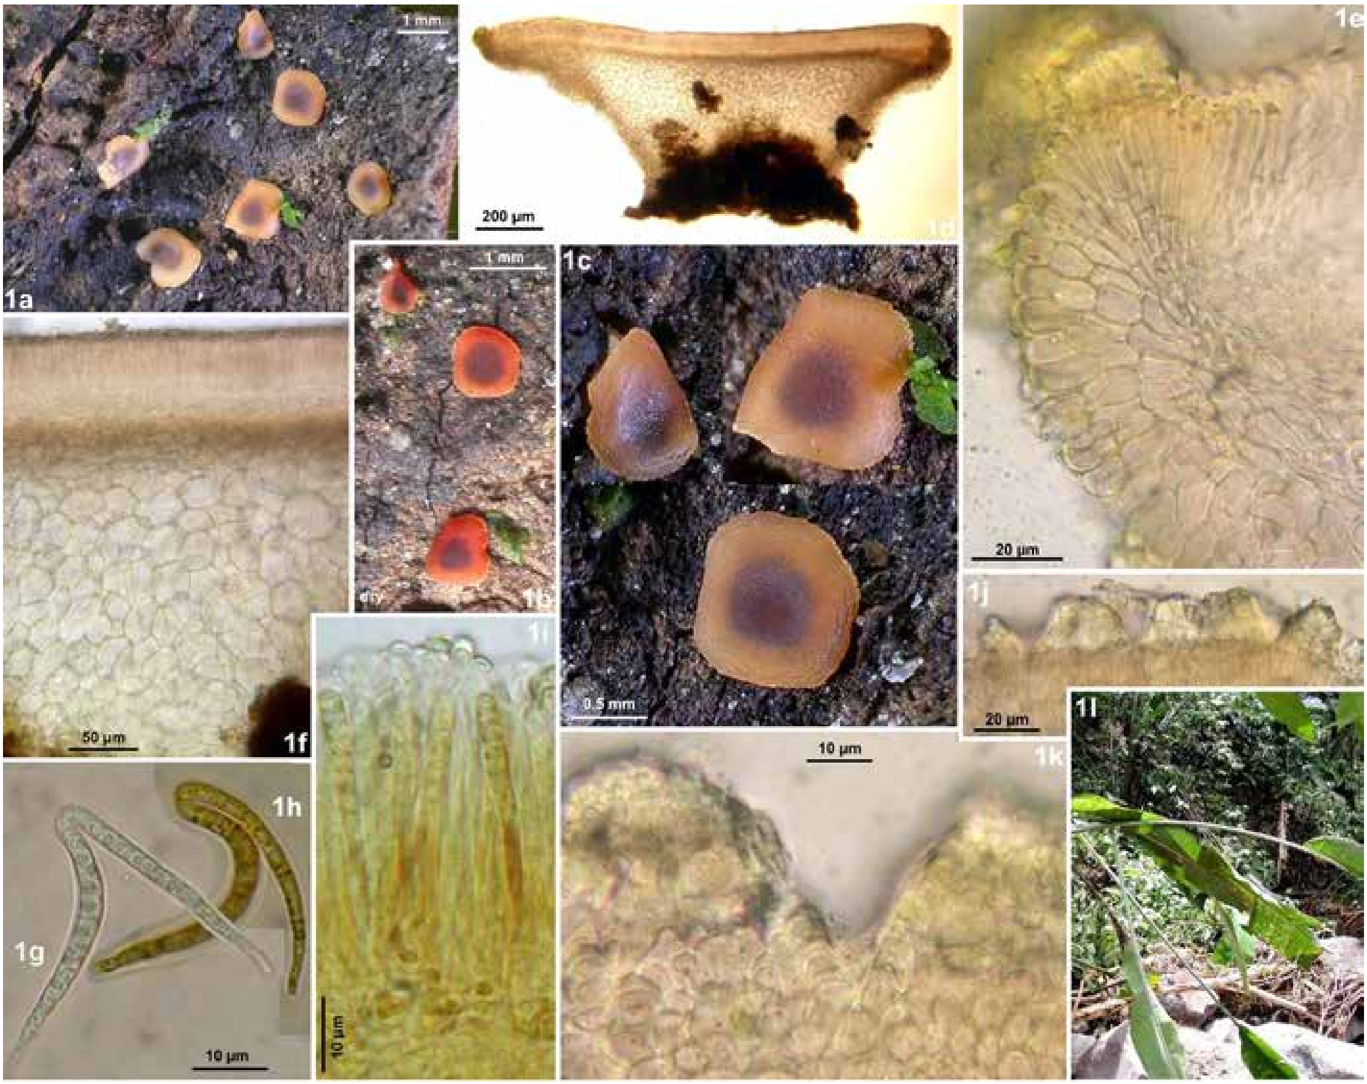

Plate 550. **1**: *Orbilia martinicensis*. – **1a**, **c**. rehydrated apothecia; **1b**. dry apothecia; **1d**. apothecium in median section; **1e**. id., marginal ectal excipulum; **1f**. id., central part of apothecium; **1j–k**. toothed margin (glassy processes, top view); **1i**. asci and paraphyses; **1g–h**. conidia from substrate; **1l**. tropical rainforest at collection site. – Dead state (**1d–f**, **k** in KOH, **1j** in H_2O, **1i** in KOH+IKI, **1h** in IKI), except for **1g**. – **1l**: phot. C. Lechat. — **1a–l**. H.B. 8032 (holotype): Martinique, on indet. angiosperm.

processes at upper margin 8–30 × 3.5–4.5 µm, at submargin only 1–3 µm long, pale yellow, high-refractive, strongly stratified, ± straight, coherent to form distinct teeth, rarely absent {T}. **Anchoring hyphae** sparse (only at base of stipe), †3.5–6(–8.5) µm wide, walls 0.2–0.3 µm thick. **SCBs** not observed; **VBs** in terminal cells of paraphyses low-refractive, elongate, hyaline. **Exudate** over paraphyses forming 0.2–0.5 µm (sometimes 1–3 µm) thick, hyaline, firmly attached caps staining rose in CRB, over margin thin, yellowish. **— ANAMORPH**: unknown (but see below).

Habitat: on moist ground, corticated to ?decorticated, ~1–3 cm thick branches of unidentified broad-leaved trees {2}, on slightly to medium decayed bark (periderm) and ?wood, ungreyed, no algae. **Associated**: *Orbilia aureocrenulata* (on different branch) {1}. **Desiccation tolerance**: only a few spores survived for ~4 weeks in the herbarium. **Altitude**: 345–1475 m a.s.l. **Geology**: volcanic and Mesozoic sedimentary rock. **Phenology**: X, XII (tropical belt).

Taxonomic remarks. *Orbilia martinicensis* is tentatively placed in section *Helicoon* because of its desiccation-sensitive apothecia with a very thick, large-celled ectal excipulum, comparatively long, flexuous SBs, and presence of VBs. Within this group the species is exceptional in its very small, broadly tear-shaped ascospores and in the predominant presence of glassy processes forming teeth at the margin. It resembles at best *O. limoniformis* in which the spores are longer and more fusiform to lemon-shaped, the SBs scarcely inflated below, and the margin without glassy processes.

O. martinicensis might be sought in section *Habrostictis* because of its flexuous, filiform, basally swollen SBs but all known species of this group are desiccation-tolerant and do not possess glassy processes. Glassy processes occur frequently in section *Aurantiorubrae*, but SBs of this type are rather exceptional (e.g., in *O. poitevinica*). The holotype of *O. martinicensis* was received in the dry state with only a few viable ascospores and conidia, therefore, the presence of VBs and absence of SCBs was only observed in the paratype.

The sample from Mexico studied by L. Quijada (pers. comm.) concurs quite well with the holotype except for pale cream apothecia with a smooth margin, and shorter asci. The ascospores measured *2.8–3 × 1.9–2.1 µm according to the scale, and the SBs 2.1–2.5 × 0.6–0.8 µm.

Anamorph. Unbranched, multiseptate conidia were observed on the natural substrate of the holotype, which were extraordinary in their very sharp bend in the middle (~180°) simulating V-shaped dicranidion-like stauroconidia (Pl. 549: 1d, conidia *32–37 × 20–33(–37) µm in situ, *67–80 µm actual length, ~16–17-septate, lower part ± straight to slightly curved, upper part medium to strongly curved, cells *2.5–3 µm wide, containing several small and often 1–2 large LBs). Contrary to dicranidion-like conidia, these were obviously formed at the truncate end of the ± straight arm. They closely match *Condylospora spumigena* Nawawi except for somewhat shorter arms. However, the connection to *O. martinicensis* is improbable because a BLAST search with an LSU sequence (NBRC107639) of *C. vietnamensis* (with twice bent conidia) gave an unclear result (*Leotiomycetes* and *Dothideomycetes*).

Ecology. *O. martinicensis* was collected on slightly to medium decayed hygric angiosperm bark and ?wood in the Caribbean region. The holotype was from a tropical humid lowland rainforest in the centre of Martinique (C. Lechat pers. comm.), and the paratype from a subtropical humid (mesophilic) mountain rainforest (L. Quijada pers. comm.). Considering the large excipular cells, the habitat, and the absence of living asci and vegetative cells in the holotype, the species is obviously desiccation-sensitive like other members of section *Helicoon*.

Specimens included. **LESSER ANTILLES**: **Martinique**, 5 km NNW of Fort de France, 6 km ENE of Case Pilot, Rivière Duclos, 345 m, branch of indet. angiosperm, on bark, 4.XII.2005, C. Lechat, vid. J.P. Priou (ex C.L.L. 5525/H.B. 8032, **holotype**, M-0276509). — **MEXICO**: **Veracruz**, 8.5 km WSW of Xalapa, 1 km SW of Rancho Viejo, Rancho Agüita Fría, 1475 m, branch of indet. angiosperm, on ?wood, 22.X.2018, L. Quijada & R. Medel (doc. vid.).

Series *Pseudotripoconidium*

Orbilia subgenus ***Habrostictis*** section ***Helicoon*** series ***Pseudotripoconidium*** (Z.F. Yu & K.Q. Zhang) Baral & E. Weber, **comb**. **& stat**. **nov**., MB 815018 – Type species: *Pseudotripoconidium sinense* Z.F. Yu & K.Q. Zhang (≡ *Orbilia sinensis* (Z.F. Yu & K.Q. Zhang) Baral, Z.F. Yu & E. Weber)

Basionym: *Pseudotripoconidium* Z.F. Yu & K.Q. Zhang, in Yu et al., Mycologia 103(1): 168 (2011).

Etymology: named after the conidial shape which resembles that in *Tripoconidium* Subram.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–1.3(–1.6) mm diam., margin not protruding, smooth. **Asci** *30–60 × 3.5–5.5 µm, lower (exceptionally upper) (2–)3–5(–6) spores inverted. **Ascospores** *(4–)5–15(–17) × 0.8–1.8(–2.2) µm, cylindric-fusoid to fusiform or limoniform, apex rounded to acute, straight to slightly, in *O. arcospora* strongly curved; **SBs** (2–)2.5–7(–8) × (0.1–)0.2–0.5(–0.6) µm (actual length), filiform to subulate. **Ectal excipulum** cells near base *(9–)15–25(–35)((–45)) × (8–)10–20(–25)((–35)) µm. — **ANAMORPH**: pseudotripoconidium-like. **Conidiophores** erect, 35–165 µm long, bearing 3–8 prominent, mainly laterally projecting denticles at the tip (candelabrelloid). **Conidia** non-septate, *(4.7–)5.5–8(–9) × (3–)3.5–6(–6.5) µm, clavate or inversely tear-shaped to pyramidal, with or without 2–8 indistinct to prominent, nipple-shaped lateral protuberances at the distal end, containing 1–2(–5) rather large LBs; **conidial dimorphism** not observed.

Habitat: on hygric wood and bark of angiosperms, desiccation-sensitive, temperate to subtropical, humid.

Recognized species: 8, plus 2 unnamed species (‘affinis’).

Taxonomic remarks. Series *Pseudotripoconidium* is sharply delimited from series *Helicoon* on the basis of its peculiar anamorph. From the morphology of the teleomorph the two series can hardly be separated, however. Series *Pseudotripoconidium* tends to ascospores with narrower, more often filiform SBs. We have tentatively included in this series also three species (*O. limoniformis*, *O. subuliformis*, *O. arcospora*) in which the anamorph is unknown and molecular data lacking, merely because of their filiform SBs.

Species delimitation. The species here included in series *Pseudotripoconidium* are mainly identified by ascospore and spore body size and shape, and by spore orientation within the asci, while they are otherwise rather similar. However, there is almost a continuum in spore size and shape between many of the species, and the here presented species concept is a rather tentative one. A major part of the species was collected only 1–3 times, therefore, infraspecific variation is little known. As also stated under series *Helicoon*, the important characteristic of inverted spores is almost impossible to study in herbarium material.

Anamorph. Conidia and conidiophores in series *Pseudotripoconidium* are rather uniform, differing among the here accepted species often only slightly, especially in the number and length of protuberances on the conidia. For this reason, a majority of species of series *Pseudotripoconidium* cannot be differentiated from their anamorph alone (see also p. 240). Seifert et al. (2011) described the conidiogenesis in this genus as rhexolytic, obviously based on TEM-images by Yu et al. (2011), but LM photos of living conidia in Yu et al. clearly show that conidial secession is schizolytic.

Phylogeny. Sequences of four Chinese ascospore isolates included by Yu et al. (2011) in *Pseudotripoconidium sinense* comprise the ITS region and partly also LSU, while some of them possess the S1506 intron. In the ITS these isolates show some variation in correlation with considerable differences in ascospore length and slight deviations in conidial size (length) and shape (number of protuberances). In Yu et al.’s phylogenetic analysis they clustered in a highly supported monophyletic clade with one of Pfister’s North American ascospore isolates (D.H.P. 146, as *Orbilia* sp.), in which no anamorph developed, and, as the most basal sequence, a Chinese ascospore isolate (*O. luteorubella*, gz-08), which formed helicoon-like conidia and which is confirmed as belonging to *O. luteorubella*.

Based on our studies of teleomorph morphology and our phylogenetic analyses that include more sequences, we conclude that the four Chinese isolates with a pseudotripoconidium-like anamorph belong to three different species: *O. sinensis* (YMF 1.01843, 1.03475, D.H.P. 146), *O. tenuispora* (YMF 1.03007), and *O.* aff. *fusiformis* (YMF 1.01848). Series *Pseudotripoconidium* formed a highly supported monophyletic clade within section *Helicoon* when analysing ITS or the S1506 intron, or a clade with medium support when analysing LSU or ITS+LSU (Phyls 17–18, S18–S19) *O. tianmushanensis* clustered within the clade only in the latter two phylograms. The three recognized species appear to be heterogeneous, however, showing interspecific ITS distances of 4–8.5%, but 2.8–4% within *O. sinensis* and 2.4% within *O. tenuispora*, which questions the homogeneity of these species.

In the ITS region (Phyl. 17), *O. tianmushanensis* and a strain from Tibet (*Orbilia* sp., B.L. X079) clustered rather distant from the core of series *Pseudotripoconidium*. The two sequences show at some characteristic positions either the character of series *Helicoon* or that of series *Pseudotripoconidium*. Also *O. yuanensis*, which clustered with *O. sarraziniana* in series *Helicoon*, behaves in a similar way (Tab. 70). In the LSU D1–D2 (Phyl. 18), *O. tianmushanensis* concurs at 3 positions (176, 577, 582) with series *Pseudotripoconidium* at which series *Helicoon* deviates, and *O.* aff. *sarraziniana* (B.L. 730) at pos. 577 (Tab. 71).

Specific nucleotide positions. Nucleotides which are characteristic of series *Pseudotripoconidium* are listed in Tab. 70 for ITS and Tab. 71 for LSU. The problems of species delimitation within the series are reflected by the available molecular data showing stronger variation in the two strains of *O. sinensis* which do not cluster in a clade in the LSU phylogram (Phyl. 18), compared to *O. tenuispora*. Nevertheless, several positions in the ITS sharply separate the two species, e.g., in the ITS2 pos. 441–447 *O. tenuispora* has AC**T**C**T**GC (like series *Helicoon* p.p.) but *O. sinensis* AC**C**C**A**GC (like *O. tianmushanensis*), and within the LSU D2 pos. 524 and 562 separate *O. tenuispora* (both positions have the motif CT**C**TG) from the more variable *O. sinensis* (524: TC**T**CG or CG**T**TG, 562: CT**T**GG or CT**T**CG).

Ecology. Most of the known species grow under a (sub) tropical humid (winter-dry) climate on woody substrates lying on the moist ground. Some species were recorded in temperate areas of the northern hemisphere, though so far not in central Europe. In all of them the apothecia appear to be incapable of surviving desiccation, at least regarding the asci. The role of the peculiar shape of conidia in regard to their ecological adaptation is unknown, but we assume that conidial dispersal is different from series *Helicoon*. Series *Pseudotripoconidium* might have evolved from those Asian species of series *Helicoon* that show a golden-yellow exudate and a slight desiccation tolerance of their apothecia.

Orbilia limoniformis Baral & Hong Y. Su, in Su et al., Mycol. Progress 10: 378, fig. 4 (2011) — Pls 551–552

Etymology: named after the lemon-shaped ascospores.

Typification: China, Yunnan, Jinguangsi, branch of indet. angiosperm, 25.X.2008, H.Y. Su, X.M. Gao & Y.G. Yan (CBCD DLXYXJL1, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.5(–0.7) × 0.25–0.45 mm diam., 0.1–0.13 mm high (receptacle 0.08–0.09 → 0.07 mm), pale cream-yellow, translucent in centre, round (to elliptical), scattered to gregarious; disc slightly concave, finally flat, margin distinct, 10 µm protruding, smooth; sessile on a narrowed base, superficial; dry light yellow-orange with somewhat undulating margin. **Asci** †30–42 × (2.8–)3–3.5 µm {2}, 8-spored, spores (†) obliquely uniseriate, (2–)3–5(–6) lower spores inverted {1} (not or somewhat mixed); **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to long, thin or thick, flexuous stalk, T- or L-shaped. **Ascospores** *(3.8–)4–5(–6) × (1.7–)1.8–2(–2.2) µm {2}, fusiform to narrowly limoniform, apex acute to acuminate, base obtuse to sometimes strongly attenuated, straight to slightly inequilateral; **SBs** *3–4.2 × 0.2–0.4 µm in situ {1} (~3.5–4.5 µm actual length), filiform to subulate, slightly to strongly flexuous (sometimes uncinate). **Paraphyses** (uninflated to) slightly or medium (rarely strongly) (clavate-)capitate, terminal cells †18–23 {1} × (2–)2.5–3.5 µm {2}, *(2.2–)3–4.2(–4.8) µm wide, lower cells †5–7 × 1.3–1.8 µm {1}; never branched in upper part, hymenium pale yellow. **Medullary excipulum** pale yellowish-cream, 20–30 µm thick, of dense textura prismatica-angularis(-intricata), horizontally oriented, indistinctly to sharply delimited. **Ectal excipulum** subhyaline, cortical region especially at flanks and margin light to bright golden-yellow, of (†) thin-walled, indistinctly vertically oriented t. globulosa-angularis from base to mid flanks, 40–60 µm thick near base, cells */†9–17(–20) × 8–14.5 µm {2}; 20–30 µm thick at flanks, 10–15 µm near margin, of t. prismatica oriented at a 70 → 30–50° angle to the surface, marginal cortical cells †7–12 × 3.5–4 µm {1}; **glassy processes** absent. **Anchoring hyphae** sparse, †2–4 µm wide, walls 0.2(–0.3) µm thick {1}. **SCBs** in cells of basal ectal excipulum globose, 1.5–2.2 µm diam., medium refractive, also absent; **VBs** abundant in terminal cells of paraphyses, globose to elongate, medium refractive, pale yellow, in dead state some cells with light golden-yellow remnants. **Exudate** over paraphyses 0.3–1(–1.5) µm thick, granular-continuous, hyaline to light yellow, loosely attached, over margin and flanks 1–2(–3) µm thick, continuous to cloddy, light to bright golden-yellow. **— ANAMORPH**: unknown.

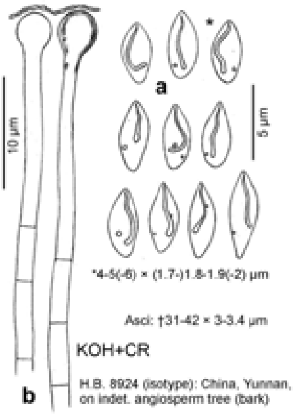

Plate 551. **1**: *Orbilia limoniformis*. – **a**. ascospores; **b**. paraphyses.

Habitat: on moist ground, decorticated or corticated branches of *Pinus* sp. {1}, unidentified woody angiosperm {1}, on medium decayed wood {1} or bark {1} (periderm), partlially blackened, green algae absent. **Associated**: *Farlowiella carmichaeliana* {1}, *Orbilia fusiformis* {1}, *O. jinguangsiensis* {1}. **Desiccation tolerance**: ascospores still viable after 3 weeks and basal excipular cells after 2.5 months. **Altitude**: 2730 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: X, XII.

Taxonomic remarks. *Orbilia limoniformis* is quite easily recognized by its fusiform to limoniform ascospores with a length/width ratio distinctly below 3, and filiform SBs of almost the length of the spores. *O. fusiformis* appears to be closely related based on its very similar SBs, but differs in longer and narrower spores. Also *O. hoana* (series *Helicoon*) differs from *O. limoniformis* in spores with a length/width ratio distinctly above 3, but also in much wider, usually tear-shaped SBs of half the spore length as a maximum. *O. martinicensis* has much shorter, tear-shaped spores and basally strongly inflated SBs, also larger, ochre-orange apothecia with glassy processes at the margin.

Variation. The two studied collections match each other very well, though they grew on very different substrates.

Ecology. *O. limoniformis* is only known from a single collection site, where it grew on medium rotten wood of *Pinus* and bark of an unidentified angiosperm in a subtropical humid (winter-dry), evergreen broad-leaved mountain forest in southern China.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, Jinguangsi virgin forest, 2730 m, branch of *Pinus*, on wood, 8.XII.2007, H.Y. Su (H.Y.S. jgs-4, CBCD, H.B. 8767). – ibid., branch of indet. angiosperm, on bark, 25.X.2008, H.Y. Su, X.M. Gao & Y.G. Yan (H.Y.S. jgs-25, CBCD DLXYXJL1, **holotype**; H.B. 8924, **isotype**).

Orbilia fusiformis Baral & Hong Y. Su, **sp. nov.**, MB 813650 — Pls 553–556

Etymology: named after the fusoid to fusiform ascospores.

Typification: China, Yunnan, Jinguangsi, branch of *Pinus*, 8.XII.2007, H.Y. Su (ex H.B. 8766a, M-0276488, holotype).

Latin diagnosis: Orbiliae limoniformi *similis sed ascosporae longiores et angustiores, apice partim obtusae, basi partim obtusae. Status anamorphicus:* Pseudotripoconidium *sp. Habitat ad lignum putridum ramorum uvidorum arborum coniferarum vel angiospermarum in zona subtropica humida Asiae meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.35–0.75 mm diam., 0.14 mm high (receptacle 0.1 → 0.06 mm), fresh whitish to pale pink or cream-yellow, rehydrated light honey-yellow to yellowish-orange, slightly gelatinous, (semi)translucent, round, scattered to subgregarious; disc concave to flat, margin thin or thick, not protruding or upwards curved, smooth; sessile on a hidden stipe 0.04 × 0.12 mm, superficial, dry light orange(-ochraceous). **Asci** †(30–)38–44 × 3–4 µm {2}, 8-spored, spores (†) ± biseriate, 3–6 lower spores inverted {2}

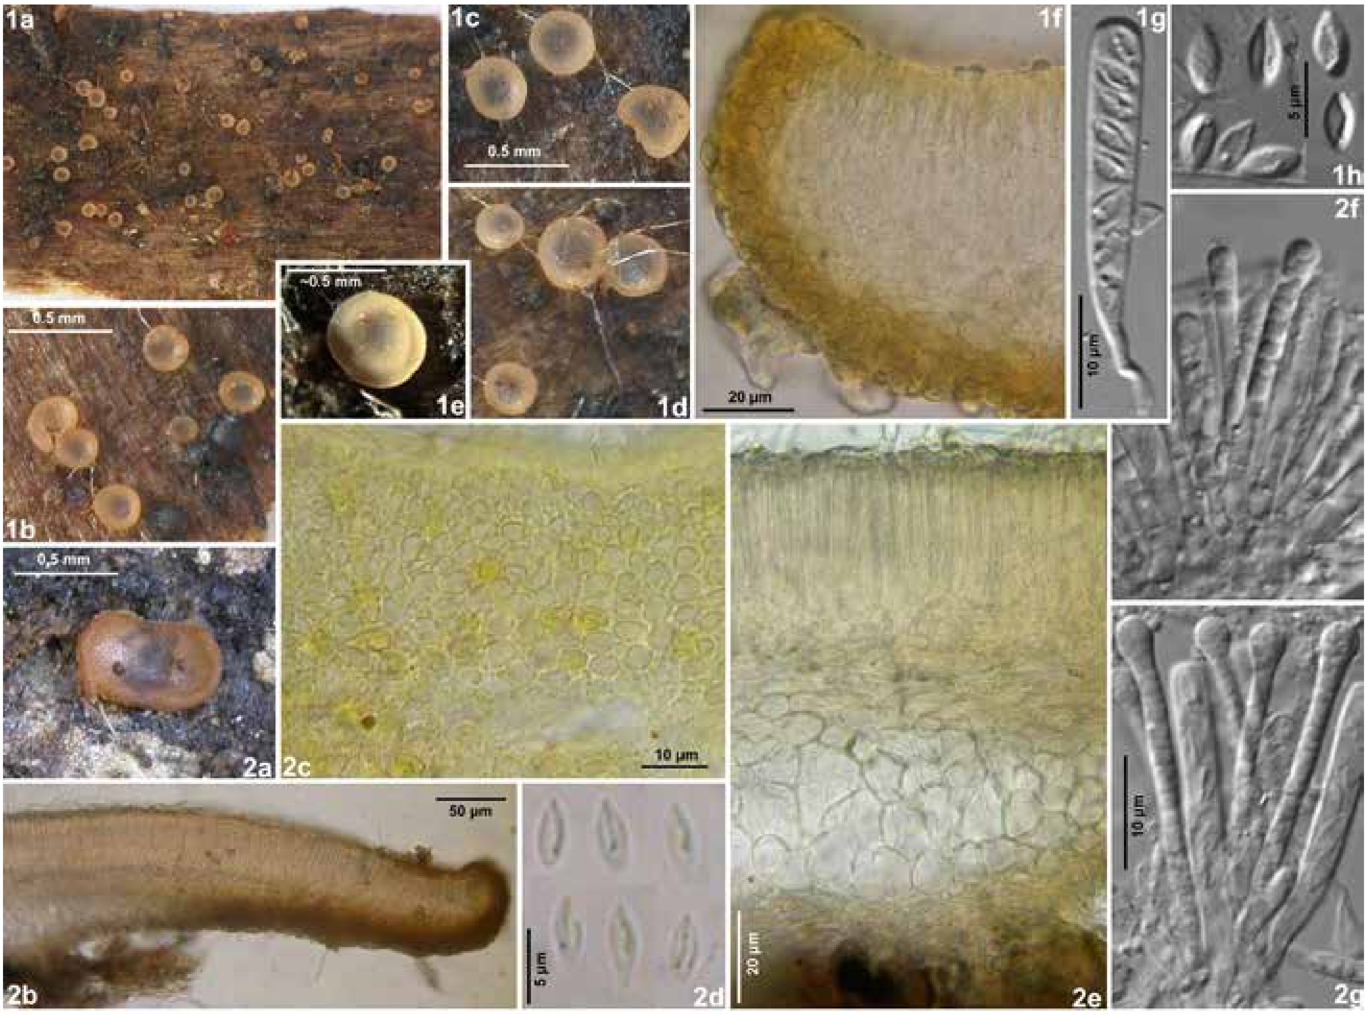

Plate 552. **1–2**: *Orbilia limoniformis*. – **1a–d**, **2a**. rehydrated apothecia; **1e**. fresh apothecium; **2b**. apothecium in median section; **1f**. id., marginal region; **2e**. id., central part of apothecium; **2c**. marginal excipulum in external view; **1g**, **2f–g**. asci and paraphyses; **1h**, **2d**. ascospores. – Living state, except for **2b–c**, **e** (in H_2O), asci in **1g**, **2g**. – **1e**, **g–h**, **2f–g**: phot. H.Y. Su (p.p. from Su et al. 2011c, DIC). — **1a–h**. H.B. 8767 (holo-/isotype): China, Yunnan, Dali, on *Pinus*; **2a–g**. H.B. 8924: ibid., on indet. angiosperm.

(often mixed, sometimes 1 upper spore inverted); **apex** (†) strongly truncate (not indented, laterally not or slightly inflated); **base** with medium to long, thin, flexuous stalk, L-shaped. **Ascospores** *(4.5–)5–7(–7.5) × 1.3–1.6(–1.7) µm {2}, †5–7 × 1.3–1.5 µm {T}, fusoid to sometimes fusiform, homopolar, apex obtuse to acute, base slightly to strongly tapered, rounded to subacute, straight to slightly inequilateral; **SBs** *3–4.5 × 0.2–0.4(–0.5) µm in situ {2} (~4–4.5 µm actual length), narrowly subulate, slightly to medium flexuous or helicoid. **Paraphyses** apically medium to very strongly clavate-capitate, terminal cells †15–22 × 2.5–4 µm {2}, lower cells †5–8 × 1.3–2 µm wide {T} (near base up to 2.5 µm wide); branching not seen, hymenium bright yellow in upper half. **Medullary excipulum** hyaline, 30 µm thick, of medium dense, slightly gelatinized, irregularly horizontally oriented textura ~prismatica, with many inflated cells, sharply delimited from ectal excipulum only towards margin. **Ectal excipulum** pale to bright yellow, of (†) thin-walled, indistinctly oriented t. globulosa-angularis from base to mid flanks, 60–70 µm thick near base, cells *14–25 × 10–20(–23) µm {T}; 40 → 20 µm thick at flanks, 18 µm at margin, of t. prismatica-globulosa oriented at a 80–90° angle to the surface, marginal cortical cells †8–9 × 3.5–5.5 µm {T}; **glassy processes** absent. **Anchoring hyphae** sparse at base, †3–4 µm wide, walls 0.2–0.3 µm thick {T}. **SCBs** not seen; **VBs** unknown. **Exudate** over paraphyses 0.2–1 µm thick, rough-cloddy, light yellow-chlorinaceous, firmly and individually attached, over margin and flanks 1–2(–2.5) µm thick. — **ANAMORPH**: pseudotripoconidium-like (from ascospore isolate {1}). **Conidiophores** not clearly seen. **Conidia** *5.5–9(–11.5) × (3.2–)3.5–3.8 µm {1}, inversely tear-shaped to clavate, without protuberances, containing 1(–2) LBs of 1.3–2 µm diam.

Habitat: on moist ground, decorticated or corticated, 4–5 cm thick branch or thicker log of *Pinus* sp. {1}, indet. angiosperm {1}, on medium decayed wood {1} or bark (periderm) {1}, partly in beetle galleries, partly darkened, without algae. **Associated**: *Farlowiella carmichaeliana* {1}, *Orbilia jinguangsiensis* {1}, *O. limoniformis* {1}, *O. tenuispora* {1}. **Desiccation tolerance**: many excipular cells and ascospores still alive after 3 months. **Altitude**: 2730 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: X, XII.

Taxonomic remarks. *Orbilia fusiformis* resembles *O. limoniformis* in the shape of the ascospores which are, however, longer and narrower, also in long and narrow SBs. *O. juruensis* (series *Helicoon*) fits well regarding spore size and shape, but differs in wider SBs and in the upper instead of lower spores being inversely oriented. *O. jinguangsiensis* deviates from *O. fusiformis* in shorter SBs and narrower spores. *O. hoana* differs in much wider SBs and a ver-

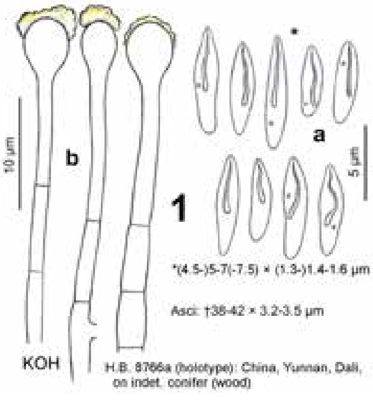

Plate 553. **1**: *Orbilia fusiformis*. – **a**. ascospores; **b**. paraphyses.

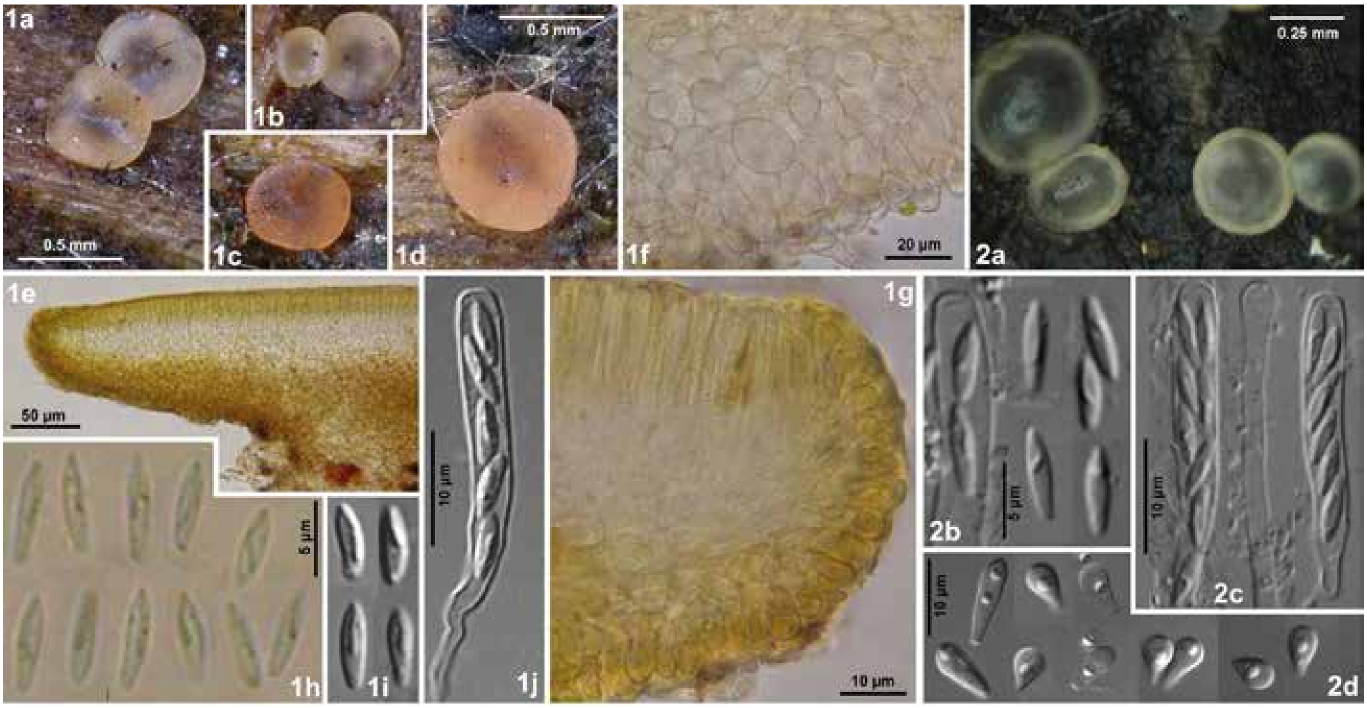

Plate 554. **1–2**. *Orbilia fusiformis*. – **1a–d**. rehydrated apothecia; **2a**. fresh apothecia; **1e**. apothecium in median section; **1g**. id., marginal ectal excipulum; **1f**. id., basal ectal excipulum: **1j**, **2c**. mature asci, paraphysis; **1h–i**, **2b**. ascospores; **2d**. conidia (from culture). – Living state, except for **1g** (in KOH), **1e** (in H_2O), asci and paraphysis in **1j**, **2b–c**. – **1i–j**, **2a–d**: phot. H.Y. Su (DIC). — **1a–j**. H.Y.S. jgs-3, H.B. 8766a (holotype): China, Yunnan, Dali, on *Pinus*; **2a–d**. H.Y.S. jgs-30: ibid., on indet. angiosperm.

mispora-like anamorph. Species of section *Habrostictis*, e.g., *O. jurana* or *O. ungulata*, resemble these collections in spore characters, but possess orange, desiccation-tolerant apothecia, the latter also crystalloid SCBs and a trinacrium-like anamorph.

Variation. Although the two included specimens grew on different substrates (holotype: on wood of conifer, paratype: on bark of angiosperm), differences worth to mention could not be discovered between them.

Not included collections. The three samples shown in Pls 555–556 resemble *O. fusiformis*, but tend to have wider spores and SBs. The one from Yingjiang (Pl. 556: 3), with spores *6–7.5(–10) × 1.4–1.8(–2) µm and SBs 3.3–4.7(–5.5) × 0.4–0.6 µm, differs also in spore orientation (often upper spores inverted and lower spores not), and in the anamorph. The anamorph of the other two is unknown, and the SBs measured here 1.8–3 × (0.2–)0.4–0.6 µm. In the collection from Australia the lower spores were usually inverted, but often also 1–2 upper spores. This collection was on a horizontal branch 0.5–1.5 m above the ground in a tropical forest and seems to exhibit a certain desiccation tolerance (many excipular cells were still viable after 11 months). It differs from *O. fusiformis* also in shorter terminal cells of the paraphyses (8–15 µm), whereas in the third sample (from Yongping) they showed a length of 18–25 µm. A close relationship of the samples from Australia and Yongping to *O. hoana* cannot be excluded.

Anamorph. The clavate conidia obtained in pure culture of the paratype differ from typical species of *Pseudotripoconidium* in the total absence of protuberances (Pl. 554: 2d). In contrast, distinct protuberances characterize the not included specimen from Yingjiang (Pl. 556: 3d–g).

Phylogeny. A sequence from an ascospore isolate of the not included specimen from Yingjiang (YMF 1.01848) comprises SSU V1–V3, S1506 intron, ITS, and LSU. In the ITS region it shows a distance of 5–8.5 % to the other species of series *Pseudotripoconidium*, the lowest percentage to the holotype of *O. sinensis* (YMF 1.01843). In the intron the distance is 8 % to *O. tenuispora* but ~16–20 % to other species of section *Helicoon*. In the LSU the distance to other sequences of series *Pseudotripoconidium* is 2–3.5 % in the D1–D2 domain. The version MH877761 in GenBank (as CBS 121220) is probably a confusion and refers to CBS 121221 by providing a cleaner LSU version of that strain (see under *O. sinensis*, p. 1006).

Ecology. The holo- and paratype of *O. fusiformis* were collected at the same site as the holo- and paratype of *O. limoniformis*, in a subtropical humid (winter-dry), evergreen broad-leaved mountain forest in southern China. Like *O. limoniformis*, *O. fusiformis* grew on medium rotten hygric wood of *Pinus* and bark of an unidentified angiosperm. Also *O.* aff. *fusiformis* grew under similar conditions in southern China, partly at the same site. The Australian collection was on a xeric branch in the tropical humid Daintree Forest in the lowlands of northeastern Australia.

Qiao (Z.F.Y. yj-1, YMFT 1.01848, anam. cult., CBS 121221, doc. vid.; sq.: MH179520, EF026114, EF026115, MH877761 as CBS 121220). — **AUSTRALIA**: **Queensland**, Wet Tropics, Daintree Forest, 21 km N of Mossman, 8 km ESE of Daintree, Cape Tribulation Rd, Daintree Swamp, 5 m, branch of *Barringtonia racemosa*, on wood, 29.VIII.2006, G. Marson (H.B. 8578c).

Orbilia subuliformis Baral, **sp. nov.**, MB 813651 — Pl. 557

Etymology: named after the subulate ascospores.

Typification: Puerto Rico, El Yunque, branch of indet. angiosperm, 18.I.1996, D.H. Pfister & F.A. Harrington (ex D.H.P. PR 43, FH 304919, holotype).

Latin diagnosis: *Differt ab* Orbilia sinensi *ascosporis multo brevioribus, ascosporis superioribus inverse orientatis. Habitat ad corticem putridum rami uvidi arboris angiospermae in zona tropica humida Americae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.5 mm diam., 0.12 mm high (receptacle 0.095 mm), pale cream(-chlorinaceous), ± scattered; disc flat, margin indistinct, not protruding, smooth; sessile on a very short stipe of 20 × 130 µm, superficial. **Asci** †~28–30 × 3.6–4 µm, 8-spored, spores †~4-seriate, upper spores inverted; **apex** (†) strongly truncate (hardly indented, laterally not inflated), thin-walled; **base** with long, thin, flexuous stalk, basal end never clearly seen. **Ascospores** †5.5–6.5 × 0.8–0.9(–1) µm, cylindric (fusoid-)clavate (subulate), apex obtuse to subacute, base widest, rounded to obtuse, straight to slightly inequilateral; **SBs** †2–2.2 × 0.3 µm, vermiform-subulate, straight. **Paraphyses** apically strongly capitate, terminal cells †14–20 × (2.5–)3–4 µm, lower cells †7–11 × 1.6–2.3 µm wide; unbranched at upper septum, hymenium pale yellow. **Medullary excipulum** 15 µm thick. **Ectal excipulum** of t. angularis from base to mid flanks, 70 µm thick near base, cells †18–28 × 10–16 µm; at margin of vertically oriented t. prismatica-globulosa, marginal cortical cells †8–12 × 4–7 µm; **glassy processes** absent. **Anchoring hyphae** not seen. **VBs** in some paraphyses seen as deformed bodies (†), yellowish, refractive, elongate-angular. **Exudate** over paraphyses 0.3–0.5 µm thick, granular, ?hyaline. — **ANAMORPH**: unknown.

Habitat: on moist ground, ~3.5 cm thick branch (‘log’) of indet. angiosperm, on slightly decayed bark (periderm). **Associated**: *Hyalorbilia citrina*. **Desiccation tolerance**: unknown, probably intolerant. **Altitude**: ~650 m a.s.l. **Phenology**: I (tropical belt).

Taxonomic remarks. *Orbilia subuliformis* is tentatively proposed as a distinct species based on the rather short and narrow ascospores of a subulate shape. The spores were only seen inside the asci, and the SBs only in one ascus when stained in KOH+IKI. Due to the heteropolar spore shape the inverse orientation of the upper spores was seen in several asci.

Ecology. The sparse holotype was collected on slightly decayed bark of a thin hygric log in a tropical humid rainforest of Puerto Rico (Caribbean region).

Specimens included. **PUERTO RICO**: Sierra de Luquillo Mts., El Yunque, trail from Sierra Palm to Mt. Britton, ~650 m, branch of indet. angiosperm, on bark, 18.I.1996, D.H. Pfister & F.A. Harrington (ex D.H.P. PR 43 [mixture with *Hyalorbilia citrina*], FH 304919, **holotype**; H.B. 5953 ø).

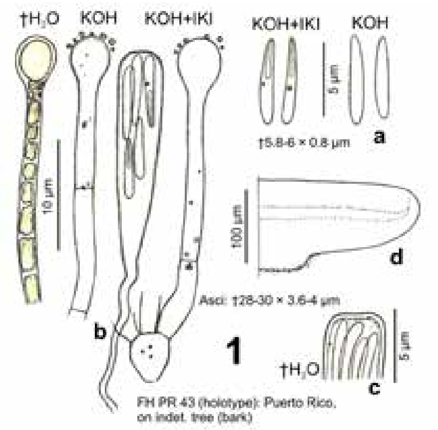

Plate 557. **1**: *Orbilia subuliformis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section.

Orbilia jinguangsiensis Baral & H.Y. Su, **sp. nov.**, MB 813652 — Pls 558–559

Etymology: named after the Jinguangsi virgin forest in Dali (Yunnan, China).

Typification: China, Yunnan, Jinguangsi, branch of indet. angiosperm, 8.XII.2007, H.Y. Su, R.X. Bi & J. Li (ex H.B. 8784, M-0276495, holotype).

Latin diagnosis: Orbiliae sinensi *similis sed ascosporae breviores et latiores, corpusculis refringentibus brevioribus. Habitat ad corticem vel lignum putridum ramorum et truncorum uvidorum arborum coniferarum vel angiospermarum in zona mesotemperata ad subtropica humida Asiae orientalis et Africae australis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.27–0.4 {3} or 0.5–1.3(–1.5) {1} mm diam., 0.12–0.3 mm high (receptacle 0.075–0.11 → 0.06–0.07 mm), pale orange when fresh, rehydrated pale cream to light honey-yellowish-amber, hardly translucent, round to irregular, scattered to subgregarious; disc slightly concave {2} or flat {1} to often medium convex {T}, margin rather thick, 7–10 µm protruding, smooth; stipe indistinct {2} or 0.07–0.15 × 0.45 mm {1}, superficial. **Asci** †(22–)27–40(–45) × 3.5–4.5(–4.8) µm {3}, 8-spored, spores †2–4-seriate, lower ~4 spores inverted {2}, pars sporifera †12–20 µm long; **apex** (†) strongly truncate (not {1} or distinctly indented {T}, laterally not inflated), thin-walled; **base** with a medium to very long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *(5–)6–7.5(–8) × 1.2–1.3(–1.4) µm {2}, †(5–)5.5–7(–7.5) × 1–1.2(–1.3) µm {4}, cylindrical to slightly fusoid or fusoid-clavate, apex subacute, base not or slightly attenuated, rounded or obtuse, straight; **SBs** *(2–)2.5–3 × 0.2–0.3 µm {2}, filiform-subulate, slightly to medium flexuous. **Paraphyses** apically uninflated or mostly slightly to medium capitate(-clavate), terminal cells */†15–19 × 2–3.3 µm {2}, lower cells *4–6 × 1.5–2 µm {1}, †3–4.5 × 2–2.5 {1} or †5.5–6 × 1.5–1.8 µm {T}; unbranched at upper septum, hymenium pale yellowish. **Medullary excipulum** hyaline to pale yellow, 20–40 µm thick, of dense textura angularis(-intricata), non- or medium gelatinous, medium to sharply delimited. **Ectal excipulum** pale yellowish, of (†) thin-walled to slightly gelatinized (common walls 0.5–1 µm), indistinctly vertically oriented t. globulosa-angularis-prismatica from base to mid flanks, 60 {1} or 170 {T} µm thick near base, cells †10–16 × 7–13 {1} or 15–35 × 10–25 µm {T}; 60 → 20 µm thick at flanks, 15 µm near margin, of t. prismatica oriented at a 70–90° angle to the surface, marginal cortical cells †7–9 × 3–4 {1} or 9–12 × 4–6 µm {T}; **glassy processes** absent. **Anchoring hyphae** medium abundant, †1.7–2(–3) µm wide, walls 0.2 µm thick {T}, forming a dense, thin, scarcely gelatinized t. porrecta at base of stipe. **VBs** very elongate, filling almost entire terminal cell, (*) medium refractive {T}, (†) pale yellowish. **Exudate** over paraphyses 0.1–0.5 {T} or 0.5–2 {2} µm thick, rough to granular-cloddy, continuous, light yellow-chlorinaceous, loosely or firmly attached, over margin and flanks 0.3–2 µm thick, rough, subhyaline to yellow. **— ANAMORPH**: pseudotripoconidium-like (from ascospore isolate {1}). **Conidiophores** erect, septate, usually unbranched, 43–165 µm high, ~2.5–3.3 µm wide at base, ~1–1.6 µm at apex, bearing (1–)4–8 denticles of 1.8–4 × 1–1.2 µm. **Conidia** *5.5–7.5 × 3.6–4.8 µm, inversely pyramidal, truncate at the narrow base, with 2–4 nipple-shaped lateral protuberances at the distal end, containing 1 large LB and sometimes also a small one. **Chlamydospores** not observed.

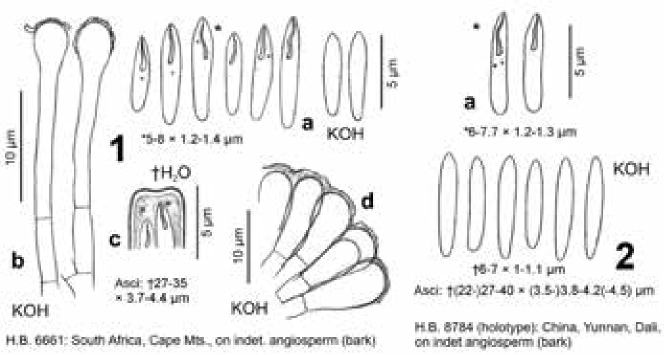

Plate 558. **1–2**: *Orbilia jinguangsiensis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. marginal ectal excipulum (median section).

Habitat: lying on moist ground, on underside {T} of corticated or decorticated branches or logs of indet. woody angiosperms {1/1}, *Pinus* sp. {1}, on bark {2} (periderm {T}) or wood {1}, medium decayed, partly on old black pyrenomycete, no algae. **Associated**: *Farlowiella carmichaeliana* {1}, *Orbilia fusiformis* {1}, *O. limoniformis* {1}, small moss {1}. **Desiccation tolerance**: only ~20% of ascospores viable after 3 months. **Altitude**: 265–2730 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: XII.

Taxonomic remarks. *Orbilia jinguangsiensis* is characterized by comparatively small, cylindrical to slightly fusoid ascospores with rather short SBs. The taxon is only tentatively separated from *O. sinensis* (see p. 1004). A collection from Japan referred to *O. sinensis* (Pl. 560: 2) has a spore size similar to *O. jinguangsiensis*, though the SBs are distinctly longer. *O. yuanensis* (series *Helicoon*) differs in obtuse spore apices and shorter SBs, in addition to the vermispora-like anamorph, but in one collection (Pl. 545: 2) the SBs are similar as in *O. jinguangsiensis*. *O. subuliformis* differs in smaller, subuliform spores and in the upper spores being inversely oriented.

Variation. The collections from Yunnan (China) deviate from that from South Africa in much smaller and thinner, more unstalked apothecia which mostly have a concave disc, also in smaller ectal excipular cells and a thicker exudate over the paraphyses, finally in a tendency to more cylindrical spores.

Anamorph. The pseudotripoconidium-like anamorph obtained in the holotype of *O. jinguangsiensis* closely resembles that of *O. sinensis* in its conidia with 2–4 very short protuberances.

Ecology. *O. jinguangsiensis* is known from a subtropical humid (winter-dry), evergreen broad-leaved mountain forest in southern China (type locality), and from a warm-temperate humid afromontane evergreen forest in the coastal Cape Mountains of South Africa.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, Jinguangsi virgin forest, 2730 m, branch of *Pinus*, on wood, 8.XII.2007, H.Y. Su (H.Y.S. jgs-3, CBCD, H.B. 8766b, mixture in M-0276488 [type of *O. fusiformis*]). – ibid., branch of indet. angiosperm, on bark, 8.XII.2007, H.Y. Su, R.X. Bi & J. Li (H.Y.S. jgs-13, CBCD, **isotype**, anam. cult.; ex H.B. 8784, M-0276495, **holotype**). — **SOUTH AFRICA**: **Eastern Cape** (border to Western Cape), Cape Mts., 77 km E of Knysna, Tsitsikamma, Garden Route, 1.5 km NE of Stormsriver, near 'Big Tree', 265 m, log of indet. ?angiosperm, on bark, 17.II.2000, V. Kummer (H.B. 6661).

Orbilia sinensis (Z.F. Yu & K.Q. Zhang) Baral, Z.F. Yu & E. Weber, in Zhang et al., Phytotaxa 203: 252 (2015) — Pls 560–561

≡ *Pseudotripoconidium sinense* Z.F. Yu & K.Q. Zhang, in Yu et al., Mycologia 103: 168, figs 1–23 (2011).

Etymology: *sinensis*: after the geographical origin, China.

Typification: China, Yunnan, Xiaoheijiang, branch of indet. tree, 9.VI.2005, M. Qiao (YMF 1.01843, holotype; ex-type culture: CBS 121220; sq.: MH179519, DQ480727).

Misapplied name: Liu (2006: 102, fig. 40, HMAS 96782) and Liu et al. (2006b: 116, fig. 4), as *O. rectispora*.

Description: — **TELEOMORPH**: **Apothecia** fresh 0.35–1(–1.5) mm diam., 0.18–0.28 mm high (receptacle 0.12–0.16 → 0.08–0.1 mm), pale yellowish-cream to usually light carneous-rose pr almost whitish, slightly to strongly translucent, round to somewhat undulating, medium scattered to subgregarious; disc slightly concave to slightly convex, margin thin, not protruding, smooth; sessile or with a ± obconical stipe 0.1–0.13 × 0.15–0.25 mm, superficial; dry light chlorinaceous-yellow to bright orange-rose. **Asci** *33–39 × 4–4.2 µm {1}, †(29–)33–40(–44) × 3–4(–4.8) µm {5}, 8-spored, spores *3–4-seriate, 3–5 lower spores inverted {4} (often mixed, sometimes apical spores inverted and lower spores not {2}), pars sporifera *14–18 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with medium to very long, thin, flexuous stalk, L- or T-shaped. **Ascospores** *(7–)7.5–10(–11) × (0.8–)0.9–1.2(–1.3) µm {6}, †(7–)8–9.5 × 0.8–1.1(–1.2) µm {3}, narrowly cylindric-fusoid, apex subacute to acute, base not or slightly (rarely medium) attenuated, straight or slightly (rarely medium) curved or geniculate; **SBs** *(2.3–)3–4(–5) × (0.1–)0.2–0.4(–0.5) µm in situ {4} (~2.5–5.5 µm actual length), filiform to narrowly subulate, slightly to medium flexuous, overmature tear-shaped, ~1.5 × 0.5–0.6 µm wide. **Paraphyses** apically slightly to strongly capitate(-clavate), terminal cells *14–24 × 2.8–3.5(–4) µm {2}, †15–24 × 2–3.5 µm {2}, below apex *(1–)1.5–2 µm wide, lower cells *4–7.5(–10) × 2–2.8 µm {3}, †4–6 × 1.8–2.5 µm {1}; unbranched at upper septum. **Medullary excipulum** 10–15 µm thick, of dense small-celled textura intricata, sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly (near medulla sometimes medium) gelatinized, indistinctly oriented t. globulosa from base to margin, 140–200 µm thick near base, cells of inner part */†(10–)20–30(–45) × (10–)18–25(–35) µm {3}, near cortex *10–17 × 9–14 µm {1}, near medulla †8–18 × 4–8 µm {1}; 20–25 µm thick near margin, oriented at an 80–90° angle to the surface, marginal cortical cells */†9–14(–16) × (5–)6–8(–10) µm {2}; **glassy processes** absent. **Anchoring hyphae** very sparse at base, */†2–3(–4) µm wide, walls 0.2(–0.3) µm thick {2}. **SCBs** not observed. **VBs** in terminal cells of paraphyses subglobose to very elongate, slightly or strongly refractive, hyaline {3}, also absent {1}; in marginal ectal excipulum absent. **Exudate** over paraphyses and margin absent or granular, ± firmly attached, 0.2–1 µm thick, hyaline. **— ANAMORPH**: pseudotripoconidium-like (from ascospore isolate {3}): **Conidiophores** erect, simple or occasionally branched, 110–140 µm high, 2.5–3.0 µm wide at base, gradually tapering to 1 µm near the tip, septate {1}; conidia formed either singly at the apex, or most often on 3–7 denticles, lateral denticles 1.5–2 × 1–2 µm, apical denticle 2.5–5 µm long. **Conidia** *5–9 × 3–4.3 µm {1} (including protuberances), inversely pyramidal, somewhat truncate at the base, with 2–3 nipple-shaped lateral protuberances at the distal end, containing 1–5 globose LBs of 1.3–2.5 µm diam. **Chlamydospores** frequently seen in older

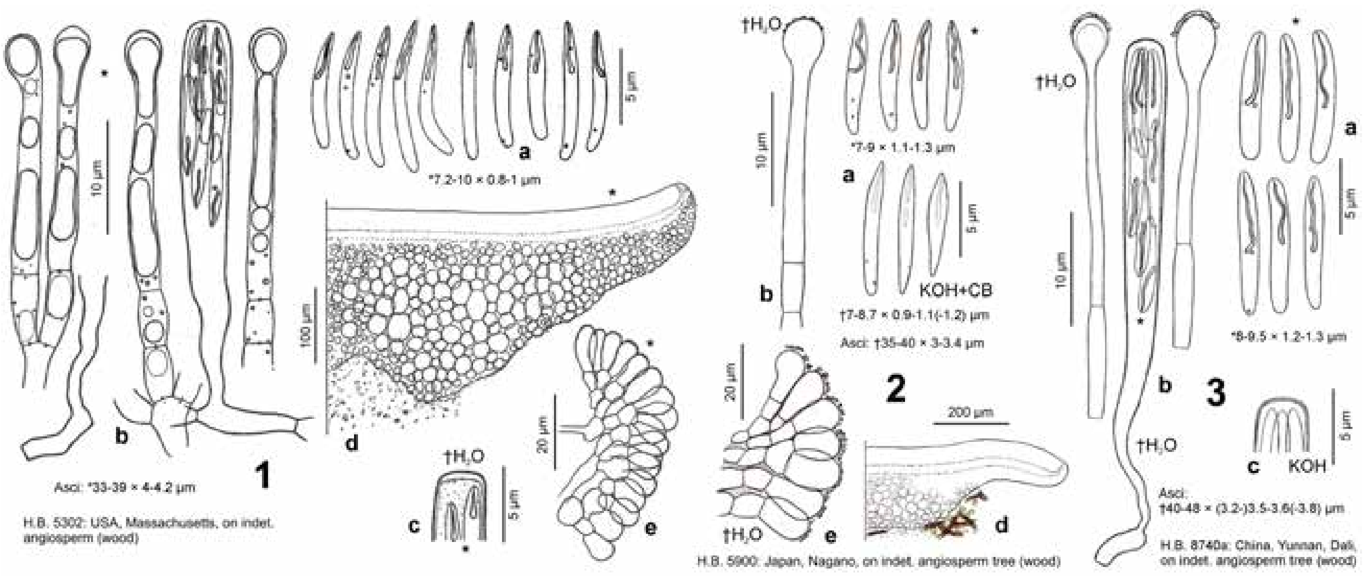

Plate 560. **1–2**: *Orbilia sinensis*; **3**: *O.* aff. *sinensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum.

cultures, subglobose to ellipsoid, *7.5–14.5 µm wide, containing 1–3 ± large LBs, forming intercalary chains.

Habitat: on damp ground adjacent to a pond, decorticated, 5–6 cm thick branches or ~20–30 cm thick logs of *Abies* sp. {1}, *Fagus sylvatica* {1/1}, *Populus* {1}, *Ulmus* sp. {2}, indet. woody angiosperms {3}, indet. trees {2}, on wood {6} or bark {2}, partly on underside, wood 1 mm deep or much deeper medium to strongly decayed, strongly greyed, with some or many green algae. **Associated**: *Orbilia epipora* {1}, *O. nemaspora* (on different log of same tree) {1}. **Desiccation tolerance**: fully alive after dry for ~½ day but dead after 8 days, spores viable after 1 month. **Altitude**: 45–1025 m (northern USA, Europe), 720–3100 m (eastern Asia). **Geology**: China: Jurassic-Cretaceous & Tertiary sedimentary and mafic volcanic rock; USA: Archean to Ordovician-Silurian granite; Europe: serpentinite near Cretaceous flysch, Eocene siliceous sandstone & shale. **Phenology**: I, V–VIII.

Taxonomic remarks. *Orbilia sinensis* closely resembles *O. luteorubella* and *O. rosea* from which it differs in distinctly narrower, more cylindrical ascospores and slightly narrower SBs. O. *jinguangsiensis* (Pl. 558–559) is tentatively separated by its shorter and wider spores and shorter SBs. *O. subuliformis* (Pl. 557: 1) differs in smaller, especially shorter spores, and in the upper spores inverted within the asci. For the very similar *O. tenuispora* see below. *O.* aff. *fusiformis* differs in much wider spores and the upper spores being predominantly inverted. *O. sinensis* and also *O. tenuispora* have been confused with *O. rectispora* (section *Arthrobotrys*), although the latter species can easily be distinguished in the living state by globose SBs. Yu et al. (2011) named the teleomorph of the present species *O.* aff. *luteorubella* because of a close similarity in the teleomorph and a very different anamorph.

Variation. *O. sinensis* varies in spore size among the included collections, particularly in width. The E-Asian specimens tend to have wider spores, also the asci are partly wider. The shape of SBs is unknown in the collection from Caucasus (Pl. 561: 2) because it was only studied in the dead state. Spore orientation was variable in two specimens (H.B. 5302, Massachusetts; 15.VIII.2008, Laojunshan), with the upper instead of the lower spores being inverted in some asci. The Japanese specimen (Pl. 560: 2) deviates from the other examined collections in a distinctly gelatinized inner part of the ectal excipulum, also in wider spores, and comes herewith close to *O. jinguangsiensis*.

Yu et al. (2011) described the apothecia in the type specimen as rather large (0.7–2 mm diam.). Yet, they did not add a scale to their macrophoto (Pl. 561: 1a), and the sectioned apothecium on their fig. 2 has a wrong scale. That scale yields a diameter of only 185 µm, hence the correct size of the apothecia remains unclear.

Kumar et al. (2012) investigated with the TEM an *Orbilia* sp. which according to their molecular data clearly belongs to the *O. sinensis* clade. The spores were given as 7.35–8.33 × 1.23 µm, and the SBs 3 × 0.5 µm. However, according to the scale on the TEM images the data would be 5–6 × 0.9–1 µm and 1.8–2.4 × 0.4 µm, respectively. On their LM image (fig. 1) the scale is not 5 µm as indicated in the legend but more probably 10 µm, and spore length would then range around 10 µm.

Two samples on *Fagus* from Spain and Serbia (IVV: 15.V.2017, 20.VIII.2019) represent the only known European records of series *Pseudotripoconidium*. They fit so well the collection from Massachusetts, that we have included them in the description of *O. sinensis*.

Not included collections. A sample from Hong Kong (W.H. Ho, IVV: VI.1997) might be conspecific, but here no spore size is known, therefore it could also be *O. tenuispora*. A record from Taiwan (IVV: H.B. 7258) is only known in the dead state, therefore, spore orientation was difficult to discern (apparently the lower spores are mostly not inverted). Another collection (Pl. 560: 3) which grew in association with the similar *O. tenuispora* deviates in consistently obtuse spore apices.

Spore length in two Spanish collections on *Fraxinus* (Pl. 561: 5–6) is at the upper end of the range (*7.5–11 × 1–1.2 µm), approaching *O. tenuispora*. Since no sequence data could be gained from them and the anamorph is unknown, their identity remains uncertain.

Misapplication. From various provinces of China, Liu (2006: 102) reported 10 collections under the name *Orbilia rectispora*, a species treated by us in series *Neodactylella* of section *Arthrobotrys*. Two of them originate from Tibet (at 3100–3500 m altitude), and the remaining from Beijing, Hunan, Yunnan, Anhui, Hubei, and Zhejiang (at 600–1300 m). Liu (2006) and Liu et al. (2006b) reported a globose SB at one end of the spores, but living spores were seen by B. Liu (pers. comm.) only in a

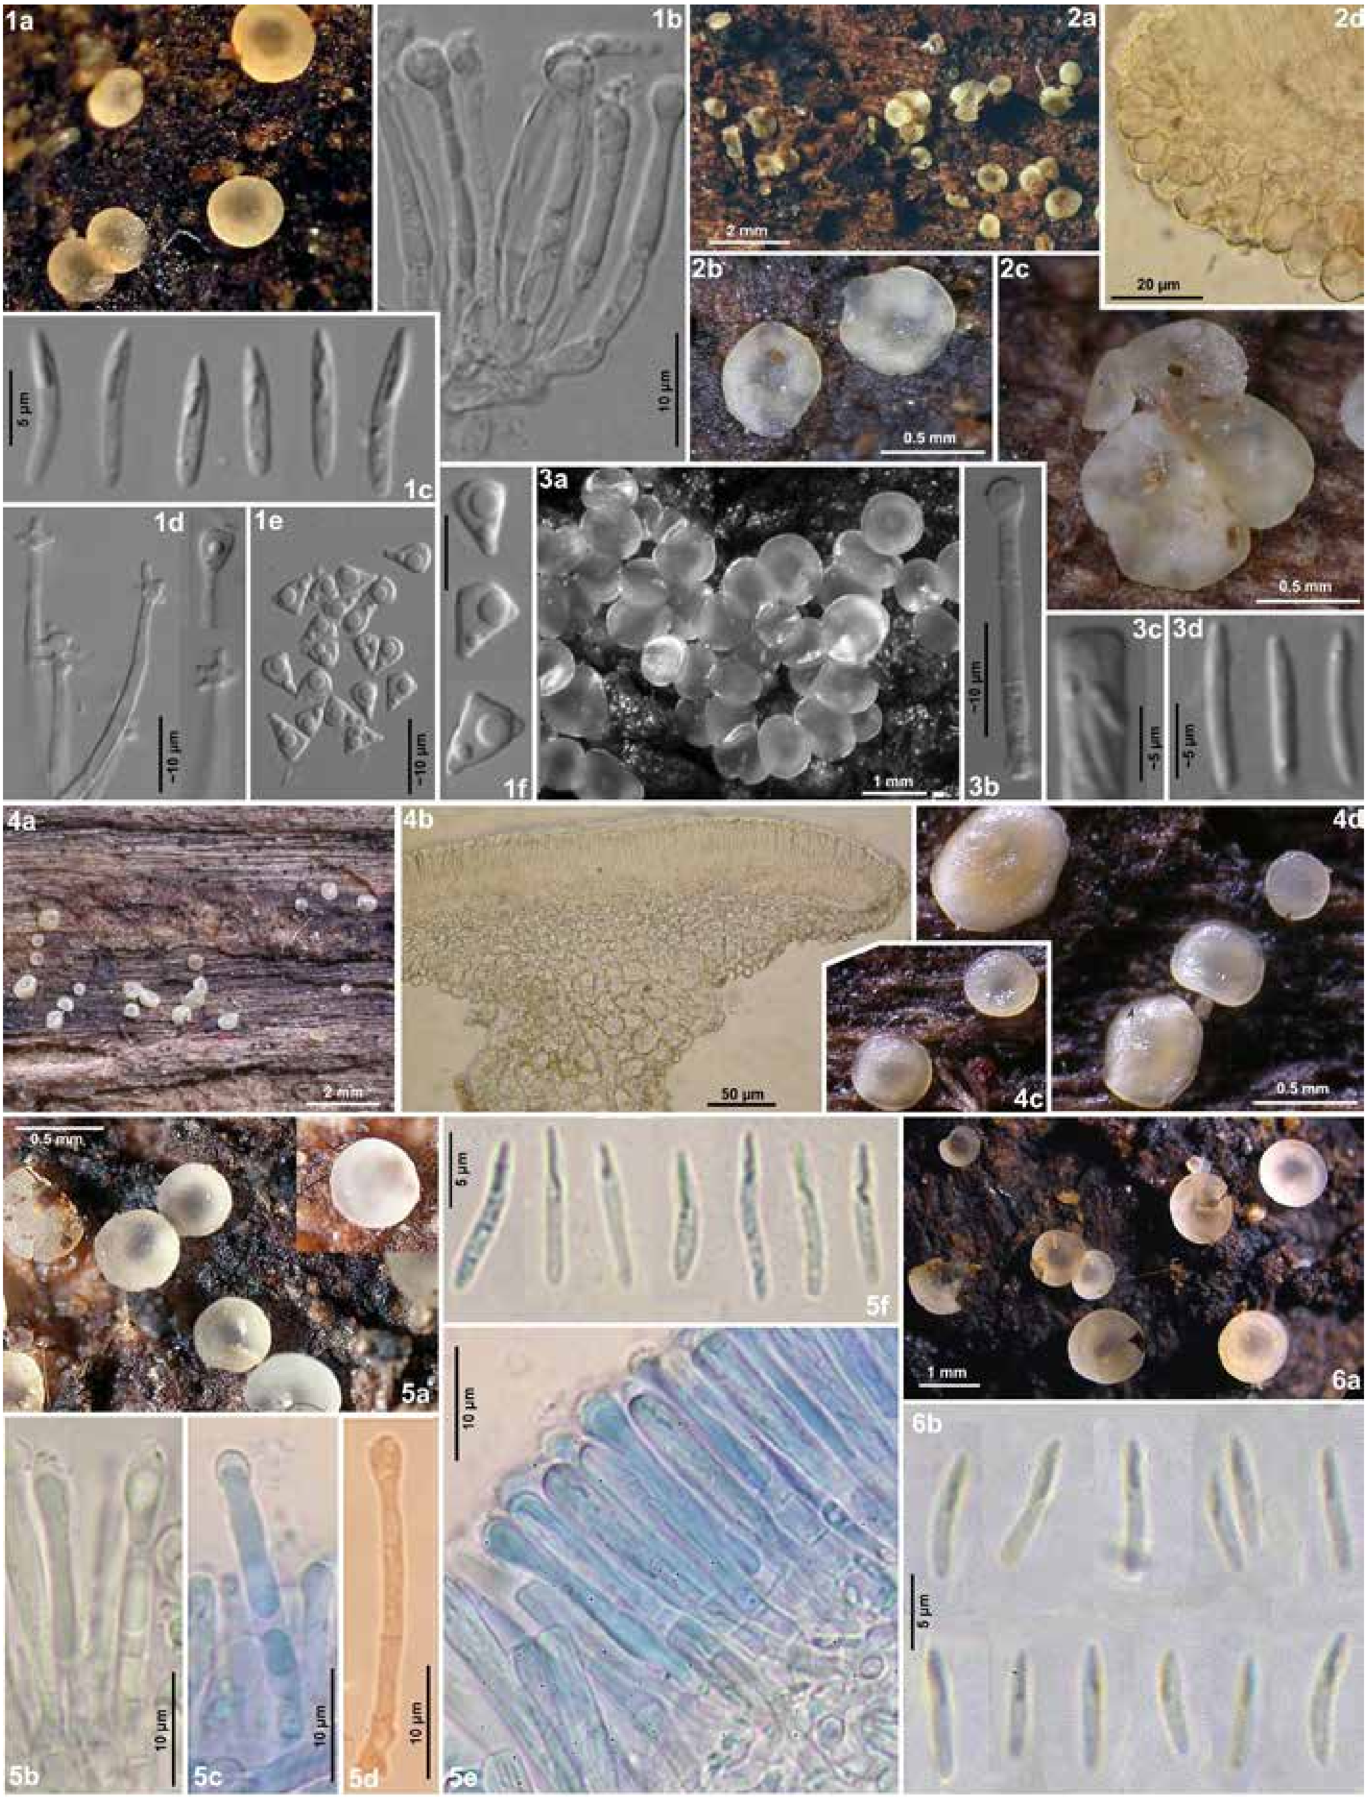

Plate 561. **1–4**: *Orbilia sinensis*; **5–6**: *O*. cf. *sinensis*. – **1a**, **3a**, **5a**, **6a**. fresh apothecia; **2a–c**, **4a**, **c–d**. rehydrated apothecia; **4b**. apothecium in median section; **2d**. id., marginal ectal excipulum; **1b**, **3b**, **5b–d**. paraphyses; **5e**. asci and paraphyses; **3c**. ascus apex; **1c**, **3d**, **5f**, **6b**. ascospores; **1d**. conidiophores (from culture); **1e–f**. conidia. – Living state (**5c**, **e** in CRB), except for **3b–d** (in H_2O), **4b** (in KOH), **5d** (in CR). – **1a–f**: from Yu et al. 2011 (DIC), **3a–d**: from Liu et al. (2006b, DIC), **5a–f**: phot. E. Rubio, **6a–b**: phot. J. Martin. — **1a–f**. YMF 1.01843 (holotype): China, Yunnan, Pu'er, indet. branch; **2a–d**. H.B. 7990: Azerbaijan, on *Ulmus*; **3a–d**. HMAS 96782: China, Tibet, Nyingchi, on *Abies*; **4a–d**. H.B. 5900: Japan, Nagano, on *Populus*; **5a–e**. E.R.D. 6143/H.B. 10043: Spain, Asturias, Obaya, on ?*Fraxinus*; **6a–b**. H.B. 10015: Spain, País Vasco, Tolosa, on *Fraxinus*.

few of the collections, and his photographs of the collection from Tibet show apparently only dead spores of 7–10 × 0.9–1.2 µm. At least one of the Tibet collections (Liu 2006, Liu et al. 2006b fig. 4, HMAS 96782) is treated here as *O. sinensis*, two further as *O. tenuispora* (see p. 1009).

Anamorph. Yu et al. (2011) described the new genus and species *Pseudotripoconidium sinense* based on an anamorph which was at that time very distinctive and unique within *Orbilia* and which the authors obtained in ascospore isolates of four collections from Yunnan, China. However, two of them are regarded here as belonging to other, closely related species (see below). Another collection included by us in *O. sinensis* (ljs-1, from Dali) also produced this type of anamorph, but the culture was contaminated and not documented (H.Y. Su pers. comm.). The conidia of *O. sinensis* as seen in the holotype (YMF 1.01843) and paratype (YMF 1.03475) might be characteristic in showing distinct though not or only slightly protruding protuberances in the living state, whereas in the dead state under the SEM they protrude strongly.

Phylogeny. Within the present concept of *O. sinensis* the available five ITS sequences are remarkably different. Three geographically remote samples (YMF 1.03475 from Yunnan, HMAS 96782 from Tibet, MIN 921434 from Minnesota) are almost identical in the ITS region, differing from each other by only 1–3 gaps, whereas two further samples (YMF 1.01843 from Yunnan [type of *O. sinensis*], D.H.P. 146 from Massachusetts), show about 3% distance to those and even 4% between each other. The S1506 intron is absent in the Minnesota strain, while in the remaining sequences its absence is uncertain. The two available LSU sequences (type of *O. sinensis* D1–D3, strain from Tibet D1–D2) differ in the D1–D2 by 3.5%, although both differ from *O.* aff. *sinensis* (Benedict's strain) and *O.* aff. *fusiformis* (YMFT 1.01848) by only 2.3–2.7%.

For the type of *O. sinensis* also SSU V1–V3 and two LSU D1–D3 sequences exist in GenBank: MH179519 and DQ480728 (as YMF 1.01843), and MH877761 (as CBS 121220). However, the latter two LSU sequences differ by 13 nt (9 in D1–D2). MH877761 is closer to *O.* aff. *fusiformis* (CBS 121221, EF026115, YMF 1.01848), differing by only 7 nt, of which 5 adjacent nt in the D2 of *O.* aff. *fusiformis* are perhaps erroneous. A confusion seems likely and MH877761 probably refers to CBS 121221 and provides a cleaner LSU version of that strain, whereas the true LSU sequence of the type of *O. sinensis* (CBS 121220) does not exist in the CBS database. LSU exists also for D.H.P. 146 (R. Healy pers. comm.) but was not available.

O. sinensis as circumscribed here differs by 5–6.5% from *O. tenuispora* and *O.* aff. *fusiformis*. The sequence from Tibet (ITS+LSU) was obtained by B. Liu from a sample on *Abies* and named *O. rectispora* (illustrated in Liu 2006: fig. 40 and Liu et al. 2006b: fig. 4). It clustered in Liu et al.'s (2006a) ITS analysis with D.H.P. 146 (as *O. luteorubella*) in a clade, whereas another of Liu's strains under the name *O. rectispora* (from Zhejiang, here referred to *O. tenuispora*) and one under the name '*O. vinosa*' (without morphological data, 'Benedict's strain') are found more distantly. In Liu et al.'s analysis of LSU, the Tibet strain clustered sister to two strains referable to *O. tenuispora* by showing a distance of 2.5–3% in that gene region.

Benedict's strain has been deposited in 1972 under the name *O. vinosa* in different culture collections (CBS 917.72, AFTOL-ID 905, CCRC/BCRC 33149), and sequences of it were included in the past in various phylogenetic analyses. This strain shows in the ITS region a distance of 4–5% to *O. sinensis* and 6.5% to *O. tenuispora* and *O.* aff. *fusiformis*. In the LSU (D1–D2) it is closer to *O. tenuispora* (1.8–2%) than to *O. sinensis* (2.3%). Therefore, we hesitate to include it in the scope of either species, but refer to it as *O.* aff. *sinensis* because of the distinctly lower ITS distance to this species. Sequences of it were submitted to GenBank by Liou & Tzean (1997; U51981, ITS), James et al. (2006; DQ491511, ITS), and Spatafora et al. (2006; DQ471000, entire SSU; DQ470952, LSU D1–D3; DQ471071, EF1a; DQ471145, RPB1). The culture was obtained by R.G. Benedict, but its geographical origin could not be clarified. Probably it derives from USA, since Benedict worked at that time at the University of Washington in Seattle (the same applies to a strain which he identified as *O. coccinella*, see under *O. dryadum*, p. 1390).

Ecology. *O. sinensis* was found on rotten wood but also bark of hygric to semiaquatic branches and logs of different angiosperm trees but also *Abies* at lakes or ponds and streams in cold-temperate to suprasubmediterranean humid deciduous forests of midwest North America and southern Europe (Spain, Balkan, Caucasus), and in continental, orotemperate (altimontane) humid (winter-dry) areas in southern and eastern Asia (Himalaya, Japan). Further included but also not included collections are from subtropical humid (winter-dry), evergreen broad-leaved mountain forests of southern China and Taiwan. The two not included European collections on *Fraxinus* are from thermo- to mesotemperate humid atlantic lowlands of northern Spain.

Specimens included. **USA**: **Massachusetts**, Middlesex, 2.8 km NNE of Concord, Punkatasset Hill, Hutchins Pond, 45 m, log of *Ulmus*, on wood, 12.VII.1995, D.H. Pfister & S.H. Orbilia tenuispora E. Weber, Baral, H.Y. Su, M.L. Wu, Y.C. Su & Bin Liu, **sp. nov.**, MB 813653 — Pls 562–563

Etymology: named according to the narrow ascospores.

Typification: China, Yunnan, Jinguangsi, branch of indet. angiosperm, 8.XII.2007, H.Y. Su, R.X. Bi & J. Li (ex H.Y.S. jgs-11, CBCD, holotype).

Misapplied names: Liu (2006: 102, HMAS 139702, 139707), as *O. rectispora*; Schweinitz (1832: 177 p.p.), as *Peziza vinosa*; Seaver (1911: 108), as *O. vinosa*.

Latin diagnosis: Orbiliae aciculari *similis sed ascosporis minoribus, basi plerumque non vel leniter attenuatis, conidiis plures protuberantias mastoideas longiores ferentibus, ab* Orbilia sinensi *ascis et ascosporis longioribus, conidiis plures protuberantias mastoideas multo longiores ferentibus differt.*

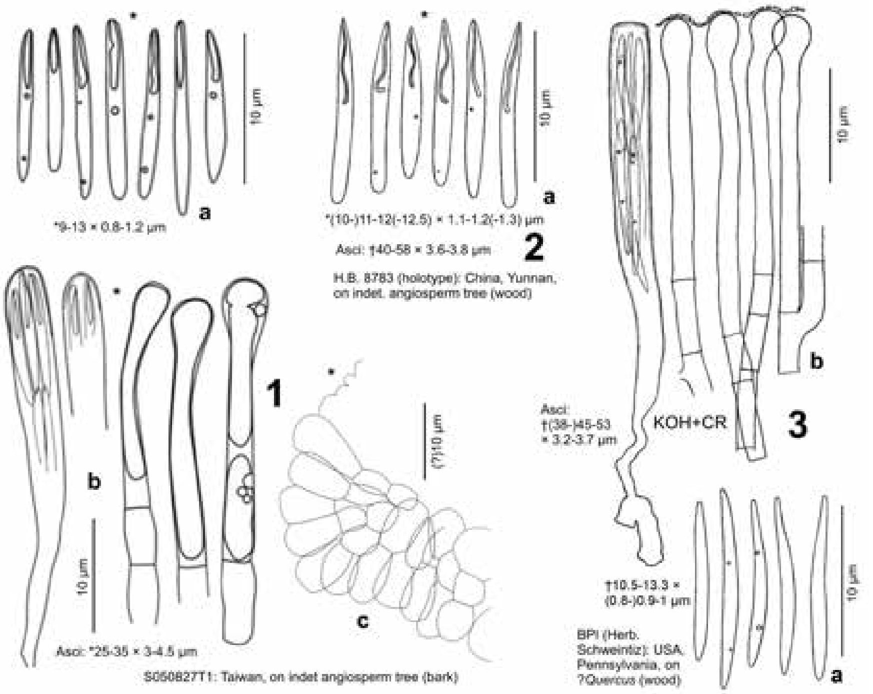

Plate 562. **1–3**: *Orbilia tenuispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. marginal ectal excipulum in median section. – **1a–c**: del. Y.C. Su.

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated (0.25–)0.35–0.9(–1.1) mm diam., 0.1–0.21 mm high (receptacle 0.06–0.1 → 0.05–0.075 mm), whitish to pale or light cream to greyish- or yellowish-ochraceous, sometimes with a reddish tint, translucent, therefore darker in centre, round, scattered to gregarious; disc slightly concave to flat or medium convex, margin thin, not protruding, smooth; sessile on a broad base or with a distinct broad stipe 0.05–0.1 × 0.2–0.4 mm, superficial; dry light yellowish to orange-rose. **Asci** †(36–)38–55(–58) × (3.2–)3.4–3.8(–4) µm {7}, 8-spored, spores †1–4-seriate, ~4 lower spores inverted {4} (often mixed, sometimes some lower spores not inverted), pars sporifera †26–34 µm long; **apex** (†) strongly truncate (sometimes slightly indented, laterally not or slightly inflated), hemispherical in side view, thin-walled; **base** with medium to very long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *(8.5–)10–12(–13) × (0.9–)1–1.2(–1.3) µm {7}, †((7.5–))(9–)9.5–11.5(–13.5) × (0.8–)0.9–1.2(–1.3) µm {6}, narrowly cylindric-fusoid (acicular), apex subacute to acute or obtuse, not or slightly to medium tapered towards base, base rounded to obtuse, sometimes subacute, straight to very slightly curved; **SBs** *(4–)4.5–6(–6.5) × 0.2–0.4(–0.5) µm in situ {3}, filiform, straight or slightly to medium flexuous, rarely uncinate, with a few minute LBs. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells *17–25 × 2.8–4(–5) µm {2}, †18–25(–29) {3} × (2.2–)2.5–3.7(–4.2) {5} µm, lower cells *4–7 × 1.8–3 µm {2}, †(3.5–)4–6(–7) × 1.4–2.2 µm {2}; unbranched at upper septum. **Medullary excipulum** hyaline, 20–30 µm thick, of dense, small-celled textura globulosa-intricata, medium to very sharply delimited. **Ectal excipulum** hyaline, of (†) ± thin-walled t. globulosa from base to mid flanks or margin, 40–140 µm thick near base, cells *10–30 µm diam., †9–19 × 7.5–10 {1} or 15–25 × 10–25 µm {2}; 15–20 µm thick near margin, of. t. prismatica-globulosa oriented at a 80–90° angle to the surface, marginal cortical cells *7–11 × 5–8 µm {2}, †(6.5–)8–11(–13) × (3.2–)4–6(–7) µm {6}; **glassy processes** absent (but sometimes with exudate caps). **Anchoring hyphae** ± sparse, rarely abundant, †2.5–4(–5) µm wide, walls 0.2(–0.3) µm thick {2}, when abundant forming a 60 µm thick, dense, slightly gelatinized t. intricata. **SCBs** in paraphyses globose, 0.8–1.3 µm diam. {1}; **VBs** in paraphyses and marginal cortical cells rather strongly refractive, large, globose to angular, later very elongate, hyaline, densely filling apical region of paraphyses {1}, or absent {1}. **Exudate** over paraphyses 0.2–0.5(–1) µm thick, rough to granular, also cap-like, very pale yellowish, firmly or more loosely attached, also absent, over margin and flanks 0.3–1.2 or sometimes 1–3 µm thick, cap-like. — **ANAMORPH**: pseudotripoconidium-like (from ascospore isolate {2}): **Conidiophores** erect, septate, unbranched, apically with ~4–6 prominent denticles. **Conidia** *6–8 × 5–6.5 µm {1}, †4.5–6 × 4–5.2 µm {1} (including protuberances), inversely pyramidal, at the distal end with 5–8 prominent lateral or sometimes terminal protuberances, containing 1 or 2 large LBs. **Chlamydospores** not observed.

Habitat: on moist or wet ground, corticated or sometimes decorticated branches of ?*Quercus* sp. {1}, indet. angiosperms {7}, indet. ?gymnosperm {1}, on medium to strongly decayed wood {3} and bark (periderm) {5}, mostly blackened, no algae. **Associated**: *Orbilia fusiformis* {1/1}, *O.* ?*sinensis* {1}. **Desiccation tolerance**: only a few spores alive after 3.5 months. **Altitude**: 100–2730 m a.s.l. **Geology**: Cambrian-Ordovician & Jurassic sedimentary and felsic plutonic rock. **Phenology**: IV, VI, VIII, X–I (probably throughout the year).

Taxonomic remarks. *Orbilia tenuispora* differs from *O. sinensis* mainly in longer asci and ascospores, and from *O. acicularis* in narrower asci and smaller spores. *O. tenuispora* appears to form a transition between the two species. However, differences are noted in the anamorph (see below).

Variation. Spore length was mostly in the range of 9–13 µm. Only in two collections (H.B. 8961a, 9985) a few 7.5 µm long spores were observed. Spore body shape varied from filiform, 0.2–0.3 µm wide (Yunnan: 2a) to vermiform-subulate, 0.4(–0.5) µm wide (Taiwan: Pl. 562: 1a, SBs apparently drawn a bit too wide; Pl. 563: 3b, d). The specimens from Taiwan and apparently also Kunming (qlx-6) differ from the remaining samples in a tendency to obtuse spore apices. The marginal cortical cells were given for the Taiwan sample as 10–20 × 8–15 µm (M.L. Wu pers. comm.), but on a photo of that sample (IVV: 27.VIII.2005) they do not exceed 9.5 × 8 µm, therefore, we assume that the scale in Pl. 562: 1c must be 10 µm rather than 20 µm, which would be in accordance with our data from other specimens. We have also reduced the spores in 1a by 90 %, because they then better fit the size evaluated by Y.C. Su for this collection.

Two collections from Spain with intermediate spore length (*7.5–11 × 1–1.2 µm) mentioned under *O. sinensis* might instead belong to *O. tenuispora*. However, due to the lack of molecular data this is uncertain and they even might belong to series *Helicoon*.

Misapplication. Among the 10 Chinese collections reported by Liu (2006: 102) under the name *O. rectispora*, two were reexamined in the present study (see Pl. 563: 7–8). Although

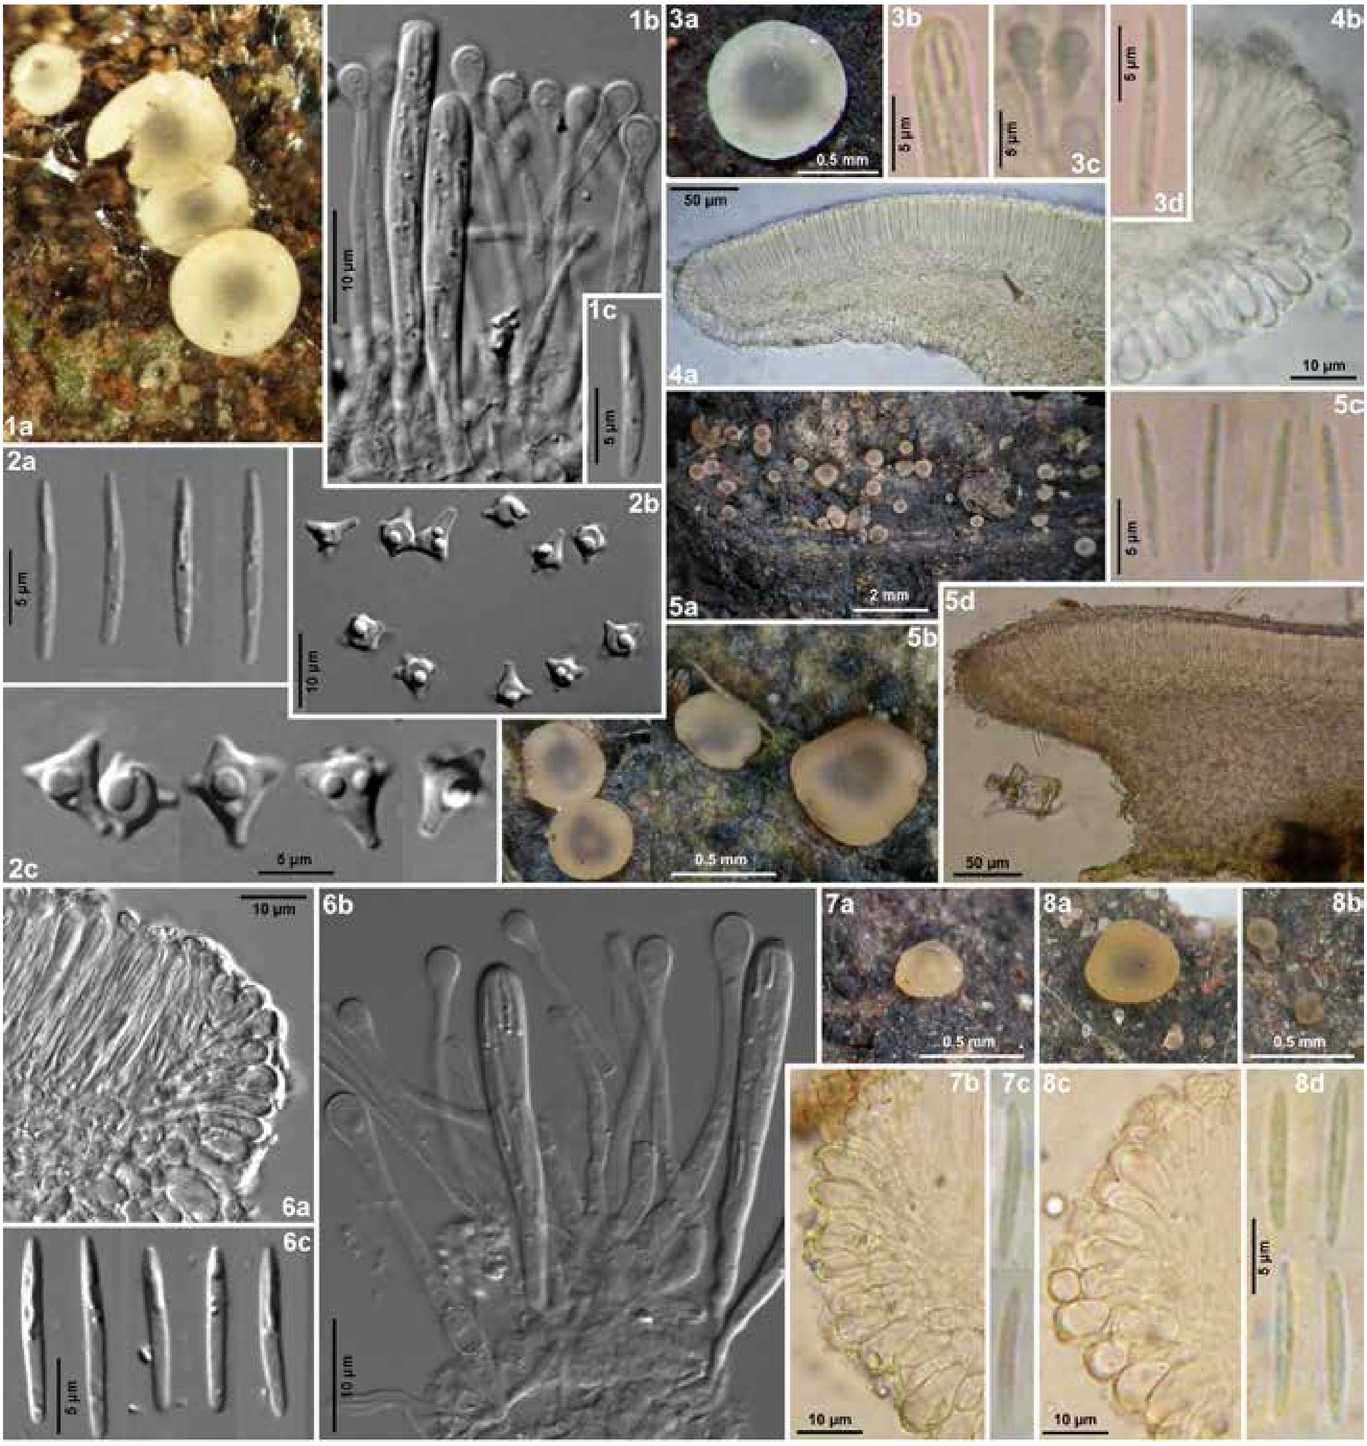

Plate 563. **1–8**: *Orbilia tenuispora*. – **1a**, **3a**. fresh apothecia; **7a**, **8a–b**. rehydrated apothecia (**8b** young); **4a**, **5d**. apothecia in median section; **4b**, **6a**, **7b**, **8c**. id., marginal ectal excipulum; **1b**, **6b**. paraphyses and mature asci; **3b**. ascus apex; **3c**. apices of paraphyses containing VBs; **1c**, **2a**, **3d**, **5c**, **6c**, **7c**, **8d**. ascospores; **2b–c**. conidia (from culture). – Living state, except for **5c–d**, **6a** (in H_2O); **4a–b**, **7b–c**, **8c–d** (in KOH), asci and paraphyses in **1b**, asci in **3b**, **6b**. – **1a–c**, **2a–c**: phot. H.Y.S. jgs-11 (holotype): ibid., on indet. angiosperm; **3a–c**. TMUE S050827T1: Taiwan, on indet angiosperm; **4a–b**. BPI (925-182): USA, ?Pennsylvania, on *Quercus*; **5a–d**. H.B. 8961a: China, Yunnan, Dali, on indet. angiosperm; **6a–c**. H.B. 8740b (Z.F.Y. tw6-20): China, Yunnan, Kunming, on indet. angiosperm; **7a–c**. H.B. 9200: China, Zhejiang, Lin'an, on indet. angiosperm; **8a–d**. H.B. 9201: China, Yunnan, Xishuangbanna, on indet. angiosperm.

the two originated from very remote areas of China, they concur morphologically very well and also fit the type of *O. tenuispora*, especially in spore size (†9–11 × 1–1.3 µm). No trustable information on spore body morphology is available for these specimens, however, and this was the reason why they have been confused with the rather distantly related *O. rectispora*. Moreover, these 10 Chinese specimens are heterogeneous and include also *O. sinensis* (see Phylogeny).

A North American collection in the Schweinitz Herbarium under the name *Peziza vinosa* (Pls 562: 3; 563: 4) matches Chinese *O. tenuispora* quite well, but differs in more fusoid spores that are tapered at both ends though the widest part tends to be closer to one end. Spore shape, especially the slight curvature at the somewhat tail-like end, suggests that the SB was located in the broader end, but this is not sure since no traces of SBs could be seen in this old material. Due to the mentioned similarity with other samples, we here assume that the narrower, gradually attenuated spore end represents the spore apex. Spore orientation within the asci appears to be variable, with a possible tendency of the upper spores to point with their broader end upwards, but also the lower spores sometimes showed this orientation. A possibly unimportant difference to Chinese *O. tenuispora* lies in the much more abundant anchoring hyphae that form a thick, slightly gelatinized textura intricata. The specimen also resembles *O. acicularis*, which differs in distinctly wider spores. Seaver (1911: 108) reported under the name *O. vinosa* a specimen with ~10–15 × 1.5 µm large spores and gregarious, bright flesh-red apothecia 1–2 mm diam., which might belong to *O. tenuispora*.

Anamorph. Conidia were obtained in the type of *O. tenuispora* from Dali (H.Y. Su pers. comm.) and in a specimen from Kunming which was wrongfully included in *Pseudotripoconidium sinense* by Yu et al. (2011). They appear to differ from those of *O. sinensis* in having more (5–8 vs. 2–3) and distinctly longer protuberances (Pl. 563: 2b–c).

Phylogeny. Sequences from three ascospore isolates here referred to *O. tenuispora* were available: YMF 1.03007 (Kunming, SSU V1–V3, S1506 intron, ITS, LSU), HMAS 139703 (Zhejiang, ITS & LSU, S1506 intron region not covered), HMAS 139707 (Xishuangbanna, LSU). The Kunming strain was included by Yu et al. (2011) in *O. luteorubella*/*Pseudotripoconidium sinense*, whereas the other two samples were originally identified by Liu (2006) as *O. rectispora*. Another specimen identified by B. Liu as *O. rectispora* (from Tibet, HMAS 96782, Pl. 561: 3) is included here in the scope of *O. sinensis* based on shorter spores and deviating DNA data.

In the ITS region the two former strains show a distance of 2.5 %. In the LSU D1–D2 the three strains differ by 1–2 nt in the D2 domain. From *O. sinensis* these sequences differ by 5–6.5 % in the ITS and 2.5–3 % in the LSU, and from *O.* aff. *fusiformis* (YMF 1.01848) by 7–8.5 % in the ITS and 2.2 % in the LSU. Also Benedict's strain (CBS 917.72) differs from *O. tenuispora* by 6.5 % in the ITS and 1.8–2 % in the LSU.

Ecology. Schweinitz' collection from eastern North America is supposed to derive from a cold-temperate or warm-continental humid lowland climate with an altitude between 50 and 500 m. Collections from southern China are from evergreen broad-leaved forests in subtropical humid (winter-dry) highlands, those from eastern China and Taiwan from comparable subtropical monsoon forests at lower altitude. Also in the lowland collection from Ibaraki (Japan) the climate is humid (winter-dry) and almost subtropical.

Specimens included. **USA**: **?Pennsylvania**, ?Bethlehem, branch of ?*Quercus*, on wood, undated, collector unknown (herb. Schweinitz 925-182, BPI, PH, H.B. 7603 ø). — **JAPAN**: **Honshu**, **Ibaraki**, 9 km WNW of Takahagi, Hananuki-keikoki, 325 m, indet. angiosperm wood, 21.VI.1991, T. Orbilia acicularis Baral & Hong Y. Su, **sp. nov.**, MB 831504 — Pls 564–565

≡ *Orbilia acicularis* Baral & Hong Y. Su, in Su et al., Mycol. Progress 10: 374, figs 1–2 (2011), nom. inval., ICN Art. 39.1 (Latin diagnosis missing)

Etymology: named after the straight needle-shaped ascospores.

Typification: China, Yunnan, Jinguangsi, branch of indet. angiosperm, on bark, 1.II.2008, H.Y. Su (ex H.Y.S. jgs-7, CBCD, holotype).

Latin diagnosis: *Apothecia 0.4-1 mm diam., superficialia, dispersa, sessilia, translucentia, pallide flava vel rosea, disco plano, margine laevi, non elevato. Asci in statu emortuo 40–59 × 3.8–5 µm, 8-spori, anguste cylindrico-clavati, basi angustati, furcati, apice truncati. Ascosporae 12–17 × 1.3–1.7 µm in statu vivo, non septatae, aciculares, apicibus acutis, corpusculum filiforme subulatum continentibus. Paraphyses apice valde capitatae. Status anamorphicus:* Pseudotripoconidium *sp. Habitat ad lignum et corticem putridum ramorum uvidorum arborum angiospermarum in zona subtropica humida Asiae meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.4–1(–1.6) mm diam., 0.11–0.18 mm high (receptacle 0.1 → 0.08 mm), whitish or pale to light pink, also yellowish-cream (when fresh or rehydrated), translucent in centre, ± round, scattered to gregarious; disc flat, margin indistinct, not protruding, smooth; sessile on a narrow base or with a stipe 0.07–0.09 × 0.3 mm, superficial; dry somewhat undulating and inrolled, pale yellowish-cream or light rose-orange. **Asci** †40–52(–59) × 3.8–4.5(–5) µm {3}, 8-spored, spores (†)3–4-seriate, 2–4 lower spores inverted {1} (sometimes strongly mixed); **apex** (†) strongly truncate (not or very slightly indented, laterally sometimes slightly inflated); **base** with medium to long, thin, flexuous stalk, L-shaped. **Ascospores** *(11.5–)13–16(–17) × (1.3–)1.4–1.6(–1.7) µm {3}, †(10–)12–16(–17) × (1.2–)1.3–1.5(–1.7) µm {2}, narrowly fusoid (acicular), apex subacute to acute, base slightly to strongly attenuated, straight or sometimes slightly curved; **SBs** *(4–)5–6.5(–8) × 0.3–0.6 µm in situ {3} [5–7(–8.5) µm actual length], filiform to subulate, ± straight to often ± flexuous. **Paraphyses** apically medium to mostly (very) strongly clavate-capitate, rarely moniliform, terminal cells †19–28 × (2–)2.7–3.8 µm {2}, lower cells †6–7(–10) × 1.3–1.8 µm {2}; unbranched at upper septum. **Medullary excipulum** 20–30 µm thick, of medium dense textura intricata-globulosa, not or very slightly gelatinized, very indistinctly to sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, indistinctly vertically oriented t. globulosa-angularis from base to margin, near base 50–90 µm thick, cells *10–20(–24) × 9–16 µm {1}, †8–15 × 6–13 µm {T}; 30–40 µm thick at flanks, 15–18 µm near margin, of t. globulosa-prismatica

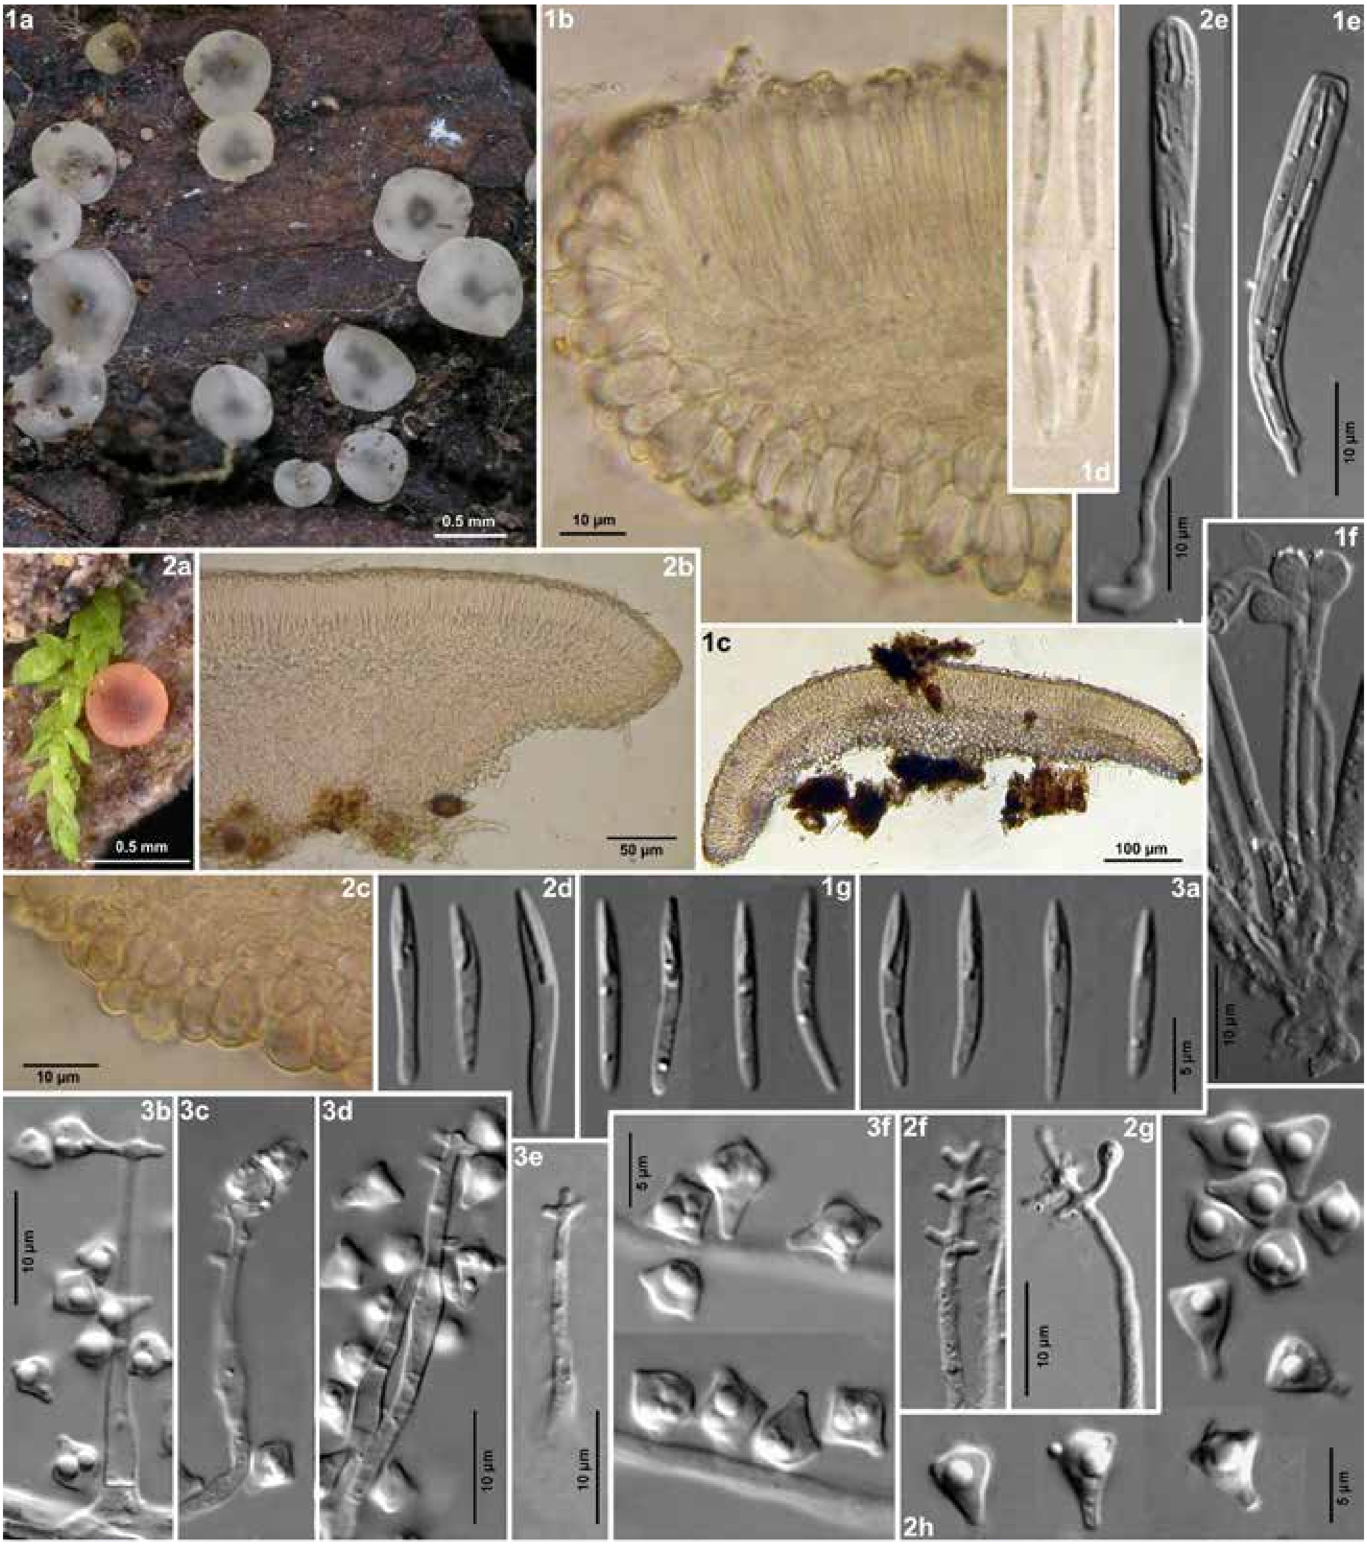

Plate 565. **1–3**: *Orbilia acicularis*. – **1a**, **2a**. rehydrated apothecia; **1c**, **2b**. apothecia in median section; **1b**. id., ectal excipulum near margin; **2c**. id., flanks; **1e**, **2e**. mature asci; **1f**. paraphyses; **1d**, **g**, **2d**, **3a**. ascospores; **2f–g**, **3b–e**. conidiophores with conidia; **2h**, **3f**. conidia (both from culture). – Living state, except for **1b–c**, **2c**, **2f–g**, **3e** (in H_2O); asci and paraphyses in **1e–f**, **2e**. – **1e–g**, **2d–h**, **3a–f**: phot. H.Y. Su (DIC). — **1a–g**. H.B. 8765 (**1e–g** from holotype, **1a–d** from isotype): China, Yunnan, Dali, on indet. angiosperm; **2a–h**. H.B. 8764: ibid., on indet. angiosperm; **3a–f**. oriented at 70–80°, marginal cortical cells *9–12 × 5–6 µm {1}, †10–14 × 5–8 µm {T}; **glassy processes** absent. **Anchoring hyphae** sparse, †1.5–3(–5.5) µm wide, walls 0.2(–0.3) µm thick {1}. **SCBs** in paraphyses globose. **Exudate** over paraphyses and margin 0.2–1(–2) µm thick, granular-cloddy to cap-like, hyaline, ± firmly attached. — **ANAMORPH**: pseudotripoconidium-like (from ascospore isolate {2}). **Conidiophores**, erect, ± branched, single branches 35–66 µm long {2}, 2.4–2.8 µm wide at base, 1.2–1.8 µm at apex, here with 2–7 denticles of 3.5–6 × 1–1.4 µm {2}. **Conidia** *4.7–7 × 3.6–5(–5.7) µm including protuberances {2}, inversely pyramidal, truncate at the base, with (2–)3–4 nipple-shaped lateral protuberances at the distal end, containing 1(–2) large LBs (~2–2.5 µm) and some small ones. **Chlamydospores** not observed {2}.

Habitat: lying on moist ground, corticated, ~15–20 mm thick branches of unidentified angiosperm trees {3}, on bark (bast and periderm) {1} or wood {2}, 0.5–0.8 mm deep medium to very rotten, partly darkened, green algae sparse or absent. **Associated**: indet. bryophyte. **Desiccation**

tolerance: some ascospores and many cells of ectal and medullary excipulum still viable after 2 weeks. **Altitude**: 2730 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: XII, II.

Taxonomic remarks. *Orbilia acicularis* closely resembles *O. tenuispora* in having long and narrow, acicular ascospores with rather long, filiform to narrowly subulate SBs, and a pseudotripoconidium-like anamorph. Three samples of *O. tenuispora* (Pls 562: 2; 563: 1–2, 5) emanate from the very same virgin forest (Jinguangsi) where the three of *O. acicularis* have been collected. *O. acicularis* seems readily recognized by its rather long and wide spores. The spore size of *O. tenuispora* hardly overlaps with that of *O. acicularis*. For differences in the anamorph see below.

O. arcospora mainly differs in curved ascospores. The very distantly related *O. vinosa* (section *Hemiorbilia*) has also similar spores but differs in thick-walled, hemispherical ascus apices, apically much less inflated paraphyses, and a thicker exudate.

Variation. The three included collections differ from each other in ascus length and in apothecial colour (whitish vs. light pink), but only slightly in spore size. The spores are often attenuated towards the base, but untapered spore bases also occur.

Anamorph. The conidia of *O. acicularis* are very similar to those of *O. tenuispora* but deviate in shorter protuberances which are less in number. The published description of the anamorph in Su et al. (2011c) was copied by mistake from the protologue of *P. sinense* which deviates in several important details from the true data given above.

Ecology. *O. acicularis* was detected on hygric, ± rotten bark and wood of unidentified angiosperm trees in a subtropical humid (winter-dry), evergreen broad-leaved mountain forest in southern China.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, Jinguangsi virgin forest, 2730 m, branch of indet. angiosperm, on wood, 8.XII.2007, H.Y. Su, R.X. Bi & J. Li (H.Y.S. jgs-12, CBCD, anam. cult., doc. vid.). – ibid., branch of indet. angiosperm, on wood, 1.II.2008, H.Y. Su (H.Y.S. jgs-8, anam. cult., H.B. 8764). – ibid., branch of indet. angiosperm, on bark, 1.II.2008, H.Y. Su (H.Y.S. jgs-7, CBCD, **holotype**; H.B. 8765, **isotype**).

Orbilia arcospora Baral & Hong Y. Su, in Su et al., Mycol. Progress 10: 377, fig. 3 (2011) — Pls 566–567

Etymology: named after the ascospores being curved like an arch.
Typification: China, Yunnan, Jinguangsi, branch of indet. angiosperm, 1.II.2008, H.Y. Su (H.Y.S. jgs-9, CBCD, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.5–1(–1.2) mm diam., 0.16 mm high (receptacle 0.1 → 0.07 mm), pale pink when fresh, rehydrated light rose-cream, translucent in centre, ± round, subgregarious; disc flat to medium convex, margin indistinct, not protruding, smooth; sessile on a rather narrow base, superficial; dry light rose-orange. **Asci** †41–53 × 3.4–4.4 µm, 8-spored, spores †2–3-seriate, ~3–4 lower spores inverted (mixed or not); **apex** (†) strongly truncate (very slightly indented, laterally sometimes slightly inflated); **base** with long to very long, thin, flexuous stalk, L- to Y-shaped. **Ascospores** *(8–)9–12 × 1.1–1.3 µm in situ (actual length ~10.5–14 µm), †(8–)9–12(–13) × 1–1.2 µm in situ, narrowly fusoid (acicular), apex obtuse to subacute, base slightly to rather strongly attenuated, (slightly to) medium to strongly curved (arcuate) in both living and dead state; **SBs** *4–5 × 0.3–0.4(–0.5) µm, filiform(-subulate), ± straight to often somewhat flexuous. **Paraphyses** apically strongly to very strongly clavate(-capitate), terminal cells */†24–27 × (2.5–)3–4.7 µm, lower cells †5–7.5 × 1.7–2 µm; unbranched at upper septum. **Medullary excipulum** 20 µm thick, of medium dense textura prismatica, horizontally oriented, sharply delimited. **Ectal excipulum** of (†) thin-walled (to slightly gelatinized), indistinctly vertically oriented t. globulosa-angularis(-prismatica) near base, here 50–80 µm thick, cells †13–23(–36) × 8–16(–20) µm; 25–30 µm thick at flanks, of vertical t. prismatica, 15–18 µm thick near margin, of t. prismatica oriented at 70–90°, marginal cortical cells *7–10(–12) × (3–)4–5 µm; **glassy processes** absent. **Anchoring hyphae** not examined. **SCBs** in paraphyses globose, 2–2.8 µm diam., in ectal excipulum not observed. **VBs** absent. **Exudate** over paraphyses and margin 0.3–1 µm thick, cloddy to cap-like, hyaline to very pale yellowish, firmly attached. — **ANAMORPH**: unknown (not formed in pure culture).

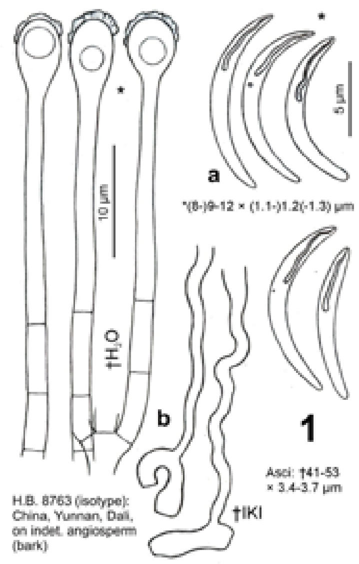

Plate 566. **1**: *Orbilia arcospora*. – **a**. ascospores; **b**. paraphyses and ascus bases.

Habitat: lying on moist ground, corticated, 10 mm thick branch of indet. angiosperm tree, on medium rotten bark (periderm), partially blackened, green algae very sparse. **Associated**: indet. bryophyte. **Desiccation tolerance**: some spores, paraphyses, ectal and medullary excipular cells still viable after 2 weeks. **Altitude**: 2730 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: II.

Taxonomic remarks. *Orbilia arcospora* is easily recognized in the living state by its narrowly fusoid, strongly curved (arcuate) ascospores with long, filiform SBs. From *O. acicularis* it differs mainly in spore curvature. For the similar *O. falciformis* see p. 994. When studying herbarium material, *O. arcospora* may be confused with species of section *Arthrobotrys*, which differ in a more rounded spore apex, and in much shorter SBs.

In the protologue the apothecia were described as up to 1.9 mm diam., but we believe that this value is erroneous. The macrophoto in Su et al. (2011c: fig. 3a) is without a scale, but the very same apothecia were rediscovered in the isotype and were calibrated accordingly, showing a size of rehydrated 0.55–0.75 mm (Pl. 567: 1a–c).

Anamorph. Conidia were not obtained by H.Y. Su in pure culture of *O. arcospora*, therefore, a possible relation to series *Pseudotripoconidium* is derived from its similarity with *O. acicularis*.

Ecology. *O. arcospora* was detected on hygric bark of an unidentified angiosperm tree in a subtropical humid (winter-dry), evergreen broad-leaved mountain forest in southern China.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, Jinguangsi virgin forest, 2730 m, branch of indet. angiosperm, on bark, 1.II.2008, H.Y. Su (H.Y.S. jgs-9, CBCD, **holotype**; H.B. 8763, **isotype**).

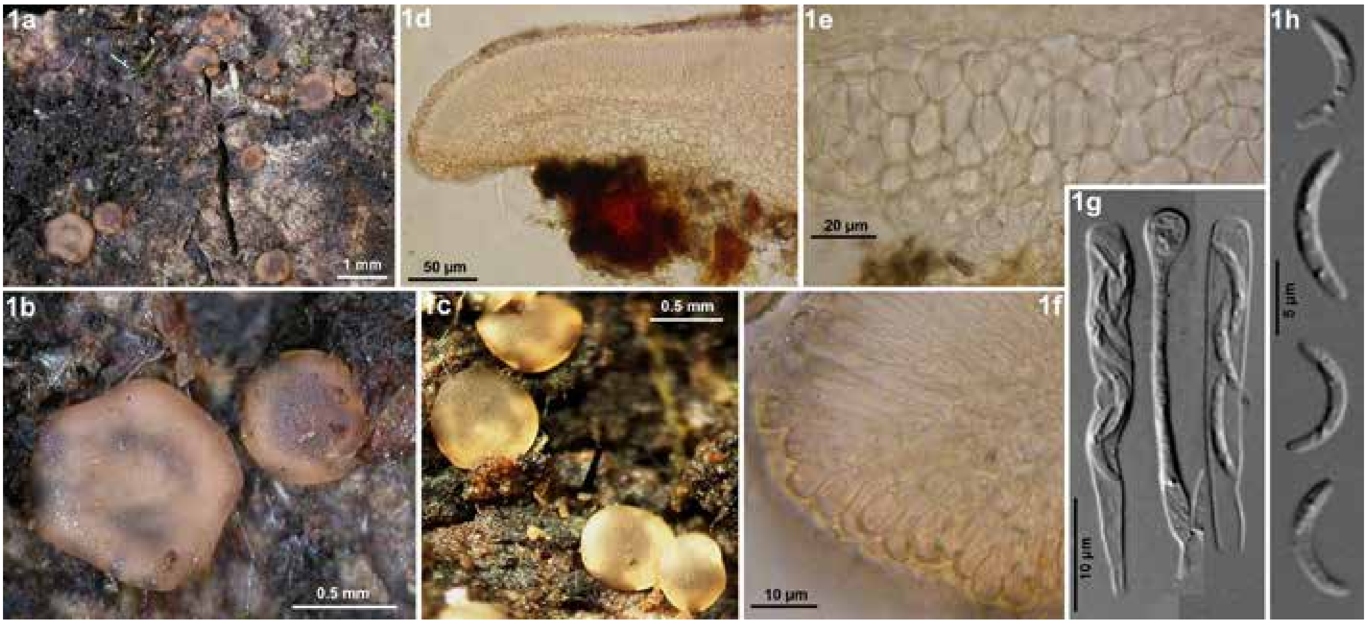

Plate 567. **1**: *Orbilia arcospora*. – **1a–b**. rehydrated apothecia; **1c**. fresh apothecia; **1d**. apothecium in median section; **1e**. id., basal ectal excipulum; **1f**. id., marginal region; **1g**. asci and paraphysis; **1h**. ascospores. – Dead state (in H_2O), except for spores in left ascus of **1g**, **1h**. – **1c**, **g–h**: phot. H.Y. Su (p.p. from Su et al. 2011c, DIC). — **1a–h**. H.B. 8763, H.Y.S. jgs-9 (holo/isotype): China, Yunnan, Dali, on indet. angiosperm.

Section *Habrostictis*

Orbilia subgenus ***Habrostictis*** section ***Habrostictis*** – Lectotype species: *H. rubra* Fuckel (= *Orbilia carpoboloides*)

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–1(–1.8)((–4)) mm diam., pale to bright rose(-lilaceous) to (ochraceous-) orange-red, margin ± smooth or denticulate to fimbriate, sessile or with a short stipe, partly erumpent. **Asci** 8- up to 128-spored, *(29–)35–90(–123) × (4–)5–10(–12) µm, some or many of the lower (rarely upper) spores inverted; **apex** (†) slightly or mostly medium to strongly truncate, not or distinctly indented and/or laterally inflated, hemispherical in profile view, thin-walled; **base** only exceptionally H-shaped. **Ascospores** *(3.3–)4–17(–19.5) × (1.3–)1.6–4(–5) µm, cylindric, ellipsoid, ovoid, tear- to lemon-shaped, fusiform, or clavate, apex rounded to acuminate, straight to strongly curved, especially near base, **SBs** apically affixed to spore wall, rarely subapically (in a few taxa of series *Ellipsospermae*), (1.5–)3–10(–15) × (0.2–)0.3–1(–1.5) µm (actual length), filiform to vermiform or subulate, sometimes distinctly swollen below, straight to often ± flexuous or helicoid, sometimes uncinate, apically narrowed to a small point, filum absent or present. **Paraphyses** slightly to strongly inflated at the apex (clavate-capitate, spathulate, lageniform, mammiform), terminal cells (0.2–)0.5–1.5(–3)× longer than lower cells, unbranched or sometimes branched near apex. **Ectal excipulum** of vertically or indistinctly, sometimes horizontally oriented textura (globulosa-)angularis(-prismatica), (†) thin-walled or slightly gelatinized (common walls 0.3–1.5 µm thick); **glassy processes** absent, exceptionally with small refractive caps, **hairs** sometimes present. **SCBs** globose or mixed with crystalloid ones, also absent; **VBs** consistently absent; **carotenoids** in LBs rarely observed. — **ANAMORPH**: trinacrium-like, sometimes tridentaria- or rarely vermispora- to anguillospora-like. **Conidiophores** 3–30 µm long, unbranched or sometimes branched. **Conidiogenous cells** sympodial. **Conidia** unbranched (phragmosporous), slightly to medium curved, or often branched (staurosporous), with a stipe and 2–6 arms. **Trapping organs**: none observed.

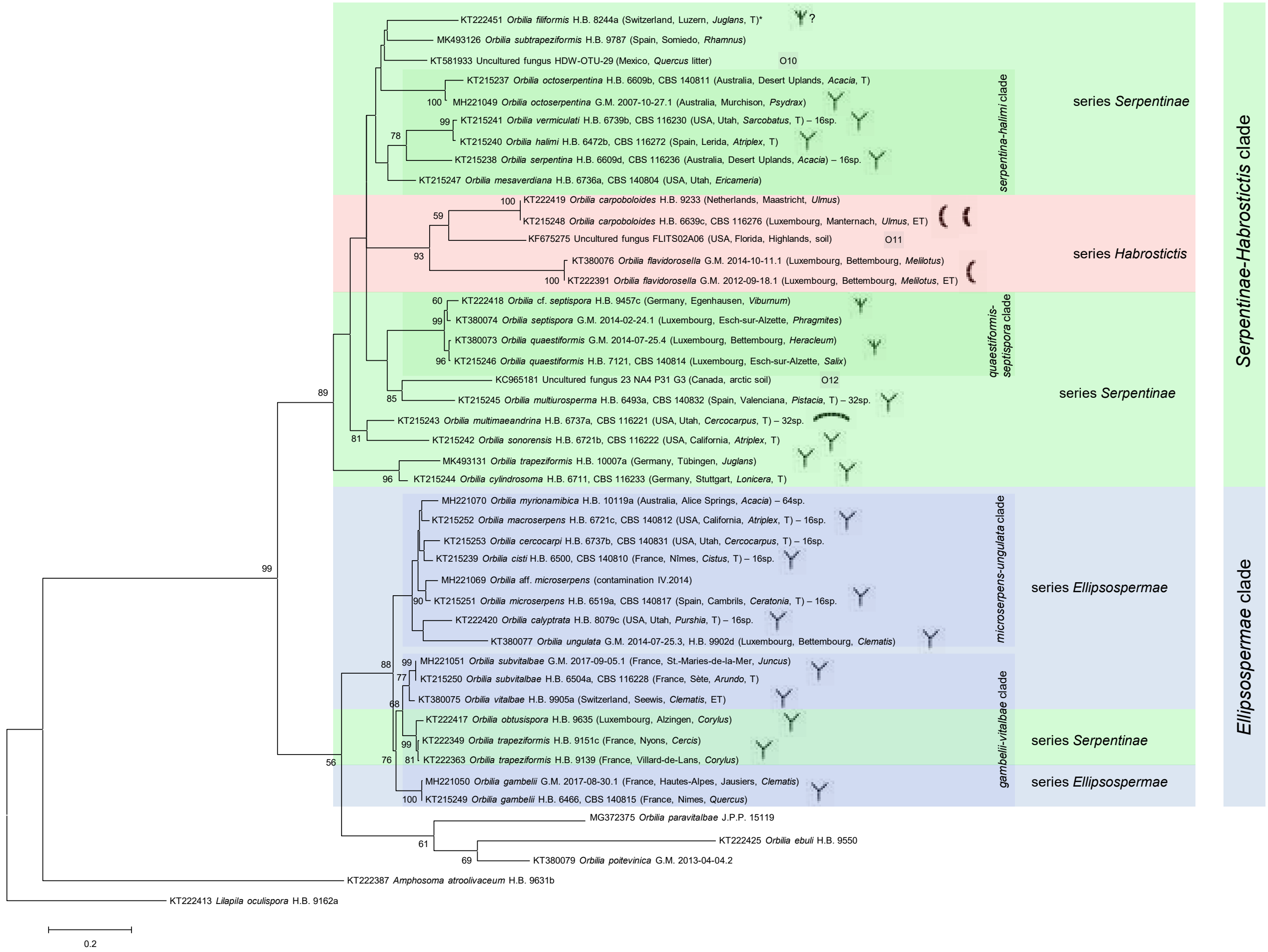
Habitat: all taxa desiccation-tolerant.

Recognized series: *Ellipsospermae*, *Habrostictis*, and *Serpentinae*, with 91 recognized species plus 2 with a provisional name and 18 unnamed species (‘affinis’).

Taxonomic remarks. Section *Habrostictis* includes in the present circumscription three series: *Habrostictis*, *Serpentinae*, and *Ellipsospermae*. Within the genus *Orbilia* it forms the largest section regarding taxa with a known teleomorph. Members of this group are characterized by ascospores containing elongate, usually filiform or vermiform to subulate, flexuous or helicoid, sometimes uncinate SBs which are apically narrowed to a small point and basally often ± inflated. Further characteristics are: always reddish, desiccation-tolerant apothecia, frequently multispored asci, ± equidistantly septate paraphyses being always apically ± inflated in mature apothecia, and the frequent presence of crystalloid SCBs. Glassy processes are consistently absent, though very small glassy caps irregularly occur in *O. jurana* and *O. ophiosoma*. *O. poitevinica*, a species with distinct glassy processes, would otherwise fit section *Habrostictis*, and *O. paravitalbae* closely concurs in its morphology with *O. vitalbae*, but both appear to belong to the paraphyletic section *Aurantiorubrae* based on their rDNA data.

Series delimitation. The three recognized series are largely founded on morphological criteria. Their delimitation is rather complicated because sharp limits are lacking and morphology not always supported by molecular data. The small series *Habrostictis* is characterized by paraphyses with spathulate to mammiform apices, a tendency to have septate hairs at the margin, apothecia that open rather late, and a vermispora-like anamorph. However, in many species of the two large series *Serpentinae* and *Ellipsospermae* a few spathulate paraphyses were often observed among the capitate-clavate ones, and in a few 16- or higher-spored taxa they even predominate. Moreover, a vermispora-like anamorph is connected to *O. multimaeandrina* of series *Serpentinae*.

Series *Serpentinae* and *Ellipsospermae* differ in spore shape. Typical members of series *Serpentinae* have fusiform, apically subacute to acute spores, whereas typical members of series *Ellipsospermae* have ellipsoid to fusoid, apically obtuse to rounded spores. However, a lot of exceptions confirm this rule. For instance, *O. quaestiformis* and *O. septispora* have rounded to obtuse spore apices but acute bases, and are nevertheless



Phylogenetic analysis 19. Phylogram of section *Habrostictis* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (45 sequences, 726 positions, aligned with MAFFT) using the GTR+G model in MEGA6 (500 replicates). Three environmental strains from GenBank are included representing unidentified species (O10–O12). The tree is rooted with *Lilapila oculispora* and *Amphosoma atroolivaceum* and three members of section *Aurantiorubrae*. Asci 8-spored except when otherwise stated; T = type, ET = epitype, * = without most of ITS1, 5.8S and partial ITS2.

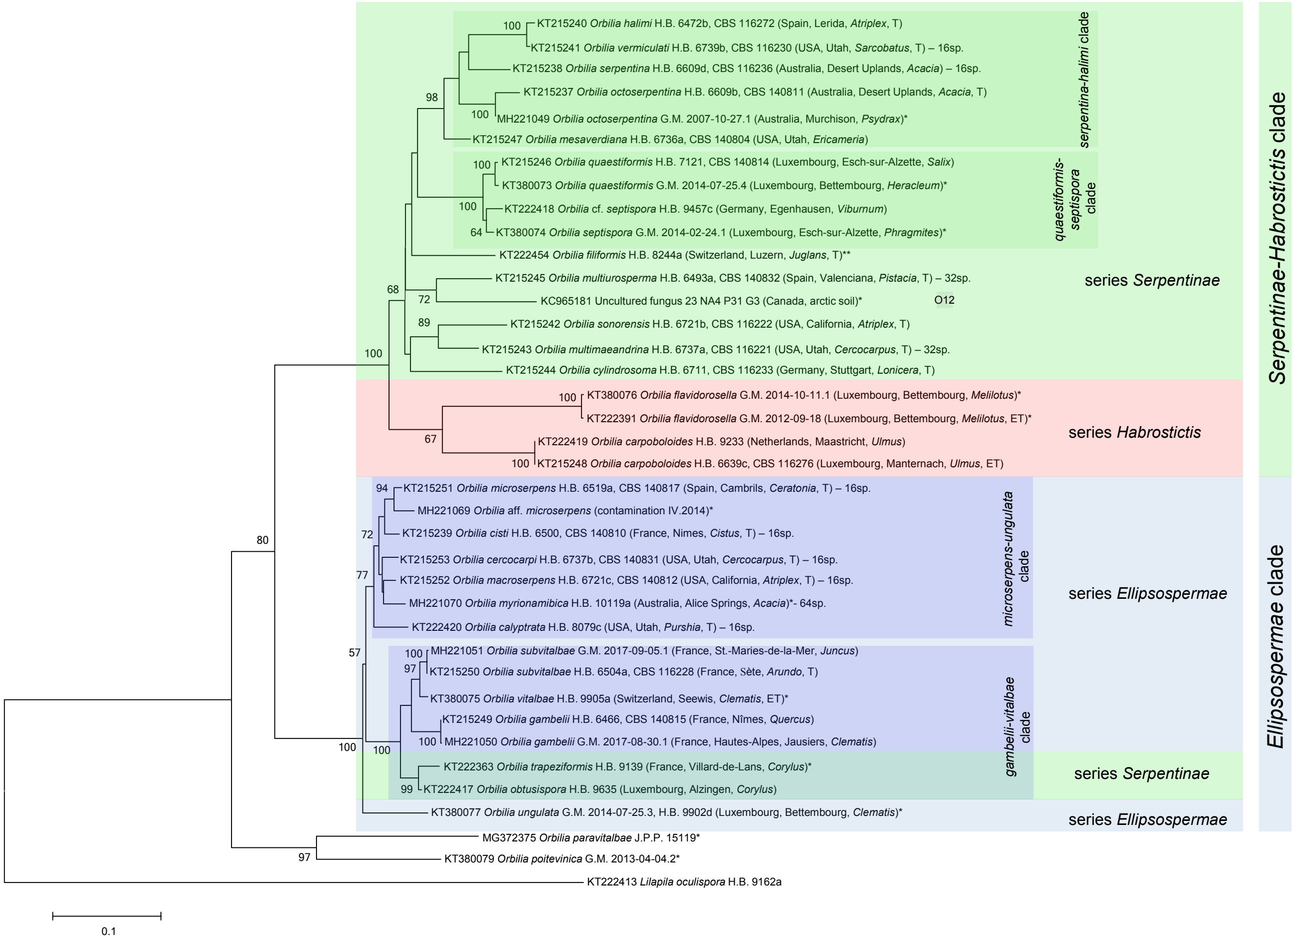
included in series *Serpentinae* (see also under Phylogeny). An option would be to place them in a separate series based on their tridentaria-like anamorph, but also *O. filiformis*, which has fusiform, apically acute spores and clustered in series *Serpentinae*, appears to have a tridentaria-like anamorph.

Anamorphs. Conidia are mostly staurosporous (trinacrium-like, sometimes tridentaria-like), but in series *Habrostictis* and in one species of series *Serpentinae* (*O. multimaeandrina*) they are phragmosporous (vermispora-like). Conidia of series *Serpentinae* and *Ellipsospermae* are very often of the *Trinacrium robustum*-type, being in most of the species quite consistent in shape, usually with tapering arms. Yet, this type of conidia occurs also in section *Hemiorbilia* (e.g., *O. montigena*). Tridentaria-like conidia were only observed in a few members of series *Serpentinae*, whereas two strains from CBS (as *Tridentaria implicans* and *T. subuliphora*) cluster in series *Orbilia*. The conidia of series *Habrostictis* resemble those vermispora-like conidia which occur in sections *Aurantiorubrae* and *Lentiformes*.

Conidiophores were only rarely observed. They are comparatively short, often irregularly flexuous, and usually only with one terminal conidiogenous locus, sometimes also with a few lateral scars. In *O. carpoboloides*, in contrast, conidiophores are remarkable in carrying densely aggregated short denticles.

Phylogeny. Sequences were available for only 31 % of the species of section *Habrostictis* known at present, comprising ITS and mostly also SSU and LSU. Our phylogenetic analyses confirm that the rather easily recognizable section *Habrostictis* forms a natural, strongly supported monophyletic group (Baral et al. 2017b, Phyl. 7). They also confirm that the type species of *Habrostictis* with spathulate to mammiform paraphyses and conspicuous hairs belongs to this group, in spite of its deviating features. Our analyses of SSU+ITS+LSU or LSU (Phyls 20, S22), suggest two sharply delimited, strongly supported, large monophyletic clades within section *Habrostictis*, which represent series *Serpentinae* and *Ellipsospermae* as we have morphologically defined them here, except that three species clustered in the 'wrong' clade, judging from their spore shape, and that the *Serpentinae-Habrostictis* clade, as we call it here, includes also series *Habrostictis*. In such cases, we have maintained our morphology-based system, although the molecular result was contradictory. In fact, many of the species have only once been treated by molecular methods, thus the present results are to be considered as preliminary. Moreover, a majority of species are without molecular data and we have not found a clue to recognize their affiliation in one of the two clades by morphology alone.

The above-mentioned exceptions suggest that the shapes of ascospore apex and paraphysis apex have a limited taxonomic value above species level. For instance, *O. obtusispora* is included in series *Serpentinae* because of the difficulty to separate it from *O. trapeziformis* and *O. subtrapeziformis*, in spite of its unequivocal molecular placement in series *Ellipsospermae*. The latter two species and the very similar *O. cylindrosoma*



Phylogenetic analysis 20. Phylogram of section *Habrostictis* inferred from combined ML analysis of SSU (V8–V9)+ITS1-5.8S-ITS2+LSU (D1–D2) rDNA dataset (38 sequences, 1677 positions, aligned with MAFFT) using the GTR+G+I model in MEGA6 (500 replicates). An environmental strain from GenBank is included representing an unidentified species (O12). The tree is rooted with *Lilapila oculispora* and two members of section *Aurantiorubrae*. Asci 8-spored except when otherwise stated; T = type, ET = epitype, * = SSU incomplete or absent, ** = ITS incomplete.

and *O. filiformis* belong from their morphology and rDNA to series *Serpentinae*. Moreover, our concept of *O. trapeziformis* appears to be heterogeneous because two of our three samples with a sequence clustered very close to *O. obtusispora*, although their spores do not markedly differ from those of the third sample which clustered with *O. cylindrosoma*. Finally, *O. myrioolneyae* clustered in the *Serpentinae-Habrostictis* clade although we treat it in the *Ellipsospermae* clade. Because of this difficulty, we refrained from providing a key for identifying the two large series.

Sequences within the small, morphologically more easily recognizable series *Habrostictis* (with vermispora-like conidia) were only available for two species. Their clade received strong support in Baral et al. (2017b, SSU+ITS+LSU) and our analysis of ITS (Phyl. 19), despite a high ITS distance between them, but medium to weak support in our analyses of SSU+ITS+LSU (Phyls 7, 20) or without support when analysing SSU (Phyl. S20). When analysing LSU alone (S22) the two species did not even group together. In the mentioned combined analyses series *Habrostictis* clustered sister to the medium to weakly supported rest of the *Serpentinae-Habrostictis* clade, while when only analysing ITS or LSU it clustered unresolved within that clade.

The two species which formed tridentaria-like conidia in culture (*O. quaestiformis*, *O. septispora*) clustered in a strongly supported subclade (*quaestiformis-septispora* clade, Phyls 19–20). However, a third species in which tridentaria-like conidia were often observed on the natural substrate (*O. filiformis*), does not cluster with them. Although *O. quaestiformis* and *O. septispora* are very similar in the ITS region, they surprisingly did not form a clade when analysing LSU (S22).

In our combined analysis a further subclade is formed within series *Serpentinae*, the strongly supported *serpentina-halimi* clade. Also within the *Ellipsospermae* clade two more or less supported subclades can be recognized (Phyls 19–20, S20), the *microserpens-ungulata* clade and the *gambelii-vitalbae* clade, the latter containing *O. obtusispora* and *O. trapeziformis* p.p.

Specific nucleotide positions. Nucleotides that unequivocally characterize section *Habrostictis* within *Orbilia* have not been found. In the SSU V8–V9 region pos. 154–166 (starting with CCTTAGATGTT) is consistently **G**AGTCATCAGCT**C**, while **A**AGTCATCAGCT**T** in most other groups of *Orbiliomycetes*, except for a few members of series *Hesperideae* which concur with section *Habrostictis* (see p. 553), and *O. pleistoeuonymi* (section *Lentiformes*) which shows the variant **G**AGTCATCAGTT**C**. Within section *Habrostictis* the two main clades differ in characteristic motifs and gaps in the ITS1 and ITS2 region, leading to sharp differences in the alignment. Also in the LSU D1–D2 domain a number of positions are characteristic (Tab. 72). In the 5.8S region two groups can be recognized based on variance at pos. 121, which recall to some extent the *Serpentinae-Habrostictis* (**C**TTGGTA) and *Ellipsospermae* (**T**TTGGTA) clade, but with a number of species in the wrong group when comparing our phylogenetic analyses of more informative gene regions.

Table 72. Characteristic nucleotides in the LSU D1–D2 domain (highlighted in bold) that differ between the two main clades of section *Habrostictis* or between the two subclades of the *Ellipsospermae* clade (pos. 509). Note intermediate position of *O. multiurosperma* (r). G = *gambelii-vitalbae* clade, M = *microserpens-ungulata* clade, c = *O. carpoboloides*, d = *O. cylindrosoma*, f = *O. flavidorosella*, h = *O. halimi*, i = *O. cisti*, l = *O. filiformis*, m = *O. multimaeandrina*, p = *O. serpentina*, q = *O. quaestiformis*, r = *O. multiurosperma*, s = *O. sonorensis*, t = *O. septispora*, u = uncultured fungi, v = *O. vermiculati*, y = *O. calyptrata*, without annotation = more than three species. Position numbers starting with TGACCT by omitting predominant gaps in alignment of all groups of *Orbiliomycetes*.

		TTACTTGC^{i}				

In the SSU V8–V9 region the *Serpentinae-Habrostictis* clade differs at 2 positions from the *Ellipsospermae* clade: pos. 244 (GGA**C**TGG vs. GGA**T**TGG) and pos. 281 (CCG**G**AAA vs. CCG**A**AAA), respectively. Even in this gene region the *Ellipsospermae* clade is sharply split into two subclades, a uniform *microserpens-ungulata* clade and a variable *gambelii-vitalbae* clade (S20), based on 6 consistent positions, 2 in V8 and 4 in V9. At pos. 235 of SSU V9, series *Serpentinae* (excluding *O. obtusispora* and *O. trapeziformis* p.p.) sharply differs from any other group of *Orbilia* (including series *Habrostictis*) in having TGAG**A**C vs. TGAG**G**C, respectively. This appears to indicate that this group is apomorphic within section *Habrostictis*, while the *Ellipsospermae* clade and series *Habrostictis* are ancestral. Yet, nucleotides in the LSU suggest that also the *Ellipsospermae* clade could be apomorphic: e.g., at pos. 124 it has C and at 129 A (Tab. 72), whereas any other *Orbiliomycetes* taxa, including the *Serpentinae-Habrostictis* clade, have at pos. 124 G (rarely T or A) and at pos. 129 C, T or G.

Two cases of characteristic gaps occur in a few species across the two main clades of section *Habrostictis*. *O. multiurosperma* concurs with *O. calyptrata* in the LSU D1 domain at pos. 129 and 132–133 by 3 gaps, which any other sequence of section *Habrostictis* does not have (Tab. 72). For *O. multiurosperma* the gaps are affirmed by two independent sequences. When analysing LSU, both species formed a basal sister taxon to the remaining members of their clade (Phyl. S22). A similar coincidence of 2 associated gaps is observed at pos. 542–544 between *O. halimi*/*O. vermiculati* (series *Serpentinae*) and *O. microserpens* (series *Ellipsospermae*).

In conclusion, series *Habrostictis* appears to represent the plesiomorphic (ancestral) group within section *Habrostictis*. If this proves true, we may conclude that series *Habrostictis* unites some plesiomorphic characteristics, such as cleistohymenial apothecial development, marginal hairs, spathulate to mammiform paraphyses, crystalloid SCBs, ± acute spore apices, and vermispora-like conidia. In more advanced groups these features partly disappeared by regression or, in the case of the anamorph, developed from phragmo- to stauroconidia.

Ecology. All species of section *Habrostictis* are desiccation-tolerant and grow on exposed (xeric), woody or herbaceous substrates. The highest species diversity is observed in semihumid to arid regions, but the group is also present with a rather high number of species in humid temperate and montane, rarely subalpine-boreal areas. Species of this group have been recorded worldwide.

Key to series of section *Habrostictis*

1. Paraphyses always or predominantly narrowed above (spathulate, mammiform, lageniform-lanceolate), distinctly protruding beyond dead asci; apothecial margin often protruding beyond disc, often with a conspicuous whitish fringe of short thin-walled hairs; asci 8–16-spored .... **series *Habrostictis***, (p. 1015)

1. Paraphyses predominantly capitate or clavate, in some taxa more ellipsoid, if spathulate then capitate-clavate or ellipsoid apices more abundant or asci > 16-spored, never mammiform; apothecial margin smooth to crenulate, protruding or not, never fringed with thin-walled hairs; asci 8–128-spored .... **series *Serpentinae* & *Ellipsospermae*** (p. 1016)

Key to series *Habrostictis*

1. Asci 32-spored: compare *O. multidelphinus*, *O. multitrapezoidea*, *O. multimaeandrina*, *O. osteospermae*, in which spathulate paraphyses partly occur .... see series *Serpentinae*, Key E (p. 1022)

1. Asci 16-spored 2

1. Asci 8-spored 4

2. Spores *(5.5–)6–10 × (2.4–)2.8–3(–3.3) µm, apex rounded to obtuse; crystalloid SCBs absent; bark & wood of *Lonicera*, orotemperate (sub)humid central Asia .... ***O. mongolica***, p. 1041

2. Spores *1.7–2.5 µm wide 3

3. Spores *9–11 × 2–2.4 µm, apex subacute; paraphyses only slightly spathulate, without glassy caps; crystalloid SCBs absent; wood of *Cupressus*, submediterranean Europe .... ***O. subdelphinus*** (series *Serpentinae*), p. 1111

3. Spores *(4.7–)5.5–9(–11) × 1.7–2.3(–2.5) µm; paraphyses spathulate, often tipped by glassy caps; crystalloid SCBs present; wood of various gymno- and angiosperm shrubs, temperate to subtropical, subhumid to semiarid western North America .... ***O*. *calyptrata*** (series *Ellipsospermae*), p. 1187

4. Paraphyses uninflated or ± lanceolate; spores *4.8–6.3 × (1.8–)2–2.3(–2.5) µm, cylindric-clavate with broadly subacute tips; apothecia 0.3–0.55 mm diam., cup-shaped; angiosperm bark, afromontane humid northeastern Africa .... ***O*. *aethiopica*** (series *Abutilones* of section *Aurantiorubrae*), p. 912

4. Paraphyses mammiform to lageniform, also spathulate to lanceolate but then spore size different 5

5. Spores predominantly < *2(–2.2) µm wide 6

5. Spores predominantly > *(2–)2.2 µm wide 11

6. Spores *1–1.7 µm wide, with or without a basal constriction .... series ***Abutilones*** of section *Aurantiorubrae*, p. 885

6. Spores *1.4–2.2 µm wide 7

7. Spores *(5.5–)7.3–12(–14) × 1.4–2.5 µm; apothecia < 1.5 mm diam. 8

8. Paraphyses often broadly mammiform, *3–6 µm wide; spore apices rounded to acute; Australia 9

8. Paraphyses predominantly narrowly mammiform to spathulate, *(2.2–)2.5–4(–4.7) µm wide; spore apices mostly (sub)acute; Europe, Macaronesia 10

9. Paraphysis apices mostly with abrupt beak; crystalloid SCBs present; spore apices subacute to acute; bark of climbers, tropical subhumid eastern Australia .... ***O*. *mammifera***, p. 1043

9. Paraphysis apices only sometimes beaked; crystalloid SCBs absent; spore apices rounded to obtuse; bark of *Vachellia* or climbers, subtropical arid western Australia .... see ***O*. *farnesianae*** (section *Aurantiorubrae*), p. 923

10. Spores *(6.8–)7.3–10(–11.3) × (1.5–)1.7–2(–2.2) µm, SBs (3–)4–6.5(–7.5) µm long; paraphyses narrowly spathulate to mammiform; apothecial margin with distinct whitish fringe of short septate hairs; crystalloid SCBs present; herbaceous stems, bark of angiosperms, temperate humid to mediterranean Europe and Macaronesia .... ***O*. *flavidorosella***, p. 1045

An orosubmediterranean sample on *Cytisus* twigs deviates by longer spores of *11.3–14.5(–16) × 1.7–2.2 µm and SBs of (5.5–)7–8.5 µm (p. 1048).

10. Spores *9.5–12(–13) × 1.4–1.6 µm, SBs 3.7–4.5 µm long; paraphyses almost uninflated to narrowly spathulate; apothecial margin not fringed; stems of *Solidago*, temperate humid Europe .... ***O*. *solidaginis***, p. 1048

11. Living spores consistently without SBs, *11.5–20.5 × 2.4–3.5 µm; wood of *Euphorbia*, subtropical (semi)arid Macaronesia .... ***O*. *asomatica*** (section *Arthrobotrys*, series *Neodactylella*), p. 1487

11. Living spores with distinct SBs 12

12. Spores min. *(3.2–)3.4–3.7 µm wide; asci †(5–)5.5–6.5(–7) µm wide 13

12. Spores *2–3.2(–3.5) µm wide; asci †4.2–5.5 µm wide 14

13. Spores *(6–)7–9 × (3.2–)3.6–4.5(–5) µm; wood & bark of gymnosperms, cold-temperate (sub)humid western North America .... ***O*. *ophiosoma*** (series *Serpentinae*, key A), p. 1050

13. Spores *9–11 × 3.2–3.6 µm; bark of *Prosopis*, warm-temperate semiarid western North America .... ***O*. cf. *carpoboloides***, p. 1035

14. Upper spores predominantly inverted within asci; spores *(10–)11–15(–17) × (2.1–)2.3–2.6(–2.8) µm; apothecial margin not hairy; wood & bark of angiosperms, temperate humid to semiarid western North America .... ***O*. *spathulata*** (series *Serpentinae*), p. 1112

14. Lower spores predominantly inverted; spores *(7.7–)8.5–14(–17) × (2–)2.2–3(–3.5) µm 15

15. Apothecia < 0.3 mm diam., with smooth margin; spores with ± obtuse apex; SBs filiform, partly as long as spores; crystalloid SCBs absent; wood of *Castanea*, temperate humid southern Europe .... ***O*. cf. *quercus-ilicis*** (series *Serpentinae*), p. 1162

15. Apothecia 0.4–1.5 mm diam., with lacerate, often hairy margin; spores with (sub)acute apex; SBs about half as long as spores; crystalloid SCBs present, at least in excipulum 16

16. SBs filiform, (0.2–)0.3–0.4(–0.5) µm wide; apothecial margin toothed or lobed, not distinctly hairy; bark of a climber, tropical subhumid Australia .... ***O*. *scandens***, p. 1042

16. SBs vermiform or mostly subulate, often inflated to (0.4–)0.6–1(–1.3) µm at base; apothecial margin toothed or often with a fringe of septate hairs; bark (rarely wood) of various angiosperms, often *Ulmus*, hemiboreal to subtropical (semi)humid Europe, North & South America, ?Australia .... ***O*. *carpoboloides***, p. 1025

Samples with long and narrow spores (including type of *Habrostictis rubra* and *Orbilia lasia*) might be specifically distinct from O. *carpoboloides* s.str.

Key to species of series *Serpentinae* and *Ellipsospermae*

Remark: Although spore numbers are usually very consistent, more or less reduced numbers down to half the normal case may sometimes occur in a few of the asci, but asci with the normal spore number are always present among the aberrant ones. Some species of series *Phanosomates* (subgenus *Hemiorbilia*) resemble members of series *Ellipsospermae* because of a similar spore body shape, but differ in the dead immature asci lacking distinctly shouldered apices which are often thick-walled instead, and in globose SCBs (exception: *O. cercidis*) in contrast to frequently crystalloid SCBs in series *Ellipsospermae*. Members of section *Helicoon* partly resemble the present group in spores and SBs but differ in growing on hygric substrate.

Asci	8-spored	16-spored	32-spored	64–128-spored
Spores predominantly < 9 µm long	key A	key C	key E	key F
Spores predominantly > 9 µm long	key B	key D		

KEY A (asci 8-spored, spores predominantly < 9 µm long)

1. Spores subglobose to ellipsoid-ovoid-fusoid, length/width ratio mainly < 2.5 2
1. Spores more elongate, length/width ratio in most spores > 2.5 3

2. Spore apex predominantly acute to subacute, spores *(6–)7–9 × (3.2–)3.6–4.5(–5) µm; SBs as long as spores or shorter; only globose SCBs present; wood & bark of gymnosperms, cold-temperate (sub)humid western North America .... ***O. ophiosoma***, p. 1050
2. Spore apex predominantly rounded to obtuse, spores *(4.5–)5–8(–9) × (2.2–)2.5–3.5(–3.8) µm; SBs often longer than spores (rarely only half as long); crystalloid SCBs present, at least in ectal excipulum; wood & bark of angiosperms, rarely gymnosperms or stems of herbs, orosubmediterranean to subtropical, humid to semiarid western North America, Europe, Macaronesia .... ***O. gambelii***, p. 1200
Compare also short-spored specimens of the Australian *O. octocercocarpi* (p. 1213).

3. Spores predominantly < *2 µm wide 4
3. Spores predominantly > *2 µm wide 8

4. Spores medium to very strongly curved, *(5–)6–8(–9.5) × 1.8–2.1(–2.3) µm; bark & wood of *Jacksonia*, subtropical semihumid Australia .... ***O. curvativitalbae***, p. 1193
4. Spores straight or only slightly curved near base 5

5. Excipular cells containing very distinct crystalloid SCBs; spores *(4–)5–7.5(–8.5) × 1.6–2.2 µm; apothecial margin not protruding; wood of angiosperms, herbaceous stems, temperate humid to mediterranean Europe .... ***O. ungulata***, p. 1180
Similar collections with longer asci (*47–53 instead of 29–45 µm) and partly also longer spores (*8–9 µm) were on *Krascheninnikovia* (western North America) and *Petteria* (southern Europe, p. 1183). Compare also *O.* aff. *coniferarum* with filiform SBs on *Picea* from Mongolia (p. 1165).
5. Excipular cells consistently without crystalloid SCBs; spores distinctly exceeding 7 µm in length 6

6. SBs 1.3–2(–2.5) µm long; spores *6–8.5(–9) × 1.6–1.9 µm; wood of *Arctostaphylos*, warm-continental subhumid western North America .... ***O*. aff. *dixiensis***, p. 1179
6. SBs > 2.5 µm long 7

7. Spores *5.5–8.8 × 1.4–1.8 µm, narrowly fusoid; SBs 2.5–3.5 × 0.3–0.5 µm, subulate; SCBs absent; apothecial margin protruding for 15–30 µm; bark of *Tilia*, temperate humid montane central Europe .... ***O. jurana***, p. 1190
7. Spores *(5–)5.5–9.5(–11) × (1.5–)1.8–2.5(–2.8) µm, cylindric-ellipsoid(-fusoid); SBs 2.5–6.8 × 0.3–1.3 µm, with abruptly inflated lower part; SCBs globose; apothecial margin protruding for 0–5 µm; wood & bark of angiosperms, herbaceous stems, temperate to mediterranean, also thermoboreal Europe .... ***O. vitalbae***, p. 1172
If SBs subulate compare *O. ungulata* in which crystalloid SCBs were rarely absent (p. 1180).

8. Margin with 10–20 µm long glassy processes; spores *(6–)7–9 × 2.6–2.8(–3) µm; bark of *Fraxinus*, atlantic to subcontinental Europe .... see ***O. poitevinica*** (series *Poitevinicae* of section *Aurantiorubrae*), p. 913
8. Margin without glassy processes 9

9. Excipular cells (and paraphyses) with crystalloid SCBs 10
9. Excipular cells (and paraphyses) without crystalloid SCBs 14

10. Spores *(6–)7.5–11(–13.3) × 2.1–2.7 µm; SBs 1/3–1/2 of spore length, filiform; wood of various angiosperms, petioles of *Livistona*, (sub)tropical subhumid to arid Australia, Africa .... ***O. acaciae***, p. 1072
10. Spores shorter and partly wider 11

11. SBs about as long as spores 12
11. SBs only about half as long as spores 13

12. Spores *6.5–8.5 × (2.2–)2.5–2.8 µm, SBs strongly helicoid, usually much longer than spores .... see under 2 (*O. gambelii*)
See also the Australian *O. octocercocarpi* with *2.8–3.5 µm wide spores (p. 1212).
12. Spores *5.8–8 × 2.2–2.5(–2.7) µm; SBs only slightly flexuous, shorter than spores; branch of *Rosa*, orosubmediterranean Spain .... Pl. 701: 2, ***O*. aff. *subvitalbae***, p. 1180

13. Spores *(5.5–)7.5–8.5(–9.5) × (2.2–)2.7–3(–3.3) µm, base slightly, rarely medium tapered; culms of *Arundo* and *Juncus*, mesomediterranean Europe .... ***O. subvitalbae***, p. 1179
Similar samples on *Amelanchier* from western North America with rather small crystalloid SCBs seen in the excipulum only are mentioned under *O. commarosa* (p. 1198).
13. Spores *(7.3–)8–10.5(–11.3) × 2.8–3.5(–4) µm, base medium to strongly tapered; branches of *Cactaceae*, subtropical semiarid western North America .... ***O. cactacearum***, p. 1143
A collection on *Krascheninnikovia* deviates in longer spores (*11–13 × 3–3.5 µm) and asci (*67–106 vs. *52–70 µm) (p. 1145).

14. SBs ± sharply divided into a short to long, filiform to subulate upper part and an abruptly thickened lower part; spores *(5–)6–9.5(–11.8) × (1.5–)1.8–2.5(–2.8) µm, cylindrical to fusoid 15
14. SBs subulate to vermiform, gradually thicker towards base, only sometimes slightly swollen at base; spores *(6–)8–12 × 2–3.6 µm, fusoid to fusiform 18

15. Spores straight to slightly curved, not or only slightly to medium tapered at base 16
15. Spores usually slightly to strongly curved, predominantly strongly tapered at base 17

16. SBs often longer than half the spore length (but also shorter); spores cylindric to ellipsoid-fusoid, straight; temperate Europe .... see under 7 (*O. vitalbae*)

16. SBs usually shorter than half the spore length; spores subcylindrical, some slightly curved; bark & wood of *Artemisia*, *Ericameria*, *Salix*, boreal humid to temperate semiarid western North America .... ***O. dixiensis***, p. 1177
A Spanish collection on bark of *Berberis* (E.R.D. 7892) appears to be closely related to *O. dixiensis* (p. 1179).

17. Spore apex obtuse, rarely subacute; upper part of SBs filiform; apothecia 0.3–0.8 mm diam., bright (pink-)rose, rarely orange-rose; bark (& wood) of *Acacia*, (sub)tropical semihumid to arid Australia .... ***O. commarosa***, p. 1195
17. Spore apex mostly subacute; upper part of SBs mainly subulate; apothecia 0.2–0.4 mm diam., light orange; petioles of *Livistona*, subtropical subhumid Australia .... ***O.* cf. *commarosa*** (H.B. 6424c), p. 1198

18. Spores *1.8–2.5(–2.7) µm wide 19
18. Spores *2.8–3.5 µm wide 22

19. Spores *(6–)7–8.8 × 1.9–2.1 µm, ± straight; wood of *Picea*, orotemperate (sub)humid central Asia (absence of crystalloid SCBs uncertain; anamorph unknown) .... ***O.* aff. *coniferarum***, p. 1165
19. Spores (1.8–)2–2.5(–2.7) µm wide; anamorph trinacrium-like 20

20. Spores *(6–)7.5–11(–12.5) × (1.8–)2–2.5(–2.8) µm, fusoid, apex (obtuse to) subacute; SBs vermiform to subulate, not or only slightly inflated near base; herbaceous stems, angiosperm wood & bark, temperate to mesomediterranean Europe ...... ***O. cylindrosoma***, p. 1068
20. SBs filiform to subulate, gradually or abruptly slightly to strongly inflated near base; on woody substrates 21

21. Spores *(6.5–)8–13(–14) × (1.8–)2.1–2.5(–2.7) µm, fusoid(-clavate) to subcylindrical; wood & bark of various angiosperms (often *Quercus*), exceptionally gymnosperms, orotemperate to mesomediterranean Europe, temperate subhumid to semiarid western North America .... ***O. obtusispora***, p. 1061
21. Spores *(5–)6.5–9.5(–11) × (2–)2.2–2.8(–3.2) µm, fusoid(-clavate); wood & bark of various angiosperms, rarely gymnosperms, temperate to mesomediterranean Europe .... ***O. trapeziformis***, p. 1055

22. Spore apex rounded to obtuse, spore bases slightly to strongly tapered; anamorph tridentaria-like; wood (& bark) of gymnosperms, orosub- to mesomediterranean Europe, boreal to temperate (sub)humid western North America .... ***O. coniferarum***, p. 1163
22. Spore apex obtuse, subacute or acute 23

23. Spores ± fusiform, *6–11.5 × 2.8–3.5 µm, apex subacute to acute; apices of paraphyses *3–8 µm wide; wood & bark of angiosperms, temperate to subtropical subhumid to arid western North America & Australia .... ***O. macrotrapeziformis***, p. 1098
23. Spores fusoid-clavate, apex obtuse to subacute 24

24. Spore bases sometimes tail-like; anamorph trinacrium-like; wood & bark .... see under 21 (*O. trapeziformis*)
If spores more elongate and/or more subcylindrical compare *O. obtusispora* (p. 1061) and *O. cylindrosoma* (p. 1068).
24. Spore bases mostly tail-like or with short tail; anamorph tridentaria-like; leaves of *Quercus ilex*, supra(sub)mediterranean Europe .... ***O. quercus-ilicis***, p. 1162
A collection on *Humulus* from Belgium referred to *O. trapeziformis* (Pl. 593: 6) differs from *O. quercus-ilicis*, e. g., in more subacute spore apices.

KEY B (asci 8-spored, spores predominantly > 9 µm long)

1. Spore apices mainly rounded to obtuse, only occasionally subacute 2
1. Spore apices subacute to acute or acuminate, if obtuse to subacute then SBs strongly flexuous or curled 14

2. Some or most spores distinctly curved, spore base predominantly strongly tapered 3
2. Spores more or less straight or only a few slightly to medium curved, non-septate 11

3. Spores predominantly 1-septate inside mature living asci, *(10–)11–15(–17) × (2.5–)2.8–3.7(–4.2) µm, often ± tapered and curved at base; culms of larger grasses, also herbaceous stems or angiosperm wood, temperate humid, atlantic to subcontinental Europe........ ***O. septispora***, p. 1158
3. Spores non-septate inside mature living asci, overmature septate or not 4

4. Excipular cells (& paraphyses) without crystalloid SCBs 5
4. Excipular cells (& paraphyses) with crystalloid SCBs 8

5. SBs with filiform upper part and abruptly inflated, 0.5–0.8 µm wide lower part; apothecia 0.3–0.7 mm diam., bright pink-rose; anamorph unknown; Australia .... see key A under 17 (*O. commarosa*)
5. SBs entirely filiform or gradually enlarged towards base, 0.2–0.5 µm wide; apothecia 0.15–0.5 mm diam., light orange-rose; anamorph tridentaria-like 6

6. SBs predominantly shorter than half the spore length (in situ), spores *(7–)9–13(–14.5) × 2.3–3 µm; conidial arms *2.5–4(–4.7) µm wide; herbaceous stems of mono- and dicots, also wood (& bark) of angiosperms, hemiboreal humid to thermomediterranean semihumid Europe .... ***O. quaestiformis***, p. 1151
6. SBs often longer than half the spore length, spores *6.5–13 × 2.5–3 µm 7

7. Spore bases slightly to strongly tapered; conidial arms *4.5–5.5 µm wide; conifer wood & bark.... see key A under 22 (*O. coniferarum*)
7. Spore bases ± strongly tapered; conidial arms *2.5–4 µm wide: *Quercus ilex* leaves .... see key A under 24 (*O. quercus-ilicis*)
A sparse collection on wood of *Castanea* hardly differs herefrom, except for the partly lageniform to moniliform paraphyses (p. 1162).

8. Spores *(6.5–)9–9.5(–11.5) × 2.3–2.6(–2.9) µm; branch of *Rosa*; supramediterranean semihumid Europe........ ***O. rosicola***, p. 1168
8. Spores > 2.8 µm wide 9

9. Spores *(9.5–)10.5–15(–17) × 3–3.5(–4) µm, mostly medium to very strongly curved (often entirely); bark of *Artemisia*, *Ericameria*, temperate subhumid to semiarid western North America .... ***O. mesaverdiana***, p. 1148

9. Spores *8–12 µm long, slightly to sometimes medium curved (only at base) 10

10. SBs 5–7.5 µm long; spores *(7–)8–12 × 2.8–3.2 µm; bark of climber, (sub)tropical (semi)arid Australia .....***O***. ***octocercocarpi***, p. 1212

10. SBs 3.5–4.5 µm long; spores *(7.3–)8–10.5(–11.3) × 2.8–3.5(–4) µm; on *Cactaceae*, subtropical semiarid western North America .... ***O***. ***cactacearum***, p. 1143

11. Spores *(8–)8.5–12(–12.8) × (3.2–)3.5–4.3(–4.8) µm; crystalloid SCBs present; wood of different angiosperm shrubs, warm-temperate to subtropical (semi)arid western North America .... ***O***. ***sonorensis***, p. 1145

A collection on *Juglans* was without crystalloid SCBs and might be distinct.

11. Spores < 3 µm wide 12

12. Excipular cells (& paraphyses) with crystalloid SCBs; spores *(6–)7.5–11(–13.3) × 2.1–2.7 µm; SBs 3–5 µm long, filiform .... see key A under 10 (*O. acaciae*)

12. Excipular cells (& paraphyses) without crystalloid SCBs 13

13. SBs divided into a short to long, filiform to subulate upper part and a ± abruptly thickened lower part; spores *(5–)6–9.5(–11.8) × (1.5–)1.8–2.5(–2.7) µm .... see key A under 16 (*O. dixiensis* & *O. vitalbae*)

13. SBs subulate to vermiform, gradually thicker towards base, only sometimes slightly swollen; spores *(6–)8–14(–18) × (1.8–)2–2.5(–2.7) µm 30

14. Spores predominantly > *2.5 µm wide 15

14. Spores predominantly < *2.5–2.7 µm wide 24

15. Excipular cells (& paraphyses) with crystalloid SCBs 16

15. Excipular cells (& paraphyses) without crystalloid SCBs 18

16. Spores *(12–)13–17 × 3.1–3.8 µm, base strongly tapered and slightly to strongly curved; SBs 8–14 µm long; felty bark of *Solanum lasiophyllum*, subtropical arid Australia .... ***O***. ***urosperma***, p. 1135

16. Spores shorter, or straight and only slightly tapered at base 17

17. SBs 5–7.5 µm long; spores *(9–)10–13.5(–15) × (2.7–)2.9–3.5(–3.7) µm, base mostly medium to strongly tapered and somewhat curved; wood & bark of various angiosperms, herbaceous stems, temperate to subtropical semihumid to arid western North America and southern Europe .... ***O***. ***bicknellensis***, p. 1129

A collection on *Baccharis* from North America differs in 9.5–12 µm long SBs (Pl. 655: 4).

17. SBs 7–11 µm long; spores *(9–)12–15.5(–18.3) × 3.2–3.8(–4.2) µm, base mostly not or only slightly tapered and straight; wood & bark of different angiosperms, (sub)tropical semihumid to arid Australia .... ***O***. ***octoserpentina***, p. 1122

18. Upper spores predominantly inverted within asci; spores *12–19.5 × (2.5–)2.7–3.5(–4.5) µm; bark of *Acacia*, subtropical (semi)humid western Australia .... ***O***. ***wannerooensis***, p. 1104

18. Lower spores predominantly inverted within asci 19

19. Spores strongly curved near base, which is not or only slightly to medium tapered, *(10–)11–13.5(–14.5) × (2.5–)2.7–3.3 µm; bark of *Quercus gambelii*, wood of *Euphorbia balsamifera*, temperate humid western North America, subtropical arid Macaronesia .... ***O***. ***curvatitrapeziformis***, p. 1101

19. Spores ± straight or only slightly curved near base, if more curved then strongly tapered below 20

20. Spores *(10–)12–17(–20.3) × (2.4–)2.6–3.2(–3.8) µm, with obtuse to subacute apices, base partly ± strongly attenuated (tail-like) or with distinct tail; SBs often uncinate to curled; wood of gymno- and angiosperms, temperate (sub)humid western North America .... ***O***. ***flexisoma***, p. 1095

20. Spores with (subacute to) acute apex and slightly to strongly tapered base, never with a distinct tail 21

21. Spores strongly fusiform, often with acute base, *(12.5–)13.5–17 × (2.8–)3–3.7 µm; asci *70–100 µm long; paraphyses without SCBs; wood of *Pinus edulis*, cold-temperate subhumid western North America .... ***O***. ***edulis***, p. 1102

21. Spores with slightly to strongly attenuated base, mainly *2.2–3.3 µm wide; asci max. *80(–92) µm long; paraphyses with globose SCBs 22

22. Actual length of SBs ≥ spore length; spores *11–13.3 × 2.9–3.3 µm; wood of *Fraxinus*, orotemperate humid southern Europe .... ***O***. ***pyrenaica***, p. 1100

22. Actual length of SBs < spore length 23

23. Spores *(8–)9–13(–15.5) × (2.7–)2.8–3.3(–3.8) µm; wood & bark of angiosperms and succulents, temperate to subtropical semihumid to arid western North America, Australia .... ***O***. ***macrotrapeziformis***, p. 1098

23. Spores *(8.5–)9–14.5(–16) × (2.1–)2.2–2.9(–3) µm; wood & bark of angio- & gymnosperms, boreal to orosubmediterranean (sub) humid Europe, North America, Asia .... see under 31 (*O. subtrapeziformis*)

24. Spores *(12–)13–18(–19.3) × 1.8–2.5 µm; SBs (5.5–)7–10.5 µm long; crystalloid SCBs absent; wood of *Amelanchier*, *Cercocarpus*, *Ribes*, temperate to boreal (sub)humid western North America .... ***O***. ***idahoensis***, p. 1094

24. Spores **(6–)**8–16(–18) µm long 25

25. Excipular cells (& paraphyses) with crystalloid SCBs 26

25. Excipular cells (& paraphyses) without crystalloid SCBs; lower spores inverted within asci 28

26. Paraphysis apices ellipsoid to spathulate; upper spores predominantly inverted within asci; spores *(10–)11–15(–17) × (2.1–)2.3–2.6(–2.8) µm; SBs 7–11.5 µm long; wood & bark of *Artemisia*, *Populus*, humid to semiarid western North America ..***O***. ***spathulata***, p. 1112

26. Paraphyses with capitate-clavate apices; lower spores predominantly inverted within asci; spores *2–2.5 µm wide; SBs 5–8 µm long ..27

27. Spores *(7–)8–11 × 2–2.5 µm, medium tapered towards base; SBs 0.5–0.8 µm wide; wood of *Atriplex halimus*, mesomediterranean semiarid Europe .... ***O. halimi***, p.1091
A collection on bark of *Olea* deviates by spores of *10–13(–15) × 2.4–2.7 µm with wider SBs (1–1.2 µm, p. 1092).
27. Spores *12–14.5 × 2–2.4 µm, strongly tapered towards base; SBs 0.7–1(–1.2) µm wide; on *Phragmites*, tropical semihumid Australia .... ***O. phragmitis***, p. 1093
Compare also *O. filiformis* with narrower (0.2–0.4 µm), filiform SBs (paraphyses usually without crystalloid SCBs, p. 1083).

28. Spore apices obtuse to subacute 29
28. Spore apices predominantly subacute to acuminate 31

29. Spores *(10–)11–16(–18) × 2–2.5 µm, often with a tail-like base or tail; SBs vermiform to subulate; wood & bark of angiosperm trees, temperate humid to subtropical semihumid to semiarid Australia .... ***O. austroobtusispora***, p. 1065
29. Spores *(6–)8–12(–14) × 1.8–2.7 µm 30

30. SBs often rather broad up to the apex (vermiform) though upper part also distinctly narrower than below, apically narrowed to a distinct short filum .... see key A under 20 (*O. cylindrosoma*)
30. SBs gradually thinner towards apex (subulate), with ± inflated base.......... see key A under 21 (*O. obtusispora*)

31. Spores *(8.5–)9–14.5(–16) × (1.8–)2–2.7(–3) µm; SBs (4–)5–7.5(–8) × (0.5–)0.6–1(–1.2) µm, subulate; wood & bark of angio- & gymnosperms, alpine-boreal to orosubmediterranean humid Europe, Africa, Asia, North America .... ***O. subtrapeziformis***, p. 1088
31. Spores *(8–)9–13(–14) × 1.8–2.3(–2.5) µm; SBs 5–10(–11) × 0.2–0.3(–0.4) µm, filiform (scarcely thicker towards base); wood of *Acer*, *Populus*, *Salix* etc., orotemperate humid to submediterranean (semi)humid Europe .... ***O. filiformis***, p. 1083
A collection from Africa differs in rather short SBs and only slightly attenuated and curved spore bases, also in less inflated paraphysis apices (p. 1086).

KEY C (asci 16-spored, spores predominantly < 9 µm long)

1. Spores crescent-shaped, *3.3–5 × 1.4–2 µm; on wood of *Acacia*, subtropical semihumid Australia.......... ***O. pleiocrescens***, p. 1227
1. Spores ± straight (if curved and 8–10 µm long see key D) 2

2. Spores subglobose to ellipsoid-ovoid-fusoid, length/width ratio predominantly < 2.5 3
2. Spores more elongate, length/width ratio in most spores > 2.5 14

3. Spore apex predominantly rounded or obtuse 4
3. Spore apex predominantly acute or subacute 12

4. With crystalloid SCBs in ectal excipulum and often also paraphyses.......... 5
4. Without crystalloid SCBs 8

5. Spores *(5–)6–7.5(–8.5) × (3.2–)3.5–4.2(–4.5) µm; wood of *Acacia*, *Atriplex*, climber, tropical arid Australia and apparently also temperate to subtropical semiarid North America .... ***O. barrowensis***, p. 1199
5. Spores < *3.5 µm wide 6

6. SBs ± abruptly inflated at base, 0.4–0.9 µm wide; crystalloid SCBs in paraphyses small, only present in lower part; spores *(4.3–)5.2–7(–8) × (2.3–)2.5–3.3(–3.5) µm; wood & bark of various angiosperms, (oro)mediterranean Europe ....***O. pleiogambelii***, p. 1205
6. SBs only gradually inflated at base, 0.3–0.5 µm wide; crystalloid SCBs in paraphyses large, also in apex 7

7. Spores *(3.8–)4.5–6.5(–7) × 1.9–2.3 µm; SBs only half as long as spores; asci *6–6.5 µm wide; on a climber (*Vitaceae*), subtropical subhumid southern USA .... ***O.* cf. *pleioungulata***, p. 1186
7. Spores *(5–)5.5–8.5(–9) × (2.3–)2.5–3(–3.4) µm; SBs often as long as spores or longer; asci *6.7–10.5 µm wide; wood of *Cercocarpus*, *Coleogyne*, temperate subhumid to semiarid western North America .... ***O. cercocarpi***, p. 1213

8. Spores *(3.5–)4–6.5(–7.7) × (1.8–)2–2.3(–2.5) µm; wood (& bark) of various angiosperms (exceptionally gymnosperms), subtropical (mediterranean) semihumid to arid Europe, Australia .... ***O. microserpens***, p. 1223
8. Spores predominantly > *2.4 µm wide 9

9. Spores *6–9(–9.5) × (2.8–)3–3.7 µm, ellipsoid-clavate; SBs 1/2–3/4 of spore length; wood of *Atriplex*, temperate arid western North America.......... ***O. macroserpens***, p. 1215
9. Spores *(4.6–)5–7.5(–9) × (2.3–)2.6–3.2(–3.5) µm, predominantly (cylindric-)ellipsoid or fusoid; SBs partly as long as spores or even longer 10

10. Spores (cylindric-)ellipsoid(-fusoid), *(4.6–)5–7.5(–8.2) × (2.4–)2.6–3.2(–3.5) µm; SCBs globose or absent; wood & bark of different angiosperms, (sub)tropical sub- or semihumid to arid western North America & western Australia .... ***O. pleioserpens***, p. 1219
10. Spores ± fusoid..........11

11. Spores *4.5–7.5 × 2.2–3.2 µm; with or without globose and crystalloid SCBs; wood of *Shepherdia*, temperate subhumid western North America, ?bark of *Banksia*, subtropical semihumid Australia .... ***O.* cf. *pleioserpens***, p. 1220
11. Spores *6–9 × 2.3–2.9 µm; without any SCBs; wood of *Cistus*, mediterranean Europe.......... ***O. cisti***, p. 1217

12. Crystalloid SCBs present; spores *6.5–8.5 × 3–4 µm; on *Salix* and *Psydrax*, temperate to subtropical semiarid western North America and western Australia.......... ***O.* aff. *lacrimispora***, p. 1053
12. Only globose SCBs present..........13

13. Spores *(6.8–)7.5–10(–11.2) × 3.5–4.4(–4.8) µm; wood of *Ephedra*, *Larrea*, *Canotia*, subtropical semiarid western North America .... ***O. lacrimispora***, p. 1053
13. Spores *(6–)7–9.5(–11) × (2.3–)2.5–3.5(–3.8) µm .... see under 25 (*O. maeandrina*)

14. Crystalloid SCBs present; spores without distinct tails 15
14. Crystalloid SCBs absent 18

15. Spores *(7–)8–12.5(–14) × 2.6–3.7 µm, apex ± acute .... see key D under 12 (*O. serpentina*)
15. Spores *(4.7–)5.5–9(–11) µm long, apex rounded to obtuse 16

16. Spores *(5–)5.5–8.5(–9) × (2.3–)2.5–3(–3.4) µm .... see under 7 (*O. cercocarpi*)
16. Spores *1.7–2.3(–2.5) µm wide 17

17. Paraphyses spathulate with a small glassy cap; apothecial margin pubescent; wood of angio- and gymnosperm shrubs, temperate to subtropical subhumid to semiarid western North America .... ***O. calyptrata***, p. 1187
17. Paraphyses at least partly clavate-capitate, without glassy cap; apothecial margin smooth; wood (rarely bark) of various angiosperm shrubs, also gymnosperms, (sub)tropical semihumid to arid Australia, Macaronesia, Europe .... ***O. pleioungulata***, p. 1184

18. Spores with distinct, ± bent tails, *6.5–9(–10.5) × 2.5–3 µm, apex obtuse to subacute; wood of *Parkinsonia*, subtropical semiarid western North America .... ***O. paloverdensis***, p. 1169
18. Spores without distinct tails 19

19. Spore apex at least partly rounded or obtuse 20
19. Spore apex predominantly acute or subacute 25

20. Spores *4.5–7.7(–8.3) µm long 21
20. Spores *7–9.5 µm long 23

21. SBs ± as long as spores (in situ, partly strongly flexuous), at base only slightly inflated to 0.2–0.4(–0.7) µm; spores *3.5–7.7 × 1.8–2.5 µm; paraphyses without SCBs .... see under 8 (*O. microserpens*)
21. SBs 1/2–3/4 of spore length (in situ, only slightly flexuous); wood of *Allocasuarina*, subtropical arid Australia 22

22. SBs at base not or very slightly swollen to 0.3–0.4 µm; spores *6–7.5(–8.3) × 1.7–1.9(–2) µm .... ***O. pleioobtusispora***, p. 1067
22. SBs at base abruptly inflated to 0.7–0.9 µm; spores *6–7 × 2.3–2.5 µm .... ***O. pleiovitalbae***, p. 1191

23. Spores ± fusoid, *6–9 × 2.3–2.9 µm; SBs 0.2–0.5 µm wide .... see under 11 (*O. cisti*)
23. Spores partly distinctly clavate, *(6.2–)7–9.5(–11) µm long 24

24. Spores *(2–)2.2–2.7(–2.9) µm wide; SBs 0.4–0.7 µm wide; bark of *Acacia*, *Casuarina*, subtropical subhumid to semiarid Australia .... ***O. cf. saguarina***, p. 1223
24. Spores *1.9–2.4(–2.6) µm wide; SBs 0.2–0.4(–0.5) µm wide; branches of *Cactaceae*, subtropical semiarid western North America .... ***O. saguarina***, p. 1221

25. Spores *(6–)7–9.5(–11) × (2.3–)2.5–3.5(–3.8) µm; wood of various angiosperms, rarely gymnosperms, boreal humid to subtropical arid North America, Africa, southern Europe, Asia, Australia .... ***O. maeandrina***, p. 1075
25. Spores *7–10.5 × 2–2.7 µm; wood of *Salix*, boreal humid western North America .... ***O. cf. macrodelphinus***, p. 1116

KEY D (asci 16-spored, spores predominantly > 9 µm long)

1. Spore apex predominantly rounded to obtuse 2
1. Spore apex acute to subacute 8

2. Spores fusoid-clavate, base medium tapered, not or only slightly curved, *6.2–11 × 1.9–2.9 µm .... see key C under 24 (*O. saguarina*)
2. Spore base predominantly strongly tapered, some or most spores distinctly curved 3

3. Spores †8–10 × 1.6–1.8 µm; bark of *Dodonaea*, subtropical arid Australia .... ***O. pleiovirgula***, p. 1238
3. Spores *(8–)9–15(–16.5) × 2.2–3.5 µm 4

4. Spores *2.2–2.5 µm wide; bark of *Chrysothamnus*, temperate subhumid western North America .... ***O. aff. delphinus***, p. 1108
4. Spores *2.6–3.5 µm wide 5

5. Ectal excipulum and paraphyses with crystalloid SCBs (living state!); spores with rounded to obtuse apex and only slightly to medium tapered base, *10.5–13.5 × 2.8–4 µm; SBs partly longer than half the spore length; wood of *Parkinsonia*, *Atriplex*, temperate to subtropical (semi)arid western North America .... ***O. aff. pleiomesaverdiana***, p. 1150
5. Ectal excipulum and paraphyses without crystalloid SCBs 6

6. Spores often with distinct tails with slight basal inflation; paraphyses without SCBs; bark of ?*Vachellia*, subtropical arid southeastern Africa .... ***O. caudimaeandrina***, p. 1168
6. Spores with gradually tapered, slightly to strongly curved base; paraphyses with globose SCBs 7

7. Spores *(2.8–)3–3.5(–3.7) µm wide; SBs vermiform, 0.6–1.2 µm wide; wood of *Sarcobatus*, *Atriplex*, temperate semiarid western North America .... ***O. vermiculati***, p. 1166
7. Spores *2.6–3.2(–3.4) µm wide; SBs filiform, 0.3–0.4 µm wide; bark of *Acacia*, subtropical semihumid Australia .... ***O. pleioquaestiformis***, p. 1157

8. Spores *9–13(–15) × 1.8–2.3(–2.5) µm; asci up to *7.5 µm wide ... 9

8. Spores often or consistently exceeding *2.5 µm in width; asci > *7.5 µm wide (but in *O. macrodelphinus* partly not exceeding *7.5 µm) ... 10

9. Excipulum and paraphyses without crystalloid SCBs (rarely a few in paraphyses); SBs 5–8 × 0.7–1 µm; wood (rarely bark) of gymno- and angiosperms, boreal to cold-temperate (montane to subalpine) humid to semiarid western North America, southern Europe, Asia (also warm-temperate atlantic Europe?) ... ***O. delphinus***, p. 1105

9. Excipulum and paraphyses with crystalloid SCBs; SBs 6–9 × 0.4–0.6 µm; wood and bark of *Cupressus*, mesosubmediterranean semihumid Europe ... ***O. subdelphinus***, p. 1111

10. Spores *6.8–10(–11.2) × 3.6–4.4(–4.8) µm; crystalloid SCBs absent ... see key C under 13 (*O. lacrimispora*)

10. Spores less than *3.5 µm wide ... 11

11. Paraphyses & excipular cells with crystalloid SCBs ... 12

11. Paraphyses & excipular cells without crystalloid SCBs ... 14

12. Spores *(7–)8–12.5(–14) × (2.6–)2.8–3.5(–3.7) µm, with slightly to strongly tapered base, straight or only slightly (to medium) curved; wood & bark of various angiosperms, inflorescence stems of *Agave*, *Yucca*, temperate to tropical humid to arid southern Europe, Macaronesia, Africa, North America, Australia ... ***O. serpentina***, p. 1124

Collections from western North America on *Artemisia* and *Opuntia* differ in spores with basal tails (Pl. 652: 8–9). A sample from Australia on *Acacia* differs in narrower spores (*2.4–2.8 µm, Pl. 652: 10).

12. Spores *(9–)11–14(–16.5) × (2.5–)2.8–3.2(–3.5), base consistently strongly tapered and strongly curved ... 13

13. Spore apex subacute, base medium to strongly tapered; SBs distinctly shorter than half the spore length; wood & bark of *Koeberlinia*, ?*Chrysothamnus*, temperate to subtropical semiarid to arid western North America ... ***O. pleiomesaverdiana***, p. 1149

13. Spore apex acute to acuminate, base mostly with a distinct, abrupt and strongly curved tail; wood & bark of indet. angiosperm, subtropical (semi)arid North America ... ***O. pleiourosperma***, p. 1136

14. Spores *(6–)7–9.5(–11) × (2.3–)2.5–3.5(–3.8) µm, usually only slightly tapered and curved at base; SBs 4–9 µm long ... see key C under 25 (*O. maeandrina*)

14. Spores *(9–)10–12.5(–13.5) × (2–)2.4–2.8(–3) µm, often strongly tapered and ± curved at base; SBs 4.5–12 µm long; bark & wood of angio- and gymnosperms, boreal to subtropical humid to semiarid western North America ... ***O. macrodelphinus***, p. 1113

A collection on *Larrea* deviates by larger spores (*11.5–16.5 × 2.5–3.5 µm).

KEY E (asci 32-spored)

1. Spores > *3.7 µm or < 2 µm wide ... 2

1. Spores *2–3.8 µm wide ... 3

2. Spores *6–9.7(–11.2) × 1.4–1.8(–2) µm, apex rounded, base often ± attenuated in a long and strongly curved tail; SBs filiform, 1/3–1/2 of spore length; wood of *Larrea*, temperate semiarid western North America ... ***O. multivirgula***, p. 1236

2. Spores *6–8(–9) × 3.7–4.2(–4.5) µm, lemon-shaped, broadly ovoid; SBs vermiform, much longer than spores; bark of *Juniperus*, temperate subhumid western North America ... ***O. multihamulata***, p. 1054

3. Spores ellipsoid or cylindrical, apex predominantly rounded to obtuse; often with crystalloid SCBs ... 4

3. Spores broadly to narrowly fusoid, apex predominantly acute to subacute (rarely predominantly obtuse); nearly always without crystalloid SCBs ... 9

4. Spores always with a ± strongly attenuated, more or less bent tail-like base, *(6–)7–10(–10.5) × (2.5–)2.7–3.5 µm; crystalloid SCBs present; wood of *Atriplex*, *Pistacia*, *Larrea*, warm-temperate to subtropical/thermomediterranean semihumid to semiarid southern Europe & western North America ... ***O. multiurosperma***, p. 1137

4. Spores only partly somewhat tapered at base ... 5

5. Spores *(5.3–)6–8.5(–9.5) × 2.3–2.9 µm, predominantly cylindrical; SBs usually subapically inserted; crystalloid SCBs present; wood of ?*Vachellia*, subtropical arid Africa ... ***O. namibica***, p. 1238

5. Spores ellipsoid(-clavate) to fusoid, if cylindrical then crystalloid SCBs absent; SBs mainly apically inserted ... 6

6. Without crystalloid and almost without globose SCBs; spores cylindrical to mostly ellipsoid, *(3.3–)4–5.7(–6.7) × 1.8–2.4(–2.7) µm; wood & bark of various angiosperms, petioles of *Livistona*, subtropical subhumid to arid Australia & North America, mediterranean semihumid southern Europe ... ***O. multiserpens***, p. 1227

Similar Australian collections on *Eucalyptus* have larger, ellipsoid-fusoid spores *5.2–7.2 × 2–2.8 µm (Pl. 744: 7–8). If paraphyses contain globose SCBs see abnormal records of *O. multigambelii* (p. 1209).

6. With crystalloid SCBs (rarely only globose); spores *2.2–3.3 µm wide ... 7

7. Spores *~5–7 × 2–2.5 µm; on wood of *Fouquieria*, subtropical semiarid western North America ... ***O*. aff. *multicercocarpi***, p. 1215

7. Spores *(2.4–)2.6–3.2(–3.6) µm wide ... 8

8. Spores *(5.5–)6.5–7.5(–8.7) µm long; wood of *Larrea*, *Parkinsonia*, subtropical semiarid western North America ***O. multicercocarpi***, p. 1214

8. Spores *(4.2–)4.7–6.5 µm long; wood (& bark) of various angiosperms, temperate to tropical semiarid to arid western North America, Australia ... ***O. multigambelii***, p. 1209

9. Spores > *2.7 µm wide ... 10

9. Spores < *2.7 µm wide; generally without crystalloid SCBs ... 16

10. Spores with obtuse apex, heteropolar (fusoid-clavate) 11
10. Spores with predominantly subacute to acute apex, homo- or heteropolar; without crystalloid SCBs 12

11. SBs about as long as spores; crystalloid SCBs absent; spores often with attenuated but never tail-like base, *(6–)6.5–8.8 × 2.8–3(–3.2) µm; bark of *Acacia*, subtropical semiarid western Australia .... ***O.*** **aff.** ***multitrapezoidea*** (Pl. 645: 4), p. 1119
11. SBs max. half as long as spores; crystalloid SCBs present; spores always with ± strongly attenuated, more or less bent tail-like base, *6–10.5 × 2.5–3.5 µm .... see under 4 (*O. multiurosperma*)

12. SBs mostly longer than spores; spores *(4.8–)5.5–7(–8) × 2.7–3.4 µm, fusiform (amygdaliform), ± homopolar; paraphyses ellipsoid-spathulate; wood & bark of *Juniperus*, temperate subhumid western North America .... ***O. osteospermae***, p. 1082
12. SBs predominantly shorter than spores; spores longer 13

13. Spores spermoid, with abrupt tail, †6.5–10 × 3–3.5(–3.8) µm; wood of *Fraxinus*, temperate semiarid western North America .... ***O.*** **aff.** ***paloverdensis***, p. 1170
13. Spores without a distinct tail 14

14. SBs 0.8–1.2 µm wide; globose SCBs 0.5–1.3 µm diam.; spores *(5.5–)6.5–9.5(–10.5) × 2.8–3.5 µm, often heteropolar; wood & bark of various angiosperms, temperate humid to arid western North America .... ***O. multimaeandrina***, p. 1078
14. SBs 0.4–0.7 µm wide; globose SCBs 1–2.5 µm diam. 15

15. Spores *6.5–8.2 × 3–3.3(–3.5) µm; SBs 6–7.5 µm long; *Atriplex* branch, subtropical arid Australia ***O.*** **cf.** ***livistonae*** (Pl. 647: 3), p. 1121
15. Spores *8–12(–14) × (2.6–)2.8–3.2(–3.4) µm; SBs 5.5–9.5 µm long; *Livistona* petioles, subtropical (sub)humid eastern Australia .... ***O. livistonae*** (Pl. 647: 1), p. 1120

16. SBs constistently shorter than half the spore length 17
16. SBs predominantly longer than half the spore length 18

17. Spores *6.7–9.3(–10.4) × (1.8–)2–2.4 µm, straight or slightly curved at ± medium tapered base; paraphyses with capitate to clavate apices; wood of *Larrea*, temperate semiarid western North America .... ***O.*** **aff.** ***multidelphinus*** (Pl. 644: 3), p. 1116
17. Spores *8–13 × (2–)2.2–2.5 µm, often ± strongly curved at ± strongly tapered base; paraphyses with ellipsoid to spathulate apices; wood & bark of (?)*Chrysothamnus*, temperate subhumid western North America .... ***O.*** **aff.** ***multidelphinus*** (Pl. 644: 2), p. 1116

18. Spores predominantly > *7–7.5 µm long 19
18. Spores predominantly < *7–7.5 µm long 21

19. Spores *(9.5–)11–14.7 × 2.3–2.6 µm, base consistently strongly tapered and ± curved; SBs 7–9.5 µm long; SCBs absent; bark of *Juniperus*, temperate subhumid western North America .... ***O. multidelphinus***, p. 1116
19. Spores mainly *7–11 × 2.2–2.7 µm 20

20. SBs ± subulate, 0.6–1.2 µm wide, always inflated at base; wood & bark of angiosperm shrubs and coniferous trees, temperate subhumid to arid western North America .... ***O. multitrapezoidea***, p. 1117
20. SBs ± filiform, 0.4–0.7 µm wide, ± not inflated at base; wood of *Pittosporum*, subtropical subhumid eastern Australia .... ***O.*** **cf.** ***livistonae*** (Pl. 647: 2), p. 1121

21. SBs almost as long as spores or even longer; spores ellipsoid-fusoid, with obtuse apex, *5.2–7.2 × 2–2.8 µm; wood & bark of *Eucalyptus* .... see under 6 (*O.* cf. *multiserpens*)
21. SBs 1/2–2/3 of spore length; spores fusoid, with subacute apex, *(5–)6–7.5(–8.5) × 2–2.3 µm; wood of *Atriplex*, subtropical arid central Australia .... ***O.*** **aff.** ***multitrapezoidea*** (Pl. 645: 5), p. 1119

KEY F (asci 64–128-spored)

1. Spores > *2.8 µm wide; asci 64-spored; paraphyses and excipular cells with crystalloid SCBs 2
1. Spores < *2.8 µm wide 3

2. Spores *5.2–8 × (2.8–)3–3.8(–4.2) µm, fusiform, straight, sometimes with tail-like base; wood & bark of *Parkinsonia*, *Larrea*, *Quercus*, temperate humid to subtropical semiarid western North America .... ***O. sedonensis***, p. 1142
2. Spores *(6–)7–9.5(–11) × (2.7–)2.9–3.3(–3.5) µm, fusiform or fusoid-ovoid, often with distinct, ± bent tail, also with tail-like or attenuated base; wood & bark of angiosperm shrubs, subtropical semiarid to arid western North America . ***O. myriourosperma***, p. 1141

3. Asci 128-spored; SBs with strongly inflated basal part; SCBs absent; spores *4.5–5.5(–6) × 1.7–2 µm; bark of *Eremaea*, subtropical semihumid Australia .... ***O. pleistovitalbae***, p. 1192
3. Asci 64-spored; SBs filiform to vermiform, rarely basally inflated 4

4. Spores *6–8.5 µm long, ellipsoid- or fusoid-clavate, consistently slightly to strongly curved near base; SBs filiform 5
4. Spores *3.6–8 µm long, straight or only slightly curved 6

5. Crystalloid SCBs absent; spores mainly *6–7.5 µm long, medium to strongly curved; SBs 0.3–0.5 µm wide; bark of *Acacia*, subtropical semiarid Australia .... ***O. curvatimyriella***, p. 1234
5. Crystalloid SCBs present; spores mainly *7.2–8.5 µm long, slightly to medium curved; SBs 0.2–0.3 µm wide; wood of *Acacia*, tropical arid Australia .... ***O. myriofusoidea***, p. 1236

6. SBs 5–7 µm long (actual length), occupying min. 3/4 of spore length; crystalloid SCBs present 7
6. SBs 1.2–3 µm long (actual length), occupying 1/4–2/3 of spore length 8

7. Spores *4.2–6.5 × (2.2–)2.4–2.6 µm, ellipsoid-clavate; SBs filiform, 0.2–0.3 µm wide, often longer than spore length, always apically inserted; wood of ?*Vachellia*, subtropical arid Africa.. ***O*. *myrioflexa***, p. 1211
7. Spores *6–8 × 2.2–3 µm, cylindric(-clavate); SBs vermiform-subulate, 0.3–0.6 µm wide, rarely longer than spore length, often subapically inserted; wood of *Acacia*, subtropical arid Australia.. ***O*. *myrionamibica***, p. 1239

8. Crystalloid SCBs present, distinct, orange; spores *4–5.7 × 1.8–2.1 µm, hardly tapered at base; SBs 1/4 of spore length, with inflated base; wood of *Vachellia*, subtropical arid Australia.. ***O*. aff. *myriella*** (Pl. 748: 3), p. 1234
8. Crystalloid SCBs absent 9

9. Spores *(4–)4.3–6(–6.5) × (1.3–)1.5–2 µm, cylindric(-ellipsoid), rarely slightly tapered at base; SBs 0.2–0.3 µm wide; wood of *Acacia*, subtropical (semi)arid Australia .... ***O*. *myriella***, p. 1233
9. Spores predominantly > *1.8 µm wide; SBs 0.3–0.5 µm wide 10

10. Spores *(4.5–)5–6.5(–7.5) × 1.8–2.2(–2.5) µm, cylindric-ellipsoid, partly distinctly tapered at base, some with short tail; SBs 1/4–1/3 of spore length; wood & bark of *Olneya*, subtropical semiarid western North America ....***O*. *myrioolneyae*** (Pl. 746: 1–2), p. 1231
10. Spores *3.6–4.6 × 2–2.3 µm, ellipsoid; SBs 1/2–2/3 of spore length; bark of *Pittosporum*, subtropical subhumid eastern Australia
.... ***O*. aff. *myrioolneyae*** (Pl. 746: 3), p. 1232

Series *Habrostictis*

Orbilia subgenus ***Habrostictis*** section ***Habrostictis*** series ***Habrostictis*** – Lectotype species: *H. rubra* Fuckel (= *Orbilia carpoboloides*), designated by Höhnel (1917: 330)

= *Cheilodonta* Boud., Bull. Soc. Mycol. Fr. 1: 114 (1885) – Lectotype species: *Peziza carpoboloides* P. & H. Crouan (≡ *Orbilia carpoboloides*), indirectly designated by Höhnel (1917: 333)

= *Orbilia* subgroup VI *Ascophorae* Velen., Opera Bot. Čech. 4: 104 (1947, unranked) – Type species: *O. vacini* Velen. (= *Orbilia carpoboloides*)

Etymology: *Ascophorae*: referring to the extraordinarily large asci; *Cheilodonta*: a toothed lip; *Habrostictis*: a delicate or soft derivative of a *Stictis* (*Ostropales*).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–1(–1.5)((–4)) mm diam., light to bright rose-orange to yellow-ochraceous, margin usually distinctly protruding, whitish to yellowish pruinose, crenulate to lacerate or fimbriate, rarely smooth, sessile or with a distinct short stipe, superficial or often ± erumpent. **Asci** *(48–)55–95(–123) × (4–)4.5–6.8 µm, 8- to 16-spored, (2–)3–5(–6) lower spores inverted if 8-spored, 6–8 spores inverted if 16-spored; **base** never H-shaped. **Ascospores** *(5.5–)7–14(–17) × (1.4–)1.6–2.8(–3.3) µm, fusiform or fusiform-clavate, also ellipsoid-fusoid(-clavate) to subcylindrical, apex subacute to acuminate, also rounded to obtuse, straight to slightly or medium curved near base, **SBs** apically attached to spore wall, (3–)4–8(–8.5) × (0.2–)0.3–0.9 µm (actual length), filiform to subulate. **Paraphyses** slightly to strongly inflated at the apex, spathulate to mammiform or lageniform to lanceolate, terminal cell (0.7–)1–2(–3)× longer than lower cells. **Ectal excipulum** of (†) thin-walled to slightly gelatinized (common walls 0.3–1.2 µm), vertically to horizontally oriented textura prismatica-angularis, cells near base *(5.5–)8–25(–36) × (5–)7–16(–22) µm, **hairs** often present, *20–50(–80) × (2.5–)3.5–6.5(–8.5) µm, septate, thin- to firm-walled, agglutinated or ± free, also as indistinct hair-like hyphae. **SCBs** globose, often mixed with crystalloid ones. **Exudate** 0.1–1.5(–4) µm thick, continuous to granular, firmly attached, hyaline or yellowish, also absent. **— ANAMORPH**: vermispora-like (data only from *O. carpoboloides*). **Conidiophores** 2–30 × 1.5–4 µm, irregularly shaped, partly proliferating, 0–1-septate. **Conidiogenous cells** sympodial, with 1–15 nodules or short denticles. **Macroconidia** phragmosporous, */†19–44 × 2.8–5.7 µm, slightly to medium curved (C-shaped or curved mainly near the ends), 3–7-septate. **Microconidia** */†9–14.5 × 2–3.5 µm, strongly curved (c-shaped), (0–)1-septate.

Habitat: on bark and wood of angiosperms (rarely gymnosperms), also caulicolous or on textile, temperate to subtropical, humid to semiarid.

Recognized species: 7.

Taxonomic remarks. Series *Habrostictis* is defined here by paraphyses with spathulate to mammiform or lageniform apices in combination with curved phragmosporous conidia, and apothecia with a ± protruding, fimbriate or crenulate to lacerate margin due to ± agglutinated septate hairs, though a smooth, non-protruding margin may occasionally occur. These characteristics might turn out unsuitable to define a monophyletic group, because they could have developed convergently in different lineages from capitate paraphyses and smooth apothecia, particularly in those four species in which the anamorph is unknown. A remarkable characteristic of the type species of series *Habrostictis*, *O. carpoboloides*, is a cleistohymenial apothecial development (see p. 38), which probably occurs also in some other members of this series.

High diversity is noted in the spore apices which are typically subacute to acuminate, but in *O. mongolica* rounded to obtuse, and it remains unclear whether spore shape should be given a higher taxonomic value than paraphysis shape and *O. mongolica* be placed instead in series *Ellipsospermae*. In the comparable case of *O. calyptrata*, which has spathulate paraphyses similar to series *Habrostictis* and obtuse spore apices as in series *Ellipsospermae*, sequence data refers this species to the latter group. On the other hand, series *Serpentinae* comprises also some species with rounded apices, according to our phylogenetic analysis, and quite a few taxa show intermediate spores with obtuse to subacute apices.

Members of series *Piliferae* may easily be misplaced in series *Habrostictis* due to their similar paraphysis shape and hairy margin. They are affiliated in section *Aurantiorubrae*, although their rDNA data are intermediate to section *Habrostictis*, to which they would better fit by their trinacrium-like conidia. From section *Habrostictis* they differ in short, tear-shaped to globose SBs, but some species have rod-shaped to subulate SBs similar to that section. Also *O. asomatica* may be taken as a member of series *Habrostictis*, but its molecular data places it in series *Neodactylella* of section *Arthrobotrys*.

Asci in series *Habrostictis* are mainly 8-, rarely 16-spored (*O. mongolica*). Apothecia are generally medium to large-sized. Usually they exceed 0.5, often also 1 mm in diam., with the largest found in *O. brasiliensis* (1.5–4 mm). Only *O. mongolica* featured very small apothecia of 0.25–0.3 mm.

Species delimitation. Most of the included species are taxonomically problematic at the species level. *O. carpoboloides* shows high variation particularly in spore size, and its present circumscription, which includes also North American collections, must be considered as tentative. Yet, it was surprising that the two available sequences were identical, though being gained from two sites in Europe with a distance of 135 km from each other. The question of spore length applies also to the Australian *O. scandens*, which is separated from *O. carpoboloides* only with some hesitation. *O. solidaginis* possibly represents merely an atypical form of *O. flavidorosella*.

Anamorph. Within series *Habrostictis*, vermispora-like conidia are known in *O. carpoboloides* and *O. flavidorosella*, and are presumed for *O. mongolica*. In *O. carpoboloides* two types of conidia may simultaneously occur on the natural substrate: didymosporous micro- and phragmosporous macroconidia. However, only didymoconidia were so far obtained in pure culture.

Conidiophores in series *Habrostictis* were only seen in *O. carpoboloides*. They are remarkable in being irregularly bent and carrying short, densely aggregated denticles, comparable to the arthrobotryoid nodes of series *Arthrobotrys*, or the conidiophores of *O. pleistoeuonymi* (section *Lentiformes*).

Phylogeny. Sequence data were only available for two of the seven included species of series *Habrostictis*, *O. carpoboloides* and *O. flavidorosella*. In analyses of SSU+ITS+LSU (Baral et al. 2017b) or ITS (Phyl. 19), they clustered in a strongly supported clade but with a high ITS distance between each other. The position of the clade within the *Serpentinae-Habrostictis* clade remained somewhat unclear, although a sister position to series *Serpentinae* received medium or low support in the combined analyses (Baral et al. 2017b, Phyls 7, 20). Its phylogenetic affiliation in the *Serpentinae-Habrostictis* clade is supported by characteristic nucleotides (Tab. 72) and in concordance with very similar, apically acute ascospores in the two series, whereas the deviating anamorph supports recognition as a series of its own.

Specific nucleotide positions. Motifs in the rDNA that characterize series *Habrostictis* have not been found. Informative positions in the LSU D1–D2 either concur with those of the *Serpentinae-Habrostictis* clade or sometimes the *Ellipsospermae* clade, or differ between *O. carpoboloides* and *O. flavidorosella*. Under section *Habrostictis* the hypothesis is expressed that series *Habrostictis* represents the ancestral group of section *Habrostictis*.

Globose **SCBs** often present in paraphyses, 1–2.2 µm diam; crystalloid SCBs present {37}, rarely absent {2}, in paraphyses ring- to spool-/S-shaped, hyaline to pale yellow; in ectal excipulum at flanks and margin C-, spool-, ring-, horseshoe- to keyhole-shaped, or rhomboid, pale yellow-orange, 4–9(–10) × (2–)3–5 µm, abundant, near base hyaline and smaller. **Exudate** over paraphyses absent or 0.1–0.3(–1) µm thick, hyaline or sometimes bright yellow, finely rough to granular, rarely cloddy, firmly attached to beak and inflated part, exceptionally forming ~1 µm thick glassy caps {H.B. 5619b}; on marginal excipulum or cortical hyphae absent or sparse to abundant, rough-granular or homogeneous, loosely or firmly attached, up to 0.5–1 µm thick, hyaline or light to bright yellow(-chlorinaceous), colour unchanged in KOH. — **ANAMORPH**: vermispora-like (from ascospore isolate {3, microconidia}, including data of Haines & Egger 1982 and Pfister 1997; from natural substrate {13× macro-, 4× microconidia}). **Microconidiophores** *9–17 × 2.5–4 µm {1}, †(2–)5–20(–30) × 1.5–3 µm {2}, 0–1-septate, cylindrical to lageniform or moniliform, sometimes branched by proliferation, with 1–4 {2} up to 6–15 {1} distinct nodules or short denticles. **Macroconidia** */†19–32(–35) × (3–)4.5–5.5 µm {7}, C-shaped or curved especially near ends (canoe-shaped), (3–)5–7-septate {6}. **Microconidia** *((7.5–))(9–)10–13.5(–14.5) × (2.2–)2.5–3.2(–3.5) µm {2}, †9–13(–14) × 2–3.2 µm {3}, strongly curved (c-shaped), (0–)1-septate.

Habitat: collected 0–3 m above the ground, or 'in top 3rd of trees that have been dead over 1 year' (J. Ginns in sched., type of *O. piloboloides*), corticated or partially decorticated, 6–30 mm thick branches, sometimes thick trunks, of living to completely dead, standing trees or shrubs of ?*Ailanthus altissima* {1}, *Albizia julibrissin* {1}, *Alnus* sp. {1}, *Calicotome villosa* {1}, *Cercis siliquastrum* {4}, *Colutea arborescens* {1}, *Cytisus scoparius* {2/1}, *Gleditsia triacanthos* {1}, *Lupinus arboreus* {1}, *Maclura pomifera* {2}, *Malus domestica* {1}, *Morus* sp. {1}, *M. rubra* {1}, *Passiflora caerulea* {3}, *Prunus dulcis* {1}, *P. padus* {1}, *Robinia pseudoacacia* {1}, *Rosa* sp. {1}, *Salix* sp. {8}, *Ulex europaeus* {2}, *Ulmus* sp. {29}, *U. americana* {3}, *U. glabra* {1}, *U. laevis* {4}, *U. minor* {6/1}, indet. angiosperm {2}; herbaceous stems of *Melilotus* sp. {1}, indet. herb {1}, twine or textile of plant fibres {3}; on slightly to strongly decayed bark {72} (often loosely attached), on periderm {8} or bast {26}, periderm locally removed, on outer, rarely inner surface of bast, but mostly breaking through small holes in periderm caused by dark hyphomycetes (often *Diplodia*), partly hidden beneath detaching periderm, rarely on 0.5–1.5 mm deeply rotten wood {6}, also on living to very old *Vuilleminia comedens* {1}, *Cyclothyriella rubronotata* {1}, *Diatrype stigma* {1}, *Valsaria insitiva* {1}, indet. pyrenomycete {2}, or on boring dust in beetle galleries, ± strongly greyed, green algae absent or sparse to very abundant. **Associated**: *Aglaospora profusa* {1}, ?*Bacidia* sp. {1}, *Baggea* sp. {1}, *Bionectria pallidula* {1}, *Cucurbitaria elongata* {1}, *Dacrymyces* sp. {1}, *Diaporthe eres* {1}, *Didymosphaeria oblitescens* {1}, *Diplodia* sp. {5}, *Durella* ?*compressa* {1}, *Eutypella stellulata* {1}, *Hyalorbilia orbiliicola* (on *O. aurantiorubra*) {2}, *Lachnella villosa* {1}, *Melanelixia* ?*subaurifera* {1}, *Mollisia* sp. {1}, *Nectria pseudopeziza* {2}, *Nitschkia* sp. {1}, *N. broomeana* {1}, *N. cupularis* {1}, *Orbilia siculispora* {1}, *O. aurantiorubra* {10}, *O. caulicola* {1}, *O. cercidicola* {2}, *O. comma* {2}, *O. eucalypti* {1}, *O. flavidorosella* {1}, *O. gambelii* {1}, *O. maeandrina* {1}, *O. myriosphaera* {1}, *O. phragmotricha* {1}, *O. pleiogambelii* {1}, *O. polyspora* {1}, *O. subaristata* {2}, *O. trapeziformis* {1}, *Parmelia* sp. {1}, *Patellaria atrata* {1}, *Phragmiticola* sp. {1}, *Physcia* sp. {4}, *Schizoxylon compositum* {1}, *Stictis radiata* {1}, *Trichopeziza perrotioides* {1}, *Unguiculella eurotioides* {1}, *Valsaria insitiva* {1}, *Xanthoria parietina* {2}, old undetermined pyrenomycete {1}, foliose lichens. **Desiccation tolerance**: fully tolerant for at least 7.5 months, paraphyses and ascospores still viable after 16 months, some excipular cells and macroconidia after 32 months. **Altitude**: 1–737 m (central and western Europe), 215–1650 m (southern Europe), 20–300 m (America). **Geology**: Proterozoic, Cambrian, Ordovician, Devonian & Permian greywacke, shale, silt, sand- & limestone, Muschelkalk, Lower Jurassic limestone, Cretaceous marl & flysch, Tertiary molasse, sand & calcareous marl, Pleistocene loess, clay, silt & sand; volcanic mafic basaltic rock, serpentinite. **Phenology**: throughout the year (long-lived).

Phenology of *O. carpoboloides* (northern hemisphere)											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
6	8	9	9	11	5	3	3	8	3	5	6

Taxonomic remarks. *Orbilia carpoboloides* is characterized by rather large apothecia with a protruding, whitish, lacerate to fimbriate margin and ochraceous-orange disc, paraphyses with spathulate or lageniform to mammiform apices, comparatively large, fusiform-clavate to cylindric-fusiform ascospores with acute apices and often slightly curved bases, striking crystalloid SCBs in the cells of excipulum and partly in paraphyses, finally by a vermispora-like anamorph with c-shaped, 1-septate microconidia and apparently also multiseptate macroconidia. American (and Australian) collections are very similar to European ones, even in their ecology, growing often on bark of *Ulmus* or in association with pycnidia of *Diplodia*.

O. carpoboloides resembles *O. pilifera* in many characteristics of its teleomorph. *O. pilifera* sharply differs in subglobose spore bodies, in the absence of crystalloid SCBs, and in a trinacrium-like anamorph. Our molecular data suggest for *O. pilifera* a marginal placement in section *Aurantiorubrae*.

For the differences to the very closely related *O. brasiliensis* (p. 1040) and *O. scandens* (p. 1042) see under these species.

Variation. *O. carpoboloides* has sometimes distinctly stipitate, almost superficial apothecia, especially in American collections (type of *O. piloboloides*, collections on *Albizia* and *Morus*), whereas in the majority of collections they are broadly sessile and partly erumpent (including the types of *O. decipiens*, *O. fibriseda* and *H. marmolense*). However, immersed stipes are easily overlooked. Haines & Egger (1982) reported the stipes to be only partly present in the type of *O. piloboloides*. The fimbriate margin varies between slightly crenulate to distinctly lacerate or dentate, but in some apothecia it may be not incised at all. The thickness of the rather dense textura intricata on

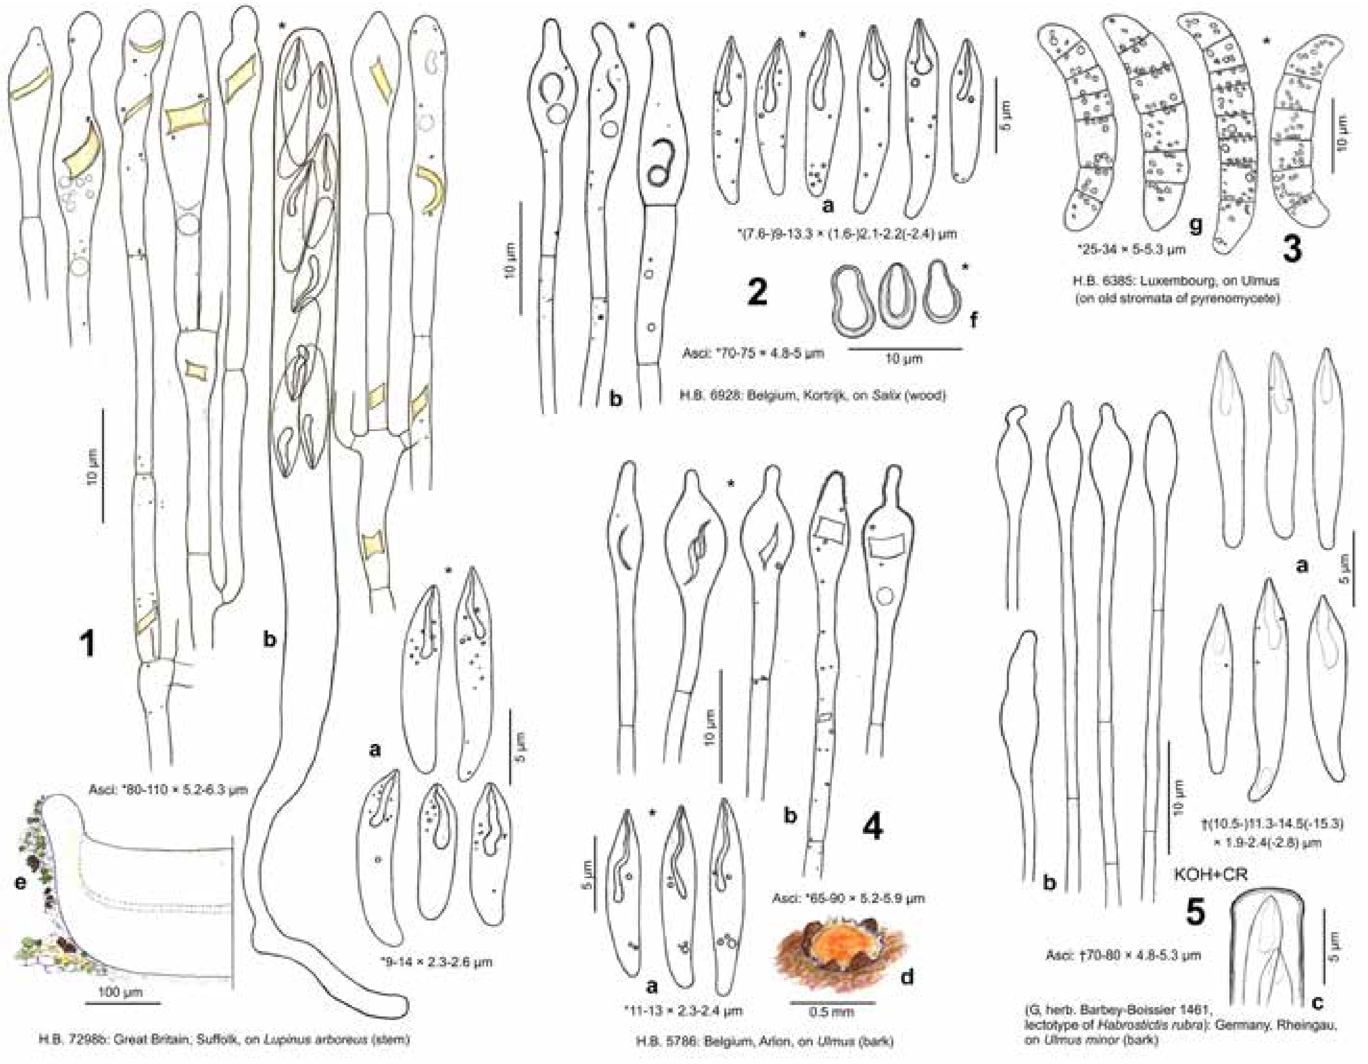

Plate 569. **1–5**: *Orbilia carpoboloides*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. erumpent apothecium (rehydrated); **e**. apothecium in median section; **f**. crystalloid SCBs; **g**. macroconidia on natural substrate.

the exterior, formed by the anchoring hyphae, varied strongly among the collections, attaining near the base a maximum of 150 µm in the topotype of *O. piloboloides*.

The presence and length of the beak on the swollen tips of paraphyses varies strongly, often within a collection. There are also usually young paraphyses with uninflated cylindrical apices present in mature apothecia among the typical ones, and sometimes only uninflated paraphyses were found although some mature asci already occurred. In the holotype of *O. carpoboloides* on twine (Pl. 570: 2) the inflated apices were consistently spathulate (without beaks) whereas beaks were mostly present in the examined types of *Habrostictis rubra* (Pl. 569: 5), *O. lasia* (Pl. 570: 1), *O. piloboloides* (Pl. 573: 1), *O. decipiens* and *Helotium marmolense* (Pl. 573: 3–4), *Peziza fibriseda* (Pl. 574: 2), and *O. rubrococcinea* (Pl. 575: 3), all on bark, often of *Ulmus*. Also records on *Passiflora* (from La Gacilly, Bretagne) partly had no beaks on the paraphyses.

The present concept of *O. carpoboloides* includes a high variation in spore size and shape. The spore apex varies among the different collections from subacute to acuminate (see also under Type studies). Asci and ascospores of the extra-European samples are usually slightly to considerably shorter than in many European ones, and the spores more fusiform. Within Europe, the holotype of *O. carpoboloides* has rather short and broad spores, whereas the spores of the *Habrostictis rubra* and *O. lasia* types are longer and narrower. Yet, the broad spores in the former type are partly due to strong artificial flattening and were probably narrower in the living state. Whether all three types belong to a single species remained uncertain. Some of the recent European collections examined show spores similar as in the *O. carpoboloides* type although having beaked paraphyses and growing on bark (e. g., Pl. 568: 2–3). On the other hand, Boudier (1904–10: pl. 459) figured a collection on rotten fabric with long and narrow spores and beaked paraphyses. Long and narrow spores were encountered in mediterranean (e. g., Pl. 571: 10) as well as temperate regions (e. g., Pls 568: 1; 569: 2; 570: 1). The longest spores of *14–18(–19) × 2–2.8 µm were observed in a recent sample from Portugal (on *Salix*), the shortest (*7–9 × 3–3.5 µm) in a recent one from New York (on *Ulmus*). In long-spored populations the spores often tend to be curved at the base, but also those with a medium spore length may show a pronounced curvature (Pl. 568: 2), whereas extra-European specimens but also, e. g., that from Netherlands (near Maastricht) showed only straight or basally slightly curved spores. Since a sharp limit between the available long- and short-spored collections could not be drawn, a split into two taxa seemed impracticable (but see under Phylogeny).

Differences in the presence of SCBs were observed among collections studied in the living state, but these did not clearly correlate with other features such as ascospore size and shape. Within the European collections, crystalloid SCBs occurred

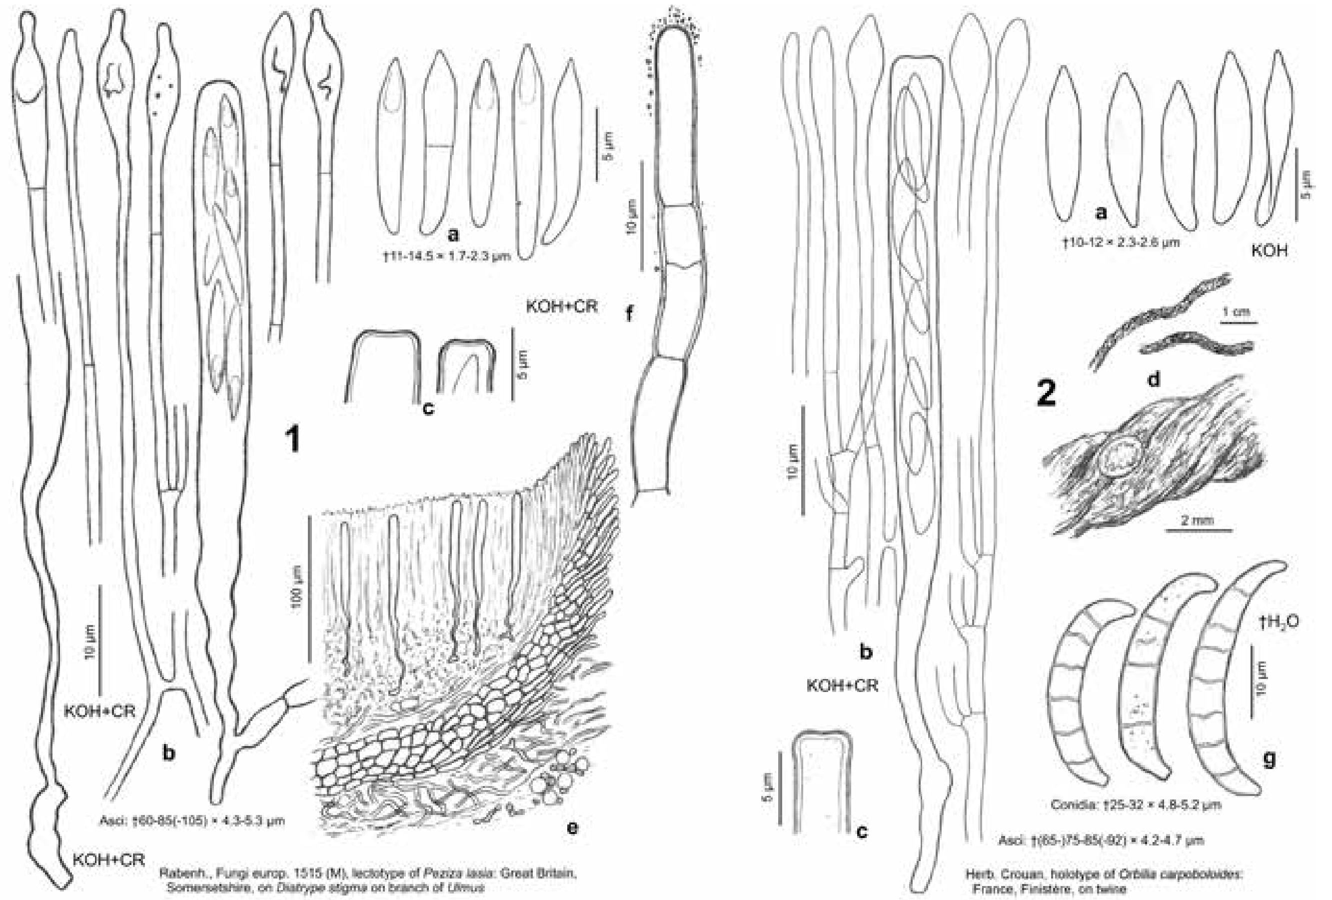

Plate 570. **1–2**: *Orbilia carpoboloides*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium on a twine; **e**. apothecium in median section; **f**. marginal hair; **g**. macroconidia from substrate. The rod-shaped structures in the inflated paraphysis apices in **1b** are a result of shrunken plasma rather than remnants of SCBs.

with a remarkable consistency in both paraphyses and excipulum, though in some specimens they were rather thin and inconspicuous. In one of the c. 20 European collections studied in the living state (H.B. 5126b, *Salix*, Briançon, montane, unillustrated) only globose SCBs were seen in the living paraphyses, while the excipular cells did not contain SCBs at all. Crystalloid SCBs were observed in both specimens from which sequences were taken.

Among the three American collections studied in the living state, that from Tennessee showed crystalloid SCBs in the basal ectal excipulum but not in the paraphyses (Pl. 574: 3b). No SCBs at all were seen in the topotype of *O. piloboloides* from Québec (Pl. 573: 1). On the other hand, in the not included sample from Arizona on *Prosopis* distinct crystalloid SCBs occurred in paraphyses and ectal excipulum.

A distinctly yellow, KOH-inert exudate was observed on the exterior of the apothecia but also on the beaks of the paraphyses in a specimen from near Maastricht (Pl. 572), in the topotype of *O. piloboloides* (Pl. 573: 1), in the specimens from Louisiana (Pl. 574: 1) and Tennessee (Pl. 575: 1h–i), and in the type of *O. rubrococcinea* (Pl. 575: 3e), also in some apothecia of a collection from Austria (Fernitz, IVV: 16.X.2010). This pigment is stable in the herbarium over many decades, and is recognizable under natural as well as LED light, but especially striking when illuminated by the Luxeon LED.

Type studies. The protologue of ***Peziza carpoboloides*** (Finistère, Bretagne, on decayed twine in a garden) includes a small sketch with microscopic elements (Crouan & Crouan 1867: pl. suppl. fig. 10; Fig. 169), but lacks any ascus and spore measurements. This somewhat rough sketch fits rather well the holotype specimen examined here (Pl. 570: 2), except that it shows oblong-ellipsoid, homopolar spores with ± obtuse ends. The spores were obviously drawn in the dead state because they do not contain spore bodies and, therefore, spore apex and base are not clearly differentiated (see Fig. 169 left). The original watercolour sketch preserved at the herbarium CO shows similar ellipsoid-fusoid spores with more subacute apices (see Fig. 169 right).

Another collection identified as *P. carpoboloides* (Paris, Bois de Vincennes, on rotten fabric) is very briefly described and illustrated by Patouillard (1886: 210, pl. 484), likewise without microscopic measurements. According to the scale of Patouillard's illustration, Saccardo (1889: 135, as *Humaria carpoboloides*) evaluated the asci as 40–45 × 5 µm and the spores as 6–7 × 2 µm. These data would point to another species, perhaps the South American *Orbilia brasiliensis*, the type of which also grew on textile. However, obviously the same specimen was depicted in detail by Boudier (1904–10: 265, pl. 459; Fig. 167), who gave the spores as 15–20 × 2–3 µm (15–19 × 2–2.9 µm evaluated from the scale), and his report clearly fits the present concept of *O. carpoboloides*, though spore length exceeds what we observed in any of the studied specimens.

This discrepancy in spore length was also noted by Le Gal (1953: 92) and Gremmen (1955). Le Gal reexamined Crouan's type material and found the spores 10–12(–16) × 1.5–2 µm, which is distinctly narrower than here found, perhaps due to artificial flattening. She stated to have seen two original convolutes of *Peziza carpoboloides*, but only one such specimen was received from CO in the present study, which is considered

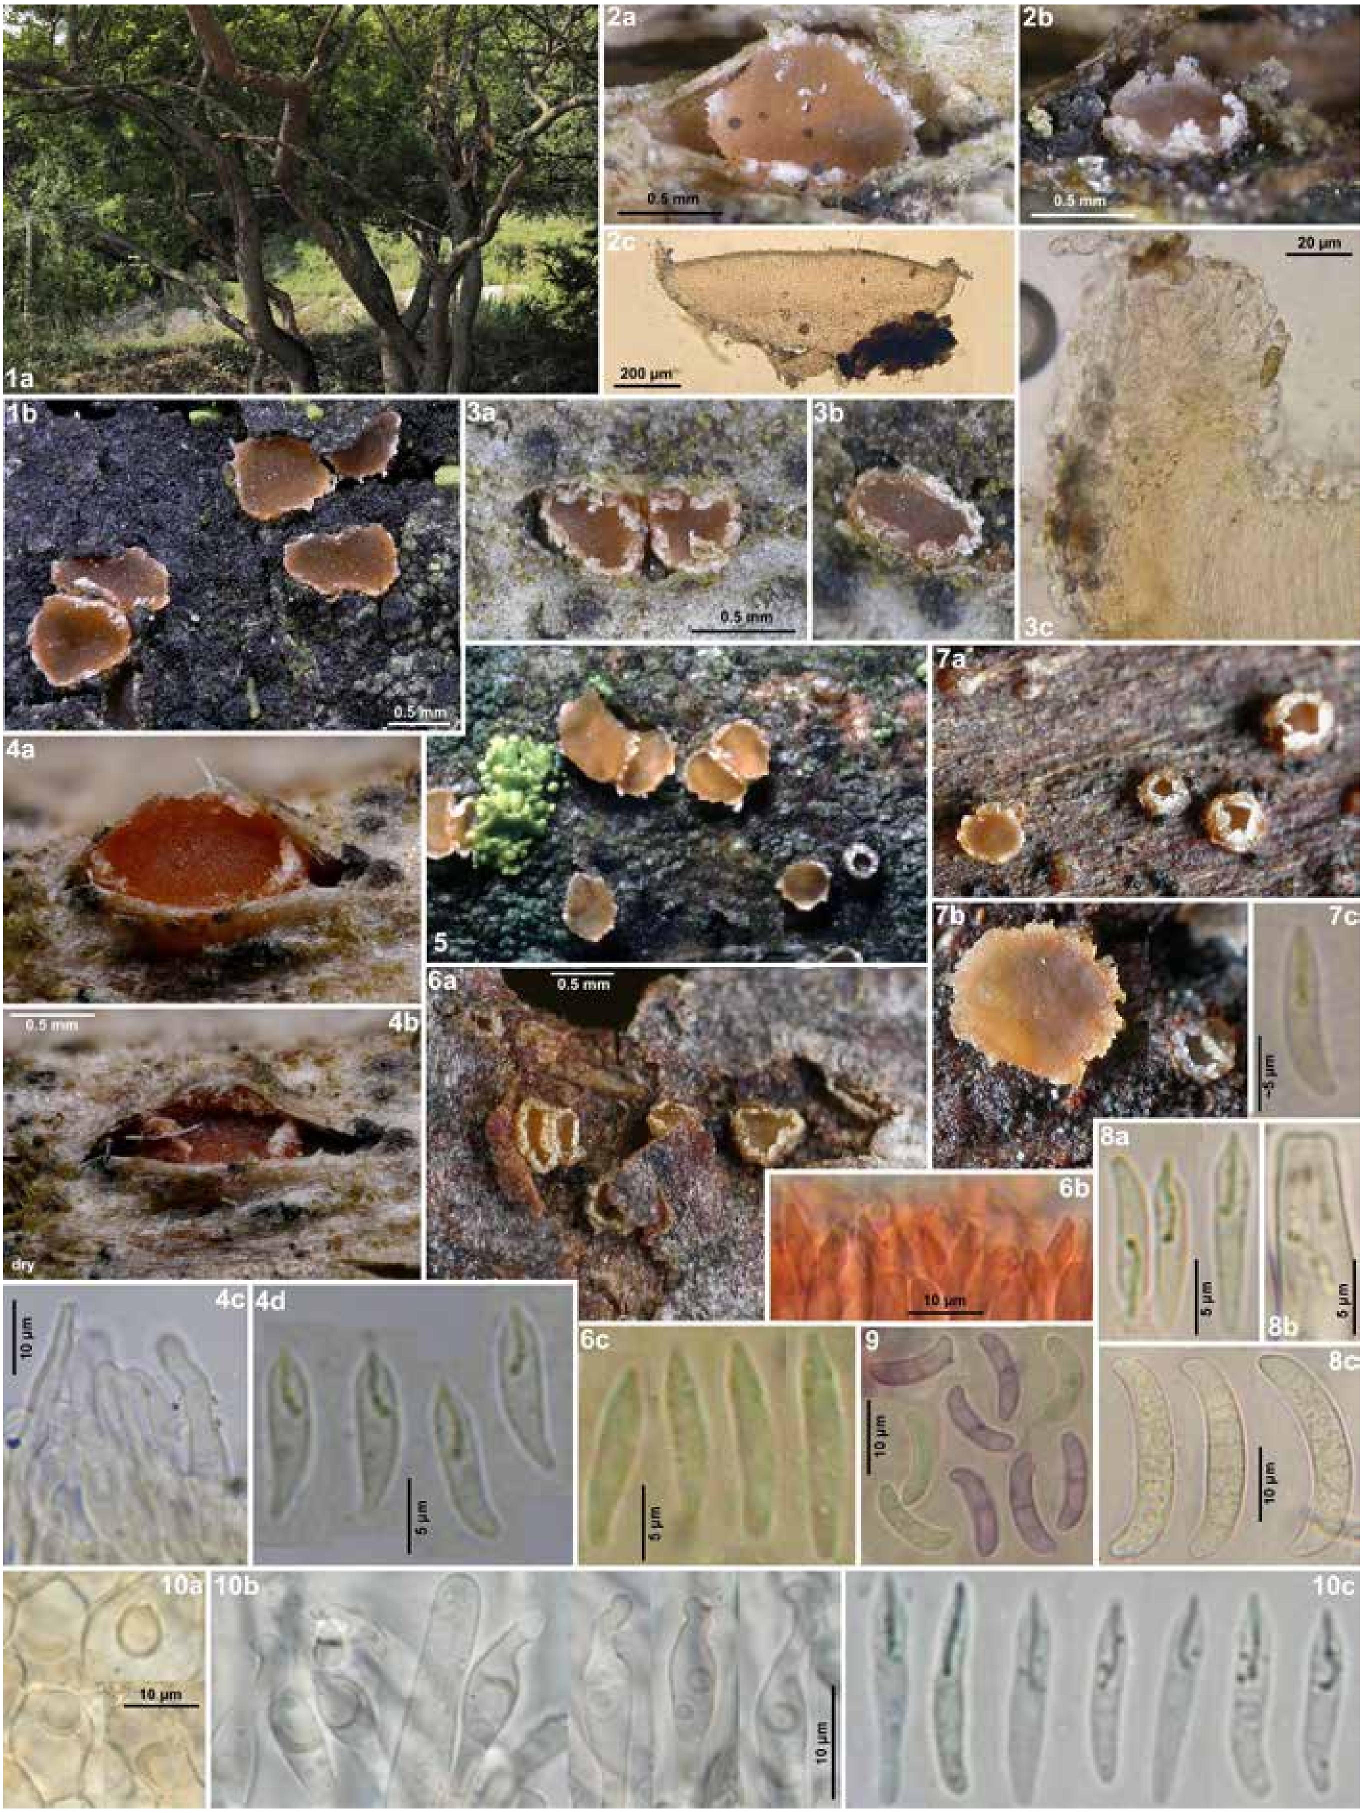

Plate 571. **1–10**: *Orbilia carpoboloides*. – **1a**. mesosubmediterranean woodland with *Cercis* trees with some dead attached branches; **1b**, **2a–b**, **3a–b**, **4a**, **5**, **6a**, **7a–b**. rehydrated apothecia; **4b**. dry apothecium; **2c**. apothecium in median section; **3c**. id., marginal excipulum; **4c**. marginal hairs; **10a**. crystalloid SCBs in cells of ectal excipulum; **8b**. ascus apex; **6b**, **10b**. paraphyses; **4d**, **6c**, **7c**, **8a**, **10c**. ascospores; **8c**. macroconidia (from substrate); **9**. microconidia (from culture). – Living state, except for **6a–c** (**6b** in KOH+CR, **6c** in KOH), **8b** (ascus). – **7a–c**: phot. here to be the holotype. Gremmen studied a collection from the Netherlands (on *Ulmus* bark) and Boudier's specimen (on textile), and found spores of (11.5–)12.5–13.4(–15.4) × 2.8–3 µm, with one end broader than the other, 'often with a small central oil droplet'. Regrettably, no trace of SBs can be seen in the drawings of Crouan, Patouillard, and Boudier, even though these authors were used to work with fresh collections, and no trace of them could be discerned in the present study. The acute spore apex is clearly seen in Pl. 570: 2 as well as on Boudier's drawing.

The illustration of a specimen from Luxembourg (Manternach, on *Ulmus*, H.B. 6639c ø, Pls 568: 3; 571: 9), from which a pure culture (CBS 116276) and a sequence were gained, is designated here as **epitype** of *O. carpoboloides*.

The protologue of ***Peziza ulmicola*** (under dead *Ulmus* bark, spring, dépt. Finistère, Bretagne, France) is without illustration, and no type material could be located at CO. According to J.P. Priou (pers. comm.) there exist two documents: (1) a watercolour sketch which bears the signature '*Peziza ulmicola* Crn. mscr.' but no date, and (2) an authentic specimen [Brest, Coataudon ('Coatodon'), in cracks of *Ulmus* bark, IVV: 9.IX.1869] which includes a microscopic pencil drawing with the same date. Both sketches obviously represent *Orbilia carpoboloides* as redescribed here from the holotype. Reexamination of this specimen by J.P. Priou (spores †12–15 × 2–2.5 µm, fusoid, with partly visible vermiform SBs) confirms this identity. The specimen cannot, however, be designated as lectotype because it was collected about 2 years after *P. ulmicola* was published.

The protologue of *P. ulmicola* describes the paraphyses as 'filiform, longer than the asci', and the spores as 'ovoid with 2 sporidioles' (Saccardo 1889 as 'binucleate'). These rather severe microscopical differences to the collection from 1869 appear to hint at two different species. Spore shape would fit *O. pilifera*, a species growing exclusively on *Ulmus* bark. However, *O. pilifera* was so far not detected in the northwest of France but only in sub- to eumediterranean regions in western France, Spain, and southern Austria (see Map 85). The spathulate paraphyses and uniguttulate spores of *O. pilifera* also hardly fit the protologue of *P. ulmicola*. Perhaps the apothecia in the type of *P. ulmicola* were rather young and the paraphyses still filiform.

Nevertheless, it remains a mystery why the Crouan brothers named the collection from Coataudon *P. ulmicola*, although their sketches show a striking similarity with their watercolour sketch of *P. carpoboloides* in regard to paraphyses with strongly swollen spathulate-lanceolate apices and narrowly fusoid spores without inclusions, The habit of the apothecia differs, however: those of *P. carpoboloides* are depicted as cupulate and bright orange (yellow ferruginous in the protologue), whereas those of *P. ulmicola* are flat, light rose to orange. Both drawings concur in showing a dentate margin. Because the watercolour sketch of *P. ulmicola* does not fit the protologue but concurs well with the microscopic drawing inside the authentic specimen, it also cannot be considered as holotype of this species.

Fuckel's (1870) unillustrated protologue of ***Habrostictis rubra*** (Germany, Hessen, Oestrich, on bark of *Ulmus minor*, as *U. campestris*, spores 12 × 2.5 µm) well agrees with that of *O. carpoboloides*, in spite of the different substrate. The presumed synonymy between *H. rubra* and *O. carpoboloides* is confirmed in the present reexamination of type material of *H. rubra* in G (herb. Barbey-Boissier 1461 ex herb. Fuckel 1894, 'isotype', Pls 569: 5; 571: 6). This shows apothecia with a strongly protruding and distinctly lacerate whitish margin. Already Gremmen (1955) could not find any differences between Boudier's specimen on textile and his collection on *Ulmus* bark, both showing a distinctly toothed margin.

Verkley (1999: 151) examined the 'holotype' of *H. rubra* in G (herb. Fuckel 1894) and three 'isotypes', among them Barbey-Boissier 1461. Verkley regarded these specimens as holo- and isotype according to the original handwritten description and drawing in the 'holotype'. The 'holotype' was not examined in the present study because only 1–2 apothecia were seen inside. We here designate one of the 'isotypes', i. e., Fuckel's collection (Fuckel 1894) as **lectotype** of *H. rubra* (Art. 9.11, Turland et al. 2018).

Berkeley & Broome's (1873) detailed illustration (Great Britain, Somersetshire, *Ulmus*, Fig. 168) leaves no doubt that ***Peziza lasia*** is conspecific with *O. carpoboloides* (spore size was given as 0.0005 × 0.0001 inch = 12.7 × 2.5 µm). The presumed synonymy of *P. lasia* with *O. carpoboloides* is confirmed in the present study from the syntype in M (herb. Rabenh., Fungi europ. 1515, 'isotype', Pl. 570: 1). The margin is distinctly protruding (Pl. 570: 1e). No substrate and date was indicated in this specimen, but the location is that of the protologue, and the bark fragment may well be *Ulmus* as mentioned in the protologue. Whether a syntype of *O. lasia* exists at K is not clear, since the British checklist of fungi (FRDBI) does not list the type collection. Fungi europ. 1515 (M) is designated here as **lectotype** of *Peziza lasia*.

When Boudier (1885) erected *Cheilodonta* for two species, *Peziza carpoboloides* and *P. lasia*, he overlooked Fuckel's genus *Habrostictis* with the type *H. rubra*. It was apparently Rehm (1891: 456) who first suggested synonymy of *O. lasia* and *H. rubra* based on the examination of type material of *H. rubra* (Fungi Rhen. Exs. 2554) and a specimen of W. Phillips (Elvell. brit. 117). Rehm named the species *O. lasia* although *H. rubra* has priority over Berkeley & Broome's taxon. Also Höhnel (1917: 331) confirmed the identity of *O. lasia* with *H. rubra*. However, he doubted the description and illustration of a lacerate-fimbriate margin by Berkeley & Broome as well as Saccardo (1883: pl. 1365, *H. rubra*) and obviously also Fuckel, because he found the margin in Fungi Rhen. Exs. 2554 and a specimen by H. Sydow (Mycoth. germ. 613, on bark of '*Malus*', according to Höhnel perhaps *Phellodendron amurense*) to be neither dentate nor fimbriate, and only slightly protruding. The erumpent growth of the apothecia of *H. rubra* on bark was a further argument for him to keep *Peziza carpoboloides* separate based on a strongly toothed margin and a superficial growth on textile. Thus, Höhnel retained *P. carpoboloides* in *Cheilodonta* and accepted *O. lasia* as a synonym of *H. rubra* in a separate genus *Habrostictis*. Nannfeldt (1932: 96) did not study the type of *P. carpoboloides*, but followed Boudier (1907) in synonymising *Cheilodonta* under *Habrostictis* (see p. 201).

The holotype of ***Peziza fibriseda*** in K (USA, Virginia, on *Ulmus americana*, Pl. 574: 2) was examined. It concurs macroscopically with the unillustrated protologue which is very brief and devoid of microscopic features. The label shows an ascus probably drawn by the authors, but no spores which they apparently did not see. Massee (1894b: 100) examined the seemingly same specimen from K and found the micromorphology not different from *Peziza cruenta* Schwein. (the identity of this taxon could not be clarified in the present monograph, see p. 1668). In a combined description, Massee

Plate 572. **1**: *Orbilia carpoboloides*. – **1a–b**, **d–g**, **i–k**. rehydrated apothecia; **1c**, **h**. dry apothecia; **1j**. fragment of apothecium in external view showing whitish stipe and yellow pruina at margin; **1i**, **k**. apothecia in median section (**1k** young apothecium with covering layer), **1l**. id., marginal region; **1m**. id., ectal excipulum at flanks; **1n**. crystalloid SCBs in cells of ectal excipulum at flanks; **1o–q**. asci; **1r–t**. paraphyses; **1u**. ascospores; **1v**. macroconidium (from substrate); **1w**. microconidia (from substrate). – Living state, except for **1o** (ascus), **1p** (right ascus), **1v** (in H_2O). — **1a–w**. H.B. 9233: Netherlands, Maastricht, Bemelen, on *Ulmus*.

reported the spores of *P. cruenta* as 'cylindric-oblong, ends obtuse, 4–5 × 1.5 µm', and the paraphyses as 'clavate or lanceolate at the tips'. However, Massee synonymised also some other taxa with *P. cruenta* and did not specify from which material the spore characters were obtained (see also under Misapplication).

The present type study of *P. fibriseda* revealed the spores to be much larger than indicated by Massee. The specimen appears to fit the type of *O. carpoboloides* better than that of *O. piloboloides* concerning ascus length and spore length and shape, although the host is *Ulmus americana* in *O. fibriseda* and *O. piloboloides*. The examined specimen was annotated as 'part of type', but no further duplicate appears to exist at K.

The type of ***Calloria rubrococcinea*** in S (USA, Kentucky, bark of *Gleditsia triacanthos*) consists of two convolutes. One (S-F9979) bears the diagnosis in Rehm's handwriting and is designated here as **lectotype**. The other (S-F88326) seems to represent the same undated collection and can thus be considered as isolectotype. Rehm's (in Winter 1883) brief diagnosis includes scarlet-red apothecia of 1–3 mm diam., asci 40–50 × 5 µm, clavate, apically thickened, 8-spored, spores 12–15 × 3 µm, clavate, and paraphyses apically hardly inflated to 3 µm. The present reexamination revealed mammiform paraphyses with ± strongly inflated, clavate to fusoid apices [terminal cell 18–32 × 2.5–4(–5) µm] with distinct beaks covered by a thin cap of yellow exudate (Pl. 575: 3e–f). The spores are distinctly smaller [in KOH 8–10(–11.8) × (2–)2.2–2.5 µm] and vary between fusiform and fusiform-clavate (3g–i). The asci have long and slender stipes and measured (45–)50–55(–60) × 4–5 µm. Rehm's statement 'Asci ... apice incrassati' refers to the lateral inflation of the truncate, thin-walled apex (Pl. 575: 3d). The hairs at the protruding, only slightly crenulate margin are ±

appressed and agglutinated by a yellow exudate.

C. rubrococcinea was described without specification of a collection date and site. The specimen possibly derives from Lexington where W.A. Kellerman worked at the Agricultural College and where he repeatedly collected on *Gleditsia*, e. g., in June 1882 the type of *Pleonectria denigrata* G. Winter. *C. rubrococcinea* fits in all relevant respects the description of *Orbilia piloboloides* and, except for shorter asci, also more or less the revised holotypes of *O. fibriseda* and *O. carpoboloides*.

Thind et al. (1983: 252) described under *O. rubrococcinea* a fungus growing on decaying cotton cloth, with much smaller, basally strongly tapered spores (4–7 × 1.4–1 7 µm). Judging from their illustration this could be *O. caudata* Starbäck.

The type of ***Calloria decipiens*** (Australia, Brisbane, on old twine) was described by W. Phillips (in Cooke 1887) with apothecia of 1.3–1.8 mm diam. (evaluated from original drawing in sched.), with a 'pale flesh-coloured, orange-red or pale brown' disc and protruding denticulate margin, ascospores 'fusiform, 5–7 × 1–2 µm', and paraphyses 'apically abruptly inflated'. The species was compared with *Calloria lasia* but was said to differ in the enlarged paraphysis apices with a more irregular outline, in the spores being only half as long and more obtuse at the ends, and in the glabrous exterior of the cups.

Reexamination of the holotype at K revealed distinctly larger spores (6.7–8 × 2–2.8 µm), and consistently mammiform paraphysis apices (Pl. 573: 4). In spore characters the taxon approaches *O. brasiliensis* which, however, seems to be sharply delimited by its shorter and narrower spores. Because of the rather short spores with slightly less acute apices we refrained from including *O. decipiens* in the description of *O. carpoboloides*. However, Spooner's (1987: 194) type study of *O. decipiens* revealed in the same material distinctly larger spores (7–9.5 × 2–3.5 µm). Spooner explained the high variation in spore width in this material by a flattening effect. Therefore, the living spores were probably narrower than those figured by him.

Spooner (1987: 196) stated that the type of *Habrostictis carpoboloides* differs from the type of *H. decipiens* in 'its much more conspicuously laciniate margin, much narrower ascospores and in the acute tips to its paraphyses'. Our specimens of *O. carpoboloides* actually appear to show a stronger tendency to a deeply lacerate margin than in the type of *O. decipiens*, but the difference in spore width noted by Spooner is not confirmed: the spores in the type of *O. carpoboloides* (Pl. 570: 2) are found here to be much longer than in the type of *O. decipiens* (Pl. 573: 4), but virtually not narrower. This applies also to the specimen figured by Boudier (1904–10: pl. 459) under the name *H. carpoboloides*, to which Spooner probably referred. The apices of paraphyses are indeed different between the two type specimens, but we found them too variable in all the specimens studied in order to supply valuable differences at the species level.

Helotium marmolense was described by Spegazzini (1909) from Argentina on dry decayed branches of *Maclura aurantiaca* (= *M. pomifera*), with concave, deeply carmine apothecia 2–3 mm diam., asci 40–45 × 5 µm, spores 8–10 × 3–4 µm, with small polar droplets, and filiform paraphyses with slightly clavate apices (*Schizoxylon argentinum* Speg. was reported from the same locality and substrate, perhaps in association). Dennis (1954) supplied a small sketch of the holotype (without scale and description) which includes a single apically clavate paraphysis (Fig. 159: G). In the present reexamination (LPS 24442) the spores were found to be distinctly narrower than indicated in the protologue, and the paraphyses consistently mammiform (Pl. 573: 3). The specimen appears to fit well the present concept of *O. carpoboloides*, except that the spore apices are subacute rather than acute. A recent collection on the very same host from a park in Wien (Austria) showed longer and rather narrow spores (*11.5–12 × 2–2.1 µm) with acute apices and cylindrical middle part (B. Wergen, IVV: 24.XII.2015).

Helotium chordicola, described by Spegazzini (1909) from Argentina on a decayed rope, was placed in synonymy with *Habrostictis decipiens* by Spooner (1987: 194), based on an unpublished note and sketch taken by Dennis from the type, leaving 'little doubt of the synonymy'. The type of *H. chordicola* was not studied by us, but we had the opportunity to see a copy of the handwritten and illustrated original diagnosis as well as a sketch of Dennis' revision (IVV: 7.VII.1906). Spegazzini described the apothecia as 2–3 mm diam., indistinctly saturn-red, with smooth margin, the spores 6–8 × 3–3.5 µm, fusoid with subacute ends, and the filiform paraphyses with 'clavate-capitate' apices (however, both Spegazzini's and Dennis' drawings show strongly inflated, spathulate to lageniform apices). The rather short spores and the smooth apothecial margin are reminiscent of *O. decipiens* as redescribed here, and we preferred not to include the types of both taxa in the description of *O. carpoboloides*.

Orbilia ulicis might be a further synonym of *O. carpoboloides* (which was twice recorded on *Ulex*), according to the original illustration, except for the apically rounded spores. Type material of this taxon, which was described on bark of *Ulex* in Nantes (France) under the name *Hyalinia ulicis*, could not be located in PAD and NTM. According to J.P. Priou (pers. comm.), the herbarium of J.E. Chenantais (Musée des Sciences naturelles de Nantes) contains only pyrenomycetes but no discomycetes. In addition to the illustration reproduced in black & white, a watercolour sketch exists in the library of the Société Mycologique de France (Paris, J.P. Priou pers. comm.), which corresponds to the published figure (see Fig. 151: 3). Chenantais illustrated living ascospores (cylindric-clavate with a tapered base, comma-like curved, 12–13 × 2 µm) with a short, vermiform, straight spore body in the rounded end. Judging from his drawing the spores are wider than indicated, perhaps 2.5–3 µm. The spores would closely match *O. quaestiformis*, but the strongly lacerate margin and the apically non-capitate paraphyses forbid that synonymy. The lacerate margin of the young urceolate apothecia (0.5–1 mm diam., 'lilaceous or flesh-coloured', but bright rose-orange on the watercolour sketch) and the stated ascus size (70 × 6 µm) point to synonymy with *O. carpoboloides*. However, the spores of *O. carpoboloides*, which are indeed sometimes curved at the base, are always more or less acute at the distinctly conical apex. Possibly, Chenantais' drawing is inexact herein. The two figured paraphyses are apically only slightly inflated and only partly very indistinctly lanceolate (especially the right paraphysis on the watercolour sketch), a feature also observed in young apothecia of *O. carpoboloides*.

The holotype of ***Orbilia vacini*** contains several fragments of *Ulmus* bark (as '*Quercus*'), on which only a single strongly overmature apothecium could be discovered. This contained only a few asci, no ascospores, and a few strongly mammiform paraphyses. Svrček (1954) already suggested synonymy with *Habrostictis rubra* and the substrate to be *Ulmus*.

O. piloboloides was described by Haines & Egger (1982) based on several collections on bark of *Ulmus americana* from the provinces of Québec and Ontario (Canada). The taxon

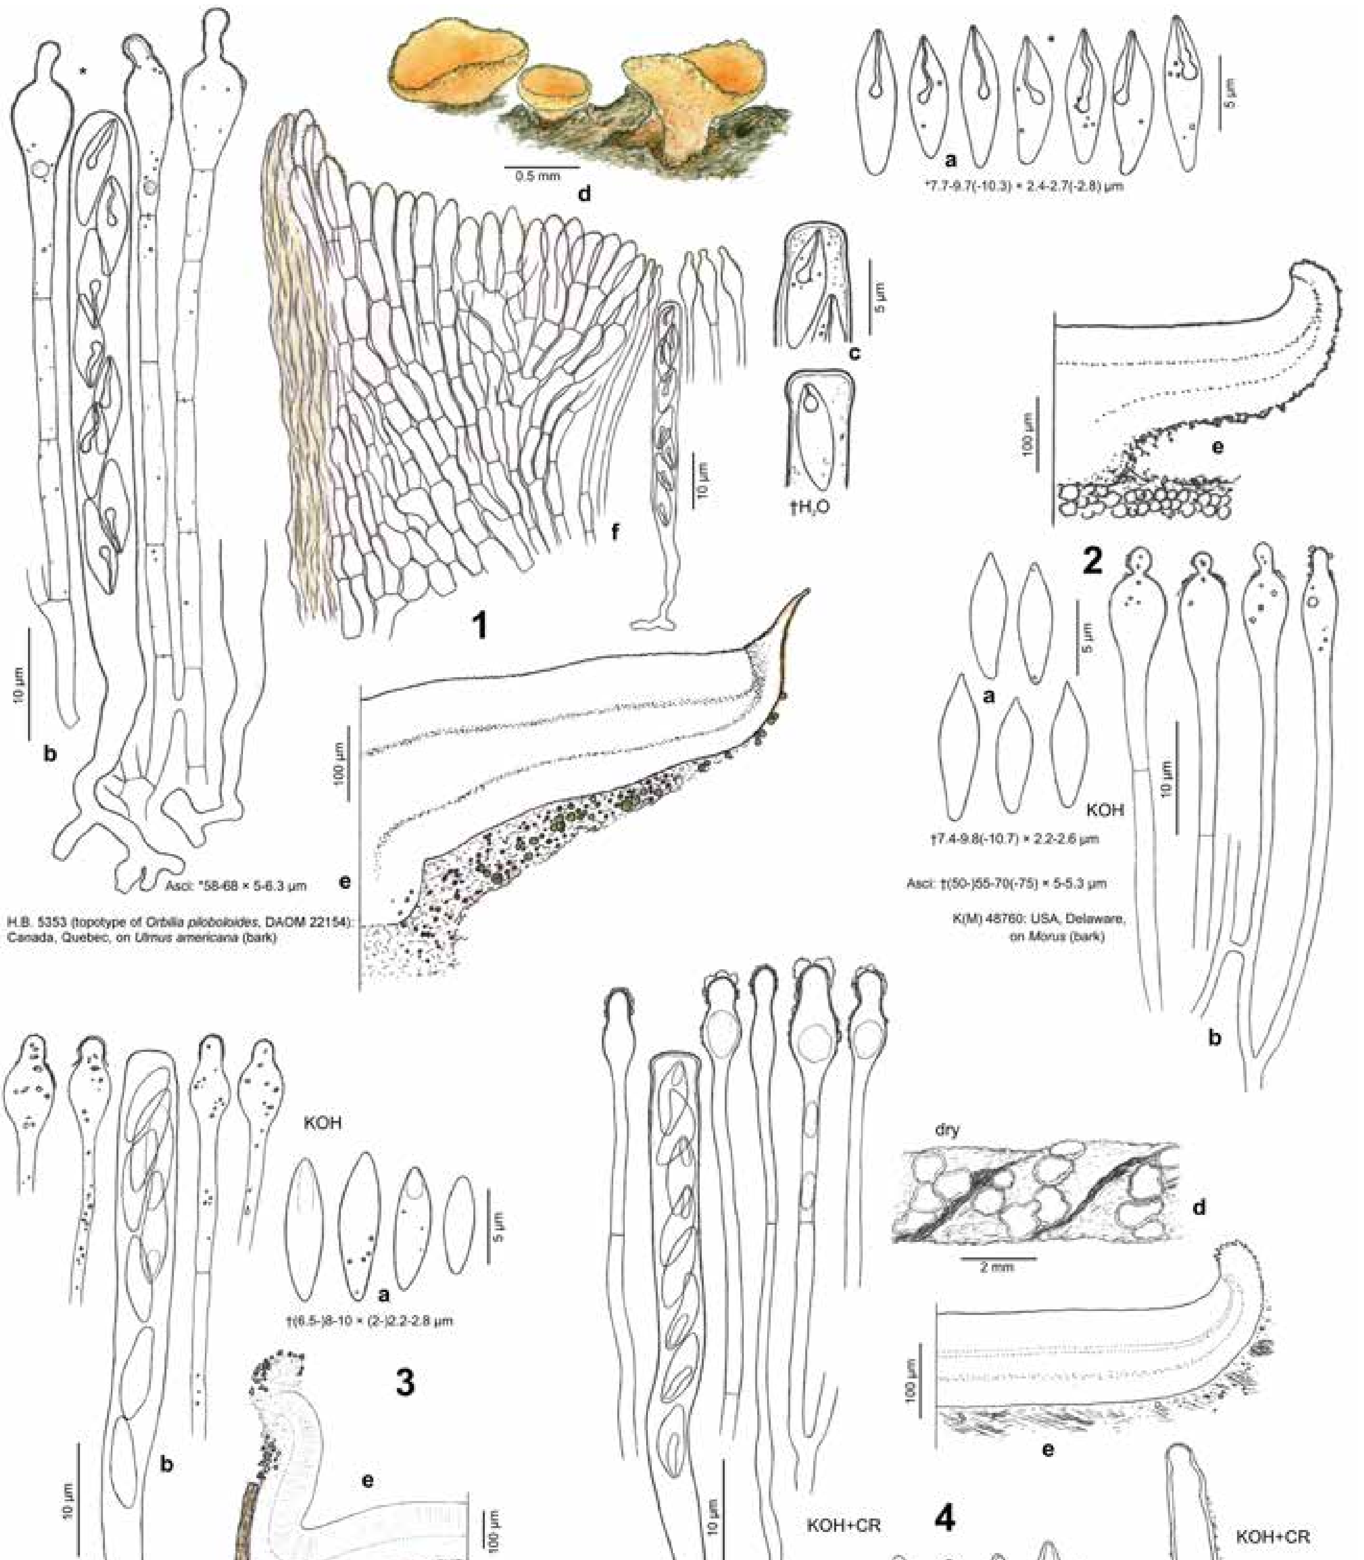

Plate 573. **1–3**: *Orbilia carpoboloides*; **4**: *O.* cf. *carpoboloides*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., marginal ectal excipulum and part of hymenium; **g**. id., marginal hairs.

was considered to be remarkable in its strongly mammiform ('subapically swollen') paraphyses and fusiform ('fusoid'), short-navicular spores, also in its occurrence on comparatively undecayed bark attached to the upper parts of standing dead trees. A recent viable collection from the type locality was kindly sent by J.H. Ginns and D.H. Pfister (Pl. 573: 1). This concurs very well with the protologue which reports orange-yellow apothecia with a white fringe at the margin, asci †(33–)40–52(–56) × 3–4 µm and spores of †8–10 × 2–2.5 µm. The short ascus length is apparently due to broken ascus bases (see Fig. 162), but the dead asci were here with †54–64 × 4–4.7 µm also distinctly wider. Apart from slight differences in ascus and spore length, *O. piloboloides* well corresponds to the type of *O. fibriseda* which grew on the same host species.

Misapplication. When doing a redescription of type specimens, Massee (1894b) concluded that *Peziza fibriseda*, *P. regalis*, *P. rufula* and *P. saccharifera* are synonyms of *P. cruenta*. Based on this result but without personal studies, Nannfeldt (1932: 252) believed that all these taxa represented possible synonyms of *Hyalinia rubella* (s. Nannfeldt, = *Orbilia phragmotricha*). However, none of these synonymies were confirmed in the present study, except for *P. cruenta*, for which no authentic specimen could be located.

Breitenbach & Kränzlin's (1981, fig. 261) report of *Habrostictis rubra* represents a mixture of three species: the microscopic drawing shows the elements of *Orbilia carpoboloides* (= *H. rubra*), but the colour photo illustrates *O. comma*, according to a reexamination of the cited specimen in LU. Besides *O. comma*, a further species, *O. phragmotricha*, was detected, whereas no trace of *O. carpoboloides* could be found.

Not included collections. A North American sample on bark of *Prosopis velutina* (Pls 574: 4; 575: 2) differs in distinctly wider spores (*9.5–11 × 3.4–3.7 µm) and asci (†63–84 × 5.7–6.5(–7) µm), also in smaller macroconidia and a deviating substrate, therefore it is not included in the description. For the not included *Hyalinia ulicis*, *Peziza ulmicola*, *Helotium chordicola*, and *O. decipiens*, see under Type studies.

Anamorph. The anamorph obtained by us in pure culture of *O. carpoboloides* (Pls 568: 3j; 571: 9) matches very well that described by Haines & Egger (1982) from pure culture of the holotype of *O. piloboloides*. Both isolates show 1-septate, c-shaped conidia of a very similar size, formed sympodially on distinct nodules or denticles. Haines & Egger's description includes conidiophores with 1–3 denticles at the apex and conidia of †9–12 × 2–3 µm. From a topotype (D.H.P. 192) Pfister (1997: fig. 10) obtained the same anamorph in pure culture with 1–4 denticles on unbranched or branched conidiophores, but figured the conidia without septa, *~7.5–13 × 2.3–3.5 µm as evaluated from scale. Our isolate deviates from both in conidiophores with ~6–15 denticles being rather densely arranged on the ± swollen conidiogenous cells.

This anamorph was compared by Haines & Egger (l.c.) with genera such as *Diplorhinotrichum* Höhn. (= *Dactylaria* Sacc.), *Idriella* P.E. Nelson & S. Wilh., and *Microdochium* Syd. These are, however, morphologically more or less strongly different from the anamorphs of *Orbilia*, and belong from their molecular data in *Sordariomycetes* (Hernández-Restrepo et al. 2015).

The same type of microconidia was observed on the natural substrate close to the apothecia of four collections here identified as *O. carpoboloides* (Pls 574: 1i, 3i, 572: 1w, IVV: 12.V.2019), often together with similar but larger, (3–)5–7-septate macroconidia. Such C-shaped macroconidia were observed on the natural substrate in various other samples of *O. carpoboloides* (Pls 569: 3g; 570: 2g; 571: 8c; 572: 1v), including G.F. 20090147 and LE 248299, and the type of *P. ulmicola* (IVV: 9.IX.1869). They resemble the conidia of *O. aurantiorubra* (section *Aurantiorubrae*), which sometimes grew in association. However, the closely related *O. flavidorosella* formed in culture comparable C-shaped, 3-septate, but narrower conidia, and in addition also one 1-septate microconidium (Pl. 583: 6).

The assumption that the two types of curved conidia might represent the same fungus is supported by a further collection. Abundant conidia still attached to conidiophores were found on xeric bark of (?)*Pseudotsuga* (Pl. 574: 5, among apothecia of *O. lentiformis* and *O. magnifica*). Two types of conidia were observed: (1) strongly curved, 0–1-septate, c-shaped conidia formed on swollen conidiogenous cells *5–6.5 × 3–3.5 µm with a single denticle, and (2) (1–)3-septate, nearly straight to medium curved, C-shaped conidia formed intermingled on the same hyphal texture. This conidial state appears to be very similar to that here reported for *O. carpoboloides*, thus possibly represents a closely related species on a coniferous host. However, no apothecia of series *Habrostictis* were detected in this collection. A connection to the associated species of *Orbilia* seems less probable, although the anamorph of *O. lentiformis* forms similar macroconidia.

In this collection as well as in the sample on *Albizia* (Pl. 574: 1) the conidia were formed inside black old pycnidia-like fruitbodies of unidentified fungi. In A. Polhorský's documentation (IVV: 12.V.2019) the macroconidiophores emerged from the wall of living pycnidia of *Cyclothyriella rubronotata* in vicinity of apothecia of *O. carpoboloides*.

Distinctly longer, medium curved phragmoconidia with 5–8 septa, which were observed on the natural substrate in two collections, are of doubtful connection and, therefore, not shown on the plates: on herbaceous stems of *Melilotus* (Lorraine, Pl. 571: 4, conidia *38–44 × 5.4–5.7 µm, IVV: 13.VI.2009) and on bark of *Morus* (Tennessee, Pl. 574: 3, conidia *48–53 × 4.5–5.3 µm, IVV: H.B. 7406). In the deviating collection on *Prosopis* (H.B. 8683a) some C-shaped, distinctly smaller (†16–17 × 3–3.5 µm), 3-septate conidia were found on the natural substrate (Pl. 575: 2j).

Höhnel (1915: 209) reported *Tuberculariella sanguinea* (Fuckel) Höhn. as anamorph of *Habrostictis rubra*. Nannfeldt (1932) and Korf (1973: 290) referred to Höhnel when stating that *H. rubra* is connected to *Cryptosporiopsis*, the anamorph of *Pezicula*. According to Verkley (1999: 152, 155), *T. sanguinea* appears to belong to the *Dermateaceae*, as *Cryptosporiopsis sanguinea* (Fuckel) Petrak, in which family *Habrostictis* had been placed by Höhnel, Nannfeldt, Korf, and others. Verkley did not see the type material of *T. sanguinea* but examined a collection under that name in the Petrak herbarium, which he tentatively referred to *Cryptosporiopsis grisea* (Pers.) Petr., the anamorph of *Pezicula cinnamomea* (DC.) Sacc.

Phylogeny. The two available sequences of *O. carpoboloides* on *Ulmus* (Manternach, from pure culture; Maastricht, from apothecia) comprise SSU (with S1506 intron), ITS, and LSU. They are completely identical in the overlapping part (1912 nt), which supports the here presented hypothesis that *O. piloboloides* from North America (which resembles the Maastricht collection) is conspecific with *O. carpoboloides* from Europe. The apothecia from Maastricht concur with those from the type of *O. piloboloides* in showing a yellow exudate on their outside, but also the Manternach sample was externally yellowish. The Maastricht sample showed slightly smaller ascospores [*9.5–11.7(–13) × 2.7–3(–3.5) µm] compared to

Manternach [*10–14 × 3–3.4(–3.8) µm]. A sequence of the type culture of *O. piloboloides* in DAOM would create clarity about this taxon.

A recently gained ITS sequence of the Portugal sample (on *Salix*, intron region not covered) differs from *O. carpoboloides* s.str. by 14% while being much closer to *O. flavidorosella* (4.5–4.7%). A similar but narrower-spored sample on *Cytisus* from the same area, mentioned under *O. flavidorosella*, is without sequence. Various collections included here in *O. carpoboloides* might in fact be conspecific with the *Salix* sample but are without sequence data, while a clear morphological delimitation from short-spored populations was not possible.

When analysing ITS or SSU+ITS+LSU, *O. carpoboloides* clustered with *O. flavidorosella* in a clade (Phyls 19, 20), though with a 13.5–14% distance in the ITS and 1.4% in the LSU (D1–D2). However, the distance to some other species of the *Serpentinae-Habrostictis* clade is comparably high (e.g., 16.5% to *O. mesaverdiana*, 1.3% in LSU). In the intron the distance to other members of section *Habrostictis* is also rather high, in spite of a full identity of the two sequenced strains of *O. carpoboloides* also in this region (the two *O. flavidorosella* strains deviate from *O. carpoboloides* in lacking the intron).

An environmental DNA soil isolate (ITS) from Florida (FLITS02A06) clustered in the series *Habrostictis* clade (Phyl. 19), but with a distance of 15% to *O. carpoboloides* (s.str.) and 16% to *O. flavidorosella*.

Ecology. *O. carpoboloides* occurs on slightly to strongly rotten bark (rarely wood) of xeric branches and trunks of various angiosperm trees and shrubs, rarely herbaceous stems. In the specimens examined by us this species showed a strong preference for *Ulmus* {44} and various genera of *Fabales* {14}, but it occurred also on some other genera of different relationships. According to Haines & Egger (1982), the standing *Ulmus* trees on which *O. piloboloides* was collected have been killed by the Dutch elm disease, and this was also the case at many of the European sites. A report from supramediterranean Sierra Nevada, Granada (Spain) was on bark of ?*Ficus* (Malençon & Llimona 1980: 55, R. Galán in Pando & Hernández 2001: 123).

The included records mainly derive from atlantic to continental, oro- to mesotemperate or rarely hemi- to thermoboreal humid western to eastern Europe, but also from orosub- to meso-, rarely thermomediterranean humid to semihumid southern Europe. In the nemoral zone the natural vegetation is mainly represented by moist, partly shady floodplain (*Querco-Ulmetum minoris*) and boulder forests (*Fraxino-Aceretum pseudolatani*). In southern Europe it was, e.g., a supramediterranean *Quercus pyrenaica* forest with *Castanea sativa* etc. *O. carpoboloides* occurs also in the Caspian Volga floodplain forests in warm-continental subhumid steppic southwestern Russia.

The extra-European collections derive from hemiboreal humid northeastern North America (around Ottawa), cold-temperate humid Virginian Appalachian mountains, warm-temperate humid lowlands of the east and south of Northern America, and subtropical humid lowlands of South America (La Plata, Buenos Aires). The not included collections comprise a warm-temperate semiarid riparian mesquite scrub (*Prosopis*) in the Sonoran Desert and a cold-temperate humid ponderosa pine forest (*Pseudotsuga*) in the Colorado Plateau in the southwest of Northern America, and subtropical humid sites in the southeast of Northern America and in eastern Australia.

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, 4 km ESE of Halesworth, NNW of Wenhaston, path from Chapel to Bicker's Heath, 20 m, branch of *Ulmus*, on bark and old pycnidium, 4.IV.2004, E. Batten (E.B. 4506). – 9.5 km SW of Southwold, 5.5 km NNE of Leiston, Minsmere Haven, 12 m, branch of *Ulex europaeus*, on bark, 3.VII.2004, E. Batten (ø). – 4.5 km NE of Leiston, Minsmere Haven, S of Sluice, 1 m, twig of *Lupinus arboreus*, on wood, 15.II.2003, E. Orbilia brasiliensis (Speg.) Sacc., Syll. Fung. 8: 631 (1889) — Pl. 576

≡ *Calloria brasiliensis* Speg., Bol. Acad. Nac. Cienc. Córdoba 11: 209, n. 393 (1889)

Etymology: collected in Brazil.
Typification: Brazil, Apiaí (Apiahy), on textile, X.1888, J. Puiggari (Puig. 2781, LPS 28075, lectotype, designated here, MBT202378).
Misinterpretation of *O. brasiliensis*: Liu (2006: 59), = *O.* aff. *farnesianae*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 1.5–4 mm diam., 0.12 mm high, now light cream-ochre to reddish (Spegazzini: dry orange-red), round or somewhat undulating, ± scattered; disc flat, margin distinct, 50 µm protruding, ± crenulate; broadly sessile, superficial; dry bright orange-red, only slightly contracted. **Asci** †50–65 × 3.4–3.8(–4.2) µm, 8-spored, spores †1–2-seriate; **apex** (†) strongly truncate (slightly indented, laterally somewhat inflated); **base** with long, thin, flexuous stalk, L-shaped. **Ascospores** †5.7–6.7 × 1.7–2 µm, fusoid-fusiform, apex subacute (to acute), base medium to strongly attenuated, straight or slightly inequilateral; **SBs** visible as a transparent region, seemingly tear-shaped, †~1.7–2.5 µm long, straight; **Paraphyses** apically spathulate to lageniform, beak 2 × 2 µm, terminal cells †14–22 × 2.5–4(–5.3) µm, exceeding the dead asci by 4–5 µm, lower cells †8–18 × 1–2 µm. **Medullary excipulum** 50 µm thick. **Ectal excipulum** of thin-walled, horizontally oriented textura prismatica-angularis from base to margin, 25–30 µm thick near base, cells †10–15 × 7–9 µm; at margin ~40–100 µm thick, oriented at a 0–20° angle to the surface. **Anchoring hyphae** abundant, †1.5–2.5(–3) µm wide, walls †0.2–0.5 µm thick, forming a dense hyaline t. intricata ~50–80 µm thick. **SCBs** no data available. **Exudate** over paraphyses 0.1–0.2 µm thick, finely rough, firmly attached; over margin and flanks 0.3–1.5 µm thick, granular. **— ANAMORPH**: unknown.

Habitat: on remnants of textile (probably cotton) lying on ground, slightly decayed. **Associated**: *Orbilia neocomma* (in the type convolute, but on different kind of fabric). **Desiccation tolerance**: unknown (probably desiccation-tolerant). **Altitude**: 900 m a.s.l. **Phenology**: X (southern hemisphere).

Taxonomic remarks. *Orbilia brasiliensis* differs from *O. carpoboloides* in distinctly smaller spores and narrower asci. The margin was described as completely smooth in the protologue, but here it is found to be somewhat crenulate in the dry state and also strongly protruding. With its rather smooth margin, *O. brasiliensis* resembles the type of *O. decipiens* in which the margin is also not strongly lacerate, in contrast to *O. carpoboloides*.

The spore body in *O. brasiliensis* is only faintly seen as a ± tear-shaped area (Pl. 576: 1a) which is slightly shorter than in the type of *O. decipiens*. In the other characters the types of these two taxa strongly resemble the European *O. pilifera* which is sharply separated in the living state from *O. carpoboloides* in having broad, ± subglobose spore bodies. According to morphological and molecular data, *O. pilifera* belongs rather in section *Aurantiorubrae*. Based mainly on SB shape in dead spores, *O. brasiliensis* and also *O. decipiens* are tentatively placed in section *Habrostictis*.

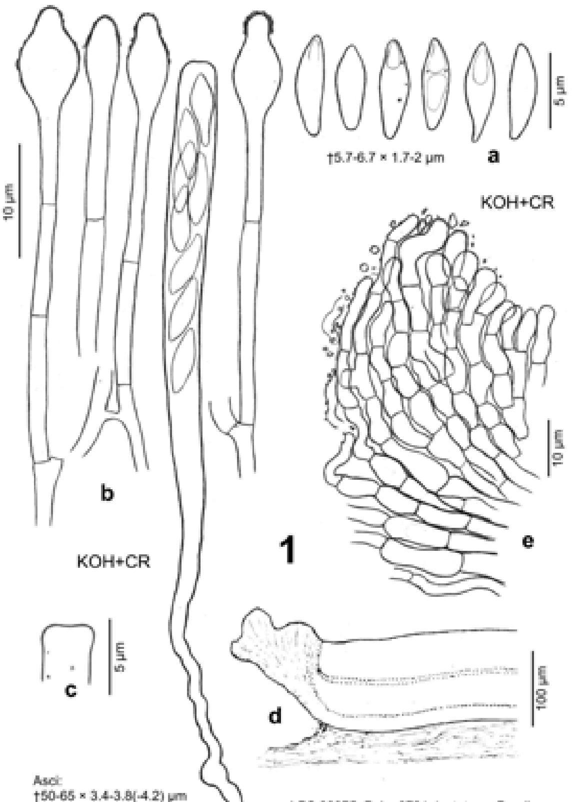

Plate 576. **1**: *Orbilia brasiliensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex. **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Liu (2006: 59) assigned to *O. brasiliensis* a Chinese specimen found on a xeric twig (HMAS 139700), based on the present drawing of the type collection (in Baral & Marson 2005). However, the spores in Liu's specimen are distinctly larger. The original shape of the SBs is also unknown in this collection which was studied by Liu only in the dead state. This collection appears to represent an undescribed species close to *O. farnesianae*, with a characteristic trinacrium-like anamorph and sequence data which refer it in series *Piliferae*.

Type studies. The type of *O. brasiliensis* in LPS (Speg. Col. micol. 28075) represents a mixture of two different species. This is already obvious from Spegazzini's original sketches on the two convolutes, into which the material was early divided, apparently by the finder J. Puiggari who gave them two different numbers. Both contain fragments of textile, but the type of textile differs between the two convolutes. One (Puig. 2781, IVV: H.B. 6951a) contains the specimen illustrated in Pl. 576 (original data: asci 45–50 × 4 µm, spores fusoid, 5 × 1–1.5 µm). The other (Puig. 2335, Pl. 424: 4) contains *O. neocomma* (original data: asci 30 × 2–3 µm, spores rod-shaped, no size given). Spegazzini's (1889) protologue gives exactly the measurements of asci and spores of the former convolute. Therefore, this convolute (Puig. 2781) is designated here as **lectotype** of *O. brasiliensis*. The apical inflation of the paraphyses was overlooked by Spegazzini, perhaps because he studied a submature apothecium.

Ecology. *O. brasiliensis* is only known with certainty from the type collection on slightly decayed textile collected in a garden in subtropical humid eastern South America.

Specimens included. **BRAZIL**: **São Paulo**, ~110 km NNE of Curitiba, Apiaí (as Apiahy), ~900 m, on textile, X.1888, J. Puiggari (Puig. 2781, LPS 28075, **lectotype**, H.B. 6951a ø).

Orbilia mongolica Baral, **sp. nov.**, MB 813654 — Pls 577–578

Etymology: named after the occurrence in Mongolia.

Typification: Mongolia, Tsengel, branch of *Lonicera altaica*, 9.VIII.2005, P. Karasch (ex H.B. 7893a, M-0276516, holotype).

Latin diagnosis: *Similis* Orbiliae carpoboloidi *sed ascosporae ellipsoideo-clavatae, apice obtusae, asci 16-spori. Habitat ad corticem et lignum rami putridi sicci* Lonicerae altaicae *in zona orotemperata (sub)humida Asiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.3 mm diam., 0.11 mm high, pale cream-orange, round; disc strongly concave, margin 40–50 µm protruding, somewhat fimbriate to crenulate; broadly sessile, superficial. **Asci** *65–83 × 6–6.7 µm, †53–70 × 5–6 µm, 16-spored, spores *2–3-seriate, ~6–8 lower spores inverted (somewhat mixed), pars sporifera *44 µm long; **apex** (†) strongly truncate (very slightly indented, laterally not or scarcely widened); **base** with or without short, thin or thick, flexuous stalk, T- to Y-shaped. **Ascospores** *(5.5–)6–10 × (2.4–)2.8–3(–3.3) µm, ellipsoid-fusoid-clavate, apex rounded to obtuse, rarely subacute, base slightly to medium attenuated, straight or up to medium curved near base; **SBs** *4.2–5.7 × 0.2–0.4 µm in situ (total length ~4.5–6.5 µm), filiform to vermiform, partly subulate, straight to medium flexuous, rarely slightly uncinate. **Paraphyses** apically mammiform to lageniform, beak 1–5 × 1.6–1.8 µm, terminal cells *18–33 × 3–3.5 µm, scarcely exceeding the living asci, lower cells *9–15.5 × 1.5–2 µm; never branched at upper septum. **Medullary excipulum** very pale orange, 25 µm thick, of dense textura intricata with many inflated cells, unsharply delimited. **Ectal excipulum** very pale orange, of thin-walled, irregularly horizontally oriented t. globulosa-angularis(-prismatica), 20 µm thick near base, cells *5.5–13 × 5–10 µm; 25 µm thick near margin, of t. prismatica-angularis oriented at a 0–10° angle to the surface, marginal cells forming fascicles of ± coherent hyphae (†3–5.5 µm thick, walls 0.2–0.4 µm) protruding as indistinct teeth or hairs. **Anchoring hyphae** abundant, †2–4 µm wide, walls 0.2–0.8 µm thick. **SCBs** in paraphyses globose, 1–2 µm diam.; in ectal excipulum not observed. **Exudate** over paraphyses and margin absent. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). **Conidiophores** not observed. **Conidia** unbranched, *24–31.5(–39?) × 2.8–3 µm {1}, 3-septate, slightly curved.

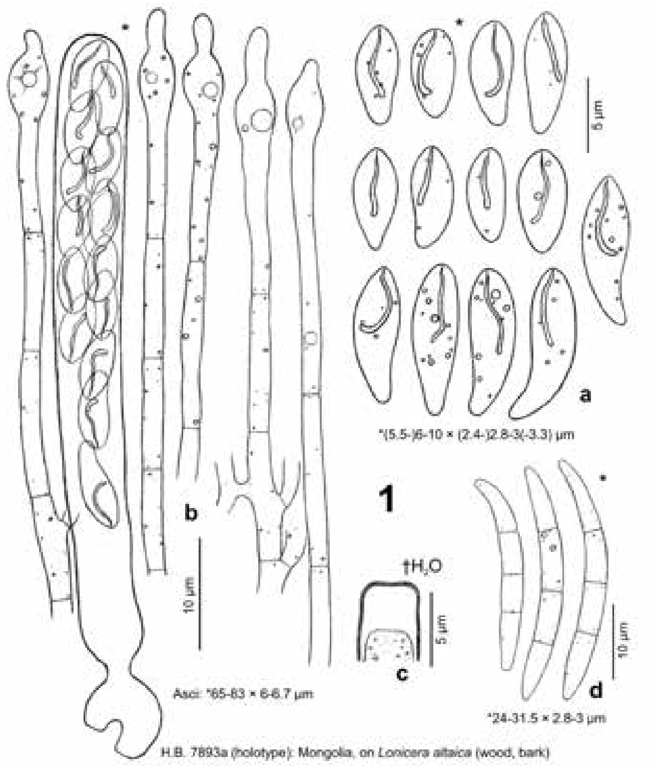

Plate 577. **1**: *Orbilia mongolica*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. conidia from substrate.

Habitat: xeric, corticated branch of *Lonicera altaica*, on 24 mm thick node, on medium rotten bark (periderm), also on wood of broken side twig, greyed, with some green algae. **Associated**: ?*Hypoxylon* sp., *Orbilia delphinus*, *O. ocellata*. **Desiccation tolerance**: fully tolerant for at least 1 month. **Altitude**: 2200 m a.s.l. **Geology**: Paleozoic sediment. **Phenology**: VIII (probably long-lived).

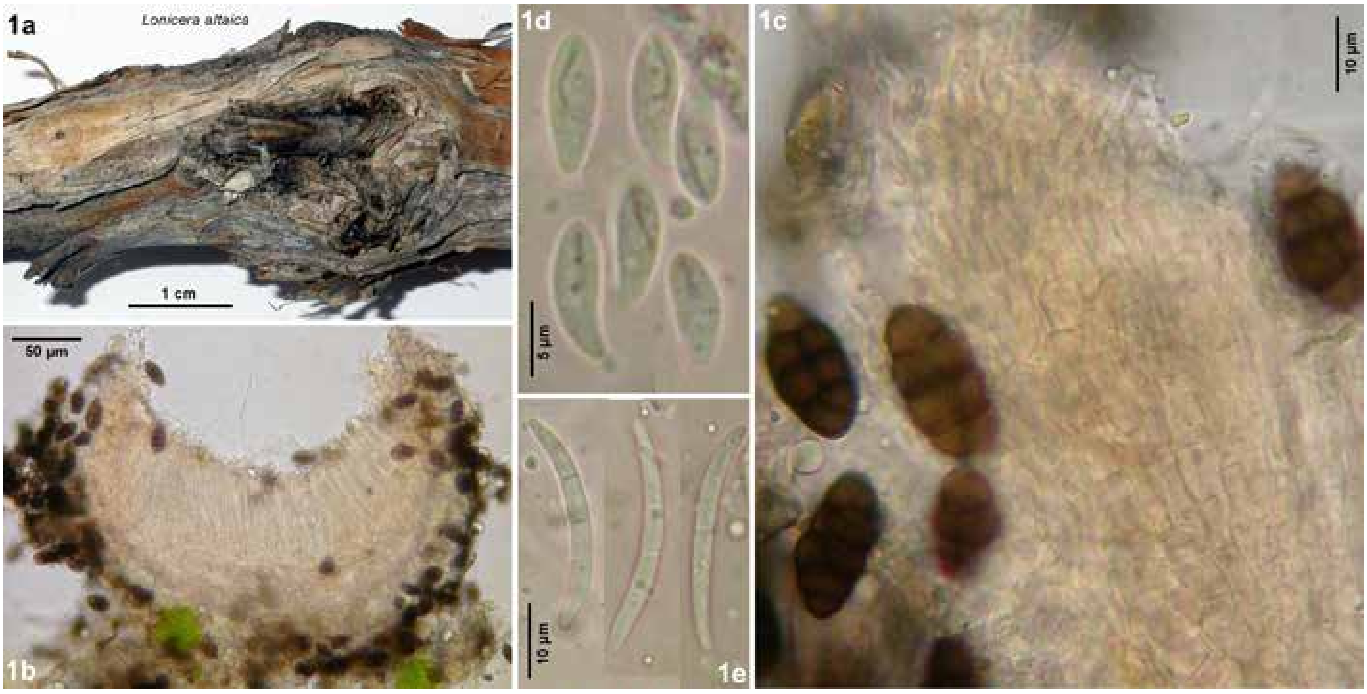

Plate 578. **1**: *Orbilia mongolica*. – **1a**. dead corticated branch of *Lonicera altaica*; **1b**. apothecium in median section; **1c**. id., marginal ectal excipulum (with brown conidia of a coelomycete); **1d**. ascospores; **1e**. conidia from substrate. – Living state. — **1a–e**. H.B. 7893a (holotype): Mongolia, on *Lonicera altaica*.

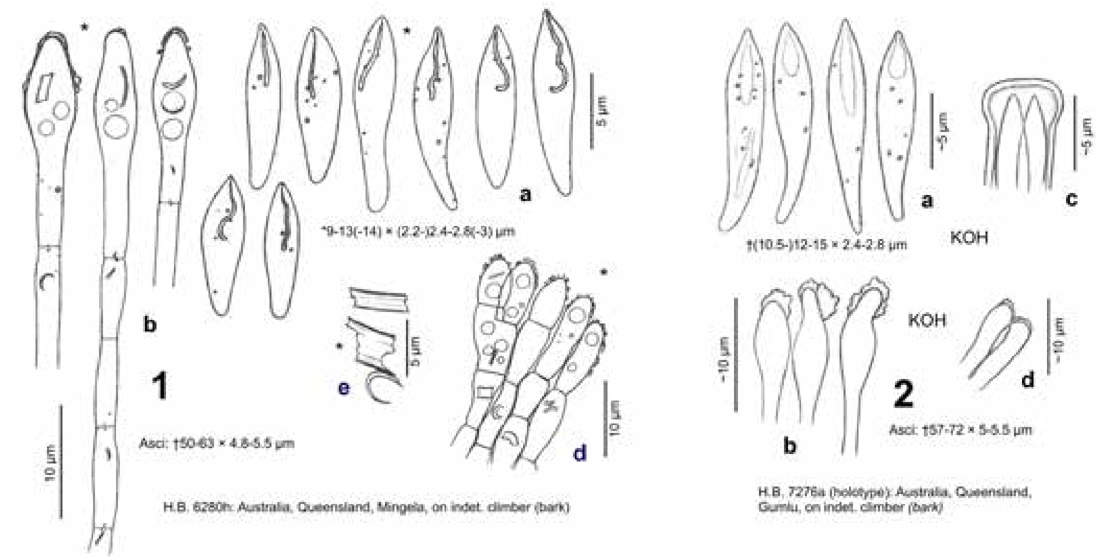

Plate 579. **1–2**: *Orbilia scandens*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. marginal ectal excipulum in median section; **e**. crystalloid SCBs in ectal excipulum.

Taxonomic remarks. *Orbilia mongolica* resembles *O. carpoboloides* in the mammiform paraphyses and fimbriate margin of the apothecia. The species is well characterized by ascospores with rounded to obtuse apices, and particularly by 16-spored asci. The spores of the 16-spored *O. calyptrata* (series *Ellipsospermae*) may show a similar shape, but are much smaller, also the paraphysis apices are never mammiform and mostly bear glassy caps.

Anamorph. The vermispora-like conidia found on the natural substrate near apothecia of *O. mongolica* are distinctly narrower than the presumed macroconidia of *O. carpoboloides*, but they resemble those of *O. flavidorosella*.

Ecology. *O. mongolica* was found on medium rotten bark and wood of a xeric branch of *Lonicera altaica* in a grazed moist-mossy mountain taiga (*Laricetum*) with *Betula rotundifolia* and *Salix* on the northern slope of a side valley of the Khod river in continental, orotemperate (sub)humid, subalpine western Mongolia.

Specimens included. **MONGOLIA**: **Bayan Ölgii**, Altay Mts., 10 km SW of Tsengel, side valley of Khovd river, 2200 m, branch of *Lonicera altaica*, on bark & wood, 9.VIII.2005, P. Karasch (ex H.B. 7893a, M-0276516, **holotype**, anam. substr.).

Orbilia scandens Baral & G. Marson, **sp. nov.**, MB 813655 — Pls 579–580

Etymology: named after the occurrence on stems of a climber.

Typification: Australia, Queensland, Gumlu, branch of indet. climber, 19.X.1998, G. Marson (ex H.B. 7276a, BRI AQ799190, holotype).

Latin diagnosis: *Similis* Orbiliae carpoboloidi *sed ascosporae in statu vivo corpusculum refringens filiforme, multo angustius continentes, margines apotheciorum absque pilis. Habitat ad corticem in caulibus ligneis volubilibus putridis siccis angiospermarum in zona tropica subhumida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1 mm diam., 0.16–0.27 mm high, pale to bright orange(-ochraceous), scarcely translucent, round to elliptical, scattered to subgregarious; disc slightly to medium concave, margin 20–50 µm protruding as ± distinct whitish teeth or lobes, finely powdered to indistinctly fimbriate; broadly sessile, slightly to deeply erumpent; dry light orange-ochraceous. **Asci** †50–75(–85) × 4.5–5.5 µm {2}, 8-spored, spores *2–3-seriate, 4–5 lower spores inverted {1} (sometimes mixed), pars sporifera †35–42 µm long; **apex** (†) (medium to) strongly truncate (not or distinctly indented, laterally not or often ± strongly inflated); **base** with or without short to long, thin or thick, ± flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(9–)11–14(–15.2) × (2.2–)2.4–2.8(–3) µm {2}, †10.5–15 × 2.4–2.8 µm {1}, (fusoid-)fusiform to fusiform-clavate, apex subacute to acute (to acuminate), base medium to strongly attenuated, partly tail-like, straight to slightly curved below; **SBs** *4–5.5 × (0.2–)0.3–0.4(–0.5) µm in situ {1} (~4–6 µm actual length), filiform to subulate, straight to strongly flexuous. **Paraphyses** apically medium to strongly spathulate, rarely mammiform, terminal cells *12.5–20 × 3–6 µm {2}, †(2.5–)3–4(–5) µm wide {1}, rarely with a distinct beak up to 2.5 µm long, exceeding the dead asci by 5–8 µm, lower cells *6–13.5 × 2–2.3(–2.8) µm {2}; not branched at upper septum. **Medullary excipulum** 30–40 µm thick, of dense textura intricata with many inflated cells, medium to sharply delimited. **Ectal excipulum** of (†) ± thin-walled, vertically oriented t. angularis(-prismatica) from base to mid flanks, 40–100 µm thick near base, cells †10–21 × 7–12 µm {1}; 30–35 µm thick near margin, of t. porrecta oriented at a 10–40° angle to the surface, marginal cortical cells */†6.5–13 × 3–5 µm {2}, partly running out into hyphae agglutinated by exudate. **Anchoring hyphae** medium to very abundant, †2–3 µm wide, walls 0.2–0.3 µm thick {1}, forming an up to 60 µm thick gelatinized t. intricata at base and a 5–10 µm thick layer at flanks and margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.5 µm diam., also angular, rod- or C-shaped {2}. **Exudate** over paraphyses 0.2–1 µm thick, finely rough to cloddy, firmly attached, forming individual caps; over margin and flanks ~0.2 µm thick. — **ANAMORPH**: unknown.

Habitat: collected 0.2–3.5 m above the ground, corticated or partially decorticated, 7–16 mm thick woody stems of indet. climber {2}, on strongly decayed bark {2} (bast & periderm), greyed, green algae lacking. **Associated**: *Hyalorbilia ?erythrostigma* {2}, *Hysteropatella ?prostii* {2}, *Orbilia brachychitonis* {1}, *O. mammifera* {2}, *O. neocomma* {2}, *O. paracaudata* {1}, *O. subfabacearum* {1}, *Rhytidhysteron ?rufulum* {1}. **Desiccation tolerance**: after 2 months only spores, paraphyses and excipular cells viable. **Altitude**: 12–286 m a.s.l. **Geology**: granite. **Phenology**: X (southern hemisphere, probably long-lived).

Taxonomic remarks. *Orbilia scandens* is very similar to *O. carpoboloides* but differs in consistently filiform, much narrower SBs which are not distinctly inflated at the base, also in the absence of free marginal hairs. In the type of *O. decipiens* from eastern Australia the spores are much shorter than in *O. scandens*. *O. acaciae* seems to be closely related to *O. scandens* but has somewhat shorter spores with more obtuse (to subacute) apices, never distinctly spathulate paraphysis apices, and smaller apothecia with a less protruding, hardly lacerate margin. For the similar *O. mammifera* which grew in association in both samples see below.

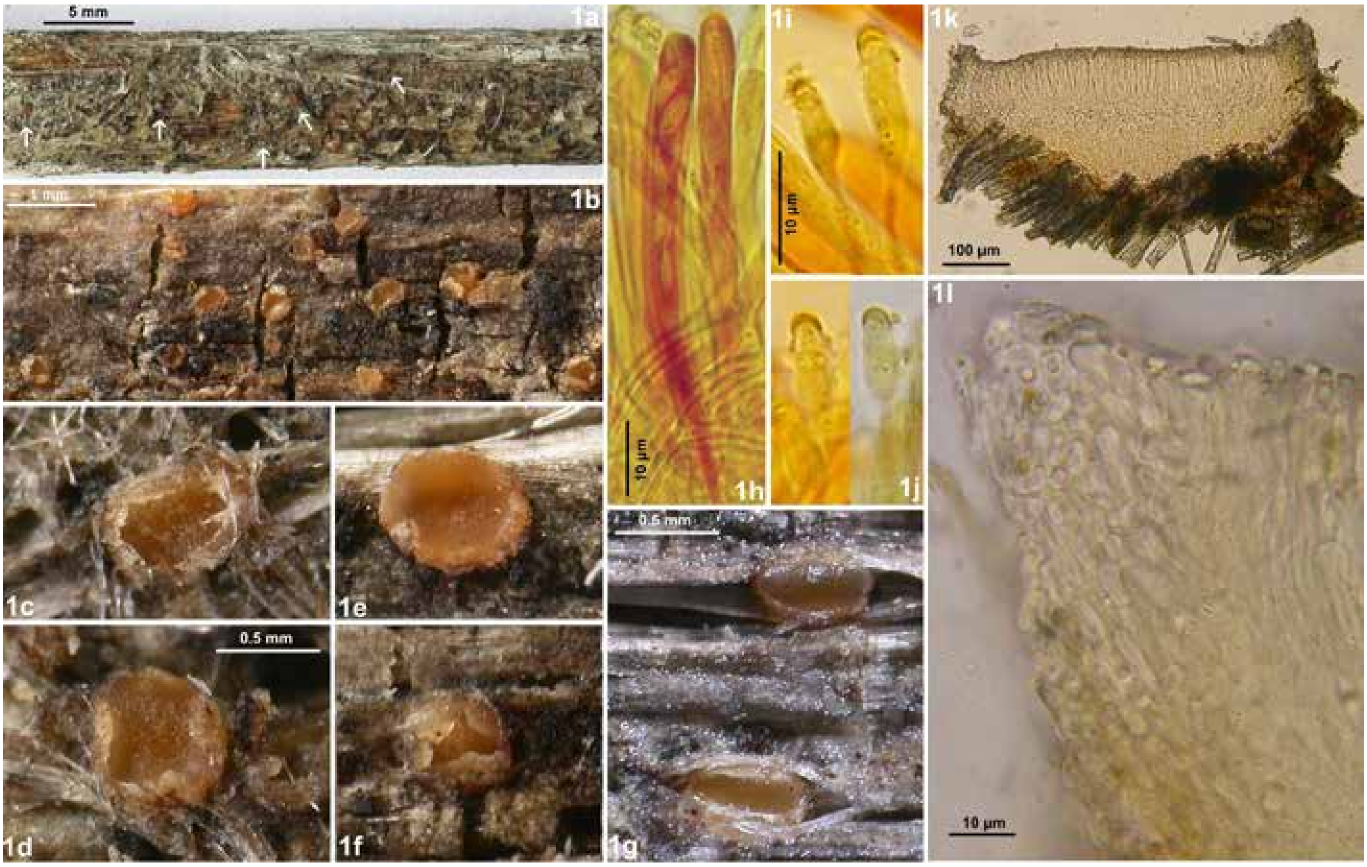

Plate 580. **1**: *Orbilia scandens*. – **1a**. dead xeric stem; **1b–g**. rehydrated apothecia; **1k**. apothecium in median section; **1l**. id., marginal ectal excipulum; **1h**. asci; **1i–j**. paraphyses. – Dead state (**1h–j** in KOH+IKI, **1k–l** in KOH). — **1a–l**. H.B. 7276a (holotype): Australia, Queensland, Gumlu, on indet. climber.

Variation was only noted in the marginal ectal excipulum which was oriented at a low angle in the holotype but at a moderate angle in the paratype.

Ecology. *O. scandens* was collected on rotten bark of branches of apparently two different unidentified climbers in eucalypt open woodlands with a tropical subhumid savannah climate, 5 and 75 km away from the coastline of northeastern Australia east of Great Dividing Range. The two collection sites are only about 120 km from each other (roughly the same latitude). In both samples the less abundant *O. mammifera* grew in close association.

Specimens included. **AUSTRALIA**: **Queensland**, Einasleigh Uplands, 75 km SSW of Townsville, 2 km WSW of Mingela, 286 m, branch of indet. climber, on bark, 17.X.1998, G. Marson (H.B. 6280h). – 49 km SE of Ayr, 4 km ESE of Gumlu, 12 m, branch of indet. climber, on bark, 19.X.1998, G. Marson (ex H.B. 7276a, BRI AQ799190, **holotype**).

Orbilia mammifera Baral, **sp. nov.**, MB 813657 — Pls 581–582

Etymology: named after the mammiform apices of paraphyses.

Typification: Australia, Queensland, Gumlu, branch of indet. climber, 19.X.1998, G. Marson (ex H.B. 7276d, BRI AQ799191, holotype).

Latin diagnosis: *Similis* Orbiliae flavidorosellae *sed paraphyses ad apicem multo magis inflatae, mammiformes. Habitat ad corticem in caulibus ligneis volubilibus putridis siccis angiospermarum in zona tropica subhumida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.5–1.3 mm diam., 0.12–0.22 mm high, pale to bright orange(-ochraceous), scarcely translucent, round to elliptical, scattered to medium gregarious; disc slightly concave to slightly (or medium) convex, margin ± distinct, thin or thick, smooth or finely crenulate or fringed, 0–15 µm protruding; broadly sessile, slightly to deeply erumpent between bast fibres or over cracks in periderm; dry light to bright orange-ochraceous. **Asci** †47–68 × (3.5–)4–4.5(–4.7) µm {2}, 8-spored, spores †2–3-seriate, ~3–5 lower spores inverted {2} (sometimes mixed), pars sporifera †35–44 µm long; **apex** (†) strongly truncate (not or with distinctly indented, laterally often inflated); **base** with medium to long, thin, flexuous stalk, L-shaped. **Ascospores** *8–10 × 1.8–2 µm {1}, †8–11.5(–14) × 1.5–2 µm {2}, narrowly fusoid-fusiform-clavate, apex subacute to acute, base slightly to medium attenuated (partly somewhat tail-like), nearly straight or slightly to strongly curved near base; **SBs** *2.5–4.2 × 0.3–0.5 µm {1}, filiform to subulate, straight to slightly flexuous. **Paraphyses** apically medium to mostly strongly mammiform, terminal cells *11–22 × 4–5.2 µm {1}, †20–23 × (2.7–)3–5(–6) µm {T}, beak 2–3.5 × 1.7–2.3 µm, exceeding the dead asci by 5–10 µm, lower cells *9–16 × 1.3–1.6(–2.5) µm {1}, †10 × 1.3–1.7 µm {T}; not branched near apex. **Medullary excipulum** 30–50 µm thick, of dense textura intricata with many inflated cells, very sharply delimited from ectal excipulum, at flanks partly by a 10 µm thick t. porrecta. **Ectal excipulum** of (†) slightly gelatinized (common walls 0.7–1.2 µm), indistinctly oriented t. globulosa-angularis from base to margin, 60–100 µm thick near base, cells */†11–25 × 9–19(–22) µm {2}; 20–40 µm thick at flanks, cells †10–28 × 8–16 µm, 20–30(–100) µm thick near margin, of t. angularis oriented at a 70–80° angle to the surface, marginal cortical cells †6–11(–14) × 3–7 µm {2}, sometimes forming short free **hairs**. **Anchoring hyphae** abundant, †1.5–2.7 µm wide, walls 0.2(–0.4) µm thick {2}, forming a 20–40 µm thick gelatinized t. intricata {2} that partly covers also the flanks. **SCBs** in paraphyses globose {1}, mixed with crystalloid ones (angular- or C-shaped) {1}. **Exudate** over paraphyses 0.1–0.2(–1.5) µm thick, finely rough, sometimes forming firmly attached apical caps; over excipulum 0.2 µm thick, continuous. — **ANAMORPH**: unknown.

Habitat: collected 0.5–3 m above the ground, corticated, 7–8 mm thick woody stems of indet. climbers {2}, strongly decayed bark {2} (periderm and bast), greyed, with a few to many green algae. **Associated**: *Hyalorbilia ?erythrostigma* {2}, *Hysteropatella ?prostii*

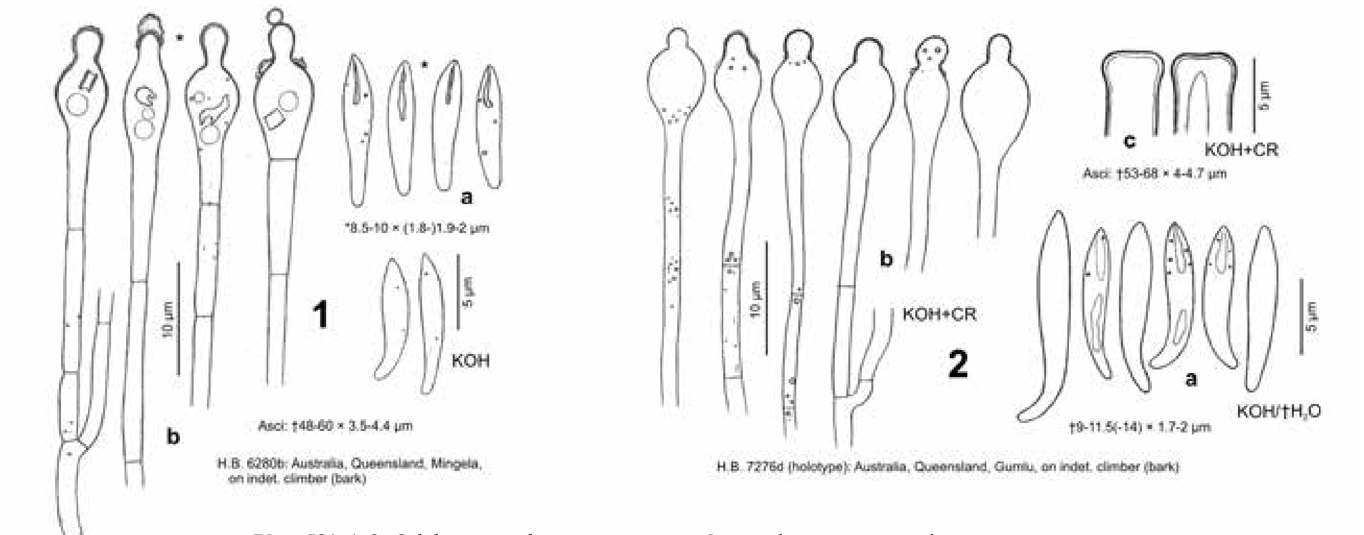

Plate 581. **1–2**: *Orbilia mammifera*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices.

{2}, *Orbilia brachychitonis* {1}, *O. neocomma* {2}, *O. paracaudata* {1}, *O. scandens* {2}, *O. subfabacearum* {1}, *Rhytidhysteron ?rufulum* {1}. **Desiccation tolerance**: fully drought-tolerant for at least 2 months. **Altitude**: 12–286 m a.s.l. **Geology**: granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia mammifera* closely resembles the European *O. flavidorosella* in size and shape of the ascospores. The spore bodies are shorter and thinner in *O. mammifera*, but this might be an accidental difference. *O. mammifera* mainly differs in much more inflated paraphysis apices with often very abrupt beaks (very similar to *O. carpoboloides*). *O. scandens* differs in distinctly wider spores and in paraphyses with only rarely mammiform apices, also in apothecia with an often lacerate margin.

The similar western Australian *O. farnesianae* (section *Aurantiorubrae*) differs in obtuse spore apices and in paraphysis apices mostly without abrupt beaks (predominantly capitate-clavate but also spathulate to lageniform), apparently also in wider SBs and somewhat narrower marginal cortical cells (†6–12 × 2.5–4.2 µm). The species is closely related to *O. pilifera*, and its presumed anamorph is trinacrium incurvum-like very similar as in *O. pilifera*.

Variation. The apothecial margin was either fringed (H.B. 6280b, collection consisting of only one apothecium) similar as in *O. flavidorosella*, or smooth to finely crenulate (holotype). The spores in the holotype are longer and the paraphyses a bit more inflated than in the paratype.

Ecology. *O. mammifera* was collected on rotten bark of woody stems of unidentified climbers in eucalypt open woodlands with

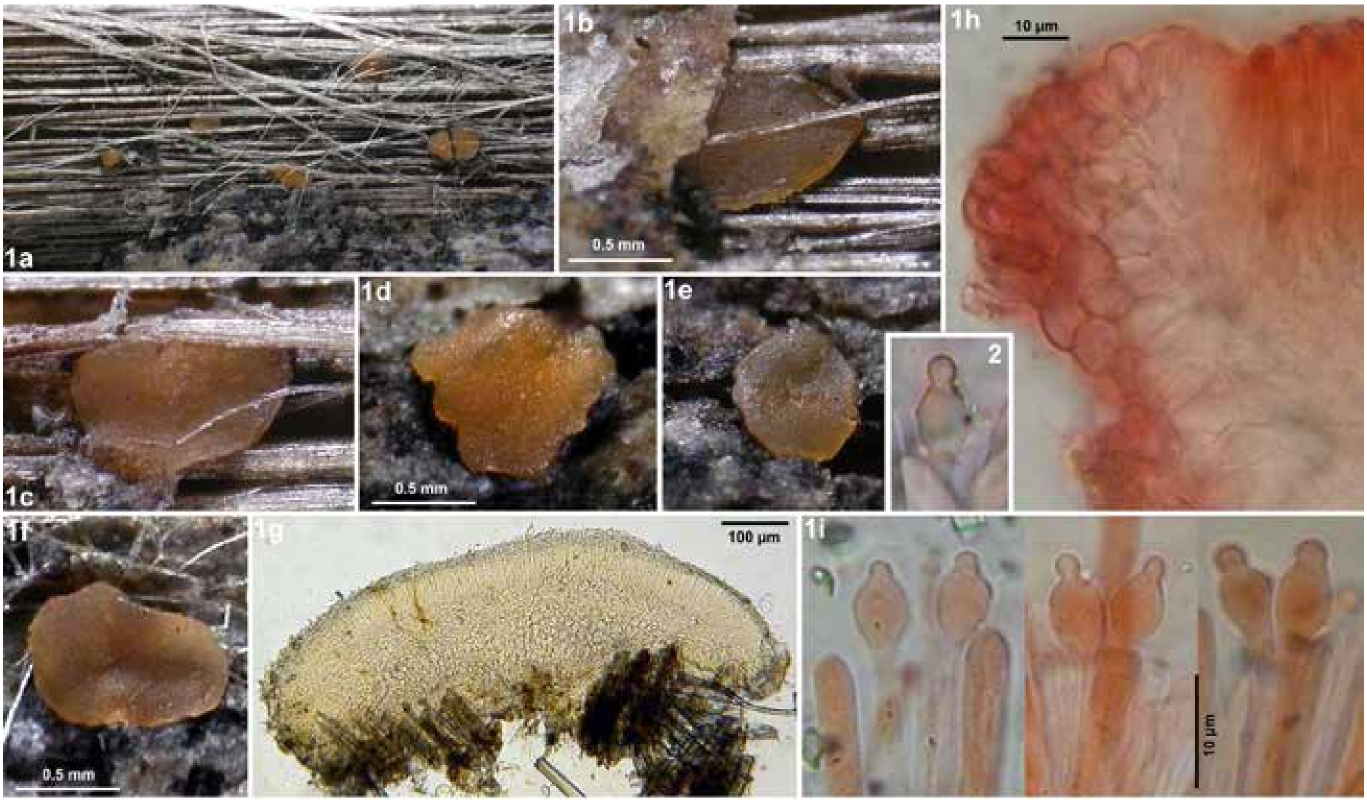

Plate 582. **1–2**: *Orbilia mammifera*. – **1a–f**. rehydrated apothecia; **1g**. apothecium in median section; **1h**. id., marginal ectal excipulum; **1i**, **2**. apices of paraphyses (and asci). – Dead state (**1g** in KOH, **1h–i**, **2** in KOH+CR). — **1a–i**. H.B. 7276d (holotype): Australia, Queensland, Gumlu, on indet. climber; **2**. H.B. 6280b: ibid., Mingela, on indet. climber.

a tropical subhumid (winter-dry) savannah climate, 5 and 75 km away from the coastline of northeastern Australia east of the Great Dividing Range. The two collection sites are about 120 km from each other (roughly the same latitude). The paratype consists of only one apothecium, while about 15 were seen in the holotype. In both samples the more abundant *O. scandens* grew in close association (in the holotype the two species were found fruiting on opposite sides of the same branch).

Specimens included. **AUSTRALIA**: **Queensland**, Einasleigh Uplands, 75 km SSW of Townsville, 2 km WSW of Mingela, 286 m, branch of indet. climber, on bark, 17.X.1998, G. Marson (H.B. 6280b). – Brigalow Belt North, 49 km SE of Ayr, 4 km ESE of Gumlu, 12 m, branch of indet. climber, on bark, 19.X.1998, G. Marson (ex H.B. 7276d, BRI AQ799191, **holotype**).

Orbilia flavidorosella Rehm in Sydow, Hedwigia 33, Beibl.: 31 (1894) — Pls 583–584, Map 92

≡ *Orbilia flavidorosella* Rehm, in Sydow, Mycotheca marchia, cent. 39: no. 3846 (1893), nom. inval., ICN Art. 38.1 (diagnosis missing)

≡ *Hyalinia flavidorosella* (Rehm) Svrček, Česká Mykol. 9: 113 (1955, as *flavideroseola*)

Etymology: named after the apothecial colour described as yellowish-rose in the protologue.

Typification: Germany, Nauen, stem of *Vincetoxicum hirundinaria*, VI.1893, H. Sydow (S-F6405, holotype); Luxembourg, Bettembourg, stem of *Melilotus*, 18.IX.2012 (ex G.M. 2012-09-18.1, illustration [Pl. 584: 5], epitype, designated here, MBT385128; sq.: KT222391).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.3–0.9(–1.2) mm diam., 0.1–0.2 mm high (receptacle 0.09–0.12 mm), light to bright (yellowish-)orange(-ochraceous), more rarely whitish to pale (cream-)rose, ± round, scattered or somewhat gregarious, partly in clusters; disc young medium concave (urceolate), finally slightly concave to flat or even convex, margin whitish, finely to distinctly fimbriate or with distinct teeth (30–80 × 30–100 µm), hairs or teeth protruding 20–50 µm beyond disc; sessile or with a distinct stalk 0.05 × 0.1 mm, ± erumpent to superficial; dry bright ochraceous-orange or greyish-cream, margin incurved, sometimes almost entirely closing the disc (± hysteriform). **Asci** *48–61 × 4–4.8(–5) µm {4}, †(33–)38–56 × 3.3–4.3(–4.6) µm {4}, 8-spored, (2–)3–5(–6) lower spores inverted {7} (sometimes mixed), pars sporifera *24–32 µm, **apex** (†) medium to strongly truncate (sometimes slightly indented, laterally not widened), **base** with rather short or often long, flexuous stalk, L- to h-shaped. **Ascospores** *(6.8–)7.3–10.5(–12.3) × (1.5–)1.7–2(–2.2) µm {9}, †(7–)7.5–9.5(–10.3) × 1.5–1.8 µm {2}, fusoid(-fusiform) to fusoid-clavate, with or without cylindrical middle part, apex subacute to acute, rarely obtuse, base very slightly to medium (rarely strongly) attenuated, straight or slightly curved near base; **SBs** (3–)4–6.5(–7.5) × (0.3–)0.5–0.8(–1.1) µm in situ {8}, ~4.5–6.5(–8) µm actual length, subulate to vermiform, base often slightly to medium (rarely strongly) inflated, mostly ± flexuous to helicoid. **Paraphyses** apically uninflated or mostly (sub)lageniform to obtusely lanceolate or spathulate, sometimes mammiform, beak 2–5 × 1.5–2.8 µm, terminal cells *11–28 × (2.2–)2.5–4(–4.7) µm {6}, †14.5–20 × 2.2–3.2 µm {1}, protruding 2–5 µm beyond dead asci, lower cells (6–)8–12(–15) × 1.3–2.7(–5) µm {5}, †7–12.5 × 1.5–2.5(–2.8) µm {T}, rarely branched at upper septum. **Medullary excipulum** hyaline, 30–60 µm thick, of ± dense textura intricata with some or many inflated cells, ± sharply delimited. **Ectal excipulum** hyaline, partly light orange-rose towards margin, of ± thin-walled, vertically (to horizontally) oriented t. (globulosa-)angularis(-prismatica), 30–60(?–100) µm thick near base, cells *10–23 × 8–16 µm {4}; from lower flanks to margin 20–40(–75) µm thick, of t. prismatica-angularis(-globulosa) oriented at a 0–30° angle, cells *6–18 × 5–18 µm {2}; marginal protruding part 30–35 µm thick, consisting of (1–)2–3-celled **hairs** */†20–50(–80) × (3–)4–6(–8.5) µm {7} (individual cells 7.5–15 µm long), terminal cells cylindrical, also clavate or spathulate to ± lageniform, walls *0.2–0.5(–0.8) µm thick, hairs ± free or agglutinated to form distinct triangular teeth. **SCBs** globose, in paraphyses 1.3–2.5 µm diam., 1–2 per cell, in ectal excipulum (1.5–)2.5–3.5(–4.5) µm diam., 1–3 or more per cell; cells of paraphyses, margin and mid flanks also with crystalloid SCBs {10}, 2.5–6 × 1.7–4.5 µm, spool- to sickle-, ring-, or horseshoe-shaped, hyaline to light yellowish-orange. **Exudate** over paraphyses lacking or finely granular, rarely cap-like, firmly attached to apical beak, 0.2–0.4(–1) µm thick; over margin and flanks absent. **Anchoring hyphae** sparse to abundant, *2–3(–4) µm wide, walls 0.2–0.5(–0.7) µm thick {4}, forming a 5–20 µm thick, ± gelatinized layer on base and flanks, partly up to the margin. — **ANAMORPH**: vermispora-like (from lid of Petri dish {1}). **Conidiophores** not observed. **Conidia** unbranched, slightly to medium curved (C-shaped), *22–34 × 3–3.2 µm {1}, 3-septate; a single microconidium seen: *15 × 2.5 µm, 1-septate.

Habitat: 0.1–3(–9) m above the ground, on ~1–2 years dead, standing, herbaceous stems of *Ephedra gerardiana* {1}, *Melilotus* sp. {6}, *M. albus* {1}, *Vincetoxicum hirundinaria* {1}, indet. dicot {1}, epidermis ± removed; on 7–10 mm thick, partially corticated twigs and branches of *Cytisus scoparius* {1}, *Prunus dulcis* {1}, *Salix* (?)*caprea* {1}, *Spartocytisus supranubius* {2}, on medium decayed bark {5} (periderm and bast); also on remnants of cotton textile {1}; ± greyed, with or without many algae, sometimes very close to old pycnidia of ?*Phoma* {2}. **Further associated**: *Cistella grevillei* {1}, *Cyathicula cacaliae* {1}, *Karstenia rhopaloides* {1}, *Orbilia carpoboloides* {1}, *O. caulicola* {2}, *O. flavida* {2}, *O. quaestiformis* {4}, *O. vitalbae* {1}. **Desiccation tolerance**: fully viable for min. 3–4 weeks, excipular cells still viable after 2.5 months. **Altitude**: 40–440 m (central Europe), 937–1300 m a.s.l. (southern Europe), 2090–2190 m (Macaronesia). **Geology**: Neoproterozoic shale & greywacke, Keuper (peat over Stubensandstein), Lower Jurassic sandstone & shale, dolomite; phonolite. **Phenology**: III–XII (throughout the year, long-lived).

Taxonomic remarks. *Orbilia flavidorosella* is very similar to *O. carpoboloides* in the shape of paraphyses and hairs, but differs in narrower ascospores and shorter asci, narrower paraphysis apices, also in paler-coloured apothecia. For the closely related *O. mammifera* and *O. solidaginis* see p. 1043 and p. 1048. The similar 16-spored North American *O. calyptrata* (series *Ellipsospermae*) turned out to be not closely related. *O. subtrapeziformis* (series *Serpentinae*) has spores similar to *O. flavidorosella* but differs in capitate paraphyses and the absence of crystalloid SCBs.

Variation. *O. flavidorosella* seems to be a rather constant species. The type specimen (on *Vincetoxicum*, Pl. 583: 2) deviates in paraphyses with lanceolate-spathulate apices from many of the recent collections which instead often showed lageniform apices. However, paraphysis shape often varied considerably within a sample or an apothecium, and both types occurred in varying frequency in Pls 583: 1b; 584: 1e and in many other samples. A collection on *Vincetoxicum* from Czechia is described with lageniform apices (see Svrček 1955, fig. 2). Also spore length varies somewhat, between *7–9 (*Ephedra*, *Melilotus*, 1 & 3) and *8.5–12.5 µm (*Cytisus*, IVV: E.R.D. 7600), the latter having also the longest SBs.

Nomenclature, **type studies and literature reports**. There are three different orthographic variants of this taxon: (1) *Orbilia flavidorosella* was used by Sydow in sched., Mycotheca Marchica Nr. 3846 (1893, 'Rehm, nov. sp. in litt. ad me') and by Sydow (1894: 31), and as *O. flavido-rosella* by Saccardo (1895: 426) who referred to Sydow Nr. 3846; (2) *O. flavide-roseola* was used by Rehm (1895: 1224); (3) *O. flavido-roseola* was used by Saccardo (1896: XXXVIII, 1899: 803) who referred to Rehm (1895). It seems to have been intention that Saccardo corrected Rehm's (1895) variant *flavide-roseola* to *flavidoroseola*, the former being grammatically against the Code (ICN Art.

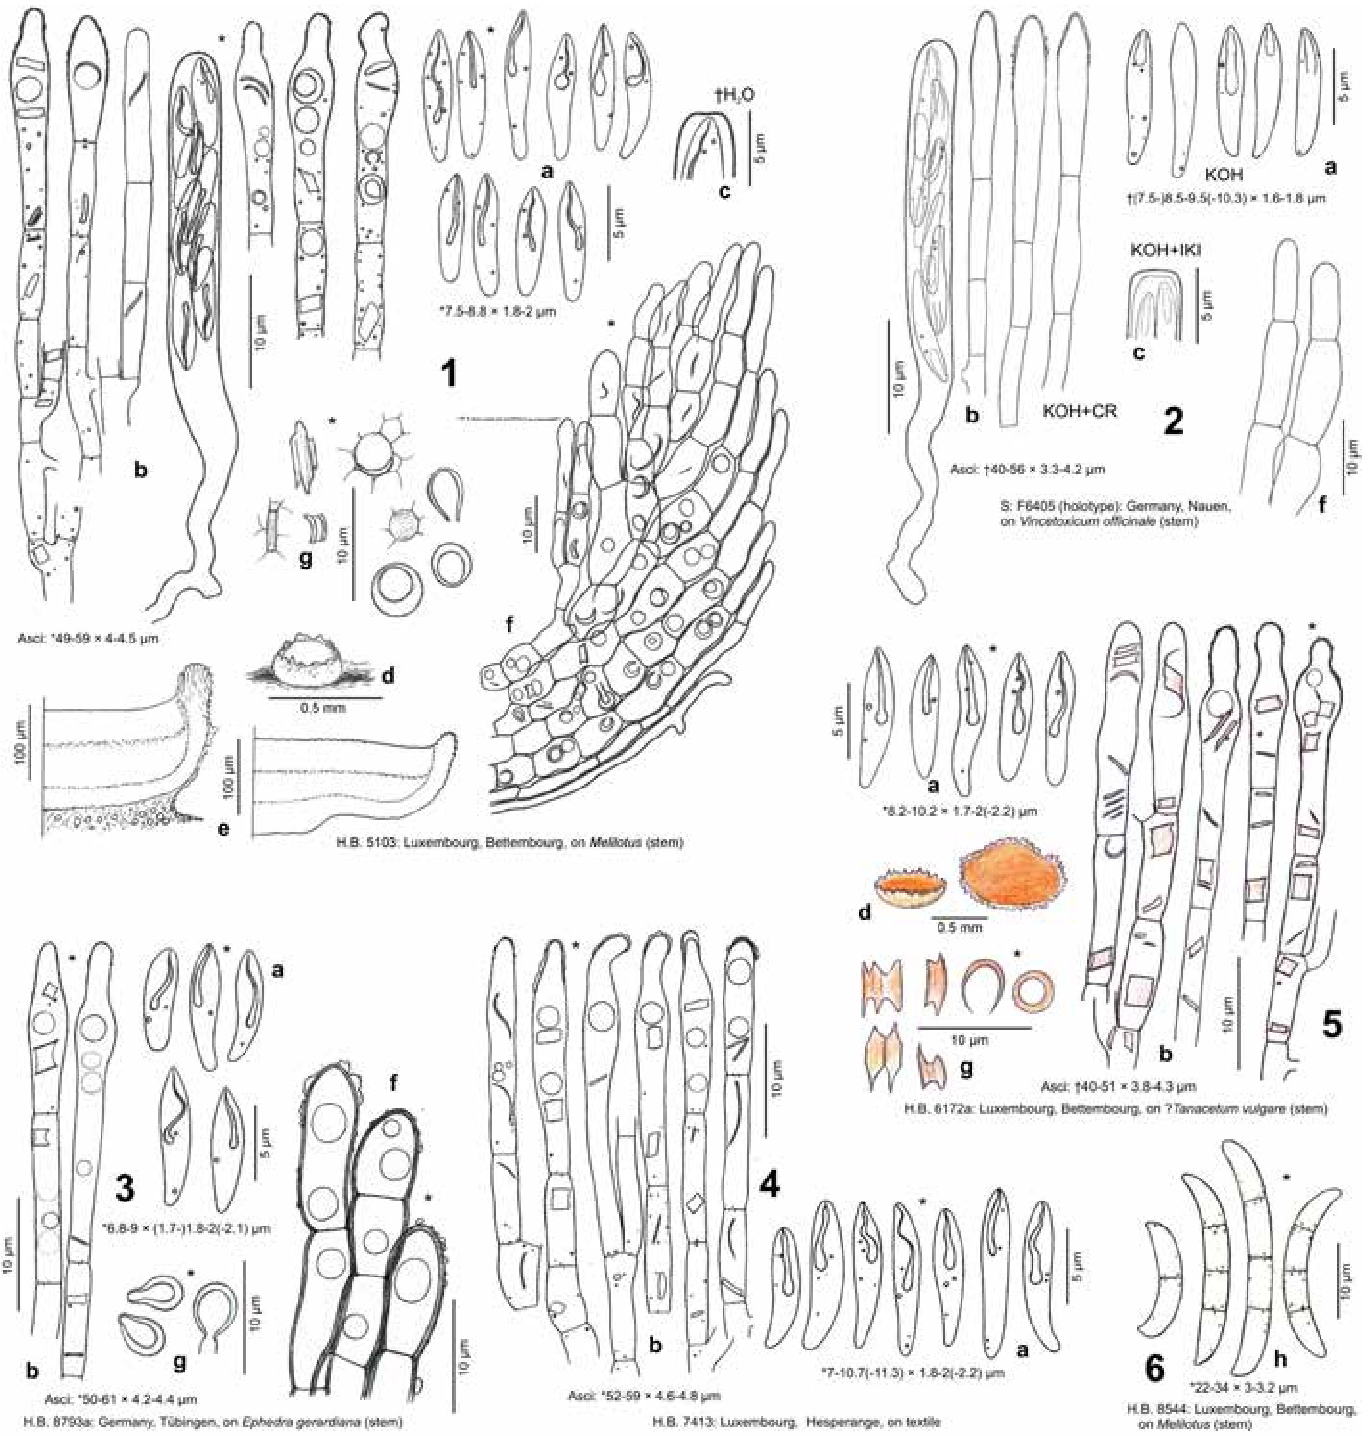

Plate 583. **1–6**: *Orbilia flavidorosella*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia with denticulate margin; **e**. apothecia in median section; **f**. id., marginal ectal excipulum; **g**. crystalloid SCBs in excipular cells at mid flanks and margin; **h**. conidia from culture.

60.10, 60G.1(b), Turland et al. 2018). We are convinced that Sydow (1894) represents the first valid publication (the label of Mycotheca Marchica Nr. 3846 is without a diagnosis). Therefore, the spelling *flavidorosella* must be adopted which is grammatically correct.

O. flavidorosella was originally described by Rehm (in Sydow 1894) with erumpent, pale yellow-rose apothecia (interestingly as '*flavido-roseola*') of 0.3–0.8 mm diam., asci 45 × 5 µm, 6-spored, with rounded apex, straight or slightly curved, oblong or subfusiform ascospores 7–9 × 2 µm, and filiform paraphyses with a widened apex up to 3 µm, sometimes subcurvate. In correspondence to his sketch in the type convolute in S, Rehm described the spore apices as obtuse, whereas the present reexamination revealed subacute to acute apices, also the paraphyses were found to be distinctly (sub)lanceolate (Pl. 583: 2). A yellowish component of the fresh apothecial colour as mentioned by Rehm could only partly be observed in the recent material studied.

In addition to Rehm's protologue of 1894, which is also found with some alterations in Rehm (1895) and Saccardo (1896), only one further published record of *O. flavidorosella* came to our notice: Svrček (1955) provided a detailed description in Czech, based on a collection from around Praha, and combined the species in *Hyalinia*, apparently because of the marginal hairs. The paraphyses were depicted by him with distinctly lageniform apices. Like Rehm, Svrček did not report spore bodies or SCBs.

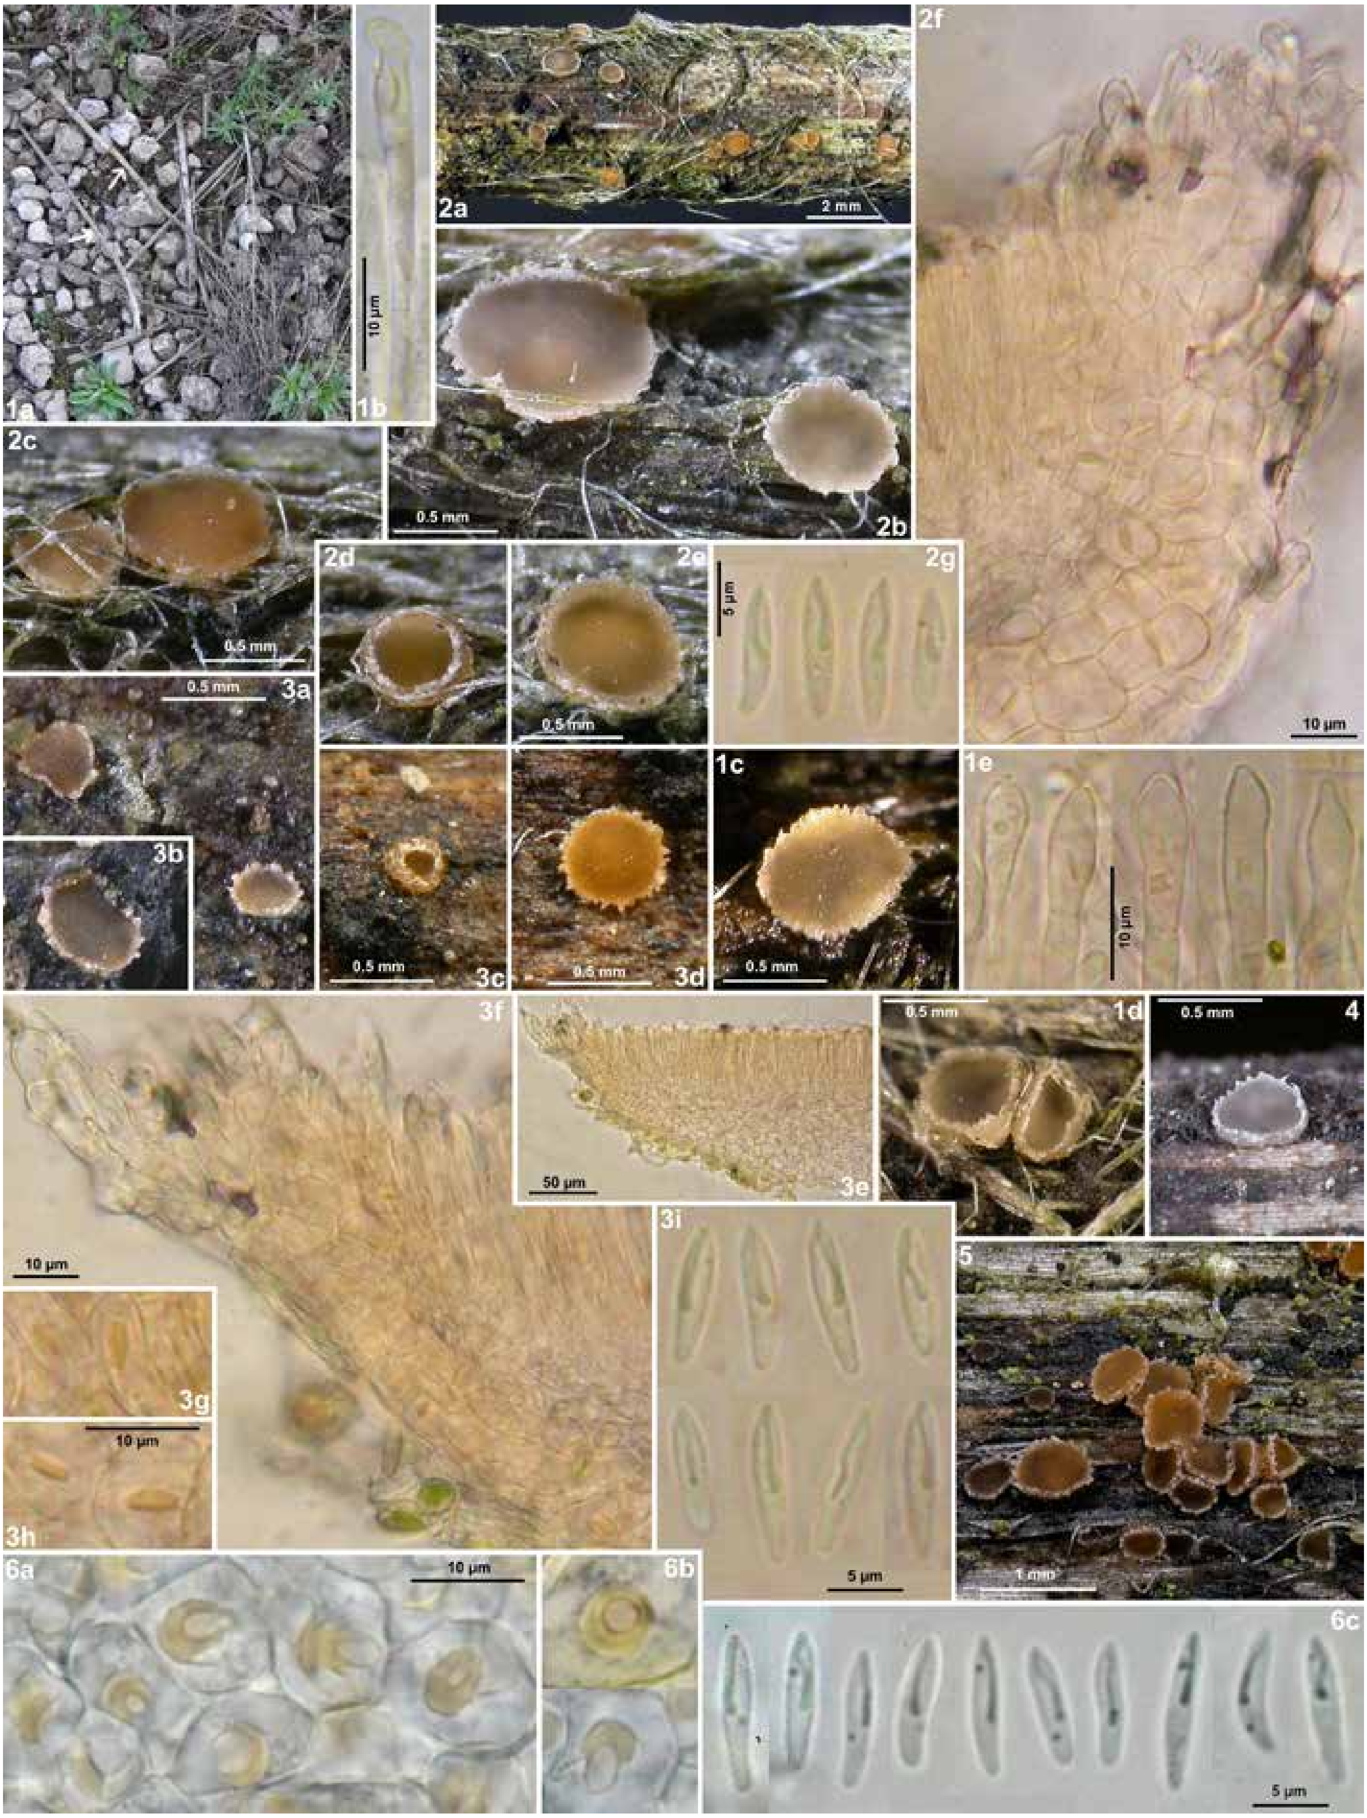

Plate 584. **1–6**: *Orbilia flavidorosella*. – **1a**. ruderal place along a railway track; **1c–d**, **2a–e**, **3a–d**, **4**. rehydrated apothecia; **5**. dry apothecia; **3e**. apothecia in median section; **2f**, **3f**. id., marginal ectal excipulum; **3g–h**, **6a–b**. crystalloid SCBs in ectal excipulum at flanks and margin; **1b**, **e**. paraphyses; **2g**, **3i**, **6c**. ascospores. – Living state. – **6a–c**: phot. R. Tena. — **1a–e**. H.B. 8544: Luxembourg, Bettembourg, on *Melilotus*; **2a–g**. H.B. 8539a: ibid., on *Melilotus*; **3a–i**. H.B. 8234a: ibid., on *Melilotus*; **4**. H.B. 8793a: Germany, Tübingen, on *Ephedra*; **5**. G.M. 2012-09-18.1 (epitype): Luxembourg, Bettembourg, on *Melilotus*; **6a–c**. R.T.L. 10122202: Spain, Teruel, on *Prunus*.

Spooner (1987: 196) doubted placement in *Hyalinia* because the hairs are described as simple, non-glassy, and suggested that the species might belong to *Habrostictis*.

A collection from Ukraine was reported by Yatsiuk (2018). It was originally misidentified as *O. carpoboloides* (Prylutskyi & Akulov 2017), but micrographs sent by I.I. Yatsiuk (pers. comm.), which included some living asci, ascospores, and paraphyses, suggested identity with *O. flavidorosella*.

The macrophoto of a specimen from Luxembourg (Bettembourg, on *Melilotus*, G.M. 2012-09-18.1, Pl. 584: 5), from which an unpreserved ascospore isolate and a sequence were gained, is designated here as **epitype** of *O. flavidorosella*. Samples from the same site and substrate but without a sequence are illustrated in Pl. 583: 1 and Pl. 584: 1–3.

Not included collections. A recent sample from an orosubmediterranean site in Portugal on 1–2 mm thick corticated *Cytisus* twigs (IVV: 22.XI.2019) has much longer spores of *11.3–14.5(–16) × 1.7–2.2 µm with longer SBs of (5.5–)7–8.5 × 0.4–0.7 µm but otherwise fits *O. flavidorosella*. An unpreserved sample from South America (Colombia, on indet. angiosperm) consisted of only a single apothecium. It was examined in the living state but only briefly documented and not illustrated. The microfeatures concurred rather well with *O. flavidorosella*, but no crystalloid SCBs could be found and the marginal hairs were slightly narrower.

Anamorph. Vermispora-like conidia were formed on the mycelium which grew out of an apothecium inside a Petri dish (Pl. 583: 6h). Most of them were 3-septate and resemble the macroconidia reported for *O. carpoboloides*, though being distinctly narrower. A single 1-septate conidium (583: 6h left, IVV: H.B. 8544) closely concurs with the microconidia of *O. carpoboloides*.

Phylogeny. Sequences of two samples of *O. flavidorosella* on *Melilotus* from Luxembourg (G.M. 2012-09-18.1, epitype, from pure culture; G.M. 2014-10-11.1, from apothecia) comprise ITS and LSU. In contrast to *O. carpoboloides*, the S1506 intron is absent in both. The two sequences deviate from each other by only 1 nt and 2 gaps in ITS1 (or 4 nt and no gap under a compact alignment), but show a high distance to *O. carpoboloides* (ITS 13.5–14 %), and even higher distances are noted to other members of section *Habrostictis* (e.g., 19.5 % to *O. mesaverdiana*). In LSU (D1–D2) the lowest distance was 1 % to *O. filiformis* and *O. mesaverdiana*, but 1.4 % to *O. carpoboloides*.

Ecology. *O. flavidorosella* was collected on old xeric, predominantly herbaceous stems of different dicotyledons (mainly *Melilotus*) but also on bark of thin branches of different angiosperm trees. In one collection the fruitbodies grew on a cleaning cloth that was hanging several years outside the window 9.5 m above the ground. The holotype was collected on *Vincetoxicum* in northeastern Germany (Osthavelland, Märkische Tiefebene). A sample on *Ephedra* was from the Chinese Alpinum in the Botanical Garden of Tübingen. Most specimens originate from thermophilous ruderal places, e.g., along railway tracks where the stems were partly lying on the gravel (Pl. 584: 1a). The present data suggest a subcontinental, cold-temperate humid distribution. Yet, two Spanish collections were from a montane, orotemperate humid (on *Cytisus*) and a supramediterranean semihumid climate (abandoned almond plantation with *Cupressus arizonica*), and two upper mesomediterranean semihumid (dry) sites in Macaronesia, in a *Pinus canariensis* woodland with summit brooms (*Sideritido solutae-Pinetum canariensis*) and in the Cañadas del Teide in a summit broom scrub without trees (*Spartocytisetum supranubii*). The not included record from Colombia was in a subtropical humid forest with planted tropical fruit trees.

Map 92. Known distribution of *O. flavidorosella* in Europe and Macaronesia.

Specimens included. **GERMANY**: **Brandenburg**, Havelland, 26 km WNW of Berlin, ~10 km ESE of Nauen, Bredower Forst, ~40 m, stem of *Vincetoxicum hirundinaria*, VI.1893, H. Orbilia solidaginis Baral, **sp. nov.**, MB 813658 — Pl. 585

Etymology: named after the substrate, stems of *Solidago*.

Typification: Germany, Stuttgart, stem of *Solidago*, 14.III.1999, A. Gminder (ex H.B. 6335, M-0276586, holotype).

Latin diagnosis: *Differt ab* Orbilia flavidorosella *ascosporis longioribus et angustioribus, paraphyses et cellulae marginales excipuli exsudato granuloso copioso tectae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–0.7 mm diam., 0.1–0.16 mm high, pale dirty cream-ochraceous(-reddish), round, very scattered to subgregarious; disc flat, margin thin, not protruding, finely crenulate, rarely smooth; broadly sessile, superficial. **Asci** †40–61 × 3.8–4.7 µm, 8-spored, spores †2–3-seriate, ~4 lower spores inverted (sometimes mixed); **apex** (†) slightly to medium truncate (not indented, laterally not widened); **base** with medium to very long, thin, flexuous stalk, L- to Y-shaped. **Ascospores**

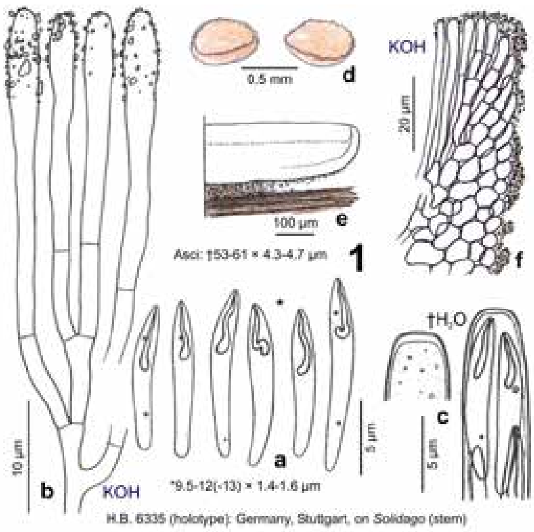

Plate 585. **1**: *Orbilia solidaginis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices; **d**. rehydrated apothecia with crenulate margin; **e**. apothecium in median section; **f**. id., marginal ectal excipulum.

*9.5–12(–13) × 1.4–1.6 µm, †8.5–11.5 × 1.5–1.7 µm, narrowly (cylindric-)fusoid, apex subacute, base slightly attenuated, straight to slightly curved; **SBs** *3.7–4.5 × 0.5–0.7 µm in situ (~4–4.7 µm actual length), vermiform to subulate, base ± distinctly inflated, straight to mostly slightly to strongly flexuous. **Paraphyses** apically only slightly inflated, narrowly spathulate-clavate, terminal cells †19–29 × 2–3.5 µm, exceeding the dead asci by 5–10 µm, lower cells †7–10 × 1.6–1.8 µm; unbranched at upper septum. **Medullary excipulum** 40–70 µm thick, of dense textura intricata, medium sharply delimited from ectal excipulum only towards flanks. **Ectal excipulum** of thin-walled, partly horizontally oriented t. angularis from base to submargin, 30 µm thick near base, cells †9–15 × 5–10 µm; 15–25 µm thick near margin, of t. prismatica oriented at a 30° angle to the surface, marginal cortical cells †8–11 × 2.7–3.5(–4) µm, not forming free hairs. **Anchoring hyphae** medium abundant, †1.5–2.7 µm wide, walls 0.15–0.2 µm thick. **SCBs** no data available. **Exudate** over paraphyses 0.2–0.5 µm thick, granular, firmly attached, covering also the lateral wall; over margin and flanks forming a 2–4 µm thick, granular, very pale yellowish layer. — **ANAMORPH**: unknown.

Habitat: lying close to ground, 6 mm thick previous year's stem of *Solidago* sp., on medium decayed epidermis-free area, slightly greyed, no algae. **Associated**: on separate stems *Cyathicula cyathoidea*, *Trichopeziza* aff. *mollissima*. **Desiccation tolerance**: after 2 weeks only ascospores viable. **Altitude**: 450 m a.s.l. **Geology**: Keuper (Stubensandstein). **Phenology**: III.

Taxonomic remarks. *Orbilia solidaginis* differs from *O. flavidorosella* in longer and narrower spores, in paraphyses with narrowly spathulate, roughly warted apices, also in the margin lacking distinct hairs but being, instead, abundantly covered by granular exudate. Also the anchoring hyphae are more thin-walled than in *O. flavidorosella*. The species may also be confused with *O. ebuli* (section *Aurantiorubrae*), which differs in strongly capitate paraphyses and an often strongly inflated lower part of the SBs. *O. luteorubella* (section *Helicoon*) differs in a smooth apothecial margin composed of usually broader, more clavate cells, and in ± capitate paraphyses. Only the spores were viable in the type collection when studied, therefore, it is unknown which kind of SCBs occurred in paraphyses and excipulum.

Ecology. The single known collection grew on a previous year's stem of *Solidago* in an old quarry in a rather moist valley in the Glemswald forest near Stuttgart in subcontinental, cold-temperate humid central Europe.

Specimens included. **GERMANY**: **Baden-Württemberg**, Glemswald, 7 km W of Stuttgart, 2 km S of Gerlingen, Schillerhöhe, Banwald, 450 m, stem of *Solidago*, 14.III.1999, A. Gminder (ex H.B. 6335, M-0276586, **holotype**).

Series *Serpentinae*

Orbilia subgenus ***Habrostictis*** section ***Habrostictis*** series ***Serpentinae*** Baral & E. Weber, **ser. nov.**, MB 815019 – Type species: *Orbilia serpentina* Pat.

Etymology: named after the type species, *O. serpentina*.

Latin diagnosis: *Ascosporae *5–19.5 × 1.6–4.2 µm, fusiformes vel ellipsoideo-clavatae, apice obtuso ad acuminato, raro rotundatae, intus corpusculo refringenti, longe filiformi, flexuoso, ad apicem affixo. Paraphyses ad apicem leniter vel fortiter inflatae, clavato-capitatae. Status anamorphicus typo* Trinacrium, *raro* Tridentaria *vel* Vermispora.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.7(–1.2) mm diam., pale to bright rose to (yellowish-)orange(-ochre), margin smooth to finely rough or crenulate, partly protruding, sessile or with an ill-defined stipe. **Asci** 8- up to 64-spored, *(35–)40–85(–90) × (4.5–)5–8.5(–9.5) µm when 8-spored, up to *75–100(–120) × 9–11(–12) µm when 16- up to 64-spored, lower ((1–))(2–)3–5(–6)((–7)) spores inverted when 8-spored, (3–)6–10(–12) spores inverted when 16-spored, 9–18 spores inverted when 32-spored; **base** exceptionally H-shaped. **Ascospores** *(5–)6–17(–19.5) × (1.6–)1.8–4.2(–5) µm, fusiform-clavate to cylindric-ellipsoid or tear- to lemon-shaped or ovoid, apex obtuse to acuminate (rarely rounded), straight to slightly, sometimes strongly curved near base, non-septate (but sometimes becoming septate during germination), **SBs** apically affixed to spore wall, *(2.5–)3.5–12(–15) × (0.2–)0.3–1.2(–1.5) µm (actual length), filiform to vermiform or subulate, distinctly swollen at base or not, straight or often slightly to strongly flexuous or helicoid to uncinate, apically narrowed to a small point, without or with a very short filum. **Paraphyses** slightly to strongly clavate-capitate at the apex (rarely predominantly spathulate), terminal cells (0.2–)0.3–1.5(–2)× longer than lower cells. **Ectal excipulum** (†) thin-walled to slightly gelatinized (common walls †0.3–1.5 µm), vertically or sometimes horizontally or indistinctly oriented textura (globulosa-)angularis(-prismatica), cells near base *(5–)7–20(–32) × (4–)6–15(–20) µm; near margin exceptionally with **glassy caps** (*O. ophiosoma*), **hairs** absent. **SCBs** globose or mixed with crystalloid ones, also absent. **Exudate** (0.1–)0.3–1(–2)((–3)) µm thick, continuous to cloddy-granular, loosely to usually firmly attached, hyaline or pale yellowish, sometimes sparse or thin (especially at margin). — **ANAMORPH**: trinacrium-, rarely tridentaria- or vermispora-like. **Conidiophores** 3–25 µm long, unbranched or branched. **Conidiogenous cells** monoblastic or sympodial. **Conidia** mostly staurosporous, trinacrium-like, 2-armed, Y-, rarely T-shaped, *18–50 × 12.5–71 µm, arms tapering; sometimes tridentaria-like, 3–6-armed, *23–70 × 18–83 µm; rarely phragmo- to scolecosporous, vermispora- to anguillospora-like: *75–107 × 5.5–6 µm (actual length), 9–26-septate, straight or slightly to strongly curved {*O. multimaeandrina*}.

Habitat: on wood and bark of both gymno- and angiosperms, sometimes on herbaceous stems or petioles of palms, humid to arid, temperate to subtropical.

Recognized species: 51, plus 1 species with a provisional name and 11 unnamed species ('affinis').

Taxonomic remarks. Series *Serpentinae* is circumscribed here in a rather broad sense, comprising quite different shapes of ascospores and spore bodies. Typical are fusoid to fusiform spores with subacute to acuminate apices and tapered, straight to more or less curved bases. Obtuse to rounded apices in combination with often strongly tapered bases occur, e.g., in *O. obtusispora* and *O. multiurosperma*, and particularly in species around *O. cactacearum* and *O. quaestiformis*. Some of the included species have limoniform to ovoid spores with ± acute apices. Some species might better be affiliated in series *Ellipsospermae*, but various intermediate taxa make a decision highly difficult which is merely based on spore morphology. Further morphological traits that are correlated with our molecular data have not been found, and alternative groupings would also be difficult to establish. Future molecular investigations will hopefully lead to a clearer series concept within section *Habrostictis*.

O. multimaeandrina and *O. osteospermae* are somewhat extraordinary within series *Serpentinae* in their often spathulate paraphyses. A relation to series *Habrostictis* would be supported by a vermispora-like anamorph obtained in *O. multimaeandrina*. In two further species, *O. multidelphinus* and *O. multitrapezoidea*, a similar variation in paraphysis shape between capitate and spathulate was noted, but their anamorph is unknown. Except for *O. multimaeandrina*, molecular data are wanting for these 32-spored taxa which do not appear to be closely related to each other. More probably, some of them are related to 16-spored taxa with a similar spore shape but predominantly capitate paraphyses. Also in a 16-spored collection (*O.* aff. *subdelphinus*, Pl. 638: 3) most of the paraphyses were spathulate.

Species delimitation. Difficulties in separating species frequently occurred in series *Serpentinae*. For instance, various intermediate collections have been observed between the following 10 morphologically very similar 8-spored species: *O. trapeziformis*, *O. cylindrosoma*, *O. obtusispora*, *O. flexisoma*, *O. subtrapeziformis*, *O. macrotrapeziformis*, *O. curvatitrapeziformis*, *O. edulis*, *O. pyrenaica*, and *O. filiformis*. Separation between *O. serpentina* and *O. maeandrina*, based mainly on the presence vs. absence of crystalloid SCBs, was not clear in every case and proved almost impossible with dead material, leaving the identity of the type of *O. serpentina* a little uncertain. Species limits between the species are actually often subtle and blurred, for instance, between the 16-spored *O. delphinus*, *O. subdelphinus* and *O. macrodelphinus*, between the 64-spored *O. myriourosperma* and *O. sedonensis*, or between the 8-spored *O. quaestiformis* and *O. septispora*. In any case, the few available sequences confirm a high species diversity in series *Serpentinae*.

Anamorph. The known anamorphs within series *Serpentinae* are very often trinacrium robustum-like and quite similar among each other. For instance, conidial morphology does not substantially differ between *O. serpentina*, *O. trapeziformis*, *O. cylindrosoma*, *O. halimi*, and *O. vermiculati*. But also some taxa of series *Ellipsospermae* have quite the same type of anamorph (e. g., *O. gambelii*, *O. multigambelii*, *O. cisti*).

O. quaestiformis and some other species with obtuse spore apices (*O. septispora*, *O. quercus-ilicis*, *O. coniferarum*) are associated with a tridentaria-like anamorph (obtained in pure culture, except for *O. coniferarum*). But also in *O. filiformis*, a species with acute spore apices, tridentaria-like conidia were frequently observed, though only on the natural substrate.

The vermispora- to anguillospora-like anamorph of *O. multimaeandrina* appears to be quite out of the ordinary within this series and suggests affinities with series *Habrostictis*. Yet, similar cases in series *Lentiformes* question the taxonomic value of branched vs. unbranched conidia.

Phylogeny. Sequences were available for 30%, i. e., 15 of the 50 accepted species of series *Serpentinae* (excluding two typical members of series *Serpentinae*, *O. obtusispora* and *O. trapeziformis* p.p., which nevertheless clustered in the *Ellipsospermae* clade). Most of these sequences belong to species with trinacrium-like conidia, which represent the typical anamorph of series *Serpentinae*. However, the *Serpentinae-Habrostictis* clade includes also three taxa with vermispora-like conidia (*O. multimaeandrina* and two species of series *Habrostictis*) and three with tridentaria-like conidia (*O. quaestiformis*, *O. septispora*, *O. filiformis*). The present molecular data do not support recognition of groups based on these anamorphs. Also the shape of the ascospore apex does not permit to recognise groups: *O. mesaverdiana* and *O. vermiculati* closely resemble *O. quaestiformis* in having obtuse spore apices, but they clustered in our combined analysis of SSU+ITS+LSU instead in a strongly supported subclade with three species with acute apices (*O. halimi*, *O. serpentina*, *O. octoserpentina*, Phyl. 20), whereby *O. vermiculati* shows a very low ITS distance to *O. halimi*.

Specific nucleotide positions. Various nucleotide positions in the ITS and LSU D1–D2 (Tab. 72) characterize series *Serpentinae*, but these positions mostly include also series *Habrostictis* and exclude *O. obtusispora* and *O. trapeziformis* p.p. The only observed nucleotide that separates series *Habrostictis* from series *Serpentinae* is pos. 235 of SSU V9 (see under section *Habrostictis*, p. 1015).

Orbilia ophiosoma Baral & G. Marson, **sp. nov**., MB 813659 — Pls 586–587, Map 93

Etymology: referring to the meandering, snake-like SBs within the ascospores.

Typification: USA, Utah, Cedar City, branches of *Juniperus osteosperma*, 24.VIII.1994, G. Marson (ex H.B. 5175a, M-0276544, holotype).

Latin diagnosis: *Apothecia rehydratata 0.15–0.7 mm diam., aurantiaca, margine subglabro. Asci octospori. Ascosporae *6–9 × 3.2–5 µm, lacrimiformes vel limoniformes, in statu vivo corpusculum refringens vermiforme, flexuosum vel uncinatum continentes. Habitat ad corticem vel lignum putridum ramorum siccorum coniferarum in zona temperata subhumida ad humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.5(–0.7) mm diam., 0.11–0.19(–0.21) mm high, light to bright (rose-) orange(-ochre), scarcely translucent, round, ± scattered; disc medium concave to flat, margin ± thin, 0–15 µm protruding, smooth to finely rough; broadly sessile, erumpent to nearly superficial; dry deep orange-red. **Asci** *62–82 × 6.2–8.2(–9.3) µm {4}, †(55–)60–75(–80) × (5–)5.5–6.5(–7) µm {4}, 8-spored, spores *1(–2)-seriate, (2–)3–5(–6) lower spores inverted {3} (sometimes strongly mixed), pars sporifera *35–44 µm long; **apex** (†) strongly truncate (very slightly indented, laterally sometimes inflated); **base** with short to long, thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(6–)7–9((–11)) × (3.2–)3.6–4.5(–5) ((–5.5)) µm {6}, †5.5–9.2 × 3.3–4.1(–4.4) µm {3}, ovoid or mainly tear-shaped to fusiform (limoniform or amygdaliform), apex subacute to acuminate, exceptionally obtuse, base rounded or ± tapered; straight to slightly inequilateral, rarely medium curved at the very base; **SBs** *(4–)5.5–7(–7.7) × (0.7–)0.9–1.1(–1.3) µm in situ {4} (~5–9 µm actual length), vermiform to subulate, not or slightly inflated at base, straight or mostly flexuous, partly uncinate; in aged spores globose with short filum. **Paraphyses** apically slightly to very strongly capitate-clavate or sometimes spathulate, rarely moniliform, terminal cells *6–25 × 3–5(–6) µm {5}, †2.5–3.5 µm wide {1}, partly tipped by 0.5–1.5 µm thick **glassy caps**, lower cells *8–15 × 1.2–2.5(–3) µm {5}; occasionally or frequently branched near apex, hymenium in upper part pale orange. **Medullary excipulum** subhyaline, 20–60 µm thick, of ± loose to dense textura intricata with a few to many inflated cells, ± sharply delimited. **Ectal excipulum** hyaline to light orange (mainly at margin), of (†) ± thin-walled, vertically to horizontally oriented t. angularis(-prismatica) from base to margin or mid flanks, (10–)15–40(–50) µm

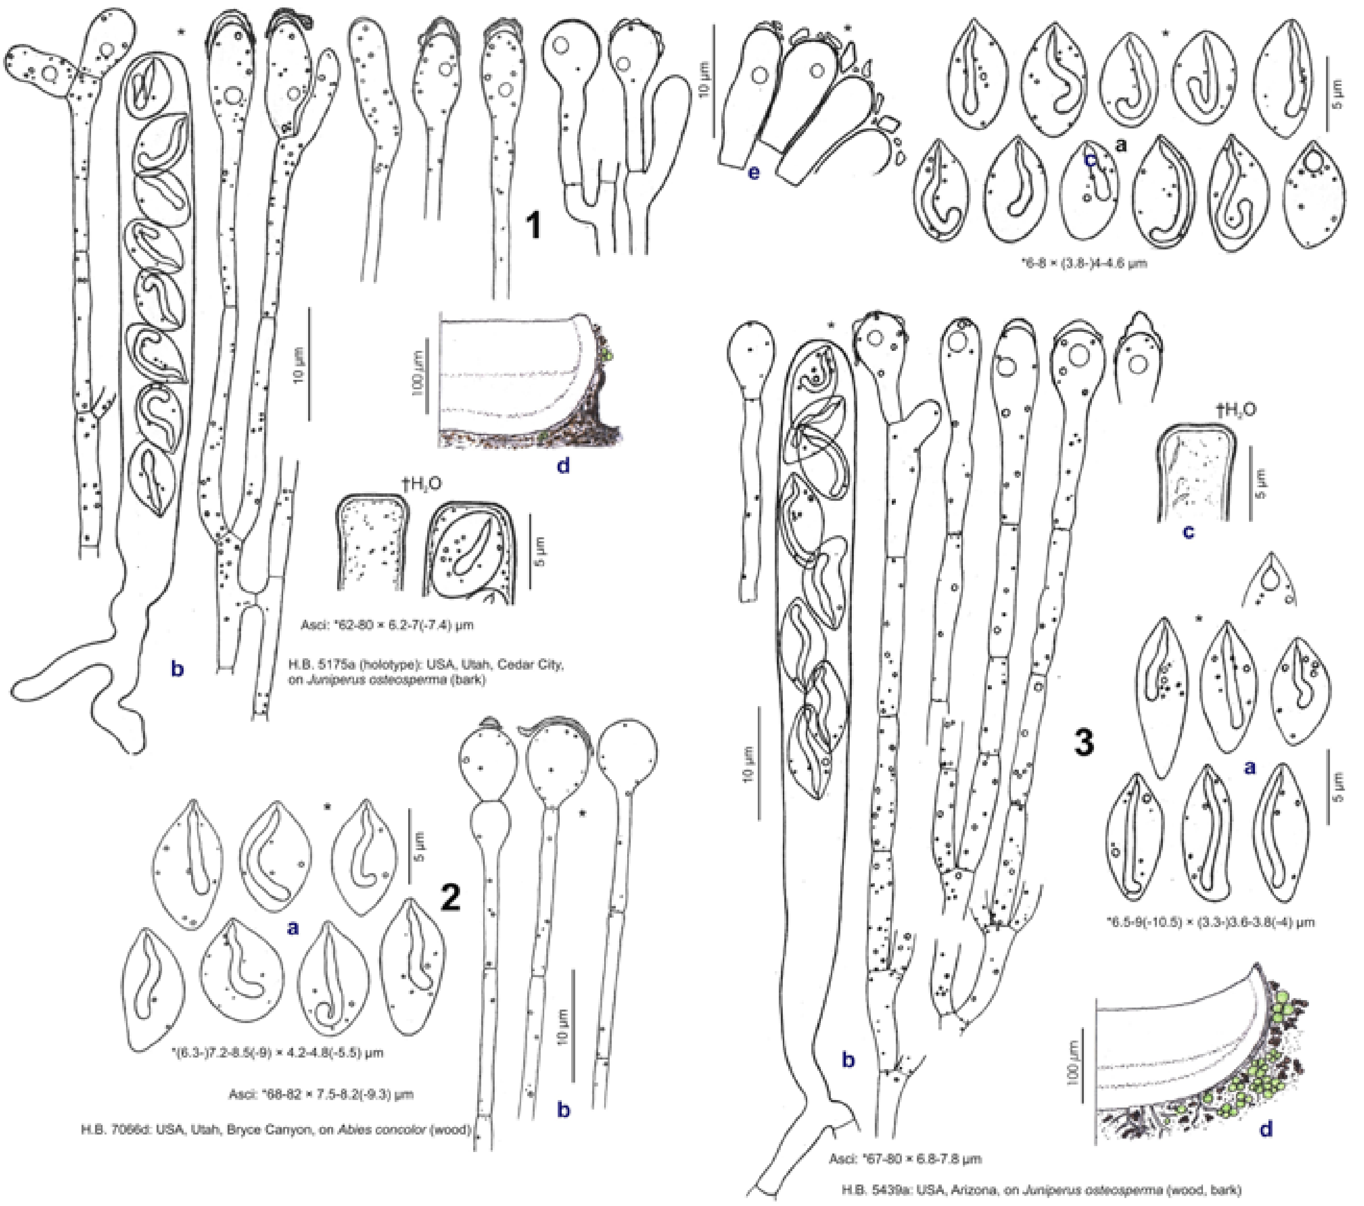

Plate 586. **1–3**: *Orbilia ophiosoma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., cortical cells of ectal excipulum at uppermost margin.

thick near base, cells *(5–)8–17 × (4–)5–10(–12) µm {3}; 20–35 µm thick at lower flanks, 12–20(–40) µm at mid flanks and margin, of t. globulosa-angularis or t. prismatica(-porrecta), at margin oriented at a 10–60° angle, marginal cortical cells *8–16 × 2.7–5 µm {2}, partly tipped by 0.5–1.5 µm thick **glassy caps**. **Anchoring hyphae** sparse to medium abundant, *1.5–4.3 µm wide, walls 0.2–0.5(–0.8) µm thick {3}, sometimes or regularly forming an up to 10–15 µm thick hyaline layer at flanks and margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2 µm diam. {4}, or absent {1}. **Exudate** over paraphyses absent or 0.2–1.2(–2) µm thick, ± loosely attached, cloddy-continuous or granular; over margin and flanks 0.2–1.5 µm thick, granular-crystalloid. **— ANAMORPH**: unknown.

Habitat: collected 0.5–3 m above the ground, corticated or decorticated, 4–50 mm thick twigs and branches of *Abies concolor* {2/1}, *Juniperus osteosperma* {3}, on 0.2–1 mm deep medium to strongly decayed wood {5} and partially detached bark (periderm and bast) {3}, ± strongly greyed, without or with a few to many green algae. **Associated**: *Caloplaca* sp. {1}, *Carestiella ?schizoxyloides* {1}, *Hypogymnia* sp. {1}, *Lachnellula* sp. {1}, ?*Melanelixia* sp. {1}, *Melaspilea emergens* {2}, *Orbilia calyptrata* {1}, *O. clavipisca* {1}, *O. coniferarum* {2}, *O. cucumispora* {1}, *O. delphinus* {2}, *O. flexisoma* {2}, *O. macrodelphinus* {1}, *O. maeandrina* {1/1}, *O. multidelphinus* {1}, *O. multihamulata* {1}, *O. multitrapezoidea* {1}, *O. navajoana* {1}, *O. octosporoides* {1}, *O. osteospermae* {1}, *O. pisciculus* {1}, *Sclerococcum* sp. {1}, *Tryblidaria fenestrata* {1}, *Xanthoria* sp. {1} and other lichens. **Desiccation tolerance**: fully tolerant for at least 19 months, paraphyses, excipular cells and some ascospores still viable after 33 months. **Altitude**: 1815–2778 m a.s.l. **Geology**: Permian and Upper Cretaceous sand- & limestone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia ophiosoma* is well characterized by its rather large, tear- to lemon-shaped ascospores containing long and thick, flexuous to uncinate SBs, and 8-spored asci, also by growing on coniferous substrate. *O. lacrimispora* mainly differs in 16-spored asci, and *O. macrotrapeziformis* in longer and narrower spores; both appear to occur exclusively on angiosperm hosts.

Variation. The collections vary among each other in spore width, also in the paraphysis apices (partly in shape and width, partly in the presence of small glassy caps), but these differences are not clearly correlated with the host genus. In two collections on *Abies* (e.g., Pl. 586: 2) the paraphyses are predominantly strongly capitate while spathulate apices are rather rare. On the contrary, in two samples on *Juniperus* (e.g., Pl. 586: 1) spathulate apices are predominant.

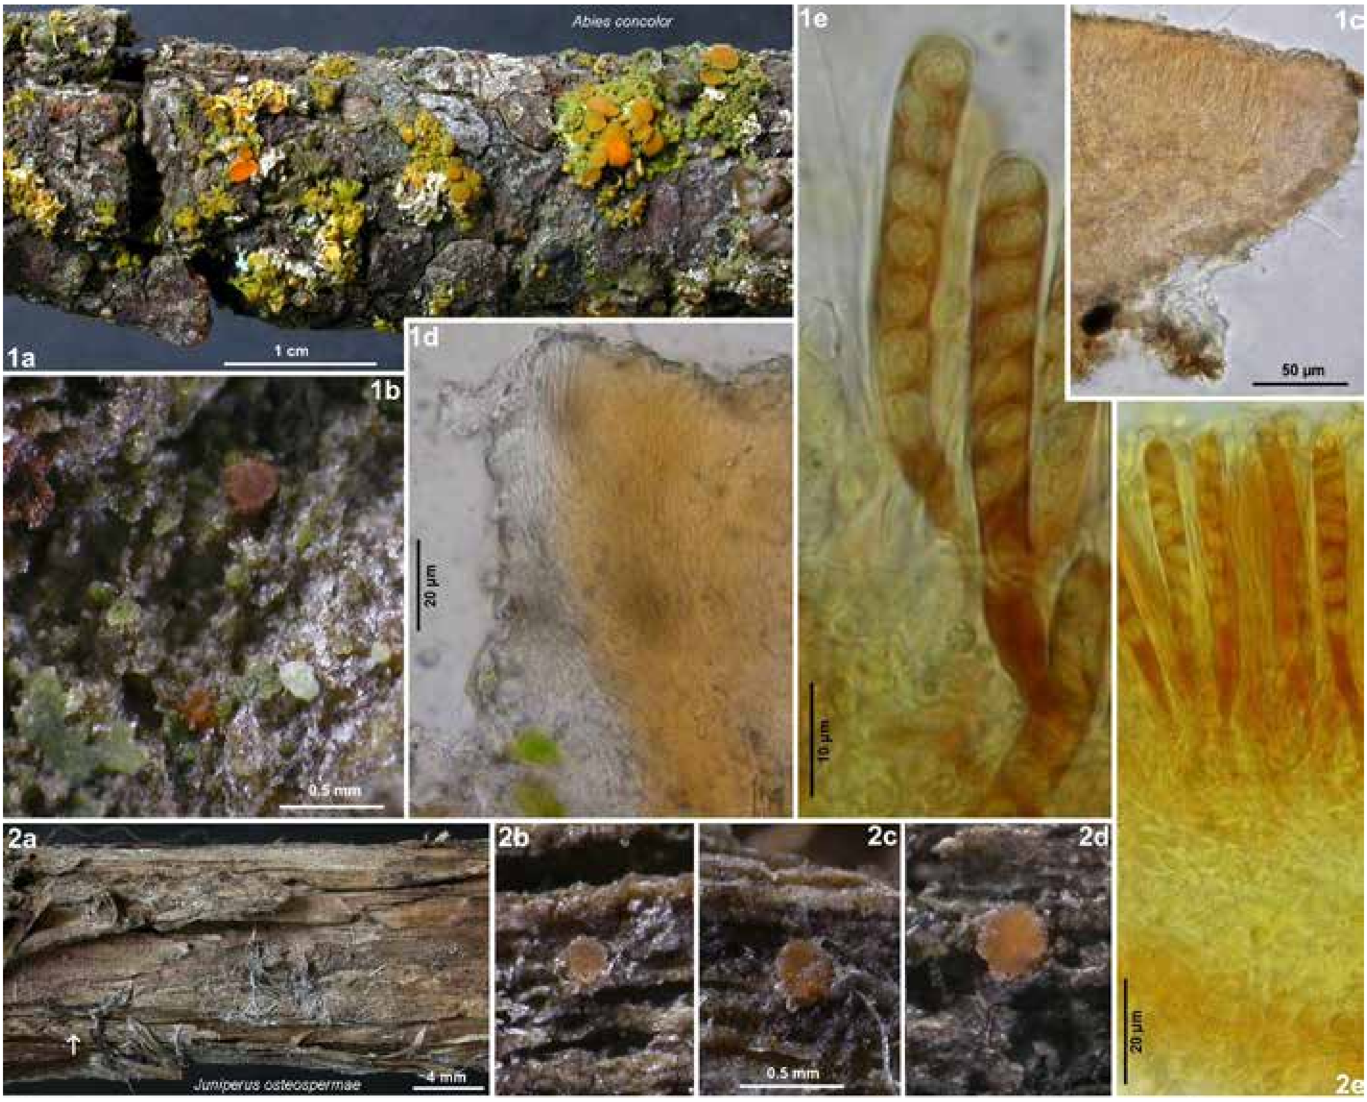

Plate 587. **1–2**: *Orbilia ophiosoma*. – **1a**, **2a**. dead corticated branches (**1a** with *Xanthoria* and other lichens); **1b**, **2b–d**. rehydrated apothecia; **1c**. apothecium in median section; **1d**. id. marginal ectal excipulum (orange) with hyaline covering layer; **2e**. id., hymenium, medullary and ectal excipulum; **1e**. asci. – Dead state (**1c** in H_2O, **1d** in KOH, **1e**, **2e** in KOH+IKI). — **1a–e**. H.B. 8095d: USA, Utah, Bryce Canyon, on *Abies concolor*; **2a–e**. H.B. 5175a (holotype): ibid., Cedar City, on *Juniperus osteosperma*.

Not included collection. A briefly studied unillustrated sample on *Populus tremuloides* resembles *O. ophiosoma* in the spores (*8–11 × 3.3–4 µm, with acuminate apex, helicoid SBs) but is not included because of the deviating substrate, also because of rather long SBs.

Ecology. *O. ophiosoma* was found on ± rotten wood and bark of xeric twigs and branches of gymnosperms in cold-temperate to boreal subhumid pinyon-juniper woodlands and humid Douglas fir and Engelmann spruce forests of the Utah Mountains, Coconino Plateau, and Sacramento Mountains at the northeastern border of the Chihuahuan Desert in western North America. The not included collection on *Populus* was in a boreal humid Engelmann spruce forest in the Utah Mountains.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 1.5 km ESE of Cedar City, 1815 m, branches of *Juniperus osteosperma*, on bark, 24.VIII.1994, G. Marson (M-0276544, **holotype**; **isotype** in H.B. 5175a). – Bryce Canyon, 42 km SSE of Panguitch, Rainbow Point, 2778 m, branch of *Abies concolor*, on wood, 20.VI.2000, G. Marson (H.B. 7066d ø). – 32 km SE of Panguitch, 13 km WSW of Tropic, near Trough Spring, 2500 m, branch of *A. concolor*, on bark & wood, 13.VI.2003, G. Marson (H.B. 8095d). – **Arizona**, Grand Canyon, Coconino Plateau, 3.5 km N of Tusayan, 2075 m, branch of *J. osteosperma*, on wood, 17.VI.2003, G. Marson (H.B. 8097f). – 3 km S of Tusayan, 2033 m, branches of *Juniperus osteosperma*, on bark & wood, 28.VIII.1994, G. Marson (H.B. 5439a). – **New Mexico**, Sacramento Mountains, 21 km ENE of Alamogordo, Cloudcroft, 2650 m, branches of *A.* ?*concolor* on wood, 25.V.1996, G. Marson (H.B. 5670).

Not included. **USA**: **Utah**, Utah Mts., Dixie Forest, 22 km ESE of Cedar City, 18 km WNW of Duck Creek Village, Zion Overlook, 2980 m, branch of *Populus tremuloides*, on wood, 24.VIII.1994, G. Marson (H.B. 5230e).

Orbilia lacrimispora Baral & G. Marson, **sp. nov.**, MB 813660 — Pls 588–589

Etymology: named after the tear-shaped ascospores.

Typification: USA, Arizona, Wickenburg, branch of *Ephedra ?viridis*, 4.V.1995, G. Marson (ex H.B. 5894a, M-0276497, holotype).

Latin diagnosis: *Similis* Orbiliae ophiosomati *sed asci 16-spori*, *lignum putridum fruticum angiospermarum inhabitans in zona temperata ad subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3(–0.5) mm diam., 0.14–0.15 mm high, light to bright (rose-)orange(-ochraceous), round, ± scattered; disc flat, margin distinct, 0–20 µm protruding, finely rough; broadly sessile, immersed in host fibres. **Asci** *75–87 × 8.5–9.6(–10.5) µm {2}, †(58–)70–90 × 7–8.5(–9.3) µm {3}, 16-spored, spores *4-seriate, ~8 lower spores inverted {3} (sometimes strongly mixed), pars sporifera †54–63 µm; **apex** (†) strongly truncate (± distinctly indented, laterally sometimes distinctly widened); **base** with short, thick stalk, Y- to h-shaped. **Ascospores** *(6.8–)7.5–10(–11.2) × 3.5–4.4(–4.8) µm {3}, †6.5–9(–10) × 3.5–4 µm {2}, ellipsoid-lacrimiform or amygdaliform, apex acute to acuminate, exceptionally obtuse, base ± rounded, rarely very slightly attenuated, straight to slightly inequilateral; **SBs** *6–9 × (0.5–)0.7–1(–1.4) µm in situ {2} (~9–11 µm actual length), vermiform (to subulate), not or slightly inflated at base, strongly flexuous or helicoid, partly uncinate. **Paraphyses** apically (slightly to) medium to strongly clavate-capitate or slightly spathulate, terminal cells *7–17 × (2.5–)3–4.5 µm {2}, †(1.5–)2–3 µm wide, lower cells *9–13 × 1.5–2 µm {1}; unbranched at upper septum, hymenium pale rose-orange. **Medullary excipulum** pale rose-orange, 30 µm thick, of ± dense textura intricata with inflated cells, medium sharply delimited. **Ectal excipulum** pale rose-orange, of (†) slightly gelatinized t. angularis from base to margin, 30 µm thick near base, cells †6–11 × 5–7 µm {1}; 20 µm thick near margin, oriented at a 70–90° angle to the surface, marginal cortical cells †6–10 × 2.8–3.7 µm {1}. **Anchoring hyphae** medium abundant, */†(2–)2.5–3(–3.5) µm wide, walls 0.2–0.4 µm thick {1}, extending ± to the margin as a thin layer. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–1.5 µm diam. {3}. **Exudate** over paraphyses 0.3–0.8(–2) µm thick, rough, firmly attached; over margin and flanks rather thin. — **ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, decorticated, 14–25 mm thick branches of *Canotia holacantha* {1}, *Ephedra ?viridis* {1}, *Larrea tridentata* {1}, on 0.5–1 mm deep strongly decayed wood {3}, eroded, greyed, green algae sparse. **Associated**: ?*Baggea* sp. {1}, *Hysterobrevium mori* {3}, *Melaspilea emergens* {1}, *Orbilia arizonensis* {2}, *O. bicknellensis* {1}, *O. calyptrata* {3}, *O. cryptogena* {1}, *O. macrodelphinus* {2}, *O. macrohesperidea* {1}, *O. maeandrina* {1}, *O. multigambelii* {1}, *O. multiserpens* {1}, *O. sonorensis* {1}, *O. trapeziformis* {1}, *O. ?vitalbae* {1}, *Patellaria* '*andina*' {1}, *P. atrata* {2}, *Schizoxylon* sp. {1}, crustose lichen. **Desiccation tolerance**: fully tolerant for at least 1 year; some immature asci and paraphyses and many ascospores still viable after 39 months. **Altitude**: 615–1073 m a.s.l. **Geology**: Triassic and Oligo- to Miocene sand-, lime- & mudstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia lacrimispora* is easily recognised by its rather large, tear-shaped to amygdaliform ascospores containing long and thick, flexuous to helicoid SBs, and by 16-spored asci. The similar *O. ophiosoma* differs in 8-spored asci and in growing typically on coniferous hosts. *O. serpentina* and *O. maeandrina* both differ in narrower, less tear-shaped spores, the former also in crystalloid SCBs. Nevertheless, the narrowest spores of *O. lacrimispora* concur with the widest spores of *O. maeandrina*.

Not included collections. Two briefly illustrated samples with spores very similar to *O. lacrimispora* (Pl. 588: 3–4) differ in the presence of crystalloid SCBs and in narrower spores and

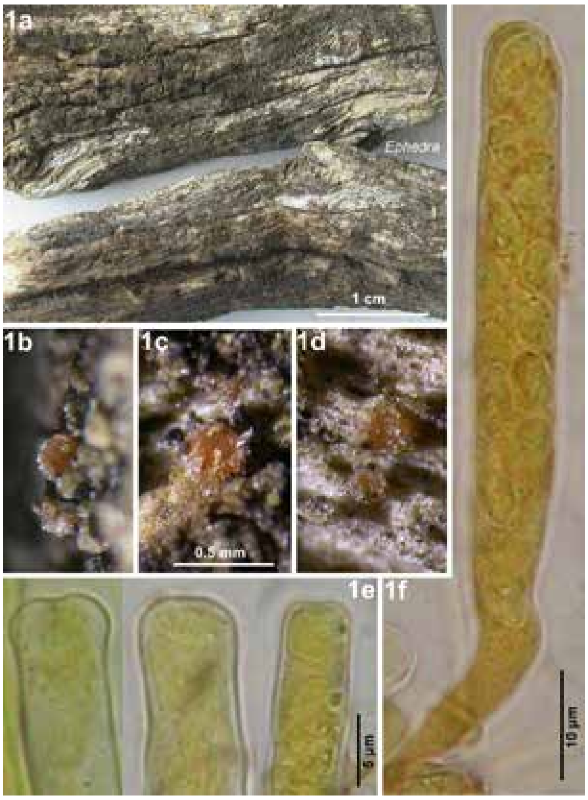

Plate 589. **1**: *Orbilia lacrimispora*. – **1a**. decorticated branches; **1b–d**. rehydrated apothecia; **1e**. ascus apices; **1f**. ascus. – Dead state (in KOH+IKI). — **1a–f**. H.B. 5894a (holotype): USA, Arizona, on *Ephedra ?viridis*.

asci, therefore they might represent a separate species.

Ecology. *O. lacrimispora* grew on rotten wood of xeric branches of angiosperm shrubs in warm-temperate to subtropical semiarid paloverde-mixed cacti desert scrubs of the Sonoran Desert in the southwest of Northern America. The not included collections were from a cold-temperate semiarid sagebrush desert scrub with *Salix* on Triassic calcareous sand in the Utah Mountains and a subtropical semiarid acacia shrubland (mulga) on Archean to Paleoproterozoic sedimentary rock in the Pilbara desert in western Australia.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 82 km NW of Phoenix, ~1.5 km SE of Wickenburg, 615 m, branch of *Ephedra ?viridis*, on wood, 4.V.1995, G. Marson (ex H.B. 5894a, M-0276497, **holotype**). – 68 km SSW of Flagstaff, 5.5 km NNE of Camp Verde, Montezuma Castle, 975 m, branch of *Larrea tridentata*, on wood, 8.V.1995, G. Marson (H.B. 5684f ø). – ibid., 9 km NNE of Camp Verde, 4 km NE of Montezuma Castle, 1073 m, branch of *Canotia holacantha*, on wood, 12.VI.2000, G. Marson (ø).

Not included. **USA**: **Utah**, Utah Mts., 13 km ESE of Bicknell, ~1.5 km ESE of Torrey, ~2075 m, on *Salix ?exigua*, 15.V.1995, G. Marson (ø). — **AUSTRALIA**: **Western Australia**, centre of Pilbara, 30 km NW of Newman, 706 m, twigs of *Psydrax latifolia*, on bark, 27.XI.2001, G. Marson (H.B. 7416c).

Orbilia multihamulata Baral & G. Marson, **sp. nov.**, MB 813661 — Pls 590–591

Etymology: with 32-spored asci and uncinate (hamulate) spore bodies.
Typification: USA, Arizona, Page, branch of *Juniperus osteosperma*, 27.VIII.1994, G. Marson (ex H.B. 5224b, M-0276522, holotype).

Latin diagnosis: *Similis* Orbiliae ophiosomati *sed asci 32-spori. Habitat ad corticem putridum ramorum siccorum* Juniperi osteospermae in z*ona temperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.4 mm diam., 0.16–0.18 mm high, light orange-ochraceous, round, scattered to medium gregarious or in small clusters; disc flat, margin 5–20 µm protruding, finely whitish puberulent-crenulate; broadly sessile, mostly erumpent through slits in the outer layers of bark; dry apothecia bright orange. **Asci** *(83–)90–100(–120) × 9–11 µm {2} → 110–118 × 10–11 µm, †83–98 × 8–9.5 µm {2}, 32-spored, lower spores inverted, some of upper spores oriented in all directions, pars sporifera *65–77 → 50–56 µm, †75–85 µm; **apex** (†) medium to strongly truncate (very slightly indented, laterally inflated); **base** without or with very short, slightly flexuous stalk, Y- to h-shaped. **Ascospores** *6–8(–9) × 3.7–4.2(–4.5) µm {2}, †5.5–7.8 × (3.3–)3.8–4.2 µm {2}, broadly (ellipsoid-)ovoid to fusiform (lemon-shaped or amygdaliform), apex subacute to acute, rarely obtuse, base rounded or often ± acute, straight. **SBs** *5.5–7.5(–8.5) × 0.7–1 µm in situ {2} (~9–11 µm actual length), vermiform to subulate, not or slightly swollen at base, flexuous to helicoid, mostly strongly uncinate. **Paraphyses** apically medium to strongly clavate(-capitate) or spathulate, rarely slightly mammiform, terminal cells (5–)9–26(–32) × (3.5–)4–5.5(–6.5) µm {2}, †3–4.7 µm wide {2}, lower cells *(9.5–)14–20 × 1.2–2.4 µm {2}, †1–1.4 µm wide, near base *2.5–3 µm, sometimes branched near apex. **Medullary excipulum** hyaline, 40–50 µm thick, of ± loose textura intricata with many ± distinct inflated cells, sharply delimited. **Ectal excipulum** hyaline to pale rose-orange, of firm-walled, seemingly horizontally oriented (though cells also vertically elongate) t. angularis from base to margin, 20–35 µm thick

near base, cells *7–13 × 7–12 µm {2}; 15–20 µm thick at mid flanks, cells *7–11 × 7–10 µm, 15–20 µm thick at margin, marginal cortical cells *5–14 × 3–6.5 µm {2}. **Anchoring hyphae** abundant, *2.5–4 µm wide {2}, walls *0.2–0.4 µm thick, †0.2–0.6(–1.2) µm {2}, forming a thin layer from base to flanks. **SCBs** absent. **Exudate** over paraphyses 0.2–0.8 µm thick, ± warted, hyaline to very pale rose-orange, firmly attached and restricted to each paraphysis tip; over margin and flanks thin, granular. **— ANAMORPH**: unknown.

Habitat: collected 1.5 m above the ground, ± corticated, undecayed, dead, 12–?40 mm thick branches of *Juniperus osteosperma* {2}, on medium decayed, loosely attached, or detached hanging bark {2}, on thin layers of bark, greyed, green algae sparse or absent. **Associated**: *Orbilia cucumispora* {2}, *O. ?maeandrina* {1}, *O. multidelphinus* {1}, *O. octosporoides* {1}, *O. ophiosoma* {1}, *O. osteospermae* {1}, *O. pisciculus* {1}, *Ostropales* {1}. **Desiccation tolerance**: fully tolerant for at least 5 months. **Altitude**: 1225–1815 m a.s.l. **Geology**: Triassic-Jurassic-Cretaceous sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multihamulata* is well characterized by its rather large, broadly ovoid-fusiform ascospores with very long, thick, always uncinate SBs and by 32-spored asci. The species appears to be closely related to the 8-spored *O. ophiosoma* (on gymnosperms) and 16-spored *O. lacrimispora* (on angiosperms). *O. multimaeandrina* (on angiosperms) differs from *O. multihamulata* in narrower spores with shorter, not uncinate SBs. *O. osteospermae* grew with *O. multihamulata* on the same host; its spores are similar in shape but much smaller.

Variation. The rich holotype collection slightly deviates in more lemon-shaped spores from the sparse paratype in which ovoid spores predominated.

Ecology. *O. multihamulata* was collected on ± rotten bark of xeric branches of *Juniperus osteosperma* in ravines or broad valleys near small rivers in the warm-temperate semiarid to cold-temperate subhumid pinyon-juniper woodlands of the Great Basin adjacent to Utah Mountains and Canyonlands section of Colorado Plateau adjacent to Grand Canyon in western North America.

Specimens included. **USA**: **Utah**, Utah Mts., 1.5 km ESE of Cedar City, Dixie Forest, 1815 m, branch of *Juniperus osteosperma*, on bark, 24.VIII.1994, G. Marson (H.B. 5198a). – **Arizona**, Canyonlands, 35 km WNW of Page, Paria Canyon, ~1225 m, branch of *J. osteosperma*, on bark, 27.VIII.1994, G. Marson (ex H.B. 5224b, M-0276522, **holo- & isotype**).

Orbilia trapeziformis Baral & G. Marson, **sp. nov.**, MB 814375 — Pls 592–594, Map 94

Etymology: referring to the trapezoid (rhomboid) ascospore shape.

Typification: France, Ancerville, branch of *Quercus robur*, 10.V.1993, H.O. Baral (ex H.B. 4874a, M-0276601, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–1 mm diam., aurantiaca, margine laevi vel subcrenulato. Asci 8-spori. Habitat: collected (0–)0.8–4(–16) m above the ground, corticated to decorticated, 8–35(–150) mm thick branches, rarely trunks, of *Acer* sp. {1}, *A. campestre* {1}, *Carpinus betulus* {3}, *Castanea sativa* {1}, *Cercis siliquastrum* {3}, *Corylus avellana* {2/1}, *Cytisus scoparius* {1}, *Euonymus europaeus* {1}, *Fagus sylvatica* {3}, *Fraxinus excelsior* {2}, *Juglans nigra* {1}, *J. regia* {10}, *Juniperus oxycedrus* {1}, *J. thurifera* {1/1}, *Malus domestica* {2}, *Pinus sylvestris* {1}, *Populus ?canadensis* {1}, *Prunus avium* {2}, *P. mahaleb* {1}, *P. spinosa* {1}, *Quercus* sp. {7}, *Q. cerris* {2}, *Q. ilex* {1}, *Q. pubescens* {3}, *Q. robur* {4}, *Q. suber* {1}, *Rhus typhina* {1}, *Robinia pseudoacacia* {1}, *Rosa* sp. {1}, *Rubus fruticosus* {1}, *Salix ?alba* {1}, *S. caprea* {3/1}, *Sorbus domestica* {1}, *S. torminalis* {1}, *Tilia* sp. {1}, *T. cordata* {1}, *T. platyphyllos* {1}, on herbaceous stem of *Humulus lupulus* {1}, on 0.3–2 mm deep slightly to mostly strongly decayed wood {58} and bark {20} (periderm {3} and bast {9}), sometimes on very old *Vuilleminia ~comedens* {6} or in beetle galleries on boring dust, wood often white-rotten, (strongly) greyed, often eroded, with a few to many green algae. **Associated**: *Baggea* sp. {1}, *Claussenomyces* sp. {1}, *Coniochaeta* sp. {2}, *C. ?pulveracea* {1}, *Cryptocoryneum condensatum* {1}, *Dacrymyces* sp. {3}, *Diplodia* sp., {1}, *Durella ?compressa* {1}, *D. connivens* {2}, *Frullania dilatata* {1}, *Hyalorbilia juliae* {1}, *H. subfusispora* {2}, *Hypogymnia physodes* {1}, *Hypoxylon fuscum* {1}, *H. udum* {2}, *Hysterium angustatum* {1}, *Hysteropatella elliptica* {1}, *Karstenia* sp. {1}, *K. rhopaloides* {1}, *Lasiobelonium variegatum* {1}, *Lecanora* sp. {1}, *Lophiostoma myriocarpum* {1}, *Melanelia glabratula* {2}, *Nitschkia broomeana* {1}, *Orbilia aprilis* {1}, *O. aristata* {1}, *O. aurantiorubra* {1}, *O. carpoboloides* {1}, *O. cejpii* {1}, *O. cercidicola* {2}, *O. clavuliformis* {1}, *O. eucalypti* {2}, *O. ?ficicola* {1}, *O. filiformis* {2}, *O. flagellispora* {2}, *O. gambelii* {1}, *O. myriolentiformis* {1}, *O. myriosphaera* {2}, *O. patellarioides* {1}, *O. pleioeuonymi* {1}, *O. polyspora* {1}, *O. quaestiformis* {1}, *O. septispora* {1}, *O. sphaerospora* {1}, *O. subaristata* {3}, *O. subclavuliformis* {1}, *O. subocellata* {1}, *O. subvinosa* {1}, *O. ?tremulae* {1}, *O. vinosa* {2}, *O. vitalbae* {1}, *Orthotrichum* sp. {1}, *Ostropales* {2}, *Parmelia sulcata* {1}, *Patellaria atrata* {8}, *P.* '*crassispora*' {5}, *Peniophora* sp. {1}, *Phragmiticola* sp. {1}, *Pseudevernia furfuracea* {1}, *Physcia* sp. {3}, *Proliferodiscus tricolor* {1}, *Propolis farinosa* {1}, *Trichopeziza* sp. {2}, '*Tympanis*' *xylophila* {1}, *Xanthoria parietina* {3}, various crustose lichens. **Desiccation tolerance**: fully tolerant for at least 3 months; immature asci still viable after 13 months, some spores after 32 months. **Altitude**: 4–720 m (central and western Europe), 21–1385 m (southern Europe). **Geology**: Cambrian, Ordovician & Devonian quartzitic or calcareous greywacke and clayey silt, Permian (Rotliegend), Muschelkalk, Keuper (Gipskeuper, Schilfsandstein, Knollenmergel), Lower to Upper Jurassic and Cretaceous clay, marl, sand- & limestone, Minette, flysch, dolomite, Tertiary sand, marl & molasse, Quaternary loess, sand, silt & clay; granite. **Phenology**: throughout the year (long-lived).

Phenology of *O. trapeziformis*

Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
5	4	8	8	9	6	7	7	8	4	4	5

Taxonomic remarks. *Orbilia trapeziformis* is characterized by fusoid(-trapezoid) to fusoid-clavate, rather short, often almost homopolar ascospores with obtuse to mostly subacute apices and ± attenuated bases, 8-spored asci, and the absence of crystalloid SCBs. Delimitation from *O. obtusispora* and *O. cylindrosoma*, which mainly differ in more elongate spores (the latter also in vermiform SBs), is not very clear-cut, though a majority of collections could rather clearly be assigned. *O. vitalbae* differs in spores with more obtuse apices and only slightly tapered bases, also in abruptly swollen spore bodies. The more montane *O. subtrapeziformis* differs in longer spores with more acute apices. The mediterranean *O. bicknellensis* has similar fusiform-clavate but distinctly larger and apically acute spores, and also differs in the presence of distinct crystalloid SCBs. The also mediterranean foliicolous *O. quercus-ilicis* differs in more rounded spore apices and more strongly attenuated, tail-like bases, basally non-inflated SBs, somewhat wider asci, and a tridentaria-like anamorph.

Two further taxa closely resemble *O. trapeziformis* in ascospore characters: *O. maeandrina* differs in 16-spored asci, and the Australian and American *O. macrotrapeziformis* in longer and/or wider spores, and in wider asci. One of them, the sample on *Mahonia fremontii* from Utah mentioned under *O. macrotrapeziformis* (Pl. 625: 6) differs from *O. trapeziformis* merely in wider spores. Australian populations referred to *O. commarosa* (Pl. 715: 3, 4, 6) resemble *O. trapeziformis* in spore shape but differ in a tendency to strongly curved spore bases and SBs with wider, more abrupt basal inflation. Their homogeneity and delimination from *O. trapeziformis* is not certain, however. The type of the Australian *O. octocercocarpi* (on *Atriplex*, Pl. 727: 2) resembles *O. tapeziformis*, particularly the *Humulus* sample, except for its crystalloid SCBs.

Variation. *O. trapeziformis* varies somewhat in spore size (especially in length) and shape among the collections, but such variation is also often observed within a collection. Spore length is mostly *6.5–9.5 µm, often also *7.5–11 µm, but rarely only *5–7.5 µm. The spore apex is predominantly subacute but also obtuse and rarely acute. The spore base varies from medium to usually strongly attenuated and then often tail-like and ± curved.

A collection on herbaceous stem of *Humulus* from Belgium (Pl. 593: 6) appears to belong to *O. trapeziformis*, in spite of its consistently curved, tail-like spore bases and rather narrow SBs. It was associated with a tridentaria-like anamorph similar as in *O. filiformis* or *O. quaestiformis* and might in fact belong to one of these species.

In a sparse collection on *Cercis* (Pl. 594: 6d–e) the two small groups of apothecia differed distinctly among each other in spore size and shape, though both were full mature and the SBs of a similar length. Nevertheless, the two groups are considered here as belonging to a single species, especially because a third collection from the same substrate and site (Pl. 592: 3) shows somewhat intermediate spores (short but with more tapered spore base), and a fourth (H.B. 7077g, unillustrated) shows long and basally tapered but not strongly curved spores.

Ascus width was usually in the range of *4.8–5.7 µm, but in the collections on *Robinia* and *Humulus* (Pl. 593: 1, 6) it measured *6–7.5 µm, although the spores were here hardly larger.

Not included collections. A specimen from Pakistan on a twig of *Hibiscus* (Pl. 592: 8) deviates in slightly smaller asci and spores and more obtuse spore apices. It somewhat resembles *O. vitalbae*, but the spores are quite consistently fusoid-clavate, with a strongly tapered base, the SBs not abruptly inflated, and the terminal cells of paraphyses rather long (†17–24 µm). Only the spores were alive when the apothecia were studied.

A sample from southwestern Canada on *Arbutus* studied by O. & A. Ceska (pers. comm.) matches *O. trapeziformis* in the spores and 8-spored asci, but no further data were taken from the single collected apothecium. For the not included conidial sample from Luxembourg see under Anamorph.

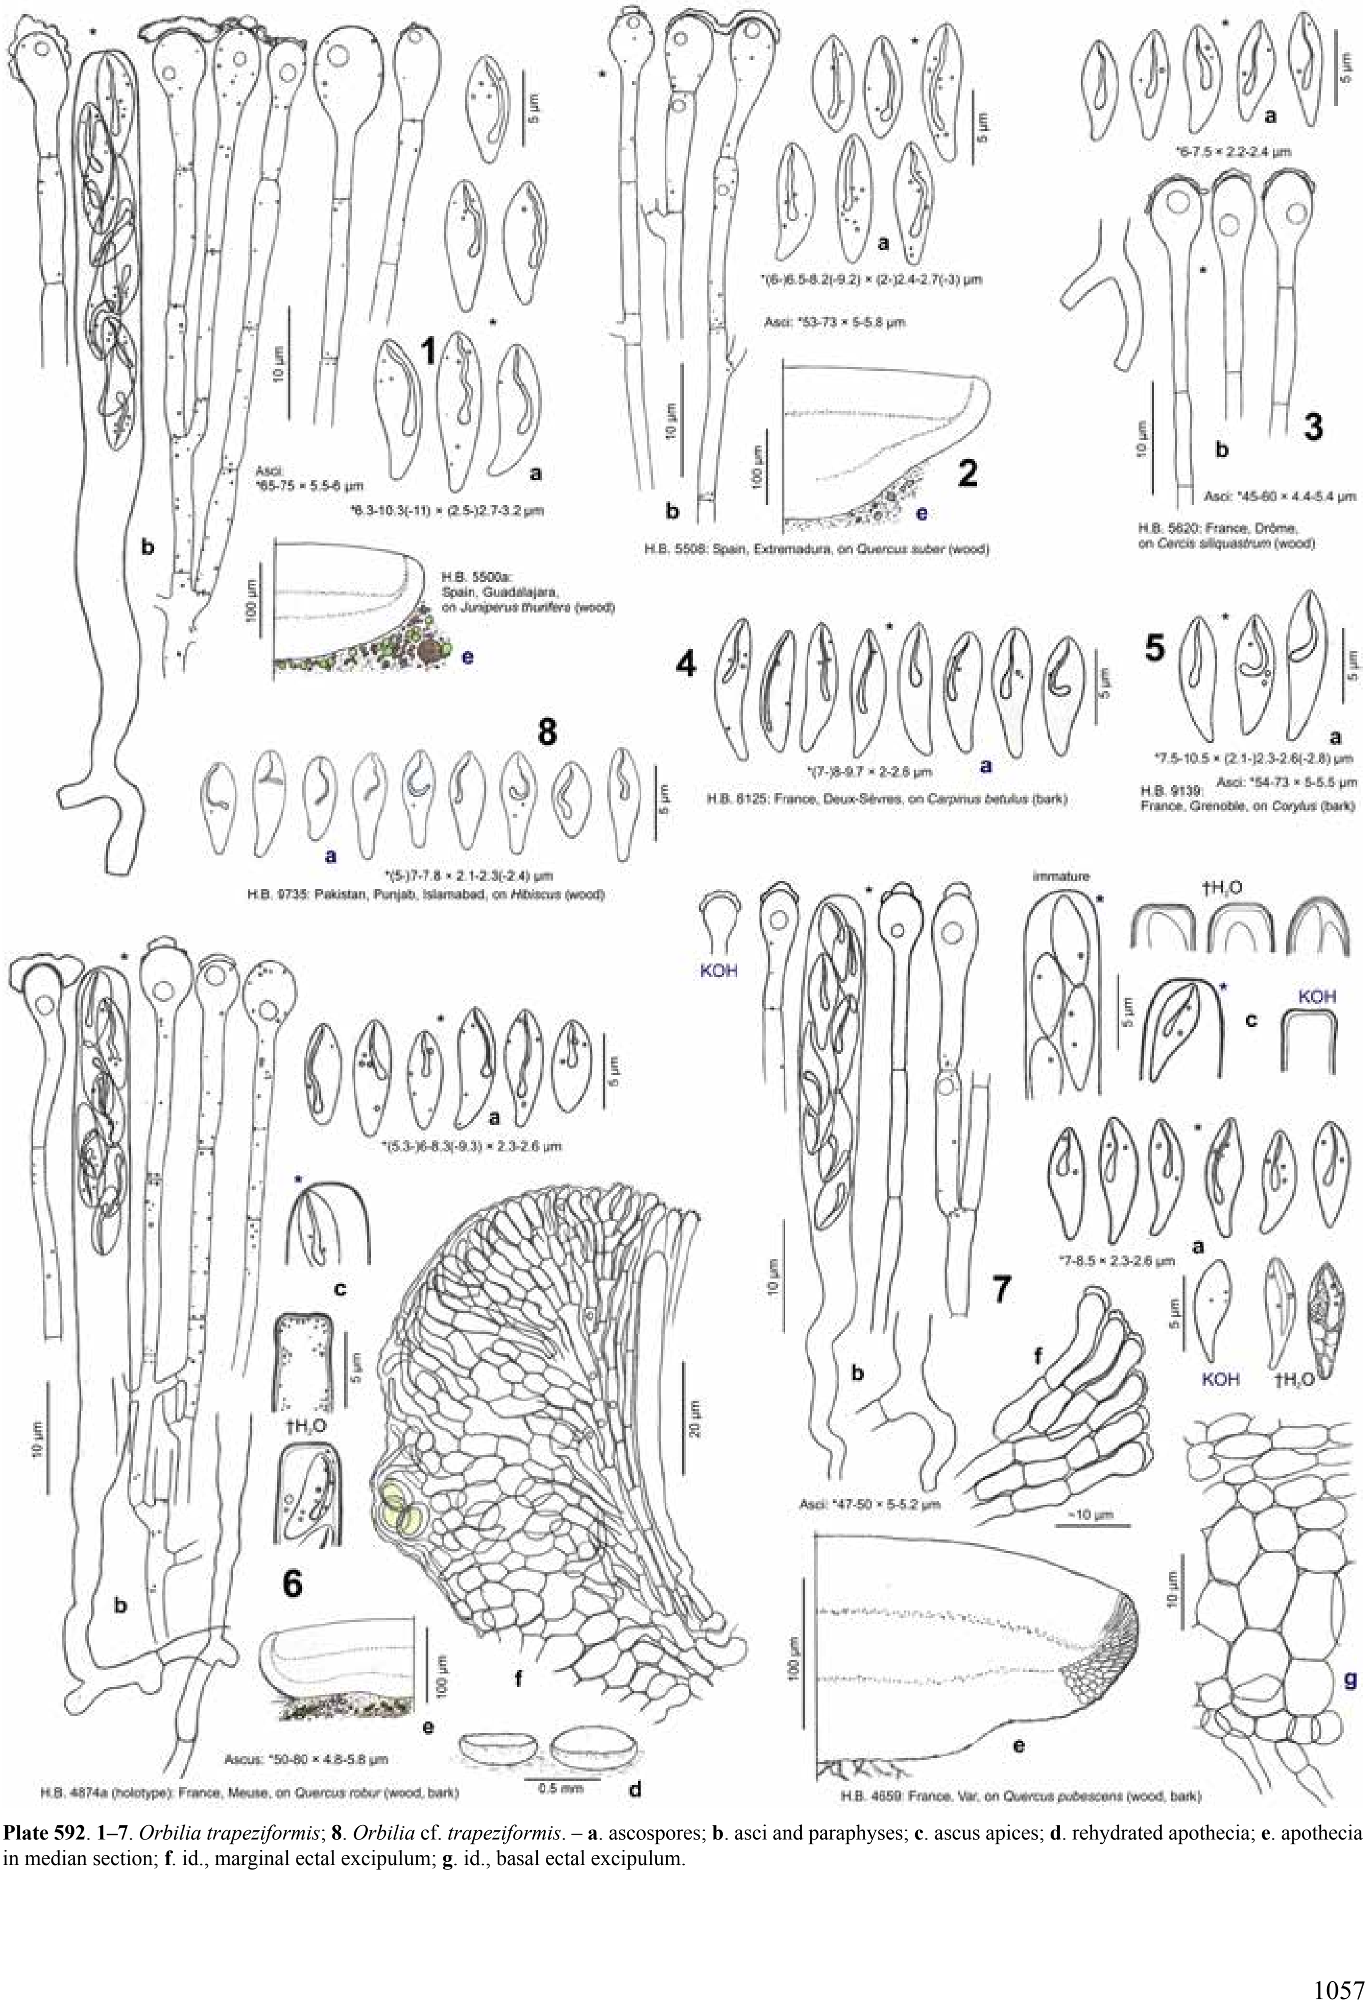

Plate 592. **1–7**. *Orbilia trapeziformis*; **8**. *Orbilia* cf. *trapeziformis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., marginal ectal excipulum; **g**. id., basal ectal excipulum.

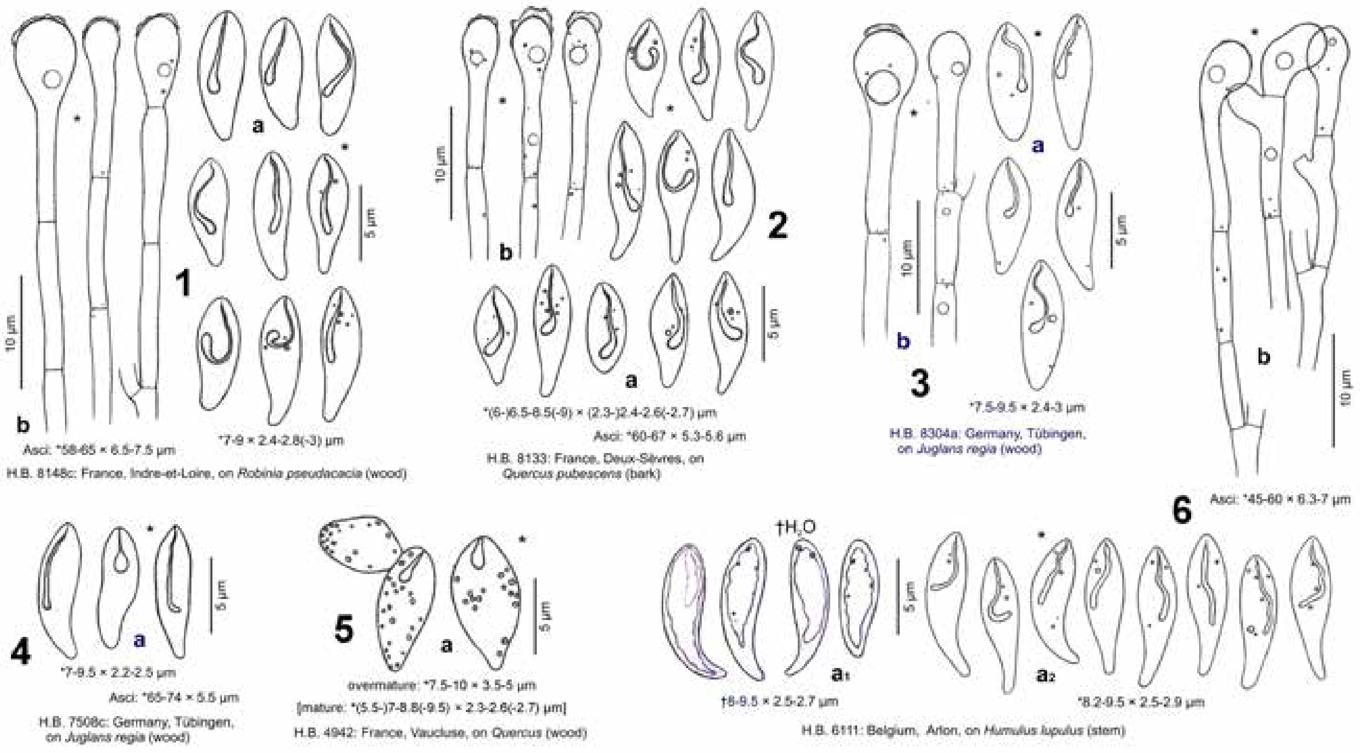

Plate 593. **1–6**. *Orbilia trapeziformis*. – **a**. ascospores (**5a** during germination); **b**. asci and paraphyses.

Anamorph. The trinacrium robustum-like conidia observed on the natural substrate hardly differ from those observed in the very closely related *O. obtusispora*, whereas in much more distant *O. cylindrosoma* they show a clear tendency to longer arms and stipes. In association with the conidia figured in Pl. 594: 12 no apothecia of *O. trapeziformis* were recorded, therefore, they could instead belong to *O. obtusispora*.

Phylogeny. Sequences were gained from apothecia of two samples from southern France (on *Cercis*, H.B. 9151c; on *Corylus*, H.B. 9139), one from Slovakia (on *Quercus*, A.P. 18/55), and one from southern Germany (on *Juglans*, H.B. 10007a), comprising ITS, that on *Corylus* also LSU. The S1506 intron is present in the three former but absent in the *Juglans* sample. In the ITS region the three former strains differ by 0.2 % (each 1 nt) and 3 gaps, while the distance to *O. obtusispora* is 0.8–1.2 %. This raises the question whether they might be conspecific with *O. obtusispora*, although the spores are distinctly longer in the *O. obtusispora* sample (see also under that species, p. 1063). The *Juglans* sample shows a high distance of 19 % to the three other *O. trapeziformis* samples, but only 6 % to *O. cylindrosoma*.

In the LSU region *O. trapeziformis* (H.B. 9139) and *O. obtusispora* are identical (540 nt) and show a minimum distance of 0.4–0.7 % to *O. subvitalbae*, *O. vitalbae*, *O. gambelii*, and *O. ungulata*. In the intron the three sequences of *O. trapeziformis* differ by 1–1.6 % in the overlapping 314 nucleotides, whereas *O. obtusispora* and the *Juglans* sample do not possess the intron.

In our analysis of the ITS region (Phyl. 19), the strain from *Juglans* clustered strongly supported with *O. cylindrosoma* in the *Serpentinae-Habrostictis* clade, whereas the two strains from France and *O. obtusispora* clustered in the *Ellipsospermae* clade. *O. trapeziformis* shows indeed morphological similarities to *O. cisti*, *O. gambelii*, *O. ungulata*, and *O. vitalbae*, which all belong in the *Ellipsospermae* clade, and its spore apices sometimes vary between acute and obtuse. Although *O. trapeziformis* appears to be heterogeneous according to these DNA data, we here treat *O. trapeziformis* and *O. obtusispora* in series *Serpentinae* because of the strong morphological similarity between these two species and *O. cylindrosoma*, *O. filiformis*, and *O. subtrapeziformis*.

Ecology. *O. trapeziformis* grew on ± rotten wood and bark of xeric branches (rarely trunks) of various angiosperm (sometimes gymnosperm) trees and shrubs, often on *Quercus*. Contrary to the similar *O. cylindrosoma* and *O. obtusispora*, *O. trapeziformis* was so far never encountered on herbaceous substrates (with one exception on *Humulus lupulus*). Its distribution comprises warm- to cold-temperate, rarely hemiboreal humid regions of atlantic western and subcontinental central Europe, from planar to montane altitudes. In southern Europe it occurs from orosubmediterranean to mesomediterranean, ± semihumid zones. The vegetation is often thermophilous and includes various temperate humid (e. g., *Querco-Carpinetum*, *Fagetum*, *Alno-Fraxinetum*) forests but also mesosub- to mesomediterranean semihumid shrublands (e. g., *Quercetum ilicis*, or *Juniperetum thuriferae*). The not included collections are from a *Hibiscus* twig in subtropical humid southern Asia (Punjab) and an *Arbutus* branch in mild-maritime humid southwestern Canada.

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, 9.5 km SW of Southwold, 5.5 km NNE of Leiston, Minsmere Haven, 12 m, branch of *Quercus robur*, on wood, 3.VII.2004, S.M. Ceska (ø, doc. vid.).

Orbilia obtusispora Baral & E. Weber, **sp. nov.**, MB 813662 — Pls 595–597, Map 95

Etymology: derived from the predominantly obtuse ascospore apices.
Typification: France, La Tranche-sur-Mer, branches of *Quercus ilex*, 3.VI.2003, E. Weber & H.O. Baral (ex H.B. 7359a, M-0276539, holotype).

Latin diagnosis: *Similis* Orbiliae *trapeziformi sed ascosporae saepe longiores, apice obtusiores. Habitat ad lignum vel corticem putridum ramorum siccorum arborum angiospermarum*, *raro coniferarum vel ad caules herbarum*, *in locis thermophilis in zona temperata ad mediterranea Europae et Macaronesiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.9(–1) mm diam., 0.13–0.26 mm high, pale to usually bright (yellow-) orange(-apricot), rarely rose-orange or ochraceous, non- or medium translucent, round, sometimes elliptical, scattered to gregarious; disc slightly concave when young, soon ± flat, margin distinct, ± thick, 5–30 µm protruding (saucer-shaped), including exterior smooth to finely or strongly rough to crenulate; broadly sessile, rarely with an indistinct stipe up to 0.08 × 0.2 mm, superficial or slightly erumpent; dry light to deep orange–red, ± contracted, often distinctly cupulate with thick margin. **Asci** *(40–)50–80(–90) × ((4.5–))(5–)5.5–6.5(–7.5) µm {17}, †(48–)53–68(–78) × 4.5–5.3 µm {4}, 8-spored, spores *3–4-seriate, ((1–))(2–)3–5 lower spores inverted {16} (not or sometimes mixed), pars sporifera *24–39 → 18–24 µm long, †36–45 µm; **apex** (†) medium to strongly truncate (rarely indented, without lateral inflation); **base** with short to long, thin or thick, flexuous stalk, L- to Y-shaped. **Ascospores** *((5.5–))(6.5–)8–13(–14)((–15)) × (1.8–)2.1–2.5(–2.7) ((–3)) µm {30}, †(7–)8.5–11(–12.7) × 1.8–2.5 µm {4}, fusoid to fusoid-clavate, also narrowly ellipsoid to subcylindrical, apex obtuse to subacute, sometimes rounded, exceptionally acute, base slightly to strongly, rarely not attenuated, sometimes with a tail-like base, straight to slightly curved near base; **SBs** *((3–))(3.5–)4–7(–8.3) × (0.2–)0.3–0.8(–0.9) µm in situ {21} (~4–8.5 µm actual length), filiform to subulate, not or slightly to distinctly inflated towards base, straight to strongly flexuous, rarely uncinate; germinating spores *10.5–12.3 × 2.3–3.7 µm, with 1(–2) septa {1}. **Paraphyses** apically slightly to (very) strongly clavate-capitate, sometimes moniliform, terminal cells *(5–)7–20(–23) {8} × (2–)2.8–4.3(–4.8) µm {11}, lower cells *(5–)7–15(–17) × 1.2–2.2(–2.6) µm {7}; never branched at upper septum. **Medullary excipulum** subhyaline to light rose, 40–80 µm thick, of loose or dense textura intricata with many inflated cells, indistinctly delimited from ectal excipulum (at flanks partly very sharply by a horizontal t. porrecta), subhymenium pale to light orange.

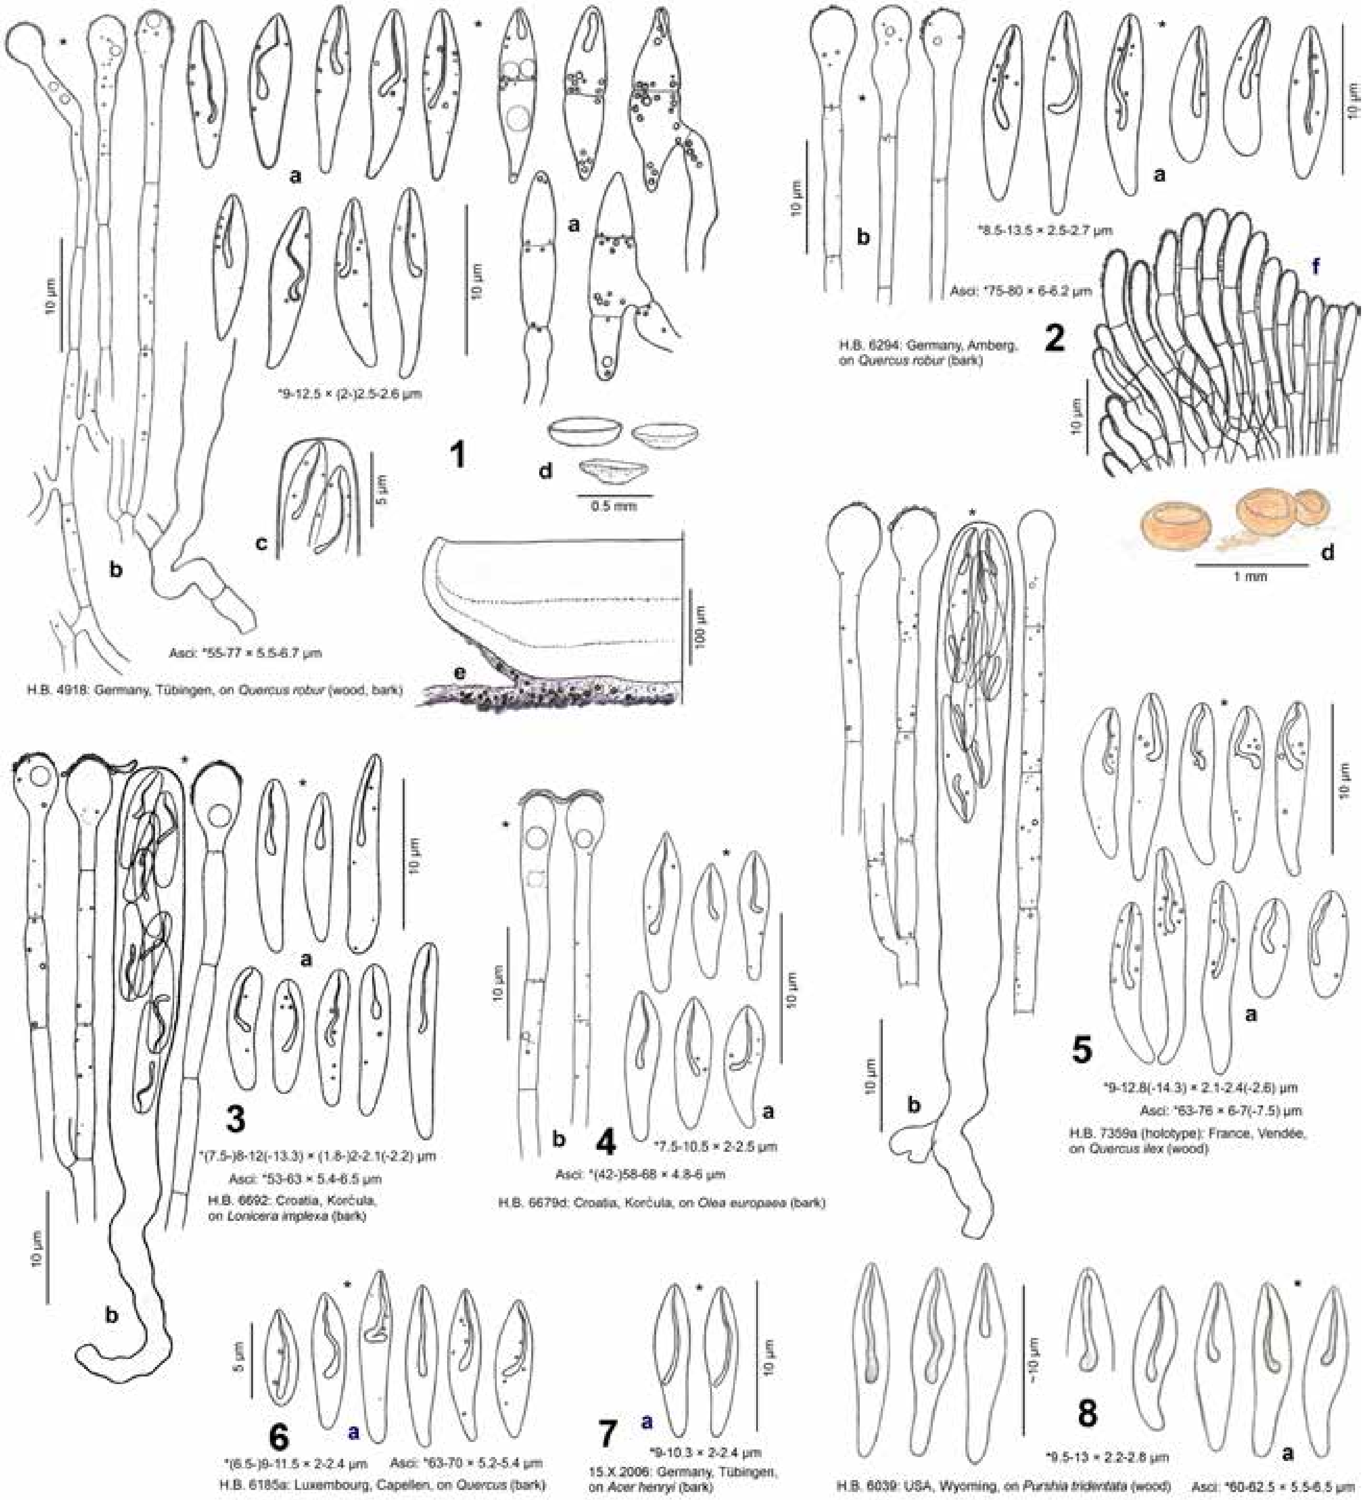

Plate 596. **1–7**: *Orbilia obtusispora*; **8**: *O.* cf. *obtusispora*. – **a**. ascospores (**1** right: germinating); **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum at upper margin.

Ectal excipulum subhyaline to light rose, of (†) thin-walled (to very slightly gelatinized), vertically (or horizontally) oriented t. angularis(-prismatica) from base to mid flanks, 25–70(–100) µm thick near base, cells *(6–)7–16(–22) × 5–11(–16)((–20)) µm {7}; 20–25(–30) µm thick at flanks, 15–30 µm thick at margin, at mid flanks and margin of t. globulosa-angularis oriented at a 60–90° angle to the surface, cells *5–11 × 4–7 µm {2}, marginal cortical cells *4–12 × 2–4.4 µm {4}, thin- or firm-walled. **Anchoring hyphae** very abundant, *2–3(–4) µm wide, walls 0.2–0.3(–0.5)((–0.7)) µm thick {7}, forming a dense or loose hyaline t. intricata 20–90 µm thick at base, often also covering flanks and margin by a 5–20 µm thick layer of ± gelatinized hyphae. **SCBs** in paraphyses and ectal excipulum (near margin) globose {8}, 1–2 µm diam., or consistently absent {6}. **Exudate** hyaline to pale yellowish-cream, over paraphyses (0.1–)0.2–0.5(–1.3) µm thick, granular-cloddy or finely rough, soon firmly attached; over margin and flanks forming a 0.1–0.3 µm thick continuous or granular layer. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {4}). **Conidiophores** not seen. **Conidia** Y-shaped, total size */†23–40 × 26–36 µm, stipe */†12–19 × 4–5 µm, 2–4-septate, arms */†18–25 × 4–5 µm, 3–5-septate, arms and stipe strongly tapering {4}; very rarely unbranched phragmoconidia observed.

Habitat: collected (0–)1–5 m above the ground, corticated or often half to entirely decorticated (often with the periderm rolling aside), 7–40 mm thick branches of *Acer henryi* {1}, *A. negundo* {1}, *Artemisia thuscula* {1}, *Atriplex hastata* {1}, *Castanea sativa* {2}, *Clematis vitalba* {1}, *Corylus avellana* {1}, *Cupressus macrocarpa* {1}, *Euphorbia balsamifera* {1}, *E. canariensis* {1}, *Ficus carica* {1}, *Fraxinus excelsior* {2}, *Hedera helix* {1}, *Laburnum anagyroides* {1}, *Lonicera implexa* {1}, *Olea europaea* {2}, *Populus* sp. {3}, *Prunus dulcis* {1}, *P. spinosa* {1}, *Quercus* sp. {10}, *Q. ilex* {2}, *Q. robur* {5}, *Rhamnus alpina* {1}, *Rubia fruticosa* {1}, stems of *Rubus fruticosus* agg. {1}, *Salix alba* {1}, on 0.1–3 mm (or even deeper) medium to mostly strongly decayed wood {28} and bark {17} (on bast, rarely periderm), if corticated then often on old *Vuilleminia* {9} or *Colpoma quercinum* {1} (with the periderm rolling apart), sometimes on boring dust of bark beetles, ± greyed or not (wood often white-rotten), with a few to many green algae. **Associated**: *Acanthostigma minutum* {1}, *Claussenomyces ?dacrymycetoideus* {1}, *Coenogonium* sp. {1}, *Colpoma quercinum* {1}, *Cryptodiscus foveolaris* {2}, *Dacrymyces* sp. {1}, *Frullania dilatata* {1}, *Hyalorbilia fusispora* {1}, *H. juliae* {1}, *H. latispora* {1}, *H. subfusispora* {1}, *Hyaloscypha minuta* {1}, *Hyphodiscus* sp. on *Vuilleminia* {1}, *Hysterium angustatum* {3}, *Lecanora* sp. {1}, *Lecophagus ellipsoideus* {1}, *Melanelia ?glabratula* {2}, *Mellitiosporiella pulchella* {1}, *Mollisia ligni* {1}, *?Monodictys* sp. {1}, *Orbilia eucalypti* {3}, *O. euonymi* {1}, *O. gambelii* {1}, *O. hesperidea* {1}, *O. myriosphaera* {1}, *O. pleioeuonymi* {1}, *O. subaristata* {1}, *O. ?tremulae* {1}, *O. vinosa* {4}, *O. vitalbae* {2}, *Orthotrichum* sp. {1}, *Parmelia caperata* {1}, *P. sulcata* {2}, *Patellaria atrata* {1}, *Physcia* sp. {3}, *Proliferodiscus pulveraceus* {1}, *Propolis farinosa* {3/1}, *P. viridis* {1}, *Sclerococcum* sp. {3}, *S. stygia* {1/1}, *Stictis* sp. {1}, *Xanthoria* sp. {3}. **Desiccation tolerance**: fully tolerant for at least about 1 month. **Altitude**: 5–880(–1650) m a.s.l. **Geology**: Devonian, Carboniferous & Permian (calcareous) sandstone, Keuper (clay, marl, sandstone), Lower to Upper Jurassic (sand- & limestone, Minette), Cretaceous limestone, Tertiary marl & molasse, Quaternary sand, silt & loess, peat; granite, gneiss, basaltic flow. **Phenology**: throughout the year (long-lived).

Phenology of *O. obtusispora*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
3	2	0	12	7	8	1	0	1	2	3	4

Taxonomic remarks. *Orbilia obtusispora* is similar to *O. trapeziformis*, from which it differs in ascospore shape: the spores of *O. obtusispora* tend to be subcylindrical with obtuse apices, though fusoid(-clavate) spores with subacute apices are also frequent. Typically, the apothecia are bright orange and rather large, with a thick protruding margin. The morphological distinction from the predominantly herbicolous *O. cylindrosoma* (p. 1068) and the subalpine *O. subtrapeziformis* (p. 1088) is also not very sharp. Also the distinction from *O. trapeziformis* and *O. filiformis* is sometimes difficult to draw, due to a variability in size and shape of spores and SBs. The few available sequence data indicate, however, that all these taxa merit distinction at the species level, except that the distance between *O. obtusispora* and samples of *O. trapeziformis* from France is very low.

The extra-European *O. macrotrapeziformis* and *O. flexisoma* differ from *O. obtusispora* in wider spores and SBs, whereas the Australian *O. acaciae* sharply differs in the presence of crystalloid SCBs. *O. vinosa* (section *Hemiorbilia*) may be confused with narrow-spored collections of *O. obtusispora* on account of somewhat similar spores and SBs, but is readily distinguished by hemispherical, thick-walled ascus apices, non-capitate paraphyses, and by narrower spores with straight, cylindrical SBs with a broader attachment. Five Australian specimens differ in longer spores and are described below as *O. austroobtusispora*.

Variation. Like *O. trapeziformis*, *O. obtusispora* varies in size (particularly length) and shape of the ascospores. Particularly collections from (sub)mediterranean western and southern Europe tend to have somewhat longer and/or narrower, more cylindrical spores with obtuse to rounded apices and only slightly attenuated bases (especially Pl. 596: 3) but specimens with more subacute apices and more tapered bases, or with short spores, also occur there. Moreover, some long-spored collections were also made in central Europe. Further variation of *O. obtusispora* was noted in the paraphyses, being apically only slightly to medium inflated in many of the collections, but partly strongly so in others. Also the presence of globose SCBs and their size vary among the populations.

Not included collections. A few collections were problematic in deciding whether they represent *O. obtusispora* or *O. trapeziformis*. Two from France (IVV: H.B. 8144) and Greece (Pl. 595: 6) have rather short spores of *7–10 × 2.3–2.7 µm, which are too obtuse to belong to *O. trapeziformis*. One from Germany (Pl 595: 3) is included in the above description despite its apically subacute spores. An old German record from Erlach (Oberfranken, mixture in lectotype of *O. vitalbae*, see p. 1176 and IVV) is somewhat uncertain because the morphology of the spore body is unknown.

Four North American samples on *Purshia* (Pl. 596: 8), *Cercocarpus* (IVV: 10.V.1995, 12.VI.1996), and *Shepherdia* (H.B. 7154a, unillustrated) appear to fit quite well European *O. obtusispora*, while differing from North American *O. flexisoma* and *O. macrotrapeziformis* in slightly narrower, from the former also in shorter spores. However, the limits between these taxa are not clear, and we prefer not to include extra-European samples in *O. obtusispora* at present. Another specimen (on *Larrea*, IVV: H.B. 5684g), resembles *O. obtusispora*, but the spores are a bit too small (~8–10 × 2 µm) and the apothecia rose-violaceous, therefore, it resembles also *O. vitalbae*.

Anamorph. The trinacrium-like conidia observed on the natural substrate hardly differ from those of the very closely related *O. trapeziformis*, whereas in *O. cylindrosoma* they show a tendency to longer arms and stipes.

Phylogeny. A sequence comprising SSU (without S1506 intron), ITS, and LSU was gained from apothecia of a sparse specimen of *O. obtusispora* from Luxembourg (IVV: H.B. 9635), showing a spore size of *(9–)11–13(–14) × 2.2–2.5(–3) µm. The rather low ITS distance of 1–1.2% to the two French collections of *O. trapeziformis* (0% in LSU) questions distinction of these two species, although spore length in the French collections was only *5–9 µm in H.B. 9151c (Pl. 594: 6d–e) and *7.5–10.5 µm in H.B. 9139 (Pls 592: 5). In our analyses of ITS and SSU+ITS+LSU, *O. obtusispora* and *O. trapeziformis* from France formed a strongly supported subclade which surprisingly clustered within the *Ellipsospermae* clade. However, a further collection of *O. trapeziformis* (from Germany) clustered in the *Serpentinae-Habrostictis* clade, far away from the former (Phyl. 19). Despite the morphological similarity, the ITS distance between *O. obtusispora* and *O. subtrapeziformis* lies at 16%.

Ecology. *O. obtusispora* grows on ± rotten wood and bark of xeric branches of various angiosperm trees and shrubs, often *Quercus*, exceptionally conifers, often on old fructifications of *Vuilleminia*, also on woody branches of *Euphorbia* spp. Its distribution within Europe is atlantic to subcontinental, warm- to cold-temperate or orotemperate humid but also mesosub- to thermomediterranean semihumid, occurring from

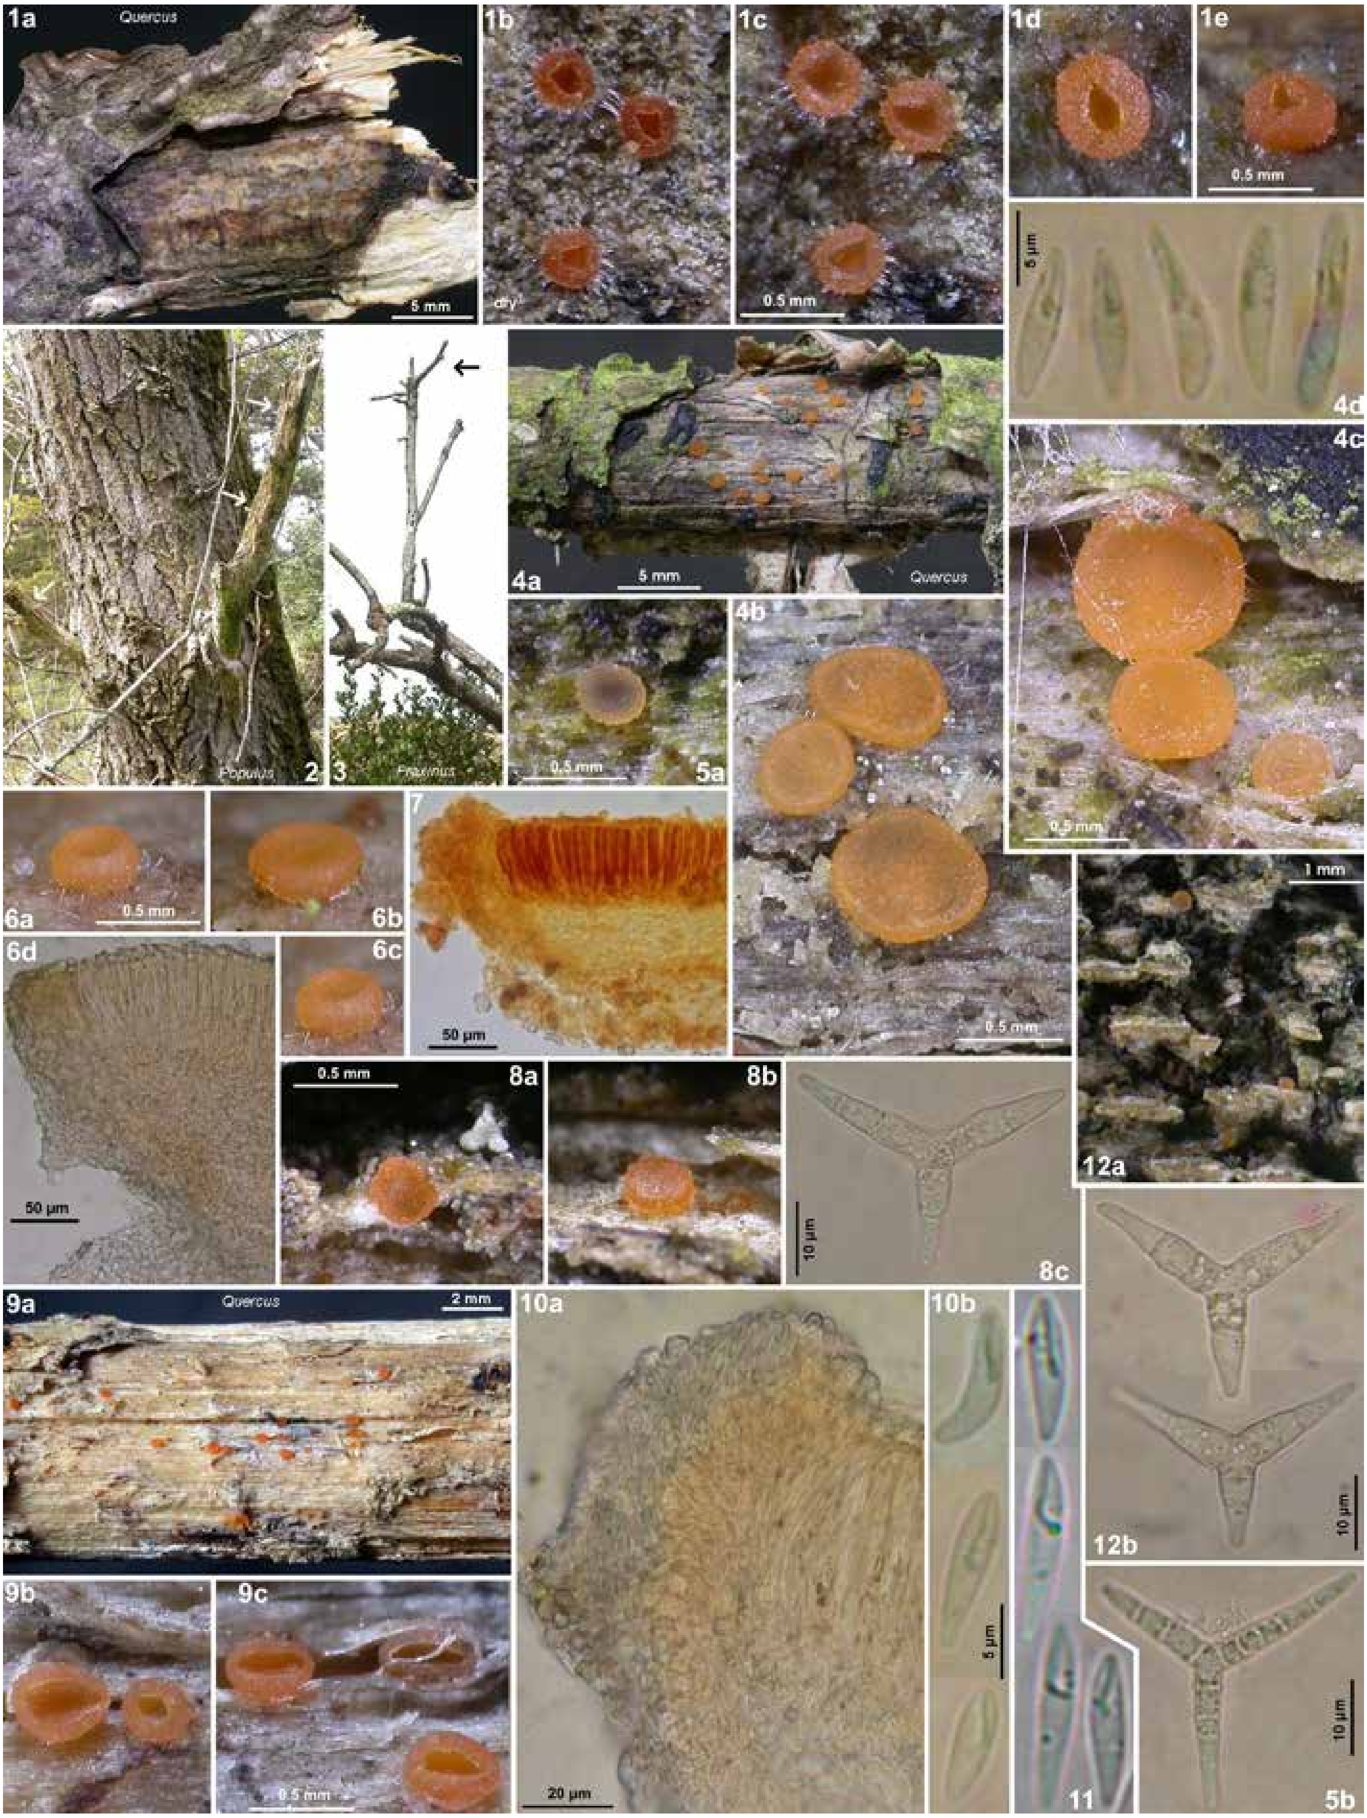

Plate 597. **1–11**. *Orbilia obtusispora*; **12**. *O.* cf. *obtusispora*. – **1a**, **2–3**, **4a**, **9a**. xeric decorticated or corticated branches; **12a**. inner surface of *Fagus* bark; **1c–e**, **4a–c**, **5a**, **6a–c**, **8a–b**, **9a–c**. rehydrated apothecia; **1b**. dry apothecia; **6d**, **7**. apothecia in median section; **10a**. id., marginal ectal excipulum; **4d**, **10b**, **11**. ascospores; **5b**, **8c**, **12b**. conidia from substrate. – Living state, except for **5b** (in H_2O), **7** (in KOH+IKI), some cells in **8c**, **12b**. — **1a–e**. H.B. 9289: France, Loire, on *Castanea*; **11**. 28.IV.2011: France, Île de Ré, on *Atriplex*; **12a–b**. H.B. 8144: France, Forêt d'Aulnay, on *Fagus*.

planar to montane altitudes, once even subalpine (Asturias). In Macaronesia it occurred on *Euphorbia* in the lower meso- and inframediterranean (semi)arid Tabaibal-Cardonal. The not included collections from western North America were in a boreal humid Douglas fir mixed forest of the Middle Rocky Mountains (*Purshia*) and cold-temperate subhumid pinyon-juniper woodlands of the Colorado Plateau (*Cercocarpus*, *Shepherdia*), also in a warm-temperate semiarid paloverde-mixed cacti desert scrub of the Sonoran Desert adjacent to Mogollon Rim (*Larrea*).

Specimens included. **GERMANY**: **Brandenburg**, 8.5 km NW of Fürstenwalde, 3 km NE of Hangelsberg, Forst Hangelsberg, 55 m, branch of *Quercus robur*, on bark & wood, 24.XI.2007, R.K. Schumacher (R.S., H.B. 8691). – **Thüringen**, 17 km NE of Coburg, 2 km W of Sonneberg, Schillings-Sandgrube, 370 m, branch of *Quercus*, on wood, 13.I.2010, I. Wagner (I.W. 100113 ø, doc. vid.). – **Baden-Württemberg**, 7 km NNW of Tübingen, 3.3 km NW of Bebenhausen, Glashau, 500 m, branch of *Quercus*, on wood & bark, 1.V.2002, H.O. Baral (H.B. 7125). – 2.7 km NW of Tübingen, Wanne, Arboretum, 470 m, branch of *Acer henryi*, on bark, 15.X.2006, H.O. Baral (ø). – 4 km N of Tübingen, 1 km WSW of Bebenhausen, Goldersbach, Schwefelbrünnele, 380 m, branch of *Prunus spinosa*, on wood & bark, 27.II.1992, H.O. Baral & E. Weber (ø). – 6.5 km NE of Tübingen, 1.5 km NNE of Pfrondorf, Brand, 460 m, branch of *Quercus robur*, on bark & wood, 18.VII.1993, H.O. Baral (H.B. 4918). – 0.5 km E of Pfrondorf, Auchtert, 400 m, branch of *Laburnum anagyroides*, on wood, 24.V.2003, H.O. Orbilia austroobtusispora Baral, **sp. nov.**, MB 813663 — Pls 598–599, Map 96

Etymology: named after the similarity to *O. obtusispora* and the occurrence in Australia.

Typification: Western Australia, Nerren Nerren, trunk of *Lamarchea hakeifolia*, 8.XI.2007, G. Marson (ex H.B. 9020c, MEL 2389275A, holotype).

Latin diagnosis: *Similis* Orbiliae obtusisporae *sed ascosporae longiores. Habitat ad lignum et corticem putridum rami sicci* Acaciae *et* Myrtacearum *in* *zona temperata humida ad subtropica semiarida Australiae occidentalis et orientalis.*

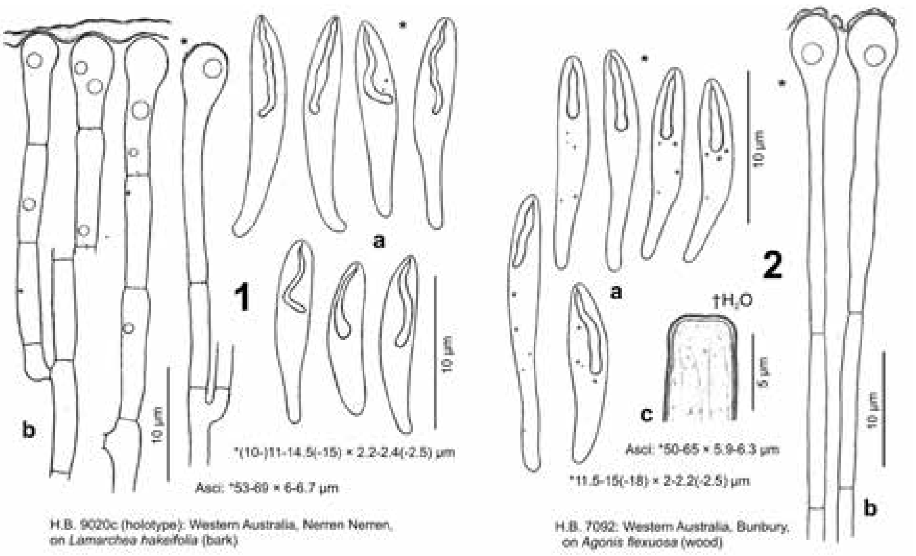

Plate 598. **1–2**: *Orbilia austroobtusispora*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.22–0.55 mm diam., 0.11–0.17(–0.2) mm high, (pale to) light orange(-red) or orange-rose, hardly translucent, round, scattered or in small groups; disc flat, margin distinct, (0–)5–20(–30) µm protruding (saucer-shaped), including exterior smooth to finely rough; broadly sessile or with a hidden stipe 40–60 × 60–90 µm, ± superficial. **Asci** *50–69 × 6–7(–8) µm {3}, †43–59 × 5.2–5.6(–6) µm {3}, 8-spored, spores †3–4-seriate, 2–6 lower spores inverted {5} (± mixed), pars sporifera *27–30 µm long; **apex** (†) strongly truncate (not or slightly indented and laterally inflated); **base** with short to medium long, thick, flexuous stalk, L- to h-shaped. **Ascospores** *(10–)11–16(–18) × 2–2.5 µm {4}, †(11–)12–15(–16.7) × (1.8–)2–2.2 µm {2}, cylindric- to fusoid-clavate, apex obtuse or partly subacute, base medium to mostly strongly attenuated, often with a tail-like base or distinct tail, straight to slightly curved; **SBs** *4–7.5 × (0.3–)0.4–0.8 µm in situ or actual length {4}, vermiform to subulate, not inflated at base, straight to medium or strongly flexuous; overmature 1–2-septate, apical cell swollen to *4.5 µm in width {T}. **Paraphyses** apically slightly to very strongly clavate-capitate, terminal cells *(7–)8–15(–21) {T} or 25–28 {1} × 3–4.3(–4.7) µm {2}, †3–4.7 µm wide {1}, lower cells *(5–)8–12(–15) × 1.4–2.3 µm {2}; exceptionally branched at upper septum. **Medullary excipulum** subhyaline to pale rose, 30–60 µm thick, of dense textura intricata with many inflated cells, medium to sharply delimited from ectal excipulum. **Ectal excipulum** subhyaline, of thin-walled, irregularly oriented t. globulosa-angularis from base to submargin, 25–45 µm thick near base, cells *(7–)8–14(–16) × (6–)8–11(–13) µm {2}; 15–30 µm thick at margin, of t. prismatica(-porrecta) oriented at a 10–50° angle to the surface, marginal cortical cells *5–10 × 2.5–4 µm {T}, †8–12 × 3–4.5 µm {1}. **Anchoring hyphae** medium abundant, *2–3.5 µm wide, walls 0.2–0.3 µm thick {T}. **SCBs** in paraphyses and often also ectal excipulum (near margin) globose {4}, 1–2 µm diam., rarely absent {1}. **Exudate** over paraphyses (0.2–)0.5–2 µm thick, cloddy-continuous, loosely to firmly attached, over margin and flanks 1–3 µm thick, forming large clods, hyaline to pale yellowish. — **ANAMORPH**: unknown.

Habitat: collected 1–3 m above the ground, corticated to decorticated, 7–13 mm thick branches of *Acacia* sp. {1}, *Agonis flexuosa* {1}, *Eucalyptus* sp. {1}, *Lamarchea hakeifolia* {1}, *Melaleuca* sp. {1}, on 0.1 mm deep strongly decayed wood {3} or bark (bast & periderm) {4}, on outer and sometimes inner surface of bark {T}, ± strongly greyed, without or with sparse to abundant green algae. **Associated**: *Capronia* sp. {1}, *Claussenomyces* sp. {1}, *Frullania* sp. {1}, *Gloniopsis praelonga* {1}, *Hyalorbilia pleioerythrostigma* {1}, *Hysterium angustatum* {1}, *Ionomidotis ?australis* {1}, *Opegrapha ?varia* {1}, *Orbilia acaciae* {1}, *O. amberina* {1}, *O. australiensis* {1/1}, *O. austrocylindrica* {1}, *O. aviflagellata* {1}, *O. ?cejpii* {1}, *O. gemma* {1}, *O. helicoobliqua* {1}, *O. hesperidea* {1}, *O. kingsiana* {1}, *O. lamarcheae* {1}, *O. microserpens* {2}, *O. multiserpens* {1}, *O. myriolilacina* {2}, *O. myrioobliqua* {1}, *O. nothovinosa* {2}, *O. paraobliqua* {1}, *O. pleioaustraliensis* {1}, *O. pleioaustrocylindrica* {1}, *O. pseudoflagellispora* {1}, *O. pubescens* {1}, *Ostropales* {2}, *Patellaria ?andina* {1}, *?Triblidium* sp. {1}, *Symbiotaphrina desertorum* {1}, *?Xerotrema* sp. {1}, foliose lichen {1}. **Desiccation tolerance**: fully viable for at least 2 years, after 7.5 years many excipular cells still alive. **Altitude**: 10–1073 m a.s.l. **Geology**: Archean, Permian-Triassic and Cretaceous sedimentary rock, Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia austroobtusispora* closely resembles the European (and North American) *O. obtusispora* and *O. cylindrosoma* in spore shape, concerning *O. cylindrosoma* also in tending to vermiform SBs. It differs from both in a strong tendency to longer spores. Although in *O. obtusispora* rarely a few extraordinarily long spores were encountered (Pl. 596: 5), each of the five Australian specimens included in *O. austroobtusispora* showed some spores of at least 15 µm in length. Often the spores have a tail-like base, while such spores are only exceptionally seen in *O. obtusispora* from Europe and USA. *O. obtusispora* usually differs also in a thinner exudate.

Variation. The sample on *Agonis* shows vermiform SBs similar to *O. cylindrosoma*, while in other records the SBs are partly (holotype) or consistently subulate. In the *Agonis* sample the cells of the paraphyses are much longer than in the type. The paraphysis apices are only slightly to medium inflated in the type while often (very) strongly inflated in the other specimens.

Ecology. *O. austroobtusispora* grew on wood and bark of xeric branches of *Acacia* and different *Myrtaceae*, mainly in subtropical semiarid to semihumid eucalypt open woodlands in southwestern and eastern Australia, and in a warm-temperate humid eucalypt open forest in southeastern Australia (Great Dividing Range).

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 78 km NE of Wubin, 18 km W of Mt. Singleton, 380 m, branch of *Acacia*, on wood & bark, 24.XI.2001, G. Marson (H.B. 7204n). – Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, trunk of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (ex H.B. 9020c, MEL 2389275A, **holotype**). – Swan Coastal Plain, 14 km NNE of Bunbury, 6 km S of Binningup, 10 m, branch of *Agonis flexuosa*, on wood, 17.XII.2001, G. Marson (H.B. 7092 ø). – **Queensland**, Brigalow Belt South, 80 km N of Goondiwindi, 10 km S of Moonie, 278 m, branch of *Melaleuca*, on wood & bark, 23.X.1998, G. Marson (ø). – **New South Wales**, Sydney Basin, 95 km WNW of Sydney, 11.5 km SE of Lithgow, SE of Mt. York, 1073 m, branch of *Eucalyptus*, on bark, 26.X.1998, G. Marson (H.B. 6782 ø).

Orbilia pleioobtusispora Baral, **sp. nov.**, MB 813664 — Pl. 600

Etymology: named after the 16-spored asci and the ascospores resembling *O. obtusispora*.

Typification: Australia, Northern Territories, Yulara, branch of *Allocasuarina decaisneana*, 12.X.1998, G. Marson (ex H.B. 6617e, MEL 2389214A, holotype).

Latin diagnosis: *Similis* Orbiliae obtusisporae *sed asci 16-spori*, *ascosporae multo minores. Habitat ad lignum putridum rami sicci* Allocasuarinae decaisneanae *in zona subtropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.35 mm diam., 0.09 mm high, pale rose-cream-greyish, round, subgregarious in a small group; disc flat, margin thin, 10 µm protruding, smooth; broadly sessile, superficial. **Asci** *40–54 × 5.4–5.8 µm, †42–54 × 4.8–5.6 µm, 16-spored, spores *4–5-seriate, lower spores inverted (± mixed), pars sporifera *25–28 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to medium long, ± thin stalk, L-shaped. **Ascospores** *6–7.5(–8.3) × 1.7–1.9(–2) µm, †5.5–7.5 × 1.5–2 µm, subcylindrical, sometimes slightly clavate or slightly fusoid, apex rounded to obtuse, base rounded, not or only very slightly attenuated, straight or very slightly inequilateral; **SBs** *2.8–3.5(–3.8) × 0.3–0.4 µm, ± subulate, not or very slightly swollen at base, straight to slightly flexuous. **Paraphyses** apically slightly to medium (rarely strongly) clavate-capitate, terminal cells *5.5–15.5 × 3.8–5 µm, lower cells *8–11 × 1.8–2.5(–3) µm; unbranched at upper septum. **Medullary excipulum** 15 µm thick, of ± dense textura intricata with some inflated cells, medium sharply delimited. **Ectal excipulum** of (†) thin-walled, irregularly oriented t. angularis from base to submargin, 20 µm thick near base, cells †6–10 × 5–8 µm; 10–15 µm thick near margin, of t. prismatica oriented at a 10–30° angle to the surface, marginal cortical cells †8–10 × 2–4 µm. **Anchoring hyphae** ± sparse, †1.6–3.3 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose, 1–2.7 µm diam. **Exudate** over paraphyses 0.5–1 µm thick, granular-cloddy, firmly attached to each paraphysis; over margin and flanks 0.2–1 µm thick scattered granules. **— ANAMORPH**: unknown.

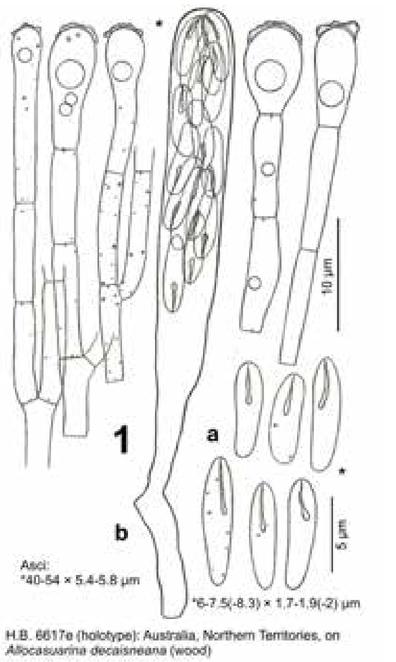

Plate 600. **1**: *Orbilia pleioobtusispora*. – **a**. ascospores; **b**. ascus and paraphyses.

Habitat: collected 3–4 m above the ground, decorticated, 8 mm thick branch of *Allocasuarina decaisneana*, on 0.2 mm deep strongly decayed wood, strongly greyed, no algae. **Associated**: *Orbilia macrotrapeziformis*, *O. multivinosa*, *O. phanosoma*, *O. pleiolentiformis*, *O. pleiovitalbae*, *O. pluristomachia*, *O. serpentina*, *Teichosporella dura*, *Symbiotaphrina desertorum*. **Desiccation tolerance**: fully tolerant for at least 20 months. **Altitude**: 500 m a.s.l. **Geology**: Cenozoic regolith (red-brown sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleioobtusispora* is very similar to *O. pleioungulata*, from which it mainly differs in the absence of crystalloid SCBs. It deviates from *O. obtusispora*, besides 16-spored asci, in distinctly smaller ascospores and narrower spore bodies.

Ecology. Only a few apothecia were found in the type collection, which grew on rotten wood of a xeric branch of *Allocasuarina decaisneana* in a subtropical arid acacia open shrubland northeast of Ayers Rock at the southeastern end of the Great Sandy Desert of central Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Great Sandy Desert, 11.5 km ENE of Yulara, 14 km NNE of Ayers Rock (Uluru), 500 m, branch of *Allocasuarina decaisneana*, on wood, 12.X.1998, G. Marson (ex H.B. 6617e, MEL 2389214A, **holotype**).

Orbilia cylindrosoma Baral, E. Weber & G. Marson, **sp. nov.**, MB 813665 — Pls 601–603, Map 97

Etymology: named after the predominantly cylindrical spore bodies.

Typification: Germany, Stuttgart, branch of *Lonicera*, 23.VI.2000, H.O. Baral (ex H.B. 6711, M-0276469, holotype; ex-type culture: CBS 116233; sq.: KT215244).

Latin diagnosis: *Similis* Orbiliae obtusisporae *sed corpuscula refringentia ascosporarum vermiformia, apothecia caules siccos herbarum sed etiam lignum, raro corticem putridum ramorum arborum vel fruticum deciduarum incolentes, in locis thermophilis in zona temperata humida et mediterranea semihumida ad semiarida Europae centralis et meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.15–0.4(–0.5) mm diam., 0.1–0.16 mm high, very pale to light cream-rose-orange to orange, rarely pure rose, slightly or medium translucent, round, very scattered to subgregarious, rarely gregarious in small groups; disc flat, sometimes slightly convex, margin distinct or not, 0–5 µm protruding, smooth to finely rough; broadly sessile, superficial to slightly erumpent; dry light to bright (rose-)orange. **Asci** *(37–)40–60(–65) × (4.4–)5–6(–6.5) µm {8}, †33–55 × 4.5–5.2(–5.5) µm {3}, 8-spored, spores *3-seriate, ((2–))3–5(–6) lower spores inverted {11} (rarely mixed), pars sporifera *18–26(–29) µm long; **apex** (†) strongly truncate (not or slightly to distinctly indented, laterally sometimes inflated); **base** with short to medium long, ± thick, flexuous stalk, L- to T-shaped. **Ascospores** *((5.5–))(6–)7.5–11(–12.5)((–13.5)) × (1.8–)2–2.5(–2.8)((–3.1)) µm {17}, †(6.5–)7.5–9(–10) × (1.5–)1.7–2(–2.2) µm {2}, fusoid to fusoid-clavate, sometimes narrowly ellipsoid or subcylindrical, apex obtuse to subacute, sometimes acute, exceptionally rounded, base slightly to medium (rarely strongly) attenuated, straight to slightly curved at base; **SBs** *(3–)3.5–5(–5.5)((–6)) × ((0.2–))(0.3–)0.4–0.8(–0.9) µm in situ or actual length {13}, vermiform to subulate, base not or slightly inflated, sometimes slightly constricted, straight to slightly, exceptionally strongly flexuous, overmature 1.5–4 × 0.8–1.2 µm, pear-shaped to globose. **Paraphyses** apically medium to very strongly capitate(-clavate), terminal cells *(4.5–)7–17(–19) × (2–)3–5(–5.5) µm {9}, lower cells *((4–))(5.5–)7–12 × 1.3–2(–2.3) µm {8}; exceptionally branched at upper septum. **Medullary excipulum** 10–40 µm thick, of dense textura intricata with many inflated cells, hardly to sharply delimited. **Ectal excipulum** subhyaline, of thin-walled, irregularly oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 30–60 µm thick near base, cells *7–20 × 6–15(–18.5) µm {2}; 20–30 µm at margin, of t. prismatica(-angularis) oriented at a 40–80° angle to the surface, marginal cortical cells */†5–10(–12) × 3–4.5 µm {3}, inner cells *10–12 × 4–6.5 µm. **Anchoring hyphae** sparse to abundant, *2–3 µm wide, walls 0.2 µm thick {2}, not covering flanks and margin. **SCBs** in paraphyses and often also ectal excipulum (near margin) globose {10}, rarely absent {1}, (1–)1.5–2(–3) µm diam., in excipulum 1.5–3.5 µm. **Exudate** over paraphyses 0.2–1(–2) µm thick, granular-cloddy, soon firmly attached; over margin and flanks 0.3–2 µm thick, rough-cloddy to continuous. **— ANAMORPH**: trinacrium-like (from ascospore isolate {2} and natural substrate {7}). **Conidiophores** *16 × 2–2.2 µm, conidia formed terminally. **Conidia** Y-shaped, total size *28–45 × 30–50 µm, †26–33 × 22–41 µm, stipe *12–22 × 4–6 µm, †13–18 × 3.8–4 µm, (1–)2–4-septate, arms *20–30(–38) × (3.2–)4–5.5 µm, †(14–)16–24 × 3.5–4 µm, 2–4-septate {11}, arms and stipe strongly tapering.

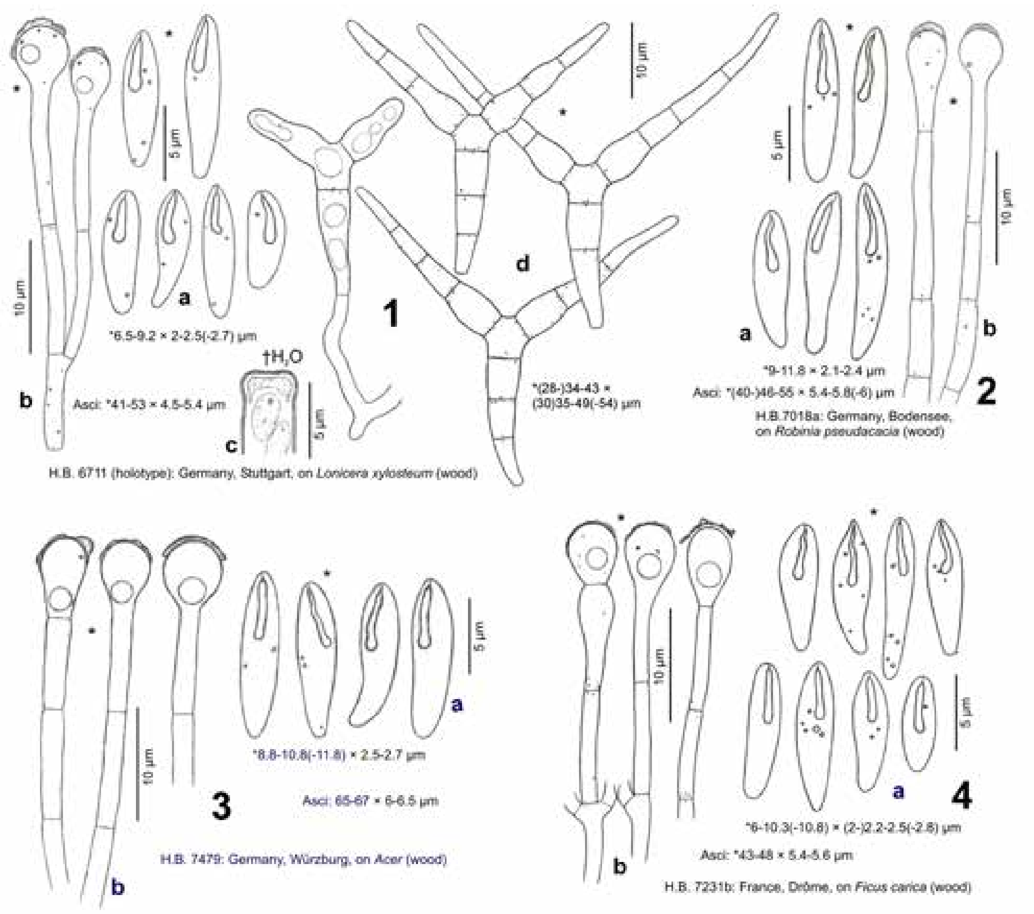

Plate 602. **1–4**: *Orbilia cylindrosoma* on woody substrates. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. conidia from culture.

Geology: Keuper (gypsum), Lower Jurassic sandstone & shale, Tertiary molasse, Quaternary silt & sand; gabbro & basalt. **Phenology**: I–II, IV–X (throughout the year, long-lived).

Taxonomic remarks. *Orbilia cylindrosoma* closely resembles *O. obtusispora* in ascospore shape and size. The taxon is tentatively separated because of the spore bodies being more vermiform instead of subulate or filiform, i. e., predominantly rather broad up to the subapex and only slightly inflated at the lower end. This difference is not sharp, however, especially since in some collections the spore body shape was not very constant, perhaps as a result of different degrees of maturity, or of external influence (Pl. 601: 1a), and in some of the spores the SBs were distinctly subulate. In any case, the frequent cylindrical, vermiform shape was correlated with the rather frequent occurrence on herbaceous substrates, whereas in only one sample of *O. obtusispora* the SBs were rarely cylindrical (Pl. 595: 4). Collections on woody substrates are considered as conspecific with samples on herbaceous stems. As a tendency, *O. cylindrosoma* has basally slightly less tapered spores and smaller, paler coloured apothecia with less protruding margins in comparison to *O. obtusispora*. Further possible characteristics of *O. cylindrosoma* are a less differentiated marginal excipulum of wider cells oriented at a high angle, the absence of hyphae covering flanks and margin, also a tendency to more inflated paraphyses with larger SCBs. *O. trapeziformis* differs in somewhat shorter and wider spores, and in SBs being consistently narrowed towards apex (subulate) and abruptly inflated at the base. For the similar Australian *O. austroobtusispora* see below.

Variation. Differences between specimens from woody and herbaceous substrates could not be found. The ascospore apex varies rather strongly between obtuse and subacute, sometimes acute, even within a collection (see especially Pls 601: 6; 602: 4). As already stated above, the observed variation in SB shape occurs occasionally within a collection and has obviously no molecular origin. Variation between vermiform and subulate SBs was noted in most of the specimens, though the vermiform (cylindrical) shape predominated. In addition to this, spore length and also width vary considerably within several of the included specimens (e. g., Pl. 601: 1a).

Not included collections. In two samples on herbaceous stems (*Foeniculum*, Pl. 601: 7; ?*Cirsium*, IVV: 27.V.1999) only subulate SBs were seen, therefore these are not included in the description. Spores and SBs resemble also *O. obtusispora*, but this species was not yet found with certainty on herbs.

Anamorph. The trinacrium robustum-like conidia of *O. cylindrosoma* resemble those observed in the very close *O. obtusispora* and *O. trapeziformis* but differ in longer arms and stipes. *O. cylindrosoma* frequently grows in association with *O. flavida* (section *Lentiformes*). Both species have similar conidia, but those of *O. flavida* have distinctly shorter arms.

Phylogeny. A sequence was taken from the ex-type culture, comprising SSU (without S1506 intron), ITS, and LSU. When analysing the ITS region, *O. cylindrosoma* clustered with a 6 % distance with the German collection of *O. trapeziformis* in a highly supported subclade that stands unresolved in the *Serpentinae-Habrostictis* clade (Phyl. 19). However, *O. cylindrosoma* strongly deviates in this region from the morphologically similar *O. obtusispora* and the two French collections of *O. trapeziformis* (17 % distance and many gaps and indels) which fell in the *Ellipsospermae* clade. *O. cylindrosoma* showed a rather high distance to any further species of series *Serpentinae*: min. 12 % in the ITS to *O. multimaeandrina* (2.7 % in LSU) and min. 1.4 % in the LSU to *O. carpoboloides* (20 % in ITS).

Ecology. *O. cylindrosoma* was collected on xeric herbaceous stems of dicot (rarely monocot) plants and on rotten wood (and bark) of xeric branches of different angiosperms. The collections are mainly from subcontinental, cold-temperate humid central Europe, but also from suprasub- to mesosubmediterranean and mesomediterranean semihumid to semiarid southwestern Europe (thermomediterranean for the not included collection

Orbilia acaciae Baral & G. Marson, **sp. nov.**, MB 813666 — Pls 604–605, Map 98 [non *Orbilia acaciae* Gaikwad, nom. nud., ?section *Helicoon*]

Etymology: named after the substrate of the type, *Acacia georginae*.

Typification: Australia, Queensland, Karoon Station, branches of *Acacia georginae*, 16.X.1998, G. Marson (ex H.B. 6615b, BRI AQ799189, holotype).

Latin diagnosis: *Similis* Orbiliae obtusisporae *et* O. cylindrosomati *sed cellulae excipuli et paraphysium in statu vivo corpuscula crystalloidea continentes. Habitat ad lignum putridum ramorum siccorum arborum angiospermarum, etiam ad petiolos* Livistonae *et caules* Euphorbiae, *in zona tropica vel subtropica subhumida ad hyperarida Australiae, Africae australis et Macaronesiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.5(–0.7) mm diam., (0.12–)0.14–0.21(–0.25) mm high, (pale to) light (to bright) (rose-)orange(-ochraceous), not or slightly translucent, round (to elliptical), scattered to subgregarious; disc slightly concave to flat, margin distinct, 0–20 µm protruding, smooth or often (very) finely rough to crenulate or fimbriate; broadly sessile, superficial to slightly or strongly erumpent; dry bright orange, slightly to strongly contracted. **Asci** *(35–)40–65(–72) × (5–)5.5–6.5(–7) µm {6}, †40–60 × 4.7–5.7 µm {3}, 8-spored, spores *2–3-seriate, (2–)3–5(–7) lower spores inverted {6} (sometimes mixed), pars sporifera *(19–)23–28(–31) µm long; **apex** (†) medium to strongly truncate (not indented, laterally distinctly inflated or not); **base** without or with short to long, thin or thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(6–)7.5–11(–13.3) × ((1.8–))2.1–2.7((–2.8)) µm {7}, subcylindric to narrowly ellipsoid or often fusoid-clavate, apex obtuse, sometimes rounded or subacute, base mostly slightly to medium (exceptionally strongly) attenuated, sometimes forming a short and thick tail, straight or slightly (rarely medium) curved, especially near base; **SBs** *(2–)2.5–4.5(–5.2) {6} × 0.2–0.5(–0.6) {5} or (0.5–)0.6–0.9 {1} µm (in situ and actual length), filiform to subulate, not or slightly inflated at base, straight to slightly flexuous, rarely uncinate. **Paraphyses** apically slightly to medium clavate-capitate, in some collections (not) rarely ellipsoid to subspathulate, terminal cells */†5.5–18 × (2–)2.5–4.2(–5) µm {7}, lower cells *(5.5–)7–12(–15) × 1.3–2.5(–3.3) µm {6}; rarely branched at upper septum. **Medullary excipulum** very pale orange, 25–60 µm thick, of dense textura intricata with many inflated cells, sharply delimited only at flanks. **Ectal excipulum** pale orange, of (†) thin-walled, indistinctly to vertically oriented t. angularis or t. prismatica from base to margin, (40–)60–80(–105) µm thick near base, cells *8–17 × 7–12 µm {2} or (10–)15–35(–45) × (8–)10–17(–20) µm {1}; 15–30 µm thick near margin, oriented at a (0–)10–45° angle to the surface, marginal cortical cells */†7–11(–13) × (2–)2.5–4(–5) µm {5} or *6–8 × 5–6 µm {1}, often protruding as 10–20 µm long 1-septate hairs which converge by forming small teeth {4}, also hairless {2}. **Anchoring hyphae** ± sparse, *2–3 µm wide, walls 0.2 µm thick {2}, sometimes also covering the margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–3 µm diam.; also rod- or ring- to horseshoe-shaped {6}, hyaline to very pale orange, in excipulum at flanks 3–9 × 2–4.5 µm. **Exudate** over paraphyses 0.2–1(–2) µm thick, rough, firmly attached; over margin and flanks ± absent or usually 0.1–0.3 µm {2} up to 0.2–1.5(–4) µm {4} thick, rough to cloddy, very pale to light yellow-chlorinaceous. **— ANAMORPH**: unknown.

Habitat: collected 0.2–5 m above the ground, decorticated, 4–25 mm thick twigs and branches of *Acacia georginae* {1}, *Brachychiton gregorii* {1}, *Euphorbia canariensis* {5}, *Geijera parviflora* {1}, *Melaleuca* sp. {1}, *Vachellia erioloba* {1}, 0.2–1 mm deep strongly decayed wood {6}, also on petioles of *Livistona nitida* {1}, slightly to strongly greyed, no algae. **Associated**: *Capronia* sp. {1}, *Diatrypaceae* {1}, *Frullania* sp. {1}, *Gloniopsis* sp. {1}, *Hyalorbilia ?orbiliicola* (parasitic on *O. acaciae*) {1}, *Hysteropatella* sp. {1}, *Mellitiosporiella* sp. {1}, *Orbilia albidorosea* {1}, *O. asomatica* {1}, O. ?*australiensis* {2}, *O. austroobtusispora* {1}, *O. brachychitonis* {1}, *O. cejpii* {1}, *O.* ?*commarosa* {1}, *O. corculispora* {1}, *O. coronohesperidea* {1}, O. ?*dixiensis* {1}, *O. geijerae* {1}, *O. livistonae* {1}, *O. microserpens* {1}, *O. multiserpens* {1}, *O. myrioeuonymi* {1}, *O. nothovinosa* {1}, *O. palmicola* {1}, *O. parviclava* {1}, *O.* ?*pleiogambelii* {1}, *O. pleiohesperidea* {1}, *Rhytidhysteron* sp. {1}, *Thyronectria* sp. {1}. **Desiccation tolerance**: fully tolerant for at least 25 months. **Altitude**: 10–570 m a.s.l. **Geology**: Permian & Jurassic sedimentary rock, Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia acaciae* resembles European *O. obtusispora* and *O. cylindrosoma* in the ascospores and a slightly crenulate or hairy margin, but differs in abundant crystalloid SCBs in paraphyses and excipulum which are absent in those species. Because of its spore shape *O. acaciae* might better be placed in series *Ellipsospermae*. For instance, it can be compared with the southern European *O. subvitalbae* on monocots, sharing similar spores and crystalloid SCBs. *O. subvitalbae* differs in shorter and wider spores, basally inflated SBs, and a smooth margin (though *O. acaciae* has sometimes a smooth margin too). Also the Australian *O. octocercocarpi* (p. 1212) differs from *O. acaciae* in wider spores and appears to show closer affinities to *O. gambelii*. *O. ungulata* differs in distinctly smaller spores and is so far only known from Europe, and *O. pleioungulata* mainly differs in 16-spored asci and slightly smaller spores while showing a similar distribution as *O. acaciae*.

Variation. The collection on petioles of *Livistona* differs from the six on woody substrates (including that on *Euphorbia*)

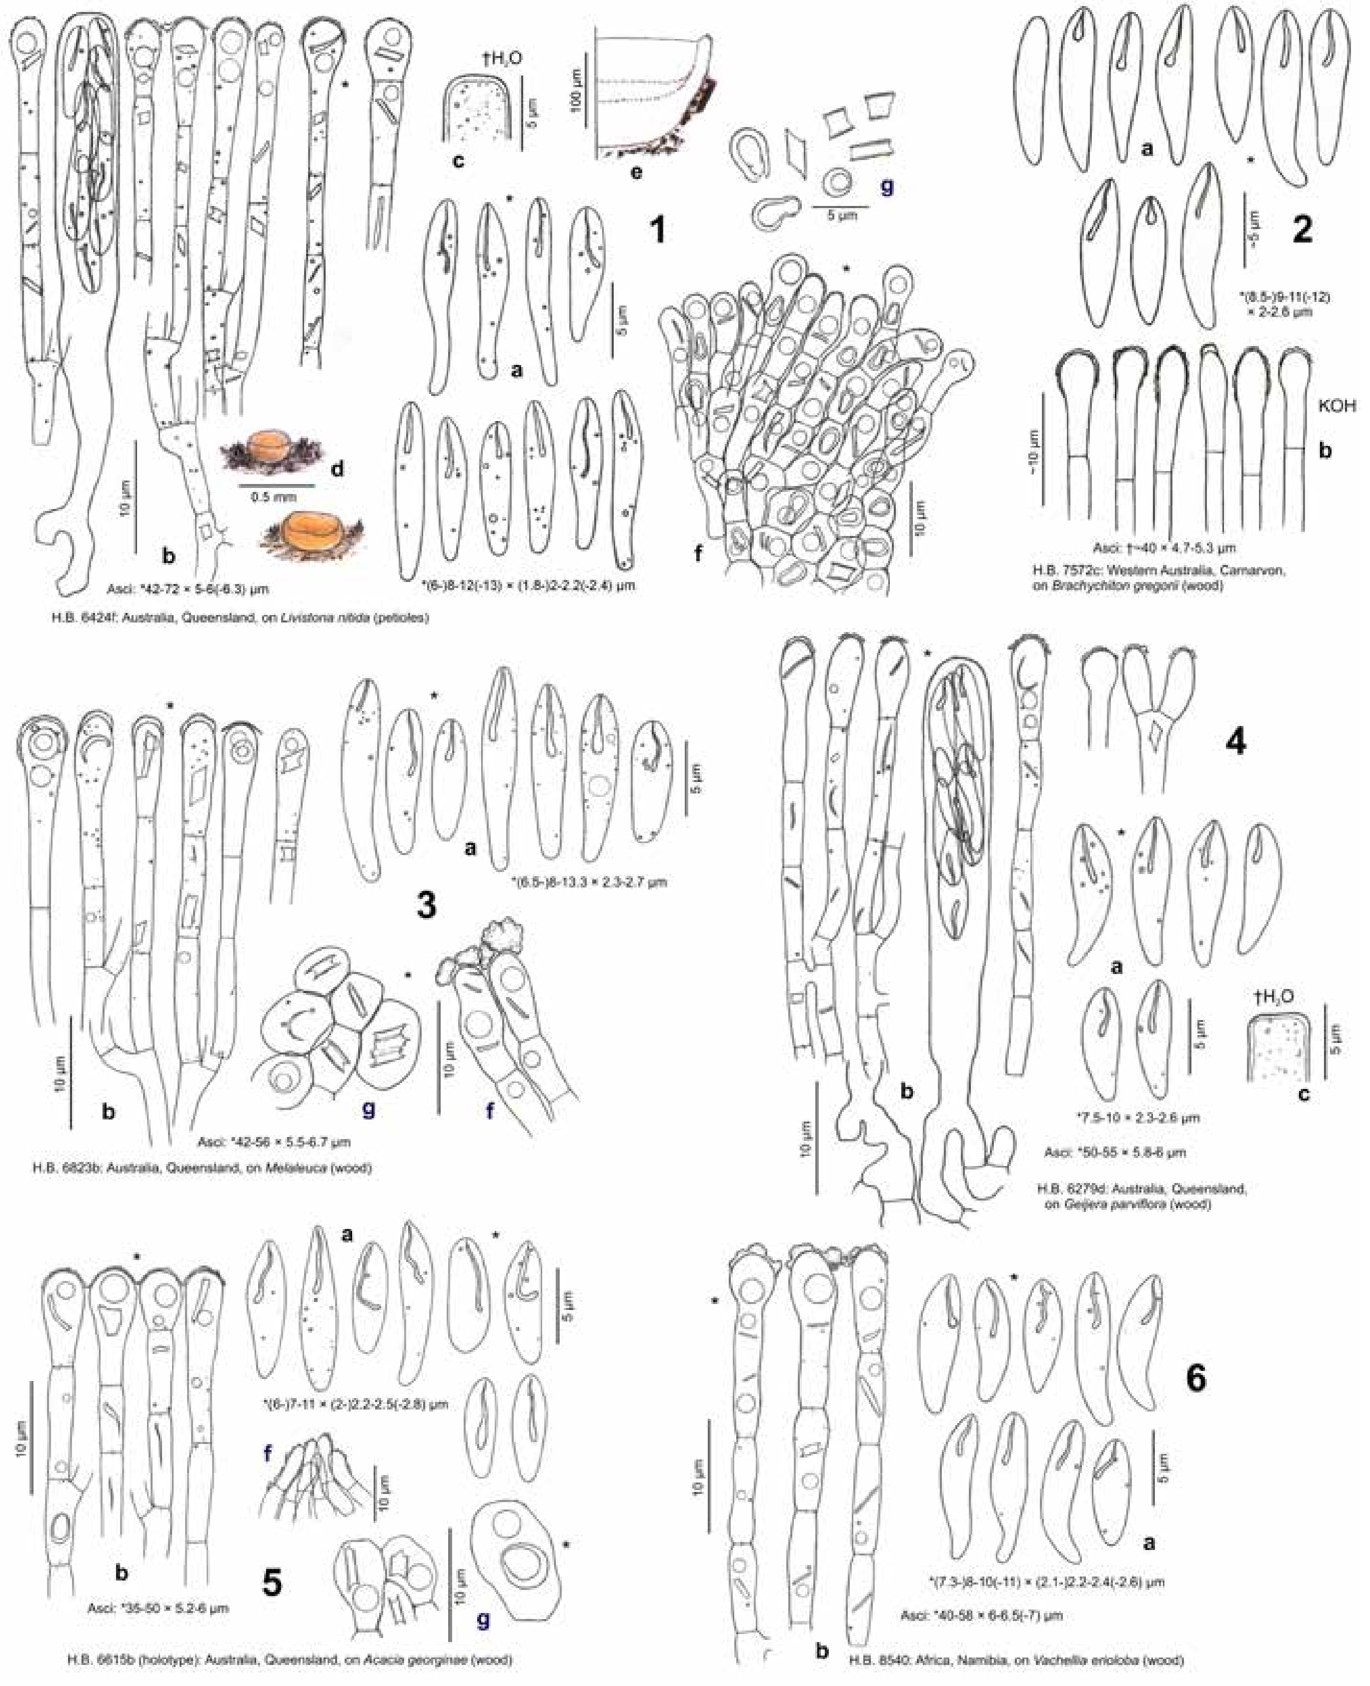

Plate 604. **1–6**: *Orbilia acaciae*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum (but surface view in **5f**); **g**. crystalloid SCBs in cells of ectal excipulum.

in slightly narrower spores, but the other collections also vary in spore length and width. The southwestern African and Macaronesian collections here referred to *O. acaciae* are without hair-like protrusions at the margin, and also in most of the Australian collections some of the apothecia had rather smooth margins. In the only collection from western Australia (Pl. 604: 2, on *Brachychiton*) merely the spores were viable when studied, therefore, its identity remains a bit unsure.

In the Macaronesian collections on *Euphorbia* (Pl. 605: 3) the SBs were distinctly wider (0.5–0.9 instead of 0.2–0.6 µm),

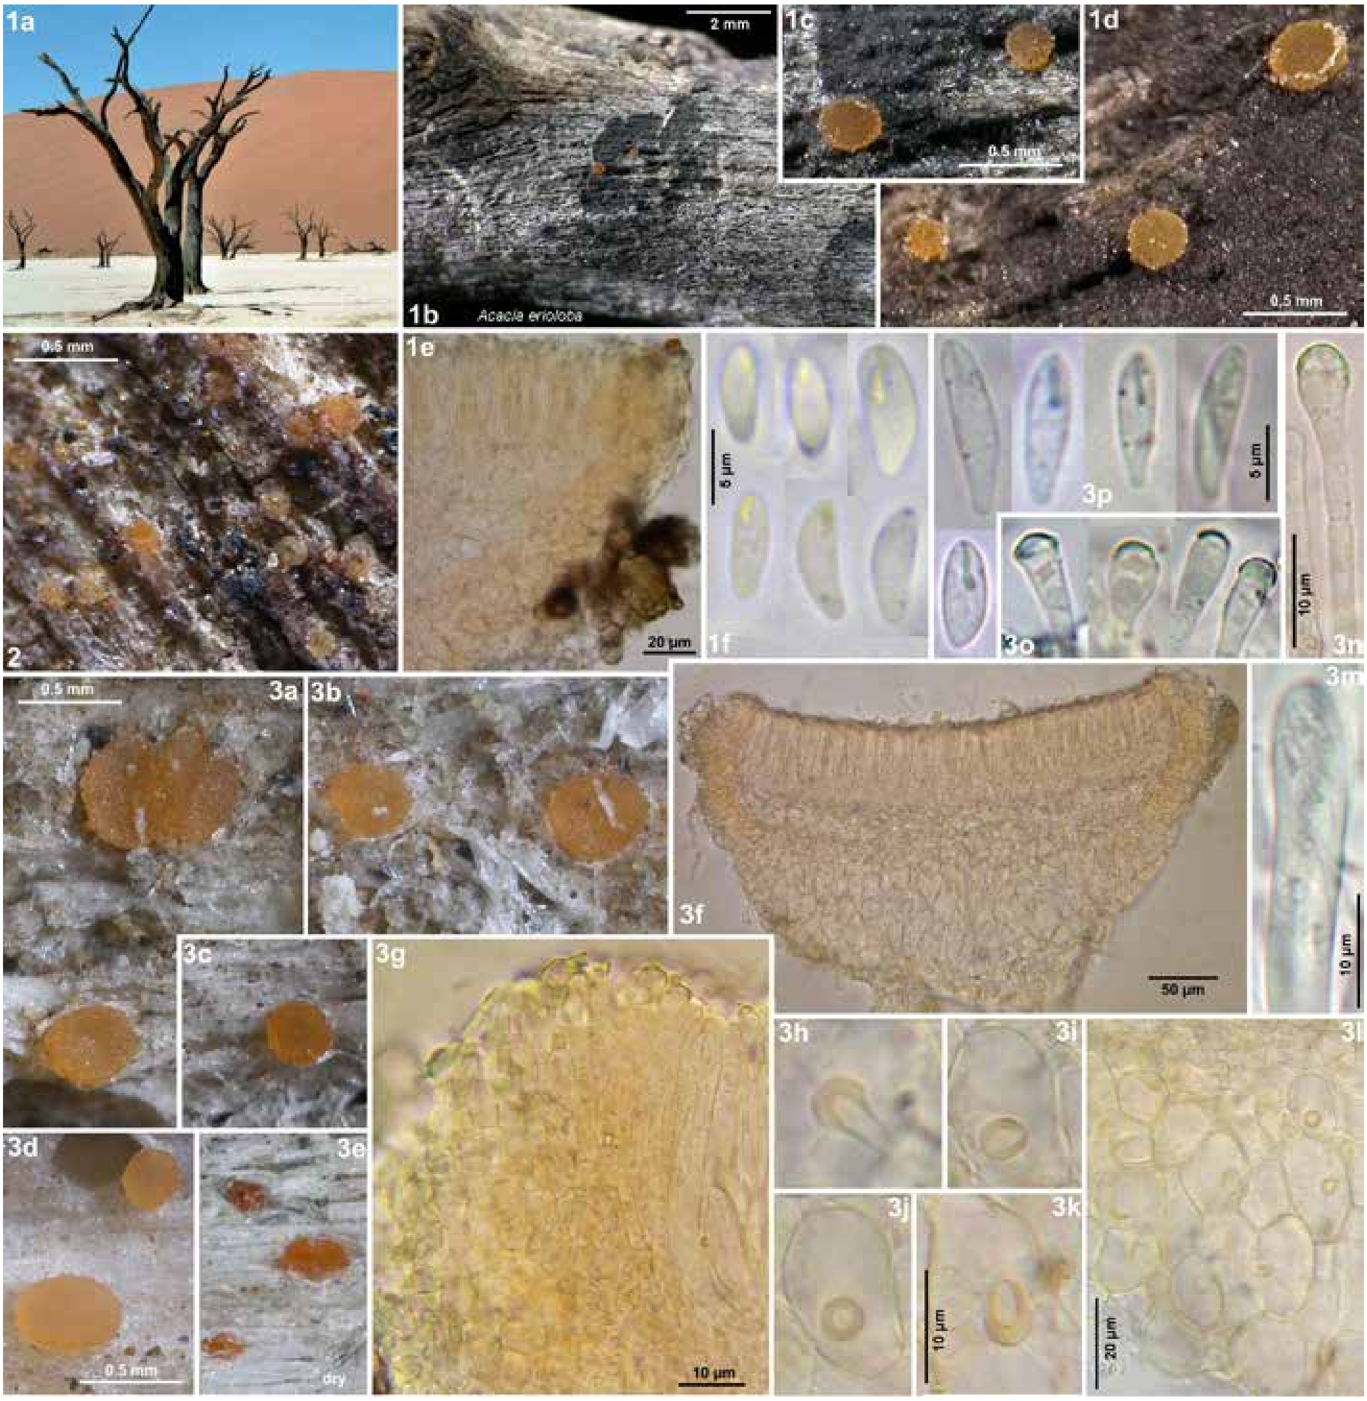

Plate 605. **1–3**: *Orbilia acaciae*. – **1a**. dead *Vachellia* trees in Namib Desert; **1b–e**, **2**, **3a–d**. rehydrated apothecia; **3e**. dry apothecia; **1e**, **3f**. apothecia in median section; **3g**. id., marginal ectal excipulum; **3l**. id., basal ectal excipulum with crystalloid SCBs; **3h–k**. id., closeup; **3m**. ascus; **3n–o**. upper part of paraphyses; **1f**, **3p**. ascospores. – Living state; **1a**: phot. C. Traving (from internet), **3m**, **o–p**: phot. L. Quijada. — **1a–f**. H.B. 8540: Africa, Namibia, on *Vachellia*; **2**. H.B. 6615b (holotype): Australia, Queensland, on *Acacia*; **3a–p**. H.B. 9153a: Macaronesia, Tenerife, on *Euphorbia*.

the basal excipular cells much larger (10–45 × 8–20 instead of 8–17 × 7–12 µm), and the apothecia thicker (160–250 instead of 120–170 µm), nevertheless, we believe that they are conspecific. The apothecia were usually rather small (0.15–0.4 mm diam., including holotype), but in that from Macaronesia they measured 0.3–0.6 mm and in that on *Brachychiton* 0.35–0.7 mm.

Ecology. *O. acaciae* was found on rotten wood of xeric twigs and branches of angiosperms including succulents, also on petioles of a palm. The species appears to occur worldwide in the subtropical and tropical belt. In northeastern and eastern Australia (Great Dividing Range) and in western Australia near the coastline it occurred in tropical to subtropical semiarid to subhumid acacia shrublands, eucalypt woodlands, and savannahs. The site in southwestern Africa is a subtropical hyperarid dry riverbed ('Deadvlei') that did not get groundwater since over 500 years because it was cut off by a sand dune, and *O. acaciae* grew there on the attached twig of a tree of *Vachellia erioloba* which had died since about that time; the place is not far from the salt pan where the active though also mostly dry riverbed ends in the Namib Desert. In Macaronesia *O. acaciae* was repeatedly discovered in three areas of Tenerife on *Euphorbia canariensis* in subtropical (inframediterranean) semi- to hyperarid xerophytic scrublands, mainly in the tabaibal dulce (*Ceropegio fuscae-Euphorbietum balsamiferae*) but also in the *Artemisio thusculae-Rumicion lunariae* (Quijada, 2010).

Map 98. Known distribution of *O. acaciae* in Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 160 km SSE of Carnarvon, Peron Peninsula, 18 km SE of Shell Beach, 48 m, branch of *Brachychiton gregorii*, on wood, 8.XII.2001, G. Marson (H.B. 7572c). – **Queensland**, Desert Uplands, 57 km E of Hughenden, 3 km WSW of Karoon Station, 437 m, branches of *Acacia georginae*, on wood, 16.X.1998, G. Marson (ex H.B. 6615b, BRI AQ799189, **holotype**). – Brigalow Belt South, 80 km N of Goondiwindi, 10 km S of Moonie, 278 m, branches of *Melaleuca*, on wood, 23.X.1998, G. Marson (H.B. 6823b). – 138 km SSW of Rockhampton, 11 km SW of Banana, 136 m, branch of *Geijera parviflora*, on wood, 22.X.1998, G. Marson (H.B. 6279d). – 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, leaves of *Livistona nitida*, on petioles, 22.X.1998, G. Marson (H.B. 6424f). — **NAMIBIA**: **Hardap**, Namib-Naukluft, 300 km SW of Windhoek, Sossusvlei, Deadvlei, 570 m, branch of *Vachellia erioloba*, on wood, 19.V.2007, G. Parisot (H.B. 8540). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Arico, 1 km WSW of Abades, Barranco la Vera, 50 m, branch of *Euphorbia canariensis*, on wood, 5.VI.2009, L. Quijada, R. Castro & E.V. Rodríguez (TFC Mic. 22165, 22242, H.B. 9153a). – San Miguel de Abona, 4 km SSW of Las Chafiras, 1.5 km NE of Costa del Silencio, Montaña Amarilla, 30 m, on *E. canariensis* (TFC Mic. 22674, 22675, 22677, 22861, non vid.). – ibid. 1.2 km ENE of Costa del Silencio, 10 m, on *E. canariensis* (TFC Mic. 22167, 22170, 22171, non vid.). – Buenavista del Norte, 7 km WSW of Buenavista del Norte, ~4 km W of Teno Alto, Punta de Teno, 20–200 m, on *E. canariensis*, TFC Mic. 22258, 22274, 22279, 22285, 22287, 22293, 22295-6, non vid.). – ibid., 2.8 km WNW of Teno Alto, Punta de Teno, 130 m, on *E. canariensis* (TFC Mic. 22861, non vid.).

Orbilia maeandrina Baral & G. Marson, **sp. nov.**, MB 813667 — Pls 606–607, Map 99

Etymology: named after the flexuous, meandering spore bodies.

Typification: USA, Utah, Dixie Forest, Zion Overlook, branch of *Populus tremuloides*, 24.VIII.1994, G. Marson (ex H.B. 5230a, M-0276506, holotype).

Latin diagnosis: *Similis* Orbiliae trapeziformi *sed asci 16-spori, locis subtropicis aridis ad borealibus humidis Americae, Africae et Asiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.25–0.6(–0.8) mm diam., 0.13–0.23 mm high, light to bright orange (to dirty brick-red), round, scattered to often medium gregarious; disc (slightly concave to) flat, margin distinct, thin, 5–40 µm protruding, ± smooth or finely rough by covering hyphae; sessile, superficial or mostly distinctly erumpent from beneath outer host tissue or immersed in biofilm. **Asci** *(50–)60–84(–95)((–108)) × (6–)7–8.5(–9.7) µm {13}, †(50–)55–75(–88) × (5–)5.5–7.5(–8) µm {10}, 16-spored, spores *2–4-seriate, (3–)6–9(–10) lower spores inverted {7} (not or slightly mixed), pars sporifera *(29–)35–45(–50) µm long, †40–60 µm; **apex** (†) (slightly to) medium or strongly truncate (sometimes slightly or strongly indented, laterally strongly inflated or not); **base** with short to long, thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(6–)7–9.5(–11) × (2.3–)2.5–3.5(–3.8)((–4)) µm {21}, †(6–)7–9(–10) × (2–)2.2–3.3 µm {7}, fusoid to fusiform, also fusoid-clavate, amygdaliform or tear-shaped, apex subacute to acute (to acuminate), rarely obtuse, base not or slightly to strongly attenuated, never with a distinct tail-like base; straight to slightly inequilateral, sometimes slightly curved at base; **SBs** *(4–)5–8(–9) × 0.6–1.2 µm in situ {13} (~4.5–9.5 µm actual length), vermiform to subulate, base not or very slightly inflated, slightly to strongly flexuous, sometimes uncinate. **Paraphyses** apically medium to (very) strongly clavate-capitate, sometimes moniliform, terminal cells *(4.5–)8–21 × (2.5–)3–5(–6) µm {9}, †(2.5–)3–5 µm wide {2}, lower cells *7–19 × (1–)1.5–2(–2.5) µm {6}, †0.8–2 µm wide; rarely or not infrequently branched at upper septum, hymenium pale orange-rose. **Medullary excipulum** very pale orange, 20–50 µm thick, of loose to dense textura intricata, partly horizontally oriented, with many inflated cells, sharply delimited. **Ectal excipulum** hyaline († pale rose), of thin-walled, (†) slightly to medium gelatinized (common walls 0.7–1.3 µm), vertically or indistinctly oriented t. (globulosa-)angularis(-prismatica) from base to margin, 30–50(–100) µm thick near base, cells *8–25(–32) × 6–14(–17) µm {7}; 25–30 µm thick at flanks, 20–35 µm near margin, irregularly oriented at a 70–90° or 10–40° angle to the surface, marginal cortical cells *5–11 × (2–)3–5(–6) µm {3}, †6–10 × 2.5–4 µm {2}. **Anchoring hyphae** very sparse to abundant, */†2–3.8 µm wide, walls *0.2–0.4 µm thick, †0.2–0.7 µm {5}, forming an up to 50 µm thick dense, medium gelatinized t. intricata, partly covering flanks and margin as a 10–20 µm thick layer. **SCBs** in paraphyses and ectal excipulum (near margin) globose {16}, (0.6–)1–2.5(–3) µm diam. (up to 3.7 µm in excipulum). **Exudate** over paraphyses and excipulum (margin and flanks) 0.2–2 µm thick, granular-cloddy, hyaline to very pale yellowish, loosely attached, often lacking. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** not observed. **Conidia** Y-shaped, total size †(20–)25–30 × (12.5–)32–33 µm, stipe †14–20 × 4.5–6 µm, 2-septate, arms †(5–)16–17 × 4.5–5 µm, 2–3-septate {1}, arms and stipe more or less abruptly tapering.

Habitat: collected (0–)0.1–3 m above the ground, partially to entirely decorticated, 4–30 mm thick twigs and branches of *Abies concolor* {1}, *Acacia* sp. {1}, *Amelanchier ?alnifolia* {1}, *A. utahensis* {2}, *Cercocarpus betuloides* {1}, *C. ledifolius* {1}, *Ephedra ?viridis* {1}, *Lonicera microphylla* {1}, *Olneya tesota* {2}, *Parkinsonia microphylla* {1/1}, *Picea* sp. {1}, *P. sitchensis* {1}, *Populus tremuloides* {3}, *Prunus virginiana* {1}, *Purshia stansburyana* {4}, *Ribes cereum* {1}, *Salix* sp. {1}, *Sarcobatus vermiculatus* {1}, *Ulmus* sp. {1}, ?*Vachellia* sp. {1}, indet. angiosperms {2}, on 0.3–1.5 mm deep (medium to) strongly decayed wood {21}, rarely bark {4}, partly eroded, sometimes in galleries and on boring dust of bark beetles, medium to strongly greyed, green algae absent or sparse. **Associated**: *Acanthostigma ellisii* {1}, ?*Baggea* sp. {1}, ?*Calloriaceae* {1}, *Caloplaca* sp. {1}, *Candelariella* sp. {1/1}, *Capronia* sp. {1}, *Carestiella schizoxyloides* {1}, '*Chlorosplenium*' *viridulum* {1}, *Crumenulopsis* sp. {1}, *Cyathicula* sp. {1}, *Dothideales* {1}, *Durella* sp. {2/2}, *D.* ?*atrocyanea* {1}, *Hypogymnia* sp. {1}, *Hysterobrevium mori* {3}, *Hysteropatella* sp. {1}, ?*Melanelia* sp. {1}, *Melaspilea emergens* {4}, *Mellitiosporiella macrospora* {1}, *M. pulchella* {3}, *Odontotrema oregonensis* {1}, *Orbilia aristata* {1}, *O. arizonensis* {3}, *O. barrowensis* {1/1}, *O. basiflexa* {1}, *O. calyptrata* {2}, *O. carpoboloides* {1}, *O. clavipisca* {1}, *O.* ?*commarosa* {1}, *O. concoloris* {1}, *O. coniferarum* {2}, *O. delphinus* {12}, *O. euonymi* {1}, *O. flexisoma* {1/3}, *O.* ?*gambelii* {1}, *O. idahoensis* {1}, *O. lacrimispora* {1}, *O. lentiformis* {2/2}, *O. macrodelphinus* {3}, *O. macrohesperidea* {1}, *O. magnifica* {2}, *O. microsoma* {1}, *O. multicercocarpi* {1}, *O. multicreosoteris* {2}, *O. multigambelii* {2}, *O. multimaeandrina* {3}, *O.* ?*multiphanosoma* {1}, *O. multiserpens* {1}, *O. myrioflexa* {1}, *O. myrioolneyae* {3}, *O. myriourosperma* {3}, *O. namibica* {1}, *O. ocellata* {1}, *O. ophiosoma* {1/1}, *O. paloverdensis* {1}, *O. pleionavajoana* {1}, *O. pleioserpens* {1}, *O. pleiostomachia* {1}, *O. pleioungulata* {1}, *O. pluristomachia* {3}, *O. pubescens* {1}, *O. purshiae* {4}, *O. sedonensis* {1}, *O. serpentina* {1}, *O. sonorensis* {2}, *O. stansburyanae* {1}, *O. subovoidea* {1}, *Patellaria atrata* {3}, *P. andina* {4}, ?*Peniophora* sp. {1}, *Perrotia flammea* {4}, *Propolis farinosa* {1}, ?*Schizoxylon* sp. {1}, *S.* ?*argentinum* {2}, *Sclerococcum* sp. {1}, *Stenocybe* sp. {1},

Taxonomic remarks. *Orbilia maeandrina* is characterized by 16-spored asci, medium-sized, amygdaliform to rhomboid ascospores with ± long, vermiform SBs, and globose SCBs. It resembles the 8-spored European *O. trapeziformis* especially in the spores and absence of crystalloid SCBs. The very close 16-spored *O. serpentina* can be segregated from *O. maeandrina* mainly based on the consistent presence of crystalloid SCBs, also on very slightly longer spores. *O. delphinus* differs from *O. maeandrina* in narrower, usually longer spores and appears to be sharply delimited although often growing in association. *O. macrodelphinus* differs from *O. maeandrina* in longer and/or narrower, partly basally distinctly curved spores, but the distinction is not sharp. *O. cisti* (series *Ellipsospermae*) differs in more obtuse spore apices, much narrower SBs, narrower asci, and absence of any kind of SCBs. A collection mentioned under *O. pleioserpens* (Pl. 736: 4) differs in shorter, apically more obtuse spores.

Variation. Some of the included specimens (Pl. 606: 5, and H.B. 6037c) have partly tear-shaped spores with acuminate apices, and particularly the single Australian collection (Pl. 606: 4) also rather long, basally hooked SBs similar as in *O. lacrimispora*. Great variation in apothecial size and colour was noted among the collections, but the microscopical features support that only one species is involved. Spores and paraphyses in the collection from southern France (IVV: H.B. 9086a) fit well those of the extra-European ones, particularly Pl. 606: 5.

Anamorph. The trinacrium-like conidia observed on the natural substrate are similar to those of *O. trapeziformis* or *O. serpentina*.

Ecology. *O. maeandrina* grew on rotten wood (rarely bark) of xeric twigs and branches of various angiosperm trees and shrubs, rarely gymnosperms. The species was mainly collected in western North America in subtropical semiarid Sonoran paloverde-mixed cacti desert scrubs, cold-temperate subhumid pinyon-juniper woodlands of the Great Basin and Colorado Plateau, and in cold-temperate to boreal humid ponderosa pine, Douglas fir, and Engelmann spruce forests of Middle and Southern Rocky Mountains. Single records are from the hot, subtropical arid (winter-dry) Kalahari highland thornbush savannah in southwestern Africa, a continental, orotemperate (sub)humid (winter-dry), south-exposed subalpine scrub with *Juniperus sabina* in central Asia, and a tropical arid acacia open shrubland in central Australia. In southern France it occurred on *Ulmus* in the thermomediterranean zone.

Specimens included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Var**, Îles d'Hyères, Île de Porquerolles, centre of island, ~40 m, branch of *Ulmus*, on wood, 1.XI.2006, H. Map 99. Known distribution of *O. maeandrina* in North America.

Orbilia multimaeandrina Baral & G. Marson, **sp. nov.**, MB 813668 — Pls 608–609, Map 100

Etymology: named after the resemblance to *O. maeandrina* in the teleomorph but differing in 32-spored asci.

Typification: USA, Utah, Moab, branches of *Cercocarpus betuloides*, 16.VI.2000, G. Marson (ex H.B. 6737a, M-0276523, holotype; ex-type culture: CBS 116221; sq.: KT215243).

Latin diagnosis: *Similis* Orbiliae maeandrinae *sed asci 32-spori*, status anamorphicus *conidiis multiseptatis, plus minusve curvatis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5(–0.7) mm diam., 0.16–0.21 mm high, light to bright orange(-ochraceous), hardly translucent, round, scattered to gregarious; disc

H.B. 6737a (holotype): USA, Utah, Moab, on *Cercocarpus*.

amygdaliform or lemon-shaped, apex subacute to acute, rarely obtuse, base slightly to strongly attenuated, sometimes with a tail-like base, straight to slightly inequilateral, also slightly (to strongly) curved at base; **SBs** *(4–)5–7(–8.3) × 0.8–1.2(–1.3) µm in situ {6} [~5–8(–9) µm actual length], vermiform to subulate, mostly slightly to strongly swollen at base, slightly to strongly flexuous to helicoid, never distinctly uncinate. **Paraphyses** apically (slightly to) medium to (very) strongly clavate-capitate or equally often spathulate (to lageniform), terminal cells *(4.5–)8–22(–35) × (2.2–)3–5(–6.3) µm {6}, lower cells *8.5–22 × 1.3–2.3 µm {4}; occasionally or infrequently branched at apical septum. **Medullary excipulum** hyaline, 30–60 µm thick, of loose or dense textura intricata with many inflated cells, very sharply delimited. **Ectal excipulum** subhyaline, of (†) thin-walled or distinctly gelatinized (common walls up to †0.5–1.5 µm thick), irregularly or usually vertically oriented t. prismatica-angularis-globulosa from base to margin, 15–50 µm thick near base, cells */†(6–)9–22 × (4–)7–16 µm {3}; 15–25 µm thick at flanks, cells *8–20 × 5–12 µm, 10–25 µm near margin, oriented at a 0–45° angle to the surface, marginal cortical cells *5–16 × 4–8 µm {2}; margin sometimes covered by conglutinate hyphoid processes †10–25 × 2–2.5 µm. **Anchoring hyphae** sparse to very abundant, */†(2–)2.5–4(–4.8) µm wide, walls */†(0.2–)0.4–1(–1.5) µm thick {5}, forming a loose t. intricata, partly also an up to 10 µm thick covering layer of dead hyphae up to the margin. **SCBs** in paraphyses and ectal excipulum (near margin) absent {2} or globose {4}, 0.5–1.3 µm diam. **Exudate** over paraphyses 0.2–1(–2) µm thick, ± rough, firmly attached; over margin and flanks as scattered granules 0.2–0.7 µm thick. — **ANAMORPH**: anguillospora-/vermispora-like (from ascospore isolate {1}). **Conidiophores** not observed. **Conidia** unbranched, *75–107 × 5.5–6 µm (actual length, in situ partly only 53 µm long), 9–26-septate, straight or slightly to very strongly curved, slightly tapering towards both ends, conidia in masses pale orange-coloured {1}.

Habitat: collected 0–3 m above the ground, partly buried in ground, ± corticated to decorticated, 7–22 mm thick branches of (?)*Acer* sp. {1}, *Amelanchier utahensis* {1}, *Artemisia filifolia* {1}, *Baccharis salicifolia* {1}, *Cercocarpus betuloides* {2}, *Coleogyne ramosissima* {1}, *Ericameria nauseosa* {1}, *Fraxinus anomala* {1}, *Populus tremuloides* {1}, *Purshia stansburyana* {3}, indet. angiosperm {1}, on 0.1–0.5 mm deep (slightly to) strongly decayed wood {10} and bark {4} (bast, sometimes ± detached and hanging), partly strongly eroded, greyed, without or with a few green algae, with or without internal beetle galleries. **Associated**: *Caloplaca* sp. {1}, *Candelariella* sp. {1}, *Carestiella schizoxyloides* {2}, *Dothideales* {1}, *Hysteropatella* sp. {1}, *Melaspilea emergens* {1}, *Mellitiosporiella macrospora* {1}, *M. pulchella* {1}, *Odontotrema oregonense* {1}, *Orbilia arizonensis* {1}, *O. bicknellensis* {1/1}, *O. calyptrata* {1}, *O. cercocarpi* {1}, *O. ?commarosa* {1}, *O. cupularis* {1}, *O. delphinus* {2}, *O. dixienis* {1}, *O. ?flexisoma* {1}, *O. lentiformis* {4/1}, *O. macrodelphinus* {3}, *O. macroserpens* {1}, *O. maeandrina* {3}, *O. mesaverdiana* {1}, *O. microsoma* {1}, *O. multiphanosoma* {2}, *O. multitrapezoidea* {3}, *O. myriophanosoma* {1}, *O. navajoana* {1}, *O. ocellata* {5}, *O. ?paloverdensis* {1}, *O. plurilentiformis* {3}, *O. purshiae* {1}, *O. serpentina* {2}, *Patellaria ?atrata* {1}, *Psiloglonium lineare* {1}, *Schizoxylon* sp. {1}, *Stictis* sp. {1}, *Teichospora* sp. {1}, *Symbiotaphrina desertorum* {1}, *Tryblidaria* sp. {1}, *Xanthoria* sp. {2}. **Desiccation tolerance**: fully tolerant for at least 1 year, after 2 years some mature asci and many paraphyses, after 28 months some spores, paraphyses and excipular cells still viable. **Altitude**: 1315–2600 m a.s.l. **Geology**: Proterozoic-Cambrian sedimentary rock, Pennsylvanian-Permian to Triassic-Jurassic red carbonate sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multimaeandrina* is characterized by 32-spored asci and lemon-shaped to amygdaliform ascospores similar as in the 16-spored *O. maeandrina*. The paraphyses deviate from *O. maeandrina* in being quite often spathulate and in containing smaller SCBs. The probably closely related *O. multitrapezoidea* differs from *O. multimaeandrina* in narrower spores, and *O. multiurosperma* in always showing some spores with a distinct, curved basal tail and in the presence of crystalloid SCBs. *O. osteospermae* (on *Juniperus osteosperma*) is very similar to *O. multimaeandrina* (on angiosperms) but has distinctly smaller spores. The Australian *O. livistonae* deviates in longer spores with narrower SBs, and in capitate (to spathulate) paraphyses with much larger globose SCBs. A specimen tentatively assigned to *O. livistonae* (Pl. 647: 2) concurs with *O. multimaeandrina* in spore size and shape, but in the other characters it better fits *O. livistonae*.

Not included collection. A sample on *Purshia* (IVV: ~13. VI.2000) deviates in spores with untapered, predominantly rounded bases.

Variation. The collections of *O. multimaeandrina* showed little variation. They were mostly rather sparse, except for that on *Amelanchier* (Pls 608: 6; 609: 2): in 3 out of 19 apothecia examined in that specimen, some spores possessed distinct basal tails (Pl. 608: 6a); yet, also in the collection on *Populus* (Pl. 608: 5) some of the apothecia contained spores with tail-like bases.

Anamorph. An anamorph was only obtained in pure culture on CMA:2 when fragments of sterilized filter paper were added. At the border of these fragments abundant conidia were formed. This type of anamorph with its consistently unbranched conidia is exceptional within series *Serpentinae*, in which Y-shaped conidia are typical, while phragmoconidia occur only in small quantities among the branched ones, but it resembles that observed in series *Habrostictis*, except for its much longer conidia.

Phylogeny. A sequence taken from the ex-type culture comprises SSU, ITS and LSU, another from apothecia ITS+LSU. The S1506 intron is absent in both. The two samples have a 2.7 % ITS distance while in the overlapping part of LSU (D1) they are identical.

In our ITS or combined analyses, *O. multimaeandrina* clustered medium supported with *O. sonorensis* in the *Serpentinae-Habrostictis* clade (Phyls 19, 20), though with a rather high distance in both ITS (8–9 %) and LSU D1–D2 (2.4 %), in accordance with the different morphology of *O. sonorensis*. In the LSU the lowest distance is 2.2 % to *O. carpoboloides*, although the ITS distance to this species is 16–16.5 %.

Ecology. *O. multimaeandrina* was collected on rotten wood and bark of xeric branches of various angiosperm trees and shrubs in western North America, where it occurs in warm- to cold-temperate semiarid to subhumid pinyon-juniper woodlands, warm-continental semiarid sagebrush and warm-temperate arid saltbush desert scrubs, and cold-temperate subhumid to humid ponderosa pine and Douglas fir mixed forests in the Colorado Plateau (mainly in the Canyonlands section, also Grand Canyon, Uinta Basin, Utah Mts.) and Mojave Desert.

Specimens included. **USA**: **Colorado**, Uinta Basin, 50 km ESE of Vernal, 6 km NE of Dinosaur, 2100 m, on *Cercocarpus betuloides*, 12.VI.1996, G. Marson (ø). – **Utah**, Canyonlands, 33 km W of Blanding, 2 km NNE of Bears Ears East, 2600 m, branch of *Populus tremuloides*, on bark & wood, 14.VI.2000, G. Marson (H.B. 7180a). – 41 km W of Blanding, Natural Bridges, 2097 m, branches of *Amelanchier utahensis*, on wood, 14.VI.2000, G. Marson (H.B. 7133a). – 22.5 km W of Moab, 1779 m, branches of *Coleogyne ramosissima*, on wood, 9.III.2003, G. Marson (G.M. 2003-06-09.1, sq.: MT358338). – 36 km S of Moab, 5 km WNW of Hatch Rock, 1813 m, branch of *Ericameria nauseosa*, on bark, 16.VI.2000, G. Marson (H.B. 6736b, in holotype of *O.*

Map 100. Known distribution of *O. multimaeandrina* in North America (yellow = not included collection).

mesaverdiana). – ibid., 35 km SSW of Moab, E of Needles Overlook, Hatch Point, 1905 m, branches of *Cercocarpus betuloides*, on wood, 16.VI.2000, G. Marson (H.B. 8079b ø). – 20 km NNW of Moab, Arches, Salt Valley Wash, 1427 m, branch of *Artemisia filifolia*, on bark, 18.VI.2000, G. Marson (H.B. 6740b). – 25 km NNW of Moab, Devils Garden, Landscape Arch, 1590 m, branch of *Fraxinus anomala*, on wood, 8.VI.2003, G. Marson (H.B. 8051b). – 40 km WSW of Hanksville, 23 km E of Torrey, Capitol Reef, 1555 m, branch of *Baccharis salicifolia*, on wood & bark, 19.VI.2000, G. Marson (H.B. 6741a). – Utah Mts., Bryce Canyon, 33 km SE of Panguitch, 8 km WSW of Tropic, Navajo Trail SE of Sunset Point, 2300 m, branch of *Acer*, on wood, 25.VIII.1994, G. Marson (H.B. 5164c). – **Arizona**, Grand Canyon, Kaibab Plateau, 28 km ESE of Fredonia, 13 km NNW of Jacob Lake, 2115 m, branch of *Purshia stansburyana*, on wood, 15.VI.2003, G. Marson (H.B. 8002k). – **California** (border to Nevada), Mojave Desert, 20 km SW of Beatty, 16 km SW of Rhyolite, E of Death Valley, Daylight Pass, 1315 m, branch of indet. angiosperm, on wood, 2.V.1995, G. Marson (H.B. 8528c ø).

Not included. **Utah** (border to Arizona): Utah Mts., ~4 km WNW of Colorado City, S of Zion, ~1510 m, on *Purshia stansburyana*, ~13.VI.2000, G. Marson (ø).

Orbilia osteospermae Baral & G. Marson, **sp. nov.**, MB 813669 — Pls 610–611

Etymology: named after the host species, *Juniperus osteosperma*.

Typification: USA, Utah, Cedar City, branches of *Juniperus osteosperma*, 24.VIII.1994, G. Marson (ex H.B. 5175c, M-0276545, holotype).

Latin diagnosis: *Similis* Orbiliae multimaeandrinae *sed ascosporae minores*, *corpuscula refringentia longiora quam ascospora*, *ergo valde helicoidea*, *interdum uncinata. Habitat ad lignum vel corticem ramis siccis* Juniperi osteospermae *in zona temperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5 mm diam., 0.12–0.19 mm high, light to bright orange(-ochraceous), scarcely translucent, round, scattered; disc slightly concave to flat, margin distinct, 0–20 µm protruding, finely whitish powdered; broadly sessile, superficial but deeply immersed in biofilm. **Asci** *68–105 × 7.7–8.3(–9) µm, †69–94 × 6–7.2 µm, 32-spored, spores *4-seriate, lower spores inverted (mixed in middle part), pars sporifera *40–59(–67) µm long; **apex** (†) medium to strongly truncate (not indented, laterally scarcely inflated); **base** without or with short to medium long, thick stalk, L-, Y- or h-shaped. **Ascospores** *(4.8–)5.5–7(–8) × 2.7–3.4 µm, broadly fusoid to fusiform (amygdaliform), apex subacute to acute, rarely obtuse, straight to very slightly inequilateral; **SBs** *(4–)5–6.5(–7.5) × (0.4–)0.6–0.9 µm in situ [~(5–)6–8.5 µm actual length], vermiform to subulate, with slightly to strongly inflated base, medium to strongly helicoid, sometimes uncinate. **Paraphyses** apically medium to strongly spathulate, rarely clavate or lageniform, terminal cells *8–22 × 3.3–5(–5.5) µm, †2.5–4.5 µm wide, lower cells *(6–)9–19 × 1.3–1.8 µm (near base 2.5–3.2 µm, near apex up to 4.2 µm wide); sometimes branched near apex, hymenium very pale rose. **Medullary excipulum** subhyaline, 40–60 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose, of (†) thin-walled to slightly gelatinized, vertically oriented t. angularis from base to submargin, 50–60 µm thick near base, cells *7–13 × 6–12 µm; 30 µm thick at flanks and margin, at margin of t. prismatica-angularis oriented at a 10–30° angle to the surface, cells †8–9 × 4–5 µm, marginal cortical cells *9–12 × 3–4.5 µm. **Anchoring hyphae** sparse to medium abundant, *2.5–4.5 µm wide, walls 0.3–0.8 µm thick, partly extending to the margin as a thin layer. **SCBs** in paraphyses and ectal excipulum near margin absent. **Exudate** over paraphyses 0.2–1.5 µm thick, cloddy, mostly firmly attached to each apex; over margin and flanks 0.2 µm thick, continuous. **— ANAMORPH**: unknown.

Habitat: ± corticated to decorticated, 10–22 mm thick branches of *Juniperus osteosperma*, on strongly decayed wood and ± detached bark (bast & periderm), medium to strongly greyed, with sparse green algae. **Associated**: *Carestiella schizoxyloides*, *Orbilia cucumispora*, *O. ?maeandrina*, *O. multidelphinus*, *O. multihamulata*, *O. octosporoides*, *O. ophiosoma*, *O. pisciculus*. **Desiccation tolerance**: fully tolerant for at least 4 months. **Altitude**: 1815 m a.s.l. **Geology**: Upper Cretaceous sedimentary rock. **Phenology**: long-lived.

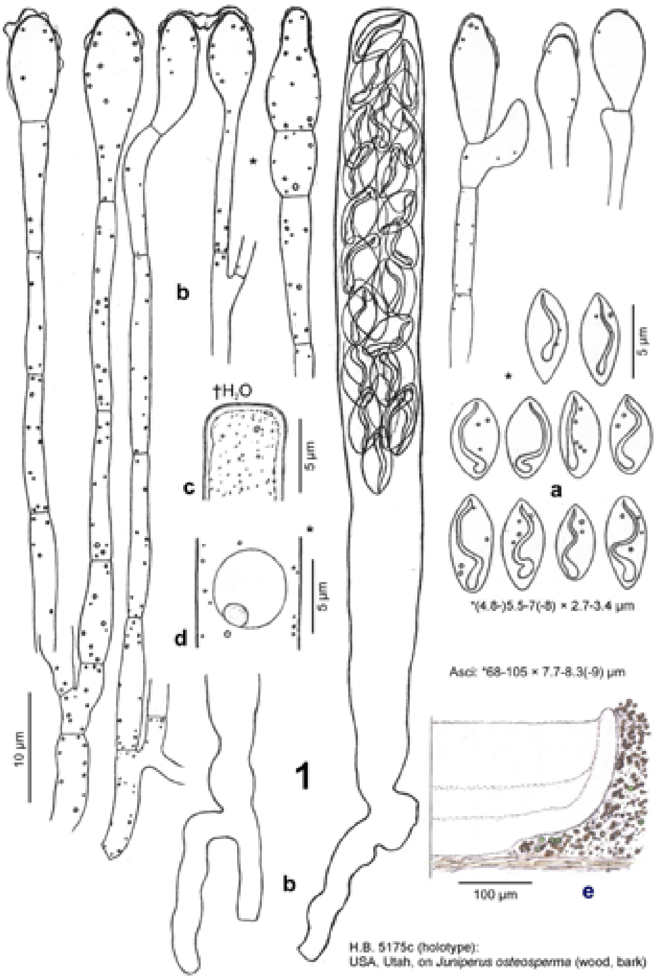

Plate 610. **1**: *Orbilia osteospermae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. fusion nucleus in young ascus; **e**. apothecium in median section.

Taxonomic remarks. *Orbilia osteospermae* is very close to *O. multimaeandrina*, from which it differs in smaller ascospores, also in spore bodies being mostly longer than the spore length and, therefore, medium to strongly helicoid or uncinate, finally in growing on coniferous substrate.

Variation. In some apothecia of the rather rich type collection a few 16-spored asci were observed among the 32-spored ones, with slightly larger spores of *(5–)6–8 × 3–3.8 µm. However, a single apothecium studied much later in the dead state had consistently 16-spored asci with †5–6.5 × (2–)2.5–3 µm large spores (IVV: H.B. 5175f). It could belong to *O. maeandrina*, but in the absence of vital characters its identity remains unclear. From 16-spored *O. lacrimispora* this apothecium deviates in much smaller spores.

Ecology. *O. osteospermae* is only known from a single collection on ± rotten wood and bark of xeric branches of *Juniperus osteosperma* in a dry riverbed in a cold-temperate subhumid pinyon-juniper woodland of Utah Mountains in western North America.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 1.5 km ESE of Cedar City, 1815 m, branches of *Juniperus osteosperma*, on wood & bark, 24.VIII.1994, G. Marson (M-0276545, **holotype**; **isotype** in H.B. 5175c).

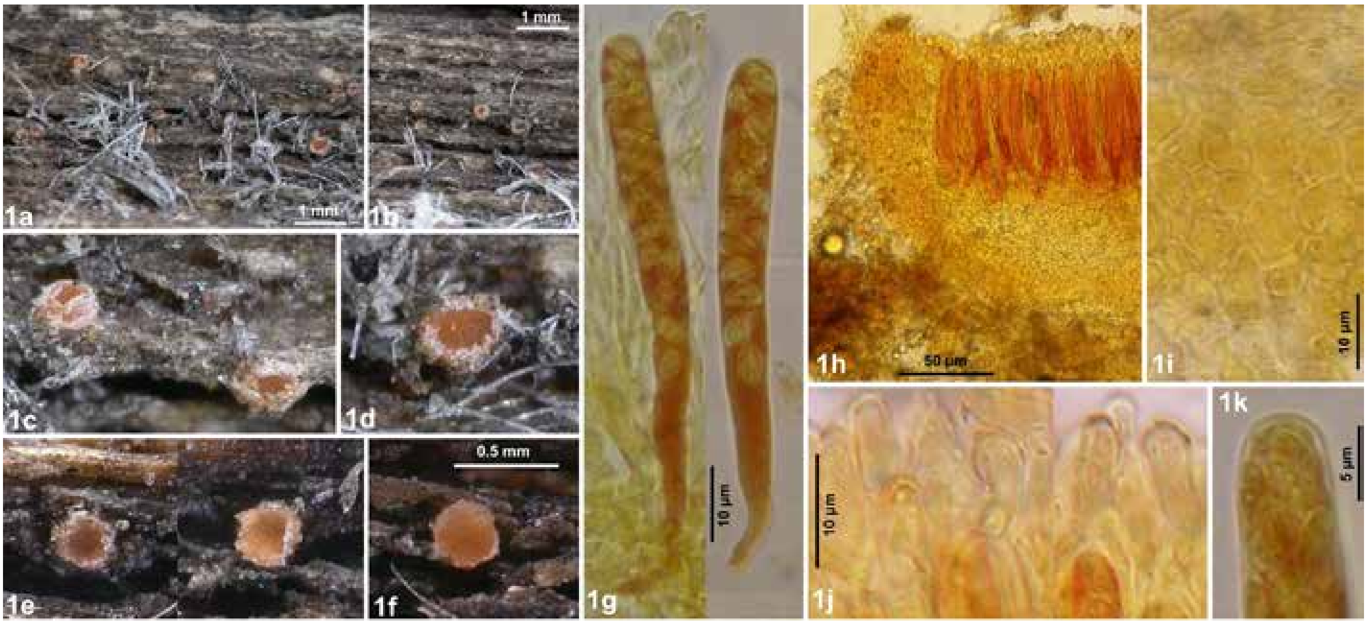

Plate 611. **1**: *Orbilia osteospermae*. – **1a–f**. rehydrated apothecia on detached bark of *Juniperus osteosperma*; **1g**. asci; **1h**. median section of apothecium; **1i**. id., basal ectal excipulum; **1j**. apices of paraphyses; **1k**. ascus apex. – Dead state (in KOH+IKI). — **1a–g**. H.B. 5175c (holotype): USA, Utah, on *Juniperus*.

Orbilia filiformis Baral, E. Weber & P. Perz, **sp. nov.**, MB 813670 — Pls 612–614, Map 101

Etymology: named according to the filiform spore bodies.

Typification: Switzerland, Hergiswil, branch of *Juglans regia*, 18.VIII.2006, E. Weber (ex H.B. 8244a, M-0276480, holotype; sq.: KT222451, KT222454).

Latin diagnosis: *Similis* Orbiliae subtrapeziformi *sed ascosporae angustiores, corpuscula refringentia longiora et multo angustiora. Habitat ad lignum vel corticem ramorum siccorum arborum angiospermarum, raro in caulibus ligneis volubilibus, in zona (oro)temperata ad submediterranea vel hemiboreale humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.5(–0.7) mm diam., 0.1–0.2(–0.3) mm thick, pale to light (or bright) (yellowish-)rose to orange(-cream), ± translucent or not, round, very scattered to subgregarious; disc young somewhat urceolate, soon flat to slightly, rarely medium convex, margin ± indistinct, thin, 0–15 µm protruding, smooth or very finely crenulate; broadly sessile, young somewhat erumpent, soon superficial; dry light to bright orange. **Asci** *(40–)45–67(–86) × (5–)5.3–6(–6.5) µm {6}, †(36–)45–60(–62) × (4–)4.5–5.2(–6) µm {5}, 8-spored, spores *(2–)3-seriate, (2–)3–5(–6) lower spores inverted {7} (often mixed), pars sporifera *17–32 µm long; **apex** (†) strongly truncate (slightly to distinctly indented, laterally scarcely or distinctly inflated); **base** with medium to long, thin or thick, ± flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *((6.5–))(8–)9–13(–14)((15.5) × 1.8–2.3(–2.5)((–2.7)) µm {40}, †(8.5–)9–13(–14) × (1.5–)1.6–2.1(–2.2) µm {8}, narrowly fusiform to fusiform-clavate, sometimes cylindrical in middle part, apex acute (to acuminate), exceptionally obtuse, base mostly medium to strongly attenuated, rarely or often with a tail-like base, straight or mostly slightly to medium curved near base; **SBs** *((4.5–))5–10(–11)((–12)) × 0.2–0.3(–0.4) µm in situ {30} (~5–12 µm actual length), filiform, sometimes slightly subulate, not or only very slightly inflated near base, straight to strongly flexuous, exceptionally uncinate; SBs in aged spores shorter, with a 0.5–1 µm wide basal inflation. **Paraphyses** apically (slightly to) medium to very strongly capitate(-clavate), terminal cells *(7–)15–26(–29) × (2.5–)3.5–4.5(–5.2) µm {5}, †3–5.3 µm wide {2}, lower cells *7–13(–16) × 1.2–2.2 µm {4} (near base 4–8 µm long); rarely branched at upper septum. **Medullary excipulum** subhyaline to very pale rose, 20–50, rarely 60–200 µm thick, of dense textura globulosa-intricata, indistinctly to medium sharply delimited. **Ectal excipulum** subhyaline, of thin-walled, irregularly or vertically oriented t. globulosa-angularis-prismatica from base to submargin, (20–)30–50(–70) µm thick near base, cells *(7–)9–18(–21) × (5–)7–14(–17) µm {7}; 20(–40) µm thick near margin, upper margin of t. globulosa-angularis or mostly prismatica-porrecta oriented at a (10–)20–50(–70)° angle to the surface, marginal cortical cells *5–10 × 3–4.5(–5) µm {5}. **Anchoring hyphae** sparse to abundant, *1.8–3(–3.5) µm wide, walls 0.2(–0.4) µm thick {3}, covering flanks and margin as a thin layer. **SCBs** in paraphyses and ectal excipulum absent {14}, rarely in some paraphysis apices rod-shaped {2} or large globose SCBs {2} observed. **Exudate** over paraphyses 0.2–1 µm thick, continuous to granular, hyaline, firmly attached; over margin (0.2–)1–2 µm thick, mostly continuous. **— ANAMORPH**: tridentaria-like (presumed, from natural substrate {17}). **Conidiophores** not seen. **Conidia** 3–4(–5)-armed, total size *45–70 × 24–75 µm, stipe *(5.5–)16–22 × (2.5–)3–3.5(–4.3) µm, (0–)1–2(–3)-septate, arms tapering, *(21–)28–48 × 3–4.5 µm, 3–6(–7)-septate {10}.

Habitat: collected (0–)1–4 m above the ground, corticated to decorticated, 5–35 mm thick twigs and branches (rarely a 30 cm thick trunk) of *Acer* sp. {2}, *A. campestre* {3}, *A. pseudoplatanus* {6}, *Aesculus hippocastanum* {1}, *Berberis vulgaris* {1}, *Carpinus betulus* {1}, *Clematis vitalba* {5}, *Cornus sanguinea* {1}, *Corylus avellana* {3}, *Fagus sylvatica* {2}, *Fraxinus excelsior* {2}, *Gleditsia sinensis* {1}, *Juglans regia* {2}, *Juniperus communis* {2}, *Lonicera xylosteum* {2}, *Malus domestica* {1}, *Populus* × *canadensis* {1}, *P. tremula* {2}, *Prunus spinosa* {1}, *Quercus rotundifolia* {1}, *Robinia pseudoacacia* {1}, *Salix* sp. {2}, *S. appendiculata* {1}, *S. caprea* {4/1}, *S. ?caprea* × *aurita* {1}, *Sambucus nigra* {3}, *S. racemosa* {1}, *Sorbus aria* {1}, *S. domestica* {1}, *Tilia platyphyllos* {2}, stems of *Rubus ?bifrons* {1}, on 0.2–1(–2) mm deep (slightly to) strongly decayed wood {50} and bark {12} (bast), partly on splitted wood or below detaching bark, rarely on inner surface of bark; rarely on herbaceous stems of *Atropa belladonna* {1}, *Rumex* sp. {1}; slightly to strongly greyed, green algae sparse to very abundant. **Associated**: *Ascotaiwania limnetica* {1}, *Dothideales* {1}, *Durella connivens* {1}, *Echinosphaeria strigosa* {1}, *Eichleriella deglubens* {1}, *Eutypa maura* {1}, *Glyphium elatum* {2}, '*Helotium*' *uvidulum* {1}, *Hyalorbilia fusispora* {1}, *H. juliae* {1}, *H. latispora* {1}, *H. subfusispora* {2}, *Hyaloscypha minuta* {2}, *Hypogymnia physodes* {1}, *Hysteropatella elliptica* {1}, *H. prostii* {1}, *Karstenia rhopaloides* {3}, *Lecanora* sp. {1}, *Lecophagus ellipsoideus* {1}, *Lophiostoma* sp. {1}, *Melanelia glabratula* {1}, *Merismodes* sp. {2}, *Olla millepunctata* {1}, *O. scrupulosa* {1}, *O. transiens* {2}, *Orbilia arachnovinosa* {1}, *O. aristata* {7}, *O. breviaristata* {1}, *O. cylindrosoma* {1}, *O. eucalypti* {2}, *O. euonymi* {1}, *O. flagellispora*

Phenology of *O. filiformis*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
2	2	3	8	3	9	3	12	10	4	2	3

Taxonomic remarks. *Orbilia filiformis* is very similar in ascospore shape to *O. subtrapeziformis*, from which it differs in much narrower, filiform, often very long spore bodies, also in slightly narrower spores and in the predominant absence of any kind of SCBs. *O. obtusispora* and *O. cylindrosoma* differ

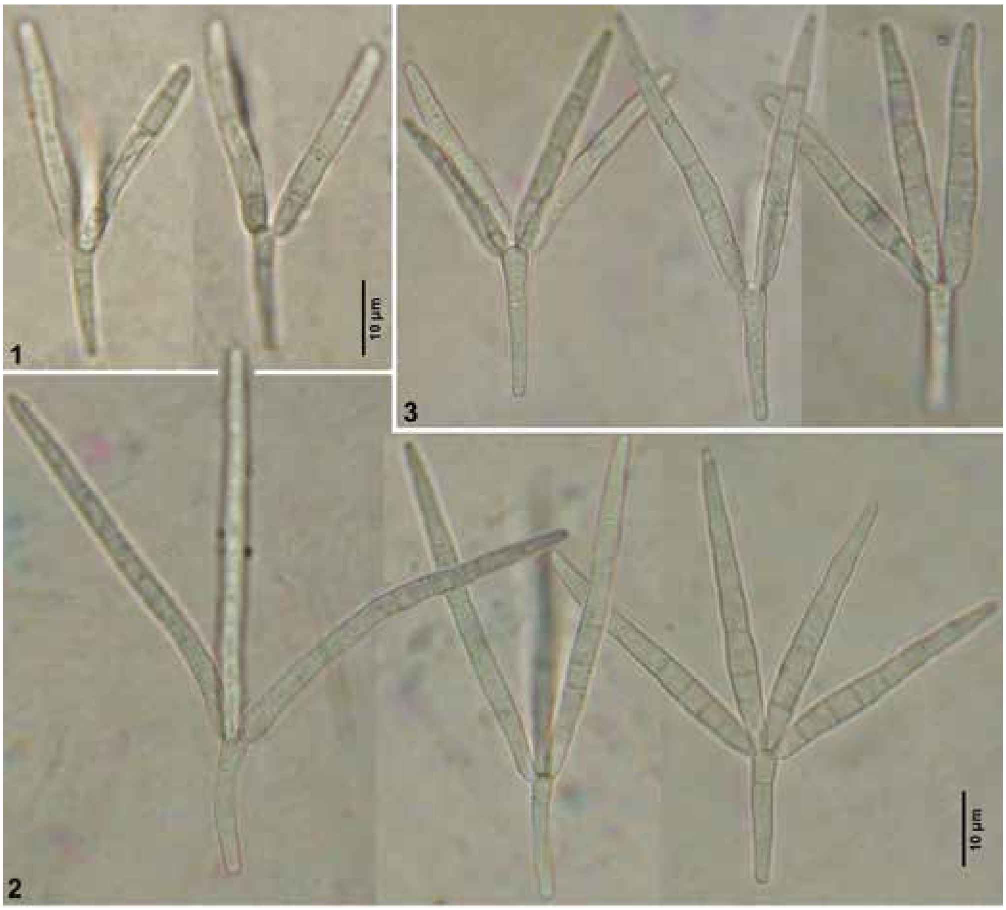

Plate 614. **1–3**: *Orbilia filiformis*. – Conidia of presumed anamorph, from substrate (living state). — **1**. H.B. 9007a: Germany, München, on *Clematis*; **2**. H.B. 8244a (holotype): Switzerland, Luzern, on *Juglans*; **3**. H.B. 8517: Denmark, Ringsted, on *Corylus*.

in more obtuse spore apices and thicker spore bodies, also in slightly wider spores (separation from *O. obtusispora* is not always clear). Although *O. filiformis* and *O. subtrapeziformis* are quite common in mountainous areas of central Europe, they have so far never been found growing in association. However, in one collection (Pl. 612: 8) *O. filiformis* grew intermingled with *O. cylindrosoma* and *O. vitalbae*, and recognition of the three also macroscopically very similar species required careful microscopic examination of the living spores. With its filiform SBs *O. filiformis* resembles *O. quaestiformis* which, however, sharply differs in wider spores with rounded to obtuse apices. Even the tridentaria-like anamorph of the two taxa are very similar, but that of *O. filiformis* is so far not ascertained in pure culture.

Variation. *O. filiformis* shows some variation in spore size and shape, and in SB length. Especially the spore bases vary from straight to medium curved and from (rarely) slightly to (mostly) strongly attenuated and partly tail-like. Three collections (Denmark, on *Corylus*, H.B. 8517; southern Germany, on *Salix*, H.B. 9459c, Pl. 613: 13; ibid., on *Heracleum*, Pl. 612: 4) deviate in rather short spores of *(6.5–)7–11(–12) × 2–2.4 µm, reminiscent of *O. trapeziformis* or *O. obtusispora*, but similar spores were exceptionally also seen in other collections (e. g., Pl. 612: 7, lower spores).

Not included collections. A sparse African sample (Pl. 612: 11) differs in rather short SBs (3.5–6.2 µm), spores with consistently only slightly attenuated and curved bases, and less swollen paraphysis apices which consistently contain globose SCBs. However, the specimen was immature when collected, and its maturation in a moist chamber was possibly incomplete. two environmental DNA isolates are too distant from our sequence to be considered as conspecific.

Anamorph. In 17 collections of *O. filiformis* tridentaria-like conidia were found on the substrate near the apothecia, in three of them also trinacrium-like ones. The observed trinacrium-like conidia resemble the presumed anamorph of *O. trapeziformis* or *O. obtusispora*, whereas the frequently observed tridentaria-like conidia very probably represent the anamorph of *O. filiformis*. Such conidia were otherwise only observed in a small group of species around *O. quaestiformis* in which the ascospores have obtuse apices.

Phylogeny. SSU (without S1506 intron), partial ITS1 (23 nt), partial ITS2 (102 nt), and LSU were gained from apothecia of the holotype on *Juglans* from Switzerland. *O. filiformis* clustered in our analyses of ITS, LSU, and SSU+ITS+LSU unresolved in the *Serpentinae-Habrostictis* clade (Phyls 19–20, S22), although it shows to *O. flavidorosella* and *O. carpoboloides* the lowest LSU D1–D2 distances of 1.1 % and 1.4 %, respectively, whereas in comparison, the distance to *O. cylindrosoma* is 1.7 %, to *O. quaestiformis* 2.5 %, and to *O. trapeziformis* and *O. obtusispora* at 3.9–4 %. In the partial ITS2 the distance to other species of series *Serpentinae* is very high, but the alignment clearly shows that *O. filiformis* is a member of the *Serpentinae-Habrostictis* clade. This result is also confirmed when analysing the SSU (S20).

Two environmental DNA isolates (*Picea* stump, Sweden, KP887834, ITS2; *Quercus* litter, Mexico, HDW-OTU-29, KT581933, ITS) formed with *O. filiformis* a medium supported clade when analysing the ITS2 region (NJ tree, not shown), though with a high distance among each other.

Ecology. *O. filiformis* was collected on xeric twigs and branches of various angiosperm trees and shrubs, the most often recorded being *Acer* {11} and *Salicaceae* {10}, rarely also conifers (*Juniperus*), stems of *Rubus*, and herbaceous stems. It was found in colline to altimontane and atlantic to subcontinental, oro- to supratemperate humid central Europe but also in hemi- to thermoboreal Scandinavia and in supra- or especially mesosubmediterranean, rarely supramediterranean (semi)humid southern Europe. The vegetation includes various thermophilous or shady forest types. The not included samples were from a tropical humid (winter-dry) coastal open woodland in Senegal (western Africa), a subtropical, possibly semiarid oak forest in central Mexico, and a (?hemi)boreal humid spruce forest in Sweden.

Orbilia subtrapeziformis Baral, E. Weber & G. Marson, **sp. nov.**, MB 813671 — Pls 615–616, Map 102

Etymology: in reference to the similar *O. trapeziformis*.

Typification: France, Hautes-Alpes, Villar-d'Arêne, branches of *Sorbus aucuparia*, 14.VII.1994, G. Marson (ex H.B. 5138a, M-0276599, holotype).

Latin diagnosis: *Similis* Orbiliae trapeziformi *sed ascosporae distincte longiores. Habitat in locis borealibus ad orosubmediterraneis (sub)humidis Europae*, *Macaronesiae*, *Asiae et Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.5(–0.8) mm diam., (0.085–)0.1–0.15(–0.22) mm high, (pale to) light (to bright) orange(-ochraceous), more rarely rose, non- or slightly to medium translucent, round, sometimes slightly elliptical, scattered to medium, sometimes densely gregarious; disc young slightly concave, soon flat, finally slightly convex, margin indistinct or distinct, 0–25 µm protruding, smooth to finely or sometimes strongly rough to crenulate; broadly sessile, rarely with a stipe 0.03 × 0.07 mm, superficial or slightly immersed; dry light to bright orange. **Asci** *(45–)53–75((–90)) {9} or 85–100 {1} × 5.7–7(–7.2)((–7.7)) µm {10}, †(40–)45–70(–79) {7} or 82–96(–100) {1} × 5–6.3 µm {8}, 8-spored, spores *3–4-seriate, (1–)3–5(–6) lower spores inverted {13} (rarely mixed), pars sporifera *27–35 → 20 µm long; **apex** (†) strongly truncate (very slightly to distinctly indented, laterally inflated or not); **base** with short to very long, thin or thick, flexuous stalk, T-, L-, Y- or h-, exceptionally H-shaped. **Ascospores** *((7.7–))(8.5–)9–14.5(–16) × (1.8–)2–2.7(–3) µm {26}, †8.5–13.5(–15.5) × 2–2.5 µm {4}, (fusoid to) fusiform, also fusiform-clavate, apex acute, rarely obtuse to subacute or acuminate in some spores, base mostly strongly, rarely slightly to medium attenuated, with or without a tail-like base, slightly to medium curved especially near base, rarely straight; **SBs** *(4–)5–7.5(–8) × (0.5–)0.6–1(–1.2) µm in situ {16} (~5–8 µm actual length), subulate (to vermiform), not or sometimes distinctly swollen at base, ± flexuous, sometimes ± uncinate, rarely straight; in aged spores 2.5–4.5 × 1.2–1.5 µm, globose with long filum, germinating spores not observed. **Paraphyses** apically (slightly to) medium to very strongly (clavate-)capitate, rarely moniliform, terminal cells *(5–)10–19(–25) × (2.5–)3.3–5(–6) µm {6}, †3–4 µm wide {1}, lower cells *(5.7–)9–14(–17) × 1.2–2.3 µm {3}; never branched at upper septum, hymenium subhyaline. **Medullary excipulum** pale orange, 30–50 µm thick, of dense textura intricata with many inflated cells, indistinctly to medium sharply delimited. **Ectal excipulum** subhyaline to pale orange, of thin-walled, (indistinctly) vertically or horizontally oriented t. prismatica-angularis(-globulosa) from base to mid flanks, 20–40 µm thick near base, cells *(5–)7–16 × 5–11 µm {3}; 25 µm thick at flanks, 15–25(–30) µm at margin, oriented at a 10–45° angle to the surface at mid flanks (t. globulosa-angularis) and 0–10° at margin (t. prismatica-porrecta), cortical cells *6–7 × 4–5 µm {1} at submargin, *7–12 × 3–4 µm at upper margin {2}. **Anchoring hyphae** ± abundant, */†2–3.3(–4) µm wide, walls 0.2–0.3(–0.5) µm thick {3}, with or without gel sheath, forming a loose t. intricata up to 40 µm thick at base, partly also covering flanks and margin as a thin layer. **SCBs** in

paraphyses and ectal excipulum (near margin) globose {11}, (1–)1.5–2.5(–3) µm diam. **Exudate** over paraphyses (0.2–)0.5–1.5(–2) µm thick, hyaline, granular-cloddy or finely rough, soon firmly attached; over margin and flanks 0.2–1.5 µm thick. **— ANAMORPH**: unknown.

Habitat: collected (0.1–)0.3–2.5(–4) m above the ground, corticated to decorticated, 4–30 mm thick twigs and branches, rarely ~8–25 cm thick trunks, of *Acer* sp. {1}, *Alnus alnobetula* {6}, *Berberis vulgaris* {1}, *Betula pubescens* {1}, *Cytisus scoparius* {1/1}, *C. supranubius* {1}, *Fagus sylvatica* {1}, *Laburnum alpinum* {1}, *Pinus sylvestris* {1}, *Populus tremula* {1}, *Prunus* sp. {1}, *P. domestica* {1}, *Pyrus caucasica* {1}, *Rhamnus alpina* {3}, *Ribes petraeum* {3}, *Robinia pseudoacacia* {1}, *Rosa* sp. {2}, *R. canina* {1}, *Salix* sp. {2}, *S. ?bebbiana* {1}, *S. cantabrica* {1}, *S. ?caprea* {1}, *S. ?herbacea* {1}, *Sambucus racemosa* {1}, *Sorbus aucuparia* {2}, *S. domestica* {1}, *Ulmus* sp. {1}, indet. angiosperm shrub {1}, on 0.1–0.2 mm deep slightly to strongly decayed wood {32} and bark {8} (bast), also on pith {1}, scarcely to strongly greyed, covered by a few to many green algae. **Associated**: *Baggea* sp. {1}, *Cenangiopsis alpestris* {1}, *Crumenulopsis* sp. {1}, *Cyathicula* sp. {1}, *C. hysterioides* {1}, *C. nigrofusca* {1}, *Durella connivens* {1}, *Godronia fuliginosa* {1}, *Hymenoscyphus infarciens* {1}, *Hyphodiscus ?hymeniophilus* {1}, *Karstenia* sp. {1}, *K. idaei* {1}, *Lindgomyces griseosporus* {1}, *Mellitiosporiella pulchella* {1}, *Mollisia rosae* {2}, *Neodasyscypha cerina* {1}, *Orbilia arachnovinosa* {1}, *O. aristata* {4}, *O. asturiensis* {1}, *O. coniferarum* {1}, *O. delphinus* {4}, *O. eucalypti* {1}, *O. fabacearum* {1}, *O. flagellispora* {1}, *O. flexisoma* {1}, *O. gambelii* {1}, *O. multiphanosoma* {1}, *O. ovalis* {3}, *O. patellarioides* {1}, *O. phragmotricha* {1}, *O. pleiogambelii* {1}, *O. somedana* {2}, *O. vinosa* {1}, *O. vitalbae* {1}, *Ostropa barbara* {1}, *Otthia spiraeae* {1}, *Parmelia sulcata* {1}, *Patinellaria sanguinea* {1}, *Perrotia flammea* {2}, *Physcia* sp. {1}, *Pleurosticta acetabulum* {1}, *Propolis farinosa* {1}, *Pseudohelotium ?sordidulum* {1}, *Pyrenopeziza aquosa* {1}, *Sarea resinae* {1}, *Sclerococcum* sp. {1}, *Usnea* sp. {1}, crustose lichens. **Desiccation tolerance**: fully tolerant for at least 2 months, some spores still viable after 10 months. **Altitude**: 470–550 m a.s.l. (Scandinavia), (928–)1385–1950 m (European Alps), 1350–1650 m (Spain). **Geology**: America: Proterozoic to Cambrian-Ordovician sediments; Europe: Middle & Upper Jurassic and Cretaceous marl, limestone & siliceous chalk, dolomite, Eocene flysch; granite, diorite, gneiss, migmatite, andesite, quartz, mica schist, amphibolite, (trachy-) basaltic flow. **Phenology**: (II–)VI–X (probably throughout the year, long-lived, but difficult to collect during winter).

Phenology of *O. subtrapeziformis*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0	1	0	1	1	14	7	13	2	2	0	0

Taxonomic remarks. *Orbilia subtrapeziformis* is characterized by medium-sized, fusiform ascospores having acute apices and mostly strongly tapered, often ± curved bases, and subulate, somewhat flexuous spore bodies being basally ± distinctly inflated. *O. filiformis* has a very similar spore shape, but the spores tend to be slightly narrower and the often distinctly longer SBs are distinctly narrower. *O. obtusispora* differs in less fusiform spores with more obtuse apices, and a colline to atlantic or mediterranean distribution. The Australian *O. phragmitis* differs in the presence of crystalloid SCBs and a subtropical habitat. *O. idahoensis* resembles *O. subtrapeziformis* in the spores which have, however, a considerably higher length/width ratio. For the similar *O. macrotrapeziformis*, known from warm-temperate to subtropical semihumid to semiarid Australia and North America, see p. 1098. *O. delphinus* resembles *O. subtrapeziformis* in spore shape but differs in 16-spored asci.

Variation. The collections from the Alps show some variation in spore size (especially length), shape, and curvature, but this variation was observed to a considerable extent also within a population. In the sample from Norway (Pl. 615: 3) the spores were only slightly to medium tapered and hardly curved at the base, reminiscent of *O. macrotrapeziformis*, but such spores occurred also in other collections together with the more typical ones. Two samples from North America (Pl. 615: 6; IVV: H.B. 6234c) and one from Mongolia (Pl. 616: 13) fit rather well those from central Europe. Their spore length is at the lower end of the range: H.B. 6234c †9.5–11 × 2.3–2.4 µm, Mongolia *(8.3–)9–11(–12.5) × 2.3–3 µm. The apothecia in the Mongolian specimen are remarkable in having a short stipe. On the contrary, spore length in the Macaronesian specimen (Pl. 616: 12) is at the upper end of the range (*12.5–16 × 2.3–2.6 µm). One of the two samples from Lapland (Pl. 616: 1) deviates in extraordinarily long asci (*85–100 µm), also in unusually large and thick apothecia (0.5–0.8 mm diam., 1b), measurements which do not even overlap with most of the other collections.

Phylogeny. A somewhat incomplete sequence of the ITS region was gained from apothecia of a collection on *Rhamnus* from Asturias. It clustered unresolved and with high distance in the *Serpentinae-Habrostictis* clade (~15% to *O. trapeziformis* from Germany, on *Juglans*) (Phyl. 19). The similar *O. obtusispora* (distance 16%) and two samples identified as *O. trapeziformis* (from France, on *Corylus* and *Cercis*) surprisingly clustered with high support in the *Ellipsospermae* clade.

Ecology. *O. subtrapeziformis* was collected on ± rotten wood and bark of xeric twigs and branches of various angiosperm (exceptionally gymnosperm) trees and shrubs. The species appears to be restricted within Europe to hemi- to oroboreal, orotemperate (altimontane to subalpine) and orosubmediterranean humid areas. One of the more frequently recorded vegetation types is the subalpine green alder dwarf shrub (*Alnetum viridis*). However, sparse records suggest a wide, possibly worldwide distribution, which includes orotemperate humid southeastern Europe (Caucasus), continental, orotemperate (sub)humid (winter-dry), alpine central Asia (Mongolia), the supramediterranean semihumid summit broom scrub (*Spartocytisetum supranubii*) in the caldera of the volcano Teide in Tenerife (Macaronesia), and boreal humid Douglas fir forests with *Salix*, *Populus* and *Acer* in the Canadian Rocky Mountains and Utah Mountains of western North America.

Specimens included. **NORWAY**: **Oslo**, 8 km NW of Oslo, 1.8 km NNE of Holmenkollen, N of Frognerseteren, 470 m, branch of *Populus tremula*, on bark, 14.VIII.2002, G. Orbilia halimi Baral & E. Weber, **sp. nov.**, MB 813672 — Pls 617–618

Etymology: named after the specific epithet of the host species.
Typification: Spain, Lérida, branch of *Atriplex halimus*, 21.IX.1999, H.O. Baral (ex H.B. 6472b; M-0276491, holotype; ex-type culture: CBS 116272; sq.: KT215240).

Latin diagnosis: *Similis* Orbiliae subdelphino *sed asci octospori, ab* Orbilia phragmitis *sporis brevioribus differt. Habitat ad lignum vel corticem putridum ramorum siccorum* Atriplicis halimi *in zona mesomediterranea semiarida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3(–0.45) mm diam., 0.11–0.15 mm high, pale to light (yellowish-)orange, hardly translucent, round, scattered to subgregarious; disc flat, margin distinct, thin or thick, not protruding, ± smooth; broadly sessile, almost superficial to entirely immersed between fibres. **Asci** *50–68 × 5.7–6.3 µm, †39–58 × 4.3–5.5 µm, 8-spored, spores (†) biseriate, 3–5 lower spores inverted (often mixed, sometimes upper spores inverted) {2}; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to medium long, ± thick, flexuous stalk, L- to h-shaped. **Ascospores** *(7–)8–11 × 2–2.5 µm {2}, †7–11 × 1.9–2.3 µm, fusoid- to fusiform-clavate, apex acute to acuminate, base medium attenuated to a rounded, partly tail-like end, straight to often slightly or medium curved at base; **SBs** *5–6.7 × 0.5–0.8 µm in situ (~5–7.5 µm actual length), vermiform to subulate, usually slightly to medium swollen at base, straight to medium flexuous. **Paraphyses** apically medium to strongly clavate-capitate, terminal cells *6–16 × 4–5 µm, †3–5(–5.5) µm wide, lower cells *11–14 × 1.5–2.2 µm; rarely branched near apex. **Medullary excipulum** 20–40 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** of thin-walled, indistinctly oriented t. angularis from

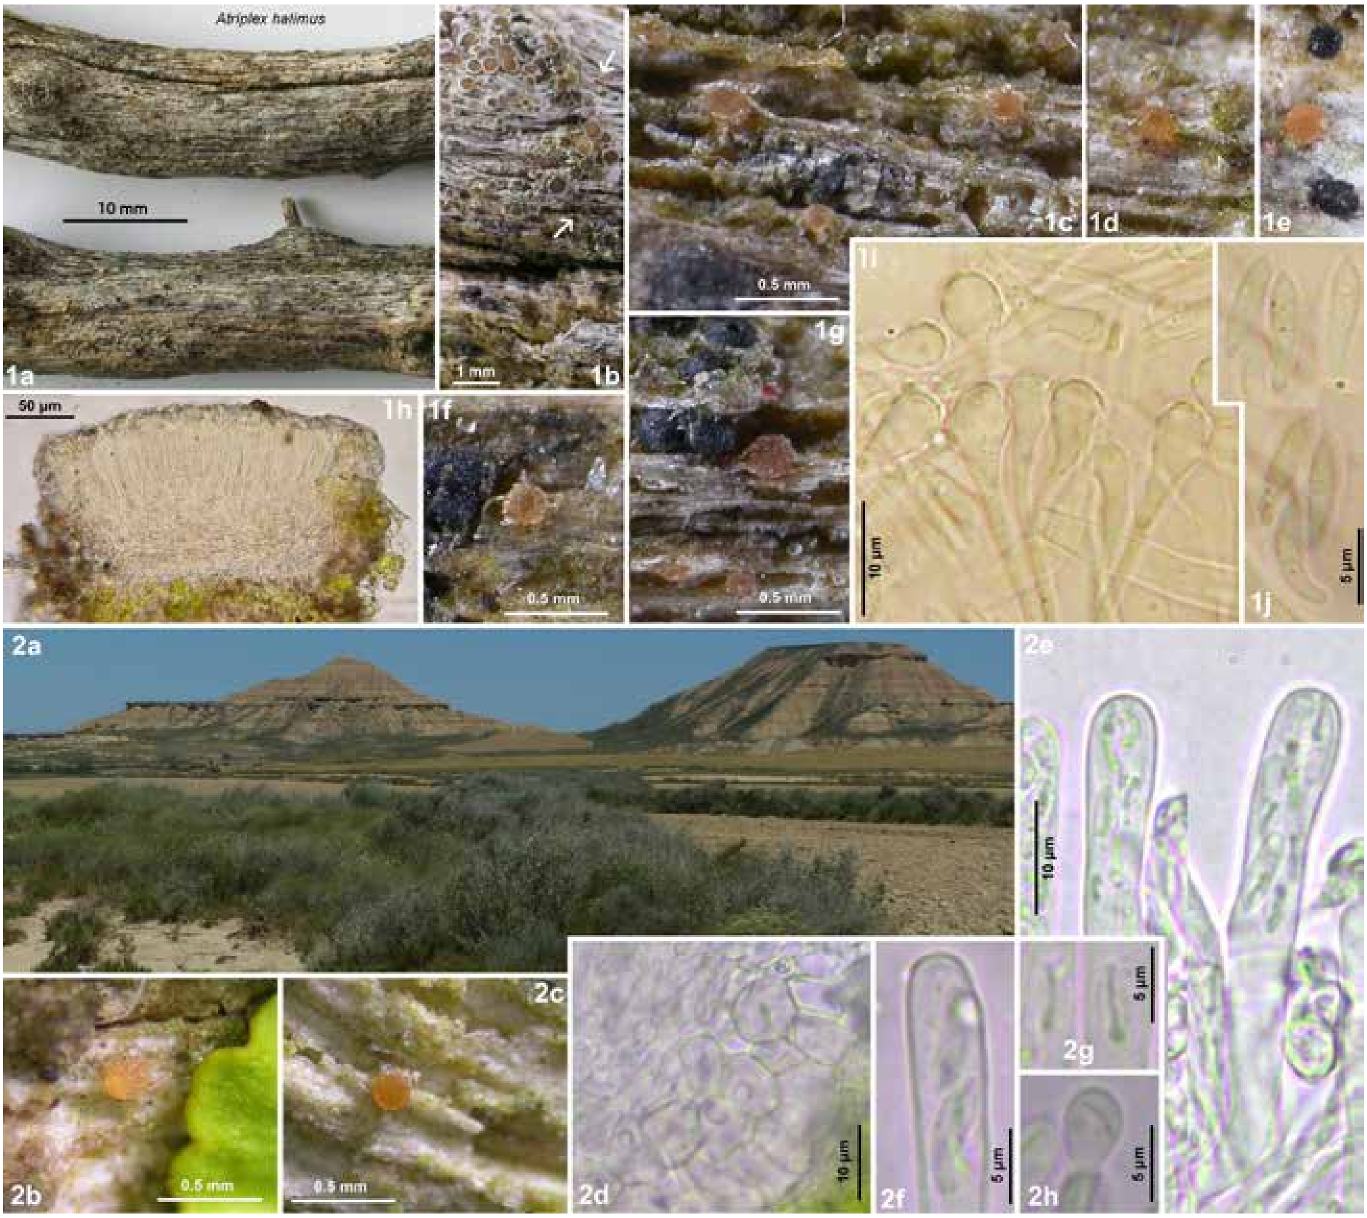

Plate 618. **1–2**: *Orbilia halimi*. – **2a**. halophilous mediterranean scrub with *Atriplex halimus*; **1a**. decorticated xeric branches; **1b**. apothecia growing near *Lecanora* sp.; **1c–g**, **2b–c**. rehydrated apothecia (**2b** with thallus of *Xanthoria*); **1h**. apothecium in median section; **2d**. id., ectal excipulum at flanks, with crystalloid SCBs; **2e**. asci; **2f**. ascus apex; **1i**, **2h**. paraphysis apices; **1j**, **2f**. ascospores; **2g**. spore apices with SBs. – Living state, except for **1h–j** (in KOH), **2f** (ascus). — **1a–j**. H.B. 6472b (holotype): Spain, Lérida, on *Atriplex*; **2a–h**. J.P.P. 15108: Spain, Navarra, on *Atriplex*.

base to mid flanks, 30–40 µm thick near base, cells †8–14 × 6–13 µm; 20–25 µm thick near margin, of t. prismatica-porrecta oriented at a 10–40° angle to the surface, marginal cortical cells †7–10 × 2.5–5 µm. **Anchoring hyphae** rather sparse, †2–3 µm wide, walls 0.2 µm thick, extending to the margin as a thin layer. **SCBs** in paraphyses and ectal excipulum (near margin) crystalloid {2}, hyaline, also globose {1}. **Exudate** over paraphyses and margin 0.2–0.7 µm thick, cloddy-granular, firmly attached, hyaline. — **ANAMORPH**: trinacrium-like (from ascospore isolate and natural substrate {1}). **Conidiophores** not observed. **Conidia** Y-shaped, total size *30–38 × 25–36 µm, stipe *16–20 × (4.5–)5.5–6.7 µm, 2-septate (exceptionally 3–4-septate), arms *15–20 × 4.7–5.5(–6) µm, 2-septate, arms and stipe always more or less abruptly tapering; unbranched phragmoconidia very sparse, e. g. *44 × 5.5 µm, 4-septate.

Habitat: collected 2–80 cm above the ground, corticated or decorticated, 9–17 mm thick branches of *Atriplex halimus* {2}, on 0.1–0.2 mm deep strongly decayed wood {2} and bark (bast) {1}, somewhat greyed, with many green algae. **Associated**: *Eutypella* sp. {1}, *Lecanora* sp. {1}, *Orbilia multiurosperma* {2}, ?*Phoma* sp. {1}, *Xanthoria* sp. {1}. **Desiccation tolerance**: fully viable for at least 5 months. **Altitude**: 160–283 m a.s.l. **Geology**: Quaternary clay, sand & gravel. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia halimi* appears to be closely related to *O. bicknellensis*, from which it markedly differs in smaller, particularly narrower ascospores, also in narrower SBs. *O. subdelphinus* differs from *O. halimi* mainly in 16-spored asci. An Australian collection on *Atriplex nummularia* here assigned to *O. bicknellensis* (Pl. 655: 2) has spores very similar to *O. halimi* though distinctly wider, and may well form a transition between the two species. The Australian *O. phragmitis* also appears to be closely related to *O. halimi*, but differs in much longer spores with more strongly attenuated bases. The montane *O. subtrapeziformis* differs from *O. halimi* in the consistent absence of crystalloid SCBs and in slightly larger spores.

Not included collection: A mediterranean collection from Portugal on bark of *Olea* (IVV: H.B. 9114) deviates from *O. halimi* in larger spores of *10–13(–15) × 2.4–2.7 µm with wider SBs (5.5–7 × 1–1.2 µm). In spore morphology this specimen resembles *O. obtusispora*, and particularly *O. subtrapeziformis*. However, crystalloid SCBs were observed in many of the paraphyses, though not in the excipular cells. Spore morphology and crystalloid SCBs are reminiscent of *O. subdelphinus*, a species with 16-spored asci.

Phylogeny. A sequence was gained from the ex-type culture which comprises SSU (without S1506 intron), ITS, and LSU. This sequence differs only slightly from that of *O. vermiculati* (1.5% in ITS, 0.8% in LSU), with which it formed a strongly supported clade (Phyls 19–20), although the two species have very different spore apices and SCBs. The two clustered with *O. serpentina* in a medium (ITS) or unsupported clade (SSU+ITS+LSU).

Ecology. *O. halimi* was collected on rotten wood and bark of xeric branches of *Atriplex* in desertic halophilous ruderal *Atriplex* scrubs (*Agrostio-Tamaricetum canariensis*) in mesomediterranean semiarid southwestern Europe. In both collections *O. multiurosperma* grew in association. The not included sample was from a mesomediterranean semihumid *Quercetum ilicis*.

Specimens included. **SPAIN**: **Navarra**, 19 km SSW of Carcastillo, 7 km NE of Arguedas, Bardenas Reales, 283 m, branches of *Atriplex halimus*, on wood, 17.V.2015, J.P. Priou (J.P.P. 15108, doc. vid.). – **Cataluña**, **Lérida**, 10 km WSW of Lérida, 2.5 km NW of Alcarràs, 160 m, branch of *A. halimus*, on wood & bark, 21.IX.1999, H.O. Baral (M-0276491, **holotype**; **isotype** in H.B. 6472b; anam. cult., anam. substr., CBS 116272; sq.: KT215240).

Not included. **PORTUGAL**: **Santarém**, 10 km NNW of Santarém, 2.3 km NE of Romeira, Val de Flores, 60 m, branch of *Olea europaea*, on wood, 5.V.2009, J.P. Priou (J.P.P. 29080 ø, H.B. 9114 ø).

Orbilia phragmitis Baral, sp. nov., MB 813673 — Pls 619–620

Etymology: named after the host, *Phragmites australis*.

Typification: Australia, Queensland, Mossman, leaves of *Phragmites australis*, 28.VIII.2006, G. Marson (ex H.B. 8501b, BRI AQ799194, holotype).

Latin diagnosis: *Similis* Orbiliae subtrapeziformi *sed cellulae excipuli in statu vivo corpuscula crystalloidea pallide aurantiaca continentes. Habitat ad culmos siccos* Phragmitis australis *in zona tropica humida Australiae septentrio-orientalis.*

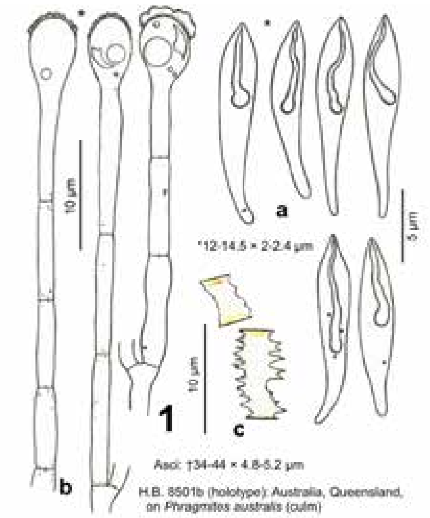

Plate 619. **1**: *Orbilia phragmitis*. – **a**. ascospores; **b**. paraphyses; **c**. crystalloid SCBs in basal cells of ectal excipulum.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.22–0.33 mm diam., 0.09–0.12 mm high, light orange, somewhat translucent, round, scattered; disc flat, margin distinct, not protruding, ± smooth; broadly sessile, superficial. **Asci** †34–44 × 4.8–5.2 µm, 8-spored, spores (†) ± biseriate, 3–4 lower spores inverted (not mixed); **apex** (†) medium to strongly truncate (not indented nor inflated); **base** with short to medium long, ± thick, flexuous stalk, T-, L-, Y- to h-shaped. **Ascospores** *12–14.5 × 2–2.4 µm, †11–13.5 × 1.9–2.2 µm, (strongly) fusiform to fusiform-clavate, apex acute to acuminate, base (very) strongly attenuated (often tail-like), straight to slightly curved, especially at base; **SBs** *(5–)6–7(–8) × 0.7–1(–1.2) µm in situ (~6–8.5 µm actual length), subulate, in aged spores 3 × 1.5 µm, ampulliform. **Paraphyses** apically medium to strongly clavate-capitate, terminal cells *13–20 × 3.5–4.6 µm, lower cells *7.5–12 × 1.3–1.7 µm (near base 6–8 × 1.8–2 µm); unbranched at upper septum, hymenium pale orange.

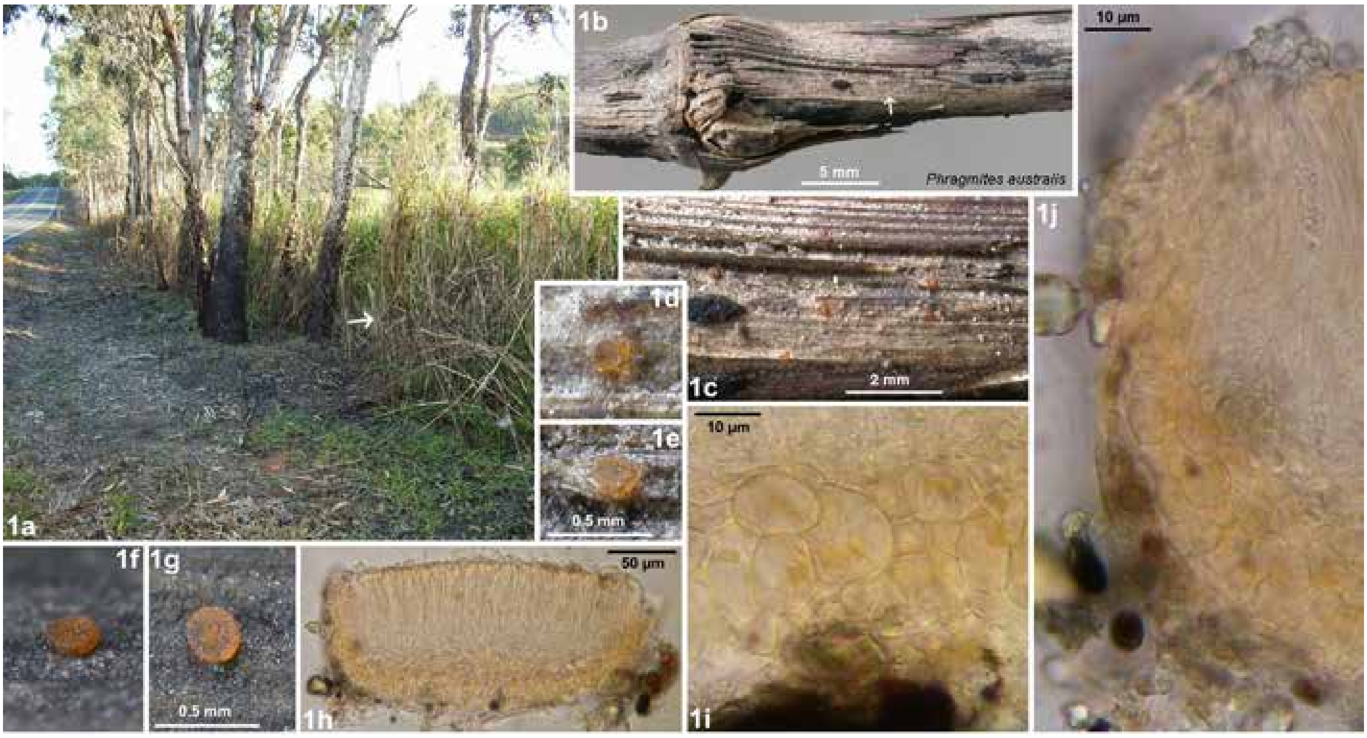

Plate 620. **1**: *Orbilia phragmitis*. – **1a**. tropical humid *Phragmites* stand; **1b**. dead (originally) standing culm; **1c–g**. rehydrated apothecia; **1h**. apothecium in median section; **1i**. id., basal ectal excipulum with SCBs; **1j**. id., marginal ectal excipulum. – Living state. — **1a–j**. H.B. 8501b (holotype): Australia, Queensland, on *Phragmites*.

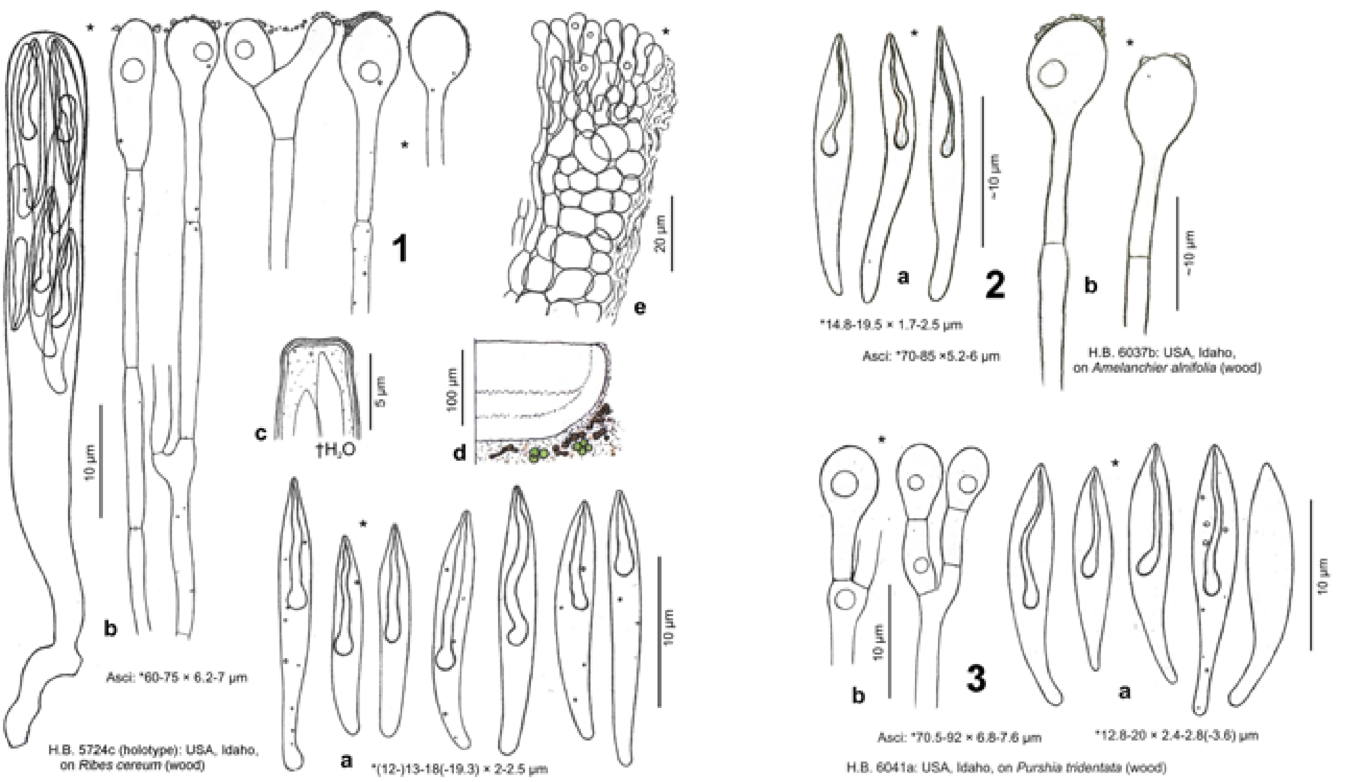

Plate 621. **1–2**: *Orbilia idahoensis*; **3**: *O.* cf. *idahoensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Medullary excipulum pale orange, 10–20 µm thick, of dense textura intricata with many inflated cells, sharply or indistinctly delimited. **Ectal excipulum** light orange, of (†) thin-walled, vertically oriented t. angularis-prismatica from base to mid flanks, 25–40 µm thick near base, cells *8–19 × 6–11(–13) µm; 15–20 µm thick near margin, of t. prismatica oriented at a 40–70° angle to the surface, marginal cortical cells *7–10 × 3–3.5 µm. **Anchoring hyphae** medium abundant, †2–2.8 µm wide, walls 0.2(–0.3) µm thick. **SCBs** in paraphyses globose, 0.8–2.3 µm diam., also crystalloid, subhyaline, in ectal excipulum from lower flanks to margin crystalloid, pale to light orange, 3–8 × 3–4(–6) µm. **Exudate** over paraphyses 0.2–0.3(–1) µm thick, granular-cloddy, hyaline, firmly attached, over margin and flanks 0.2–2 µm thick, rough-cloddy. **— ANAMORPH**: unknown.

Habitat: collected 0.1–0.5 m above the ground, on dead, standing, 7–9 mm thick culms of *Phragmites australis*, in region of node at the base of the medium strongly rotten leaf sheaths, greyed, no algae. **Associated**: *Arthrinium arundinis*, *Orbilia* ?*atlantis*, *O.* ?*breviaristata*, *O.* ?*puyae*, *O. stilbospora*. **Desiccation tolerance**: fully tolerant for at least 9 months (except for asci). **Altitude**: 390 m a.s.l. **Geology**. Devonian sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia phragmitis* closely resembles European *O. subtrapeziformis*, from which it markedly differs in the living state in the presence of crystalloid SCBs, particularly in the ectal excipulum. Also *O. halimi* on *Atriplex halimus* from Spain is very similar, differing mainly in distinctly shorter ascospores.

Ecology. The only known collection of *O. phragmitis* was on standing, dead, xeric culms of *Phragmites* which was covered over large areas by a black conidial layer of *Arthrinium arundinis*. The floodplain bordering the road is located between savannah and rainforest in tropical (sub)humid northeastern Australia.

Specimens included. **AUSTRALIA**: **Queensland**, Einasleigh Uplands (border to Wet Tropics), 22 km SSW of Mossman, 2 km N of Mount Molloy, Mossman Mt. Molloy Rd, 390 m, leaves of *Phragmites australis*, 28.VIII.2006, G. Marson (ex H.B. 8501b, BRI AQ799194, **holotype**).

Orbilia idahoensis Baral & G. Marson, **sp. nov.**,

MB 813674 — Pls 621–622

Etymology: named after the state Idaho (USA) in which the type was collected. **Typification**: USA, Idaho, Arco, twig of *Ribes cereum*, 4.VI.1996, G. Marson (ex H.B. 5724c, M-0276494, holotype).

Latin diagnosis: *Similis* Orbiliae subtrapeziformi *sed ascosporae distincte longiores et paulo angustiores. Habitat ad lignum putridum ramulorum et ramorum siccorum fruticum angiospermarum* in *zona temperata subhumida ad boreali humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.43 mm diam., 0.12–0.13 mm high, light to bright orange to brick-red, scarcely translucent, round, ± scattered; disc slightly concave to flat, margin distinct, 0–10 µm protruding, ± smooth; broadly sessile, superficial to slightly erumpent. **Asci** *(60–)70–75(–85) × (5.4–)6–7 µm {2}, †(45–)55–70 × 5.3–6 µm {2}, 8-spored, spores *3–4-seriate, 3–5 lower spores inverted {1} (often mixed), pars sporifera *30–37 µm long; **apex** (†) strongly truncate (slightly indented, laterally slightly widened); **base** with short, thick, ± flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(12–)13–18(–19.3) × 1.8–2.5 µm {3}, narrowly fusiform(-clavate), apex acute (to acuminate), base medium attenuated (tail-like), slightly curved near base; **SBs** *(5.5–)7–10.5 × (0.8–)1–1.3(–1.5) µm {2}, vermiform to subulate, with slightly to strongly swollen base, straight to medium flexuous. **Paraphyses** apically (slightly to) medium to very strongly clavate-capitate, rarely moniliform or lageniform, terminal cells *7.5–19 × (3–)4–5.3 µm {1}, lower cells *14–19 × 1.3–2(–3) µm {1}; rarely branched at upper septum. **Medullary excipulum** subhyaline, 30–40 µm thick, of loose textura intricata with many inflated cells. **Ectal excipulum** pale rose, of medium gelatinized (common walls †0.5–1.3 µm), vertically oriented t. globulosa-angularis from base to submargin, 20–35 µm thick near base, cells *12–21 × 10–15 µm {1}; 20 µm thick near margin, upper margin of t. prismatica oriented at a 10° angle to the surface, marginal cortical cells *10–15 × 3.5–5 µm {1}. **Anchoring hyphae** abundant, *2.5–3 µm wide, walls 0.2–0.4 µm thick {1}, forming a dense, ± gelatinized, hyaline t. intricata up to 40 µm thick, covering flanks and margin as a 5–12 µm thick layer. **SCBs** in paraphyses and ectal excipulum (upper margin) globose, 1.5–2 µm diam. **Exudate**

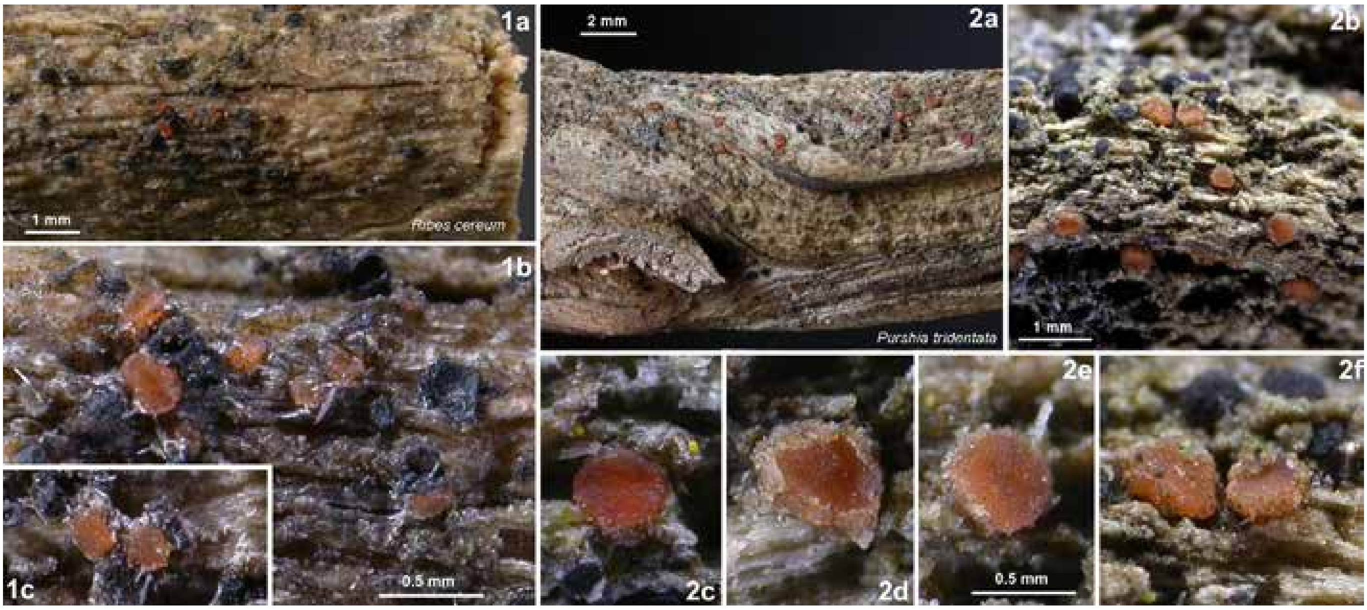

Plate 622. **1**: *Orbilia idahoensis*; **2**: *O.* cf. *idahoensis*. – **1a**, **2a**. decorticated xeric branches; **1b–c**, **2b–f**. rehydrated apothecia. — **1a–b**. H.B. 5724c (holotype): USA, Idaho, on *Ribes*; **2a–f**. H.B. 6041a: USA, Idaho, on *Purshia*.

over paraphyses and marginal excipulum 0.2–0.7 µm thick, granular-cloddy, firmly attached. **— ANAMORPH**: unknown.

Habitat: partially to entirely decorticated, 4–16 mm thick twigs and branches of *Amelanchier* (?)*alnifolia* {1}, *Cercocarpus* sp. {1}, *Ribes cereum* {1}, on 0.2–0.5 mm deep strongly decayed wood {2}, greyed, no algae. **Associated**: *Cyathicula* sp. {1}, *Melaspilea emergens* {1}, *Mellitiosporiella macrospora* {2}, *Orbilia delphinus* {2}, *O. maeandrina* {1}, *Pyrenopeziza* sp. {1}, *Teichospora* sp. {2}. **Desiccation tolerance**: fully tolerant for at least 9 months. **Altitude**: 1750–2570 m a.s.l. **Geology**: Mississippian & Permian carbonate sedimentary rock; volcanic mafic basaltic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia idahoensis* appears to be well characterized by its long and narrow, fusiform ascospores and rather wide, subulate spore bodies with a ± bulbous basal inflation. European *O. subtrapeziformis* differs in shorter and slightly wider spores, also the extra-European *O. macrotrapeziformis* and *O. flexisoma* differ in shorter and/or wider spores. *O. idahoensis* might be confused with *O. vinosa* (section *Hemiorbilia*), from which it differs in distinctly longer SBs and more acute spore apices, besides thin-walled truncate ascus apices.

Not included collection. A sample on *Purshia* (Pls 621: 3; 622: 2) appears to be intermediate to *O. flexisoma* in its wider spores and is, therefore, not included in either description.

Ecology. *O. idahoensis* was found on rotten wood of xeric twigs and branches of different angiosperm shrubs in the cold-temperate subhumid pinyon-juniper woodland at Craters of the Moon and Snake River Plain of the Columbia Plateau, and in boreal humid Douglas fir mixed forests of the Uinta Mountains in the Middle Rocky Mountains in western North America.

Specimens included. **USA**: **Idaho**, Columbia Plateau, 28 km SW of Arco, Craters of the Moon, 1752 m, twig of *Ribes cereum*, on wood, 4.VI.1996, G. Marson (ex H.B. 5724c, M-0276494, **holotype**). – 60 km E of Idaho Falls, 47 km W of Jackson, Swan Valley, 1750 m, twig & branch of *Amelanchier ?alnifolia*, on wood, 5.VI.1996, G. Marson (H.B. 6037b). – **Utah**, Uinta Mts., 34 km NNE of Vernal, 34 km SE of Manila, 2570 m, on *Cercocarpus*, 11.VI.1996, G. Marson (ø).

Not included. **USA**: **Idaho**, Columbia Plateau, 28 km SW of Arco, Craters of the Moon, 1752 m, twigs & branches of *Purshia tridentata*, on wood, 5.VI.1996, G. Marson (H.B. 6041a).

Orbilia flexisoma Baral & G. Marson, **sp. nov**., MB 813675 — Pls 623–624, Map 103

Etymology: named after the flexuous spore bodies.

Typification: USA, Arizona, Grand Canyon, Tusayan, branches of *Juniperus osteosperma*, 28.VIII.1994, G. Marson (ex H.B. 5438a, M-0276482, holotype).

Latin diagnosis: *Differt ab* Orbilia obtusispora *ascosporis majoribus. Habitat ad lignum putridum ramorum siccorum arborum angiospermarum vel coniferarum in zona temperata (sub)humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.7(–0.9) mm diam., 0.14–0.21 mm high (receptacle 0.14 mm), light to bright (yellowish-)orange, non-translucent, round (to elliptical), scattered to subgregarious; disc ± concave, soon flat, margin distinct, 0–80 µm protruding, finely rough to somewhat denticulate, whitish-powdered; broadly sessile, slightly to deeply immersed; dry brick-red. **Asci** *(60–)75–100(–113) × (6–)6.5–7.5(–8)((–8.8)) µm {3}, †(55–)60–90 × 5.5–6.5(–7) µm {3}, 8-spored, spores *2–3-seriate, (2–)3–5(–6) lower spores inverted {3} (often mixed), pars sporifera *(30–)40–60(–80) µm long; **apex** (†) strongly truncate (not or very slightly indented, laterally sometimes inflated); **base** with short to medium long, thick, flexuous stalk, T-, Y- to h-shaped. **Ascospores** *((9–))(10–)12–17(–20.3) × (2.4–)2.6–3.2(–3.8) µm {5}, †(9–)11–15(–17.3) × (2.5–)2.7–3.2(–3.5) µm {3}, fusoid- to fusiform-clavate, rarely also narrowly ellipsoid-obclavate, apex subacute, also acute or obtuse, base not or slightly to mostly medium to strongly attenuated in a tail-like base or a distinct, sometimes basally inflated tail, straight or slightly to sometimes strongly curved near base; **SBs** (4–)5–9 × 0.5–1(–1.2) µm in situ {2} (~6–11 µm actual length), vermiform to subulate, not or slightly (also distinctly) swollen at base, mostly strongly flexuous, sometimes uncinate; with or without some medium-sized LBs, hymenium pale rose. **Paraphyses** apically slightly to medium clavate, exceptionally spathulate, terminal cells *4.5–13 × (2–)2.8–4(–?5) µm {2}, lower cells *9.5–17 × 1.3–2(–2.3) µm {1}; unbranched at upper septum. **Medullary excipulum** pale rose, 30–70 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose, of (†) thin-walled to distinctly gelatinized, irregularly vertically oriented t. globulosa-angularis from base to mid flanks or submargin, 30–100 µm thick near base, cells *6–16(–20) × 6–13(–15) µm {2}; 20 µm thick at flanks, 15–30 µm near margin, of t. porrecta oriented at a 10–30° angle to the surface, upper margin up to 50 µm thick if protruding, with incurved, periphyses-like marginal cortical cells †8–14 × 2–3 µm {1}. **Anchoring hyphae** medium abundant, */†2.5–4 µm wide, walls 0.2–0.4 µm thick {1}, partly covering flanks and margin as a gelatinized layer. **SCBs** in paraphyses and ectal excipulum absent {2} or present

decayed wood {5}, strongly greyed, with sparse to abundant green algae. **Associated**: *Baggea* sp. {1}, *Caloplaca* sp. {1}, *Crumenulopsis* sp. {1}, *Dothideales* {1}, *Durella* sp. {1}, *Melanohalea subolivacea* {1}, *Mellitiosporiella* sp. {1}, *Odontotrema* sp. {1}, *Orbilia arizonensis* {2}, *O. calyptrata* {1}, *O. curvatitrapeziformis* {1}, *O. delphinus* {2}, *O. euonymi* {1}, *O. gambelii* {2/1}, *O. macrodelphinus* {1}, *O. maeandrina* {2}, *O. multiphanosoma* {1}, *O. multitrapezoidea* {1}, *O. navajoana* {1}, *O. ocellata* {1}, *O. ophiosoma* {2}, *O. ovalis* {1}, *O. purshiae* {1}, *O. subovoidea* {1}, *O. subtrapeziformis* {1}, *Patellaria atrata* {1}, *Perrotia flammea* {2}, *Sclerococcum* sp. {1}, *Tryblidaria ?fenestrata* {1}, crustose lichens. **Desiccation tolerance**: fully viable for at least 20 months, many excipular and paraphysis cells still viable after almost 3 years. **Altitude**: 830–2500 m a.s.l. **Geology**: USA: Mississippian & Permian carbonate sand-, shale- & limestone, rarely basaltic lava & cinders; Canada: alluvial deposits from Proterozoic-Cambrian-Ordovician sediments. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia flexisoma* is tentatively segregated from *O. obtusispora* based on slightly wider and mostly also longer ascospores, and from *O. macrotrapeziformis* based on mostly longer spores with more strongly flexuous SBs, somewhat less acute spore apices, and the partial presence of distinct spore tails, though spore tails were rarely also seen in *O. macrotrapeziformis*, and finally on much larger apothecia. *O. spathulata* resembles *O. flexisoma* in spores and SBs, but deviates in the apical spores being inversely oriented within the asci, paraphyses with predominantly spathulate apices, and presence of crystalloid SCBs. For the similar *O. edulis* (p. 1102) and *O. pyrenaica* (p. 1100) see there. In one of the two samples on *Quercus* (Pl. 623: 4) a separate population deviated in basally always medium to strongly curved spores and in growing on bark instead of wood. We have segregated this population as a distinct species, *O. curvatitrapeziformis* (Pl. 629: 2).

Variation. *O. flexisoma* strongly varies in spore shape from fusoid-clavate (slightly to strongly attenuated, with or without a distinct tail) to ellipsoid-obclavate. Globose SCBs are completely absent in the holotype and in the sample on *Cercocarpus*, but they were seen in other specimens, at least in some of the paraphyses. In one of the *Quercus* collections the spores were consistently provided with a tail (Pl. 623: 3). However, another examined apothecium showed such tails only in some of the spores, which was also the case in the other *Quercus* collection and in those on *Juniperus* (1–2, 4). Likewise, in the collection on *Cercocarpus* (Pl. 623: 5) variation in spore length and shape was noted between different apothecia.

Not included collections. Two samples on *Purshia* (Pls 623: 6–7; 624: 4–5) resemble both *O. flexisoma* and *O. macrotrapeziformis* in the spores, but the large apothecia of (0.3–)0.4–0.8(–1.2) mm diam., 0.16–0.31 mm high, with a whitish powdered-crenulate margin that protrudes about 20 µm, closely concur with those seen in, e. g., *O. flexisoma* and *O. idahoensis*. A third sample on *Purshia* (IVV: H.B. 7462c) featured small apothecia of 0.25–0.3 mm diam. just as in *O. macrotrapeziformis*, but was studied only in the dead state. We refrain here from including these three collections on *Purshia* in the description. Also a collection on *Larrea* was only studied in the dead state (IVV: H.B. 8477e); its apothecia strongly resemble those of *O. flexisoma*, but the spores are too short (†8.5–9.5 × 3.3–3.8 µm) to be included in that species.

Ecology. *O. flexisoma* was found on rotten wood of xeric branches of mainly *Juniperus* and *Quercus*, in the cold-temperate subhumid pinyon-juniper woodlands and humid ponderosa pine forests in the Grand Canyon and Mogollon Rim of Colorado Plateau the southwest of Northern America, also in a boreal humid conifer forest with *Populus tremuloides* and *Acer* in the Canadian Rocky Mountains. The not included collections on *Purshia* were from similar sites, while that on *Larrea* was from the warm-temperate arid Mojave creosotebush desert scrub.

Map 103. Known distribution of *O. flexisoma* in North America (yellow = not included collections).

Specimens included. **CANADA**: **British Columbia**, Canadian Rocky Mountains, 61 km SE of Golden, 1 km SE of Spillimacheen, 830 m, branch of *Acer*, on wood, 20.VIII.1997, G. slightly protruding, ± smooth; broadly sessile, superficial or immersed between fibres or in biofilm. **Asci** *(45–)50–65(–75) × (6–)6.5–7.5 µm {5}, †(48–)55–65 {2} × 5–5.8 {1} or 6–6.5(–7) µm {1}, 8-spored, spores *(obliquely) 2-seriate, (2–)3–5 lower spores inverted {5} (often mixed); **apex** (†) strongly truncate (partly distinctly indented and laterally inflated); **base** with short to medium long, ± thick, flexuous stalk, L- or h-shaped. **Ascospores** *(8–)9–13(–15.5) × (2.7–)2.8–3.3(–3.8) µm {5}, †(6–)8–10(–11) × 2.8–3.3 µm {2}, fusiform(-clavate), apex subacute to acute, rarely obtuse or acuminate, base slightly or medium, rarely strongly attenuated, straight or slightly curved; **SBs** *(4–)5–7.5(–10) × (0.6–)0.8–1(–1.2) µm in situ {4} [~5–11 µm actual length], vermiform to subulate, very slightly to medium inflated at base, slightly to strongly flexuous. **Paraphyses** apically medium to very strongly clavate-capitate, rarely moniliform, terminal cells *(4–)6–13(–25) {3} × (2–)3–4.5(–5) {3} or 5–7 {2} µm, †7–13 × 5–8 µm {T}, lower cells *7.5–16.5 × 1.3–2 µm {2} (subapically rarely up to 4 µm wide); not or rarely to often branched at upper septum, pale orange. **Medullary excipulum** pale orange, 35 µm thick, of dense textura intricata-angularis, sharply delimited. **Ectal excipulum** pale orange, of (†) ± thin-walled, indistinctly oriented t. angularis from base to margin, 30–45 µm thick near base, cells †6–11 × 5–10 µm {1}; 35–40 µm thick near margin, oriented at a high angle to the surface, marginal cortical cells not examined. **Anchoring hyphae** medium abundant, †2–2.7 µm wide, walls †0.2 µm thick {1}. **SCBs** in paraphyses and partly also in ectal excipulum (near margin) globose {4}, 1–3 µm diam.; **LBs** in ectal excipular cells pale yellow-orange {1} (carotenoids). **Exudate** over paraphyses, margin and flanks absent or 0.2–0.8 µm thick, rough, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 0–2 m above the ground, partially corticated to decorticated, 9–35 mm thick branches of *Acacia* sp. {1}, *Allocasuarina decaisneana* {1}, *Cylindropuntia versicolor* {1}, *Jacksonia* sp. {1}, on 0.1 mm deep strongly decayed wood {4} or bark {3}, inflorescence

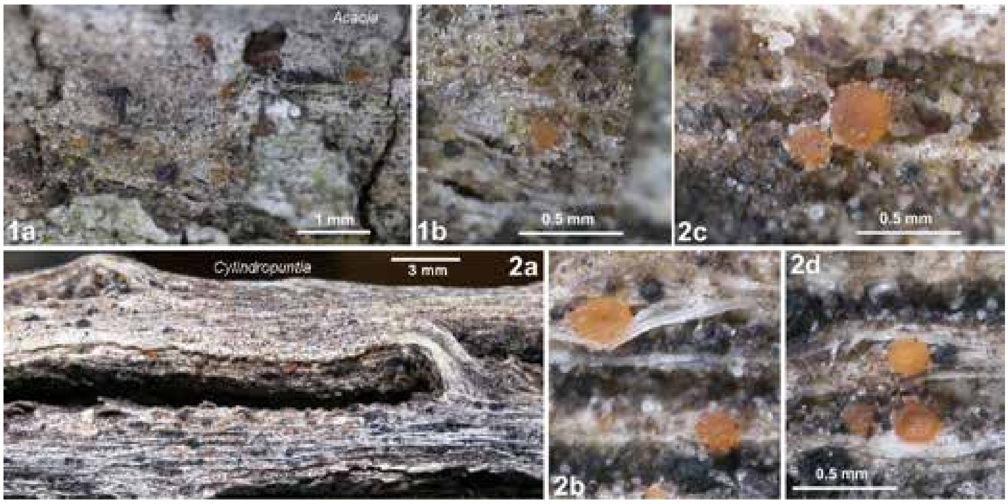

Plate 626. **1–2**: *Orbilia macrotrapeziformis*. – Rehydrated apothecia. — **1a–b**. 8745l: Western Australia, Wanneroo, on *Acacia*; **2a–d**. H.B. 8678 (holotype): USA, Arizona, on *Cylindropuntia*.

stem of *Yucca elata* {1}, very greyed, without or with many green algae. **Associated**: *Amandinea* sp. {1}, *Baggea* sp. {1}, *Caloplaca* sp. {1}, *Claussenomyces* sp. {1}, *Cyathicula nigrofusca* {1}, *Durella* sp. {1}, *D.* aff. *connivens* {1}, *Gloniopsis praelonga* {1}, ?*Hysteropatella* sp. {1}, *Hypoxylon* sp. {1}, *Muellerella lichenicola* {1}, *Orbilia albidorosea* {1}, *O. australiensis* {1}, *O. bicknellensis* {1}, *O. commarosa* {1}, *O. curvativitalbae* {1}, *O. eucalypti* {1}, *O. kingsiana* {1}, *O. microserpens* {2}, *O. multigambelii* {1}, *O. multivinosa* {1}, *O. myriofusiclava* {2}, *O. myrioobliqua* {1}, *O. nothovinosa* {1}, *O. phanosoma* {1}, *O. pleiolentiformis* {1}, *O. pleioobtusispora* {1}, *O. pleioquaestiformis* {1}, *O. pleiovitalbae* {1}, *O. pluristomachia* {2}, *O. serpentina* {2/1}, *O. wannerooensis* {1}, *O. yuccae* {1}, *Patellaria atrata* {1}, *Schizoxylon* sp. {1}, *Teichosporella dura* {2}, *Symbiotaphrina desertorum* {1}. **Desiccation tolerance**: fully viable for 18 months. **Altitude**: 37–500 m (Australia), 615–1120 m (North America). **Geology**: Cretaceous sedimentary rock, Cenozoic sand-, lime- and mudstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia macrotrapeziformis* differs from the three predominantly European species *O. trapeziformis*, *O. subtrapeziformis* and *O. obtusispora* in wider asci and ascospores, from *O. trapeziformis* also in longer spores. The North American *O. bicknellensis* and *O. spathulata* differ from *O. macrotrapeziformis* in the presence of crystalloid SCBs, the latter also in the upper spores being predominantly inverted, and in spathulate paraphysis apices. The Australian *O. wannerooensis* deviates from *O. macrotrapeziformis* in consistently inverted upper spores. *O. idahoensis* differs in longer and narrower, basally tapered spores and larger apothecia, but a collection on *Purshia* (Pl. 621: 3) appears to be somewhat intermediate to *O. macrotrapeziformis* (or *O. flexisoma*?) because of wider spores. *O. edulis*, *O. flexisoma* and *O. pyrenaica* are only tentatively separated from *O. macrotrapeziformis*.

Variation. *O. macrotrapeziformis* varies only slightly in spore size and shape and in SB size. The spore bases vary between slightly and strongly attenuated, but this variation occurs usually within an apothecium. The three Australian samples certainly belong to a single species, whereas the two North American ones deviate from those in slightly longer and narrower asci, rather short spores with partly obtuse apices, partly rather short SBs, and apically more strongly capitate, much wider paraphyses of around *5–7 compared to *3–4.5 µm. Macroscopically they concur well with the samples from Australia.

Not included collection. A North American sample on *Mahonia fremontii* (Pl. 625: 6), which somewhat resembles *O.* cf. *sonorensis* (Pl. 671: 3), is not included in the description because of rather short spores.

Ecology. *O. macrotrapeziformis* was found on different angiosperms in a subtropical semihumid banksia-eucalypt woodland and acacia mixed shrubland of southwestern Australia and in a subtropical arid acacia open shrubland of central Australia (Ayers Rock area). The samples from western North America derive from warm-temperate semiarid mixed grass-scrubland in the Chihuahuan Desert and a subtropical semiarid Sonoran paloverde-mixed cacti desert scrub, the not included sample from the warm-continental semiarid pinyon-juniper woodland in the Colorado Plateau.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 30 km NE of Perth, 4 km N of Upper Swan, W of Walyunga, 37 m, branch of *Jacksonia*, on wood & bark, 23.XI.2001, G. Marson (H.B. 7284m ø). – 30 km NNW of Perth, 1 km NW of Kinross, Tamala Park, 40 m, branch of *Acacia*, on bark, 23.X.2007, G. Marson (H.B. 8745l ø). – **Northern Territories**, Great Sandy Desert, 11.5 km ENE of Yulara, 14 km NNE of Ayers Rock, 500 m, branch of *Allocasuarina decaisneana*, on wood, 12.X.1998, G. Marson (H.B. 6617c). — **USA**: **Arizona**, Sonoran Desert, 82 km NW of Phoenix, ~1.5 km SE of Wickenburg, 615 m, branch of *Cylindropuntia versicolor*, on wood & bark, 4.V.1995, G. Marson (ex H.B. 8678, M-0281050, **holotype**). – **New Mexico**, Chihuahuan Desert, ~13 km W of Artesia, ~1120 m, inflorescence stem of *Yucca elata*, on wood, 25.V.1996, G. Marson (H.B. 5655f).

Not included. **USA**: **Utah**, Canyonlands, 35 km WSW of Moab, Upheaval Dome, Whale Rock, 1745 m, branch of *Mahonia fremontii*, on wood, 17.VI.2000, G. Marson (H.B. 6735a ø).

Orbilia pyrenaica Baral, Priou & E. Weber, **sp. nov.**, MB 813679 — Pls 627–628

Etymology: named after the geographical origin, eastern Pyrenees.

Typification: France, Font-Romeu-Odeillo-Via, branch of *Fraxinus excelsior*, 18.X.2008, J.P. Priou (ex H.B. 8945, M-0276575, holotype).

Latin diagnosis: *Similis* Orbiliae macrotrapeziformi *sed corpuscula refringentia multo longiora, apothecia majores, margine crenulata. Habitat ad lignum putridum rami sicci* Fraxini excelsioris in *zona orotemperata humida Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5 mm diam., 0.15 mm high, light to bright dull orange, slightly translucent, ± round, scattered to subgregarious; disc flat, margin whitish to pale orange, 5–10 µm protruding, distinctly crenulate; broadly sessile, immersed between fibres and biofilm, dry medium contracted, with dark orange to brick-red disc. **Asci** *65–80(–85) × 6.3–7 µm, †65–72 × 5.5–6.5 µm, 8-spored, spores *(obliquely) 2-seriate, 2–6(–7) lower spores inverted (rarely mixed), pars sporifera *36–45 µm long; **apex** (†) strongly truncate (hardly indented, laterally not inflated); **base** with short to long, ± thick, flexuous stalk, T- or L-shaped. **Ascospores** *11–13.3 × 2.9–3.3 µm, fusoid to fusiform, apex acute (to acuminate), base slightly or medium attenuated, straight or slightly inequilateral; **SBs** *8–12.7 × 0.7–1 µm in situ (~12–15 µm actual length), vermiform-subulate, slightly to medium inflated at base, strongly flexuous. **Paraphyses** apically medium to very strongly clavate-capitate, rarely spathulate, terminal cells *6–17.5(–20) × (3.5)4.5–5.5(–6) µm, lower cells *(8–)11–16 × 1.5–2 µm (subapically up to 3.3 µm wide); unbranched at upper septum, hymenium pale orange. **Medullary excipulum** pale orange, 40 µm thick, of ± loose textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** pale orange, of (†) thin-walled, irregularly oriented t. angularis-prismatica from base to submargin, 25–40 µm thick near base, cells *10–16 × 7–9 µm; 30–40 µm thick near margin, of t. prismatica-angularis oriented at

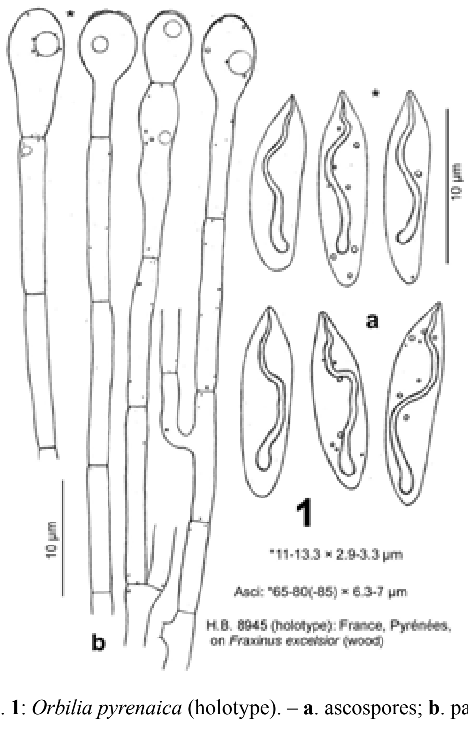

Plate 627. **1**: *Orbilia pyrenaica* (holotype). – **a**. ascospores; **b**. paraphyses.

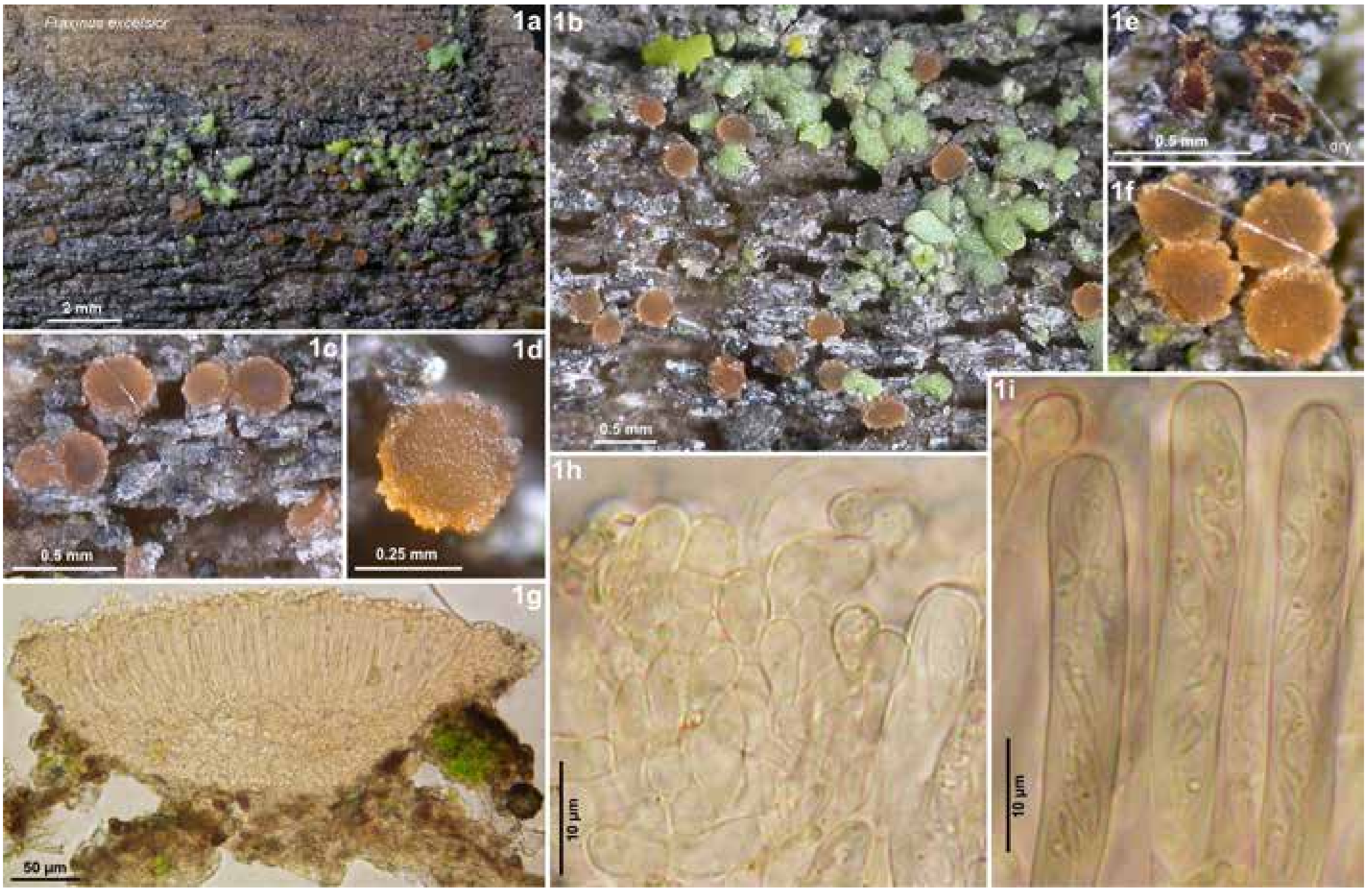

Plate 628. **1**: *Orbilia pyrenaica*. – **1a–d**, **f**. rehydrated apothecia; **1e**. dry apothecia; **1g**. apothecium in median section; **1h**. id., marginal ectal excipulum; **1i**. asci. – Living state; **1e–f**: phot. J.P. Priou. — **1a–i**. H.B. 8945 (holotype): France, Pyrenees, on *Fraxinus*.

a 0–20° angle to the surface, marginal cortical cells *8–12 × 4.5–6(–7) µm. **Anchoring hyphae** sparse, *2–3.3 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.3–3 µm diam. **Exudate** over paraphyses and margin 0.1–0.3 µm thick, rough, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 2.5 m above the ground, decorticated, 15 mm thick branch of *Fraxinus excelsior*, on wood, outer 0.2–0.5 mm strongly decayed and greyed, with many green algae. **Associated**: *Orbilia ?obtusispora*, *?Physcia* sp., *Xanthoria* sp. **Desiccation tolerance**: fully viable for 2 weeks, after 30 months still some excipular cells, paraphyses and ascospores alive. **Altitude**: 1540 m a.s.l. **Geology**: granite. **Phenology**: long-lived.

Taxonomic remarks. With its medium-sized apothecia with a light orange disc and a whitish crenulate margin, *O. pyrenaica* closely resembles *O. flexisoma*, from which it is separated by ascospores with acute apices and without tail-like bases or distinct tails, and by longer SBs. The extra-European *O. macrotrapeziformis* differs from *O. pyrenaica* in shorter SBs, while a North American collection with very long SBs mentioned under *O. bicknellensis* (Pl. 655: 4) differs in having crystalloid SCBs in the paraphyses; both deviate also in smaller apothecia with a ± smooth margin. The Australian *O. livistonae* with very similar ascospores differs in 32-spored asci.

A few associated, minute, carmine-red apothecia with an indistinct margin were briefly studied by J.P. Priou (IVV: J.P.P. 28166 p.p.) and might belong to *O. obtusispora*. Their fusoid-clavate spores (*10–12 × 3 µm) with a strongly attenuated lower part and SBs only half as long as the spores are quite different from those of *O. pyrenaica*.

Ecology. *O. pyrenaica* grew on rotten wood of xeric, attached branches of *Fraxinus* in an orotemperate humid high plateau on acidic soil in the eastern Pyrenees in southwestern Europe, at the road side of a solar power station in a cut grassland with planted old ash trees.

Specimens included. **FRANCE**: **Languedoc-Roussillon**, **Pyrénées-Orientales**, 4 km N of Saillagouse, 1.5 km SW of Font-Romeu-Odeillo-Via, Four Solaire d'Odeillo, 1540 m, branch of *Fraxinus excelsior*, on wood, 18.X.2008, J.P. Priou (ex H.B. 8945, M-0276575, **holotype**; **isotypes** in J.P.P. 28195, 28166 p.p.).

Orbilia curvatitrapeziformis Baral, G. Marson & Quijada **sp. nov.**, MB 813704 — Pls 629–630

Etymology: named after the curved ascospores and the resemblance to *O. macrotrapeziformis*.

Typification: USA, Arizona, Parks, branch of *Quercus gambelii*, 29.VIII.1994, G. Marson (ex H.B. 8682b, M-0276468, holotype).

Latin diagnosis: *Differt ab* Orbilia macrotrapeziformi *et* O. flexisomati *ascosporis magis curvatis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.23-0.75 mm diam., 0.2–0.25 mm high, light to bright brick-orange, ± non-translucent, round (to ellipsoid), scattered to subgregarious; disc flat, margin distinct, thick, (5–)10–25 µm protruding, rough, partly whitish pulverulent; sessile on an obconical base, ± erumpent from cracks or between fibres. **Asci** *60–72 × 6.5–8 µm {T} or *85–98(–117) × 6.7–7.5 µm {1}, †57–70 × 6–7.7 {T} or †(53–)65–80 × 5.7–6.3 µm {1}, 8-spored, spores *2–3-seriate, 2–5 lower spores inverted {2}, pars sporifera *30–45 µm long; **apex** (†) strongly truncate (distinctly indented, laterally inflated); **base** with short to long, thick, gradually tapered, slightly flexuous stalk, L- to Y-, rarely H-shaped. **Ascospores** *(10–)11–13.5(–14.5) × (2.5–)2.7–3(–3.3) µm {2}, †9–12.3 × 2.5–2.7 µm {1}, cylindric to fusoid-clavate, apex (subacute to) acute, base not or slightly to medium attenuated but also slightly thickened, slightly to very strongly curved near base; **SBs** *(4–)5–7(–8) × 0.7–1 µm in

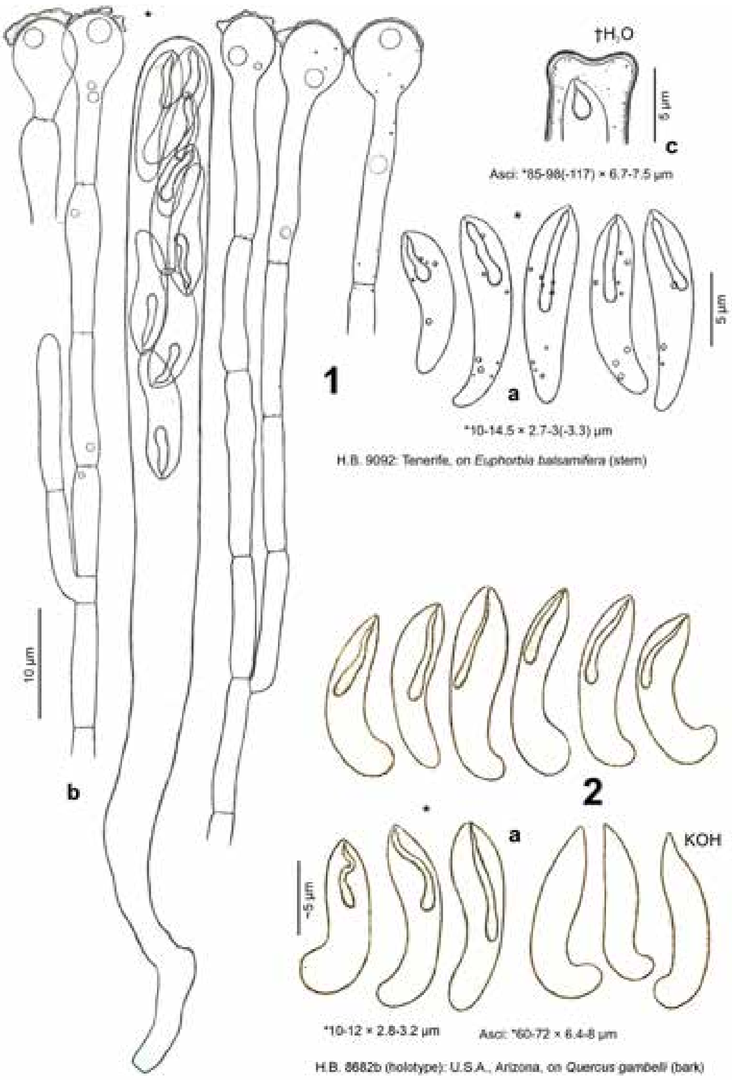

Plate 629. **1–2**: *Orbilia curvatitrapeziformis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

situ {2} → 3–5 × 1.1–1.3 µm, vermiform to subulate, partly distinctly inflated at base, straight to slightly, rarely strongly flexuous. **Paraphyses** apically medium to (very) strongly (clavate-)capitate, terminal cells *(9–)12–24(–33) × (3–)4–6.2 µm {1}, lower cells *8–17 × 2–3 µm {1}; unbranched at upper septum. **Medullary excipulum** pale orange, 40–90 µm thick, of dense textura intricata, with distinct inflated cells only near margin, indistinctly to medium sharply delimited. **Ectal excipulum** subhyaline, of (†) slightly gelatinized, very indistinctly oriented t. globulosa-angularis from base to submargin, 40–60 µm thick near base, cells *9–20 × 7–14(–18) µm {1}; 30–40 µm thick at mid flanks and margin, at margin of t. prismatica-angularis, oriented at a 10–20° angle to the surface, marginal cortical cells *10–17 × 4–5(–6) µm {1}. **Anchoring hyphae** sparse, †2–4 µm wide, walls 0.2–0.3 µm thick {1}, covering flanks and margin as a thin layer. **SCBs** in paraphyses globose, 0.7–2.5 µm diam. {2}; **Exudate** over paraphyses and margin 0.2–2 µm thick, cloddy-tuberculate, hyaline, firmly attached. — **ANAMORPH**: unknown.

Habitat: attached, corticated, 10–14 mm thick branch of *Quercus gambelii* {1}, on strongly decayed bark (bast) {1}, rotten decorticated branches of *Euphorbia balsamifera* {1} lying on ground, ± greyed, green algae sparse. **Associated**: *Durella* sp. {1}, *Orbilia flexisoma* {1}, *O. gambelii* {1}, *Patellaria atrata* {1}, *Perrotia flammea* {1}. **Desiccation tolerance**: fully viable for at least 3 months. **Altitude**: 2165 m a.s.l. (USA), 17 m (Macaronesia). **Geology**: USA & Tenerife: Basaltic lava and cinders with andesite & rhyolite. **Phenology**: long-lived.

Taxonomic remarks. The holotype of *O. curvatitrapeziformis* closely resembles *O. macrotrapeziformis* and *O. flexisoma*, from which it differs in distinctly curved ascospores. However, some slightly curved spores also occur in these latter taxa, though never in the strength of the holotype of *O. curvatitrapeziformis*.

Variation. The Macaronesian collection on *Euphorbia* differs from the North American holotype in much longer asci, less curved and basally more strongly tapered spores, slightly shorter, hardly subulate SBs, and larger apothecia. Possibly, these differences warrant recognition as a separate species, but with only two collections the morphological variation of *O. curvatitrapeziformis* remains unknown. Because the holotype was only briefly studied when it was alive, the description of paraphyses and excipular characters is mainly based on the paratype.

Ecology. The holotype of *O. curvatitrapeziformis* was collected on bark of a xeric branch of *Quercus gambelii* in the cold-temperate humid ponderosa pine forest in the Mogollon Rim (southwest of Northern America), whereas the paratype was on a xeric decorticated branch of *Euphorbia balsamifera* in the subtropical (inframediterranean) hyperarid tabaibal dulce (*Ceropegio fuscae-Euphorbietum balsamiferae*) at the southernmost part of Tenerife (Macaronesia).

Specimens included. **USA**: **Arizona**, Mogollon Rim, 28 km WNW of Flagstaff, 23 km E of Williams, SE of Parks, 2165 m, branch of *Quercus gambelii*, on bark, 29.VIII.1994, G. Marson (ex H.B. 8682b, M-0276468, **holotype**). — **MACARONESIA**: **Canary Islands**, **Tenerife**, San Miguel de Abona, 9.5 km SSW of San Miguel de Abona, 1.1 km ENE of Costa del Silencio, Montaña Amarilla, 17 m, branch of *Euphorbia balsamifera*, on wood, 12.IV.2009, L. Quijada, R. Castro & E.V. Rodríguez (TFC Mic. 22038, H.B. 9092).

Orbilia edulis Baral & E. Weber, **sp. nov.**,
MB 813680 — Pls 631–632

Etymology: named after the host species, *Pinus edulis*.

Typification: USA, Utah, Mexican Hat, branches of *Pinus edulis*, 14.VI.2000, G. Marson (ex H.B. 7149a, M-0276477, holotype).

Latin diagnosis: *Differt ab* Orbilia macrotrapeziformi *ascosporis valde fusiformibus et basi attenuatis, cellulis vivis excipuli et paraphysium corpusculis globosis carentibus, apotheciis majoribus. Habitat ad lignum putridum ramorum siccorum* Pini edulis *in zona temperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.6 mm diam., 0.16–0.25 mm high, light orange to brick-red, scarcely translucent, round, scattered; disc slightly concave to flat, margin distinct, 5–10 µm protruding, smooth or whitish powdered; broadly sessile, immersed in fibres or biofilm. **Asci** *(70–)80–100 × 6.5–7.5 µm, †65–95 × 5.8–7 µm, 8-spored, spores *obliquely biseriate, 4–5 lower spores inverted (not mixed), pars sporifera *47–55 µm long; **apex** (†) strongly truncate (sometimes slightly indented and/or laterally inflated); **base** with short to long, ± thick and flexuous stalk, Y- or L-shaped. **Ascospores** *(12.5–)13.5–17 × (2.8–)3–3.7 µm, †14.5–16 × 3.3–4 µm (flattened), strongly fusiform (to fusiform-clavate), apex acute to acuminate, base (very) strongly attenuated, mostly slightly curved; **SBs** *(7.5–)10–12(–13) × 1–1.4 µm in situ [~(8–)11–15 µm actual length], vermiform to subulate, not or slightly inflated at base, slightly to strongly flexuous. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells *7.5–18 × 3.5–5.5 µm, lower cells *8.5–18 × 1.6–2.5 µm (near apex sometimes up to 4.5 µm wide); rarely branched near apex. **Medullary excipulum** 50–60 µm thick, of loose or dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a 10 µm thick layer of t. porrecta. **Ectal excipulum** of (†) distinctly gelatinized, irregularly vertically oriented t.

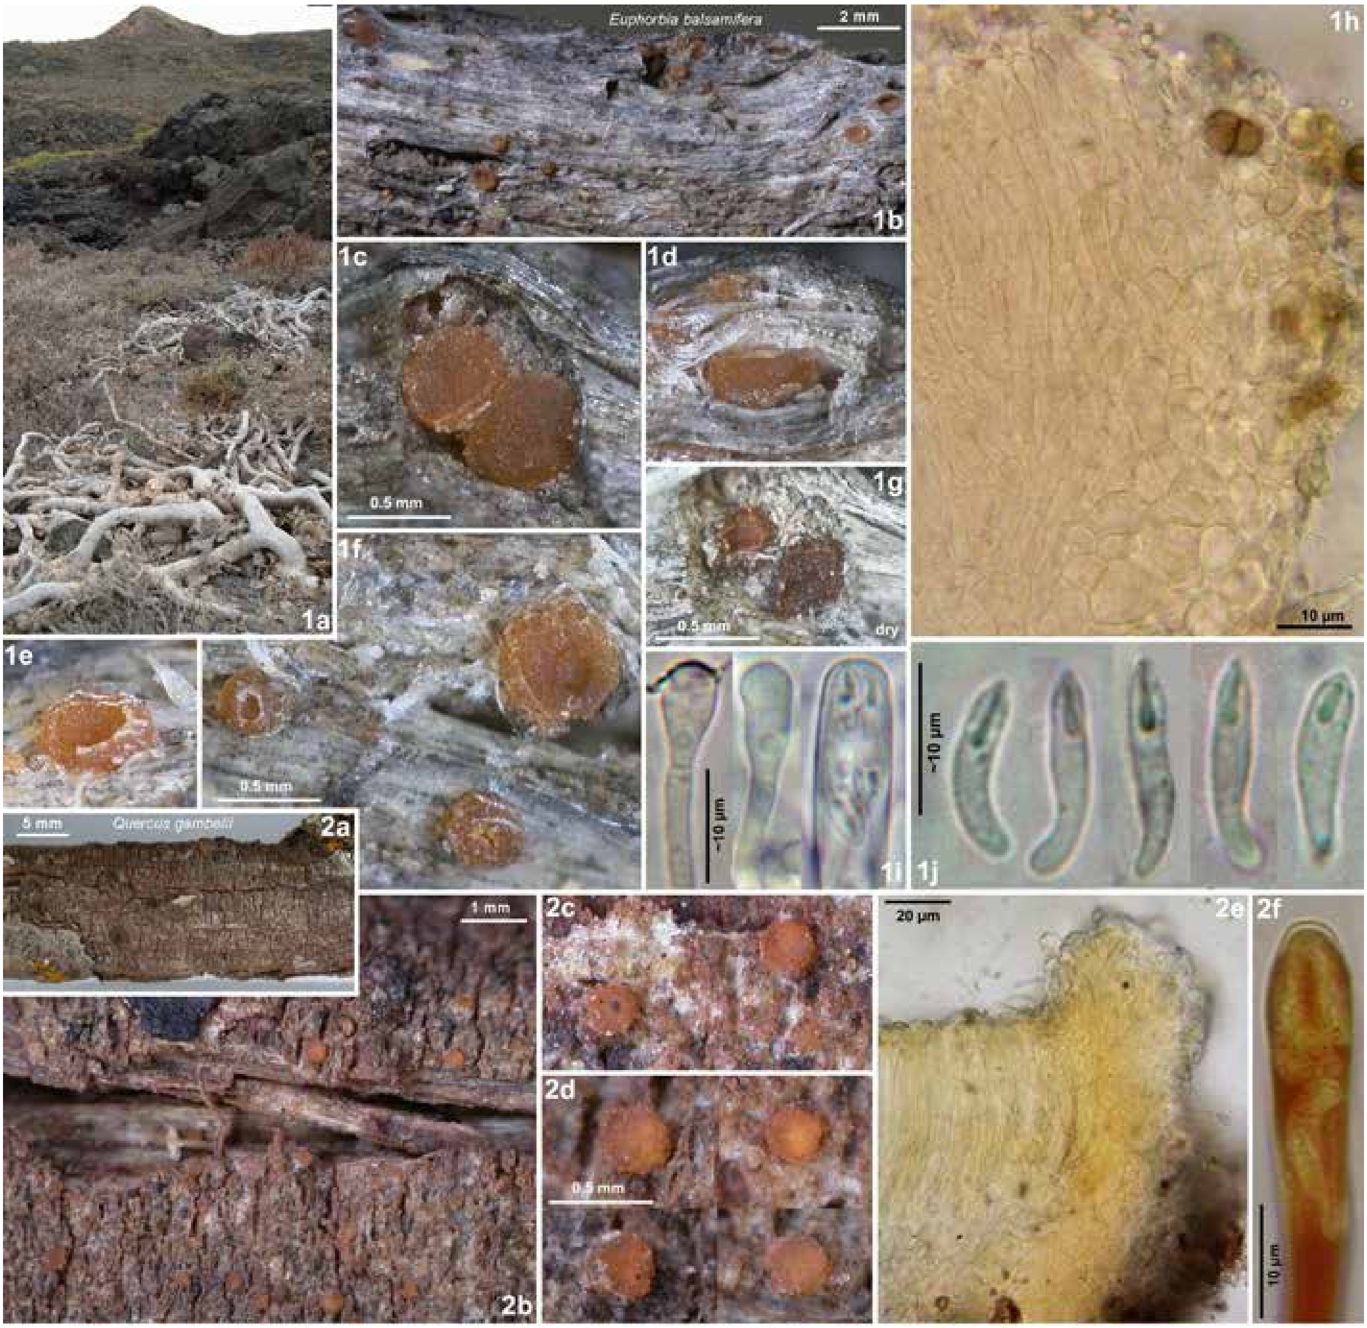

Plate 630. **1–2**: *Orbilia curvatitrapeziformis*. – **1a**. Hyperarid tabaibal dulce with dead branches of *Euphorbia balsamifera*; **2a**. dead corticated xeric branch of *Quercus gambelii*; **1b–f**, **2b–d**. rehydrated apothecia; **1g**. dry apothecia (same as **1c**); **1h**, **2e**. marginal ectal excipulum in median section; **1i**, **2f**. apices of paraphyses and asci; **1j**. ascospores. – Living state, except for **2e** (in KOH), **2f** (in KOH+IKI). – **1a**, **1i–j**: phot. L. Quijada. — **1a–j**. H.B. 9092: Tenerife, on *Euphorbia*; **2a–f**. H.B. 8682b (holotype): USA, Arizona, on *Quercus*.

globulosa-angularis from base to submargin, 30–45 µm thick near base, cells *8–20 × 5–15 µm; 30 µm thick near margin, upper margin of t. prismatica oriented at a 40–70° angle to the surface, marginal cortical cells *8–10 × 3–5 µm. **Anchoring hyphae** medium abundant, *2–3.3(–4) µm wide, walls †(0.2–)0.3–0.5(–1) µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) absent. **Exudate** over paraphyses 0.1–0.3 µm thick, over margin and flanks 1–1.5 µm, granular-cloddy, ± firmly attached. **— ANAMORPH**: unknown.

Habitat: decorticated, 13–24 mm thick branches of *Pinus edulis*, on 0.2–0.5 mm deep very decayed and furrowed wood, strongly greyed, with green algae. **Associated**: *Amandinea* sp., *Orbilia clavipisca*, *O. multitrapezoidea*, *Tryblidaria* ?*fenestrata*. **Desiccation tolerance**: fully viable for at least 2 years. **Altitude**: 1965 m a.s.l. **Geology**: Pennsylvanian-Permian mixed carbonate clastic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia edulis* is very similar to *O. macrotrapeziformis* but is tentatively separated by the consistent absence of SCBs in paraphyses and excipular cells, rather long asci, strongly fusiform and somewhat larger ascospores with very attenuated, often acute bases, slightly larger spore bodies, larger apothecia, and occurrence on coniferous substrate. *O. flexisoma* differs in more obtuse spore apices and differently shaped spore bases, and *O. pyrenaica* in smaller spores with only slightly tapered bases and in the presence of globose SCBs.

Ecology. *O. edulis* was found in a woodland with *Pinus edulis* and *Shepherdia rotundifolia* in a cold-temperate subhumid (almost semiarid) pinyon-juniper woodland in the Colorado Plateau at the border of Canyonlands and Navajo section in western North America.

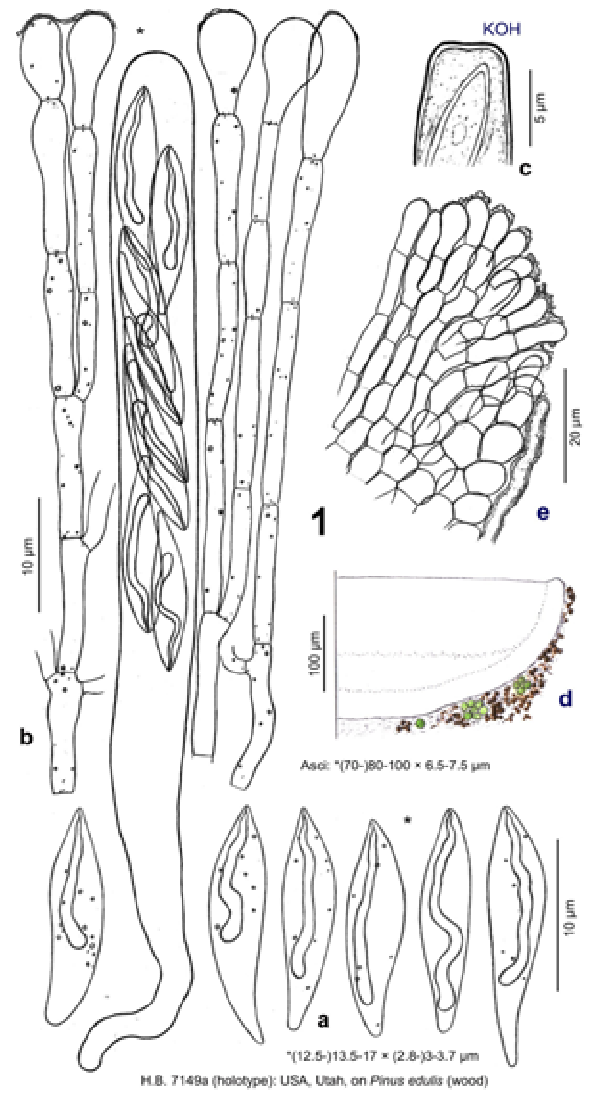

Plate 631. **1**: *Orbilia edulis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Specimens included. **USA**: **Utah**, Canyonlands, 16 km NNW of Mexican Hat, 1 km N of Mokee Dugway, Cedar Mesa, 1965 m, branches of *Pinus edulis*, on wood, 14.VI.2000, G. Marson (ex H.B. 7149a, M-0276477, **holotype**).

Orbilia wannerooensis Baral & G. Marson, **sp. nov.**,
MB 813681 — Pls 633–634

Etymology: named after the type locality, Wanneroo, Western Australia
Typification: Western Australia, Kinross, branch of *Acacia*, 23.X.2007, G. Marson (ex H.B. 8745d, MEL 2389253, holotype).

Latin diagnosis: *Differt ab* Orbilia macrotrapeziformi *ascosporis superioribus inverse orientatis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.35 mm diam., 0.11–0.19 mm high, light to bright orange, non-translucent, round, scattered; disc flat, margin distinct, 5–30 µm protruding, smooth but partly crowned by irregular teeth of whitish remnants of substrate; broadly sessile, superficial to slightly erumpent. **Asci** *63–80 × 7.5–8.5 µm {1}, †51–75 × 6–7(–7.7) µm {2}, (6–)8-spored, spores *2–4-seriate, 3–4 upper spores inverted {2} (sometimes mixed), pars sporifera *37–50 µm long; **apex** (†) strongly truncate (often distinctly indented, laterally slightly to strongly inflated); **base** with short, thick, flexuous stalk, L-, Y- to h-shaped. **Ascospores** *(12–)13–18(–19.5) × (2.5–)2.7–3.5(–4.5) µm {2}, cylindric-fusiform, apex acute to acuminate, base not or slightly to medium attenuated, rounded, straight to slightly inequilateral or curved near base; **SBs** *8–14 × 1–1.3 µm in situ {2} (~9–15 µm actual length), vermiform-subulate, not or with ± distinct globose inflation at base, flexuous, never uncinate. **Paraphyses** apically slightly to strongly clavate-capitate, sometimes spathulate or moniliform, terminal cells *5–16 × 2.5–5.5 µm {2}, lower cells *(5.5–)7.5–14(–19.5) × 1.5–2.5 µm {2} (near apex 3–5 µm wide); frequently branched at upper septum, hymenium pale orange. **Medullary excipulum** pale orange, 20–50 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited from ectal excipulum only at flanks. **Ectal excipulum** pale orange, of (†) ± thin-walled, irregularly vertically oriented t. angularis(-prismatica) from base to (sub)margin, 20–40 µm thick near base, cells *6–14 × 4–9 µm {1}; 20–25 µm thick near margin, of indistinctly oriented t. angularis, upper margin of t. prismatica(-angularis) at a 10–20° angle to the surface, marginal cortical cells *6–10(–13) × 3.5–5.5 µm {1}. **Anchoring hyphae** abundant, *2–3.5 µm wide, walls 0.2 µm thick {1}, covering the marginal excipulum as a hyaline, medium gelatinized, 5–10 µm thick layer. **SCBs** globose, in paraphyses 1–2 µm diam., in marginal excipulum 1.5–2.5 µm. **Exudate** over paraphyses 0.2–1(–2) µm thick, rough, loosely to firmly attached, over margin and flanks sparse, 0.2–1 µm thick. **— ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, corticated, 8–20 mm thick branches of *Acacia* sp. {1}, *Casuarina cunninghamiana* {1}, on ~0.2 mm deep medium to very decayed bark (bast, sometimes periderm) {2} and wood {1}, slightly to strongly greyed, with sparse to medium abundant green algae. **Associated**: *Baggea* sp. {1}, *Hypoxylon* sp. {1}, ?*Hysteropatella* sp. {1}, *Muellerella lichenicola* {1}, *Orbilia commarosa* {1}, *O. livistonae* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {1}, *O. myriofusiclava* {1}, *O. pleioquaestiformis* {1}, *O. pluristomachia* {1}, *O.* ?*serpentina* {1}, *Schizoxylon* sp. {1}. **Desiccation tolerance**: fully viable for at least 3 months. **Altitude**: 40–537 m a.s.l. **Geology**: Devonian to Carboniferous sedimentary rock, Cenozoic regolith (whitish sand). **Phenology**: long-lived.

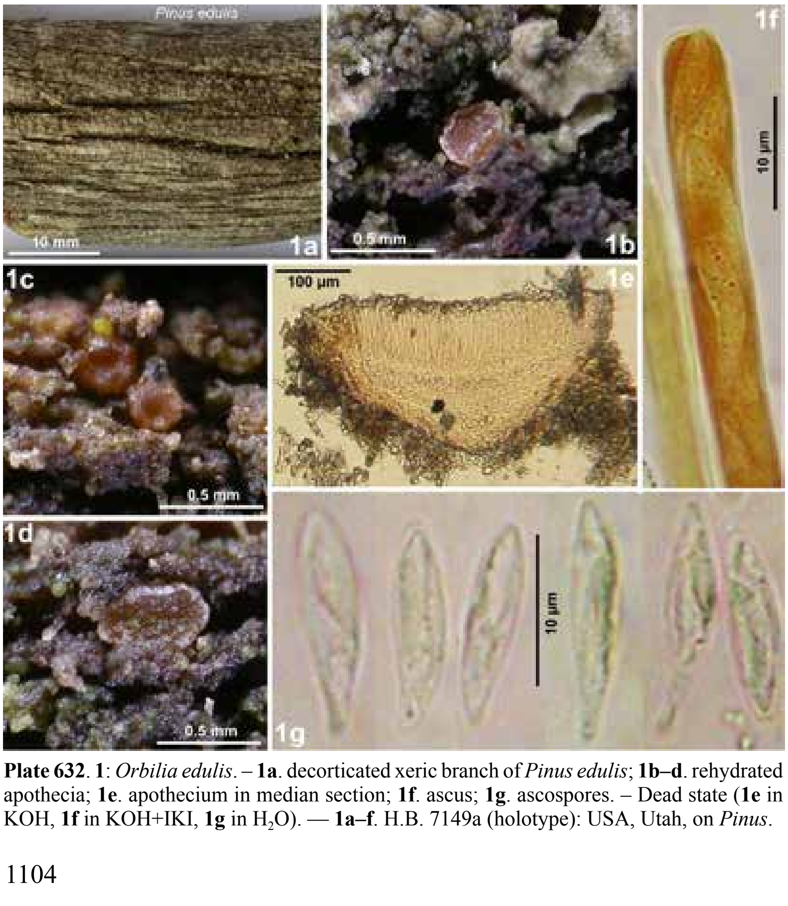

Plate 632. **1**: *Orbilia edulis*. – **1a**. decorticated xeric branch of *Pinus edulis*; **1b–d**. rehydrated apothecia; **1e**. apothecium in median section; **1f**. ascus; **1g**. ascospores. – Dead state (**1e** in KOH, **1f** in KOH+IKI, **1g** in H_2O). — **1a–f**. H.B. 7149a (holotype): USA, Utah, on *Pinus*.

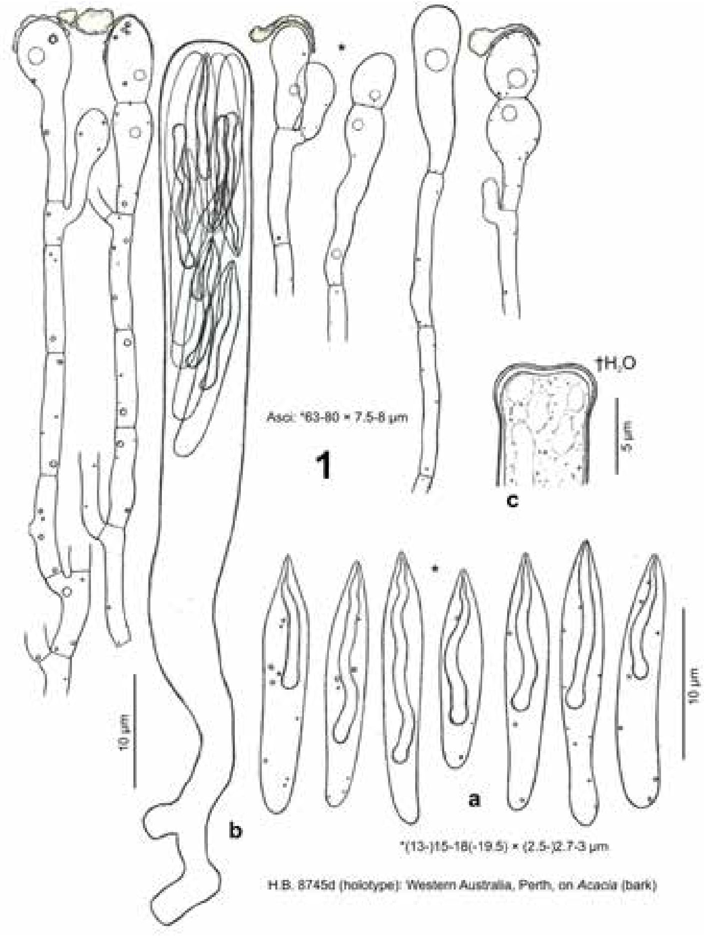

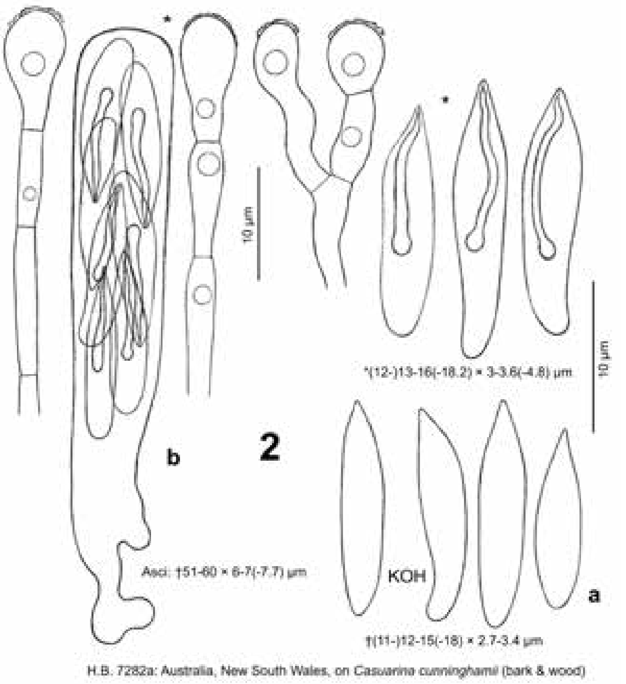

Plate 633. **1–2**: *Orbilia wannerooensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex.

Taxonomic remarks. *Orbilia wannerooensis* is very similar to *O. macrotrapeziformis* and *O. edulis* regarding ascospore characteristics, but differs in the upper instead of lower spores being consistently inversely oriented (*O. edulis* also differs in basally tapered spores and in lacking SCBs). A comparable case of apically inverted spores was observed in a 32-spored collection treated under *O. livistonae* (Pl. 646: 2), which much resembles the *Casuarina* collection of *O. wannerooensis* in spore size and shape, but which was only studied in the dead state.

Variation. The two known collections of *O. wannerooensis* are from very remote sites of Australia and show some Variation. the paratype from southeastern Australia (on *Casuarina*) has wider, slightly shorter spores and more inflated paraphysis apices compared to the holotype from southwestern Australia (on *Acacia*).

Ecology. *O. wannerooensis* grew on rotten bark but also wood of xeric branches of *Acacia* in a subtropical semihumid acacia mixed shrubland on sand dunes in southwestern Australia and of *Casuarina* in a subtropical humid eucalypt woodland in the Great Dividing Range of southeastern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 30 km NNW of Perth, 1 km NW of Kinross, Tamala Park, 40 m, branch of *Acacia*, on bark, 23.X.2007, G. Marson (ex H.B. 8745d, MEL 2389253, **holotype**). – **New South Wales**, South Western Slopes, 183 km NW of Sydney, 20 km SE of Mudgee, 537 m, branches of *Casuarina cunninghamiana*, on bark & wood, 25.X.1998, G. Marson (H.B. 7282a).

Orbilia delphinus Baral & G. Marson, **sp**. **nov**.,
MB 813682 — Pls 635–637, Map 104

Etymology: named after the ascospores which partly resemble a dolphin.

Typification: USA, Colorado, Denver, branches of *Ribes cereum*, 14.VI.1996, G. Marson (ex H.B. 5705e, M-0276472, holotype).

Latin diagnosis: *Differt ab* Orbilia subtrapeziformi *ascis 16-sporis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.12–)0.25–0.45(–0.6) mm diam., 0.12–0.2 mm high, (pale) light (bright) rose-orange to orange(-ochraceous), ± translucent, round, very scattered to ± gregarious; disc slightly concave to flat, finally slightly to medium convex, margin ± distinct, 0–20 µm protruding, smooth or often finely rough to crenulate; sessile, superficial or slightly to completely immersed among fibres or biofilm; dry light to deep orange. **Asci** *(52–)60–80(–92) × (5.5–)6–7(–7.6) µm {18}, †(48–)55–75(–80) × (5–)5.2–6.5(–7) µm {9}, 16-spored, spores *(3–)4-seriate, (5–)7–9(–10) lower spores inverted {14} (mostly strongly mixed), pars sporifera *(30–)35–47(–50) µm long; **apex** (†) (medium to) strongly truncate (very slightly indented, laterally distinctly inflated or not); **base** with short to medium long, ± thick, flexuous stalk, T-, L- or h- (exceptionally H-)shaped. **Ascospores** *(8–)9–13(–15) × ((1.7–))(1.8–)1.9–2.3(–2.5)((–2.6)) µm {30}, †8–12 × (1.6–)1.8–2.2(–2.3) µm {4}, narrowly fusiform to fusiform-clavate, sometimes with ± cylindrical middle part, apex acute to acuminate, base slightly to medium attenuated (rarely not or strongly so), straight to slightly (or medium) curved; **SBs** *(4–)5–8(–10.5) × (0.6–)0.7–1(–1.3) {17} → 4–6(–7.5) × 1–1.4 µm in situ (actual length hardly longer), (vermiform to) subulate, base not or slightly to medium, rarely strongly inflated, slightly to strongly flexuous, very rarely uncinate; overmature 4.5–5.5 × 1–1.5 µm {1}, globose with a long filum. **Paraphyses** apically (slightly to) medium to very strongly capitate-clavate, rarely spathulate or lageniform, terminal cells *(6–)10–24 {9} × (2.5–)3–5(–5.8) µm {12}, †2.8–4 µm wide, lower cells *(7–)8.5–17(–19) × (1–)1.3–2(–2.3) µm {5}; rarely branched at

excipular cells still viable after 28 months. **Altitude**: 1083–1900 m a.s.l. (Europe), 2100–2500 m (Asia), 1440–2980 m (USA). **Geology**: Paleo- to Mesozoic calcareous sand- & limestone, slate, dolomite; gneiss, basalt, rhyolite-andesite lava. **Phenology**: V–X (but certainly throughout the year, long-lived).

Taxonomic remarks. *Orbilia delphinus* is characterized by 16-spored asci and narrowly fusiform-clavate ascospores with subulate, ± flexuous spore bodies, also by the general absence of crystalloid SCBs, and a montane distribution. The very similar, likewise subalpine-boreal but mainly European *O. subtrapeziformis* mainly differs in 8-spored asci, and the North American montane/boreal *O. multidelphinus* in 32-spored asci.

O. subdelphinus (Pls 638–639) differs merely in the consistent presence of crystalloid SCBs and an atlantic-mediterranean distribution. *O. maeandrina* sharply differs in wider, also slightly shorter, more amygdaliform ascospores (with a markedly lower length/width ratio). Based on wider asci and spores, *O. macrodelphinus* is tentatively segregated from *O. delphinus* (see p. 1113).

Variation. There is some variation in ascus length, also in spore length and width, but such deviations are not clearly linked to ecological or geographical data and even occur within a collection. Due to the variation in spore width, a sharp delimitation from *O. macrodelphinus* proved to be very difficult. One of the North American collections (Pl. 635: 6) has extraordinary long spores. In another sample, asci and spores had the typical size of *O. delphinus* in all ~10 apothecia examined by the first author (Pl. 635: 4), whereas the third author (IVV: H.B. 5705e) found much larger spores (*13.5–15 × 2.4–2.8 µm) though only slightly larger asci (*70–90 × 6.4–7 µm). Crystalloid SCBs were inconsistently seen in a few of the paraphysis and excipular cells in three North American collections (Pl. 633: 4, on *Ribes*; 9.V.1995, 11.VI.1996, on *Populus*) but never in the few European specimens.

For a mediterranean collection on *Cupressus* (Pl. 638: 3) with spathulate paraphyses see under *O. subdelphinus* (p. 1111).

Not included collections. A North American sample on *Chrysothamnus* (Pl. 636: 1) differs in a strong tendency to subacute or obtuse spore apices, basally partly more strongly inflated SBs, and wider asci. It might form a transition to *O. macrodelphinus*, and grew together with a 32-spored variant that deviates in similar features from typical *O. multidelphinus*. However, a collection on a similar *Asteraceae* (*Ericameria*, IVV: H.B. 6736e) has acute spore apices and represents quite typical *O. delphinus*.

Two records from Bretagne (France) on *Malus* and *Quercus* are not included because of the low altitude. Since crystalloid SCBs were not observed and the substrate is not coniferous, identity with *O. subdelphinus* seems improbable.

Ecology. *O. delphinus* was recorded from rotten wood, more rarely bark, of xeric twigs and branches of angiosperm or more rarely gymnosperm trees and shrubs. The species occurs in the cold-temperate to boreal, subhumid to humid, ± montane

Map 104. Known distribution of *O. delphinus* (white, yellow = not included collection), *O. subdelphinus* (blue) and *O.* aff. *subdelphinus* (orange) in North America, Europe, and central Asia (western Mongolia).

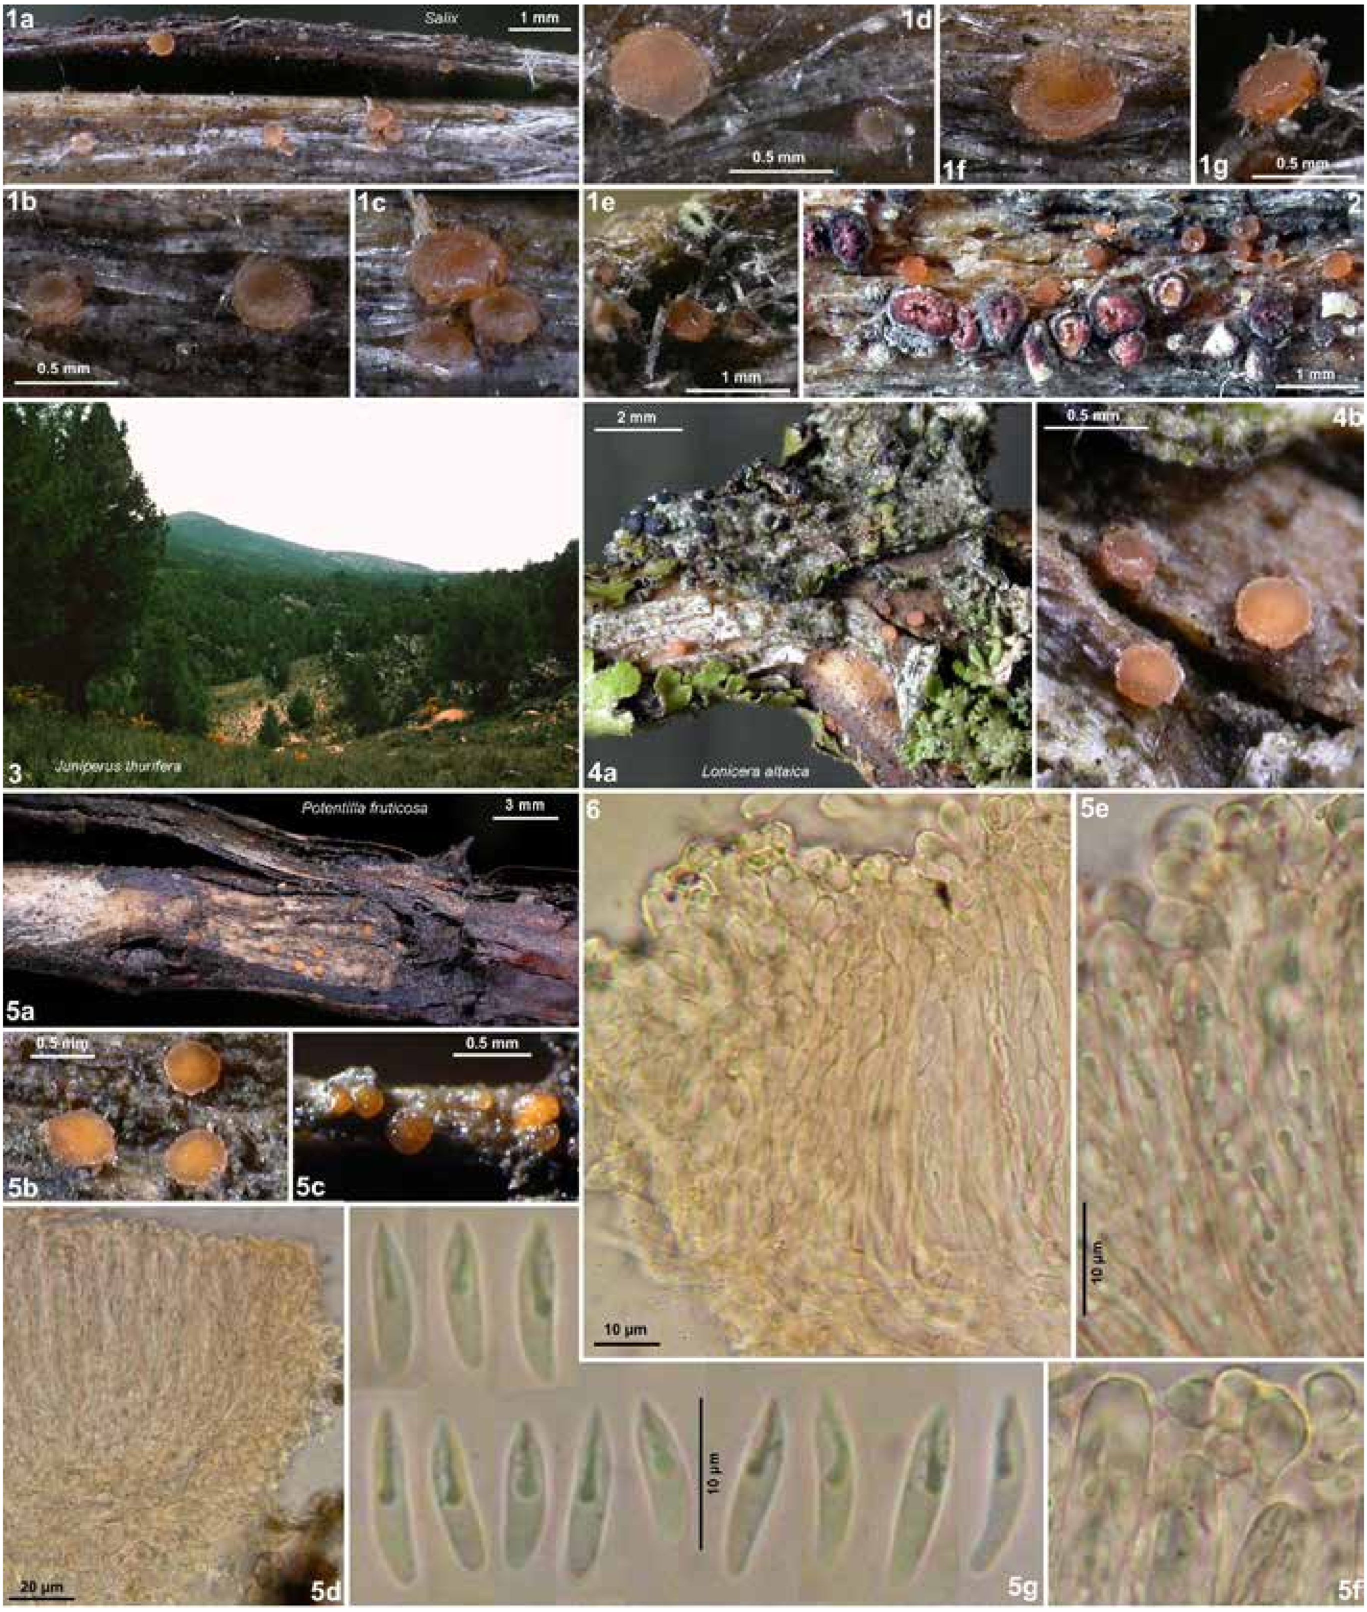

Plate 637. **1–6**: *Orbilia delphinus*. – **3**. montane *Juniperetum thuriferae* on calcareous soil; **1a–g**, **2**, **4a–b**, **5a–c**. rehydrated apothecia (**1e** with '*Chlorosplenium*' *viridulum*, **2** with *Perrotia flammea*); **5d**. apothecium in median section; **6**. id., marginal ectal excipulum; **5e–f**. asci and paraphyses; **5g**. ascospores. – Living state. — **1a–g**. pinyon-juniper woodlands and ponderosa pine, Douglas fir, and Engelmann spruce forests, rarely in warm-continental semiarid to cold-temperate subhumid sagebrush desert scrubs of Middle and Southern Rocky Mountains and Colorado Plateau in western North America. It was also found in continental, orotemperate (sub)humid (winter-dry), subalpine western Mongolia (central Asia) and in orotemperate or oro- to suprasubmediterranean humid Southern French Alps and different mountain ranges of Spain (southern Europe). *O. delphinus* appears to be absent in temperate to boreal Eurasia as well as from subtropical to tropical regions. The not included collections from Bretagne, however, were from an atlantic warm-temperate lowland area.

Orbilia subdelphinus Baral, **sp. nov.**, MB 813683 — Pls 638–639

Etymology: named according to the strong similarity with *O. delphinus*.
Typification: France, Ile de Ré, branch of *Cupressus macrocarpa*, 16.IV.2008, H.O. Baral (ex H.B. 8816, M-0276595, holotype).

Latin diagnosis: *Differt ab* Orbilia delphino *cellulis vivis excipuli et paraphysium corpuscula crystalloidea continentibus. Habitat ad lignum et corticem putridum ramorum siccorum Cupressi macrocarpi in zona atlantica mesosubmediterranea Europae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.6 mm diam., 0.16–0.22 mm high, light to bright brick-orange, hardly translucent, round, scattered; disc flat, margin distinct, 10–30(–70) µm protruding, ± rough to irregularly crenulate; broadly sessile, ± superficial; dry slightly contracted, bright (dirty) brick-red. **Asci** *67–100 × 6.5–7.5 µm {2}, †(56–)65–83 × 5.7–6.7 µm {1}, 16-spored, spores *3–4-seriate, 8–9 lower spores inverted {1}, pars sporifera *35–52 µm long (slightly mixed); **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to long, ± thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(7–)9–12(–14) × 1.9–2.5 µm {2}, †8–11 × 2–2.4 µm {1}, fusoid- to fusiform(-clavate), apex subacute to acute, base medium to strongly (rarely only slightly) attenuated, ± inequilateral to mostly slightly to strongly curved near base; **SBs** *(5–)6–9(–10) × (0.3–)0.4–0.6 µm in situ {1} (~6–11 µm actual length), filiform-subulate, somewhat inflated at base, ± flexuous to helicoid. **Paraphyses** apically slightly to strongly clavate-capitate, also somewhat spathulate, exceptionally lageniform, terminal cells *(5–)10–15 × (2.5–)3–4(–4.5) µm {2}, lower cells *8–14 × 1.5–2.3(–3) µm {2}; rarely branched at upper septum. **Medullary excipulum** very pale rose, 40–100 µm thick, of dense textura intricata with some inflated cells, medium sharply delimited. **Ectal excipulum** very pale rose, of (†) thin-walled to slightly gelatinized, irregularly to vertically oriented t. globulosa(-prismatica), 30–50 µm thick near base, cells *7–12 × 6–10 µm {1}; at lower and mid flanks of vertical to indistinctly horizontal t. angularis, 25–40 µm thick near margin, of. t. porrecta oriented at a 0–40° angle to the surface, marginal cortical cells †7–9 × 2–3 µm {1}. **Anchoring hyphae** medium abundant, †1.7–3.3 µm wide, walls 0.2–0.3(–0.7) µm thick {1}, extending to the margin as a thin layer. **SCBs** in paraphyses globose, 1–2 µm diam., also crystalloid, in ectal excipulum (at flanks and margin) crystalloid, medium refractive, 2–3(–4) × (1–)1.5–2.3 µm, hyaline to very pale orange. **Exudate** over paraphyses 0.2–2 µm thick, granular-cloddy, hyaline, ± firmly attached, over margin 0.2–1 µm thick. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** Y-shaped, total size *18–28 × 23–38 µm, stipe *10–13 × 4.5–5 µm, 2-septate, arms tapering, *14–21.5 × 4–5.5 µm, 2–4-septate {1}.

Habitat: collected ~1 m above the ground, partially to entirely decorticated, 4.5–30 mm thick, still-attached branches of *Cupressus macrocarpa* {2}, on 0.1–0.2 mm deep medium to strongly decayed wood {2} and bark {1} (bast), partly in beetle galleries, somewhat greyed, with many green algae. **Associated**: *Opegrapha* sp. {1}, *Orbilia cupressi* {1}, ?*Parmelia* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 weeks, submature asci, paraphyses and excipular cells viable for 2 months. **Altitude**: 7–19 m a.s.l. **Geology**: Quaternary marine sand over Upper Jurassic limestone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia subdelphinus* closely resembles *O. delphinus*. The taxon is tentatively separated because of the consistent presence of crystalloid SCBs in paraphyses and ectal excipulum, narrower spore bodies, and occurrence at very low altitude in an atlantic-mediterranean climate on a single host (*Cupressus*).

Not included collection. A sparse mediterranean collection on wood of *Cupressus* (Pl. 638: 3, one apothecium) is not included in either taxon as it deviates in predominantly spathulate (to sublageniform) paraphyses, with the exudate attached also on the sides of the apices, from *O. subdelphinus* also in the absence of crystalloid SCBs. In the shape of its paraphyses and spores this sample resembles the 8-spored *O. flavidorosella* (series *Habrostictis*) and *O. spathulata*.

Anamorph. The conidia observed on the natural substrate are similar to *Trinacrium robustum* which is typical for many species of section *Habrostictis*.

Ecology. *O. subdelphinus* is only known from rotten wood and bark of xeric twigs and branches of *Cupressus macrocarpa* in mesosubmediterranean semihumid (atlantic) open cypress forests in western Europe. *Cupressus macrocarpa* was introduced from California to Île de Ré over a hundred years ago for wind protection (M. Hairaud pers. comm.). *O.* aff. *subdelphinus* was collected in a park at Aranjuez in the mesomediterranean semihumid centre of Spain.

Specimens included. **FRANCE**: **Poitou-Charentes**, **Charente-Maritime**, Île de Ré, 2 km SE of St.-Martin-de-Ré, 1.8 km W of La Flotte, Les Maraises, 19 m, branch of *Cupressus macrocarpa*, on wood, 26.IV.2006, S. Helleman & G. Marson (H.B. 8160a, anam. substr.). – 2.5 km NNE of St.-Clément-des-Baleines, Forêt de St.-Clément, 7 m, branch of *C. macrocarpa*, on bark & wood, 16.IV.2008, H.O. Baral (ex H.B. 8816, M-0276595, **holotype**).

Not included. **SPAIN**: **Madrid**, 43 km SSE of Madrid, 2 km NE of Aranjuez, Jardín del Príncipe, 500 m, twig of *Cupressus* sp., on wood, 31.V.1996, H.O. Baral (H.B. 5507b).

Orbilia spathulata Baral & G. Marson, **sp. nov.**, MB 814434 — Pls 640–641

Etymology: named after the spathulate paraphyses.

Typification: USA, Utah, Page, branches of *Artemisia tridentata*, 25.VIII.1994, G. Marson (ex H.B. 5197c, M-0276587, holotype).

Latin diagnosis: *Similis* Orbiliae subtrapeziformi *sed paraphysibus apice interdum spathulatis, corpuscula crystalloidea continentibus, ascosporis superioribus plerumque inverse orientibus.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.45 mm diam., 0.13–0.17 mm high, light (yellowish-)orange-ochraceous, ± translucent, round, scattered to subgregarious in small groups; disc slightly concave to flat, margin distinct, 10–20 µm protruding, nearly smooth or finely rough; sessile, partly distinctly erumpent between fibres. **Asci** *60–79 × 6.2–7.5 µm {3}, †60–95(–105) × 5.8–6.3 µm {2}, 8-spored, spores *2–4-seriate, 3–5 spores inverted (predominantly the upper spores, but sometimes strongly mixed and sometimes only the lower spores) {3}, pars sporifera *(26–)30–38 µm long (†39–55 µm); **apex** (†) medium to strongly truncate (not indented, somewhat conical or laterally slightly widened); **base** with short to medium long, thin or thick, flexuous stalk, T- to L-shaped. **Ascospores** *(10–)11–15(–17) × (2.1–)2.3–2.6(–2.8) µm {2}, †10–14.3 × 2.3–2.7(–2.9) {1}, fusoid with ± cylindrical middle part, apex subacute to acute, base not or slightly attenuated {T}, or fusiform with acute (to acuminate) apex, base medium to strongly attenuated {1}, mostly slightly to medium curved at base; **SBs** *(7–)8–10.5(–11.5) × 0.7–1(–1.3) µm in situ {2} (actual length ~8–12 µm), vermiform to subulate, mostly slightly to medium inflated at the base, straight to mostly ± flexuous, rarely uncinate. **Paraphyses** apically spathulate to lageniform, terminal cells *(8–)10–15(–20) × (3.5–)4–4.7(–5.5) µm {2}, †2.8–4.8 µm wide, lower cells *(6–)9.5–17(–20) × 1.3–2(–2.5) µm {1}; unbranched at upper septum. **Medullary excipulum** pale orange, 40–60 µm thick, of ± loose textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** light orange, of (†) thin-walled, vertically oriented t. angularis(-prismatica) from base to margin, 25 µm thick near base, cells *9–19 × 7–11 µm {1}; 15–20 µm thick at flanks, 20–25 µm near margin, marginal cortical cells †8–15 × 4–4.5 µm {1}. **Anchoring hyphae** medium abundant, *2.2–4 µm wide (†1.7–3 µm), walls 0.2–0.4(–0.6) µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.5–2.3 µm diam., associated with rod- or ring-shaped SCBs 2–4.5 µm diam. {1}, hyaline. **Exudate** over paraphyses and uppermost excipular cells forming 0.1–2 µm thick, firmly attached, finely rough, refractive (glassy) caps. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** not observed.

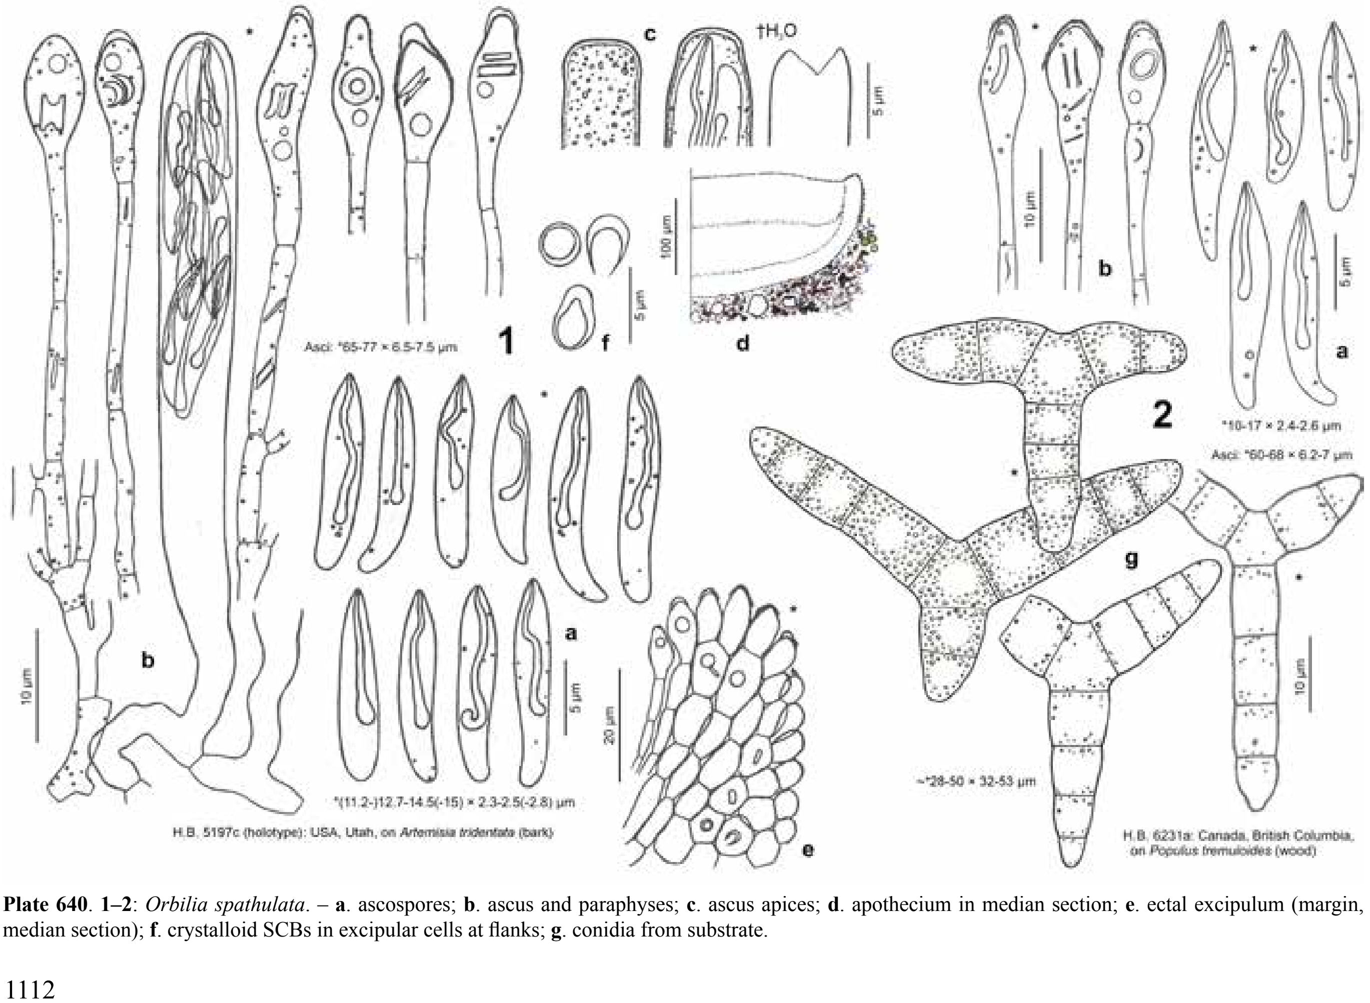

Plate 640. **1–2**: *Orbilia spathulata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. ectal excipulum (margin, median section); **f**. crystalloid SCBs in excipular cells at flanks; **g**. conidia from substrate.

Conidia Y-shaped, total size *~28–50 × 32–53 µm, with *13–32 × (6.5–)7.5–8.3(–9) µm wide stipes and arms {1}. **Habitat**: collected 0.3–0.5–?2 m above the ground, corticated or decorticated, 12–20 mm thick branches of *Artemisia tridentata* {2}, *Populus tremuloides* {1}, on 0.3–1 mm deep strongly decayed wood {1} and bark {1} (bast), partly in small clefts, greyed, with a few green algae. **Associated**: *Caloplaca* sp. {1}, *Orbilia dixiensis* {1}, *O. mesaverdiana* {2}, *Patellaria atrata* {1}, *Schizoxylon ?argentinum* {1}. **Desiccation tolerance**: fully viable for at least 13 months. **Altitude**: 830 m a.s.l. (Canada), 1700–1795 m (USA). **Geology**: Canada: alluvial deposits from Paleozoic sedimentary rock, USA: Mesozoic sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia spathulata* is characterized by rather long ascospores and SBs, and by spathulate to lageniform paraphysis apices which contain crystalloid SCBs. Spore orientation in the 8-spored asci is rather variable but shows, as a tendency, the upper spores inverted in all three collections examined. This feature is rather rare in subgenus *Habrostictis*, where it was otherwise only seen in *O. wannerooensis* and in a 32-spored specimen mentioned under *O. livistonae*.

O. spathulata might be confused with *O. carpoboloides* (series *Habrostictis*), which has very similar spores but differs in having a hairy margin and usually more lageniform to mammiform heads of paraphyses. Some similar taxa (*O. flexisoma*, *O. subtrapeziformis*, *O. idahoensis*) mainly differ in the absence of crystalloid SCBs and in capitate paraphyses, whereas *O. bicknellensis* and *O. octoserpentina* differ in wider spores and capitate paraphyses. All mentioned species differ from *O. spathulata* in the consistent inverse orientation of the lower spores.

Variation. The sample on wood of *Populus* somewhat deviates in more fusiform spores with more acute apices and a tendency to more tapered spore bases from those on *Artemisia* in which the spores often have a cylindrical middle part.

Anamorph. The trinacrium-like conidia observed on the natural substrate have extraordinarily wide stipes and arms, distinctly wider than in similar anamorphs of section *Habrostictis*, and also wider than described in *Trinacrium robustum*. The stipe appears to be often much shorter than the arms, but due to their very similar shape it was very difficult to distinguish between arms and stipe.

Ecology. *O. spathulata* grew on xeric branches of angiosperm trees and shrubs, and is so far only known from three sites of North America with two quite different climatic regions. The record on wood of *Populus* derives from a boreal humid conifer forest with *Populus tremuloides* and *Acer* in a valley in the Canadian Rocky Mountains, while the other two are from bark of *Artemisia* in cold-temperate to warm-continental semiarid sagebrush and saltbush desert scrubs in the eastern part of the Colorado Plateau in the southwest of Northern America.

Specimens included. **CANADA**: **British Columbia**, Canadian Rocky Mountains, 61 km SE of Golden, 1 km SE of Spillimacheen, 830 m, branch of *Populus tremuloides*, on wood, 20.VIII.1997, G. Marson (H.B. 6231a ø, anam. substr.). — **USA**: **Utah**, Canyonlands, 60 km NW of Page, Cottonwood Canyon, ~1700 m, branches of *Artemisia tridentata*, on bark, 25.VIII.1994, G. Marson (M-0276587, **holotype**; **isotype** in H.B. 5197c). – 16 km WNW of Blanding, 1795 m, on *A. tridentata*, 14.V.1995, G. Marson (ø).

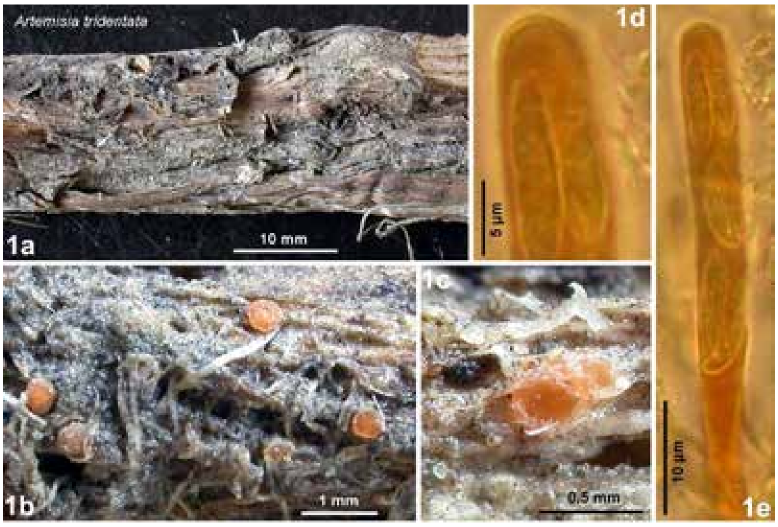

Plate 641. **1**: *Orbilia spathulata*. – **1a**. dead corticated branch; **1b–c**. rehydrated apothecia; **1d–e**. asci with ascospores. – Dead state (in KOH+IKI). — **1a–e**. H.B. 5197c (holotype): USA, Utah, on *Artemisia*.

Orbilia macrodelphinus Baral & G. Marson, **sp. nov.**, MB 813684 — Pls 642–643, Map 105

Etymology: similar to *O. delphinus* but with wider ascospores.

Typification: USA, Utah, Torrey, branch of *Baccharis salicifolia*, 19.VI.2000, G. Marson (ex H.B. 6741c, M-0276503, holotype).

Latin diagnosis: *Differt ab* Orbilia macrotrapeziformi *ascis 16-sporis*, *ab* O. delphinus *ascis et ascosporis latioribus*, *ascosporis magis fusiformibus*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.6(–0.9) mm diam., 0.11–0.14 mm up to 0.19–0.23 mm high, pale to bright yellowish-orange to orange, rarely rose, scarcely translucent, round, scattered to subgregarious; disc medium concave to flat, rarely finally convex, margin distinct, 0–20 or sometimes 30–60 µm protruding, smooth to finely rough or crenulate (partly whitish); (broadly) sessile, ± immersed but also superficial; dry bright to dark orange. **Asci** *65–82(–88) {4} × 6–7 {1} or (6.5–)7.5–8(–8.5) {2} or 8–9.5 {1} µm, †(54–)60–81(–90) × (5.3–)5.5–7.5(–8)((–8.7)) µm {9}, 16-spored, spores *3–4-seriate, 6–12 lower spores inverted {2} (rarely mixed), pars sporifera *46–55 µm long; **apex** (†) strongly truncate (not or distinctly indented, laterally not or scarcely widened); **base** with short to medium long, ± thin, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *((8–))(9–)10–12.5(–13.5)((–16.5)) × (2–)2.4–2.8(–3)((–3.5)) µm {7}, †(8.5–)9–13(–14) × 2.1–2.8 µm {7}, fusiform to fusiform-clavate or fusoid-clavate, apex subacute to acute, rarely obtuse, base mostly (medium to) strongly attenuated, rarely with a tail-like base, here mostly slightly to medium (rarely strongly) curved; **SBs** *4.5–6 {2} or 6–7 {1} or 6–12 {2} × 0.8–1.3(–1.5) µm in situ {4} (~5–13 µm actual length), vermiform to subulate, not or often distinctly inflated at base, straight to ± strongly flexuous. **Paraphyses** apically (slightly to) medium to very strongly clavate-capitate, rarely spathulate, terminal cells *5–23 × (2.5–)3.3–5(–6) µm {3}, lower cells *8–19.5 × 1.3–2.3 µm {2}; rarely branched at upper septum. **Medullary excipulum** 30–80 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale to light orange, of (†) thin-walled to slightly gelatinized, irregularly oriented t. angularis from base to (sub) margin, 15–60 µm thick near base, cells *7–13(–19) × (4–)5–10.5 µm {2}, †5–10 × 4–5 µm {1}; 15–30 µm thick near margin, of t. prismatica-angularis or t. porrecta oriented at a 10–40° angle to the surface, marginal cortical cells †(4–)8–10 {1} × 2.3–4 µm {2}, at upper margin sometimes protruding as very short hairs. **Anchoring hyphae** rather abundant, */†2–3 µm wide, walls 0.2(–0.3) µm thick {2}, partly covering flanks and extending beyond margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose {9}, 1–2.7 µm diam., rarely absent {3}, sometimes a few crystalloid SCBs present {2}. **Exudate** over paraphyses and marginal excipulum 0.3–2 µm thick, granular-cloddy, firmly attached. **— ANAMORPH**: unknown.

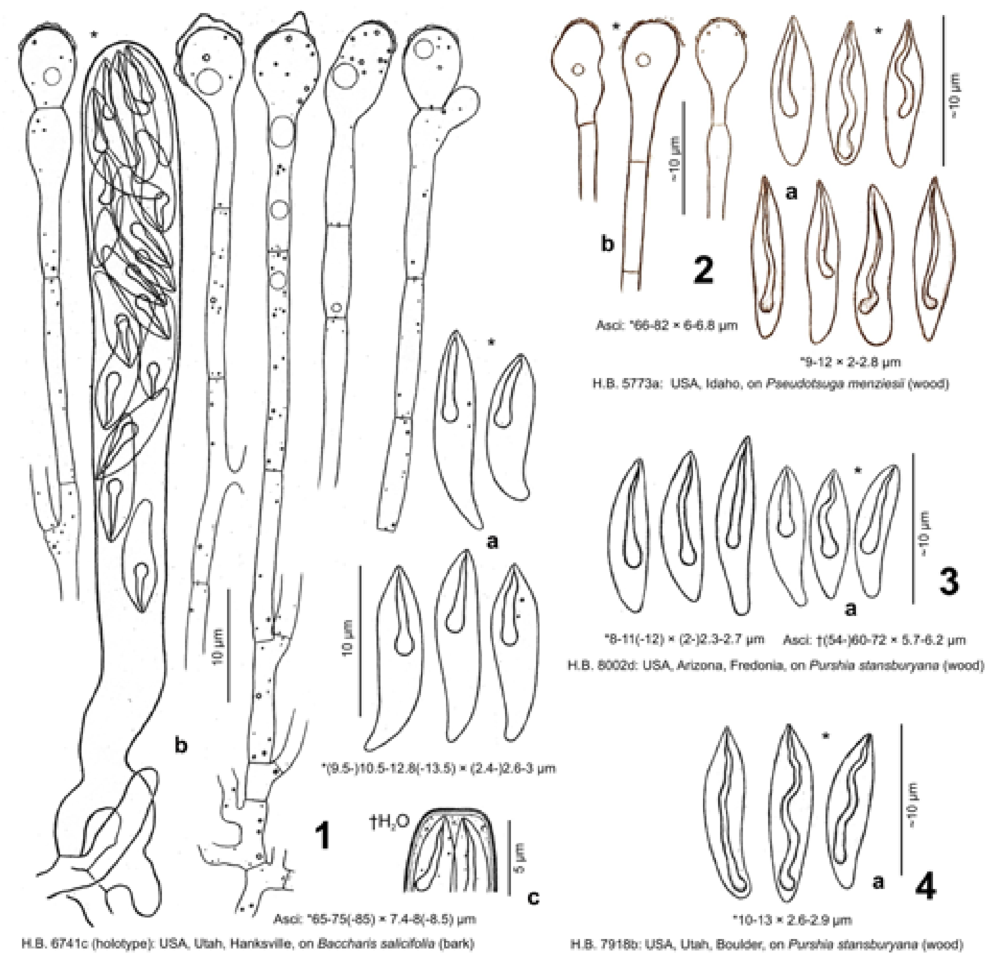

Plate 642. **1–4**: *Orbilia macrodelphinus*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Habitat: collected 0.5–2.5 m above the ground, decorticated or ± corticated, 4–14 mm thick twigs and branches of *Baccharis salicifolia* {1}, *Canotia holacantha* {1}, *Cytisus supranubius* {1}, *Juniperus osteosperma* {1}, *Larrea tridentata* {1}, *Picea sitchensis* {1}, *Pseudotsuga menziesii* {2}, *Purshia stansburyana* {4}, on 0.2–1 mm deep (medium to) strongly decayed wood {9} and bark {2} (bast), strongly greyed, a few or many green algae. **Associated**: *Caloplaca* sp. {1}, *Candelariella* sp. {1}, ?*Cryptodiscus* sp. {1}, *Dothideales* {1}, *Durella* sp. {1}, *Hysterobrevium mori* {2}, *Mellitiosporiella pulchella* {2}, *Odontotrema* sp. {1}, *O. oregonensis* {1}, *Orbilia arizonensis* {4}, *O. bicknellensis* {2/1}, *O. calyptrata* {3}, *O. coniferarum* {2}, *O. cryptogena* {1}, *O. flexisoma* {1/1}, *O. lacrimispora* {2}, *O.* ?*lentiformis* {1}, *O. maeandrina* {3}, *O. magnifica* {1}, *O. stansburyanae* {1}, *O. microsoma* {1}, *O. multigambelii* {1}, *O. multimaeandrina* {2/1}, *O. navajoana* {1}, *O. ocellata* {1}, *O. ophiosoma* {1}, *O. plurilentiformis* {1}, *O. purshiae* {2}, *O. serpentina* {2}, *O.* ?*vitalbae* {1}, *Patellaria* '*andina*' {1}, *P. atrata* {2/1}, ?*Phaeophyscia* sp. {1}, *Propolis farinosa* {1}, ?*Schizoxylon* sp. {1}, *Teichospora* sp. {1}, *Teichosporella dura* {1}, *Sclerococcum* sp. {1}, *Symbiotaphrina desertorum* {1}, various crustose (*Caloplaca*) and foliose (*Parmelia* s.l.) lichens. **Desiccation tolerance**: fully viable for at least 9 months, after nearly 3 years many excipular cells and paraphyses and some ascospores, and after 39 months paraphyses still viable. **Altitude**: 975–2650 m a.s.l. **Geology**: USA: Paleo- to Cenozoic lime-, mud- & sandstone, rarely granite or basalt; Tenerife: phonolitic eruptive fissure. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia macrodelphinus* resembles *O. delphinus* and *O. maeandrina* in its 16-spored asci, ascospores with ± acute apices, thick and medium long, subulate SBs, and in the predominant absence of crystalloid SCBs. Those collections assigned to the latter two species are very different from each other concerning their spores, whereas *O. macrodelphinus* forms an intermediate taxon which is only tentatively separated from both of them. It differs from *O. delphinus* in a tendency to wider asci and spores, and more distinctly fusiform spores, and from *O. maeandrina* in longer, basally more tapered and curved spores. However, spore and ascus size overlaps in some of the collections. *O. pleiourosperma* and *O. serpentina* differ in wider spores and the consistent presence of crystalloid SCBs, the former also in the spores having always distinct tail-like bases. *O. macrodelphinus* appears to be closely related to *O. macrotrapeziformis* and *O. flexisoma*, which differ in 8-spored asci and somewhat larger spores.

Variation. *O. macrodelphinus* shows considerable variation in both length and width of the spores, and especially in length of the SBs. In most collections (especially Pl. 642: 4) the SBs are rather long, partly almost as long as the spores, whereas in the holotype (but also in those one in 2–3) they are distinctly shorter. Due to this variation the taxon is very difficult to delimit from both *O. delphinus* and *O. maeandrina*.

Great variation among the collections is observed in apothecial size, ranging from 0.2–0.3 mm up to 0.4–0.9 mm in diameter and from 0.11 mm up to 0.23 mm in height, consequently also in the height of the ectal and medullary excipulum and in cell size of the former, finally in the margin varying from smooth and not protruding to rough or crenulate and strongly protruding. In the case of protruding margins, the hymenia of young apothecia are covered by the marginal hyphal texture except for a very small central pore.

Map 105. Known distribution of *O. macrodelphinus* in North America.

Plate 643. **1–6**: *Orbilia macrodelphinus*. – **4a**. Retamar with *Cytisus supranubius* and *Adenocarpus viscosus*; **1a**. decorticated xeric branch with (?)*Physcia*; **3a**. corticated branch with ?*Phaeophyscia*; **1b–d**, **2**, **3a–f**, **4b–c**, **6a–b**. rehydrated apothecia; **1e**, **5**. apothecia in median section; **1f**, **6c**. id., marginal ectal excipulum; **3g**. ascus; **4e**. ascus apex; **4d**. paraphyses; **4f–g**. ascospores. – Living state, except for **3g**, **5b** (in KOH+IKI), **4e** (in H_2O), **4f** (3 right spores), **4g** (ascus). – **4a**, **d–g**: phot. L. Quijada. — **1a–f**. H.B. 8097d: USA, Arizona, Grand Canyon village, on *Juniperus osteosperma*; **2**. H.B. 8002d: USA, Arizona, Fredonia, on *Purshia*; **3a–g**. H.B. 5773a: USA, Idaho, on *Pseudotsuga*; **4a–g**. H.B. 9223: Tenerife, Teide, on *Cytisus*; **5a–b**. H.B. 5605: USA, Idaho, on *Pseudotsuga*; **6a–c**. H.B. 8545d: USA, Utah, on *Picea*.

A collection on *Larrea tridentata* (IVV: H.B. 5684c) from a hot semidesert environment has rather large, especially wide asci [*78–88 × 8.5–9(–9.5) µm] and large spores (*11.5–16.5 × 2.5–3.5 µm). The specimen is somewhat heterogeneous, varying in spore length among the collected branches between *11.5–13.5 and 13–16.5 µm. One (on *Canotia holacantha*, only seen in the dead state, IVV: H.B. 7218e) fits *O. macrodelphinus* in spore size (†10–14.5 × 2.1–2.6 µm) though their shape would also match *O. delphinus*, but it has extraordinarily wide asci [†60–73 × (7–)7.5–8(–8.7) µm].

Not included collection. A North American sample on *Salix* (IVV: H.B. 5411) has rather short spores (*7–11 × 2–2.7 µm) and narrow asci (†60–75 × 5–6 µm). In association grew the similar *O. delphinus* in which the spores did not overlap in length (*12–14 × 2.2–2.4 µm), therefore, the two populations are obviously not conspecific.

Ecology. *O. macrodelphinus* was found on rotten wood, rarely bark (*Baccharis*), of xeric twigs and branches of both angio- and gymnosperm trees and shrubs. In western North America it occurred in cold-temperate subhumid to warm-temperate semiarid pinyon-juniper woodlands and boreal humid Douglas fir mixed forests of the Middle Rocky Mountains and adjacent Columbia Plateau and mainly in the Colorado Plateau, also in warm-temperate semiarid paloverde-mixed cacti desert scrubs in the Sonoran Desert adjacent to Mogollon Rim. The Macaronesian collection was in the supramediterranean semihumid summit broom scrub (*Spartocytisetum supranubii*) in the caldera of the volcano Teide in Tenerife. The not included sample on *Salix* is from a boreal humid open woodland in the Middle Rocky Mountains.

Specimens included. **MACARONESIA**: **Canary Islands**, **Tenerife**, La Orotava, Las Cañadas del Teide, 3.5 km SE of Teide, Mirador del Tabonal Negro, 2333 m, branches of *Cytisus supranubius*, on wood, 13.II.2009, L. Quijada, J. Diaz Armas & E. Beltrán-Tejera (TFC Mic. 21458, 21460, H.B. 9223). — **USA**: **Idaho**, Middle Rocky Mountains, Grand Teton, 67 km ENE of Idaho Falls, 9 km WSW of Victor, Pine Creek Pass, 2080 m, branches of *Pseudotsuga menziesii*, on wood, 5.VI.1996, G. Marson (H.B. 5773a). – Columbia Plateau, 60 km E of Idaho Falls, 47 km W of Jackson, Swan Valley 1750 m, branches of *P. menziesii*, on wood, 5.VI.1996, G. Marson (H.B. 5605). – **Utah**, Canyonlands, Capitol Reef, 40 km WSW of Hanksville, 23 km E of Torrey, 1557 m, branch of *Baccharis salicifolia*, on bark, 19.VI.2000, G. Orbilia multidelphinus Baral, **sp. nov.**, MB 813685 — Pl. 644

Etymology: named after the 32-spores asci and after the ascospores resembling *O. delphinus*.

Typification: USA, Utah, Cedar City, branch of *Juniperus osteosperma*, 24.VIII.1994, G. Marson (ex H.B. 5198b, M-0276520, holotype).

Latin diagnosis: *Differt ab* Orbilia delphino *ascis 32-sporis*, *ascosporis basi multo attenuatis*, *paraphysibus vivis ad apicem absque corpusculis globosis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.3 mm diam., 0.17–0.2 mm high, light orange, round, gregarious in a small group; disc flat, margin thin, not protruding, slightly rough, whitish; sessile, slightly to entirely immersed. **Asci** *78–93 × (7.6–)8–8.5 µm {1}, †72–93 × 6.5–7.5 µm {1}, 32-spored, spores *4-seriate, 14–18 lower spores inverted (± strongly mixed), pars sporifera *55–65(–70) µm long; **apex** (†) medium to strongly truncate conical (partly very slightly indented, laterally not inflated), hemispherical-subconical in profile view, thin-walled; **base** with rather short and thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(9.5–)11–14.7 × 2.3–2.6 µm {1}, †9.5–11.5 × 2–2.3(–2.4) µm {1}, narrowly fusiform-clavate, apex acute, base strongly attenuated (tail-like), here slightly curved; **SBs** *(4–)7–9.5 × (0.6–)0.8–1(–1.4) µm in situ {1} (~7.3–10 µm actual length), vermiform-subulate to almost filiform, base not or slightly to strongly inflated, slightly to strongly flexuous. **Paraphyses** apically medium clavate to spathulate (rarely moniliform), terminal cells *(5–)8–20(–22) × (3.3–)4–5.7 µm {1}, lower cells *7–20 × 1.3–2(–2.5) µm {1} (near base 2–2.7 µm wide); very frequently branched near apex. **Medullary excipulum** pale orange, 40–60 µm thick, of textura intricata with ± abundant inflated cells, medium sharply delimited. **Ectal excipulum** very pale orange, of ± thin-walled, inconclusively oriented t. angularis from base to margin, 15–30 µm thick near base, cells *7–14 × 7–11 µm {1}; 20 µm thick at flanks, 10–15 µm near margin, of t. porrecta oriented at a 0–10° angle to the surface, marginal cortical cells */†8–14 × 3–5 µm {1}. **Anchoring hyphae** medium abundant, */†2–3.7 µm wide, walls 0.2–0.3(–0.8) µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) absent. **Exudate** over paraphyses 0.3–0.5 µm thick, cap-like, firmly attached, sparse (often lacking); over margin and flanks very sparse, granular. **— ANAMORPH**: unknown.

Habitat: corticated, 12 mm thick branch of *Juniperus osteosperma* {1}, on medium decayed, detaching bark {1}, greyed, without or with many green algae. **Associated**: *Orbilia cucumispora*, *O. ?maeandrina*, *O. multihamulata*, *O. octosporoides*, *O. ophiosoma*, *O. osteospermae*, *O. pisciculus*, *Ostropales*. **Desiccation tolerance**: fully viable for at least 4 months. **Altitude**: 1815 m a.s.l. **Geology**: Upper Cretaceous calcareous sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multidelphinus* is characterized by 32-spored asci and comparatively long, narrowly fusiform-clavate ascospores with acute apices and distinct, slightly curved tail-like bases, containing very long, cylindric-subulate spore bodies. Remarkable are also the consistently truncate-conical ascus apices in the dead state. From *O. delphinus* the species differs not only in 32-spored asci, but also in much more attenuated spore bases, a tendency to more spathulate paraphyses, and the absence of SCBs.

Not included collections. A sample from the Colorado Plateau (Bryce Canyon) on *Chrysothamnus* (Pl. 644: 2) resembles *O. multidelphinus*. It is not included in the description because of partly obtuse spore apices, shorter asci and spores, much shorter SBs, and the presence of globose SCBs. This population grew in association with a very similar 16-spored taxon (*O.* cf. *delphinus*, Pl. 636: 1), to which it seems to be more closely related than to *O. multidelphinus*. A collection from the Chihuahuan desert on *Larrea* (Pl. 644: 3) resembles that on *Chrysothamnus* concerning SBs and SCBs, though the spores are shorter and hardly curved. This collection also resembles *O. multitrapezoidea* in size and shape of the spores, but differs in much shorter SBs.

Ecology. The sparse holotype of *O. multidelphinus* grew on medium rotten bark of a xeric branch of *Juniperus* in a cold-temperate subhumid pinyon-juniper woodland of the Dixie Forest (Utah Mountains) in western North America. The not included collection on *Chrysothamnus* was from a similar climate and geology in a ponderosa pine forest of the Bryce Canyon (Utah Mountains), that on *Larrea* from the warm-temperate semiarid Chihuahuan creosotebush-tarbush at the border to Mesa and Plains.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 1.5 km ESE of Cedar City, 1815 m, branch of *Juniperus osteosperma*, on bark, 24.VIII.1994, G. Marson (ex H.B. 5198b, M-0276520, **holotype**).

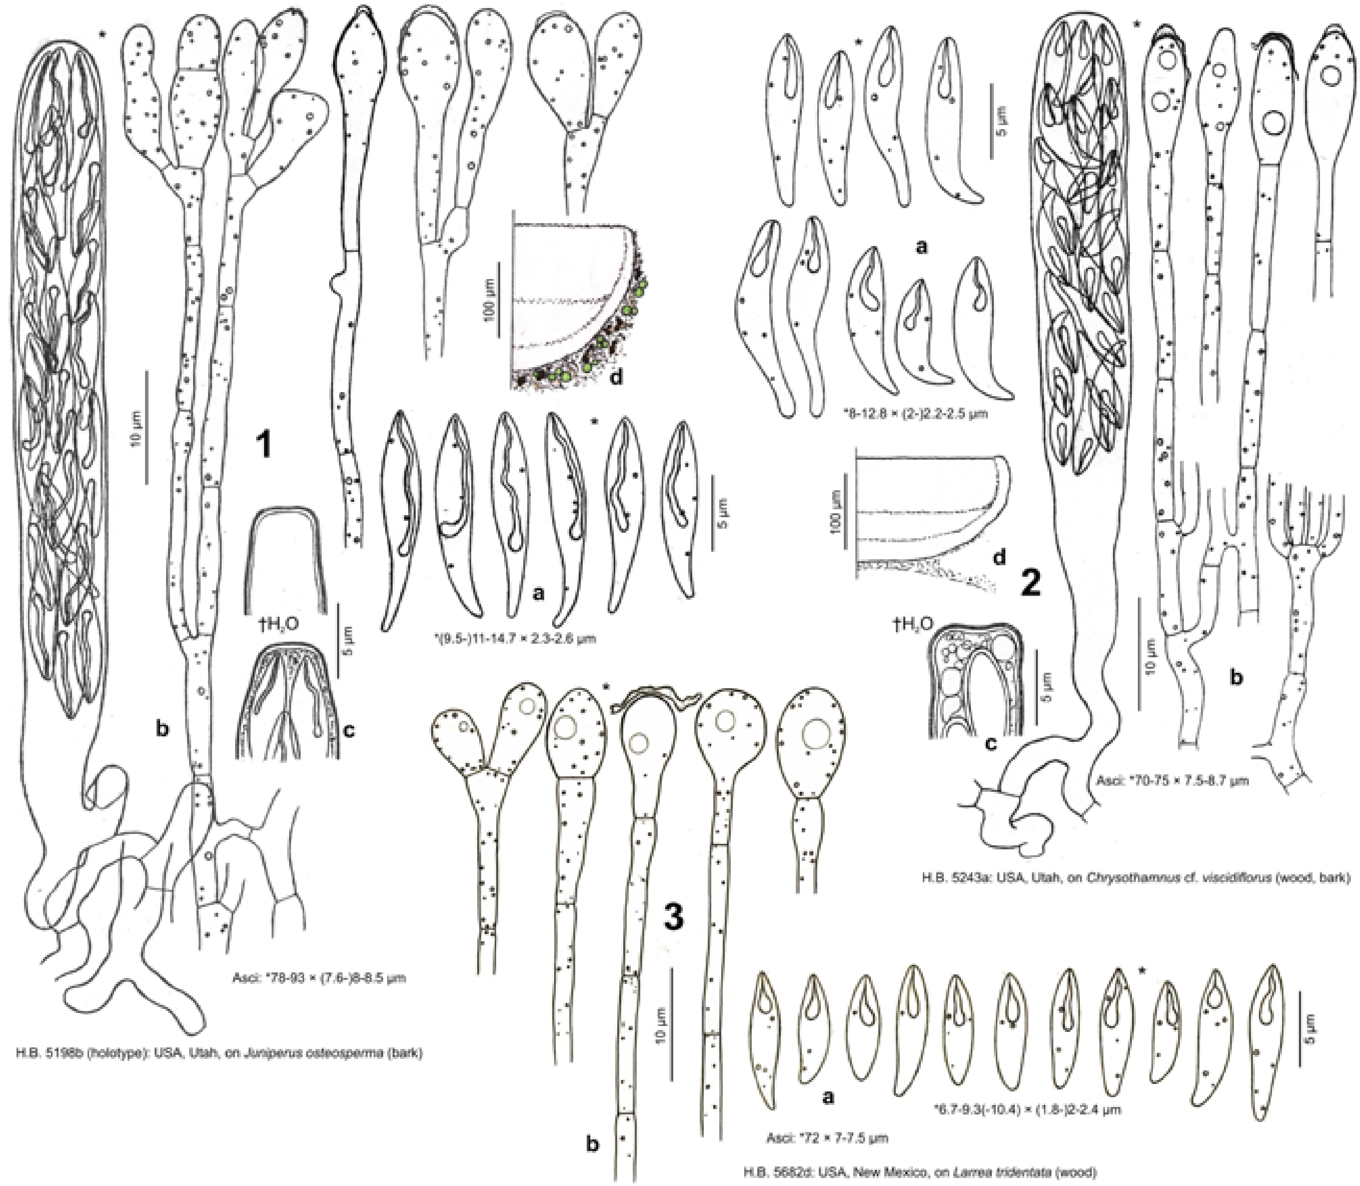

Plate 644. **1**: *Orbilia multidelphinus*; **2–3**: *O.* aff. *multidelphinus*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section.

Not included. **USA**: **Utah**, Utah Mts., Bryce Canyon, 30 km SE of Panguitch, 7.5 km WNW of Tropic, 2410 m, twigs of *Chrysothamnus ?viscidiflorus*, on wood & bark, 24.VIII.1994, G. Marson (H.B. 5243a). – **New Mexico**, Chihuahuan Desert, 25.5 km SE of Carlsbad, Malaga, Hwy 285 (S), 915 m, branch of *Larrea tridentata*, on wood, 17.VI.1996, G. Marson (H.B. 5682d).

Orbilia multitrapezoidea Baral & G. Marson, **sp. nov.**, MB 813686 — Pls 645–646, Map 106

Etymology: referring to the 32-spored asci and somewhat trapezoid (rhomboid) ascospores.

Typification: USA, Arizona, Grand Canyon, Tusayan, branches of *Juniperus osteosperma*, 28.VIII.1994, G. Marson (ex H.B. 5439b, M-0276526, holotype).

Latin diagnosis: Orbiliae multimaeandrinae *similis sed ascosporae angustiores.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.45 mm diam., 0.14–0.2 mm high, light to bright orange(-ochraceous), round, scattered to medium gregarious; disc slightly concave, margin 5–20 µm protruding, ± smooth or very finely crenulate-pubescent; sessile, somewhat immersed in biofilm. **Asci** *(60–)70–90 × (7–)8–9(–10) µm {3}, †(60–)65–80(–100) × 6.3–7.5 µm {3}, 32-spored (30 spores counted), spores (*) ~4-seriate, lower spores inverted {3} (strongly mixed), pars sporifera *44–63 µm long; **apex** (†) strongly truncate, (very) slightly indented, laterally scarcely inflated; **base** with short, thick stalk, L-, Y- or h-shaped. **Ascospores** *(5–)7–10.5(–12.5) × 2.1–2.7(–3.3) µm {4}, †7–12.5 × 2.2–2.4 µm {2}, fusoid to fusoid-clavate, apex subacute to acute, base medium to strongly tapered (sometimes tail-like), straight or slightly to medium curved near base; **SBs** *4.5–8.5 × 0.6–1.2 µm in situ {4} (~5.5–9 µm actual length), vermiform to subulate, base not or often slightly to medium inflated, almost straight to medium flexuous or helicoid. **Paraphyses** apically slightly to strongly (clavate-)capitate but some or many ± distinctly spathulate or lageniform, terminal cells *7–21 × 3–5.7(–6.5) µm {3}, lower cells *9–17.5 × 1.5–2(–2.6) µm {2}; sometimes branched near apex. **Medullary excipulum** hyaline, 20–80 µm thick, of ± dense or loose textura intricata with many inflated cells, (medium) sharply delimited. **Ectal excipulum** hyaline to pale orange, of (†) thin- or firm-walled, vertically oriented t. angularis from base to submargin, 30–80 µm thick near base, cells *9–20 × 8–13(–17) µm {2}; 15 µm thick near margin, at upper margin of t. prismatica-porrecta oriented at a 0–40° angle to the surface, marginal cortical cells *7–13 × 4–8 µm {1}, †8–14 × 3–3.5 µm {1}. **Anchoring hyphae** medium abundant, *2.5–3.5 µm wide (†1.7–3 µm), walls 0.2–0.4(–0.8) µm thick {2}, covering receptacle as hyaline hyphae †2–2.8 µm wide, partly forming somewhat protruding 1–2-celled hairs at margin. **SCBs** in paraphyses and ectal excipulum (near margin) absent {2} or globose, ~1–1.5 µm diam. {3}. **Exudate** over paraphyses 0.2–1 µm thick, finely rough; over margin and flanks indistinct. **— ANAMORPH**: unknown.

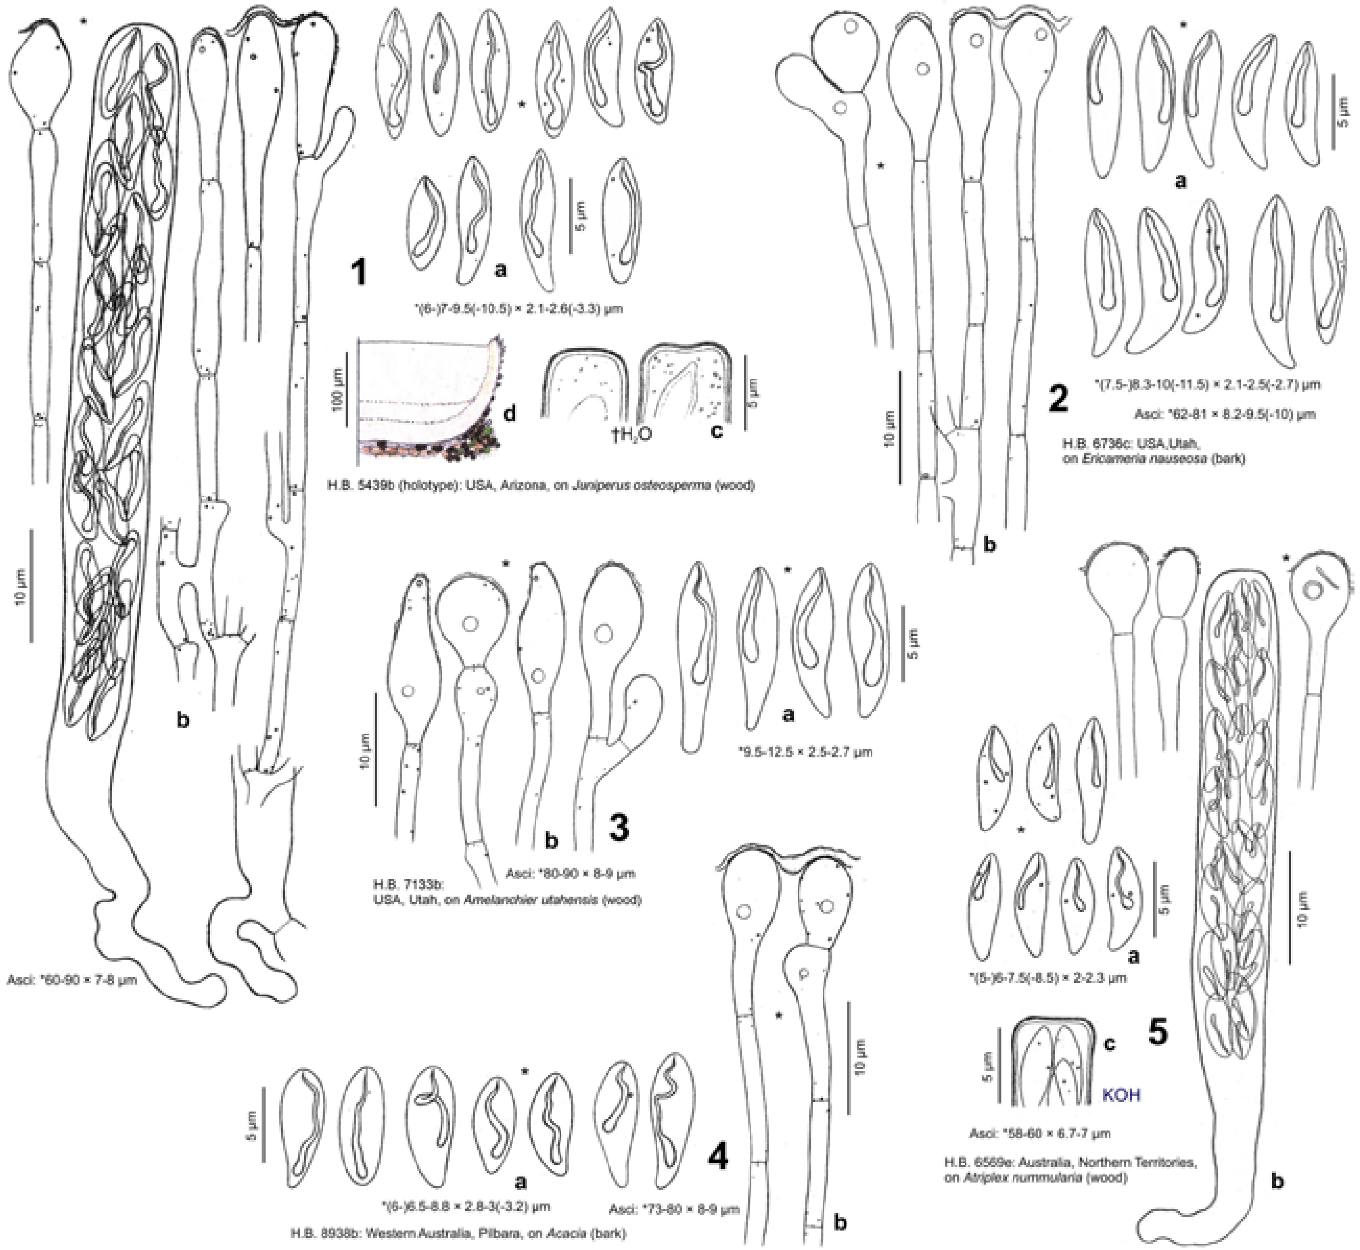

Plate 645. **1–3**: *Orbilia multitrapezoidea*; **4–5**. *O.* aff. *multitrapezoidea*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section.

Habitat: collected 0.1–0.5 m above the ground, corticated or decorticated, 8–24 mm thick branches of *Amelanchier utahensis* {1}, *Ericameria nauseosa* {1}, *Juniperus osteosperma* {1}, *Pinus edulis* {1}, indet. angiosperm {1}, on 0.5 mm deep strongly decayed wood {4} and bark {1}, strongly greyed, with a few or many green algae. **Associated**: *Carestiella schizoxyloides* {1}, *Hysteropatella* sp. {1}, *Mellitiosporiella pulchella* {1}, *Orbilia clavipisca* {1}, *O. ?commarosa* {1}, *O. delphinus* {1}, *O. dixienis* {1}, *O. edulis* {1}, *O. flexisoma* {2}, *O. lentiformis* {2}, *O. macroserpens* {1}, *O. mesaverdiana* {1}, *O. multimaeandrina* {3}, *O. multiphanosoma* {2}, *O. myriophanosoma* {1}, *O. ocellata* {2}, *O. ophiosoma* {1}, *O. plurilentiformis* {1}, *Stictis* sp. {1}, *Teichospora* sp. {1}, *Tryblidaria* sp. {1}, *Tryblidaria ?fenestrata* {2}. **Desiccation tolerance**: fully viable for about 23 months. **Altitude**: 1315–2097 m a.s.l. **Geology**: Proterozoic-Cambrian sedimentary rock, Pennsylvanian-Permian to Triassic-Jurassic red carbonate sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multitrapezoidea* is characterized by 32-spored asci, ± fusoid (trapezoid), medium-sized ascospores, and a strong tendency to a mixed presence of spathulate paraphyses among the capitate ones. Merely the width of the spores separates *O. multitrapezoidea* (mainly *2.1–2.7 µm) from *O. multimaeandrina* (*2.8–3.5 µm). Some collections resemble *O. multitrapezoidea* in spore shape, but deviate too much to be included in the description. A North American

Map 106. Known distribution of *O. multitrapezoidea* in North America.

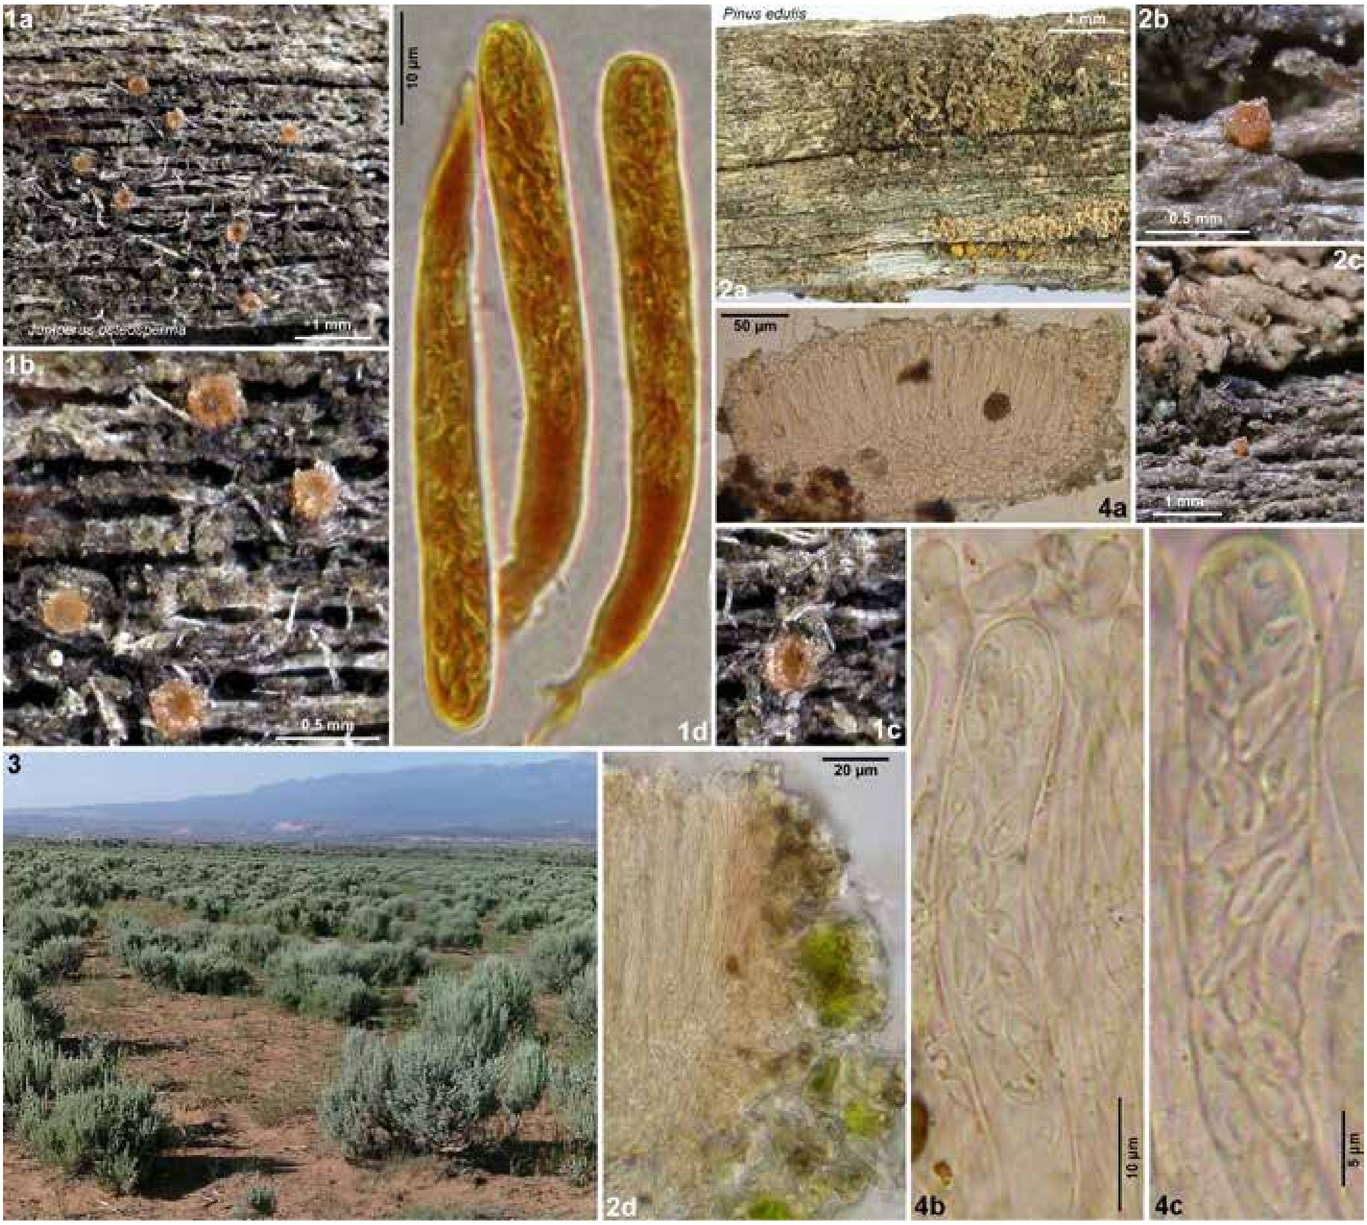

Plate 646. **1–3**. *Orbilia multitrapezoidea*; **4**. *O.* aff. *multitrapezoidea*. – **3**. semiarid sagebrush (*Artemisia tridentata*) desert scrub 2.5 km away from site with *Ericameria nauseosa*; **2a**. decorticated xeric branch (with various lichens); **1a–c**, **2b–c**. rehydrated apothecia (**2c** with *Phaeophyscia*); **4a**. apothecium in median section; **2d**. id., marginal region; **1d**, **4b**. asci and paraphyses; **4c**. ascospores in dead ascus. – Living state, except for **1d** (in KOH+IKI), **2d** (in KOH), **4c** (ascus). — **1a–d**. H.B. 5439b (holotype): USA, Arizona, on *Juniperus*; **2a–d**. H.B. 7149c: USA, Utah, Snow Flat, on *Pinus*; **3**. H.B. 6736c: USA, Utah, Canyon Lands, on *Ericameria*; **4a–c**. H.B. 8938b: Western Australia, Pilbara, on *Acacia.*

collection on *Larrea* (Pl. 644: 3) differs in distinctly shorter SBs, consistently capitate paraphyses, and larger SCBs, but might as well be related to *O.* aff. *multidelphinus* (on *Chrysothamnus*, Pl. 644: 2). The Australian *O. livistonae*, particularly the collection on *Pittosporum* (Pl. 647: 2), likewise differs in more consistently capitate paraphyses and larger SCBs but also in wider spores, and is somewhat intermediate to *O. multimaeandrina*.

The two collections of *O. multitrapezoidea* on coniferous hosts differ from those three on angiosperm shrubs in very slightly shorter spores and less inflated paraphysis apices which consistently lack globose SCBs. Further collections are needed to clarify whether these differences are merely accidental.

Not included collections. An Australian sample on *Acacia* (Pls 645: 4; 646: 4) differs from *O. multitrapezoidea* in wider spores with obtuse apices, and one on *Atriplex* (Pl. 645: 5) in distinctly shorter asci and smaller spores, and apparently also in the presence of crystalloid SCBs. The latter appears to represent a distinct species, but it consisted of only one minute apothecium and is, therefore, not recorded by a separate description.

Ecology. *O. multitrapezoidea* was found on rotten wood (rarely bark) of angiosperm shrubs and gymnosperm trees in the southwest of Northern America, in cold-temperate subhumid pinyon-juniper woodlands and warm-continental semiarid sagebrush desert scrub of the Colorado Plateau, also in a warm-temperate arid Mojave saltbush desert scrub. The two not included collections are from subtropical arid acacia open shrublands on Precambrian sedimentary rock in central and western Australia.

Specimens included. **USA**: **Utah**, Canyonlands, 36 km S of Moab, 5 km WNW of Hatch Rock, 1813 m, branches of *Ericameria nauseosa*, on bark, 16.VI.2000, G. Marson (H.B. 6736c). – 41 km W of Blanding, Natural Bridges, 2090 m, branch of *Amelanchier utahensis*, on wood, 14.VI.2000, G. Marson (H.B. 7133b ø). – 16 km NNW of Mexican Hat, 1 km N of Mokee Dugway, Cedar Mesa, 1965 m, branch of *Pinus edulis*, on wood, 14.VI.2000, G. Marson (H.B. 7149c). – **Arizona**, Grand Canyon, Coconino Plateau, 3 km S of Tusayan, 2033 m, branches of *Juniperus osteosperma*, on wood, 28.VIII.1994, G. Marson (ex H.B. 5439b, M-0276526, **holotype**). – **California** (border to Nevada), Mojave Desert, 20 km SW of Beatty, 16 km SW of Rhyolite, E of Death Valley, Daylight Pass, 1315 m, branch of indet. angiosperm, on wood, 2.V.1995, G. Marson (H.B. 8528i ø).

Not included. **AUSTRALIA**: **Western Australia**, centre of Pilbara, 49 km NW of Newman, northern border of Ophthalmia Range, 690 m, branch of *Acacia*, on bark, 28.X.2007, G. Marson (H.B. 8938b). – **Northern Territories**, northeast of MacDonnell Ranges, 15 km WNW of Alice Springs, N of Honey Moon Gap, 586 m, twig of *Atriplex nummularia*, on wood, 9.X.1998, G. Marson (H.B. 6569e).

Orbilia livistonae Baral, **sp. nov.**, MB 813687 — Pls 647–648

Etymology: named after the substrate of the type, *Livistona*.

Typification: Australia, Queensland, Taroom, leaves of *Livistona nitida*, 22.X.1998, G. Marson (ex H.B. 6424b, BRI AQ799185, holotype).

Latin diagnosis: *Similis* Orbiliae multitrapezoideae *sed corpuscula refringentia angustiora*, *basi non inflata*, *paraphyses ad apicem capitatae*. *Habitat ad petiolos putridos siccos* Livistonae nitidae *et lignum vel corticem putridum rami sicci* Casuarinae cunninghamianae *in zona subtropica subhumida ad humida Australiae orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3 mm diam., 0.12–0.15 mm high, pale to light orange, scarcely translucent, round, scattered; disc slightly concave to flat, margin thin, 0–5 µm protruding, smooth; broadly sessile, superficial or somewhat immersed. **Asci** *70–99 × 9–10.7 µm {1}, †65–89 × 7.5–9(–10) µm {2}, 32-spored, spores *4–5-seriate, lower spores inverted (scarcely mixed), pars sporifera *47–64 µm long; **apex** (†) medium to strongly truncate (not indented, laterally sometimes distinctly inflated); **base** with very short, thick, flexuous stalk, h-shaped. **Ascospores** *8–12(–14) × (2.6–)2.8–3.2 µm {1}, †8.5–11(–12) × (2.5–)2.7–3(–3.2) µm {2}, (fusoid to) fusiform(-clavate), apex acute, (†) also acuminate, base medium attenuated, straight or only slightly inequilateral, exceptionally slightly curved at base; **SBs** *(5.5–)6–8.5(–9.5) × 0.5–0.7 µm in situ {1} (~6–10.5 µm actual length), vermiform to subulate or filiform, base not or only very slightly inflated, medium to strongly flexuous, sometimes uncinate. **Paraphyses** apically medium to strongly capitate, terminal cells *7–22 × 3–5.2 µm {1}, lower cells *7–19 × 1.2–2(–2.8) µm {1} (basal cells 8–12 × 2–3 µm); branched or unbranched at upper septum. **Medullary excipulum** ~15–30 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** of (†) ± thin-walled, vertically or irregularly oriented t. globulosa-angularis-prismatica from base to mid flanks, 20–30 µm thick near base, cells *9–15 × 6–10 µm {1}; 15–20 µm thick near margin, of t. prismatica-angularis or prismatica-porrecta oriented at a 0–45° angle to the surface, marginal cortical cells *7–12(–16) × 3–5.2 µm {1}. **Anchoring hyphae** ± abundant, †1.7–3 µm wide, walls 0.2–0.5 µm thick {1}, distinctly gelatinized, partly covering the margin. **SCBs** globose, in paraphyses 1–2 µm diam., in ectal excipulum (near margin) 1.5–2.5 µm. **Exudate** over paraphyses 0.2–1 µm thick, granular to continuous, ± loosely attached; over margin and flanks 0.2–1(–1.5) µm thick, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 0.2–3 m above the ground, on petioles of *Livistona nitida* {1}, on strongly decayed and greyed upperside, on 8–12 mm thick, ± corticated branch of *Casuarina cunninghamiana* {1}, on wood and bark, with some green algae. **Associated**: *?Gloniopsis*

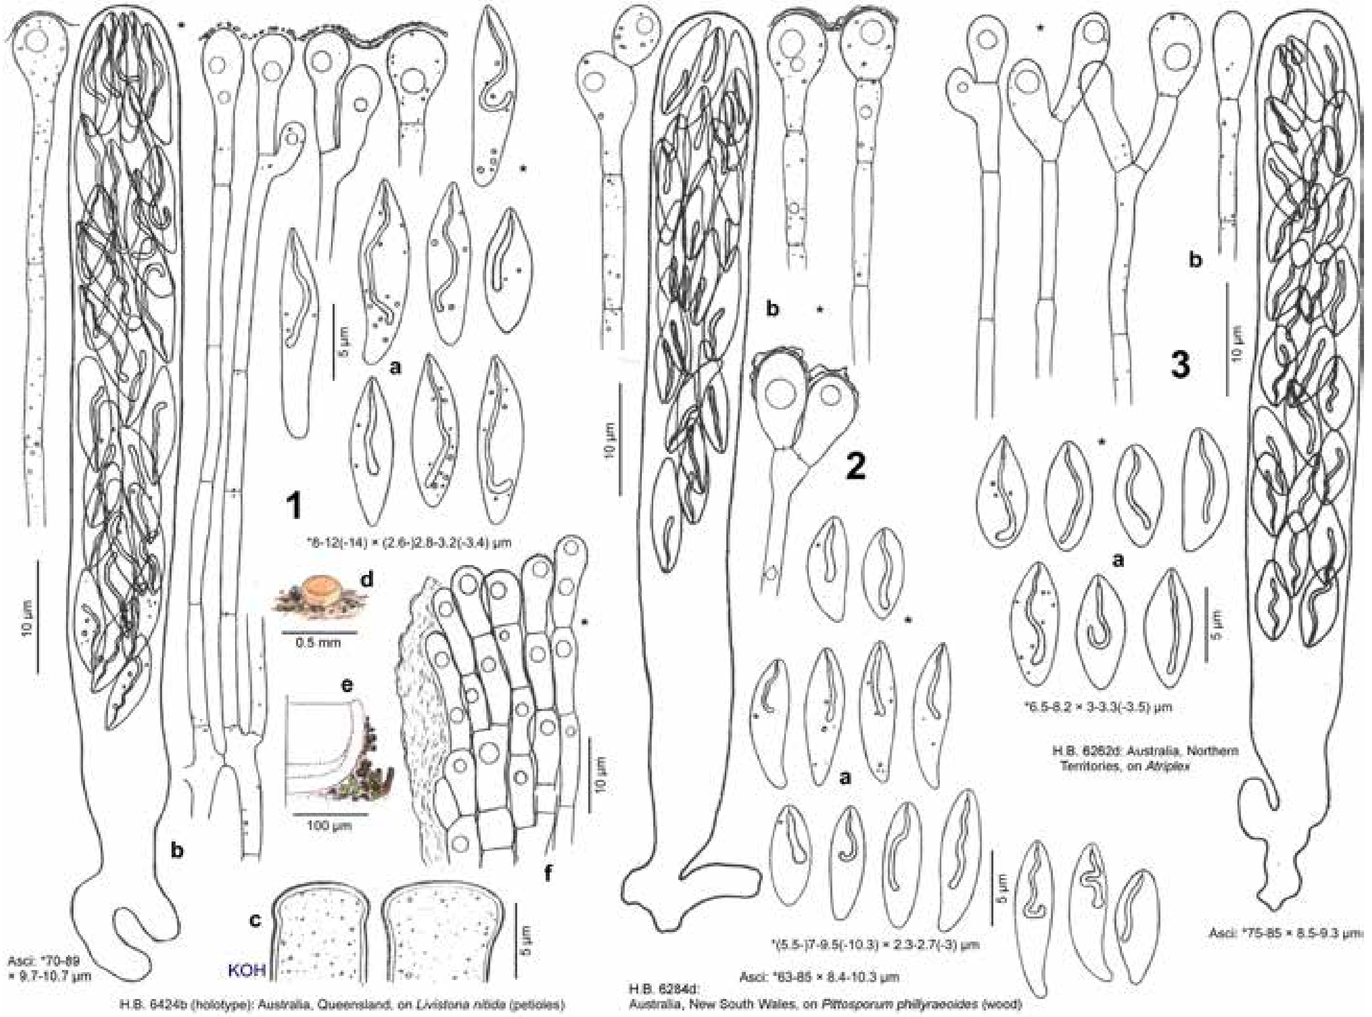

Plate 647. **1**: *Orbilia livistonae*; **2–3**: *O.* cf. *livistonae*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium; **e**. apothecia in median section; **f**. ectal excipulum (margin, median section).

praelonga {1}, *Mellitiosporiella* sp. {1}, *Orbilia acaciae* {1}, *O.* ?*australiensis* {1}, *O.* (?)*commarosa* {1}, *O. coronohesperidea* {1}, *O.* (?)*dixienis* {1}, *O. multiserpens* {1}, *O. myrioeuonymi* {1}, *O. palmicola* {1}, *O. parviclava* {1}, *O.* ?*pleiohesperidea* {1}, *O. wannerooensis* {1}. **Desiccation tolerance**: fully viable for at least 9 months. **Altitude**: 200–537 m a.s.l. **Geology**: Proterozoic and Jurassic sedimentary rock, Cenozoic regolith; volcanic mafic basaltic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia livistonae* is characterized by 32-spored asci, medium-sized fusiform ascospores with rather long and narrow spore bodies, and by the absence of crystalloid SCBs. The species differs from the similar North American *O. multitrapezoidea* and *O. multimaeandrina* mainly in narrower SBs with hardly inflated bases, but also in the absence of spathulate paraphyses, and from the latter species in longer and narrower spores.

Variation. The collection on *Casuarina* (IVV: H.B. 7282b) was only examined in the dead state. It appears to fit well the holotype, with the fusiform spores slightly shorter (†8.5–10 × 3–3.2 µm).

Not included collections. Four Australian samples are not included in the description. two of them differ in spore size: the collection on *Atriplex* (Pl. 647: 3) has distinctly shorter spores, while that on *Pittosporum* (2) mainly deviates in narrower spores. In both the spore apices are more subacute or sometimes even obtuse. No vital characters are known from a collection on twigs of *Acacia coriacea* (Pl. 648: 2, see also IVV: H.B. 7226d), except for some living paraphyses which contained globose SCBs. This specimen matches *O. livistonae* in spore size [†9–11 × 2.3–2.8(–3) µm] and shape, but it differs in the upper spores being always inversely oriented while the lower spores are oriented with their acute end upwards. Likewise, no vital characters are known from a specimen from the Pilbara desert (on *Ipomoea*, IVV: H.B. 8726a), with rather short spores [†7–9(–10) × 2.8-3 µm] with consistently obtuse apices.

Ecology. The holotype of *O. livistonae* was collected on rotten xeric petioles of *Livistona* in a subtropical subhumid (winter-dry, savannah) eucalypt woodland in the Palm-Tree Creek, the paratype on rotten wood and bark of a xeric branch of *Casuarina* in a subtropical humid eucalypt woodland (both in the Great Dividing Range, eastern and southeastern Australia). The three not included collections are from more arid areas from northwestern, central and eastern Australia: those on *Acacia* and *Atriplex* in subtropical arid central Australia northeast of Macdonnell Ranges in acacia open shrublands, that on *Ipomoea* in a similar climate in northwestern Australia, and that on *Pittosporum* in a eucalypt woodland in subtropical humid eastern Australia.

Specimens included. **AUSTRALIA**: **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, leaves of *Livistona nitida*, on petioles, 22.X.1998, G. Marson (ex H.B. 6424b, BRI AQ799185, **holotype**; **isotype** in MEL 2389208). – **New South Wales**, South Western Slopes, 183 km NW of Sydney, 20 km SE of Mudgee, 537 m, branch of *Casuarina cunninghamiana*, on wood & bark, 25.X.1998, G. Marson (H.B. 7282b).

Not included. **AUSTRALIA**: **Northern Territories**, Burt Plain, 48 km NNW of Alice Springs, 15 km SW of Yambah, 711 m, branch of *Acacia coriacea*, on wood & bark, 13.X.1998, G. Marson (H.B. 7226d). – 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, 480 m, branch of *Atriplex*, on wood, 8.X.1998, G. Marson (H.B. 6262d). – **New South Wales**, Brigalow Belt

Marson (H.B. 6284d). – **Western Australia**, Pilbara, 58 km WSW of Karratha, 37 km NE of Fortescue River Roadhouse, 46 m, twig & branch of *Ipomoea costata*, on bark & wood, 4.XII.2001, G. Marson (H.B. 8726a).

Orbilia octoserpentina Baral & G. Marson, **sp. nov.**, MB 813688 — Pls 649–650

Etymology: an 8-spored derivative of *O. serpentina*.

Typification: Australia, Queensland, Hughenden, branches of *Acacia*, 16.X.1998, G. Marson (ex H.B. 6609b, BRI AQ799187, holotype; ex-type culture: CBS 140811; sq.: KT215237, MH878183).

Latin diagnosis: *Similis* Orbiliae bicknellensi *sed ascosporae basi non vel leniter attenuatae, ascosporae partim longiores, corpuscula refringentia partim longiora, asci partim latiores. Habitat ad lignum vel corticem putridum ramorum siccorum angiospermarum in zona subtropica semihumida ad tropica arida Australiae occidentalis et orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.6 mm diam., 0.13–0.2 mm high, light to bright orange(-rose), slightly translucent, round, scattered to subgregarious; disc flat, margin distinct, 5 µm protruding, smooth to distinctly whitish crenulate; broadly sessile, superficial or slightly to deeply immersed in fissures. **Asci** *(63–)70–85(–94) {4} × 6.2–8 {2} or 8–8.7 µm {2}, †(50–)60–70 × 6–7 µm {2}, 8-spored, spores *(2–)3-seriate, 3–5 lower spores inverted {3} (not mixed), pars sporifera *50–58 µm long; **apex** (†) (medium to) strongly truncate (sometimes slightly indented and laterally somewhat inflated); **base** with short to medium long, ± thick and flexuous stalk, Y-to h-shaped. **Ascospores** *(9–)12–15.5(–18.3) × 3.2–3.8(–4.2) µm {4}, †(9–)10–13(–15) {2} or 14.8–16.5(–17.7) {1} × 3–4 µm {3}, fusiform to narrowly amygdaliform, often with cylindric middle part, apex acute to acuminate, exceptionally obtuse, base not or only slightly attenuated, rounded, straight to slightly inequilateral, at the very base sometimes medium tapered and slightly curved; **SBs** *(5.5–)7–11(–12.7) × 0.8–1(–1.2) µm in situ {1} (~7.5–13 µm actual length), vermiform (to subulate), base scarcely to medium inflated, straight to strongly flexuous, rarely uncinate. **Paraphyses** apically medium to often very strongly capitate, rarely spathulate, terminal cells *6–23 × 4–6.5(–7.5) µm {2}, lower cells *9–16 × 1.3–2.5(–3) µm {2}; not branched near apex. **Medullary excipulum** 20–50 µm thick, of ± loose textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized t. globulosa-angularis from base to submargin, 20–50 µm thick near base, cells *10–19 × 8–12 µm {1}; 15–20 µm thick near margin, of t. prismatica-globulosa oriented at a 20–50° angle to the surface, marginal cortical cells †5–10 × 2.5–5 µm {2}. **Anchoring hyphae** abundant, †2–2.8(–3.3) µm wide, walls 0.2–0.3(–0.4) µm thick {1}, forming a ~5 µm thick covering layer at flanks and margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.3 µm diam., and rod- or ring-shaped {3}, pale to bright orange, 3.5–6 × 1–4 µm. **Exudate** over paraphyses and marginal excipulum 0.3–1 µm thick, cloddy, finely rough, or continuous, hyaline, partially detaching. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** Y-shaped, total size †17–26 × 21–40 µm, stipe †10–10.5 × 3.2–4 µm, 1–2-septate, arms tapering, †10–23 × 3.2–4 µm, 2–4-septate {1}.

Habitat: collected 0.1–2 m above the ground, ± corticated, 4–35 mm thick twigs and branches of *Acacia* sp. {1}, *Arbutus andrachne* {2}, *Psydrax latifolia* {2}, *Quercus robur* {1}, on (medium to) very decayed wood {3} and bark (bast) {3}, strongly greyed, no algae. **Associated**: *Gloniopsis* sp. {1}, *Hyalorbilia ?orbiliicola* (parasitic on *O. octoserpentina*) {1}, *Nectria* sp. {1}, *Orbilia corculispora* {1}, *O. coronohesperidea* {1}, *O. curvativitalbae* {2}, *O. ?lacrimispora* {1}, *O.*

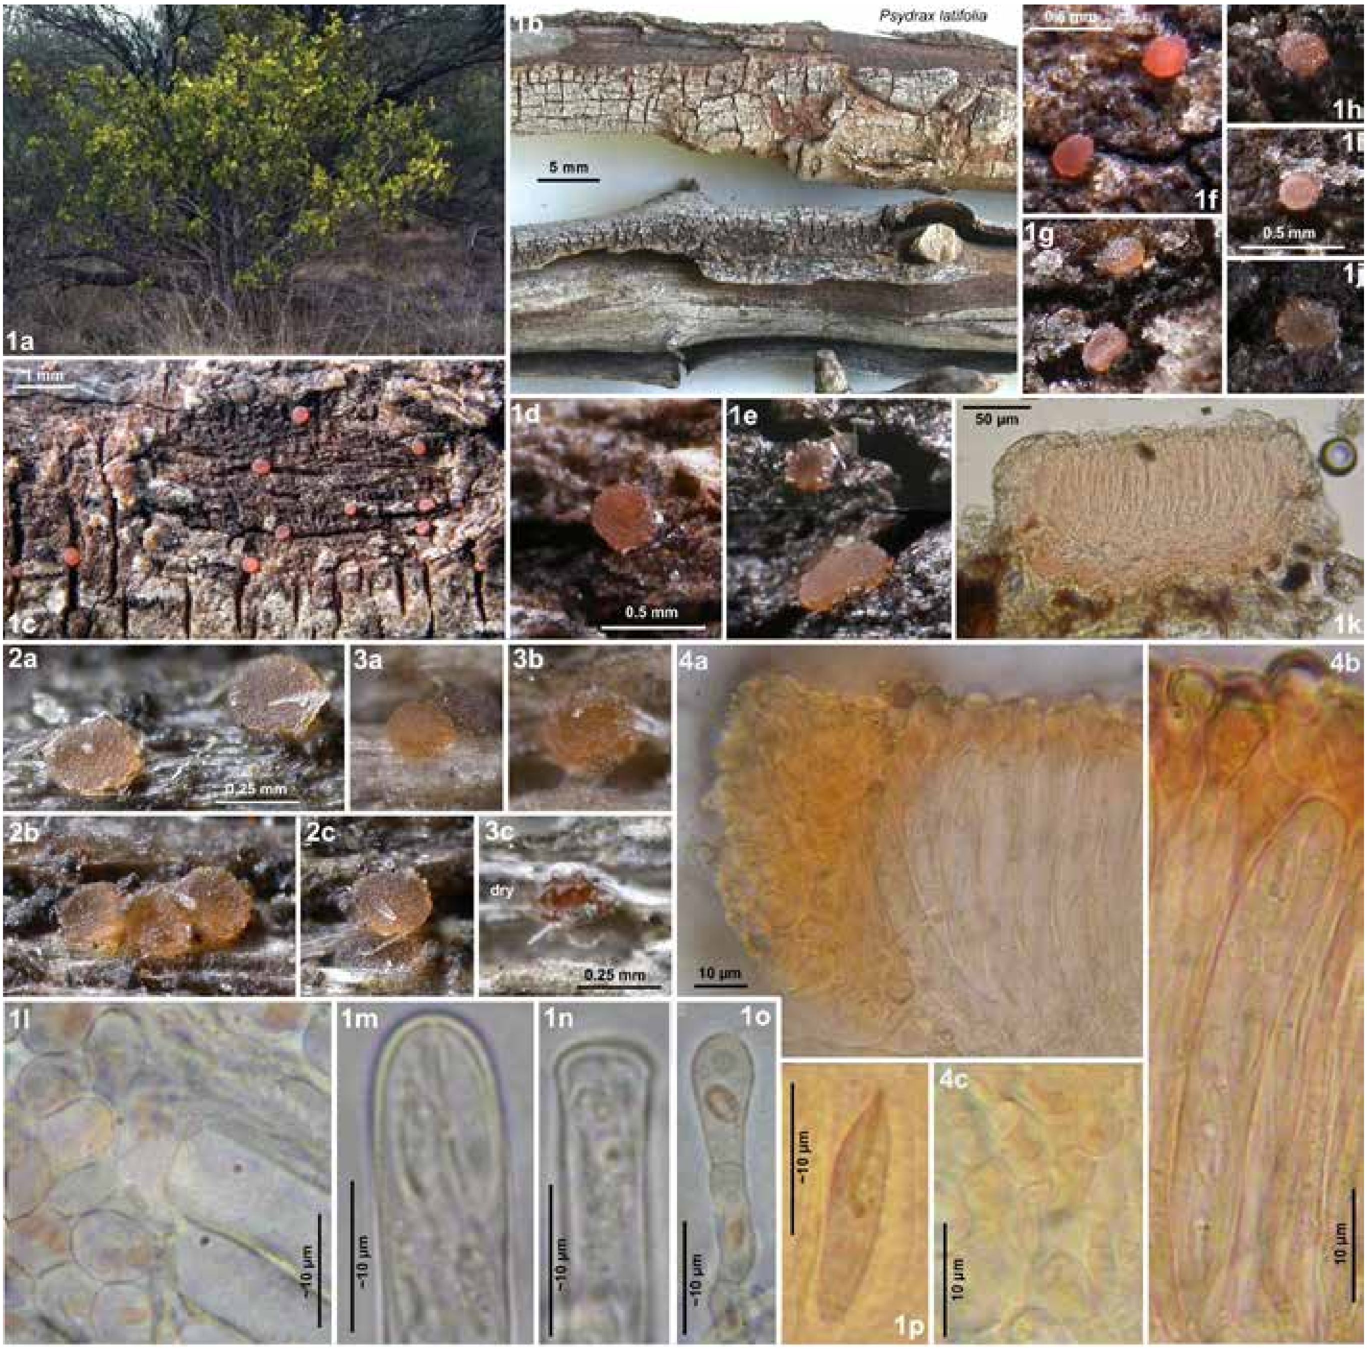

Plate 650. **1–4**: *Orbilia octoserpentina*. – **1a**. tropical arid acacia shrubland with *Psydrax* shrub; **1b**. partly decorticated xeric branches; **1c–j**, **2a–c**, **3a–b**. rehydrated apothecia; **3c**. dry apothecium; **1k**. apothecium in median section; **4a**. marginal ectal excipulum and hymenium in median section; **4b**. asci and paraphyses; **1m–n**. apices of asci; **1l**, **o**. apices of paraphyses with reddish SCBs; **4c**. crystalloid SCBs at margin; **1p**. ascospore. – Living state, except for **1n** (in H_2O). — **1a–p**. H.B. 7416a: Western Australia, Pilbara, on *Psydrax*; **2a–c**. 18.XII.2001: Western Australia, Perth, on *Quercus*; **3a–c**. H.B. 8649a: ibid., on *Arbutus*; **4a–c**. H.B. 8690d: Western Australia, Perth, on *Arbutus*.

multiserpens {1}, *O. octocercocarpi* {1}, *O. serpentina* {3}, *Patellaria* ‘*andina*’ {1}, *P. atrata* {2}, ?*Stictis* sp. {1} *Trichopeziza perrotioides* {2}. **Desiccation tolerance**: fully viable for at least 22 months. **Altitude**: 45–706 m a.s.l. **Geology**: Archean to Paleoproterozoic and Cretaceous sedimentary rock, Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia octoserpentina* is characterized by large, ± fusiform ascospores with acute to acuminate apices, an often cylindrical middle part and at the base mostly only slightly tapered and almost straight, also by rather long spore bodies and by the presence of crystalloid SCBs. For the very similar *O. bicknellensis* (especially the collection on *Baccharis*, Pl. 655: 4) see p. 1129. *O. serpentina* differs in 16-spored asci and shorter spores.

Variation. The three collections from southwestern Australia differ from those from Pilbara/Murchison (on *Psydrax*) and Queensland (on *Acacia*) in shorter spores, also in narrower asci, but are thought to belong in the scope of this species.

Anamorph. The sparse trinacrium robustum-like conidia observed in *O. octoserpentina* are very similar to those of the closely related *O. serpentina*.

Phylogeny. Sequences were gained from the ex-type culture from Queensland (on *Acacia*) and from apothecia of a sample from Western Australia (Murchison, on *Psydrax*). Both comprise the S1506 intron, ITS, and LSU, the holotype also SSU. In the ITS2 region they deviate by 5 % (10 nt and 7 gaps) and in entire ITS by 3 % (the ITS1 of the *Psydrax* strain is incomplete), but in the LSU (D1–D2) only by 1 nt (0.2 %). Although these sequences are rather close to *O. serpentina* in the LSU D1–D2 (0.5–0.6 %), a high ITS distance of 12.5–13.5 % is noted. Lower distances are observed to *O. mesaverdiana* (10.5–11 %) or *O. halimi* and *O. vermiculati* (10–12.5 %). Despite such high distances to other species of the *Serpentinae-Habrostictis* clade, *O. octoserpentina* clustered in the combined analysis with these four species in a highly supported clade (Phyl. 20), in the LSU with three of them in a medium supported clade (Phyl. S22), and unresolved in the ITS analysis (Phyl. 19).

In the ITS and LSU the two *O. octoserpentina* strains clustered in a strongly supported clade due to the comparatively low distance. In the intron region a high distance of 13 % is observed between them. Apparently therefore, they did not cluster in a clade but the *Psydrax* strain with weak support with *O. mesaverdiana* and the *Acacia* strain unresolved (Phyl. S21).

Ecology. *O. octoserpentina* was collected on ± rotten wood and bark of xeric twigs and branches of different angiosperm trees. The holotype was on *Acacia* in a tropical semiarid eucalypt open woodland in northeastern Australia (west of Great Dividing Range), while the paratypes derive from southwestern Australia on introduced trees (*Arbutus* and *Quercus*) planted in a subtropical semihumid botanical garden in the Swan Coastal Plain, and from western Australia on *Psydrax* in a tropical arid acacia shrubland (mulga) of the Pilbara desert and subtropical semiarid acacia woodland in the Murchison ecoregion.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, Perth, Kings Park, 45 m, branch of *Quercus robur*, on wood, 18.XII.2001, G. Marson (ø). – ibid., branches of *Arbutus andrachne*, on wood, 18.XII.2001, G. Marson (H.B. 8649a). – ibid., branch of *A. andrachne*, on bark, 19.X.2007, G. Marson (H.B. 8690d). – centre of Pilbara, 30 km NW of Newman, northern end of Ophthalmia Range, 706 m, branches of *Psydrax latifolia*, on bark, 27.XI.2001, G. Marson (H.B. 7416a). – Murchison, 105 km NNE of Meekatharra, 557 m, branch of *Psydrax latifolia*, on wood & bark, 27.X.2007, G. Marson (G.M. 2007-10-27.1; sq.: MH221049). – **Queensland**, Desert Uplands, 29 km E of Hughenden, 13 km W of Prairie, 390 m, branches of *Acacia*, on wood & bark, 16.X.1998, G. Marson (ex H.B. 6609b, BRI AQ799187, **holotype**, **isotype** in MEL 2389211, anam. cult. & anam. substr., CBS 140811; sq.: KT215237, MH878183).

Orbilia serpentina Pat., Énum. champ. Tunisie: 11, Illustr. esp. Tunisie: pl. II fig. 6 (1892) — Pls 651–653, Map 107

Etymology: referring to the shape of the spore bodies being flexuous like a snake. **Typification**: Tunisia, Kasserine, Sbeitla, twig of *Artemisia herba-alba*, 17.III.1891, N. Patouillard (FH 00304812, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.4(–0.65) mm diam., 0.12–0.2 mm high, (pale to) light or bright orange(-rose), round, rarely elliptical, very scattered to subgregarious; disc flat, margin indistinct to distinct, 0–10(–20) µm protruding, smooth or finely rough; sessile, nearly superficial to entirely erumpent. **Asci** *(52–)60–100(–115) × (7–)7.5–9(–10.5) µm {12}, †(55–)60–88(–94) × (5.6–)6.5–8.2 µm {6}, 16-spored, spores *3–4-seriate, (4–)6–10(–12) lower spores inverted {11} (not or sometimes mixed), pars sporifera *40–67 µm long, †48–63 µm; **apex** (†) (medium to) strongly truncate (sometimes very slightly indented, laterally sometimes distinctly inflated); **base** with short to long, ± thick, flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(7–)8–12.5(–14) × (2.6–)2.8–3.5(–3.7) ((–4.2)) µm {14}, †(7.5–)9–10.7 × 2.8–3.5 µm {2}, fusoid to fusiform (narrowly amygdaliform), also ellipsoid-fusoid or fusiform-clavate, apex (subacute to) acute (to acuminate), exceptionally obtuse, base very slightly up to sometimes strongly attenuated (rarely tail-like), straight to slightly inequilateral, sometimes slightly to medium curved at base; **SBs** *((4–))(4.5–)5–8(–9) × (0.6–)0.8–1.2(–1.4) µm in situ {8} (~5–9 µm actual length) → 3–3.5 × 1–1.4 µm, vermiform to subulate, base often slightly to medium inflated, mostly slightly to strongly flexuous. **Paraphyses** apically (slightly to) medium to very strongly capitate-clavate, sometimes spathulate-sublageniform or moniliform, terminal cells *(4.5–)9–21(–27) × (2–)4–6.5(–7.5) µm {11}, †(2–)3–5.5 µm wide {3}, lower cells *8.5–20 × 1.3–2.2(–2.8) µm {9}, †1–1.7 µm wide; unbranched or branched at upper septum. **Medullary excipulum** pale rose, 25–50 µm thick, of ± dense textura intricata with many inflated cells, indistinctly or, especially at flanks, sharply delimited. **Ectal excipulum** subhyaline to light orange, of (†) not or slightly gelatinized (common walls 0.5–1 µm thick), irregularly to ± vertically oriented t. angularis(-prismatica) from base to mid flanks, 20–80 µm thick near base, cells *8–24 × 6–15 µm {4}, †8–17 × 7–12 µm {2}; 10–20 µm thick near margin, of t. prismatica oriented at a 10–30° up to 50–60° angle to the surface, marginal cortical cells *(5–)7–10(–12) × (3–)3.5–5(–7) µm {3}. **Anchoring hyphae** medium abundant, */†2–3.5(–4) µm wide, walls 0.2–0.4(–0.7) µm thick {4}, partly somewhat gelatinized, covering the excipulum at flanks and sometimes up to margin as a 5–15 µm thick hyaline layer. **SCBs** in paraphyses and ectal excipulum (from base or flanks up to margin) globose, 1–3 µm diam., and rod- or ring- to keyhole-shaped {15}, subhyaline to pale orange, 1.5–11 × 1.5–5 µm. **Exudate** over paraphyses 0.2–1 µm thick, rough-granular to cloddy, ± continuous, hyaline, ± firmly attached, over marginal excipulum 0.5–2 µm thick. — **ANAMORPH**: trinacrium-like (from ascospore isolate {2} and natural substrate {1}). **Conidiophores** rather short, branched. **Conidiogenous cells** *8–14 × 3–3.5 µm. **Conidia** Y-shaped, total size *(21–)25–34(–38) × (13–)18–25(–32) µm, stipe *15–22 × 5.2–6(–7) µm, 2–5(–7)-septate, arms partly tapering, partly lageniform, also nearly cylindrical with obtuse ends, *9–17 × 3.5–4.8(–6) µm, 1–2(–3)-septate {2}; sometimes unbranched phragmoconidia observed {1}.

Habitat: collected 0–5 m above the ground, corticated or often partially or entirely decorticated, 3–25 mm thick twigs and branches of *Acacia* sp. {2}, *A. aneura* {1}, *A. ?saligna* {1}, *Allocasuarina decaisneana* {1}, *Arbutus andrachne* {2}, *Artemisia herba-alba* {1}, *A. tridentata* {1}, *Baccharis salicifolia* {1}, *B. sarothroides* {1}, *Ericameria nauseosa* {1}, *Juglans major* {1}, *Myrtus communis* {1}, *Olea europaea* {1}, *Purshia stansburyana* {1}, *Ulex parviflorus* {1}, on 0.2–0.5 mm deep (medium to) strongly decayed wood {13} and bark {8} (periderm and bast), on 20–35 mm thick inflorescence stems of *Agave americana* {1}, *Yucca elata* {1}, not or mostly strongly greyed, without or with sparse to abundant green algae. **Associated**: *Baggea* sp. {1}, *Caloplaca* sp. {1}, *Candelariella* sp. {1}, *Coniochaeta sarothamni* {1}, *Cyathicula nigrofusca* {1}, *Didymosphaeria futilis* {1}, *Dothideales* {1}, *Eutypa* sp. {1}, *Gloniopsis* sp. {1}, *Hypoxylon* sp. {1}, *Hysterographium fraxini* {1}, *?Hysteropatella* sp. {1}, *Lophiostoma caulium* {1}, *Muellerella lichenicola* {1}, *Nectria* sp. {1}, *Odontotrema oregonensis* {1}, *Orbilia arizonensis* {1}, *O. bicknellensis* {5/1}, *O. commarosa* {1}, *O. corculispora* {1}, *O. coronohesperidea* {1}, *O. curvativitalbae* {2}, *O. flavida* {1}, *O. ?flexisoma* {1}, *O. ?lentiformis* {1}, *O. macrodelphinus* {2}, *O. macrotrapeziformis* {3}, *O. maeandrina* {1}, *O. microserpens* {3}, *O. multigambelii* {1}, *O. multimaeandrina* {2}, *O. multiphanosoma* {1}, *O. multivinosa* {1}, *O. myriofusiclava* {1}, *O. ocellata* {3}, *O. octocercocarpi* {1}, *O. octoserpentina* {3}, *O. phanosoma* {2}, *O. pleiolentiformis* {2}, *O. pleiomicrosoma* {1}, *O. pleioobtusispora* {1}, *O. pleioquaestiformis* {1}, *O. pleiovitalbae* {1}, *O. plurilentiformis* {1}, *O. pluristomachia* {3}, *O. purshiae* {1}, *O. ?sonorensis* {1}, *O. subclavuliformis* {1}, *O. wannerooensis* {1}, *O. yuccae* {1}, *Patellaria* ‘*andina*’ {1}, *P. atrata* {3/1}, *Pragmopora* sp. {1}, *Schizoxylon* sp. {1}, *?Stictis* sp. {1}, *Teichosporella dura* {3}, *Trichopeziza perrotioides* {2}, *Symbiotaphrina desertorum* {2}, *Tryblidaria fenestrata* {1}, crustose lichen {1}. **Desiccation tolerance**: mature asci still viable after 19 or even 34 months, paraphyses and ectal excipulum still viable after 30–34 months. **Altitude**: 12–563 m a.s.l. (southern Europe), 1060–2115 m (western North America), 45–515 m (Australia). **Geology**: USA: Proterozoic to Ordovician and Permian to Jurassic sandstone, Miocene mafic volcanic rock, basalt lava flow; Europe: limestone (micrite), sand, marl & clay; Australia: Cretaceous

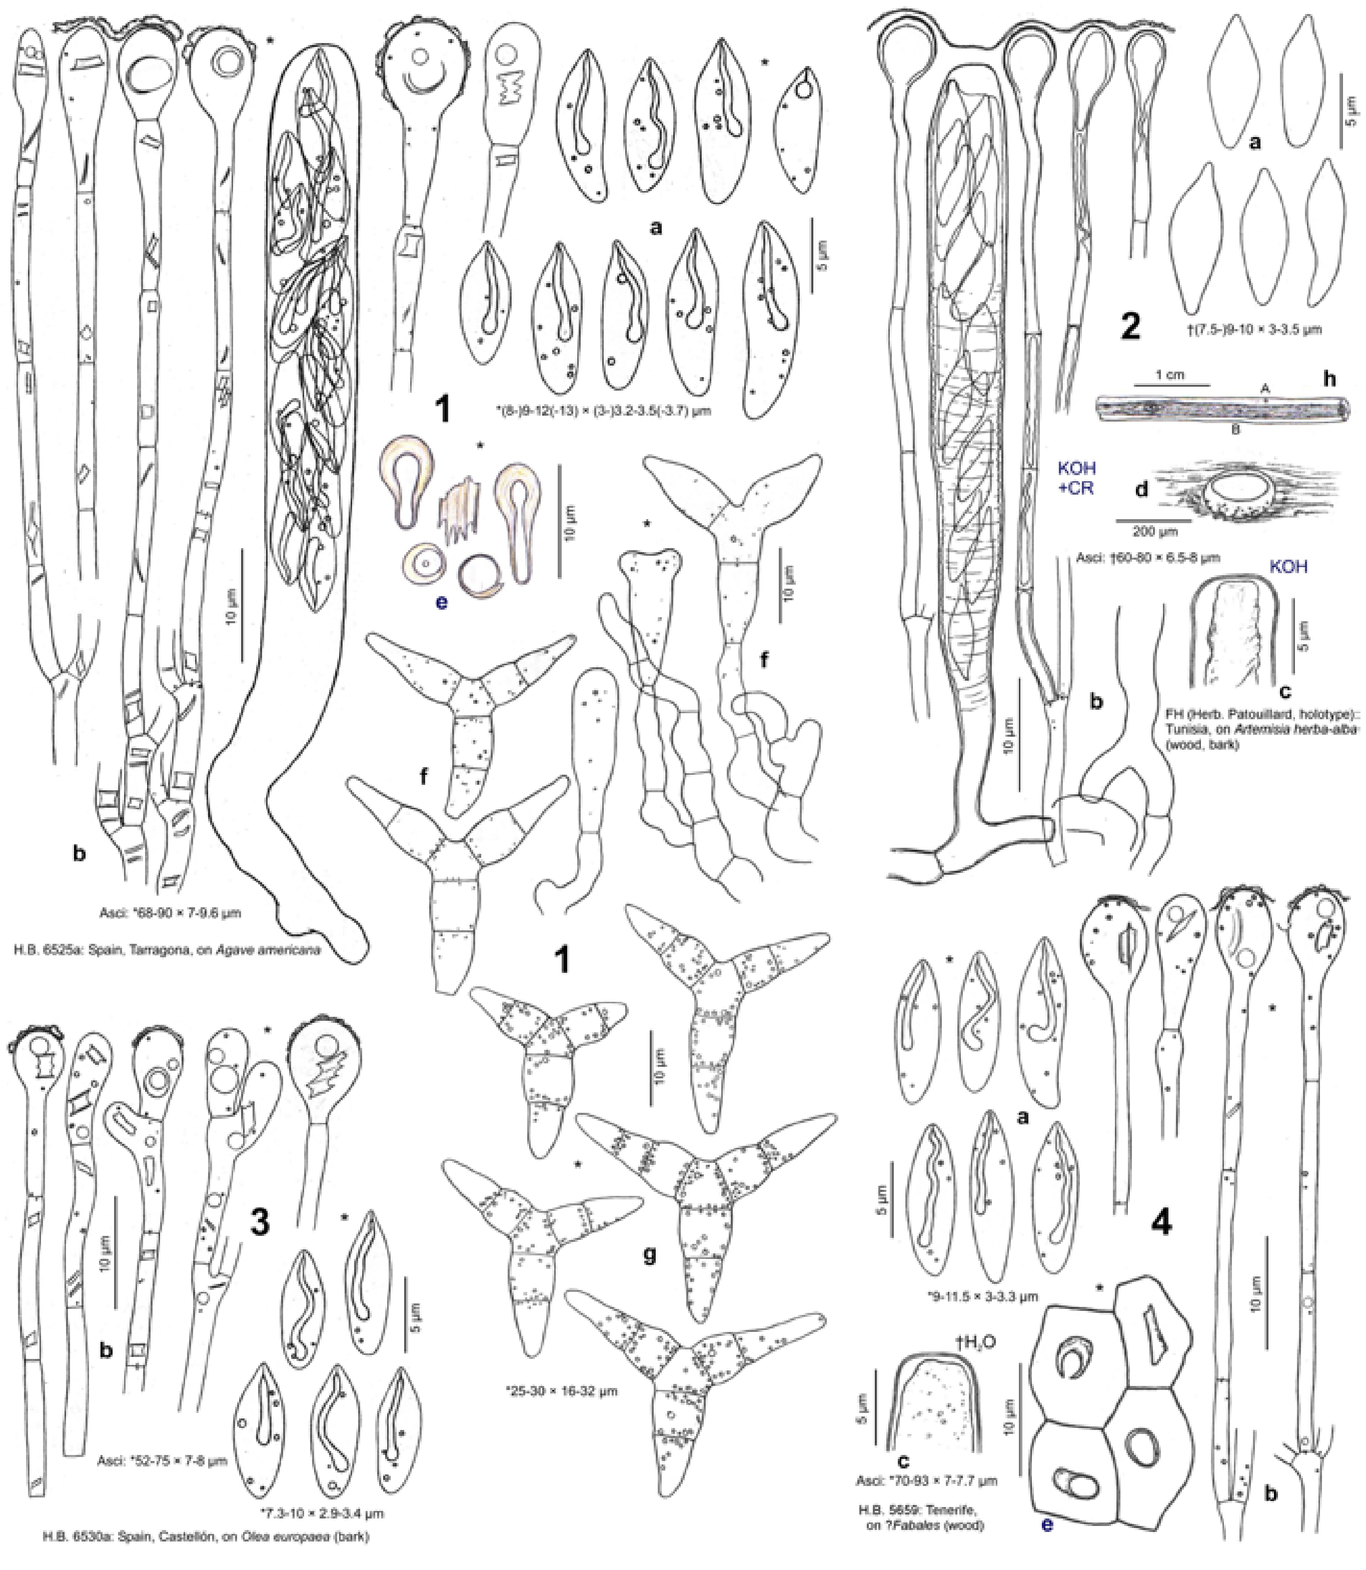

Plate 651. 1–4: *Orbilia serpentina*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium (on wood); **e**. crystalloid SCBs in cells of ectal excipulum at flanks and margin; **f**. conidiophores with conidia from culture; **g**. conidia from substrate; **h**. twig fragment of *Artemisia herba-alba* (**A**: apothecium on bark, **B**: on wood).

sedimentary rock, Cenozoic regolith (sand); Tenerife: trachybasalt and phonolite. **Phenology**: certainly throughout the year (long-lived).

Taxonomic remarks. *Orbilia serpentina* is characterized by 16-spored asci and medium-sized, more or less fusiform (amygdaliform) ascospores with rather long and wide, flexuous SBs, and by the presence of crystalloid SCBs. The close *O. maeandrina* mainly differs in the absence of these SCBs, besides very slightly shorter spores. *O. serpentina* is very close to the 8-spored *O. bicknellensis* or *O. octoserpentina* which sometimes grew in association. *O. pleiourosperma* and the somewhat heterogeneous *O. pleiomesaverdiana* are tentatively separated by their strongly tapered spore bases being almost always distinctly curved, the latter species also by obtuse to subacute spore apices. *O. lacrimispora* differs in wider spores with often acuminate apices and rounded bases, and absence of crystalloid SCBs. However, two collections with similar

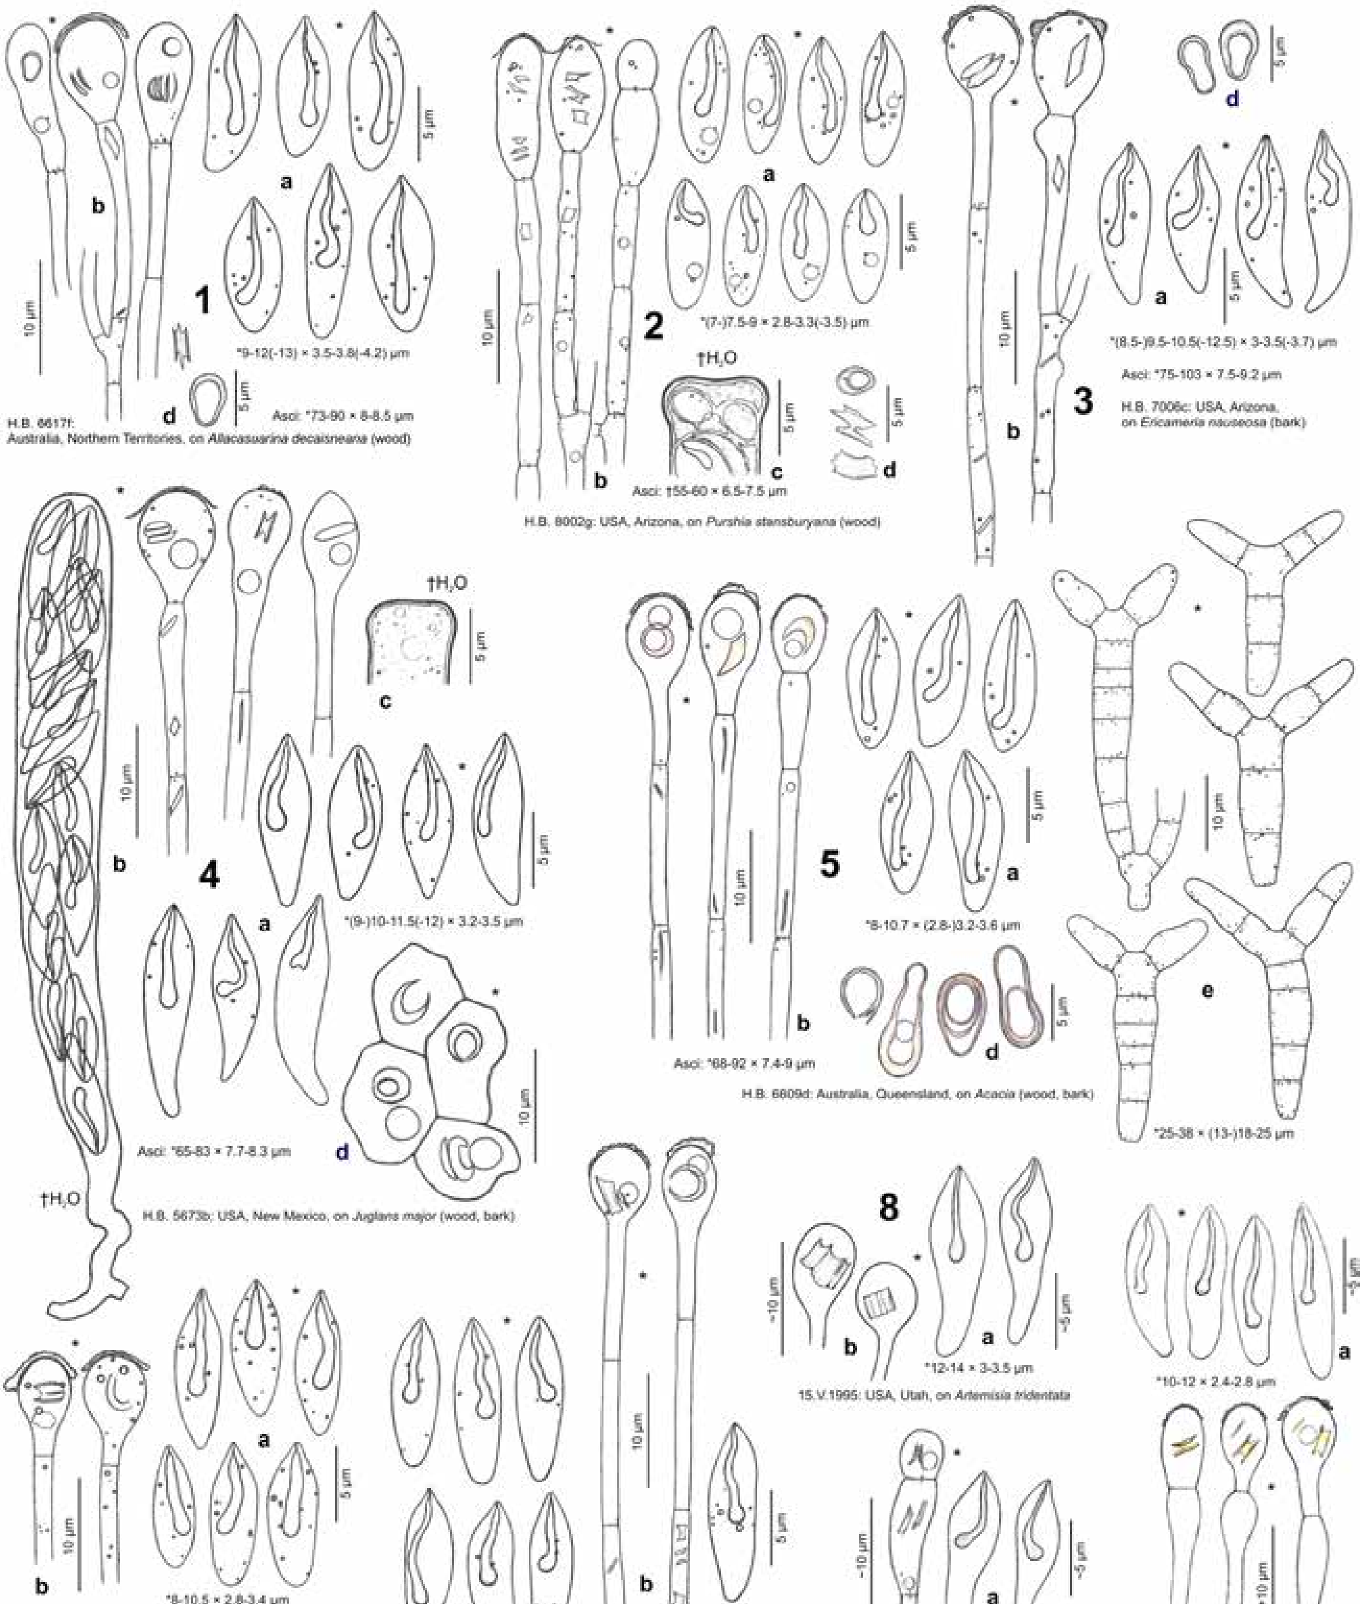

Plate 652. **1–7**: *Orbilia serpentina*; **8–10**. *O.* cf. *serpentina*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. crystalloid SCBs in ectal excipulum; **e**. conidia from culture.

lacrimiform spores mentioned under *O. lacrimispora* (Pl. 588: 3–4) have distinct crystalloid SCBs and rather short spores and are, therefore, not included in either species. *O. macrodelphinus* differs in narrower spores and absence of crystalloid SCBs.

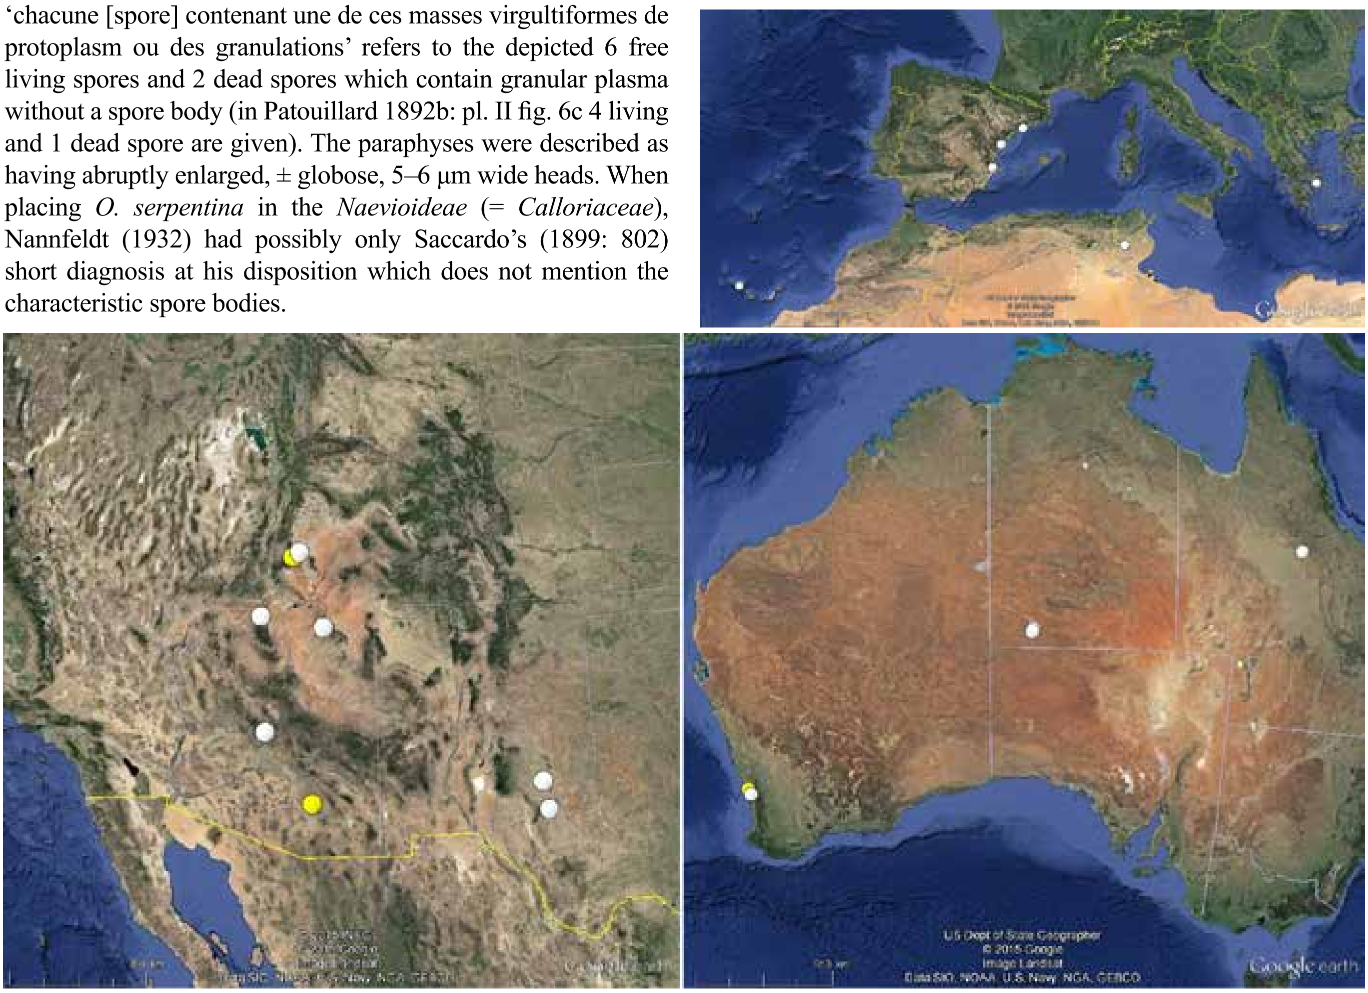
Variation. The ascospore base of *O. serpentina* varies in shape and curvature between slightly and strongly attenuated (with or without a tail-like base) and between straight and medium curved. This variation is partly observed within a collection: both slightly and strongly tapered spore bases occur, e. g., in Pl. 652: 6), and both straight and curved spore bases in Pl. 652: 3–4. In the type of *O. serpentina* the spores showed mainly strongly tapered, straight spore bases (Pl. 651: 2a, see also Fig. 151). Likewise, spore size varies among the collections. Longer spores were especially noted in those having tail-like bases, and these tend to occur at higher altitudes. The collection on *Purshia* (Pls 652: 2; 653: 4) deviates in rather short spores with partly obtuse apices. The asci also vary somewhat in length and width among the collections, but this variation is not found to be correlated with spore size.

Type studies. Patouillard (1892a, b) described and illustrated living spores that contain very elongate, gradually enlarged (subulate), somewhat flexuous spore bodies (see also original drawing at PC, Fig. 151: 1). His measurement of 10–12 × 3–4 µm is at the upper end of the range of the present scope of *O. serpentina*, and the SBs were about half as long as the spores. Patouillard erroneously believed the asci to be finally 8-spored, although his remark 'Thèques ... contenant d'abord 14–16 masses virgultiformes de protoplasma, réfringentes' undoubtedly indicates that they were 16-spored. On his drawing 12–14 SBs per ascus can be counted, and their length which is ± equal to that of the paraphyses indicates that these asci were mature, not immature as he believed. Patouillard depicted dead asci that contain living spores; this can be concluded from the fact that the spores are dispersed down to the ascus base and only the SBs are visible while the spore walls are mostly invisible. His remark 'chacune [spore] contenant une de ces masses virgultiformes de protoplasm ou des granulations' refers to the depicted 6 free living spores and 2 dead spores which contain granular plasma without a spore body (in Patouillard 1892b: pl. II fig. 6c 4 living and 1 dead spore are given). The paraphyses were described as having abruptly enlarged, ± globose, 5–6 µm wide heads. When placing *O. serpentina* in the *Naevioideae* (= *Calloriaceae*), Nannfeldt (1932) had possibly only Saccardo's (1899: 802) short diagnosis at his disposition which does not mention the characteristic spore bodies.

In the present reexamination of the holotype only two apothecia could be discerned on the single, partially decorticated twig fragment (Pl. 651: 2). One (on bark) was in bad condition, with ± empty asci, but the other (on wood) was in good shape, with the asci and spores matching the protologue. The holotype material quite well concurs with the collections here assigned to *O. serpentina*, with a single exception: the spore bases in the type are partly more strongly attenuated, causing a fusiform (trapezoid) spore shape, but they are never distinctly curved as in *O. pleiourosperma*. Patouillard did not report the presence of crystalloid SCBs, therefore, the identity of *O. serpentina* remains somewhat uncertain in respect to the otherwise very similar *O. maeandrina*. Spore size as evaluated in the holotype fits the here presented concept of *O. serpentina* a bit better than that of *O. maeandrina*, therefore, we tentatively adopt Patouillard's taxon for the species with crystalloid SCBs.

Not included collections. Three records were not included in the description. In two from North America on *Artemisia* and *Opuntia* (Pl. 652: 8–9) the spores have more or less distinct tails; yet, only a few spores have been documented and the samples were not preserved. A very sparse collection from Australia (bark of *Acacia*, Pl. 652: 10) deviates in distinctly narrower spores. In the collection on *Opuntia* the apothecia were comparatively large (0.4–0.8 mm diam).

Anamorph. In pure culture *O. serpentina* formed a trinacrium robustum-like anamorph. Slight differences between our two strains were noted: the Spanish strain (Pl. 651: 1f) differs from the Australian one (Pl. 652: 5e) in



Map 107. Known distribution of *O. serpentina* North America Australia, and in Europe (including Macaronesia, yellow = not included collections).

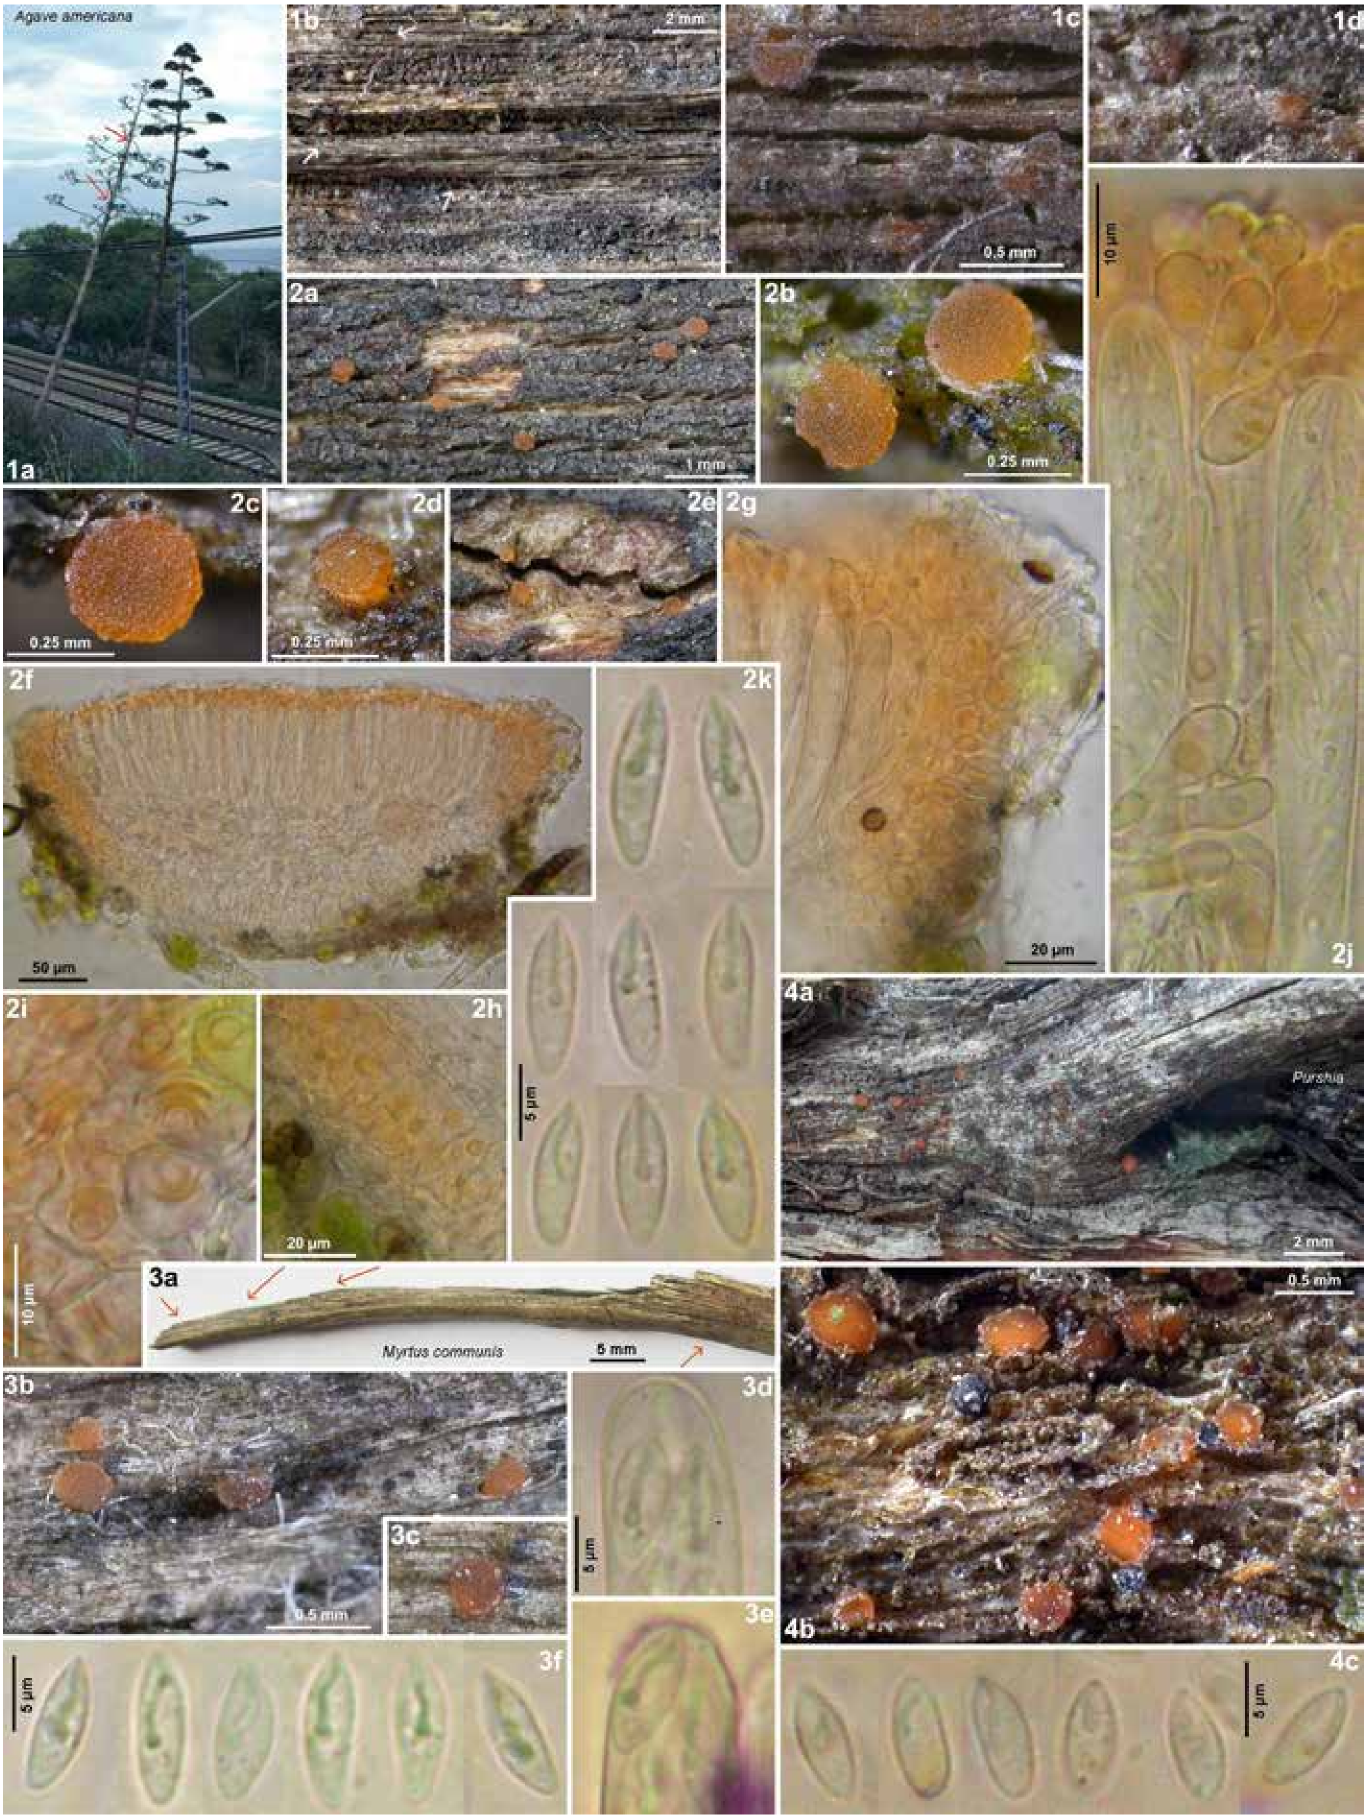


Plate 653. **1–4**: *Orbilia serpentina*. – **1a**. alive and dead inflorescence of *Agave americana* between road and railway at mediterranean sea shore (arrows = collected parts); **1b**. closeup of inflorescence stem; **3a**. xeric, still-attached branch stub of *Myrtus*; **1c–d**, **2a–e**, **3b–c**, **4a–b**. rehydrated apothecia; **2f**. apothecium in median section; **2g**. id., marginal ectal excipulum; **2h–1**. id., at flanks, with orange crystalloid SCBs; **2j**. asci and paraphyses (with SCBs); **3d–e**. ascus apices; **2k**, **3f**, **4c**. ascospores. – Living state. – **3d–e**, **3f** p.p.: phot. S. Helleman. — **1a–d**. H.B. 6525a: Spain, Tarragona, on *Agave*; **2a–k**. H.B. 8690b: Western Australia, Perth, on *Arbutus*; **3a–f**. H.B. 9102: Greece, Athens, on *Myrtus*; **4a–c**. shorter stipes with consistently two septa, also in somewhat longer, more tapered arms. This difference was also evident in the abundant conidia on the natural substrate in the Spanish collection (Pl. 651: 1g).

Phylogeny. A sequence was gained from pure culture of the specimen from Queensland, comprising SSU (without S1506 intron), ITS, and LSU. *O. serpentina* shows a rather high distance of 12.5–13.5 % in the ITS region to *O. octoserpentina*, although in the LSU D1–D2 the distance is only 0.5–0.6 %. The minimum distance is 11–12.5 % (ITS) and 1–1.3 % (LSU) to *O mesaverdiana*, *O. halimi*, and *O. vermiculati*. *O. serpentina* forms with these four species a strongly supported clade (Phyl. 20).

Ecology. *O. serpentina* was collected on rotten wood and bark of xeric twigs and branches of various angiosperm trees and shrubs, but also on inflorescence stems of *Agave* and *Yucca*. The small apothecia often occur rather scattered and sparse. The records emanate from subtropical, thermomediterranean semihumid to semiarid southern Europe and northern Africa, e. g., from the maquis (*Ulex*), ruderal places (*Agave*), parks (*Myrtus*), old olive tree plantations, or the semihumid pine forest (*Sideritido solutae-Pinetum canariensis*) in Tenerife (Macaronesia). The western North American collections derive from cold- to warm-temperate semiarid to subhumid sagebrush and saltbush scrubs and riparian scrubs and woodlands in the Sonoran and Chihuahuan Desert, and pinyon-juniper woodlands in the Colorado Plateau. A single record from western North America comes from a cold-temperate humid site (B. Liu, IVV: VIII.2011). The only subtropical North American sample (on *Opuntia* from semiarid Sonoran paloverde-mixed cacti desert scrub) is morphologically deviating, as is one from the border of a boreal humid Douglas fir forest (on *Artemisia tridentata*). Those from Australia were in subtropical semihumid banksia-eucalypt-acacia open wood- and shrublands in the southwest, subtropical arid acacia open shrublands in the centre, and a tropical semiarid eucalypt open woodland in the northeast.

Specimens included. **SPAIN**: **Cataluña**, **Tarragona**, 3.7 km E of Tarragona, 7 km WSW of Altafulla, Cala Romana, 12 m, inflorescence stem of *Agave americana*, 28.IX.1999, G. Marson & H.O. Baral (H.B. 6525a, [CBS 116237, not survived], anam. cult., anam. substr.). – **Com. Valenciana**, **Castellón**, 50 km N of Alicante, 3.5 km NNW of Muro de Alcoy, Puerto de Benicadell, 563 m, branch of *Ulex parviflorus*, on wood, 4.I.2008, J.P. Priou (J.P.P. 28005, doc. vid.). – 13.5 km NNW of Castellón, 3.2 km WSW of Vilafamés, Camí de Costur, 400 m, branch of *Olea europaea*, on bark, 27.IX.1999, H.O. Baral (H.B. 6530a). — **GREECE**: **Attika**, Athens, 0.6 km NW of Akropolis, Stoà di Attalo, 65 m, twig of *Myrtus communis*, on wood, 12.VI.2009, S. Helleman (H.B. 9102). — **TUNISIA**: **Kasserine**, W of Sbeitla, ~600 m, twig of *Artemisia herba-alba*, on wood & bark, 17.III.1891, N.T. Orbilia bicknellensis Baral & G. Marson, **sp. nov.**, MB 813689 — Pls 654–656, Map 108

Etymology: named according to the town Bicknell (Utah), near which the first sample was recorded.

Typification: Spain, Alcalá de Henares, stem of *Foeniculum vulgare*, 23.IX.1999, H.O. Baral & G. Marson (ex H.B. 6480a, M-0276442, holotype).

Latin diagnosis: *Similis* Orbiliae serpentinae *sed asci octospori. Habitat ad lignum vel corticem siccum angiospermarum vel caules in zona temperata ad subtropica subhumida ad arida.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.13–)0.2–0.4(–0.6) mm diam., 0.12–0.17 mm high, pale to bright orange(-rose), round, very scattered to (sub)gregarious; disc flat (to slightly convex), margin thin, 0–10 µm protruding, ± smooth; broadly sessile, superficial or distinctly erumpent from beneath outer tissue; dry bright orange to brick-red. **Asci** *(50–)55–82(–95) × (5.6–)6–7.5(–8) µm {12}, †48–75 × 5–7(–7.5) µm {4}, 8-spored, spores *2–3-seriate, (2–)3–5(–6) lower spores inverted {11} (rarely slightly to strongly mixed), pars sporifera *36–43 µm long; **apex** (†) medium to strongly truncate (not or very slightly indented, laterally not or partly inflated); **base** with short to medium long, thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(9–)10–13.5(–15) × ((2.5–))(2.7–)2.9–3.5(–3.7)((–4.3)) µm {20}, †(9–)10–13(–15) × 2.5–3.4 µm {4}, fusiform to fusiform-clavate, sometimes with short-cylindrical middle part (navicular), apex acute to acuminate, sometimes subacute, base (slightly to) medium to strongly attenuated, partly tail-like, mostly inequilateral or slightly to medium curved near base; **SBs** *(4–)5–7.5(–9)((–10.5)) × (0.7–)0.9–1.3(–1.6) µm {11} in situ, (vermiform to) subulate, base mostly slightly to medium inflated, straight to medium flexuous; overmature divided into an abruptly swollen, subglobose lower part and a short filum, 2.5–3.3 × 1.3–1.7 µm. **Paraphyses** apically medium to (very) strongly clavate-capitate, sometimes spathulate, rarely sublageniform or moniliform, terminal cells *(6–)8–19(–23) × (3–)4.5–6.3(–7) µm {9}, †(3–)4–5.8 µm wide {2}, lower cells *7.5–18 × (1.3–)1.6–2(–3) µm {4}; rarely branched at upper septum. **Medullary excipulum** pale rose, 40–50 µm thick, of ± dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose, of thin-walled, irregularly oriented t. globulosa-angularis from base to margin, 30–45 µm thick near base, cells *(5–)8–20(–27) × 5–13(–18) µm {3}; 20 µm thick at flanks, 15–20 µm near margin, oriented at a 20–30° angle to the surface, marginal cortical cells *5–13 × 4–6 µm {1}. **Anchoring hyphae** sparse to abundant, */†(1.5–)2–3.5(–5) µm wide, walls 0.2–0.5 µm thick {2}, partly covering the excipulum up to the margin. **SCBs** in paraphyses and ectal excipulum (near margin) rod- or ring- to keyhole-shaped {17}, hyaline to pale yellowish-orange, partly also globose, 2–3 µm diam. **Exudate** over paraphyses 0.2–1.5(–3) µm thick, rough to granular-cloddy, loosely attached; over margin and flanks 0.2–0.5 µm thick, granular. — **ANAMORPH**: unknown (but see below).

Habitat: collected 0–5 m above the ground, corticated to often decorticated, 3–30(–70) mm thick twigs and branches of *Atriplex nummularia* {1}, *Baccharis salicifolia* {1}, *B. sarothroides* {1}, *Canotia holacantha* {1}, *Coleogyne ramosissima* {1}, *Ericameria nauseosa*

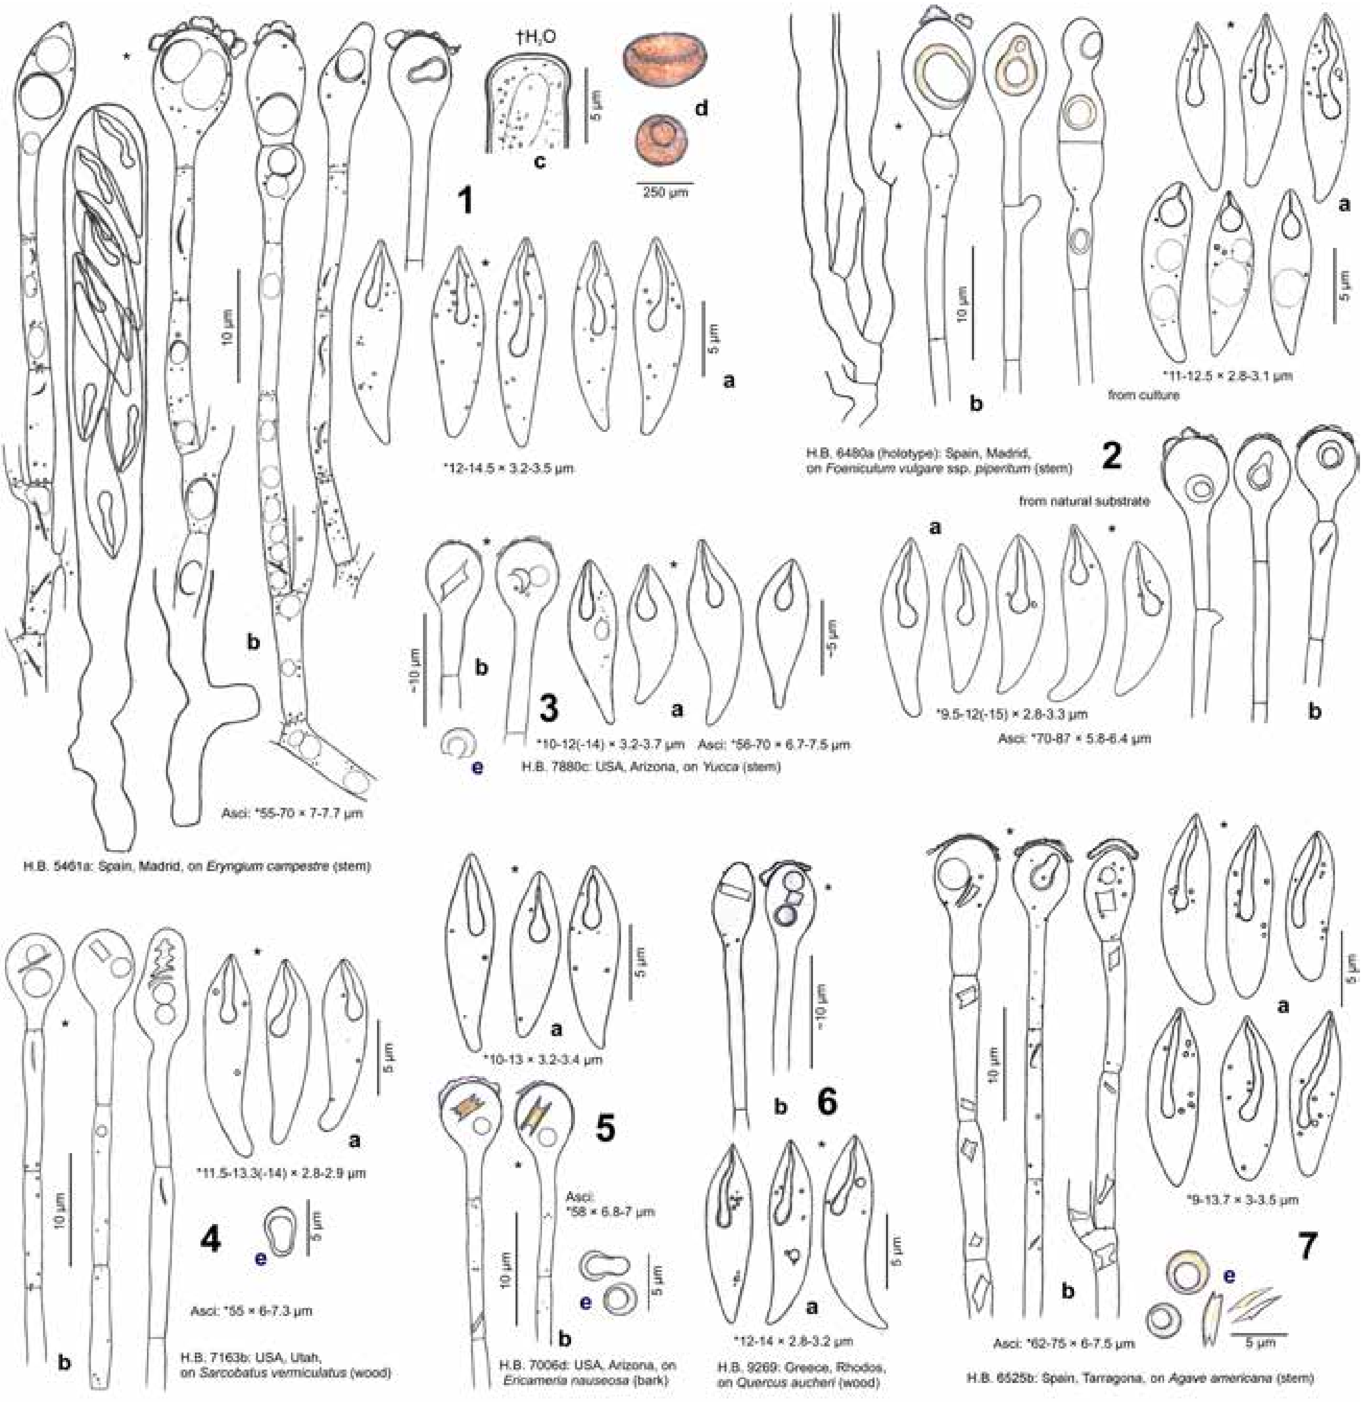

Plate 654. **1–7**: *Orbilia bicknellensis*. – **a**. ascospores (middle row in **2a** immature); **b**. ascus, ascus bases, paraphyses; **c**. ascus apex; **d**. rehydrated apothecia; **e**. crystalloid SCBs in ectal excipulum.

{1}, *Krascheninnikovia lanata* {2}, *Nicotiana glauca* {1}, *Opuntia* sp. {1}, *Pistacia terebinthus* {1}, *Populus × canadensis* {1}, *Quercus aucheri* {1}, *Robinia pseudoacacia* {1}, *Salix ?exigua* {1}, *Sarcobatus vermiculatus* {2}, *Thymelaea hirsuta* {1}, on 0.1–0.5 mm deep (medium) strongly decayed wood {12} and bark {3} (bast), stems of *Rubus fruticosus* {1}, previous year's herbaceous, partly inflorescence stems of *Agave americana* {1}, *Cichorium intybus* {1}, *Eryngium campestre* {1}, *Foeniculum vulgare* {1}, *Yucca elata* {2}, indet. angiosperm {1}, ungreyed to strongly greyed, green algae sparse to many, partly in old beetle galleries, sometimes exclusively on boring dust of bark beetles {1}. **Associated**: *Caloplaca* sp. {2}, *Cyathicula cyathoidea* {1}, *C. nigrofusca* {1/1}, *Dothideales* {1}, *Hysterobrevium mori* {1}, *Melaspilea emergens* {1}, *Orbilia arizonensis* {1}, *O. atriplicis* {1}, *O. ?bicknellensis* {1}, *O. ?cactacearum* {1}, *O. calyptrata* {3}, *O. cercocarpi* {1}, *O. denticulata* {1}, *O. flavida* {2}, *O. lacrimispora* {1/1}, *O. lentiformis* {2}, *O. macrodelphinus* {2}, *O. macrotrapeziformis* {1}, *O. multigambelii* {3}, *O. multimaeandrina* {1}, *O. multiphanosoma* {1}, *O. ?multitrapezoidea* {1}, *O. myriostomachia* {1}, *O. ocellata* {2}, *O. paradoxoides* {1}, *O. pleiolentiformis* {2}, *O. pleiomicrosoma* {2}, *O. pleistoeuonymi* {1}, *O. plurilentiformis* {2}, *O. pluristomachia* {1}, *O. sarcobati* {1}, *O. serpentina* {5}, *O. ?ungulata* {1}, *O. vermiculati* {2}, *O. yuccae* {1}, *Patellaria* '*andina*' {1}, *P. atrata* {4/1}, *Pragmopora* sp. {1}, *Schizoxylon* sp. {1}, *Teichospora* sp. {1}, *Teichosporella dura* {2}, *Symbiotaphrina desertorum* {1}. **Desiccation tolerance**: many mature asci still viable after 28 months. **Altitude**: 3–610 m a.s.l. (southern Europe), 975–2075 (western North America). **Geology**: Australia: Neoproterozoic sedimentary rock; Meso- to Cenozoic sand-, lime- & mudstone, basaltic lava and felsic volcanic rock, andesite & rhyolite; Spain: Tertiary calcareous sand, gravel, marl & clay. **Phenology**: long-lived.

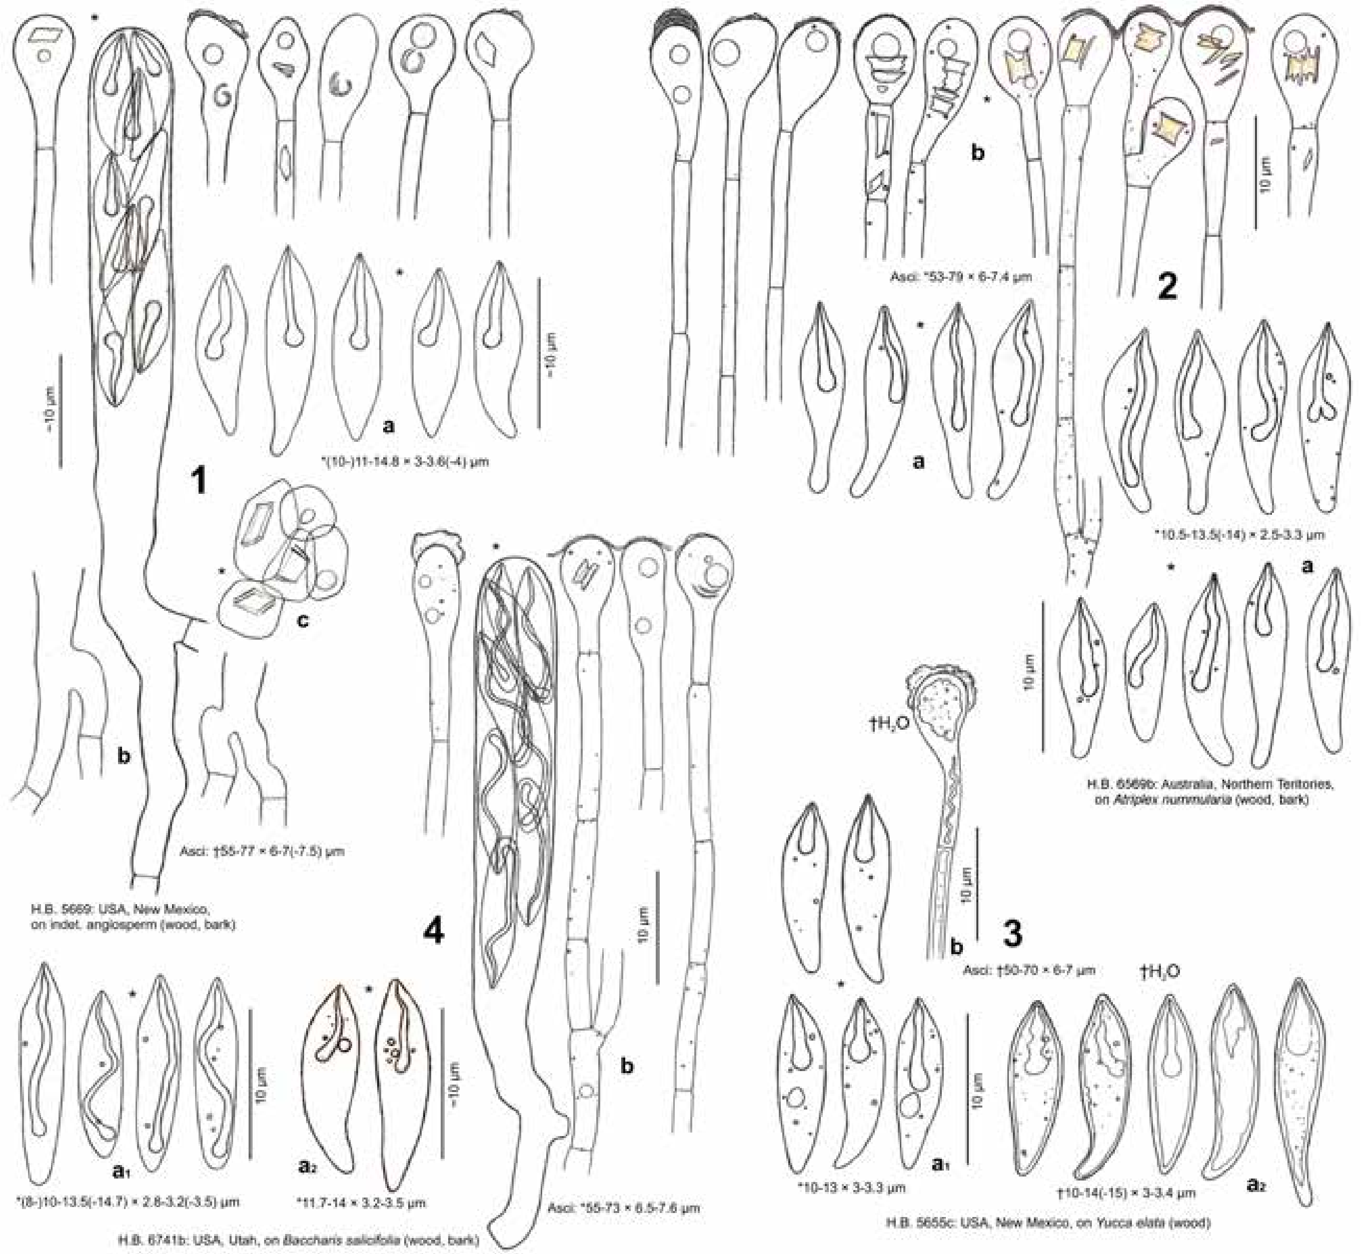

Plate 655. **1–3**: *Orbilia bicknellensis*; **4**: *O.* cf. *bicknellensis*. – **a**. ascospores (**4a$_2$**: kept in Petri dish for some time); **b**. asci and paraphyses (with crystalloid SCBs); **c**. ectal excipular cells with crystalloid SCBs.

Taxonomic remarks. *Orbilia bicknellensis* is characterized by 8-spored asci, rather large, fusiform, basally often attenuated and ± curved ascospores, subulate, comparatively wide spore bodies, and by the presence of crystalloid SCBs. *O. trapeziformis* and especially *O. macrotrapeziformis* have similarly shaped spores but always lack crystalloid SCBs, the former also differs in distinctly smaller spores with less acute apices. The Australian *O. octoserpentina* is only tentatively separated by the spores being often only scarcely tapered and only rarely curved at the base, also by partly longer spores with longer SBs, and by a tendency to wider asci.

O. serpentina mainly differs in 16-spored asci, but also in somewhat shorter and basally usually less attenuated spores. *O. serpentina* grew sometimes in association with *O. bicknellensis*, e.g. in the Spanish collection on *Agave* (Pls 651: 1, 654: 6). Here the two taxa had very similar spores, both with only slightly attenuated bases, therefore, with the spores alone their distinction is hardly possible. In a North American sample on *Yucca* (Pls 652: 6, 655: 3), in which the two taxa grew together, *O. serpentina* differed from *O. bicknellensis* in much less tapered spore bases.

Variation. *O. bicknellensis* strongly varies in spore shape, especially in the spore bases which were usually strongly attenuated but sometimes only slightly or medium so (e.g., Pl. 654: 7, *Agave*). The Australian sample on *Atriplex* (Pl. 655: 2) and the mentioned North American ones on *Yucca* and *Salix* deviate in more tail-like spore bases and form a transition to *O. urosperma*. *O. halimi* is similar to the collection on *Atriplex*, but has much narrower spores and is, therefore, separated at the species level.

Not included collections. Two samples on *Euphorbia* from Macaronesia (Pl. 656: 7–8) have slightly smaller, especially narrower spores of *8.7–12(–13.5) × 2.3–3.3(–3.6) µm. They appear to be intermediate between *O. bicknellensis* and *O. halimi* and are not included in either description.

With its very long SBs (Pl. 655: 4a$_1$), the not included North American sample on *Baccharis* closely resembles *O. pyrenaica*.

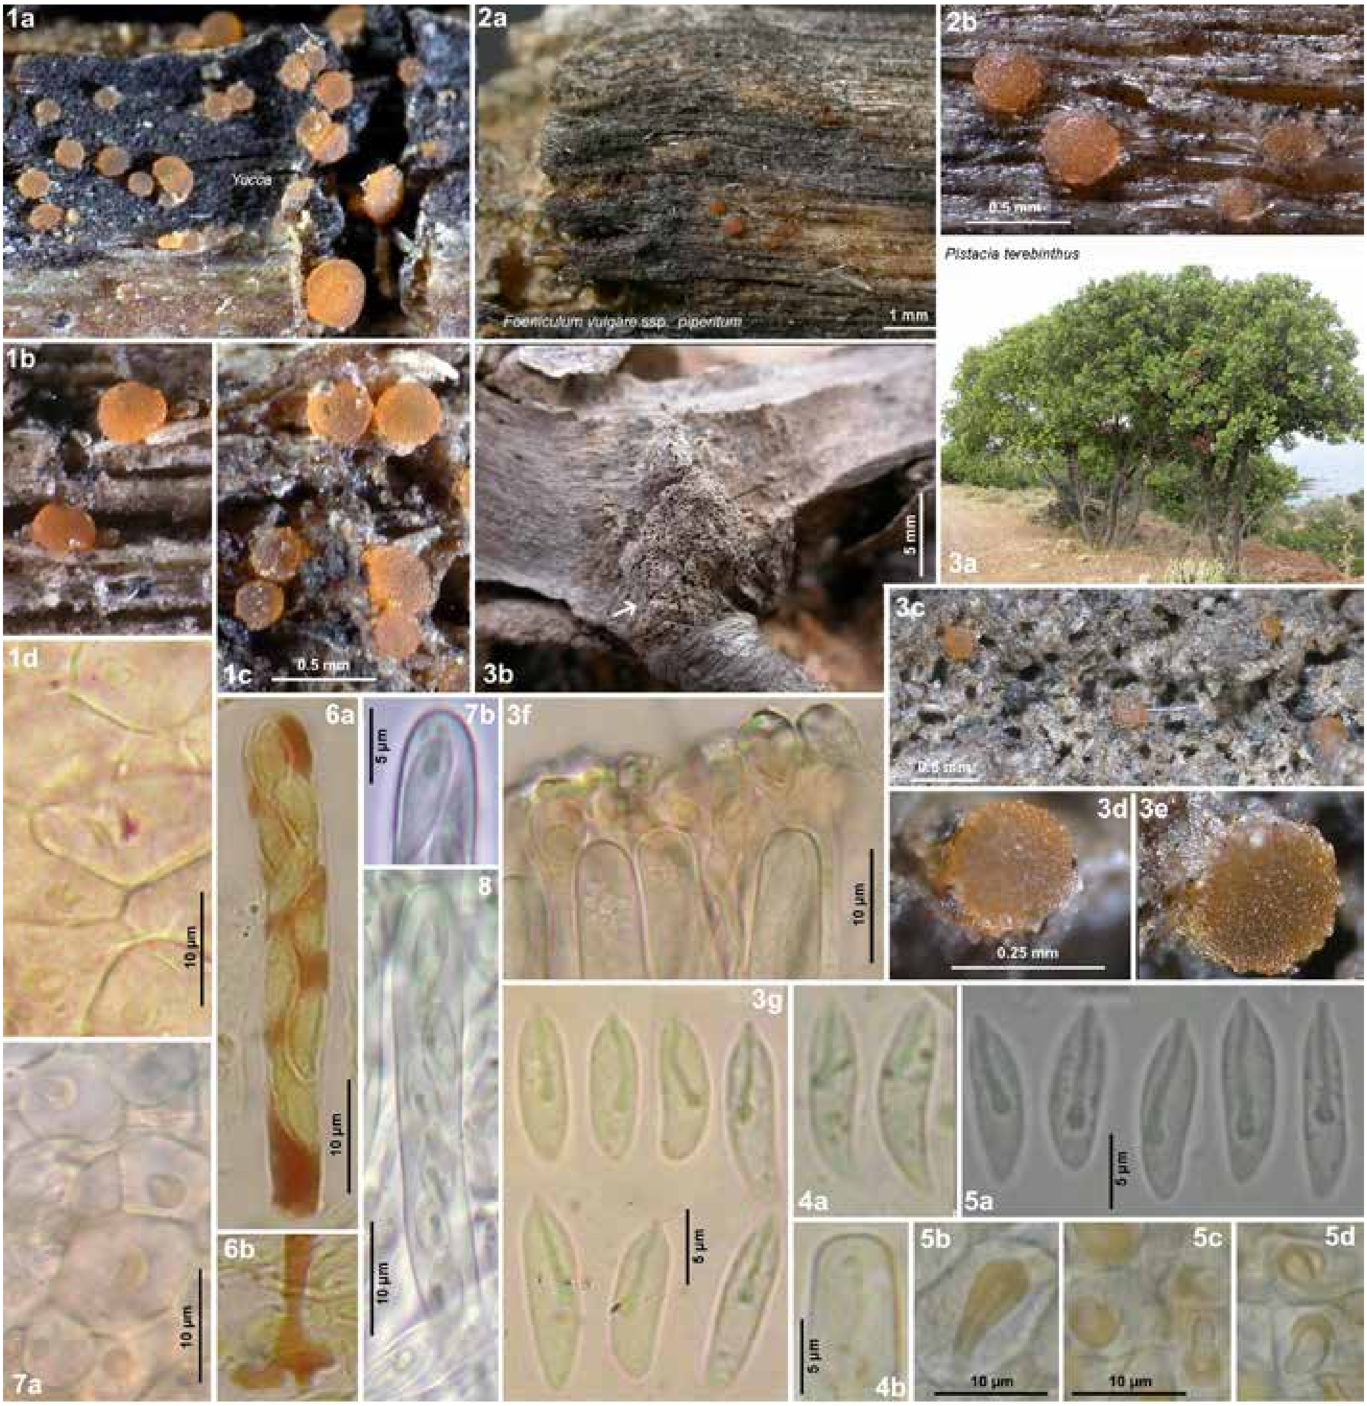

Plate 656. **1–6**: *Orbilia bicknellensis*; **7–8**: *O.* cf. *bicknellensis*. – **3a**. *Pistacia terebinthus* trees in a mediterranean maquis; **3b**. decorticated xeric branch of *Pistacia*, with boring dust; **1a–c**, **2a–b**, **3c–e**. rehydrated apothecia; **1d**, **5b–d**, **7a**. crystalloid SCBs in basal ectal excipulum; **3f**, **6a**, **8**. asci and paraphyses; **6b**. ascus base; **4b**, **7b**. ascus apices; **3g**, **4a**, **5a**. ascospores. – Living state, except for **6a–b** (in KOH+IKI). – **3a**: phot. S. Helleman, **5a–d**: phot. R. Tena, **7a–b**, **8**: phot. L. Quijada. — **1a–d**. H.B. 7880c: USA, Arizona, on *Yucca*; **2a–b**. H.B. 6480a (holotype): Spain, Madrid, on *Foeniculum*; **3a–g**. H.B. 9093a: Greece, on *Pistacia*; **4a–b**. H.B. 9269: Greece, Rhodos, on *Quercus*; **5a–d**. R.T.L. 12111001: Spain, Valencia, on *Populus*; **6a–b**. H.B. 5669: USA, New Mexico, on indet. angiosperm; **7a–b**. TFC Mic. 22684: Tenerife, on *Euphorbia*; **8**. TFC Mic. 22657: Tenerife, on *Euphorbia*.

Yet, some of the paraphyses contained crystalloid SCBs, contrary to *O. pyrenaica*. When trying to cultivate the associated *O. multimaeandrina*, an apothecium which was fixed to the lid of a Petri dish was reexamined after some time: it turned out to be 8-spored but showed typical *O. bicknellensis* spores (4a$_2$), being slightly broader and with much shorter SBs compared to the doubtful collection of 4. The question whether these spores developed from those with long SBs, or the two examined apothecia belonged to two different taxa could not be answered.

Anamorph. In the single available pure culture of *O. bicknellensis* (Pl.654: 2) no conidia developed, neither on CMA:2 nor on water agar. However, apothecia were formed on water agar to which wood fragments were added (2, upper row). Two times, trinacrium robustum-like conidia were found on the substrate near apothecia of *O. bicknellensis* (IVV: H.B. 6739a, 1 conidium of *28 × 18 µm; unillustrated: H.B. 6525b, 2 conidia), but other *Orbilia* species grew intermingled, so it is not certain that the conidia belonged to *O. bicknellensis*.

Ecology. *O. bicknellensis* was collected on rotten wood and bark of xeric twigs and branches of various angiosperm shrubs (and trees), and on herbaceous stems of different mono- and dicotyledons, including inflorescence stems of *Agave* and *Yucca*.

Map 108. Known distribution of *O. bicknellensis* in North America and Europe (including Macaronesia, yellow = not included collections).

The records are from meso- to thermomediterranean, semihumid to semiarid areas of southern Europe, e. g. in ruderal places and maquis. Samples from the southwest of Northern America are from cold- to warm-temperate but also subtropical, subhumid to mainly semiarid paloverde-mixed cacti, blackbrush, sagebrush, saltbush and winterfat desert scrubs or mixed grassland or riparian scrubs, but also in the pinyon-juniper woodland of the Sonoran and Chihuahuan Desert and Colorado Plateau. A single record was in a subtropical arid acacia open shrubland northeast of Macdonnell Ranges in central Australia.

The two not included collections from Tenerife were in infra- to thermomediterranean arid to hyperarid xerophytic scrublands in the south and west of the island.

Specimens included. **SPAIN**: **Cataluña**, **Tarragona**, 20 km WSW of Tarragona, 3 km W of Cambrils, Carrer Gotic, La Dorada, 15 m, branches of *Robinia pseudoacacia*, on wood and boring dust, 27.IX.1999, G. Marson & H.O. Baral (H.B. 6518). – 3.7 km E of Tarragona, 7 km WSW of Altafulla, Cala Romana, 12 m, inflorescence stem of *Agave americana*, 28.IX.1999, G. Marson & H.O. Baral (H.B. 6525b). – **Aragón**, **Zaragoza**, 16.3 km SSW of Fraga, 1 km E of Mequinenza, 90 m, stem of *Rubus fruticosus*, 24.X.2012, B. Fellmann (ø, doc. vid.). – **Madrid**, 3.5 km NE of Alcalá de Henares, University Campus, 610 m, stem of *Foeniculum vulgare*, 23.IX.1999, H.O. Baral & G. erumpent or immersed; dry slightly retracted, bright orange to orange-rose. **Asci** *60–72 × 7–7.5 µm {2}, †48–68 × 5–6.5 µm {3}, 8-spored, spores *2–3-seriate, 2–4 lower spores inverted {3}; **apex** (†) strongly truncate (slightly to distinctly indented, laterally hardly inflated); **base** with short to long, ± thin, flexuous stalk, L-shaped. **Ascospores** *(9–)10–14(–15) × (2.6–)3–3.5(–3.7) µm {4}, fusiform-clavate, apex acute to acuminate, base strongly attenuated, often with a tail-like base, slightly to strongly curved especially near base; **SBs** *(3–)4–5.3 × 0.7–1.2 µm in situ {4} (actual length ~4–6 µm), subulate (to vermiform), medium to strongly flexuous, attached by a small point. **Paraphyses** apically medium to very strongly capitate (rarely clavate), terminal cells *(15–)20–27 {T} × (4–)4.5–6(–7) µm {3}, lower cells *9.5–13 × 1.3–1.7(–2.2) µm {T}; never branched at upper septum. **Medullary excipulum**, **Ectal excipulum** and **Anchoring hyphae** not examined. **SCBs** in paraphyses and ectal excipulum (near margin) globose {3}, 1.7–2.5 µm diam. **Exudate** over paraphyses 0.2–0.4 µm thick, hyaline, rough-granular, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected ~1–2 m above the ground, 3.5–20 mm thick, corticated to decorticated twigs and branches of *Berberis vulgaris* {1}, *Clematis vitalbae* {1}, *Corylus avellana* {1}, *Fraxinus excelsior* {1}, on strongly rotten wood {4} and bark {1}. **Associated**: *Caloplaca* sp. {1}, *Lecanora* sp.{1}, *Physcia* sp. {1}. **Desiccation tolerance**: fully alive after at least 2.5 months. **Altitude**: 985–1775 m a.s.l. **Geology**: Spain: Tertiary calcareous marl breccia; France: granite & black schist with pyrite; Switzerland: amphibolite. **Phenology**: VI–X (but certainly long-lived).

Taxonomic remarks. *Orbilia jacaensis* differs from *O. bicknellensis* in lacking crystalloid SCBs, and from *O. subtrapeziformis* in wider ascospores with often acuminate apex, from both also in consistently strongly tapered, often more curved spore bases and in a tendency to shorter SBs.

Variation. The collection from les Angles differs from the other two in narrower and slightly longer spores of *12–

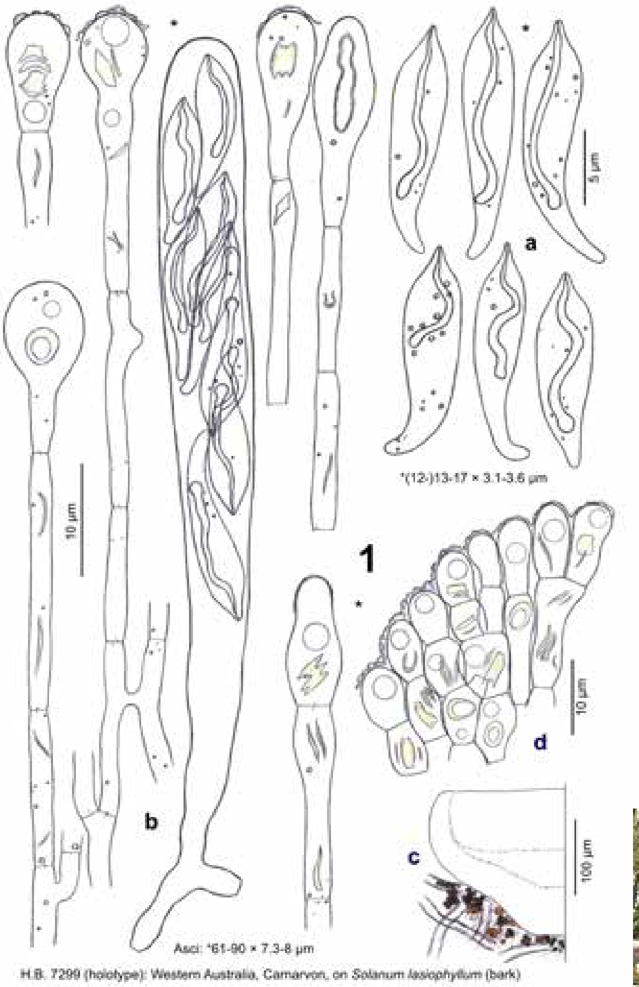

Plate 659. **1**: *Orbilia urosperma* (holotype). – **a**. ascospores; **b**. ascus and paraphyses; **c**. apothecium in median section; **d**. id., marginal ectal excipulum.

15 × 2.6–3.1 µm vs. mainly *10–14 × 3–3.3(–3.5) µm in the other two samples.

Ecology. *O. jacaensis* was found on xeric rotten wood and bark of different angiosperms in a suprasubmediterranean semihumid *Quercetum rotundifoliae* (holotype) in the western Pyrenees and orotemperate humid open woodlands in the eastern Pyrenees and Swiss Alps in southwestern Europe. In comparison, *O. bicknellensis* shows a thermo- to mesomediterranean distribution.

Specimens included. **SPAIN**: **Aragón**, **Huesca**, 12.7 km N of Jaca, NNE of Villanúa, 985 m, twigs of *Clematis vitalba*, on wood & bark, 9.X.2016, H.O. Baral (H.B. 10026, AH 52846, **holotype**). — **FRANCE**: **Languedoc-Roussillon**, **Pyrénées-Orientales**, 4 km N of Saillagouse, 1.5 km SW of Font-Romeu-Odeillo-Via, Four Solaire d'Odeillo, 1540 m, branch of *Fraxinus excelsior*, on wood, 22.IX.2016, J.P. Priou (J.P.P. 16196, doc. vid.). – 2 km NW of Les Angles, S of Estany de Vallsera, Lac de Balcère, 1775 m, branch of *Corylus avellana*, on wood, 20.IX.2016, J.P. Priou (J.P.P. 16239, doc. vid.). — **SWITZERLAND**: **Graubünden**, 1 km SE of Zernez, 1507 m, branch of *Berberis vulgaris*, on wood, 23.VI.2018, B. Senn-Irlet (B.S.I. 18/80, doc. vid.).

Orbilia urosperma Baral & G. Marson, **sp. nov.**, MB 813690 — Pls 659–660

Etymology: named after the ascospores being strongly curved at the base.

Typification: Western Australia, Mia Mia, stems of *Solanum lasiophyllum*, 6.XII.2001, G. Marson (ex H.B. 7299, MEL 2389234, holotype).

Latin diagnosis: *Similis* Orbiliae bicknellensi *sed asci et ascosporae longiores*, *corpuscula refringentia longiora*, *ascosporae apice acuminatae*, *basi magis curvatae. Habitat ad caules ligneos siccos* Solani lasiophylli *in zona subtropica arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.45 mm diam., 0.16–0.2 mm high (receptacle 0.15–0.16 mm), light to bright orange-red, scarcely translucent, round, scattered to subgregarious; disc slightly concave, margin distinct, 0–10 µm protruding, smooth; sessile on a ± distinct stipe-like base, superficial but immersed in dense hair felt of host periderm; dry deep carmine. **Asci** *61–90 × 7.3–8(–8.6) µm, †65–77 × 6.5–7.5(–8.5) µm, 8-spored, spores *2–3-seriate, 3–6 lower spores inverted (not mixed), pars sporifera *(34–)45–55 µm long; **apex** (†) strongly truncate (slightly indented and laterally widened); **base** with short, thick, flexuous stalk, Y- or h-shaped. **Ascospores** *(12–)13–17 × 3.1–3.8 µm, †12–17 × 3–3.6 µm, fusiform-clavate, apex consistently acuminate, base strongly attenuated (mostly tail-like), slightly to strongly curved at base; **SBs** *(6.5–)8–13.3 × 0.7–1 µm in situ (~8–14.5 µm actual length), vermiform to somewhat subulate, slightly inflated at base, medium to strongly flexuous or helicoid. **Paraphyses** apically medium to very strongly clavate-capitate, rarely sublageniform, terminal cells *10–25 × (4–)5–7 µm, lower cells *13–23 × 1.6–2.3 µm, near base 9–13 × 3–3.5 µm; unbranched near apex.

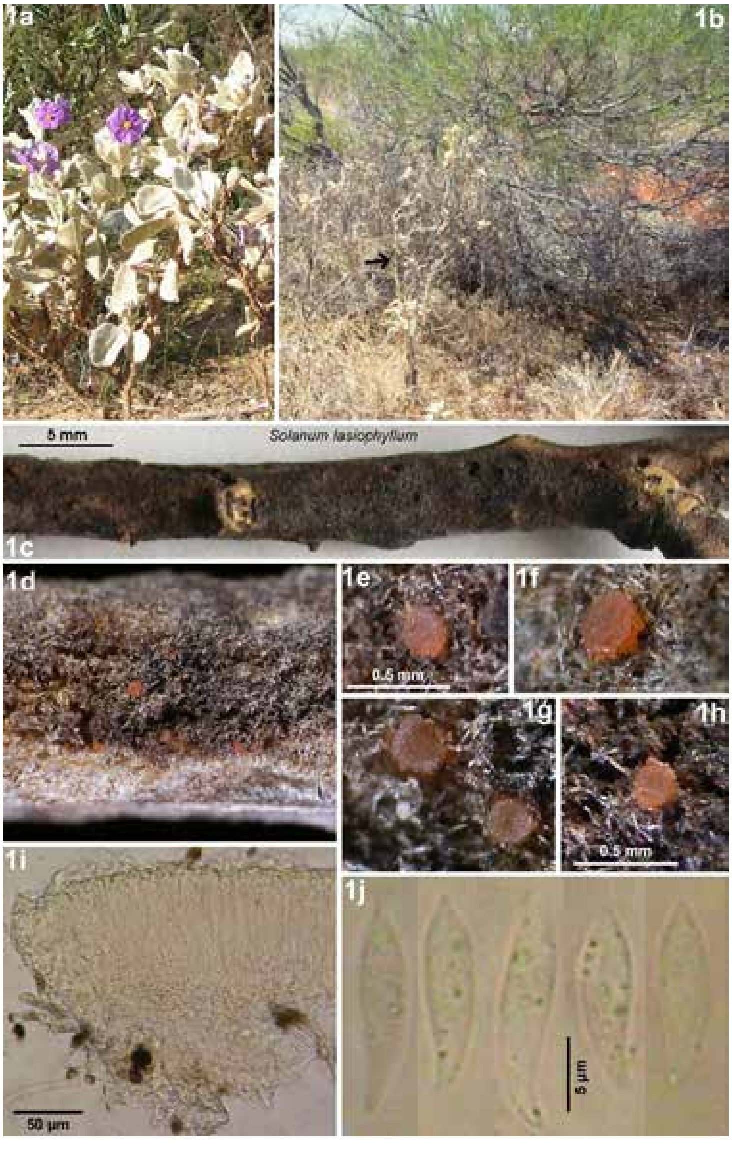

Plate 660. **1**: *Orbilia urosperma*. – **1a**. living *Solanum lasiophyllum*; **1b**. hummock grassland with *Acacia* and dead *Solanum*; **1c**. dead stem of *Solanum* with felty bark; **1d–h**. rehydrated apothecia; **1i**. apothecium in median section; **1j**. ascospores. – Dead state (**1i–j** in KOH). — **1a–j**. H.B. 7299 (holotype): Western Australia, Carnarvon.

Medullary excipulum 30–50 µm thick, of dense textura globulosa-angularis, at least on upper flanks sharply delimited from ectal excipulum by a distinct, narrow, parallel layer of t. porrecta. **Ectal excipulum** of (*) thin-walled, indistinctly vertically oriented t. globulosa-angularis from base to mid flanks, 40–70 µm thick near base, cells *11–21 × 8–17 µm; 15–30 µm thick near margin, of t. prismatica-angularis oriented at a 50–60° angle to the surface, at upper margin also of t. porrecta oriented at 10°, marginal cortical cells *7–11(–14) × 3.5–6(–7) µm. **Anchoring hyphae** abundant, */†2–3.5(–4.5) µm wide, walls 0.2–0.4 µm thick. **SCBs** in terminal cells of paraphyses and ectal excipulum (near margin) globose, 1–2.5 µm diam., in all cells of paraphyses and ectal excipulum rod- to angular or ring-shaped SCBs, pale yellow-orange. **Exudate** granular-cloddy, firmly attached, over paraphyses 0.2–0.5 µm thick, over margin and flanks 0.5–1 µm. — **Anamorph**: unknown.

Habitat: collected 0.2–1 m above the ground, corticated, 3–6 mm thick twigs of *Solanum lasiophyllum*, on medium decayed bark (periderm), greyed, no algae. **Associated**: none observed. **Desiccation tolerance**: fully viable for at least 15 months. **Altitude**: 35 m a.s.l. **Geology**: Cenozoic regolith (red-brown gravel). **Phenology**: long-lived.

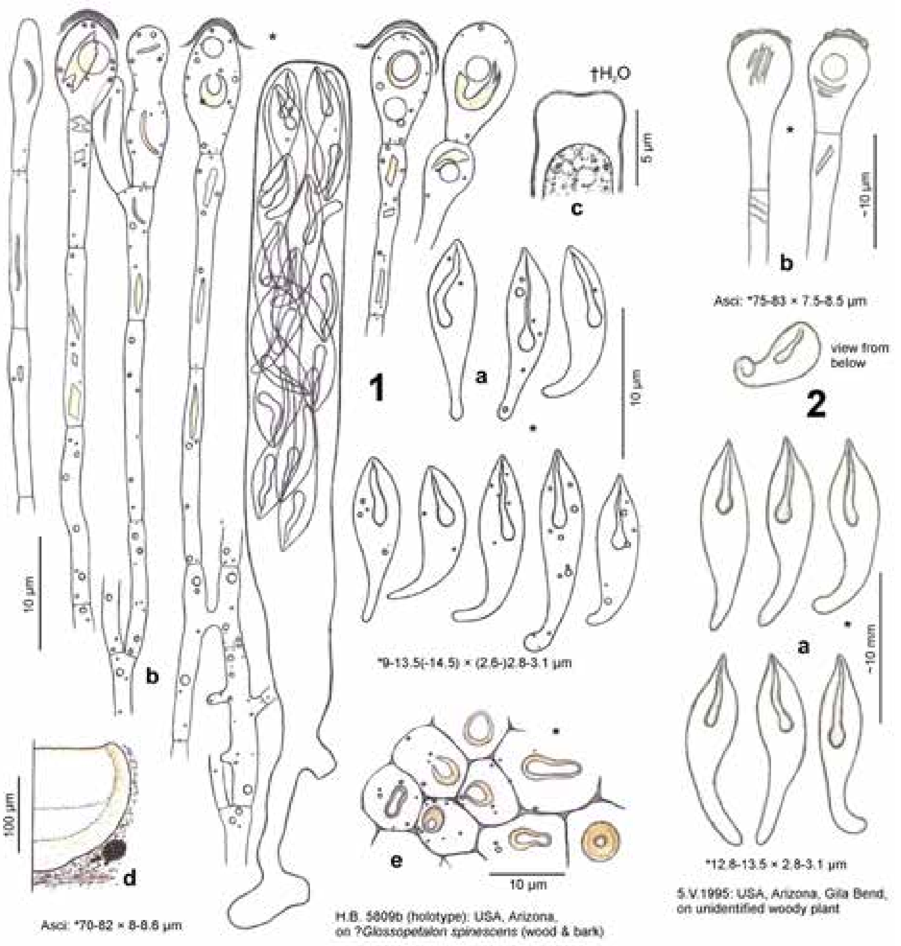

Plate 661. **1–2**: *Orbilia pleiourosperma*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. crystalloid SCBs in ectal excipulum at flanks.

Taxonomic remarks. *Orbilia urosperma* is characterized by large ascospores with strongly acuminate apices and very tapered, partly strongly curved bases. The species resembles *O. bicknellensis*, particularly the Australian collection (on *Atriplex*, Pl. 655: 2), from which it differs in longer asci, spores and spore bodies, and in more strongly curved spore bases. A North American collection tentatively referred to *O. bicknellensis* (on *Baccharis*, Pl. 655: 4) resembles *O. urosperma* in the spores which, however, are basally not curved. The North American *O. pleiourosperma* differs in 16-spored asci and smaller spores with shorter SBs.

Ecology. The single collection of *O. urosperma* was made on bark of xeric woody stems of *Solanum lasiophyllum*, a herbaceous plant growing near sand dunes in a subtropical arid hummock grassland with scattered acacia shrubs in western Australia west of the Pilbara desert.

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 159 km NNE of Carnarvon, 28 km SW of Mia Mia, 35 m, woody stems of *Solanum lasiophyllum*, on bark, 6.XII.2001, G. Marson (ex H.B. 7299, MEL 2389234, **holotype**).

Orbilia pleiourosperma Baral & G. Marson, **sp. nov.**, MB 813691 — Pls 661–662

Etymology: a 16-spored derivative of *O. urosperma*.

Typification: USA, Arizona, Lukeville, branches of ?*Glossopetalon spinescens*, 5.V.1995, G. Marson (ex H.B. 5809b, M-0276563, holotype).

Latin diagnosis: *Similis* Orbiliae urospermae *sed asci 16-spori, ascosporae breviores, in statu vivo corpuscula refringentia breviora. Habitat ad lignum et corticem putridum ramorum siccorum angiospermarum in zona subtropica (semi)arida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.35 mm diam., 0.13–0.17 mm high, light to deep orange (apricot), scarcely translucent, round, scattered to subgregarious; disc slightly concave to flat, margin distinct, 15 µm protruding, ± smooth; broadly sessile, slightly to strongly erumpent between fibres. **Asci** *70–83 × (7.5–)8–8.6 µm {2}, †60–75 × 6–7.5(–8.5) µm {1}, 16-spored, spores *4-seriate, 8–9 lower spores inverted {1} (often mixed), pars sporifera *48 µm long; **apex** (†) strongly truncate (distinctly indented, laterally inflated); **base** with short to medium long, thin or thick, flexuous stalk, T- to L-shaped. **Ascospores** *(9–)11–13.5(–14.5) × (2.6–)2.8–3.1 µm {2}, †8–12.5 × 2.7–3(–3.3) µm {1}, fusiform-clavate, apex acute to acuminate, base strongly attenuated in a tail-like end or short tail, here slightly to often strongly geniculate; **SBs** *4–6.5 × 0.8–1.3 µm {1}, vermiform to mostly subulate, base slightly to medium inflated, straight to slightly flexuous. **Paraphyses** apically (medium to) strongly clavate-capitate, sometimes spathulate or moniliform, terminal cells *(6–)8–20 × (2.8–)3.8–7 µm {1}, lower cells *11–19 × 1.7–2.3 µm {1}; rarely branched at upper septum, hymenium light orange. **Medullary excipulum** hyaline, 35–40 µm thick, of dense textura globulosa-intricata, sharply delimited. **Ectal excipulum** pale to light orange, of thin-walled, vertically oriented t. angularis-prismatica from base to mid flanks, 25–40 µm thick near base, cells *10–20 × 9–12 µm {1}; 15–20 µm thick near margin, of t. prismatica-angularis oriented at a 10–40° angle to the surface, marginal cortical cells */†5–12 × 3–4 µm {1}, ± thick-walled (0.3–0.5 µm). **Anchoring hyphae** medium abundant, *2–3.5 µm wide, walls 0.2–0.4 µm thick {1}, sometimes forming a loose, hyaline, 20 µm thick layer that covers flanks and margin. **SCBs** in apex of paraphyses globose, 1.5–1.7 µm diam.; in paraphyses and ectal excipulum (from base to margin) rod- or ring- to horseshoe- or keyhole-shaped {2}, pale to bright orange, 3–5(–8) × 2.5–4(–5.2) µm.

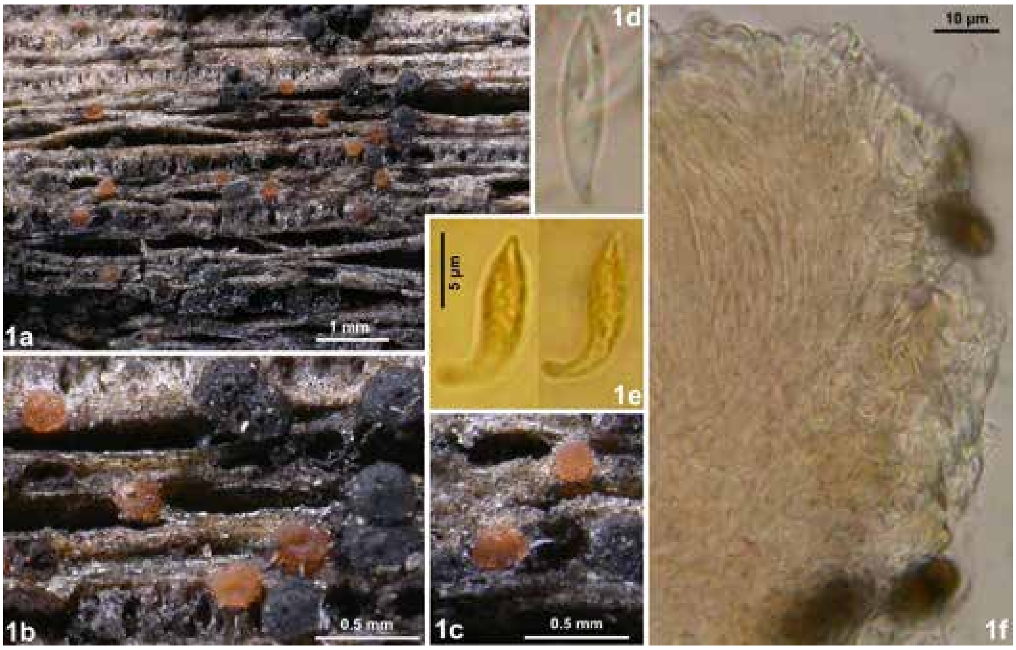

Plate 662. **1**: *Orbilia pleiourosperma*. – **1a–c**. rehydrated apothecia (with *Teichosporella dura*); **1d–e**. ascospores; **1f**. median section of marginal ectal excipulum. – Dead state (**1d**, **f** in H_2O, **1e** in IKI). — **1a–f**. H.B. 5809b (holotype): USA, Arizona, on ?*Glossopetalon*.

Exudate over paraphyses 0.3–0.6 µm thick, finely rough, continuous, ± firmly attached; over margin and flanks 0.2 µm thick, continuous. — **ANAMORPH**: unknown.

Habitat: collected above the ground, partially to entirely decorticated, 7–10 mm thick branches of ?*Glossopetalon spinescens* {1}, unidentified woody angiosperm {1}, on 0.2 mm deep strongly decayed wood {1} and bark {1}, often along clefts, medium greyed, algae very sparse. **Associated**: *Orbilia lentiformis* {1}, *O. myriourosperma* {1}, *O. pluristomachia* {1}, *Schizoxylon* sp. {1}, *Teichosporella dura* {1}. **Desiccation tolerance**: fully viable for at least 25 months. **Altitude**: 250–710 m a.s.l. **Geology**: alluvial sand, silt and clay; felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiourosperma* resembles the Australian *O. urosperma*, from which it mainly differs in 16-spored asci and in shorter ascospores and spore bodies. *O. pleiomesaverdiana* is tentatively segregated from *O. pleiourosperma* based on subacute spore apices. Collections of *O. serpentina* with tapered spore bases differ from *O. pleiourosperma* in that they are only tail-like and much less curved. For the separation from higher-spored taxa see under *O. myriourosperma*, p. 1141.

Ecology. *O. pleiourosperma* is known from two collections on rotten wood and bark of xeric branches of angiosperm shrubs in subtropical semiarid to arid Sonoran paloverde-mixed cacti (in Gila Bend riparian, adjacent to creosotebush-bursage desert scrub) in the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branches of ?*Glossopetalon spinescens*, on wood & bark, 5.V.1995, G. Marson (M-0276563, **holotype**: **isotype** in H.B. 5809b). – ~5 km SSW of Gila Bend, Rte. 85, 250 m, on indet. angiosperm, 5.V.1995, G. Marson (ø).

Orbilia multiurosperma Baral & G. Marson, **sp. nov.**, MB 814439 — Pls 663–664

Etymology: named after the 32-spored asci and resemblance to *O. pleio- and myriourosperma*.
Typification: Spain, Alcanar, branches of *Pistacia lentiscus*, 27.IX.1999, H.O. Baral (ex H.B. 6493a, M-0276527, holotype; ex-type culture: CBS 140832; sq.: KT215245, MH878192).

Latin diagnosis: *Similis* Orbiliae pleiourospermae *sed asci 32-spori, sed ascosporae breviores, apice minus acutae, basi minus attenuatae et caudatae, corpusculis refringentibus brevioribus continentes.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.35(–0.5) mm diam., 0.12–0.18 mm high, pale to light orange, round, sometimes compressed, scattered to gregarious; disc slightly concave to flat, margin thin, not protruding, ± smooth; sessile, slightly erumpent. **Asci** *63–87(–92) × (7–)8–9.7(–10.3) µm {4}, †(55–)60–85(–98) {4} × 5.7–7 {1} or 7.5–9.5(–10.2) {3} µm, 32-spored (28–32 counted), spores (*) ~4-seriate, lower spores inverted {2} (somewhat mixed), pars sporifera *40–59 µm long; **apex** (†) medium to strongly truncate (not or distinctly indented, laterally inflated or not); **base** without or with medium short, ± thick and flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(6–)7–10(–10.5) {4} × (2.5–)2.7–3(–3.2) {4} or 3–3.5 {1} µm, †(6–)7–10(–11) × 3–3.7(–4) µm {3}, ellipsoid- to fusoid-clavate, apex obtuse to subacute, base strongly attenuated in a tail-like end or short tail, mostly slightly to medium curved near base; **SBs** *(2.5–)3–3.5(–4) × 0.5–0.9 µm in situ {3} (~2.5–5 µm actual length), rod-shaped to subulate with uninflated or slightly to strongly swollen base, or divided into an abruptly swollen, subglobose to tear-shaped lower part and a fine filum of ± equal length, straight to medium flexuous, rarely uncinate. **Paraphyses** apically (slightly to) medium to strongly capitate(-clavate), terminal cells *(4–)5–16 × (3–)4–6(–6.7) µm {3}, †3–6(–7) µm wide, lower cells *(5–)8–17(–18.5) × 1.5–3 µm {3}; sometimes branched near apex. **Medullary excipulum** 10–50 µm thick, of dense, horizontally oriented textura porrecta-intricata with many inflated cells, ± indistinctly delimited. **Ectal excipulum** hyaline to pale rose-orange, of thin-walled, indistinctly oriented t. globulosa-angularis from base to submargin, 10–40 µm thick near base, cells *6–11 × 5–9.5 µm {2}; 10–30 µm thick near margin, not or slightly gelatinized, of t. prismatica-porrecta oriented at a 10–40° angle to the surface {1}, or of t. angularis-prismatica at 40–90° {3}, marginal cortical cells *10–14 × 3–3.5(–5) {1} or *7–9 × 4–7 µm {1}. **Anchoring hyphae** sparse, †1.7–3.3 µm wide, walls 0.2–0.3(–0.4) µm thick {2}, forming a thin layer that partly covers also the margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–3 µm diam., and rod- or ring-shaped {4}, very pale orange. **Exudate** over paraphyses 0.2–0.8(–1.5) µm thick, rough to granular, ± loosely attached, partly lacking; over margin and flanks thin, pale yellowish. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {2}). **Conidiophores** not observed. **Conidia** Y- to T-shaped, total size */†21–30(–37) × 17–32(–35) µm, stipe *15–19 × 5.2–5.5 µm, 2(–3)-septate, arms tapering, *(5.5–)8.5–15.5 × 4.5–6 µm, (0–)1–2(–3)-septate {2}; exceptionally 3-armed (cross-like), with one arm dichotomously branched.

Habitat: collected 0–1.5 m above the ground, entirely or only upper side decorticated, 4–16 mm thick twigs and branches of *Atriplex halimus* {2}, *Larrea tridentata* {4}, *Pistacia lentiscus* {1}, on 0.2–1 mm deep strongly decayed wood {7}, eroded, bleached or medium to strongly greyed, without or with some green algae, partly along longitudinal cleft. **Associated**: *Carestiella ?schizoxyloides* {2}, *Eutypella* sp. {1}, *Coniochaeta* sp. {1}, ?*Muellerella* sp. {1}, *Lecanora* sp. {1}, *Orbilia ?breviclava* {1}, *O. cryptogena* {3}, *O. halimi* {2}, *O. multicercocarpi*

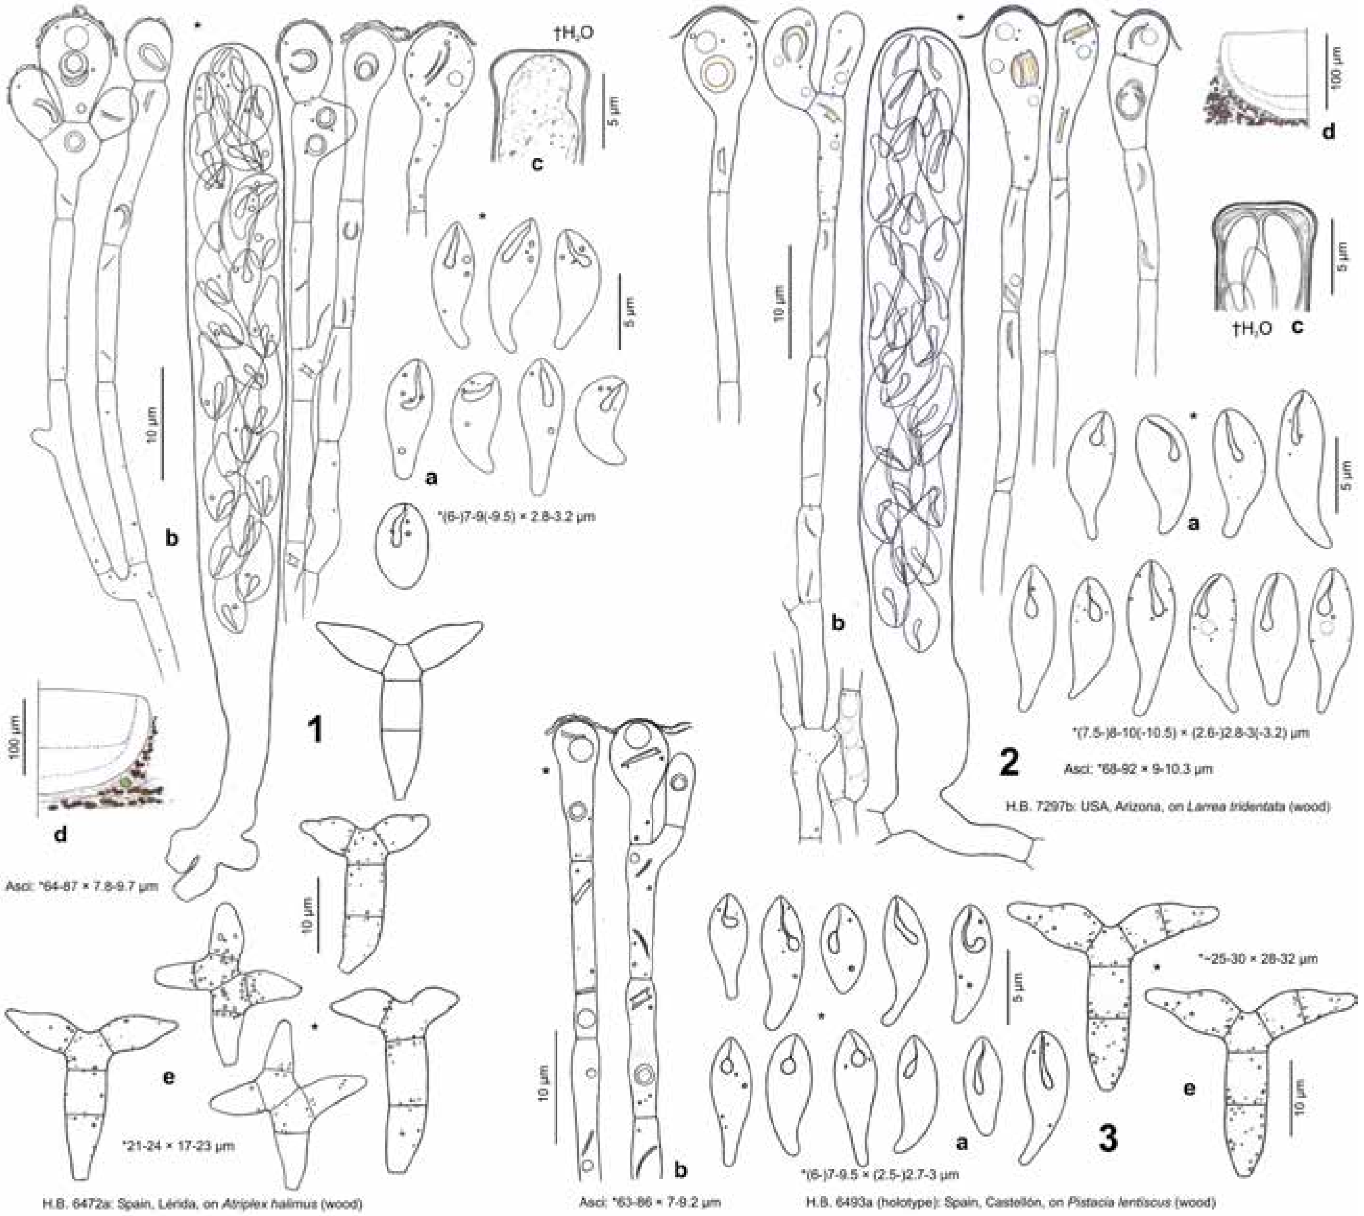

Plate 663. **1–3**: *Orbilia multiurosperma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. conidia from substrate.

{1}, *O.* ?*navajoana* {1}, *O. pluristomachia* {3}, *O. sedonensis* {1}, *O. sonorensis* {1}, *Patellaria atrata* {1}, ?*Phoma* sp. {1}, *Symbiotaphrina larreae* {2}. **Desiccation tolerance**: fully viable for at least 10 months. **Altitude**: 3–283 m a.s.l. (Spain), 500–1145 m (Arizona). **Geology**: Cenozoic sand-, lime- and mudstone, marl, sand & gravel, silt & clay; alluvial deposits from granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multiurosperma* is characterized by 32-spored asci and ellipsoid-clavate ascospores with obtuse to subacute apices, curved tail-like bases or short tails, and rather short spore bodies. *O. multimaeandrina* differs in more acute spore apices, mostly absent spore tails, longer SBs, and in lacking crystalloid SCBs. For the differences to *O. myriourosperma* see p. 1141.

An Australian collection mentioned under *O. multivirgula* (Pl. 755: 2) was only studied in the dead state and possibly represents a species of its own. The spores are distinctly narrower compared to *O. multiurosperma*, but they are too wide to be included in *O. multivirgula*. A collection from Utah (Pl. 693: 2) mentioned under *O. paloverdensis* deviates from *O. multiurosperma* in longer, more abrupt spore tails and longer asci, but its vital characters are largely unknown. Only a few living paraphyses were seen which did not contain any crystalloid SCBs

Variation. The four North American collections of *O. multiurosperma* on *Larrea* match quite well the three European ones. In one of them (H.B. 7397b), the marginal excipulum deviated in a t. prismatica-porrecta oriented at a low angle, but in another (H.B. 9573c) it was of t. angularis-prismatica oriented at 50–80°, similar as in the European specimens. The North American collections showed a tendency to longer or wider spores and especially larger asci. In a Spanish collection a single abnormal ascus with mostly broadly ellipsoid spores was observed (Pl. 663: 1a below).

Anamorph. The trinacrium robustum-like conidia of *O. multiurosperma* resemble those of *O. serpentina* in shape, but the arms tend to project more laterally (T-shaped). A single conidium was obtained in pure culture of the holotype. It was larger than all conidia observed on the substrate near apothecia (total size †37 × 35 µm, 3-septate arms and stipe).

Phylogeny. A sequence was gained from the ex-type culture which comprises SSU (without S1506 intron), ITS, and LSU.

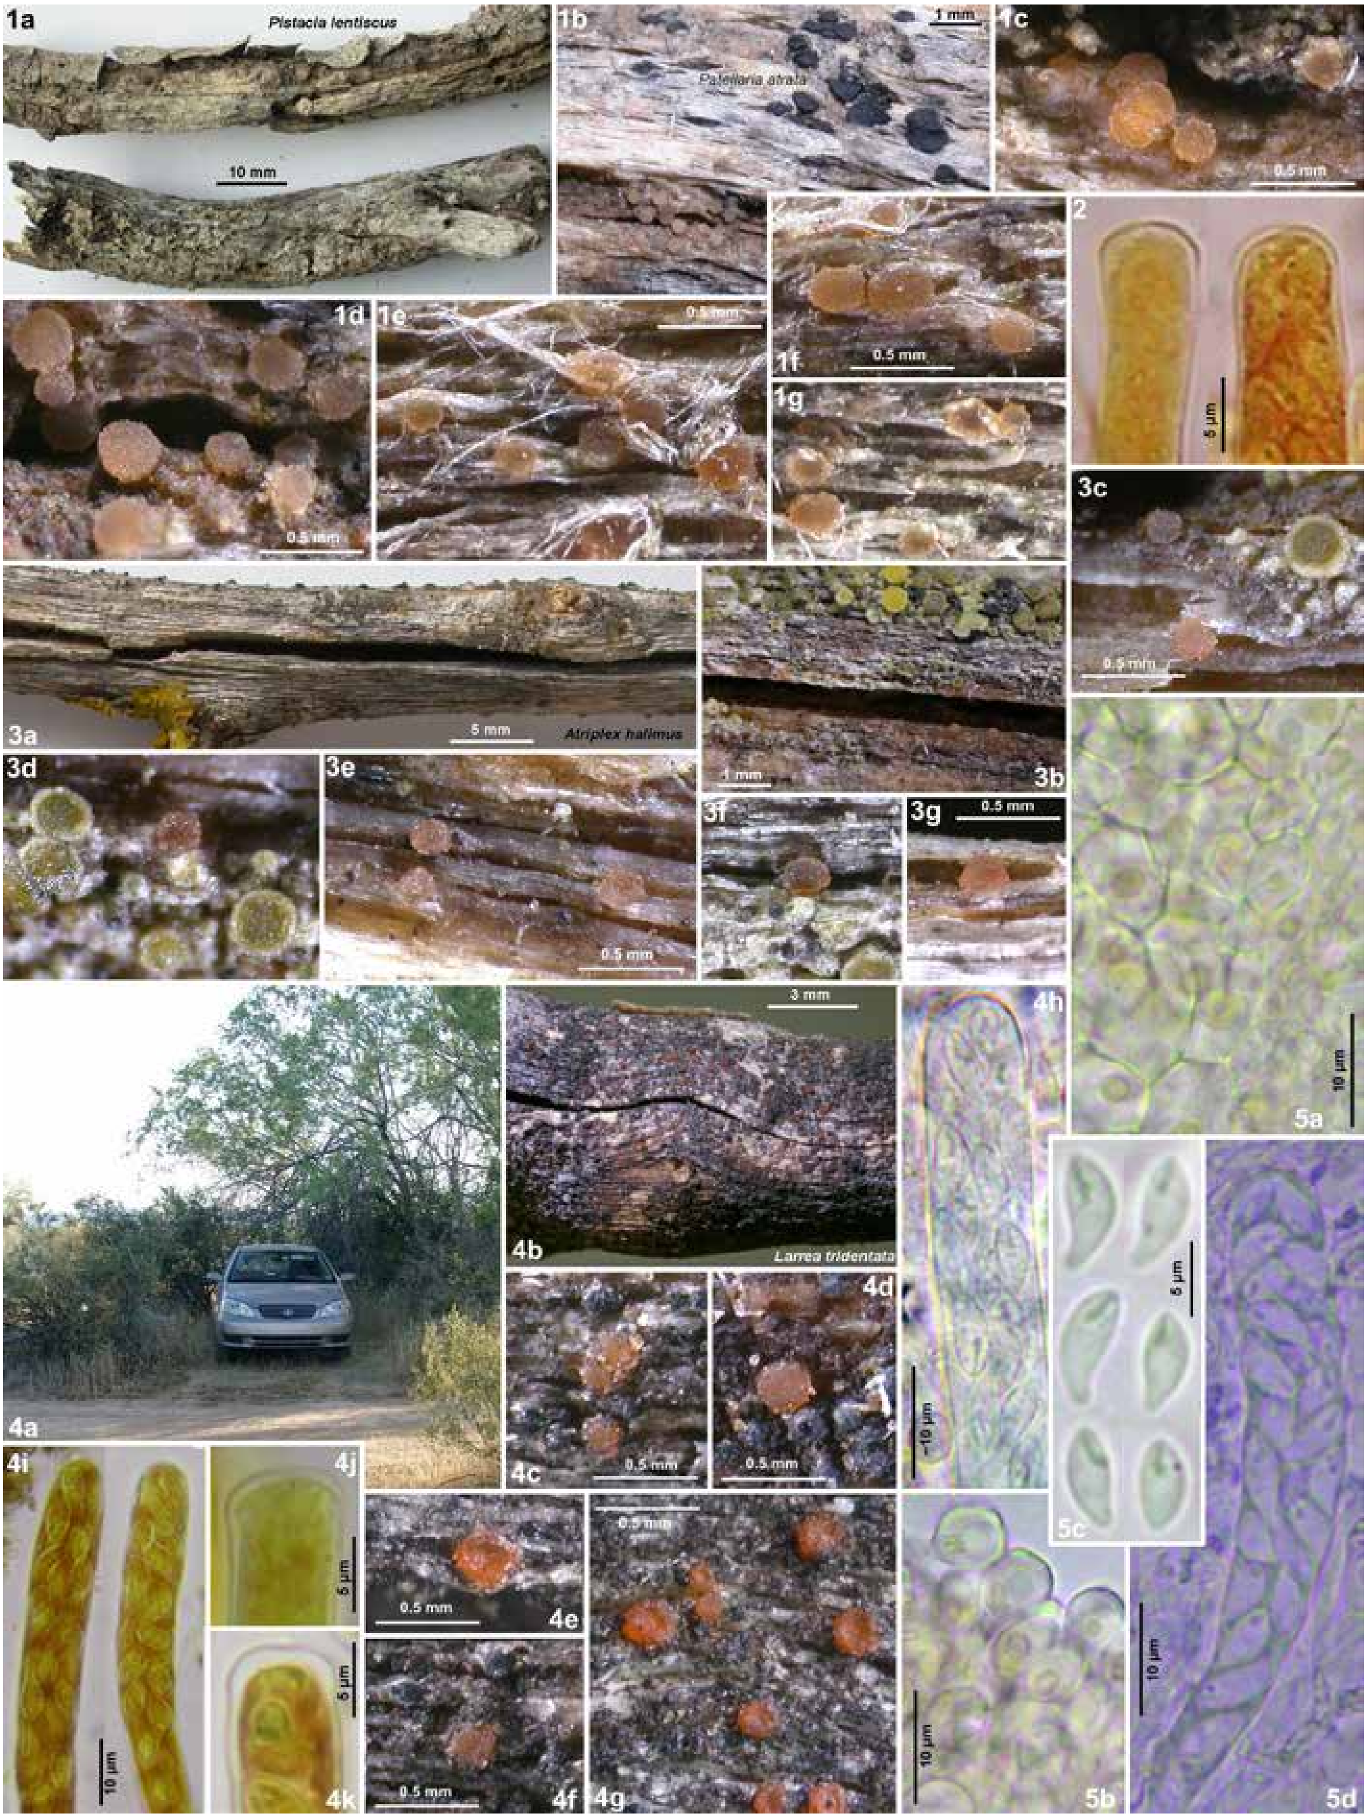

Plate 664. **1–4**: *Orbilia multiurosperma*. – **4a**. *Larrea tridentata* desert scrub with *Prosopis glandulosa* and *Coleogyne ramosissima* in dry riverbed of Sonoran Desert; **1a**, **3a**, **4b**. decorticated xeric branches; **1b–g**, **3b–h**, **4c–h**. rehydrated apothecia (**1b** with *Patellaria atrata*, **3** with *Lecanora*); **2**. apices of asci, **4i–j**. upper part of asci with ascospores. – Dead state (**2**, **4i** in KOH+IKI), except for **4j**. — **1a–g**. H.B. 7397b: USA, Arizona, Phoenix, on *Larrea*.

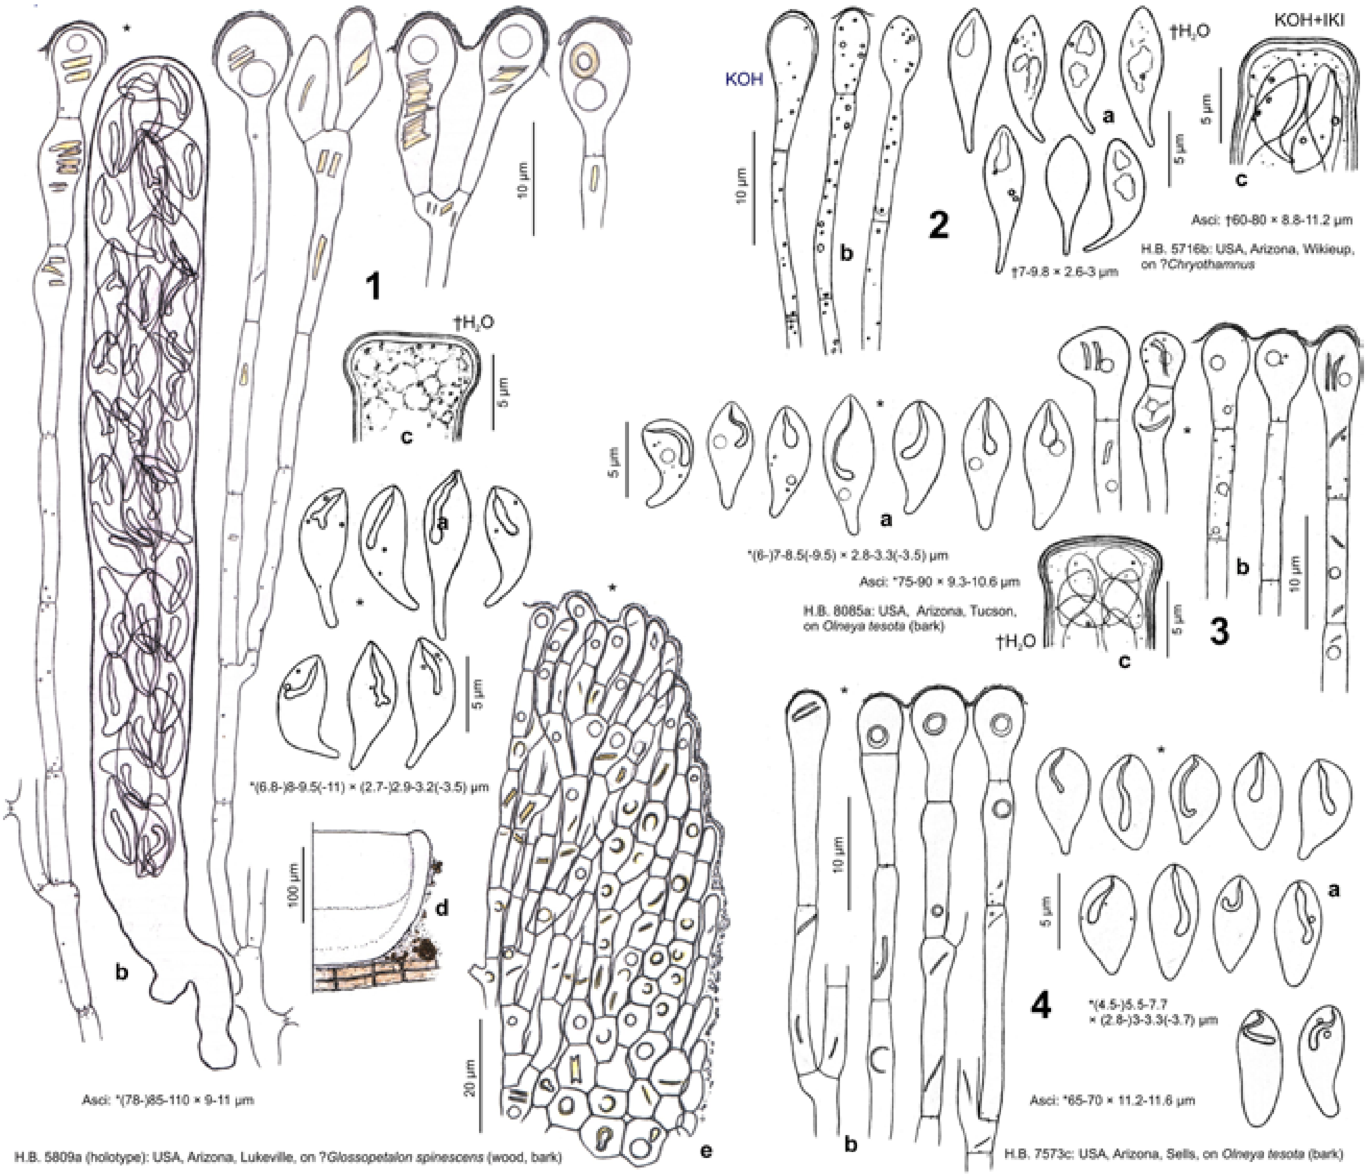

Plate 665. **1–4**: *Orbilia myriourosperma*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum (with crystalloid SCBs).

O. multiurosperma clustered unresolved in the *Serpentinae-Habrostictis* clade, even when including all three gene regions in the analysis (Phyl. 20). The lowest distance in the LSU was 1.6% to *O. carpoboloides* (despite a 17.5% ITS distance to this species), and the lowest ITS distance was 14% to *O. halimi* (LSU 2.9%). Although its affiliation in series *Serpentinae* is confirmed, a few dignostic nucleotides in the LSU D1 (128–129, 132–135) concur with members of series *Ellipsospermae* (Tab. 72).

An environmental sequence from Canadian arctic soil (Prince Patrick Island, KC965181, ITS & LSU) clustered in the analyses of ITS or SSU+ITS+LSU in a medium supported clade with *O. multiurosperma* (Phyls 19–20), but with a 13% ITS distance. Another environmental sequence from there (Banks Island, KC965560, ITS2 & LSU) clustered in a strongly supported clade with KC965181 when analysing LSU D1–D2 (S22), with a 1.3% distance in this domain, but with a minimum distance of 2.2–2.5% to *O. flavidorosella* and *O. filiformis* and 2.5–3% to *O. multiurosperma*.

Ecology. *O. multiurosperma* was collected on rotten wood (and bark) of xeric twigs and branches of different angiosperm shrubs in desertic halophilous ruderal *Atriplex* scrubs (*Agrostio-Tamaricetum canariensis*) and other ruderal places in meso- to thermomediterranean semiarid to semihumid southwestern Europe. Collections from western North America were in subtropical semiarid to arid paloverde-mixed cacti and creosotebush-bursage desert scrubs in the Sonoran Desert but also in the adjacent warm-temperate semiarid Chihuahuan creosotebush-tarbush desert scrub in the Mogollon Rim.

Specimens included. **SPAIN**: **Navarra**, 19 km SSW of Carcastillo, 7 km NE of Arguedas, Bardenas Reales, 283 m, branches of *Atriplex halimus*, on wood, 17.V.2015, J.P. Orbilia myriourosperma Baral & G. Marson, **sp. nov.**, MB 813692 — Pls 665–666, Map 109

Etymology: named after the 64-spored asci and a close resemblance to *O. multiurosperma*.

Typification: USA, Arizona, Lukeville, branches of ?*Glossopetalon spinescens*, 5.V.1995, G. Marson (ex H.B. 5809a, M-0276534, holotype).

Latin diagnosis: *Similis* Orbiliae multiurospermae *sed asci 64-spori.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.35(–0.55) mm diam., 0.12–0.18 mm high, pale to light pure orange(-rose), round, ± scattered; disc flat, margin distinct, 0–10 µm protruding, smooth or finely rough; broadly sessile, slightly to half immersed; dry deep orange-red. **Asci** *65–70 {1} or (74–)85–100(–110) {4} × 8.8–11(–12) µm {5}, †(60–)65–85(–105) × (7.7–)8.5–10(–11)((–12)) µm {5}, 64-spored (50–60 spores counted), spores (*) ~4-seriate, lower spores inverted (strongly mixed), pars sporifera *48–74 µm long; **apex** (†) medium to strongly truncate (rarely slightly indented, laterally ± inflated or not); **base** without or with a short to medium long, thick, flexuous stalk, Y-, L- or h-shaped. **Ascospores** *((4.5–))(6–)7–9.5(–11) × (2.7–)2.9–3.3(–3.5)((–4)) µm {5}, †6.5–9(–10) × (2.4–)2.6–3(–3.3) µm {3}, broadly fusoid- to fusiform-clavate, also ellipsoid-fusoid, apex subacute to acute {3}, also obtuse or rounded {2}, base usually strongly attenuated in a tail-like end or distinct tail *1–3 × 0.5–0.7(–1) µm, †0.3–0.5 µm wide, slightly to strongly geniculate near base; **SBs** *(2–)3–4.5(–5.5) × (0.3–)0.4–0.8(–1.1) µm in situ {3} (~3–6.5 µm actual length), vermiform to subulate, base sometimes slightly inflated, straight to medium flexuous, rarely uncinate. **Paraphyses** apically (slightly to) medium to (very) strongly clavate-capitate, rarely moniliform or spathulate to mammiform, terminal cells *(4.5–)7–19(–27) × (3–)4–5.5(–6.7) µm {3}, †6–13 × 2–4.8 µm {1}, lower cells *(6–)9–18(–22) × 1.5–2.5(–3) µm {3}, †8–18 × 1–2 µm wide {1}; rarely to often branched at upper septum. **Medullary excipulum** 25–60 µm thick, of ± dense textura globulosa-intricata, sharply delimited from ectal excipulum mainly towards margin. **Ectal excipulum** very pale to light orange-rose (especially towards margin), of (†) thin-walled (partly slightly gelatinized), indistinctly oriented t. (globulosa-)angularis from base to mid flanks, 20–30 µm thick near base, cells */†7–12 × (4–)6–10(–11) µm {3}; 20–25 µm thick at mid flanks, 20–30 µm near margin, of t. angularis to t. (prismatica-)porrecta oriented at a 10–20° angle to the surface, marginal cortical cells */†6–13 × 2.5–5(–6) µm {3}, partly firm-walled (wall 0.2–0.4 µm). **Anchoring hyphae** sparse, */†1.3–4 µm wide, walls 0.2–0.3(–0.8) µm thick {3}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–3(–4) µm diam., and rod-, ring- or keyhole-shaped {5}, 2–4.5 × 2–3 µm, hyaline or pale to light yellowish-orange-rose. **Exudate** over paraphyses 0.1–0.4 µm thick, finely rough, closely attached; over margin a 0.1–2 µm thick finely granular layer, partly almost absent. **— ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, corticated or partially to almost entirely decorticated, 6–14 mm thick branches of ?*Chrysothamnus* sp. {1}, ?*Glossopetalon spinescens* {1}, *Olneya tesota* {2}, indet. angiosperm {1}, stem of indet. herbaceous (slightly woody) dicotyledonous plant {1}, on 0.2–0.3 mm deep (medium to) strongly decayed wood {2} and bark {4} (bast), often along (partly in)

Map 109. Known distribution of *O. myriourosperma* in North America.

longitudinal or transversal clefts, ± strongly greyed, with some green algae. **Associated**: *Hysterobrevium mori* {1}, *Orbilia ?barrowensis* {1}, *O. lentiformis* {2}, *O. maeandrina* {3}, *O. multicreosoteris* {1}, *O. multigambelii* {2}, *O. ?multiphanosoma* {1}, *O. myrioolneyae* {2}, *O. pleiomesaverdiana* {1/1}, *O. pleiourosperma* {1}, *O. pluristomachia* {1}, *O. sonorensis* {1}, *Patellaria* '*andina*' {3}, *Schizoxylon* sp. {1}, *S. ?argentinum* {1}, *Teichosporella dura* {1}, *Symbiotaphrina desertorum* {1}. **Desiccation tolerance**: fully viable for at least 25 months, after 33.5 months most paraphyses and excipular cells still viable. **Altitude**: 600–745 m a.s.l. **Geology**: Oligo- to Miocene sand-, lime- and mudstone, silt and clay, volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriourosperma* is easily recognized by its 64-spored asci and broadly fusoid ascospores which terminate at the base in more or less strongly bent and abrupt tails and contain rather short spore bodies in their apex, also by the presence of crystalloid SCBs. *O. pleiourosperma* is very similar but mainly differs in 16-spored asci and longer spores with consistently acute apices. *O. multiurosperma* differs from these two taxa mainly in 32-spored asci, from the latter also in more obtuse spore apices and less pronounced spore tails.

Variation. The collections here included in *O. myriourosperma* are somewhat heterogeneous. Only in the type collection and that on a herbaceous plant (Pl. 665: 1–2) the spores are consistently provided with distinct, more or less strongly bent tails. In the samples on *Olneya* (Pl. 665: 3–4) and indet. angiosperm (Pl. 666: 3) the tails are somewhat shorter and thicker and mostly only slightly bent. In the two collections on *Olneya* the spore apices are more obtuse than in those on the other substrates, and in one of them (Pl. 666: 4) the spores are mostly tailless and the asci shorter compared to the others though rather wide. This specimen approaches *O. myrioolneyae*, with which it grew in association, but which differs in much narrower spores and in lacking crystalloid SCBs. In their more indistinct tails the collections on *Olneya* and indet. angiosperm also appear to form a transition to *O. sedonensis*, in which the spores are wider and either without tails or only with thick tail-like bases.

Ecology. *O. myriourosperma* was collected on rotten wood and bark of xeric branches of different angiosperm shrubs in subtropical semiarid (to arid) Sonoran paloverde-mixed cacti desert scrubs in the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 200 km NW of Phoenix, Wikieup, ~600 m, branch of *?Chrysothamnus*, on wood, 3.V.1995, G. Marson (H.B. 5716b). – 82 km NW of Phoenix, ~1.5 km SE of Wickenburg, 615 m, branch of indet. angiosperm, on bark, 4.V.1995, G. Marson (H.B. 8579a). – 25 km WNW of Tucson, 5 km S of Picture Rocks, Saguaro, 745 m, branches of *Olneya tesota*, on bark, 30.V.2003, G. Marson (H.B. 8085a). – 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branches of ?*Glossopetalon spinescens*, on wood & bark, 5.V.1995, G. Marson (M-0276534, **holotype**; **isotype** in H.B. 5809a). – 100 km WSW of Tucson, 10 km NW of Sells, 683 m, branch of *Olneya tesota*, on bark, 28.V.2003, G. Marson (H.B. 7573c).

Orbilia sedonensis Baral & G. Marson, **sp. nov.**, MB 813693 — Pls 667–668

Etymology: named after the collection from Oak Creek Canyon north of the town Sedona (Arizona).

Typification: USA, Arizona, Tucson, branch of *Parkinsonia* (?)*microphylla*, 6.V.1995, G. Marson (ex H.B. 5671a, M-0276584, holotype).

Latin diagnosis: *Similis* Orbiliae myriourospermae *sed ascosporae basi non vel breviter caudatae*, *subrectae*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.12–0.4(–0.8) mm diam., 0.15 mm high, light to bright orange, translucent, round, scattered to subgregarious; disc flat, margin thin, not protruding, smooth; sessile, ± half immersed in host tissue; dry deep orange. **Asci** *83–112 × 9.2–11(–12) µm {3}, †78–88 × 7.2–9.2 µm {1}, 64-spored (49–58 spores counted), spores *4–6-seriate, lower spores inverted (strongly mixed), pars sporifera *67–80 µm long; **apex** (†) medium to strongly truncate (not indented, laterally distinctly inflated); **base** without or with very short, thick, flexuous stalk, L- or h-shaped. **Ascospores** *5.2–8 × (2.8–)3–3.8(–4.2) µm {3}, †5–7 × (2.6–)3–3.2(–3.8) µm {1}, broadly fusiform (to fusiform-clavate), rhomboid, apex subacute, also acute, base strongly attenuated, also with a thick

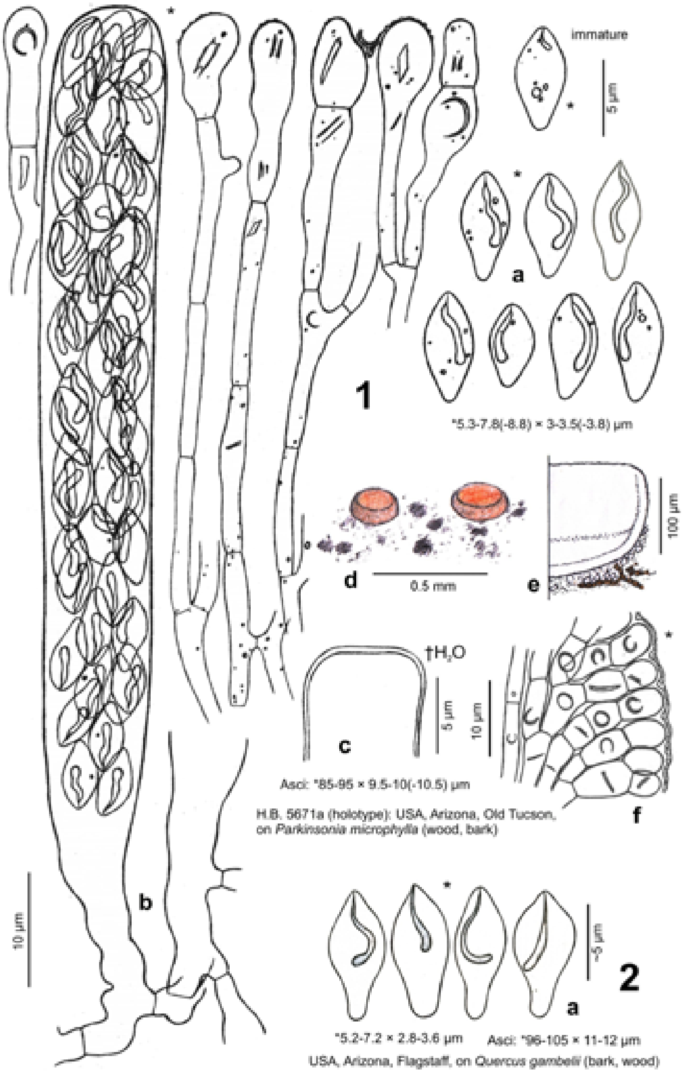

Plate 667. **1–2**: *Orbilia sedonensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum (with crystalloid SCBs).

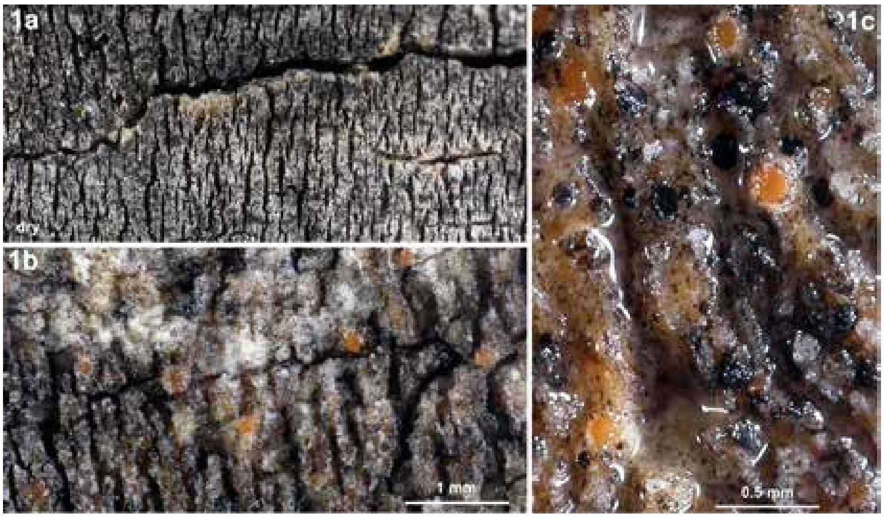

Plate 668. **1**: *Orbilia sedonensis*. – **1a**. clefty outer surface of dead corticated xeric branch (dry state); **1b–c**. rehydrated apothecia. — **1a–c**. H.B. 5671a (holotype): USA, Arizona, on *Parkinsonia* (?)*microphylla* (paloverde).

and short tail-like base, straight or scarcely inequilateral; **SBs** *4–5(–6) × 0.6–0.8(–1) µm in situ {1} (~4–7 µm actual length), vermiform to subulate, base not or slightly inflated, slightly to strongly flexuous, rarely uncinate. **Paraphyses** apically slightly to strongly clavate-capitate, sometimes spathulate-lageniform, terminal cells *(4–)8–22 × 3–5.3 µm {1}, lower cells *11–17 × 1.3–2 µm {1}; sometimes branched at upper septum. **Medullary excipulum** hyaline, 30–40 µm thick, of dense textura angularis, medium sharply delimited. **Ectal excipulum** pale orange-rose, of slightly gelatinized, horizontally oriented t. (globulosa-)angularis(-prismatica) from base to margin, 10–15 µm thick near base, cells *5–9 × 5–7.5 µm {1}; 10–15 µm thick at mid flanks and margin, oriented at a 10–80° angle to the surface, marginal cortical cells *5–10 × 4–5.5 µm {1}. **Anchoring hyphae** medium abundant, *2–4 µm wide, walls 0.2–0.3 µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) pale yellow-orange, rod- or ring-shaped {3}. **Exudate** over paraphyses 0.3–1 µm thick, finely granular, partly absent; over margin and flanks 1–2 µm thick, continuous. **— ANAMORPH**: unknown.

Habitat: collected 1.5–2.5 m above the ground, ± corticated, 18–19 mm thick branches of *Parkinsonia* (?)*microphylla* {1}, *Larrea tridentata* {1}, *Quercus gambelii* {1}, on 0.2–0.5 mm deep very decayed wood {3} and bark {2} (bast), greyed, no algae. **Associated**: *Orbilia ?breviclava* {1}, *O. calyptrata* {1}, *O. cryptogena* {1}, *O. gambelii* {1}, *O. maeandrina* {1}, *O. multicercocarpi* {1}, *O. multiurosperma* {1}, *O. ?navajoana* {1}, *O. paloverdensis* {1}, *O. pleioserpens* {1}, *O. pluristomachia* {1}, *O. sonorensis* {1}, *Patellaria* '*andina*' {1}. **Desiccation tolerance**: fully viable for at least 19 months. **Altitude**: 615–1955 m a.s.l. **Geology**: Permian and Triassic sand-, lime- & mudstone; volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia sedonensis* is characterized by 64-spored asci, broadly fusiform (trapezoid) ascospores, and by the presence of crystalloid SCBs. The spores of the 32-spored *O. multimaeandrina* are partly similar, but in this species crystalloid SCBs are absent. *O. myriourosperma* differs from *O. sedonensis* in the spores having pronounced and partly distinctly bent tails. However, collections on *Olneya* (Pl. 665: 3–4) approach *O. sedonensis* in having more or less indistinct spore tails.

Variation. The three collections of *O. sedonensis* varied only slightly in spore shape. Particularly in the record on *Quercus* (Pl. 667: 2) the spore bases are partly tail-like though rather thick.

Ecology. *O. sedonensis* is only known from western North America where it was recorded on rotten bark and wood of xeric branches of angiosperm shrubs (paloverde and creosotebush) in subtropical semiarid Sonoran paloverde-mixed cacti desert scrubs but also on *Quercus gambelii* in a cold-temperate humid ponderosa pine forest of the Mogollon Rim.

Specimens included. **USA**: **Arizona**, Mogollon Rim, 22 km SSW of Flagstaff, 17.5 km N of Sedona, Oak Creek Viewpoint, 1955 m, branch of *Quercus gambelii*, on wood & bark, 8.V.1995, G. Marson (ø). – Sonoran Desert, 82 km NW of Phoenix, ~ 1.5 km SE of Wickenburg, 615 m, branch of *Larrea tridentata*, on wood, 4.V.1995, G. Marson (H.B. 5658b). – 19 km W of Tucson, W of Old Tucson Studios, 810 m, branch of *Parkinsonia* (?)*microphylla*, on bark & wood, 6.V.1995, G. Marson (ex H.B. 5671a, M-0276584, **holotype**).

Orbilia cactacearum Baral & G. Marson, **sp. nov.**, MB 813694 — Pls 669–670

Etymology: named after the occurrence on *Cactaceae*.

Typification: USA, Arizona, Lukeville, stems of *Stenocereus thurberi*, 5.V.1995, G. Marson (ex H.B. 5686, M-0276446, holotype).

Latin diagnosis: *Similis* Orbiliae coniferarum *sed ascosporae paulo latiores, corpusculum refringens brevius, cellulae vivae excipuli et paraphysium corpuscula crystalloidea continentes. Habitat ad lignum siccum, leniter vel valde putridum* Cactacearum *in zona subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.12–)0.2–0.45(–0.65) mm diam., 0.12–0.22 mm high, pale to bright orange, medium translucent, round, subscattered to subgregarious; disc medium concave to flat, margin distinct, 0–20 µm protruding, ± smooth; broadly sessile, slightly erumpent between fibres; dry bright orange. **Asci** *52–60 × (5.7–)6–7(–7.5) µm {2}, †47–66 × 5.5–6.5(–7) µm {2},

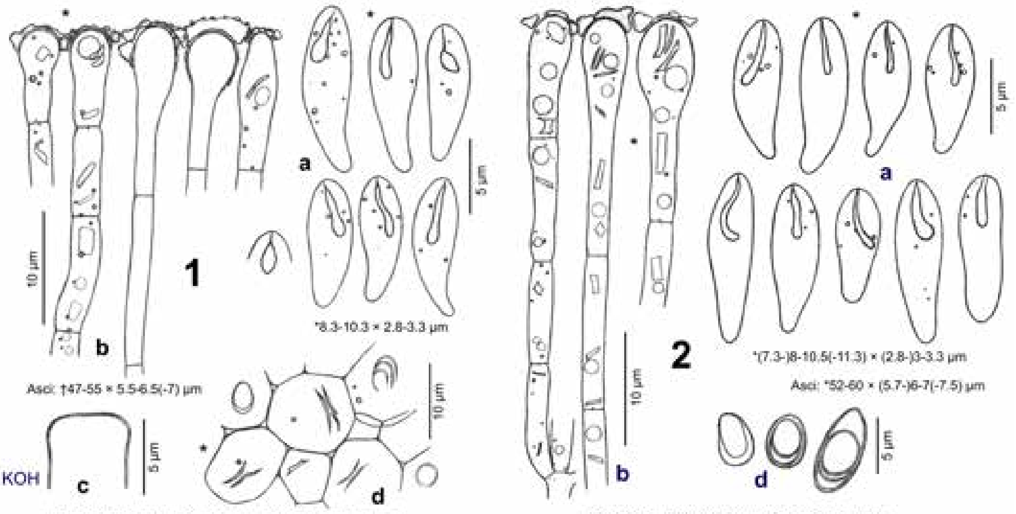

Plate 669. **1–2**: *Orbilia cactacearum*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. crystalloid SCBs in cells of ectal excipulum.

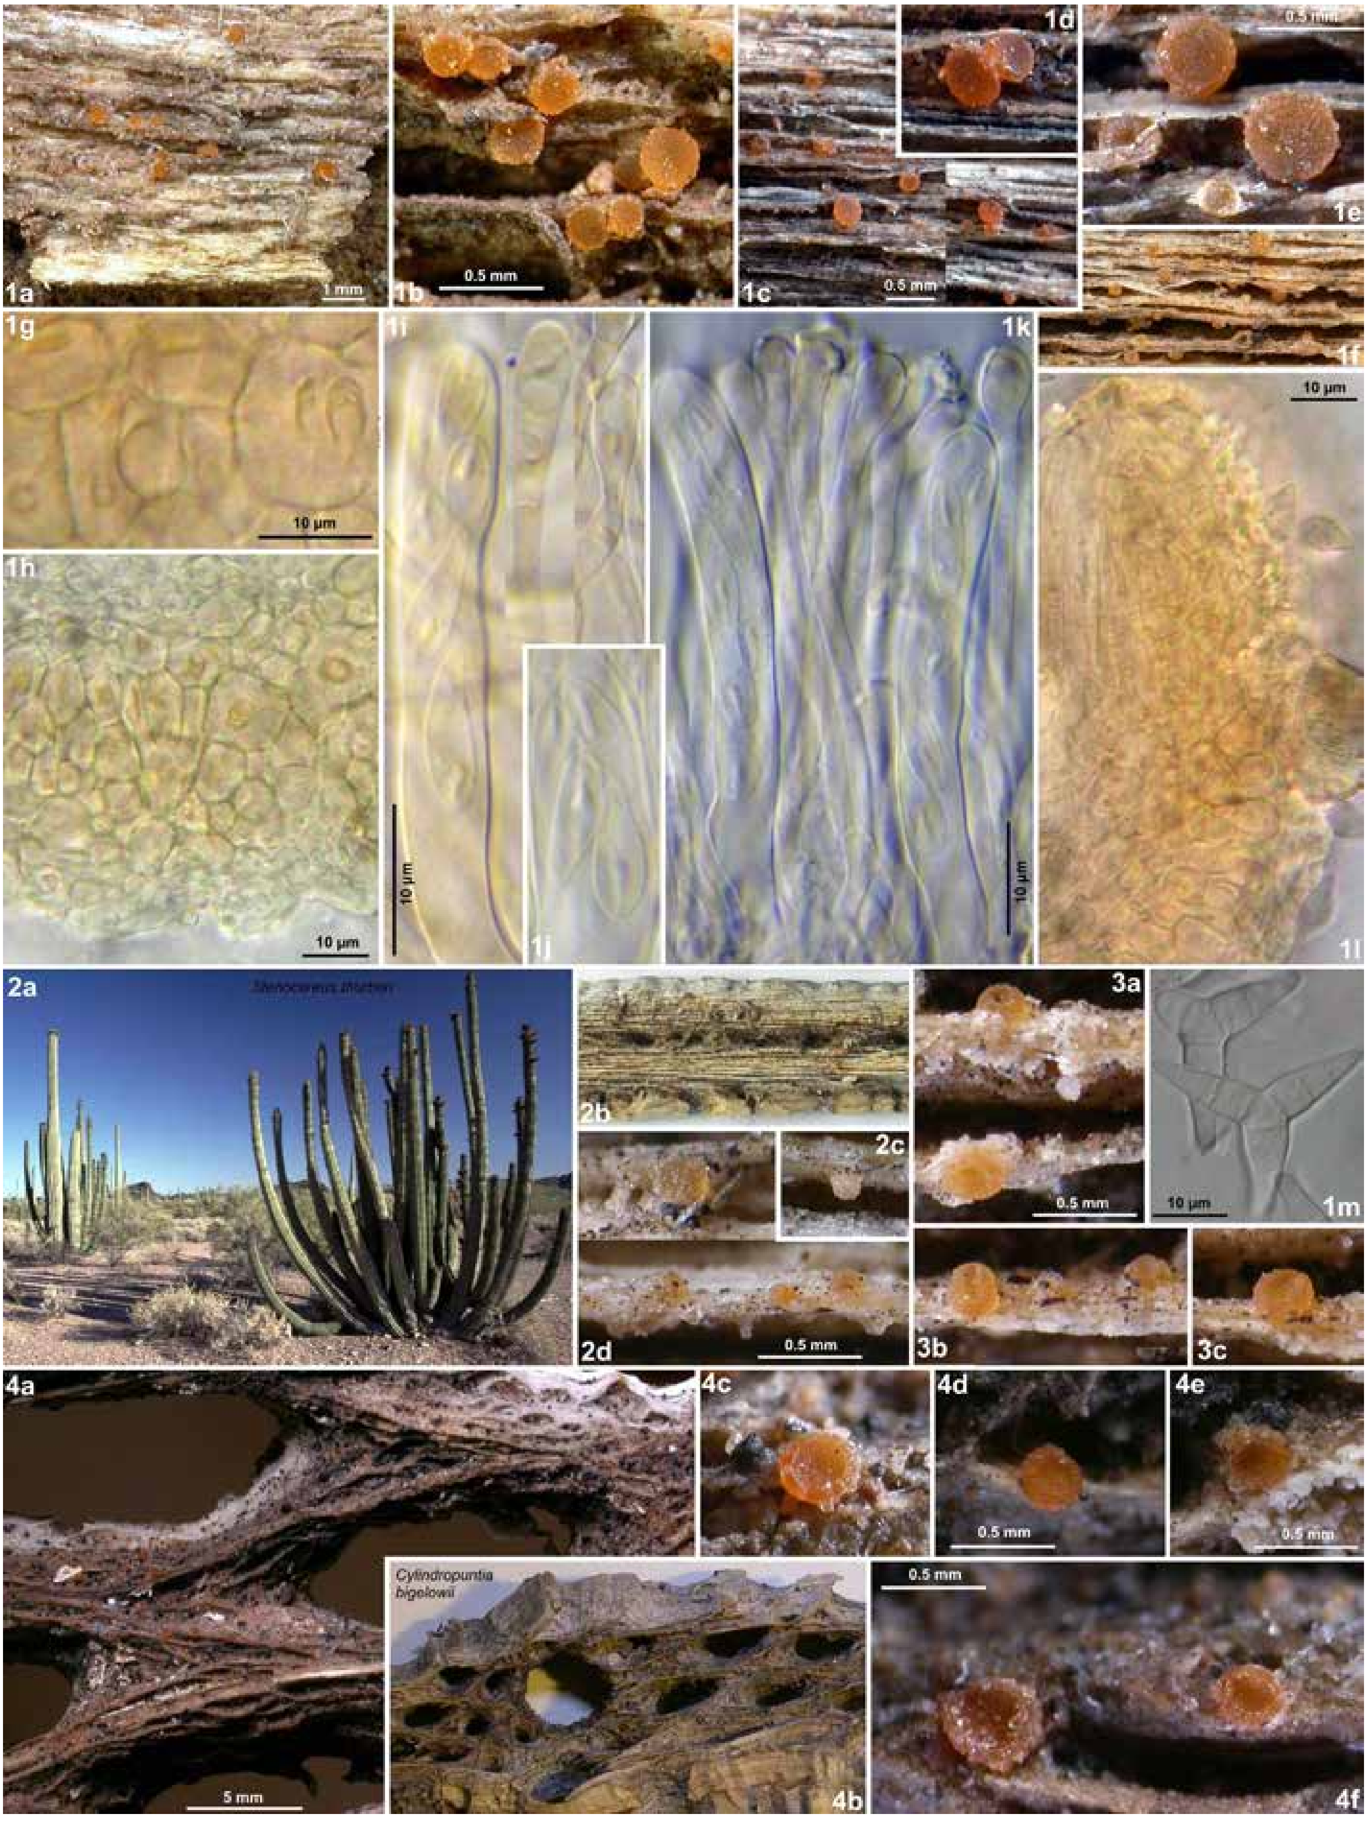

Plate 670. **1–4**: *Orbilia cactacearum*. – **2a**. semiarid cacti desert scrub with *Stenocereus thurberi* and *Carnegiea gigantea*; **2b**, **4a–b**. rotten skeleton parts of *Stenocereus thurberi* and *Cylindropuntia bigelovii*; **1a–f**, **2c–d**, **3a–c**, **4c–f**. rehydrated apothecia; **1l**. median section of marginal ectal excipulum (with conidia of *Acremonium limoniforme*); **1g–h**. id. but near base, with crystalloid SCBs; **1i–k**. paraphyses and asci with mature spores; **1m**. conidia from substrate. – Living state. — **1a–m**. 8-spored, spores (*) biseriate, (2–)3–4(–5) lower spores inverted {3} (not mixed), pars sporifera *23–28 µm long; **apex** (†) medium (to strongly) truncate (not indented, laterally not or distinctly widened); **base** with short to medium long, thick or thin, flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(7.3–)8–10.5(–11.3) × 2.8–3.5(–4) µm {3}, †7–11 × 2.5–3.3 µm {2}, ellipsoid-clavate, apex rounded to obtuse, base medium to strongly attenuated, sometimes tail-like, straight or slightly curved at base; **SBs** *(3–)3.5–4.5(–5) × (0.3–)0.5–0.8(–1.1) µm in situ {3} (~3.5–5 µm actual length), subulate, sometimes narrowly pear-shaped, base not or slightly inflated, straight to medium flexuous; SBs in aged spores ~3 × 1–1.1 µm, with a broadly fusoid lower part and a distinct filum. **Paraphyses** apically slightly to medium (to strongly) clavate-capitate, sometimes spathulate, rarely sublageniform, terminal cells *6–23 × 3–5 µm {2}, †2.7–4 µm wide, lower cells *8–15 × 1.8–2.5(–3.3) µm {2}; never branched near apex. **Medullary excipulum** hyaline to pale orange, 40–90 µm thick, of ± loose or dense textura intricata with a few or many inflated cells, sharply delimited from ectal excipulum (at flanks by a 5–10 µm thick t. porrecta). **Ectal excipulum** subhyaline to pale rose, of slightly gelatinized, vertically oriented t. angularis(-prismatica) from base to mid flanks or margin, 25–60 µm thick near base, cells *8–22 × 6–16 µm {3}; 15–30 µm thick near margin, of t. porrecta oriented at a 0–30° angle to the surface, or of t. angularis oriented at 70°, marginal cortical cells *5–11 × 2.8–4 µm {2}. **Anchoring hyphae** medium to abundant, */†2–4.2 µm wide, walls 0.2–0.5 µm thick {3}, partly covering flanks and margin as a thin layer. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.5 µm diam., together with rod- or ring-shaped ones {4}, 3–7.5 × 2.5–3.8 µm, hyaline to pale orange. **Exudate** over paraphyses, margin and flanks 0.3–2 µm thick, cloddy, ± firmly attached. **— ANAMORPH**: unknown (but see below).

Habitat: lying on dry ground or up to 0.5 m above the ground, 15–30 mm thick branches of *Carnegiea gigantea* {1}, *Cylindropuntia bigelovii* {1}, *Stenocereus thurberi* {2}, on slightly to strongly decayed wood {4} (outer layers removed), on outer and inner side, greyed, no algae. **Associated**: *Acremonium limoniforme* (parasitic in *O. cactacearum*) {1}, *Orbilia carnegieae* {1/1}, *O. saguarina* {2}, *Teichosporella dura* {1}, ?*Trichopeziza* sp. {1}. **Desiccation tolerance**: fully viable for at least 28 months. **Altitude**: 710–750 m a.s.l. **Geology**: felsic volcanic rock, lava breccia of basalt, andesite, dacite & rhyolite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia cactacearum* is similar to *O. coniferarum*, from which it differs in shorter spore bodies, slightly wider ascospores, and the presence of crystalloid SCBs. For the similar *O. sonorensis* see p. 1145. Also *O. multiurosperma* seems to be very similar, except for 32-spored asci and more tailed and curved spore bases.

Variation. The collections on *Stenocereus* and *Carnegiea* fit very well in shape of ascospores and SBs, also in size of asci and spores; that on *Cylindropuntia* was insufficiently documented but appears to match this species.

Not included collection. A very similar collection on *Krascheninnikovia* (IVV: H.B. 6085g) featured much longer asci (*67–106 × 6.5–7.5 µm, †65–88 × 6.5–7 µm) and longer spores (*11–13 × ~3–3.5 µm) and is, therefore, not included in the description. It grew in association with *O. bicknellensis*, from which it merely differs in rounded spore apices.

Anamorph. Some trinacrium robustum-like conidia were found near the apothecia on the natural substrate (Pl. 670: 1m), partly even in the hymenium. Their arms and stipes are narrower (5.2–6 µm wide) than those found near the associated *O. saguarina*. Yet, also some tridentaria-like conidia were found intermingled, and also a few unbranched conidia occurred.

Ecology. *O. cactacearum* was so far only found within a small area of the Sonoran Desert in the southwest of Northern America, where it grew on xeric branches of different large *Cactaceae* (cholla, organ pipe, saguaro) in the subtropical semiarid (almost arid) Sonoran paloverde-mixed cacti desert scrub. The not included collection on a *Krascheninnikovia* shrub (*Amaranthaceae*) was in a similar but warm-temperate vegetation with *Larrea* etc. in a valley at the border to the Mogollon Rim.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branches of *Cylindropuntia bigelovii*, on wood, 5.V.1995, G. Marson (H.B. 8355b). – ibid., branches of *Stenocereus thurberi*, on wood, 5.V.1995, G. Marson (M-0276446, **holotype**; **isotype** in H.B. 5686). – ibid., 11.VI.2000, G. Marson (H.B. 7217a). – ibid., 750 m, branches of *Carnegiea gigantea*, on wood, 28.V.2003, G. Marson (H.B. 7764c).

Not included. **USA**: **Arizona**, Sonoran Desert, 68 km SSE of Flagstaff, 5.5 km NNE of Camp Verde, Montezuma Castle, 975 m, branch of *Krascheninnikovia lanata*, 8.V.1995, G. Marson (H.B. 6085g ø).

Orbilia sonorensis Baral & G. Marson, **sp. nov.**, MB 813695 — Pls 671–672, Map 110

Etymology: named after the Sonoran Desert in which the species was repeatedly found.

Typification: USA, California, branches of *Atriplex confertifolia*, 23.VI.2000, G. Marson (ex H.B. 6721b, M-0276505, holotype; ex-type culture: CBS 116222; sq.: KT215242).

Latin diagnosis: *Similis* Orbiliae cactacearum *sed ascosporae latiores. Habitat ad lignum siccum valde putridum fruticum in zona temperata ad tropica (semi) arida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.12–)0.2–0.4(–0.6) mm diam., 0.12–0.15 mm high, pale to bright (greyish- or yellowish-)orange, non-translucent, round to broadly elliptical, subgregarious; disc flat, margin distinct, 10–15 µm protruding, rough, with or without irregular teeth; broadly sessile, distinctly erumpent between fibres (half to entirely immersed). **Asci** *(57–)60–75(–84) × (6.8–)7.2–8.5(–8.8) µm {7}, †50–68 × 6.8–7.8 µm {3}, 8-spored, spores *(1–)2(–3)-seriate, 2–4(–6) lower spores inverted {4} (often mixed), pars sporifera *35 µm long (†37–44 µm); **apex** (†) medium to strongly truncate (sometimes slightly indented, laterally distinctly inflated or not); **base** with very short to medium long, thick, flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(8–)8.5–12(–12.8) × (3.2–)3.5–4.3(–4.8) µm {7}, †8–11 × 3.5–4 µm {3}, ellipsoid to fusoid or fusoid-clavate, ± amygdaliform, apex obtuse (to subacute), rarely rounded, base not or slightly, sometimes medium attenuated, straight to slightly inequilateral, base rarely slightly curved; **SBs** *(5–)6–7(–8.5) × 0.8–1.2 µm in situ {2} (~5.5–8.5 µm actual length), vermiform to subulate, base slightly to strongly inflated, slightly to medium flexuous; aged spores *7.5–11 × 3.7–4.3 µm, SBs 1.7–2.5 × 1.3–1.4 µm. **Paraphyses** apically slightly to strongly clavate-capitate, often moniliform, terminal cells *(3.5–)5–12(–15) × (2.5–)3.5–5(–5.5)((–7.5)) µm {3}, lower cells *5–10(–15) × 1.7–2.3 µm {1} (subapical cells often 3–4.5 µm wide); frequently branched at upper septum. **Medullary excipulum** hyaline, 15–40 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** hyaline, of (†) slightly gelatinized, ± vertically oriented t. angularis from base to submargin, 30–45 µm thick near base, cells *10–20 × 8–13 µm {1}, †8–13 × 6–8.5 µm {1}; 15 µm thick near margin, of t. prismatica-porrecta oriented at a 20–30° angle to the surface, marginal cortical cells *6–8 × 3.5–4 µm {1}. **Anchoring hyphae** abundant, †2–3 µm wide, walls 0.1–0.5 µm thick {1}, covering flanks and margin as a ± thick layer. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 0.6–1.2 µm diam., and rod- or ring-shaped {5}, hyaline. **Exudate** over paraphyses 0.2–0.5 µm thick, finely rough, continuous, firmly attached. **— ANAMORPH**: trinacrium-like (from ascospore isolate and natural substrate {1}). **Conidiophores** not seen. **Conidia** Y-shaped, total size †23–25 × 19–26 µm, stipe †13–15 × 5–5.5 µm, 1–2-septate, arms tapering, †10–14 × 4–5 µm, 1–2-septate {1}.

H.B. 5658e: ibid., on *Larrea*.

Map 110. Known distribution of *O. sonorensis* in North America (yellow = not included collection).

Habitat: partially to entirely decorticated, 10–25 mm thick branches of *Atriplex confertifolia* {1}, ?*Chrysothamnus* sp. {1}, *Ephedra* ?*viridis* {1}, *Larrea tridentata* {4}, indet. angiosperm shrub {1}, on 0.2–1 mm deep strongly decayed wood {6}, very greyed, no algae. **Associated**: ?*Baggea* sp. {1}, *Carestiella schizoxyloides* {1/1}, *Hysterobrevium mori* {2}, *Hysteropatella* sp. {1}, *H. oregana* {1}, *Melaspilea emergens* {1}, *Odontura rhaphidospora* {1}, *Orbilia* ?*breviclava* {1}, *O. calyptrata* {2}, *O. cryptogena* {1}, *O.* ?*flexisoma* {1}, *O. lacrimispora* {1}, *O. lentiformis* {2}, *O. macrohesperidea* {1}, *O. macroserpens* {1}, *O. maeandrina* {2}, *O. multigambelii* {1}, *O.* ?*multiphanosoma* {1}, *O. multiserpens* {1}, *O. multiurosperma* {1}, *O. myriourosperma* {1}, *O.* ?*navajoana* {2}, *O. pleiocreosoteris* {1}, *O.* ?*pleionavajoana* {1}, *O. pluristomachia* {1}, *O. sedonensis* {1}, *O. vermiculati* {1}, *Patellaria* '*andina*' {1}, ?*Schizoxylon* sp. {1}, ?*Teichospora* sp. {1}, *Symbiotaphrina larreae* {3}. **Desiccation tolerance**: a few nearly mature asci still viable after 28 months. **Altitude**: 250–960 m a.s.l. **Geology**: Mississippian & Permian sand-, mud- & limestone; Oligocene felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia sonorensis* is characterized by rather large, ellipsoid to fusoid ascospores with medium long, vermiform-subulate spore bodies and by the presence of crystalloid SCBs. *O. cactacearum* differs in narrower spores with more rounded apices and more strongly tapered and curved bases. *O. bicknellensis* has narrower spores with acute apices. The European *O. cylindrosoma* has much narrower spores and lacks crystalloid SCBs.

Variation. The spores of *O. sonorensis* vary somewhat in shape between ellipsoid and fusoid-clavate, also the SBs vary in the strength of their basal inflation.

Not included collection. A montane sample on *Juglans* (Pl. 671: 3) differed in lacking crystalloid SCBs and the deviating substrate.

Anamorph. A few trinacrium robustum-like conidia were obtained in pure culture of the holotype, but were not documented. They concurred with those found on the natural substrate in the same collection (Pl. 671: 2e).

Phylogeny. A sequence taken from the ex-type culture comprises SSU (without S1506 intron), ITS, and LSU. It clustered in our ITS and combined analyses medium supported with *O. multimaeandrina* (Phyls 19–20), though with rather high distance in both ITS (9%) and LSU D1–D2 (2.4%). The lowest LSU distance was 1.7% to *O. carpoboloides*, but here the ITS distance is 15%.

Ecology. *O. sonorensis* was collected on strongly rotten wood of different angiosperm shrubs in subtropical semiarid (to arid) Sonoran paloverde-mixed cacti and warm-temperate arid Mojave creosotebush and saltbush desert scrubs in western North America. The not included collection on *Juglans* was in a riparian grove in the warm-temperate semiarid Chihuahuan Desert.

Specimens included. **USA**: **California**, Mojave Desert, 130 km NNE of Los Angeles, 14 km NW of California City, 830 m, branches of *Atriplex confertifolia*, on wood, 23.VI.2000, G. Marson (M-0276505, **holotype**; **isotype** in H.B. 6721b;

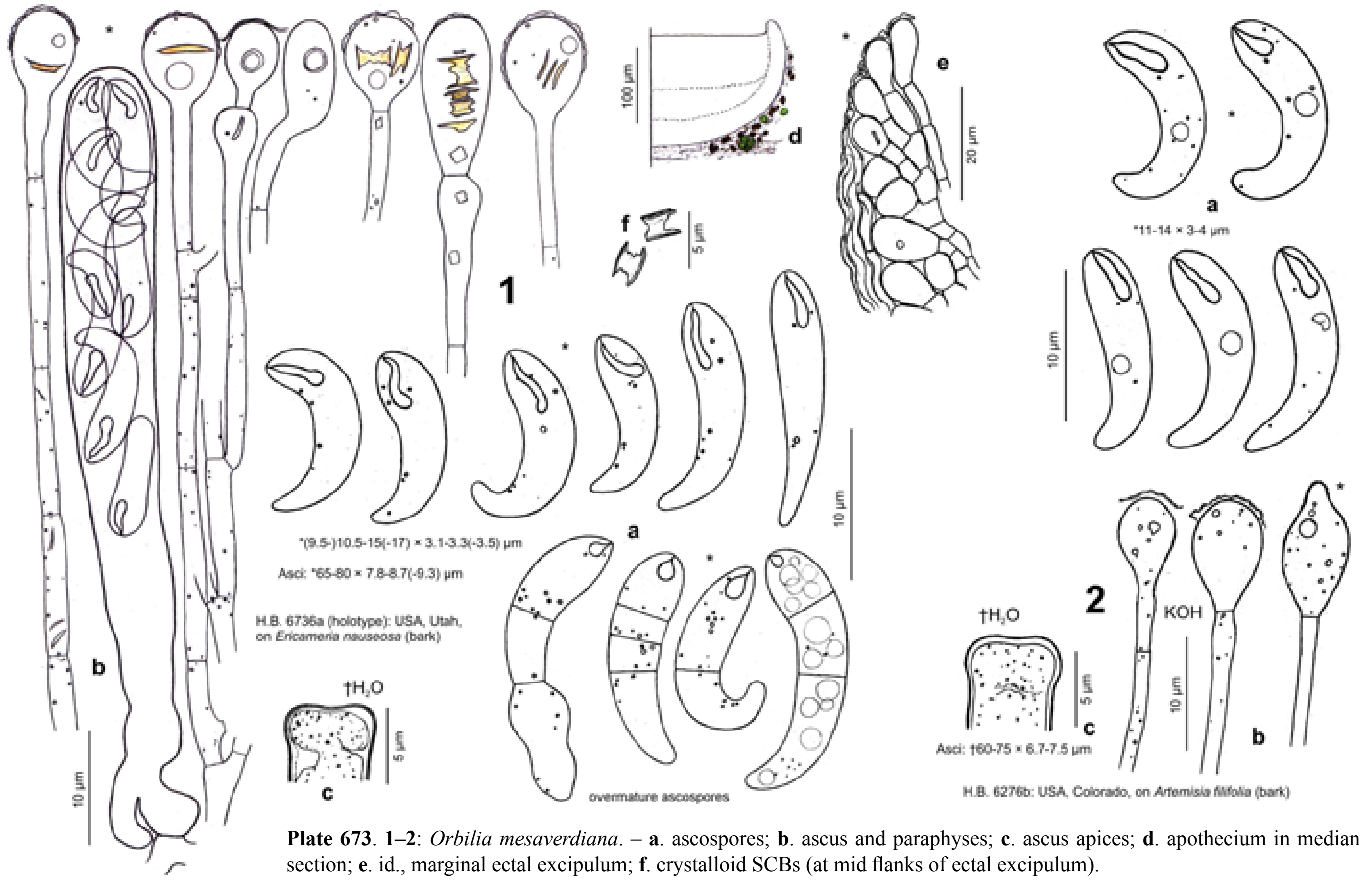

Plate 673. **1–2**: *Orbilia mesaverdiana*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs (at mid flanks of ectal excipulum).

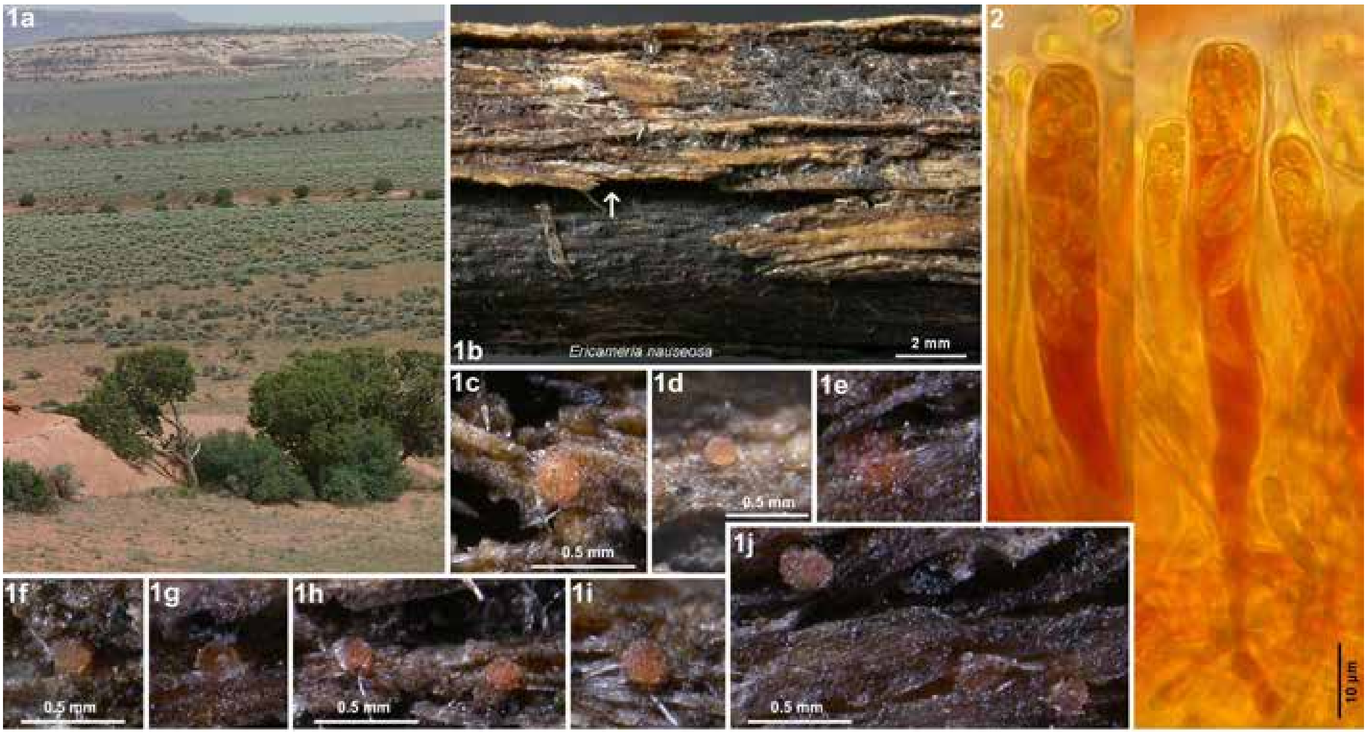

Plate 674. **1–2**: *Orbilia mesaverdiana*. – **1a**. semiarid sagebrush scrub (*Artemisia* spp.), ?*Pinus edulis* in foreground, not far from site with *Ericameria nauseosa*; **1b**. dead corticated xeric branch of *Ericameria*; **1c–j**. rehydrated apothecia; **2**. asci and paraphyses (in KOH+IKI). — **1a–j**. Marson (H.B. 8477c). – 30 km SE of Las Vegas, 7 km W of Boulder, Railroad Pass, 675 m, branch of *Larrea tridentata*, on wood, 8.VI.2000, G. Marson (H.B. 10117b) – **Arizona**, Sonoran Desert, 82 km NW of Phoenix, ~1.5 km SE of Wickenburg, 615 m, branch of indet. angiosperm, on wood, 4.V.1995, G. Marson (H.B. 8579c). – ibid., branch of *Larrea tridentata*, on wood, 4.V.1995, G. Marson (H.B. 5658e). – ibid., branch of *Ephedra* ?*viridis*, on wood, 4.V.1995, G. Marson (H.B. 5894d). – ~5 km SSW of Gila Bend, 250 m, of ?*Chrysothamnus*, 5.V.1995, G. Marson (ø). – 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branch of *Larrea tridentata*, 5.V.1995, G. Marson (H.B. 5687h ø).

Not included. **USA**: **New Mexico**, Chihuahuan Desert, 30 km SW of Carlsbad, ~4 km NW of Whites City, ~3 km NE of Carlsbad Caverns, 1200 m, branch of *Juglans major*, on bark, 24.V.1996, G. Marson (H.B. 5673e ø).

Orbilia mesaverdiana Baral & G. Marson, **sp. nov.**, MB 813696 — Pls 673–674

Etymology: named after the locality of the first studied specimen, Mesa Verde (Colorado).

Typification: USA, Utah, Hatch Rock, branches of *Ericameria nauseosa*, 16.VI.2000, G. Marson (ex H.B. 6736a, M-0276511, holotype; ex-type culture: CBS 140804; sq.: KT215247, MH878179).

Latin diagnosis: *Asci octospori*, *ascosporae *9.5–17 × 3–4 µm*, *clavatae*, *valde arcuatae*, *apice rotundatae vel obtusae*, *in statu vivo corpusculum refringens breviter vermiforme continentes*, *paraphyses vivae valde capitatae*, *corpuscula crystalloidea continentes. Habitat ad corticem putridum ramorum siccorum fruticum* Artemisiae *et* Ericameriae *in zona temperata subhumida ad semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.4(–0.5) mm diam., 0.12–0.16 mm high, light to bright pure orange, round, very scattered; disc slightly concave to flat, margin thin, 0–20 µm protruding, smooth to very finely crenulate; sessile, slightly to strongly immersed. **Asci** *65–80 × 7.8–9.6 µm {2}, †60–75 × 6.7–8.5(–9.2) µm {2}, 8-spored, spores (*) biseriate, (2–)3–5 lower spores inverted {3} (very rarely mixed), pars sporifera *31–41(–55) µm long, †(26–)32–37 µm; **apex** (†) strongly truncate (distinctly indented, laterally inflated); **base** with short and thick, or long, thin and flexuous stalk, L- or h-shaped. **Ascospores** *(9.5–)10.5–15(–17) × 3–3.5(–4) µm {2}, †(8–)10–13.5(–14) × 2.7–3.3(–3.5) µm {3}, (cylindric-)clavate, apex rounded to obtuse (rarely subacute), base medium to strongly attenuated, (slightly to) medium to very strongly curved (falcate, partly mainly curved near base); **SBs** *3–4.8 × 0.7–1.2 µm {2}, rod-shaped to subulate or narrowly tear- to pear-shaped, straight or sometimes ± flexuous; aged spores with 1–3 septa, SBs 1.7–2.5 × 1.5 µm, broadly tear-shaped to subglobose. **Paraphyses** apically strongly to very strongly capitate(-clavate), rarely spathulate, terminal cells *7–21 × (3–)4–7.3 µm {1}, †3.5–6.2 µm wide {2}, lower cells *12–17 × 1.5–2.2 µm {1}; sometimes branched at upper septum. **Medullary excipulum** very pale rose, 50 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose, of thin-walled, vertically oriented t. angularis-prismatica from base to submargin, 35 µm thick near base, cells *10–16 × 7–9 µm {1}; 15–25 µm thick near margin, oriented at a 30–45° angle to the surface, marginal cortical cells *8–12 × 5–8 µm {1}. **Anchoring hyphae** medium abundant, */†2–3.5 µm wide, walls 0.2–0.3 µm thick {1}, forming a thin hyaline layer of dead hyphae up to submargin. **SCBs** in paraphyses and ectal excipulum (near margin) globose and mainly rod- or ring-shaped, hyaline to pale orange {2}, 2–5 µm diam. **Exudate** over paraphyses and marginal excipulum 0.2–1 µm thick, rough. **— ANAMORPH**: unknown.

Habitat: collected 0.1–0.6 m above the ground, corticated, 6–20 mm thick branches of *Artemisia filifolia* {1}, *A. tridentata* {2}, *Ericameria nauseosa* {1}, on strongly decayed, loosely attached bark {3} (periderm and bast), greyed, with many green algae. **Associated**: *Orbilia delphinus* {1}, *O. dixienis* {2}, *O. lentiformis* {1}, *O. multimaeandrina* {1}, *O. multiphanosoma* {1}, *O. multitrapezoidea* {1}, *O. myriophanosoma* {1}, *O. ocellata* {2}, *O. plurilentiformis* {2}, *O. spathulata* {2}, *O. subsiculispora* {1}, *Schizoxylon* ?*argentinum* {1}. **Desiccation tolerance**: fully viable for at least 1.5 months, a few ascospores and paraphyses viable for 29 months. **Altitude**: 1700–2290 m a.s.l. **Geology**: Triassic to Upper Cretaceous (red) sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia mesaverdiana* is easily recognized by its large, clavate, strongly curved (falcate) ascospores. It differs from *O. quaestiformis* in the presence of crystalloid SCBs and in the spores which are partly curved also in their upper part, finally in rather wide spore bodies. Contrary to *O. quaestiformis*, in which only rarely 1-septate overmature spores were seen (Pl. 678: 1), those of *O. mesaverdiana* got 1–3 septa when incubated at the lid of a Petri dish. *O. pleiomesaverdiana* differs in 16-spored asci and subacute spore apices.

Variation. Spore curvature varies rather considerably in *O. mesaverdiana* in all three collections for which spore measurements were taken. The typical spores when seen in profile view are strongly curved as a whole, but some were rather straight, especially in their upper part. Spores with subacute apices were only exceptionally observed.

Phylogeny. A sequence taken from pure culture of the holotype comprises SSU (with S1506 intron), ITS, and LSU. *O. mesaverdiana* clustered in a strongly supported clade with *O. serpentina*, *O. octoserpentina*, *O. halimi*, and *O. vermiculati* when analysing SSU+ITS+LSU (Phyl. 20). It shows a rather high difference in the ITS region to members of the *Serpentinae*-*Habrostictis* clade, the lowest percentage being 10% to *O. halimi* and *O. vermiculati* (1.6–1.8% in LSU). In the LSU the minimum distance is 1% to *O. flavidorosella*, though 19.5% in the ITS.

Ecology. *O. mesaverdiana* inhabits rotten bark of xeric branches of angiosperm shrubs in the cold-temperate to warm-continental subhumid to semiarid sagebrush and saltbush desert scrubs in the Colorado Plateau of western North America.

Specimens included. **USA**: **Utah**, Canyonlands, 60 km NW of Page, Cottonwood Canyon, ~1700 m, branch of *Artemisia tridentata*, on bark, 25.VIII.1994, G. Marson (H.B. 5197b ø). – 36 km S of Moab, Canyonlands, 5 km WNW of Hatch Rock, 1813 m, branches of *Ericameria nauseosa*, on bark, 16.VI.2000, G. Marson (M-0276511, **holotype**; **isotype** in H.B. 6736a, CBS 140804; sq.: KT215247, MH878179). – 16 km WNW of Blanding, 1795 m, branch of *Artemisia tridentata*, 14.V.1995, G. Marson (ø). – **Colorado**, Canyonlands, 15.5 km SSE of Cortez, Mesa Verde, 5 km NNW of Spruce Tree House, 2290 m, branch of *A. filifolia*, on bark, 31.V.1996, G. Marson (H.B. 6276b).

Orbilia pleiomesaverdiana Baral & G. Marson, **sp. nov.**, MB 813697 — Pls 675–676

Etymology: named after the 16-spored asci and the resemblance to *O. mesaverdiana*

Typification: USA, Arizona, Wikieup, branches of ?*Chrysothamnus*, 3.V.1995, G. Marson (ex H.B. 5716a, M-0276560, holotype).

Latin diagnosis: *Similis* Orbiliae mesaverdianae *sed asci 16-spori, ascosporae apice subacutae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.45(–0.6) mm diam., 0.18–0.25 mm high, (light to) bright orange(-red), scarcely translucent, round, somewhat gelatinous, very scattered to subgregarious; disc slightly concave to flat, margin distinct, 20–60 µm protruding, ± smooth; broadly sessile, slightly to half immersed (erumpent); dry bright to deep orange-red. **Asci** *(69–)80–95(–102) × 7.5–9(–9.5) µm {2}, †(66–)75–100(–110) × (6–)6.5–8(–8.7) µm {2}, 16-spored, spores *3–4-seriate, 7–9 lower spores inverted {2} (slightly to strongly mixed), pars sporifera *45–50 µm long (†50–60 µm); **apex** (†) medium to strongly truncate (partly distinctly indented, laterally distinctly inflated or not); **base** with short to long, thin or thick, flexuous stalk, T-, L- or Y-shaped. **Ascospores**

*(10–)11–14(–16.5) × (2.5–)2.8–3.2(–3.5) µm {2}, †9–13.5 × 3–3.3 µm {1}, fusoid-clavate, apex subacute (to acute), base medium to often strongly attenuated in a tail-like end or short tail, medium to strongly curved mainly near base; **SBs** *3.5–5.5(–6) × 0.8–1.2 µm {2}, (rod-shaped to) subulate, sometimes narrowly pyriform, straight to somewhat flexuous. **Paraphyses** apically medium to very strongly (clavate-)capitate, sometimes spathulate to lageniform, terminal cells *8–22 × (2–)3.7–6 µm {T}, †8–14 × (3–)4.3–7.7 µm {1}, lower cells *11–18 × 1.3–1.8(–2.4) µm {T}, †10–18 × 1.2–1.5(–2.5) µm {1} (basal cells †5–10 × 2–2.3 µm); not or rarely, sometimes frequently branched at upper septum. **Medullary excipulum** 60–100 µm thick, of loose textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, indistinctly oriented t. angularis from base to submargin, 40–60 µm thick near base, cells *7–16 × 8–10 µm {1}; 20 µm thick near margin, upper part of t. prismatica-porrecta oriented parallel to the surface, marginal cortical cells †8–10 × 2.5–3.5 µm {1}. **Anchoring hyphae** medium abundant, */†2–4 µm wide, walls 0.2–0.6 µm thick {2}, somewhat gelatinized, sometimes forming a t. prismatica near basal excipulum, hyphae covering receptacle up to margin. **SCBs** in paraphyses and ectal excipulum (near margin) sometimes globose, mainly crystalloid, rod- or rectangular {2}, ?hyaline. **Exudate** over paraphyses 0.2–0.7 µm thick, granular-cloddy, loosely attached, also absent; over margin 0.2–1 µm thick, granular, sparse. **— ANAMORPH**: unknown.

Habitat: collected 1.5–2.5 m above the ground, corticated to decorticated, 3.5–9 mm thick twigs and branches of *Koeberlinia spinosa* {1}, ?*Chrysothamnus* {T}, on 0.2–0.3 mm deep slightly to strongly decayed wood {1} or bark {T}, slightly to strongly greyed, no algae. **Associated**: *Helicogermslita celastri* {1}, *Orbilia lentiformis* {1}, *O. myriourosperma* {1}, *O.* ?*pleiomesaverdiana* {1}, *Symbiotaphrina desertorum* {1}. **Desiccation tolerance**: many mature asci still viable after 20 months. **Altitude**: 600–915 m a.s.l. **Geology**: Quaternary sand, silt & clay sediments. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiomesaverdiana* differs from *O. serpentina* in somewhat longer, more strongly curved ascospores with less acute apices and partly distinct tails, also in shorter spore bodies. *O. pleiourosperma* differs in spores with acute apices and abruptly narrowed and geniculate tails, also in longer SBs.

Variation. The collection on *Koeberlinia* (Pl. 675: 2) is only tentatively included. It differs from the holotype in slightly narrower asci and spores, less curved spores, and in growing on wood.

Not included collections. Three samples (Pls 675: 3–4; 676: 3, IVV: H.B. 5716d, 8476a/b) differ in slightly shorter and wider spores with partly more rounded apices and much less tapered bases, also in a tendency to longer SBs. One of them grew in association with the type of *O. pleiomesaverdiana*. These collections appear to represent a separate species which differs from *O. pleiomesaverdiana* and *O. serpentina* in predominantly ± obtuse spore apices, from the latter also in often curved spore bases.

Ecology. *O. pleiomesaverdiana* was found on slightly to strongly rotten xeric wood and bark of warm-temperate semiarid Chihuahuan creosotebush-tarbush and subtropical arid Sonoran paloverde-mixed cacti desert scrub in the southwest of Northern America. The holotype location is a broad dry riverbed with a dense scrub of *Larrea tridentata*, *Chrysothamnus* (or *Ericameria*) and *Cylindropuntia versicolor*, surrounded by an area of very scattered shrubs. The not included collections were on similar substrates and habitats.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 200 km NW of Phoenix, Wikieup, ~600 m, branches of ?*Chrysothamnus*, on bark, 3.V.1995, G. Marson (ex H.B. 5716a, M-0276560, **holotype**). – **New Mexico**, Chihuahuan Desert, 25.5 km SE of Carlsbad, Malaga, 915 m, branches of *Koeberlinia spinosa*, on wood, 17.VI.1996, G. Marson (H.B. 6019a).

Not included. **USA**: **Nevada**, Mojave Desert, 6 km SW of Beatty, 2.6 km SSE of Rhyolite, E of Death Valley, S of Ladd Mt., 1030 m, branch of *Atriplex*, on wood, 2.V.1995, G. Marson (H.B. 8676a). – **Arizona**, Sonoran Desert, 200 km NW of Phoenix, Wikieup, ~600 m, branch of ?*Chrysothamnus*, on wood, 3.V.1995, G. corpuscula globosa continentes. Habitat ad lignum siccum putridum, etiam corticem ramorum fruticum vel arborum angiospermarum, raro coniferarum, saepe ad caules siccos putridos, in zona hemiboreale et temperata humida vel submediterranea semihumida, atlantica ad continentali Europae.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.45(–0.6) mm diam., 0.09–0.16 mm high, pale to light rose-orange, not or medium translucent, round to broadly elliptical, very scattered to medium gregarious; disc slightly concave to flat, finally often slightly (to strongly) convex, margin indistinct to distinct, thin or thick, 0–20 µm protruding, smooth or finely crenulate; broadly sessile, superficial or mostly erumpent from beneath epidermis or outer layers of wood or bark, often immersed in biofilm; dry light to bright orange-red. **Asci** *45–65(–73) × (5.2–)5.5–7.2(–7.7) µm {13} → 80 × 7–7.5 µm, †(40–)45–55(–63)((–70)) × (4.5–)5–5.7(–6) µm {8}, 8-spored, spores *2–3-seriate, (2–)3–5(–6) lower spores inverted {17} (not or sometimes mixed), pars sporifera *(22–)25–35(–42) µm long (†32–39 µm); **apex** (†) (slightly to) medium to strongly truncate (not or very slightly indented, laterally not widened); **base** without or with short to long, ± thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(6.7–)8–9(–11) {3} or mostly *((8–))9–13(–14.5)((–16)) {31} × ((2–))2.3–3(–3.3) ((–3.7)) µm {24}, †8.5–12.5 × 2–2.8 µm {2}, strongly clavate (to fusoid-clavate), apex rounded to obtuse, towards base medium to mostly strongly attenuated (tail-like, rarely with a distinct tail), slightly to strongly curved near base; non-septate within living asci, rarely turning 1-septate when overmature {2}, *14–15.3(–17) × 3.2–3.5(–3.7) µm, germinating *3.8–4.5 µm wide; **SBs** *(3–)4–6(–7)((–8.2)) × 0.2–0.4(–0.6) µm in situ {16} [~4–7(–8)((–9.5)) µm actual length], filiform to vermiform, often subulate, base never inflated, slightly to strongly flexuous or helicoid, sometimes or often uncinate; immature spores with 1–3 LBs of 0.3–1 µm diam. {7}. **Paraphyses** apically (slightly to) medium to (very) strongly capitate(-clavate), rarely moniliform, terminal cells *(6.5–)8–17(–21) × (2–)3–5(–5.3) µm {6}, †2.5–4.3 µm wide {1}, lower cells *6–13(–17) × 1.2–2(–2.3) µm {4} (near base or apex sometimes 3–4.5 µm wide); unbranched or often branched near apex, hymenium pale rose. **Medullary excipulum** pale rose, 20–50 µm thick, of ± dense textura intricata with a few to many indistinct to strongly inflated cells, very indistinctly delimited from ectal excipulum near base, ± sharply at flanks. **Ectal excipulum** pale rose, of thin-walled, indistinctly or horizontally oriented t. angularis-prismatica from base to margin, 25–45(–60) µm thick near base, cells *6–13(–16) × (4–)5–11(–

16) µm {6}; 15–30 µm thick at mid flanks and margin, oriented near margin at a 10–45° angle to the surface, marginal cortical cells *(4–)6–12(–15) × (2.5–)3–6(–8) µm {6}; thin-walled or sometimes slightly gelatinized [walls †0.2–0.5(–1.2) µm], partly agglutinated to form minute squamules. **Anchoring hyphae** sparse or often abundant, partly forming projecting strands of agglutinated hyphae near base, *1.8–3.5 µm wide, walls 0.2–0.3(–0.4) µm thick {5}, sometimes forming a thin hyaline layer of dead hyphae covering flanks and margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose {23}, 1–2.8 µm diam., rarely entirely lacking {3}. **Exudate** over paraphyses 0.2–1.2(–2.5) µm thick, rough-cloddy, firmly attached; over margin 0.3–2.5 µm thick, rough-cloddy. — **ANAMORPH**: tridentaria-like (from ascospore isolate {2} and natural substrate {8}). **Conidiophores** short. **Conidia** with (2–)**3**–4(–5) arms, total size *32–59.5 × (32–)50–70(–83) µm {5}, stipe *(10–)12.5–23 × 2–4.4 µm, 1–2(–3)-septate (if 1-septate then septum often close to the branching point), arms gradually tapering or cylindrical and only terminally tapering, *18–44 × 2.5–4(–4.7) µm, 2–5-septate, constricted and movable at the base.

Habitat: collected 0–3 m above the ground, corticated to decorticated, 6–80 mm thick twigs and branches of *Acacia* sp. {1}, *Acer pseudoplatanus* {2}, *Clematis vitalba* {1}, *Cytisus scoparius* {3}, *Lonicera periclymenum* {1}, *Picea abies* {1}, *Pinus pinaster* {1}, *Populus tremula* {1}, *Quercus robur* {1}, *Rosa canina* {1}, *Rhus typhina* {1}, *Robinia pseudoacacia* {2}, *Rosa* sp. {1}, *Salix* sp. {5}, *S. alba* {1}, *S.* (?)*caprea* {1}, *Sambucus nigra* {2}, *S. racemosa* {1}, *Tamarix ramosissima* {1}, *Ulmus minor* {1}, *Viburnum lantana* {1}, on 0.1–1 mm deep (medium to) strongly decayed wood {29}, rarely bark {5} (bast), exceptionally on resin, sometimes in beetle galleries; also on stems of *Rubus armeniacus* {1}, *R. fruticosus* agg. {3}, 1–2 years old herbaceous, sometimes inflorescence stems or culms, rarely leaves, of *Ammophila arenaria* {3}, *Apiaceae* {1/1}, *Atropa belladonna* {1}, *Digitalis purpurea* {1}, *Echinops sphaerocephalus* {3}, *Epilobium ?angustifolium* {1}, *Foeniculum vulgare* {1}, *F. vulgare* subsp. *piperitum* {1}, *H. sphondylium* {4}, *Melilotus* sp. {4/2}, *M. albus* {3}, *Phragmites australis* {1}, *Pooideae* {2}, *Reynoutria* sp. {1}, *R. japonica* {1}, *Senecio* sp. {1}, *Tanacetum vulgare* {2}, *Typha* sp. {3}, *T.* (?)*latifolia* {1}, *Verbascum densiflorum* {1}, *Yucca* sp. {4} ± obliquely standing or lying on dry ground, exceptionally on textile (rope) {1} or dung of *Equus caballus* {1}; sometimes eroded, strongly greyed or not, very few to many green algae. **Associated**: *Bulbillomyces* sp. {1}, *Capronia ?pilosella* {1}, *Cistella grevillei* {1}, *Cyathicula cacaliae* {1}, *C. cyathoidea* {2/1}, *Diaporthe* sp. {1}, *D. arctii* {1}, *Durella connivens* {1}, *Eutypa maura* {1}, *Hyalorbilia erythrostigma* {1}, *H. fusispora* {1}, *H. latispora* {1}, *Hydropisphaera arenula* {1}, *Lachnella alboviolascens* {1}, *L. ?villosa* {1}, *Lophodermium arundinaceum* {1}, *Mollisia ligni* {1}, *M. ?prunicola* {1}, *Mollisina rubi* {1}, *Neodasyscypha cerina* {1}, *Olla millepunctata* {1}, *O. scrupulosa* {1}, *Orbilia aristata* {2}, *O. caulicola* {8}, *O. cylindrosoma* {1}, *O. eucalypti* {2}, *O. euonymi* {1}, *O. filiformis* {2}, *O. flavida* {12}, *O. flavidorosella* {4}, *O. gambelii* {1}, *O. ?obtusispora* {1}, *O. pilifera* {1}, *O. septispora* {3}, *O. subclavuliformis* {2}, *O. trapeziformis* {1/2}, *O. ungulata* {2}, *O. vitalbae* {6}, *Patellaria atrata* {4}, *Phoma* sp. {2}, *Phyllactinia guttata* {1}, *Physcia* sp. {4}, *Pirottaea* sp. {1}, *Propolis farinosa* {2}, *Pseudolachnea hispidula* {1}, *Pyrenopeziza* sp. {1}, *P. ?escharodes* {1}, *Ramichloridium ?schulzeri* {1}, *?Stictis* sp. {1}, *Stereum sanguinolentum* {1}, *Trichopeziza lizonii* {1}, *Unguiculariopsis ilicincola* {2}, *Urceolella ?pani* {1}, *Xanthoria parietina* {4}, crustose lichens. **Desiccation tolerance**: fully viable for at least 3 weeks. **Altitude**: 1–620 m a.s.l. **Geolog**: Ordovician, Devonian & Permian siltstone & schist, Rotliegend, Muschelkalk, Keuper (Gipskeuper, Rhätsandstein), Lower Jurassic sandstone & shale, Minette, Cretaceous & Tertiary lime-, clay-, sand- & marlstone, tuff, Pleistocene loess, sand; granite, gneiss & migmatite. **Phenology**: throughout the year (long-lived).

Phenology of *O. quaestiformis*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
1	1	5	7	7	14	11	6	6	11	7	3

Taxonomic remarks. *Orbilia quaestiformis* is characterized by clavate, comma-shaped ascospores with rounded to obtuse apices and strongly attenuated, slightly to strongly curved bases, further by rather narrow, filiform to vermiform, basally not inflated, flexuous spore bodies which are sometimes uncinate like a question mark, finally by the tridentaria-like anamorph.

O. quaestiformis resembles *O. septispora* concerning both teleomorph and anamorph features. The ascospores of the two species have a similar shape, but spores and asci of *O. septispora* are somewhat larger, and a majority of spores 1(–2)-septate while still inside the living asci, whereas in the many studied collections of *O. quaestiformis* septate spores have almost never been observed, and never inside living asci. The spores of *O. quaestiformis* contain longer and thinner SBs, also smaller and fewer LBs. Concerning substrate preferences both species inhabit a very wide range of hosts, but with the difference that most of the records of *O. septispora* were on *Phragmites*.

Also *O. quercus-ilicis*, a foliicolous eumediterranean species, is very similar to *O. quaestiformis*. It differs in shorter, more fusoid-clavate spores, spore bodies which are partly even longer than in *O. quaestiformis*, and in the tridentaria-like conidia having shorter arms. The North American *O. coniferarum* differs from *O. quaestiformis* in slightly shorter spores with less tapered and curved bases, partly slightly longer spore bodies, and in the occurrence on coniferous substrates. Its presumed tridentaria-like anamorph has mostly 4, much thicker, more upwards oriented arms. The North American *O. vermiculati* has spores very similar to *O. quaestiformis* but differs in 16-spored asci, thicker SBs, and a trinacrium-like anamorph. *O. mesaverdiana* deviates in the spores being more strongly curved as a whole, and in the presence of crystalloid SCBs. *O. rosicola* (Pl. 692) differs in rather short spores with distinct tails, and in the presence of crystalloid along with globose SCBs.

An anamorph very similar to that of *O. quaestiformis* was frequently observed in association with *O. filiformis* on the natural substrate. This species has also filiform SBs but differs in narrowly fusiform, less curved spores with acute apices.

Variation. Among the many collections of *O. quaestiformis* studied, variation was especially noted in spore size, which ranges from *9–11.5 µm up to *10–13.5 µm in length (rarely up to 15 µm) and from *2.3–2.5 up to *2.5–3 µm in width, but also in shape and curvature of the spore bases, and in size and curvature of the SBs. In at least two collections (Luxembourg, 21.VII.2008, on *Acer*; Germany, 22.XI.2010, on *Viburnum*) the spores measured only *(6.7–)8–9(–11) × 2.5–2.7 µm, but spore shape and other features suggest that these belong in the scope of *O. quaestiformis*. The texture of the ectal excipulum at the flanks varies between a horizontally oriented textura prismatica or a t. angularis. All this variation did not show a clear correlation with the inhabited host.

A population on a *Salix* pole from Poland seemed to be somewhat intermediate between *O. quaestiformis* and *O. septispora*. When first collected and examined, it showed many septate, partly germinating spores (Pl. 678: 1), though, in contrast to *O. septispora*, the spores within the living asci were always non-septate (Pl. 680: 1l–m). After hanging the branch outside over a year, new apothecia developed in which no septate spores were observed (IVV: H.B. 8232b), and this was also the case in a later collection from the same place in Poland (Pl. 680: 2a). In the latter two populations the non-septate spores had with *(9–)10–13(–15) × 2.8–3 µm the typical size of *O. quaestiformis* and the asci were with *62–73 × 7.3–7.5 µm at the upper end of the

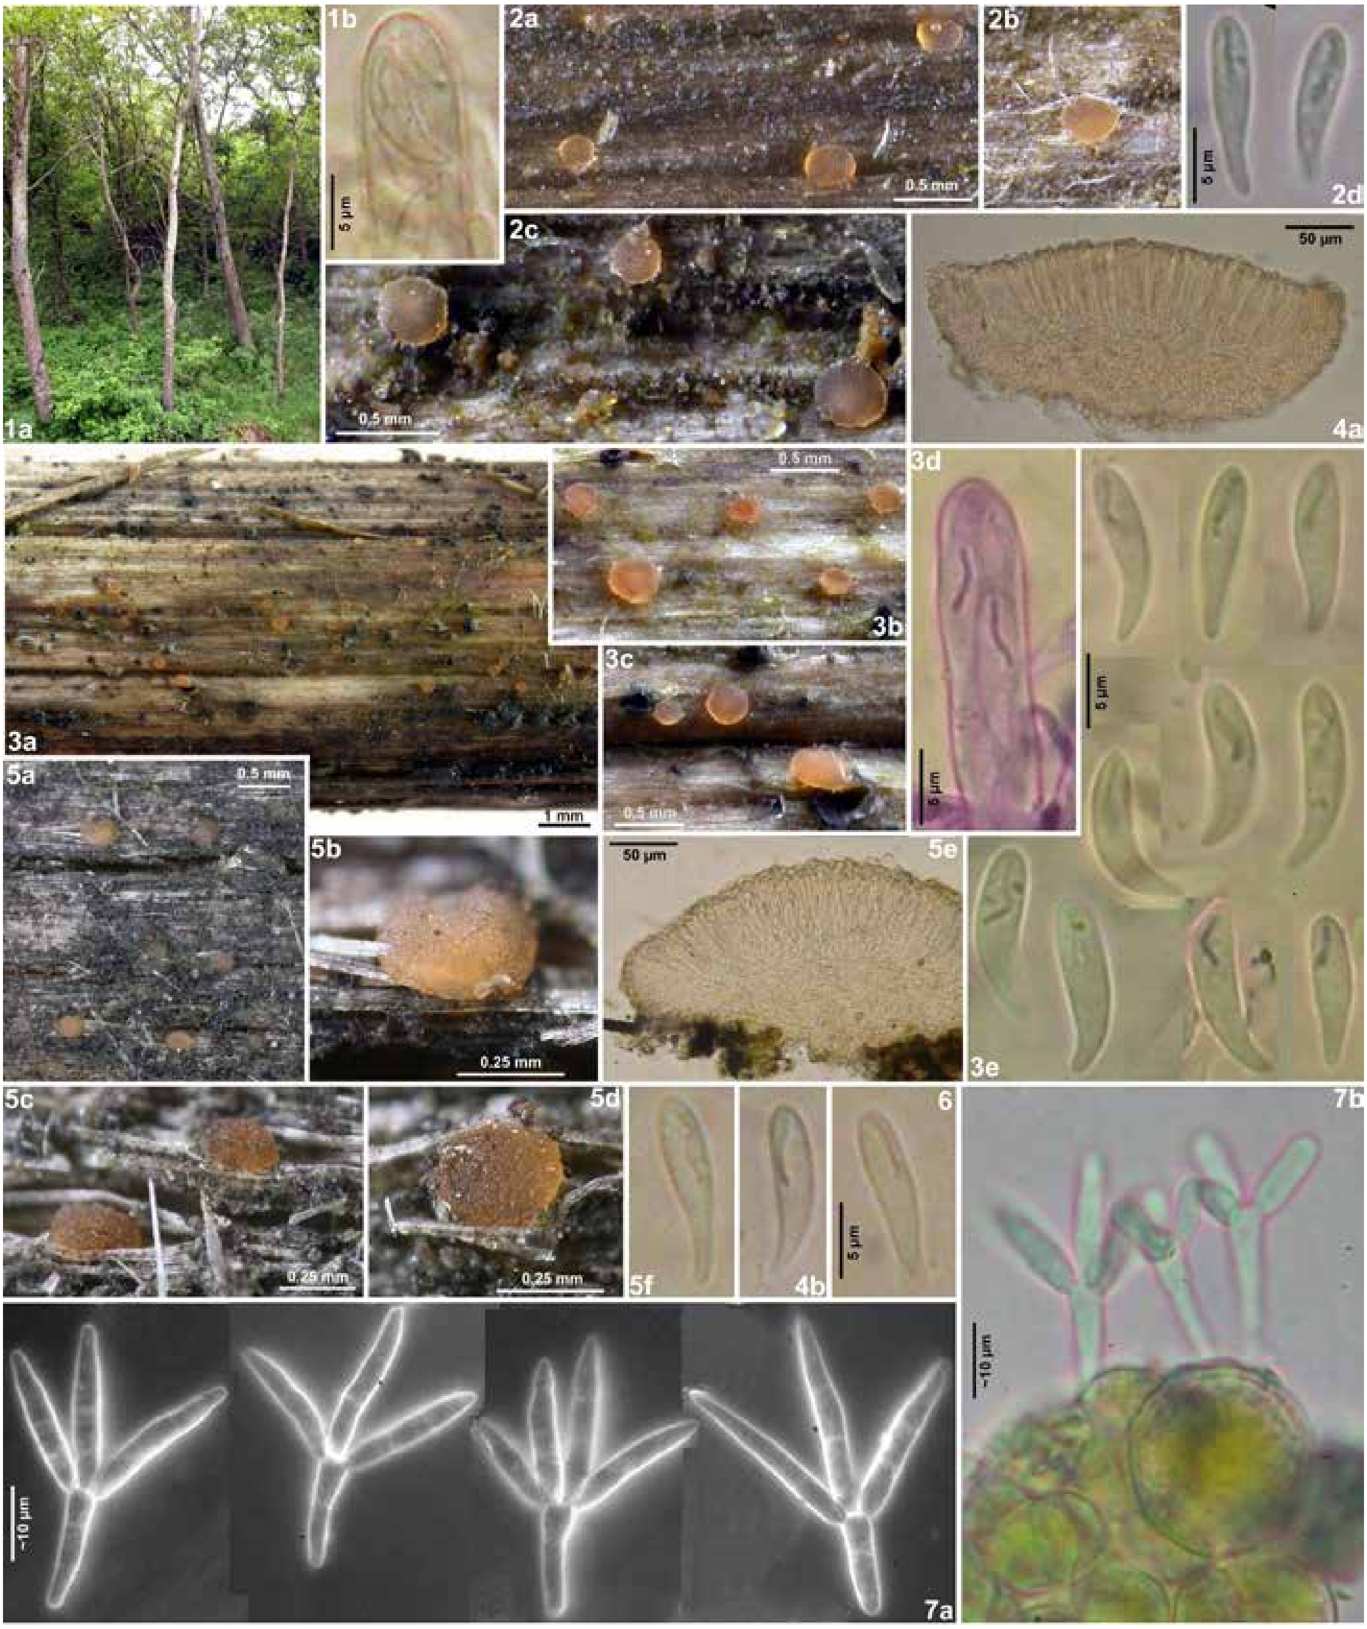

Plate 679. **1–7**: *Orbilia quaestiformis*. – **1a**. range of the typical ascus length, whereas the population with septate spores was intermediate to *O. septispora* in both spore size and ascus width. Also a sparse sample on *Picea* bark at the same site did not differ from typical *O. quaestiformis* (IVV: P.P. 20061028). In all the remaining collections of *O. quaestiformis*, septate spores have never been seen, except for a single spore inside a dead ascus observed by M. Hairaud (pers. comm.) in a sample from Île d'Oléron (27.XI.2010).

Anamorph. The anamorph of *O. quaestiformis* with its mostly 3-armed conidia, which hardly differs from that of

O. septispora, closely resembles *Tridentaria subuliphora* as described from decaying leaves in Australia. However, the arms of *T. subuliphora* are less diverging (see Fig. 21: a), and a strain under this name in CBS 700.93, gained from conifer litter in Europe, clusters in series *Orbilia*. Descals (1997: 461) figured a similar fungus as *Tridentaria* sp., which was isolated from streams in the Catalan Pyrenees and might belong to either *O. quaestiformis* or *O. septispora*. The similar *T. glossopaga* and *T. implicans* are ruled out by their very long conidiophores and, together with the also similar *T. tylota*, in preying on nematodes or rhizopods.

In H.B. 7121 (Pl. 678: 3) masses of conidia were obtained by flooding the culture with water, whereas conidia were only sparsely produced without flooding. Due to motility of the conidial arms at the branching point, the arms move upwards when the preparation is about to dry out and the cover slip exerts pressure on them. The conidia germinate at the tips of arms and stipes and form anastomoses among each other.

The conidia observed on the *Salix* branch (Pls 678: 1c, 680: 1p) differ from typical anamorphs of *O. quaestiformis* and *O. septispora* in having rather short and thick arms. In this character they somewhat resemble the anamorph of *O. coniferarum*.

Map 111. Known distribution of *O. quaestiformis* in Europe.

However, a year later also long-armed conidia were found on this branch along with the short-armed ones (Pl. 680: 1q).

Phylogeny. Sequences of *O. quaestiformis* were taken from two specimens from Luxembourg (H.B. 7121, on *Salix*, ascospore isolate; G.M. 2014-07-25.4, on *Heracleum*, from apothecia) comprising S1506 intron, ITS, and LSU, the former also SSU. They deviate by 0.7 % (4 nt and 1 gap) in the ITS and 0.3 % (2 nt) in the LSU (D1–D2). When analysing ITS or SSU+ITS+LSU, *O. quaestiformis* formed with *O. septispora* a highly supported subclade that stands unresolved in the *Serpentinae-Habrostictis* clade (Phyls 19–20). The distance to this species in the ITS region is only 2.8 %, but 1.9 % in the LSU (D1–D2, 635 nt), which correlates with the result that in the LSU analysis the two species cluster distantly and unresolved (S22).

The S1506 intron of *O. quaestiformis* is much longer in the *Salix* strain (641 nt) than in that on *Heracleum* (~435 nt). The two strains show here an extraordinary distance of 18.5 % in the overlapping region (409 nt but with various gaps). Here *O. septispora* differs by 22 % from the *Heracleum* strain and 25 % from that on *Salix*. When analysing the intron region, the *Heracleum* strain clustered strongly supported with *O. septispora* but the *Salix* strain nested distantly hereof in a medium supported clade which contains members of both series of section *Habrostictis* (S21). All these results raise the question whether *O. quaestiformis* could be a species aggregate.

Ecology. *O. quaestiformis* inhabits a wide range of substrates: rotten wood (rarely bark) of xeric twigs and branches of various angiosperm trees and shrubs, as well as herbaceous stems of various mono- and dicotyledonous perennial plants. two collections were on coniferous hosts. *O. quaestiformis* was recorded in atlantic to continental Europe, mainly in cold- to warm-temperate humid, also meso- (or supra-)submediterranean semihumid, preferably thermophilous western and central Europe. Sometimes it was found in hemi- or thermoboreal northern Europe or in thermomediterranean semihumid southern or warm-continental subhumid steppic eastern Europe. The altitude was planar to colline, rarely submontane. The vegetation includes borders of forests, ruderal places, dry grasslands, hedges and heaths, old quarries, old plantations (*Olea*, *Vitis* etc.), and wetlands (*Salicetum*, *Typhetum*).

Specimens included. **NORWAY**: **Oslo**, 3.5 km NW of Oslo, Marienlyst, Blindern University, 88 m, branch of *Acer pseudoplatanus*, on wood, 13. VIII.2002, G. Orbilia pleioquaestiformis Baral & G. Marson, **sp. nov.**, MB 814374 — Pls 681–682

Etymology: after the 16-spored asci and a strong similarity with *O. quaestiformis*. **Typification**: Western Australia, Perth, Kinross, branch of *Acacia*, 23.X.2007, G. Marson (ex H.B. 8745h, MEL 2389254, holotype).

Latin diagnosis: *Differt ab* Orbilia quaestiformi *ascis 16-sporis. Habitat ad corticem siccum Acaciae in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.28 mm diam., 0.1–0.14 mm high, bright orange-rose, hardly translucent, round, scattered; disc slightly concave, margin distinct, 10 µm protruding, finely rough; broadly sessile, erumpent from bast fibres. **Asci** *(64–)68–88 × 7–8.6 µm, †61–75 × 6.5–7.3 µm, 16-spored (often only 11–13 spores developed), spores *~2–3-seriate, 6–9 lower spores inverted (± mixed or not), pars sporifera *37–48 µm long; **apex** (†) strongly truncate (slightly indented, laterally slightly inflated); **base** with short to medium long, thick, ± flexuous stalk, L- or Y-shaped. **Ascospores** *(8.5–)9.5–12.3(–13) × 2.6–3.2(–3.4) µm, †8–11 × (2–)2.5–3 µm, ellipsoid-clavate, apex obtuse, base strongly attenuated (partly tail-like), medium to strongly curved near base; **SBs** *4.2–5.5 × 0.3–0.4 µm in situ (~5–6.5 µm actual length), vermiform, flexuous to helicoid or almost uncinate, with a few small LBs. **Paraphyses** apically medium to strongly clavate-capitate, rarely moniliform, terminal cells *7–18 × 3–4.3 µm, lower cells *9–14 × 1.5–2 µm {near apex up to 3–3.8 µm}; unbranched in upper part, hymenium pale (in uppermost part light) orange. **Medullary excipulum** pale to light orange, 15–30 µm thick, of dense textura intricata with many large inflated cells, medium sharply delimited from ectal excipulum. **Ectal excipulum** pale (near margin light) orange, of (†) slightly gelatinized, vertically oriented textura prismatica-globulosa from base to mid flanks, 25–35 µm thick near base, cells *8–18(–22) × 6–12(–14) µm; 25 µm thick near margin, of t. globulosa-angularis, at upper margin of very irregularly oriented t. globulosa-prismatica at a 10–80° angle to the surface, marginal cortical cells *7–12 × 3–4 µm. **Anchoring hyphae** medium abundant, †2–3 µm wide, walls 0.2–0.3 µm thick, forming a 5–10 µm thick hyaline layer of interwoven hyphae at flanks and margin. **SCBs** globose, in paraphyses (1–)1.5–2.8 µm diam., in ectal excipulum (near margin) 2.3–3 µm. **Exudate** 0.2–1 µm thick, over paraphyses cloddy-continuous, loosely attached, cortical hyphae agglutinated by exudate. — **ANAMORPH**: unknown.

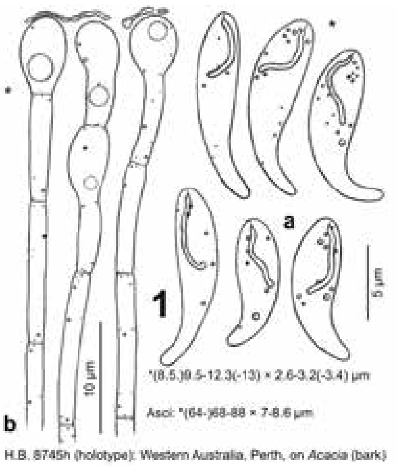

Plate 681. **1**: *Orbilia pleioquaestiformis*. – **a**. ascospores; **b**. paraphyses.

Habitat: collected 1 or 2 m above the ground, on inner surface of bark detached from a 15 mm thick branch of *Acacia* sp., slightly to strongly decayed, slightly greyed, without algae. **Associated**: *Baggea* sp., *Hypoxylon* sp., *?Hysteropatella* sp., *Muellerella lichenicola, Orbilia commarosa, O. macrotrapeziformis, O. microserpens, O. myriofusiclava, O. pluristomachia, O. serpentina, O. wannerooensis, Schizoxylon* sp. **Desiccation tolerance**: fully viable for at least 3 months. **Altitude**: 40 m a.s.l. **Geology**: Cenozoic regolith (whitish sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleioquaestiformis* closely resembles European *O. quaestiformis*, from which it sharply differs in the (11–)16-spored asci.

Ecology. The single sparse collection was made on xeric bark of *Acacia* in a subtropical semihumid acacia mixed shrubland in southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 30 km NNW of Perth, 1 km NW of Kinross, Tamala Park, 40 m, branch of *Acacia*, on bark, 23.X.2007, G. Marson (ex H.B. 8745h, MEL 2389254, **holotype**).

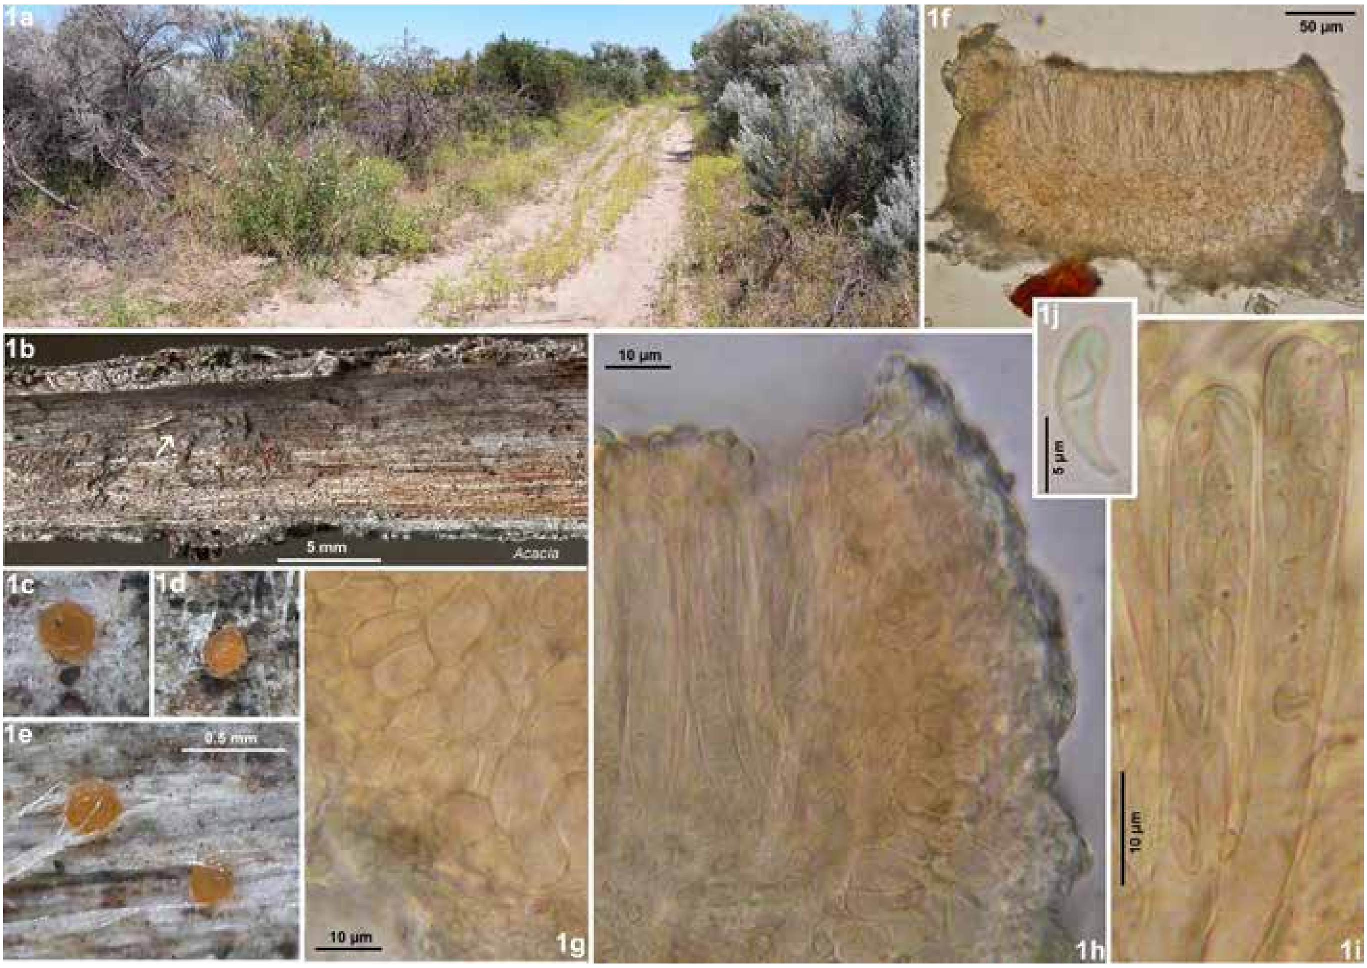

Plate 682. **1**: *Orbilia pleioquaestiformis*. – **1a**. acacia shrubland on white sandy soil; **1b**. inner surface of detached bark; **1c–e**. rehydrated apothecia; **1f**. apothecium in median section; **1h**. id., marginal ectal excipulum; **1g**. basal excipular cells; **1i**. asci (and paraphyses); **1j**. ascospore. – Living state. — **1a–j**. H.B. 8745h (holotype): Western Australia, Perth, on *Acacia*.

Orbilia septispora Baral, Z. Mykol. 55: 126 (1989) — Pls 683–684, Map 112

Etymology: named after the ascospores that get 1(–2)-septate within the living asci.

Typification: Germany, Tübingen, stem of *Melilotus albus*, 29.VII.1988, G. Marson & H.O. Baral (ex H.B. 3490, M-0276585, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.3(–0.5) mm diam., 0.11–0.12 mm high, pale or light orange-rose, round, scattered to ± gregarious; disc slightly concave to slightly convex, margin thin, 0–20 µm protruding, smooth; broadly sessile, rarely with an indistinct immersed stipe, erumpent from beneath epidermis; dry light ochraceous-orange. **Asci** *((45–))(50–)55–75(–90) × 7.3–9(–9.3) µm {9}, †(44–)50–65(–68) × (5.5–)6.2–7.5 µm {4}, 8-spored, in some asci only 4–6 spores reaching maturity, (1–)3–5(–6) lower spores inversely oriented {9} (sometimes mixed), pars sporifera *(24–)30–40(–45) µm; **apex** (†) slightly to strongly truncate (slightly indented, laterally not or scarcely widened); **base** with a short to medium long, flexuous stalk, L-, T-, Y- or h-shaped. **Ascospores** *((9–))(10–)11–15(–17) × (2.5–)2.8–3.7(–4.2) µm {11}, 19–21.5 µm long in 4-spored asci {1}, †10.5–17 × 2.7–3(–3.2) µm {2}; (0–)1(–2)((–3))-septate within living asci prior to discharge {9}; cylindric-clavate, apex rounded, base slightly to strongly attenuated and geniculate, rarely straight; **SBs** only in apical cell, (2–)3–4(–5.8) × (0.3–)0.4–0.7(–0.9) µm {7}, rod-shaped to subulate, straight or slightly curved, often obliquely oriented, with a small number of LBs up to 0.7–1.5(–2) µm diam. grouped in each cell. **Paraphyses** apically medium to strongly capitate-clavate, sometimes lageniform or moniliform, terminal cells *(5–)8–21 × (2–)3–4.8(–5.3) µm {6}, †(1.5–)2–4.2 µm wide {1}; lower cells *(5–)7–15.5 × 1.2–2(–2.3) µm {4}, sometimes branched at upper septum. **Medullary excipulum** ± hyaline, 30–40 µm thick, of ± dense textura intricata with many inflated cells, medium delimited from ectal excipulum only towards margin. **Ectal excipulum** subhyaline, of thin-walled, vertical or horizontal t. globulosa-angularis(-prismatica) from base to mid flanks or margin; 15–35 thick near base, cells *(5–)7–13(–16) × (4–)6–9(–11) µm {5}, with or without 1 lipid body of 1.2–3.3 µm in each cell; 15–30 µm thick at flanks and margin, cells *6–15 × 6–10 µm, oriented at a very low or irregular angle, marginal cortical cells (*) thin-walled, (†) distinctly gelatinized, *4–12 × 2.5–6 µm {4}. **Anchoring hyphae** sparse to medium abundant, */†2–3 µm wide, wall 0.2(–0.4) µm thick {2}, covering the exterior by a thin layer up to submargin. **SCBs** in apices of paraphyses and excipulum globose, 1.2–3 µm diam. {6}. **Exudate** over paraphyses and marginal excipulum 0.2–1 µm thick, hyaline, granular-cloddy to continuous, loosely to firmly attached. — **ANAMORPH**: tridentaria-like (from ascospore isolate {2} and natural substrate {5}). **Conidiophores** not observed. **Conidia** with (2–)3(–4–5) arms, total height */†23–35 × 18–27 µm {4}, stipe *9.5–15 × 2.5–4.8 µm {3}, †9–10 × 3–4 µm {2}, 1–2-septate, arms *14–32 × 2.7–5 µm {4}, †15–18 × 3–4 µm, gradually or only terminally tapering, 2–4-septate (including basal septum), constricted at base.

Habitat: collected near ground or up to 0.4–1.5 m above the ground, on ~ 1–2 years old, lying or often standing culms {18} and leaf sheaths {5} of *Phragmites australis* {27}, leaves of *Typha* sp. {1}, stem of *Melilotus albus* {1}; also on 6–10 mm thick decorticated twigs or branch stubs of *Juglans regia* {1}, *Lonicera periclymenum* {1}, *Rosa* sp. {1}, on medium to very rotten wood {3}; at areas covered with green algae, often greyed. **Associated**: ?*Cryptodiscus* sp. {1}, *Lachnum controversum* {2}, *Orbilia clavuliformis* {1}, *O. eucalypti* {1}, *O. graminis* {2}, *O. quaestiformis* {3}, *O. trapeziformis* {1}, *O. vitalbae*

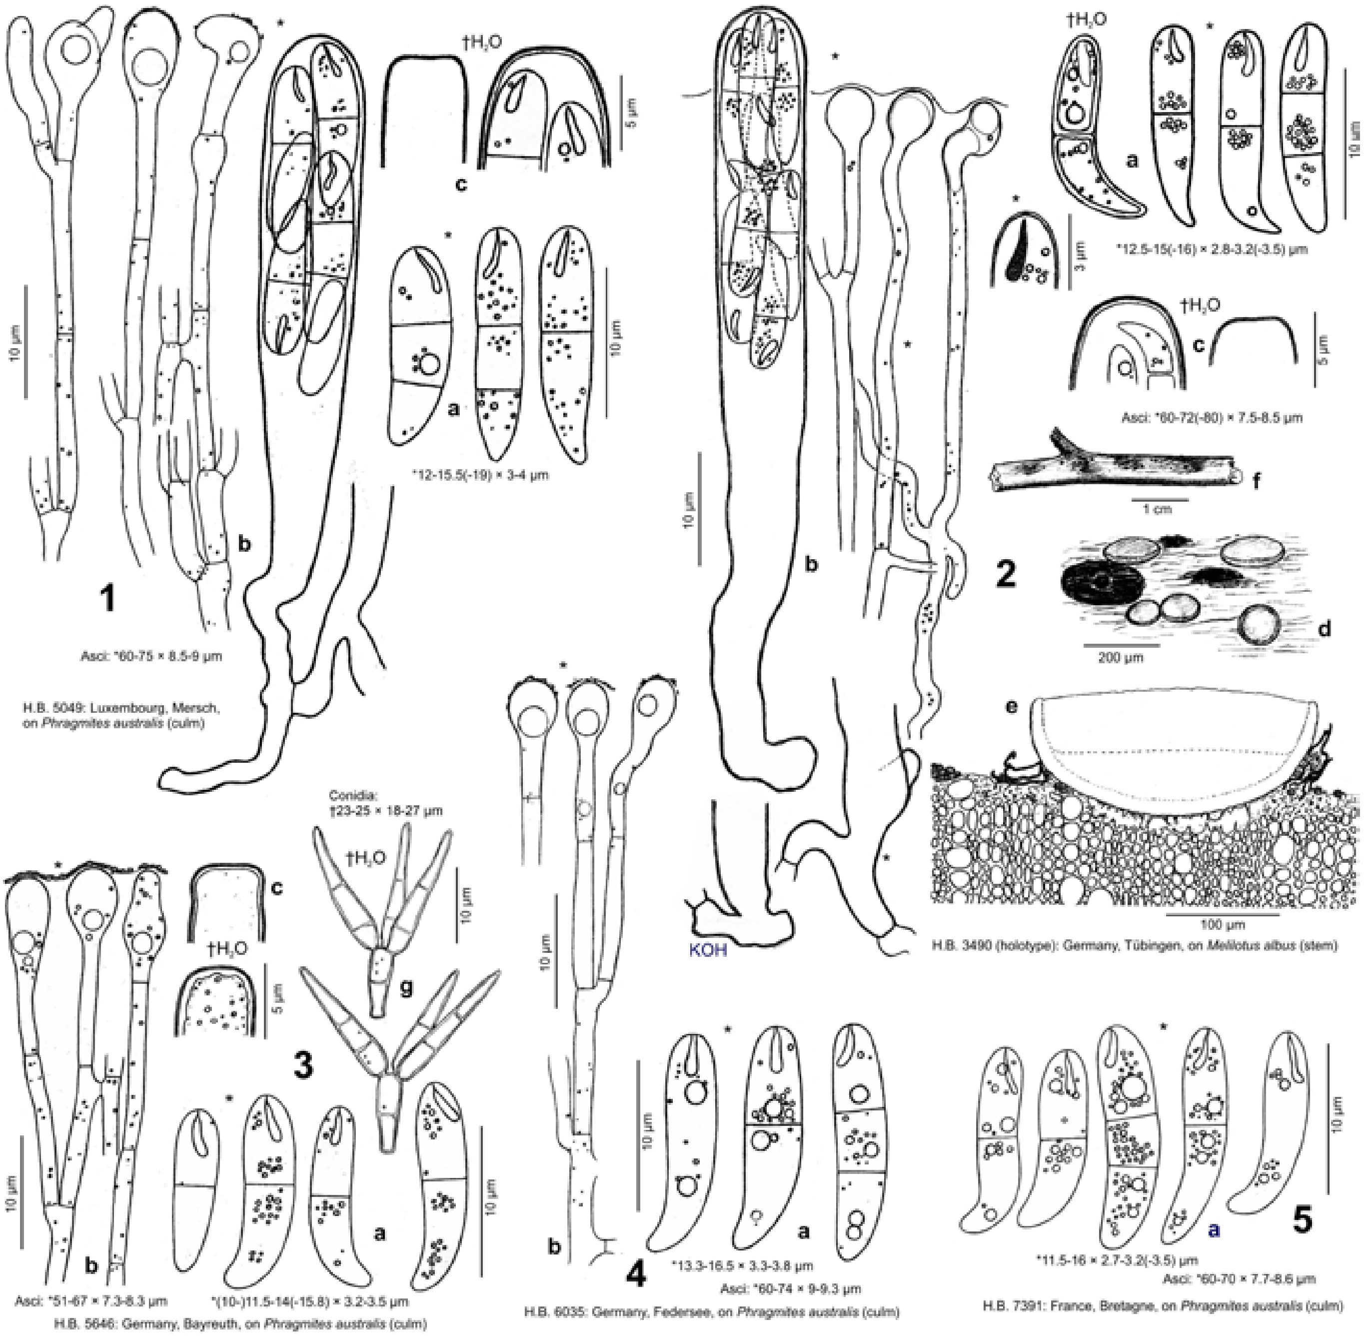

Plate 683. **1–5**: *Orbilia septispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. dead stem of *Melilotus*; **g**. conidia from substrate.

{2}, ‘*Pezizella*’ *nigrocorticata* {1}, ?*Stictis* sp. {1}, ?*Scirrhia* sp. {1}, *Unguiculariopsis* sp. {1}. **Desiccation tolerance**: fully viable for at least 3.5 months. **Altitude**: 1–578 m a.s.l. **Geology**: Buntsandstein, Muschelkalk, alluvial deposits from Keuper (gypsum, clay), Lower & Middle Jurassic shale, sand- & limestone, Cretaceous calcareous clay- & marlstone, Tertiary molasse, sand & marl, Quaternary loess, silt & sand, peat. **Phenology**: throughout the year (long-lived).

Phenology of *O. septispora*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
3	3	4	5	3	1	3	0	2	1	2	4

Taxonomic remarks. *Orbilia septispora* is easily recognized by its large, septate, cylindric-clavate, basally usually ± attenuated and geniculate ascospores. It is the only known species within the *Orbiliomycetes* which forms predominantly septate spores within the living asci prior to discharge. A description of one of the here studied specimens (Pl. 683: 3) was also illustrated by Beyer (1997: 52, 1998: 192). *O. septispora* closely resembles *O. quaestiformis* in spore shape and in the tridentaria-like anamorph. In a collection referred to *O. quaestiformis* (Pl. 678: 1) and in the similar *O. mesaverdiana* the spores were likewise partly septate, but such spores have never been observed within the living asci. *O. mesaverdiana* further differs in spores being strongly curved as a whole.

Variation. A certain variation in spore size and in spore bases was noted among the collections. The spores possess usually 1 septum when mature. However, single non-septate spores are sometimes found in some of the living asci, but also 2-septate spores may occur, and in one collection a few 3-septate spores were found. As a very rare exception, a few of the living asci contained 6 non-septate and only 2 1-septate spores, though the SBs were fully developed in all of them. The septa are rather delicate and easily overlooked. They are formed at a very late

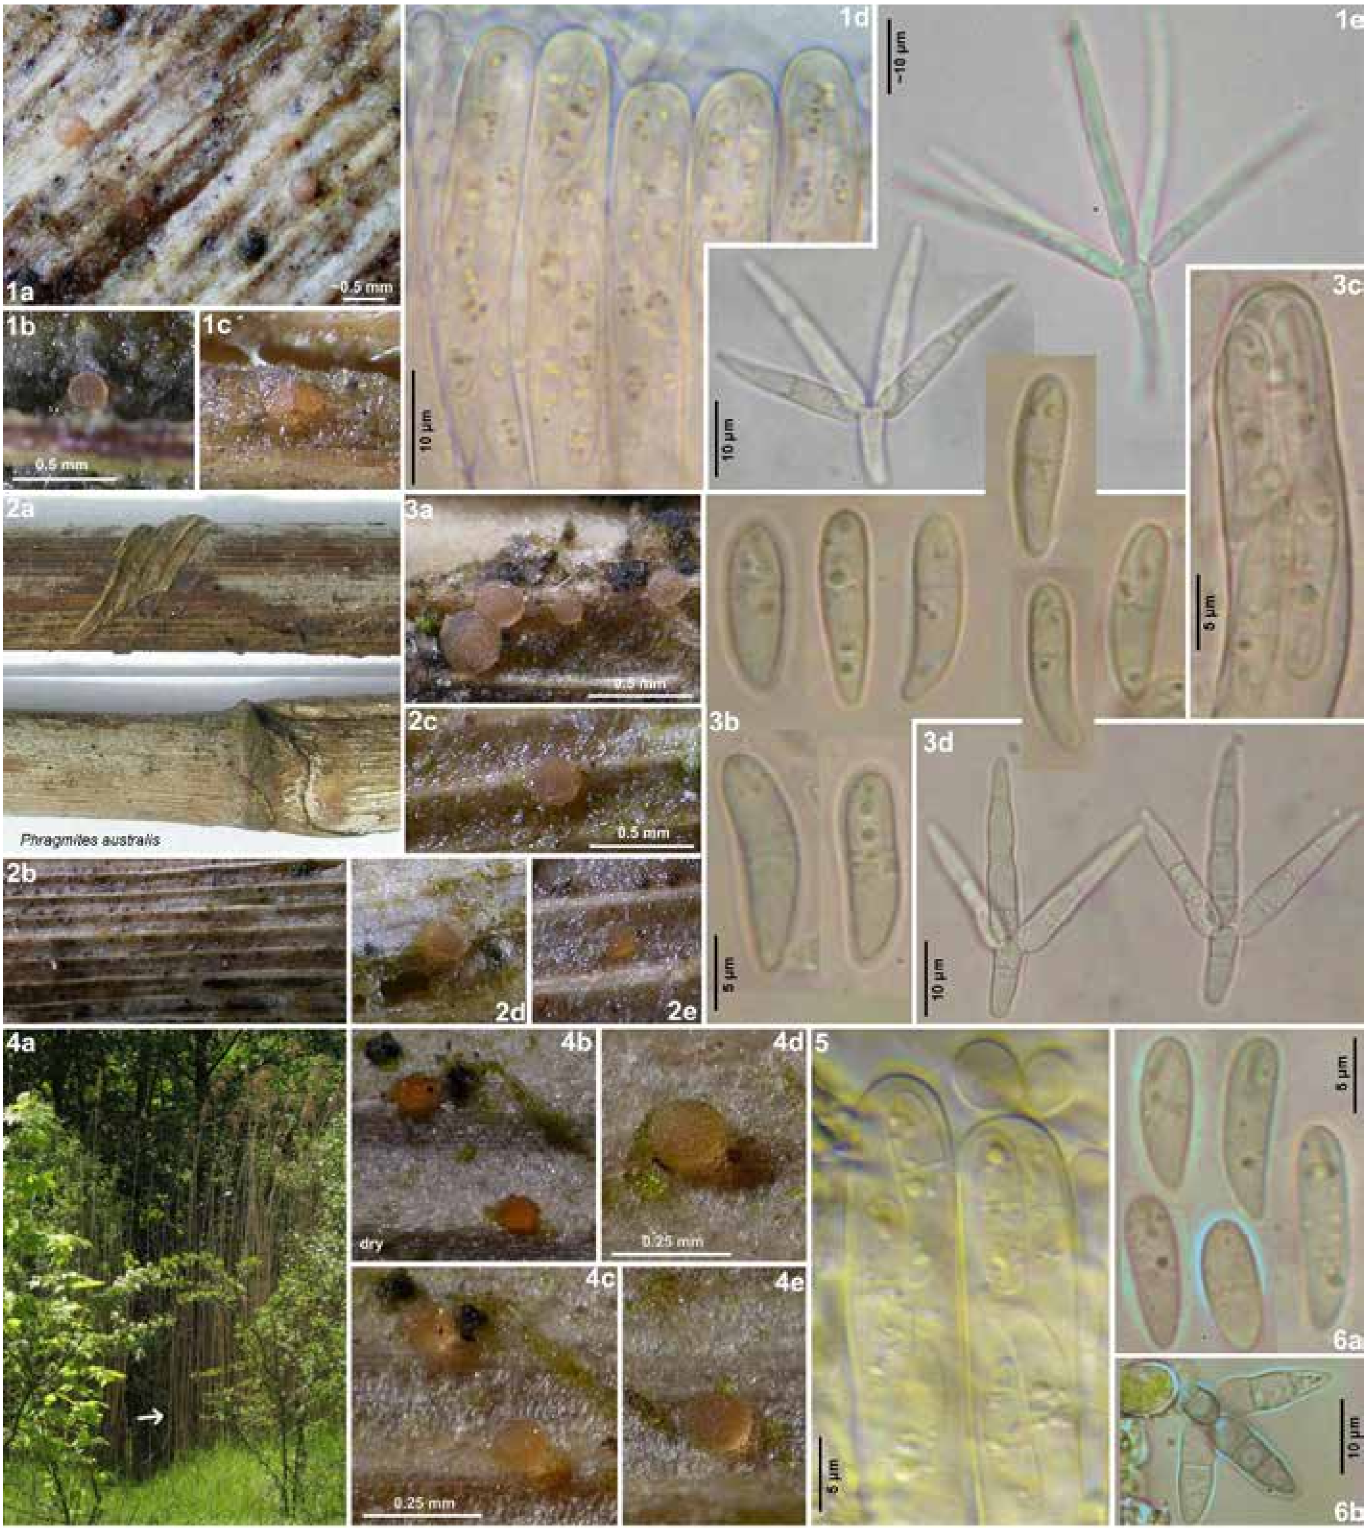

Plate 684. **1–6**: *Orbilia septispora* (on *Phragmites*, except for **6** on *Juglans*). – **4a**. wet *Phragmitetum* with *Fraxinus*; **2a**. dead standing culms of *Phragmites*; **1a–c**, **2b–e**, **3a**, **4c–e**. rehydrated apothecia; **4b**. dry apothecia; **1d**, **3c**, **5**. asci; **3b**, **6a**. ascospores; **1e**, **3d**, **6b**. conidia from substrate. – Living state. – **6a–b**: phot. P. Perz. — **1a–e**. H.B. 7267a: Luxembourg, Sandweiler; **2a–e**. H.B. 7391: France, Bretagne; **3a–d**. stage of spore maturation, after the SBs started to develop. Only the apical cell contains the spore body. In the rare case of 3-septate spores, however, the SB penetrated the pore of the uppermost septum.

Anamorph. *O. septispora* and *O. quaestiformis* have very similar anamorphs which both closely resemble *Tridentaria subuliphora* (see under *O. quaestiformis*, p. 1154).

Phylogeny. Sequences from three samples on *Phragmites* from Luxembourg were available: two from Lankelzerwues (ascospore isolate, G.M. 2014-02-24.1; from apothecia, G.M. 2016-09-20.1), and an inofficial sequence in the CBS database from Aire-de-Berchem (ascospore isolate, G.M. 2012-03-12.1, CBS 133219). The former two comprise S1506 intron, ITS, and LSU, that from 2016 also the entire SSU and LSU D1–D10, while the CBS sequence only ITS. In the ITS region the three strains fully concur, except for 2–3 ambiguous positions in the ITS1 which appear to vary within a population. The intron of the 2014 sample was incompletely obtained, and the few deviations from the complete intron of the 2016 sample are uncertain. The two strains with LSU are identical in the overlapping D1–D3 domain.

O. septispora clustered in a highly supported clade with *O. quaestiformis* (see p. 1156, Phyls 19–20), from which it differs by ~15 nt (2.8%) in the ITS region and by 19 nt and 2 gaps (1.9%) in the overlapping region of LSU (D1–D3) when compared to G.M. 2014-07-25.4. The S1506 intron of *O. septispora* shows to *O. quaestiformis* in the overlapping region a distance of 22–25% (for more details see under *O. quaestiformis*).

A further sequence comprising SSU (without intron), ITS, and LSU was gained from apothecia on *Viburnum* from Baden-Württemberg (H.B. 9457). It was thought to belong to *O. vitalbae* (H.B. 9457a), but the obtained sequence clustered in the *quaestiformis-septispora* clade. At first we assumed that it derived from the associated *O. quaestiformis* (H.B. 9457b), which had rather short spores (*8–9 µm) but seemed otherwise typical *O. quaestiformis*. Only a single apothecium was found to belong to this species during microscopic examination. However, in the ITS region this sequence is closer to *O. septispora* (3.5%; 4.2–4.5% to *O. quaestiformis*), whereas a confidental sequence of *O. vitalbae* (H.B. 9905a) is very distant from all of them (~21%). Also in the LSU (D1–D2) the sequence is closer to *O. septispora* (0.4%, 2 nt), compared to 1.3–1.5% to *O. quaestiformis*, whereas the two available sequences of *O. vitalbae* differ in this domain by 4.7–5.5% from *O. quaestiformis* and *O. septispora*, and by 3.3% from the doubtful sequence. Therefore, we identified this sequence as *O.* cf. *septispora* and gave it the number H.B. 9457c. In the SSU no differences occur among all these sequences, except for a deviation in the ITS1 primer in *O.* cf. *septispora*.

Ecology. The first collection of *O. septispora* (holotype) was exceptional in growing on a stem of *Melilotus albus* together with *Lachnum controversum*, which is known to be confined to *Phragmites*. There is no doubt about the identity of the host species, although the place was only about 2 m away from a pond with a *Phragmitetum*. Most later collections of *O. septispora* were made on monocotyledonous substrate, mainly *Phragmites*. However, some samples were on wood of trees and shrubs. The species is so far only known from cold- to warm-temperate humid, atlantic to subcontinental Europe. Typically it occurs on standing, xeric, perhaps often 2 year's old, greyed and algae-covered culms, though usually with rather sparse apothecia, in undisturbed *Phragmites* stands in moist places or near rivulets and lakes, e.g., with *Alnus*, *Fraxinus*, *Salix*, *Populus*, or *Prunus spinosa*, but also in tree- and shrubless vegetation, e.g., at the Atlantic coastline. In the holotype the stem was lying on gravel in a sun-exposed ruderal area with *Pastinaca sativa*, *Melilotus albus*, and *Solidago canadensis*. Van Ryckegem (2005: 319) reported *O. septispora* during his study on fungi on *Phragmites* in the Scheldt estuarine ecosystem near Antwerpen (Belgium), and Olariaga et al. (2015: 80) in their study of *Phragmitetum* formations in Gipuzkoa (País Vasco).

Specimens included. **GREAT BRITAIN**: **Yorkshire**, **South Yorkshire**, 11 km E of Doncaster, 1.8 km SSE of Lindholme, Hatfield Moor, 1 m, culm of *Phragmites australis*, 17.V.2011, B.M. Spooner (K(M) 170691). – **East England**, **Suffolk**, 9 km SE of Halesworth, Dunwich Forest, 5 m, branch of *Lonicera periclymenum*, on wood, 13.I.2006, E. Batten (E.B. 4663 ø, doc. vid.). — **DENMARK**: **Sjælland**, 0.5 km S of Vordingborg, 4 m, culm of *P. australis*, 31.V.2007, H.O. Baral (ø). — **BELGIUM**: **Vlaanderen**, **West-Vlaanderen**, 13 km N of Brügge, 4 km WSW of Knokke-Heist, SW of Molenhoek, Kleiputten, 2 m, culm of *P. australis*, 2.IV.2000, B. Map 112. Known distribution of *O. septispora* in Europe.

Orbilia quercus-ilicis Baral & E. Weber, **sp. nov.**, MB 813700 — Pls 685–686

Etymology: named after the occurrence on dead leaves of *Quercus ilex* agg.

Typification: Spain, Almadrones, leaves of *Quercus rotundifolia*, 24.IX.1999, H.O. Baral (ex H.B. 6477b, M-0276577, holotype).

Latin diagnosis: *Similis* Orbiliae quaestiformi *sed ascosporae breviores, magis fusoideo-clavatae, corpusculum refringens partim longius. Habitat ad folia coriacea, sicca, leniter putrida* Quercus ilicis *in zona supramediterranea semihumida Europae meridio-occidentalis.*

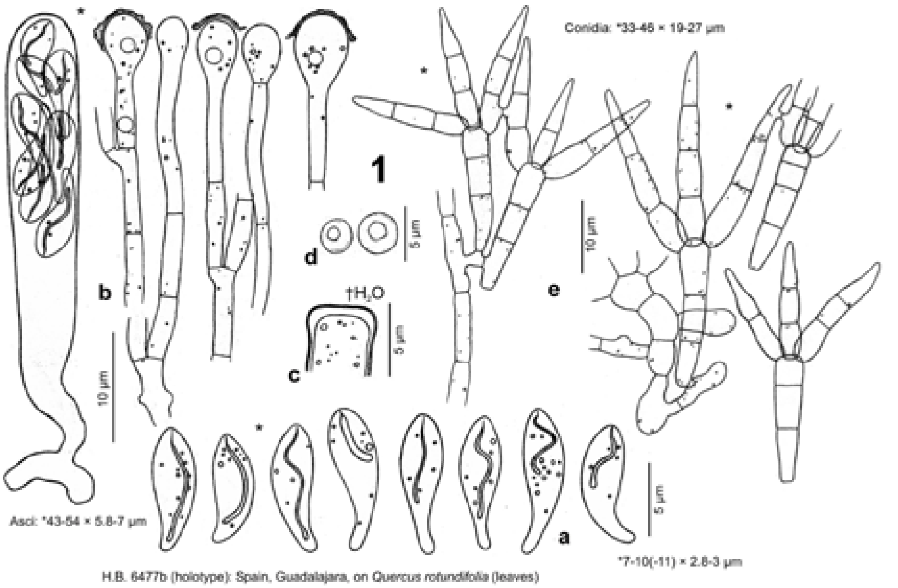

Plate 685. **1**: *Orbilia quercus-ilicis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. ring-shaped SCBs in ectal excipulum; **e**. conidiophores and conidia from culture.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3(–0.5) mm diam., 0.09–0.12 mm high, light orange(-rose), slightly translucent, round, scattered to subgregarious; disc flat, margin indistinct, not protruding, smooth; broadly sessile, superficial; dry light apricot. **Asci** *43–54 × 5.8–7 µm {T}, †40–53(–61) × 5.2–7 µm {2}, 8-spored, spores *2–3-seriate, 2–5 lower spores inverted {2}, pars sporifera *20–23 µm long; **apex** (†) medium to strongly truncate (not indented, laterally sometimes inflated); **base** with short to medium long, thick, flexuous stalk, T-, L- or Y-shaped. **Ascospores** *7–10(–11) × 2.8–3 µm {1}, †7.5–8.5 or sometimes 11–13 × 2.5–3 µm {1}, fusoid-clavate, apex obtuse (to subacute), rarely rounded, base strongly attenuated, mostly tail-like or sometimes with a short tail, slightly to medium curved near base; **SBs** *4–8 × 0.2–0.3(–0.5) µm in situ {1} (~5–9.5 µm actual length), filiform to vermiform, partly subulate, not enlarged at base, slightly to strongly flexuous or helicoid, LBs sparse to medium abundant, ± small. **Paraphyses** apically medium to strongly capitate, terminal cells *5.5–18 × 2.5–5.2 µm {1}, lower cells *5.5–13 × 1.4–2(–2.4) µm {1}; sometimes branched at upper septum. **Medullary excipulum** hyaline, 20 µm thick, of ± dense textura intricata-angularis, medium sharply delimited. **Ectal excipulum** hyaline, of (†) thin-walled, ± horizontally oriented t. angularis-prismatica from base to margin, 20 µm thick near base, cells †5–9 × 4–5 µm {1}; 10 µm thick near margin, oriented at a 20–30° angle to the surface, marginal cortical cells */†5–10 × 3–4 µm {1}. **Anchoring hyphae** †1.7–3 µm wide, walls 0.2(–0.3) µm thick {2}. **SCBs** in paraphyses globose, 1.3–1.5 µm diam.; in ectal excipulum globose, 2.5–3.8 µm diam., low-refractive, hyaline, also ring-shaped or absent. **Exudate** over paraphyses 0.3–0.6(–1) µm thick, slightly rough, firmly attached; over margin and flanks 0.3–1 µm thick, cloddy, pale yellowish. **— ANAMORPH**: tridentaria-like (from apothecium on agar {1}). **Conidiophores** very short. **Conidia** with 3 arms, *33–46 × 19–27 µm, stipe *16–20 × 3.5–4 µm, 2(–3)-septate, arms *(11–)20–26 × 2.5–4 µm, gradually tapering or cylindrical and abruptly tapering only near apex, 2–4-septate, constricted at base {1}.

Habitat: collected 0.4–1.5 m above the ground, still-attached dead leaves of *Quercus ilex* {1}, *Q. rotundifolia* {1}, on medium decayed lower surface, among the host's hairs, strongly greyed, with a few green algae. **Associated**: *Calycellina* aff. *albida* {2}, ?*Durella* sp. {1}, ?*Micraspis* sp. {1}, *Micropeziza mollisioides* {1}, *Orbilia foliicola* {1}, *Rutstroemia coracina* {1}. **Desiccation tolerance**: fully viable for at least 10 months. **Altitude**: 485–1065 m a.s.l. **Geology**: Cretaceous lime- & marlstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia quercus-ilicis* is characterized by fusoid-clavate ascospores with very long, ± filiform spore bodies. The species is undoubtedly closely related to *O. coniferarum* (p. 1163) and *O. quaestiformis* (p. 1151). The presence of ring-shaped (?crystalloid) SCBs in the ectal excipulum might be a further difference but needs confirmation from further collections.

A subatlantic collection on stems of *Humulus* (Pl. 593: 34 Fig. 6) included in *O. trapeziformis* matches *O. quercus-ilicis* to some extent, from which it differs in the substrate, more subacute spore apices, and apothecia with a more distinct and rough margin.

Variation. In the rather sparse paratype which was only studied in the dead state, a single apothecium deviated in distinctly longer spores (†11–13 µm, asci 8-spored) compared to the other apothecia examined (†7.5–8.5 µm), while no further differences could be observed.

Not included collection. A submediterranean sample on wood of *Castanea* (Pl. 686: 3) is not included because of the deviating habitat and the partly lageniform to moniliform paraphyses.

Anamorph. The tridentaria-like anamorph of *O. quercus-ilicis* resembles that of *O. quaestiformis* but differs in shorter conidial arms. As a consequence, in *O. quercus-ilicis* the arms are only slightly longer than the stipes. In the collection on *Humulus*, conidia similar as in *O. quercus-ilicis* but with shorter stipes and longer arms were found in association, which might instead belong to *O. quaestiformis* or *O. filiformis*.

Ecology. *O. quercus-ilicis* grew on the greyed hairy lower surface of dead, xeric, coriaceous leaves of *Quercus ilex* agg. in the suprasub- to supramediterranean semihumid maquis (*Quercetum ilicis*) of southern Europe. The only further *Orbilia* found in this extraordinary habitat, *O. foliicola*, is macroscopically indistinguishable and grew in association in the holotype, though on separate leaves. Both were so far only found on still-attached leaves but not on leaves lying on the ground. The not included collection on *Castanea* wood was from a temperate humid region at the southern foothills of the Italian Alps.

Specimens included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Vaucluse**, Préalpes du Dauphiné, 14 km SE of Carpentras, 4 km SE of Venasque, Aire de Pic-Nique de Venasque, 485 m, leaves of *Quercus ilex*, 9.X.2002, G. Marson (H.B. 8388b ø). — **SPAIN**: **Castilla-La Mancha**, **Guadalajara**, Sistema Central, 18 km SW of Sigüenza, 2.5 km NE of Almadrones, 1065 m, leaves of *Quercus rotundifolia*, 24.IX.1999, H.O. Baral (M-0276577, **holotype**; **isotypes** in H.B. 6477b, K(M) 64409 and J.T.P. [with *Rutstroemia coracina* & *O. foliicola*]; anam. apoth.).

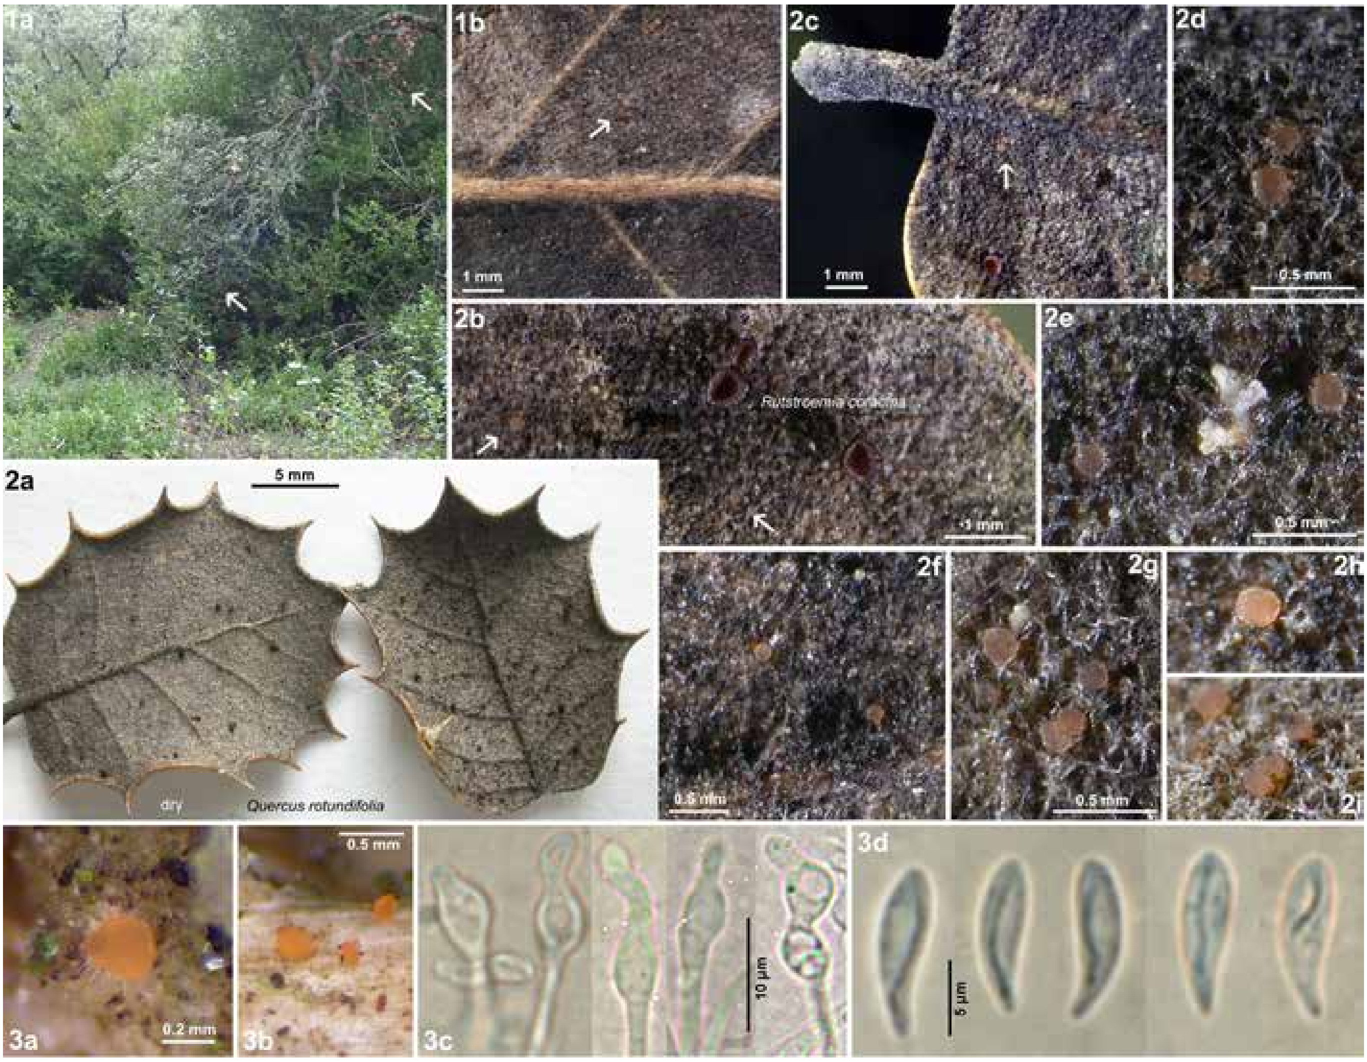

Plate 686. **1–2**: *Orbilia quercus-ilicis*; **3**: *O.* cf. *quercus-ilicis*. – **1a**. mediterranean maquis, *Quercus ilex* with dead attached leaves; **1b**, **2a–c**. rehydrated lower surface of dead leaves with apothecia of *Rutstroemia coracina* and *O. quercus-ilicis*; **2d–i**, **3a–b**. rehydrated apothecia; **3c**. paraphyses; **3d**. ascospores. – Living state. – **3a–d**: phot. M. Bemmann. — **1a–b**. H.B. 8388b: France, Provence, on *Quercus ilex*; **2a–i**. H.B. 6477b (holotype): Spain, Guadalajara, on *Quercus rotundifolia*; **3a–d**. 1.VI.2012: Italy, Piemont, Lago Maggiore, on *Castanea*.

Not included. **ITALY**: **Piemonte**, **Verbano-Cusio-Ossola**, Lago Maggiore, 17 km SSW of Locarno, S of Trarego Viggiona, 730 m, branch of *Castanea sativa*, on wood, 1.VI.2012, M. Bemmann (ø, doc. vid.).

Orbilia coniferarum Baral & E. Weber, **sp. nov.**, MB 813701 — Pls 687–688, Map 113

Etymology: named after the occurrence on coniferous hosts.

Typification: USA, Utah, Panguitch, branches of *Abies concolor*, 20.VI.2000, G. Marson (ex H.B. 7066b, M-0276461, holotype).

Latin diagnosis: *Similis* Orbiliae quaestiformi *sed ascosporae breviores*, *basi minus attenuatae et curvatae*, *corpusculum refringens partim longius*, *conidia brachiis multo latioribus. Habitat ad lignum vel corticem leniter vel valde putridum siccum ramorum coniferarum in zona mediterranea ad boreali semihumida ad humida Americae septentrionalis et Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5(–0.7) mm diam., 0.11–0.19 mm high, light to bright orange(-rose), not or slightly translucent, round, scattered to subgregarious; disc flat, margin indistinct to distinct, slightly thickened, 0–5 µm protruding, finely rough; ± broadly sessile, slightly erumpent or immersed; dry bright orange-red. **Asci** *(38–)50–65(–70) × (5.3–)6–7(–7.3) µm {4}, †(41–)50–60(–65) × 4.8–5.7(–6.3) µm {4}, 8-spored, spores *3(–4)-seriate, (2–)3–5 lower spores inverted {5} (often mixed), pars sporifera *24–27 µm long; **apex** (†) medium to strongly truncate (partly very slightly indented, laterally distinctly inflated or not); **base** with short to medium long, ± thick, flexuous stalk, L-, T-, Y- or h-shaped. **Ascospores** *(6.5–)8–10(–11.5)((–13)) × (2.3–)2.5–3(–3.2) µm {6}, †(7–)8–10(–11) × 2.4–3(–3.2) µm {4}, ellipsoid- to fusoid-clavate, apex rounded to obtuse, base mostly medium to strongly attenuated, straight or slightly to medium curved near base; **SBs** *(3–)4–7.5(–10) × (0.2–)0.3–0.5((–0.8)) µm in situ {3} (~4–10 µm actual length), filiform to vermiform, partly subulate, not or sometimes very indistinctly swollen at base, slightly to strongly flexuous or helicoid, sometimes uncinate; LBs sparse, small. **Paraphyses** apically slightly to strongly clavate-capitate, sometimes slightly spathulate, terminal cells *(6–)10–19 × (2–)2.7–4.5(–5.3) µm {2}, †2.5–4 µm wide {1}, lower cells *10.5–14(–17.5) × 1.3–2.2 µm {2}, †1–1.5 µm wide {1}; rarely or sometimes branched at upper septum. **Medullary excipulum** subhyaline, 40–60 µm thick, of dense textura intricata with slightly inflated cells, indistinctly to very sharply delimited from ectal excipulum by an inconsicuous t. porrecta. **Ectal excipulum** subhyaline to pale orange, of thin-walled, (irregularly) vertically oriented t. angularis(-prismatica) from base to mid flanks, 30–70 µm thick near base, cells *8–16 × 5–10(–16.5) µm {2}; 30 µm thick at flanks, 20–25 µm near margin, of t. prismatica-porrecta oriented at an 80–90° angle to the surface, marginal cortical cells */†8–15 × 2–5.5 µm {1}, thick-walled (†0.3–1 µm), somewhat free and agglutinated as indistinct minute teeth. **Anchoring hyphae** medium sparse to abundant, */†2.2–3.5(–4.2) µm wide, walls (0.2–)0.3–0.6 µm thick {2}, forming a thin covering layer at flanks. **SCBs** in paraphyses globose, 1–1.5 µm diam., in excipulum not observed. **Exudate** over paraphyses 0.2–0.7 µm thick, granular-cloddy, firmly attached; over margin and flanks thin, granular. **— ANAMORPH**: tridentaria-like (presumed,

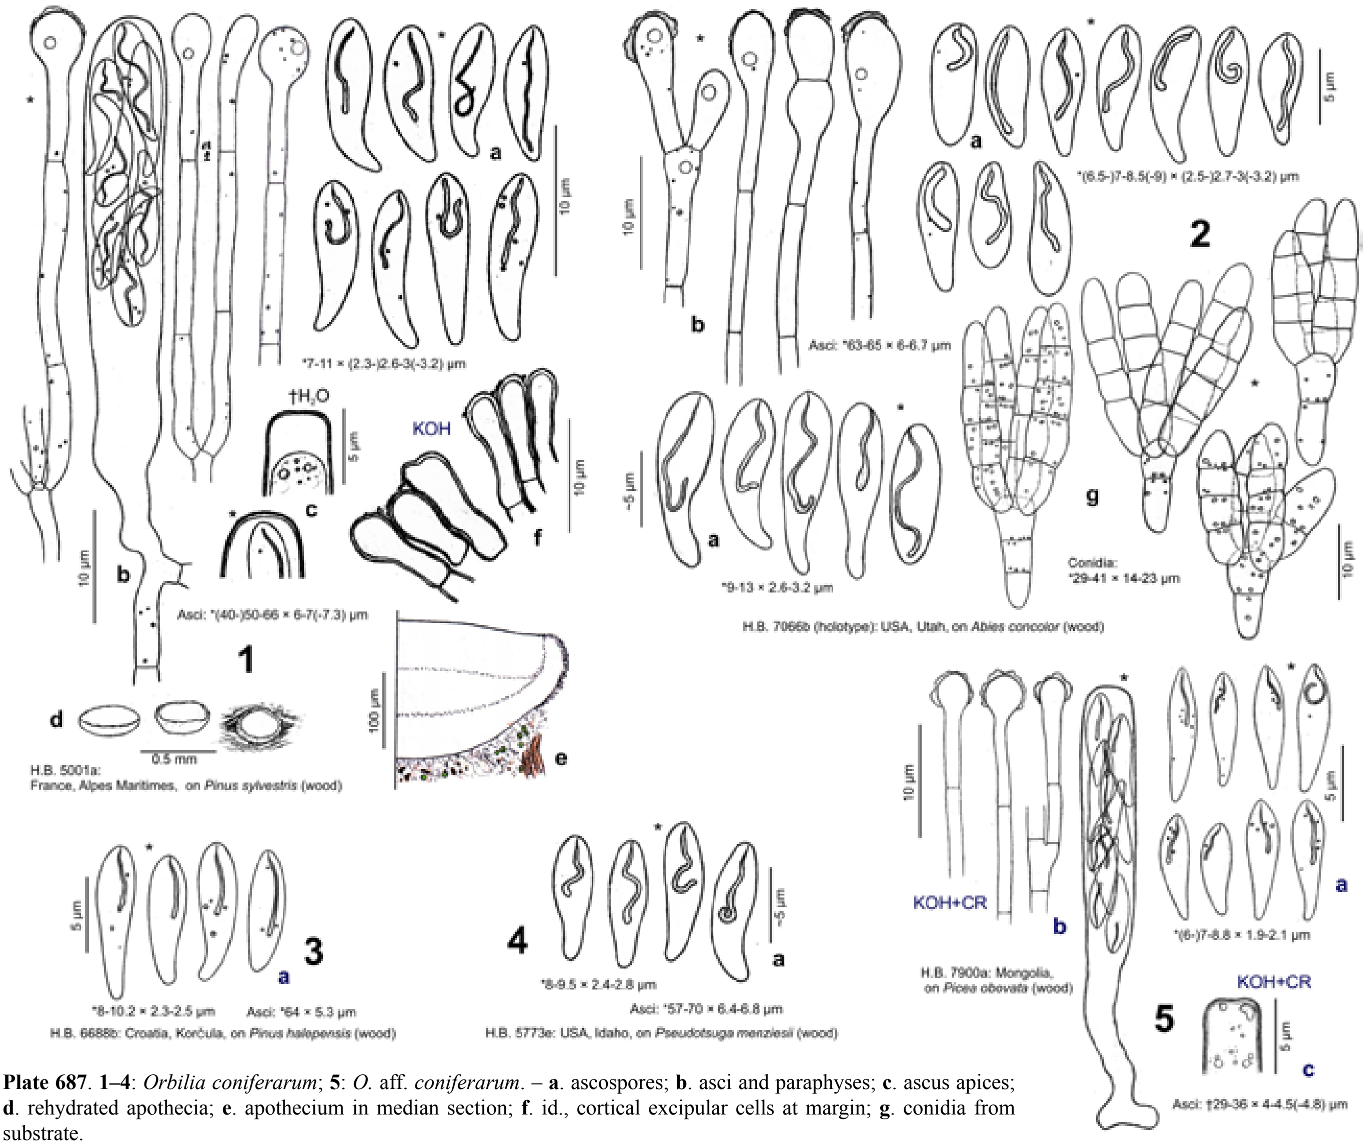

Plate 687. **1–4**: *Orbilia coniferarum*; **5**: *O.* aff. *coniferarum*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., cortical excipular cells at margin; **g**. conidia from substrate.

from natural substrate {2}). **Conidiophores** not seen. **Conidia** with (3–)4–5(–6) arms, *29–40 × 11.5–17 µm, stipe *10–13.5 × 4–5.5 µm, †11 × 3.2 µm, 1(–2)-septate, arms *14–28.5 × 4.5–5.5 µm, †24–25 × 4 µm, (2–)4–5-septate, cylindrical, apically mostly slightly to strongly tapering {2}.

Habitat: collected 0.5–3 m above the ground, decorticated, 8–80 mm thick branches of *Abies concolor* {2}, *Juniperus* (?)*occidentalis* {1}, *Picea sitchensis* {1}, *Pinus halepensis* {1}, *P. sylvestris* {1}, *Pseudotsuga menziesii* {1}, on 0.1–0.4 mm deep medium to strongly decayed wood {6} or bark {2}, partly in beetle galleries or close to resin, slightly to strongly greyed, green algae sparse to medium abundant. **Associated**: ?*Cryptodiscus* sp. {1}, *Dacrymyces* sp. {1}, *Diplolaeviopsis* sp. {1}, *Hypogymnia* sp. {1}, *Melaspilea emergens* {2}, *Mellitiosporiella pulchella* {1}, *Orbilia clavipisca* {1}, *O. delphinus* {3}, *O.* ?*gregorii* {1}, *O. hesperidea* {1}, *O. macrodelphinus* {2}, *O. maeandrina* {2}, *O. magnifica* {1}, *O. ophiosoma* {2}, *O. patellarioides* {1}, *O. subtrapeziformis* {1}, ?*Phaeophyscia* sp. {1}, *Pseudohelotium* ?*sordidulum* {1}, *Sarea resinae* {1}, ?*Schizoxylon* sp. {1}, *Teichospora* sp. {1}. **Desiccation tolerance**: fully viable for at least 17 months, after 33 months a few spores and paraphyses still alive. **Altitude**: 1–1405 m a.s.l. (southern Europe), 380–2778 m (North America). **Geology**: Triassic-Jurassic-Cretaceous lime- and calcareous sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia coniferarum* is characterized by rather long, filiform, basally uninflated, flexuous spore bodies and medium-sized ascospores of somewhat variable, ellipsoid- to fusoid-clavate shape (often basally attenuated and curved), also by the occurrence on coniferous substrate. The foliicolous *O. quercus-ilicis* has similar spores and SBs, but differs in more consistently strongly tapered spore bases and a tridentaria-like anamorph with narrower arms. A marginal

Map 113. Known distribution of *O. coniferarum* in North America.

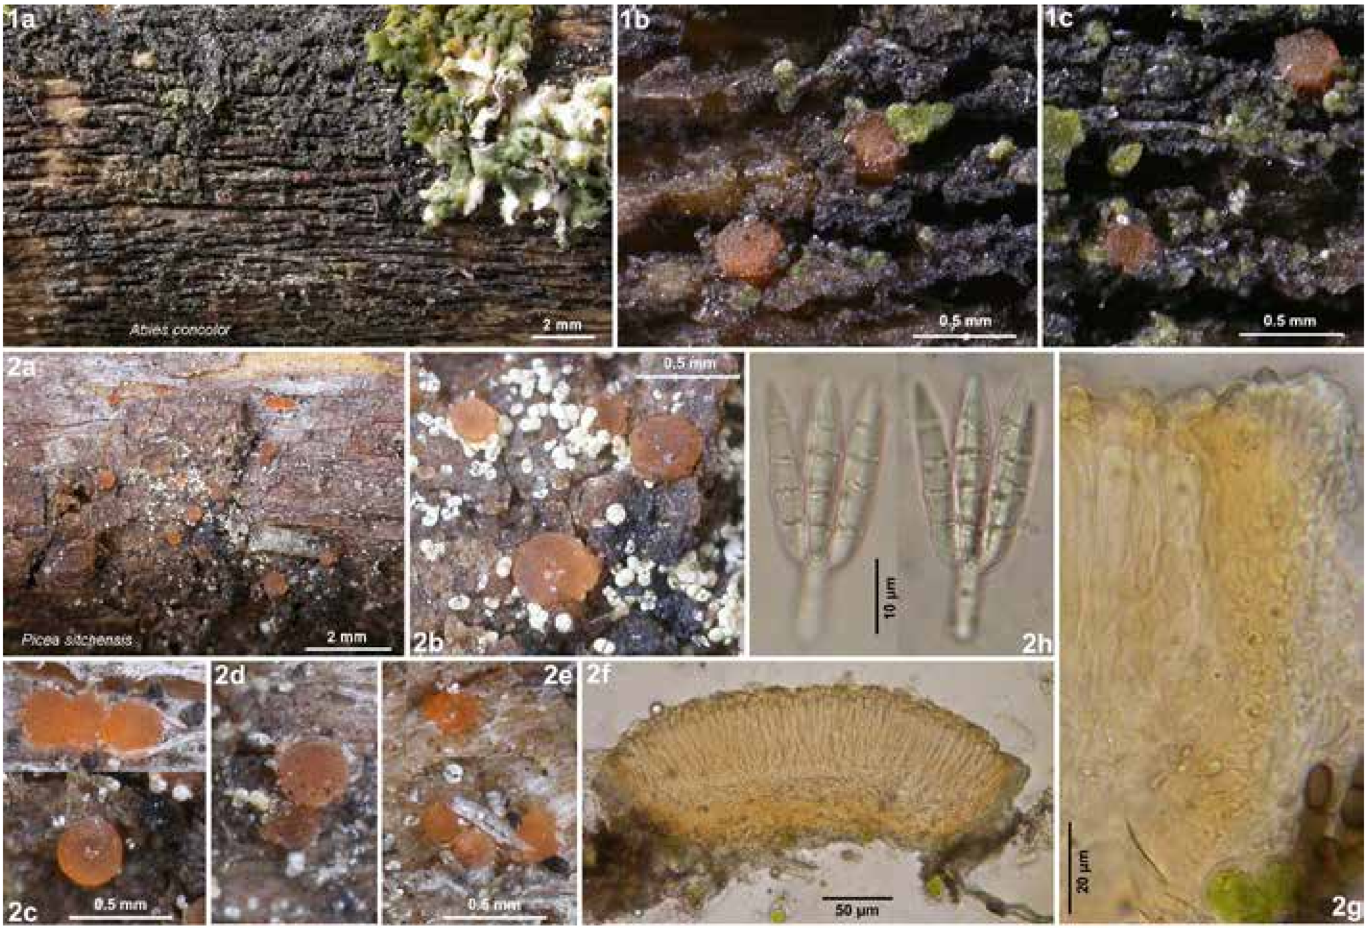

Plate 688. **1–2**: *Orbilia coniferarum*. – **1a**. decorticated branch of *Abies concolor*, with *Hypogymnia*; **2a**. corticated branch of *Picea sitchensis*; **1a–c**, **2a–e**. rehydrated apothecia (**2b** with *Pinus* pollen); **2f**. apothecium in median section; **2g**. id., marginal ectal excipulum; **2h**. conidia from substrate. – Dead state (**2f**, **h** in H_2O, **2g** in KOH). — **1a–c**. H.B. 8095a: USA, Utah, Tropic, on *Abies*; **2a–h**. H.B. 8545b: id., Torrey, on *Picea*.

collection of *O. trapeziformis* (Pl. 593: 6) differs from both taxa in subacute spore apices. For the difference between *O. coniferarum* and *O. quaestiformis* or *O. cactacearum* see p. 1151 and p. 1143.

Variation. In the holotype, spore length varied between 6.5–9 and 9–13 µm depending on the apothecium examined (Pl. 687: 2). In European collections (1, 3) the SBs were slightly thinner (0.2–0.4 µm) than in those from America (mainly 0.3–0.5 µm, 2, 4). In the sample from Texas (on *Juniperus*, IVV: H.B. 6027a), a deviating variant with consistently long SBs was observed in which the spores were mainly ellipsoid, reminiscent of *O. gambelii*, and their bases only sometimes tapered (IVV: H.B. 6027b). A similar variation in spore shape, coupled with SBs only half as long as those spores with a tapered base, was noted in *O. octocercocarpi*.

Not included collection. A Mongolian collection on *Picea* (Pl. 687: 5) deviates in much narrower, almost straight spores, and resembles *O. ungulata* in spore shape; no living paraphyses and excipular cells were seen, therefore, no information on SCBs is available.

Anamorph. The conidia observed in *O. coniferarum* are only slightly shorter than those of *O. quaestiformis*, but differ in having thicker arms and stipes, also in having predominantly 4–5 instead of 3–4 arms.

Ecology. *O. coniferarum* inhabits slightly to strongly rotten wood or bark of xeric branches of different coniferous trees and shrubs. In southern Europe it was rarely found in orosubmediterranean humid and thermomediterranean semihumid pine forests. In Northern America it occurred in the west in boreal humid Douglas fir mixed forests of the Middle Rocky and Utah Mountains, and in the south in warm-temperate subhumid woodland with *Quercus virginiana* in the Edwards Plateau (Oaks and Prairies). The not included sample derives from a north-exposed mountain taiga (*Larix* and *Picea*) in a continental, orotemperate (sub)humid (winter-dry) western Mongolia of central Asia.

Specimens included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Alpes Maritimes**, Préalpes de Grasse, 19 km NNE of Grasse, 4 km NNE of Gréolières, Gréolières les Neiges, 1405 m, branch of *Pinus sylvestris*, on wood, 1.X.1993, G. Marson (H.B. 5001a). — **CROATIA**: **Dubrovnik-Neretva**, **Korčula**, 2.5 km ESE of Korčula, Badija island, turističko-sportski centar, 1 m, branch of *Pinus halepensis*, on wood, 8.VI.2000, H.O. Baral (H.B. 6688b ø). — **USA**: **Idaho**, Middle Rocky Mountains, Grand Teton, 67 km ENE of Idaho Falls, 9 km WSW of Victor, Pine Creek Pass, 2080 m, branch of *Pseudotsuga menziesii*, on wood, 5.VI.1996, G. Marson (H.B. 5773e ø). – **Utah**, Utah Mts., Dixie Forest, 22 km SSE of Torrey, 13 km S of Grover, 1 km N of Pleasant Creek Campground, 2650 m, branch of *Picea sitchensis*, on wood & bark, 19.VI.2000, G. Marson (H.B. 8545b, anam. substr.). – Bryce Canyon, 32 km SE of Panguitch, 13 km WSW of Tropic, near Trough Spring, 2500 m, branch of *Abies concolor*, on wood, 13.VI.2003, G. Marson (H.B. 8095a). – 42 km SSE of Panguitch, Rainbow Point, 2778 m, branches of *Abies concolor*, on wood, 20.VI.2000, G. Marson (ex H.B. 7066b, M-0276461, **holotype**, anam. substr.). – **Texas**, Edwards Plateau, 65 km W of Austin, ~2 km WSW of Johnson City, 380 m, branch of *Juniperus* (?)*occidentalis*, on bark, 18.VI.1996, G. Marson (H.B. 6027a/b).

Not included. **MONGOLIA**: **Bayan Ölgii**, Sagsai, Altay Mts., Tavan Bogd, 25 km SE of Dayan lake, 8 km NE of Chinese border, Songino Gol river valley, 2100 m, branch of *Picea obovata*, on wood, 15.VIII.2005, P. Karasch (P.K. 15082005-19, H.B. 7900a).

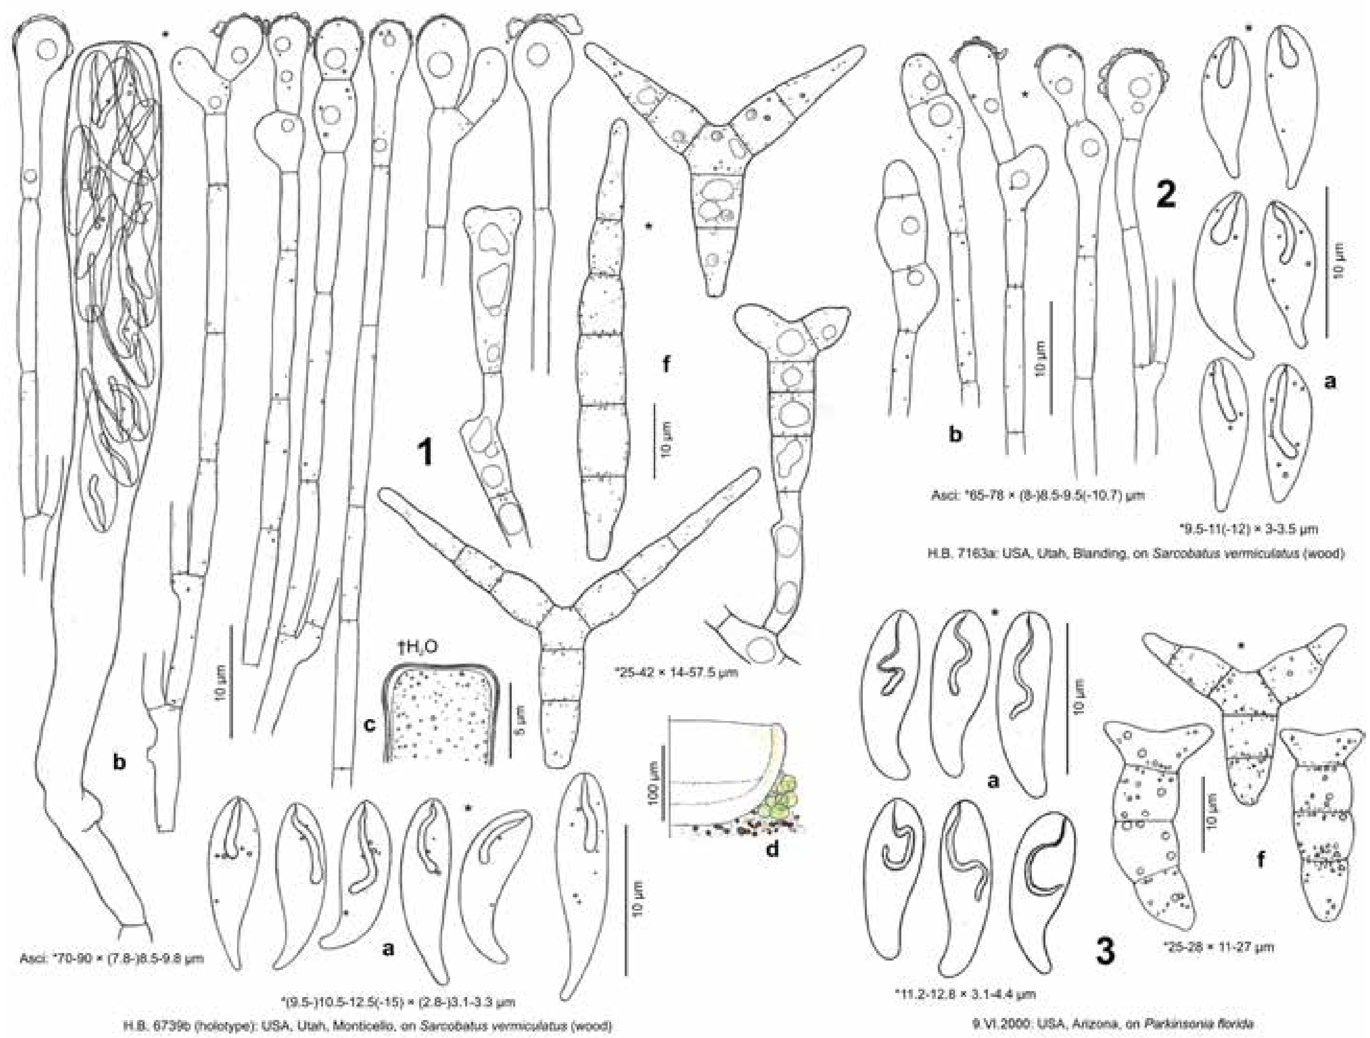

Plate 689. **1–2**: *Orbilia vermiculati*; **3**: *O.* cf. *vermiculati*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecia in median section; **e**. id., marginal ectal excipulum; **f**. conidiophores and conidia (**1f** from culture, **3f** from substrate).

Orbilia vermiculati Baral & G. Marson, **sp. nov.**, MB 813702 — Pls 689–690, Map 114

Etymology: named after the substrate of the type, *Sarcobatus vermiculatus*.

Typification: USA, Utah, Monticello, branches of *Sarcobatus vermiculatus*, 15.VI.2000, G. Marson (ex H.B. 6739b, M-0276605, holotype; ex-type culture: CBS 116230; sq.: KT215241).

Latin diagnosis: *Similis* Orbiliae quaestiformi *sed asci 16-spori*, *conidia triradiata. Habitat ad lignum putridum ramorum siccorum* Sarcobati vermiculati *in zona temperata semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3(–0.5) mm diam., 0.13–0.17 mm high, light to bright pure orange, round, scattered to subgregarious; disc flat, margin thin, protruding for 5–30 µm, smooth to finely rough; sessile, ± superficial to half immersed. **Asci** *65–97 × 7.8–9.5(–10.7) µm {3}, †50–93 × (7–)8–9 µm {2}, 16-spored, spores *4-seriate, (3–)6–10(–12) lower spores inverted (scarcely or somewhat mixed) {3}, pars sporifera *39–56 µm long; **apex** (†) strongly truncate (very slightly indented, laterally sometimes inflated); **base** unstalked or with short to medium long, thick, ± flexuous stalk, L- or T-shaped. **Ascospores** *(9–)9.5–12.5(–15) × (2.8–)3–3.5(–3.7) µm {4}, clavate to ellipsoid-clavate, apex obtuse, sometimes rounded or subacute, base slightly to strongly attenuated, often tail-like, here slightly to strongly curved; **SBs** *3–6.5 × 0.6–1.2 µm {4}, vermiform to somewhat subulate, not or slightly inflated at base, straight to medium, also strongly flexuous, in more aged spores pyriform narrowed to a ± wide point. **Paraphyses** apically (slightly to) medium to (very) strongly clavate-capitate, sometimes moniliform, terminal cells *(3.5–)6–12(–20) × (2–)3–5(–5.7) µm {3}, lower cells *8–13(–16.5) × 1.6–2.4 µm {2}, near apex often 4–9 × 3–5 µm; sometimes branched near apex. **Medullary excipulum** hyaline, 30–50 µm thick, of textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** very pale rose, of (†) slightly gelatinized, irregularly oriented t. (globulosa-)angularis(-prismatica) from base to margin, 20–30 µm thick near base, cells *7–14(–18) × 6–9(–11) µm {2}; 10–20 µm thick near margin, oriented at a 10–45° angle to the surface, inner part of t. prismatica-porrecta, marginal cortical cells *5–11 × 3.8–5.5(–6.5) µm {2}. **Anchoring hyphae** medium abundant, *2–3(–4.5) µm wide, walls 0.2(–0.3) µm thick {2}, forming a thin layer of dead hyphae up to the margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2 µm diam. **Exudate** over paraphyses 0.2–0.5 µm thick, rough, firmly attached, partly absent; over margin and flanks thin, rough. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1}). **Conidiophores** *~19–25 × 3.8–4.5 µm. **Conidiogenous cells** sympodial. **Conidia** Y-shaped, total size *25–42 × (14–)37–57.5 µm, stipe *17–18 × 5.5–7.5 µm, 2(–3)-septate, usually shorter than arms, arms gradually to somewhat abruptly tapering, *20–30.5 × 5–6 µm, 2–3-septate; a single unbranched conidium seen: *58.5 × 6.7 µm, 5-septate.

Habitat: collected 0.05–0.8 m above the ground, partially to nearly decorticated, 4–16 mm thick twigs and branches of *Sarcobatus vermiculatus* {4}, on 0.1–0.3 mm deep strongly decayed wood {4}, slightly to strongly greyed, with a few to many green algae. **Associated**: *Caloplaca* sp. {1}, *Orbilia bicknellensis* {2}, *O. lentiformis* {1}, *O. sarcobati* {2}, *Schizoxylon ?argentinum* {1}, *Teichospora* sp. {2}, foliose and crustose lichens. **Desiccation tolerance**: some mature asci

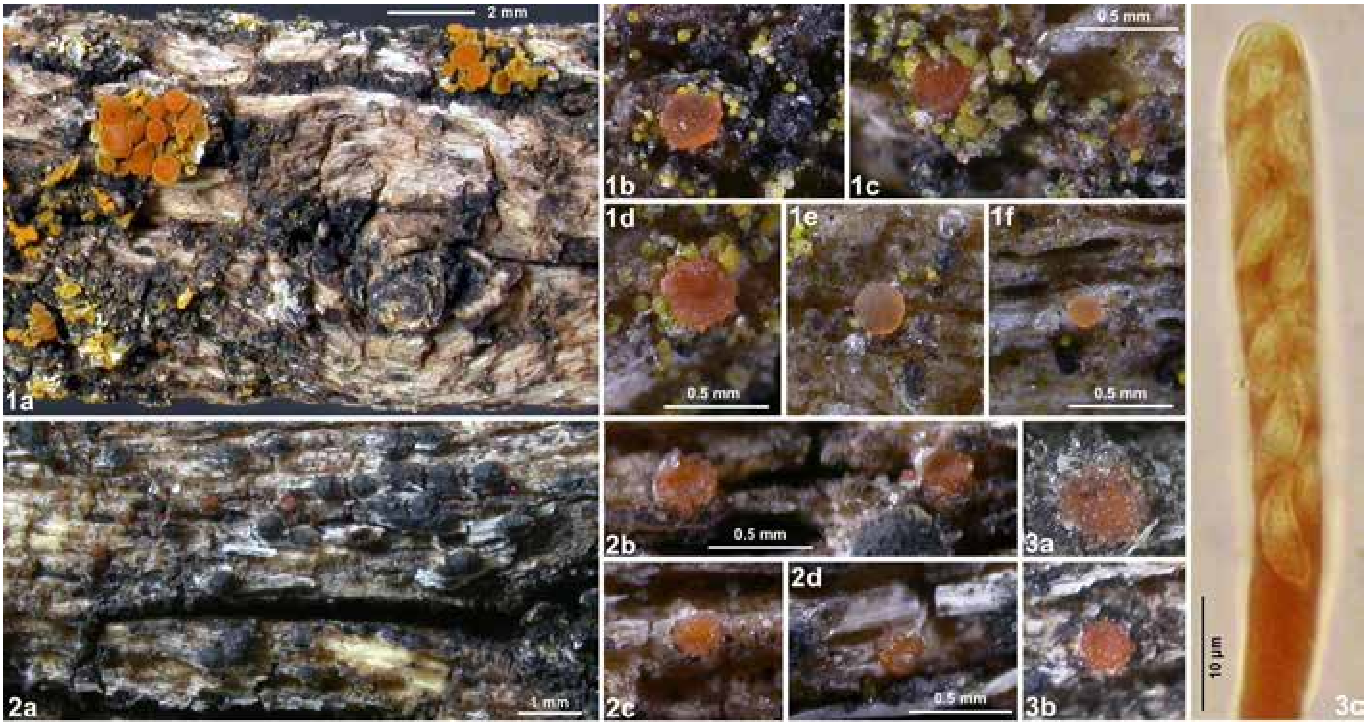

Plate 690. **1–2**: *Orbilia vermiculati*; **3**: *O.* cf. *vermiculati*. – **1a**, **2a**. decorticated, eroded xeric branches, with *Xanthoria* (**1**), *Teichospora* (**2**); **1b–f**, **2a–d**, **3a–b**. rehydrated apothecia; **3c**. ascus (dead state, in KOH+IKI). — **1a–f**. H.B. 7163a: USA, Utah, Blanding, on *Sarcobatus vermiculatus*; **2a–d**. H.B. 6739b (holotype): ibid., Monticello, on *S. vermiculatus*; **3a–c**. H.B. 6721e: USA, California, on *Atriplex*.

and all paraphyses still viable after 26 months. **Altitude**: 1475–1905 m a.s.l. **Geology**: Pennsylvanian-Permian and Jurassic-Cretaceous (carbonate) red sandstone; alluvial deposits from granite & gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia vermiculati* is characterized by 16-spored asci and (ellipsoid-)clavate, rather large ascospores with attenuated, curved, tail-like bases and comparatively short, ± vermiform spore bodies. Concerning spore shape the species resembles the 8-spored European *O. quaestiformis*, but a close relationship seems improbable based on the deviating anamorph. *O. pleiomesaverdiana* and *O.* aff. *pleiomesaverdiana* (Pls 675–676) differ in having crystalloid SCBs, the former also in more acute spore apices, the latter in less tapered spore bases. *O. sarcobati* (section *Ovoideae*) occurs with *O. vermiculati* on the same host and sometimes in mixed association (e. g., in the holotype), but differs in rounded or rarely only shortly attenuated spore bases, and in short, globose to tear-shaped SBs.

Map 114. Known distribution of *O. vermiculati* in North America (yellow = not included collections).

The Australian *O. pleioquaestiformis* (on bark of *Acacia*, Pls 681–682) closely resembles *O. vermiculati*. It differs in slightly narrower asci and spores, and particularly in much narrower SBs (4.2–5.5 × 0.3–0.4 µm). Apart from its 16-spored asci this species matches the 8-spored European *O. quaestiformis*, to which it is probably closely related. The African *O. caudimaeandrina* differs from *O. vermiculati* in spores with distinct tails and with SBs being mostly longer than half the spore length, and in lacking SCBs. Surprisingly, a close molecular relationship with *O. halimi* is observed (see below), which differs in spores with acute apices, 8-spored asci, and in possessing crystalloid SCBs.

Variation. The four collections on *Sarcobatus* here referred to *O. vermiculati* vary somewhat in spore shape. Sometimes the spores contained much shorter and thicker SBs (Pl. 689: 2), which strongly resemble those of *O. sarcobati* (section *Ovoideae*), but which might represent overmature stages.

Not included collections. A sparse specimen on wood of *Atriplex* (Pl. 690: 3) was only studied in the dead state. In its persistent characters (spores †10–11 × 3–3.3 µm) it closely resembles *O. vermiculati*, but is not included in the description, as was a collection on *Parkinsonia florida* (Pl. 689: 3) which differs from samples on *Sarcobatus* in spores with less tapered bases and longer, strongly flexuous SBs. Both samples are geographically distant from those on *Sarcobatus* (Map.).

Anamorph. Although the ascospores of *O. vermiculati* resemble *O. quaestiformis*, trinacrium-like conidia developed in pure culture in contrast to *O. quaestiformis* which has a tridentaria-like anamorph. In the collection on *Parkinsonia* (Pl. 689: 3f) conidia were found on the natural substrate which resemble those obtained in pure culture of the holotype, but differ in shorter arms and longer and thicker stipes.

Phylogeny. A sequence was gained from pure culture of the holotype which comprises SSU (with S1506 intron), ITS and LSU. *O. vermiculati* clustered in the *Serpentinae-Habrostictis* clade very close to *O. halimi* by showing only 1.5 % ITS distance (3 nt difference in ITS1, 5 nt and 1 gap in ITS2) and 0.8 % in LSU. Contrary to *O. vermiculati* the sequence of *O. halimi* lacks the intron.

Ecology. *O. vermiculati* grew on rotten wood of xeric twigs and branches of *Sarcobatus vermiculatus* (greasewood), to which it might be restricted. It was found in cold-temperate to warm-continental semiarid (to subhumid) saltbush desert scrubs in a small area around the Abajo Mountains in the Canyonlands section of the Colorado Plateau in the southwest of Northern America. The not included samples on *Atriplex* (saltbush) and *Parkinsonia* (blue paloverde) originate from warm-temperate to subtropical arid saltbush and creosote desert scrubs of the Mojave and Sonoran Desert.

Specimens included. **USA**: **Utah**, Canyonlands, 15.5 km N of Monticello, Peters Canyon, 1905 m, branches of *Sarcobatus vermiculatus*, on wood, 15.VI.2000, G. Marson (M-0276605, **holotype**; **isotype** in 6739b; CBS 116230, anam. cult.; sq.: KT215241). – 67 km NNW of Blanding, 48 km SSW of Moab, Salt Creek, near Cave Spring Trail, 1475 m, branch of *S. vermiculatus*, on wood, 15.VI.2000, G. Marson (ø). – 15 km WSW of Blanding, Cottonwood Road, Brushy Basin Wash, 1602 m, branch of *S. vermiculatus*, on wood, 15.VI.2000, G. Marson (H.B. 7183b). – 5.8 km SSW of Blanding, Westwatercreek, 1700 m, branches of *S. vermiculatus*, on wood, 15.VI.2000, G. Marson (H.B. 7163a).

Not included. **USA**: **Arizona**, Mojave Desert, 15 km SE of Havasu Lake City, N of Aubrey Hills, 355 m, branch of *Parkinsonia florida*, 9.VI.2000, G. Marson (ø, anam. substr.). – **California**, Mojave Desert, 130 km NNE of Los Angeles, 14 km NW of California City, 830 m, branch of *Atriplex confertifolia*, on wood, 23.VI.2000, G. Marson (H.B. 6721e, in M-0276505 [*O. sonorensis* & *O. macroserpens*]).

Orbilia caudimaeandrina Baral & G. Marson, **sp. nov.**, MB 813703 — Pl. 691

Etymology: named after the resemblance to *O. maeandrina* and the distinct spore tails.

Typification: Namibia, Rehoboth, branch of indet. angiosperm, 25.VIII.1995, R. Reuter (ex H.B. 5389, M-0276450, holotype).

Latin diagnosis: Orbiliae maeandrinae *similis, sed ascosporae caudis praeditae, cellulae vegetativae absque corpusculis globosis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.2 mm diam., 0.1 mm high, light orange-rose, round, very scattered; disc flat, margin 0–5 µm protruding, smooth; sessile, ± superficial. **Asci** *(53–)57–76 × 8.3–10.3 µm {1}, †48–60 × 8–9 µm, (13–)16-spored, spores *2–3-seriate, (4–)7–9 lower spores inverted, pars sporifera *38–40(–56) µm long; **apex** (†) strongly truncate (not or very slightly indented, laterally uninflated), hemispherical in side view, thin-walled; **base** without or with very short, thick stalk, Y-shaped. **Ascospores** *9–14 × 3–3.6(–3.8) µm, †8–12 × 2.8–3.2 µm, ellipsoid-fusoid, mostly with a distinct tail, apex obtuse to subacute, tail *1–4 × 1–1.2(–1.6) µm, straight to slightly, rarely medium curved near base; **SBs** *5–7.8 × 0.7–0.9 µm in situ (~5.5–9 µm actual length), vermiform, slightly to strongly flexuous. **Paraphyses** apically slightly to medium clavate-spathulate, rarely lageniform, terminal cells *4–9(–14) × (2.5–)3–4(–4.8) µm, †2.2–3.2 µm wide, lower cells *(6–)8–15 × 1.5–2.5(–3) µm (near base 2.3–2.8 µm); frequently branched near apex. **Medullary excipulum** 20 µm thick, with inflated cells. **Ectal excipulum** of (†) indistinctly oriented textura angularis from base to mid flanks, 20 µm thick near base, 10–15 µm thick at flanks and margin, cells at flanks *7–9 × 5–7 µm; at margin of t. prismatica oriented at a 10–20° angle to the surface, marginal cortical cells *6–10 × 3–4.5 µm. **Anchoring hyphae** not examined. **SCBs** in paraphyses and ectal excipulum absent. **Exudate** over paraphyses 0.5–1.2 µm thick, continuous, finely rough, ± loosely attached, over margin 1.5–3 µm thick, hyaline, indistinctly layered. **— ANAMORPH**: unknown.

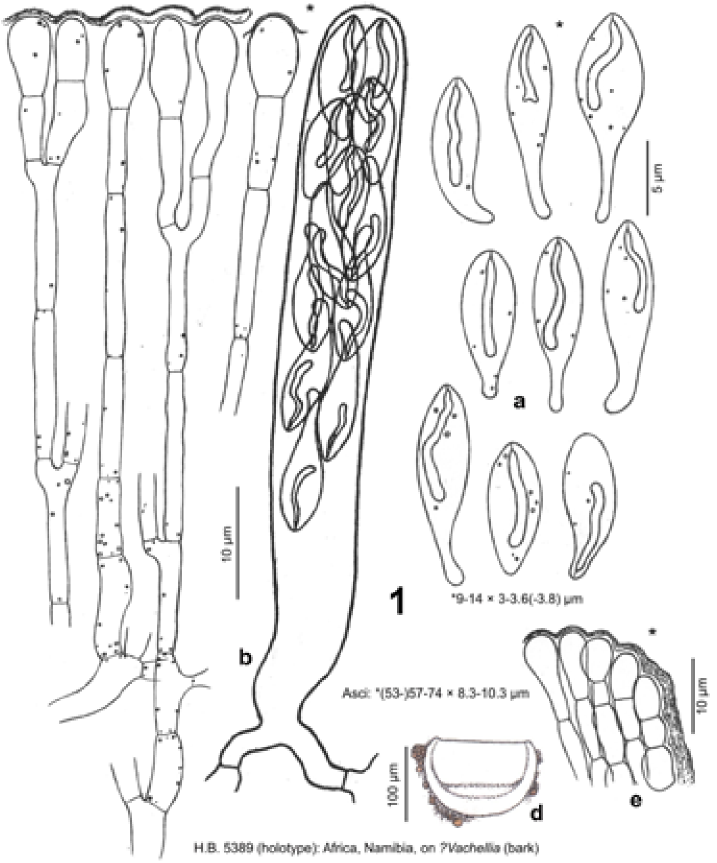

Plate 691. **1**: *Orbilia caudimaeandrina*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecia in median section; **e**. id., marginal ectal excipulum.

Habitat: attached, mainly corticated, 18 mm thick branch of unidentified angiosperm (?*Vachellia*), on medium decayed bark (bast), medium greyed, no algae. **Associated**: *Dothideales*. **Desiccation tolerance**: fully viable for at least 4 months. **Altitude**: 1560 m a.s.l. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia caudimaeandrina* resembles *O. maeandrina* in the ascospores and 16-spored asci, but sharply differs in having distinct spore tails in most of the spores, and in lacking SCBs. For the similar *O. vermiculati* and *O. paloverdensis* see p. 1166 and p. 1169.

Variation. Usually all spores of an ascus had distinct tails. However, some asci were encountered in which the tails were absent or very short in all spores or only in the apical spores (see Pl. 689: 1b).

Ecology. *O. caudimaeandrina* grew on medium rotten bark of a xeric angiosperm branch (?*Vachellia*) in the hot, subtropical arid (winter-dry) Kalahari highland thornbush savannah about 150 km away from the Namib Desert in southwestern Africa.

Specimens included. **NAMIBIA**: **Khomas**, 60 km S of Windhoek, 25 km N of Rehoboth, Central Plateau, Auas Mts., 1560 m, branch of ?*Vachellia*, on bark, 25.VIII.1995, R. Reuter (ex H.B. 5389, M-0276450, **holotype**).

Orbilia rosicola Baral & E. Weber, **nom. prov.** — Pl. 692

Etymology: according to the substrate, *Rosa* sp.

Typification: Spain, Guadalajara, Tamajón, branch of *Rosa*, 14.V.1996, H.O. Baral (H.B. 5511g, unpreserved).

Latin diagnosis: *Differt ab* Orbilia quaestiformi *ascosporis plerumque caudatis, corpuscula refringentia filo breve affixa continentibus, paraphysibus apice interdum spathulatis, corpuscula crystalloidea continentibus.*

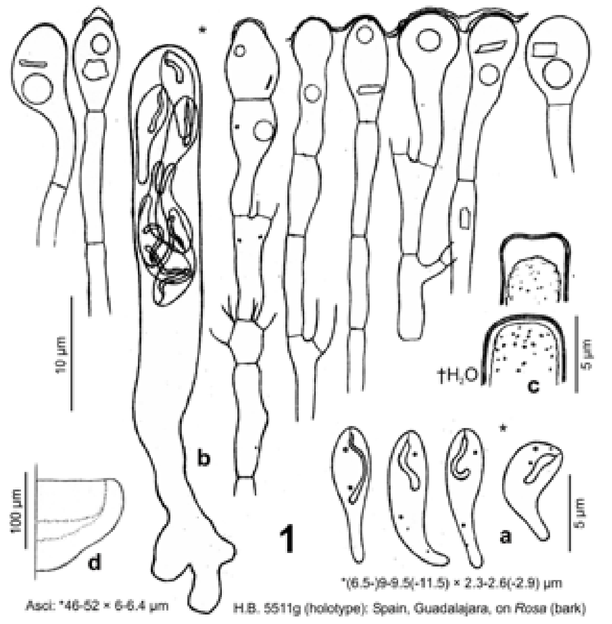

Plate 692. **1**: *Orbilia rosicola*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.22 mm diam., 0.12 mm high, light to bright pure orange, round, scattered; disc flat, margin smooth, not protruding; sessile on a narrowed base. **Asci** *46–52 × 6–6.4 µm, 8-spored, spores *3–4-seriate, 4 lower spores inverted (not or slightly mixed), pars sporifera *23 µm long; **apex** (†) medium to strongly truncate (partly distinctly indented, laterally sometimes slightly inflated), hemispherical in side view, thin-walled; **base** with short, thick, flexuous stalk, Y- to h-shaped. **Ascospores** *(6.5–)9–9.5(–11.5) × 2.3–2.6(–2.9) µm, with an ellipsoid-fusoid head and a ± distinct tail, apex obtuse (to subacute), tail *2–3.2(–5) × 0.7–0.8 µm, straight to ± strongly curved near base; **SBs** *3–5 × 0.3–0.5(–0.7) µm in situ (~3.2–6 µm actual length), vermiform (to subulate), medium to strongly flexuous, helicoid, or uncinate. **Paraphyses** apically medium to strongly clavate-capitate, also spathulate, terminal cells *7–15 × (2.3–)3.3–5.5 µm, lower cells *7–13 × 1.8–2.3 µm; sometimes branched near apex. **Medullary excipulum** 25 µm thick, indistinctly delimited. **Ectal excipulum** of (*) thin-walled, indistinctly vertically oriented textura angularis from base to margin, 40 µm thick near base, cells *8–14 × 5–8 µm; 25 µm thick near margin, marginal cortical cells *6–8 × 4–5 µm. **Anchoring hyphae** not studied. **SCBs** in paraphyses and ectal excipulum (near margin) globose, (1–)1.5–2.5 µm diam., in paraphyses also trapezoid to rod-shaped, low-refractive. **Exudate** over paraphyses 0.3–1(–2) µm thick, finely rough, continuous or sometimes forming small caps, firmly attached, over margin and flanks thin. — **ANAMORPH**: unknown.

Habitat: collected 1 m above the ground, ± decorticated, 11 mm thick branch of *Rosa* sp. {1}, on patches of medium decayed, fissured bark (bast), slightly detaching, ungreyed. **Associated**: *Baggea* sp., *B. pachyascus*, ?*Calloria* sp., '*Chlorosplenium*' *viridulum*, *Mellitiosporiella pulchella*, *Mollisia rosae*, *Orbilia gambelii*, *O. pleiogambelii*, *O. subaristata*, *O. subclavuliformis*, *O. subovoidea*, *Schizoxylon* sp. **Desiccation tolerance**: fully viable for at least 6 weeks. **Altitude**: 1040 m a.s.l. **Geology**: Tertiary dolomite with sand & marl. **Phenology**: long-lived.

Taxonomic remarks. The sparse and only collection of *O. rosicola* consisted of two apothecia, in which only a few asci were mature. Because these were used up during examination and the branch was not preserved, also because the limits against other species could not enough be explored, *O. rosicola* is not validly described here.

Based on the available characteristics, the species differs from *O. quaestiformis* in the frequent presence of a spore tail, spore bodies with a distinct short filum, and paraphyses with a tendency to spathulate apices that mostly contain besides globose also angular (crystalloid) SCBs. In spore shape *O. rosicola* resembles the 16-spored North American *O. paloverdensis* and the central African *O. caudimaeandrina*, but here the living paraphyses do not contain any SCBs, also the apothecia of the former are much larger. In ascospore and paraphysis characters *O. rosicola* resembles also the 32-spored *O. multiurosperma*.

Ecology. *O. rosicola* was collected on medium decayed bark of a xeric branch of *Rosa* in a supramediterranean semihumid juniper shrubland with *Cistus ladanifer* (*Juniperetum thuriferae*) in central Spain (southwestern Europe).

Specimens included. **SPAIN**: **Castilla-La Mancha**, **Guadalajara**, Sistema Central, 43 km NNW of Guadalajara, 2 km NNW of Tamajón, Ermita de los Enebrales, 1040 m, branch of *Rosa*, on bark, 14.V.1996, H.O. Baral (H.B. 5511g ø).

Orbilia paloverdensis Baral & G. Marson, **sp. nov**.,

MB 813705 — Pls 693–694

Etymology: named after the substrate, *Parkinsonia* (= paloverde).

Typification: USA, Arizona, Tucson, branches of *Parkinsonia* (?)*microphylla*, 6.V.1995, G. Marson (ex H.B. 5671e, M-0276549, holotype).

Latin diagnosis: *Differt ab* O. caudimaeandrina *ascosporis multo minoribus, paraphysibus apice valde inflatis. Habitat ad lignum putridum siccum ramorum* Parkinsoniae *in zona subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.4–0.8(–1) mm diam., 0.15–0.2 mm high, light to bright brick-red, non-translucent, round, gregarious; disc ± flat, margin ± thick, 0–10 µm protruding, indistinctly rough; broadly sessile, superficial or often ± immersed in clefts. **Asci** *56–77.5 × 5.5–6.8 µm {1}, †58–66 × 5–6 µm {1}, 16-spored, spores *~3-seriate, ~8 lower spores inverted (± mixed), pars sporifera †36–48 µm long; **apex** (†) medium to strongly truncate (partly distinctly indented and laterally inflated), hemispherical in side view, thin-walled; **base** with short to medium long, thick,

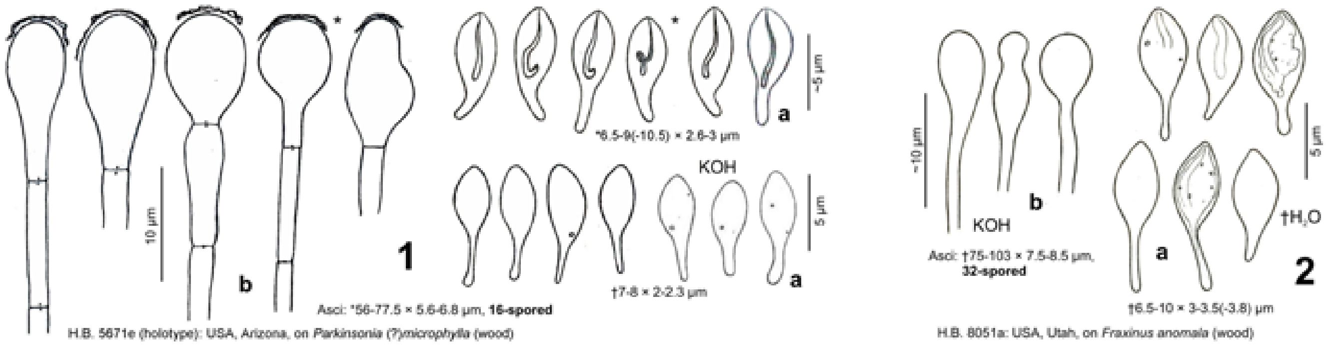

Plate 693. **1**: *Orbilia paloverdensis*; **2**. *O.* aff. *paloverdensis*. – **a**. ascospores; **b**. paraphyses.

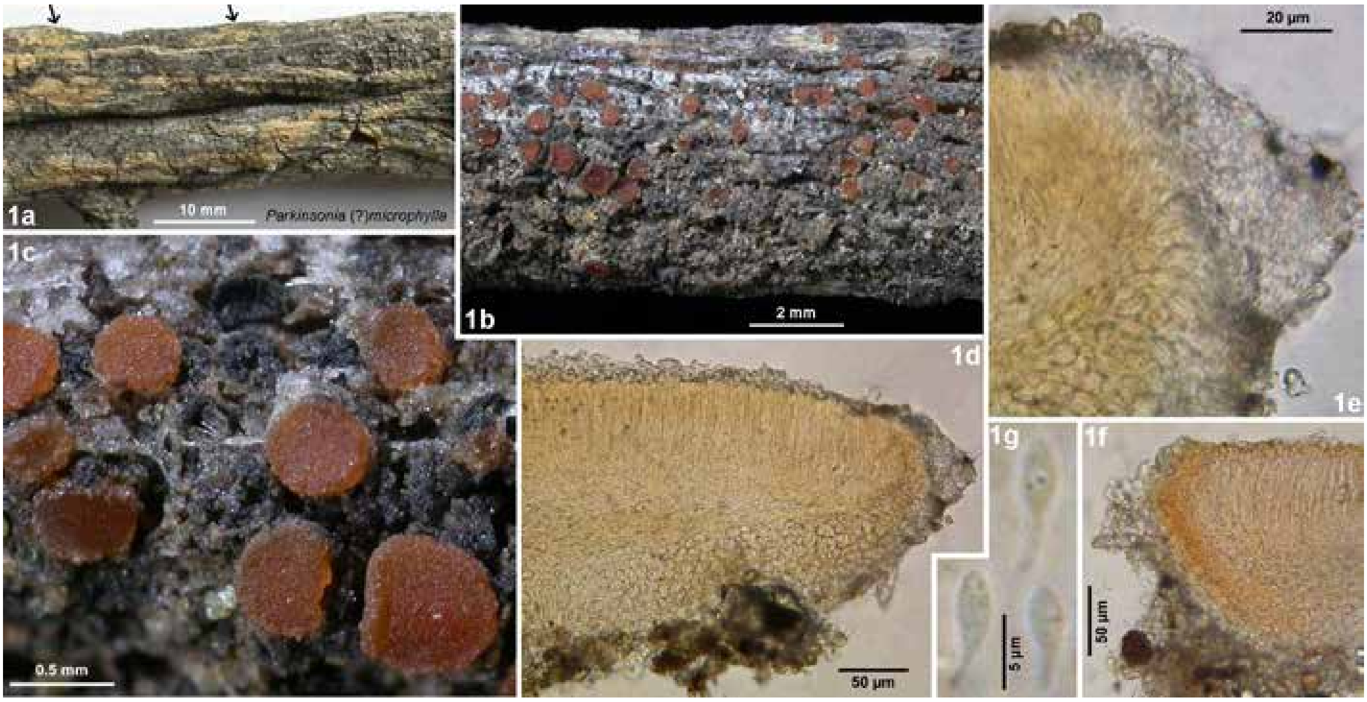

Plate 694. **1**: *Orbilia paloverdensis* (holotype). – **1a–b**. decorticated, rotten xeric branches; **1b–c**. rehydrated apothecia; **1d**, **f**. apothecia in median section; **1e**. id., marginal ectal excipulum with hyaline covering layer; **1g**. ascospores. – Dead state (**f** in H_2O; **d–e**, **g** in KOH). — **1a–g**. H.B. 5671e: USA, Arizona, on *Parkinsonia*.

flexuous stalk, L- to Y-shaped. **Ascospores** *6.5–9(–10.5) × 2.5–3 µm, †7–8 × 2–2.3 µm, with an ellipsoid-fusoid head and a distinct tail, apex obtuse to subacute, tail *~1.3–2.6 × 0.7–0.9 µm, †2–3.2 × 0.4–0.8 µm; straight or often slightly to medium curved at base (less so in dead state, here tail partly swollen at base); **SBs** *~4–5 × 0.3–0.5 µm in situ (~5–5.5 µm actual length), vermiform to subulate, not swollen at the base, slightly to strongly flexuous or helicoid, partly uncinate. **Paraphyses** apically (medium to) strongly or very strongly clavate-capitate (rarely lageniform), terminal cells *9.5–14 × 4.5–7.2 µm, †9–14 × 3.5–6 µm, lower cells *~10–14 × 1.7–2.3 µm (near apex up to 3.5 µm wide); unbranched at upper septum, hymenium light orange. **Medullary excipulum** pale orange, 30–70 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale orange (at margin partly bright orange), of (†) irregularly oriented textura (globulosa-)angularis from base to submargin, overall (thin-walled to) slightly gelatinized [common walls ~1(–1.5) µm thick], 35–50 µm thick near base, cells †(5–)7–13(–16) × (5–)6–9(–10) µm; 25–30 µm thick near margin, upper margin of t. prismatica oriented at a 30–60° angle to the surface, marginal cortical cells †~5–8 × 2.5–3 µm. **Anchoring hyphae** rather abundant, 1.8–3 µm wide, walls 0.2–0.4 µm thick, forming a dense, 10–30 µm thick hyaline layer at flanks and margin. **SCBs** in paraphyses absent. **Exudate** over paraphyses and margin 0.3–1 µm thick, granular-cloddy, firmly attached, hyaline. — **ANAMORPH**: unknown.

Habitat: attached, partially or mostly entirely decorticated, 6–16 mm thick branches of *Parkinsonia* (?)*microphylla*, on 0.5–1 mm deep strongly decayed wood, strongly greyed, no algae. **Associated**: *Orbilia calyptrata*, *O. maeandrina*, *O. multicercocarpi*, *O. pleioserpens*, *O. sedonensis*, *Patellaria* '*andina*'. **Desiccation tolerance**: fully viable for at least 1 year. **Altitude**: 810 m a.s.l. **Geology**: Permian-Triassic-Jurassic sandstone; volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia paloverdensis* differs from *O. vermiculati* in smaller ascospores with more distinct tails, also in the spore bodies being mostly longer than half the spore length, in much larger apothecia, and in unbranched paraphyses. *O. caudimaeandrina* differs from *O. paloverdensis* in a similar way, except for having also distinct spore tails and long SBs. With its spore characteristics *O. paloverdensis* further resembles *O. multiurosperma* which, however, differs in 32-spored asci, shorter SBs, partly branched paraphyses, and in having crystalloid SCBs.

Not included collection. A sample from Utah on *Fraxinus* (Pl. 693: 2) resembles *O. paloverdensis* in the spores, but differs in 32-spored asci. Only a few cells of paraphyses and ectal excipulum were alive when studied 32 months after collecting, and no SCBs have been seen in them. The sparse apothecia measured rehydrated 0.4–0.5 mm diam., and had a bright brick-orange disc and a slightly protruding, rough, whitish margin. Undoubtedly this represents a species of its own, but in the absence of vital characters we refrained from describing it as a new species.

Ecology. *O. paloverdensis* was found on rotten wood of xeric branches of *Parkinsonia* (?)*microphylla* (foothill paloverde) in a subtropical semiarid Sonoran paloverde-mixed cacti desert scrub in the southwest of Northern America. The not included collection was on xeric wood of *Fraxinus* in a warm-continental semiarid pinyon-juniper woodland of the Colorado Plateau.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 19 km W of Tucson, W of Old Tucson Studios, 810 m, branches of *Parkinsonia* (?)*microphylla*, on wood, 6.V.1995, G. Marson (ex H.B. 5671e, M-0276549, **holotype**).

Not included. **USA**: **Utah**, Canyonlands, Arches, 25 km NNW of Moab, Devils Garden, Landscape Arch, 1590 m, branch of *Fraxinus anomala*, on wood, 8.VI.2003, G. Marson (H.B. 8051a).

Series *Ellipsospermae*

Orbilia subgenus ***Habrostictis*** section ***Habrostictis*** series ***Ellipsospermae*** Baral & E. Weber, **ser**. **nov**., MB 815020 – Type species: *Orbilia gambelii* Baral & G. Marson

Etymology: named after the usually ± ellipsoid ascospores with rounded to obtuse ends.

Latin diagnosis: *Ascosporae *3.3–11.8 × 1.3–3.5(–4.5) µm, obovoideae vel ellipsoideo-clavatae, apice hemisphaerico vel obtuso, intus corpusculo refringenti, longe filiformi, flexuoso, ad apicem affixo. Paraphyses ad apicem clavato-capitatae. Status anamorphicus typo* Trinacrium.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.8(–1) mm diam., pale to bright rose or (yellowish-)orange(-ochre), margin smooth to finely rough or crenulate, partly protruding, sessile or with an ill-defined stipe. **Asci** 8- up to 128-spored, *(29–)35–70(–78) × 4–6.5(–7) µm when 8-spored, (40–)45–85(–101) × (4.5–)5–8(–9) µm when 16-spored, (50–)60–90(–120) × (6.2–)7–10(–11.5) µm when 32–128-spored, lower (1–)2–5(–6) spores inverted when 8-spored, (5–)7–10(–11) when 16-spored; **base** never H-shaped. **Ascospores** *(3.3–)4–10(–11.8) × (1.3–)1.5–3.2(–3.5) (rarely 3.5–4.5) µm, ellipsoid-ovoid to fusoid-clavate, also subcylindrical, apex rounded to obtuse, sometimes subacute or even acute, base sometimes tail-like, straight to slightly or sometimes strongly curved near base. **SBs** apically affixed to spore wall, rarely subapically affixed (in *O. namibica* and *O. myrionamibica*, rarely *O. microserpens*), (1.5–)2–8(–12) × (0.2–)0.3–1(–1.3) µm (actual length), filiform to subulate, with or without a thickened lower part, apically narrowed to a small point, without or with a very short filum, straight or often slightly to strongly flexuous, partly helicoid or uncinate. **Paraphyses** slightly or often medium to strongly clavate-capitate at the apex, terminal cells (0.3–)0.5–1.5(–2.5)× longer than lower cells. **Ectal excipulum** of (†) thin-walled or slightly gelatinized (common walls 0.3–1.5 µm), vertically or indistinctly, rarely horizontally oriented textura (globulosa-)angularis(-prismatica), cells near base *(5–)8–20(–30)((–41)) × (4–)6–14(–19) µm; near margin exceptionally with 2–5 µm thick **glassy caps** (*O. jurana*), **hairs** absent. **SCBs** globose or mixed with crystalloid ones. **Exudate** 0.2–1(–3)((–6)) µm thick, granular or granular-cloddy to continuous, loosely to mostly firmly attached, hyaline or pale yellowish-reddish, rarely only 0.1 µm thick or absent. — **ANAMORPH**: trinacrium-like. **Conidiophores** up to 30 µm long. **Conidia** Y-shaped, rarely 3–4-armed by repeated dichotomous branching, *19–55 × 17–56 µm, with or without unbranched phragmoconidia *25–61 × 4.5–6.2 µm, 3–7-septate.

Habitat: on wood and bark of angiosperms, exceptionally gymnosperms, also herbaceous stems or petioles of palms, humid to arid, temperate to predominantly warm-temperate to subtropical.

Recognized species: 33, plus 1 with a provisional name and 7 unnamed species ('affinis').

Taxonomic remarks. Series *Ellipsospermae* is segregated here from series *Serpentinae* based on typically ellipsoid ascospores with rounded to obtuse apices and not or only slightly attenuated bases. Representative members are *O. vitalbae*, *O. microserpens*, *O. gambelii* and allied taxa, but undoubtedly closely related species deviate in basally tapered, also often in more or less curved spores. Our molecular analysis confirms subdivision of the bulk of section *Habrostictis* into two large groups (see Phyls 19–20). As a result, also species with medium to strongly tapered spore bases are included in series *Ellipsospermae*, for instance *O. calyptrata*, but also two with fusoid to fusiform spores with obtuse to acute apices (*O. trapeziformis*, *O. obtusispora*) which we have retained in series *Serpentinae* based on spore morphology and a close resemblance to species such as *O. cylindrosoma*, *O. filiformis*, and *O. subtrapeziformis*. Exceptions in spore shape are actually not rare in both series and make series recognition based on morphology quite problematic. For instance, three taxa with apically obtuse and basally attenuated spores similar to *O. calyptrata* (*O. quaestiformis*, *O. mesaverdiana*, *O. vermiculati*) cluster in series *Serpentinae*. Quite a few taxa, for which no sequence was available, are only tentatively assigned to a series.

For instance, species around *O. vitalbae*, including *O. ungulata* and *O. jurana*, are considered here as closely related to typical members of series *Ellipsospermae*, but they differ in narrower, often more fusoid spores with apices varying from rounded to obtuse, obtuse to subacute, or subacute to acute, respectively. However, morphologically *O. vitalbae* and *O. subvitalbae* strongly resemble three further species with obtuse spore apices (*O. dixiensis*, *O. acaciae*, *O. pleioobtusispora*) which are tentatively assigned to series *Serpentinae* because of similarities with *O. obtusispora* which clustered close to *O. serpentina*. Likewise, *O. trapeziformis* and *O. cisti* resemble *O. maeandrina* and *O. multimaeandrina* in their fusoid-clavate spores with partly subacute apices, but their sequence data refer them to series *Ellipsospermae*, whereas *O. multimaeandrina* clusters in series *Serpentinae*.

O. namibica and *O. myrionamibica* deviate from most other members of series *Ellipsospermae* in their SBs being often subapically affixed, but this feature is also sometimes seen in *O. microserpens*. *O. jurana* is extraordinary, even within the entire section *Habrostictis*, because of very short glassy processes at the margin.

Species delimitation. Similar as in series *Serpentinae*, difficulties in species delimitation were also frequently encountered in series *Ellipsospermae*. For instance, *O. vitalbae* comprises populations with a very different spore length and also shape, and probably includes two species. Variation in spore size and shape is also noted, e.g., in *O. commarosa*, *O. barrowensis*, *O. gambelii*, *O. microserpens* etc. This variation obscures the limits to other taxa, e.g. between *O. gambelii* and *O. cercocarpi*. Almost each taxon made problems as soon as a couple of collections became available for study.

Anamorph. The conidia of series *Ellipsospermae* closely concur with those observed in series *Serpentinae*, being more or less of the *Trinacrium robustum*-type and often very similar among each other. In *O. ungulata* the two arms form a narrower, V-like angle. In some species, repeated dichotomous branching of the arms was noted (e.g., in *O. pleioungulata*).

Phylogeny. Sequence data were available for 10 of the 33 species included in series *Ellipsospermae*. Two additional species, *O. trapeziformis* and *O. obtusispora*, are tentatively treated by us in series *Serpentinae* for morphological reasons, but possibly belong partly to series *Ellipsospermae* based on available molecular data, except for one of the *O. trapeziformis* samples which fell in series *Serpentinae*. However, in the absence of such data in 66% of the species of this series we feel unable at the moment to make proper affiliations for all members of section *Habrostictis* according to the molecular concept.

The *Ellipsospermae* clade received high (SSU+ITS+LSU, LSU) or medium (ITS) bootstrap support in our phylogenetic analyses (Phyls 19–20, S22). Indeed, the alignment of the ITS region looks more homogeneous here compared to the more variable *Serpentinae-Habrostictis* clade.

In analyses of different rDNA regions (Phyls 19, 20, S20), two subclades can be recognized within series *Ellipsospermae*, though only with limited support. The *gambelii-vitalbae* clade includes, besides *O. gambelii*, *O. vitalbae*/*O. subvitalbae* and *O. obtusispora*/*O. trapeziformis* each clustering with high or medium support when analysing SSU+ITS+LSU or ITS. The moderately supported *microserpens-ungulata* clade includes also *O. macroserpens*, *O. cisti*, *O. cercocarpi*, *O. myrionamibica*, and *O. calyptrata*, whereas *O. ungulata* clustered unresolved in the *Ellipsospermae* clade (Phyl. 20).

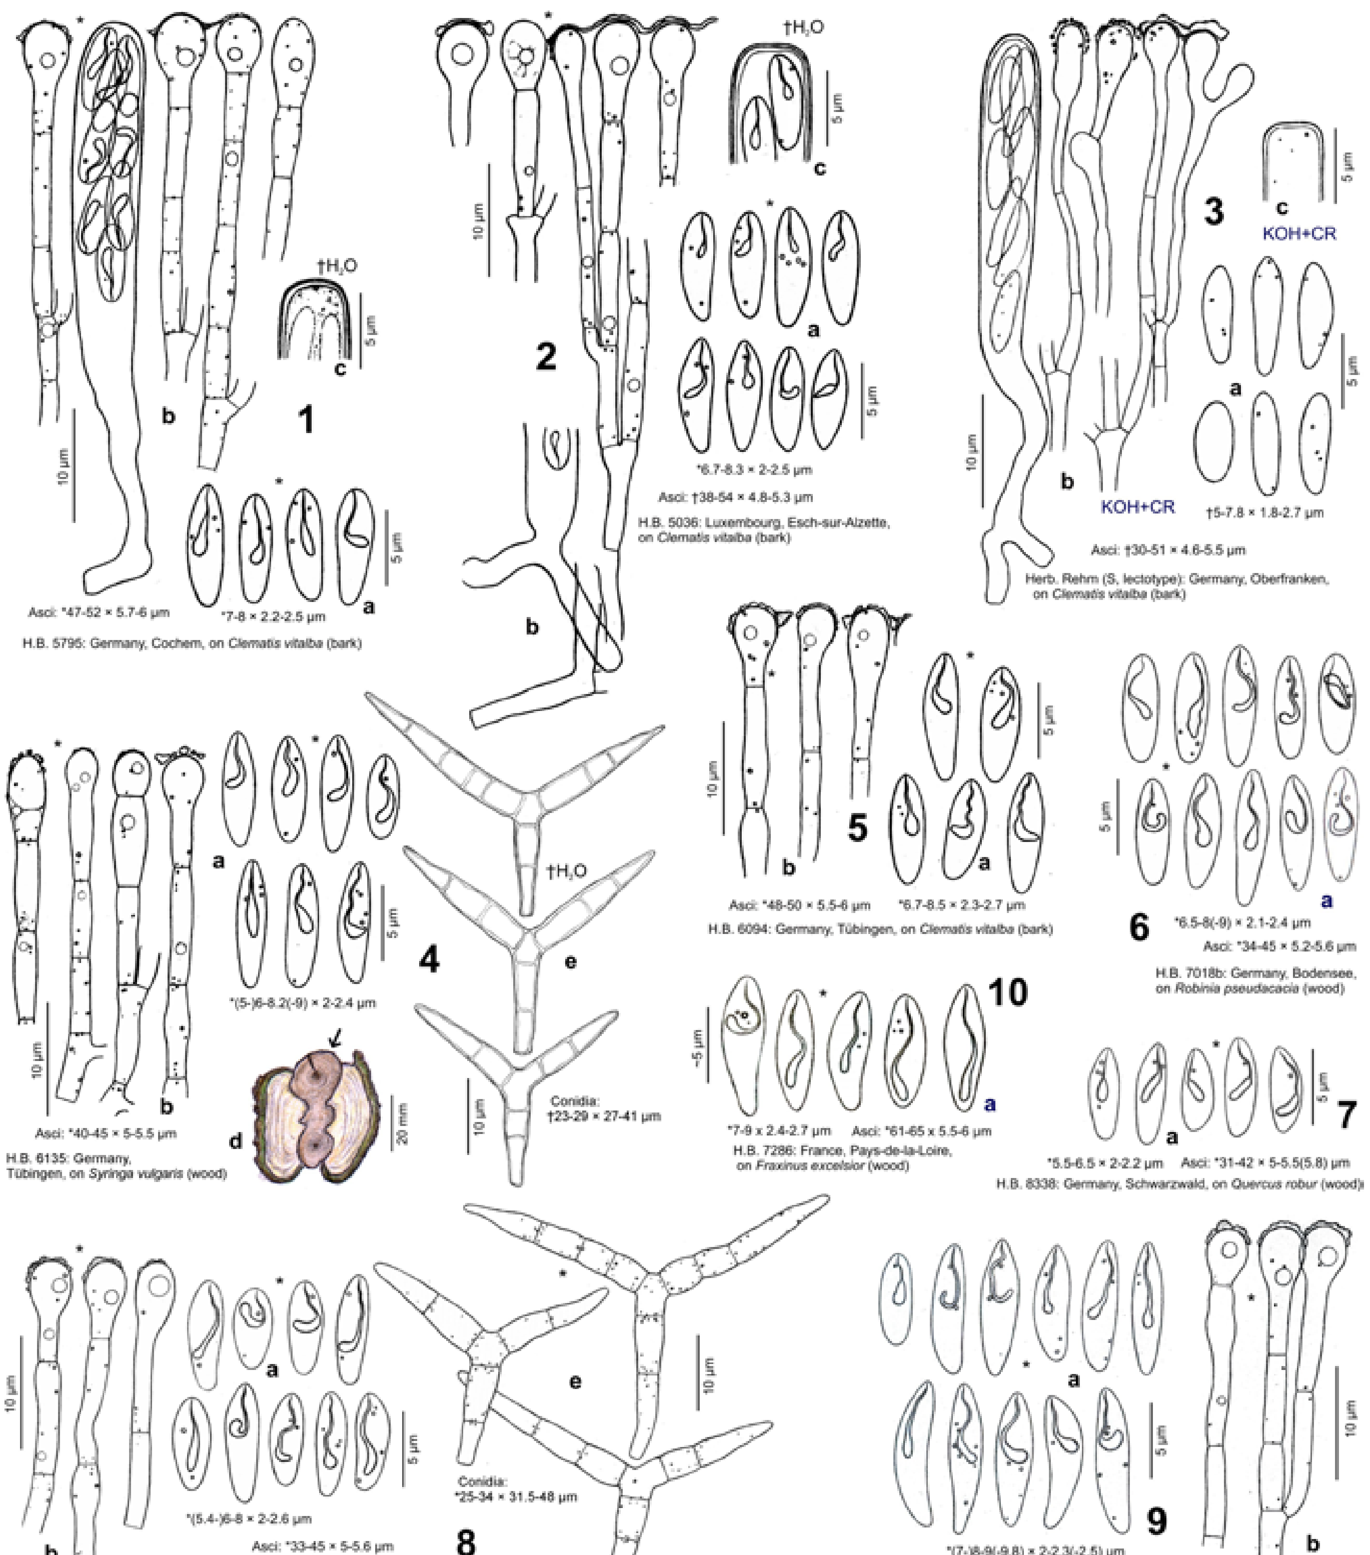

Plate 695. **1–9**: *Orbilia vitalbae*; **10**. *O.* cf. *vitalbae*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. living branch in cross section, with decorticated areas (same collection in Pl. 697: 3); **e**. conidia from substrate.

Specific nucleotide positions. Various nucleotide positions characterize the *Ellipsospermae* clade (see under section *Habrostictis*, p. 1014, and Tab. 72). These positions concur also with our phylogenetic result regarding two taxa (*O. obtusispora*, *O. trapeziformis* p.p.) which would from their fusoid spores with obtuse to subacute apices rather belong to series *Serpentinae*.

Orbilia vitalbae Rehm, in Ade, Hedwigia 64: 315 (1923) — Pls 695–698, Map 115

Etymology: named after the host in the holotype, *Clematis vitalba*.

Typification: Germany, Weismain, twig of *Clematis vitalba*, 30.III.1912, A. Ade (S-F9983, short-spored apothecia, lectotype, designated here, MBT202379); Switzerland, Seewis, twigs of *Clematis vitalba*, 20.VIII.2014, E. Weber & H.O. Baral (ex H.B. 9905a, M-0276607, epitype, designated here, MBT202380; sq.: KT380075).

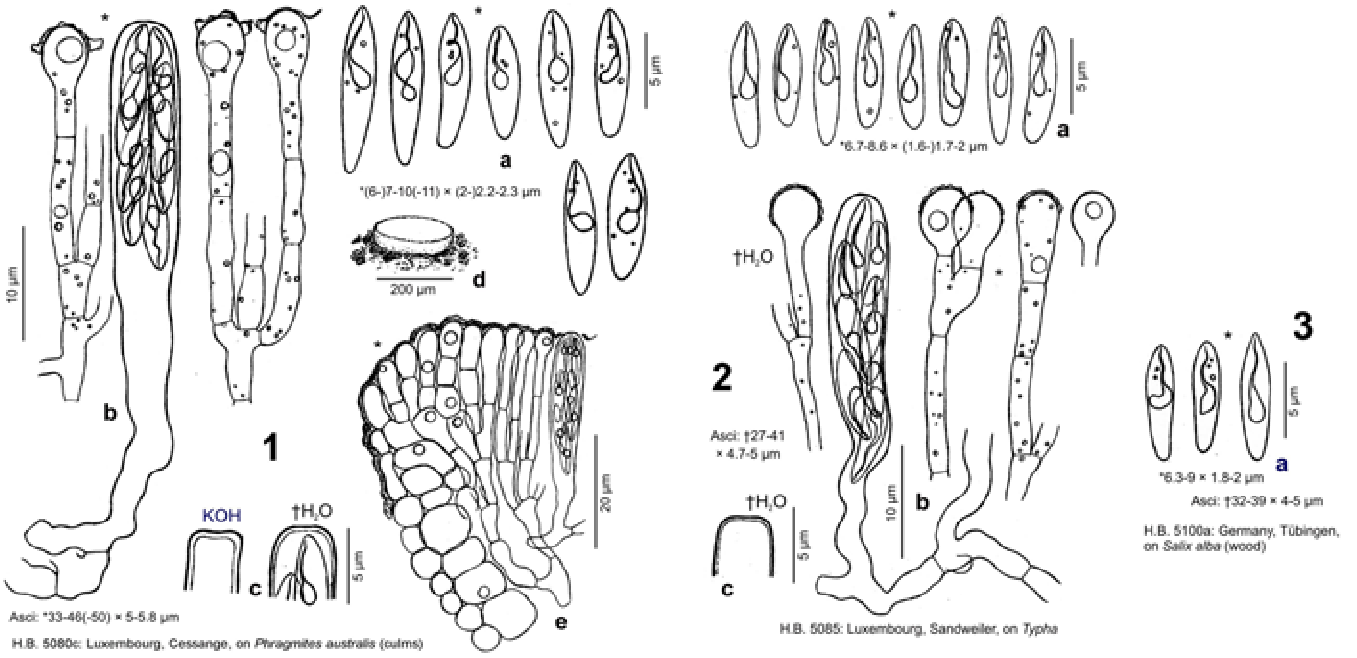

Plate 696. **1–3**: *Orbilia* cf. *vitalbae*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium; **e**. apothecium in median section.

Misinterpretation of *O*. *vitalbae*: Baral in Krieglsteiner (1999: 271), = *Hyalorbilia subfusispora*; Quijada et al. (2016: 244f.), ?= *O. paravitalbae*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.4 mm diam., 0.09–0.15(–0.2) mm high, very pale to bright cream-amber, (yellowish-)orange(-rose) or pure isabelline to (vinaceous-) rose, ± translucent, round, very scattered to gregarious; disc flat, sometimes finally slightly convex, margin indistinct or distinct, thin, 0–5 µm protruding, smooth or sometimes finely crenulate; sessile on a broader or narrower base, superficial to slightly immersed in biofilm or erumpent from beneath epidermis; dry light to deep cream, orange, rose. **Asci** *(31–)35–55(–60) × 4.6–5.7(–6) µm {15}, †(27–)30–50(–54) × (3.5–)4–5.3(–5.5) µm {7}, 8-spored, spores *2–3-seriate, (2–)3–5 lower spores inverted {18} (sometimes mixed), pars sporifera *17–25 µm long; **apex** (†) (slightly to) strongly truncate (without or sometimes very slightly indented, laterally rarely slightly inflated); **base** with short to medium long, ± thin, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(5–)5.5–9.5(–11) × (1.6–)1.8–2.5(–2.8) µm {27}, †5–8(–10) {4} × 1.4–1.6 {1} or 1.8–2.5(–2.7) µm {3}, (narrowly) ellipsoid to fusoid(-clavate), also subcylindric, apex rounded to obtuse, sometimes subacute, base not or slightly (to medium) attenuated, straight to slightly inequilateral; **SBs** *(2.5–)3–5.5 × (0.4–)0.5–1.1(–1.3) µm in situ {23} [~(3–)4–6(–7) µm actual length], divided into a ± abruptly swollen, subglobose, tear- or stomach-shaped or fusoid to fusiform lower part and a filiform or continuously thickened upper part of 0.5–1.5× the length of the inflated part, slightly to strongly flexuous, sometimes uncinate. **Paraphyses** apically slightly to (very) strongly capitate(-clavate), rarely spathulate, terminal cells *(4–)6–16 {10} or (11–)13–25 {3} × (2.8–)3.5–5 µm {13}, †2–5.7 µm wide {4}, lower cells *(5–)7–12(–15) × (1.3–)1.5–2.3(–2.7) µm {4}; very rarely branched at upper septum, hymenium pale rose. **Medullary excipulum** pale rose, 25–40 µm thick, of ± dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** very pale to light rose or pink, of (†) thin-walled or slightly gelatinized t. globulosa-angularis from base to (sub)margin, 20–60(–105) µm thick near base, cells *6–15(–19.5) × 6–12(–16) µm {6}; 12–30 µm thick at mid flanks and margin, cells *5–9(–12) × 6–9(–11) µm, oriented at a 10–80° angle to the surface, marginal cortical cells */†6–10 × (3–)3.8–6 µm {4}. **Anchoring hyphae** sparse to ± abundant, *2–3.3(–4) µm wide, walls 0.2–0.3(–0.5) µm thick {6}, sometimes forming a thin covering layer up to the margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose {11}, 1–1.8(–2.5) µm diam., also ± absent {3}. **Exudate** over paraphyses 0.2–1(–1.5) µm thick, granular-cloddy to continuous, mostly firmly attached, sometimes lacking; over margin and flanks 0.2–2 µm thick, cloddy to granular. **— ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {6}). **Conidiophores** not seen. **Conidia** on substrate Y-shaped, total size */†23–34 × 27–49 µm, stipe */†10–21 × 3–4 µm, 2(–3)-septate, arms tapering, */†15.5–27 × 3–4.3 µm, 2–4(–5)-septate {4}; in culture Y-shaped, total size *(23–)25–34 × (23–)25–47(–57) µm {1}, stipe *13–17 × 3.7–4.3 µm, 2-septate, arms tapering, *13–27(–32) × 3.5–4.5 µm, 2–4(–5)-septate {1}, sometimes unbranched, narrowly fusoid, *33–46 × 3.8–4.7 µm, 5–7-septate {1}.

Habitat: collected 0.1–6 m above the ground, corticated to decorticated, 5–40 mm thick, dead or sometimes still-living twigs and branches of *Acer pseudoplatanus* {1}, *Berberis vulgaris* {2}, *Buxus sempervirens* {1}, *Clematis vitalba* {9}, *Crataegus monogyna* {1}, *Ficus carica* {2}, *Hedera helix* {1}, *Juglans regia* {1}, *Lonicera etrusca* {1}, *Quercus* sp. {1}, *Q. robur* {1}, *Robinia pseudoacacia* {1}, *Rubus* (?)*bifrons* {1}, *R. fruticosus* {3}, *Salix alba* {1}, *S. caprea* {2/2}, *S.* ?*viminalis* {1}, *Sambucus nigra* {1}, *S. racemosa* {2}, *Syringa vulgaris* {1}, *Viburnum lantana* {1}, indet. angiosperm {1}, on 0.1–0.5 mm deep (or entirely) medium to strongly decayed wood {25} and bark (bast) {11}, also on textile (rope) {1}, ~1–2 year's old herbaceous stems and culms or leaves of ?*Cirsium* sp. {1}, *Pastinaca sativa* {1}, *Phragmites australis* {2}, *Sambucus ebulus* {1}, *Solidago canadensis* {1}, *Typha* sp. {2}, *T. latifolia* {1}, *Verbascum* sp. {1}, still standing or lying on dry ground, epidermis removed; partly eroded, slightly to strongly greyed, with a few to often many green algae. **Associated**: *Allophylaria sublicoides* {1}, *Bulbillomyces* sp. {1}, *Calloriopsis* sp. {1}, *Cryptodiscus foveolaris* {1}, '*Dasyscyphus*' *castaneus* {1}, *Durella connivens* {1}, *Eutypa acharii* {1}, *Eutypella* ?*scoparia* {1}, *Hohenbuehelia* sp. {1}, *Hyalorbilia juliae* {1}, *H. latispora* {3}, *H. subfusispora* {2}, *Hyaloscypha minuta* {1}, *Karstenia rhopaloides* {3}, *Lachnella* ?*villosa* {1}, *Lasiobelonium sublonicerae* {1}, *Lecophagus ellipsoideus* {1}, *Mollisia ligni* {1}, ?*Nectria* sp. {1}, *Neodasyscypha cerina* {1}, *Olla scrupulosa* {1}, *Orbilia albovinosa* {1}, *O. aristata* {2}, *O. breviaristata* {3}, *O. caulicola* {3}, *O. clavuliformis* {2}, *O. comma* {1}, *O. cylindrosoma* {2}, *O. eucalypti* {2}, *O. euonymi* {1}, *O. ficicola* {1}, *O. filiformis* {4}, *O. flavida* {4}, *O. flavidorosella* {1}, *O. gambelii* {1}, *O. obtusispora* {2}, *O. pleioeuonymi* {1}, *O. pleiolentiformis* {1}, *O. quaestiformis* {6}, *O. septispora* {2}, *O. subclavuliformis* {2}, *O. subtrapeziformis* {1/1}, *O. trapeziformis*

Phenology of *O. vitalbae*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0	1	3	2	10	8	5	5	6	3	5	0

Taxonomic remarks. *Orbilia vitalbae* is characterized by predominantly homopolar, narrowly ellipsoid to fusoid-clavate or subcylindrical, ± straight ascospores with rounded to obtuse ends. The most distinctive character concerns the spore body which consists of a ± filiform upper part and a ± abruptly and strongly swollen, often strongly bent lower part (resembling a music note or a stomach with oesophagus). The length of the SBs (in situ) is mostly 1/2–3/4 of spore length. *O. vitalbae* has often very minute apothecia (0.15–0.3 mm) and is then very difficult to detect when sparsely occurring over the greyed host surface.

The mediterranean *O. subvitalbae* (on *Arundo*) differs from *O. vitalbae* in the presence of distinct crystalloid SCBs and in slightly wider spores. *O. trapeziformis* and *O. obtusispora* usually differ in more distinctly fusoid spores with more often subacute apices, and in narrower SBs without an abrupt swelling of its lower part. However, these taxa are not sharply delimited. *O. ungulata* differs from *O. vitalbae* in smaller spores and the presence of crystalloid SCBs.

O. paravitalbae (section *Aurantiorubrae*, Pl. 489–490) deviates from *O. vitalbae* in rather long and narrow, more subcylindrical spores with predominantly rounded apices, and apothecia with a distinctly crenulate margin. In this respect, *O. paravitalbae* shows some similarities to *O. rosella* and *O. ebuli* of section *Aurantiorubrae*. A somewhat intermediate Macaronesian collection on *Sideritis* is mentioned under *O. paravitalbae* (p. 911, IVV: TFC Mic. 23937) although it was identified in Quijada et al. (2016) as *O. vitalbae*.

The North American *O. dixiensis* is very similar to *O. vitalbae* (for the differences see p. 1177). A North American collection on *Larrea* (IVV: H.B. 5684g) with rose-violaceous apothecia mentioned under *O. obtusispora* resembles also *O. vitalbae* and *O. dixiensis*. Its rather long SBs are not very abruptly inflated at the base, but the material was too scanty to make a detailed study. Two North American collections on *Amelanchier* (Pl. 715: 5; IVV: H.B. 8056h) mentioned under *O. commarosa* resemble *O. vitalbae* and *O. dixiensis* in their SBs, but the former deviates from these two taxa in rather strongly tapered, somewhat curved spore bases, also in the presence of small crystalloid SCBs in the excipulum.

Identification of *O. vitalbae* from dead herbarium material is highly problematic because some other species, such as *O. rosella* and *O. obtusispora*, and partly *O. eucalypti*, have a very similar spore size and shape, though strongly differing in their spore bodies. *O. rosella* (section *Aurantiorubrae*) resembles the long-spored specimens of *O. vitalbae* in spore size and shape, but appears to differ in rather short SBs, judging from a restudy of the type. *O. rosella* further differs in producing short, septate marginal hairs which are occasionally tipped by small glassy processes. In spore shape and size, short-spored collections of *O. vitalbae* come close to long-spored collections of *O. eucalypti* (section *Orbilia*), and may with certainty be distinguished only in the living state by their very different SBs. Also the dubious taxon *O. inconspicua* (p.p., on leaves and stems of *Dryas*) resembles *O. vitalbae*, regrettably it was only studied in the dead state (see p. 1674).

Variation. *O. vitalbae* shows a very high variation in ascospore length and width, also in spore body shape and size, and in the length of the terminal cells of paraphyses. A majority of collections have rather short and wide, ± ellipsoid spores measuring *5–9 × 2–2.5(–2.8) µm, with a length/width ratio of mostly 2.5–3.5 (Pl. 695: 1–8), particularly those on the type substrate *Clematis*. Others have slightly longer and narrower, more subcylindric to fusoid-clavate spores measuring *6–10(–11) × 1.6–2.3 µm, with a length/width ratio of 3–5 (Pl. 696: 1–3). In quite a few of the long-spored populations, the spores are predominantly only *1.7–2 µm wide. Yet, intermediate populations sometimes occur (e.g., Pls 695: 4; 696: 1), and the host range encompasses woody and herbaceous substrates in both cases. The shape of the spore apex varies among the included collections from obtuse to subacute. Finally, variation in SB shape is rather high among the collections as can be seen on the drawings, but within a population SB length, curvature, shape, and width of the basal inflation also varies to some extent.

A somewhat marginal collection (Pls 695: 9; 697: 6) has partly fusoid spores with subacute apex and tapered base, resembling *O. trapeziformis* or *O. obtusispora*, but some other spores are ellipsoid-subcylindrical and the SBs partly stomach-shaped as is typical of *O. vitalbae*.

Type studies. The protologue of *O. vitalbae* is based on two collections, both 'in furrows of bark of *Clematis vitalba*': 30.III.1912, Oberfranken, Erlach near Weismain; 1.V.1913, Unterfranken, Homburg castle ruin near Gössenheim. A specimen of the first collection exists in S and was reexamined in the present study; the second collection could not be located in S and M.

On the label is a sketch of two oblong ascospores with rounded ends, one with a single large central drop and one with a small drop near each end. The spore size is given as 7 × 2 µm, the ascus size 35 × 5 µm, and the paraphyses with globose apices up to 4 µm wide. The protologue, however, gives the spores as narrowly fusiform, acute, straight, 5–6 × 2–2.5 µm, with minute oil drops, the ascus size as 20–33 × 4.5–5.5 µm, and the paraphyses apically 'elongate rounded' (?clavate), 3 µm wide. These differences indicate that the microscopic data of the protologue were not gained from this collection. However, in the absence of a voucher specimen of the second collection the specimen from Erlach must serve as lectotype of *Orbilia vitalbae*.

In this specimen eight apothecia were found, four of which were examined. As a result, this sample is a mixture of two or perhaps ?three macroscopically identical and even microscopically similar taxa growing in close vicinity on the same stem. They differ in spore size and shape: two apothecia (taxon 1) have spores 5–7.8 × 1.8–2.7 µm, with rounded to obtuse ends (Pl. 695: 3), whereas another apothecium (taxon 2, IVV: H.B. 6348b) has spores 8–10.7 × 2–2.3 µm, with ± distinctly acute upper ends. Also in the fourth apothecium the spores are apically ± acute, but measure only 7–8 × 2.2–2.5 µm. This apothecium appears to be intermediated between taxon 1 and 2.

Taxon 1 fits well the sketch on the label, whereas taxon 2 was probably overlooked by Rehm. Taxon 1 is obviously conspecific with our short-spored specimens in the present concept of *O. vitalbae*, particularly those on *Clematis*. Therefore, the name *O. vitalbae* is adopted here. Taxon 2 might be the species here reported as *O. obtusispora*. The apothecium with intermediate characters could also belong to taxon 1, but the acute spore apices would better fit *O. trapeziformis*. Due to the fact that shape and size of the SBs cannot be recognized in dead herbarium material, the identity of these taxa remains somewhat uncertain. In order to settle this confusing situation we here designate those apothecia with short spores and rounded to obtuse ends (Pl. 695: 3) in the collection from Erlach near Weismain (30.III.1912, S-F9983) as **lectotype** of *O. vitalbae*. Because of the paucity of the lectotype and the uncertainty of its identity, a specimen from Switzerland (Seewis, on *Clematis*, ex H.B. 9905a, Pl. 698), from which a sequence was gained, is designated here as **epitype** of *O. vitalbae*.

Before studying the type, the name *O. vitalbae* was erroneously applied by one of us (H.B., in Krieglsteiner, 1999: 271) to two collections now referred to *Hyalorbilia subfusispora*. In fact, the protologue data which report rather short asci without information on the ascus base, could as well refer to a species of *Hyalorbilia*.

Not included collections. Two specimens (France, on *Fraxinus*, Pl. 695: 10; Tübingen, on *Carpinus*, IVV: 4.VIII.2002) are not included in the description because the spore bodies show a more gradual than abrupt basal inflation, also the asci are extraordinarily long (*59–78 × 5.5–5.8 µm in the latter specimen). Both show a certain similarity in spore shape to *O. trapeziformis*, but appear to be better accomodated near *O. vitalbae* because of the shape of the spores that predominantly lack a strongly tapered base. However, J.P. Priou's drawing of H.B. 7286 shows spores typical of *O. trapeziformis*. Whether this refers to variation, interpretation, or to a mixture could not be clarified.

Map 115. Known distribution of *O. vitalbae* in Europe (yellow = not included collection).

Anamorph. Trinacrium robustum-like conidia were found on the natural substrate near apothecia of *O. vitalbae* (Pls 695: 4e, 8e; 697: 7), and quite the same conidia were obtained in pure culture (Pl. 698: 2). The rather large conidia with slender arms and stipe resemble those of *O. subvitalbae* or *O. pleiovitalbae*, but also those of *O. cylindrosoma*. Quite a few unbranched conidia occurred in pure culture, which were also obtained in culture of *O. pleiovitalbae* (Pl. 710: 1) but which were not seen on the natural substrate.

Phylogeny. Two sequences of *O. vitalbae* were available, both on *Clematis* (XI.2013, Luxembourg, LSU, from pure culture; H.B. 9905a, Switzerland, ITS+LSU, from apothecia, epitype). They fully concur in the LSU (D1–D2) and form with *O. subvitalbae* a strongly or medium (ITS) supported subclade (Phyls 19–20, S22), with a distance of 0.2% in the LSU and 2.7% in the ITS. The S1506 intron is absent in H.B. 9905a. The morphologically similar *O. paravitalbae* (p. 910, from Spain, on *Daphne*) strongly deviates and does not even cluster in section *Habrostictis* but in section *Aurantiorubrae*.

Ecology. *O. vitalbae* occurs on ± rotten wood (more rarely bark) of xeric twigs and branches of various angiosperm trees and shrubs (including *Rubus*), with a preference for *Clematis*, but also on herbaceous stems of both mono- and dicotyledonous plants. The species was mainly collected in subcontinental cold-temperate humid central Europe at colline to montane and even subalpine altitudes, often in thermophilous, sun-exposed vegetation such as heaths, hedges, old quarries, borders of forests, banks of rivers and lakes, and wetlands (*Salicetum*, *Phragmitetum*, *Typhetum*). However, it occurs also in orotemperate to orosubmediterranean humid and meso(sub) mediterranean semihumid areas of southern Europe, and in thermoboreal humid Scandinavia.

Specimens included. **FINLAND**: **North Karelia**, 42 km WNW of Joensuu, 1 km W of Outokumpu, Mökkivaara, 140 m, branch of *Sambucus racemosa*, on wood, 4.IV.2012, M. Pennanen (M.P., doc. vid.). — **GERMANY**: **Thüringen**, 2.5 km S of Sonneberg, WSW of Oberlind, An der Müß, 355 m, stem of *Solidago canadensis*, 22.XI.2015, I. Wagner (ø, doc. vid.). – **Rheinland-Pfalz**, 0.5 km SSE of Cochem, SE-slope of Cochem castle, 125 m, twig of *Clematis vitalba*, on bark, 12.V.1997, H.O. Baral (H.B. 5795 ø). – **Baden-Württemberg**, 3.2 km SE of Altensteig, 1.1 km EE of Egenhausen, Egenhäuser Kapf, 620 m, branch of *Viburnum lantana*, on wood, 22.XI.2010, H.O. Baral (H.B. 9457a ø). – ibid., branch of *Salix* ?*caprea*, on wood, 22.XI.2010, H.O. Orbilia dixiensis Baral & G. Marson, **sp. nov.**, MB 813706 — Pls 699–700

Etymology: named after the geographical origin, Dixie Forest (Utah, USA).
Typification: USA, Utah, Grover, branch of *Salix* ?*bebbiana*, 15.V.1995, G. Marson (ex H.B. 5410a, M-0276475, holotype).
Latin diagnosis: *Similis* Orbiliae vitalbae *sed ascosporae saepe leniter curvatae, corpusculum refringens saepe brevius quam longitudo dimidiata ascosporae. Habitat ad lignum vel corticem ramorum siccorum fruticum in zona temperata semiarida ad boreali humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.4 mm diam., 0.11–0.17 mm high, light to bright orange, also or yellow-ochraceous, scarcely translucent, round, subgregarious; disc slightly concave to flat, margin distinct, 0–10 µm protruding, smooth to finely rough; broadly sessile, somewhat immersed. **Asci** *45–62 × 5.4–6.4 µm {2}, †42–63 × 5–5.5 µm {1}, 8-spored, spores *2–3-seriate, 1–5 lower spores inverted {2} (sometimes mixed), pars sporifera *25–35 → 18–22 µm long; **apex** (†) strongly truncate (not distinctly indented, laterally hardly inflated); **base** with very short, thick stalk, L-, Y- or h-shaped. **Ascospores** *(6–)7.5–10(–11.8) × (1.9–)2.1–2.4(–2.6) ((?–2.8)) µm {3}, subcylindric (to fusoid-clavate), apex rounded to obtuse, base not or slightly (to medium) attenuated, straight to slightly (or medium) curved; **SBs** (2.4–)2.8–4.3(–5) × (0.3–)0.4–0.7(–0.8) µm in situ {3}, vermiform to subulate, basally often slightly to strongly inflated, sometimes also subapically so (dumbbell-shaped), straight or ± flexuous. **Paraphyses** apically medium to very strongly clavate-capitate, terminal cells *6–15(–21) × (2.5–)3–4.5(–5.5) µm {2}, lower cells *8–16 × 1.4–2.6 µm {2}; unbranched at upper septum. **Medullary excipulum** very pale yellow-orange, 30–50 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** very pale rose, of (†) thin-walled, vertically oriented t. angularis-prismatica from base to mid flanks, 20–50 µm thick near base, cells *8–20 × 6–12 µm {1}; 20–25 µm thick at flanks, of t. globulosa, cells *6–12 × 5–7 µm, 20 µm thick near margin, of t. porrecta oriented at a 30–45° angle to the surface, marginal cortical cells *7–14 × 2–4 µm {1}, converging as small teeth. **Anchoring hyphae** medium abundant, *2–3.5 µm wide, walls 0.2–0.4 µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 0.8–2.2 µm diam. **Exudate** over paraphyses 0.2–1 µm thick, rough-cloddy to continuous, very pale yellowish-orange, firmly attached, over margin and flanks 1–2.5 µm thick. **— ANAMORPH**: unknown.

Habitat: collected 0.1–0.5 m above the ground, corticated or decorticated, 8–15 mm thick branches of *Artemisia tridentata* {1}, *Ericameria nauseosa* {1}, *Salix* ?*bebbiana* {1}, on 0.5–1 mm deep strongly decayed wood {1} and bark (bast) {2}, sometimes in clefts, bark partially detached, strongly greyed or not, with a few to many green algae. **Associated**: *Diplolaeviopsis* sp. {1}, *Hysterographium* sp. {1}, *Lophiostoma* sp. {1}, *Orbilia delphinus* {1}, *O. gambelii* {1}, *O. lentiformis* {1}, *O. mesaverdiana* {2}, *O. multimaeandrina* {1}, *O. multiphanosoma* {1}, *O. multitrapezoidea* {1}, *O. myriophanosoma*

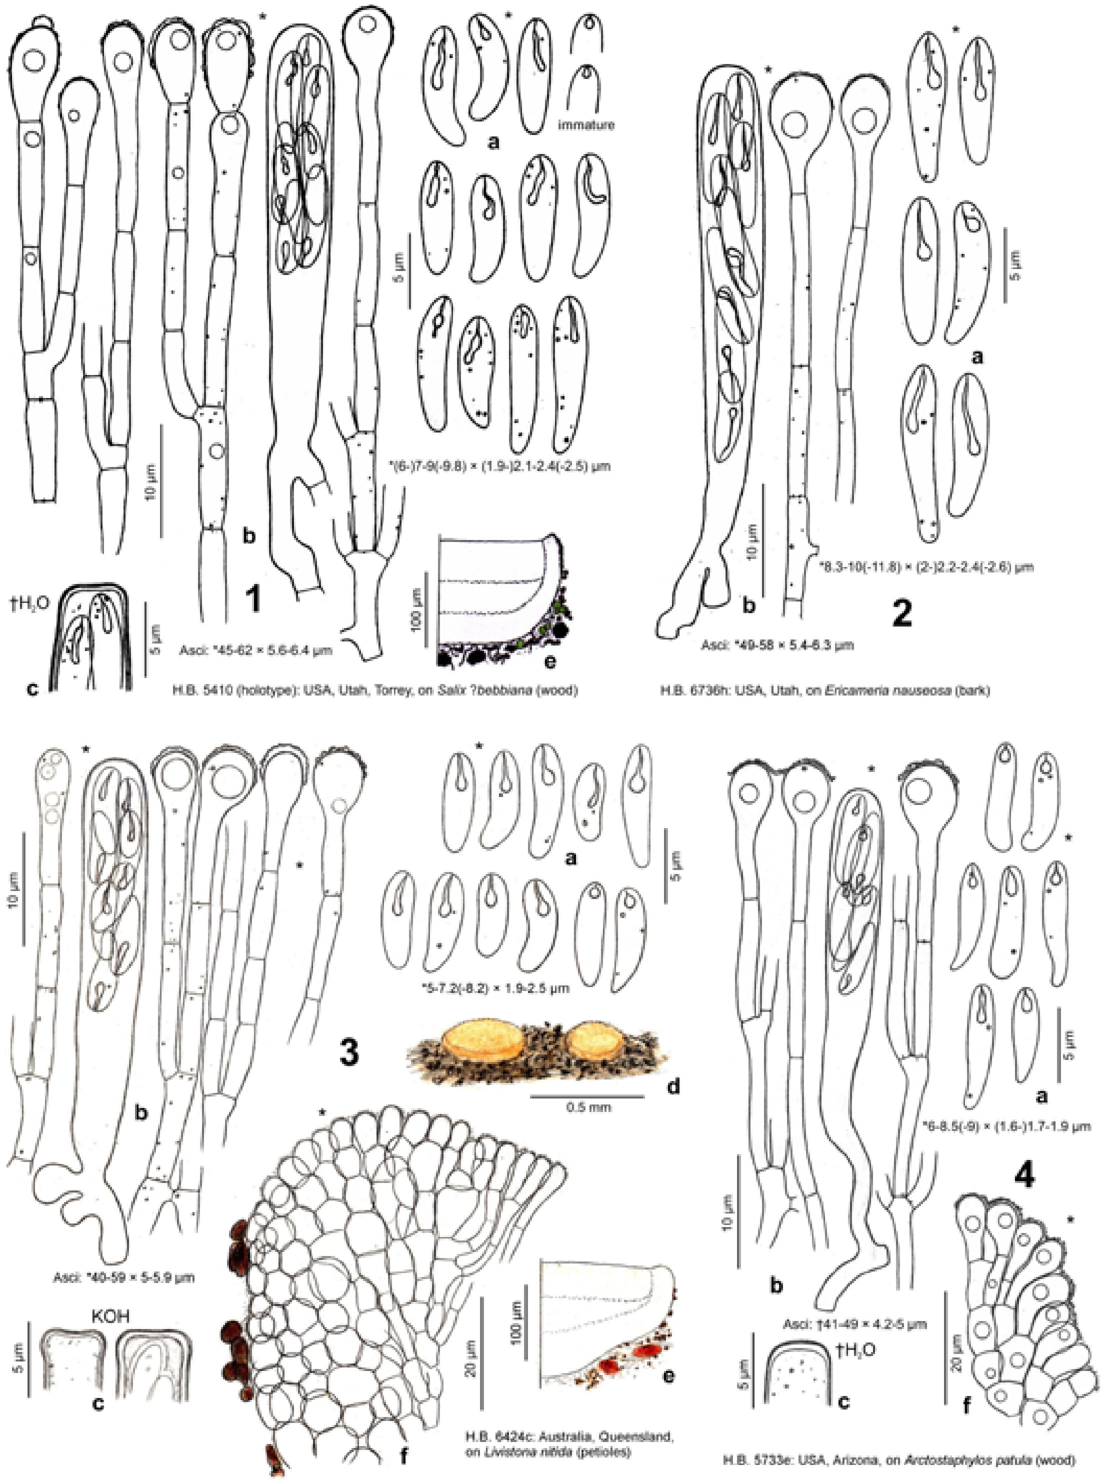

Plate 699. **1–2**: *Orbilia dixiensis*; **3**: *O.* cf. *dixiensis*; **4**: *O.* aff. *dixiensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., marginal ectal excipulum.

{1}, *O. navajoana* {1}, *O. ocellata* {1}, *O. plurilentiformis* {1}, *O. spathulata* {1}, *Perrotia flammea* {1}, *Schizoxylon argentinum* {1}, *Unguiculariopsis* sp. {1}, crustose lichens. **Desiccation tolerance**: fully viable for at least 9 months. **Altitude**: 1700–2825 m a.s.l. **Geology**: Triassic-Jurassic-Cretaceous sand & sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia dixiensis* is very similar to European *O. vitalbae*, from which it is tentatively separated by somewhat shorter spore bodies (usually shorter than half the spore length), and by often slightly curved ascospores. Two North American collections on *Amelanchier utahensis* mentioned under *O. commarosa* (Pl. 715: 5, IVV: H.B. 8056h) deviate from *O. dixiensis* especially in more strongly tapered spore bases, also in the presence of small crystalloid SCBs. The two European species *O. subvitalbae* and *O. ungulata* differ from *O. dixiensis* in the presence of crystalloid SCBs, the latter also in smaller spores.

Variation. The holotype slightly differs from the samples on *Artemisia* and *Ericameria* in less inflated paraphysis apices and shorter, partly dumbbell-shaped SBs.

Not included collections. An Australian sample on *Livistona* (Pl. 699: 3) deviates from *O. dixiensis* merely in slightly shorter spores and wider marginal cortical cells (*8–10 × 4–8 µm). This

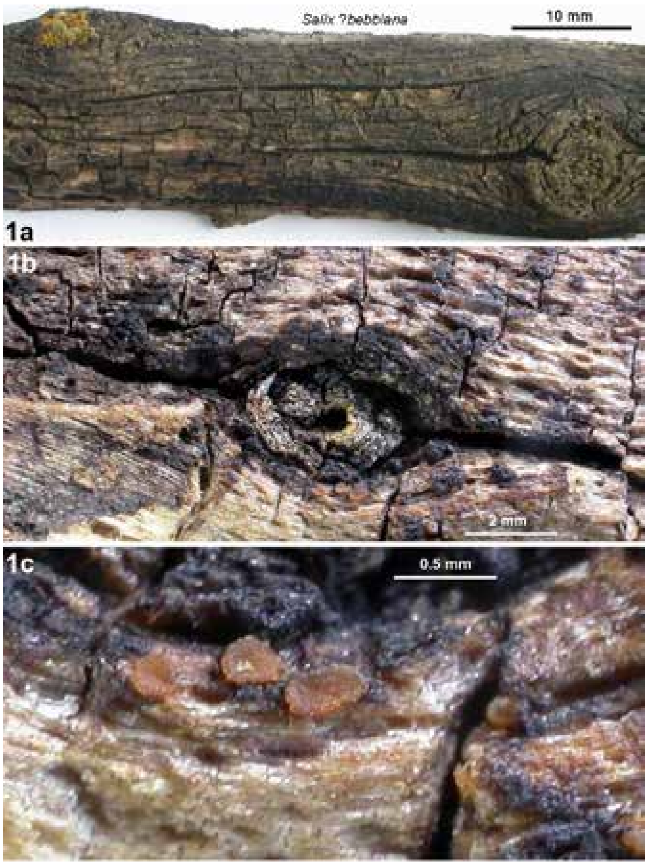

Plate 700. **1**: *Orbilia dixiensis*. – **1a**. decorticated xeric branch; **1b–c**. apothecia (rehydrated 9.5 years later). — **1a–c**. H.B. 5410a (holotype): USA, Utah, on *Salix*.

population grew associated with apothecia which gradually deviated by ± strongly curved spores (illustrated and mentioned under *O. commarosa*, Pl. 715: 6). A collection on *Arctostaphylos* (Pl. 699: 4) differs from *O. dixiensis* in smaller, especially narrower spores and mostly very short SBs, a feature for which this specimen is also mentioned under *O. pseudocylindrospora* (series *Regales*, section *Aurantiorubrae*). A sample on *Berberis* from Spain with spores of *(7.7–)8–10(–12.3) × 2–2.2(–2.4) µm (IVV: E.R.D. 7892) resembles long-spored *O. vitalbae*, but the often slightly curved spore bases better fit *O. dixiensis*.

Ecology. *O. dixiensis* grew on very rotten wood and bark of xeric branches of different angiosperm shrubs in western North America. The holotype on *Salix* wood was collected in the boreal humid Douglas fir mixed forest in the Dixie Forest of Utah Mts., the two paratypes on bark of *Artemisia* and *Ericameria* at lower altitude in cold-temperate to warm-continental semiarid sagebrush desert scrubs of the Colorado Plateau (Utah Mountains and Canyonlands). The not included North American collection was in a warm-continental subhumid manzanita chaparral scrubland (pinyon-juniper woodland) in the Mogollon Rim adjacent to Sonoran Desert, that from Australia in a subtropical semihumid eucalypt woodland on Jurassic sedimentary rock, and that from Europe in a suprasubmediterranean semihumid area of northern Spain.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 27 km SSE of Torrey, 18 km S of Grover, 3 km N of pass, 2825 m, branch of *Salix ?bebbiana*, on wood, 15.V.1995, G. Marson (M-0276475, **holotype**; **isotype** in H.B. 5410a). – Canyonlands, 60 km NW of Page, Cottonwood Canyon, ~1700 m, branches of *Artemisia tridentata*, on bark, 25.VIII.1994, G. Marson (H.B. 5197a ø). – 36 km S of Moab, Canyonlands, 5 km WNW of Hatch Rock, 1813 m, branch of *Ericameria nauseosa*, on bark, 16.VI.2000, G. Marson (H.B. 6736h).

Not included. **USA**: **Arizona**, Mogollon Rim, 37 km SSW of Flagstaff, ~1 km NE of Sedona, 1320 m, branch of *Arctostaphylos patula*, on wood, 8.V.1995, G. Marson (H.B. 5733e). — **AUSTRALIA**: **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, leaves of *Livistona nitida*, on petioles, 22.X.1998, G. Marson (H.B. 6424m ø). — **SPAIN**: **Asturias**, 49 km NW of León, E of Rabanal de Luna, 1142 m, branch of *Berberis vulgaris*, on bark, 18.IV.2019, E. Rubio (E.R.D. 7892, doc. vid.).

Orbilia subvitalbae Baral & E. Weber, **sp. nov.**, MB 813707 — Pl. 701

Etymology: named after the resemblance to *O. vitalbae*.

Typification: France, Hérault, Sète, culms of *Arundo donax*, 20.IX.1999, G. Marson & H.O. Baral (ex H.B. 6504a, M-0276600, holotype; ex-type culture: CBS 116228; sq.: KT215250).

Latin diagnosis: *Similis* Orbiliae vitalbae *sed ascosporae latiores*, *cellulae vivae excipuli et paraphysium corpuscula crystalloidea pallide aurantiaca continentes. Habitat ad culmos putridos* Arundinis *et* Junci *in zona mesomediterranea Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.35(–0.45) mm diam., 0.08–0.1 mm high, pale to light (sometimes dirty) orange, medium translucent, round or sometimes elongate, scattered to subgregarious; disc flat, margin distinct or not, 0–10 µm protruding, smooth; broadly sessile, nearly superficial or slightly to entirely immersed (erumpent). **Asci** *50–64 × 5.5–6.6 µm, †42–50 × 5–5.4 µm, 8-spored, spores *2(–3)-seriate, 2–5 lower spores inverted (somewhat mixed), pars sporifera *28–33 µm long; **apex** (†) medium to strongly truncate (not distinctly indented, laterally inflated or not); **base** with very short to medium long, thin or thick, flexuous stalk, L- or Y-shaped. **Ascospores** *(5.5–)7.5–8.5(–9.5) × (2.2–)2.7–3(–3.3) µm, subcylindric to fusoid-clavate, apex rounded to obtuse, rarely subacute, base not or slightly to medium attenuated, straight to somewhat inequilateral, rarely slightly curved at base; **SBs** *3–5(–6) × (0.3–)0.5–1 µm in situ, divided into a narrowly to broadly tear-shaped lower part and a filiform to subulate upper part, slightly to medium flexuous or helicoid. **Paraphyses** apically medium to strongly (clavate-)capitate, terminal cells *(4.5–)6–16 × (2.5–)3–5.3 µm, lower cells *(4–)5.5–12.5(–14) × 1.4–2.2(–3.3) µm; sometimes branched at upper septum. **Medullary excipulum** 15 µm thick, of ± dense textura intricata with indistinctly inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled, ± horizontally oriented t. globulosa-angularis from base to margin, 20–35 µm thick near base, cells *7–13 × 5–11 µm; 15–30 µm thick near margin, oriented at a 10° angle to the surface, uppermost margin of t. prismatica, marginal cortical cells *5–10 × 3–5 µm. **Anchoring hyphae** ± sparse, †2–3 µm wide, walls 0.2 µm thick. **SCBs** in apices of paraphyses and upper margin globose, 1–2.5 µm diam., lower part of paraphyses and ectal excipulum from base to margin with rod-, angular or ring-shaped crystalloid SCBs of 2–5.5 × 1–3.5 µm, very pale to light yellowish-orange. **Exudate** over paraphyses 0.3–0.7 µm thick, cloddy, ± firmly attached; over margin and flanks 0.5–1.3 µm thick, rough-cloddy. **— ANAMORPH**: trinacrium-like (from ascospore isolate and natural substrate). **Conidiophores** not seen. C**onidia** (from substrate) Y-shaped, total size *23.5–36 × 28.5–53 µm, stipe *12–19.5 × 4–4.5 µm, 1–3-septate, arms gradually tapering, *14–30.5 × 4.5–6 µm, 2–3-septate; a single 3-armed conidium was seen, with one arm again dichotomously branched.

Habitat: 13–17 mm thick culms of *Arundo donax* {1} lying on the dry ground, 2–3 mm thick standing culms of *Juncus acutus* {1}, medium to very decayed, partially greyed, with a few green algae. **Associated**: *Lophiostoma* sp. {1}, *Patellaria atrata* {1}. **Desiccation tolerance**: fully viable for at least 8 months. **Altitude**: 0–1 m a.s.l. **Geol**: calcareous marine sand dunes. **Phenology**: IX, but long-lived.

Taxonomic remarks. *Orbilia subvitalbae* resembles *O. vitalbae* and *O. dixiensis* in the ascospores, but differs in wider spores and mainly in the presence of distinct crystalloid SCBs.

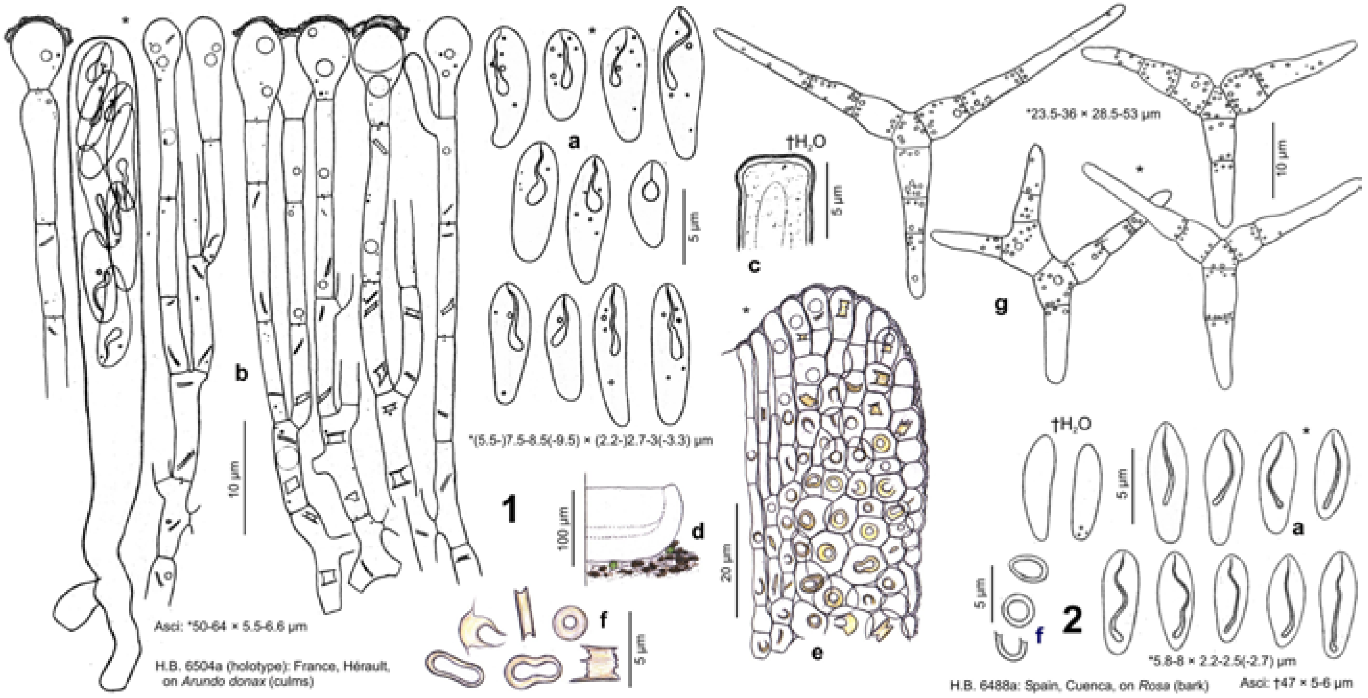

Plate 701. **1**: *Orbilia subvitalbae*; **2**: *O.* aff. *subvitalbae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs in ectal excipular cells at lower flanks; **g**. conidia from substrate.

Long-spored collections of *O. gambelii* approach *O. subvitalbae* but differ in slightly wider spores and particularly in much longer spore bodies. *O. ungulata* differs from *O. subvitalbae* in distinctly smaller spores.

Not included collection. A Spanish collection on *Rosa* (Pl. 701: 2) differs from *O. subvitalbae* mainly in subulate, narrower and longer SBs.

Anamorph. A few trinacrium robustum-like conidia were obtained in pure culture of the holotype. They were not documented but concurred with those found on the natural substrate (Pl. 701: 1g). This anamorph is very similar to that obtained in *O. vitalbae*.

Phylogeny. Sequences were gained from pure culture of the holotype and from apothecia of the paratype. Both comprise SSU (without S1506 intron), ITS, and LSU. The two strains are fully identical in the SSU (V8–V9, except for 2 gaps), ITS, and LSU (D1–D2). In the ITS region, *O. subvitalbae* shows 2.7 % distance to *O. vitalbae* (0.2 % in LSU), 4 % to *O. gambelii* (0.8 % in LSU), and 4.5–5 % to *O. trapeziformis* (0.4 % in LSU).

Ecology. *O. subvitalbae* was collected on medium decayed, xeric culms of *Arundo* and *Juncus* on sand dunes of lagunas at the sea shore in mesomediterranean semihumid southern France. The not included collection on bark of *Rosa* was in an orosubmediterranean, south-exposed, (semi)humid pine-juniper woodland in eastern Spain.

Specimens included. **FRANCE**: **Languedoc-Roussillon**, **Hérault**, 7 km SW of Sète, 13 km NE of Cap d'Adge, 1 m, culms of *Arundo donax*, 20.IX.1999, G. Marson & H.O. Baral (M-0276600, **holotype**; **isotype** in H.B. 6504a; anam. substr., anam. cult., CBS 116228; sq.: KT215250). – **Provence-Alpes-Côte d'Azur**, **Bouches-du-Rhône**, 2 km ENE of St.-Maries-de-la-Mer, Réserves des Impériaux (lagune), 0 m, culms of *Juncus acutus*, 5.IX.2017, G. Marson (G.M. 2017-09-05.1; sq.: MH221051).

Not included. **SPAIN**: **Castilla-La Mancha**, **Cuenca**, Sierra de Albarracín, 43 km NE of Cuenca, 8 km SW of Guadalaviar, S of Mt. Mogorrit, 1600 m, twig of *Rosa*, on bark, 26.IX.1999, H.O. Baral (H.B. 6488a).

Orbilia ungulata Baral, G. Marson & Matočec, **sp. nov.**, MB 813708 — Pls 702–703, Map 116

Etymology: referring to the horseshoe-shaped SCBs in the ectal excipulum.

Typification: Luxembourg, Hesperange, stem of *Reynoutria sachalinensis*, 4.VII.1999, G. Marson (ex H.B. 6412a, M-0276604, holotype).

Latin diagnosis: *Similis* Orbiliae vitalbae *sed asci et ascosporae minores, cellulae vivae excipuli corpuscula crystalloidea hyalina continentes. Habitat ad lignum vel corticem siccum putridum ramorum fruticum vel ad caules siccos in zona temperata humida ad thermomediterranea semihumida Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.35(–0.5) mm diam., 0.08–0.11 mm high, whitish-hyaline to pale or light cream-amber to orange-rose, translucent, round, scattered to subgregarious; disc slightly concave to flat, sometimes slightly convex, margin indistinct, thin, not protruding, ± smooth; broadly sessile or with a short obconical base, superficial; dry light orange. **Asci** *(29–)31–40(–45) × (4.2–)4.5–5(–5.5) µm {8}, †(23–)25–38(–45) × 4–4.3(–4.5) µm {3}, 8-spored, spores *2–3-seriate, (1–)3–4(–5) lower spores inverted {8} (rarely mixed), pars sporifera *(11.5–)14–18(–21) µm long; **apex** (†) strongly truncate (slightly indented, laterally sometimes inflated); **base** with short to medium long, ± thin, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(4–)5–7.5(–8.5) ((–9.5)) × ((1.4–))(1.6–)1.7–2(–2.2) µm {13}, †5–7.5 × 1.5–1.8 µm {1}, narrowly ellipsoid to fusoid or often fusoid-clavate, apex obtuse to subacute, base mostly slightly to strongly attenuated, straight to slightly inequilateral, sometimes slightly curved near base; **SBs** *(1.7–)2–4(–4.5) × (0.2–)0.3–0.6(–0.8) µm in situ {9}, subulate, base not or slightly inflated, narrowly tear-shaped to fusoid, straight to ± flexuous, in more aged spores divided into an abruptly swollen, tear-shaped lower part and a fine filum of ± equal length. **Paraphyses** apically slightly to strongly capitate(-clavate), terminal cells *(6–)8–14(–15) × (2.5–)3–4.5(–5) µm {5}, †(2.2–)2.5–4(–5) µm wide {2}, lower cells *4–8(–12.5) × 1.5–2(–2.3) µm {4}; unbranched at upper septum. **Medullary excipulum** 15–50 µm thick, of ± dense textura intricata with many inflated cells, indistinctly to medium sharply delimited. **Ectal excipulum** of thin-walled, vertically oriented t. (globulosa-)angularis from base to margin, 25–40 µm thick near base, cells *(8–)10–15(–24) × 7–13(–18) µm {5}; 12–20 µm thick near margin, oriented at a 10–45° or higher angle to the surface, marginal

?*Nectria* sp. {1}, *Olla millepunctata* {4}, *Ophioceras leptosporum* {1}, *Orbilia albovinosa* {1}, *O. caulicola* {4}, *O. cylindrosoma* {2}, *O. filiformis* {1}, *O. flavida* {4}, *O.* ?*obtusispora* {1}, *O. pleiolentiformis* {1}, *O. pleistoeuonymi* {1}, *O. quaestiformis* {2}, *O. vitalbae* {2}, *Patellaria atrata* {4}, *Pirottaea imbricata* {1/1}, *Pyrenopeziza ebuli* {1}, *Ramichloridium* ?*schulzeri* {1}, *Trichopeziza lizonii* {1}, *T.* ?*perrotioides* (immature) {1}, *Trichopezizella rubroguttata* {1}, *Stictis stellata* {1/1}, *Urceolella* ?*pani* {1}. **Desiccation tolerance**: fully viable for at least 1–2 weeks, after 2 months a few mature asci still alive. **Altitude**: 4–475 m a.s.l. **Geology**: Buntsandstein, Lower Jurassic, Cretaceous & Tertiary marl- & sandstone, flysch, Pleistocene sand & loess; alluvial deposits from granite. **Phenology**: IV–XI (but probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia ungulata* resembles *O. vitalbae* but differs in shorter and narrower, slightly more fusoid ascospores, shorter and narrower asci, and particularly in the consistent presence of crystalloid SCBs in the ectal excipulum, though virtually never in the paraphyses. Although it is unknown whether SCBs occurred in the lectotype of *O. vitalbae*, the dimensions of the dead asci and spores clearly exclude *O. ungulata.* As *O. ungulata*, the similar *O. subvitalbae* and the extra-European *O. acaciae* possess crystalloid SCBs but likewise differ in distinctly larger spores.

Variation. *O. ungulata* seems to be a fairly constant species. However, a few specimens deviated from the typical ones. The only sample from Germany (Thüringen), examined by I. Wagner (IVV: 24.VII.2017) on hygric *Reynoutria* stems, lacks crystalloid SCBs but otherwise seems to fit *O. ungulata* better than *O. vitalbae* because of narrow spores and not abruptly swollen SBs. It is included here because it concurs with a sample from Luxembourg on xeric *Reynoutria* stems (H.B. 7819) in its whitish apothecia growing associated with *Olla millepunctata*. The two Serbian samples deviate by comparatively long and narrow spores of *(5–)6–7.5(–8.5) × (1.4–)1.5–1.7(–1.8) µm and rather indistinct (*Fraxinus*) or seemingly absent (*Clematis*) crystalloid SCBs.

Not included collections. A Croatian sample on *Petteria* studied by N. Matočec (Pl. 702: 9) deviates by distinctly longer asci and slightly longer SBs (3–5.3 × 0.5–0.6 µm), although spore size and shape fit well. A specimen on *Krascheninnikovia lanata* from semiarid North America (IVV: H.B. 6085e) likewise differs in longer asci (*50–53 × 4.8–5.3 µm) and slightly longer spores (*8–9 × 1.6–2 µm).

Anamorph. The conidia of the anamorph of *O. ungulata* (Pls 702: 7i, 8i; 703: 2k, 3a–c) have somewhat converging arms reminiscent of *Trinacrium gracile* (with narrower stipe and arms) or some members of the genus *Dicranidion*, especially *D. gracile* (with somewhat shorter more converging arms).

Phylogeny. Sequences were gained from two samples of *O. ungulata* from Luxembourg, one from pure culture (17. VIII.2013, LSU) and one from apothecia (25.VII.2014, S1506 intron, ITS, LSU). In the LSU (D1–D2) the two are identical. When analysing ITS, LSU, or SSU+ITS+LSU, *O. ungulata* clustered unresolved in the highly or medium (ITS) supported *Ellipsospermae* clade (Phyls 19–20, S22). When analysing LSU a distance of only 0.5–1 % is noted to most other species of series *Ellipsospermae*, whereas in the ITS the minimum distance is 10–11 %. In the intron the distance is very high to any other species that has this intron.

An environmental strain from Australia (JQ026988, LSU) clustered with medium support and 1 % distance with *O. ungulata* in a clade (S22).

Ecology. *O. ungulata* was collected on rotten wood or bark of xeric branches of angiosperm trees and shrubs, but often also on xeric herbaceous stems of large dicotyledonous plants. Collections emanate from atlantic to subcontinental central warm- to cold-temperate humid Europe at planar to colline altitudes, but include also suprasub- to thermomediterranean semihumid areas of southern Europe. In central Europe the species appears to prefer thermophilous sites, e. g., sun-exposed ruderal places, e.g., along railways, but also forests with *Fraxinus*, *Salix*, *Alnus*, *Rhamnus*, and *Ilex*. In southern Europe the vegetation includes a *Quercus pubescens* forest with *Ruscus* and an old *Olea-Prunus persica* plantation. *O. ungulata* is so far absent in (hemi)boreal zones.

The not included collection on *Krascheninnikovia* (*Chenopodiaceae*) was in a warm-temperate semiarid Sonoran paloverde-mixed cacti desert scrub in a valley between Mogollon Rim and Sonoran Desert in the southwest of Northern America, that on *Petteria* (*Faboideae*) in a mesomediterranean semihumid shrubland in Dalmatia.

Specimens included. **FRANCE**: **Bretagne**, **Morbihan**, 5.3 km S of La Gacilly, 2 km N of St.-Vincent-sur-Oust, La Provostaie, 4 m, stem of *Reynoutria japonica*, 28.XI.2006, J.P. narrowly ellipsoid-fusoid), apex rounded to obtuse, base not or slightly (rarely medium to strongly) attenuated, straight to slightly inequilateral; **SBs** *2.5–3(–3.7) {3} or 4–6.5 {2} × 0.3–0.6 µm in situ {5} (~3–4 µm actual length), subulate, sometimes medium inflated in lower part, straight to slightly flexuous. **Paraphyses** apically slightly to medium (to strongly) clavate-capitate, rarely sublageniform, terminal cells *(6–)9–17(–21) × (2.5–)3.3–4.5(–5.2) µm {3}, lower cells *(5.5–)7–15 × 1.5–2.5(–3) µm {3}; unbranched at upper septum. **Medullary excipulum** 25–70 µm thick, of dense textura intricata-prismatica-angularis, sharply delimited. **Ectal excipulum** subhyaline, of (†) thin-walled, vertically oriented t. angularis(-prismatica) from base to margin, 20–35 µm thick near base, cells *(6–)8–15(–20) × (4–)6–10(–13) µm {3}, †5–10 × 4–7 µm {1}; 15–20 µm thick near margin, oriented at a 10–30 or 45–80° angle to the surface, marginal cortical cells */†5–7 × 2.5–5 µm {2}, sometimes projecting as short hyphoid elements. **Anchoring hyphae** abundant, *2–3(–5) µm wide, walls 0.2–0.4 µm thick {1}, forming a 5 µm thick covering layer up to mid flanks. **SCBs** in paraphyses, whole ectal excipulum and partly medullary excipulum globose, 1–2.5 µm diam., and rod- or ring- or spool-shaped {6}, (1–)2–5 µm diam., pale orange. **Exudate** over paraphyses 0.5–1.5 µm thick, granular-cloddy, hyaline, firmly attached; over margin and flanks ~1 µm thick, rough-cloddy. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** in H.B. 7226c: Y-shaped or often (70%) 3–4-armed by repeated branching (3-dimensional), total size *~(19–)30–35 × (25–)28–56 µm, stipe *11–17 × 5.5–7.5 µm, 1–2-septate, arms (unbranched) *(11–)25–28 × 4.5–5.5 µm, often abruptly tapering into a long and narrow terminal part, (1–)2-septate; in R.T.L. 12092902: Y-shaped, *28 × 27 µm, stipe *16 × 5.7 µm, 2-septate, arms *12–14 × 5 µm, 2-septate, tapering but without narrow part (only 1 conidium).

Habitat: 0–0.1 {Australia} or 0.5–3 m {Spain} above the ground, decorticated, 6–70 mm thick branches of *Acacia* sp. {3}, *A. coriacea* {1}, *Aeonium lindleyi* {1}, *Asparagus* sp. {1}, *Euphorbia balsamifera* {2}, *Juniperus phoenicea* var. *turbinata* {1}, *Lavandula canariensis* {1}, *Lycium intricatum* {1}, *Periploca laevigata* {1}, *Pinus pinea* {1}, *Plocama pendula* {3}, *Rubia fruticosa* {1}, on 0.1–0.2 mm deep (medium to) strongly decayed wood {6}, also on inner surface of bark {1}, slightly to strongly greyed, green algae absent or rather abundant. **Associated**: *Acanthostigma ellisii* {1}, *Capronia* sp. {1}, *Melaspilea emergens* {1}, *Orbilia barrowensis* {1}, *O. corculispora* {1}, *O. ?livistonae* {1}, *O. macrocarpa* {1}, *O. maeandrina* {1}, *O. ?multivirgula* {1}, *O. myriella* {1}, *O. myriomuscula* {1}, *O. pleiostomachia* {1}, *O. pluristomachia* {1}, *O. ?pseudeuphorbiae* {1}, *O. subaristata* {1}, *Ostropales* {2}, *Peniophora* sp. {1}, *Rhizodiscina* sp. {1}, *Symbiotaphrina desertorum* {1}, *Tryblidaria* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 weeks. **Altitude**: 6–711 m a.s.l. **Geology**: Australia: Paleo- & Mesoproterozoic sedimentary rock, Cenozoic regolith (sand), granulite with granitic gneiss; Tenerife: (trachy)basaltic and phonolitic flows and pyroclasts. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleioungulata* is characterized by 16-spored asci, ± homopolar, subcylindrical ascospores with typically rather short, subulate, only slightly flexuous SBs, and abundant crystalloid SCBs in the cells of paraphyses and ectal excipulum. The very similar *O. pleioobtusispora* is tentatively separated merely by the absence of crystalloid SCBs. *O. pleiovitalbae* differs in slightly broader spores with SBs divided into a filiform upper part and a strongly tear-shaped basal part, in more strongly swollen paraphysis apices, and in the absence of crystalloid SCBs. *O. acaciae* and the European *O. ungulata* appear to be closely related to *O. pleioungulata*, but differ in 8-spored asci, the former also in longer spores, the latter in more fusoid spores and in crystalloid SCBs being restricted to the ectal excipulum. *O. microserpens* differs in the consistent absence of crystalloid SCBs, and *O. pleiogambelii* in much wider (or shorter), ellipsoid spores; both differ from Australian samples of *O. pleioungulata* also in much longer SBs. The North American *O. calyptrata* differs in consistently spathulate to lageniform paraphyses, also in more fusoid-clavate, partly curved spores and in having very short marginal hairs.

Variation. In an Australian collection from Alice Springs the spores were partly strongly tapered at the base, particularly in the dead state (Pl. 704: 4). Collections from Tenerife (Macaronesia, on various substrates) and Valencia (Spain, on *Pinus*) fit quite well those from Australia, but tend to have longer SBs (3–4 or 4–6.5 µm, respectively, Pl. 705: 3–4, 7–8, L. Quijada & R. Tena pers. comm.), that from Valencia differs also in a tendency to rather large apothecia with a crenulate margin. Whether these differences are indicative for different taxa remains to be clarified, although a similar variation in SB length was noted in *O. ungulata*.

Not included collection. A North American sample on *Vitaceae* (Pls 704: 2; 705: 6) differs in comparatively short asci and spores.

Anamorph. Two types of conidia were observed on the natural substrate. In one type the conidia have 2 rather short arms and resembles *Trinacrium robustum* (Pl. 705: 6, 8f; 1 conidium of Pl. 704: 4h). In the other type the arms form long and narrow terminal cells, which are extraordinary in the *Orbiliomycetes*, also in having frequently 3 or 4 arms (Pl. 704: 4h). Both types occurred in abundance in H.B. 7226c, and it remains unclear which of them (or perhaps both?) belong to *O. pleioungulata*.

Also the not included collection from North America showed trinacrium robustum-like conidia, with a total size of †18–21 × 21–23 µm, 2-septate stipes of †11–12 × 5 µm, and 1–2-septate, gradually tapering arms of †10–12 × (3–)4–5 µm.

Ecology. *O. pleioungulata* was found on rotten wood (and bark) of xeric branches of *Acacia*, in subtropical to tropical arid acacia open woodlands and mainly shrublands (mulga) of western and central Australia. In Tenerife L. Quijada (pers. comm.) found it at a total of eight sites. Besides the records listed below, *O. pleioungulata* grew there in the inframediterranean arid *Ceropegio fuscae-Euphorbietum balsamiferae* and thermomediterranean semiarid juniper woodland with *Euphorbia* spp. (*Junipero canariensis-Oleetum cerasiformis*). The collection from Spain was in a thermomediterranean semihumid woodland with *Pinus pinea*, *Quercus coccifera* and *Myrtus communis*. *O.* cf. *pleioungulata* grew on rotten wood of a xeric branch of an unidentified *Vitaceae* in a warm-temperate subhumid woodland with *Quercus virginiana* in the Edwards Plateau (south of Northern America).

Specimens included. **AUSTRALIA**: **Northern Territories**, Burt Plain, 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, 480 m, branches of *Acacia*, on wood, 8.X.1998, G. Marson (ex H.B. 6260a, MEL 2389192, **holotype**). – 48 km NNW of Alice Springs, 15 km SW of Yambah, 711 m, branches of *Acacia coriacea*, on wood, 13.X.1998, G. Marson (H.B. 7226c, anam. substr.). – **Western Australia**, Gascoyne, southern border of Collier Range, 175 km NE of Meekatharra, 41 km SW of Kumarina Roadhouse, 560 m, branches of *Acacia*, on bark, 26.XI.2001, G. Marson (H.B. 8697b). – Murchison, southern border of Collier Range, 117 km NE of Meekatharra, 6.5 km WSW of Doolgunna, 573 m, branch of *Acacia*, on wood, 26.XI.2001, G. Marson (ø). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Buenavista del Norte, 5 km WSW of Buenavista del Norte, 3 km NW of Teno Alto, Punta de Teno, Lomo las Toldas, 190 m, branches of *Plocama pendula*, 27.XII.2012, L. & C. Quijada (TFC Mic. 23832, 23833, non vid.). – ibid., branch of *Lycium intricatum* (TFC Mic. 23839, non vid.). – ibid., branch of *Periploca laevigata* (TFC Mic. 23840, 23841, non vid.). – St. Cristóbal de la Laguna, 5.7 km NNE of Tegueste, 1.5 km E of Punta de Hidalgo, Andén de la Cruz, 75 m, on *Plocama pendula*, 27.X.2012, L. Quijada, I. Pérez-Vargas & R. Hernández (TFC Mic. 22704, non vid.). – ibid., on *Asparagus*, 11.X.2009, L. Quijada & E.V. Rodríguez (TFC Mic. 22365, non vid.). – ibid., on *Aeonium lindleyi* (TFC Mic. 22366, non vid.). – Tacoronte, 2.7 km NNE of El Sauzal, SSW of Mesa del Mar, Hoya las Higueras, 90 m, branches of *Euphorbia balsamifera*, on wood, 26.XI.2009, L. Quijada & E.V. Rodríguez (TFC Mic. 22641, non vid.). – Candelaria, 5.5 km NE of Güímar, 1 km S of Candelaria, Barranco Samarines, 40 m, on *Rubia fruticosa*, 12.XI.2009, L. Quijada & E.V. Rodríguez (TFC Mic. 22504–06, non vid.). – Arico, 3 km NNE of Abades, 0.7 km NNE of Porís de Abona, Llanos de Porís, 40 m, branches of *Euphorbia balsamifera*, on wood, 13.XI.2009, L. Quijada & E.V. Rodríguez (TFC Mic. 22541, doc. vid.). – 2.2 km NW of Abades, Montaña Centinela, 160 m, on *Lavandula canariensis*, 23.I.2010, L. Quijada & E.V. Rodríguez (TFC Mic. 22766, non vid.). – Guía de Isora, 5 km NNW of Guía de Isora, 1.7 km NW of Chío, Los Corchos, 640 m, branch of *Juniperus phoenicea* var. *turbinata*, 24.X.2014, L. Quijada, C. Quijada & J. Kout (L.Q. F-9, F-23, doc. vid.). – San Miguel de Abona, 4 km SSW of Las Chafiras, 1.5 km NE of Costa del Silencio, Montaña Amarilla, 35 m, on *Plocama pendula* (TFC Mic. 23678, non vid.). — **SPAIN**: **Com**. **Valenciana**, **Valencia**, 14 km SSE of Valencia, 3.5 km S of El Saler, SSE of Les Gavines, Gola de Puçol, 6 m, branches of *Pinus pinea*, on wood, 30.IV.2012, R. Tena (R.T.L. 12043003, doc. vid.). – ibid., 29.IX.2012, R. Tena (R.T.L. 12092902, anam. substr., doc. vid.).

Not included. **USA**: **Texas**, Oaks and Prairies, Edwards Plateau, 65 km W of Austin, ~2 km WSW of Johnson City, 380 m, branch of *Vitis*, on wood, 18.VI.1996, G. Marson (H.B. 5554a).

Orbilia calyptrata Baral & G. Marson, **sp. nov**., MB 813711 — Pls 706–707, Map 118

Etymology: named according to the paraphyses being tipped by cap-like glassy exudate.

Typification: USA, Utah, Moab, branches of *Purshia stansburyana*, 10.VI.2003, G. Marson (ex H.B. 8079c, M-0276447, holotype; sq.: KT222420).

Latin diagnosis: *Apothecia rehydratata 0.2–1 mm diam., aurantiaca, margine pruinoso vel breviter fimbriato. Asci 16-spori. Ascosporae *4.7–11 × 1.7–2.5 µm, ellipsoideo- vel fusoideo-clavatae, apice obtusae. Paraphyses ad apicem spathulatae vel sublageniformes, exsudato calyptriforme tectae. Habitat ad lignum putridum siccum arborum, fruticum vel plantae succulentae in zona subtropica semiarida vel temperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.7(–1) mm diam., 0.12–0.21 mm high, light to bright (rose-)orange(-ochraceous), round, broadly elliptical when growing in a cleft, scattered or gregarious in small groups; disc slightly to strongly concave, sometimes flat, margin thin or thick, ± whitish pruinose-pubescent, protruding 10–70 µm (incl. hairs), sometimes torn into broad lobes; broadly sessile, erumpent (slightly to completely immersed, especially in biofilm); dry urceolate with small opening. **Asci** *(48–)55–71(–78) × (4.8–)5.2–6.4(–6.8) µm {6}, †(46–)50–65(–70) × 4–5.7 µm {7}, 16-spored, spores 2–3-seriate, (4–)8(–10) lower spores inverted (sometimes mixed), pars sporifera *(23–)30–36(–45) µm long; **apex** (†) medium to strongly truncate (without or distinctly indented, laterally never or partly inflated); **base** with short to medium long, ± thick, flexuous stalk, L-, T- or h-shaped. **Ascospores** *(4.7–)5.5–9(–11) × 1.7–2.3(–2.5) µm {12}, †4.7–8(–9) × 1.5–2(–2.2) µm {5}, ellipsoid- to fusoid-clavate, apex (rounded to) obtuse (rarely subacute), base mostly slightly to strongly attenuated, straight or often slightly to medium curved near base; **SBs** *(2.5–)3.5–5(–5.8) × 0.2–0.7 µm in situ {3} [(2.5–)4–6.5 µm actual length], filiform to vermiform, often subulate, sometimes inflated at base, straight or often flexuous, rarely uncinate; overmature divided into a tear-shaped basal part and a fine filum of ± equal length. **Paraphyses** apically spathulate to sublageniform, terminal cells */†(8.5–)11–23(–27?) × (2.5–)3–4.3(–5) µm {5}, exceeding the dead asci by 3–8 µm, lower cells *9–14(–16) × 1.4–2.4(–2.8) µm {2}; unbranched at upper septum. **Medullary excipulum** subhyaline, pale orange near margin, 20–70(–100) µm thick, of ± dense textura intricata with some or many inflated cells, sharply delimited. **Ectal excipulum** subhyaline to pale rose-orange, of thin-walled to distinctly gelatinized, vertically oriented t. angularis(-prismatica) from base to mid flanks, 20–90 µm thick near base, cells */†(8–)12–24(–30) × (5–)8–14(–17) µm {6}; 15–40 µm thick at mid flanks and margin, of t. angularis-prismatica oriented at a 20–40(–70)° angle to the surface, cells *6–9 × 5–7 µm, uppermost margin of t. prismatica(-porrecta) oriented at 0–10°, marginal cortical cells */†7–18 × 2.5–5 µm {4}, firm-walled, partly forming somewhat flexuous, ± free hairs up to 20–30(–40) µm long and 2–3-celled, walls 0.2–0.4(–1) µm thick. **Anchoring hyphae** abundant, */†2–3.3 µm wide, walls 0.2–0.3(–0.8) µm thick {4}, covering the excipulum up to mid flanks. **SCBs** in paraphyses globose (sparse), mainly crystalloid {8}, 2.5–7 × 0.1–0.7 µm; in excipulum from lower flanks up to margin rod-shaped to trapezoid or ring-shaped, refractive, hyaline to pale orange, 2–6(–8) × 1–4.5 µm. **Exudate** on apices of paraphyses cap-like, 0.5–1.5(–3) µm thick, glassy, firmly attached, rarely only 0.3 µm thick and granular; over margin and flanks absent or sparse, granular. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** not observed. A single **conidium** seen, Y-shaped, †27 × 18 µm, stipe †17 × 5.8 µm, 3-septate, arms †8 × 5 µm, 2-septate.

Habitat: collected 0.2–2.5 m above the ground, decorticated, 4–20 mm thick twigs and branches of *Canotia holacantha* {2}, *Ephedra ?viridis* {1}, *Juniperus osteosperma* {2}, *Krascheninnikovia lanata* {1}, *Larrea tridentata* {3}, *Opuntia* sp. {1}, *Parkinsonia* (?)*microphylla* {1}, *Purshia stansburyana* {2}, on 0.2–1 mm deep strongly decayed, eroded wood {9}, often in longitudinal clefts, also on splitted wood, strongly greyed, green algae absent or few to many. **Associated**: *?Baggea* sp. {1}, *Candelariella* sp. {1}, *Hysterobrevium mori* {3}, *Hysteropatella* sp. {1}, *?Lecidea* sp. {1}, *Melaspilea emergens* {3},

?*Menispora* sp. {1}, *Odontotrema* sp. {1}, *Odontura rhaphidospora* {1}, *Orbilia arizonensis* {2}, *O. bicknellensis* {3}, *O. ?cactacearum* {1}, *O. cryptogena* {2}, *O. flexisoma* {1}, *O. lacrimispora* {3}, *O. lentiformis* {2/1}, *O. macrodelphinus* {3}, *O. macrohesperidea* {1}, *O. maeandrina* {2}, *O. multicercocarpi* {1}, *O. multigambelii* {3}, *O. multimaeandrina* {1}, *O. multiserpens* {1}, *O. navajoana* {1/1}, *O. ophiosoma* {1}, *O. paloverdensis* {1}, *O. ?pleionavajoana* {1}, *O. pleioserpens* {1}, *O. purshiae* {1}, *O. sedonensis* {1}, *O. sonorensis* {2}, *O. ?ungulata* {1}, *O. ?vitalbae* {1}, *Patellaria* '*andina*' {2}, *P. atrata* {2}, *Psiloglonium lineare* {1}, *Schizoxylon* sp. {1/1}, *Sclerococcum* sp. {1}, *Symbiotaphrina larreae* {2}. **Desiccation tolerance**: fully tolerant for 20 months; paraphyses, excipular cells and ascospores survive for up to 35 months. **Altitude**: 615–2075 m a.s.l. **Geology**: Pennsylvanian-Permian and Jurassic-Cretaceous-Tertiary sand-, lime- and mudstone; granite & diorite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia calyptrata* somewhat resembles *O. flavidorosella* (series *Habrostictis*) in the ascospores and tapered paraphysis apices, but differs in 16-spored asci and obtuse spore apices. The predominant presence of cap-like (glassy) exudate on the paraphyses, which looks like a thickened apical cell wall, is rather untypical for section *Habrostictis*, being otherwise only observed in the similar *O. spathulata* (series *Serpentinae*). *O. delphinus* differs in larger spores with acute apices, paraphyses apically mainly globose and without glassy caps, and in lacking crystalloid SCBs. A European mediterranean collection on *Cupressus* mentioned under *O. subdelphinus* (Pl. 638: 3) seems to be somewhat intermediate due to slightly spathulate paraphyses. For the similar *O. pleioungulata* see p. 1184.

Variation. Rather high variation was noted in spore shape and size. In a part of the collections the spores are predominantly ellipsoid-clavate and rather short and broad, whereas in others they are more fusoid-clavate and tend to be longer and narrower. However, this variation was repeatedly also observed within a population (e.g., Pl. 706: 1a). Paraphysis shape varies from spathulate to less often sublageniform. Also the cap-like exudate strongly varies in thickness, being partly ± absent (2b).

Phylogeny. A sequence of *O. calyptrata* was gained from apothecia of the holotype (from Utah, on *Purshia*) which comprises SSU (with S1506 intron), ITS, and LSU. In spite of its spathulate paraphyses which resemble those of series *Habrostictis*, the species clustered with high or medium (ITS) support in the *Ellipsospermae* clade (Phyls 19–20, S22), with a minimum distance of 6.5% in the ITS (0.5–0.9% in LSU) to *O. cercocarpi*, *O. cisti*, and *O. microserpens*. In the SSU *O. calyptrata* concurs with 4 other species of the *microserpens-ungulata* clade but sharply deviates from members of the *gambelii-vitalbae* clade (S20).

Ecology. *O. calyptrata* was found on very rotten wood of xeric twigs and branches of various gymno- and angiosperm shrubs (and trees), but also on old branches of *Opuntia*, in warm-temperate to subtropical semiarid paloverde-mixed cacti desert

Orbilia jurana Baral, **sp. nov.**, MB 813712 — Pls 708–709

Etymology: named after the geology of the collection site in the Swabian Jura.
Typification: Germany, Eningen, branch of *Tilia*, 3.III.2002, H.O. Baral (ex H.B. 7104c, M-0276496, holotype).

Latin diagnosis: Similis Orbiliae ungulatae *sed cellulae vivae excipuli absque corpusculis crystalloideis*, *ascosporae apice magis acutae*, *apothecia majora*, *margine eminenti*, *subtiliter crenulato*, *cellulis plerumque processis vitreis brevibus praeditis. Habitat ad corticem putridum rami sicci* Tiliae *in zona temperata humida subcontinentali montana Europae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.5(–0.8) mm diam., 0.14–0.15 mm high, light to bright orange(-rose), round, elliptical when large, subgregarious; disc slightly to medium concave, margin very distinct, 15–30 µm protruding, very finely crenulate; sessile on a broad stipe-like base, nearly superficial but ± immersed in crevices of bast; dry bright orange-apricot. **Asci** *42–55 × 4–4.2 µm, †35–44 × 3.3–3.6 µm, 8-spored, spores (*) biseriate, 4 lower spores inverted (sometimes strongly mixed, rarely upper spores inverted), pars sporifera *21–25 µm long; **apex** (†) slightly to medium, rarely strongly truncate (not indented, laterally rarely slightly inflated); **base** with short to medium long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *5.5–8.8 × 1.4–1.8 µm, fusiform(-clavate), apex subacute to acute, base medium to strongly attenuated, sometimes tail-like, straight, sometimes slightly curved near base; **SBs** *2.5–3.5 × 0.3–0.5 µm in situ, mostly subulate, base sometimes slightly inflated, slightly to medium flexuous. **Paraphyses** apically slightly to medium capitate(-clavate), terminal cells *(14–)16–26(–32) × (2–)2.8–3.7 µm, lower cells *7–12 × 1.8–2.3 µm; unbranched at upper septum, hymenium subhyaline. **Medullary excipulum** subhyaline, 40 µm thick, of dense textura globulosa-angularis with a few hyphae, medium sharply delimited. **Ectal excipulum** very pale orange, of thin-walled, vertically oriented t. angularis(-prismatica) from base to mid flanks, 50–70 µm thick near base, cells *11–19 × 8–14 µm; 30–40 µm thick at flanks, 30 µm at margin, oriented at a 30–45° angle to the surface, marginal cortical cells *10–17 × 2.5–4 µm; mostly with **glassy caps** 2–5 × 3–4 µm, high-refractive, not stratified. **Anchoring hyphae** abundant, *2–4 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum absent, with or without minute, scattered, very pale orange **LBs** (carotenoids). **Exudate** over paraphyses 0.2–0.3 µm thick, finely granular, firmly attached to each tip, partly absent; very sparse over margin and flanks. **— ANAMORPH**: unknown.

Habitat: collected 3 m above the ground, corticated, 30 mm thick, dead branch of *Tilia cordata*, on medium decayed bark (bast), with some algae and a few brown hyphae. **Associated**: *Cistella ?mali*, *Parmelia sulcata* (on periderm), *Patellaria atrata*. **Desiccation tolerance**: fully viable for at least 17 days. **Altitude**: 745 m a.s.l. **Geology**: Upper Jurassic limestone. **Phenology**: III (but rather long-lived).

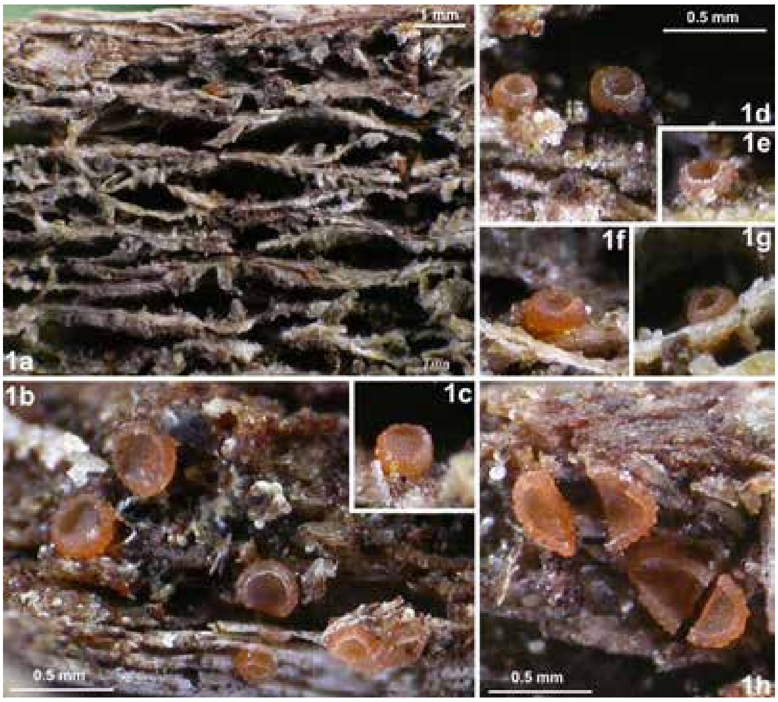

Plate 709. **1**: *Orbilia jurana* (holotype). – **1a**: exterior of bast of xeric branch (rehydrated); **1b–h**. rehydrated apothecia. — **1a–h**. H.B. 7104c: Germany, Reutlingen, on *Tilia*.

Taxonomic remarks. *Orbilia jurana* resembles *O. ungulata* in ascospore size and shape but differs in lacking any kind of SCBs, in more acute spore apices, in larger apothecia with protruding, finely crenulate margin, and in short glassy caps on the marginal cells. *O. vitalbae* differs in broader spore bodies and in often broader spores with obtuse apices. *O. obtusispora* and *O. subtrapeziformis* (series *Serpentinae*) have distinctly larger spores.

Ecology. *O. jurana* grew on medium decayed bark of a xeric branch of one of several free-standing, old, planted *Tilia cordata* trees (small-leaved lime) on a grassland close to a *Fagetum* on the very calcareous Upper Jurassic (malm α–β) at the edge of the high plateau of the Schwäbische Alb in cold-temperate humid montane central Europe.

Specimens included. **GERMANY**: **Baden-Württemberg**, Schwäbische Alb, 7 km ESE of Reutlingen, 3 km E of Eningen, Renkenberg, 745 m, branch of *Tilia cordata*, on bark, 3.III.2002, H.O. Baral (ex H.B. 7104c, M-0276496, **holotype**).

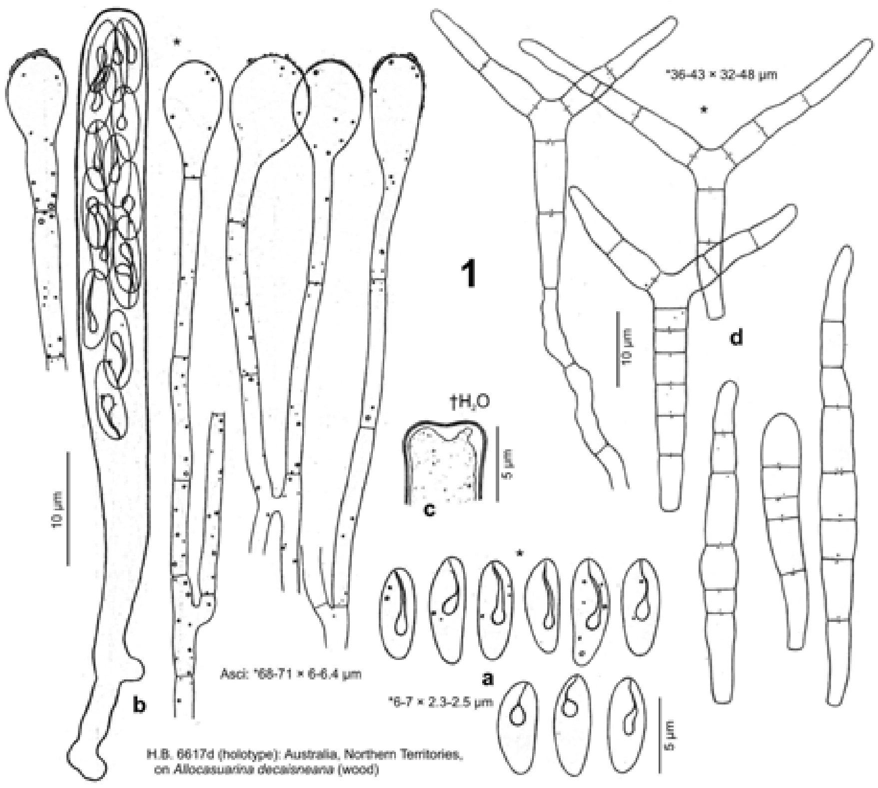

Plate 710. **1**: *Orbilia pleiovitalbae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. conidiophore and conidia from culture.

Orbilia pleiovitalbae Baral, **sp. nov.**, MB 813713 — Pl. 710

Etymology: named after the 16-spored asci and the resemblance to *O. vitalbae*.

Typification: Australia, Northern Territories, Yulara, branch of *Allocasuarina decaisneana*, 12.X.1998, G. Marson (ex H.B. 6617d, MEL 2389213, holotype).

Latin diagnosis: *Similis* Orbiliae vitalbae *sed asci 16-spori, apices paraphysium latiores. Habitat ad lignum vel corticem putridum rami sicci* Allocasuarinae decaisneanae *in zona subtropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4 mm diam., 0.13 mm high, light dirty orange, round, scattered to subgregarious; disc flat, margin thin, 10 µm protruding, smooth; broadly sessile, slightly erumpent. **Asci** *68–71 × 6–6.4 µm, †50 × 5–5.8 µm, 16-spored, spores *2–3-seriate, ~8 lower spores inverted (strongly mixed), pars sporifera *34–39 µm long; **apex** (†) medium to strongly truncate (partly distinctly indented, not so in KOH, laterally sometimes inflated); **base** with medium long and thick, somewhat flexuous stalk, L-shaped. **Ascospores** *6–7 × 2.3–2.5 µm, narrowly ellipsoid to fusoid-clavate, apex rounded to obtuse, base not or slightly attenuated, straight to slightly inequilateral; **SBs** *4–4.7 × 0.7–0.9(–1.1) µm in situ, divided into a ± abruptly swollen, tear-shaped lower part, and a subulate or filiform upper part, slightly to medium flexuous. **Paraphyses** apically medium to very strongly (clavate-)capitate, terminal cells *10–20 × (4–)5–6(–7) µm, lower cells *11–19 × 1.3–2.4 µm (basal cells 7–9 µm long); unbranched near apex. **Medullary excipulum** 30 µm thick, of dense textura intricata with inflated cells, rather sharply delimited. **Ectal excipulum** of (†) ± thin-walled, indistinctly vertically oriented t. angularis from base to mid flanks, 30 µm thick near base, cells †8–15 × 5–10 µm; 20 µm thick near margin, of t. prismatica oriented at a 10° angle to the surface, marginal cortical cells 8–11 × 3.5–6 µm. **Anchoring hyphae** rather sparse, †2–3.5 µm wide, walls 0.2(–0.4) µm thick. **SCBs** in paraphyses ?and ectal excipulum absent. **Exudate** over paraphyses 0.2–0.3 µm thick, granular, firmly attached, over margin and flanks 0.2 µm thick, granular, scattered. — **ANAMORPH**: trinacrium-like (from ascospore isolate). **Conidiophores** *~30 × 3 µm. **Conidia** Y-shaped, total size *36–43 × 32–48 µm, stipe *19–28 × 3.9–4.5 µm, 2(–3–6)-septate, arms slightly tapering, *17–21(–28) × 3.8–4.3 µm, 2–3-septate; phragmoconidia quite equally frequent, fusoid, rarely clavate, *31–61 × 4.5–5 µm 4–7-septate.

Habitat: collected 3–4 m above the ground, rather decorticated, 15 mm thick branch of *Allocasuarina decaisneana*, on 0.1 mm deep strongly decayed wood (and bast), strongly greyed, no algae. **Associated**: *Orbilia macrotrapeziformis*, *O. multivinosa*, *O. phanosoma*, *O. pleiolentiformis*, *O. pleioobtusispora*, *O. pluristomachia*, *O. serpentina*, *Teichosporella dura*, *Symbiotaphrina desertorum*. **Desiccation tolerance**: fully viable for at least 30 months. **Altitude**: 500 m a.s.l. **Geology**: Cenozoic regolith (red-brown sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiovitalbae* appears to be very closely related to European *O. vitalbae*, from which it mainly differs in 16-spored asci, also in wider paraphysis apices. The ascospores fit rather well those of *O. vitalbae*, especially in the basally ± abruptly inflated spore bodies, also regarding spore size which matches short-spored populations of *O. vitalbae*. The North American *O. macroserpens* differs

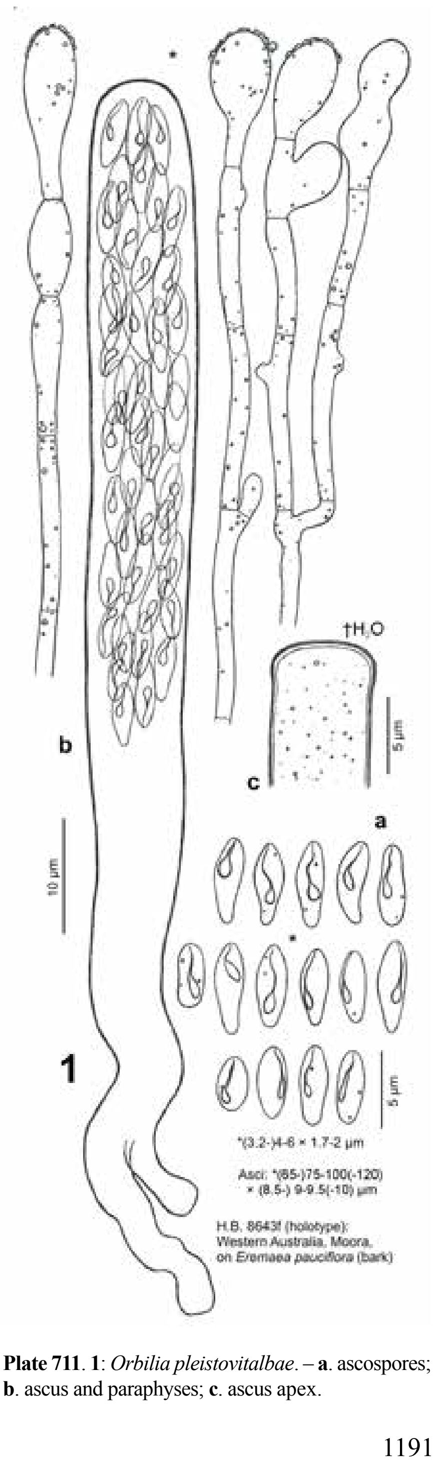

Plate 711. **1**: *Orbilia pleistovitalbae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

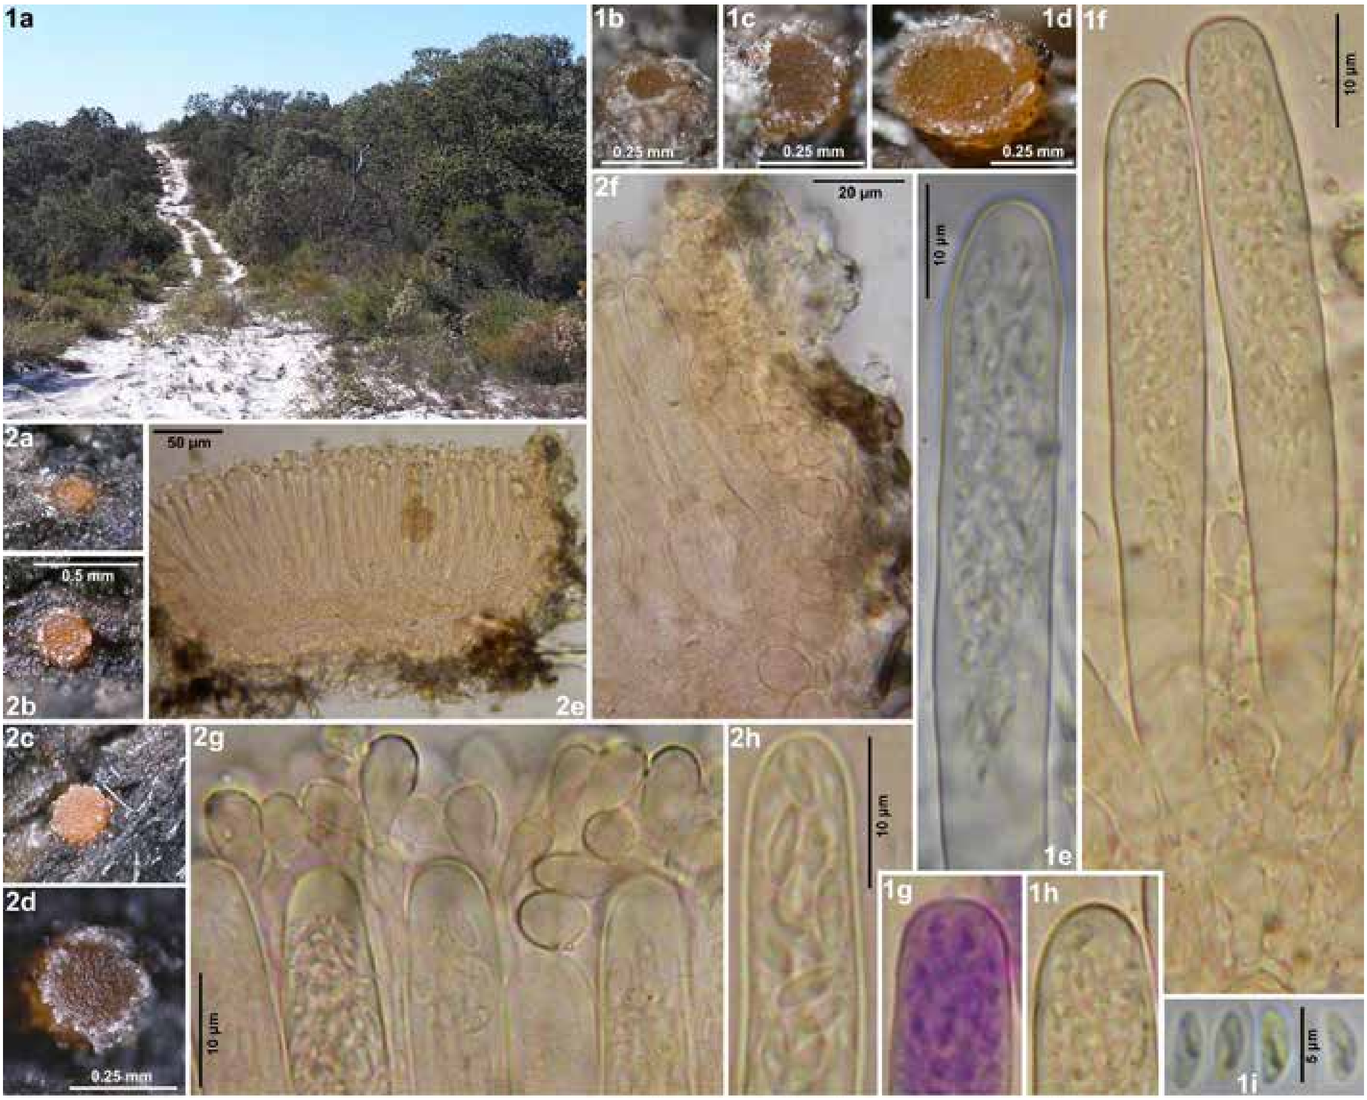

Plate 712. **1–2**: *Orbilia pleistovitalbae*. – **1a**. semihumid banksia-eucalypt-acacia open wood- and shrubland; **1b–d**, **2a–d**. rehydrated apothecia; **2e**. apothecium in median section; **2f**. id., marginal ectal excipulum; **1e–f**. mature asci; **1g–h**, **2g–h**, apices of asci and paraphyses; **1i**. ascospores. – Living state, except for asci in **1g**, **2g–h** (**1g** in CRB). — **1a–i**. H.B. 8643f (holotype): Western Australia, Moora, on *Eremaea*; **2a–h**. H.B. 8775h: ibid.

in distinctly larger spores and less inflated SBs. Australian collections of *O. microserpens* have a very similar spore size and shape, but differ in much longer, more flexuous, sometimes uncinate SBs with much less swollen bases. *O. pleioserpens* differs in wider spores with subulate to vermiform SBs and in less inflated paraphysis apices. The North American *O. cercocarpi* and an Australian collection of *O. pleioungulata* differ in the presence of crystalloid SCBs, the former also in basally uninflated SBs. Further collections of *O. pleiovitalbae* are required to find out whether the taxon is distinct from *O. microserpens*.

Anamorph. The branched, trinacrium-like, Y-shaped conidia resemble those of European *O. vitalbae* but also those of *O. microserpens*. The frequent occurrence of unbranched conidia in our culture seems remarkable, though very similar conidia occurred also in our culture of *O. vitalbae*. Similar multiseptate conidial stipes were seen in *O. microserpens* but not in *O. vitalbae*.

Ecology. The sparse apothecia in the only known collection of *O. pleiovitalbae* grew on rotten wood (rarely bark) of a xeric branch of *Allocasuarina decaisneana* in a subtropical arid acacia open shrubland northeast of Ayers Rock at the southeastern end of the Great Sandy Desert of central Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Great Sandy Desert, 11.5 km ENE of Yulara, 14 km NNE of Ayers Rock, 500 m, branch of *Allocasuarina decaisneana*, on wood, 12.X.1998, G. Marson (ex H.B. 6617d, MEL 2389213, **holotype**, anam. cult.).

Orbilia pleistovitalbae Baral & G. Marson, **sp. nov.**, MB 813714 — Pls 711–712

Etymology: named after the 128-spored asci and the ascospores resembling those in *O. vitalbae*.

Typification: Western Australia, Cowalla, branches of *Eremaea pauciflora*, 5.IX.2006, G. Marson (ex H.B. 8643f, MEL 2389246, holotype).

Latin diagnosis: *Apothecia rehydratata 0.18–35 mm diam., aurantiaca, margine laevi vel albido-crenulato. Asci 128-spori. Ascosporae *4.5–6 × 1.7–2 µm, fusoideae, in statu vivo corpusculum lacrimiforme, ad apicem filo longo flexuoso affixum continentes. Paraphyses ad apicem modice vel valde capitato-clavatae. Cellulae vivae excipuli et paraphysium absque corpusculis crystalloideis et globosis. Habitat ad corticem putridum ramorum siccorum* Eremaeae pauciflorae *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.18–)0.25–0.35 mm diam., (0.12–)0.15–0.19 mm high, light (brick-)orange, non-translucent, round, scattered; disc flat, margin distinct, (0–)20–30 µm protruding, almost smooth or mostly distinctly whitish-crenulate; broadly sessile, ± half immersed (erumpent) to almost superficial. **Asci** *(65–)70–90(–120) × 8.5–10 µm {2}, †65–73 × (6.3–)7–7.5(–8) or 75–92 × 8–9 µm {1}, 128-spored (evaluated from volume, ~80–100

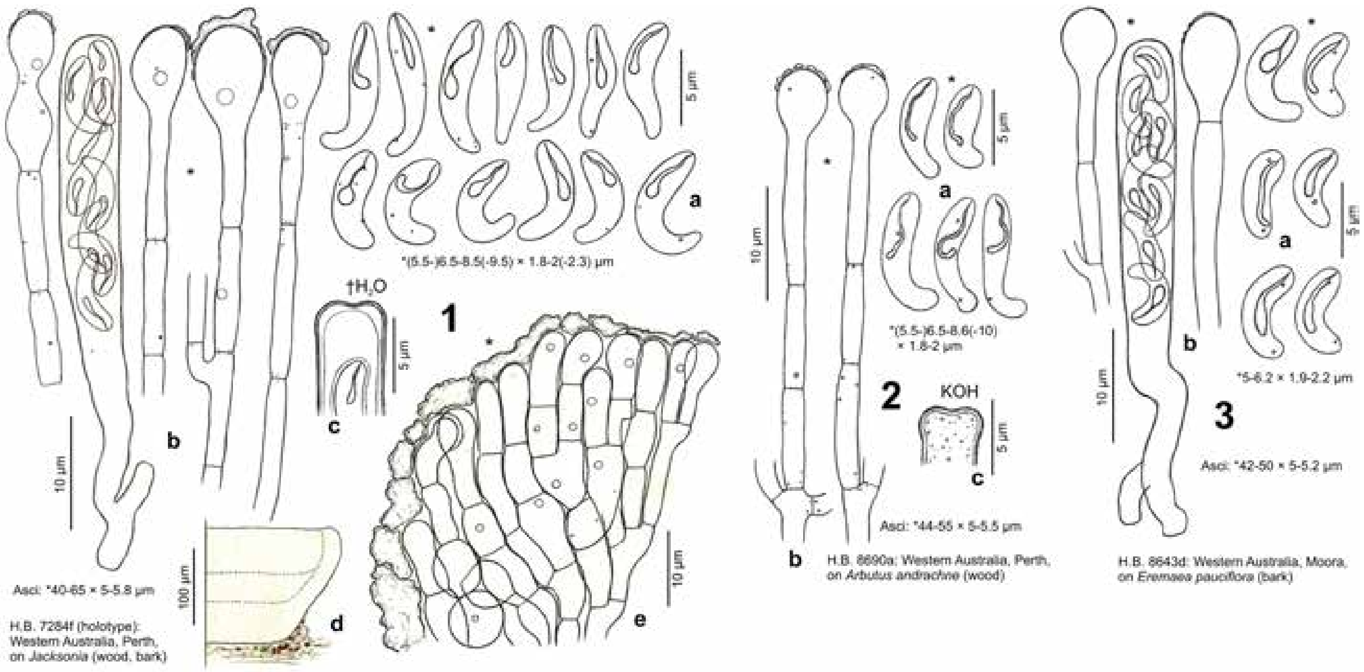

Plate 713. **1–3**: *Orbilia curvativitalbae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

spores counted), spores multiseriate, lower spores inverted (strongly mixed), pars sporifera *40–50 {1} or 50–66(–70) {2} µm long; **apex** (†) medium to strongly truncate (not indented, laterally sometimes slightly inflated); **base** unstalked or with short to medium long, thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *4.5–5.5(–6) × 1.7–2 µm {2}, †4–5.3 × 1.5–1.9(–2) µm {2}, (ellipsoid-)fusoid to fusoid(-clavate), apex obtuse, base slightly to medium attenuated, straight to slightly inequilateral; **SBs** *2.5–4.2 × 0.3–0.8 µm in situ {1} (~3–5 µm actual length), with a rod- to tear-shaped or subglobose lower part and a narrow filiform part of varying length, ± flexuous, never uncinate. **Paraphyses** apically medium to strongly clavate-capitate, sometimes mammiform, terminal cells *(5.5–)8–17(–19) × (3–)4–5(–5.5) µm {2}, lower cells *(7–)10–18 × 1.5–2 µm {1} (near apex 3–4 µm wide); sometimes branched at upper septum. **Medullary excipulum** 30–50 µm thick, of ± dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** very pale orange-rose, of (†) thin-walled to slightly gelatinized, irregularly vertically or horizontally oriented t. angularis(-prismatica) from base to mid flanks, 30–50 µm thick near base, cells *8–16 × 6–11 µm {1}; 20–25 µm thick near margin, of t. prismatica-angularis oriented at a 0–10° angle to the surface, marginal cortical cells *7–10 × 3–5 µm {1}. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2–0.3(–0.8) µm thick {1}, loosely covering the flanks, at margin forming a ~20–30 µm thick hyaline layer of ± thick-walled hyphae oriented at 10–70° and protruding as agglutinated small teeth. **SCBs** in paraphyses and ectal excipulum absent. **Exudate** over paraphyses absent or 0.2–0.3(–0.5) µm thick, firmly attached, over margin 0.2–1.5 µm thick, continuous, hyaline. — **ANAMORPH**: unknown.

Habitat: collected 0–0.5 m above the ground, corticated, 4.5–12 mm thick branches of *Eremaea pauciflora* {2}, on strongly decayed bark {2} (bast), strongly greyed, green algae sparse. **Associated**: *Capronia* sp. {1}, *Corticiaceae* {1}, *Durella* aff. *connivens* {1}, ?*Eutypa* sp. {1}, *Gloniopsis praelonga* {2}, *Hyalorbilia juliae* {1}, *Orbilia amberina* {1}, *O. austrocylindrica* {2}, *O. curvativitalbae* {1}, *O. eremaeae* {1}, *O. eucalypti* {1}, *O. microserpens* {1}, O. *multicurvula* {2}, *O. plurililacina* {1}, *Proliferodiscus olivaceoviridis* {2}, *Rhizodiscina lignyota* {1}. **Desiccation tolerance**: fully viable for at least 13 months. **Altitude**: 77 m a.s.l. **Geology**: Cretaceous sedimentary rock (white sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleistovitalbae* resembles *O. vitalbae* and *O. pleiovitalbae* in the shape of ascospores and spore bodies, but differs in much larger asci with a much higher spore number, also in smaller spores. *O. myriella* differs in 64-spored asci, more cylindrical spores with shorter and especially narrower, subulate SBs, and in having large globose SCBs. For the similar *O. pleistolilacina* (subgenus *Orbilia*) see p. 1271.

Variation. Ascus and pars sporifera length in the holotype varied remarkably between apothecia from different branches. Those illustrated in Pl. 711 and Pl. 712: 1e are at the upper end of the range (*80–120 µm, 50–70 µm, respectively). Thereby, spore size and number did not differ in apothecia with shorter asci (*65–83 µm, 40–48 µm, Pl. 712: 1f). The paratype was somewhat between these data (*65–90 µm, 55–66 µm).

Ecology. *O. pleistovitalbae* was found on decayed bark of xeric branches of *Eremaea pauciflora* in a subtropical semihumid banksia-eucalypt-acacia open wood- and shrubland in southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 59 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Rd, 77 m, branches of *Eremaea pauciflora*, on bark, 5.IX.2006, G. Marson (ex H.B. 8643f, MEL 2389246, **holotype**). – ibid., branch of *E. pauciflora*, on bark, 23.X.2007, G. Marson (H.B. 8775h).

Orbilia curvativitalbae Baral & G. Marson, **sp. nov.**,
MB 813715 — Pls 713–714

Etymology: named after the often strongly curved ascospores which otherwise resemble those of *O. vitalbae*.

Typification: Western Australia, Walyunga, branches of *Jacksonia*, 23.XI.2001, G. Marson (ex H.B. 7284f, MEL 2389233, holotype).

Latin diagnosis: *Similis* Orbiliae vitalbae *sed ascosporae valde curvatae. Habitat ad corticem vel lignum putridum ramorum siccorum angiospermarum in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.35 mm diam., 0.09–0.2 mm high, pale to light (rose-)orange(-cream), medium translucent, round or sometimes elliptical, scattered; disc flat (to slightly convex), margin indistinct or distinct, 0–10 µm protruding, smooth or finely rough; broadly sessile, superficial or erumpent from between fibres, rarely deeply immersed in bast; dry light orange. **Asci** *(40–)44–55(–65) × 5–5.5(–5.8) µm {4}, †36–60 × 4–5 µm {4}, 8-spored, spores *2–3-seriate, 3–5 lower spores inverted {5}

(sometimes mixed), pars sporifera *(21–)23–26(–29) µm long; **apex** (†) medium to strongly truncate (not or ± distinctly indented, laterally not or sometimes slightly inflated); **base** with short to long, thin or thick, flexuous stalk, L-, T-, Y- or h-shaped. **Ascospores** *(5–)6–8.5(–10) × 1.8–2.1(–2.3) µm {5}, †5.5–7.5(–9) × 1.5–2 µm {2}, subcylindrical to narrowly (fusoid-)clavate, apex rounded to obtuse, base mostly slightly to medium attenuated, (slightly to) predominantly strongly to very strongly curved (cashew-shaped or often only near base); **SBs** *(3–)3.5–5(–5.3) × (0.3–)0.4–0.8(–1) µm in situ {5} (3.5–5.5 µm actual length), subulate to vermiform, often basally inflated, slightly to medium flexuous, in more aged spores with ellipsoid to globose lower part and long filum. **Paraphyses** apically (medium to) strongly to very strongly (clavate-)capitate, rarely sublageniform to moniliform, terminal cells *11–20(–24) × (2.5–)3.5–5.2 µm {3}, †3–4.5 µm wide {1}, lower cells *8–11.5(–12.5) × 1.8–2.5 µm {3}; unbranched at upper septum. **Medullary excipulum** 20–40 µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum except at the base. **Ectal excipulum** of thin-walled († slightly gelatinized), ± vertically oriented t. angularis(-globulosa) from base to submargin, 15–90 µm thick near base, cells 6–18(–24) × 6–15(–18) µm {2}, †5–9 × 3–5 µm {1}; 20–25 µm thick at flanks, 10–20 µm near margin, upper margin of t. prismatica-angularis oriented at a 40–70° angle to the surface, or of t. prismatica oriented at 10–20°, marginal cortical cells *6–10(–13) × 3–6 µm {3}. **Anchoring hyphae** sparse to abundant, †2–3(–4) µm wide, walls 0.2–0.4 µm thick {2}. **SCBs** in paraphyses and ectal excipulum (near margin) absent {2} or globose {1}, 0.8–1.5 µm diam. **Exudate** over paraphyses 0.2–1(–2.5) µm thick, firmly attached; over margin and flanks 0.3–2.5 or 2–6 µm thick, rough-cloddy, very pale chlorinaceous. — **ANAMORPH**: unknown.

Habitat: collected 0.2–3 m above the ground, corticated to partially decorticated, 5–10 mm thick twigs and branches of *Arbutus andrachne* {2}, *Eremaea pauciflora* {1}, *Jacksonia* sp. {2}, *Verreauxia reinwardtii* {1}, on 1 mm deep strongly decayed wood {4} and bark {4} (periderm and bast), at edges of clefts in bark or over splits in periderm, partly on inner surface of detached bark, greyed, algae sparse to often abundant (partly ?*Gloeocapsa*). **Associated**: *Caloplaca* sp. {1}, *Capronia* sp. {1}, *Claussenomyces* sp. {2}, *Durella* sp. {1}, *D*. aff. *connivens* {1}, *Gloniopsis* sp. {1}, *G. praelonga* {3}, *Hyalorbilia juliae* {1}, *Nectria* sp. {1}, *Orbilia albidorosea* {1}, *O. amberina* {2}, *O. australiensis* {2}, *O. austrocylindrica* {1}, *O. eucalypti* {3}, *O. kingsiana* {1}, *O. lilacina* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {2}, *O. multicurvula* {1}, *O. myrioeuonymi* {1}, *O. myriofusiclava* {2}, *O. myriooobliqua* {2}, *O. nothovinosa* {1}, *O. octoserpentina* {2}, *O. pleistovitalbae* {1}, *O. plurililacina* {2}, *O. serpentina* {2}, *O. triangulispora* {1}, *Ostropales* {1}, *Patellaria atrata* {3}, *Proliferodiscus olivaceoviridis* {2}, *Trichopeziza perrotioides* {2}. **Desiccation tolerance**: fully viable for at least 12–14 months. **Altitude**: 37–235 m a.s.l. **Geology**: Cretaceous sedimentary rock, Cenozoic regolith; granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia curvativitalbae* is easily recognizable by its quite consistently strongly curved, ± cashew-shaped, subcylindrical to fusoid-clavate, comparatively small ascospores. Except for spore curvature the species closely resembles *O. vitalbae*, especially in shape of spores and spore bodies. For the similar *O. commarosa* on *Acacia* and *O.* cf. *commarosa* on *Livistona* petioles (Pl. 715: 6) see below.

Variation. *O. curvativitalbae* varies mainly in spore length, and that within and between collections. In two samples only rather short, cashew-shaped spores were observed (H.B. 8748 and Pl. 713: 3).

Ecology. *O. curvativitalbae* was found on rotten wood and especially bark of xeric twigs and branches of different angiosperm trees and shrubs in subtropical semihumid banksia-eucalypt-acacia open wood- and shrublands in the Swan Coastal Plain of southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 150 km N of Perth, 13 km WNW of Moora, 235 m, branch of *Verreauxia reinwardtii*, on bark, 24.X.2007, G. Marson (H.B. 8748f). – 59 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Rd, 77 m, branch of *Eremaea pauciflora*, on bark, 5.IX.2006, G. Marson (H.B. 8643d). – 30 km NE of Perth, 4 km N of Upper Swan, Swan Valley, W of Walyunga, 37 m, branches of *Jacksonia*, on wood & bark, 23.XI.2001, G. Marson (ex H.B. 7284f, MEL 2389233, **holotype**). – ibid., 4 km NE of Upper Swan, 76 m, branches of *Jacksonia*, on bark & wood, 2.IX.2006, G. Marson (H.B. 8611c). – Perth, Kings Park, 45 m, twig of *Arbutus andrachne*, on wood, 18.XII.2001, G. Marson (H.B. 8649c). – ibid., branch of *A. andrachne*, on wood, 19.X.2007, G. Marson (H.B. 8690a).

Orbilia commarosa Baral & G. Marson, **sp. nov.**,
MB 813716 — Pls 715–716, Map 119

Etymology: named after the comma-shaped ascospores and the rose-coloured apothecia.

Typification: Western Australia, Kalbarri, branches of *Acacia*, 9.XII.2001, G. Marson (ex H.B. 7415a, MEL 2389236, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–0.8 mm diam., salmoneo-rosea, margine laevi. Asci 8-spori. Ascosporae *6.5–11.5 × 2.1–2.6 µm, ellipsoideo-vel fusoideo-clavatae, in statu vivo corpusculum lacrimiforme ad apicem filo longo flexuoso affixum continentes. Paraphyses ad apicem leniter vel valde capitato-clavatae. Cellulae vivae excipuli absque corpusculis crystalloideis. Habitat ad corticem putridum ramorum siccorum* Acaciae *in zona tropica vel subtropica arida ad semihumida Australiae (meridio-)occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.6(–0.8) mm diam., 0.11–0.14 {1} or 0.13–0.24 mm {3} high (receptacle 0.08–0.1 mm), light to bright salmon-rose(-lilaceous), rarely pale cream-orange, not or slightly translucent, round or somewhat irregular, (very) scattered to gregarious in small groups; disc flat, margin ± thick, 0–10 µm protruding, smooth; broadly sessile or with an abrupt hidden stipe 0.07–0.1 × 0.09–0.15 mm, erumpent through fissures of periderm or bast, also ± superficial; dry bright rose-red. **Asci** *54–67 × 4.4–4.8 µm {2}, †(42–)50–62 {5} × 3.5–4.3 {4} or 4.4–5 µm {1}, 8-spored, spores *(sub)biseriate, 3–5 lower spores inverted {5} (sometimes ± mixed), pars sporifera *33–37(–40) µm long; **apex** (†) (medium to) strongly truncate (sometimes slightly indented, laterally not or slightly to strongly inflated); **base** with medium long, thin, flexuous stalk, L- to Y-shaped. **Ascospores** *(6.5–)7–8.5(–9.5) {4} or 8.5–11.5 {2} × 2.1–2.5(–2.6) µm {6}, †(7–)7.5–8.3 {2} or 9–11 {1} × 2–2.3(–2.5) {3} µm, ellipsoid- to fusoid-clavate, apex obtuse (to rounded), sometimes predominantly subacute {1}, base strongly attenuated in a short tail-like end or tail, slightly to strongly curved at base; **SBs** *(3.5–)4–5.5(–6) × (0.5–)0.6–0.9(–1) µm in situ {5} (~4.5–6.5 µm actual length), divided into an abruptly swollen, tear- to rod-shaped or ellipsoid lower part and a long, fine, filiform, slightly to strongly flexuous upper part with (1–)2(–3)× the length of the lower part. **Paraphyses** apically uninflated or usually slightly to medium {4} but also strongly {1} clavate-capitate, terminal cells *(12–)15–23(–27.5) × (2.5–)3–4(–4.4) µm {2}, †15–22 × (2–)3–4.5 µm {1}, lower cells *8–15(–16) × 1.6–2.5(–2.8) µm {3} (near base *6–9 × 2.5–3.3 µm); never branched in upper part, hymenium usually pale rose. **Medullary excipulum** (very) pale rose, 30–40(–110) µm thick, of ± dense, in lower part sometimes more loose textura intricata with many inflated cells, indistinctly to usually sharply delimited from ectal excipulum (by a thin layer of t. porrecta). **Ectal excipulum** hyaline to pale rose, of thin-walled († slightly gelatinized), (indistinctly) vertically oriented t. angularis(-prismatica) from base to mid flanks, 25–90 µm thick near base, cells *(6–)8–20(–24) × (5–)7–12(–16) µm {4}, †7–12 × 5–8 µm {1}; 15–30 µm thick at mid flanks, 10–30 µm thick near margin, submargin of t. globulosa-prismatica oriented at a 45–80° angle to the surface, upper margin of t. prismatica-porrecta oriented at 10–30°, marginal cortical cells */†(5–)8–12(–16) × (2.5–)3–5(–6.5) µm {4}. **Anchoring hyphae** abundant, */†1.7–3(–5) µm wide, walls */†0.2–0.3(–0.5) µm thick {3}, forming a dense (basally loose), hyaline, partly gelatinized layer on base and lower flanks, 20–40 µm thick at base, rarely extending to the margin (5–10 µm thick). **SCBs** in paraphyses globose {4}, inconspicuous, (0.5–)1–1.8 µm diam., in excipulum 2–2.5 µm diam. **Exudate** over paraphyses (0.3–)1–3(–5) µm thick, cloddy, firmly or sometimes loosely attached, hyaline to pale yellowish-chlorinaceous, over margin and flanks (0.3–)1–4(–6) µm thick, subhyaline to light yellow-ochre. **— ANAMORPH**: unknown.

Habitat: collected 0.2–2 m above the ground, corticated, 6–50 mm thick branches of *Acacia* sp. {6}, *A. aneura* {1}, on slightly to medium decayed, partly ± detached bark {7}, on bast, often in fissures through periderm, also often on edges and especially on inner surface of bark, exceptionally on 0.2 mm deep very rotten wood {1}, slightly to strongly greyed, without or with a few green algae. **Associated**: *Baggea* sp. {1}, *Caloplaca* sp. {2}, *Gloniopsis* sp. {1}, *Hypoxylon* sp. {1}, *Hysterobrevium mori* {1}, ?*Hysteropatella* sp. {1}, *Muellerella lichenicola* {1}, *Orbilia australiensis* {1}, *O. eucalypti* {1/1}, *O. euphorbiae* {1}, *O. macrocarpa* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {2}, *O. multigambelii* {1}, *O. multimicrosoma* {2}, *O.* ?*multiserpens* {1}, *O. myrioauris* {1}, *O. myriofusiclava* {2}, *O.* ?*pleiohesperidea* {1}, *O. pleioquaestiformis* {1}, *O. pluristomachia* {1}, *O.* ?*serpentina* {1}, *O. wannerooensis* {1}, *Patellaria* ?*andina* {1}, *Schizoxylon* sp. {1}. **Desiccation tolerance**: a few mature asci and many cells of ectal excipulum still viable after 21 months. **Altitude**: 6–300 m a.s.l. **Geology**: Silurian & Jurassic sedimentary rock (sandstone), Cenozoic whitish to red-brown sand & gravel; granitic gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia commarosa* is characterized by ± comma-shaped ascospores with usually obtuse apices and short, curved, tail-like bases, and by rather long spore bodies divided into a strongly swollen basal part and a very narrow, flexuous, long-filiform upper part, also by the bright and pure salmon-rose colour of the medium-sized apothecia with a smooth, partly rather broad margin, finally by a thick exudate.

O. curvativitalbae differs from *O. commarosa* in narrower, partly cashew-shaped spores with a much less developed tail, spore bodies with a subulate upper part, and in smaller,

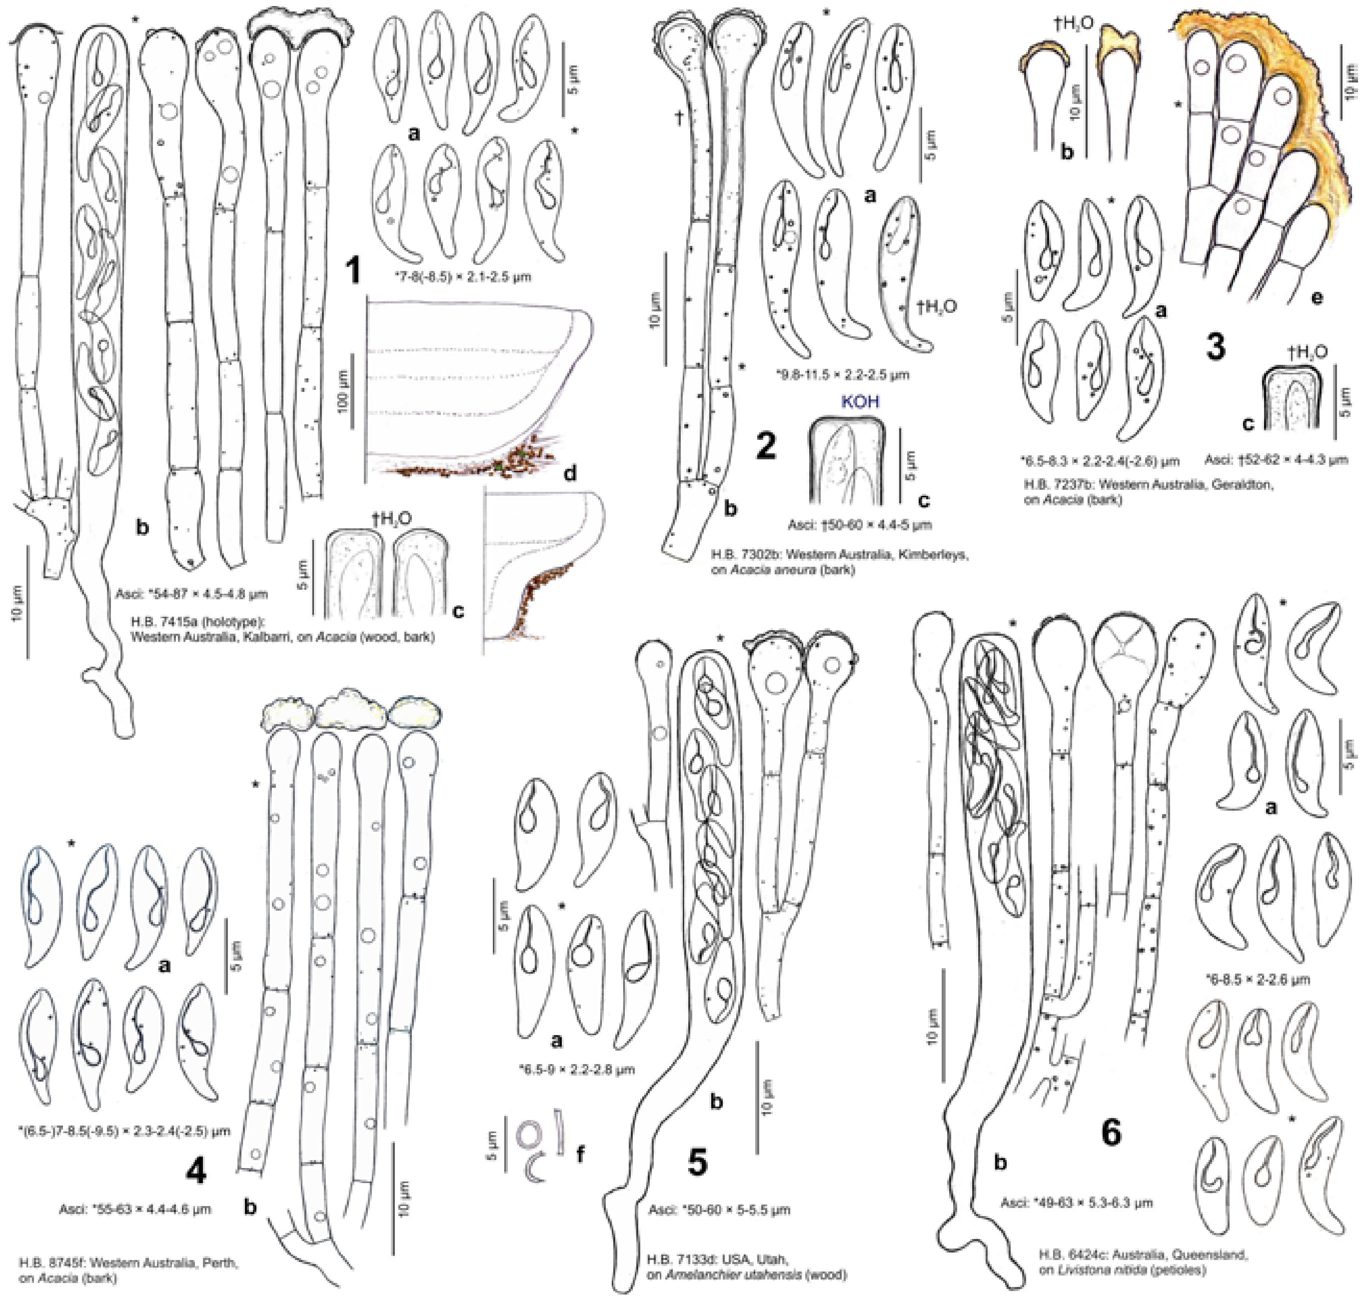

Plate 715. **1–4**: *Orbilia commarosa*; **5–6**: *O.* cf. *commarosa*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum covered by yellow-ochre exudate; **f**. crystalloid SCBs in ectal excipulum.

orange-coloured apothecia. *O. commarosa* (especially Pl. 713: 2) resembles European *O. quaestiformis* in spore shape, but the spore bodies of the latter are not swollen at the base, and the apothecia never pure rose or lilaceous.

Variation. Two of the seven included collections (Pls 715: 2; 716: 1, 4) markedly differ in longer spores, also wider asci and apically more strongly inflated paraphyses (in H.B. 7302b), therefore, the measurements of these samples are separately given in the description. We prefer to consider them as conspecific because of the similar shape of the spores and SBs, the remarkable macroscopy of the apothecia, and the uniform ecology in the seven included collections. Yet, in one specimen (Pls 715: 4; 716: 2) the apothecial colour varied from pale cream-orange to mostly bright pink-red.

Map 119. Known distribution of *O. commarosa* in Australia (yellow = not included collection).

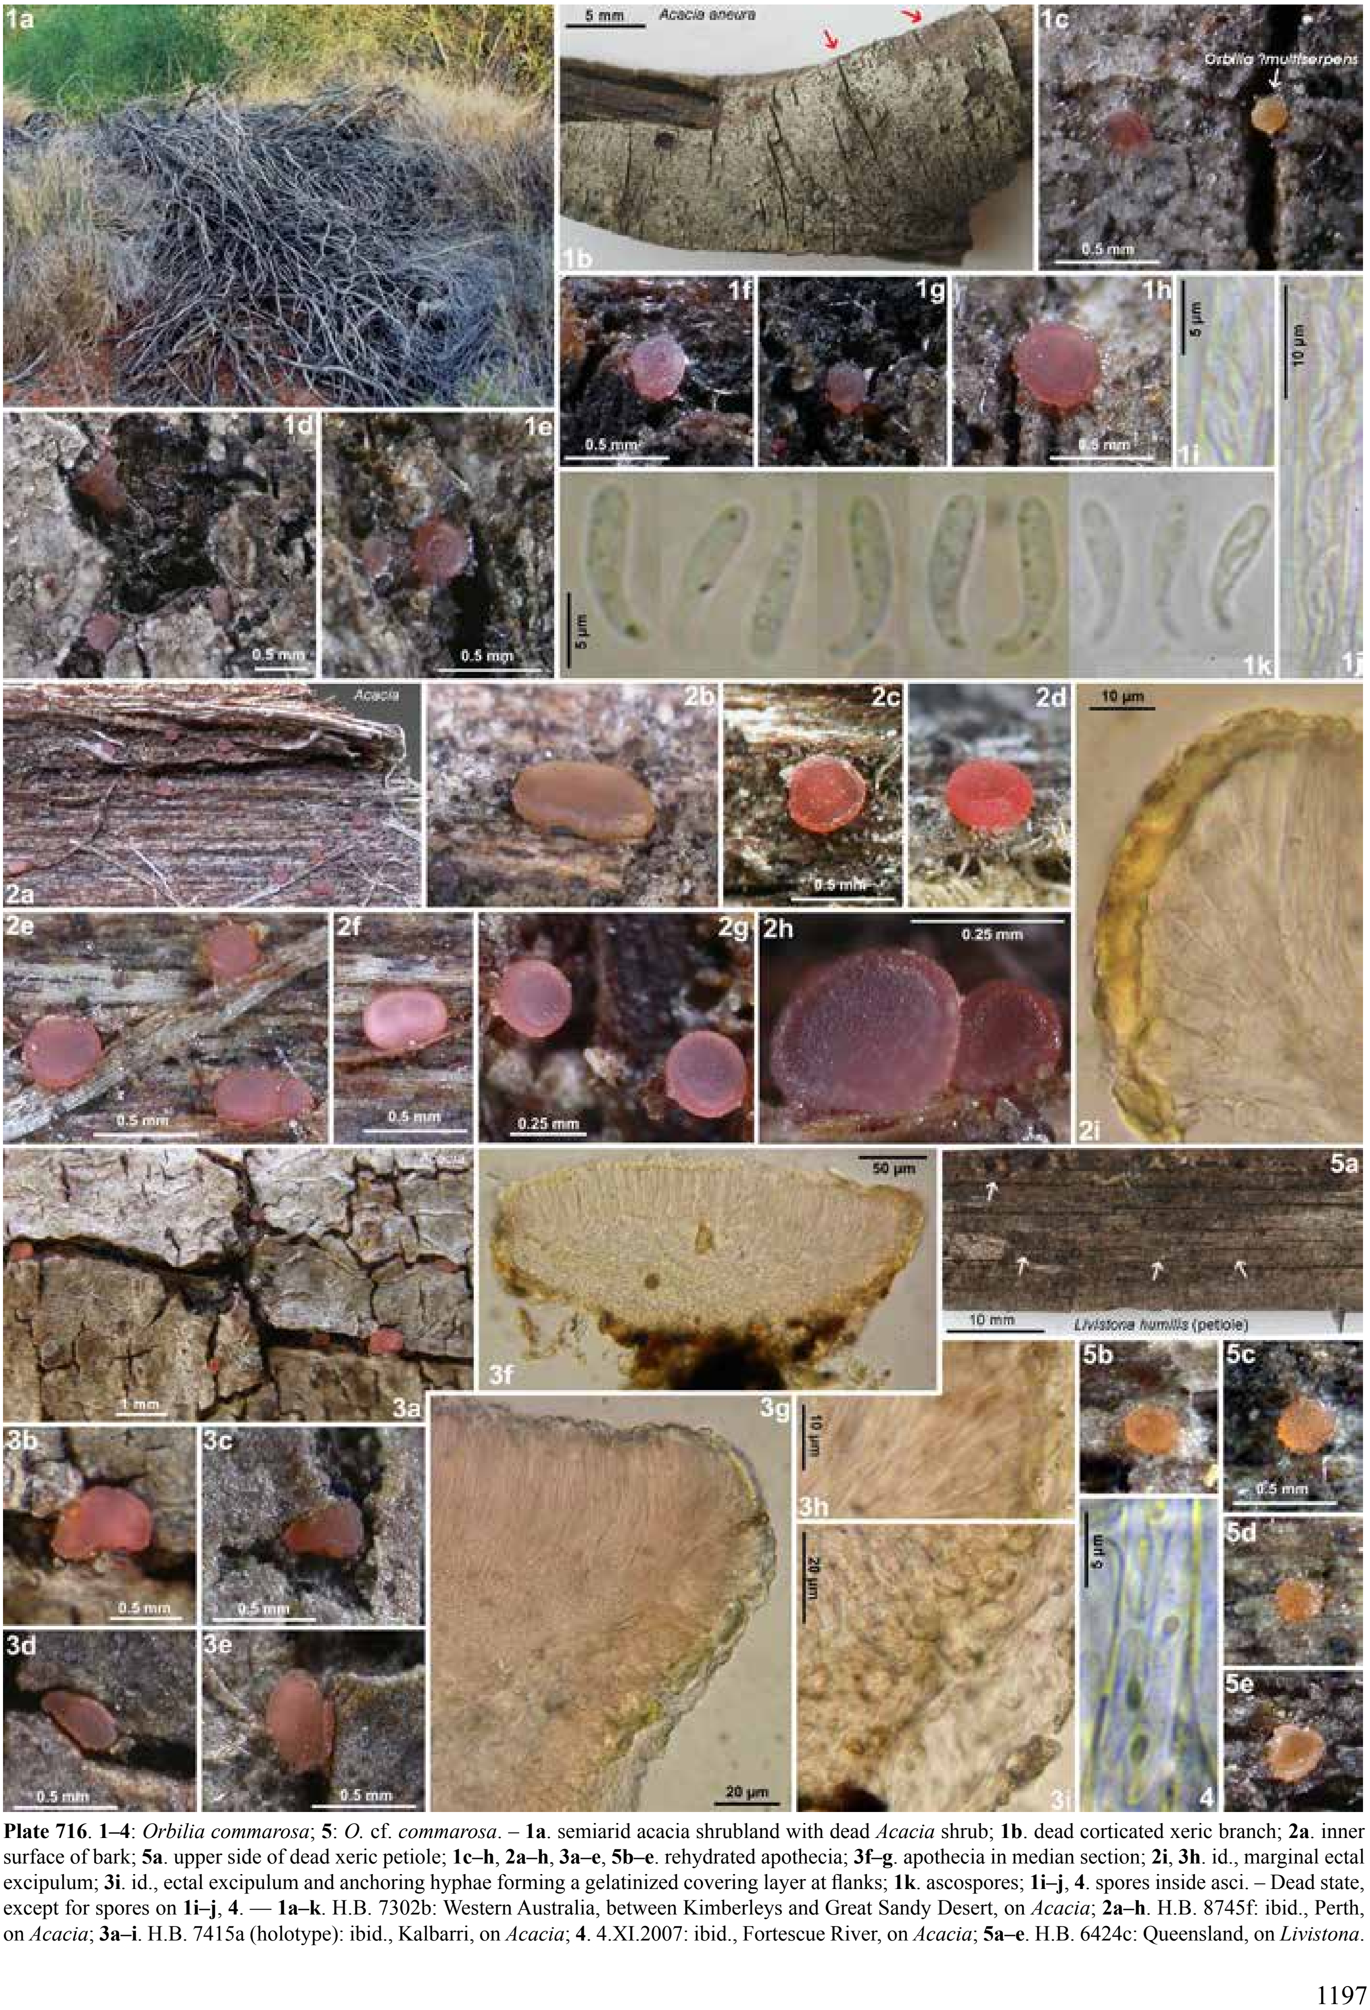

Plate 716. **1–4**: *Orbilia commarosa*; **5**: *O.* cf. *commarosa*. – **1a**. semiarid acacia shrubland with dead *Acacia* shrub; **1b**. dead corticated xeric branch; **2a**. inner surface of bark; **5a**. upper side of dead xeric petiole; **1c–h**, **2a–h**, **3a–e**, **5b–e**. rehydrated apothecia; **3f–g**. apothecia in median section; **2i**, **3h**. id., marginal ectal excipulum; **3i**. id., ectal excipulum and anchoring hyphae forming a gelatinized covering layer at flanks; **1k**. ascospores; **1i–j**, **4**. spores inside asci. – Dead state, except for spores on **1i–j**, **4**. — **1a–k**. H.B. 7302b: Western Australia, between Kimberleys and Great Sandy Desert, on *Acacia*; **2a–h**. H.B. 8745f: ibid., Perth, on *Acacia*; **3a–i**. H.B. 7415a (holotype): ibid., Kalbarri, on *Acacia*; **4**. 4.XI.2007: ibid., Fortescue River, on *Acacia*; **5a–e**. H.B. 6424c: Queensland, on *Livistona*.

Not included collections. In a sample on *Livistona* (Pls 715: 6; 716: 5) the spores and spore bodies are similar to *O. commarosa*, but the apothecia are smaller and light orange, lacking any rose component, also the exudate is very thin. The spores differ from typical *O. commarosa* in having more tapered apices, therefore, they resemble those of *O. trapeziformis* (but *O. commarosa* may also sometimes have spores with subacute apices, especially in Pl. 715: 3), and some spores resemble those of *O. curvativitalbae*. Some of the apothecia had spores with obtuse apices, but these were frequently more or less straight and closely resemble the North American *O. dixiensis* (see Pl. 699: 3). Likewise, two North American specimens on *Amelanchier* (Pl. 715: 5; IVV: H.B. 8056h) have spores and SBs very similar to *O. commarosa*, but differ in orange apothecia and less curved spores. Moreover, small crystalloid SCBs were seen in the former record, therefore, they are not included in the description. All these specimens resemble also *O. vitalbae* and *O. subvitalbae.*

Ecology. *O. commarosa* grows on medium rotten bark of xeric branches of *Acacia* in tropical arid acacia shrublands (mulga, partly in a tussock grassland with *Livistona alfredii*), subtropical semiarid acacia open shrublands and semihumid open wood- and rather dense shrublands (*Acacia*, *Nuytsia*, partly on sand dunes) of western and southwestern Australia. The not included collection from Queensland was on leaves of *Livistona* in a subtropical subhumid (winter-dry savannah) eucalypt woodland of eastern Australia (Great Dividing Range), those from western North America on *Amelanchier* in cold-temperate subhumid pinyon-juniper woodlands of the Colorado Plateau on Pennsylvanian-Permian sand- and limestone.

Specimens included. **AUSTRALIA**: **Western Australia**, Dampierland, 235 km SW of Broome, 6 km E of Sandfire Roadhouse, border of Great Sandy Desert, 12 m, branches of *Acacia aneura*, on bark, 3.XII.2001, G. Marson (H.B. 7302b). – Pilbara, 96 km S of Roebourne, 42 km SSW of Python Pool, Millstream-Chichester, road crossing the Fortescue River, 300 m, branch of *Acacia*, on bark, 4.XI.2007, G. Marson (ø). – Geraldton Sandplains, 80 km NNW of Northampton, 29 km ENE of Kalbarri, near meander of Murchison, 160 m, branches of *Acacia*, on bark & wood, 9.XII.2001, G. Marson (ex H.B. 7415a, MEL 2389236, **holotype**). – 60 km N of Geraldton, 12 km N of Northampton, 278 m, branch of *Acacia*, on bark, 9.XII.2001, G. Marson (H.B. 7237b ø). – 90 km SSE of Geraldton, 21 km N of Illawong, 6 m, branch of *Acacia*, on bark, 9.XI.2007, G. Marson (H.B. 8996b ø). – 96 km SSE of Geraldton, 15 km N of Illawong, S of Cliff Head lighthouse, 7 m, branch of *Acacia*, on bark, 10.XI.2007, G. Marson (H.B. 9582b). – Swan Coastal Plain, 30 km NNW of Perth, 1 km NW of Kinross, Tamala Park, 40 m, branch of *Acacia*, on bark, 23.X.2007, G. Marson (H.B. 8745f).

Not included. **AUSTRALIA**: **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, leaves of *Livistona nitida*, on petioles, 22.X.1998, G. Marson (H.B. 6424c). — **USA**: **Utah**, Canyonlands, 41 km W of Blanding, Natural Bridges, 2090 m, branch of *Amelanchier utahensis*, on wood, 14.VI.2000, G. Marson (H.B. 7133d). – **Arizona**, Grand Canyon, Coconino Plateau, 15 km ESE of Grand Canyon Village, Grandview Point, 2260 m, branch of *A. utahensis*, on wood, 16.VI.2003, G. Marson (H.B. 8056h ø).

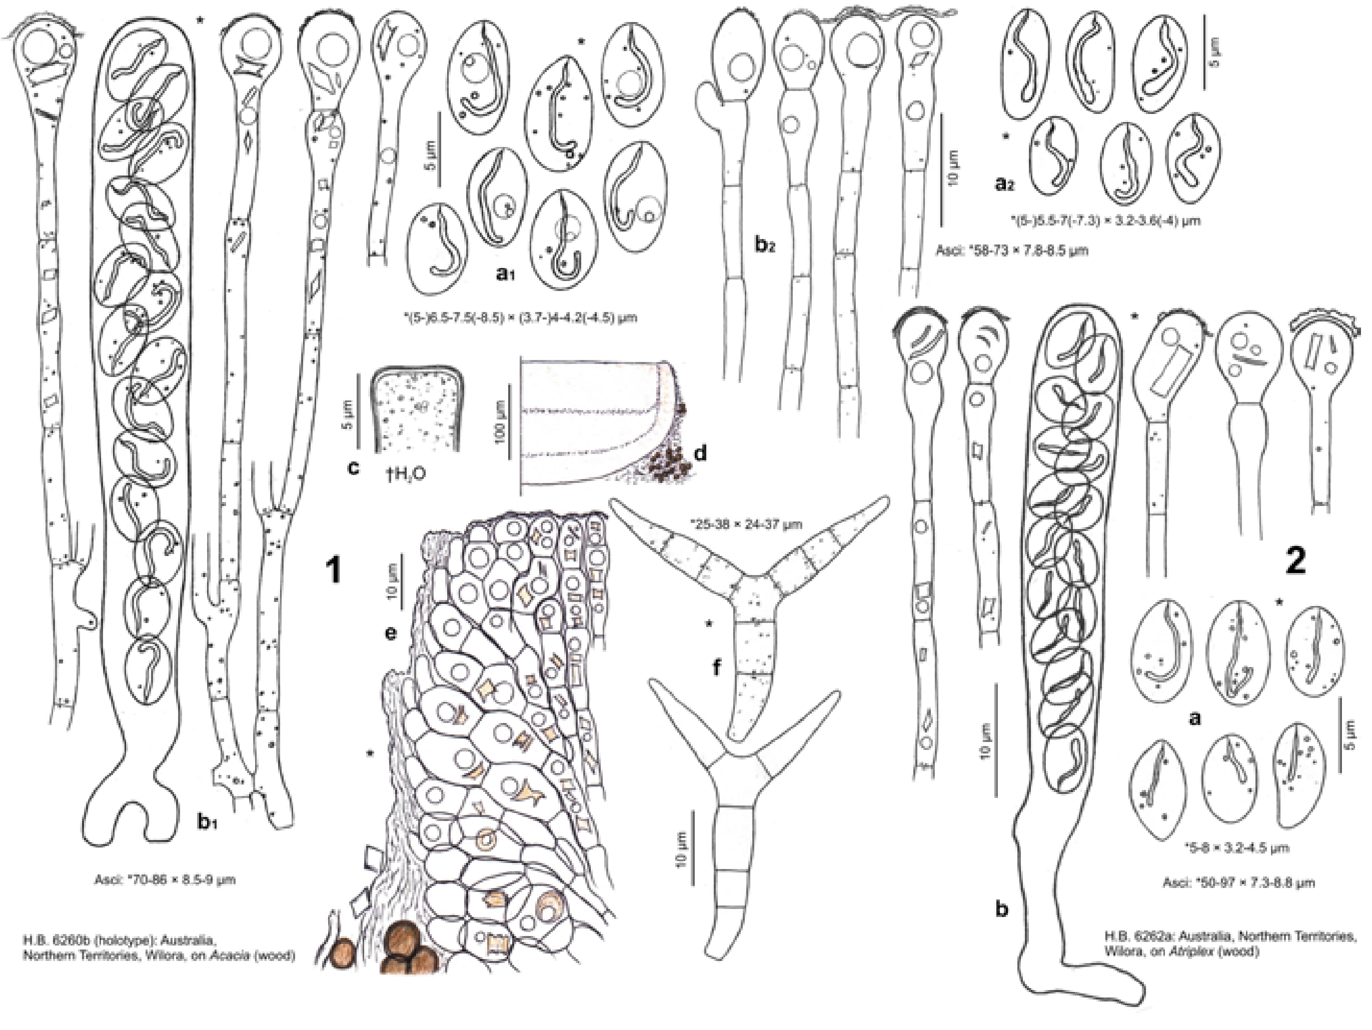

Plate 717. **1–2**: *Orbilia barrowensis* (**1a**$_2$, **b**$_2$: untypical population). – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. conidia from culture.

H.B. 6260b (holotype): Australia, Northern Territories, on *Acacia*; **2a–d**. H.B. 8085g: USA, Arizona, on *Olneya*.

Orbilia barrowensis Baral & G. Marson, **sp. nov.**, MB 813717 — Pls 717–718

Etymology: named after the origin of the two known collections (vicinity of the Barrow Creek in central Australia).

Typification: Australia, Northern Territories, Wilora, branches of *Acacia*, 8.X.1998, G. Marson (ex H.B. 6260b, MEL 2389193, holotype [large-spored population in Pl. 148 Fig. 1a$_1$, b$_1$, c–f]).

Latin diagnosis: *Apothecia rehydratata 0.2–0.4 mm diam., aurantiaca, margine subtiliter aspero. Asci 16-spori. Ascosporae *5–8.5 × 3.2–4.5 µm, ellipsoideae vel ovoideae, in statu vivo corpusculum vermiforme vel subulatum, flexuosum ad uncinatum continentes. Paraphyses ad apicem modice vel valde capitato-clavatae. Cellulae vivae excipuli corpuscula crystalloidea continentes. Habitat ad lignum putridum ramorum siccorum* Acaciae *et* Atriplicis *in zona tropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4 mm diam., 0.14–0.16 mm high, pale to bright orange, round, (very) scattered; disc medium to slightly concave, margin thin, 0–10 µm protruding, finely rough; sessile, ± erumpent; dry sunken between wood fibres. **Asci** *(50–)70–86(–97) × (7.3–)7.8–9 µm {2}, 16-spored, spores (*) biseriate (uniseriate near base), majority of lower spores inverted, pars sporifera *40–61 µm long; **apex** (†) strongly truncate (slightly indented, laterally sometimes inflated); **base** without or with short, thick stalk, L- or h-shaped. **Ascospores** *(5–)6–7.5(–8.5) × (3.2–)3.5–4.2(–4.5) µm {2}, ellipsoid to ovoid (or fusoid), both ends rounded to obtuse (rarely subacute), straight or slightly inequilateral; **SBs** *(3.5–)4.7–6.5 × 0.3–0.5(–1) µm in situ {2} [~(3.5–)6–8.5 µm actual length], vermiform or subulate, base rarely slightly thickened, flexuous to helicoid, sometimes uncinate. **Paraphyses** apically medium to (very) strongly capitate(-clavate), rarely spathulate, terminal cells *(6.5–)12–17(–22) × (3.4–)4–5.8(–6.3) µm {2}, lower cells *7.5–16(–20) × 1.5–2.3(–3.3) µm {2}; rarely branched near apex. **Medullary excipulum** hyaline, 30–60 µm thick, of ± dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, vertical t. angularis from base to margin, 25–30 µm thick near base, cells *10–18 × 8–12 µm {1}; 20 µm thick at mid flanks and margin, oriented at a 50–70° angle to the surface, marginal cortical cells *5–11 × 4–7 µm {1}. **Anchoring hyphae** abundant, *2–2.5 µm wide, walls 0.2–0.8 µm thick {1}, forming a thin layer up to margin, terminated in dead hyphal projections. **SCBs** in paraphyses and marginal ectal excipulum globose, 1–3.7 µm diam., and rod- or ring-/spool-shaped {2}, pale orange, 3–6 µm diam., rarely absent. **Exudate** over paraphyses 0.2–1 µm thick, ± rough, finally firmly attached; over margin and flanks indistinct, 0.2 µm thick. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1}). **Conidiophores** not seen. **Conidia** Y-shaped, total size *25–38 × 24–37 µm, stipe *18–23.5 × 5–5.5 µm, 2–3-septate, arms gradually tapering, *14–20 × 4–4.5 µm, 1–3-septate {1}, some conidia unbranched.

Habitat: collected 0–2 m above the ground, partially to entirely decorticated, 10–15 mm thick branches of *Acacia* sp. {1}, *Atriplex* sp. {1}, on 0.2–0.3 mm deep strongly decayed wood {2}, greyed, no algae. **Associated**: *Acanthostigma ellisii* {1}, *Capronia* sp. {1}, *Dothideales* {2}, *Orbilia lanternae* {1}, *O.* ?*livistonae* {1}, *O. maeandrina* {1}, *O. multiaustrocylindrica* {1}, *O.* ?*multigambelii* {1}, *O. octocercocarpi* {1}, *O. pleioaustraliensis* {1}, *O. pleiostomachia* {1}, *O. pleioungulata* {1}, *O. pluristomachia* {1}, *Peniophora* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 weeks. **Altitude**: 480 m a.s.l. **Geology**: Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia barrowensis* is characterized by 16-spored asci, broadly ellipsoid to ovoid, medium-sized ascospores with vermiform, partly uncinate spore bodies, and by the presence of crystalloid SCBs. European *O. pleiogambelii* differs in much narrower and partly shorter spores and in the geographical origin. In the paratype a single apothecium with consistently 32-spored asci and distinctly smaller spores was detected (see Pl. 724: 7). This appears to belong to *O. multigambelii*, a taxon which is so far mainly known from North America.

Variation. In the holotype of *O. barrowensis* one apothecium contained among the normal asci very few aberrant 8-spored asci with larger spores (*8–9 × 4.5–5.5 µm, not illustrated), which were not included in the description. On a separate branch occurred apothecia with distinctly smaller, especially narrower spores, smaller asci, and virtually absent crystalloid SCBs in paraphyses and excipular cells (Pl. 717: 1a$_1$, 1b$_2$). Because it otherwise did not deviate from typical *O. barrowensis*, this population was included in the description.

Not included collections. Two North American collections (Pl. 718: 2, on *Olneya*; H.B. 8096a, on *Coleogyne*) appear to be conspecific, but were studied almost 3 years after being collected, therefore, merely the excipular cells (containing crystalloid SCBs) and a single spore was found to be viable in one of them (*Olneya*). Although their features (asci †60–85 × 6–7.5 µm, spores †5–7 × 3–4.3 µm) fit *O. barrowensis* quite well, the two specimens are not included in the description because the vital characters are mainly unknown.

Anamorph. The trinacrium-like conidia obtained in pure culture are morphologically very similar to those reported for *O. gambelii* and *O. pleiogambelii.* They were obtained from the large-spored population (holotype).

Ecology. *O. barrowensis* was found on rotten wood of xeric branches of *Acacia* and *Atriplex* (climbing up the *Acacia*) in a tropical arid acacia open shrubland of central Australia. The not included collections on *Coleogyne* and *Olneya* are from warm-temperate to subtropical semiarid blackbrush and paloverde-mixed cacti desert scrub in the Colorado Plateau and Sonoran Desert of western North America.

Specimens included. **AUSTRALIA**: **Northern Territories**, Burt Plain, 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, 480 m, branches of *Acacia*, on wood, 8.X.1998, G. Marson (ex H.B. 6260b, MEL 2389193, **holotype**, anam. cult.; specimen contains also small-spored population). – ibid., branches of *Atriplex*, on wood, 8.X.1998, G. Marson (H.B. 6262a).

Not included. **USA**: **Arizona**, Canyonlands, 45 km SW of Page, 26 km SW of Marble Canyon, 1522 m, branch of *Coleogyne ramosissima*, on wood, 16.VI.2003, G. Marson (H.B. 8096a). – Sonoran Desert, 25 km WNW of Tucson, 5 km S of Picture Rocks, Saguaro, 745 m, branches of *Olneya tesota*, on wood, 30.V.2003, G. Marson (ex H.B. 8085g, in M-0276519 [H.B. 8085f, type of *O. multicreosoteris*]).

Orbilia gambelii Baral & G. Marson, in Karasch et al., Österr. Z. Pilzk. 14: 286 (2005) — Pls 719–721, Map 120

Etymology: referring to the host species *Quercus gambelii* in the first collection. **Typification**: Spain, Chiloeches, twig and branches of *Jasminum fruticans*, 2.V.1996, H.O. Baral (ex H.B. 5483a, M-0140894, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.15–0.6(–0.8) mm diam., 0.11–0.2 mm high, (pale to) light to bright orange(-rose) (to yellowish-ochraceous or brick-red), round, scattered to gregarious; disc (slightly concave to) flat, rarely slightly convex, margin distinct, 0–20 µm protruding, smooth to finely crenulate; ± sessile, ± immersed in biofilm. **Asci** *(42–)50–72(–78)((–86)) × (5–)5.3–6.5(–7) µm {25} → 6.5–7 µm, †(38–)42–65(–70) × (4–)4.3–5.5(–6.2) µm {9}, 8-spored, spores *1–2-seriate, (1–)3–5(–6) lower spores inverted {17} (rarely or often mixed), pars sporifera *25–38 → 16–23 µm long; **apex** (†) strongly truncate (without or distinctly indented, laterally inflated); **base** with short to medium long, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(4.5–)5–8(–9)((–10)) × (2.2–)2.5–3.5(–3.8) ((–4)) µm {60}, †(4.3–)5–7.5 × (2–)2.5–3.5 µm {4}, ellipsoid to ovoid or obovoid, sometimes fusoid (partly amygdaliform), rarely subcylindrical, apex rounded, obtuse or subacute, base not or slightly to medium attenuated, straight to sometimes slightly inequilateral, exceptionally curved at base; **SBs** *(3–)4–7(–8) × (0.2–)0.3–1(–1.2) µm in situ {23} [~(5–)6–9(–12) µm actual length], subulate, also filiform to vermiform, base not or slightly, rarely medium inflated, flexuous to helicoid, sometimes or often uncinate, in overmature spores with ovoid to globose lower and filiform upper part. **Paraphyses** apically (slightly to) medium to very strongly capitate-clavate, sometimes spathulate to sublageniform, terminal cells *(4.5–)6–17(–22) {11} × (2.5–)3–5.5(–6) µm {14}, lower cells *8–15(–17) × (1–)1.3–2(–3) µm {6}; unbranched at upper septum. **Medullary excipulum** hyaline, 30–60 µm thick, of ± loose to dense textura intricata with many inflated cells, not or medium sharply delimited. **Ectal excipulum** pale to light orange-rose, of thin-walled, ± vertically oriented t. (globulosa-)angularis(-prismatica) from base to mid flanks, (20–)30–55(–80) µm thick near base, cells *(7–)9–19(–23) × (5–)7–13(–16) µm {9}; (10–)20–30(–35) µm thick at flanks and margin, at margin of t. globulosa to t. prismatica(-porrecta) oriented at a (10–)20–50(–90)° angle, marginal cortical cells *(5–)6–12(–14) × (2.5–)3–5(–6) µm {9}, †10–12 × 2.5–3.5 µm {1}, firm-walled, sometimes somewhat free (hair-like) or slightly converging to form minute indistinct teeth. **Anchoring hyphae** sparse to very abundant, *2–3.3 µm wide, walls 0.2–0.3(–0.5) µm thick {7}, forming a 5–10 µm thick covering layer at flanks. **SCBs** in apices of paraphyses globose, 1–2.5 µm diam., in ectal excipulum near margin 2–3.2 µm; rod- or spool- to ring-shaped crystalloid SCBs in ectal excipulum {56}, hyaline to light yellowish-orange, (1.5–)2.5–5.5(–7) µm diam., rarely (partly) absent {2}, infrequently present in paraphyses. **Exudate** over paraphyses 0.3–1.5(–2) µm thick, cloddy, continuous, later breaking into firmly attached caps; over margin and flanks 1.5–3 µm thick, cloddy to granular, hyaline to pale yellowish. **— ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {3}). **Conidiophores** not observed. **Conidia** Y-shaped, total size *23–28 × 25–39.5 µm, stipe *12–16 × 5.2–6 µm, 2-septate, arms gradually to abruptly tapering, *15–21 × 5.2–5.5 µm, 2–3-septate {2}.

Habitat: collected 0.2–3.5 m above the ground, ± corticated (periderm ± removed) to decorticated, 4–30(–40) mm thick, dead (rarely living) twigs and branches of *Acer glabrum* {1}, *Adenocarpus viscosus* {1}, *Anagyris foetida* {1}, *Carpinus betulus* {1}, *Calicotome villosa* {1}, *Carlina xeranthemoides* {1}, *Cercis siliquastrum* {1}, *Cercocarpus ledifolius* {1}, *Chamaecytisus proliferus* {1}, *Cistus* sp. {1}, *Clematis vitalba* {2}, *Cytisus scoparius* {1}, *Echium leucophaeum* {1}, *Eucalyptus camaldulensis* {4}, *Euonymus europaeus* {4}, *Ficus carica* {2}, *Fraxinus excelsior* {1}, *Genista scorpius* {2}, *Ilex aquifolium* {1}, *Jasminum fruticans* {1}, *Juglans regia* {2}, *Juniperus* sp. {1}, *J. thurifera* {1}, *Lonicera etrusca* {1}, *L. ?xylosteum* {1}, *Olea europaea* {4}, *Passiflora caerulea* {3}, *Petteria ramentacea* {1}, *Pinus sylvestris* {1}, *Populus × canadensis* {1}, *P. tremuloides* {2}, *Prunus domestica* {1}, *Punica granatum* {1}, *Quercus coccifera* {4}, *Q. gambelii* {3}, *Q. ilex* {2}, *Q. rotundifolia* {2}, *Rhamnus myrtifolia* {1}, *Rosa* sp. {5}, *Rosmarinus officinalis* {4}, *Rubia fruticosa* {1}, *Rubus fruticosus* {1}, *Salix* sp. {2}, *S. alba* {1}, *S. ?bebbiana* {1}, *Spartium junceum* {1}, *Syringa vulgaris* {1}, *Ulex europaeus* {1}, *U. parviflorus* {1}, *Ulmus minor* {1}, on 0.3–1 mm deep or much deeper medium to mostly strongly decayed wood {53} and bark {23} (bast), partly strongly eroded, also on inner surface of detaching bark, sometimes in beetle galleries or longitudinal clefts, exceptionally on boring dust of a bark beetle {1}; on 15–35 mm thick herbaceous stem of *Reynoutria japonica* {1}, *Opopanax* sp. {1}; strongly greyed, sparsely to densely covered by green algae. **Associated**: *Baggea* spp. {2}, *B. pachyascus* {1}, *?Calloria* sp. {1}, *Capronia* sp. {1}, *Carestiella ?schizoxyloides* {1}, *Catillaria nigroclavata* {1}, '*Chlorosplenium*' *viridulum* {1}, *Claussenomyces* spp. {2}, *Coniochaeta ?alkalivirens* {1}, *Cyathicula* sp. {1}, *Diplolaeviopsis* sp. {2}, *Dothideales* {1}, *Durella* sp. {1/3}, *D.* aff. *connivens* {1}, *D. connivens* {2}, *Eutypa crustata* {1}, *Gloniopsis praelonga* {1}, '*Helotium*' *uvidulum* {1}, *?Herpotrichia* sp. {1}, *Hyalorbilia erythrostigma* {1}, *H. orbiliicola* {1}, *Hysterium* sp. {2/1}, *Hysteropatella* spp. {2}, *Karstenia* sp. {1}, *K. idaei* {1}, *Lasiobelonium sublonicerae* {1}, *Lecidella elaeochroma* {1}, *Lophiostoma ?quadrinucleatum* {1}, *Melanohalea subolivacea* {1}, *Melanomma seminudum* {1}, *Melaspilea emergens* {1}, *Mellitiosporiella* sp. {1}, *M. pulchella* {5}, *Mollisia ligni* {1}, *M. rosae* {1}, *Nitschkia broomeana* {1}, *Odontotrema oregonensis* {1}, *Orbilia albidorosea* {1}, *aristata* {2}, *O. ?carpoboloides* {1}, *O. ?cejpii* {1}, *O. cercidicola* {1}, *O. clavuliformis* {1}, *O. corculispora* {3}, *O. curvatitrapeziformis* {1}, *O. delphinus* {5}, *O. dixiensis* {1}, *O. euonymi* {1}, *O. flagellispora* {1}, *O. flexisoma* {2}, *O. ?gregorii* {1}, *O. ?halimi* {1}, *O. hesperidea* {1}, *O. mali* {1}, *O. microserpens* {1}, *O. microsoma* {1}, *O. multiphanosoma* {1}, *O. myriolentiformis* {1}, *O. myriosphaera* {2}, *O. navajoana* {2}, *O. obtusispora* {1/1}, *O. ocellata* {1}, *O. ovalis* {2}, *O. ovoidea* {1}, *O. pilifera* {1}, *O. pleiogambelii* {5/1}, *O. polyspora* {3}, *O. ?pubescens* {1}, *O. quaestiformis* {1}, *O. rosicola* {1}, *O. sarothamni* {1}, *O. sedonensis* {1}, *O. sphaerospora* {1}, *O. subaristata* {7},

O. subclavuliformis {5}, *O. subocellata* {1}, *O. subovoidea* {5}, *O. subtrapeziformis* {1}, *O. subvinosa* {1}, *O. trapeziformis* {1}, *O. tremuloidis* {1}, *O. vinosa* {3}, *O. vitalbae* {1}, *Ostropa barbara* {2}, *Patellaria atrata* {5}, *Patellariopsis dennisii* {1}, *Peniophora quercina* {1}, *Perrotia flammea* {5}, *Phragmiticola* sp. {2}, *Physcia leptalea* {1}, *Pirottaea* ?*imbricata* {1}, ?*Pleospora* sp. {1}, *Propolis farinosa* {2/1}, *P. viridis* {1}, *Pseudolachnea hispidula* {1}, *Psiloglonium lineare* {1}, *Schizoxylon* sp. {1}, *Sclerococcum* sp. {1}, *Teichosporella dura* {1}, *Trichopeziza perrotioides* {1}, *Tryblidaria fenestrata* {3}, *Unguiculariopsis* sp. {2}, *U. ilicincola* {1}, *Xanthoria* ?*parietina* {3}, crustose lichens. **Desiccation tolerance**: within Europe fully viable for at least 3 months (excipular cells and ascospores for 6 months), in North America for up to 2–2.5 years. **Altitude**: 1–138 m a.s.l. (western Europe), 1–1600 m (southern Europe), 1885–2825 m (western North America). **Geology**: Cambrian siltstone & quartzitic wacke, Permian sand-, clay- & limestone, Rotliegend, Middle & Upper Jurassic, Cretaceous & Tertiary clay, lime- & sandstone, dolomite, Quaternary sand, silt & clay, peat; granite, migmatite, gneiss, schist, basaltic and phonolitic lava with andesite & rhyolite. **Phenology**: throughout the year (long-lived).

Phenology of *O. gambelii*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
3	4	7	6	19	11	1	9	12	3	3	4

Taxonomic remarks. *Orbilia gambelii* is characterized by broadly ellipsoid to ovoid or obovoid, partly also fusoid ascospores, rather long, often strongly flexuous, helicoid or uncinate spore bodies, 8-spored asci, and the presence of crystalloid SCBs. *O. pleiogambelii* mainly differs in 16-spored

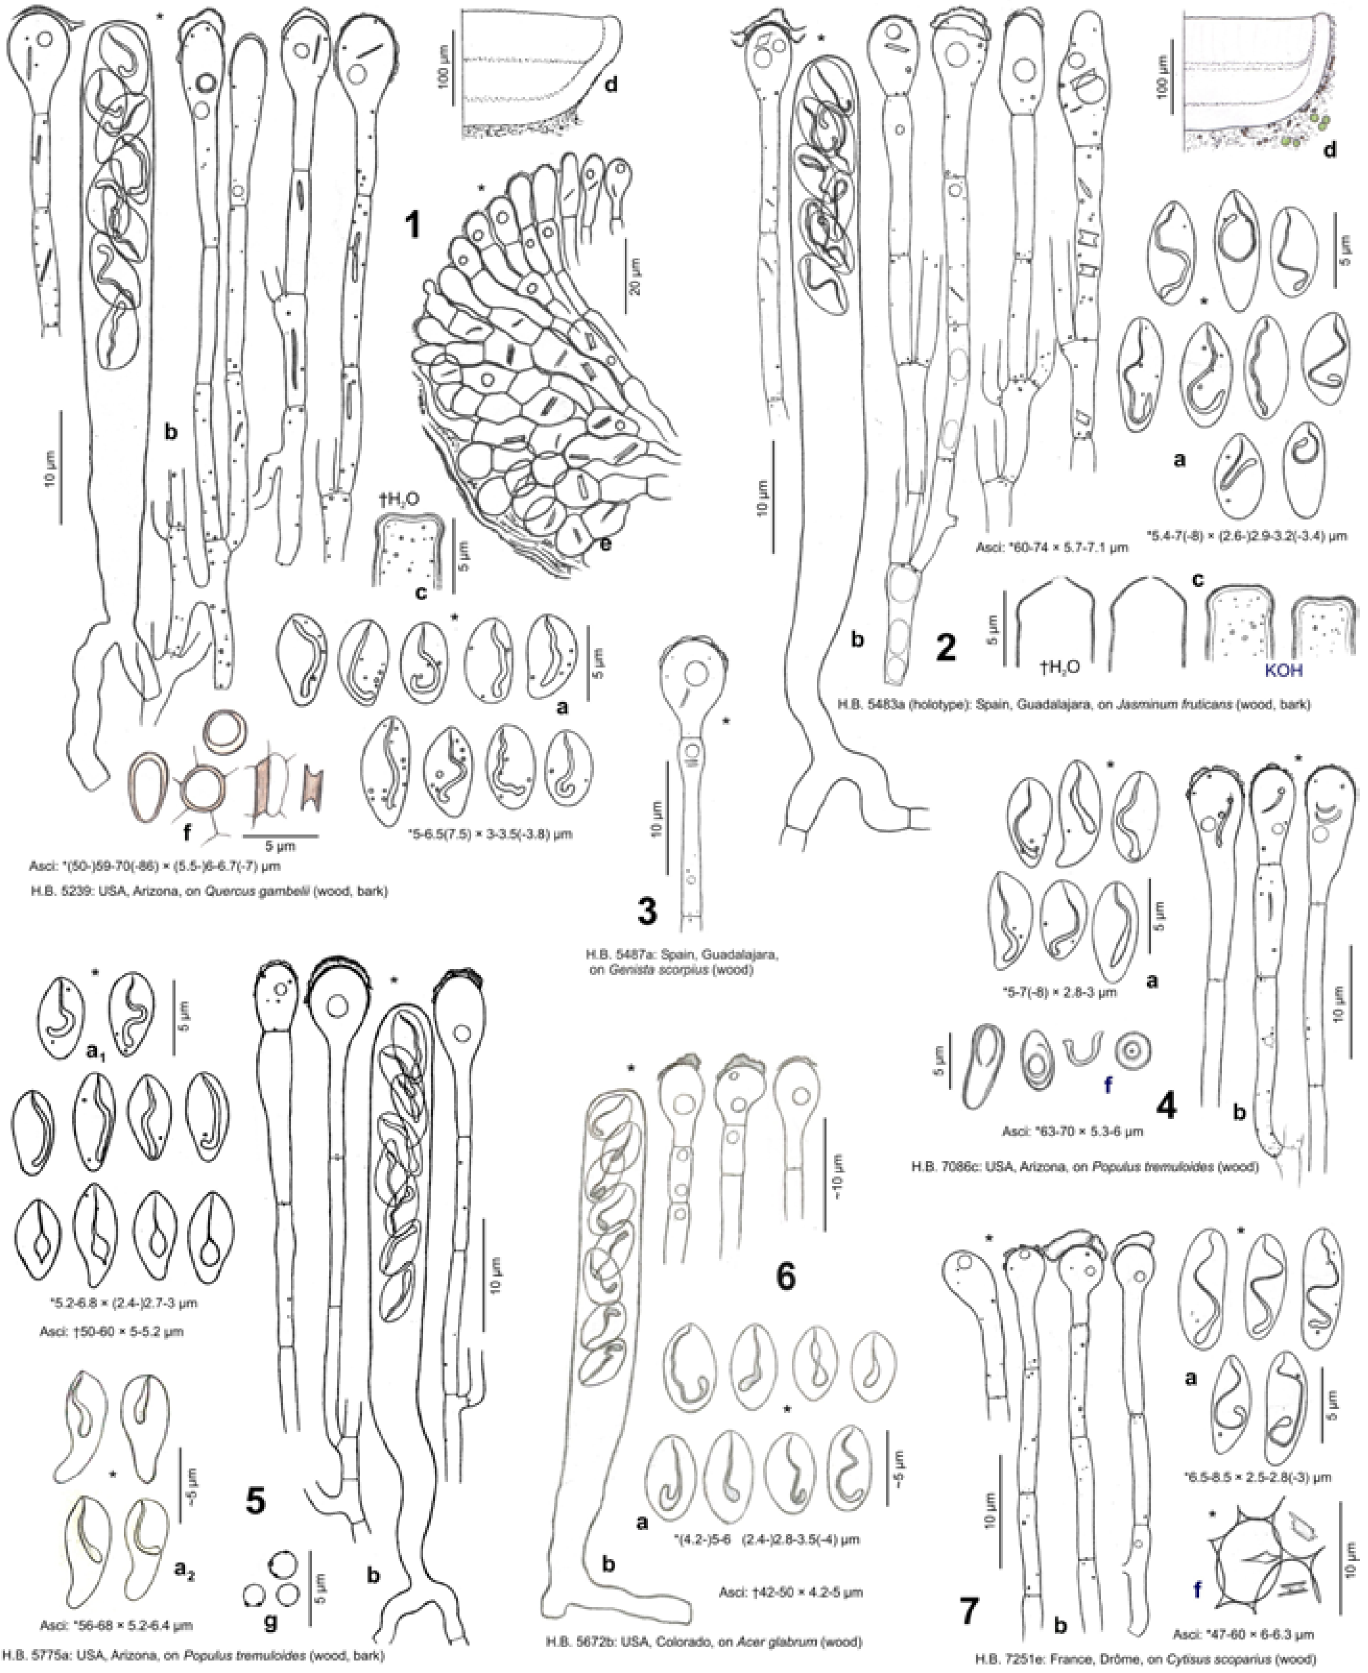

Plate 720. **1–7**: *Orbilia gambelii*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices (partly after discharge); **d**. apothecia in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs in ectal excipulum; **g**. SCB-like cytoplasmic structure in ectal excipulum.

asci, *O. trapeziformis* in consistently lacking crystalloid SCBs, somewhat longer spores with more tapered apices, and a temperate distribution. *O. subvitalbae* differs in narrower, partly subcylindrical spores and much shorter SBs, *O. cactacearum* in longer, basally more attenuated spores and shorter SBs. For the similar Australian *O. octocercocarpi* see p. 1212.

Variation. In the present circumscription the species shows a remarkable variation in size, length/width ratio, and shape of ascospores and spore bodies, also in ascus size. The spores vary from ovoid-ellipsoid to fusoid, rarely fusoid-clavate, their

Map 120. Known distribution of *O. gambelii* in Europe (including Macaronesia and Turkey) and North America.

apices being either consistently rounded to obtuse, or showing a tendency to subacute, and their bases sometimes more tapered and slightly curved, leading to a heteropolar spore shape. The SBs vary in length, being often distinctly longer than the spores and then helicoid and/or basally uncinate. Frequently they are gradually thicker towards base (subulate) but also equally thick (filiform or vermiform), and only sometimes they show a ± abruptly inflated base.

All six collections from Arizona (3× *Quercus gambelii*: Pl. 720: 1, IVV: H.B. 8682a, 8.V.1995; 2× *Populus tremuloides*: Pl. 720: 4–5; 1× *Cercocarpus*, IVV: 17.V.1995) deviate from typical European *O. gambelii* in a strong tendency of the spores to be tapered at the base. In one of them (Pl. 720: 5) crystalloid SCBs could only sometimes be observed, and the spore bases are in some of the examined apothecia partly tail-like and often medium (to strongly) curved, reminiscent of the European *O. trapeziformis* (720: 5a$_2$). But also three collections from Spain (on *Rhamnus*, Pl. 721: 7e; on *Rosmarinus*, 25.IX.1999; on *Amelanchier*, IVV: H.B. 6487d) show rather often ± strongly tapered spore bases. In the specimen on *Rosmarinus* the SBs were only about half as long as the spores, but this might be due to not fully mature apothecia. Similarly short SBs were also illustrated in some other samples, e.g., in that on *Cercocarpus*.

Anamorph. The trinacrium-like conidia obtained in pure culture and from natural substrate (Pl. 719: 7g, 9g) are of the *Trinacrium robustum*-type and do not differ in morphology from those of many other species of section *Habrostictis*.

Phylogeny. Sequences of *O. gambelii* were gained from pure culture of H.B. 6466 (on *Quercus*) and from apothecia of a specimen from southern France (G.M. 2017-08-30.1, on *Clematis*). Both comprise SSU, ITS, and LSU. In the ITS 1 nt of the ITS1 differs between the two strains, while in the overlapping SSU (V7–V9) and LSU (D1–D2) they are identical. Surprisingly, the *Clematis* strain possesses the S1506 intron, whereas the *Quercus* strain lacks it.

When analysing the ITS region or SSU+ITS+LSU, the species clustered with *O. vitalbae*, *O. subvitalbae*, *O. trapeziformis* (H.B. 9139, 9151c) and *O. obtusispora* in the strongly (SSU+ITS+LSU) or medium (ITS) supported *gambelii-vitalbae* clade (Phyls 19–20), showing a 4% distance to *O. subvitalbae* and 6% to the other three species (0.5–1% in LSU). This relationship is also seen in analyses of SSU (S20), but less so in the LSU (S22). When analysing the intron *O. gambelii* surprisingly clustered with *O. cisti* in a strongly supported clade (S21).

Ecology. *O. gambelii* was found on rotten wood and bark of xeric twigs and branches of both gymno- and angiosperm trees and shrubs, sometimes also on standing herbaceous stems of large dicotyledonous plants. The species is widely distributed in warm-temperate humid (sub)atlantic western Europe and especially in orosub- to thermomediterranean, mainly semihumid to semiarid southern Europe. Here it belongs to the most frequently collected desiccation-tolerant species, occurring in the semihumid maquis (e.g., *Juniperetum thuriferae*) and old *Olea* plantations as well as in humid conifer or broad-leaved forests and shrublands. In Macaronesia it was found in inframediterranean semiarid zones (*Periploco laevigatae-Euphorbietum canariensis*) as well as in a thermomediterranean semihumid *Chamaecytisus* (tagasaste) plantation and in the upper meso- to supramediterranean semihumid summit broom scrub (*Spartocytisetum supranubii*). An isolated sample from the southeast of Slovakia was made in a thermophilous (xerophilous) pannonian oak grove in the Danubian lowlands. This and one from eastern France (Haut Jura) represent the only records from temperate humid central Europe.

Collections from western North America were made in cold-temperate (to boreal) humid ponderosa pine forests, also in Douglas fir mixed forests or once in the upper zone of the subhumid pinyon-juniper woodland, in Southern Rocky Mountains, Utah Mountains, Grand Canyon, and Mogollon Rim.

Specimens included. **FRANCE**: **Bretagne**, **Morbihan**, 3 km NW of La Gacilly, km S of La Villio, 32 m, twigs of *Euonymus europaeus*, on wood, 28.III.2013, J.P. Priou (J.P.P. 13051, doc. vid.). – 1.7 km NNE of La Gacilly, NE of Les Villes Geffs, Pont des Boussards, rivulet of Rahun, 11 m, twig of *E. europaeus*, on wood, 27.III.2013, J.P. Orbilia pleiogambelii Baral, **sp. nov.**, MB 813718 — Pls 722–723, Map 121

Etymology: named after the resemblance to *O. gambelii* but differing in 16-spored asci.

Typification: Spain, Alocén, branch of *Calicotome villosa*, 25.IX.1999, G. Marson & H.O. Baral (ex H.B. 6482a, M-0276558, holotype).

Latin diagnosis: *Similis* Orbiliae gambelii *sed asci 16-spori.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.4 mm diam., 0.13–0.19 mm high, pale to bright (partly dirty) orange,

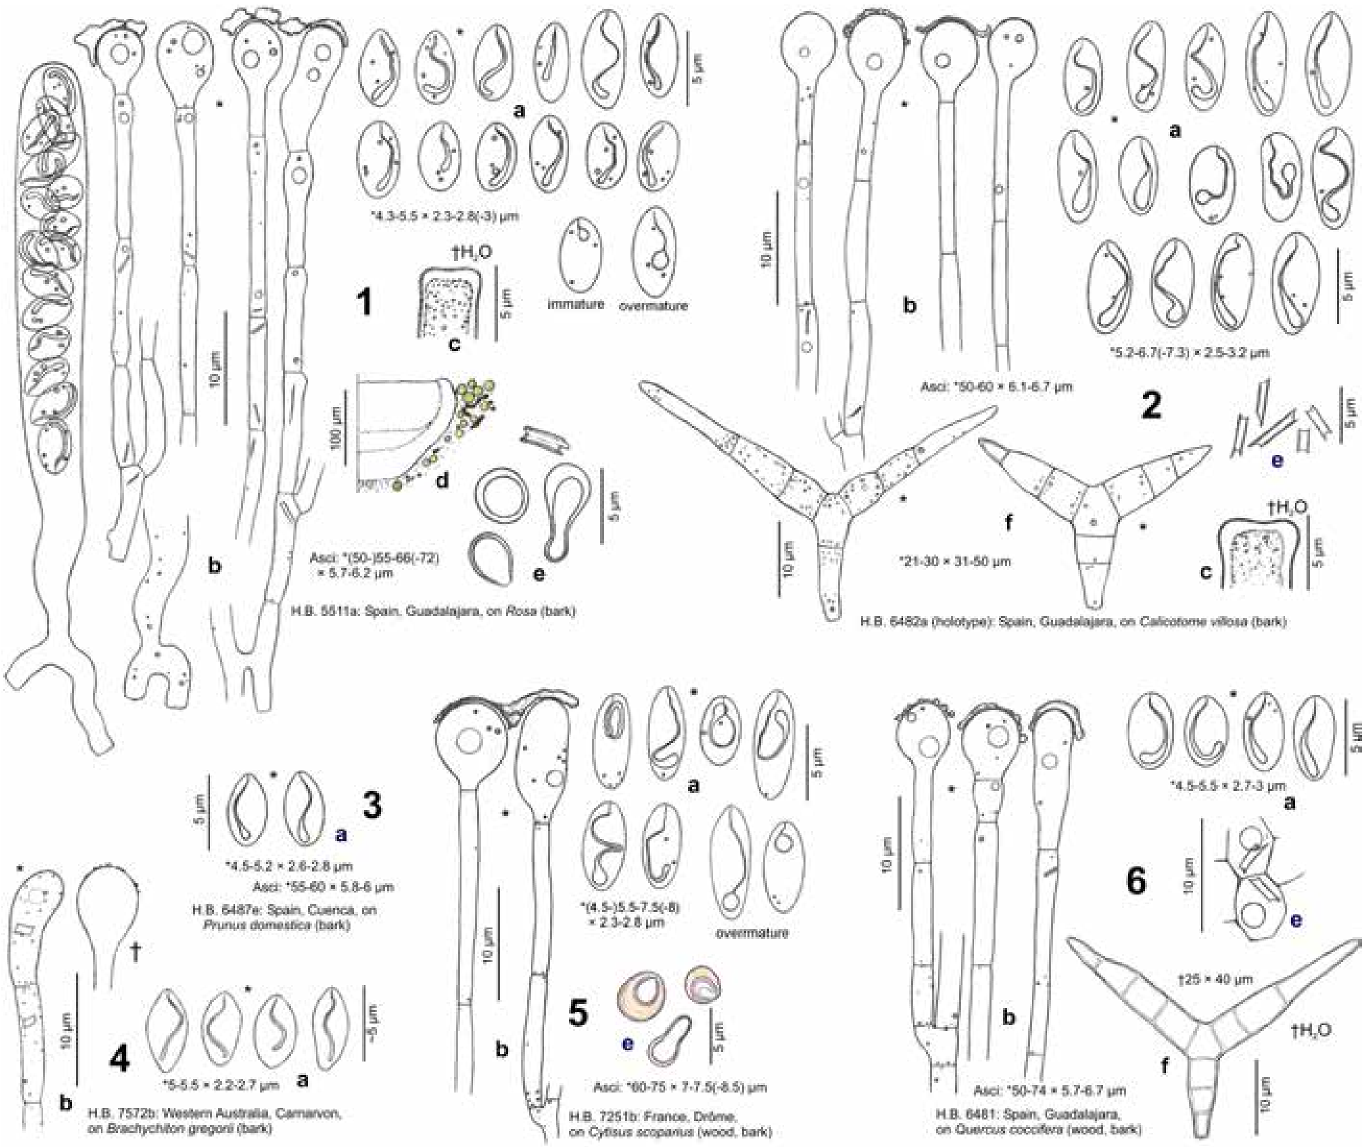

Plate 722. **1–3**, **5–6**: *Orbilia pleiogambelii*; **4**: *O.* cf. *pleiogambelii*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. crystalloid SCBs in ectal excipulum; **f**. conidia from substrate.

translucent, round, ± scattered to subgregarious; disc flat, margin distinct or not, 0–5 µm protruding, smooth; sessile, superficial or distinctly erumpent between fibres. **Asci** *(50–)55–71(–75) × (5.7–)6–7.5(–8.5) µm {6}, †50–60(–72) × (4.5–)5–6.3 µm {3}, 16-spored, spores 1–2-seriate, (5–)7–10 lower spores inverted {4} (often mixed), pars sporifera *29–48 µm long; **apex** (†) strongly truncate (distinctly indented, laterally inflated); **base** with short, ± thick, flexuous stalk, L- or h-shaped. **Ascospores** *(4.3–)5.2–7(–8) × (2.3–)2.5–3.3(–3.5) µm {11}, narrowly ellipsoid to ellipsoid(-ovoid), apex rounded to obtuse, straight, rarely slightly inequilateral; **SBs** *(3–)4–6.5(–7) × (0.2–)0.4–0.9(–1.2) µm in situ {9}, ~(4–)6–9(–10) µm actual length, subulate or filiform with slightly to strongly inflated, tear-shaped base, often strongly flexuous to helicoid, sometimes uncinate, in aged spores with globose lower and filiform upper part. **Paraphyses** apically slightly to very strongly clavate-capitate, terminal cells *6–15(–19) × 3.5–5.5(–6.3) µm {6}, lower cells *(4–)8–16(–19) × 1.2–2.2(–3) µm {4}; rarely branched at upper septum. **Medullary excipulum** hyaline, 25–90 µm thick, of ± dense textura intricata with many inflated cells, indistinctly or medium sharply delimited from ectal excipulum (partly by a t. porrecta). **Ectal excipulum** of thin-walled, ± vertically oriented t. angularis-prismatica from base to margin, 40–50 µm thick near base, cells *8–20 × 5–13 µm {3}; 15–20 µm thick near margin, oriented at a 30–45° angle to the surface, marginal cortical cells *5–12 × 2.5–5 µm {2}. **Anchoring hyphae** sparse, *2–3 µm wide, walls 0.2–0.3 µm thick {2}. **SCBs** in paraphyses globose (near apex) or rod-shaped (towards base, abundant, small); in ectal excipulum globose, or ring- (to horseshoe-) shaped {9}, 2.5–6.5 × 2.5–4 µm, hyaline to pale orange. **Exudate** over paraphyses 0.3–1(–2.5) µm thick, cloddy(-granular), ± loosely

Map 121. Known distribution of *O. pleiogambelii* in Europe and Macaronesia.

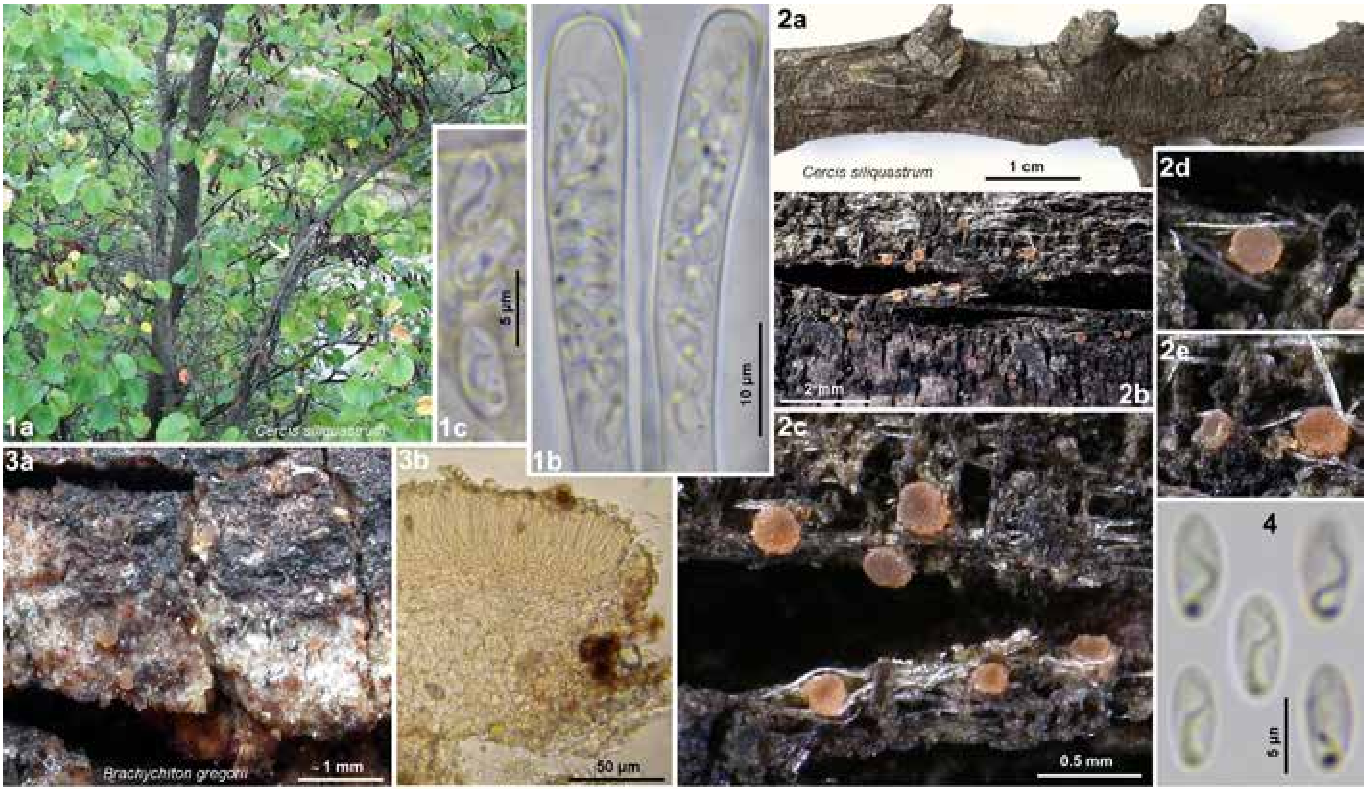

Plate 723. **1–2**, **4**: *Orbilia pleiogambelii*; **3**: *O.* cf. *pleiogambelii*. – **1a**. Mediterranean maquis with *Cercis* shrub at roadside with dead branches; **2a**. corticated xeric branch; **2b–e**, **3a**. rehydrated apothecia; **3b**. apothecium in median section; **1b**. asci; **1c**, **4**. ascospores. – Living state. — **1a–c**. attached; over margin and flanks 1–2.5 µm thick, pale chlorinaceous. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** Y-shaped, total size */†21–30 × 31–50 µm, stipe */†10.5–13 × 4–5 µm, 1–3-septate, arms ± gradually tapering, */†15–28 × 4.5–5 µm, 2–3(–4)-septate {2}.

Habitat: collected 0.1–3 m above the ground, corticated or ± decorticated, 2–20 mm thick twigs and branches of *Adenocarpus viscosus* {1}, *Berberis hispanica* {1}, *Calicotome villosa* {1}, *Cercis siliquastrum* {2}, *Cistus* sp. {1}, *Cytisus scoparius* {1}, *Prunus domestica* {1}, *Quercus coccifera* {1}, *Rosa* sp. {1}, *Spartium junceum* {2}, on 0.1–0.2 mm deep medium to strongly decayed wood {6} and bark {7} (± detaching, often on bast, periderm partially removed), slightly to strongly greyed, with a few to many green algae, sometimes in beetle galleries. **Associated**: *Baggea* sp. {1}, *B. pachyascus* {1}, ?*Calloria* sp. {1}, *Caloplaca* sp. {1}, '*Chlorosplenium*' *viridulum* {1}, *Claussenomyces* sp. {1}, *Durella connivens* {2}, ?*Evernia* sp. {1}, *Hyalorbilia erythrostigma* {1}, *Ionomidotis fulvotingens* {1}, *Mellitiosporiella pulchella* {2}, *Mollisia rosae* {1}, *Nitschkia* ?*broomeana* {1}, *Orbilia adenocarpi* {1}, *O. carpoboloides* {1}, *O.* ?*cejpii* {1}, *O. cercidicola* {1}, *O. delphinus* {1}, *O. gambelii* {5}, *O. myriosphaera* {2}, *O. ovalis* {1}, *O. polyspora* {3}, *O. rosicola* {1}, *O. sarothamni* {1}, *O. subaristata* {3}, *O. subclavuliformis* {4}, *O. subovoidea* {1}, *O. subtrapeziformis* {1}, *O.* ?*tremulae* {1}, *O. vinosa* {2}, *O. xanthoguttulata* {1}, *Ostropa barbara* {1}, *Patellaria atrata* {1}, *Propolis farinosa* {1}, *Perrotia flammea* {1}, *Schizoxylon* {1}, *Trichosphaerella decipiens* {1}. **Desiccation tolerance**: fully viable for at least 3 months, conidia viable for 3 years. **Altitude**: 383–880 m a.s.l. (southern France), 930–1600 m (Spain), 2230 m (Tenerife). **Geology**: Cretaceous & Tertiary lime-, marl- & sandstone, dolomite; phonolitic flow. **Phenology**: V, VIII–X (certainly throughout the year, long-lived).

Taxonomic remarks. *O. pleiogambelii* closely resembles *O. gambelii*, from which it merely differs in the consistently 16-spored asci. The 16-spored *O. microserpens* has similar but distinctly smaller spores and lacks any crystalloid and globose SCBs. Also *O. cisti* and *O. pleioserpens* differ in the consistent absence crystalloid and partly also globose SCBs. The extra-European *O. barrowensis* differs in distinctly wider spores whereas the also extra-European *O. pleioungulata* has narrower spores and shorter asci. The North American *O. cercocarpi* (p. 1213) is only tentatively separated from *O. pleiogambelii*.

Variation. Like *O. gambelii*, *O. pleiogambelii* varies in ascospore and SB length, also in the strength of basal inflation of SBs.

Not included collection. In an Australian sample (Pls 722: 4; 723: 3) only a few paraphyses were viable, therefore, the presence of crystalloid SCBs is uncertain. The rather short spores are more fusoid, and the SBs are filiform down to the base similar as in *O. cercocarpi* and *O. cisti*, or in *O.* cf. *pleioserpens* (Pl. 736: 4–5).

Anamorph. The conidia observed near apothecia of *O. pleiogambelii* are similar to those of *O. gambelii*, but tend to have longer arms (Pl. 722: 2f, 6f).

Ecology. *O. pleiogambelii* inhabits ± rotten wood and bark of xeric twigs and branches of various angiosperm shrubs and also trees. It was collected in supra- to mesosubmediterranean and supra- or mesomediterranean semihumid, rarely orosubmediterranean humid, maquis and forests of southern Europe (*Quercetum ilicis*, *Juniperetum thuriferae*, pine forest with *Rhus coriaria*, mixed conifer forest with *Amelanchier ovalis*) also in the upper mesomediterranean semihumid summit broom scrub (retamar, *Spartocytisetum supranubii*) in the caldera of the volcano Teide (Tenerife, Macaronesia). The not included collection on *Brachychiton* was on Cenozoic regolith in a subtropical semiarid acacia open woodland in western Australia.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Drôme**, 16.3 km E of Nyons, 2.5 km NNW of Bellecombe, Col de Soubeyrand, 880 m, twig of *Cytisus scoparius*, on wood & bark, 10.X.2002, G. Marson (H.B. 7251b). – 1 km N of Nyons, Col du Pontias, 460 m, branch of *Cercis siliquastrum*, on bark,

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.4(–0.6) mm diam., 0.13–0.2 mm high, pale to bright (to deep) orange(-ochraceous), non-translucent, round, rarely slightly ellipsoid, scattered or gregarious in small groups; disc medium concave to flat, margin distinct, 0–30 µm protruding, smooth to finely rough; broadly sessile, erumpent, nearly superficial to entirely immersed. **Asci** *(60–)70–90(–105) × (7.5–)8–8.8(–9.3) µm {5}, †(48–)60–75(–87) × 6–8(–8.8) µm {7}, 32-spored (28–31 spores counted), spores *~4-seriate, lower spores inverted {4} (partly oriented in all directions), pars sporifera *43–48 µm long; **apex** (†) slightly to strongly truncate (not indented, laterally sometimes inflated); **base** without or with short to medium long, thick, ± flexuous stalk, L-, h- to Y-shaped. **Ascospores** *(4.2–)4.7–6.5 × (2.4–)2.6–3.2(–3.5) µm {7}, †(3.5–)4.2–6((–8)) × (2.4–)2.6–3.2(–3.5) µm {5}, ellipsoid, exceptionally fusoid or clavate, apex rounded (to obtuse), base not or sometimes slightly attenuated, straight, rarely slightly inequilateral; **SBs** *2.5–4.5(–6) × 0.3–0.5(–0.8) µm in

Map 122. Known distribution of *O. multigambelii* in North America and Australia (yellow = not included collections).

situ {5} (~3–6.5 µm actual length) → 1.5–3 × 0.5–0.8(–1) µm, rod-shaped to vermiform, sometimes subulate, base not or slightly inflated, straight to strongly flexuous, sometimes uncinate, in aged spores pear- to broadly tear-shaped. **Paraphyses** apically medium to (very) strongly clavate-capitate or spathulate, sometimes moniliform, terminal cells *(4.5–)7–14(–20) × (2.5–)4–5.7 µm {4}, †(2–)3–4.5(–5.3) µm wide {3}, lower cells *(3–)7–18(–20) × 1.7–2.2(–3) µm {4}, †1–1.7 µm wide, subapical cell partly *3–5 µm wide; sometimes branched near apex. **Medullary excipulum** 30–70 µm thick, of dense textura intricata with many inflated cells, very sharply delimited from ectal excipulum, partly by a layer of t. porrecta. **Ectal excipulum** very pale rose, of thin-walled († very slightly gelatinized), vertically oriented t. angularis(-prismatica) from base to submargin, 20–90 µm thick near base, cells */†7–20 × 5–13 µm {4}; 30–35 µm thick near margin, oriented at an 80–90° angle to the surface, upper margin of t. prismatica-porrecta oriented at 30–40°, marginal cortical cells †8–14 × 2–4 µm {2}. **Anchoring hyphae** sparse, †2–3.3 µm wide, walls 0.2–0.3 µm thick {1}, also forming a t. prismatica-globulosa, cells *3–5 µm wide. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.2 µm diam.; crystalloid, rod-shaped to angular SCBs in paraphyses {8}, also in excipulum (here 3–5 µm diam.), subhyaline; sometimes ± completely absent {2}. **Exudate** over paraphyses 0.1–0.7 µm thick, granular(-cloddy), ± firmly attached over margin and flanks sparse, granular. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {2}). **Conidiophores** reduced (*~5–10 × 3 µm) or integrated (*1–1.5 × 2–2.5 µm). **Conidia** Y-shaped, total size *22–30(–38) × 17–28 µm, †20–25 × 20–28 µm, stipe *12–18(–28) × 5–6.2 µm, †11–14 × 4–5.5 µm, 2–3-septate, arms ± abruptly tapering, *8–13 × 3.7–4.2 µm, †10–17 × 4–4.5 µm, 1–3-septate {3}; a single 3-armed conidium seen (one arm again dichotomously branched); phragmoconidia in culture narrowly fusoid, *28–32 × 5–6.2 µm, 3–4-septate {1}.

Habitat: collected 0.05–2 m above the ground, mostly decorticated, 4–19 mm thick twigs and branches of *Acacia* sp. {1}, *Atriplex canescens* {1}, *Cylindropuntia versicolor* {1}, *Krascheninnikovia lanata* {2}, *Larrea tridentata* {2}, *Olneya tesota* {2}, on 0.2–2 mm deep strongly decayed wood {7}, rarely bark (bast) {1}; inflorescence stem of *Yucca elata* {1}; partly in deep clefts, strongly greyed, no algae, often on or close to pycnidia of *Diplodia*. **Associated**: *Cyathicula ?nigrofusca* {1}, *Hysterobrevium mori* {1}, *Hysteropatella* sp. (on *Larrea*) {1}, *Melaspilea emergens* {1}, *Odontura rhaphidospora* {1}, *Orbilia arizonensis* {1}, *O. ?barrowensis* {1}, *O. bicknellensis* {3}, *O. ?cactacearum* {1}, *O. calyptrata* {3}, *O. commarosa* {1}, *O. cryptogena* {1}, *O. lacrimispora* {1}, *O. lentiformis* {1}, *O. macrodelphinus* {1}, *O. macrotrapeziformis* {1}, *O. maeandrina* {2}, *O. microserpens* {1}, *O. multicreosoteris* {1}, *O. myrioauris* {1}, *O. myrioolneyae* {2}, *O. myriourosperma* {2}, *O. ?navajoana* {1}, *O. ?pleionavajoana* {1}, *O. plurilentiformis* {1}, *O. serpentina* {1}, *O. sonorensis* {1}, *O. ?ungulata* {1}, *O. vitalbae* {1}, *O. yuccae* {1}, *Patellaria 'andina'* {2}, *P. atrata* {2}, *Schizoxylon* sp. {1/1}, *S. ?argentinum* {1}, *Teichosporella dura* {2}, *Symbiotaphrina desertorum* {1}, *S. larreae* {1}. **Desiccation tolerance**: almost fully viable for 34 months. **Altitude**: 600–1645 m a.s.l. (North America), 300 m (Australia). **Geology**: Neogene & Quaternary sand-, lime & mudstone, Cenozoic regolith (red-brown sand); felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multigambelii* is characterized by 32-spored asci with rather small ellipsoid ascospores with usually long and flexuous spore bodies. *O. multiserpens* differs in shorter and especially narrower spores and in the consistent absence of crystalloid and often also globose SCBs, and *O. multicercocarpi* in distinctly longer spores.

Variation. In the present circumscription of *O. multigambelii* the ascospores vary somewhat in size and the spore bodies in length. Also the crystalloid SCBs were not consistently present. In the collections on *Yucca* (Pl. 724: 5) and *Olneya* (6) only globose SCBs could be found, but in the latter a single crystalloid SCB was seen in the excipulum. Due to the predominant absence of crystalloid SCBs, these two collections strongly resemble *O. pleioserpens* which differs in 16-spored asci, whereas the 32-spored *O. multiserpens* differs in distinctly narrower spores.

Not included collections. In an Australian population of the 16-spored *O. barrowensis* (Pl. 717: 2) a single apothecium with 32-spored asci was detected (Pl. 724: 7) which might belong to *O. multigambelii*. Both globose and crystalloid SCBs were present in the paraphyses, but the asci were wider than observed in *O. multigambelii*. In another Australian collection which consisted of only two apothecia, no data on SCBs could be gained, and only a few living spores were seen which deviated in an ellipsoid-fusoid shape (Pl. 724: 8). Both specimens are not included in the description, as is a third (H.B. 10120) which was only studied in the dead state.

Anamorph. The trinacrium robustum-like conidia of *O. multigambelii* hardly differ in morphology from those of *O. gambelii*. Some unbranched conidia occurred in pure culture which were not seen on the natural substrate.

Ecology. *O. multigambelii* was collected on rotten wood (rarely bark) of xeric twigs and branches of various angiosperm shrubs, also *Cactaceae* and stems of *Yucca*, in warm-temperate to subtropical semiarid (to arid) paloverde-mixed cacti,

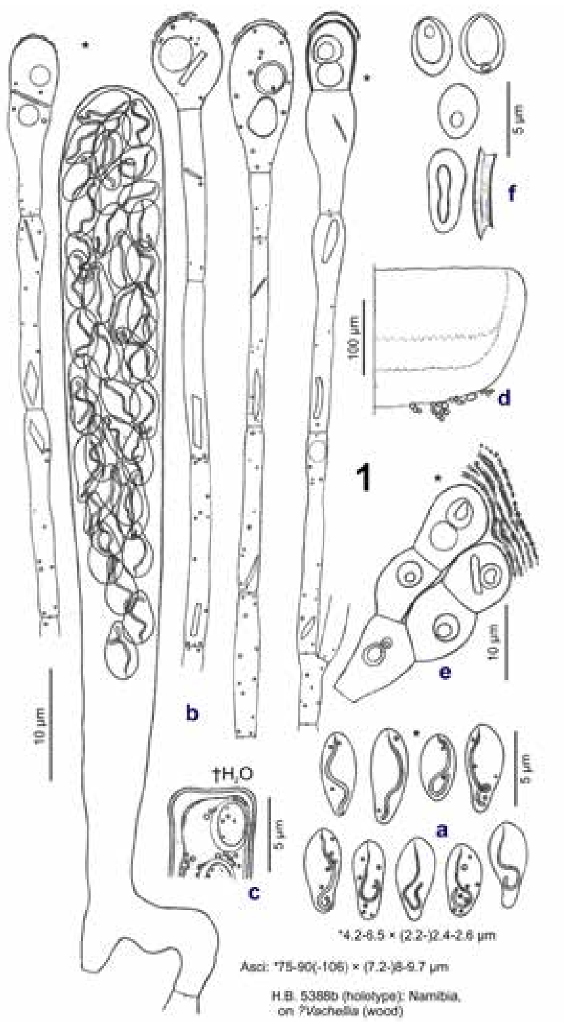

Plate 726. **1**: *Orbilia myrioflexa*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal cells of ectal excipulum; **f**. crystalloid SCBs in excipular cells.

creosotebush, and winterfat desert scrubs or mixed grass-scrubland of the Colorado Plateau, Sonoran and Chihuahuan Desert in western North America. The collection from western Australia was in an almost tropical arid acacia shrubland/tussock grassland with *Livistona alfredii* in a dry riverbed, and the three not included samples from subtropical semiarid to arid acacia shrublands.

Specimens included. **USA**: **Arizona**, Navajo, Petrified Forest, 27 km ESE of Holbrook, 1645 m, branch of *Krascheninnikovia lanata*, on wood, 29.V.1996, G. Marson (H.B. 6134d, anam. substr.). – Sonoran Desert, 68 km SSW of Flagstaff, 5.5 km NNE of Camp Verde, Montezuma Castle, 975 m, branches of *K. lanata*, on wood, 8.V.1995, G. Marson (H.B. 6085b). – ibid., branch of *Larrea tridentata*, on wood, 8.V.1995, G. Marson (H.B. 5684e). –200 km NW of Phoenix, Wikieup, ~600 m, on *Cylindropuntia versicolor*, 3.V.1995, G. Marson (H.B. 8356). – 100 km WSW of Tucson, 10 km NW of Sells, 683 m, twig of *Olneya tesota*, on wood, 28.V.2003, G. Marson (H.B. 7573d). – 25 km WNW of Tucson, 5 km S of Picture Rocks, Saguaro, 745 m, branch of *O. tesota*, on wood & bark, 30.V.2003, G. Marson (H.B. 8085b). – 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branch of *Larrea tridentata*, 5.V.1995, G. Marson (H.B. 5655b). – 25.5 km SE of Carlsbad, Malaga, 918 m, branch of *Atriplex canescens*, on wood, 17.VI.1996, G. Marson (ex H.B. 5712, M-0276521, **holotype**, anam. substr.). — **AUSTRALIA**: **Western Australia**, Pilbara, 96 km S of Roebourne, 42 km SSW of Python Pool, road crossing Fortescue River, 300 m, on *Acacia*, 4.XI.2007, G. Marson (ø, anam. cult.).

Not included. **AUSTRALIA**: **Western Australia**, Carnarvon, 165 km SSE of Carnarvon, Peron Peninsula, 24 km SE of Shell Beach, 41 m, branch of *Brachychiton gregorii*, on bark, 8.XII.2001, G. Marson (H.B. 7578b ø). – **Northern Territories**, Burt Plain, 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, 480 m, branch of *Atriplex*, on wood, 8.X.1998, G. Marson (H.B. 6262h ø). – MacDonnell Ranges, 11 km W of Alice Springs, 5 km N of White Gums, Larapinta Drive, 605 m, branch of *Atriplex*, on wood, 13.X.1998, G. Marson (H.B. 10120 ø).

Orbilia myrioflexa Baral, **sp. nov.**, MB 813720 — Pl. 726

Etymology: referring to the 64-spored asci and flexuous spore bodies.
Typification: Namibia, Rehoboth, branch of ?*Vachellia*, 25.VIII.1995, R. Reuter (ex H.B. 5388b, M-0276529, holotype).

Latin diagnosis: *Apothecia rehydratata 0.3–0.4 mm diam., aurantiaca, margine laevi. Asci 64-spori. Ascosporae *4.2–6.5 × 2.2–2.6 µm, ellipsoideo-clavatae, basi plerumque valde attenuatae, in statu vivo corpusculum refringens longum, filiforme, valde flexuosum vel uncinatum, ad apicem affixum continentes. Paraphyses ad apicem modice vel valde capitatae vel clavatae. Cellulae vivae excipuli et paraphysium corpuscula globosa et crystalloidea continentes. Habitat ad lignum putridum rami sicci* ?Vachelliae *in zona subtropica arida Africae austro-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.4 mm diam., 0.19–0.2 mm high, light orange, round; disc flat, margin 0–10 µm protruding, ± smooth; broadly sessile. **Asci** *75–90(–106) × (7.2–)8–9 µm, †72–88 × 6–7.2 µm, 64-spored (min. 50 spores counted), spores multiseriate, lower spores inverted (very strongly mixed), pars sporifera *(36–)43–60 → 29 µm long; **apex** (†) strongly truncate (slightly indented, laterally slightly inflated); **base** with short, thick, slightly flexuous stalk, h-shaped. **Ascospores** *4.2–6.5 × (2.2–)2.4–2.6 µm, †3.5–6 × 2–2.3 µm, ellipsoid or mostly ellipsoid- to ovoid-clavate, apex rounded to obtuse, base not or slightly to mostly strongly attenuated, straight or sometimes slightly inequilateral; **SBs** *3.5–5.5(–6) × 0.2–0.3 µm in situ (~5–7.5 µm actual length), filiform, not inflated at base, strongly flexuous and often uncinate. **Paraphyses** apically medium to very strongly capitate-clavate, sometimes moniliform, terminal cells *(6–)8–18 × 3.5–6.5 µm, distinctly protruding beyond living asci, subapical cell sometimes also strongly inflated, lower cells *(6–)13–20 × 1.4–2.4 µm; very rarely branched near apex. **Medullary excipulum** pale rose, 40 µm thick, of ± loose textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose, light rose-orange towards margin, of vertically oriented t. angularis-prismatica from base to margin, 35–50 µm thick near base, cells *10–22 × 7–11 µm; 25 µm thick at mid flanks and margin, cells *9–15 × 6–8 µm, oriented at a 70–90° angle to the surface, marginal cortical cells *7–10 × 5.5–8 µm. **Anchoring hyphae** not seen. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.5–3 µm diam., and crystalloid, in excipulum pale orange, ring-shaped, 2.5–6.5 × 2.5–3.5 µm. **Exudate** over paraphyses 0.2–1.5 µm thick, finely rough, ± firmly attached; over margin and flanks 3–6 µm thick, layered, granular, hyaline to pale reddish. **— ANAMORPH**: unknown.

Habitat: still-attached, decorticated, 30 mm thick branch of ?*Vachellia*, on 0.5–1 mm deep strongly decayed, eroded wood, greyed, no algae. **Associated**: *Hysterobrevium mori*, *Orbilia maeandrina*, *O. namibica*, *O. pluristomachia*, *Patellaria atrata*, ?*Peniophora* sp., *Teichospora* ?*obducens*, 3 different indet. coelomycetes. **Desiccation tolerance**: fully viable for at least 4 months. **Altitude**: 1560 m a.s.l. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myrioflexa* is characterized by 64-spored asci and rather small, ellipsoid- to ovoid-clavate ascospores with very long, filiform, flexuous, often uncinate spore bodies. Besides spore number, *O. multigambelii* and its lower-spored relatives differ in more homopolar spores. For the similar *O. myrionamibica* see p. 1239. *O. myrioserpens*, *O. myrioolneyae,* and *O. myriella* differ in much shorter SBs, partly non-clavate spores, and in the consistent absence of crystalloid SCBs.

Ecology. Only two apothecia of *O. myrioflexa* were detected in the holotype among the associated, macroscopically indistinguishable species. They grew on rotten wood of a xeric branch of an unidentified angiosperm tree (?*Vachellia*) in the

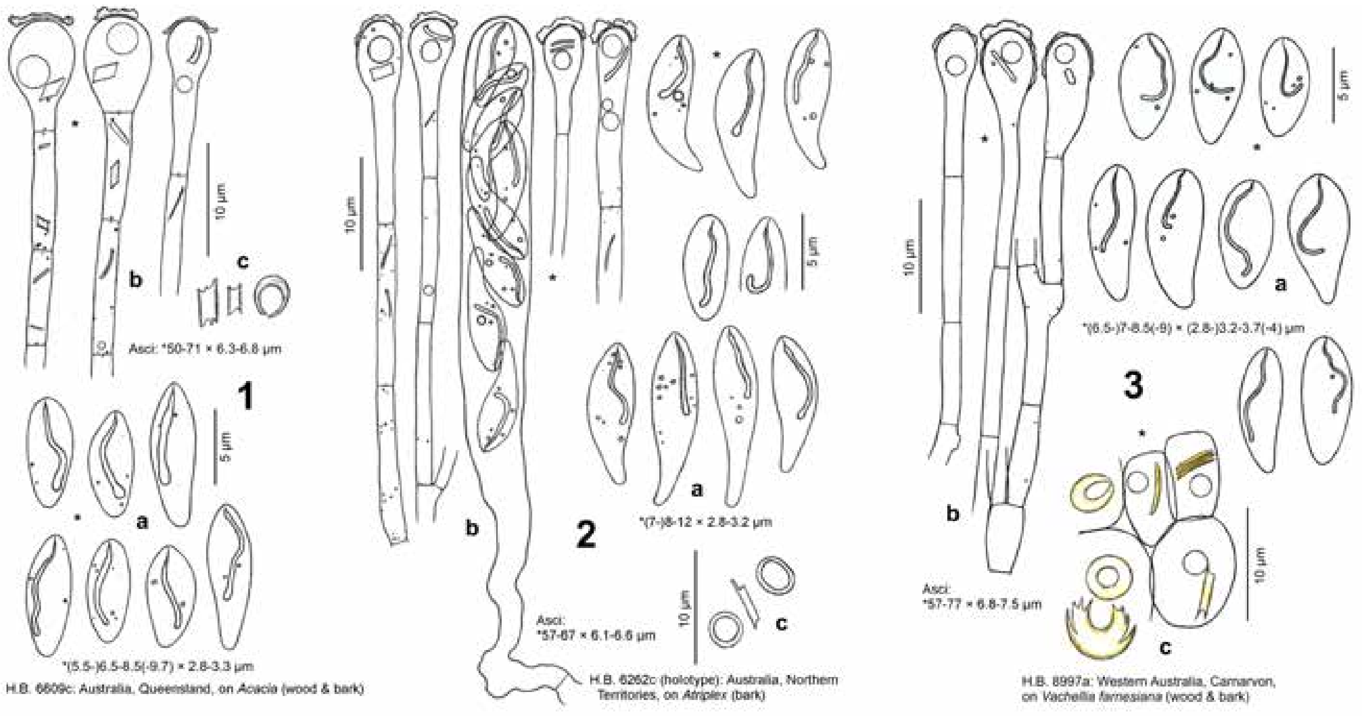

Plate 727. **1–3**: *Orbilia octocercocarpi*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. crystalloid SCBs in ectal excipulum.

hot, subtropical arid (winter-dry) Kalahari highland thornbush savannah about 150 km away from the Namib Desert in southwestern Africa.

Specimens included. **NAMIBIA**: **Khomas**, 60 km S of Windhoek, 25 km N of Rehoboth, Central Plateau, Auas Mts., 1560 m, branch of ?*Vachellia*, on wood, 25.VIII.1995, R. Reuter (ex H.B. 5388b, M-0276529, **holotype**).

Orbilia octocercocarpi Baral & E. Weber, **sp. nov.**, MB 813721 — Pls 727–728

Etymology: named after the similarity to *O. cercocarpi*, deviating in 8-spored asci.

Typification: Australia, Northern Territories, Wilora, branch of *Atriplex*, 8.X.1998, G. Marson (ex H.B. 6262c, MEL 2389196, holotype).

Latin diagnosis: *Similis* Orbiliae gambelii *sed ascosporae saepe longiores, basi valde attenuatae et leniter curvatae.*

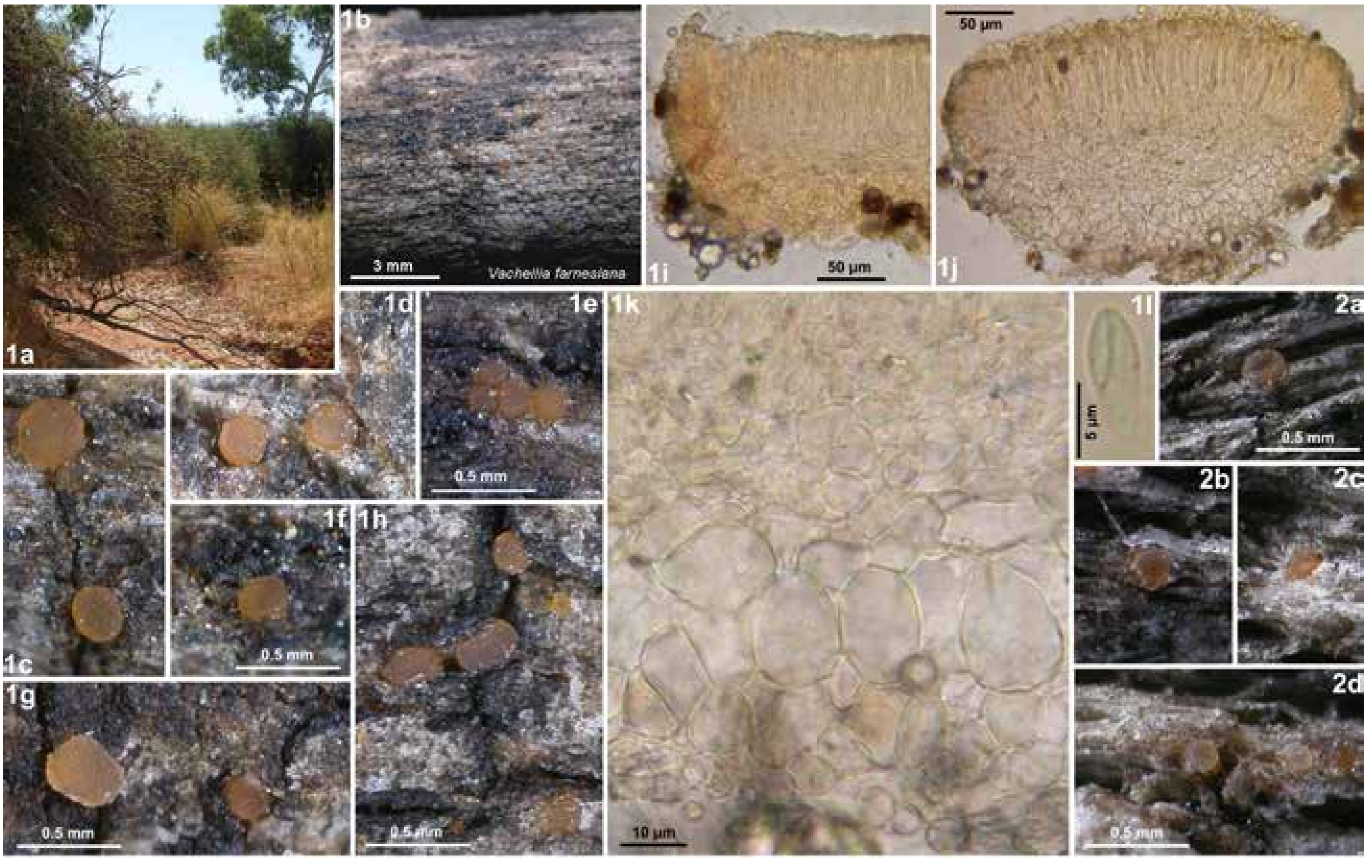

Plate 728. **1–2**: *Orbilia octocercocarpi*. – **1a**. arid *Acacia* woodland in dry riverbed; 1b. decorticated xeric branch; **1c–h**, **2a–d**. rehydrated apothecia (**2**: after 8 years); **1i–j**. apothecia in median section; **1k**. id., basal ectal excipulum; **1l**. ascospore. – Living state. — **1a–l**. H.B. 8997a: Western Australia, Carnarvon, on *Vachellia*; **2a–d**. H.B. 6609c: Australia, Queensland, on *Acacia*.

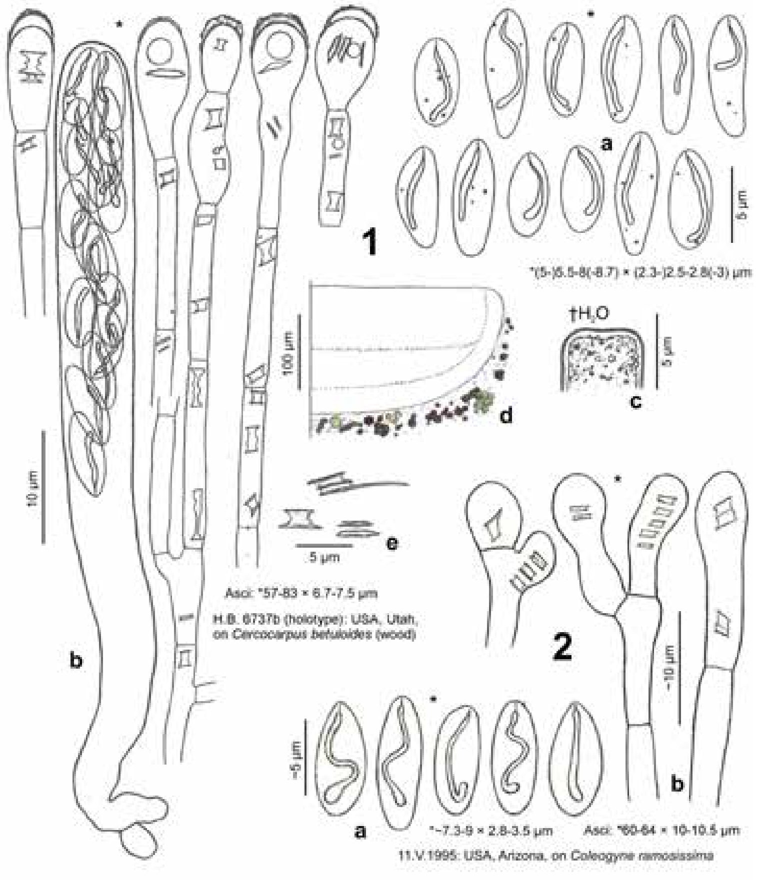

Plate 729. **1–2**: *Orbilia cercocarpi*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. crystalloid SCBs in ectal excipulum at mid flanks.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4 mm diam., 0.14–0.17(–0.19) mm high, pale to bright orange(-ochraceous), hardly translucent, round or sometimes irregularly compressed, ± scattered; disc flat, margin ± thin, 0–10 µm protruding, ± smooth; ± broadly sessile, superficial to partly entirely immersed in biofilm or in clefts. **Asci** *(50–)55–70(–77) {3} × (5.8–)6.3–6.8 {2} or 6.8–7.5 {1} µm, 8-spored, spores *2–3-seriate, (2–)3–4(–6) lower spores inverted {3} (not or sometimes mixed), pars sporifera *29–34 µm long; **apex** (†)strongly truncate (distinctly indented and laterally inflated), hemispherical in side view, thin-walled; **base** with medium long and thin, flexuous stalk, T- to L-shaped. **Ascospores** *(5.5–)6.5–8.5(–9.7) {2} or (7–)8–12 {T} × 2.8–3.5(–4) µm {3}, ellipsoid-fusoid or often ellipsoid- to fusoid-clavate, apex obtuse (to subacute), base not or slightly to strongly attenuated (tail-like), straight to slightly, sometimes medium curved; **SBs** *(4–)5–6.5(–7.5) × (0.2–)0.3–0.5(–1) µm in situ {3} [~(4.5–)5.5–7(–8) µm actual length], filiform to vermiform or subulate, slightly to strongly flexuous to helicoid, sometimes uncinate. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells *(6–)8–18(–22) × (2.5–)3–5(–6) µm {3}, lower cells *8–15 × 1.5–2(–2.7) µm {3}; rarely branched near apex. **Medullary excipulum** very pale orange, 30–50(–80) µm thick, of ± dense textura intricata with many ± inflated cells, sharply delimited. **Ectal excipulum** hyaline to pale orange (especially at margin), of (†) thin-walled, indistinctly oriented textura globulosa-angularis from base to mid flanks, 40–60 µm thick near base, cells *11–23((–38)) × 9–14(–18)((–30)) µm {1}; 15–20(–30) µm thick near margin, of t. globulosa-prismatica oriented at a 20–40° angle to the surface, marginal cortical cells *6–10 × 2.5–4.5 µm {1}. **Anchoring hyphae** rather sparse, *2–3(–4) µm wide, walls 0.2–0.3 µm thick {1}, covering flanks and margin as a 4–6 µm thick layer. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.8 µm diam., associated with angular or rod- to ring- or spool-shaped SCBs {3}, hyaline to pale orange, exceptionally absent. **Exudate** over paraphyses and margin 0.3–1(–2.5) µm thick, rough, hyaline to very pale yellowish, firmly attached. **— ANAMORPH**: trinacrium-like (from ascospore isolate {1}). **Conidia**: not examined.

Habitat: collected 0.1–2 m above the ground, corticated to decorticated, 3–14 mm thick twigs and branches of *Acacia* sp. {1}, *Atriplex* sp. {1}, *Vachellia farnesiana* {1}, on 0.1–0.3 mm deep strongly decayed wood {2} and bark {3} (on bast or periderm), often in fine fissures or larger clefts, greyed or not, without algae. **Associated**: *Dothideales* {1}, *Hysterobrevium mori* {1}, *Orbilia barrowensis* {1}, *O. corculispora* {2}, *O. coronohesperidea* {1}, *O. farnesianae* {1}, *O. lanternae* {1}, *O. ?livistonae* {1}, *O. multiaustrocylindrica* {1}, *O. ?multigambelii* {1}, *O. ?myriella* {1}, *O. octoserpentina* {1}, *O. pleioaustraliensis* {2}, *O. serpentina* {1}, *Patellaria* '*andina*' {1}, ?*Stictis* sp. {2}. **Desiccation tolerance**: fully viable for at least 17 months. **Altitude**: 13–480 m a.s.l. **Geology**: Cretaceous sedimentary rock, Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. The type of *O. octocercocarpi* deviates from European and North American *O. gambelii* in longer ascospores with strongly attenuated, partly tail-like, slightly curved bases, coupled with the spore bodies being partly only half as long as the spores. The SBs further tend to be less flexuous and not or only slightly inflated at the base. The European *O. trapeziformis* and *O. quaestiformis* resemble *O. octocercocarpi* somewhat in the spores, but differ in lacking crystalloid SCBs. *O. cercocarpi* differs in 16-spored asci and *O. acaciae* in narrower spores.

Variation. The two collections additional to the holotype are included mainly because of their Australian origin. They deviate in their spores which are shorter than in the holotype and without curved tail-like bases or even not attenuated at all, and herein resemble American collections of *O. gambelii*. However, they also closely resemble the 16-spored *O. cercocarpi* in spore characters. The specimen on *Vachellia* differs from the two other samples in wider asci and spores and in narrower SBs. Regarding data on excipular tissues and anchoring hyphae the above description is solely based on the *Vachellia* specimen, due to lack of data in the two other samples.

Anamorph. In the sample on *Acacia* a few trinacrium robustum-like conidia developed on water agar which, however, could not be studied under oil immersion.

Ecology. *O. cercocarpi* was collected on rotten wood and bark of xeric twigs and branches of *Atriplex*, *Acacia* and *Vachellia* in subtropical to tropical semiarid to arid acacia (open) shrublands in dry, rarely flooded riverbeds in northwestern, central and northeastern Australia (west of Great Dividing Range).

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 117 km NNE of Carnarvon, 7 km SSE of Minilya Roadhouse, Barrabiddy Creek, 13 m, branches of *Vachellia farnesiana*, on wood & bark, 6.XI.2007, G. Marson (H.B. 8997a). – **Northern Territories**, Burt Plain, 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, 480 m, branch of *Atriplex*, on bark, 8.X.1998, G. Marson (ex H.B. 6262c, MEL 2389196, **holotype**). – **Queensland**, Desert Uplands, 29 km E of Hughenden, 13 km W of Prairie, 390 m, branches of *Acacia*, on wood & bark, 16.X.1998, G. Marson (H.B. 6609c, anam. cult.).

Orbilia cercocarpi Baral & G. Marson, **sp. nov.**, MB 813722 — Pl. 729

Etymology: named after the substrate of the holotype, *Cercocarpus betuloides*. **Typification**: USA, Utah, Moab, branches of *Cercocarpus betuloides*, 16.VI.2000, G. Marson (ex H.B. 6737b, M-0276453, holotype; ex-type culture: CBS 140831; sq.: KT215253, MH878191).

Latin diagnosis: *Similis* Orbiliae pleiogambelii *sed ascosporae paulo longiores, partim heteropolares, corpuscula refringentia vermiformia; corpuscula crystalloidea in omnibus cellulis vivis paraphysium praesentia. Habitat ad lignum putridum ramorum siccorum* Cercocarpi betuloidis *in zona temperata subhumida ad semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.5 mm diam., 0.17 mm high, light to bright orange(-rose), round, subgregarious; disc slightly concave to flat, margin not protruding, smooth or often finely pruinose or crenulate; broadly sessile, partially to entirely immersed. **Asci** *57–83 {2} × 6.7–7.5 {T} or 10–10.5 µm {1}, 16-spored, spores *(1–)2–3-seriate, 9–10 lower spores inverted {1} (± mixed), pars sporifera *36–43 µm long; **apex** (†) strongly truncate (very slightly indented, laterally not inflated); **base** with short to medium long, thick, slightly flexuous stalk, Y-shaped. **Ascospores** *(5–)5.5–8.5(–9) × (2.3–)2.5–3(–3.5) µm {2}, ellipsoid to fusoid-clavate, rarely subcylindrical, apex rounded to obtuse, base not or slightly (to medium) attenuated, straight to slightly inequilateral; **SBs** *(3.5–)4.5–6.5 × 0.3–0.5 µm in situ {T} (~4.5–8 µm actual length), vermiform (to subulate), not or sometimes slightly inflated at base, slightly to rather strongly flexuous. **Paraphyses** apically medium to strongly clavate(-capitate), sometimes spathulate, terminal cells *6–18 × 3.5–5.5 µm {T}, lower cells *8.5–17 × 1.6–2.2 µm {T}; unbranched at upper septum. **Medullary excipulum** 50 µm thick, of dense textura intricata with many indistinctly inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, vertically oriented t. angularis from base to margin, 30 µm thick near base, cells *8–15 × 7–11 µm {T}; margin not examined. **Anchoring hyphae** not examined. **SCBs** in paraphyses globose, 1–2.3 µm diam., and crystalloid (also in ectal excipulum) {2}, hyaline. **Exudate** over paraphyses 0.2–1.5 µm thick, forming rough firmly attached caps. **— ANAMORPH**: unknown.

Habitat: collected 0–0.5 m above the ground (some immersed in sandy soil), on lower side of decorticated, 9–11 mm thick branches of *Cercocarpus betuloides* {1}, *Coleogyne ramosissima* {1}, on very decayed wood {1}, strongly greyed, no algae. **Associated**: *Orbilia bicknellensis* {1}, *O. multimaeandrina* {1}. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 1905–1975 m a.s.l. **Geology**: Triassic red calcareous sandstone; basaltic lava and cinders with andesite, dacite & rhyolite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia cercocarpi* is only tentatively segregated from European *O. pleiogambelii* based on very slightly longer, partly somewhat heteropolar ascospores, more vermiform spore bodies being often not or hardly inflated at the base, also by the crystalloid SCBs which are present in the paraphyses from base to apex. Among the 16-spored species, *O. pleioserpens* and *O. macroserpens* mainly differ in the absence of crystalloid SCBs, the latter also in slightly shorter SBs. The spores of *O. pleioungulata* are narrower than in *O. cercocarpi*, and their SBs are much shorter, often almost straight and mostly distinctly thickened in their lower half. *O. cisti* has spores very similar to *O. cercocarpi* but differs in lacking any kind of SCBs, and *O. saguarina* differs in addition in narrower spores. The Australian *O. octocercocarpi*, particularly the collection in Pl. 727: 1, resembles *O. cercocarpi*, but differs in 8-spored asci. The North American *O. multicercocarpi* differs in 32-spored asci and slightly wider spores.

Variation. In the collection on *Coleogyne* the spores are slightly larger compared to the holotype, and the SBs are more helicoid and tend to be inflated at the base. Although here the SBs resemble those of *O. pleiogambelii* in their helicoid curvature, this collection fits better the holotype of *O. cercocarpi* because of more elongate spores and the presence of crystalloid SCBs in the paraphysis apices. However, from both it differs in much wider asci (*10–10.5 µm). A North American collection on wood of *Shepherdia* (Pl. 736: 4) mentioned under *O. pleioserpens* might belong to *O. cercocarpi*, but has slightly wider SBs and some of its paraphyses were without crystalloid SCBs.

Phylogeny. A sequence was gained from pure culture of the holotype which comprises SSU (with S1506 intron), ITS, and LSU. *O. cercocarpi* shows a minimum distance of 4% in the ITS region to *O. macroserpens* and *O. cisti* (0.5–0.6% in LSU), but lower distances are observed in the LSU, e.g., 0.2% to *O. myrionamibica*. In comparison, *O. gambelii* shows a much greater distance of 7% in the ITS (0.8% in LSU). When analysing different gene regions, *O. cercocarpi* clustered in the *microserpens-ungulata* clade (Phyls 19–20, S21–S22).

Ecology. *O. cercocarpi* was found on rotten wood of xeric branches of *Cercocarpus betuloides* (mountain mahogany) and *Coleogyne ramosissima* (blackbrush) in a warm-continental semiarid pinyon-juniper woodland adjacent to a chaparral scrubland in the Canyonlands section of the Colorado Plateau and in a cold-temperate subhumid blackbrush desert scrub in the Mogollon Rim in the southwest of Northern America.

Specimens included. **USA**: **Utah**, Canyonlands, 35 km SSW of Moab, E of Needles Overlook, Hatch Point, 1905 m, branches of *Cercocarpus betuloides*, on wood, 16.VI.2000, G. Marson (ex H.B. 6737b, M-0276453, **holotype**; **isotype** in M-0276523 [holotype of *O. multimaeandrina*]; CBS 140831; sq.: KT215253, MH878191). – **Arizona**, Mogollon Rim, 52 km WNW of Flagstaff, 16 km NNE of Williams, 1975 m, on *Coleogyne ramosissima*, 11.V.1995, G. Marson (ø).

Orbilia multicercocarpi Baral & G. Marson, sp. nov., MB 813723 — Pls 730–731

Etymology: similar to *O. cercocarpi* but with 32-spored asci.

Typification: USA, Arizona, New River, branches of *Larrea tridentata*, 19.VI.2003, G. Marson (ex H.B. 7397e, M-0276518, holotype).

Latin diagnosis: *Similis* Orbiliae cercocarpi *sed asci 32-spori. Habitat ad lignum putridum ramorum siccorum fruticum angiospermarum in zona subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.3 mm diam., 0.12 mm high, light dirty orange, scarcely translucent, round,

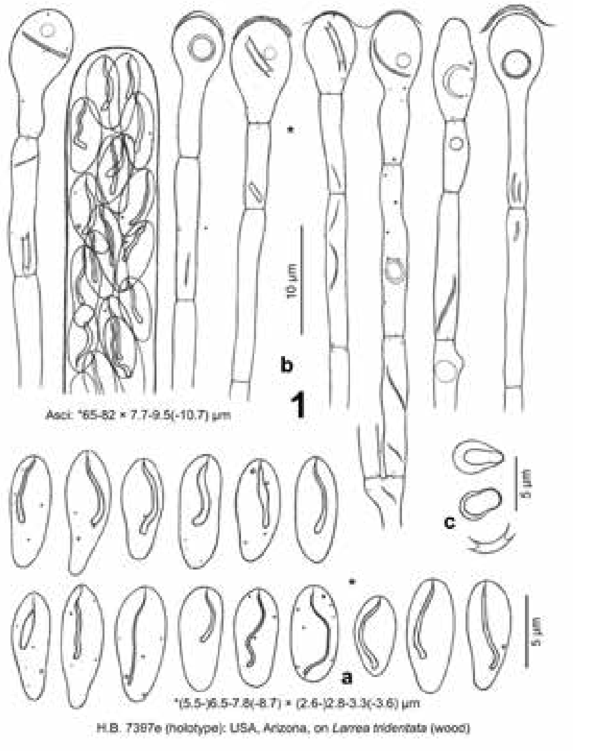

Plate 730. **1**: *Orbilia multicercocarpi*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. crystalloid SCBs in ectal excipulum.

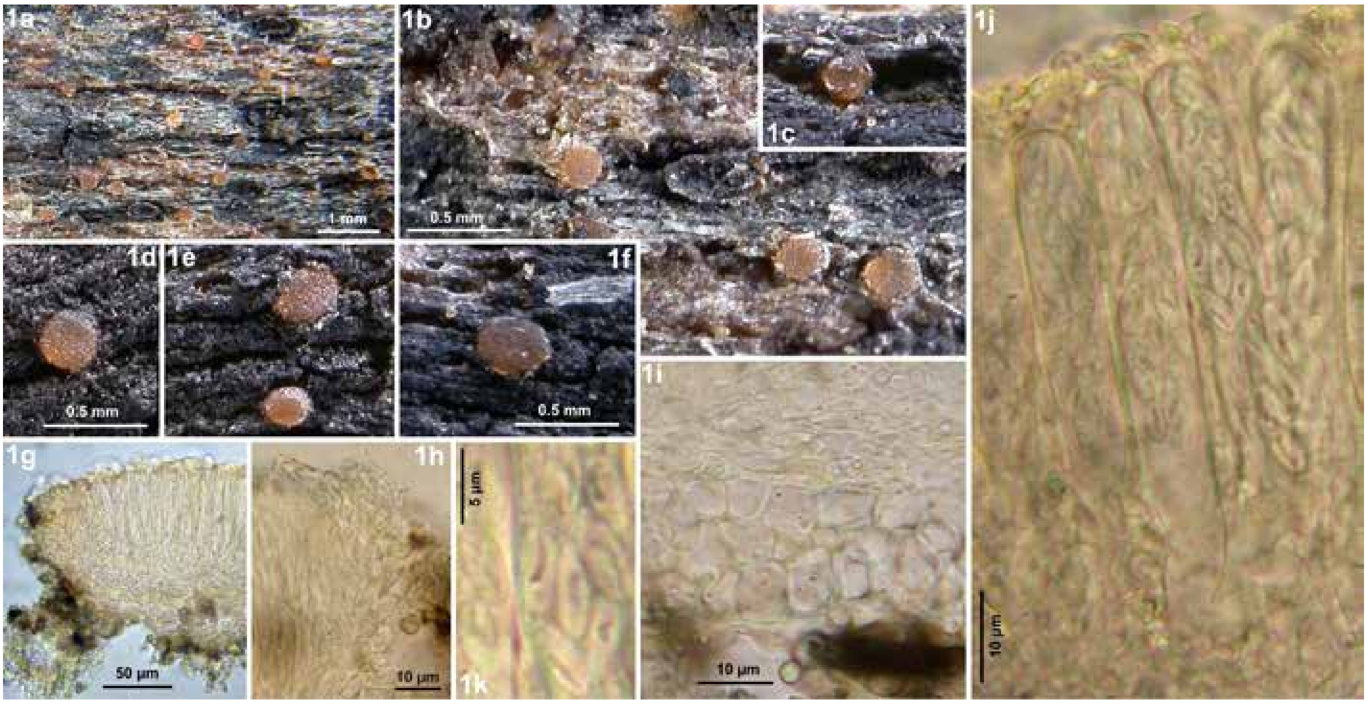

Plate 731. **1**: *Orbilia multicercocarpi*. – **1a–f**. rehydrated apothecia; **1g**. apothecium in median section; **1h**. id., marginal ectal excipulum; **1i**. id., near base; **1j**. asci (and paraphyses); **1k**. ascospores in ascus. – Living state, except for **1h–i** (in KOH), 2 right asci in **1j**. — **1a–j**. H.B. 7397e (holotype): USA, Arizona, on *Larrea*.

subgregarious; disc flat, margin ± indistinct, not protruding, smooth; broadly sessile, slightly to strongly immersed. **Asci** *65–82 × 7.7–9.5(–10.7) µm {1}, †60–80 × 7–9 µm {1}, 32-spored, spores *4-seriate, lower spores inverted {1} (± mixed), pars sporifera *43–65 µm long; **apex** (†) medium to strongly truncate (not distinctly indented, laterally sometimes distinctly inflated); **base** without or with thick, flexuous stalk, Y-, L- or h-shaped. **Ascospores** *(5.5–)6.5–7.5(–8.7) × (2.6–)2.8–3.2(–3.6) µm {2}, ellipsoid to ellipsoid-clavate, also subcylindrical, apex rounded to obtuse, base not or slightly, rarely medium attenuated (± tail-like), straight to slightly inequilateral; **SBs** *(3–)4–5.5(–6.5) × (0.2–)0.3–0.5(–0.7) µm in situ {1} (~4–7.5 µm actual length), filiform to vermiform or subulate, not or very indistinctly inflated at base, slightly to ± strongly flexuous, sometimes uncinate. **Paraphyses** apically medium to strongly clavate-capitate, sometimes spathulate to lageniform, terminal cells *7.5–19 × (3–)4–5.5 µm {1}, lower cells *9–17.5 × 1.6–2.5 µm {1}; rarely branched at upper septum. **Medullary excipulum** 20 µm thick, of dense textura intricata, horizontally oriented, with many inflated cells, medium to very sharply delimited. **Ectal excipulum** pale rose, of (†) slightly gelatinized, indistinctly or horizontally oriented t. angularis from base to mid flanks or margin, 20–30 µm thick near base, cells *6–13 × 5–10 µm {1}; 15 µm thick near margin, of t. prismatica-angularis oriented at a 10–40° angle to the surface, marginal cortical cells †5–6 × 3–5 µm {1}. **Anchoring hyphae** sparse, *2.2–3.7 µm wide, walls 0.3–0.4 µm thick {1}, covering also flanks and margin as a thin layer. **SCBs** in paraphyses and ectal excipulum globose, 1–1.2 µm diam., and crystalloid {2}. **Exudate** over paraphyses absent or 0.2–0.5 µm thick, rough, continuous, ± firmly attached; over margin and flanks 0.2 µm thick, granular, very sparse. — **ANAMORPH**: unknown.

Habitat: attached, partially to entirely decorticated, 9–16 mm thick branches of *Larrea tridentata* {1}, *Parkinsonia* (?)*microphylla* {1}, on 0.2–0.5 mm deep strongly decayed wood {2}, strongly greyed, no algae. **Associated**: *Carestiella* ?*schizoxyloides* {1}, *Coniochaeta* sp. {1}, ?*Muellerella* sp. {1}, *Orbilia calyptrata* {1}, *O. cryptogena* {1}, *O. maeandrina* {1}, *O. multiurosperma* {1}, *O. paloverdensis* {1}, *O. pleioserpens* {1}, *O. pluristomachia* {1}, *O. sedonensis* {1}, *Patellaria* ‘*andina*’ {1}, *Symbiotaphrina larreae* {1}. **Desiccation tolerance**: fully viable for at least 1.5 years. **Altitude**: 500–810 m a.s.l. **Geology**: Permian-Triassic sediment; granite, volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multicercocarpi* appears to be very closely related to *O. cercocarpi*, from which it mainly differs in the 32-spored asci. *O. multigambelii* deviates in shorter ascospores, but its delimitation from *O. multicercocarpi* seems not very sharp.

Variation. The two included specimens closely concur in every respect.

Not included collection. A sample on *Fouquieria splendens* (IVV: H.B. 8650) differs in considerably larger (0.3–0.8 mm) and thicker (0.14–0.19 mm) apothecia with a thicker, 10–20 µm protruding margin, also in slightly smaller, especially narrower spores (*5–7 × ~2–2.5 µm).

Ecology. *O. multicercocarpi* was found on rotten wood of xeric branches of *Larrea* (creosotebush) and *Parkinsonia* (foothill paloverde) in subtropical semiarid paloverde-mixed cacti and arid creosotebush-bursage desert scrub in the Sonoran Desert in western North America.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 32 km NNW of Phoenix, 13 km SW of New River, SE of Lake Pleasant, 500 m, branches of *Larrea tridentata*, on wood, 19.VI.2003, G. Marson (ex H.B. 7397e, M-0276518, **holotype**). – 19 km W of Tucson, W of Old Tucson Studios, 810 m, branch of *Parkinsonia* (?)*microphylla*, on wood, 6.V.1995, G. Marson (H.B. 5671d ø).

Not included. **USA**: **Arizona**, Sonoran Desert, 19 km W of Tucson, W of Old Tucson Studios, 810 m, branches of *Fouquieria splendens*, on wood, 6.V.1995, G. Marson (H.B. 8650).

Orbilia macroserpens Baral & G. Marson, **sp. nov.**, MB 813724 — Pls 732–733

Etymology: resembling *O. microserpens* but with larger asci and ascospores.
Typification: USA, California, branches of *Atriplex confertifolia*, 23.VI.2000, G. Marson (ex H.B. 6721c, M-0276505, holotype; ex-type culture: CBS 140812; sq.: KT215252, MH878184).
Latin diagnosis: *Similis* Orbiliae cercocarpi *sed ascosporae latiores*, *corpuscula refringentia breviora*, *cellulae vivae excipuli et paraphysium absque corpusculis crystalloideis. Habitat ad lignum putridum ramorum siccorum* Atriplicis *in zona temperata arida Americae septentrionalis.*

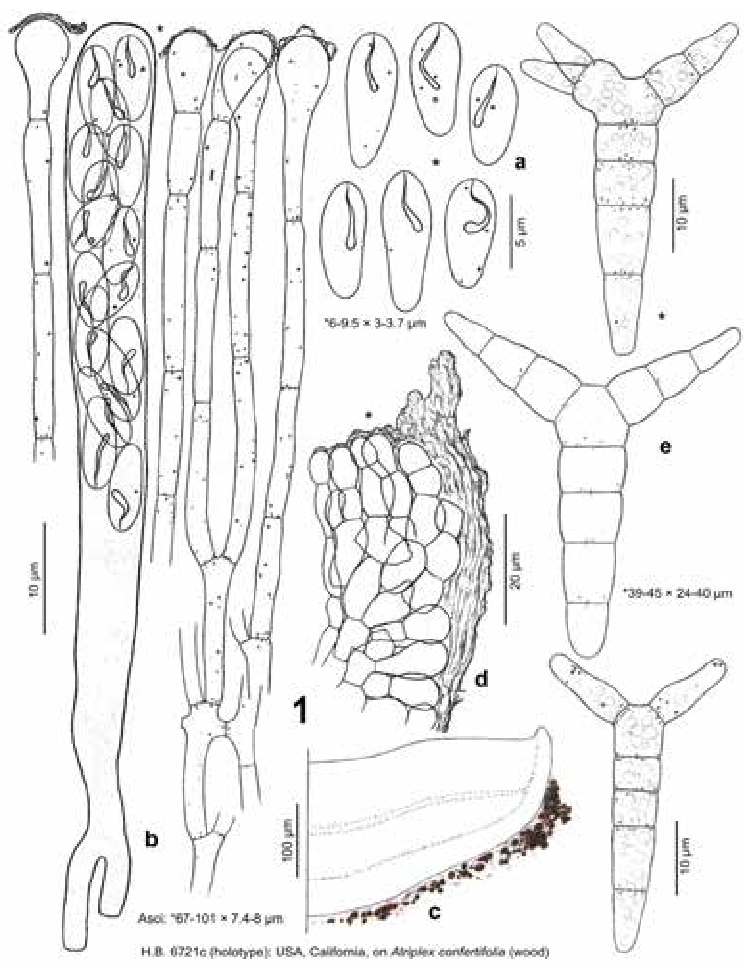

Plate 732. **1**: *Orbilia macroserpens*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. apothecium in median section; **d**. id., marginal ectal excipulum; **e**. conidia from culture.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.5(–0.7) mm diam., 0.21 mm high (receptacle 0.12–0.18 mm), pale to light greyish-orange, non-translucent, round or laterally compressed, ± gregarious in small groups; disc flat to slightly convex, margin distinct, thin, 10–20 µm protruding, smooth; sessile, superficial to immersed in clefts; dry strongly contracted. **Asci** *(67–)78–101 × (6.5–)7.5–8 µm {2}, †72–80 × 6.3–7 µm {1}, 16-spored, spores *2–3-seriate, ~8 lower spores inverted {T} (± strongly mixed), pars sporifera *40–50 µm long; **apex** (†) strongly truncate (slightly indented, laterally sometimes distinctly inflated); **base** with short to medium long, thin or thick, somewhat flexuous stalk, L-, Y- or h-shaped. **Ascospores** *6–9(–9.5) × (2.8–)3–3.7 µm {2}, †6.8–8.8 × 3–3.4 µm {1}, subcylindric-ellipsoid to clavate, apex rounded, base mostly slightly attenuated, straight, sometimes slightly inequilateral; **SBs** *3.5–4.8 × 0.25–0.7(–1) µm in situ {T} (~4–5.2 µm actual length), subulate, base not or slightly inflated, ± flexuous. **Paraphyses** apically slightly to strongly capitate(-clavate), terminal cells *7–17 × 3.3–5(–6.8) µm {T}, lower cells *7.5–18 × 1.6–2 µm {T}; sometimes branched near apex. **Medullary excipulum** 70 µm thick, of ± loose textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, vertically oriented t. angularis-prismatica from base to margin, 40–50 µm thick near base, cells *(9–)12–21 × (6.5–)8.5–11.5 µm {T}; 20 µm thick near margin, of t. angularis oriented at a 10–80° angle to the surface, marginal cortical cells *5.5–10(–13) × 4.5–7.5 µm {T}. **Anchoring hyphae** sparse, *2–4 µm wide, walls 0.2–0.5 µm thick {T}. **SCBs** in paraphyses and ectal excipulum absent. **Exudate** over paraphyses 0.3–1.5 µm thick, rough-granular to continuous, ± firmly attached; over margin and flanks 0.2–0.5 µm thick, rough-granular. **— ANAMORPH**: trinacrium-like (from ascospore isolate {T}). **Conidiophores** not observed. **Conidia** Y-shaped, total size *39–45 × 24–40 µm, stipe *30–33 × 6.4–9.5 µm, 3–4-septate, arms gradually tapering, *11.5–20 × 4–7.5 µm, 1–3-septate; rarely 3-armed conidia seen (one arm again dichotomously branched).

Habitat: collected ~0.2 m above the ground, decorticated, 14–17 mm thick branches of *Atriplex confertifolia* {1}, ?*A. polycarpa* {1}, on 0.3 mm deep strongly decayed wood {2}, on lower side, strongly greyed, no algae. **Associated**: *Carestiella schizoxyloides* {1}, *Hysteropatella* sp. {1}, *H. oregana* {1}, *Orbilia lentiformis* {1}, *O. multimaeandrina* {1}, *O. multiphanosoma* {1}, *O. multitrapezoidea* {1}, *O. sonorensis* {1}, *O. vermiculati* {1}, *Stictis* sp. {1}, *Teichospora* sp. {1/1}. **Desiccation tolerance**: fully viable for at least 1 month. **Altitude**: 830–1315 m a.s.l. **Geology**: Neoproterozoic-Cambrian sedimentary rock; alluvial sandy deposits from granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia macroserpens* is characterized by medium-sized, ellipsoid-clavate ascospores with rather short, subulate spore bodies, by the absence of any kind of SCBs, and by rather large 16-spored asci. The species resembles 8-spored *O. cactacearum* in spores and SBs, but differs in spore number and absence of crystalloid SCBs. *O. pleiovitalbae* deviates in much narrower spores and basally much more inflated SBs. *O. cercocarpi*, *O. cisti*, *O. pleioserpens*, and *O. microserpens* differ in their SBs being often almost as long as the spores, the former two also in narrower, more fusoid spores, *O. cercocarpi* also in the presence of crystalloid SCBs, and *O. microserpens* in much smaller spores.

Variation. The collection from Death Valley on an indet. angiosperm (IVV: H.B. 8528b) fully concurs with the holotype.

Anamorph. Very few trinacrium robustum-like conidia were obtained in pure culture, but only after flooding with water. In their thick arms and stipes they differ somewhat from trinacrium robustum-like anamorphs which are usually observed in section *Habrostictis*.

Phylogeny. A sequence was gained from pure culture of the holotype which comprises SSU (with S1506 intron), ITS, and LSU. In concordance with its morphology, the closest relatives

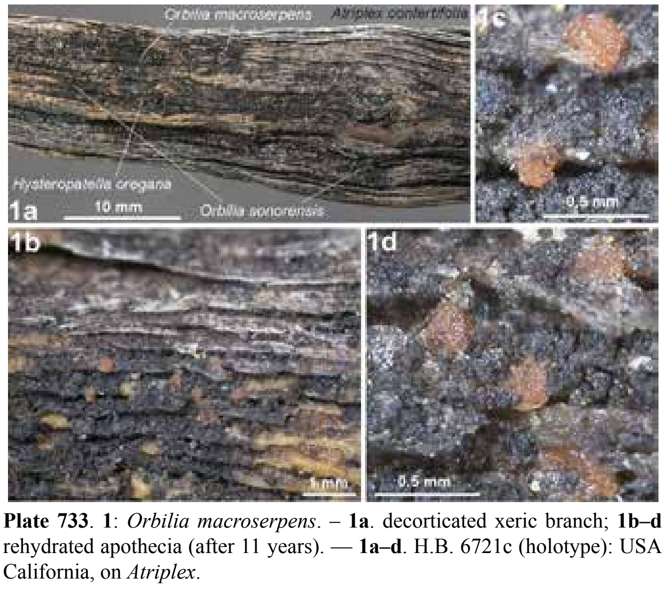

Plate 733. **1**: *Orbilia macroserpens*. – **1a**. decorticated xeric branch; **1b–d**. rehydrated apothecia (after 11 years). — **1a–d**. H.B. 6721c (holotype): USA, California, on *Atriplex*.

of *O. macroserpens*, when comparing in the ITS region, are *O. microserpens* with 3.3 % (0.6 % in LSU D1–D2), and *O. cercocarpi* or *O. cisti* with 3.5 % (0.5–0.8 % in LSU), which clustered in the *microserpens-ungulata* clade (Phyls 19–20, S21–S22).

Ecology. *O. macroserpens* grew on rotten wood of xeric branches of *Atriplex* and an indet. angiosperm in warm-temperate arid Mojave saltbush desert scrubs at the eastern border of Death Valley and southern end of Sierra Nevada in western North America.

Specimens included. **USA**: **California**, Mojave Desert, 130 km NNE of Los Angeles, 14 km NW of California City, 830 m, branches of *Atriplex confertifolia*, on wood, 23.VI.2000, G. Marson (ex H.B. 6721c, M-0276505, **holotype**, anam. cult., CBS 140812; sq.: KT215252, MH878184). – border to Nevada, Death Valley, 20 km SW of Beatty, 16 km SW of Rhyolite, Daylight Pass, 1315 m, branch of indet. angiosperm, on wood, 2.V.1995, G. Marson (H.B. 8528b ø).

Orbilia cisti Baral & E. Weber, **sp. nov.**, MB 813725 — Pls 734–735

Etymology: named after the substrate of the type, *Cistus albidus*.
Typification: France, Valliguières, branch of *Cistus albidus*, 20.IX.1999, H.O. Baral (ex H.B. 6500, M-0276454, holotype; ex-type culture: CBS 140810; sq.: KT215239, MH878182).

Latin diagnosis: *Differt ab* Orbiliae cercocarpi *cellulis vivis excipuli et paraphysium absque corpusculis crystalloideis. Habitat ad lignum vel corticem putridum ramorum siccorum* Cisti albidi *in zona arida mesomediterranea semihumida Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4 mm diam., 0.13–0.15 mm high, bright orange, scarcely translucent, ± round, scattered; disc slightly concave to flat, margin distinct, thick, 10 µm protruding, smooth; broadly sessile, erumpent, slightly to entirely immersed. **Asci** *70–87 × 6.3–6.8 µm, †52–63 × 5.5–6.5 µm, 16-spored, spores †2–3-seriate, lower spores inverted (± mixed), pars sporifera *29–36 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to medium long, ± thin, flexuous stalk. **Ascospores** *6–9 × 2.3–2.9 µm, (ellipsoid-)fusoid to fusoid-clavate, partly narrowly amygdaliform, apex obtuse to subacute, base not or mostly slightly attenuated, straight to slightly inequilateral; **SBs** *(4–)5–6.5(–7) × 0.25–0.3(–0.35) µm in situ (~4–7.5 µm actual length), filiform, base not inflated, straight or mostly ± flexuous. **Paraphyses** apically uninflated or slightly to strongly clavate-capitate, terminal cells *7–13 × 2.3–5.3 µm, lower cells *7.5–13 × 2.3–3.2 µm; unbranched at upper septum. **Medullary excipulum** pale orange, 30–40 µm thick, of ± dense textura intricata with many inflated cells. **Ectal excipulum** pale orange, of (†) ± thin-walled, indistinctly oriented t. angularis from base to submargin, 35–50 µm thick near base, cells *12–15 × 7–9 µm (†5–9 × 4–6.5 µm); 15 µm thick near margin, of t. prismatica oriented at a 40–50° angle to the surface, marginal cortical cells */†5–8 × 2.5–3 µm, embedded in exudate. **Anchoring hyphae** medium abundant, †2–3 µm wide, walls 0.2–0.3(–0.4) µm thick. **SCBs** in paraphyses and ectal excipulum absent. **Exudate** over paraphyses absent or 0.3–1(–2) µm thick, granular-cloddy, ± firmly attached; over margin and flanks 0.2–1(–2.5) µm thick, cloddy-granular. **— ANAMORPH**: trinacrium-like (from ascospore isolate). **Conidiophores** not seen. **Conidia** Y-shaped, total size *30–32 × 30–35 µm, stipe *15–16 × 5–6.5 µm, 2-septate, arms gradually tapering, *18–21 × 5–6 µm, 2–3(–4)-septate, stipe and arms hardly distinguishable.

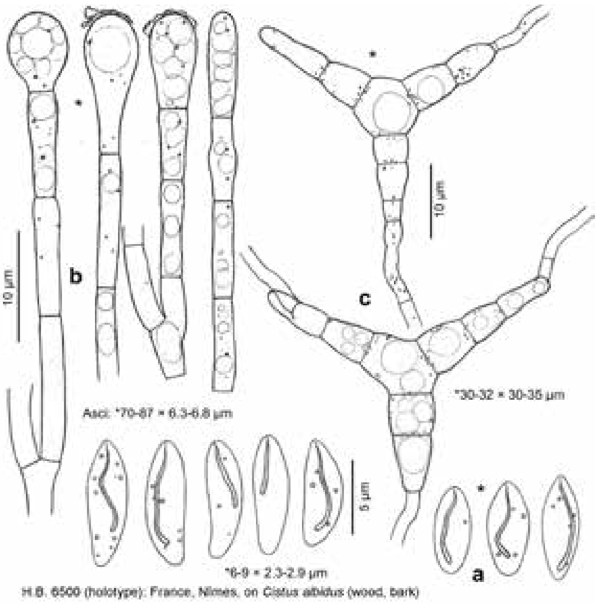

Plate 734. **1**: *Orbilia cisti*. – **a**. ascospores; **b**. paraphyses; **c**. conidia from culture.

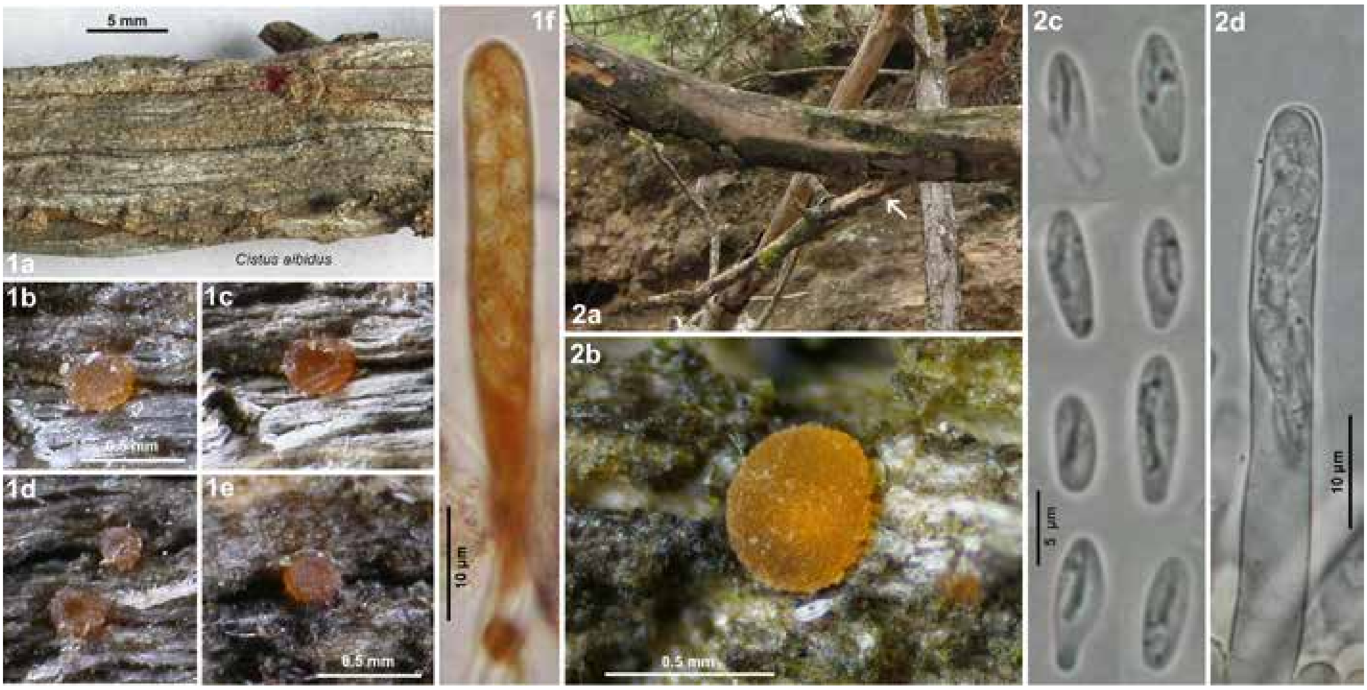

Plate 735. **1**. *Orbilia cisti*; **2**. *O.* cf. *cisti*. – **1a**, **2a**. decorticated xeric branches; **1b–e**, **2b**. rehydrated apothecia; **1f**, **2d**. mature ascus (**1f** in KOH+IKI); **2c**. ascospores. — **1a–f**. H.B. 6500 (holotype): France, Gard, Nîmes, on *Cistus*; **2a–d**: Spain, Teruel. on *Juglans*.

Habitat: collected ~0.2–0.5 m above the ground, ± decorticated, 11 mm thick branches of *Cistus albidus*, on 0.5 mm deep strongly decayed wood, also on remnants of bark (bast), eroded, partly in beetle galleries, greyed, no algae. **Associated**: sparse minute green lichen thalli. **Desiccation tolerance**: fully viable for at least ~2 weeks (certainly also much longer). **Altitude**: 135 m a.s.l. **Geology**: Lower Cretaceous (Urgonian) limestone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia cisti* is characterized by 16-spored asci and ± fusoid(-clavate) ascospores with rather thin, long, flexuous spore bodies, also by the consistent absence of any kind of SCBs. For the similar *O. cercocarpi*, *O. pleioserpens*, *O. macroserpens*, *O. maeandrina*, and *O. saguarina* see there. The spores tend to be fusoid with subacute apices similar as in species of series *Serpentinae*, such as *O. maeandrina* and *O. trapeziformis*, but they also do not essentially differ from the ellipsoid spores of, e.g., *O. macroserpens*.

Not included collection. A sample on *Juglans* fits quite well in ascus and spore size [*88–92 × 5.5–6.3 µm, *(5.5–)6–9.1 × (2.1–)2.3–2.5(–3) µm] (Pl. 735: 2). It differs in slightly narrower spores and wider SBs (4.5–7 × 0.3–0.5 µm), and a different substrate, but is probably conspecific.

Anamorph. Very few trinacrium robustum-like conidia were obtained in pure culture, but only after flooding with water. When we detected them they had already germinated, therefore, only conidia with germ tubes have been documented.

Phylogeny. A sequence was gained from pure culture of the holotype which comprises SSU (with S1506 intron), ITS, and LSU. *O. cisti* clustered in the *microserpens-ungulata* clade (Phyls 19–20, S20, S22), with a distance of 3.8–4 % in the ITS and 0.6–0.8 % in the LSU D1–D2 to other members.

Ecology. *O. cisti* was collected on rotten wood and bark of xeric branches of *Cistus albidus* in a mesomediterranean semihumid, dense maquis in a quarry in the Languedoc in southwestern Europe. The not included sample from eastern Spain was from a supramediterranean semihumid forest strip of *Pinus* and *Juglans* along a river.

Specimens included. **FRANCE**: **Languedoc-Roussillon**, **Gard**, Languedoc, 25 km NW of Nîmes, 7 km NNE of Remoulins, SSE of Valliguières, 135 m, branch of *Cistus albidus*, on wood & bark, 20.IX.1999, H.O. Baral (ex H.B. 6500, M-0276454, **holotype**, anam. cult., CBS 140810; sq.: KT215239, MH878182).

Not included. **SPAIN**: **Aragón**, **Teruel**, 2 km NNW of Teruel, Atarazanas, Alfambra river, 910 m, branch of *Juglans regia*, on wood, 19.XI.2013, R. Tena Lahoz (R.T.L. 13111902, doc. vid.).

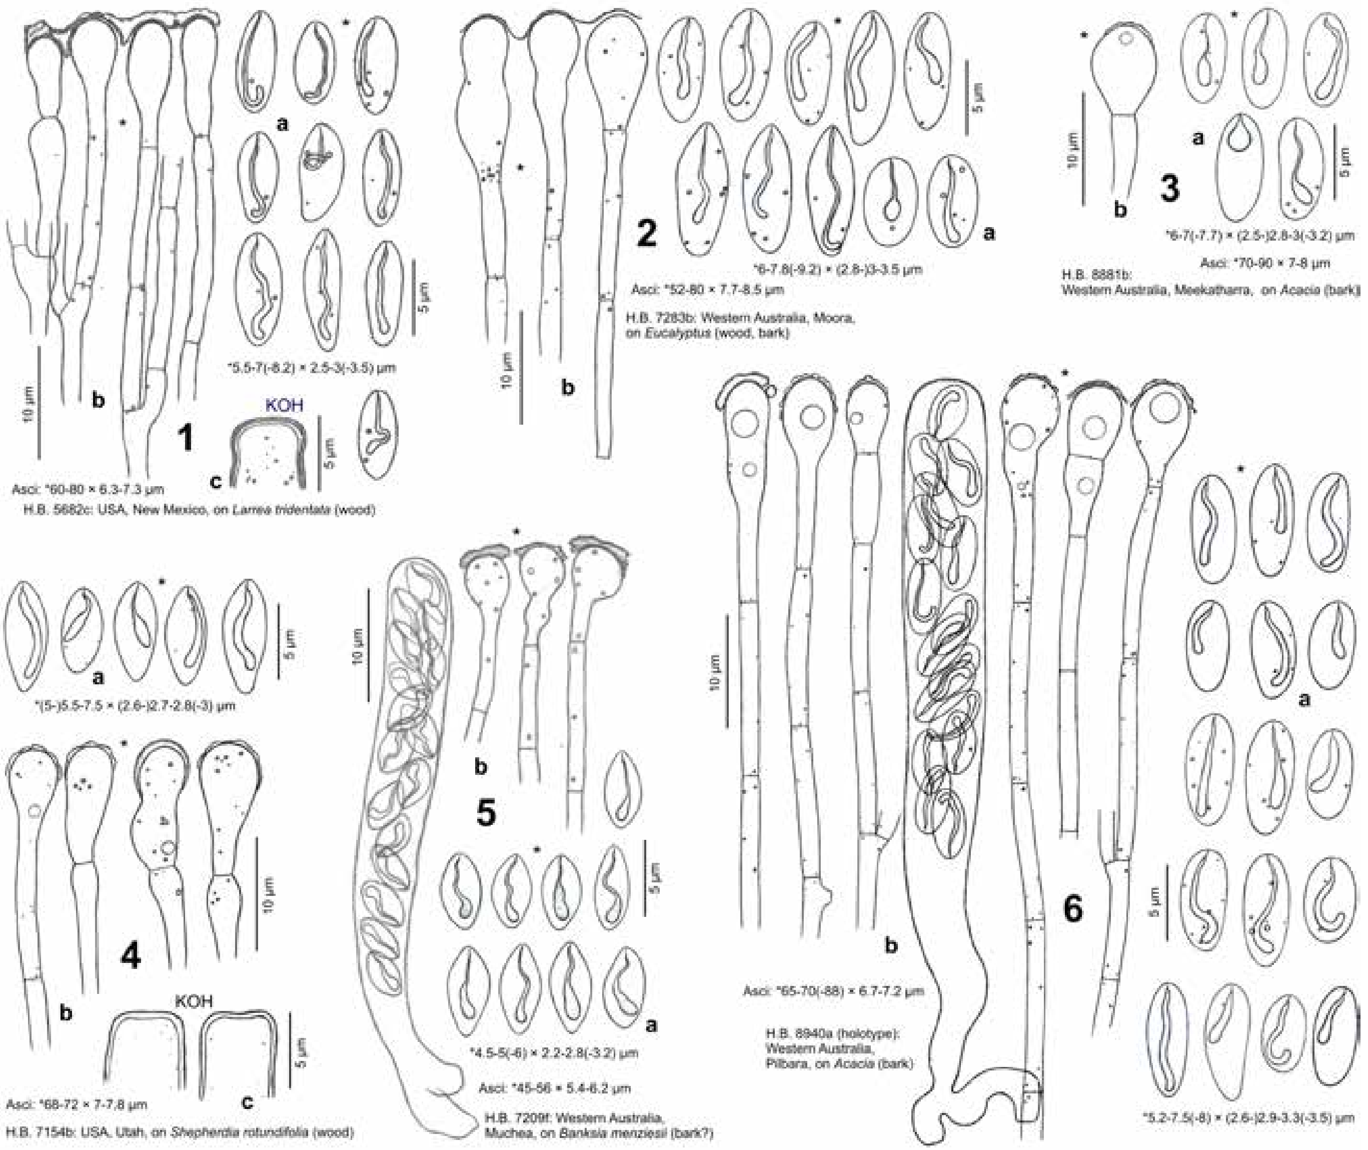

Plate 736. **1–3**, **6**: *Orbilia pleioserpens*; **4–5**: *O.* cf. *pleioserpens*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices.

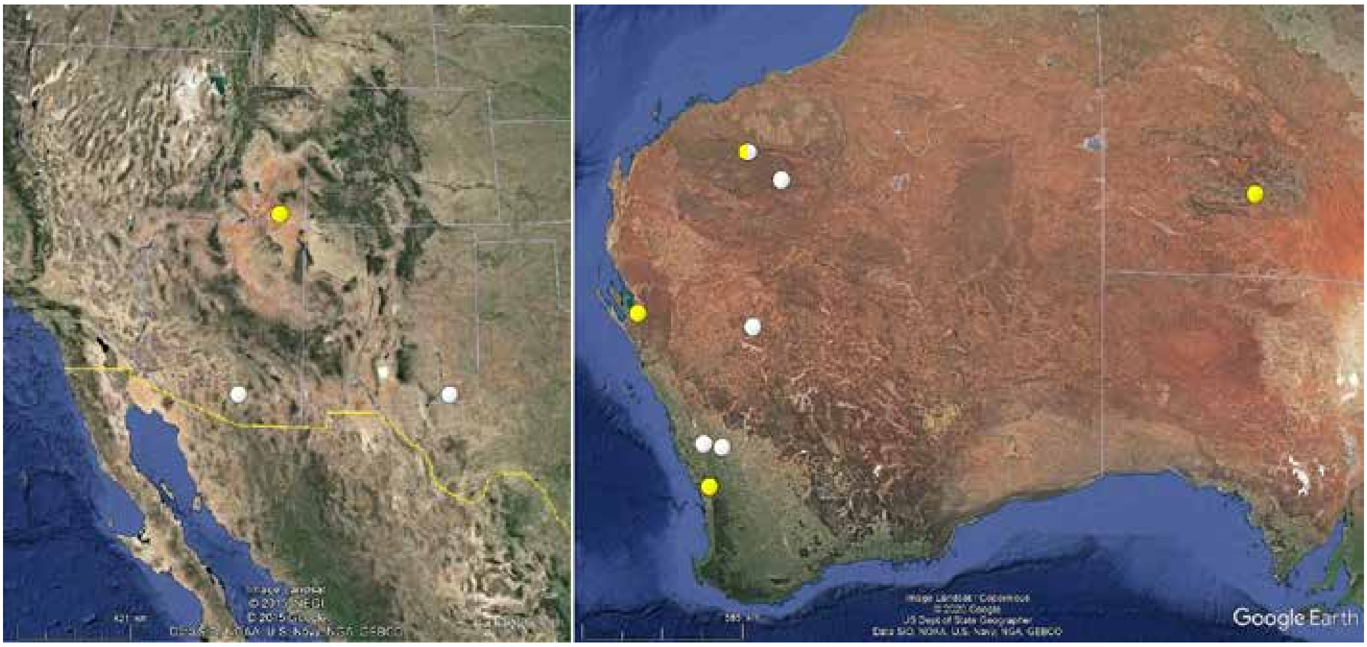
Orbilia pleioserpens Baral & G. Marson, **sp. nov.**, MB 813726 — Pls 736–737, Map 123

Etymology: named after the 16-spored asci and flexuous spore bodies.

Typification: Western Australia, Newman, branches of *Acacia*, 28.X.2007, G. Marson (ex H.B. 8940a, MEL 2389267, holotype).

Latin diagnosis: *Differt ab* Orbilia cisti *ascosporis paulo brevioribus, magis ellipsoideis, apice obtuso ad rotundato. Habitat ad lignum vel corticem putridum ramorum siccorum fruticum vel arborum angiospermarum in zona tropica vel subtropica semiarida ad arida Americae septentrionalis vel Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5(–0.6) mm diam., 0.13–0.23(–0.28) mm high (receptacle 0.12 mm), light to bright greyish or pure (brick-)orange(-ochraceous), slightly translucent, round, scattered to subgregarious; disc slightly concave to flat, margin distinct, 0–20 µm protruding, smooth or somewhat rough; broadly sessile or with a ± narrowed base, superficial to half immersed. **Asci** *(52–)60–80(–90) × (6.3–)6.5–8(–8.5) µm {6}, †(50–)55–70(–82) × (5.4–)5.7–6.5(–6.8) µm {3}, 16-spored, spores *2–4-seriate, 6–9(–11) lower spores inverted {3} (± mixed), pars sporifera *31–40 or 40–55 µm long; **apex** (†) (medium to) strongly truncate (not or very slightly indented, laterally distinctly inflated or not); **base** with short



Map 123. Known distribution of *O. pleioserpens* in North America and Australia (yellow = not included collections).

to long, thin or thick, flexuous stalk, L-, Y- to h-shaped. **Ascospores** *(4.6–)5–7.5(–8.2)((–9.2)) × (2.4–)2.6–3.2(–3.5) µm {8}, †(4–)5.3–7 × 2.4–2.9 µm {2}, ellipsoid, sometimes ellipsoid- to fusoid-clavate, subcylindrical, or fusoid, apex rounded to obtuse, exceptionally subacute, base not or sometimes slightly to medium attenuated, straight or very slightly inequilateral; **SBs** *(3.5–)5–6.5(–7.5) × (0.3–)0.4–1 µm in situ {4} [~(4–)6–8 µm actual length], vermiform to subulate, base not or slightly inflated, slightly to strongly flexuous or helicoid, sometimes uncinate, overmature with strongly inflated lower part, 2.5–3 × 1–1.5 µm. **Paraphyses** apically slightly to (very) strongly clavate(-capitate), sometimes moniliform, terminal cells *(6–)8–20(–24) × (2.5–)3–5(–5.7) µm {4}, lower cells *8–18 × 1.5–2.5(–2.8) µm {4}, near apex sometimes up to 3.3 µm wide; unbranched or sometimes branched at upper septum. **Medullary excipulum** pale orange, 30–60(–150) µm thick in centre, of dense (or loose) textura intricata with some or many inflated cells, medium to very sharply delimited from ectal excipulum at flanks. **Ectal excipulum** of pale to light orange, (†) ± thin-walled to slightly gelatinized, vertically oriented t. angularis-prismatica from base to mid flanks or margin, 20–70 µm thick near base, cells *9–20(–25) × (6–)7–12(–14) µm {4}, †5–17 × 4–9 µm {2}; (10–)15–25(–30) µm thick near margin, of t. prismatica or t. globulosa-angularis oriented at a 10–50° angle to the surface, marginal cortical cells *5–12 × 3–6 µm {2}, †~6–7 × 2.5–3.5 µm {1}. **Anchoring hyphae** sparse to medium abundant, */†1.5–3 µm wide, walls 0.2–03 µm thick {2}, extending as a thin layer up to the margin. **SCBs** partly to regularly present in paraphyses and ectal excipulum, globose, (1–)1.5–2.5(–3) µm diam. {2}, also consistently absent {2}. **Exudate** over paraphyses (0.1–)0.2–1(–1.3) µm thick, cloddy-continuous, firmly attached; over margin and flanks 0.4–2 µm thick, cloddy. **— ANAMORPH**: unknown.

Habitat: collected 0.2–2 m above the ground, decorticated, 6–12 mm thick branches of *Acacia* spp. {4}, *Allocasuarina campestris* {1}, *Eucalyptus* sp. {1}, *Larrea tridentata* {1}, *Parkinsonia* (?)*microphylla* {1}, on 0.3 mm deep strongly decayed wood {4} or bark {5} (bast), partly in clefts of periderm, medium to strongly greyed, without or with some green algae. **Associated**: ?*Baggea* sp. {1}, *Dinemasporium* sp. {1}, *Hyalorbilia* aff. *orbiliicola* (parasitic in *O. pleioserpens*) {1}, *Lophiostoma* sp. {1}, *Orbilia calyptrata* {1}, *O. coronohesperidea* {2}, *O. maeandrina* {1}, *O. microserpens* {2}, *O. multicercocarpi* {1}, *O.* ?*multidelphinus* {1}, *O. multiserpens* {1/2}, *O. multivirgula* {1}, *O. myrioaustraliensis* {3}, *O. myriofusiclava* {1}, *O. myriofusoidea* {1}, *O. myriomuscula* {2}, *O. myrionanosoma* {1}, *O. myriopseudoregalis* {1}, *O. paloverdensis* {1}, *O. phanosoma* {2}, *O. pleioaustraliensis* {1}, *O. pleiocoronohesperidea* {2}, *O. sedonensis* {1}, *Ostropales* {1}, *Patellaria* '*andina*' {3}, *P.* ?*atrata* {1}, *Proliferodiscus griseoviolaceus* {1}, ?*Teichospora* sp. {1}, ?*Trimmatostroma* sp. {1}. **Desiccation tolerance**: fully viable for at least 15 months. **Altitude**: 320–690 m a.s.l. (eastern Australia), 810–915 m (western North America). **Geology**: Archean to Proterozoic sedimentary rock (red-brown gravel), Pennsylvanian-Permian-Triassic carbonate red sandstone; granite, basalt. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleioserpens* is apparently very closely related to *O. microserpens*, from which it differs in distinctly wider ascospores and somewhat larger asci, also in the partial presence of globose SCBs. *O. pleiovitalbae* differs in slightly narrower spores and shorter and wider, basally abruptly swollen spore bodies. For the similar *O. macroserpens* see p. 1215. *O. cercocarpi* mainly differs in the presence of crystalloid SCBs. The European *O. cisti* is tentatively separated from *O. pleioserpens* based on slightly longer, more fusoid spores with more subacute apices. A collection mentioned under *O. multitrapezoidea* (on *Acacia*, Pl. 645: 4) resembles *O. pleioserpens* in the spores but has 32-spored asci.

Variation. The North American collection on *Larrea* (Pl. 736:Fig. 1) differs from the remaining in a tendency to narrower spores and SBs, but this hardly allows to separate different taxa. In spore width this collection seems to be safely distinct from *O. microserpens*. Globose SCBs were regularly present in four collections on *Acacia*, but they were consistently absent in the samples on *Eucalyptus* and *Banksia*, also in that on *Larrea*.

Not included collections. Three further samples on *Acacia* (H.B. 7215f, 8583b, 13.X.1998) were only studied in the dead state, therefore they are not included in the description. In two collections from southern Spain on *Ulex* studied by J.P. Priou (IVV: J.P.P. 27139, 28008) the rather short spores of *5–6(–6.5) × 2.5–3(–3.5) µm could instead belong to *O. pleiogambelii*, but SCBs were not observed.

An Australian sample on *Banksia* (Pl. 736: 5) tends to fusoid though shorter spores. Likewise, a North American sample on *Shepherdia* (Pl. 736: 4) differs from *O. pleioserpens* in more fusoid spores (both are not included in either description). In some examined apothecia of the *Shepherdia* sample the paraphyses contained crystalloid SCBs (IVV: H.B. 7154b), therefore, this might instead belong to *O. cercocarpi.*

Ecology. *O. pleioserpens* was found on rotten bark and wood of xeric branches of various angiosperm trees and shrubs. In western Australia it is known from tropical arid acacia open shrublands (mulga) in the Pilbara, and from subtropical semiarid acacia shrublands or eucalypt (open) woodlands, and in the southwest and south of Northern America from subtropical semiarid Sonoran paloverde-mixed cacti and warm-temperate semiarid Chihuahuan creosotebush-tarbush desert scrubs. The not included Australian collection on *Banksia* is from a subtropical semihumid banksia-eucalypt woodland, that from North America on *Shepherdia* from a cold-temperate subhumid pinyon-juniper woodland in the Colorado Plateau, and those from southwestern Europe from a mesomediterranean semihumid site with *Ulex*.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 1.5 km SW of Wittenoom, N of Karijini, Wittenoom Gorge, 467 m, branches of *Acacia*, on wood & bark, 29.X.2007, G. Marson (H.B. 8976e). – 49 km NW of Newman, northern border of Ophthalmia Range, 690 m, branches of *Acacia*, on bark, 28.X.2007, G. Marson (ex H.B. 8940a, MEL 2389267, **holotype**). – ibid., branch of *Acacia*, on bark, 28.X.2007 (H.B. 8879b). – Murchison, 72 km SW of Meekatharra, 17 km W of Reedy, 1.5 km E of Tuckanarra, 493 m, branch of *Acacia*, on bark, 27.X.2007, G. Marson (H.B. 8881b). – Avon Wheatbelt, 40 km N of Moora, 4 km NNW of Watheroo, 320 m, branch of *Allocasuarina campestris*, 25.X.2007, G. Marson (H.B. 8937d ø). – 68 km NE of Moora, 14 km S of Dalwallinu, S of Pithara, 326 m, branches of *Eucalyptus*, on bark & wood, 24.XI.2001, G. Marson (H.B. 7283b). — **USA**: **Arizona**, Sonoran Desert, 19 km W of Tucson, W of Old Tucson Studios, 810 m, branch of *Parkinsonia* (?)*microphylla*, on wood, 6.V.1995, G. Marson (H.B. 5671g ø). – **New Mexico**, Chihuahuan Desert, 25.5 km SE of Carlsbad, Malaga, 915 m, branches of *Larrea tridentata*, on wood, 17.VI.1996, G. Marson (H.B. 5682c).

Not included. **AUSTRALIA**: **Western Australia**, Pilbara, 1.5 km SW of Wittenoom, N of Karijini, Wittenoom Gorge, 467 m, branches of *Acacia*, on bark & wood, 28.XI.2001, G. Marson (H.B. 8583b). – Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, 67 m, branch of *Acacia*, on bark, 7.XII.2001, G. Marson (H.B. 7215f). – Jarrah Forest, 54 km NNE of Perth, 11 km NE of Muchea, Darling Range, 187 m, trunk of *Banksia menziesii*, on bark?, 23.XI.2001, G. Marson (H.B. 7209f ø). – **Northern Territories**, MacDonnell Ranges, 11 km W of Alice Springs, 5 km N of White Gums, Larapinta Drive, 605 m, branch of *Acacia*, on wood, 13.X.1998, G. Marson (ø). — **USA**: **Utah**, Canyonlands, 16 km NNW of Mexican Hat, 1 km N of Mokee Dugway, Cedar Mesa, 1965 m, branch of *Shepherdia rotundifolia*, on wood, 14.VI.2000, G. Marson (H.B. 7154b). — **SPAIN**: **Com**. **Valenciana**, **Castellón**, 51 km W of Castellón, 6 km SE of Barracas, 980 m, branch of *Ulex parviflorus*, on wood, 27.XII.2007, J.P. Priou (J.P.P. 27139, doc. vid., H.B. 8738c ø). – ibid., 4.I.2008 (J.P.P. 28008, doc. vid.).

Orbilia saguarina Baral & G. Marson, **sp**. **nov**.,
MB 813727 — Pls 738–739

Etymology: from the host plant in the holotype, *Carnegiea gigantea* (saguaro cactus).

Typification: USA, Arizona, Lukeville, stems of *Carnegiea gigantea*, 28.V.2003, G. Marson (ex H.B. 7764b, M-0276581, holotype).

Latin diagnosis: *Similis* Orbiliae microserpenti *sed ascosporae longiores, paraphyses ad apicem leniter inflatae. Habitat ad caules putridos siccos* Cactacearum *in zona subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.35–0.8(–1) mm diam., 0.17–0.3 mm thick, light to bright orange to brick-red, non-translucent, round (to broadly elliptical), scattered to gregarious; disc slightly concave to flat, margin distinct, 5–20 µm protruding, ± rough, partly somewhat crenulate; broadly sessile or with an obconical base, slightly to entirely immersed among fibres of host; dry bright dirty brick-red, often sunken back and inconspicuous. **Asci** *(61–)70–80(–88) × 5.8–7.2 µm {1}, †64–74 × 4.8–5.2 µm {1}, 16-spored (10–16

spores developed), spores *3–4-seriate, 6–11 lower spores inverted {2} (sometimes strongly mixed), pars sporifera *31–34 µm long; **apex** (†) medium to strongly truncate (not distinctly indented, laterally not or slightly inflated); **base** with short to medium long, thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(6.3–)7–9.5(–11) × (1.9–)2–2.4(–2.6) µm {2}, narrowly ellipsoid to often ellipsoid- to fusoid-clavate, apex obtuse, base usually more or less attenuated, straight to slightly curved near base; **SBs** *(3–)4–6(–7.8) × 0.2–0.4(–0.5) µm in situ {2} [(3–)4–8.5 µm actual length], filiform to subulate, base not or rarely slightly inflated, ± flexuous, partly helicoid or uncinate, in more aged spores rod-shaped. **Paraphyses** apically slightly to medium (to strongly) clavate(-capitate), sometimes spathulate, terminal cells *7.5–15(–24) × (3.3–)4–

5(–5.5) µm {1}, lower cells *7–17.5 × 1.6–2.8 µm {1}; rarely branched at upper septum, hymenium pale orange. **Medullary excipulum** pale orange, 50–130 µm thick, of ± dense textura intricata with some or many inflated cells, sharply delimited at flanks. **Ectal excipulum** very pale orange, of thin-walled († slightly to medium gelatinized), vertically oriented t. globulosa-angularis(-prismatica) from base to submargin, 40–100 µm thick near base, cells *9–25(–41) × 8–15(–17.5) µm {2}; 25–35 µm thick near margin, of t. prismatica(-porrecta) oriented at a 20–45° angle to the surface, marginal cortical cells *5–12 × 3–5 µm {1}. **Anchoring hyphae** medium abundant, */†2–4(–5) µm wide, walls 0.2–0.3(–0.7) µm thick {2}, sometimes moniliform. **SCBs** in paraphyses and ectal excipulum absent {2} though small globose SCBs exceptionally seen. **Exudate** over paraphyses 0.2–2 µm thick, granular-cloddy, hyaline, firmly attached; over margin and flanks 0.5–1.5 µm thick, rough-cloddy. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** Y-shaped, *18–29 × 23.5–26 µm, main axis *(14–)23–25.5 × (4.3–)7.5–8 µm, 2–3-septate, arms *10–13 × (4.5–)6.5–7 µm, 2(–3)-septate, tapering only at terminal cell.

Habitat: lying on dry ground or up to 0.5 m above the ground, ~15–50 mm thick branches (outer layers removed) of *Carnegiea gigantea* {1}, *Stenocereus thurberi* {1}, on wood {2}, in broadly excavated areas (*Carnegiea*) or only on inner surface (*Stenocereus*), strongly decayed, greyed, no algae. **Associated**: *Orbilia cactacearum* {2}, *O. carnegieae* {1}, *Teichosporella dura* {1}, ?*Trichopeziza* sp. {1}. **Desiccation tolerance**: fully viable for at least 26 months. **Altitude**: 710–750 m a.s.l. **Geology**: Lava of basalt breccia, andesite and rhyolite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia saguarina* is characterized by 16-spored asci, narrowly ellipsoid-clavate ascospores, and ± thin, flexuous spore bodies, also by rather large apothecia with partly crenulate margin.

The European *O. cisti* differs in slightly shorter and wider, more fusoid spores with more subacute apices, and a smooth apothecial margin. Similarly, the North American *O. cercocarpi* and an Australian collection (Pl. 704: 4, on *Acacia*) mentioned under *O. pleioungulata* differ in slightly wider SBs and especially in the presence of crystalloid SCBs, *O. cercocarpi* also in slightly shorter and wider spores. The European *O. microserpens* differs in distinctly shorter, ± homopolar spores and more strongly inflated paraphysis apices, but some Australian specimens referred to *O. microserpens* (Pl. 740: 3, 6) have longer, partly heteropolar spores reminiscent of but still smaller than in *O. saguarina*. *O. pleioserpens* differs in shorter and wider, predominantly homopolar spores.

Variation. Some variation in spore and SB size was noted between the examined apothecia of the holotype (Pl. 738: 1a). They derive from different branch areas, but undoubtedly belong to a single species. The collection on *Stenocereus* (organ pipe cactus, IVV: H.B. 7217b) fits well the holotype but was only sketchily documented.

Not included collections. Three sparse Australian samples (on *Acacia*, Pls 738: 2: 739: 2; on *Casuarina*, IVV: H.B. 6809d) appear to be conspecific but are not included in the description because of their geographical origin and a tendency to wider asci, wider SBs, and often also wider spores. Another collection on *Acacia* (Pl. 738: 3) deviates from the holotype mainly in wider SBs.

Anamorph. The conidia detected on the natural substrate in the holotype differ in their thick and rather short arms and stipes from those trinacrium-like anamorphs usually observed in section *Habrostictis*.

Ecology. *O. saguarina* was found on rotten skeleton fragments of xeric branches of two large *Cactaceae* in subtropical semiarid Sonoran paloverde-mixed cacti desert scrubs in the southwest of Northern America. The not included collections were on Cretaceous red-brown sand & gravel in subtropical semiarid to almost arid acacia open shrublands in the Yalgoo and Carnarvon ecoregion of western Australia, and in a subtropical subhumid savannah-like eucalypt open woodland in eastern Australia west of the Great Dividing Range.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 17 km NNE of Lukeville, Ajo Mountain Trail, Organ Pipe, 750 m, branches of *Carnegiea gigantea*, 28.V.2003, G. Marson (M-0276581, **holotype**; **isotype** in H.B. 7764b, anam. substr.). – 17.5 km NE of Lukeville, 710 m, branch of *Stenocereus thurberi*, 11.VI.2000, G. Marson (H.B. 7217b).

Not included. **AUSTRALIA**: **Western Australia**, Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, 67 m, twig of *Acacia*, on bark, 6.XI.2007, G. Marson (ex H.B. 8727g, mixture in MEL 2389251 [type of *O. myrioauris*]). – Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, branch of *Acacia*, on bark, 8.XI.2007, G. Marson (H.B. 9050c). – **Queensland**, Brigalow Belt South, 100 km S of Miles, 22.5 km NW of Moonie, 305 m, branch of *Casuarina cunninghamiana*, 23.X.1998, G. Marson (H.B. 6809d ø).

Orbilia microserpens Baral, sp. nov.,
MB 813728 — Pls 740–741, Map 124

Etymology: referring to the filiform, flexuous spore bodies inside the comparatively small ascospores.

Typification: Spain, Cambrils, branch of *Ceratonia siliqua*, 27.IX.1999, G. Marson (ex H.B. 6519a, M-0276514, holotype; ex-type culture: CBS 140817; sq.: KT215251, MH878187).

Latin diagnosis: *Apothecia rehydratata 0.15–0.45 mm diam., aurantiaca, margine laevi. Asci 16-spori. Ascosporae *3.5–7.7 × 1.8–2.5 µm, ellipsoideae vel fusoideo-clavatae, rectae vel subrectae, in statu vivo corpusculum refringens longum, filiforme, flexuosum, basaliter interdum inflatum, ad apicem affixum continentes. Paraphyses ad apicem plerumque valde capitatae. Cellulae vivae excipuli et paraphysium absque corpusculis globosis et crystalloideis. Habitat ad lignum vel corticem putridum ramulorum vel ramorum siccorum fruticum vel arborum angiospermarum, raro gymnospermarum, in zona subtropica arida ad semihumida Australiae et Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.35(–0.45) mm diam., 0.1–0.15 mm high, pale to light orange, round, scattered or ± gregarious; disc slightly concave to flat (to slightly convex), margin distinct, 0–20 µm protruding, ± smooth; sessile, superficial to completely immersed (erumpent). **Asci** *(40–)45–65(–70) {8} × 4.6–5.2 {1} or 5.3–6.4(–6.6) µm {9}, †40–55 {3} × 3.8–4.5 {1} or 4.8–5.5 µm {2}, 16-spored, spores 2–4-seriate, 7–8 lower spores inverted {5} (strongly mixed), pars sporifera *23–37(–42) µm long; **apex** (†) strongly truncate (slightly indented, laterally scarcely inflated); **base** with very short to medium long, thin or thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(3.5–)4–5(–5.3) {4} or (4.5–)5–6.5(–7) {11} or 6.5–7.7 {1} × (1.7–)1.8–2 {5} or 2–2.3(–2.5) µm {12}, subcylindrical to often narrowly ellipsoid(-ovoid) to fusoid-clavate, apex (rounded to) obtuse, sometimes subacute, base not or sometimes slightly to medium attenuated, straight or somewhat inequilateral, sometimes slightly to medium curved; **SBs** apically (rarely subapically) attached to spore wall, *(3.5–)4–5.5(–6) × 0.2–0.4(–0.7) µm in situ {8} [~(4–)5–6(–6.5) µm actual length], filiform to subulate, sometimes slightly to medium swollen at base, straight to often flexuous, sometimes uncinate. **Paraphyses** apically medium to (very) strongly capitate, also clavate or spathulate, terminal cells *6–22 {8} or 17–28 {1} × (2–)2.5–5(–6) {9} µm, lower cells *(5–)6–13(–18) × 1.1–2 µm {4}, near base 2–2.5(–3) µm; sometimes branched near apex, hymenium very pale orange. **Medullary excipulum** hyaline, 20–35 µm thick, of ± loose or dense textura intricata with many inflated cells, indistinctly to sharply delimited. **Ectal excipulum** hyaline, near margin very pale rose, of thin-walled to slightly gelatinized, irregularly oriented t. angularis from base to submargin, 20–50 µm thick near base, cells *9–20 × 7–14(–15.5) µm

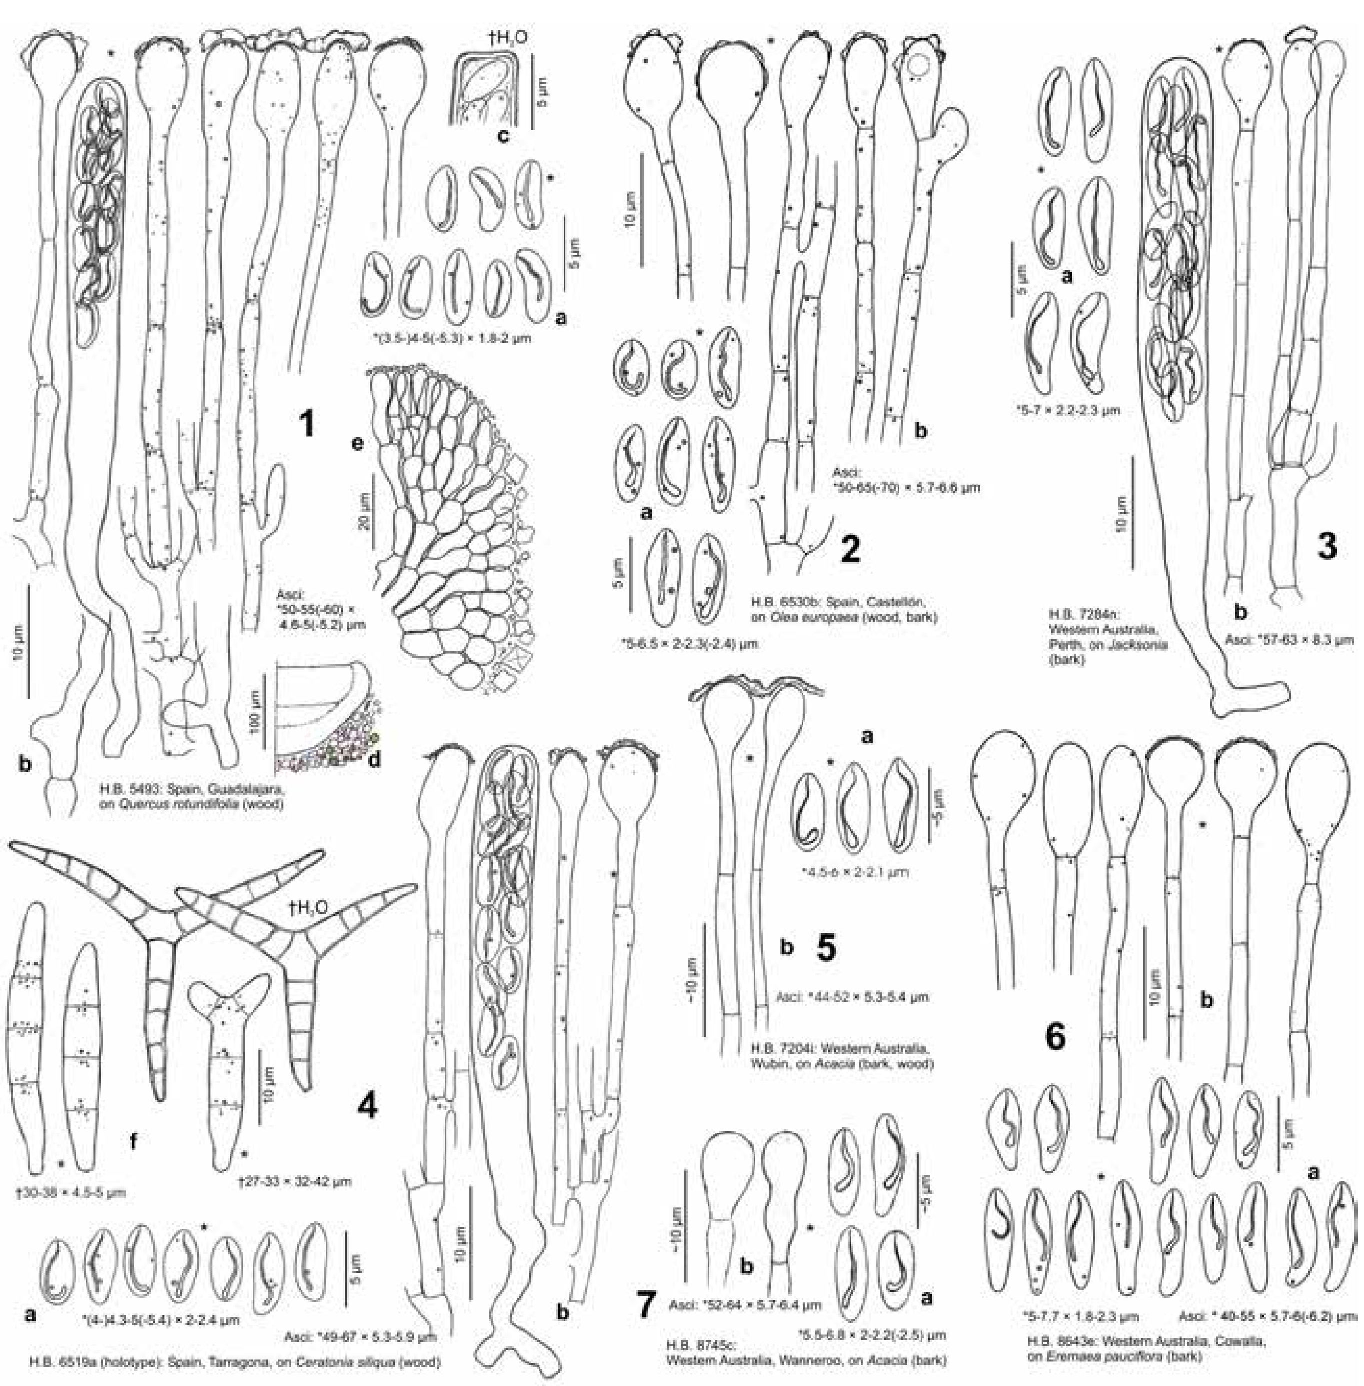

Plate 740. **1–7**: *Orbilia microserpens*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. conidia (from culture, dead conidia from substrate).

{4}; 15–25 µm thick near margin, of t. prismatica-porrecta oriented at a 0–70° angle to the surface, marginal cortical cells *6–15 × 3–5(–8) µm {3}. **Anchoring hyphae** sparse to abundant, *1.8–3 µm wide, walls 0.2–0.4(–0.7) µm thick {3}. **SCBs** absent {10}. **Exudate** hyaline to pale or light yellowish-orange, over paraphyses 0.3–2(–3) µm thick, cloddy(-granular), loosely or firmly attached; over margin and flanks 0.8–5 µm thick, granular or cloddy, very rough. **— ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {2}). **Conidiophores** not seen. **Conidia** Y-shaped, total size †~27–33 × 32–42 µm, stipe †~17–20 × 3.5–4.5 µm, (1–)4–6-septate, arms gradually slightly to strongly tapering, †/*(6–)16–22 × 3–4.5 µm, (1–)4–5-septate {1}; phragmoconidia */†25–38 × 4.5–5 µm, 3(–4)-septate, fusoid {1}.

Habitat: collected 0–2 m above the ground, corticated to entirely decorticated, 3–25 mm thick twigs and branches of *Acacia* sp. {5}, *Allocasuarina campestris* {1}, *Banksia grandis* {1}, *Eremaea pauciflora* {1}, *Ceratonia siliqua* {1}, *Eucalyptus* sp. {1}, *Genista scorpius* {1}, *Jacksonia* sp. {1}, *Melaleuca* sp. {1}, *Olea europaea* {1}, *Pinus halepensis* {1}, *Quercus rotundifolia* {2}, *Rhamnus alaternus* {1}, *Ulex* sp. {1}, *U. parviflorus* {1}, on 0.2–0.5(–1.5) mm deep strongly decayed wood {13} and bark {10} (bast, rarely periderm), bark sometimes detached, wood partly strongly eroded; greyed, green algae absent to abundant. **Associated**: *Amandinea* sp. {1}, *Baggea* sp. {1}, *Caloplaca* sp. {2}, *Capronia* sp. {1}, *Claussenomyces* sp. {1}, *Coniochaeta sarothamni* {1}, *Cosmospora* sp. {1}, *Dacrymyces* sp. {1}, *Didymosphaeria futilis* {1}, *Durella* sp. {1}, *D.* aff. *connivens* {1}, *Gloniopsis praelonga* {3}, *Hyalorbilia juliae* {1}, *Hypoxylon* sp. {1}, *Hysterium angustatum* {1}, *Hysterographium fraxini* {1}, ?*Hysteropatella* sp. {1}, *Lecanora* sp. {1}, *Lophiostoma* sp. {1}, *L. caulium* {1}, *Mellitiosporiella* sp. {1}, *Muellerella lichenicola* {1}, *Nitschkia* ?*broomeana* {1}, *Orbilia acaciae* {1}, *O. albidorosea* {1}, *O. amberina* {2}, *O. anguliobliqua* {1}, *O. australiensis* {2/1}, *O. austrocylindrica* {1}, *O. austroobtusispora* {2}, *O. aviceps*

Taxonomic remarks. *Orbilia microserpens* is characterized by 16-spored asci and small, ± ellipsoid-fusoid-clavate ascospores with long, filiform or subulate spore bodies. It differs from *O. pleiogambelii* in the consistent absence of both globose and crystalloid SCBs, and in narrower spores. The North American and Australian *O. pleioserpens* and *O. macroserpens* and the European *O. cisti* mainly differ in larger spores, the predominantly Australian *O. multiserpens* in 32-spored asci. The Australian *O. pleiocrescens* is very similar to *O. microserpens*, and differs merely in distinctly curved spores.

Variation. *O. microserpens* varies among the collections mainly in size and shape of the spores, but this variation was sometimes also observed within a collection. In a sample on *Olea* some apothecia contained some asci with extraordinarily short spores (Pl. 740: 2a, upper 2 spores). A collection on *Quercus ilex* (Pl. 740: 1) differs from all others in rather short and particularly narrow, partly reniform spores (very similar to *O. pleiocrescens*), distinctly narrower asci, and comparatively long paraphysis cells, although in another, unpreserved collection on the same substrate (Castellón, 27.IX.1999) asci and spores were of the typical size. Similarly short spores were found in the holotype on *Ceratonia* (Pl. 740: 4), but here the asci and spores were distinctly wider. The Australian specimens often tend to have slightly longer, more heteropolar spores, nevertheless they fit quite well the European specimens. A collection from the arid Pilbara desert (Pl. 741: 5) deviates from all other samples in frequently subapically inserted SBs (similar as in *O. namibica*), also in rather wide spores of *5.5–7 × 2.2–2.5 µm.

Anamorph. Mainly unbranched conidia developed near an apothecium which was placed on the lid of a Petri dish (Pl. 740: 4f). The single observed trinacrium-like conidium had rather short arms in comparison to the probably more typical conidia which we have found on the natural substrate in this collection. Also some unbranched conidia were seen on the natural substrate. This anamorph differs from *Trinacrium robustum* in narrower arms and stipes.

Phylogeny. A sequence was gained from pure culture of the holotype from Cataluña (on *Ceratonia*) which comprises SSU (without S1506 intron), ITS, and LSU. *O. microserpens* is close to *O. macroserpens* (3.3% in ITS, 0.6% in LSU D1–D2), *O. cisti* (3.6%, 0.8%), and *O. cercocarpi* (4.3%, 0.5%), and *O. myrionamibica* (4.7%, 0.6%), with which it clusters in the *microserpens-ungulata* clade (Phyls 19–20, S20, S22).

A sequence of unknown origin (MH221069) clustered with *O. microserpens* in a strongly supported subclade (ITS, SSU+ITS+LSU), with a distance of 1.8% in the ITS and 1% in the LSU (5 nt in the D2). It also differs in possessing the S1506 intron in which region it clustered unresolved in the *Ellipsospermae* clade (S21). Therefore, it is provisionally called *O.* aff. *microserpens*.

Ecology. *O. microserpens* was collected on wood and bark of xeric twigs and branches of various angiosperm trees and shrubs, rarely gymnosperms. Within Europe it was so far only found in Spain in thermo- to supramediterranean semiarid to semihumid maquis (*Quercus ilex* shrubs, old *Olea* plantations, often with *Ulex*), once also in a suprasubmediterranean semiarid shrubland with *Genista scorpius* and *Rhamnus myrtifolia* (Pancrudo). Within Australia the species occurred in subtropical semihumid acacia mixed shrublands and banksia-eucalypt woodlands (mallee) in the southwest or an eucalypt open woodland in the east, but also in (sub)tropical, semiarid to arid acacia open shrublands (mulga) in the west, one of them in an almost tropical tussock grassland with *Livistona alfredii*.

Specimens included. **SPAIN**: **Cataluña**, **Tarragona**, 20 km WSW of Tarragona, 3 km W of Cambrils, Carrer Gotic, La Dorada, 15 m, branch of *Ceratonia siliqua*, on wood, 27.IX.1999, G. Marson (ø). – **Queensland**, Brigalow Belt South, 80 km N of Goondiwindi, 10 km S of Moonie, 278 m, twig of *Melaleuca*, on wood, 23.X.1998, G. Marson (ø).

Not included. unlocalized (confusion of unclear origin, sequence taken in IV.2014; sq.: MH221069).

Orbilia pleiocrescens Baral & G. Marson, **sp. nov.**, MB 813729 — Pls 742–743

Etymology: named after the 16-spored asci and crescent-shaped ascospores.
Typification: Western Australia, Wannamal, branch of *Acacia*, 4.IX.2006, G. Marson (ex H.B. 8582b, MEL 2389242, holotype).

Latin diagnosis: *Similis* Orbiliae microserpenti *sed ascosporae semper leniter ad valde curvatae. Habitat ad corticem, raro lignum putridum ramorum siccorum* Acaciae *in zona subtropica semiarida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.35(–0.4) mm diam., 0.17–0.19 mm high, light to bright orange, hardly translucent, round, subgregarious in small groups; disc flat, margin distinct, thin, 5–15 µm protruding, smooth to somewhat crenulate (partly whitish); broadly sessile, nearly superficial to almost completely immersed. **Asci** *(40–)50–60(–65) × (4.5–)4.8–5.4(–5.7) µm, †40–54 × 4–4.5 µm, 16-spored, spores (*) biseriate, ~4–9 lower spores inverted (sometimes strongly mixed), pars sporifera *22–26 µm long; **apex** (†) strongly truncate (not or ± distinctly indented, laterally sometimes slightly inflated); **base** with short to long, ± thin and flexuous stalk, L-, T- or Y-shaped. **Ascospores** *(3.3–)3.5–4.3(–5) × (1.4–)1.5–1.8(–2) µm, cylindrical to cylindric-clavate, apex rounded to obtuse, base not or somewhat attenuated, slightly to mostly medium to (very) strongly curved (crescent-shaped), sometimes geniculate in lower half; **SBs** *2–3.8 × 0.2–0.5 µm in situ (~2–5 µm actual length), filiform to subulate, with or without a swollen, irregularly shaped lower part, ± flexuous, sometimes almost uncinate. **Paraphyses** apically medium to very strongly clavate-capitate, terminal cells *10–20 × (3–)3.4–4.5(–5) µm, lower cells *10–14 × 1–1.7 µm (near base *7–8 × 2–2.5 µm); unbranched at upper septum, hymenium very pale orange. **Medullary excipulum** 50–60 µm thick, of dense textura intricata-angularis, very indistinctly delimited. **Ectal excipulum** of thin-walled († slightly gelatinized), ± vertically oriented t. angularis(-prismatica) from base to margin, 50 µm thick near base, cells *10–22 × 7–15 µm; 20–30 µm thick near margin, upper margin of t. prismatica-porrecta oriented at a 10° angle to the surface, marginal cortical cells */†7–11 × 2.5–4 µm. **Anchoring hyphae** medium abundant, †1.7–2.5(–3) µm wide, walls 0.2(–0.4) µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) absent. **Exudate** over paraphyses 0.2–0.3(–1) µm thick, finely rough, ± continuous, pale yellow-orange, also absent, ± firmly attached, over margin and flanks 0.2–1 µm thick, continuous. **— ANAMORPH**: unknown.

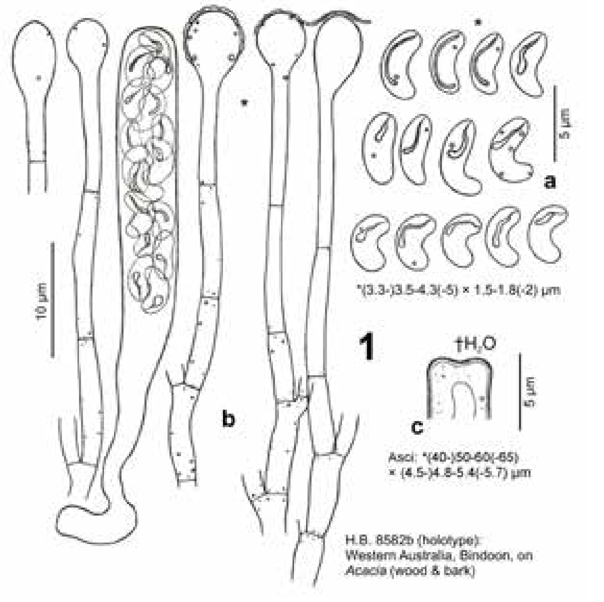

Plate 742. **1**: *Orbilia pleiocrescens*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex.

Habitat: collected 0.5–1.5 m above the ground, ± corticated, 10–12 mm thick branches of *Acacia* sp., on bark (on bast, especially in small cracks in periderm), exceptionally on wood, 0.2–0.4 mm deep strongly decayed, ± greyed, green algae sparse. **Associated**: *Orbilia albidorosea*, *O. australiensis*, *O. austroocculta*, *O. austroregalis*, *O. myriooobliqua*, crustose lichens. **Desiccation tolerance**: fully viable for at least 1 year. **Altitude**: 272 m a.s.l. **Geology**: Archean granulite with granitic gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiocrescens* is very closely related to *O. microserpens*, from which it mainly differs in predominantly strongly curved (cashew-shaped) ascospores. In a small-spored European and two large-spored Australian collections (Pl. 740: 1, 3, 6) here referred to *O. microserpens* a few spores were slightly curved by looking very similar as in *O. pleiocrescens*, whereas in the remaining collections usually no such distinct curvature could be noted. A species with similar crescent-shaped spores and subulate SBs, *O. graminis* differs in 8-spored asci with hemispherical apices and distinct apical domes and belongs to series *Vibrioides* of section *Hemiorbilia*. *O. curvativitalbae* differs in 8-spored asci and much larger spores which are often almost straight in their upper part.

Ecology. The single collection of *O. pleiocrescens* was made on rotten bark (rarely wood) of xeric branches of *Acacia* in a subtropical semihumid eucalypt woodland with *Macrozamia riedlei* in southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 272 m, branch of *Acacia*, on wood, 4.IX.2006, G. Marson (ex H.B. 8582b, MEL 2389242, **holotype**).

Orbilia multiserpens Baral & G. Marson, **sp. nov.**, MB 813730 — Pls 744–745, Map 125

Etymology: named according to the 32-spored asci and close resemblance to *O. microserpens*.
Typification: Portugal, Achete, branch of *Rhamnus alaternus*, 3.I.2007, J.P. Priou (ex H.B. 8419, M-0276525, holotype).

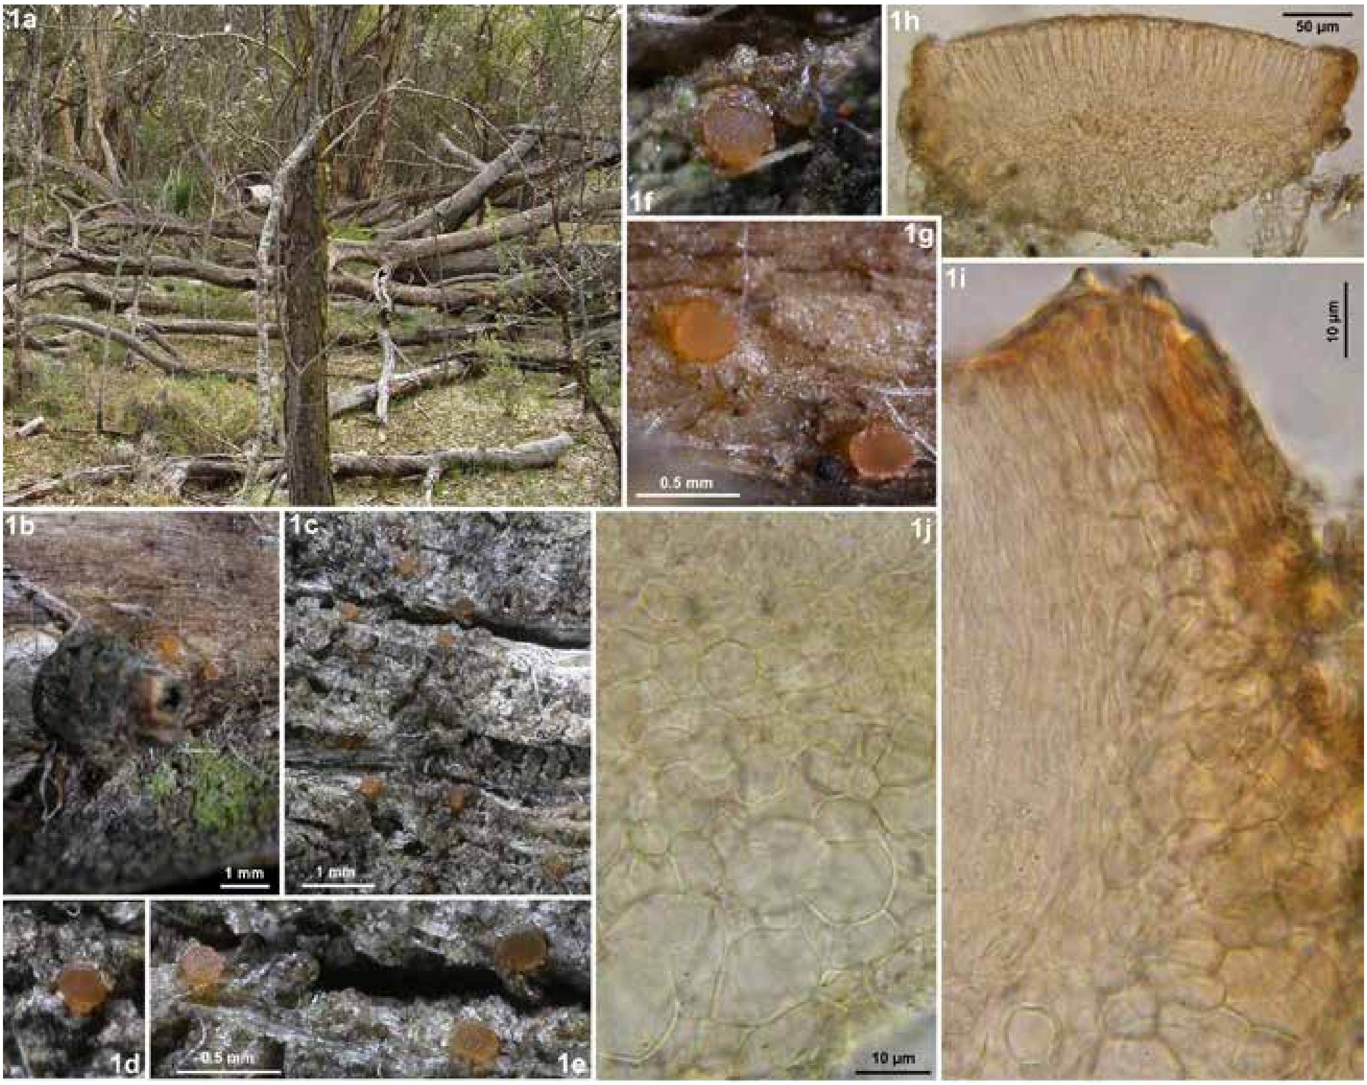

Plate 743. **1**: *Orbilia pleiocrescens*. – **1a**. semihumid eucalypt open woodland with *Acacia*; **1b–g**. rehydrated apothecia; **1h**. apothecium in median section; **1i**. id., marginal ectal excipulum; **1j**. id., basal ectal excipulum. – Living state. — **1a–j**. H.B. 8582b (holotype): Western Australia, Bindoon, on *Acacia*.

Latin diagnosis: *Similis* Orbiliae microserpenti *sed asci 32-spori. Habitat ad lignum vel corticem putridum ramulorum vel ramorum siccorum fruticum vel arborum angiospermarum, etiam ad petiolum* Livistonae, *in zona subtropica subhumida ad arida Australiae, Europae meridionalis et Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3 mm diam., 0.12–0.16 mm high, pale to light orange, round, scattered; disc flat, margin thin or thick, 10 µm protruding, smooth; sessile, slightly immersed. **Asci** *50–73(–80) × 6.2–7.5(–8.3) µm {8}, †46–60 × 5–6.2 µm {2}, 32-spored, spores multiseriate, lower spores inverted {5} (strongly mixed), pars sporifera *30–43 → 28 µm long; **apex** (†) strongly truncate (very slightly indented, laterally inflated or not); **base** with short, thick, flexuous stalk, L-, Y- to h-shaped. **Ascospores** *(3.3–)4–5.7(–6.7) × 1.8–2.4(–2.7) µm {10}, subcylindric to ellipsoid, sometimes ± fusoid(-clavate), apex rounded to obtuse, exceptionally subacute, base not or sometimes slightly attenuated, straight to slightly inequilateral; **SBs** *(2.5–)3–5.5(–6.2) × 0.2–0.5(–0.7) µm in situ {8} [~(2.5–)4–7(–8.5) µm actual length], filiform to subulate, base not or slightly, rarely strongly inflated (then probably overmature), slightly to strongly flexuous, often uncinate. **Paraphyses** apically medium to very strongly (clavate-)capitate, sometimes spathulate, terminal cells *7–18(–22) × (3–)3.5–5.8(–6.3) µm {9}, lower cells *(6–)8–15 × 1.2–2(–2.5) µm {4}; unbranched at upper septum, very pale orange-rose. **Medullary excipulum** very pale orange-rose, 30–40 µm thick, of ± dense textura intricata with inflated cells, sharply delimited. **Ectal excipulum** very pale orange-rose, of thin-walled, ± vertical t. (globulosa-)angularis(-prismatica) from base to mid flanks or margin, 30 µm thick near base, cells *8–15 × 5–12 µm {3}; 15–20 µm thick at mid flanks and margin, at margin sometimes a t. prismatica oriented at a 10–20° angle to the surface, marginal cortical cells *6–11 × 3–6 µm {3}, at submargin 3–6 × 3–5 µm. **Anchoring hyphae** not seen. **SCBs** absent {8}, rarely globose, in tips or lower cells of paraphyses. **Exudate** over paraphyses 0.2–1.5 µm thick, rough to cloddy, ± firmly attached, over margin and flanks 0.3–4 µm, granular to rough-cloddy. **— ANAMORPH**: unknown.

Habitat: collected 0–4 m above the ground, ± corticated to entirely decorticated, 2–14 mm thick twigs and branches of *Allocasuarina campestris* {1}, *Acacia* sp. {3}, *A. jennerae* {1}, *Casuarina cunninghamiana* {1}, *Ephedra ?viridis* {1}, *Pittosporum phillyreoides* {1}, *Psydrax latifolia* {1}, *Rhamnus alaternus* {1}, on 0.2–1 mm deep strongly decayed wood {5} and bark (bast) {4}; petioles of *Livistona nitida* {1}, ± greyed, green algae sparse or absent. **Associated**: *Baggea* sp. {1/1}, *Capronia* sp. {1}, *Claussenomyces* sp. {1}, *Coccomycetella* sp. {1}, *Gloniopsis* sp. {2}, *Hysterobrevium mori* {1}, *Hysterium angustatum* {1}, *Lecanora* sp. {1}, *Melaspilea emergens* {1}, *Mellitiosporiella* sp. {1}, *Orbilia acaciae* {1}, *O. amberina* {1}, *O. anguliobliqua* {1}, *O. angustoaristata* {2}, *O. australiensis* {1/2}, *O. austroobtusispora* {1}, *O. austropleiomicrosoma* {1}, *O. aviflagellata* {1}, *O. calyptrata* {1}, *O. ?commarosa* {1}, *O. coronohesperidea* {2}, *O. ?dixienis* {1}, *O. helicoobliqua* {1}, *O. hesperidea* {1}, *O. lacrimispora* {1/1}, *O. livistonae* {1/1}, *O. macrocarpa* {1}, *O. macrohesperidea* {1}, *O. maeandrina* {1}, *O. megahesperidea* {1}, *O. microserpens*

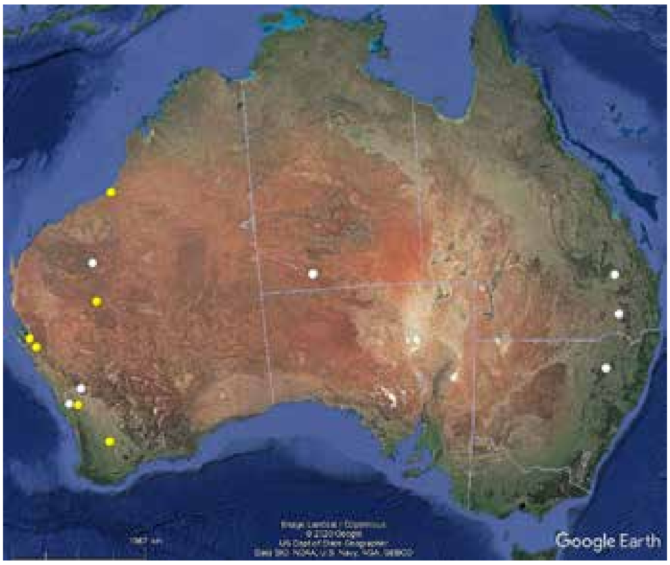
(Australia), 50 m (Portugal), 615 m (North America). **Geology**: Archean, Proterozoic, Jurassic & Cretaceous sedimentary rock, Oligo- to Miocene schist, sand-, lime- & mudstone, Cenozoic regolith; granite, granitic gneiss, volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multiserpens* closely resembles *O. pleioserpens* and *O. microserpens*, from which it mainly differs in 32-spored asci. The similar North American *O. multigambelii* differs in usually possessing abundant and conspicuous crystalloid SCBs, also in distinctly wider and slightly longer, more consistently broadly ellipsoid ascospores. The African *O. namibica* and the North American *O. multicercocarpi* differ in larger spores and the presence of crystalloid SCBs, the former also in more cylindrical spores.

Variation. The single collections of *O. multiserpens* from USA and Europe fit quite well the Australian ones. However, rather high variation in size and shape of spores and SBs is noted between but also within the populations, irrespective of their geographical origin. In a few asci of one sample (H.B. 6277h) all spores had an abnormal ovoid-subglobose shape (not figured).

Only 1–5 apothecia were detected in each of the seven Australian collections. Since the apothecia did not macroscopically differ from the many associated species of *Orbilia*, more of them might exist on the preserved branches.

Not included collections. Two partly rather abundant samples on *Eucalyptus* (Pls 744: 7–8; 745: 1, 3) differ in somewhat larger, more fusoid spores with partly subacute apices



Map 125. Known distribution of *O. multiserpens* in Australia (yellow = not included collections).

and are, therefore, not included in the description. They appear to represent a close relative of the 16-spored *O. pleioserpens*, with which one of them (Pl. 736: 2) grew together. Four further Australian collections (IVV: on *Acacia*, H.B. 7215g, 7302d, 9033c; on *Eucalyptus*, H.B. 9772d) were only studied in the dead state [spores †(3–)4–6 × 1.8–2.3 µm], therefore, spore and paraphysis contents are unknown here.

Ecology. *O. multiserpens* was found on rotten wood and bark of xeric twigs and branches of angiosperm trees and shrubs, also on palm petioles. The holotype and only European collection was on *Rhamnus* in a mesomediterranean semihumid valley 70 km northeast of Lisboa. The sample from western North America on *Ephedra* was from a subtropical semiarid Sonoran paloverde-mixed cacti desert scrub. Most collections were made in Australia, in subtropical (to tropical), subhumid to semihumid and semiarid acacia or eucalypt open wood- and shrublands in the southwest, west (Pilbara), and centre (south of MacDonnell Ranges), and the subtropical (to tropical) wet and dry (subhumid) savannah in the east (Great Dividing Range). The not included collections are from similar habitats in western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 30 km NW of Newman, northern border of Ophthalmia Range, 706 m, branch of *Psydrax latifolia*, on bark, 27.XI.2001, G. Marson (H.B. 7416b). – Avon Wheatbelt, 40 km N of Moora, 4 km NNW of Watheroo, Midlands Road, 320 m, on *Allocasuarina campestris*, 25.X.2007, G. Marson (H.B. 8937c ø). – 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, on *Acacia*, 24.XI.2001, G. Marson (H.B. 7204j ø). – **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 480 m, twig of *Acacia jennerae*, on wood & bark, 10.X.1998, G. Marson (H.B. 6277h). – **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, petioles of *Livistona nitida*, 22.X.1998, G. Marson (H.B. 6424e). – 100 km S of Miles, 22.5 km NW of Moonie, 305 m, branch of *Casuarina cunninghamiana*,

Priou (ex J.P.P. 27001 & H.B. 8419, M-0276525, **holotype**).

Not included. **AUSTRALIA**: **Western Australia**, Dampierland, 235 km SW of Broome, 6 km E of Sandfire Roadhouse, 12 m, branch of *Acacia aneura*, on bark, 3.XII.2001, G. Marson (H.B. 7302d). – Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, 67 m, branch of *Acacia*, on bark, 7.XII.2001, G. Marson (H.B. 7215g). – Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Eucalyptus*, on wood, 28.X.2007, G. Marson (H.B. 9772d). – Yalgoo, 200 km N of Geraldton, 15 km SSE of Wannoo Billabong Roadhouse, W of Toolonga, 157 m, branches of *Acacia*, on bark, 8.XII.2001, G. Marson (H.B. 9033c). – Avon Wheatbelt, 68 km NE of Moora, 14 km S of Dalwallinu, 1.5 km S of Pithara, 326 m, branches of *Eucalyptus*, on bark, 24.XI.2001, G. Marson (H.B. 7283a). – Mallee, 14 km SSW of Kondinin, 9 km NE of Kulin, 286 m, branches of *Eucalyptus*, on wood, 14.XII.2001, G. Marson (H.B. 8641a).

Orbilia myrioolneyae Baral & G. Marson, **sp. nov.**, MB 813731 — Pls 746–747

Etymology: referring to the asci containing 64 small ascospores, and to the substrate, *Olneya tesota*.

Typification: USA, California, Sells, branches of *Olneya tesota*, 28.V.2003, G. Marson (ex H.B. 7573b, M-0276531, holotype; sq.: MT408188).

Latin diagnosis: *Similis* Orbiliae myriellae *sed ascosporae paulo latiores*, *basi partim valde attenuatae*, *apice obtusae*, *corpuscula refringentia magis latiora. Habitat ad lignum vel corticem putridum ramorum siccorum* Olneyae tesotae *et* Sarcobati vermiculati *in zona subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.45 mm diam., 0.11–0.2 mm high, light to bright (yellowish-)orange(-rose), round, very scattered to subgregarious in small groups; disc flat, margin ± distinct, protruding 5–40 µm, finely rough or crenulate; broadly sessile, slightly erumpent. **Asci** *(62–)67–90(–106) {2} × 8–9(–9.7) {2} or 9.4–10.8 {1} µm, †64–83 × (6–)7–8(–9) µm {2}, 64-spored (45–50 spores counted), spores multiseriate, lower spores predominantly inverted {1} (very strongly mixed), pars sporifera *40–55 µm long (†35–50 µm); **apex** (†) (slightly to) medium to strongly truncate (sometimes very slightly indented and/or laterally distinctly inflated); **base** without or with short, flexuous stalk, h-shaped. **Ascospores** *(4.5–)5–6.5(–7.5) × 1.8–2.2(–2.5) µm {3}, †5–6(–7) × 1.7–2.2 µm {2}, subcylindric to ellipsoid- or (fusoid-)clavate, apex rounded to obtuse, base often slightly to strongly attenuated, sometimes tail-like, here often slightly to medium curved; **SBs** *(1.5–)2–2.5(–3.3) × 0.3–0.5 µm {3} (→ 1.5–2 × 0.9 µm), rod-shaped to (narrowly) pyriform, sometimes subulate, straight to slightly flexuous, broadly tear-shaped when overmature. **Paraphyses** apically slightly to medium clavate(-capitate), sometimes sublageniform or moniliform, terminal cells *6–18(–20) × 2.3–4.5(–5.5) µm {2}, †2–3.7 µm wide {1}, lower cells *8–21 × 1.6–2.3 µm {2}, near apex and base up to 3(–4) µm wide; frequently branched near apex. **Medullary excipulum** 15–30 µm thick, of dense textura intricata with many inflated cells, indistinctly to very sharply delimited. **Ectal excipulum** of thin-walled († distinctly gelatinized, common walls 0.5–1 µm), irregularly oriented t. globulosa-angularis from base to submargin, 20–90 µm thick near base, cells *7–12(–17) × 5–9(–13) µm {2}; mid flanks of t. angularis-prismatica oriented irregularly or at 10–20(–40)°, or of t. porrecta at 0°, 15–50 µm thick near margin, of t. prismatica-porrecta oriented at a 0–10° angle to the surface, marginal cortical cells *(5–)6–11(–13) × 2.5–5 µm {2}. **Anchoring hyphae** medium sparse, *2–3(–4) µm wide, walls 0.2(–0.3) µm thick {2}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 0.5–2.5 µm diam. {2}. **Exudate** over paraphyses 0.3–1.5(–2) µm thick, cloddy-continuous, loosely to firmly attached; over margin and flanks 1–3 µm thick. — **ANAMORPH**: unknown.

Habitat: collected 0.5–2.5 m above the ground, decorticated or partially corticated, 6–16 mm thick branches of *Olneya tesota* {2}, *Sarcobatus vermiculatus* {1}, on 0.3 mm deep strongly decayed wood {3} and bark {2}, strongly greyed, no or a few green algae. **Associated**: *Orbilia ?barrowensis* {1}, *O. maeandrina* {3}, *O. multicreosoteris* {2}, *O. multigambelii* {2}, *O. myriourosperma* {2}, *Patellaria* '*andina*' {2}, *Schizoxylon ?argentinum* {1}. **Desiccation tolerance**: fully viable for at least 16 months, after 34 months still many immature asci viable. **Altitude**: 683–745 m a.s.l. **Geology**: alluvial sand and gravel; felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myrioolneyae* is characterized by large, 64-spored asci and rather small, slightly curved ascospores with partly attenuated bases and short vermiform spore bodies. For the similar Australian *O. myriella* see p. 1233. The African *O. myrioflexa* differs in much longer SBs and the presence of crystalloid SCBs. In the two collections on *Olneya* the similar *O. myriourosperma* grew in association, and one of its populations (Pl. 665: 4) showed spores similar to *O. myrioolneyae* though much wider, and further differed in having crystalloid SCBs.

Variation. The three collections included in *O. myrioolneyae* hardly differ from each other. In the type collection, the rather few apothecia on bark differed in several points from the more abundant ones on wood: the apothecia were much thinner due to a much thinner basal ectal excipulum, also the marginal ectal excipulum was much thinner and formed a textura porrecta

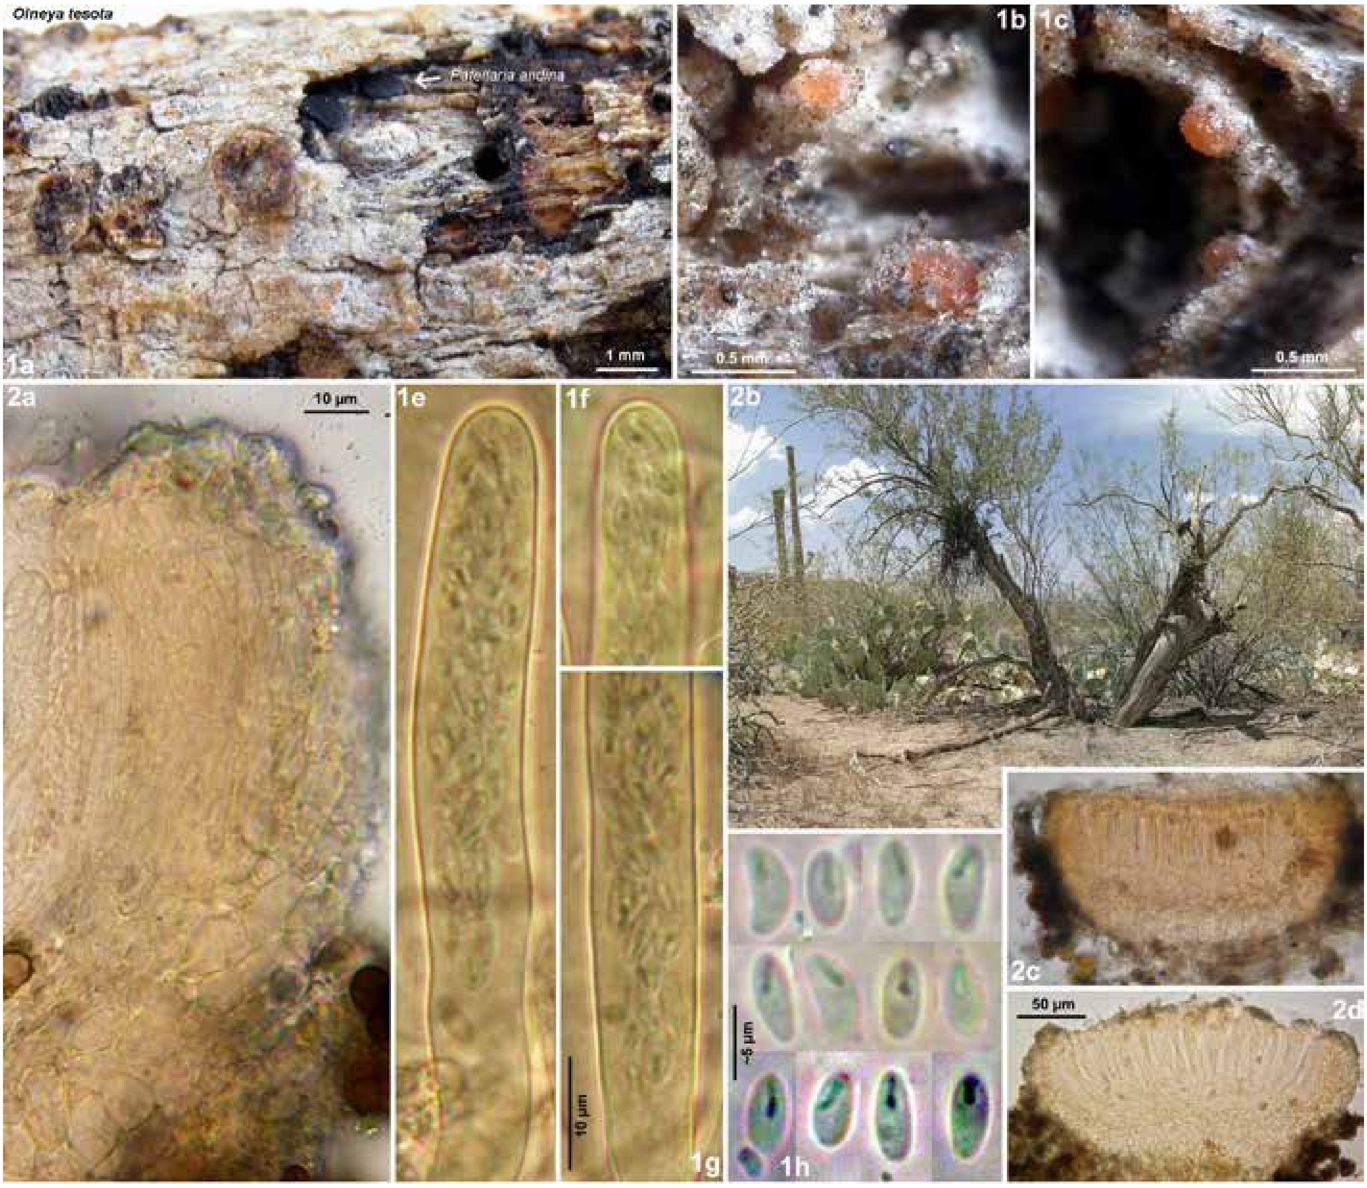

Plate 747. **1–2**: *Orbilia myrioolneyae*. – **2b**. semiarid paloverde-mixed cacti desert scrub with *Olneya tesota*, *Larrea tridentata* and *Opuntia engelmannii*; **1a**. dead corticated branch with rehydrated apothecia on bark; **1b–c**. rehydrated apothecia on wood; **2c–d**. apothecia in median section; **2a**. id., ectal excipulum at margin and mid flanks; **1e–g**. asci; **1h**. ascospores. – Living state. — **1a–h**. H.B. 7573b (holo-/isotype): USA, Arizona, Sells, on *Olneya*; **2a–d**. H.B. 8085d: ibid., Tucson, on *Olneya*.

running parallel to the outside (t. angularis-prismatica on wood), finally the asci were disctinctly wider.

Not included collection. An Australian sample on *Pittosporum phillyreoides* (Pl. 746: 3) differs in shorter, straight, ellipsoid, basally never attenuated spores. Only a single apothecium was detected, which grew in association with 32-spored *O. multiserpens*. From the latter it did not significantly differ, except for a higher spore number and apparently more thick-walled marginal cortical cells.

Phylogeny. A sequence of the holotype was taken in I.2020 from apothecia on remaining branches, comprising a short part of SSU (V9, S1506 intron absent), ITS, and LSU D1–D5. In the ITS region it differs from *O. multimaeandrina* by 11.5% and from *O. multiurosperma* by 12%. When analysing SSU+ITS+LSU it clustered in the strongly supported *Serpentinae*-*Habrostictis* clade, and here with medium support in a clade with *O. quaestiformis* and *O. septispora* (not shown in phylotree) with a 13–14% ITS distance. This result, which is in contradiction to the present placement of *O. myrioolneyae* in series *Ellipsospermae*, is supported by the morphological resemblance with broader-spored, somewhat untypical *O. myriourosperma* in the same collection (Pl. 665: 4).

Ecology. *O. myrioolneyae* was collected on rotten wood and bark of xeric branches of *Olneya tesota* (ironwood) and *Sarcobatus vermiculatus* (greasewood) in subtropical semiarid (almost arid) Sonoran paloverde-mixed cacti desert scrubs in the southwest of Northern America. The not included collection was on rotten bark of a xeric branch of *Pittosporum phillyreoides* on Cenozoic regolith in a subtropical subhumid eucalypt woodland in eastern Australia west of Great Dividing Range.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branches of *Sarcobatus vermiculatus*, on bark & wood, 5.V.1995, G. Marson (H.B. 5806a). – 25 km WNW of Tucson, 5 km S of Picture Rocks, Saguaro, 745 m, branch of *Olneya tesota*, on wood, 30.V.2003, G. Marson (H.B. 8085d ø). – Papago Indian Reservation, 100 km WSW of Tucson, 10 km NW of Sells, 683 m, branches of *O. tesota*, on wood & bark, 28.V.2003, G. Marson (M-0276531, **holotype**; **isotype** in H.B. 7573b; sq.: MT408188).

Not included. **AUSTRALIA**: **New South Wales**, Brigalow Belt South, 20 km SW of Narrabri, 248 m, branch of *Pittosporum phillyreoides*, on bark, 24.X.1998, G. Marson (H.B. 6284h ø).

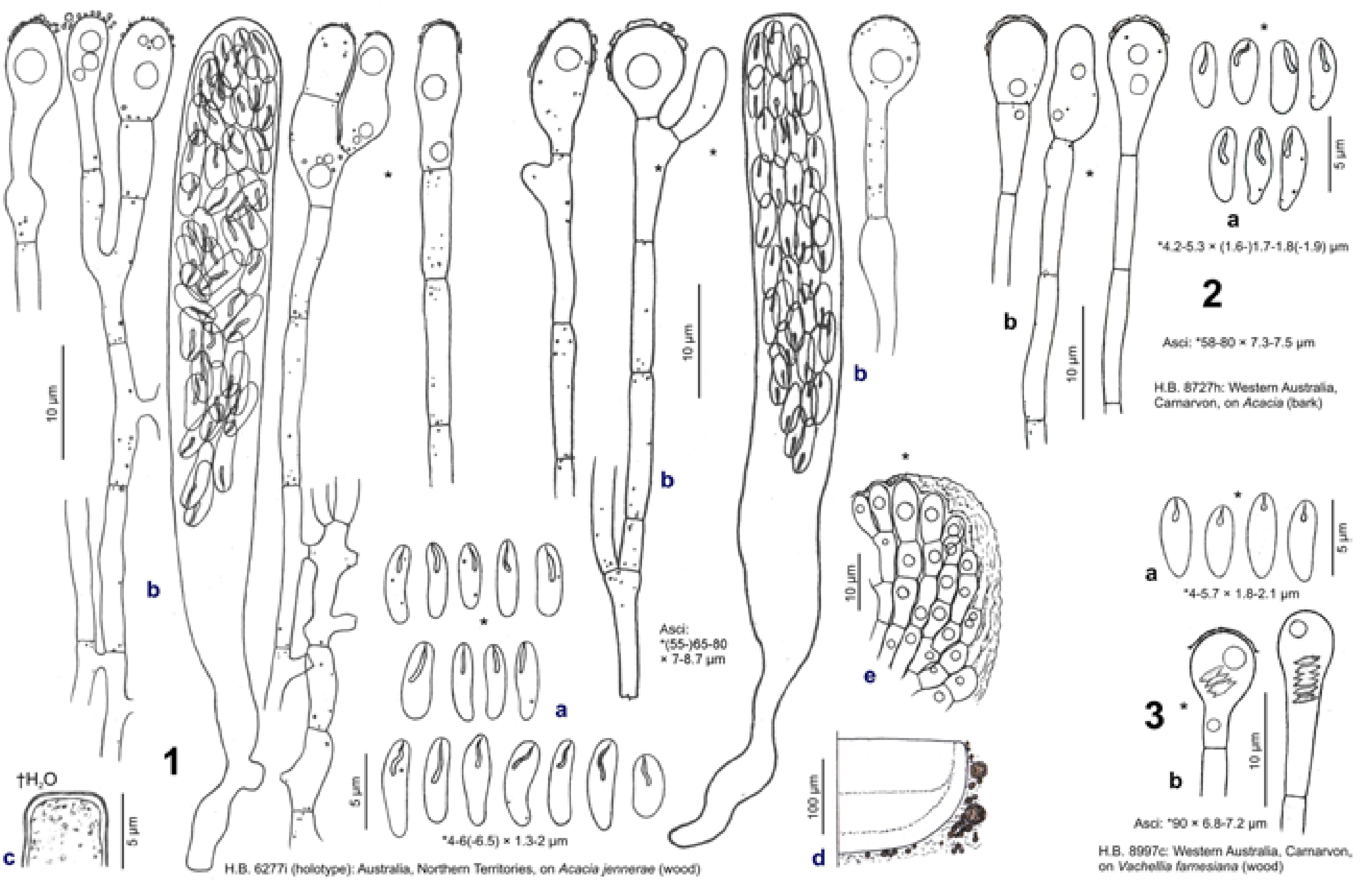

Plate 748. **1–2**: *Orbilia myriella*; **3**: *O.* aff. *myriella*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Orbilia myriella Baral & G. Marson, **sp. nov.**, MB 813732 — Pls 748–749

Etymology: referring to the asci that contain 64 small ascospores.

Typification: Australia, Northern Territories, Yulara, twigs of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277i, MEL 2389202A, holotype).

Latin diagnosis: *Apothecia rehydratata 0.25–0.35 mm diam., aurantiaca, margine laevi vel subcrenulato. Asci 64-spori. Ascosporae *4–6.5 × 1.3–2 µm, subcylindricae, apice rotundatae, interdum obtusae, rectae vel leniter curvatae, in statu vivo corpusculum refringens breve, bacilliforme, leniter flexuosum, ad apicem affixum continentes. Paraphyses ad apicem partim valde capitatae. Cellulae vivae excipuli et paraphysium corpuscula globosa continentes. Habitat ad lignum vel corticem putridum ramulorum vel ramorum siccorum* Acaciae *in zona subtropica (semi)arida Australiae occidentalis et centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.35 mm diam., 0.12–0.15 mm high, pale to light (ochraceous-)orange(-isabelline), round (to broadly elliptical), scattered to subgregarious; disc slightly concave to flat, margin ± distinct, not or slightly protruding, smooth to somewhat crenulate; broadly sessile, ± superficial or immersed. **Asci** *(55–)60–80 × 7–8(–8.7) µm {2}, †50–71 × 6–7.3(–7.7) µm {3}, 64-spored (50–60 spores counted), spores multiseriate, lower spores predominantly inverted (strongly mixed), pars sporifera *34–54 µm long; **apex** (†) medium to strongly truncate (hardly indented, laterally sometimes slightly inflated); **base** without or with short to medium long, ± thick, flexuous stalk, L-, T-, Y- or h-shaped. **Ascospores** *(4–)4.3–6(–6.5) {4} × 1.3–1.5 {1} or (1.4–)1.6–1.9(–2) {3} µm, †5–6 × 1.4–1.8 µm {1}, (sub)cylindric or sometimes slightly (fusoid-)clavate, apex rounded (to obtuse), exceptionally subacute, base in some spores slightly (to medium) attenuated, straight to slightly curved; **SBs** *1.8–2.5(–3) × 0.2–0.3(–0.4) µm {2}, rod-shaped to subulate, base not inflated, straight to medium flexuous. **Paraphyses** apically slightly to (very) strongly clavate-capitate, also spathulate to sublageniform, sometimes moniliform, terminal cells *6–15(–20) × (3–)4–5(–6.5) µm {2}, lower cells *(5.5–)9–13(–15) × 1.5–2(–2.5) µm {2}, near apex and base up to 3–3.5 µm wide; not or frequently branched near apex. **Medullary excipulum** 20–50 µm thick, of ± dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, irregularly oriented t. globulosa from base to submargin, 20–25 µm thick near base, cells *5–14 × 5–9.5 µm {2}; 15–25 µm thick near margin, of t. prismatica oriented at a 0–20° angle to the surface, marginal cortical cells *7–12 × 3.5–5 µm {2}. **Anchoring hyphae** sparse, *2–3 µm wide, walls 0.2(–0.3) µm thick {2}, present as thin layer up to margin. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–3 µm diam. {2}. **Exudate** over paraphyses and marginal excipulum 0.2–1 µm thick, granular(-cloddy), loosely or firmly attached. **— ANAMORPH**: unknown.

Habitat: on dry soil or in 1–3 m above the ground, decorticated or ± corticated, 1.5–15 mm thick twigs and branches of *Acacia* sp. {3}, *A. jennerae* {1}, on 0.3 mm deep strongly decayed wood {1} or bark {3}, on outer surface, partially detached, greyed, no algae. **Associated**: *Baggea* sp. {1}, *Coccomycetella* sp. {2}, *Hysterobrevium mori* {1}, *Orbilia anguliobliqua* {1}, *O. angustoaristata* {1}, *O. angustoobliqua* {1}, *O. ?atriplicis* {1}, *O. austropleiomicrosoma* {1}, *O. corculispora* {1}, *O. coronohesperidea* {1}, *O. curvatimyriella* {1}, *O. helicovinosa* {1}, *O. macrocarpa* {1}, *O. multiaustraliensis* {1}, *O. multiserpens* {1}, *O. ?multivirgula* {1}, *O. myrioauris* {1}, *O. myriomuscula* {1}, *O. myrionamibica* {1/1}, *O. pleioaustraliensis* {2}, *O. pleiocoronohesperidea* {1}, *O. pleioungulata* {1}, *O. pleistoobliqua* {1}, *O. ?pseudeuphorbiae* {1}, *O. saguarina* {2}, *Ostropales* {2}, *Rhizodiscina* sp. {1}, ?*Triblidium* sp. {1}, *Symbiotaphrina desertorum* {1}, *Tryblidaria* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 67–560 m a.s.l. **Geology**: Mesoproterozoic and Cretaceous sedimentary rock (red-brown sand & gravel), Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriella* is easily recognized by its 64-spored asci and small, subcylindrical ascospores that

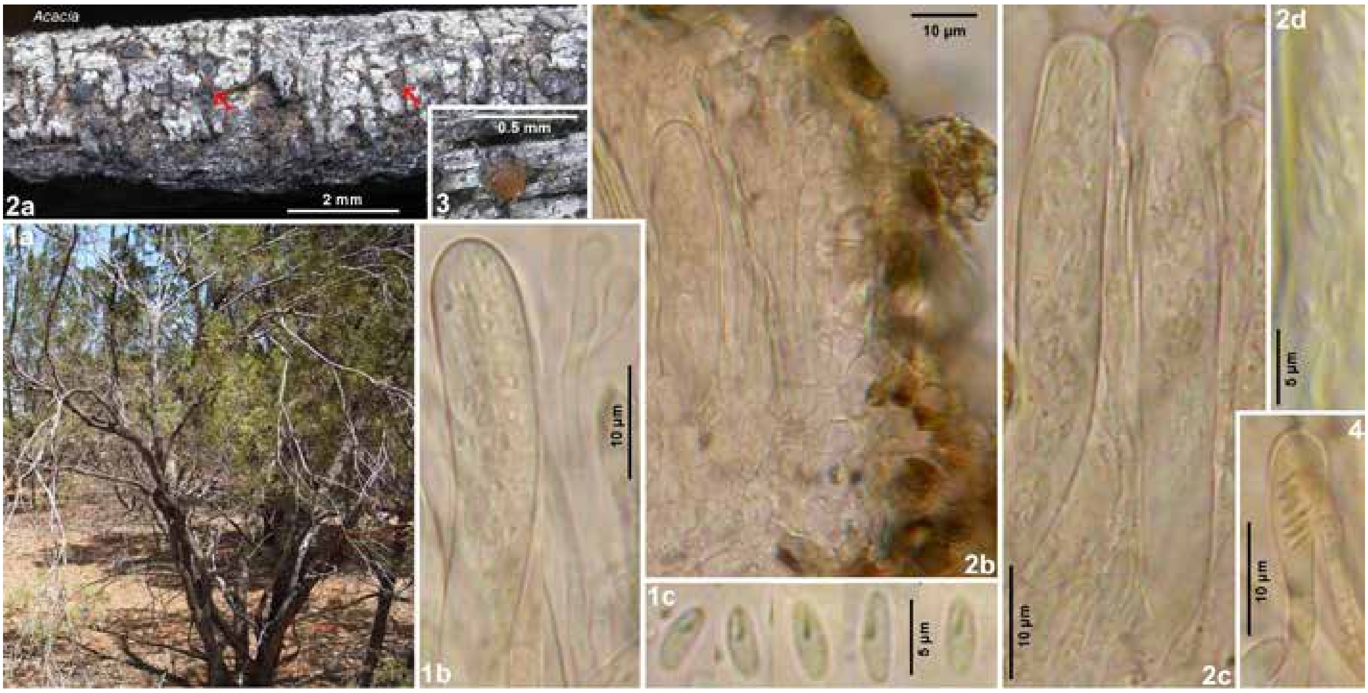

Plate 749. **1–3**: *Orbilia myriella*; **4**: *O.* aff. *myriella*. – **1a**. semiarid acacia shrubland with dead *Acacia* shrub in front; **2a**. corticated xeric branch; **3**. rehydrated apothecium; **2b**. marginal ectal excipulum in median section; **1b**, **2c**. asci and paraphyses; **1c**, **2d**. ascospores; **4**. paraphysis apex containing crystalloid SCBs. – Living state. — **1a–c**. H.B. 9050e: Western Australia, Geraldton, on *Acacia*; **2a–d**. H.B. 8727h: ibid., Carnarvon, on *Acacia*; **3**. H.B. 6277i (holotype): Northern Territories, on *Acacia*; **4**. H.B. 8997c: Carnarvon, on *Vachellia*.

contain narrowly rod-shaped spore bodies with, as a maximum, half the spore length. The North American *O. myrioolneyae* differs in slightly wider spores which usually show a stronger tendency to attenuated bases and obtuse apices (more ellipsoid-clavate, rarely with a short tail), also in wider SBs. For the similar *O. curvatimyriella* and *O. pleistovitalbae* see p. 1234 and p. 1192.

Not included collections. A sample on wood of *Vachellia* (Pls 748: 3: 749: 4) resembles *O. myriella* in the spores and SBs, but the paraphyses contained distinct crystalloid SCBs. A collection on *Eremaea* (IVV: H.B. 9132b) was only studied in the dead state.

Variation. A single ascus of *O. myriella* contained abnormal ovoid-subglobose spores *3–3.5 × 2.2–2.8 µm that resembled those of *O. myrioeuonymi*, even in SB shape, but that species has asci with hemispherical, thick-walled apices and belongs to section *Lentiformes*.

Ecology. *O. myriella* was found on rotten bark and wood of xeric twigs and branches of *Acacia* in subtropical arid (to semiarid) acacia open shrublands mainly in western but also central Australia (south of MacDonnell Ranges). The not included collection on *Vachellia* grew under similar conditions, that on *Eremaea* in a subtropical semihumid banksia-eucalypt woodland.

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, southern border of Collier Range, 175 km NE of Meekatharra, 41 km SW of Kumarina Roadhouse, 560 m, branch of *Acacia*, on bark, 26.XI.2001, G. Marson (H.B. 8697a ø). – Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, 67 m, twig of *Acacia*, on bark, 6.XI.2007, G. Marson (ex H.B. 8727h, mixture in MEL 2389251 [type of *O. myrioauris*]). – Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, branch of *Acacia*, on bark, 8.XI.2007, G. Marson (H.B. 9050e ø). — **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 480 m, twigs of *Acacia jennerae*, on wood, 10.X.1998, G. Marson (ex H.B. 6277i, MEL 2389202A, **holotype**).

Not included. **Western Australia**, Carnarvon, 117 km NNE of Carnarvon, 7 km SSE of Minilya Roadhouse, Barrabiddy Creek, 13 m, branch of *Vachellia farnesiana*, on wood, 6.XI.2007, G. Marson (H.B. 8997c ø). – Swan Coastal Plain, 20 km SW of Jurien Bay, 19.5 km NE of Cervantes, Cervantes Rd, 80 m, branch of *Eremaea*, on bark, 11.XI.2007, G. Marson (H.B. 9132b ø).

Orbilia curvatimyriella Baral & G. Marson, **sp. nov.**,
MB 813733 — Pls 750–751

Etymology: named after the curved ascospores and a resemblance to *O. myriella*.
Typification: Western Australia, Overlander Roadhouse, branch of *Acacia*, 6.XI.2007, G. Marson (ex H.B. 8727a, MEL 2389250, holotype).

Latin diagnosis: *Similis* Orbiliae myriellae *sed ascosporae valde curvatae, paulo majores, corpuscula refringentia longiora. Habitat ad corticem putridum ramorum siccorum* Acaciae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.13–0.25 mm diam., 0.1–0.14 mm high, light brick-orange, non-translucent, round, scattered; disc flat to slightly convex, margin indistinct, 0–5 µm protruding, finely rough; broadly sessile, ± immersed in biofilm or cracks of bark; dry almost invisible. **Asci** *58–73 × 8.8–10.2 µm, †54–68 × 7.8–8.3 µm, 64-spored (min. 40 spores counted), spores (*) multiseriate, basal spores inverted (strongly mixed), pars sporifera

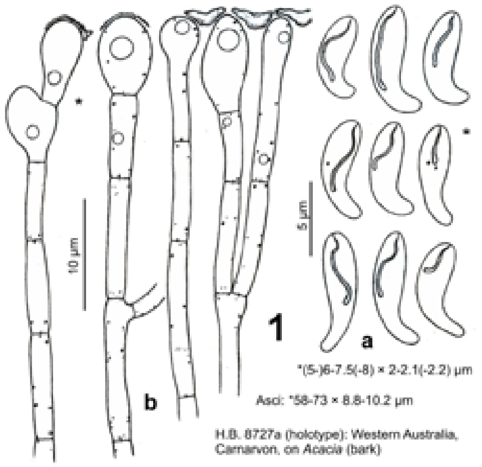

Plate 750. **1**: *Orbilia curvatimyriella*. – **a**. ascospores; **b**. paraphyses.

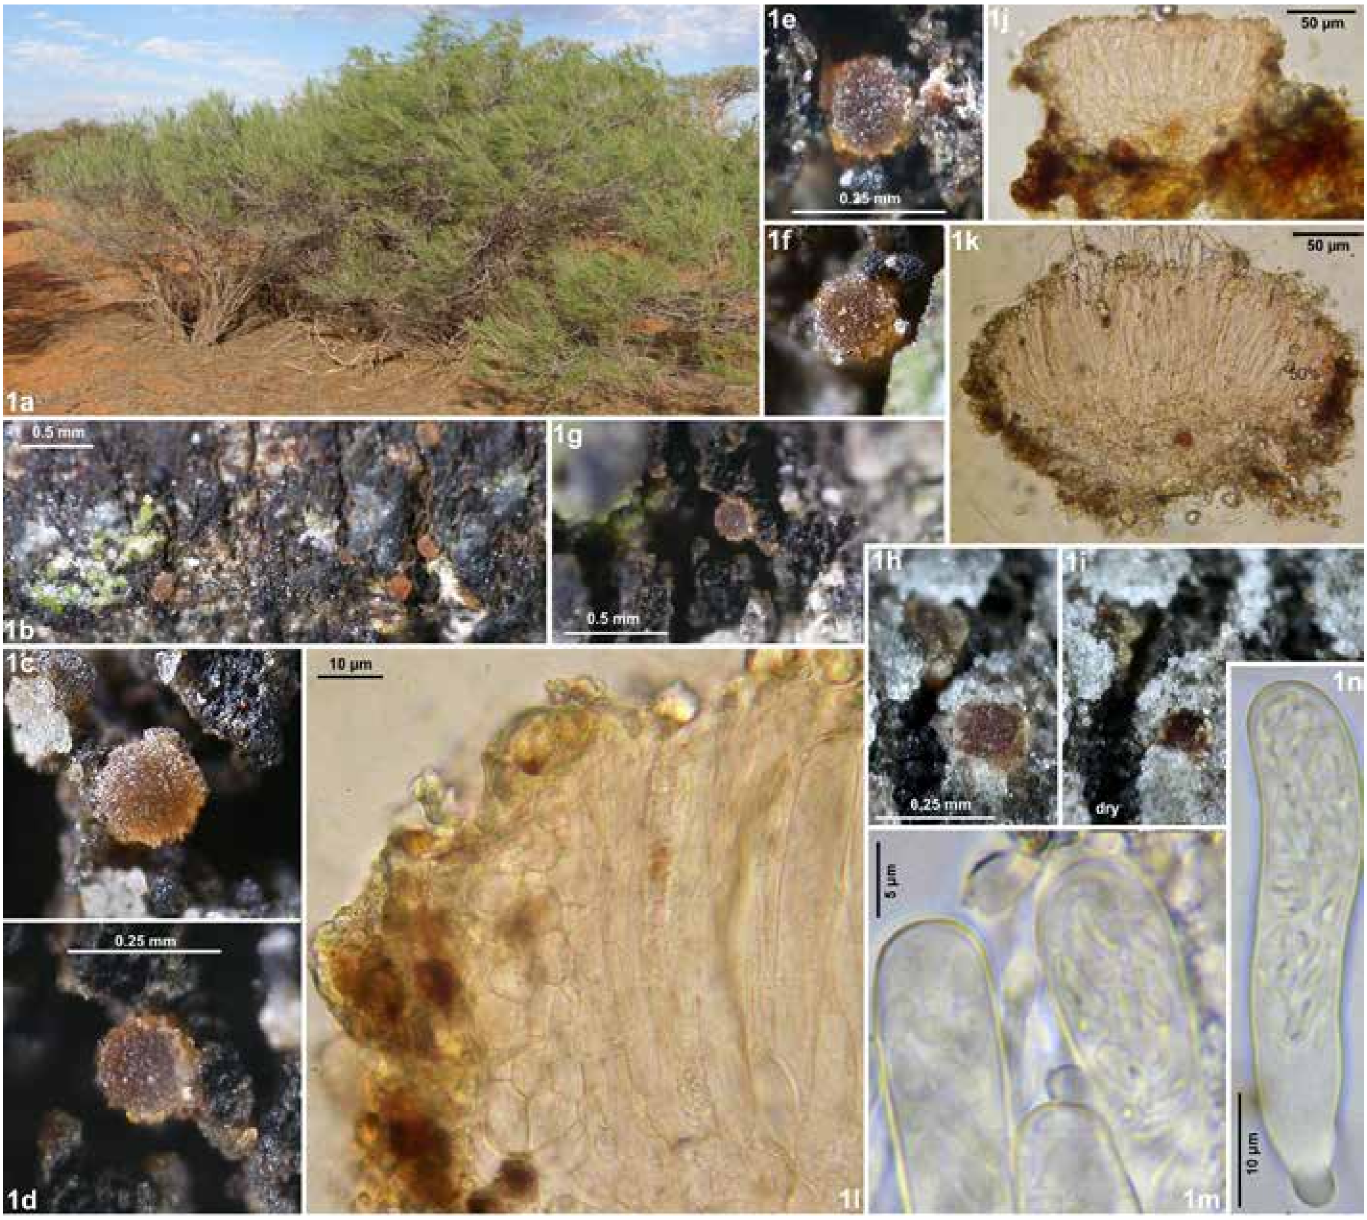

Plate 751. **1**: *Orbilia curvatimyriella*. – **1a**. arid acacia shrubland; **1b–h**. rehydrated apothecia; **1i**. dry apothecia; **1j–k**. apothecia in median section; **1l**. id., marginal ectal excipulum; **1m–n**. asci and paraphyses. – Living state. — **1a–n**. H.B. 8727a (holotype): Western Australia, Carnarvon, on *Acacia*.

*42–57 µm long; **apex** (†) (medium to) strongly truncate (not indented, laterally sometimes distinctly inflated); **base** unstalked or with short, thick stalk, Y- to h-shaped. **Ascospores** *(5–)6–7.5(–8) × 2–2.1(–2.2) µm, cylindric-ellipsoid to mostly ellipsoid-clavate, apex obtuse, base slightly to medium attenuated, here medium to often strongly curved; **SBs** *(2.7–)3.5–5.5 × 0.3–0.4(–0.5) µm in situ [~(3–)4–6 µm actual length], filiform to subulate, ± flexuous to helicoid. **Paraphyses** slightly to mostly medium to strongly clavate-capitate(-spathulate), terminal cells *(5–)7–17 × (1.8–)3–5 µm, lower cells *6–15 × 1.5–2(–2.7) µm; sometimes branched at upper septum. **Medullary excipulum** 15–40 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose, of thin-walled, irregularly (or horizontally) oriented t. (prismatica-)globulosa-angularis from base to mid flanks or margin, 15–25 µm thick near base, cells *8–11 × 6–9 µm; 10–20 µm thick near margin, oriented at a 0–20° angle to the surface, marginal cortical cells *6–12 × (3–)4–5(–6) µm. **Anchoring hyphae** sparse, †1.8–2 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose, 1–2 µm diam., in ectal excipulum (near margin) 1.5–2.5 µm. **Exudate** over paraphyses 0.3–1.5 µm thick, cloddy, ± loosely attached, over margin and flanks 0.2–2 µm thick, cloddy. — **ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, corticated, 6–8 mm thick branches of *Acacia* sp., on very decayed bark (bast), in cross-clefts of periderm, strongly greyed, with a few green algae. **Associated**: *Coccomycetella* sp., *Hysterobrevium mori*, *Orbilia myriella*, *O. myrioauris*, *O. ʔmyrionamibica*, *O. pleioaustraliensis*, *O. pleistoobliqua*, *O. ʔsaguarina*, *Ostropales*, *Tryblidaria* sp. **Desiccation tolerance**: fully viable for at least 7 weeks. **Altitude**: 67 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia curvatimyriella* is similar to *O. myriella*, from which it differs in slightly larger, consistently curved, basally always tapered ascospores, longer SBs, and apparently also wider asci. In spore characters *O. curvatimyriella* somewhat resembles taxa with different spore numbers, such as *O. quaestiformis* and *O. curvativitalbae* (8-spored), *O. saguarina* (16-spored), and *O. multivirgula* (32-spored). *O. myriofusoidea* differs in the presence of crystalloid SCBs, narrower SBs, and narrower asci.

Ecology. *O. curvatimyriella* was found on rotten bark of xeric branches of *Acacia* in an subtropical semiarid acacia open shrubland in western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, 67 m, branch of *Acacia*, on bark, 6.XI.2007, G. Marson (ex H.B. 8727a, MEL 2389250, **holotype**).

Orbilia myriofusoidea Baral, **sp. nov.**, MB 813738 — Pls 752–753

Etymology: named after the 64-spored asci and fusoid ascospores.

Typification: Western Australia, Wittenoom, branch of *Acacia*, 29.X.2007, G. Marson (ex H.B. 8976b, MEL 2389269, holotype).

Latin diagnosis: *Similis* Orbiliae curvatimyriellae *sed ascosporae basi valde attenuatae, cellulae vivae excipuli et paraphysium corpuscula crystalloidea pallide aurantiaca continentes. Habitat ad lignum putridum ramorum siccorum* Acaciae *in zona tropica arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.3 mm diam., 0.17–0.19 mm high, pale light dirty orange, indistinctly translucent, round, scattered; disc slightly concave to flat, margin thin, not protruding, smooth; broadly sessile, ± superficial but immersed in cracks. **Asci** †70–85 × 6.7–7.6 µm, 64-spored (~50 spores counted), spores (†) multiseriate; **apex** (†) strongly truncate (partly distinctly indented and/or laterally inflated); **base** with short to medium long, ± thick, flexuous stalk, L-shaped. **Ascospores** *7.2–8.5(–9.5) × 2.1–2.3 µm, ellipsoid-fusoid-clavate, apex obtuse, base medium to mostly strongly attenuated, slightly to medium curved near base; **SBs** *3.2–4.2 × 0.2(–0.3) µm in situ (~3.5–5 µm actual length), filiform, somewhat flexuous. **Paraphyses** apically medium to strongly clavate-capitate, terminal cells *9–15 × 4–5.7 µm, lower cells *12–26 × 1.5–2 µm (up to 4 µm wide above); unbranched near apex. **Medullary excipulum** 25–50 µm thick, of ± dense textura intricata with many inflated cells, medium to sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, vertically or indistinctly oriented t. angularis(-prismatica) from base to (sub)margin, 40–60 µm thick near base, cells */†8–23 × 6–13 µm; 20–30 µm thick near margin, of t. angularis-prismatica, marginal cortical cells †7–12 × 3–5 µm, slightly gelatinized. **Anchoring hyphae** sparse to abundant, †2.5–3 µm wide, walls 0.2 µm thick, partly extending as a covering layer up to the margin. **SCBs** in paraphyses globose, 2–3 µm diam., in paraphyses and ectal excipulum (near margin) also crystalloid, pale orange. **Exudate** over paraphyses 0.2–0.4 µm thick, continuous, loosely attached, over margin and flanks indistinct. **— ANAMORPH**: unknown.

Habitat: decorticated, 11–12 mm thick branches of *Acacia* sp., on 0.5 mm deep very decayed wood, strongly greyed (blackened), without algae. **Associated**: *Lophiostoma* sp., *Orbilia coronohesperidea*, *O. microserpens*, *O. pleiocoronohesperidea*, *O. pleioserpens*, *Ostropales*, *Patellaria* '*andina*', ?*Teichospora* sp., ?*Trimmatostroma* sp. **Desiccation tolerance**: excipular cells, paraphyses and many spores still viable after 14 months. **Altitude**: 467 m a.s.l. **Geology**: Precambrian sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriofusoidea* closely resembles *O. curvatimyriella*, from which it mainly differs in the presence of crystalloid SCBs, narrower SBs, and narrower asci. The ascospores also tend to be more tapered at their less curved bases. The North American *O. multivirgula* differs in 32-spored asci, narrower spores, and absence of any kind of SCBs. The central Australian *O. myrionamibica* deviates in straight, basally much less tapered, wider spores with longer and thicker SBs.

Ecology. The very sparse apothecia, which were almost used up during examination, were detected on rotten wood of xeric branches of *Acacia* in a tropical arid acacia open shrubland in the mostly dry delta of the Wittenoom Gorge in the Pilbara desert of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 1.5 km SW of Wittenoom, N of Karijini, Wittenoom Gorge, 467 m, branch of *Acacia*, on wood, 29.X.2007, G. Marson (ex H.B. 8976b, MEL 2389269, **holotype**).

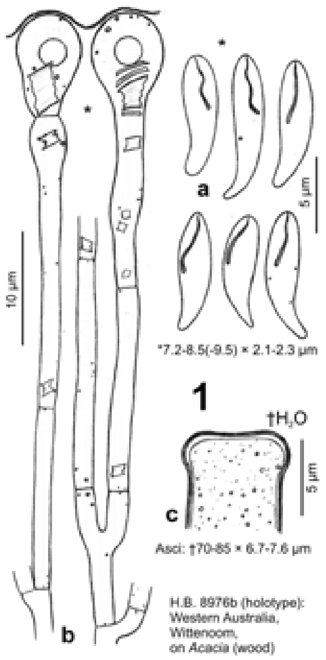

Plate 752. **1**: *Orbilia myriofusoidea*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

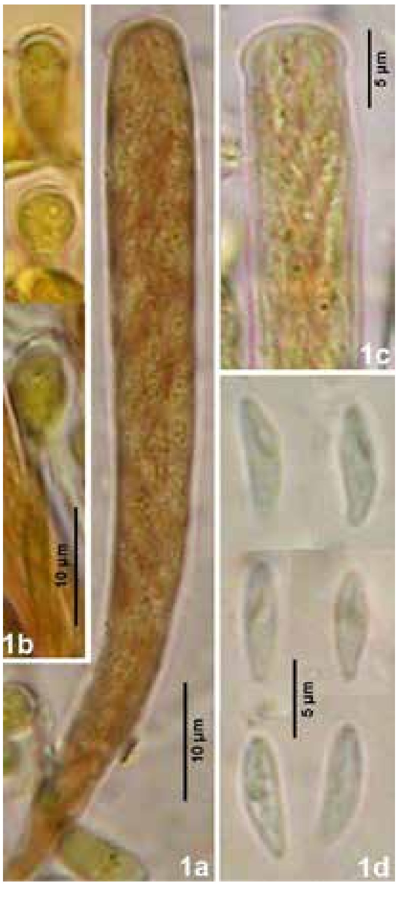

Plate 753. **1**: *Orbilia myriofusoidea*. – **1a**. ascus; **1b**. apices of paraphyses; **1c**. ascus apex; **1d**. ascospores. – Dead state (in KOH+IKI), except for **1d**. — **1a–d**. H.B. 8976b (holotype): Western Australia, Wittenoom, on *Acacia*.

Orbilia multivirgula Baral & G. Marson, **sp. nov.**, MB 813739 — Pls 754–755

Etymology: referring to the 32-spored asci and the comma-shaped ascospores (from French virgule = comma).

Typification: USA, New Mexico, Carlsbad, branches of *Larrea tridentata*, 17.VI.1996, G. Marson (ex H.B. 5682b, M-0276528, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–0.75 mm diam., aurantiaca, margine laevi. Asci 32-spori. Ascosporae *6–11.2 × 1.4–2 µm, angusto-clavatae, ad basim valde attenuatae, etiam subcylindricae, subrectae vel saepe valde curvatae, in statu vivo corpusculum refringens breve, filiforme, subrectum ad uncinatum, ad apicem affixum continentes. Paraphyses ad apicem valde clavato-capitatae. Cellulae vivae excipuli et paraphysium absque corpusculis globosis et crystalloideis. Habitat ad lignum putridum ramorum siccorum* Larreae tridentatae *in zona temperata semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.75 mm diam., 0.14–0.2 mm high, light (pure or dirty) orange, round to ± elliptical, scattered to ± gregarious; disc slightly concave to flat, margin distinct, 5–15 µm protruding, smooth; sessile, with or without a ± obconical base, slightly to entirely immersed among fibres. **Asci** *60–75(–89) × 6.5–7.4 µm, †55–70(–75) × 5.3–6.5 µm, 32-spored (25–30 spores counted), spores ~4-seriate, lower spores inverted (strongly mixed), pars sporifera *35–43 µm long; **apex** (†) strongly truncate (sometimes slightly indented and laterally widened); **base** with short to medium long, thick stalk, T-, L- or Y-shaped. **Ascospores** *6–9.7(–11.2) × 1.4–1.8(–2) µm, †6–9 × 1.3–1.5 µm, subcylindrical to narrowly clavate, apex rounded to obtuse, base not or mostly slightly to strongly attenuated in a ± long tail-like end, straight or often slightly to strongly curved (comma-shaped); **SBs** *2.5–4.7 × 0.2–0.3 µm, filiform-subulate, base not inflated, mostly slightly to strongly flexuous, sometimes uncinate. **Paraphyses** apically medium to (very) strongly clavate-capitate, also spathulate, terminal cells *9.5–26 × (3–)4–5.5(–6.5) µm, lower cells *8–10 × 1.7–2.2(–3) µm; unbranched near apex, hymenium light rose. **Medullary excipulum** hyaline, 20–70 µm thick, of ± dense textura intricata with many inflated cells, medium to very sharply delimited. **Ectal excipulum** pale rose, of non- to medium gelatinized (common walls up to †1–1.5 µm thick), vertically oriented t. angularis from base to (sub)margin, 25–65 µm thick near base, cells *11–26 × 8–19 µm, †7–10 × 5–9 µm; 35–40 µm thick at flanks, 15–35 µm near margin, marginal cortical cells *7–12 × 4–7 µm, oriented at a low angle, terminated by dead hyphoid cells †5–11 × 2–3 µm. **Anchoring hyphae** sparse to abundant, 1.8–3 µm wide, walls 0.2–0.5 µm thick, forming a ± dense t. intricata up to 100 µm thick; margin and flanks covered by an 8–10 µm thick hyaline layer of gelatinized t. intricata-porrecta. **SCBs** in paraphyses and ectal excipulum absent. **Exudate** over paraphyses 0.2–1.5 µm thick, finely to roughly granular; over margin and flanks 0.2–2 µm thick, granular-cloddy. — **ANAMORPH**: unknown.

Habitat: collected 0.2–1 m above the ground, decorticated, 7–11 mm thick branches of *Larrea tridentata*, on 0.3 mm deep very decayed, eroded wood, medium to strongly greyed or blackened, with some or many green algae. **Associated**: *Orbilia* ?*multidelphinus*, *O. pleioserpens*, *Patellaria* '*andina*', *P. atrata*. **Desiccation tolerance**: fully viable for at least 6 months. **Altitude**: 915 m a.s.l. **Geology**: Quaternary deposits from Upper Permian sandstone. **Phenology**: long-lived.

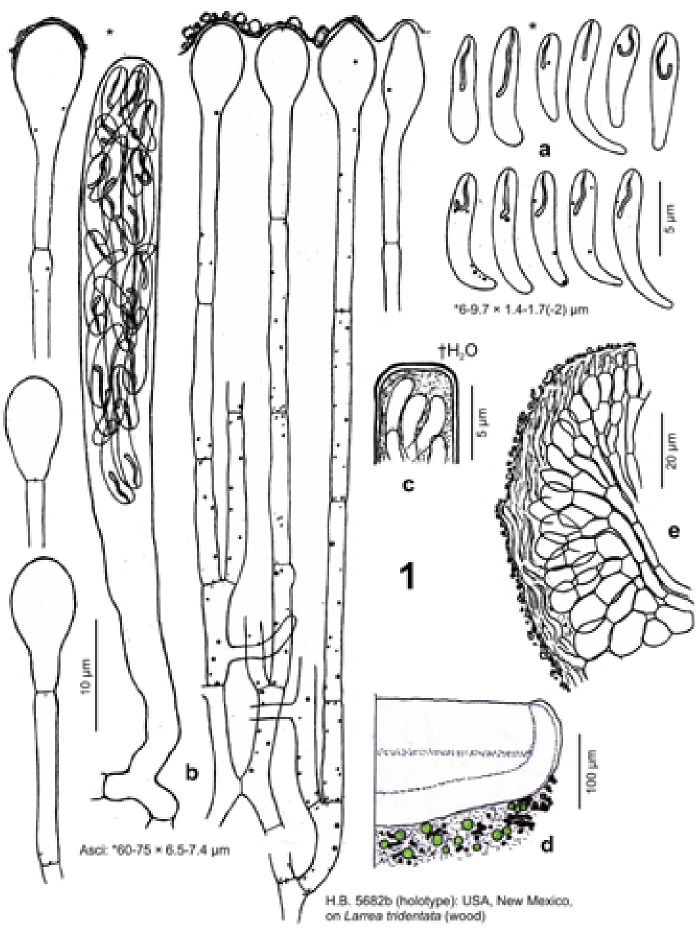

Plate 754. **1**: *Orbilia multivirgula*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Taxonomic remarks. *Orbilia multivirgula* is characterized by narrowly cylindric-clavate, often basally ± strongly attenuated and curved (comma-shaped) ascospores that contain short, narrowly subulate SBs, and by 32-spored asci. *O. myriella*, *O. curvatimyriella* and *O. myriofusoidea* are similar but differ in 64-spored asci and large globose SCBs, the latter also in crystalloid SCBs, and the former in much shorter, basally scarcely attenuated, less curved spores. *O. namibica* differs from *O. multivirgula* in much wider and likewise less curved and tapered spores, also in the presence of crystalloid SCBs. The large heads of the paraphyses and the absence of any kind of

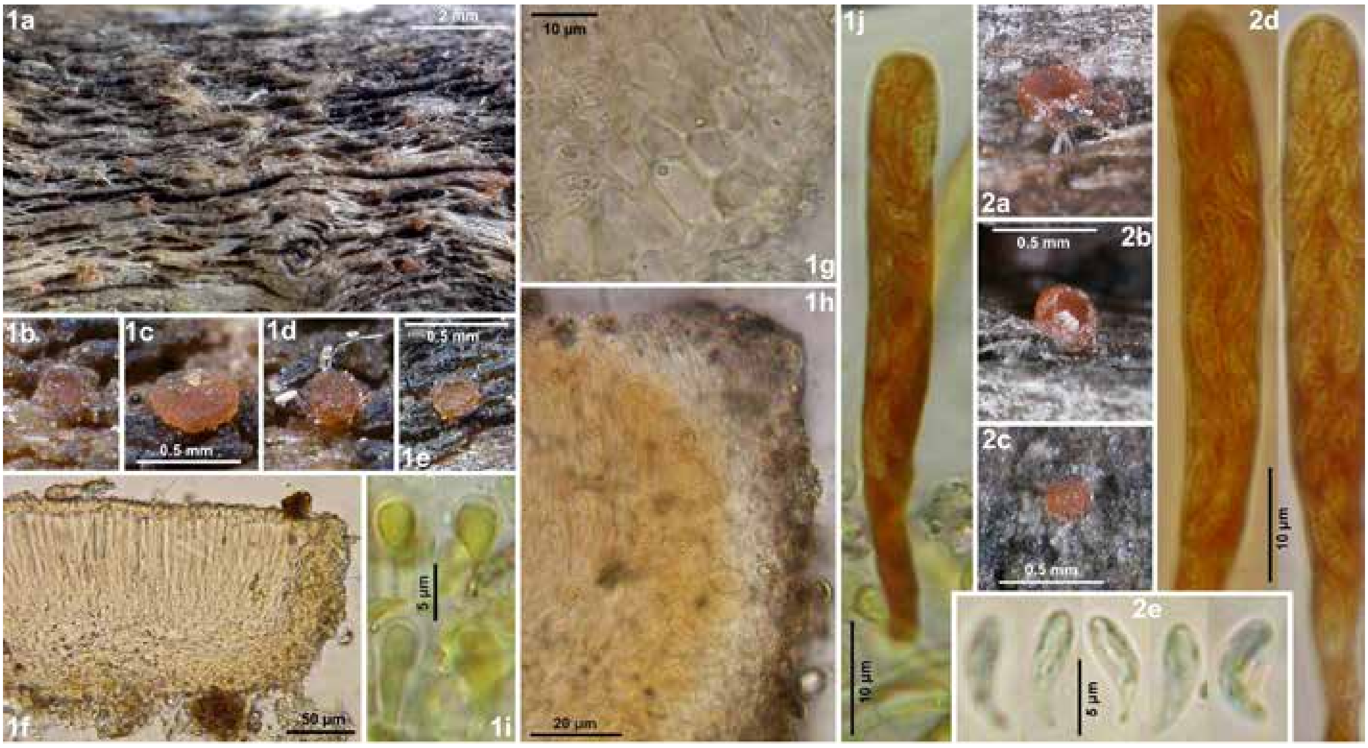

Plate 755. **1**: *Orbilia multivirgula*; **2**: *O.* aff. *multivirgula*. – **1a–e**, **2a–c**. rehydrated apothecia; **1f**. apothecium in median section; **1h**. id., marginal ectal excipulum; **1g**. id., basal excipular cells; **1i**. apices of paraphyses; **1j**, **2d**. asci; **2e**. ascospores. – Dead state (**2e** in H_2O, **1g–h** in KOH, **1i–j**, **2d** in KOH+IKI). — **1a–j**. H.B. 5682b (holotype): USA, New Mexico, on *Larrea*; **2a–e**. H.B. 9033b: Western Australia, Geraldton, on *Acacia*.

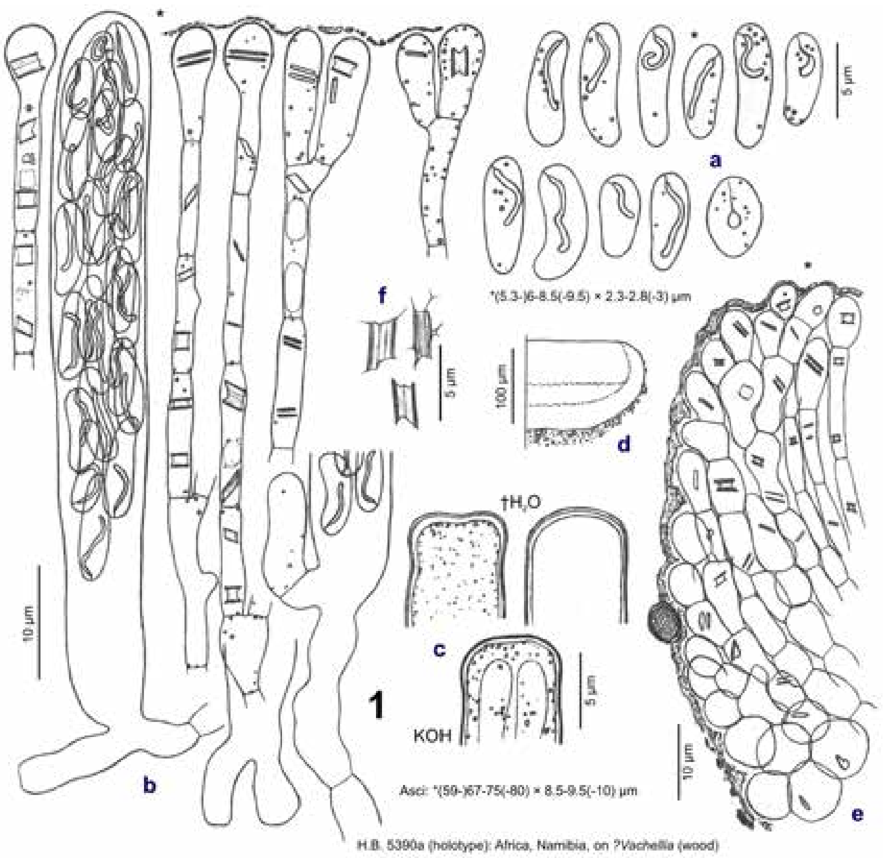

Plate 756. **1**: *Orbilia namibica*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs in ectal excipulum near margin.

SCBs in *O. multivirgula* suggest a relation to *O. microserpens* and *O. multiserpens*. In spore and SB shape it resembles the 8-spored *O. quaestiformis*.

Not included collections. Three Australian samples were only studied in the dead state. In one on *Acacia* the spores (†10.5–12.5 × 1.4–1.7 µm) are cylindrical and ± bent below (IVV: H.B. 8697i). Another on *Acacia* (Pl. 755: 2) has more ellipsoid, distinctly wider spores compared to *O. multivirgula*, but they are too narrow to be included in *O. multiurosperma*. One on *Dodonaea* (IVV: H.B. 8838f) mainly differs in 16-spored asci (spores †8–10 × 1.6–1.8 µm, as ***O. pleiovirgula*** Baral, nom. prov.).

Ecology. *O. multivirgula* was detected on rotten wood of xeric branches of *Larrea tridentata* (creosotebush) in a warm-temperate semiarid Chihuahuan creosotebush-tarbush desert scrub (at border to Mesa and Plains) in the south of Northern America. The not included collections are from subtropical semiarid to arid acacia shrublands or open woodlands on Mesoproterozoic and Cretaceous sedimentary rock in western Australia.

Specimens included. **USA**: **New Mexico**, Chihuahuan Desert, 25.5 km SE of Carlsbad, Malaga, 915 m, branches of *Larrea tridentata*, on wood, 17.VI.1996, G. Marson (M-0276528, **holotype**, **isotype** in H.B. 5682b).

Not included. **AUSTRALIA**: **Western Australia**, Gascoyne, southern border of Collier Range, 175 km NE of Meekatharra, 41 km SW of Kumarina Roadhouse, 560 m, branch of *Acacia*, on bark, 26.XI.2001, G. Marson (H.B. 8697i ø). – Yalgoo, 200 km N of Geraldton, 15 km SSE of Wannoo Billabong Roadhouse, W of Toolonga, 157 m, branch of *Acacia*, on wood & bark, 8.XII.2001, G. Marson (H.B. 9033b).

O. pleiovirgula: **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, trunk of *Dodonaea viscosa* subsp. *angustissima*, on bark, 8.XI.2007, G. Marson (H.B. 8838f).

Orbilia namibica Baral & G. Marson, **sp. nov.**, MB 813740 — Pl. 756

Etymology: named after the geographical origin of the holotype, Namibia.

Typification: Namibia, Rehoboth, branch of ?*Vachellia*, 25.VIII.1995, R. Reuter (ex H.B. 5390a, M-0276535, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–0.3 mm diam., aurantiaca, margine laevi. Asci 32-spori. Ascosporae *5.3–9.5 × 2.3–2.9 µm, subcylindricae, rectae vel leniter curvatae, in statu vivo corpusculum refringens breve vel longum, vermiforme, subrectum ad uncinatum, ad apicem vel subapicem affixum continentes. Paraphyses ad apicem leniter vel valde clavato-capitatae. Cellulae vivae excipuli et paraphysium corpuscula crystalloidea sublutea continentes. Habitat ad lignum putridum rami sicci arboris angiospermae in zona subtropica arida Africae austro-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.3 mm diam., 0.12–0.17 mm high, light (dirty) orange, round, gregarious in small groups; disc slightly concave, margin 0–25 µm protruding, ± smooth; sessile; dry deep dirty orange-red. **Asci** *(59–)67–75(–80) × 8.5–9.5(–10) µm, †54–60 × 6.4–7.8(–8.5) µm, 32-spored, spores *4–6-seriate, lower spores inverted (strongly mixed), pars sporifera *38–50 µm long; **apex** (†) slightly to strongly truncate (distinctly indented, laterally sometimes inflated); **base** not or very short- and thick-stalked, T- to h-shaped. **Ascospores** *(5.3–)6–8.5(–9.5) × 2.3–2.9 µm, †6.5–8.2 × 2–2.4 µm, subcylindrical to sometimes clavate, both ends rounded, base often slightly attenuated, straight to slightly curved; **SBs** apically or mostly subapically attached to spore wall, *(3–)4–6.2 × 0.4–0.6(–0.8) µm in situ (~5–7 µm actual length), vermiform, base not inflated, slightly to strongly flexuous (sometimes uncinate), in more aged or aberrant spores with broadly tear- to stomach-shaped lower and filiform upper part. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells *7–16.5 × 2.5–4.3 µm, lower cells *10–15 × 1.7–2.4(–2.8) µm; sometimes branched near apex, upper part of hymenium pale orange. **Medullary excipulum** pale yellowish-reddish, 30–40 µm thick, of ± dense textura intricata with many inflated cells, rather sharply delimited. **Ectal excipulum** subhyaline, of thin-walled, vertically oriented t. globulosa-angularis from base to mid flanks, 30–50 µm thick near base, cells *(7–)10–16(–20) × 8–13 µm; 20 µm thick at mid flanks and margin, oriented at a 40 → 20° angle to the surface, marginal cortical cells *5–12 × 3.5–5.5 µm. **Anchoring hyphae** very sparse, *2–4 µm wide, walls 0.3 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) very pale yellowish, rod-, spool- or ring-shaped. **Exudate** over paraphyses 0.5–1 µm thick, finely granular, loosely attached; over margin and flanks 1–3 µm thick, cloddy-granular, hyaline. **— ANAMORPH**: unknown.

Habitat: collected 0.2–1.2 m above the ground, decorticated, 30 mm thick branches of ?*Vachellia*, on 0.2 mm deep medium decayed wood, greyed. **Associated**: *Hysterobrevium mori*, *Orbilia maeandrina*, *O. myrioflexa*, *O. pluristomachia*, *Patellaria atrata*, ?*Peniophora* sp., *Teichospora* ?*obducens*, 3 different indet. coelomycetes. **Desiccation tolerance**: fully viable for at least 3.5 months. **Altitude**: 1560 m a.s.l. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia namibica* is characterized by subcylindrical, slightly clavate ascospores and vermiform, mostly subapically inserted SBs, also by the presence of crystalloid SCBs. The North American *O. multicercocarpi* and *O. multigambelii* differ in always apically inserted SBs, also in usually shorter and wider, more ellipsoid spores. *O.*

multicercocarpi approaches *O. namibica* in the more elongate spores. The mainly Australian *O. multiserpens* (Pl. 744: 5) resembles *O. namibica* in the shape of spores and SBs, but has smaller spores and is consistently without crystalloid SCBs.

Variation. Very few asci contained only aberrant, broadly ellipsoid spores with tear-shaped SBs with a long filum (Pl. 756: 1a, lower right spore).

Ecology. *O. namibica* was found on medium decayed wood of a xeric branch of an unidentified angiosperm tree (?*Vachellia*) in the hot, subtropical arid (winter-dry) Kalahari highland thornbush savannah about 150 km away from the Namib Desert in southwestern Africa.

Specimens included. **NAMIBIA**: **Khomas**, 60 km S of Windhoek, 25 km N of Rehoboth, Central Plateau, Auas Mts., 1560 m, branch of *?Vachellia*, on wood, 25.VIII.1995, R. Reuter (ex H.B. 5390a, M-0276535, **holotype**).

Orbilia myrionamibica Baral, **sp**. **nov**., MB 813741 — Pls 757–758

Etymology: referring to the 64-spored asci and the resemblance to *O. namibica*. **Typification**: Australia, Northern Territories, Curtin Springs Roadhouse, twig of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277g, MEL 2389202B, holotype).

Latin diagnosis: *Similis* Orbiliae namibicae *sed asci 64-spori. Habitat ad lignum putridum ramulorum siccorum* Acaciae *in zona subtropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.4 mm diam., 0.12 mm thick, light (yellowish-)orange(-rose), round, scattered; disc concave to flat, margin smooth or finely rough, 0–20 µm protruding; sessile, erumpent to entirely immersed. **Asci** *80–90 × 10–11.5 µm {T}, †70–90 × 8–9.7 µm {1}, 64-spored (> 50 spores counted), spores multiseriate, lower spores inverted (very strongly mixed), pars sporifera *46–65 µm long; **apex** (†) strongly truncate (sometimes slightly indented and laterally inflated); **base** unstalked or with short thick stalk, Y- to h-shaped. **Ascospores** *6–8 × 2.2–3 µm {T}, †(4.2–)6–7(–7.7) × 2.4–2.9 µm {1}, subcylindrical to (fusoid-) clavate, apex rounded (to obtuse), base not or often slightly (to medium) attenuated, straight or sometimes slightly inequilateral; **SBs** apically or partly subapically attached to spore wall, *(3–)4.5–6(–7) × 0.3–0.6 µm in situ {T} [~(4–)5–7(–8) µm actual length], vermiform to subulate, base not or sometimes slightly inflated, medium to strongly flexuous, sometimes uncinate. **Paraphyses** apically medium to very strongly capitate(-clavate), sometimes moniliform, terminal cells *8–16 × 2.5–5.5(–6.5) µm {T}, subapical cell sometimes also strongly inflated (up to 5.5 µm), lower cells *6–17 × 1.7–3 µm {T}; very rarely branched near apex. **Medullary excipulum** very pale orange, 30 µm thick, of dense t. intricata with some inflated cells, sharply delimited. **Ectal excipulum** pale orange, from base to margin of 20 µm thick, indistinctly oriented, (†) thin-walled t. angularis, cells at base †5–10 × 4–7 µm {1}, upper margin of t. porrecta oriented at a low angle, marginal cortical cells †8–11 × 4–4.5 µm {1}. **Anchoring hyphae** abundant, †1–2.5 µm wide, wall 0.2 µm thick, covering exterior up to the margin as a thin layer. **SCBs** in paraphyses globose, 1.3–2 µm diam., in paraphyses and ectal excipulum (near margin) crystalloid, pale orange, spool-shaped {T}. **Exudate** over paraphyses and margin 0.1–0.5 µm thick, very finely rough, ± firmly attached. **— ANAMORPH**: unknown.

Habitat: lying on dry ground, decorticated, 2–9 mm thick twigs and branches of *Acacia* sp. {1}, *Acacia jennerae* {T}, on 0.3 mm deep strongly decayed wood {2}, greyed, no algae. **Associated**: *Baggea* sp. {1}, *Coccomycetella* sp. {1}, *Orbilia angustoaristata* {1}, *O. austropleiomicrosoma* {1}, *O. coronohesperidea* {1}, *O. multiaustraliensis* {1}, *O. multiserpens* {1}, *O. myriella* {1}, *O. pleioaustraliensis* {1}, *O. pleiocoronohesperidea* {1}, *O. ?pleioserpens* {1}, *Ostropales* {1}, *Symbiotaphrina desertorum* {2}. **Desiccation tolerance**: fully viable for at least 1 month. **Altitude**: 480–605 m a.s.l. **Geology**: Proterozoic and Cretaceous sedimentary rock (red-brown gravel), Cenozoic regolith (sand); granite. **Phenology**: long-lived.

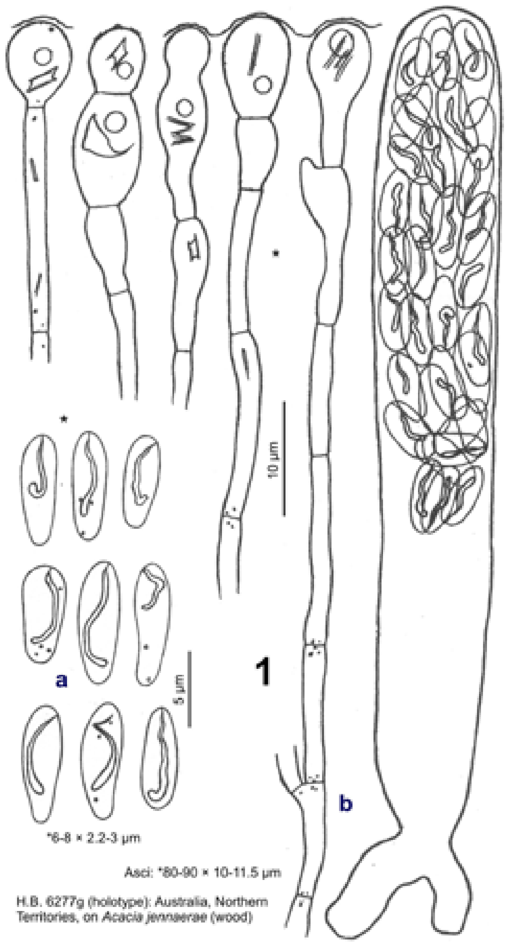

Plate 757. **1**: *Orbilia myrionamibica*. – **a**. ascospores; **b**. ascus and paraphyses.

Taxonomic remarks. *Orbilia myrionamibica* is characterized by 64-spored asci, otherwise it is similar to the African *O. namibica*. Although collected in different continents, the two species appear to be more closely related than is *O. namibica* to *O. myrioflexa* which both grew on the very same branch. The latter differs from *O. myrionamibica* in shorter, more clavate ascospores with thinner SBs which are always apically attached and always longer than the spores, also in narrower asci. In spore morphology *O. myrionamibica* resembles *O. microsoma* and *O. multimicrosoma*, from which it differs in the higher spore number and in showing crystalloid SCBs.

Only two apothecia were detected in the holotype of *O. myrionamibica* among the eight further, macroscopically almost indistinguishable species of *Orbilia*. One of them is assigned to *O. multiserpens*, which has spores and SBs very similar to *O. myrionamibica* but differs in 32-spored asci, somewhat shorter spores and in lacking crystalloid SCBs.

The paratype is tentatively placed here because it was only studied in the dead state. Its spores are partly shorter but vary strongly in length.

Not included collection. Another sample on *Acacia* (Pl. 758) differs in shorter, more homopolar spores (*4.4–5.6 × 2.2–2.4 µm) and narrower asci (*9–9.2 µm).

Phylogeny. A sequence was taken from apothecia of the paratype, comprising S1506 intron, ITS, and LSU D1–D2. However, the apothecia were only examined after the DNA was extracted, so there is some uncertainty because also *O.*

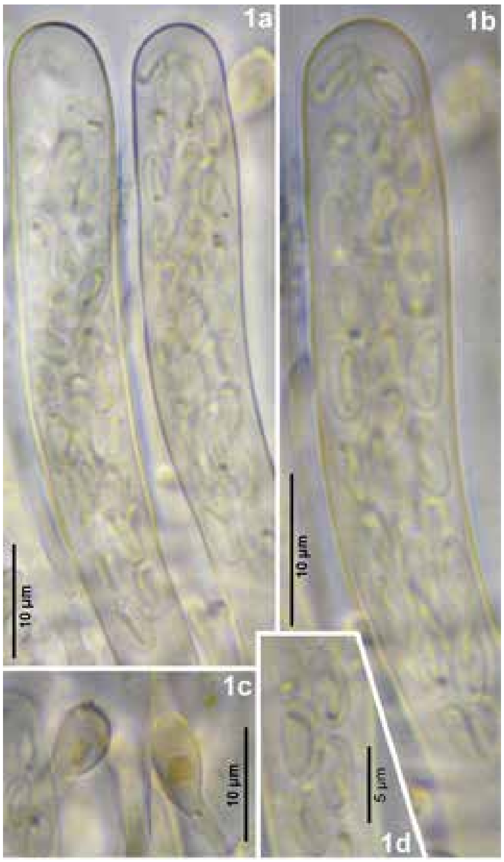

Plate 758. **1**: *Orbilia* cf. *myrionamibica*. – **1a–b**, **d**. asci and ascospores (**1a** & **b** at different scale); **1c**. apices of paraphyses. – Living state. — **1a–d**. H.B. 8727l: Western Australia, Carnarvon, on *Acacia*.

cf. *pleioserpens* was once observed on the branches (this was likewise only studied in the dead state and no documentation exists for it). *O. myrionamibica* clustered with medium support in the *microserpens*-*ungulata* clade when analysing SSU+ITS+LSU (Phyl. 20). The ITS distance lies in the range of 3.5–4.7% to *O. cisti*, *O. macroserpens*, *O.* cercocarpi, and *O. microserpens*. In the LSU (D1–D2) the closest taxon was *O. cercocarpi* (0.2%, 1 nt), but several other species differ by only 2–3 nt. In the intron region the closest species were *O. cisti* and *O. calyptrata* (~13%).

Ecology. *O. myrionamibica* is only known from two very sparse collections on rotten wood of xeric twigs and branches of *Acacia* in subtropical arid acacia open shrublands around the MacDonnell Ranges in central Australia. The not included collection was in a subtropical semiarid acacia shrubland in western Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 480 m, twig of *Acacia jennerae*, on wood, 10.X.1998, G. Marson (H.B. 6277g, MEL 2389202B, **holotype**). – MacDonnell Ranges, 11 km W of Alice Springs, 5 km N of White Gums, Larapinta Drive, 605 m, branch of *Acacia*, on wood, 13.X.1998, G. Marson (H.B. 10119a ø; sq.: MH221070).

Not included. **AUSTRALIA**: **Western Australia**, Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, 67 m, twig of *Acacia*, 6.XI.2007, G. Marson (H.B. 8727l ø).

Subgenus *Orbilia*

Orbilia Fr. subgenus ***Orbilia*** – Lectotype species: *Orbilia xanthostigma* (Fr.) Fr.

Description: — **TELEOMORPH**: **Apothecia** hydrated whitish, ochraceous, yellowish, rose, orange, lilaceous, rarely red, purplish-brownish or olivaceous-black, margin glabrous or crenulate, denticulate to dentate, or hairy, sessile or (short-)stipitate. **Ascus apex** (†) slightly to medium to strongly truncate, not or slightly to distinctly indented and laterally inflated, hemispherical in profile view, thin-walled, rarely with 1–1.4 µm thick dome, sometimes with apical chamber (section *Ovoideae* p.p.); **base** T-, L-, Y-, h- or H-shaped. **Ascospores** variously shaped; **SBs** apically, rarely laterally affixed to spore wall, globose to tear-shaped, subulate, rod-shaped, plug-shaped, dumbbell-shaped or ampulliform, rarely lens-shaped, attachment invisible or apically narrowed to a small or wide point, filum absent or very short. **Paraphyses** apically uninflated to strongly capitate-clavate, also spathulate to lanceolate. **— ANAMORPH**: arthrobotrys-like, dactylella-like, dactylellina-like, descalsia-like, dicranidion-like, drechslerella-like, gamsylella-like, trinacrium-like, vermispora-like. **Trapping organs**: unknown in sections *Ovoideae* and *Orbilia*, often present in section *Arthrobotrys*.

Habitat: on wood and bark of gymno- and angiosperms, also caulicolous, foliicolous, fungicolous, or coprophilous, from boreal to tropical climates, desiccation-tolerant or -sensitive.

Recognized sections: *Arthrobotrys*, *Orbilia*, and *Ovoideae*, with 150 recognized species (35 of them without known teleomorph, further 67 anamorphic species of section *Arthrobotrys* not treated here) plus 2 with a provisional name and 27 unnamed species ('affinis').

Taxonomic remarks. Subgenus *Orbilia* represents an assemblage of quite different morphological and ecological groups. It is circumscribed here more on the basis of morphological than phylogenetic data and includes three sections: *Ovoideae*, *Orbilia*, and *Arthrobotrys*. Characteristic are the truncate, thin-walled ascus apex and the frequent presence of an H-shaped ascus base, also the terminal cells of paraphyses being usually much longer than the lower cells. However, section *Ovoideae* deviates more or less hereof. Similar as in subgenus *Habrostictis*, desiccation-tolerant taxa occur along with desiccation-sensitive taxa, except that section *Ovoideae* and series *Microsomates* of section *Orbilia* comprise exclusively desiccation-tolerant taxa.

Section delimitation: Members of section *Ovoideae* approach subgenus *Hemiorbilia* in their ascus characters and short terminal cells of paraphyses. These two groups share also the desiccation tolerance of all their members, therefore, we believe that they have preserved some plesiomorphic characters of the genus *Orbilia*. Section *Ovoideae* is defined by a rather primitive ascospore and SB shape, but such spores and SBs also occur in section *Orbilia*.

Sections *Orbilia* and *Arthrobotrys* share paraphyses with more or less long terminal cells in comparison to the lower cells, the frequency of an H-shaped ascus base, and ascospores with comparatively small SBs. Their delimitation is problematic because they are linked to morphologically intermediate taxa which cluster in series *Neodactylella*. For a key to the sections of subgenus *Orbilia* see p. 452.

Anamorphs. In section *Ovoideae* curved phragmoconidia (vermispora-like) were observed as presumed anamorphs. Stauroconidia are frequent in section *Orbilia* (mainly dicranidion-like), but also curved (vermispora-like) and straight phragmoconidia occur. Stauroconidia of an extraordinary type characterize series *Microsomates*. Didymo- or phragmoconidia are typical of section *Arthrobotrys*, being straight or sometimes curved, with or without swollen central or terminal cell, exceptionally branched (trinacrium-like). Most members of section *Arthrobotrys* possess predatory capabilities, with the exception of series *Neodactylella*, but two predacious taxa with rather primitive trapping organs (*Tridentaria implicans*, *Dicranidion dactylopagum*) possibly belong to series *Orbilia*.

Phylogeny. Subgenus *Orbilia* clustered in the analysis of Baral et al. (2017b, SSU+ITS+LSU) as a paraphyletic group composed of three monophyletic clades which represent the three included sections. The subgenus formed a basal sister group to the subgenera *Hemiorbilia* and *Habrostictis*. However, its basal position lacks any support and also the phylogeny of the three included sections remained unresolved. The topology in the present analysis (Phyl. 7) is different but likewise unresolved. All the available analyses do not unravel the relationship between subgenera Orbilia and *Hemiorbilia* and leave our hypothesis unconfirmed that the hemispherical, thick-walled ascus apex is a plesiomorphic character, from which subgenus *Orbilia* developed by regression to a truncate, thin-walled apex.

Section *Arthrobotrys*, in which acicular-subulate, falcate ascospores are characteristic of many species and the ability to prey on nematodes unique within the genus, seems to have developed from a common ancestor with cylindric-ellipsoid spores which survived, e. g., in *O. orientalis* or *O. pilosa*, and are typical of section *Ovoideae* p.p. and section *Orbilia* p.p. From the distribution of the different traits of these three sections it can be speculated that the common ancestor of subgenus *Orbilia* was a desiccation-tolerant, non-nematophagous fungus with a hemispherical, thick-walled ascus apex and ellipsoid ascospores, represented by taxa of section *Ovoideae*, such as *O. clavipisca*, *O. eremaeae*, and *O. yuccae*, which form a morphological transition to members of subgenus *Hemiorbilia*, such as *O. arizonensis*.

Specific nucleotide positions. No molecular motifs being characteristic of subgenus *Orbilia* have been discovered in any of the frequently recorded regions of nuclear rDNA. Only for one of the three included sections (*Ovoideae*) and for all adhesive trap formers of section *Arthrobotrys* some consistent nucleotides occur by which they can be recognized (see there).

Section *Ovoideae*

Orbilia subgenus ***Orbilia*** section ***Ovoideae*** Baral & E. Weber, **sect**. **nov**., MB 815021 – Type species: *Orbilia ovoidea* Baral & G. Marson

Etymology: named after the type species, *Orbilia ovoidea*.

Latin diagnosis: *Apothecia ochracea, aurantiaca, rosea, lilacea, raro olivaceo-atra, margine ± laevi, raro fimbriato-dentato.] Asci 8- ad 128-spori, apice in statu emortuo haud vel valde truncati, non vel interdum modice crassitunicati. Ascosporae plerumque *3–12.3 × 1.3–4.3 µm, globosae ad ellipsoideae vel subcylindricae ad fusoideo-clavatae, apice rotundato ad obtuso, raro acuto, saepe ± rectae, interdum prope basin curvatae, in statu vivo corpusculum refringens globosum vel late lacrimiformem, raro obturamentiformem continentes. Excipulum ectale ad marginem partim crassitunicatum. Habitat ad lignum vel corticem putridum ramorum gymno- vel angiospermarum in aere prominentium, raro ad caules, in zona arctica ad tropica, humida ad arida.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–1(–2.2) mm diam., pale to bright ochraceous, orange, rose, lilaceous, rarely olivaceous-black, margin smooth or sometimes finely rough, rarely with prominent hairy teeth (*O. octosporoides*), ± sessile (rarely with a distinct short stipe). **Asci** *(27–)33–75(–97) × (4–)4.5–7(–7.5) µm when 8-spored, *(40–)50–90(–102) × (5.5–)6–9(–10.5) µm when 16–128-spored, (1–)3–6(–8) lower (rarely upper) spores inverted (when 8-spored), but often strongly mixed (often also oriented in all directions); **apex** (†) very slightly to strongly truncate, rarely slightly indented or laterally inflated, thin-walled, rarely with 1–1.4 µm thick dome with or without apical chamber; **base** T-, L-, Y- or h-, exceptionally H-shaped. **Ascospores** *3–10(–12.3) × (1.3–)1.7–3.8(–4.3) µm, globose, ovoid, ellipsoid, (sub)cylindrical to fusoid-clavate, apex rounded to obtuse, rarely subacute or acute, base rarely with a thick tail, straight or sometimes ± strongly curved near base, **SBs** affixed to apical spore wall, exceptionally laterally attached, (0.7–)1–2.2(–2.8) × (0.6–)0.7–1.5(–1.9) µm, globose to broadly tear-shaped, also ampulliform or broadly plug-shaped, sometimes apically narrowed to a small, rarely wide point, often with a very short, sometimes invisible filum. **Paraphyses** uninflated or slightly to strongly clavate-capitate at the apex, rarely spathulate, terminal cells (0.5–)1–2(–3)× as long as lower cells, unbranched or sometimes branched near apex. **Ectal excipulum** of textura (globulosa-)angularis(-prismatica), indistinctly or ± vertically oriented, sometimes obliquely (~45°), rarely horizontally (*O. sarcobati*), cells near base *(5–)6–20(–27)((–36)) × (4–)5–15(–18)((–20)) µm, (†) thin-walled to slightly or medium gelatinized (common walls †0.2–2 µm), cells at mid flanks and margin thick-walled or not; **glassy processes** sometimes present, 1–13 µm or rarely 5–40 µm long, **hairs** rarely present, 50–110 µm long, thin- to firm-walled, forming teeth (*O. octosporoides*). **SCBs** globose, rarely mixed with crystalloid ones (*O. octosporoides*); **VBs** consistently absent; **carotenoids** in LBs rarely observed (*O. octosporoides*). **Exudate** (0.1–)0.3–3(–5) µm thick, continuous-cloddy, also granular, loosely or partly firmly attached, hyaline or pale (rarely light) yellow, rarely dark olive. **— ANAMORPH** (presumed): vermispora-like. **Conidiophores** not observed. **Conidia** fusoid, slightly to strongly curved, */† 31–97(–127) × 4.2–9.8 µm, 7–19-septate. **Trapping organs**: unknown.

Habitat: on wood and bark of both gymno- and angiosperms, exceptionally resinicolous or caulicolous, from arctic to tropical, humid to arid areas, all species desiccation-tolerant.

Recognized species: 27, plus 1 with a provisional name and 3 unnamed species (‘affinis’).

Taxonomic remarks. Members of section *Ovoideae* share ascospores and SBs of a more or less primitive shape (spores globose, ellipsoid, fusoid-clavate or cylindrical, straight or sometimes ± curved, apex mostly rounded to obtuse; SBs globose to broadly tear-shaped). They deviate from the other two sections of subgenus *Orbilia* in the occasional presence of hemispherical ascus apices with apical thickenings, reminiscent of subgenus *Hemiorbilia*, in the predominant absence of an H-shaped ascus base, and in the tendency to an equal distribution of paraphysis septa.

Characteristic of some species are the thick-walled, partly very long marginal cortical cells which form a conglutinate texture, particularly in *O. polyspora* and *O. ovoidea*. The walls of these cells are compressible, and that is why they are much thinner when the cells are turgescent. Glassy processes are predominantly absent, but present in *O. cupularis*, *O. subsphaerospora*, and *O. octosporoides*. The latter is extraordinary in its prominent teeth composed of very long, septate hairs tipped by glassy processes, also in the presence of crystalloid SCBs. An alternative solution would be to place this species in section *Hemiorbilia*, but the complete absence of apical domes tells against such a placement.

A major part of the collections of *O. clavipisca* and *O. lilacina*, and also *O. eremaeae* differ from the general situation of section *Ovoideae* in showing predominantly distinct apical domes with an apical chamber, suggesting a relation to section *Hemiorbilia*. However, the partial absence of apical domes and the strong similarity of *O. lilacina* to polysporous taxa with lilaceous apothecia (e. g., *O. plurililacina*) underline the limited value of ascus characters in section *Ovoideae*. Actually, in at least nine species of section *Ovoideae* ascus apices varied among different populations, or even among asci of a single apothecium, the apical domes being often only exceptionally present.

O. olivacea is extraordinary within section *Ovoideae* by its dark olivaceous exudate. This species and *O. yuccae* are somewhat marginal also in their partly distinctly stipitate apothecia and in only slightly truncate ascus apices, though such asci are also found in *O. amberina* and *O. eremaeae*. Ecologically, *O. olivacea* differs in growing near resinous wounds of gymnosperms. *O. pisciculus* is exceptional in having distinct spore tails, and *O. stansburyanae* in a tendency to acute spore apices. The terminal cells of paraphyses are usually about the same or max. 1.5 × the length of the lower cells, but in some species (*O. subsphaerospora*, *O. octosporoides*, *O. yuccae*) they are often 2 × or even over 3 × as long as the lower cells.

In its small cylindrical spores and globose SBs, the 8-spored *O. subcylindrospora* resemble *O. lilacina* and its multispored allies, and *O. atriplicis*. However, it resembles also members of section *Orbilia* like *O. cylindrospora*, *O. paracylindrospora*, *O. austrocylindrica* and its multispored allies, and *O. cupressi*, *O. pseudeuphorbiae* and others of series *Neodactylella* (section *Arthrobotrys*). Molecular data refer *O. cupressi* to series *Neodactylella* where it fits indeed better because of the large, dactylella-like conidia. The subcylindrical to narrowly ellipsoid spores of *O. paracylindrospora* resemble those of *O. frangulae* and *O. eucalypti* (series *Orbilia*), with which it clusters.

Species delimitation. The limits between *O. ovoidea* and *O. subovoidea* are indistinct, particularly because *O. subovoidea* shows high variation in spore size and shape. The genetic distance between the two available sequences suggests, however, that separation between the two taxa is justified. Similar problematic groups of taxa are, e. g., *O. polyspora* and *O. plurililacina*, or *O. multicreosoteris*, *O. atriplicis* and *O. multiaustrocylindrica* (section *Orbilia*).

Anamorph. Within section *Ovoideae* we never succeeded to obtain an anamorph in pure culture. The three species of which we got an isolate failed to produce conidia, even when flooding the culture with water. In six species large, narrowly fusiform, multiseptate, vermispora-like phragmoconidia were observed on the natural substrate. These are rather similar among each other, though showing some variation in length and curvature, sometimes within a collection (see Pl. 757: 4).

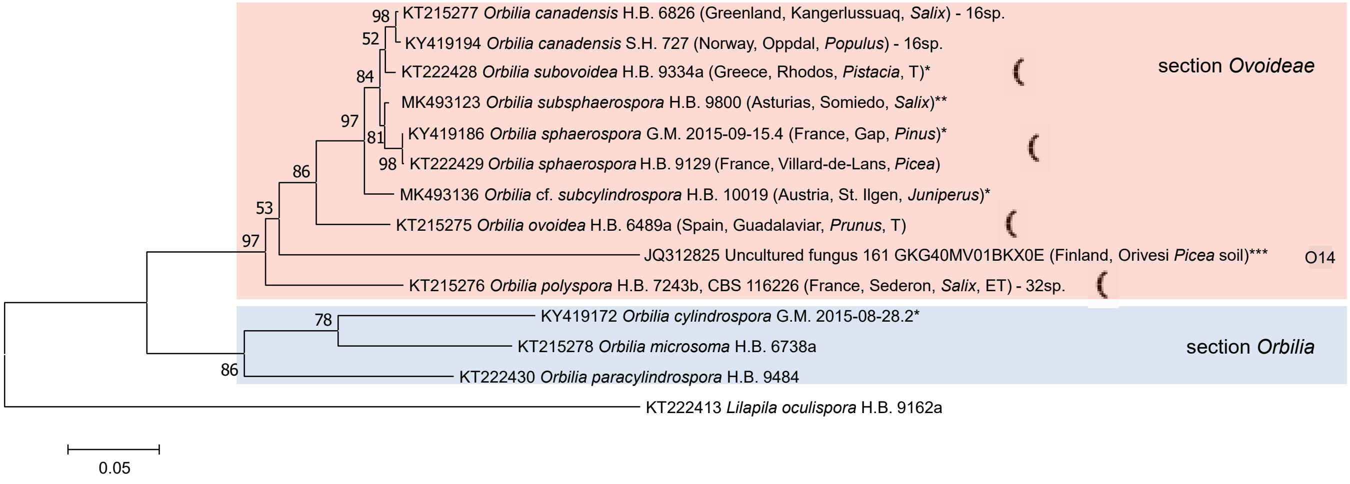
The conidia were found on very different substrates (*Pinus*, *Juniperus*, *Acer*, *Rosmarinus*, *Quercus*, etc.) in different countries (France, Spain, Turkey) or even different continents (Europe, North America). Therefore, it seems rather unlikely that these vermispora-like conidia occurred only in accidental association, and we presume that they represent the anamorph of these species.

In *O. olivacea*, a single flexuous vermispora-like conidium was seen in one collection, emerging from an anchoring hypha near an apothecium. However, the conidium looked somewhat thick-walled in the living state, whereas living orbiliaceous conidia generally have thin walls, and only in the dead state the detached cytoplasm simulates a thick wall as shown, e. g., in Pls 768: 1g; 769: 3d.

Phylogeny. Molecular data were obtained from seven species. The sequenced gene regions comprise SSU, ITS, and LSU (in *O. subovoidea* and *O.* cf. *subcylindrospora* SSU is lacking and in *O. subsphaerospora* also LSU). The S1506 intron (401 nt) was absent, except for *O. ovoidea* and *O. subovoidea*. In *O. ovoidea* a smaller intron of 70 nt (S1516) occurs at a very unusual, conservative position within the ITS1 primer at the 3'-end of SSU.

Section *Ovoideae* formed in analyses of ITS, LSU, or SSU+ITS+LSU always a highly supported monophyletic clade (Baral et al. 2017b, Phyls 7, 21, S23–S24). The two comprehensive former analyses support that section *Ovoideae* form a group different from other sections of *Orbilia*. However, molecular data were unavailable for 22 (76%) of the 29 species recognized at present. *O. polyspora* deviates rather strongly from the other species of section *Ovoideae* in both the ITS1 and ITS2 region but also in the LSU. The position of the *Ovoideae* clade is difficult to assess, as it clustered more or less unresolved in the tree, depending on, e. g., the selected gene regions and species.

Specific nucleotide positions. Several motifs are more or less unique to section *Ovoideae*, in comparison to other groups of *Orbiliomycetes*. At pos. 142–143 of the 5.8S region, which is within the primer Orb5.8s3F just upstream of GAGCGTC, section *Ovoideae* has G**CC**TGTTT or G**CT**TGTTT compared to G**TC**TGTTT (or G**TC**TGTCT) in any other *Orbilia* spp. (see Tab. 18). Within *Orbiliomycetes*, **CC** occurs only in *Hyalorbilia*



Phylogenetic analysis 21. Phylogram of section *Ovoideae* inferred from combined ML analysis of SSU (V8–V9)+ITS1-5.8S-ITS2+LSU (D1–D2) rDNA dataset (14 sequences, 1607 positions, aligned with MUSCLE) using the K2+G model in MEGA7 (500 replicates). An environmental strain from GenBank is included representing an unidentified species (O14). The tree is rooted with *Lilapila oculispora* and three members of section *Orbilia*. Asci 8-spored except when otherwise stated; T = type, ET = epitype, * = without SSU, ** = without SSU and LSU, *** = without SSU, ITS1, and LSU.

Key to species of section *Ovoideae*

1. Apothecia blackish-olivaceous; asci 8-spored; spores ellipsoid, *5–8.5 × 2.3–3.2 µm; SBs ellipsoid to ovoid; predominantly upper spores inverted within asci; resinous bark of *Pinus*, cold-temperate to orosubmediterranean humid southern Europe .... ***O. olivacea***, p. 1290
1. Apothecia pale to bright reddish, rarely ochraceous 2

2. Asci 8-spored .... SUBKEY A
2. Asci 16-spored .... SUBKEY B
2. Asci 32- up to 128-spored.. SUBKEY C

SUBKEY A (asci 8-spored)

1. Spores *1–2(–2.2) µm wide, cylindrical to fusoid 2
1. Spores min. *(2–)2.2–2.5 µm wide, variously shaped (if subglobose and 2–4 µm diam. compare also subglobose-spored *Hyalorbilia* spp.) 11

2. Spores (sub)cylindrical, *4.5–6.5 × 1.2–1.5 µm; SBs ± globose, laterally attached in centre of spore; apothecial margin distinctly dentate by glassy processes; bark of *Quercus*, suprasubmediterranean semihumid southern Europe......... ***O. beatricis*** (section *Orbilia*), p. 1322
2. Spores with apically attached SBs 3

3. Spores ± straight, never distinctly curved 4
3. Spores ± straight to distinctly curved 8

4. Spores *3–5 × 1–1.5 µm 5
4. Spores exceeding 5 µm in length or 1.5 µm in width 6

5. Spores subcylindric(-ellipsoid), *3–5 × 1.3–1.6 µm; SBs 0.3 µm wide; paraphyses apically curved or not; wood of *Euonymus*, warm-temperate humid atlantic Europe .... ***O. paracylindrospora*** (section *Orbilia*), p. 1343
5. Spores (sub)cylindrical, *1–1.5 µm wide; SBs 0.4–0.8 µm wide; paraphyses apically straight..7

6. SBs globose, in most cases a short distance from the spore apex, attachment often invisible; apothecia desiccation-sensitive, whitish, 0.3–2.3 mm diam., margin often with short glassy processes .... series ***Neodactylella*** p.p. (section *Arthrobotrys*, species with ± straight spores)
6. SBs globose, rarely tear-shaped, close to apex or with a visible connecting part; apothecia usually desiccation-tolerant, whitish to rose-orange, 0.15–0.7 mm diam. 7

7. Spores *(4–)5–6.5(–8) × (1.1–)1.3–1.7(–1.9) µm; glassy processes rarely present; bark of *Myrtaceae* and *Proteaceae*, subtropical semihumid to arid Australia.. ***O. austrocylindrica*** (section *Orbilia*), p. 1317
7. Spores *(3.7–)4–7(–8.2) × (1–)1.1–1.3(–1.5) µm; glassy processes absent; wood (& bark) of gymno- & angiosperms, orotemperate to suprasubmediterranean humid Europe .... ***O. cylindrospora*** (section *Orbilia*), p. 1314

8. Spores *7.3–9.5 × 2–2.3 µm, medium to strongly tapered and curved at base; bark of *Lonicera*, orotemperate subhumid, cold-continental central Asia .... ***O. basiflexa***, p. 1279
8. Spores *4.5–8.5 × 1.4–2 µm, not or max. medium tapered at base 9

9. Total length of SBs 1.3–2 µm; wood of *Arctostaphylos*, orotemperate subhumid western North America.. ....***O.* aff. *dixiensis*** (section *Habrostictis*) Pl. 699: 4, p. 1179
If paraphyses with glassy caps or marginal cells with glassy processes, see series *Regales* of section *Aurantiorubrae.*
9. Total length of SBs 0.6–1.4 µm..10

10. Spores *(4–)5–7.2 × (1.3–)1.6–1.8(–2.2) µm; SBs 0.6–1.2 µm long (including very short filum, or closely attached without filum); paraphyses medium to strongly capitate; wood of gymno- and angiosperms, orosub- to mesosubmediterranean humid to semihumid southern Europe.. ***O. subcylindrospora***, p. 1277
A collection from orotemperate humid central Europe has slightly larger spores and approaches *O. subovoidea* (p. 1257).
10. Spores *(3.7–)5–8.5(–9.3) × (1.5–)1.8–2(–2.3) µm; SBs 1–1.4 µm long (including very short filum); paraphyses mostly only slightly clavate-capitate to ellipsoid; wood of *Cupressus*, mesosubmediterranean western Europe.... ***O. cupressi*** (series *Neodactylella*), p. 1479

11. Spores globose or broadly ellipsoid-ovoid, *3.2–4.3 µm long.. 12
11. Spores broadly ellipsoid-ovoid to oblong or clavate, *4–10 µm long 15

12. Marginal excipulum without glassy processes, margin smooth, inner wall layers of cortical cells swellable or not; spores *(2.6–)3–3.8(–4.2) µm wide, globose to ellipsoid 13
12. Marginal excipulum with short but distinct glassy processes, margin usually finely crenulate, cortical cells thin-walled, unable to swell; spores *(2.7–)2.9–3.5(–3.8) µm wide, globose to subglobose.. 14

13. Spores *3.2–4.3 × (2.8–)3–3.8(–4.2) µm, always ± globose; inner wall layers of cortical cells swellable; apothecia 0.2–1 mm diam., rose-orange; wood (& bark) of *Picea* and *Pinus*, orotemperate to orosubmediterranean humid southern Europe .... ***O. sphaerospora***, p. 1246
13. Spores *3.7–4 × 2.6–2.8 µm, ovoid to broadly ellipsoid; cortical cells thin-walled when dead; apothecia 0.13–0.15 mm diam., orange(-brownish); bark of *Eremaea*, subtropical semihumid western Australia....***O. amberina*** p.p. (small-spored collection) Pl. 770: 3, p. 1260

14. Ectal excipulum at mid flanks abruptly changing to a horizontal textura porrecta; apothecia 0.4–2 mm diam., disc concave; wood of *Acer*, orotemperate subhumid western North America .... ***O. cupularis***, p. 1253
14. Ectal excipulum at mid flanks of vertically oriented t. angularis(-prismatica); apothecia 0.2–0.7 mm diam., disc ± flat; wood & bark of angiosperms (rarely gymnosperms), hemiboreal, orotemperate, and sub- to eumediterranean Europe.........***O. subsphaerospora***, p. 1249

15. Apothecial margin strongly dentate, teeth of agglutinated septate hairs, some of the latter tipped by glassy processes; spores *(5–)5.7–7.5(–9) × (3.7–)4–4.8 µm, broadly ellipsoid-ovoid; SBs 1.2–1.8 µm wide, globose, mostly with triangular connecting part; paraphyses with crystalloid SCBs; bark of *Juniperus*, orotemperate subhumid western North America .... ***O. octosporoides***, p. 1280
15. Apothecial margin smooth; spores *< 4 µm wide 16

16. Spores *(5–)8–11 × (2.8–)3–3.3(–4) µm, mostly with a distinct, thick, basally partly swollen tail; SBs closely attached to spore apex; terminal cells of paraphyses mostly longer than lower cells; ascus apices thin-walled; bark of *Juniperus*, orotemperate subhumid western North America .... ***O. pisciculus***, p. 1282
16. Spores with or without very short tail 17

17. Ascus apices (†) mostly with distinct apical thickening with apical chamber; SBs globose, with thin filum or triangular connecting part (half as long as globose part); cortical excipular cells (†) ± thin-walled 18
17. Ascus apices (†) without distinct apical thickening (in water), or some asci with slight wall thickening without apical chamber; SBs with or without very short filum; cortical excipular cells (†) often thick-walled 21

18. Spores *6–11 × (2.9–)3.2–4(–4.3) µm; SBs 1.6–2.5 × 0.8–1.6 µm 19
18. Spores *2.5–3(–3.3) µm wide, ellipsoid to slightly attenuated at base; SBs 1–1.8 × 0.7–1.4 µm 20

19. Spores elongate-obovoid, medium to strongly attenuated at base; SBs attached by a fine filum; apothecia (0.2–)0.4–1.2 mm diam.; wood of gymnosperms, temperate (sub)humid western North America .... ***O. clavipisca***, p. 1283
19. Spores cylindric-ellipsoid, not or slightly attenuated at base; SBs partly attached by a triangular connecting part; apothecia 0.18–0.27 mm diam.; bark of *Eremaea*, subtropical semihumid western Australia .... ***O. eremaeae***, p. 1285
Comparable collections were made on *Carya* and *Arbutus* in temperate humid eastern and western North America.

20. Apothecia rose-orange; spores *7–8 µm long; wood of ?*Abies*, boreal humid eastern North America .... ***O.* aff. *clavipisca***, p. 1284
20. Apothecia rose-lilaceous; spores *(4.5–)5–7(–8) µm long; bark of *Eucalyptus* & *Verreauxia*, subtropical semihumid western Australia .... ***O. lilacina***, p. 1265
21. Marginal cortical cells and paraphyses distinctly clavate-capitate, (†) thin-walled; asci *27–33.5 × 5.5–6 µm, apex not or only slightly truncate, slightly thick-walled; spores *4–5(–5.6) × 2.5–3 µm; SBs closely and broadly attached to apex; apothecia 0.1–0.22 mm diam., whitish-yellowish; inflorescence stem of *Yucca*, temperate semiarid western North America .... ***O. yuccae***, p. 1291
21. Marginal cortical cells only slightly inflated, (†) thin- or thick-walled; asci min. *33 µm long; SBs narrowly attached at spore apex; apothecia 0.15–0.8 mm diam., light rose-lilaceous, orange to amber-brown 22

22. Spores with very short tails, *8.3–11.5 µm long; SBs broadly tear-shaped, attached to apex by a distinct triangular upper part 23
22. Spores without tails, *4–7(–11) µm long; SBs globose, either very close to apex or attached by a fine and short filum 24

23. Spores *8.3–10 × 2.3–2.5(–2.7) µm; bark of *Brachychiton*, subtropical semiarid western Australia .... ***O. gregorii***, p. 1289
If spores *2–2.3 µm wide and tail-like base bent see ***O. basiflexa*** (p. 1279).
23. Spores *8.8–11.5 × 2.8–3.5 µm; *Sarcobatus*, temperate semiarid western North America .... ***O.*** aff. ***gregorii***, p. 1290
A similar collection was on *Juniperus* from the south of Northern America (spores *6–8 × 2–2.4 µm, Pl. 804: 2).

24. SBs rod-shaped to ampulliform or tear-shaped, mostly with a wide, broadly attached upper part; mountainous Europe, North America .... see ***O. ovalis*** (series *Ovales*, section *Lentiformes*), p. 498
24. SBs ± globose, often with a short, filiform upper part, always very narrowly attached 25

25. Asci *33–55 µm long, apex slightly to medium truncate 26
25. Asci *48–75 µm long, apex medium to strongly truncate 27

26. Apothecia rose-lilaceous; spores l:w-ratio 1.5–2.5; SBs 0.7–1.3 µm wide .... see under 20 (*O. lilacina*)
26. Apothecia orange- to amber-brown; spores l:w-ratio 1.3–1.6; SBs 1–1.5 µm wide; bark & wood of *Verreauxia* & *Acacia*, subtropical semihumid to semiarid western Australia .... ***O. amberina*** p.p. (large-spored collections, Pl. 770: 1–2), p. 1260

27. Spores *4–9 × (2–)2.2–3(–3.3) µm, rarely tapered at base; asci *50–65(–70) × 5–6(–6.3) µm; marginal cortical cells 7–15 µm long, mainly terminally thick-walled; wood and bark of angiosperms, orosub- to thermomediterranean semihumid Europe, rarely emsotemperate humid atlantic Europe or cold-temperate humid mountainous western North America .... ***O. subovoidea***, p. 1257
27. Spores *3–4 µm wide, at least partly tapered at base; asci *(55–)65–75 × (5.5–)6–7 µm 28

28. Spores *5–7(–8) µm long, partly tapered at base; marginal cortical cells 9–20 µm long, (†) overall thick-walled; wood of angio-, rarely gymnosperms, orotemperate to suprasubmediterranean humid Europe .... ***O. ovoidea***, p. 1254
28. Spores *(6–)7–10(–11) µm long, always tapered at base; marginal cortical cells 6–15 µm long, (†) ± thin-walled; wood of gymnosperms, cold-temperate to boreal (sub)humid western America .... ***O. clavipisca***, p. 1283

SUBKEY B (asci 16-spored)

1. Spores subglobose to broadly ellipsoid, *3.4–5.3 × 2.3–3.4 µm; wood (& bark) of *Betulaceae*, *Salicaceae*, orotemperate to subarctic humid northern North America and northern Europe .... ***O. canadensis***, p. 1251
1. Spores cylindrical, ellipsoid or fusoid, min. *6.5 µm long 2

2. Spores *11–17.5 × 2–3.2 µm; asci (†) with rounded to slightly truncate, slightly thick-walled apex with apical chamber .... see ***O. pleionavajoana*** (p. 573) & ***O. pleiohesperidea*** (p. 582, series *Hesperideae*, section *Hemiorbilia*)
2. Spores *6.5–12.5 µm long; asci (†) with medium to strongly truncate, thin-walled apex (though rarely immature with slight apical wall thickening in some asci) 3

3. Spores *1.5–2.5(–2.8) µm wide; Australia 4

3. Spores *3–4 µm wide; western North America 5

4. Spores *5.5–8.8 × 1.4–1.6(–1.7) µm; SBs narrowly attached; paraphysis apices *3–5 µm wide; ectal excipulum (†) distinctly thick-walled; wood of *Acacia*, *Eucalyptus*, subtropical semihumid to semiarid western Australia.......... ***O***. ***pleioaustrocylindrica*** (section *Orbilia*), p. 1319

4. Spores *(7.5–)8.5–10(–11) × 2–2.5(–2.8) µm; SBs more broadly attached; paraphysis apices *2.3–3 µm wide; ectal excipulum (†) thin-walled; bark of *Geijera*, tropical subhumid eastern Australia .... ***O***. ***geijerae***, p. 1274

5. Spores ellipsoid-fusoid, with obtuse to subacute apex, *8–12.3 × 3.2–3.5(–3.7) µm; SBs globose to broadly tear-shaped, ± closely attached; wood of *Purshia*, orotemperate subhumid .... ***O***. ***stansburyanae***, p. 1272

5. Spores cylindrical to ellipsoid, with rounded apex, SBs with distinct filum or ± thick triangular connecting part........ 6

6. Spores (9–)11–12.5 × 2.8–3.5 µm, cylindric(-ellipsoid); wood of *Larrea*, warm-temperate arid........ ***O***. ***pleiocreosoteris***, p. 1274

6. Spores *(5–)6.5–9(–11) × (2.8–)3–3.8(–4.3) µm, ellipsoid 7

7. Marginal ectal excipulum of t. porrecta; SBs globose; paraphyses rarely capitate, terminal cells *(10–)13–19(–22) µm long; apices of dead asci not indented; bark of *Pinus*, orotemperate humid........ ***O***. ***ponderosae***, p. 1286

7. Marginal ectal excipulum of t. globulosa-angularis; SBs globose to ellipsoid or tear-shaped; paraphyses always capitate, terminal cells *(3–)5–14(–17) µm long; apices of dead asci slightly to distinctly indented; bark of *Sarcobatus*, temperate semiarid . ***O***. ***sarcobati***, p. 1287

SUBKEY C (asci 32–128-spored)

1. Spores ellipsoid-obovoid to tear-shaped or fusiform, *3.8–7 × 2.7–3.3(–3.8) µm; ascus apex (†) with slight apical thickening; (sub) mediterranean southern Europe 2

1. Spores cylindrical to ellipsoid, *1.5–3 µm wide; SBs globose, close to spore apex, invisibly or narrowly attached, never with a filum; ascus apex (†) without apical thickening 3

2. Asci 64-spored; spore apex rounded to obtuse; SBs globose, with long, fine filum; wood & bark of angiosperms .... see ***O***. ***myriosphaera*** (series *Phanosomates* of section *Lentiformes*), p. 523

2. Asci 32-spored; spore apex obtuse to acute; SBs tear-shaped, with very short filum; bark (& wood) of *Cytisus* .... see ***O***. ***sarothamni*** (series *Hesperideae* of section *Hemiorbilia*), p. 668

3. Asci 128-spored; spores *3.7–6 × 1.7–2.2 µm; apothecia rose-lilaceous; wood of *Eucalyptus*, subtropical semihumid to semiarid western Australia........ ***O***. ***pleistolilacina***, p. 1271

3. Asci 32–64-spored........ 4

4. Asci 64-spored; spores *3–6.5 × 1.3–2.1 µm; apothecia rose-lilaceous or orange; bark (& wood) of *Acacia* & *Lamarchea*, subtropical semiarid western Australia........ ***O***. ***myriolilacina***, p. 1269

4. Asci 32-spored........ 5

5. Marginal cortical cells 15–50 µm long, (†) overall thick-walled; terminal cells of paraphyses *(12–)16–30(–42) µm long; spores *3.5–6 × 1.9–2.8 µm; apothecia orange; wood and bark of angiosperms, cold-temperate humid to to mesomediterranean semihumid southern Europe .... ***O***. ***polyspora***, p. 1262

5. Marginal cortical cells 5–12 µm long, (†) thin- or thick-walled; terminal cells of paraphyses *6–16(–18) µm long; North America and Australia........ 6

6. Marginal cortical cells (†) partly strongly thick-walled; spores *3.2–6 × 1.8–2.5 µm; apothecia rose-lilaceous; bark of different angiosperms, warm-temperate humid eastern and subtropical semihumid western Australia .... ***O***. ***plurililacina***, p. 1267

6. Marginal cortical cells (†) ± thin-walled; (semi)arid regions 7

7. Spores *(5–)6–8.5(–9.5) × 2–3 µm, straight or only slightly curved; SBs 1.1–1.3 µm wide, narrowly to broadly attached; bark of *Olneya* & *Sarcobatus*, subtropical semiarid western North America .... ***O***. ***multicreosoteris***, p. 1275
The likewise western North American *O*. aff. *multiaustrocylindrica* (section *Orbilia*, Pl. 831: 2) on bark of indet. angiosperm differs in somewhat narrower asci and spores (p. 1322).

7. Spores *4–7.8 × 1.5–2.3 µm; SBs 0.6–1 µm wide, narrowly attached; subtropical arid central Australia 8

8. Spores straight or slightly curved, *4–7.7 × 1.5–1.7(–2) µm; SBs 0.6–0.9 µm wide; wood of *Atriplex* .... ***O***. ***multiaustrocylindrica*** (section *Orbilia*), p. 1321

8. Spores straight to strongly curved, *5–7.8 × (1.7–)1.8–2.3(–3) µm; SBs 0.8–1 µm wide; bark of *Atriplex* .... ***O***. ***atriplicis***, p. 1276

p.p.maj. (G**CC**CGTTT), *Vermispora* (G**CC**TGTTT), and *Lecophagus vermicola* (G**CC**TGTCT). The deviation **T** at pos. 143 is unknown in any other member of *Orbiliomycetes*. Also at pos. 30 of 5.8S section *Ovoideae* differs from remaining *Orbilia* spp. by GGTTC**C**CGCAT compared to GGTTC**T**CGCAT. However, the motif GGTTC**C**CGCAT occurs also in some taxa of series *Abutilones* (*O. milinana*, *O. siculispora*, *O. ficicola*, *O. carminorosea*, *O. aethiopica*, *O. ebuli*), a few of series *Orbilia* (*O. dryadum*, and *O. cunninghamii*), and almost all *Hyalorbilia* spp., *Mycoceros*, and most predacious members of section *Arthrobotrys* (see Tab. 76), whereas other genera of *Orbiliomycetes* and other classes have GGTTC**T**CGCAT.

In the LSU D1–D2 domain, section *Ovoideae* is characterized within *Orbiliomycetes* by 3 motifs: pos. 14–16: CA**AGT**AA, rarely CA**GGC**AA (*O. polyspora*) or CA**GGT**AA (*O. ovoidea*), remaining *Orbiliomycetes* CA**GAC**AA or CA**GAC**GA, sometimes CA**GAT**GA; pos. 167–170: CG**AGGT** (*O. polyspora* CGG**AGGT)**, remaining *Orbiliomycetes* CG**GTTG**, rarely

CG**GCTG** or CG**GTCG** etc.; pos. 437–438: AGA**TC**TGC, remaining *Orbiliomycetes* AGA**CT**CGC or AGA**CT**CAC or AGA**CT**TGC, in *O. subocellata* AGA**TT**TGC. Some other, less consistent motifs of section *Ovoideae* are: pos. 201 is GA**T**GTCA but in other *Orbilia* spp. GA**C**GTCG or GA**C**GTCA, rarely GA**T**GTCA (in *O. pleistoeuonymi*, *O. gemma*, and a few of section *Arthrobotrys*) or GA**T**GTCG; pos. 218 is mostly AGA**G**TCC (AGA**A**TCC in *O. polyspora*) but in other *Orbilia* spp. mostly AGA**A**TCC (but AGA**G**TCC in *O. albovinosa*, *O. gemma*, and *Orbilia* sp. MH520123); pos. 241–245 is TTCTT (in *O. polyspora* TTCCT) but in other *Orbilia* spp. often ACTTC, also GCTTC or ATTTC or TCAAT etc.; pos. 332 is GGCG**G**GAGACC as in series *Abutilones*, *O. dryadum*, and section *Arthrobotrys* p.p.maj., but GGCG**A**GAGACC in most other *Orbilia* spp.

Ecology. All species of section *Ovoideae* are desiccation-tolerant and generally grow on exposed (xeric), woody substrates. Only one species grew on herbaceous substrate (*O. yuccae*) and one on resinous wounds (*O. olivacea*). Most species were observed in semihumid to arid regions, but one species was partly recorded in humid, montane or hemiboreal areas (*O. subsphaerospora*) and another only in boreal areas (*O. canadensis*). Records are known from North America, Europe, and Australia.

Orbilia sphaerospora Baral & G. Marson, **sp. nov.**, MB 813906 — Pls 759–760, Map 126

Etymology: referring to the globose ascospores.

Typification: France, Tête de l'Estrop, branches of *Pinus sylvestris*, 24.VIII.1996, G. Marson (ex H.B. 5608a, M-0276589, holotype).

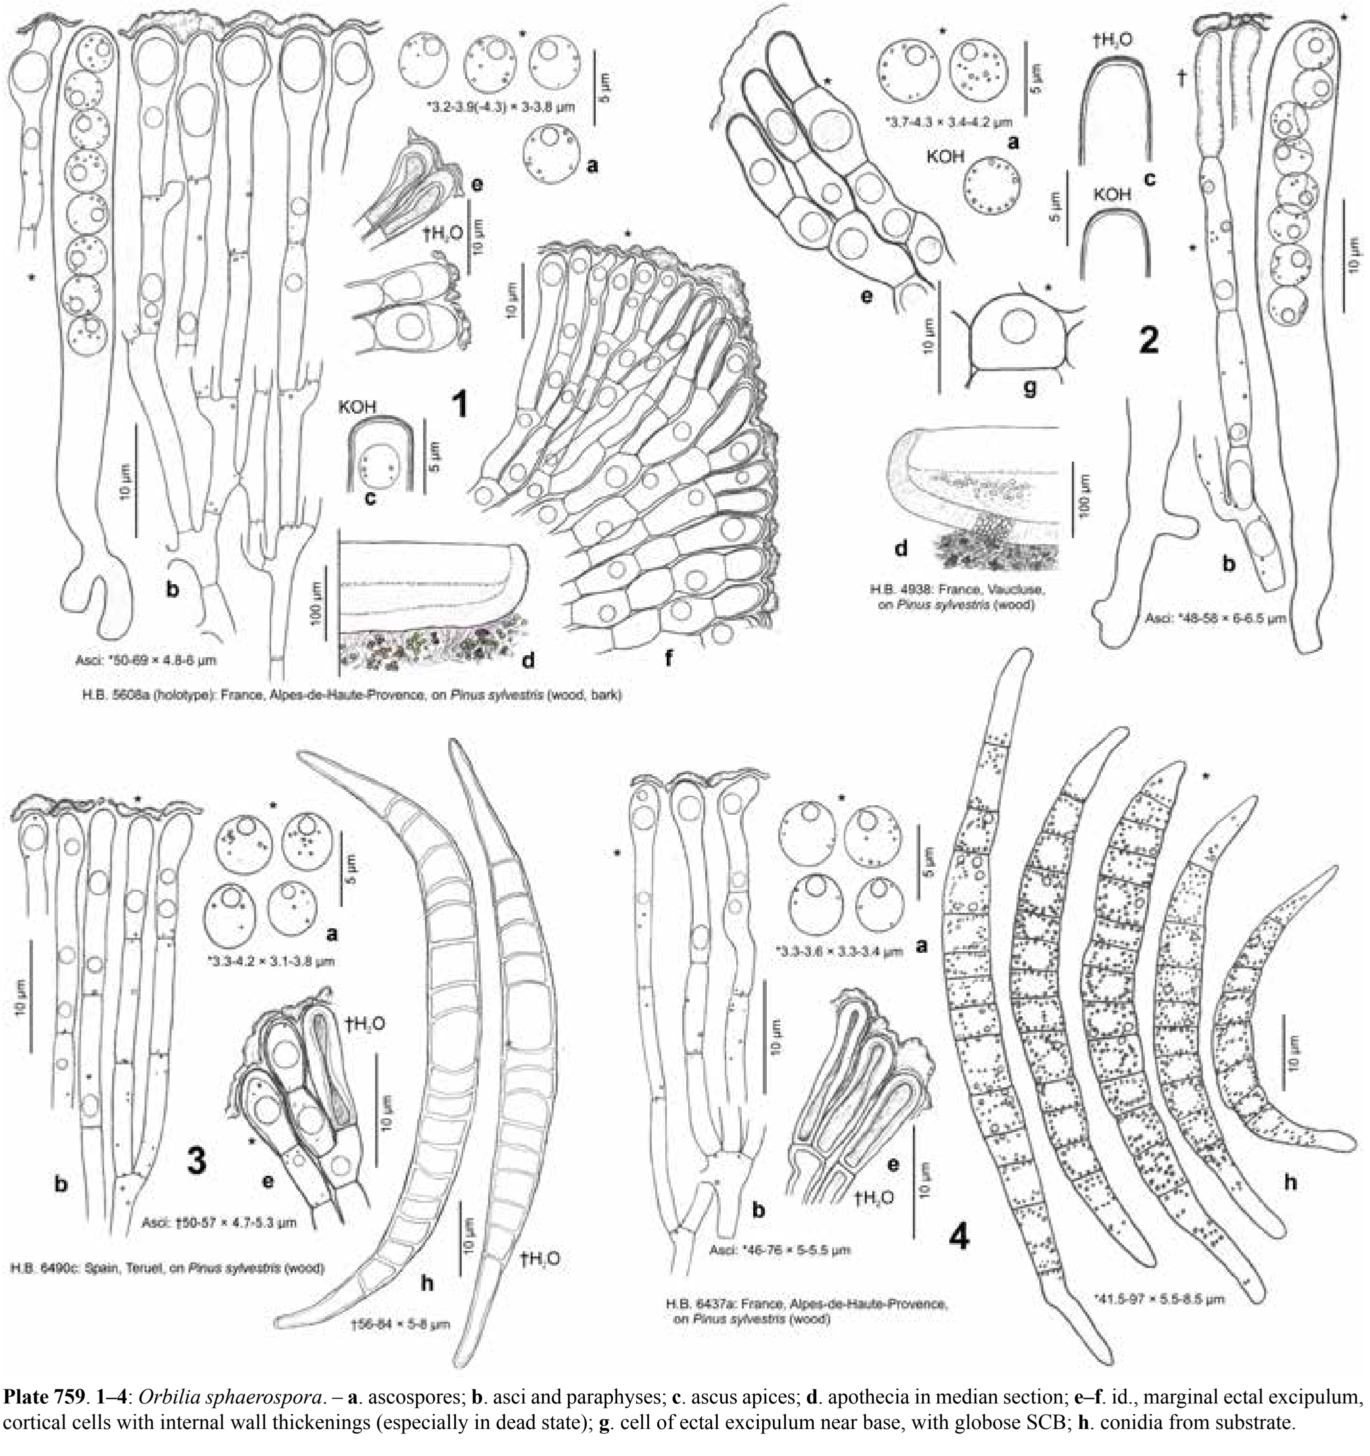


Plate 759. **1–4**: *Orbilia sphaerospora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e–f**. id., marginal ectal excipulum, cortical cells with internal wall thickenings (especially in dead state); **g**. cell of ectal excipulum near base, with globose SCB; **h**. conidia from substrate.

Plate 760. **1–3**: *Orbilia sphaerospora*. – **1a**. orotemperate *Picea* forest; **1b**. decorticated xeric branches of *Picea abies*; **1e**, **2a–b**, **3a–d**. rehydrated apothecia; **1c**, **3e–f**. apothecia in median section; **1d**, **3g**. id., marginal ectal excipulum; **1f–g**, **3h**. asci with ascospores. – Dead state, except for ascospores in **1f–g**, ascus in **1f** (**1c–d** in H_2O, **3e–g** in KOH, **3h** in KOH+IKI). — **1a–h**. H.B. 9129: France, Grenoble, on *Picea*; **2**. H.B. 9173e: France, Mont Ventoux, on *Pinus*; **3a–h**. H.B. 5608a (holotype): France, Seyne-les-Alpes, on *Pinus*.

Latin diagnosis: *Apothecia rehydratata 0.2–1 mm diam., aurantiaca vel rosea, sessilia, margine laevi. Asci 8-spori. Ascosporae *3.2–4.3 × 2.8–4.2 µm, globosae vel leniter subglobosae, corpusculum refringens globosum excentricum, cuspide minuta affixum continentes. Excipulum marginale cellulis elongatis crassitunicatis, absque processis vitreis. Habitat ad lignum leniter vel valde putridum, raro corticem, ramulorum et ramorum siccorum coniferarum, plerumque* Pini*, in zona orosubmediterranea vel orotemperata humida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.8(–1) mm diam., 0.12–0.16 mm high, pale to bright orange to brick-red or pink, medium translucent, round to somewhat irregular, ± scattered to subgregarious; disc flat, margin thin or thick, 0–5 µm protruding, smooth; broadly sessile, ± superficial; dry bright to deep rose- or brick-red to apricot. **Asci** *(40–)48–65(–76) × 4.8–6.5 µm {5}, †39–

64 × 4.4–6 µm {4}, 8-spored (rarely only 6–7 spores developed), spores (*) uni-, sometimes subbiseriate, oriention irregular, pars sporifera *25–29 µm long, †30–34 µm; **apex** (†) slightly (rarely medium) truncate, sometimes slightly laterally inflated, thin-walled; **base** with ± short to long, flexuous, ± thick stalk, T-, L- or h-shaped. **Ascospores** *3.2–4.3 × (2.8–)3–3.8(–4.2) µm {7}, †2.8–4 µm diam. {2}, globose to sometimes slightly subglobose; **SBs** *(1–)1.2–1.6 × (0.9–)1–1.2(–1.4) µm diam. {6}, globose (to subglobose), attachment often invisible, also closely attached, rarely with a very short filum. **Paraphyses** apically uninflated to slightly or medium clavate to irregularly lageniform, sometimes ± flexuous, terminal cells *(5–)9–20(–23) {5} × 1.7–3.3 {6} or (2.5–)3.5–4.3(–4.8) {T} µm, lower cells *7–17 × 1.5–2.5 µm {4}, rarely branched near apex. **Medullary excipulum** pale rose, 20–60 µm thick, of medium dense textura intricata(-angularis) with many inflated cells, sharply delimited from ectal excipulum by a distinct, parallel, ~10 µm thick layer of t. porrecta. **Ectal excipulum** pale rose, of vertically oriented t. globulosa-angularis(-prismatica) from base to lower flanks, 20–50 µm thick near base, cells *6–13 × 5–9.5 µm {2}, outer layers medium gelatinized; 30 µm thick at mid flanks, of t. prismatica oriented at a 70–80° angle to the surface, 15–20 µm thick at margin, of t. prismatica-porrecta oriented at 35–80°, cortical cells especially at mid flanks and margin thick-walled, */†5–16 × 2.2–4 µm {4}, walls (*) firm, refractive, (†) 0.6–1.2 µm thick, apically rarely 1.5–4 µm, low-refractive {4}, **glassy processes** absent {6}. **Anchoring hyphae** ± abundant, *2.2–4 µm wide, walls smooth, *(0.2–)0.3–0.5(–0.8) µm thick, †0.3–0.8 µm {4}. **SCBs** in paraphyses globose (to ellipsoid), 1–2.5(–5) µm diam. {6}; in excipular cells globose, (1–)2–3.5 µm diam. **Exudate** over paraphyses cloddy, subhyaline, 0.3–2 µm thick, loosely attached; over margin and flanks rough-cloddy, 1–4 µm. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** unbranched, slightly to strongly curved, tapered towards the ends, */†41.5–97 × (5–)5.5–8.5 µm, 7–19-septate {2}, terminal cells distinctly longer than remaining cells.

Habitat: collected ~1–2 m above the ground, mostly decorticated, 4–28 mm thick twigs and branches of *Juniperus communis* {1}, *Picea abies* {1/1}, *Pinus sylvestris* {7/1}, on wood {10}, rarely on ± loose bark {1}, sometimes on corticated branches with fresh or old resinous wounds {2} (in wound on bare wood), outer 0.1–2 mm slightly to strongly decayed, often eroded and strongly greyed, often in old beetle galleries, often with many green algae. **Associated**: *Amphosoma atroolivaceum* {3}, *Caloplaca* sp. {2}, *Ciliolarina pinicola* {1}, *Cladonia* sp. {1}, *Coniochaeta malacotricha* {1}, *Dacrymyces* sp. {3}, *Lecophagus pini* {1}, *Lilapila oculisporella* {2}, *Lophium mytilinum* {1}, *Melaspilea emergens* {1}, *Monodictys* sp. {1}, *Orbilia aristata* {1}, *O. gambelii* {1}, *O. ?graminis* {1}, *O. ?ocellata* {1}, *O. patellarioides* {3}, *O. subcylindrospora* {2}, *O. subvinosa* {4}, *O. trapeziformis* {1}, *Propolis betulae* {1}, *Resinomyces griseus* {2}, *R. kirschsteinianus* {2}, *Sarea difformis* {2}, *S. resinae* {1}. **Desiccation tolerance**: fully viable for up to 7 months. **Altitude**: 890–1385 m a.s.l. (Austria & France), 1615 m (Spain), 1200-1750 m (Montenegro). **Geology**: Middle Jurassic and Lower to Upper Cretaceous marl-, sand- & limestone, dolomite, siliceous shale, Neogene clay; migmatite, gneiss. **Phenology**: VIII–X (but certainly throughout the year, long-lived).

Taxonomic remarks. *Orbilia sphaerospora* is well characterized by its globose ascospores containing a globose, strongly eccentric spore body, and by occurring on coniferous substrate. In contrast to the otherwise very similar angiosperm-inhabiting *O. subsphaerospora*, the cortical excipular cells of *O. sphaerospora* are consistently without glassy processes but, instead, have internal wall thickenings that are able to swell. The also similar North American *O. canadensis* differs in 16-spored asci, subglobose to broadly ellipsoid spores, and occurrence on angiosperm substrate. Populations of *O. eucalypti* (section *Orbilia*) with subglobose spores may easily be confused with *O. sphaerospora* or *O. subsphaerospora*, but are sharply separated by a different, lipidic nature of the large drop in the spores which is KOH-resistant, while SBs are inconspicuous or absent, also in the absence of thick-walled marginal cortical cells or glassy processes.

Map 126. Known distribution of *O. sphaerospora*.

Variation was observed in the paraphyses which showed a much stronger apical or subapical inflation in the holotype compared to the other samples. Only slight variation occurred in spore shape. Two oversized spores in a 5-spored ascus measured 5 × 4.8 µm, with SBs 1.7 × 1.6 µm.

Anamorph. We observed two times large phragmosporous conidia on the substrate near the apothecia (Pl. 759: 3h, 4h) which are typical of section *Ovoideae*.

Phylogeny. Sequences were taken from apothecia of two collections from Southern French Alps (H.B. 9129, G.M. 2015-09-15.4), comprising ITS and LSU, the former also SSU. The S1506 intron is absent in both. The two sequences coincide in the entire ITS and overlapping LSU, except for 2 missing adjacent nt in the ITS1 in H.B. 9129 (downstream of TGCCGGCAG, confirmed from chromatogram) which are present in G.M. 2015-09-15.4 and all other available sequences of section *Ovoideae* (TGCCGGCAG**CA**). A DNA isolate from *Pinus heldreichii* needles in Montenegro (partial 5.8S and entire ITS2, Lazarević & Menkis 2020) fully coincides with them in the ITS2. *O. sphaerospora* shows in the ITS region a distance of 2% to *O. subsphaerospora*, 4.2% to *O. subovoidea*, and 4.5% to *O. canadensis*. In the SSU (V7–V9) and LSU (D1–D2) the lowest distance is 0% and 0.8% to *O. canadensis*, respectively.

Ecology. The partly rather abundant populations of *O. sphaerospora* were found on slightly to strongly decayed wood (rarely bark) of xeric twigs and branches of coniferous trees (mainly *Pinus*) in north- to south-exposed, ± open conifer forests with *Pinus*, *Picea*, *Larix*, and *Juniperus* at altimontane to subalpine altitudes. Known collections are from south Europe mountain ranges in orotemperate to orosubmediterranean humid Austrian eastern and Southern French Alps, and Spanish Sistema Iberico.

Specimens included. **AUSTRIA**: **Steiermark**, 20 km NNW of Bruck an der Mur, 3 km NNW of St. Ilgen, Karlschütt, 890 m, twig of *Juniperus communis*, on wood, 6.VIII.2016, G. Friebes (G.F. 20160172). — **FRANCE**: **Rhône-Alpes**, **Savoie**, 19 km ENE of Albertville, 4.5 km ESE of Beaufort, N of Lac de Roseland, ~1320 m, on (?)*Picea abies*, 4.VIII.1995, G. Marson (ø). – **Isère**, Vercors, 20 km SW of Grenoble, 2 km SSE of Villard-de-Lans, W of Les Glovettes, 1200 m, branches of *P. abies*, on wood, 11.VIII.2009, G. Marson, B. Liu & H.O. Baral (H.B. 9129; sq.: KT222429). – **Provence-Alpes-Côte d'Azur**, **Hautes-Alpes**, 18.3 km WNW of Gap, 1 km NW of La Montagne, SW of Pic de Bure, 1043 m, branch of *Pinus sylvestris*, on wood, 15.IX.2015, G. Marson (G.M. 2015-09-

15.4; sq.: KY419186). – **Alpes-de-Haute-Provence**, Mercantour, 13.5 km SE of Seyne-les-Alpes, 5.5 km SW of Tête de l'Estrop, SE of Vière, 1350 m, branches of *P. sylvestris*, on wood & bark, 24.VIII.1996, G. Marson (M-0276589, **holotype**; **isotype** in H.B. 5608a). – 17 km NE of Digne-les-Bains, 5 km SSW of Prads-Haute-Bléone, 0.3 km WSW of Blégier, 970 m, branch of *P. sylvestris*, on wood, 24.VIII.1996, G. Marson (H.B. 5628c). – 24 km S of Digne, 3.3 km NNW of Moustiers-Ste.-Marie, N of Canyon du Verdon, 970 m, branches of *P. sylvestris*, on wood, 6.VIII.1999, G. Marson (H.B. 6437a, anam. substr.). – 6.5 km SE of Castellane, 0.8 km NW of La Bâtie, Col de Luens, 1080 m, branch of *P.* (?)*sylvestris*, on wood, 5.X.1993, G. Marson (H.B. 5015b). – **Vaucluse**, 9.5 km NE of Bedoin, 1.5 km NW of Mt. Ventoux summit, Mt. Serein, 1385 m, branch of *P. sylvestris*, on wood, 13.VIII.2009, G. Marson (H.B. 9173e ø). – 17 km NE of Carpentras, 5.5 km E of Malaucêne, 6 km W of Mt. Ventoux summit, Les Ramayettes, 980 m, branch of *P. sylvestris*, on wood, 13.VIII.1993, G. Marson (H.B. 4938). — **SPAIN**: **Aragón**, **Teruel**, Sierra de Albarracín, 49 km W of Teruel, 5.8 km WSW of Frias de Albarracín, 1615 m, branches of *P. sylvestris*, on wood, 26.IX.1999, G. Marson & H.O. Baral (H.B. 6490c, anam. substr.). — **MONTENEGRO**: WNW & NNW of Podgorica, Orjen and Prekornica, 1200–1750 m, needles of *Pinus heldreichii*, V.2015 (2814_464, Lazarević & Menkis 2020, mol. extr., sq.: MT242183).

Orbilia subsphaerospora Baral, **sp. nov.**, MB 813907 — Pls 761–762, Map 127

Etymology: named after the similarity to *O. sphaerospora*.

Typification: Switzerland, Hergiswil, branch of *Acer pseudoplatanus*, 15.VIII.2006, H.O. Baral (ex H.B. 8236, M-0276598, holotype).

Latin diagnosis: *Similis* Orbiliae sphaerosporae *sed excipulum marginale cellulis tenuitunicatis, processis vitreis brevibus praeditis. Habitat ad lignum vel corticem putridum ramorum et truncorum siccorum fruticum vel arborum angiospermarum, raro* Juniperi, *in zona boreali, orotemperata et mediterranea Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.5(–0.75) mm diam., 0.09–0.17 mm high (receptacle 0.06–0.12 mm), pale orange-rose(-pinkish) or carneous-cream, ± translucent, round, very scattered or in small groups; disc slightly concave to flat, margin distinct, thin or thick, 0–8 µm protruding, smooth to finely crenulate; sessile on a small, ill-defined stalk; dry bright (orange-)rose or cream. **Asci** *34–55 {3} × 4.2–4.7 {2} or 5.5–6 µm {2}, †32–47(–53) × (3.2–)3.5–4.2 µm {6}, 8-spored, spores (*) uniseriate, orientation irregular, pars sporifera *19–23 µm; **apex** (†) medium (to strongly) truncate (not indented, laterally not or sometimes very slightly inflated), thin-walled; **base** with short to medium long, thin or thick, flexuous stalk, T-, L-, Y- or h-, exceptionally H-shaped. **Ascospores** *(2.9–)3.2–3.7(–4) × ((2.4–))(2.7–)2.9–3.5(–3.8) µm {13}, †2.7–3.4 × 2.6–3.2 µm {2}, globose to subglobose, rarely somewhat subcylindrical; **SBs** *(1–)1.2–1.5(–1.7) × (0.8–)1–1.3(–1.4) µm {8}, globose to subglobose, sometimes with a very short filum, or attachment invisible, also closely attached. **Paraphyses** apically (uninflated to) slightly to medium (rarely strongly) clavate-capitate, terminal cells *(12–)15–23(–25) {4} × (2.3–)3–4(–5) µm {5}, †2.5–4.5 µm wide {3}, lower cells *(4.5–)6–11 × 1.5–2.5 µm {3}; sometimes branched at upper septum. **Medullary excipulum** hyaline, 20–60 µm thick, of medium dense textura intricata-angularis, not sharply delimited. **Ectal excipulum** hyaline to pale rose, of thin-walled, irregularly vertically oriented t. angularis(-prismatica) from base to mid flanks, 20–90 µm thick near base, cells *7–14 × 5–8.5 µm {2}, †7–13 × 5–6 µm {1}; 10–30 µm thick near margin, of t. prismatica-porrecta oriented at a 10–40° angle to the surface (internal part oriented at 45–60°), marginal cortical cells *(4.5–)7–14(–16) × (2–)3–4.2 µm {5}, †5–10 × 2.5–3.5 µm {1}, **glassy processes** 0–2 {3} or 1–9(–13) {12} × (2–)2.5–4(–5) {10} µm, strongly refractive, stratified, curved outwards {4}, sometimes arranged in distinct radial rows at the margin. **SCBs** globose, indistinct, in paraphyses 1–3.3 µm diam. {1}, in ectal excipulum 1–1.3 µm (only seen in some cells). **Exudate** over paraphyses 0.1–1(–3) µm thick, ± continuous, rough, hyaline, firmly (also loosely) attached; on margin and flanks pale to light yellowish, 0.2–0.5 µm thick. **Anchoring hyphae** sparse to abundant at base, †1.5–2.5 µm wide, walls 0.15–0.3 µm thick {4}. — **ANAMORPH**: unknown.

Habitat: lying on moist ground or often hanging or standing in 1–2.3 m above the ground, corticated or decorticated, 11–40 mm thick branches or ~25–100 cm thick trunks of *Acer pseudoplatanus* {1}, *Corylus avellana* {1}, *Fagus sylvatica* {3}, *Juniperus sabina* {1}, *Lonicera* (?)*implexa* {1}, *Olea europaea* {1}, *Populus tremula* {1}, *Quercus ilex* {1}, *Q. pubescens* {1}, *Q. robur* {1}, *Q. rotundifolia* {1}, *Salix* sp. {2}, indet. tree {1}, on medium to strongly decayed wood {10} or bark (periderm or bast) {7}, 0.5 mm or very deep medium to strongly brown- or white-rotten, slightly to strongly greyed, with some or many green algae. **Associated**: *Aleurodiscus disciformis* {1}, *Amandinea punctata* {1}, *Calycina citrina* {1}, *Dacrymyces* sp. {1}, *Frullania dilatata* {4}, *Hyalorbilia inflatula* {1}, *Hypnum cupressiforme* {1}, *Hysterographium fraxini* {1}, *Metzgeria* sp. {1}, ?*Monodictys* sp. {1}, *Navicella pileata* {1}, *Orbilia arachnovinosa* {1}, *O. vinosa* {2}, ?*Parmelia* sp. {2}, *Phaeomarasmius rimulincola* {1}, *Pithyella*

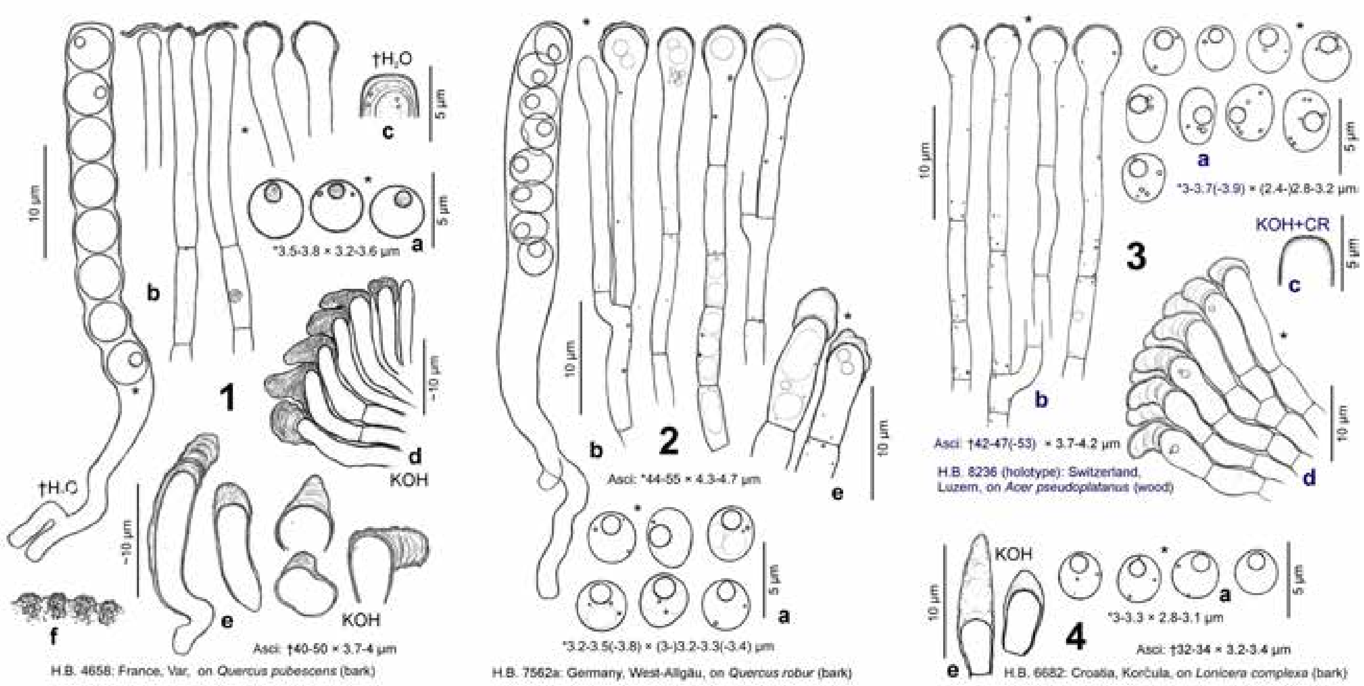

Plate 761. **1–4**: *Orbilia subsphaerospora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section; **e**. marginal cortical cells with glassy processes; **f**. margin of apothecium in external view, glassy processes forming teeth-like ribs.

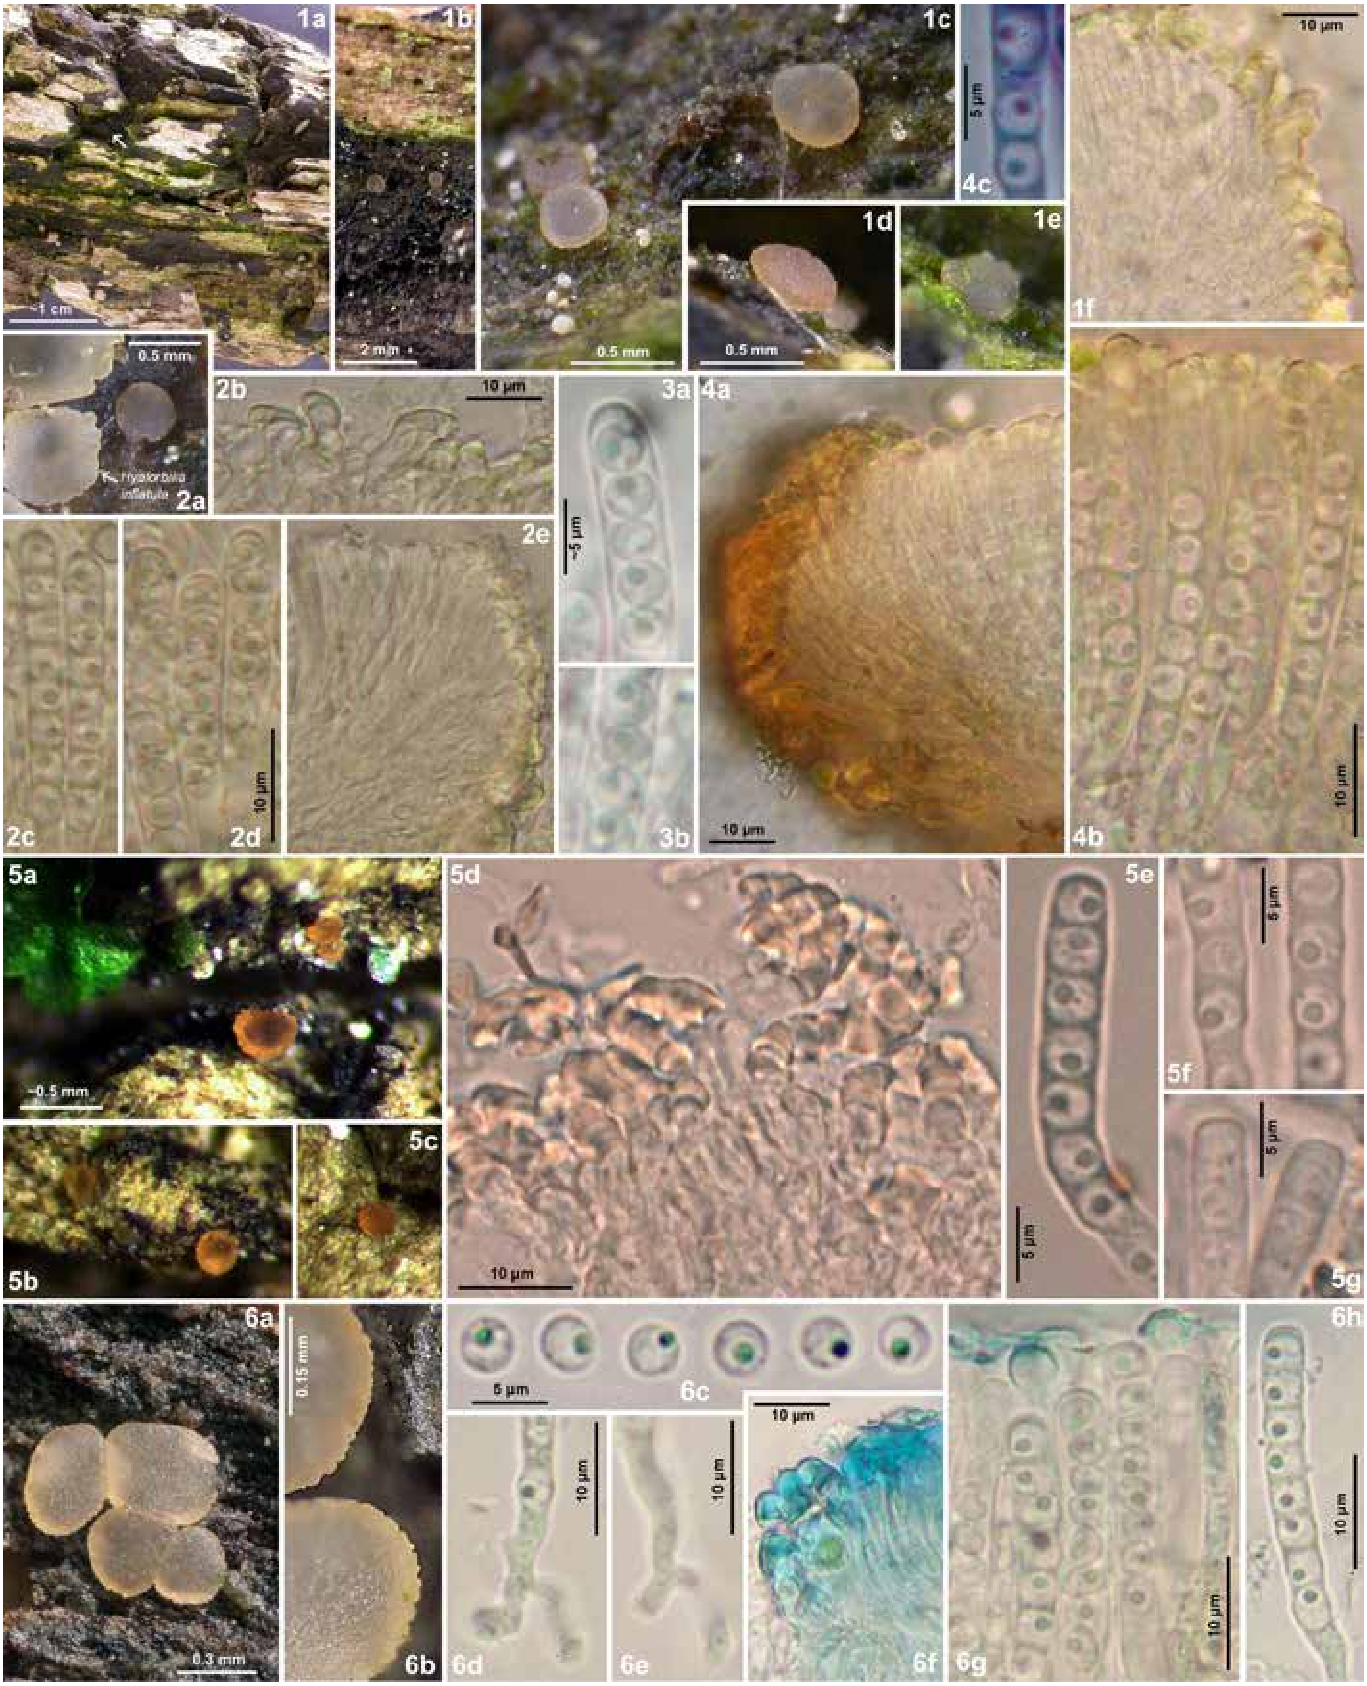

Plate 762. **1–6**: *Orbilia subsphaerospora*. – **1a**. decorticated rotten, blackened, mesic branch of *Acer pseudoplatanus*; **1b–e**, **2a**, **6a–b**. rehydrated/fresh apothecia (**2a** with *Hyalorbilia inflatula*); **5a–c**. dry apothecia; **1f**, **2e**, **4a**, **6f**. marginal ectal excipulum in median section, with glassy processes; **2b**, **5d**. id., in external view; **2c–d**, **3a–b**, **4b–c**, **5e–f**, **6g–h**. asci with ascospores; **5g**. ascus apices, **6d–e**. ascus bases; **6c**. ascospores. – Living state, except for **1f**, **5d**, **6d–e** (partly also **2e**, **4a**; in H_2O), **6f** (in CRB); asci in **2c**, **4b–c**, **5e–g**, **6g–h** p.p. (**4c** in CRB). — **1a–f**. H.B. 8236 (holotype): Switzerland, Luzern, on *Acer*; **2a–d**. H.B. 8241b: ibid., on *Fagus*; **3a–b**. H.B. 7562a: Germany, West-Allgäu, on *Quercus*; **4a–c**. H.B. 7656: Portugal, Santarém, on *Olea*; **5a–g**. UPS F-639447: Sweden, Stockholm, on *Populus*; **6a–h**. E.R.D. 6241: Spain, Asturias, on *Juniperus*.

frullaniae {1}, *Proliferodiscus pulveraceus* {1}, *P. tricolor* {1}, *Radula complanata* {1}, *Sclerococcum* sp. {1}, indet. lichens {1}. **Desiccation tolerance**: immature asci still viable after 2 weeks, paraphyses and spores sometimes after 10 months. **Altitude**: 45 m a.s.l. (hemiboreal Sweden), 730–1010 m (northern Alps), 50–1800 m (southern Europe). **Geology**: Permian (Rotliegend), Cretaceous & Miocene limestone, slate & quartz or clay, flysch; granite, amphibolite, mica schist & gneiss. **Phenology**: IV, VI–VIII, X, XII–I (throughout the year, long-lived).

Taxonomic remarks. *Orbilia subsphaerospora* is very close to the conifericolous *O. sphaerospora*, from which it differs in the cortical excipular cells, which are terminated by very short to medium long glassy processes whereas the cell walls are apparently unable to swell, also in a tendency to subglobose ascospores and to shorter lower cells of paraphyses, finally in the occurrence on angiosperm hosts. In spore features and glassy processes the North American *O. cupularis* is very similar to *O. subsphaerospora*, but differs in an ectal excipulum of textura porrecta, apically uninflated, sometimes sublanceolate paraphyses, and larger, cupulate apothecia.

Variation. No differences in micromorphology between collections from (oro-)mediterranean southern Europe and montane central Europe could be observed. A tendency to subglobose or even subcylindrical or subangular spores was noted in collections from the Alps but also in some (oro-) mediterranean ones. In all collections examined the presence of short glassy processes is strictly correlated with the substrate, except for an orotemperate collection on *Juniperus* which is assigned to *O. subsphaerospora* as it possesses glassy processes (Pl. 762: 6). This also fits well those on angiosperms because its spores were partly subglobose.

Phylogeny. An ITS sequence was taken from apothecia collected on *Salix* in Asturias. As in *O. sphaerospora*, the S1506 intron is absent. *O. subsphaerospora* shows a distance of 2% to *O. sphaerospora* and 2.7% to *O. canadensis*, but also to *O. subovoidea* the distance is only 2.6%.

Ecology. *O. subsphaerospora* was found on ± rotten bark and wood of xeric but also hygric branches and trunks of different broad-leaved trees and shrubs (mainly *Fagales*), rarely conifers (*Juniperus*). Repeatedly the species was found on bark of standing trees in close association with *Frullania* (P. Döbbeler, C. Roux, I. Olariaga pers. comm.). Collections are from mesosubmediterranean to mesomediterranean semihumid southern Europe, more or less orotemperate northern Alps and Pyrenees, and hemiboreal humid southern Scandinavia. The vegetation includes mediterranean *Quercetum ilicis* and *Junipero oxycedri-Quercetum rotundifoliae*, montane *Fagus* forests like *Abieti-Fagetum*, subalpine shrubs with *Juniperus oxycedrus*, and hemiboreal forests with *Populus tremula*.

Map 127. Known distribution of *O. subsphaerospora* in Europe.

Specimens included. **SWEDEN**: **Södermanland**, 32 km S of Stockholm, 9.7 km NE of Ösmo, Häringe, 45 m, trunk of *Populus tremula*, on bark, 6.X.2013, H.G. Thoresson & I. Olariaga (UPS F-639447, doc. vid.). — **GERMANY**: **Baden-Württemberg**, Westallgäuer Hügelland, 13 km E of Lindau, 1.8 km SSE of Scheidegg, 730 m, trunk of *Quercus robur*, on bark,15.VIII.2004, P. Karasch (H.B. 7562a ø). — **SWITZERLAND**: **Nidwalden**, 8.5 km SSW of Luzern, 2.2 km SW of Hergiswil, Renggdössen, 1010 m, branch of *Acer pseudoplatanus*, on wood, 15.VIII.2006, H.O. Latin diagnosis: *Similis* Orbiliae sphaerosporae *sed asci 16-spori, ascosporae subglobosae ad late ellipsoideae. Habitat ad lignum vel corticem putridum ramulorum et ramorum siccorum fruticum* Betulacearum *et* Salicacearum *in zona subarctica ad orotemperata humida Americae et Europae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.8 mm diam., 0.13–0.16 mm high, light to bright pure orange-rose, round, scattered to ± gregarious in small groups; disc slightly concave to flat, margin thin or thick, 0–20 µm protruding, smooth; broadly sessile, superficial or ± erumpent between wood fibres. **Asci** *(51–)55–69 × 5.4–6.4 µm {2}, †50–68 × 4.5–5.7 µm {3}, 16-spored, spores (*) (sub)biseriate, towards base uniseriate († also apically partly uniseriate), lower spores inversely oriented (strongly mixed, some laterally oriented), pars sporifera *35–50 µm long; **apex** (†) slightly to strongly truncate (not indented, laterally not widened), thin-walled, sometimes with apical thickening up to 0.5 µm (with very slight apical chamber); **base** with short to medium long, thick, ± flexuous stalk, T-, L- or h-shaped. **Ascospores** *(3.4–)3.6–4.5(–5.3) × (2.3–)2.5–3.2(–3.4) µm {4}, †3.6–4.2 × 2.4–2.7 µm {1}, subglobose to ovoid or (broadly) ellipsoid, both ends rounded to obtuse; **SBs** *1.1–1.3(–1.5) × 0.8–1.3 µm {3}, globose, sometimes with a very short filum or attachment invisible, also closely attached. **Paraphyses** apically (uninflated to) slightly to medium (rarely strongly) clavate-capitate to spathulate, rarely lageniform or moniliform, terminal cells *5.5–19.5 × (2.5–)3–5(–5.7) µm {3}, lower cells *7–16 × 1.6–2.7(–4) µm {3}; sometimes branched near apex. **Medullary excipulum** hyaline to pale rose-orange, 40–50

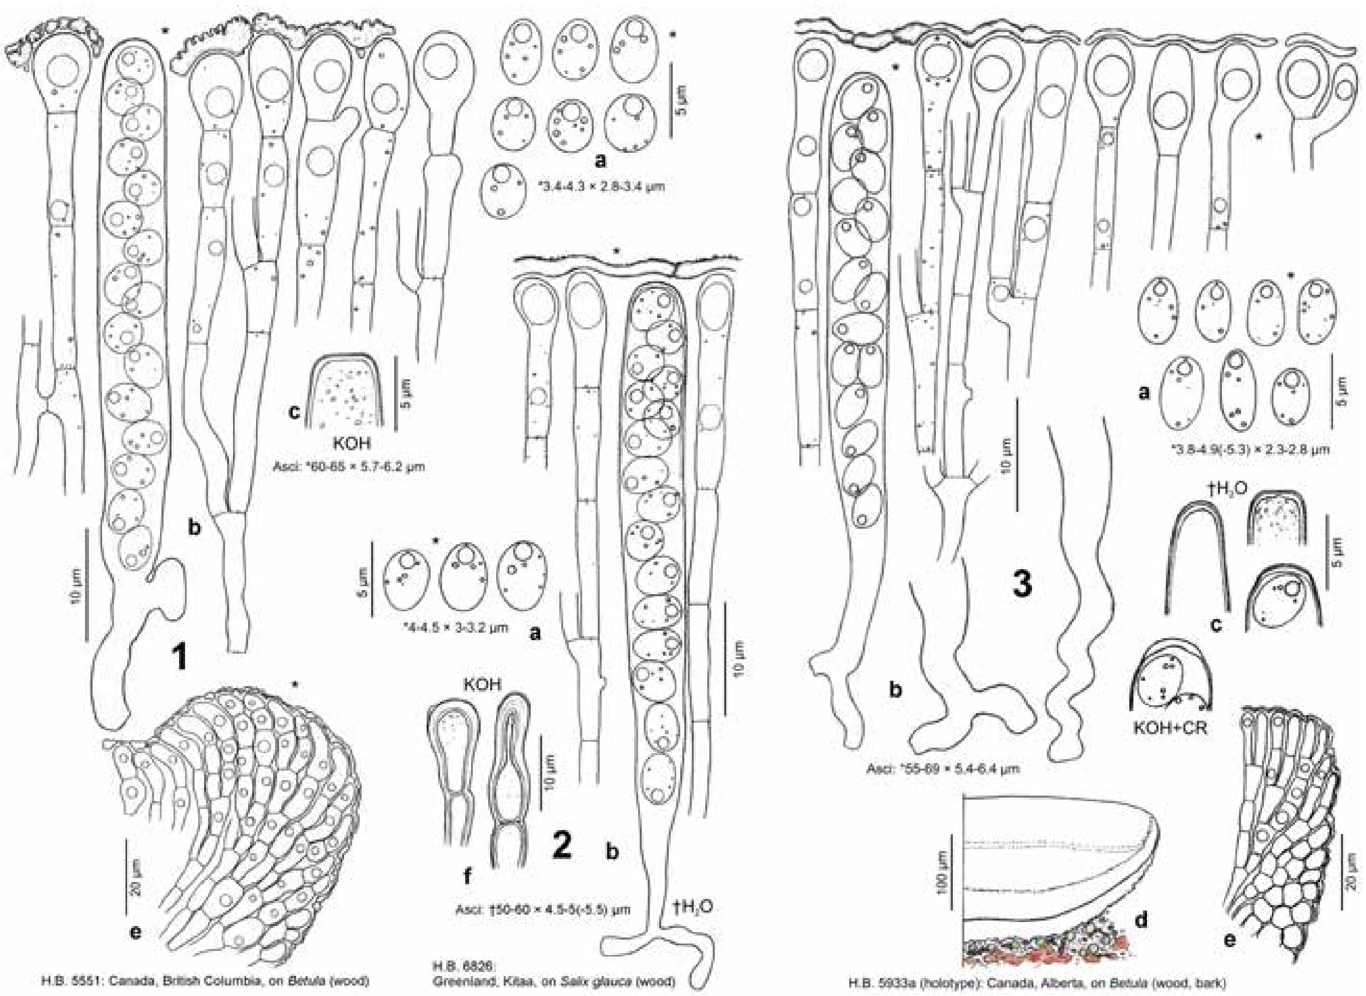

Plate 763. **1–3**: *Orbilia canadensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. cortical cells with thickened wall (but more thin-walled in living state).

µm thick, of medium dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** (very) pale rose-orange, of (†) slightly to medium gelatinized {3} (common walls 0.5–2 µm thick), vertically oriented t. angularis(-prismatica) from base to mid flanks, 25–50 µm thick near base, cells *8–22 × 6–14.5 µm {3}; 15–35 µm thick near margin, of t. prismatica oriented at a 20–45° angle to the surface, marginal cortical cells *8–18 × 2.8–3 or 4–6.5 µm {2}, (*) slightly or (†) strongly thick-walled (inner wall low-refractive), **glassy processes** absent. **Anchoring hyphae** sparse or often abundant, */†2.5–3.5(–4) µm wide, walls *0.2–0.7 µm [†0.3–0.8(–1) µm] thick {3}, forming a dense, medium gelatinized t. intricata up to 20–30 µm thick. **SCBs** globose, in paraphyses (1–)1.8–3.5 µm diam., in excipular cells 1.5–3.5 µm. **Exudate** over paraphyses 0.5–3 µm thick, continuous to cloddy, smooth to rough, very pale yellowish, ± loosely attached; over margin and flanks rough-cloddy. **— ANAMORPH**: unknown (a culture did not form conidia).

Habitat: collected 0–2.5 m above the ground, partially to sometimes entirely decorticated, 3–10 mm thick twigs and branches of (?)*Alnus* sp. {1}, *Betula* sp. {1}, *Populus alba* {1}, *Salix glauca* {1}, on 0.2–0.3 mm deep medium to strongly decayed wood {4}, also on bark (bast) {1}, ± greyed, with some green algae. **Associated**: *Lasionectria* sp. {1}, *Sclerococcum* sp. {1}, *Stictis* sp. {1}, ?*Trimmatostroma* sp. {1}, *Usnea* sp. {2}, small lichens. **Desiccation tolerance**: fully viable for at least 3 months. **Altitude**: 200 m a.s.l. (subpolar tundra), 500–1165 m (boreal forests). **Geology**: Canada & Greenland: Neoproterozoic & Devonian-Mississippian sedimentary rock; Norway: Pleistocene sand & gravel deposited from granite. **Phenology**: VI–VIII (but probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia canadensis* is easily recognized by its subglobose to broadly ellipsoid ascospores and 16-spored asci. It appears to be closely related to the 8-spored *O. sphaerospora*, which differs in ± globose spores and in growing on coniferous substrate, but also to the 8-spored *O. subovoidea* and 32-spored *O. polyspora*, the latter differing in much longer cortical cells of the marginal excipulum.

Variation. In the holotype the spores were ellipsoid (to ovoid), whereas those of the other two specimens were more ovoid to subglobose.

Phylogeny. Sequences were taken from pure culture of a sample from Greenland and from apothecia of a Norwegian collection. Both comprise SSU (without S1506 intron), ITS, and LSU. In the overlapping parts of SSU and LSU they are identical, but they deviate in the ITS by 6 nt and 1 gap (1.1%). In the ITS region a distance of 2.3–2.7% to *O. subovoidea* and *O. subsphaerospora* is observed, and 4.5% to *O. sphaerospora*. In the LSU (D1–D2) the distances are 0.5%, 0.8%, 3.3%, and 6%, respectively.

Ecology. *O. canadensis* was found on ± rotten wood and bark of xeric twigs and branches of angiosperm shrubs and trees of the families *Betulaceae* and *Salicaceae* in the subarctic humid tundra of western Greenland, in orotemperate to boreal humid mixed conifer forests such as Douglas fir in northwestern North America (Canadian Rocky Mountains), and in oroboreal western Scandinavia.

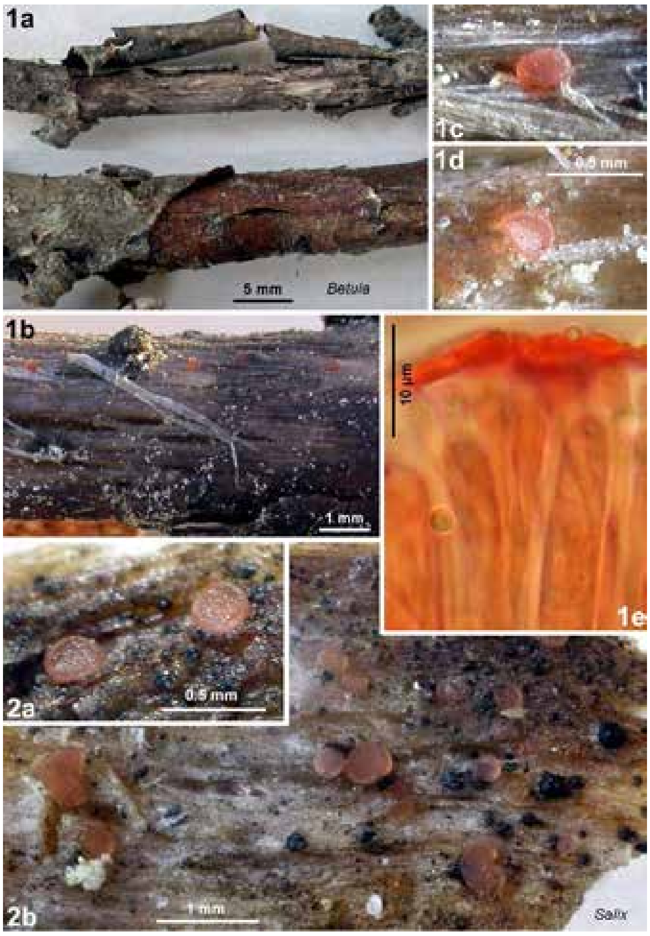

Plate 764. **1–2**: *Orbilia canadensis*. – **1a–b**. decayed semidecorticated xeric branches of *Betula*; **1b–d**, **2a–b**. rehydrated apothecia; **2e**. asci and paraphyses (in KOH+CR). — **1a–e**. H.B. 5933a (holotype): Canada, on *Betula*; **2a–b**. H.B. 6826: Greenland, on *Salix*.

Specimens included. **GREENLAND**: **Qeqqata**, 13 km WSW of Kangerlussuaq, close to Lake Helen, ~200 m, branch of *Salix glauca*, on wood, 14.VIII.2000, A. Raitviir (TAAM 137784, H.B. 6826, BBA 69366; sq.: KT215277). — **CANADA**: **British Columbia**, Canadian Rocky Mountains, ~400 km NE of Vancouver, North Thompson River, SE of Wells Gray, ?S of Blue River, 700 m, branches of (?)*Alnus*, on wood, 20.VI.1996, C. Peller (H.B. 5551). – **Alberta**, 310 km WSW of Edmonton, 7 km NE of Jasper, Maligne Canyon, 1165 m, twigs of *Betula*, on bark & wood, 17.VIII.1997, G. Marson (ex H.B. 5933a, M-0276448, **holotype**). — **NORWAY**: **Sør-Trøndelag**, 2.5 km W of Oppdal, 2 km NNE of Båggåstranda, Vang, 502 m, twig of *Populus canadensis*, on wood, 17.VII.2012, S. Helleman (S.H. 727, doc. vid.; sq.: KY419194).

Orbilia cupularis Baral & G. Marson, **sp. nov.**, MB 813909 — Pl. 765

Etymology: referring to the apothecia having a concave hymenium.

Typification: USA, Utah, Bryce Canyon, branch of *Acer*, on wood, 25.VIII.1994, G. Marson (ex H.B. 5164a, M-0276467, holotype).

Latin diagnosis: *Similis* Orbiliae subsphaerosporae *sed paraphyses leniter spathulatae ad lanceolatae, excipulum ectale ad marginem versus textura porrecta sub angulo acuto orientata, apothecia majora concava, margine magis distincte crenulata. Habitat ad lignum putridum rami sicci* Aceris *in zona orotemperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–1.3(–2) mm diam., 0.2 mm high (receptacle 0.12 mm), pale to light orange-ochre-yellowish, round to irregularly elliptical, ± gregarious; disc strongly concave, margin 10–20 µm protruding, distinctly rough-crenulate, with or without ± prominent teeth; base whitish-cream, with or without obconical stipe up to 0.1–0.2 × 0.2–0.25 mm, superficial; dry bright orange. **Asci** *40–56 × (4–)4.3–4.8 µm, †33–47 × 3.2–4 µm, 8-spored, spores (*) ± uniseriate, finally subbiseriate, irregularly oriented, pars sporifera *19–24 → 14.5–16 µm long; **apex** (†) medium to strongly truncate (not indented, laterally rarely slightly inflated), thin-walled; **base** with short to medium long, thick, slightly flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(3–)3.2–4.3(–4.7) × 2.7–3.3 µm, †2.8–3.2 × 2.5–2.8 µm, broadly ovoid to nearly globose; **SBs** *0.9–1.2(–1.3) × 0.9–1.1 µm, ± globose, eccentrical, placement in subglobose spores often close to lateral wall, attachment not seen. **Paraphyses** apically uninflated to slightly spathulate or lanceolate, partly flexuous, terminal cells *11–21 × 2–3 µm, exceeding the dead asci by 2–4 µm, lower cells *7–13.5 × 1.5–2.3 µm; branched only near base, apices covered by gel. **Medullary excipulum** hyaline, 40–100 µm thick, of medium loose textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** hyaline to pale rose, of (*) thin-walled, vertically oriented t. angularis(-prismatica) at base and lower flanks, 50–60 µm thick near base, cells *8–14 × 6–9.5 µm; 30–40 µm thick at lower flanks, about 200 µm below margin ± abruptly replaced by a strictly parallel, 15–20 µm thick t. porrecta oriented at a 0–20° angle to the surface, cells *10–16 × 2–3 µm, at margin 10–15 µm thick, marginal cortical cells *8–15 × 2–3 µm; **glassy processes** 3–12 × 2–3.7 µm at margin and flanks, medium refractive, yellowish-amber, stratified, scarcely coherent. **Anchoring hyphae** very abundant, forming a dense t. intricata-porrecta 100–120 µm thick, hyphae *1.8–2.5(–3.5) µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose, 0.8–1 µm diam., partly also in ectal excipulum. **Exudate** over paraphyses 0.1–0.2 µm thick, partly rough, firmly attached to apex and subapex, tips ?embedded in gel; on margin and flanks thin, rough; exterior of subiculum with scattered yellow-amber exudate. — **ANAMORPH**: unknown.

Habitat: on a decorticated branch (or root?) of *Acer* sp. lying in dry riverbed, 20 mm thick, surface eroded, mainly in large old beetle galleries which penetrate the wood core, on 0.5–1 mm deep strongly decayed wood, greyed, no algae. **Associated**: *Mellitiosporiella macrospora*, *Orbilia microsoma*, *O. multimaeandrina*, *O. navajoana*, indet. pyrenomycete. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 2300 m a.s.l. **Geology**: Upper Cretaceous calcareous sandstone. **Phenology**: long-lived.

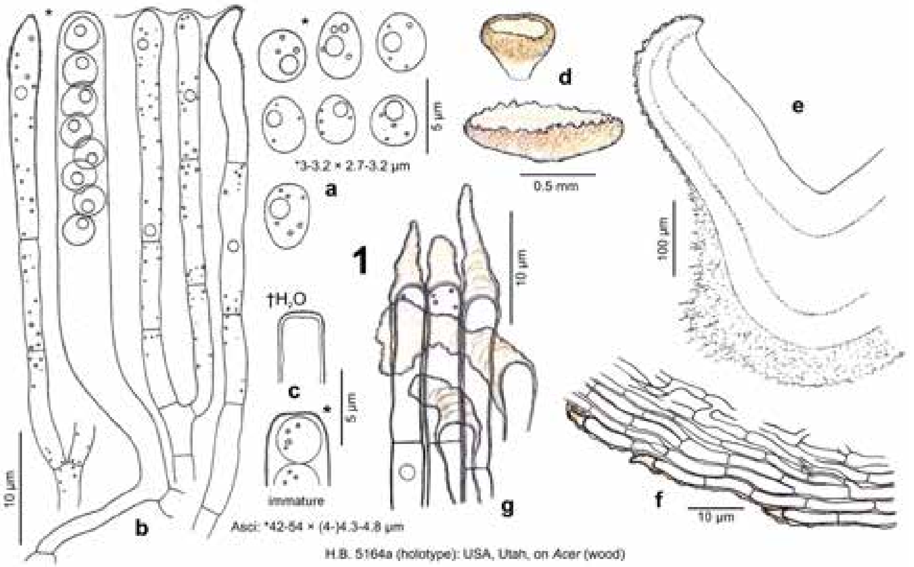

Plate 765. **1**: *Orbilia cupularis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecia with crenulate margin (rehydrated); **e**. apothecium in median section; **f**. id., ectal excipulum at flanks; **g**. cortical cells with glassy processes in external view.

Taxonomic remarks. *Orbilia cupularis* is easily recognized by ± subglobose ascospores, the paraphysis apices showing a tendency to spathulate-lanceolate, a textura porrecta oriented almost parallel to the surface from lower flanks to margin, with the cortical cells overall terminated by glassy processes, comparatively large apothecia with concave disc and crenulate margin, and a stipe-like base covered by a thick layer of anchoring hyphae. The European *O. sphaerospora* and *O. subsphaerospora* resemble *O. cupularis* in spore characters, but differ in most of the other mentioned features. The textura porrecta extending down to the flanks is extraordinary within the whole genus *Orbilia.*

Ecology. *O. cupularis* was found on rotten wood of a xeric branch of *Acer* lying in a dry riverbed in an open forest with *Quercus*, *Acer*, *Populus tremuloides* and *Cercocarpus ledifolius* in the cold-temperate subhumid ponderosa pine forest of the Utah Mountains in the southwest of Northern America. The holotype consists of ~25 apothecia and represents the only known collection of this species.

Specimens included. **USA**: **Utah**, Utah Mts., Bryce Canyon, 33 km SE of Panguitch, 8 km WSW of Tropic, Navajo Trail SE of Sunset Point, 2300 m, branch of *Acer*, on wood, 25.VIII.1994, G. Marson (ex H.B. 5164a, M-0276467, **holotype**).

Orbilia ovoidea Baral & G. Marson, **sp**. **nov**., MB 813910 — Pls 766–767, Map 128

Etymology: named after the ovoid ascospores.

Typification: Spain, Teruel, Guadalaviar, branch of *Prunus domestica*, 26.IX.1999, G. Marson (ex H.B. 6489a, M-0276547, holotype; sq.: KT215275).

Latin diagnosis: *Apothecia rehydratata 0.25–1.3 mm diam.*, *vivide aurantiaca vel roseo-rubra*, *sessilia*, *margine laevi. Asci 8-spori. Ascosporae *5–7.7 × 3–4 µm*, *ellipsoideae ad ovoideae vel late fusoideo-clavatae*, *basi partim curvatae*, *corpusculum refringens globosum*, *ad apicem cuspide brevi affixum continentes. or rose-red, slightly translucent, round to somewhat undulating, scattered to gregarious in small groups; disc slightly concave to flat, margin thick, 0–20 µm protruding, smooth; broadly sessile, mostly erumpent (immersed in cracks); dry bright to deep (rose-)orange-red. **Asci** *(60–)65–75(–81) × (5.5–)6–6.8(–7.3) µm {3}, †(51–)55–75(–80) × (4.2–)5–6(–6.5) µm {3}, 8-spored, spores (*) subbiseriate above, uniseriate below († uniseriate), (2–)3–6(–8) lower (or sometimes upper) spores inverted {3} (mostly mixed), pars sporifera *28–39 µm long; **apex** (†) (slightly to) medium truncate (not indented), thin-walled {2}, sometimes with a 0.8–1.3 µm thick dome {2}, with indistinct apical chamber; **base** with short to medium long, thick, flexuous stalk, Y- to h-shaped. **Ascospores** *5–7(–8)((–9)) × 3–3.7(–4) µm {5}, ellipsoid-(ob)ovoid or ellipsoid- to broadly fusoid-clavate, rarely subcylindric-triangular, apex rounded to often obtuse, base very variable, strongly attenuated or not, straight or slightly to medium curved at base; **SBs** *1.3–1.6(–1.8) × (1–)1.1–1.3(–1.4) µm {3}, globose, with a very short filum, attachment mostly visible. **Paraphyses** apically (uninflated to) slightly or medium clavate-capitate, also spathulate to lageniform, terminal cells *(6–)9–25 × (2–)2.5–4.3(–4.7) µm {3}, lower cells *11–19 × 1.5–2.5 µm {2}; rarely branched at upper septum, hymenium pale to light orange-rose. **Medullary excipulum** subhyaline to pale rose, 40–50 µm thick, of dense, horizontally oriented textura intricata with many inflated cells, medium sharply delimited from ectal excipulum at flanks by a 10 µm thick layer of t. porrecta. **Ectal excipulum** of (*/†) slightly gelatinized, ± vertically oriented t. angularis-prismatica from base to submargin, 35–60 µm thick near base, cells *7–20 × 6–11 {2} or 9–29 × 7–20 {T} µm; 20–50 µm thick at flanks and margin, 2-layered: inner layer of pale rose-orange t. angularis-prismatica oriented at a ~60–80° angle to the surface, cells *5–10 × 5–7 µm, outer layer of hyaline t. porrecta oriented at 30–50°, hyphae ± flexuous, conglutinate, 15–40 µm long, septate when long, walls overall strongly thickened (much thinner when viable) {4}, terminal cells */†9–20 × (2.5–)3–4.5(–5) µm {2}; **glassy processes** absent. **Anchoring hyphae** (very) abundant, *2–4 µm wide, walls (0.2–)0.3–0.7(–1) µm thick {2}. **SCBs** globose, in paraphyses 1–2(–3) µm diam.; in ectal excipulum (near margin) 1.7–2 µm diam. **Exudate** over paraphyses and excipulum (0.5–)1–2(–3.5) µm thick, cloddy, loosely attached. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). **Conidiophores** unknown. **Conidia** unbranched, medium to strongly curved, strongly tapered towards both ends, *49–80 × 5.5–9 µm, 8–13-septate {1}, terminal cells longer than remaining cells.

Habitat: collected 0.4–3 m above the ground, partially to entirely decorticated, 6–25 mm thick branches of *Acer* sp. {1}, *Cedrus atlantica* {1}, *Juglans regia* {2}, *Lonicera xylosteum* {1}, *Pinus sylvestris* {1}, *Prunus domestica* {1}, *Pyrus communis* {1}, *Rosa* sp. {1}, *Salix eleagnos* var. *angustifolia* {1}, *Ulmus* sp. {1}, on 0.2–0.5 mm deep strongly decayed wood {10}, strongly greyed, green algae medium abundant. **Associated**: *Mellitiosporiella pulchella* {1}, *Orbilia gambelii* {1}, *O. polyspora* {1}, *O. vinosa* {1}, *Perrotia flammea* {1}, *Propolis farinosa* {1}, *Sclerococcum* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 627–1600 m a.s.l. **Geology**: Jurassic & Cretaceous limestone, dolomite breccia. **Phenology**: VI–X (but long-lived).

Taxonomic remarks. *Orbilia ovoidea* is characterized by broadly ellipsoid-ovoid, basally often attenuated and somewhat curved ascospores with a large globose spore body which is apically attached by a very short filum. Very similar as in *O. polyspora*, there is a hyaline outer layer of the ectal excipulum composed of thick-walled hyphae, which resemble a textura oblita and emerge from the excipular cells at flanks and margin. The very similar but variable *O. subovoidea* differs in narrower spores, with the globose SBs mostly more close to the spore apex and often attached without a very short filum, also in shorter marginal excipular hyphae which are partially thick-walled at their ends, and in smaller asci. At one of the collection sites of *O. ovoidea*, *O. subovoidea* grew in association on the same substrate but on a different branch.

O. clavipisca differs from *O. ovoidea* in the predominant presence of an apical ascus wall thickening, longer spores with a more regularly tapered base, and in growing on coniferous hosts in North America. The Australian *O. amberina* differs in much shorter asci and slightly shorter spores, also in rather thin-walled marginal cortical cells in the dead state, and in more amber-brown apothecia.

Variation. Especially the base of the spores varies rather strongly in shape within most of the collections examined, with a tendency to be attenuated only in some of the spores. Spore size was rather consistent in a majority of collections, with the width distinctly over 3 µm in a majority of spores. In some collections spore width was sometimes only around 3 µm (e.g., J.P.P. 10130, 10133), hence delimitation from *O. subovoidea* was problematic. The length of the thick-walled marginal hyphae also differed between the collections, as did the size of the basal excipular cells.

Map 128. Known distribution of *O. ovoidea* in Europe.

Anamorph. Only once we found in *O. ovoidea*, as in the very similar *O. subovoidea*, large, slightly to strongly curved phragmoconidia on the natural substrate (Pl. 766: 1h).

Phylogeny. A sequence taken from pure culture of the holotype from Cuenca (H.B. 6489a) comprises SSU (with two introns: S1506 and S1516), ITS, and LSU. It shows in the ITS region a distance of 12–12.5% to *O. subovoidea*, *O. canadensis*, and *O.* (*sub*)*sphaerospora*, and 17% to *O. polyspora*. In the LSU (D1–D2) the distance lies in the range of 2.6–3.3%, but to *O. polyspora* 6%. The rather high distance to the similar *O. subovoidea* is astonishing, as also mentioned under that species. In the S1506 intron a 10% distance is observed to *O. subovoidea* in the overlapping 343 nt. The small intron S1516 in the region of the ITS1 primer has a length of 70 nt and was not observed in any other member of *Orbiliomycetes*.

Ecology. *O. ovoidea* was found on rotten wood of xeric branches of different angio-, rarely gymnosperm trees and shrubs in orotemperate and orosub- to suprasubmediterranean humid regions of central Europe (Austrian northern Alps) and southern Europe (Southern French Alps, Sierra de Albarracín).

Specimens included. **AUSTRIA**: **Tirol**, 2.5 km NNE of Landeck, 1 km NW of Zams, Zammer Lochoutz waterfall, 800 m, branch of *Pinus sylvestris*, on wood, 16.VI.2011, M. Orbilia subovoidea Baral, Matočec & E. Weber, **sp. nov**., MB 813911 — Pls 768–769, Map 129

Etymology: named after the similarity to *O. ovoidea*.

Typification: Greece, Laerma, twig of *Pistacia lentiscus*, 21.III.2010, V. Kummer (ex H.B. 9334a, M-0276597, holotype; sq.: KT222428).

Latin diagnosis: *Similis* Orbiliae ovoideae *sed ascosporae angustiores, corpuscula refringentia cuspide brevissime vel confertim affixa, cellulae crassitunicatae exipuli marginalis breviores. Habitat ad lignum putridum ramorum siccorum fruticorum vel arborum angiospermarum in zona thermomediterranea ad mesotemperata (semi)humida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.5(–0.7) mm diam., 0.1–0.22 mm high, pale to bright reddish-orange to rose, medium translucent, round to slightly irregular, scattered to gregarious; disc slightly concave to slightly convex, margin thin or thick, 0–5 µm protruding, smooth; sessile on a narrow base, superficial to erumpent (slightly to medium immersed); dry light to bright (carmine-) red. **Asci** *(36–)50–65(–70) × (4.5–)5–6(–6.3) µm {10}, †(40–)45–60(–75) × 4.5–5(–5.5) µm {5}, 8-spored, spores *1–2-seriate, (2–)3–6(–7) lower spores inverted {10} (often mixed), pars sporifera *25–36(–43) µm long; **apex** (†) slightly to strongly truncate (not indented, laterally not or very slightly inflated), thin-walled {9}, exceptionally with up to 1 µm thick dome {3}; **base** with short to long, thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(4–)4.5–8(–9) × (2–)2.2–3(–3.3) µm {18}, †5–7 × 2–2.3 µm {1}, subcylindric to ellipsoid(-clavate) or ovoid, more rarely fusoid-clavate, apex rounded to obtuse (exceptionally subacute), towards base not or slightly, sometimes strongly attenuated, straight or slightly to medium curved near base; **SBs** *(0.8–)1–1.3(–1.5) × (0.6–)0.8–1.1(–1.2) µm {12}, globose to very broadly tear-shaped, apically closely attached to spore wall or narrowed to a ± small point, rarely with a very short filum. **Paraphyses** apically uninflated or slightly to medium clavate-capitate, sometimes spathulate or lageniform, sometimes ± flexuous, terminal cells */†(5.5–)9–18(–25) × (1.8–)2.3–3.5(–4.2) µm {5}, lower cells *6–15 × 1.7–2.8 µm {4}; sometimes branched at upper septum, hymenium pale rose. **Medullary excipulum** pale rose, 40–70 µm thick, of medium dense textura intricata with many inflated cells, medium sharply delimited from ectal excipulum only at flanks by an indistinct 10 µm thick t. porrecta. **Ectal excipulum** pale rose, of (*/†) distinctly gelatinized, indistinctly oriented t. globulosa-angularis from base to mid flanks, 30–70 µm thick near base, cells *8–17(–21) × 6–12(–15) µm {4}; 20–25 µm thick at flanks, cells *5–10 × 3–9 µm; 15–25(–30) µm near margin, of medium gelatinized t. prismatica-porrecta oriented at a 20–80° angle to the surface, marginal cortical cells */†7–13(–15) × (2–)2.5–4(–5) µm {4}; **glassy processes** absent, but terminal cells at flanks and margin often with strongly thickened walls, especially at their apex, wall here †(1–)2–5(–6) µm thick, about half as thick when in the living state. **Anchoring hyphae** medium (to very) abundant, */†(1.7–)2–3(–3.5) µm wide, walls (0.2–)0.3–0.5(–1) µm thick {5}. **SCBs** in paraphyses and in ectal excipulum (near margin) globose, 1–2.8 µm diam. {11}. **Exudate** over paraphyses, margin and flanks (0.5–)1–2(–3) µm thick, granular-cloddy to continuous, hyaline, ± loosely attached. **— ANAMORPH**: vermispora-like (presumed, from natural substrate {3}). **Conidiophores** not seen. C**onidia** unbranched, almost straight to strongly curved, strongly tapered towards ends, *67–82 × 5.5 µm {1}, †31–74 × 4.2–5 {1}, (8–)11–13-septate; or †37–53 × 6.5–8 µm {1}, 9–12-septate; terminal cells often longer than remaining cells.

Habitat: collected 0.1–4 m above the ground, corticated to partially or often entirely decorticated, 3.5–40 mm thick twigs and branches of *Acer* sp. {1}, *Arbutus unedo* {1}, *Cercocarpus ledifolius* {1}, *Cistus* sp. {1}, *Cytisus scoparius* {1}, *Genista scorpius* {1}, *Lonicera* (?) *xylosteum* {1}, *Petteria ramentacea* {1}, *Pistacia lentiscus* {1}, *Quercus ilex* {2}, *Q. rotundifolia* {1}, *Rhamnus alaternus* {1}, *Rosa* sp. {4}, *Rosmarinus officinalis* {2}, *Salix* sp. {1}, on 0.1–1 mm deep or more (slightly to) strongly decayed wood {13} or bark {4}, slightly to strongly greyed, with a few to many green algae. **Associated**: *Baggea* sp. {1}, *B. pachyascus* {1}, ?*Calloria* sp. {2}, *Candelariella lutella* {1}, '*Chlorosplenium*' *viridulum* {1}, *Cryptodiscus* sp. {1}, *C. foveolaris* {1}, *Durella* ?*atrocyanea* {1}, *D. connivens* {1}, *Evernia furfuracea* {1}, '*Helotium*' *uvidulum* {1}, *Hysterographium fraxini* {1}, *Lecidella elaeochroma* {1}, *Mellitiosporiella pulchella* {4}, *Mollisia rosae* {1}, *Orbilia angiosubvinosa* {1}, *O. arizonensis* {1}, *O. delphinus* {1}, *O. euonymi* {3}, *O. flexisoma* {1}, *O. gambelii* {5/1}, *O. maeandrina* {1}, *O. ocellata* {1}, *O. pleiogambelii* {1}, *O. polyspora* {1}, *O. purshiae* {1}, *O. rosicola* {1}, *O. subaristata* {3}, *O. subclavuliformis* {3}, *O. vinosa* {6}, *Parmelia sulcata* {1}, *Perrotia flammea* {1}, *Physcia leptalea* {1}, *Propolis farinosa* {2}, *P. viridis* {2}, *Schizoxylon* sp. {1}, *Unguiculariopsis* sp. {1}. **Desiccation tolerance**: fully viable for at least 3 months. **Altitude**: 8–1630 m a.s.l. (Europe), 2500 m (North America). **Geology**: USA: Pennsylvanian-Permian sand- & limestone; Europe: alluvial deposits from Cambrian-Ordovician silt- & sandstone and granite, Cretaceous limestone, dolomite, marl, sand & slate. **Phenology**: III–VII, IX–XI (throughout the year, long-lived).

Taxonomic remarks. *Orbilia subovoidea* is characterized by subcylindrical to ellipsoid-ovoid, basally sometimes narrowed and slightly curved spores which contain ± globose SBs closely attached to the spore apex. From the similar *O. ovoidea* the species is not sharply separated morphologically (for the differences see p. 1256.). *O. subcylindrospora* closely resembles those specimens of *O. subovoidea* with cylindrical spores, but differs in smaller spores and SBs and a stronger tendency to curved spores; yet, transitional collections exist which suggest a continuum between the two species. Large-spored populations of *O. eucalypti* (section *Orbilia*) resemble *O. subovoidea* in many respects, but sharply differ in much smaller SBs, also in the frequent presence of medium-sized, KOH-resistant LBs in the spores, in the absence of thick-walled marginal cortical cells, and in a different anamorph.

Variation. *O. subovoidea* is very variable in spore size and shape (broadly ellipsoid or ovoid to subcylindrical or fusoid-clavate). This variation was even observed within a collection, or a single apothecium. Length varied from 4–6 µm up to 6–9 µm, and width from 2–2.3 µm up to 2.7–3.3 µm. Wider spores were usually shorter, hence the spore volume showed much less variation. In some collections broad ellipsoid spores occurred together with narrow subcylindrical spores in a similar abundance (see Pls 768: 2a, 3a; 769: 5h–j, 6c), sometimes even within a single apothecium (Pl. 769: 7), but intermediate spore shapes were also frequent. Those specimens with predominantly rather wide, ellipsoid spores are sometimes difficult to distinguish from *O. ovoidea*.

Basally curved spores were only noted in some spores of some collections. In the first studied collection (on *Acer*, Pl. 768: 1a) a few spores deviated in subacute apices and a fusoid-clavate shape. In three collections (H.B. 5511a, 7002, 7417a) a few asci had a distinct apical thickening up to †1 µm (Pl. 769: 1e). Also in the North American sample on *Cercocarpus*

Map 129. Known distribution of *O. subovoidea* in Europe.

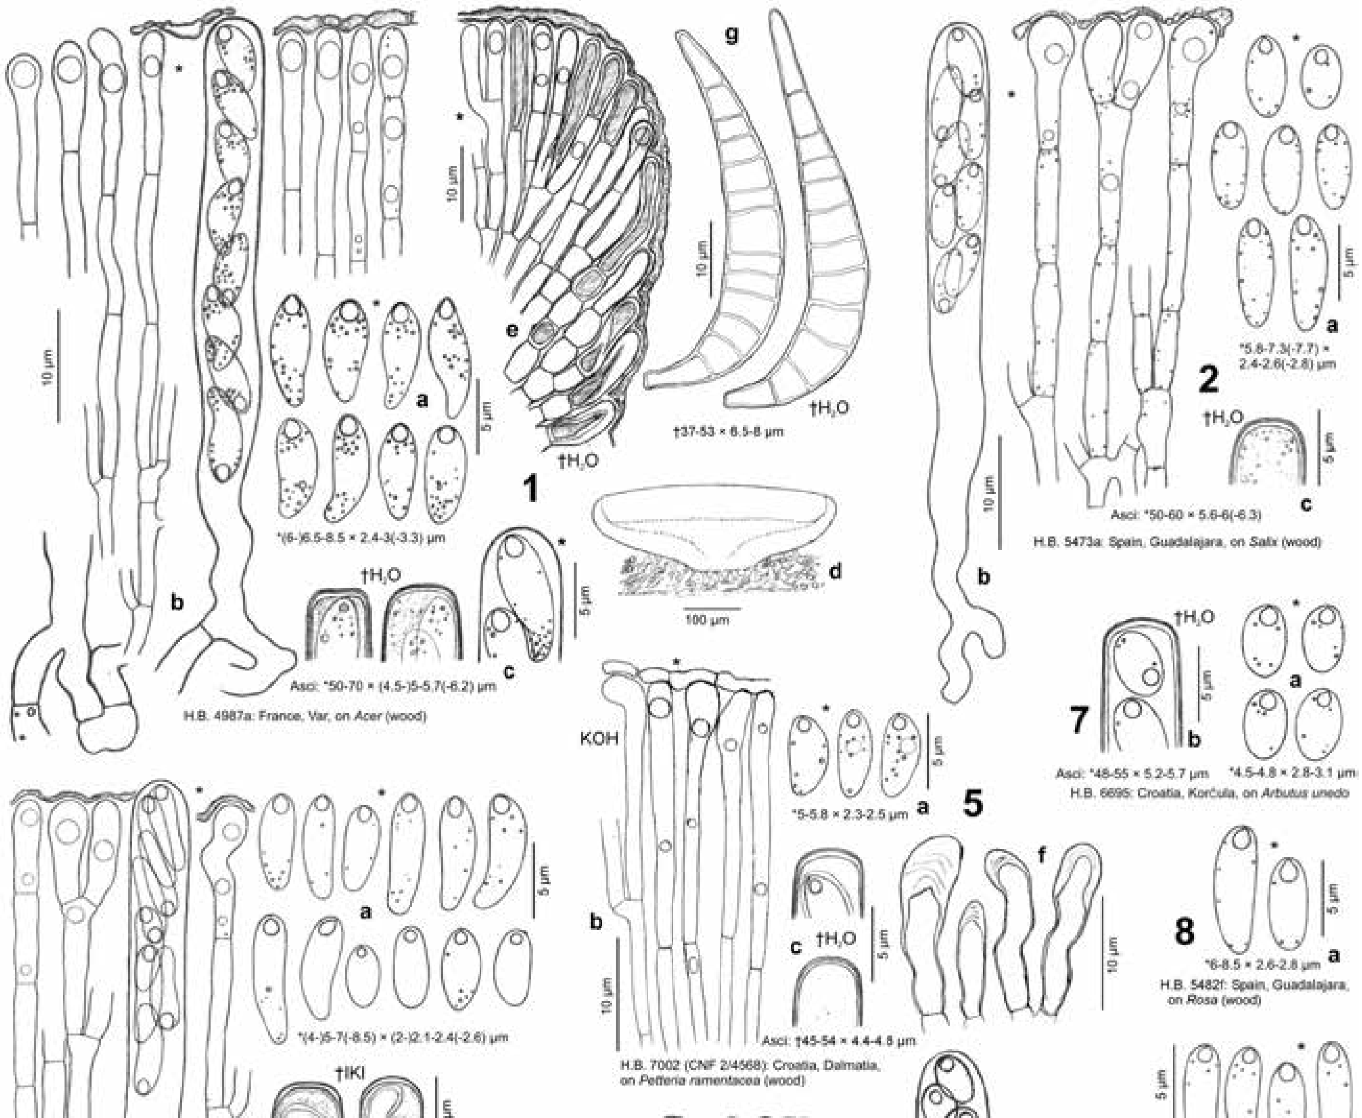

Plate 768. **1–11**: *Orbilia subovoidea*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **e–f**. marginal cortical cells with internal wall thickening when dead; **g**. conidia from substrate. – **5b** p.p. (living paraphyses), **5f**, **6a** upper 5 spores, right ascus: del. N. Matočec.

Plate 769. **1–7**: *Orbilia subovoidea*. – **1a**, **5a**. decorticated decayed xeric branches (**5a** with *Lecidella elaeochroma* & *Candelariella lutella*); **1a–c**, **3a–b**, **5b–f**, **6a–b**. rehydrated apothecia (**1** after 11 years, **3** after 13 years, **5** after 2 months, **6** after 5 days), **7a**. dry apothecia; **2c**, **5g**. apothecia in median section; **3e**, **5k**. id., marginal ectal excipulum; **1d**. exudate on margin (external view); **1e**, **3c**. ascus apices; **5l**, **7c**. apices of paraphyses; **5h**, **m–n**, **7b**. upper part of mature asci; **2a–b**, **4a–c**, **5h–j**, **6c**, **7d–e**. ascospores; **3d**. conidia from substrate. – Living state (**7d** in CRB), except for **2c**, **3d** (in H_2O); **1e**, **3c**, **e** (in KOH+IKI); asci in **2a–b**, **4a–c**, **5h–j**, **7b** left. – **6a–c**: phot. E. Rubio; **7a–e**: phot. R. Tena. — **1a–e**. H.B. 5511a: Spain, Guadalajara, on *Rosa*; **2a–c**. H.B. 7238e: France, Vaucluse, on *Lonicera*; **3a–e**. H.B. 4987a: France, Var, on *Acer*; **4a–e**. H.B. 7417a: Turkey, Balıkesir, on *Quercus*; **5a–n**. H.B. 9334a (holotype): Greece, Rhodos, on *Pistacia*; **6a–c**. E.R.D. 5265: Spain, Asturias, on *Rhamnus*; **7a–e**. 25.IV.2012: Spain, Teruel, on *Rosa*.

ledifolius (Pl. 768: 11) a slight ascus apical thickening (< 1 µm) was noted in the dead state.

Anamorph. The conidia observed on the natural substrate strongly varied in size. Those in Pls 768: 1; 769: 3d are much wider and never as long as those seen in two other specimens (Pl. 768: 10; IVV: H.B. 7417a); the conidia in the former collection strongly resemble in size and shape those of *O. ovoidea*, though being slightly shorter. *O. ovoidea* grew in association in this collection, though on a separate branch, so it could be that these shorter and wider conidia belong to *O. ovoidea*.

Phylogeny. A sequence taken from apothecia of the holotype from Rhodos comprises S1506 intron, ITS, and LSU. It shows in the ITS region a distance of 2.3–2.7% to *O. canadensis* and *O. subsphaerospora*, and 4.2% to *O. sphaerospora*. In the LSU (D1–D2) the distances are 0.5%, 0.6%, 2.8%, and 5.6%, respectively. The high distance to *O. ovoidea* is surprising, considering the difficulty to distinguish the two species morphologically.

At pos. 121 and 134 of the 5.8S region, which is part of stem-loop B8, *O. subovoidea* differs by G+C from members of section *Ovoideae* which have A+T like most *Orbilia* spp. G+C is otherwise only seen in section *Orbilia* p.p. and a few of section *Arthrobotrys* (Tab. 18).

Ecology. *O. subovoidea* was collected on ± rotten wood and bark of xeric twigs and branches of various broad-leaved trees and shrubs in thermo- to supramediterranean and supra-submediterranean semihumid, rarely orosubmediterranean or mesotemperate humid regions of southern and atlantic western Europe, moreover in a cold-temperate humid ponderosa pine forest of the Colorado Plateau in the southwest of Northern America.

Specimens included. **FRANCE**: **Bretagne**, **Morbihan**, 9.5 km SE of Malestroit, 2.7 km WNW of St.-Martin-sur-Oust, Beauvais, 8 m, branch of *Cytisus scoparius*, on wood, 1.III.2009, J.P. Orbilia amberina Baral & G. Marson, **sp. nov.**, MB 813912 — Pls 770–771

Etymology: named after the amber-coloured apothecia.

Typification: Western Australia, Moora, branch of *Verreauxia reinwardtii*, 24.X.2007, G. Marson (ex H.B. 8748c; MEL 2389257A, holotype).

Latin diagnosis: *Similis* Orbiliae ovoideae *sed asci multi breviores, ascosporae leniter breviores, cellulae excipuli marginalis tenuitunicatae. Habitat ad corticem putridum ramorum siccorum fruticorum vel arborum angiospermarum in zona subtropica semihumida ad semiarida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.13–0.35 mm diam., 0.09–0.12 mm high, light to bright orange- to amber-brown, slightly translucent, ± round, scattered; disc flat, margin distinct, thick, 5–12 µm protruding, smooth; sessile, ± deeply immersed in cracks or holes of bark. **Asci** *48–52 × 5.5–6.5 µm {1}, †(30–)34–42 × 4.2–5.2(–5.5) µm {2}, 8-spored, spores (*) uniseriate, lower spores ± inverted but often oriented in all directions (especially the middle spores), pars sporifera *33 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not inflated), thin-walled or sometimes with dome †0.3–0.8 µm thick {1}, without apical chamber; **base** with short to long, thick or thin, flexuous stalk, L-, T- or h-shaped. **Ascospores** *(3.7–)4.2–

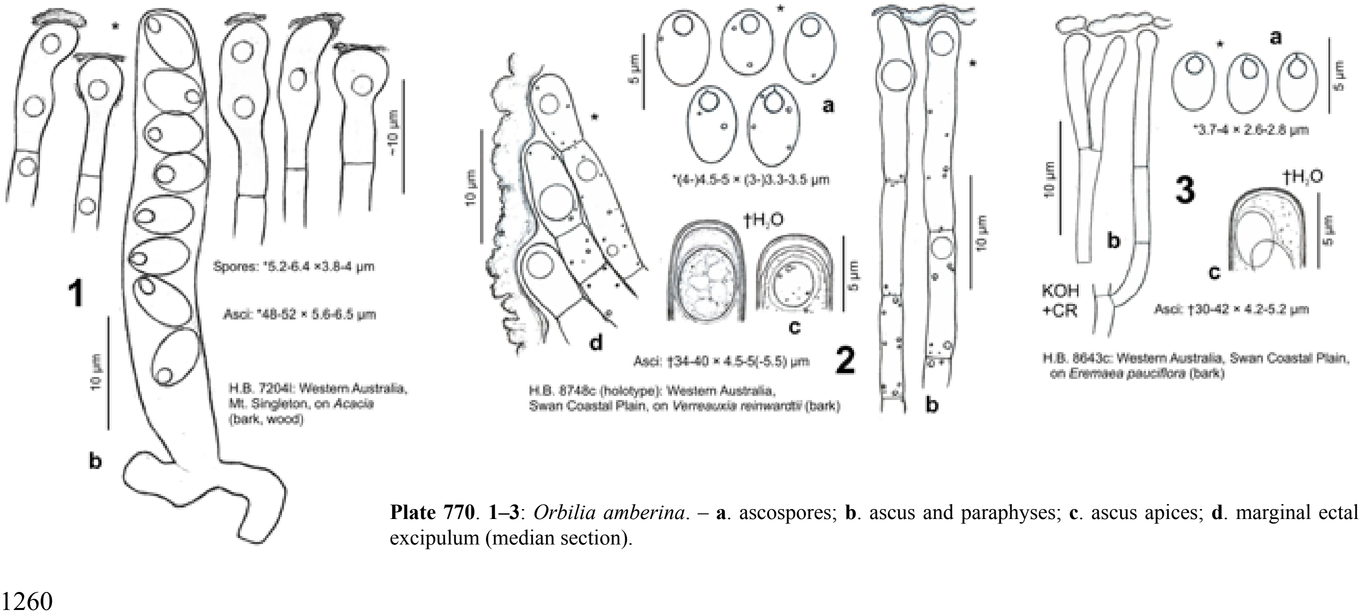

Plate 770. **1–3**: *Orbilia amberina*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum (median section).

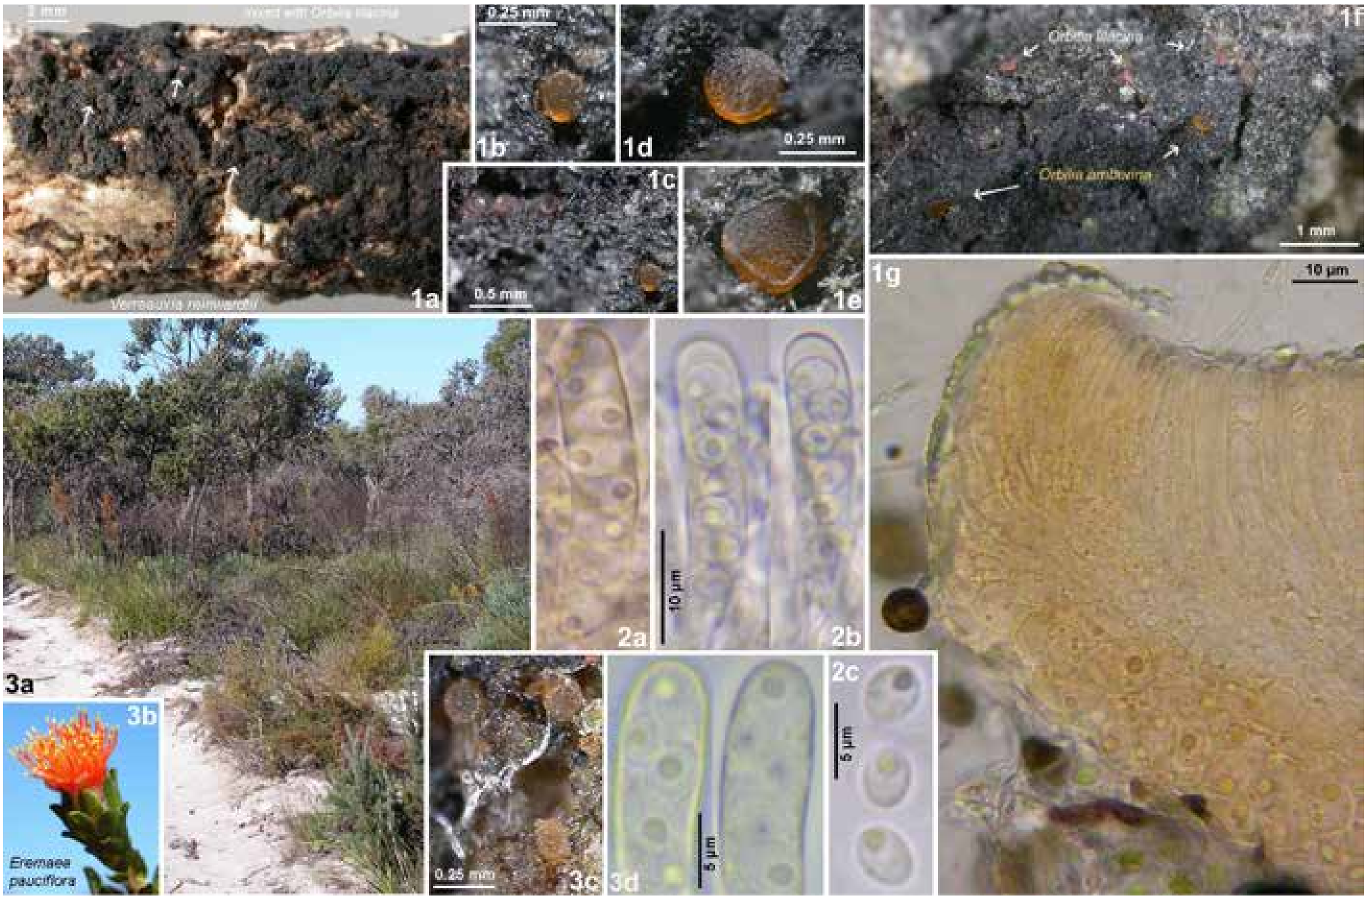

Plate 771. **1–3**: *Orbilia amberina*. – **3a**. banksia-eucalypt woodland with *Eremaea*; **3b**. flowering *Eremaea pauciflora*; **1a**, **f**. dead corticated xeric branch of *Verreauxia reinwardtii*, mixture with *Orbilia lilacina*; **1b–f**, **3c**. rehydrated apothecia; **1g**. apothecium in median section (marginal region); **2a–c**, **3d**. asci and ascospores. – Living state, except for asci in **2a**, **3d**. — **1a–f**. H.B. 8748c (holotype): Western Australia, Swan Coastal Plain, on *Verreauxia*; **2a–d**. G.M. 2006-09-03.3: ibid., on *Banksia*; **3a–d**. H.B. 8643c: ibid., on *Eremaea*.

5.5(–6.5) × (2.6–)3–3.7(–4.2) µm {4}, subglobose to broadly ellipsoid, ends rounded to obtuse, straight; **SBs** *1.5–1.9 × 1–1.5 µm {2}, globose, with a very short, sometimes invisible filum. **Paraphyses** apically uninflated or slightly to sometimes strongly clavate-capitate, sometimes lageniform, terminal cells *10–19 × 2.5–4.5 µm {2}, †8–13 × 1.5–2 µm {1}, lower cells *10–11 × 2–2.5 µm {1}, †6–10 × 1.2–1.5 µm {1}; rarely branched at upper septum, hymenium pale orange. **Medullary excipulum** hyaline to pale orange, 25–30 µm thick, of dense textura intricata with many inflated cells, indistinctly delimited. **Ectal excipulum** light orange, of (†) thin-walled to medium gelatinized (common walls 0.3–2 µm thick), indistinctly oriented t. globulosa-angularis from base to mid flanks, 25–30 µm thick near base, cells *8–11(–15) × 6–10(–11) µm {1}; 10–25 µm thick near margin, of t. prismatica oriented at a 10–30° angle to the surface, marginal cortical cells *7–10 × 3.5–4 µm {1}, †7–10 × 3–3.8 µm {1}, with thin to slightly gelatinized but unswellable walls; **glassy processes** absent. **Anchoring hyphae** sparse to ± abundant, †2–3.3(–4) µm wide, walls 0.2–0.4(–1.2) µm thick {2}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.5–3 µm diam.; **LBs** in ectal excipulum 1–3(–4) µm diam., light yellow-orange (but absent in another apothecium examined), at margin and in paraphyses much smaller. **Exudate** over paraphyses 0.3–2.5 µm thick, cloddy, hyaline to very pale yellowish, ± loosely attached, over margin and flanks 1–4 µm thick, forming large, very rough clods. — **ANAMORPH**: unknown.

Habitat: collected (0–)0.2–1 m above the ground, corticated, 8–11 mm thick branches of *Acacia* sp. {1}, *Banksia menziesii* {1}, *Eremaea pauciflora* {1}, *Verreauxia reinwardtii* {1}, on 0.3 mm deep strongly decayed bark {2} (bast), strongly greyed, without or with some or many green algae. **Associated**: *Capronia* sp. {1}, *Gloniopsis praelonga* {1}, *Hyalorbilia juliae* {1}, *Orbilia australiensis* {1}, *O. austrocylindrica* {2}, *O. austroobtusispora* {1}, *O. aviceps* {1}, *O. aviflagellata* {1}, *O. curvativitalbae* {2}, *O. eucalypti* {2}, *O. helicoobliqua* {1}, *O. hesperidea* {1}, *O. lilacina* {1}, *O. microserpens* {2}, *O. multicurvula* {1}, *O. multiserpens* {1}, *O. myriolilacina* {1}, *O. myrioobliqua* {1}, *O. nothovinosa* {1}, *O. paraobliqua* {1}, *O. pleioaustraliensis* {1}, *O. pleioaustrocylindrica* {1}, *O. pleistovitalbae* {1}, *O. plurililacina* {2}, *O. triangulispora* {1}, *Ostropales* {1/1}, ?*Parmelia* sp. {1}, *Patellaria* ?*andina* {1}, *Proliferodiscus olivaceoviridis* {2}, ?*Triblidium* sp. {1}. **Desiccation tolerance**: paraphyses and spores still viable for at least 4 months, after 13 months only spores alive. **Altitude**: 77–380 m a.s.l. **Geology**: Archean & Cretaceous sedimentary rock (whitish to ochre sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia amberina* is characterized by a remarkable amber-orange colour of the apothecia, partly due to orange LBs in the excipulum, and broadly ellipsoid ascospores with comparatively large globose SBs attached by a very short filum. The North American *O. yuccae* differs in pale yellowish apothecia and distinctly inflated apical ends of the marginal cortical cells, also in narrower spores with the SBs being closely attached to the spore apex without a filum, and in smaller asci. *O. amberina* is also similar to *O. lilacina* with which it grew in close association; the latter deviates in pure rose-lilaceous apothecia and somewhat narrower spores with distinctly smaller SBs. For the similar *O. ovoidea* see p. 1254. *O. eremaeae* (Pls 798–799) resembles *O. amberina* in apothecial colour and in the spores, but the spores are much longer, and the asci consistently possess distinct apical thickenings.

Variation. The collection on *Eremaea* deviates from the others in somewhat smaller spores (*3.7–4 × 2.6–2.8 µm, though on the photo from a different apothecium they measured

*4.2–4.6 × 3.2–3.5 µm, Pl. 771: 3d), and in smaller terminal cells of paraphyses (†8–13 × 1.5–2 µm). Also the apothecia were smaller than in the holotype. The sample on *Acacia* deviates in a tendency to strongly inflated paraphysis apices. However, for the samples on *Acacia* and *Banksia* some of these data were not available.

Ecology. *O. amberina* was found on decayed bark of xeric branches of different angiosperm trees and shrubs in the Darling Plateau of southwestern Australia, in subtropical semihumid eucalypt woodlands or banksia-eucalypt-acacia open wood- and shrublands (Swan Coastal Plain), also in a subtropical semiarid acacia shrubland (Avon Wheatbelt).

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twig of *Acacia*, 24.XI.2001, G. Marson (H.B. 7204l ø). – Swan Coastal Plain, 150 km N of Perth, 13 km WNW of Moora, Dandaragan Road, 235 m, branch of *Verreauxia reinwardtii*, on bark, 24.X.2007, G. Marson (ex H.B. 8748c; MEL 2389257A, **holotype**; **isotype** in MEL 2389257B). – 59 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Rd, 77 m, branch of *Eremaea pauciflora*, on bark, 5.IX.2006, G. Marson (H.B. 8643c). – 48 km NNE of Perth, 4.5 km NE of Muchea, Reserve Road, 97 m, branch of *Banksia menziesii*, 3.IX.2006, G. Marson (G.M. 2006-09-03.3 ø).

Orbilia polyspora Grelet, Bull. Trimest. Soc. Mycol. Fr. 42: 205 (1926) — Pls 772–773, Map 130

Etymology: referring to the 32-spored asci.

Typification: France, Toulon, unlocalized, branch of ?*Rosmarinus officinalis*, VI.1926, A.É. de Crozals (PC, herb. Grelet, holotype); France, Séderon, branches of *Salix eleagnos* var. *angustifolia*, 10.X.2002, G. Marson (ex H.B. 7243b, M-0291765, epitype, designated here, MBT385129, ex-epitype culture: CBS 116226; sq.: KT215276).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.8(–1) ((–1.2)) mm diam., (0.12–)0.14–0.21(–0.27) mm high, pale to bright orange(-rose) to brick-red(-vermilion), sometimes ochraceous, ± translucent or not, round to sometimes broadly elliptical, scattered to subgregarious; disc flat to slightly convex, margin thick, 0–25 µm protruding, concolorous or often paler to whitish, smooth or very finely pruinose to crenulate; broadly sessile, sometimes with ill-defined hidden stipe, superficial to distinctly erumpent between fibres, partly ± deeply immersed in biofilm or small clefts; dry bright to deep apricot-orange. **Asci** *(60–)65–95(–102) × (5.5–)6–6.8(–7) µm {13}, †(43–)55–85(–112) × (4.5–)5–6.2(–6.8) µm {6}, 32-spored (28–32 spores counted), spores (2–)4-seriate, about half of spores inversely oriented (strongly mixed), pars sporifera *(30–)40–50(–58) µm long; **apex** (†) (slightly to) medium (rarely strongly) truncate (always not indented, laterally not or hardly inflated), thin-walled (0.2–0.4 µm); **base** with short to medium long, ± thick, flexuous stalk, irregularly L- or h-shaped. **Ascospores** *(3.5–)4–5(–6) × (1.9–)2.1–2.5(–2.8) µm {16}, †3.5–4.7 × 2–2.3 µm {2}, (subcylindric-)ellipsoid(-fusoid), apex rounded to obtuse, straight to very slightly inequilateral; **SBs** *(0.8–)1.1–1.5(–1.6) × (0.5–)0.7–0.9(–1) µm {10}, subglobose to mostly broadly tear-shaped, apically narrowed to a small to wide point, rarely with a very short filum. **Paraphyses** apically (slightly to) medium to strongly clavate-capitate, terminal cells *(12–)16–30(–42) × (2–)3–5.5(–6.5) µm {7}, †11–32 × 2.5–4.5 µm {2}, lower cells *8–26 × 1.7–2.7 µm {3}, †11–20(–31) × 1.5–2 µm {1}; sometimes branched at upper septum, hymenium very pale to light rose(-orange). **Medullary excipulum** very pale to light rose, 30–70 µm thick, of dense textura intricata with many inflated cells, lower part of t. intricata or ± distinct horizontal t. porrecta, sharply delimited. **Ectal excipulum** (hyaline to) pale or light rose, of (*) thin-walled, (†) medium to strongly thick-walled (gelatinized), vertically oriented t. (globulosa-) angularis(-prismatica) from base to mid flanks or submargin, 20–60 µm thick at base and lower flanks, cells *(7–)10–20(–25) × (6–)8–15(–17) µm {11}; ~20–50 µm thick near margin, of t. globulosa-angularis to t. prismatica-porrecta oriented at a ~40–80° angle to the surface, cells *7–12(–17) × 5–7(–12) µm {2}, outer part of margin and mid or even lower flanks composed of abruptly hyaline, upwards curved, dense, somewhat flexuous, usually dead and then very thick-walled hair-like hyphae {22} forming a 15–45 µm thick compact layer that resembles a t. oblita, terminal cells †15–50(–94) × 2.8–4.5(–5.5) µm {8}, with 0–2 septa near base, wall †1–2 µm thick (2-layered: thin outer layer high-refractive, thick inner layer low-refractive), **glassy processes** and true **hairs** absent. **Anchoring hyphae** abundant, */†(2–)2.5–4(–5) µm wide, walls */†(0.2–)0.3–1(–1.5) µm thick {7}, sometimes forming a loose or dense, 50–100 µm thick t. intricata, also with projecting hyphal strands, at flanks gradually intergrading with the hair-like hyphae. **SCBs** globose {15}, in paraphyses 1–3 µm diam.; in inner part of marginal ectal excipulum 0.6–2 µm. **Exudate** over paraphyses 1–5 µm thick, hyaline, breaking into large clods, loosely attached but firmly so in older apothecia, over margin and flanks granular to cloddy or continuous, 0.3–3 µm thick. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {4}, culture did not produce conidia). **Conidiophores** not seen. **Conidia** unbranched, strongly attenuated at the ends, medium to strongly curved, *36–55 × 7–8.3 µm (in situ, 42–70 µm actual length), 7–10-septate {2}.

Habitat: collected 0.1–3 m above the ground, ± corticated to decorticated, 2–21 mm thick twigs and branches of *Cercis siliquastrum* {4}, *Cytisus scoparius* {3}, indet. *Fabales* {1}, *Genista scorpius* {1}, *Petteria ramentacea* {1}, *Pinus* sp. {1}, *Quercus ilex* {1/1}, *Q. rotundifolia* {2}, *Rosa* sp. {1}, *Rubus fruticosus* agg. {1}, *Salix eleagnos* var. *angustifolia* {1}, *S.* ?*viminalis* {1}, *Sorbus aria* {1}, *Spartium junceum* {5}, *Ulex parviflorus* {1}, on 0.1–1 mm deep or in total medium to strongly decayed wood {24} and bark {10} (bast and periderm), periderm often detached or removed, sometimes below detaching bark, wood partly eroded or bleached, sometimes in beetle galleries (partly on boring dust), slightly to strongly greyed, with some or often many green algae. **Associated**: *Baggea* sp. {1}, *Caloplaca* sp. {2}, *Capronia* sp. {1}, *Claussenomyces* sp. {4}, *Cyathicula* ?*cacaliae* {1}, *Dacrymyces* sp. {4}, *Durella atrocyanea* {1}, *D.* ?*compressa* {1}, *D. connivens* {1}, *D.* aff. *connivens* {1/1}, *Ionomidotis fulvotingens* {1}, *Lecanora* sp. {1}, *Mellitiosporiella pulchella* {2}, *Nitschkia broomeana* {1/1}, *Orbilia aprilis* {1}, *O. carpoboloides* {1}, *O. cercidicola* {2}, *O. corculispora* {1}, *O. eucalypti* {1}, *O. gambelii* {3}, *O. hesperidea* {1}, *O. microserpens* {1}, *O. montigena* {1}, *O. myriosphaera* {4}, *O. ovoidea* {1}, *O. pleiogambelii* {3/1}, *O. pleiomicrosoma* {1}, *O. sarothamni* {1}, *O. subaristata* {3}, *O. subclavuliformis* {3}, *O. subovoidea* {1}, *O. trapeziformis* {1}, *O.* ?*tremulae* {1}, *O. vinosa* {4}, *Patellaria atrata* {3}, *Peniophora* sp. {2}, *Phragmiticola* sp. {1}, *Trichopeziza perrotioides* {1}, *Trichosphaerella decipiens* {1}. **Desiccation tolerance**: fully viable for at least 4 months, some mature asci still alive after 7 months, paraphyses and excipular cells after 1 year. **Altitude**: 9–1202 m a.s.l. **Geology**: Middle-Upper Jurassic & Cretaceous and Miocene lime- & sandstone, dolomite, calcareous marl, clay & sand. **Phenology**: II–X, XII (throughout the year, long-lived).

Taxonomic remarks. *Orbilia polyspora* is well characterized by 32-spored asci and ± ellipsoid spores with a broadly tear-shaped to almost globose spore body, also by rather long, thick-walled, hair-like cortical excipular cells at flanks and margin, which are agglutinated to form a compact hyaline layer. Due to this layer the apothecia have a rather thick, more whitish margin and can also macroscopically be recognized. The Australian *O. plurililacina* differs mainly in shorter asci and shorter terminal cells of the paraphyses and marginal ectal excipulum. *O. canadensis* and *O. subovoidea* mainly deviate in spore number (see there). *O. sarothamni* (section *Hemiorbilia*) resembles *O. polyspora* in the 32-spored asci and somewhat similar spores, but clearly differs in acute spore apices and larger SBs, also in slightly thick-walled ascus apices and thin-walled, much shorter marginal cortical cells.

Variation. Although *O. polyspora* is quite a constant species, some variation is noted in spore and SB shape. The

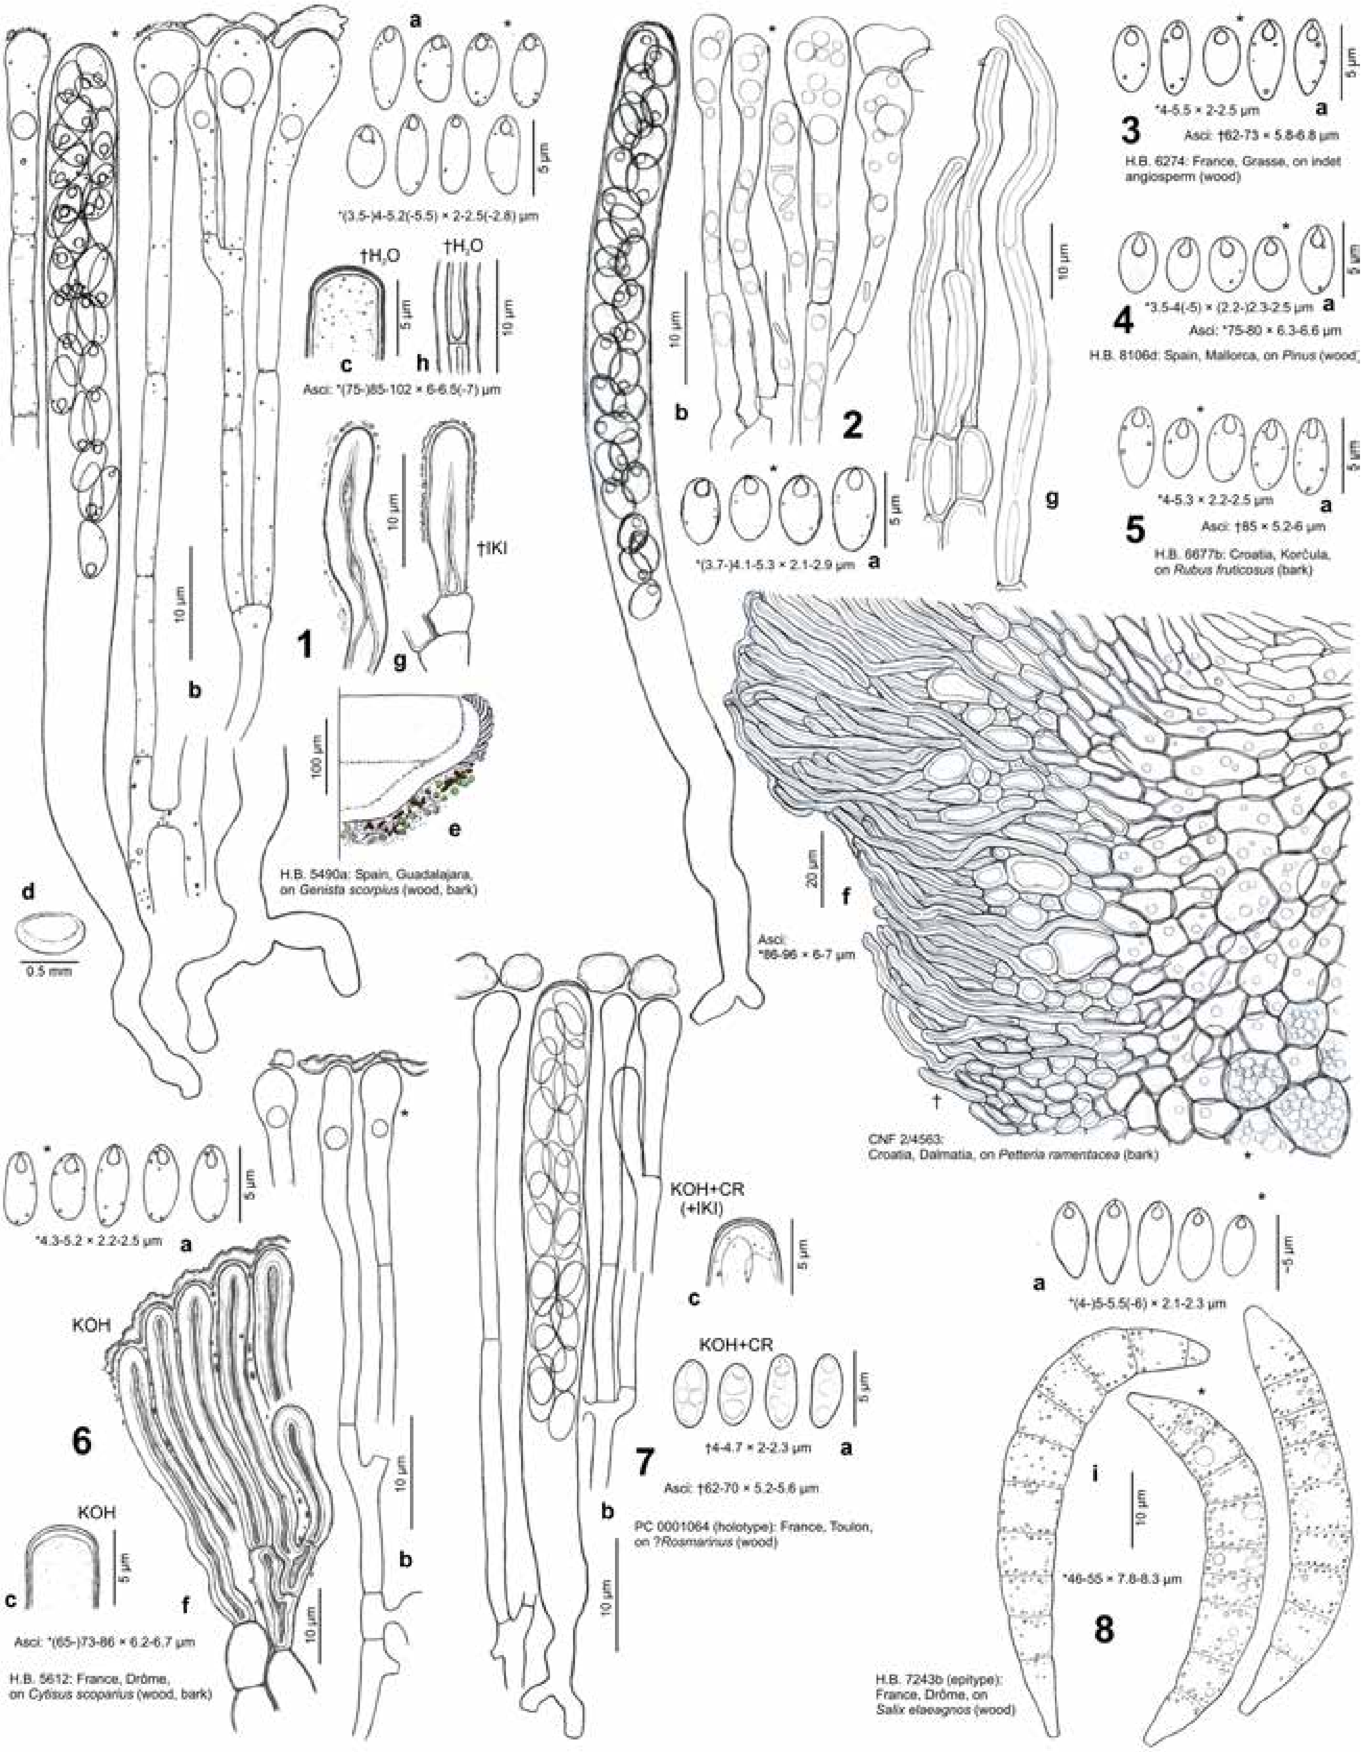

Plate 772. **1–8**: *Orbilia polyspora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium; **e**. apothecium in median section; **f**. id., marginal ectal excipulum with hair-like cortical cells (with internal wall thickenings when in the dead state); **g**. hair-like cortical cells (separated by pressure); **h**. anchoring hypha; **i**. conidia from substrate. – **2a–g**: del. N. Matočec.

SBs are attached by a smaller or larger point by a very short filum or triangular connecting part. In some collections some asci showed a spore number much less than 32, with extremely oversized spores. These large spores closely resemble those of

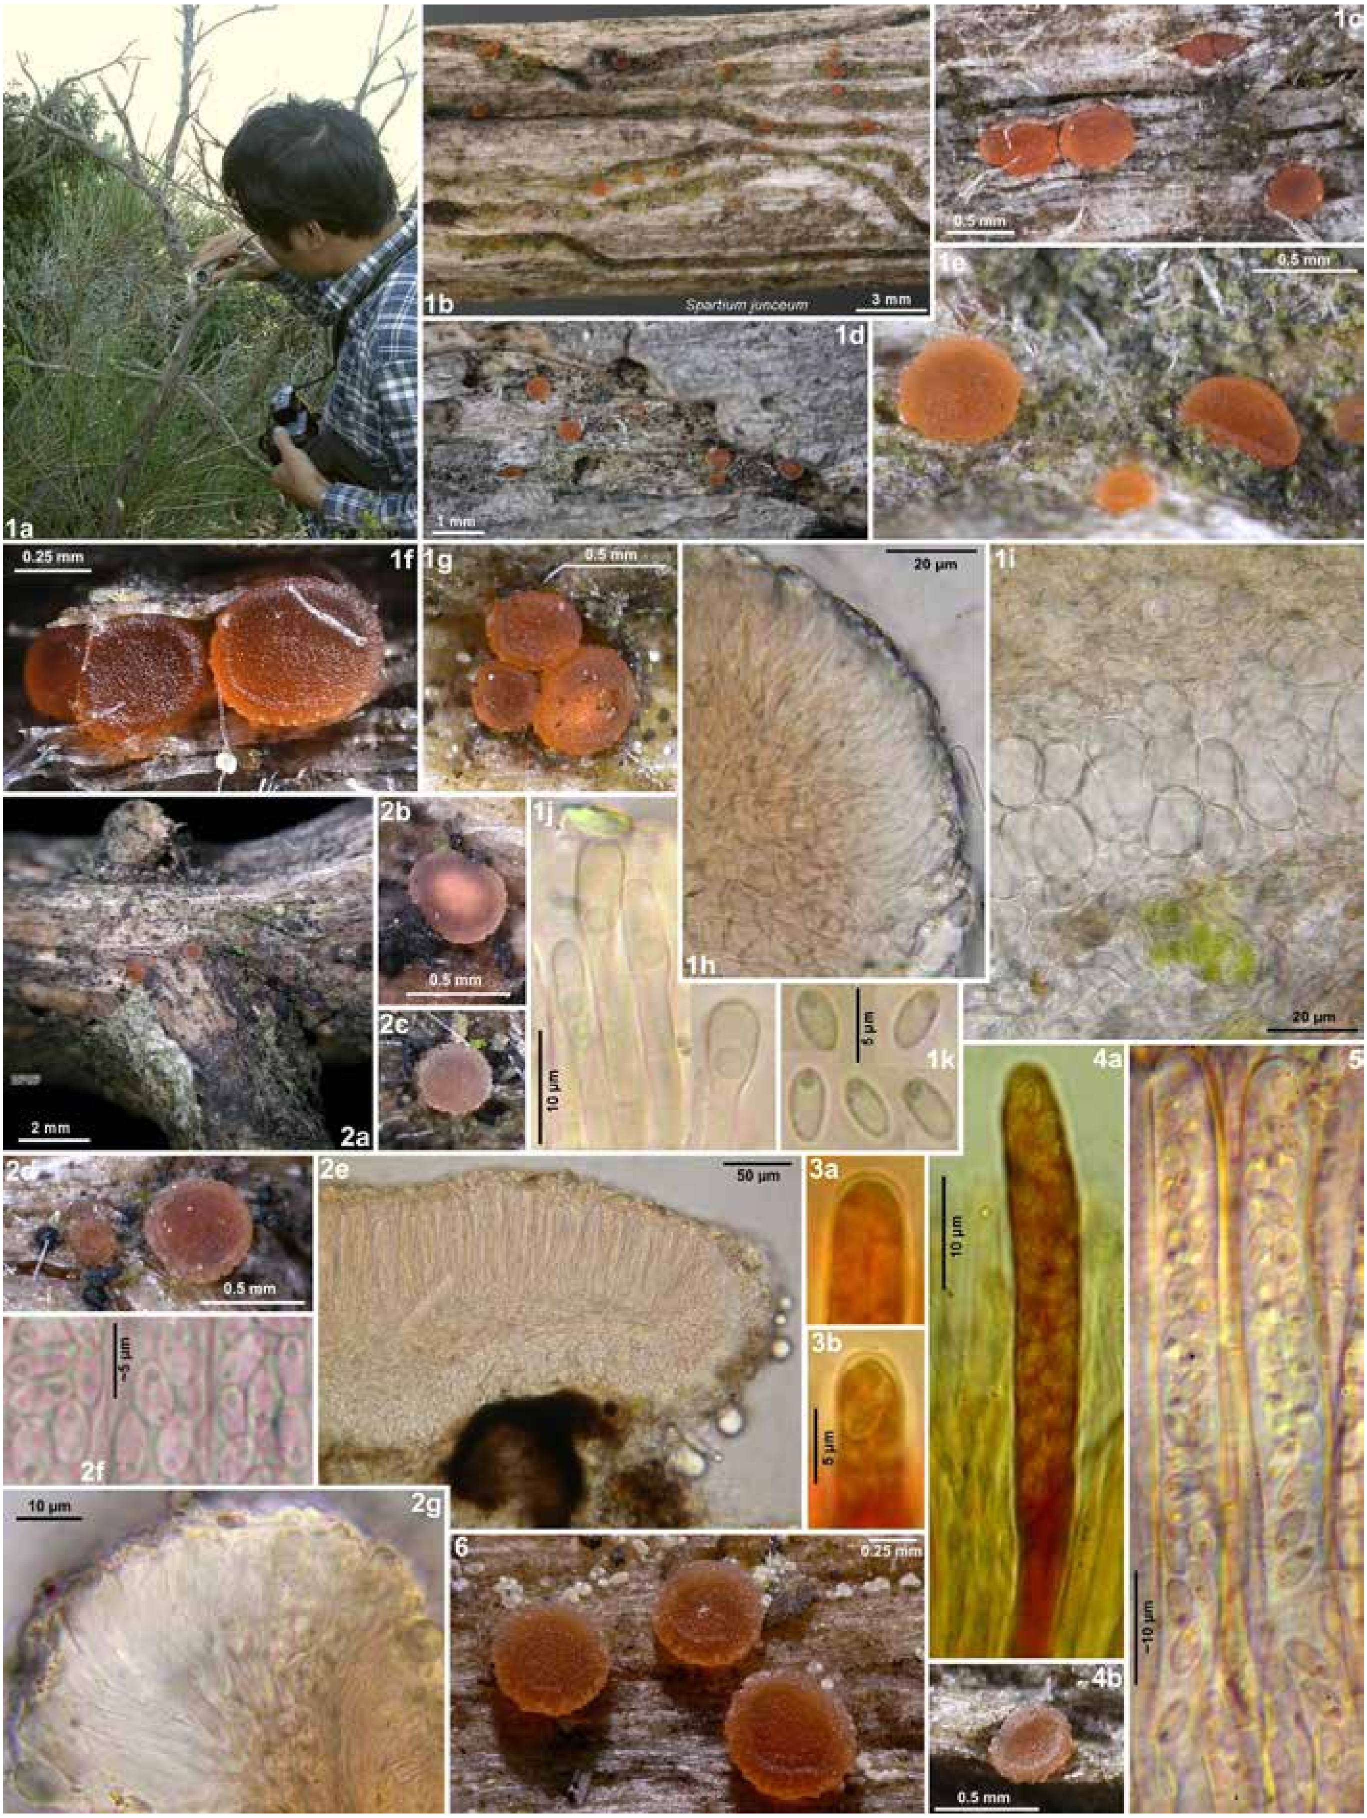

Plate 773. **1–6**: *Orbilia polyspora*. – **1a**. mediterranean macchia with *Spartium junceum*; **1b**, **2a**. decorticated xeric branches (rehydrated); **1b–g**, **2a–d**, **4b**, **6**. rehydrated apothecia; **2e**. apothecium in median section; **1h**, **2g**. id., marginal ectal excipulum with hyphoid, thick-walled cortical elements; **1i**. id., basal ectal excipulum; **3a–b**. ascus apices; **4a**, **5**. asci; **1j**. paraphyses; **1k**, **2f**. ascospores. – Living state, except for **3a–b** (in KOH+CR+IKI), **4a** (in KOH+IKI), **2g** (in H_2O), asci in **2f**. — **1a–k**. H.B. 9158b: France, Nyons, on *Spartium*; **2a–g**. H.B. 8738a: Spain, Castellón, on *Ulex*; **3a–b**. PC 0001064 (holotype): France, Toulon, on ?*Rosmarinus*; **4a–b**. H.B. 6468b: France, Narbonne, on *Spartium*; **5**. H.B. 7270a: France, Roussillon, on *Spartium*; **6**. 14.VIII.2009: France, Digne, on *Cytisus*.

the 8-spored *O. ovoidea*, which once even grew in association. Obviously, *O. ovoidea* is closely related to *O. polyspora*, but differs in the consistent absence of polysporous asci.

Type studies. Grelet (1926, 1948a: 53) considered *O. polyspora*, which he reported to grow on ‘probably *Rosmarinus officinalis*’, to be a polysporous form of *O. coccinella* (s.auct., = *O. eucalypti* or *O. tremulae*). He described the asci as ‘? ~24-spored’ or ‘usually 24-spored’, and the spores with ‘a minute guttule at each end’. Judging from his drawing (1926: pl. VIII fig. 29, 1948a: fig. 24) these guttules probably represent spore bodies. In the present reexamination of the holotype, which matches very well the protologue and the living specimens examined here, 28–32 spores were counted. Although remnants of SBs could not clearly be seen, we can assume that Grelet was in error when reporting the spores as biguttulate.

A specimen from France (Séderon, on *Salix*, Pl. 772: 8, IVV: H.B. 7243b), from which a sequence was gained, is designated here as **epitype** of *O. polyspora*.

Clements (1909:174) used the name *Orbilia polyspora* as a Latin circumscription of the genus *Myridium* (‘an *Orbilia* with polysporous asci’, see under *Orbilia myriospora*, p. 1679), not as a valid binomial.

Anamorph. In four collections we have seen large phragmoconidia near apothecia of *O. polyspora* (Pl. 772: 8). Similar conidia are presumed as anamorph of some other species of section *Ovoideae*. Since the apical conidial end looks similar as the basal end, the place of attachment cannot unequivocally be recognized, and some conidia might be wrongly oriented on the plates.

Phylogeny. A sample on *Salix* from dépt. Drôme, France (H.B. 7243b) was twice sequenced from pure culture, comprising SSU (without S1506 intron), ITS, and LSU, resulting in fully identical sequences. Another sample from the same department (on *Cercis*, not shown in phylograms) differs in 1 nt and 1 insert in the ITS1 and 1 nt in the LSU D1.

O. polyspora shows a distance of 17–19.5 % (ITS) and 5–6 % (LSU D1–D2) to the other members of section *Ovoideae*, to which it stands in sister position.

Ecology. *O. polyspora* was collected on ± rotten wood, more rarely bark of xeric twigs and branches of various angiosperm (exceptionally gymnosperm) trees and shrubs, preferably *Fabaceae*. The known distribution is ± restricted to the southern European mediterranean belt, where it occurs in suprasub- to mesomediterranean semihumid zones (see also Tkalčec et al. 2008). The vegetation includes maquis (*Quercetum ilicis*, *Juniperetum thuriferae*), and old *Olea* plantations. However, one collection (on *Sorbus aria*) was from cold-temperate humid eastern France (dépt. Doubs) in a thermophilous calcareous lawn with *Anthyllis montana* and scattered shrubs of *Juniperus communis* etc., and also a sample from Southern French Alps (on *Salix* ?*viminalis*) falls in the cold-temperate zone (border to suprasubmediterranean).

Baral (H.B. 6677b ø).

Map 130. Known distribution of *O. polyspora* in Europe.

Orbilia lilacina Baral & G. Marson, **sp. nov.**, MB 813913 — Pls 774–775

Etymology: named after the rose-lilaceous apothecial colour.

Typification: Western Australia, Moora, branches of *Verreauxia reinwardtii*, 24.X.2007, G. Marson (ex H.B. 8748b, MEL 2389256, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–0.4 mm diam., vivide roseo-lilacina, sessilia, margine laevi. Asci 8-spori. Ascosporae *4.5–8 × 2.4–3.3 µm, subcylindricae ad ellipsoideae vel fusoideae, corpusculum refringens globosum, ad apicem cuspide brevi affixum continentes. Excipulum marginale textura prismatica crassitunicata, absque processis vitreis. Habitat ad corticem putridum ramorum siccorum* Eucalypti *et* Verreauxiae *in zona subtropica semihumida Australiae meridio-occidentalis.*

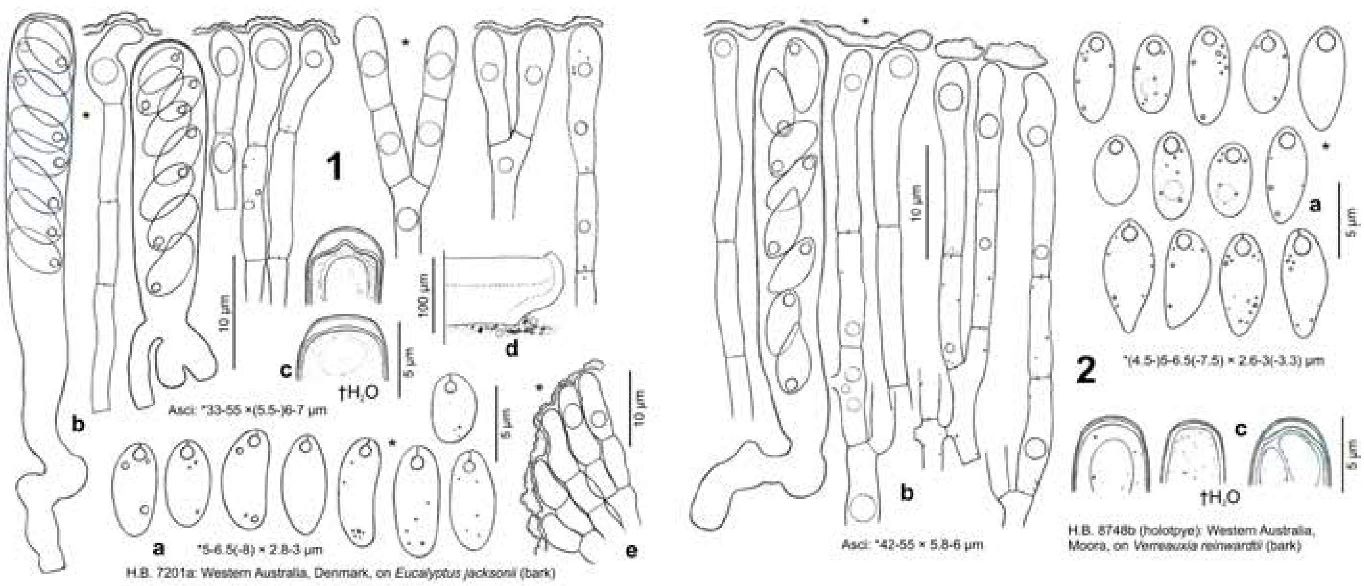

Plate 774. **1–2**: *Orbilia lilacina*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.4 mm diam., 0.09–0.15 mm high (receptacle 0.07 mm), (pale to) light to bright rose-lilaceous, semitranslucent, round, scattered; disc flat, margin distinct, thin, 5–10 µm protruding, ± smooth; sessile on a ± broad base, superficial; dry bright rose-pink(-orange). **Asci** *33–55 × 5.5–7 µm {2}, †29–46(–52) × 4.5–5 or 5.7–6.2 µm {2}, 8-spored, spores (*) obliquely subbiseriate, (2–)3–6 lower spores inverted {2} (often mixed), pars sporifera *23–32 µm long; **apex** (†) slightly to medium truncate, dome absent {1} or present, †1–1.2 → 0.8–1.2 µm thick {2}, often with distinct apical chamber; **base** without or with short to medium long, thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(4.5–)5–7(–8) × (2.4–)2.6–3(–3.3) µm {2}, subcylindrical to ellipsoid, also fusoid, both ends rounded to obtuse (exceptionally subacute), straight to slightly inequilateral; **SBs** *(1–)1.2–1.6(–1.8) × (0.7–)0.9–1.1(–1.3) µm {2}, ± globose, apically abruptly narrowed to a very short, thin filum (attachment sometimes invisible). **Paraphyses** apically uninflated or slightly (rarely medium) clavate or lageniform, sometimes flexuous, terminal cells *7–18 × 2–3.7 µm {2}, lower cells *7–15 × 1.6–2.5 µm {2}, near base partly *2.5–3(–3.5) µm wide; rarely branched

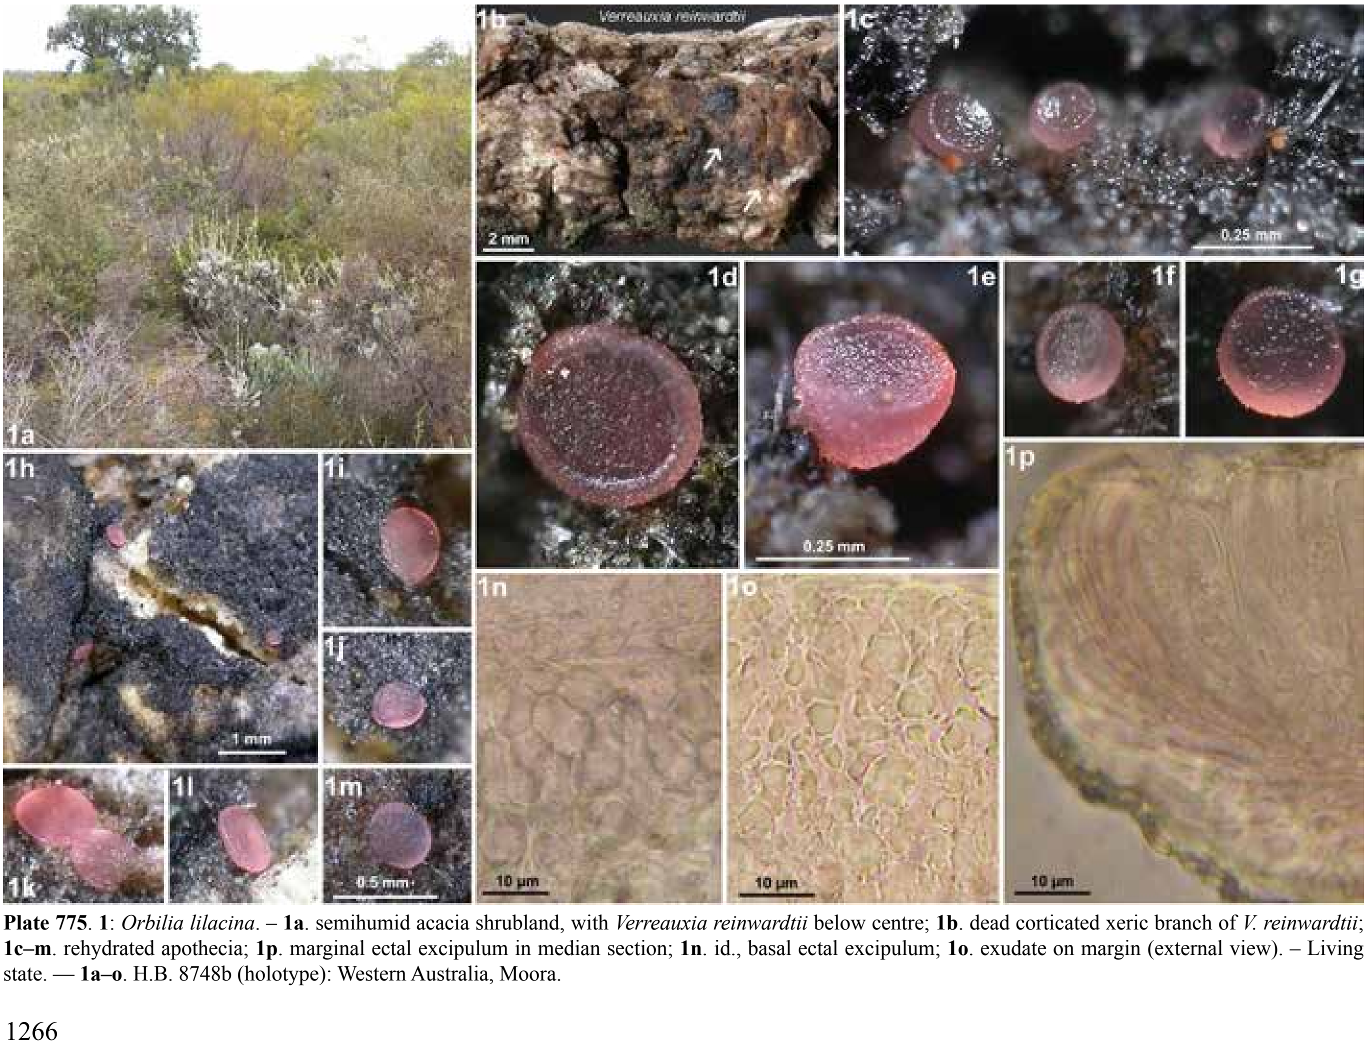

Plate 775. **1**: *Orbilia lilacina*. – **1a**. semihumid acacia shrubland, with *Verreauxia reinwardtii* below centre; **1b**. dead corticated xeric branch of *V. reinwardtii*; **1c–m**. rehydrated apothecia; **1p**. marginal ectal excipulum in median section; **1n**. id., basal ectal excipulum; **1o**. exudate on margin (external view). – Living state. — **1a–o**. H.B. 8748b (holotype): Western Australia, Moora.

at upper septum. **Medullary excipulum** pale rose or cream, 15–40 µm thick, of dense textura globulosa-intricata of partly rather large cells, non-gelatinized, indistinctly or sharply delimited at flanks by a 6–8 µm thick t. porrecta. **Ectal excipulum** hyaline to pale rose, of (†) medium gelatinized (common walls 1–2 µm thick {2}) t. globulosa-angularis(-prismatica) from base to mid flanks, 15–90 µm thick near base, cells †7–15 × 4.5–10 µm {2}; at mid flanks of t. prismatica oriented at a 30–70° angle to the surface, 10–15 µm thick near margin, of t. (angularis-)prismatica(-porrecta) oriented at 10–30°, marginal cortical cells *7–10.5 × 2.7–4 µm {2}, living cells at flanks and margin appearing thick-walled; **glassy processes** absent. **Anchoring hyphae** medium abundant, †2–3.7 µm wide, walls (0.2–)0.5–0.8 µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.5–2.5 µm diam. **Exudate** over paraphyses 0.3–0.8 or 1–2(–3) µm thick, cloddy-continuous, rough, hyaline, loosely attached; over margin and flanks 1–3 µm thick, forming very rough clods. — **ANAMORPH**: unknown.

Habitat: collected 0.2–4 m above the ground, large pieces of bark of *Eucalyptus jacksonii* {1}, entirely detached from trunk and fallen from above, now hanging in understory, 7–11 mm thick corticated branches of *Verreauxia reinwardtii* {1}, on medium to very decayed bark {2} (periderm {1} or bast {1}), strongly greyed or blackened, no or a few green algae. **Associated**: *Lachnum eucalypticola* {1}, *Orbilia amberina* {1}, *O. aviaristata* {1}, *O. curvativitalbae* {1}, *O. nanosperma* {1}, *O. plurililacina* {1}, *O. ?pseudoflagellispora* {1}, *O. triangulispora* {1}, *Ostropales* {1}, *Proliferodiscus olivaceoviridis* {1}. **Desiccation tolerance**: fully viable for at least 9 months. **Altitude**: 195–235 m a.s.l. **Geology**: Cretaceous sedimentary rock; granite with alkali feldspar. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia lilacina* resembles the European *O. subovoidea* in shape of ascospores and SBs, also in the paraphyses and their globose SCBs. *O. subovoidea* differs in more orange-rose apothecia and longer asci. *O. lilacina* is also similar to the North American conifer-inhabiting *O. clavipisca*, especially concerning the apical dome, but differs in much smaller asci and shorter, basally often not attenuated spores with smaller SBs, also in large SCBs in the paraphysis apices. Especially a Canadian collection on coniferous substrate mentioned under *O. clavipisca* (Pl. 796: 4) is similar to *O. lilacina* but deviates in light orange apothecia. *O. plurililacina*, *O. myriolilacina* and *O. pleistolilacina* differ from *O. lilacina* in polysporous asci and the consistent absence of apical domes. For the similar *O. amberina* which grew in association with *O. lilacina* see p. 1260.

Variation. The holotype collection (Pls 774: 2; 775), on corticated branches of *Verreauxia*) differs from that on detached bark of *Eucalyptus* in more lilaceous apothecia, narrower asci, the predominant absence of an apical dome, larger SBs, and longer and narrower terminal cells of paraphyses, but these differences appear to represent variation of a single species. In the holotype the spores vary between ellipsoid and fusoid, depending on the apothecium, also in the size of spores and SBs. In the four examined apothecia of the paratype the asci were consistently provided with an apical dome.

Ecology. *O. lilacina* was found on ± rotten bark of xeric branches of *Eucalyptus* (*Myrtaceae*) and *Verreauxia* (*Goodeniaceae*) at two subtropical semihumid localities in southwestern Australia: the holotype in a eucalypt open woodland at the northern end of Darling Range, and the paratype in a eucalypt open forest (karri-tingle) at the southern end of Darling Range.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 150 km N of Perth, 13 km WNW of Moora, Dandaragan Road, 235 m, branches of *Verreauxia reinwardtii*, on bark, 24.X.2007, G. Marson (ex H.B. 8748b, MEL 2389256, **holotype**, **isotype** in holotype of *O. amberina*). – Warren, 30 km SE of Pemberton, 14 km ENE of Northcliffe, W of Shannon, Middleton Road, 195 m, branch of *Eucalyptus jacksonii*, on bark, 16.XII.2001, G. Marson (H.B. 7201a).

Orbilia plurililacina Baral, G. Marson & E. Weber, **sp. nov.**, MB 813914 — Pls 776–777

Etymology: named after the 32-spored asci and the similarity with *O. lilacina*. **Typification**: Australia, New South Wales, Lithgow, branch of *Eucalyptus*, 26.X.1998, G. Marson (ex H.B. 6764a, MEL 2389215, holotype).

Latin diagnosis: Orbiliae lilacinae *similis sed asci 32-spori, apice in statu emortuo tenuitunicati, ascosporae minores. Habitat ad corticem putridum ramulorum et ramorum siccorum fruticorum vel arborum angiospermarum in zona temperata humida vel subtropica semihumida Australiae meridio-orientalis et -occidentalis.*

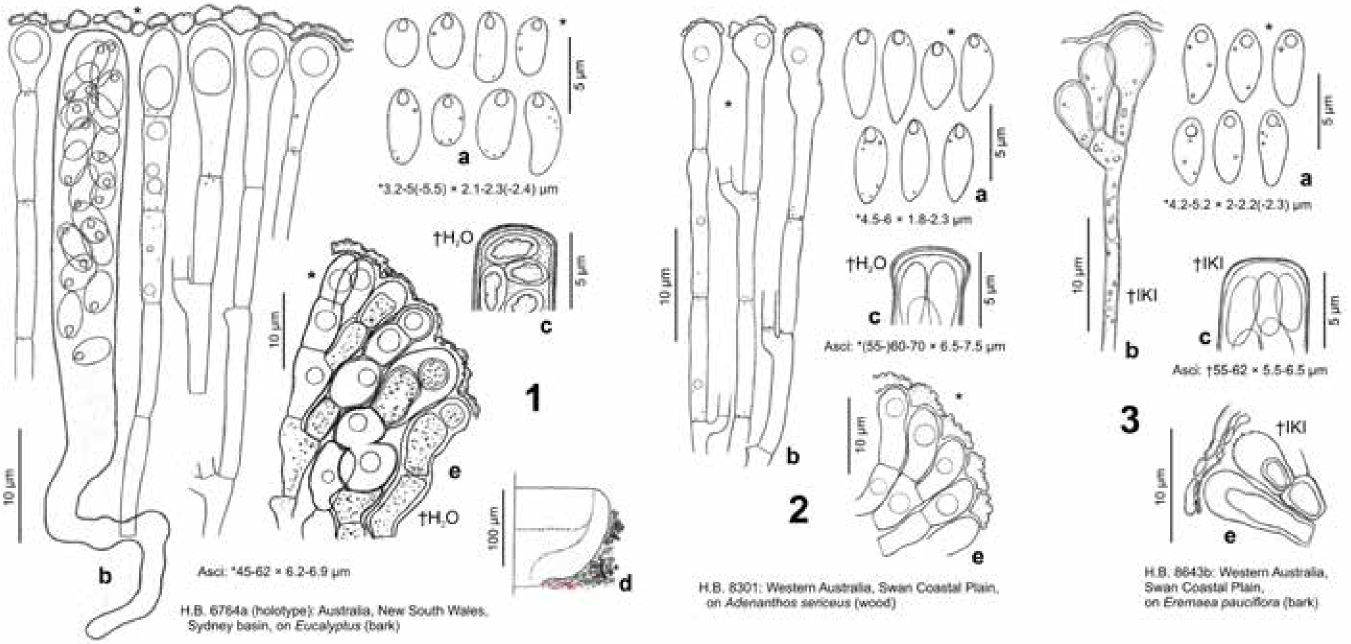

Plate 776. **1–3**: *Orbilia plurililacina*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum, cortical cells with internal wall thickenings in dead state.

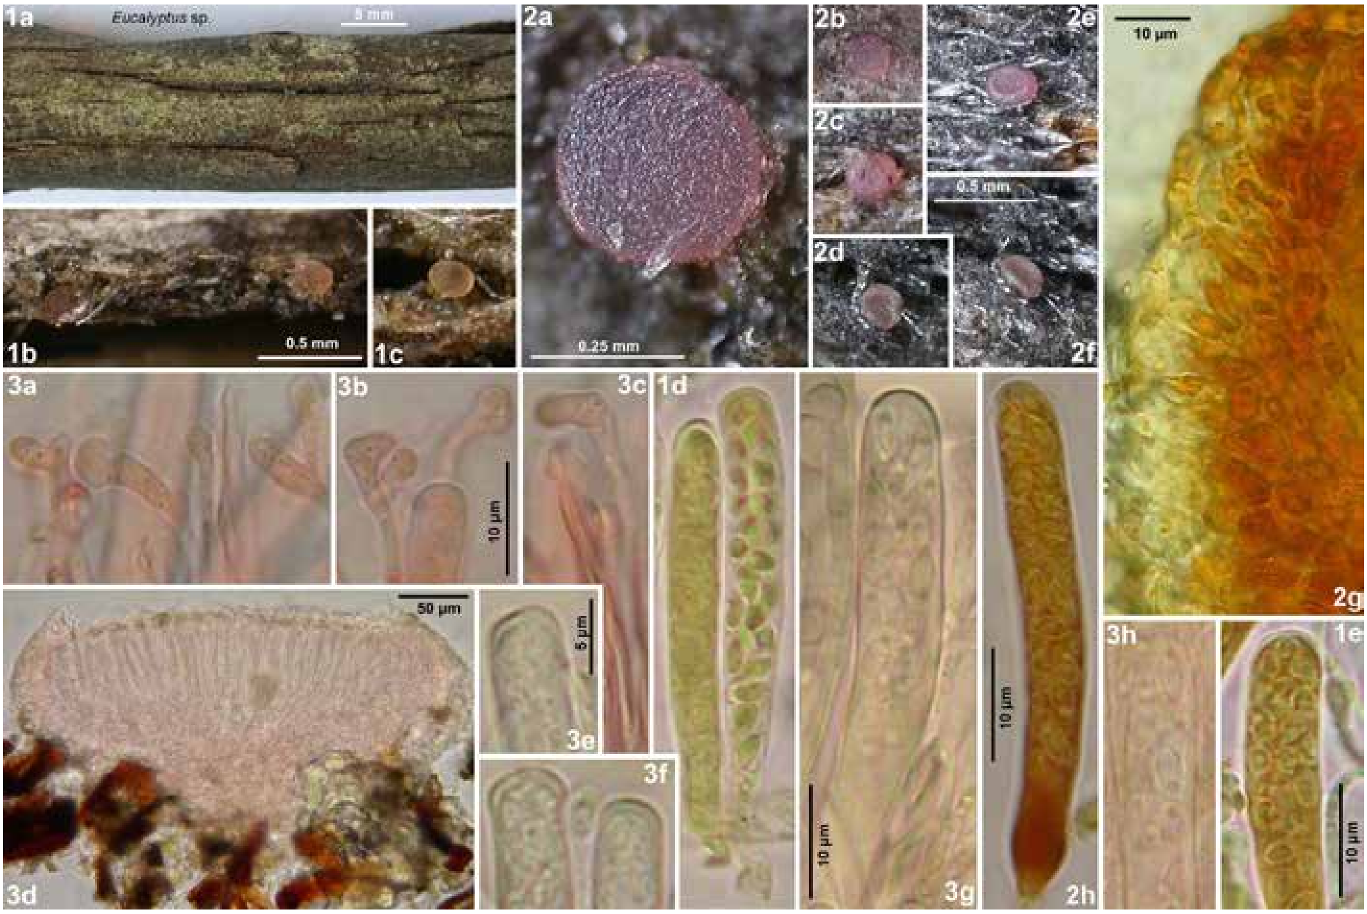

Plate 777. **1–3**: *Orbilia plurililacina*. – **1a**. dead corticated xeric branch of *Eucalyptus*; **1b–c**, **2a–f**. rehydrated apothecia (**1**: after 8 years, **2**: after 1 year); **3d**. apothecium in median section; **2g**. id., marginal ectal excipulum; **1d–e**, **2h**, **3a–c**, **g–h**. asci and paraphyses; **3e–f**. ascus apices. – Living state, except for **1d**, **2g–h** (in KOH+IKI); **3a–c** (in KOH+CR); **3e–f** (in H_2O). — **1a–d**. H.B. 6764a (holotype): Australia, New South Wales, Sydney Basin, on *Eucalyptus*; **2a–f**. H.B. 8643b: Western Australia, Swan Coastal Plain, on *Eremaea*; **3a–h**. H.B. 8301: ibid., on *Adenanthos*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.35(–0.4) mm diam., 0.08–0.15 mm high (receptacle 0.08–0.11 mm), light rose or rose-lilaceous (pink), semitranslucent, round, very scattered; disc flat, margin distinct, ± thick, 0–10 µm protruding, smooth; sessile or with ill-defined stipe up to 0.04 × 0.09 mm, superficial or slightly erumpent, ± immersed in biofilm, dry bright rose-pink. **Asci** *(40–)45–62(–70) × 6–7.5 µm {3}, †40–62(–72) × 5.5–6.5(–7) µm {3}, 32-spored, spores (2–)4-seriate, some of the spores inversely oriented (strongly mixed), pars sporifera *29–37 µm long; **apex** (†) slightly to strongly truncate (never indented, laterally rarely inflated), thin-walled; **base** with short to medium long, ± thick, flexuous stalk, L- or h-shaped. **Ascospores** *(3.2–)4–5.5(–6) × (1.8–)2–2.3(–2.5) µm {3}, †3.5–4.8 × 1.8–2.1 µm {1}, cylindric-ellipsoidal to ellipsoid-fusoid(-clavate), apex rounded or obtuse, rarely subacute, base rarely or often somewhat tapered, straight to slightly inequilateral, exceptionally slightly curved; **SBs** *(0.8–)0.9–1(–1.2) × 0.7–0.8(–0.9) µm {3}, broadly tear-shaped to subglobose or globose, apically closely attached or narrowed to a small to wide point, rarely with a very short filum. **Paraphyses** apically slightly to strongly clavate-capitate, rarely spathulate, sometimes irregularly bent, terminal cells *(6–)8–16(–18) × 3–4.3 µm {2}, †5–14 {1} × 2.7–4.5 µm {2}, lower cells *8–13 × 1.5–1.8(–2) µm {2}; rarely or often branched at upper septum. **Medullary excipulum** pale rose, 10–50 µm thick, of medium dense textura intricata with many inflated cells, medium sharply delimited from ectal excipulum by a distinct thin t. porrecta. **Ectal excipulum** of hyaline, slightly to medium gelatinized t. globulosa-angularis(-prismatica) from base to margin or mid flanks, 20–50 µm thick near base, irregularly oriented at a 45–90° angle to the surface, cells *8–15 × 5–10 µm {3}; 25–30 µm thick at flanks, 15–20 µm near margin, of t. prismatica-angularis oriented at 30–70° or of t. prismatica-porrecta at 10–30°, marginal cortical cells */†5–10 × 4–6 µm, at upper margin 5.5–12 × 3–4 µm {3}, (*) firm-walled and refractive, (†) partly strongly thick-walled: inner layer low-refractive, total wall near apex up to 1–3 µm thick, **glassy processes** absent. **Anchoring hyphae** sparse to medium abundant, *†(2–)2.5–3.5(–4.5) µm wide, walls 0.2–1.2 µm thick {3}. **SCBs** globose, in paraphyses 1.2–3.5 µm diam., in ectal excipulum 1.5–3 µm. **Exudate** over paraphyses (0.3–)1–2(–3) µm thick, over margin and flanks 1–3 µm, rough-cloddy, hyaline. — **ANAMORPH**: unknown.

Habitat: lying on dry ground or hanging in 0.2–2 m above the ground, partially or entirely corticated, 5–12 mm thick twigs and branches of *Adenanthos sericeus* {1}, *Eremaea pauciflora* {1}, *Eucalyptus* sp. {1}, *Verreauxia reinwardtii* {1}, on 0.3 mm deep medium to strongly decayed bark {4} (periderm {1} and bast {2}), bark partly loosely attached, medium to strongly greyed, no or a few to many green algae. **Associated**: *Capronia* sp. {1}, *Gloniopsis praelonga* {1}, *Hyalorbilia juliae* {1}, *Orbilia amberina* {2}, *O. austrocylindrica* {1}, *O. curvativitalbae* {2}, *O. eucalypti* {1}, *O. lilacina* {1}, *O. microserpens* {1}, *O. multicurvula* {1}, *O. ?parviclava* {1}, *O. pleistovitalbae* {1}, *O. triangulispora* {1}, indet. *Ostropales* {1}, *Proliferodiscus olivaceoviridis* {2}. **Desiccation tolerance**: ± fully viable for at least 2 years. **Altitude**: 77–1073 m a.s.l. **Geology**: Permian-Triassic and Cretaceous sedimentary rock (ochraceous to whitish sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia plurililacina* is very similar to European *O. polyspora* but differs in several respects: the asci and their pars sporifera, also the cells of the paraphyses are shorter. The ascospores closely correspond to *O. polyspora* though they are slightly narrower and the SBs somewhat shorter. The apothecia are smaller and not easy to discern, and have a pure rose(-lilaceous) colour in contrast to the usually orange apothecia of *O. polyspora*. A further difference lies in the thick-walled marginal cells of the ectal excipulum which form a thinner and much shorter-celled layer than in *O. polyspora*. *O. lilacina*, *O. myriolilacina* and *O. pleistolilacina* differ from *O. plurililacina* mainly a deviating spore number of their asci, but also somewhat in spore dimensions. *O. multiaustrocylindrica* (section *Orbilia*) differs in longer and narrower spores, more thin-walled marginal cortical cells, and orange apothecia.

Variation. The southwestern Australian collections of *O. plurililacina* on *Adenanthos*, *Eremaea* and *Verreauxia* each consisted of only 1–5 apothecia, which were larger (0.25–0.4 mm) than in the ca. 8 apothecia in the holotype on *Eucalyptus* from southeastern Australia which measured only 0.2–0.25 mm diam. In the southwestern Australian collections the spores were more fusoid with partly shortly tapered base. In the sample on *Adenanthos* the SBs differed in being more broadly attached whereas in those on *Eremaea* and *Verreauxia* the SBs were ± globose and attached by a short, hardly visible filum. Otherwise these collections match the holotype rather well.

Apothecial colour in the samples on *Eremaea*, *Eucalyptus*, *Verreauxia* was noted as light to bright rose when examined 1–2 years after collection when they were still alive, but this colour faded to brownish-cream after further 6 years (Pl. 777: 1b–c). In the collection on *Adenanthos* the apothecia were noted as rose-lilaceous when alive, but on the macrophoto of the *Eremaea* sample they look bright lilaceous (Pl. 777: 2a–f).

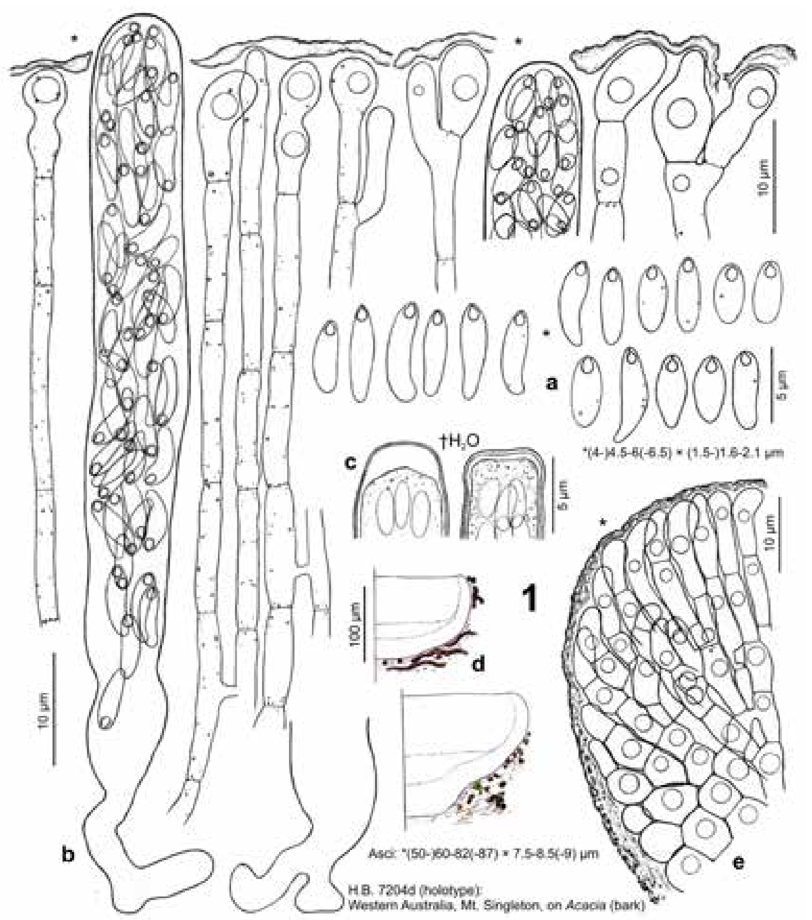

Plate 778. **1**: *Orbilia myriolilacina*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum.

Ecology. *O. plurililacina* was found on ± rotten bark of xeric twigs and branches of *Goodeniaceae*, *Myrtaceae* and *Proteaceae* in subtropical semihumid banksia-eucalypt-acacia open wood- and shrublands in the Darling Plateau of southwestern Australia and in a cold-temperate humid eucalypt open forest in the Great Dividing Range of southeastern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 57 km SW of Moora, 10 km NE of Cowalla, Moore River, Orange Springs Rd, 83 m, branch of *Adenanthos sericeus*, on bark, 5.IX.2006, G. Marson (H.B. 8301 ø). – 59 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Rd, 77 m, twig of *Eremaea pauciflora*, on bark, 5.IX.2006, G. Marson (H.B. 8643b ø). – 150 km N of Perth, 13 km WNW of Moora, Dandaragan Road, 235 m, branch of *Verreauxia reinwardtii*, on bark, 24.X.2007, G. Marson (ø). – **New South Wales**, Sydney Basin, 95 km WNW of Sydney, 11.5 km SE of Lithgow, 1.6 km SE of Mt. York, 1073 m, branch of *Eucalyptus*, on bark, 26.X.1998, G. Marson (ex H.B. 6764a, MEL 2389215, **holotype**).

Orbilia myriolilacina Baral & G. Marson, **sp. nov.**, MB 813915 — Pls 778–779

Etymology: referring to the 64-spored asci and the resemblance to *O. lilacina*.

Typification: Western Australia, Wubin, twigs & branches of *Acacia*, 24.XI.2001, G. Marson (ex H.B. 7204d, MEL 2389224, holotype).

Latin diagnosis: Orbiliae plurililacinae *similis sed asci 64-spori*, *ascosporae angustiores. Habitat ad corticem putridum*, *raro lignum*, *ramulorum et ramorum siccorum* Acaciae *et* Lamarcheae *in zona subtropica semiarida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.35 mm diam., 0.11–0.16 mm high (receptacle 0.1–0.12 mm), light brick-red(-orange) or typically rose-lilaceous (pink), scarcely translucent, round, very scattered; disc flat, margin distinct, 0–5 µm protruding, smooth; sessile or with an indistinct stipe, nearly superficial but immersed in biofilm. **Asci** *(50–)60–80(–88) × (7.3–)8–8.5(–9) µm {3}, †(45–)55–75(–82) × 6.2–7.5 µm {T} (up to 9.5 µm when flattened), 64-spored (~50–55 spores counted), spores (*) multiseriate, lower spores inverted (very strongly mixed), pars sporifera *39–65 µm long {T}; **apex** (†) medium to strongly truncate (very slightly indented, laterally slightly inflated), thin-walled; **base** with (very) short, thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(3–)3.8–5.5(–6.5) × (1.3–)1.5–1.9(–2.1) µm {3}, †4–5 × 1.4–1.6 µm {1}, subcylindrical, also fusoid to fusoid-clavate, more rarely ellipsoid, apex rounded to obtuse, rarely subacute, base not or slightly (rarely medium) attenuated, straight or slightly to medium curved in middle or lower part; **SBs** *0.8–1.1 × (0.6–)0.7–0.8(–0.9) µm {3}, (sub)globose to broadly tear-shaped, apically closely attached to spore wall, with or without a very short filum. **Paraphyses** apically slightly to strongly clavate-capitate, often moniliform or irregularly curved, rarely lageniform, terminal cells *(5–)7–15(–21) × (2.5–)3.5–5(–5.5) µm {2}, lower cells *(7.5–)9–16.5 × 1.5–2.8(–3.7) µm {1}; rarely to frequently branched at upper septum, hymenium pale rose. **Medullary excipulum** hyaline to pale rose, 10–40 µm thick, of medium dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** hyaline to pale rose, of thin-walled († slightly gelatinized), vertically oriented t. globulosa-angularis from base to submargin, 20–40 µm thick near base, cells *11–17(–23) × 10–14 µm {1}; 20–25 µm thick near margin, upper margin of t. prismatica oriented at a 20–45° angle to the surface, marginal cortical cells *7–17 × 3–4.3 µm {1} (appearing thin-walled); **glassy processes** absent. **Anchoring hyphae** sparse, *2–3 µm wide, walls 0.2–0.3 µm thick {1}. **SCBs** absent or globose, in paraphyses 1.5–2.7 µm diam., in ectal excipulum (near margin) 1.5–4.5 µm. **Exudate** over paraphyses 0.5–2 µm thick, cloddy-continuous, hyaline to very pale yellowish, loosely attached; over margin and flanks 1–2(–3) µm thick, cloddy to granular. **— ANAMORPH**: unknown.

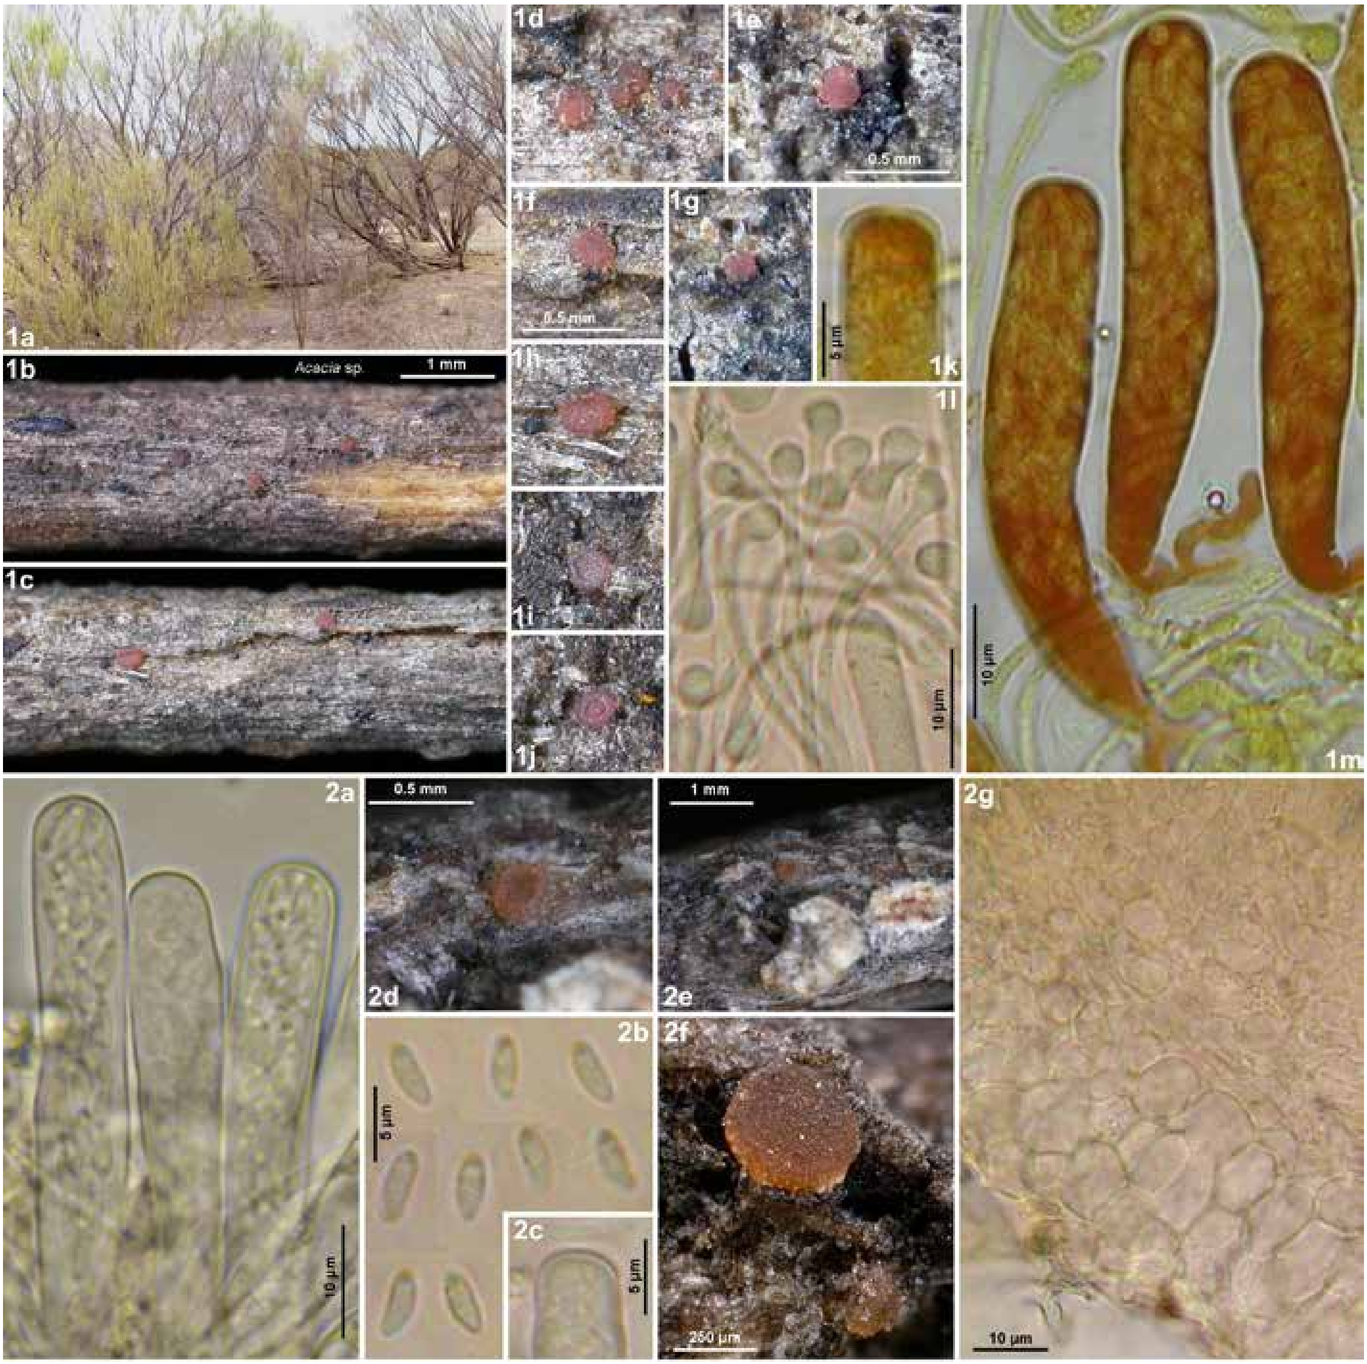

Plate 779. **1–2**: *Orbilia myriolilacina*. – **1a**. semiarid eucalypt woodland with *Acacia*; **1b–c**. decorticated xeric twigs of *Acacia*; **1b–j**, **2d–f**. rehydrated apothecia (**1b–j** after 6 years); **2g**. ectal excipulum in median section (lower flanks); **1m**, **2a**. mature asci; **1l**. paraphyses; **1k**, **2c**. ascus apices; **2b**. ascospores. – Living state, except for **2c** (in H_2O); **1l** (in KOH); **1k**, **m** (in KOH+ IKI). — **1a–m**. H.B. 7204d (holotype): Western Australia, Mt. Singleton, on *Acacia*; **2a–g**. H.B. 9020j: Western Australia, Yalgoo, on *Lamarchea*.

Habitat: collected 0.5–2 m above the ground, partially to almost entirely decorticated, 1.5–8 mm thick twigs and branches of *Acacia* sp. {2}, *Lamarchea hakeifolia* {1}, on medium to strongly decayed bark (periderm and bast) {2}, rarely on wood {1}, greyed, algae absent or sparse. **Associated**: *Amandinea* sp. {2}, *Caloplaca* sp. {1}, *Capronia* sp. {2}, *Claussenomyces* sp. {1}, *Hyalorbilia pleioerythrostigma* {1}, *Orbilia amberina* {1}, *O. anguliobliqua* {1}, *O. australiensis* {2}, *O. austroobtusispora* {2}, *O. aviflagellata* {1}, *O. curvatiobliqua* {1}, *O. gemma* {1}, *O. helicoobliqua* {2}, *O. hesperidea* {2}, *O. kingsiana* {1}, *O. lamarcheae* {1}, *O. microserpens* {1}, *O. multiserpens* {1}, *O. myriofusiclava* {1}, *O. myriomuscula* {1}, *O. myrioobliqua* {2}, *O. nothovinosa* {1}, *O. paraobliqua* {2}, *O. pleioaustraliensis* {2}, *O. pleioaustrocylindrica* {1}, *O. pseudoflagellispora* {1}, *O. ?pubescens* {1}, *Ostropales* {2}, ?*Parmelia* sp. {1}, *Patellaria ?andina* {1}, ?*Triblidium* spp. {2}, *Symbiotaphrina desertorum* {2}, ?*Xerotrema* sp. {1}. **Desiccation tolerance**: fully viable after 20 months. **Altitude**: 190–379 m a.s.l. **Geology**: Archean and Cretaceous sedimentary rock (light ochre soil, red-brown sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriolilacina* is very similar to *O. pleioaustrocylindrica* and *O. multiaustrocylindrica* (both in section *Orbilia*), from which it mainly differs in 64-spored asci and rose-red to pink apothecia. *O. pleistolilacina* with similarly pinkish apothecia differs in longer, 128-spored asci, also in thick-walled marginal excipular cells and thicker apothecia due to the longer asci. *O. plurililacina* differs in 32-spored asci and wider spores.

Variation. In a majority of examined apothecia ± subcylindrical ascospores were observed. Yet, in a few apothecia the living asci contained slightly broader and shorter, more ellipsoid spores. However, in at least one of these apothecia also more cylindrical spores occurred. The sparse collection on *Lamarchea* (Pl. 779: 2) differs in orange apothecia, but seems otherwise congruent with the typical lilaceous populations.

Ecology. *O. myriolilacina* was found on very rotten bark of xeric twigs and branches of *Acacia* (*Mimosoideae*) and *Lamarchea* (*Myrtaceae*). Most of the apothecia grew on bark and only one was found on wood but very close to small remnants of bast. The three collections are from two subtropical semiarid sites in the Darling Plateau of southwestern Australia, in a eucalypt open woodland (on *Acacia*) and an acacia shrubland (on *Lamarchea*).

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, twig of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (H.B. 9020j ø). – Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twig & branch of *Acacia*, on bark, 24.XI.2001, G. Marson (ex H.B. 7204d, MEL 2389224, **holotype**); – ibid., on *Acacia*, 26.X.2010, G. Marson (H.B. 8883k ø).

Orbilia pleistolilacina Baral, G. Marson & E. Weber, **sp. nov.**, MB 813916 — Pls 780–781

Etymology: referring to the 128-spored asci and the resemblance to *O. lilacina*. **Typification**: Western Australia, Pithara, branch of *Eucalyptus*, 25.X.2007, G. Marson (ex H.B. 8746b, MEL 2389255, holotype).

Latin diagnosis: Orbiliae myriolilacinae *similis sed asci 128-spori. Habitat ad corticem putridum ramulorum et ramorum siccorum* Eucalypti *in zona subtropica semiarida et semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.22–0.45 mm diam., 0.18–0.27 mm high, light to bright (purplish-)rose-lilaceous, non- or slightly translucent, round, scattered to subgregarious; disc flat, margin ± thick, 0–10 µm protruding, smooth; broadly sessile or with an obconical base, nearly superficial to ± immersed in biofilm; dry bright (dirty) lilaceous to purplish carmine-rose. **Asci** *80–98 × (8–)9–9.5(–10) µm {2}, †(70–)80–93(–110) × (7–)7.5–8(–9) µm {2}, 128-spored (~90–100 spores counted), spores multiseriate, pars sporifera *55–65 µm long (†48–65 µm); **apex** (†) (slightly to) medium to strongly truncate (not or very slightly indented, laterally not or very slightly inflated), thin-walled; **base** with ± short, thick, ± flexuous stalk, T-, L-, Y- to h-shaped. **Ascospores** *(3.7–)4–5(–6) × (1.7–)1.8–2(–2.2) µm {2}, †3.5–4.7 × 1.6–1.8(–2) µm {1}, subcylindrical to cylindric-ellipsoid, sometimes fusoid, apex rounded to obtuse, base not or very slightly, rarely medium attenuated, straight or slightly inequilateral; **SBs** *~0.7–1.1(–1.2) × 0.6–0.8 µm {2}, broadly tear-shaped to subglobose, apically narrowed to a small to wide point, with or without a very short filum. **Paraphyses** apically slightly to strongly clavate-capitate, sometimes spathulate to lageniform or moniliform, terminal cells *7–17 × (2.8–)3.5–5 µm {1}, †(6–)8–20 × 2.5–4 µm {1}, lower cells *12–22 × 1.6–2.2(–2.8) µm {1}, †10–20 × 1.3–1.7 µm {1}; rather frequently branched at upper septum, hymenium pale rose. **Medullary excipulum** pale (lilaceous-) rose(-orange), 30–80 µm thick, of medium dense textura intricata with many inflated cells, medium sharply delimited from ectal excipulum (at flanks by a 10 µm thick t. porrecta). **Ectal excipulum** subhyaline to light rose-lilaceous (especially towards margin, more pale in KOH), of (†) thin-walled to medium gelatinized [common walls (0.2–)0.5–1(–2) µm], indistinctly to ± vertically oriented t. globulosa-angularis from base to mid flanks or submargin, 25–70 µm thick near base, cells */†7–13(–17) × 6–11(–13) µm {2}; 20–30 µm thick near margin, submarginal cells *8–12 µm diam., inner part of upper margin of t. prismatica-angularis, cubical cells oriented at a 30–50° angle to the surface, outer part of hyaline t. prismatica-porrecta oriented at 30–40°, marginal cortical cells */†7–13(–15) × (2.5–)3–4(–5) µm {2}, apically very thick-walled (†1.5–2.5 µm at submargin, †2–4 µm at margin) {T} or apparently thin-walled; **glassy processes** absent. **Anchoring hyphae** sparse to abundant, †(2–)2.5–4(–5) µm wide, walls †0.2–1.2 µm thick {2}. **SCBs** in paraphyses and marginal excipulum globose {2}, (1–)2–3 µm diam. **Exudate** over paraphyses (0.5–)1–2.5(–4) µm thick, cloddy-continuous, hyaline, loosely attached; over margin and flanks 0.2–1(–2) µm thick. **— ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, decorticated to partially corticated, 5–14 mm thick branches of *Eucalyptus* sp. {2}, on 0.5 mm deep very decayed wood {2}, strongly greyed, green algae very sparse to abundant. **Associated**: ?*Amandinea* sp. {1}, *Dacrymyces* sp. {1}, *Gloniopsis praelonga* {1}, *G. subrugosa* {1}, *Orbilia* ?*multiserpens* {1}, *O. pleioaustrocylindrica* {1}, *Psiloglonium* ?*lineare* {1}, ?*Triblidium* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 286–326 m a.s.l. **Geology**: granite, granulite with granitic gneiss. **Phenology**: long-lived.

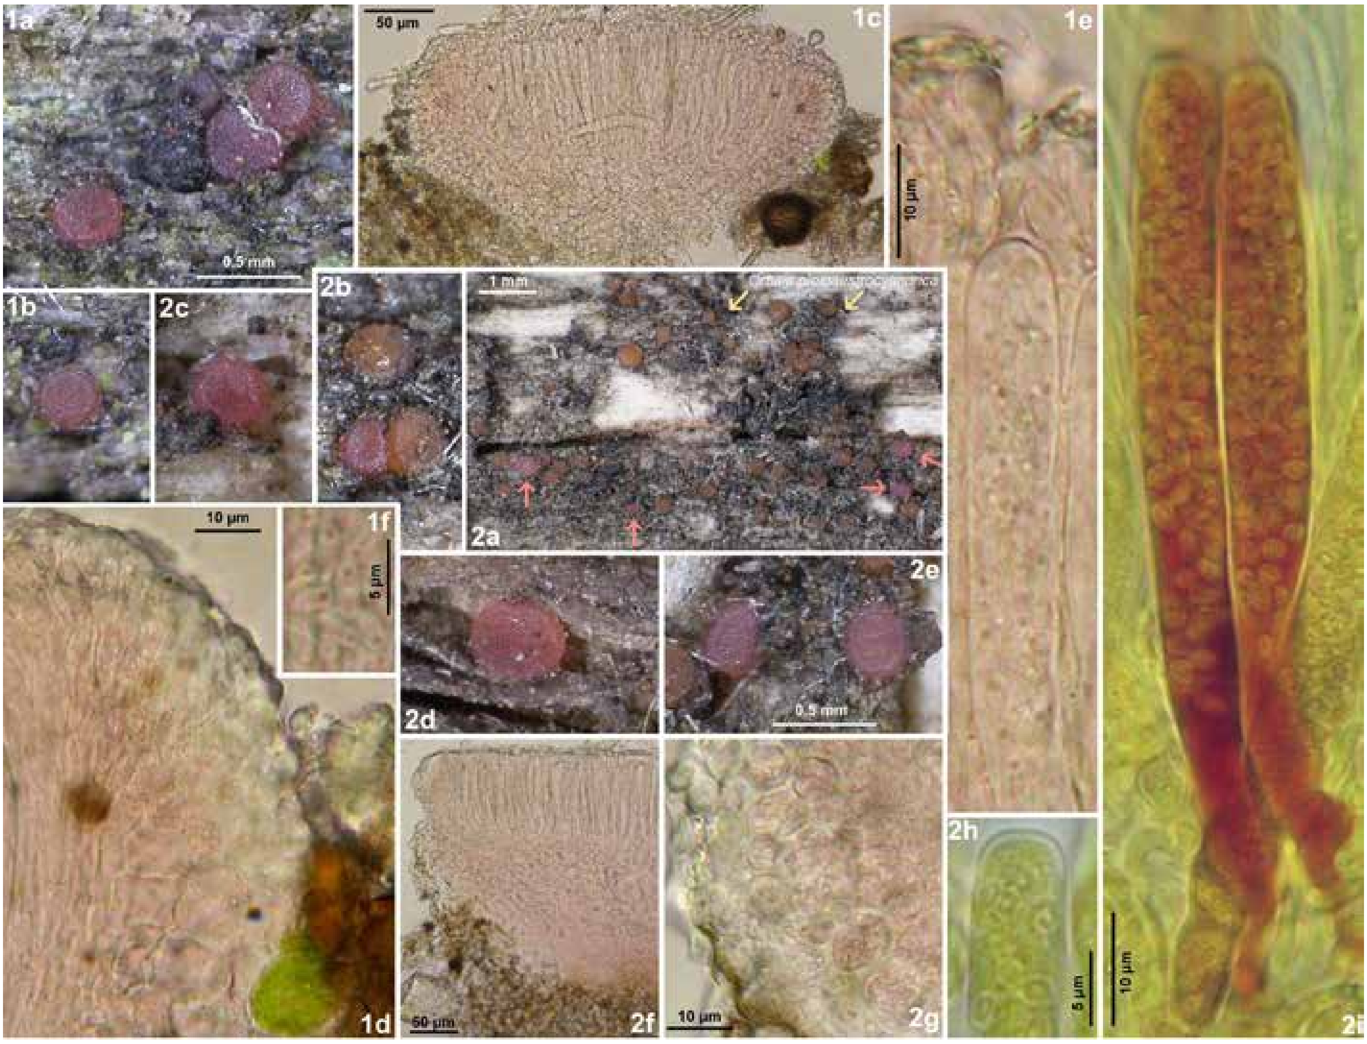

Plate 781. **1–2**: *Orbilia pleistolilacina*. – **1a–b**, **2a–e**. rehydrated apothecia (**2**: mixture with many orange apothecia of *O. pleioaustrocylindrica*); **1c**, **2f**. apothecia in median section; **1d**. id., marginal ectal excipulum; **2g**. id., ectal excipulum at flanks; **1e**, **2i**. asci and paraphyses, **2h**. ascus apex; **1f**. ascospores. – Living state, except for **2g** (in H_2O), **2h–i** (in KOH+IKI). — **1a–e**. H.B. 8746b (holotype): Western Australia, Moora, on *Eucalyptus*; **2a–h**. H.B. 8641c: ibid., Kandinin, on *Eucalyptus*.

Taxonomic remarks. *Orbilia pleistolilacina* is characterized by 128-spored asci and rose-lilaceous apothecia. The species is very closely related to *O. myriolilacina* (see p. 1269). *O. pleistovitalbae* (section *Habrostictis*) differs from *O. pleistolilacina* in elongate tear-shaped SBs, a less thick-walled ectal excipulum, a rough margin due to projecting covering hyphae, and orange apothecia. In the dead state, however, the two species are microscopically hardly distinguishable.

Variation. The paratype deviates from the holotype in narrower asci, in slightly longer spores in which the SBs are consistently narrowed to a small point, and in marginal cortical cells apparently without distinct terminal wall thickenings.

Ecology. *O. pleistolilacina* was found on very rotten wood of xeric branches of *Eucalyptus* in southwestern Australia in a subtropical semiarid eucalypt woodland in a dry floodplain (holotype) and in a semihumid small eucalypt forest in a cornfield. In the paratype (Pl. 779: 2a) the rather scattered apothecia occurred strongly intermingled among the very abundant *O. pleioaustrocylindrica* (section *Orbilia*), often in very close association, but they could easily be recognized by their striking rose-lilaceous colour. This association was very obvious on four of the five collected branch pieces, whereas the also associated *O. multiserpens* occurred more remotely. Six years after the collection was made, the difference in apothecial colour was still clearly visible, but after further 3 years the colour disappeared and the macroscopical distinction from *O. pleioaustrocylindrica* became impossible.

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 68 km NE of Moora, 14 km S of Dalwallinu, 1.5 km S of Pithara, 326 m, branch of *Eucalyptus*, on wood, 25.X.2007, G. Marson (ex H.B. 8746b, MEL 2389255, **holotype**). – Mallee, 14 km SSW of Kondinin, 9 km NE of Kulin, Fence Road, 286 m, branches of *Eucalyptus*, on wood, 14.XII.2001, G. Marson (H.B. 8641c).

Orbilia stansburyanae Baral, **sp. nov.**, MB 813917 — Pls 782–783

Etymology: named after the substrate of the type, *Purshia stansburyana*.

Typification: USA, Utah, Dixie Forest, branch of *Purshia stansburyana*, 11.VI.2003, G. Marson (ex H.B. 7918a, M-0276512, holotype).

Latin diagnosis: *Apothecia rehydratata 0.17–0.22 mm diam., aurantiaca, sessilia, margine laevi. Asci 16-spori. Ascosporae *8–12.3 × 3.2–3.7 µm, ellipsoideo-fusoideae vel fusoideo-clavatae, rectae, apice obtusae ad acutae, corpusculum refringens magnum, globosum ad late lacrimiformem, ad apicem confertim affixum continentes. Excipulum marginale absque processis vitreis. Habitat ad lignum putridum rami sicci* Purshiae stansburyanae *in zona orotemperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.22 mm diam., 0.12–0.14 mm high (receptacle 0.1–0.11 mm), light orange, slightly translucent, round, gregarious in a small group; disc flat, margin thin, not protruding, smooth; sessile on a narrowed base, slightly erumpent from wood fibres or immersed in biofilm; dry light orange.

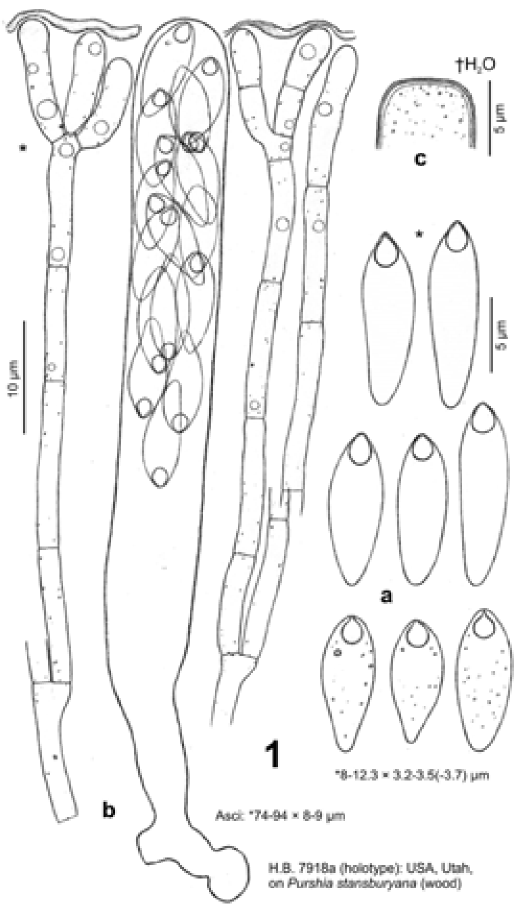

Plate 782. **1**: *Orbilia stansburyanae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Asci *74–94 × 8–9 µm, †65–80(–90) × 7–8(–9.5) µm, 16-spored, spores *3–4-seriate, 6–9 lower spores inverted (mostly ± mixed), pars sporifera *41–46 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not inflated), thin-walled; **base** with short to medium long, thick, ± flexuous stalk, L- to Y-shaped. **Ascospores** *8–12.3 × 3.2–3.5(–3.7) µm, ellipsoid-fusoid to fusoid-clavate, apex obtuse to acute, base slightly to strongly attenuated, straight to very slightly inequilateral; **SBs** *(1.7–)2–2.2 × (1.4–)1.5–1.8(–1.9) µm, globose to broadly tear-shaped, apically attached either very closely or narrowed to a small point. **Paraphyses** apically uninflated (to very slightly clavate), terminal cells *5–12 × 2.2–2.8(–3) µm, lower cells *9–15 × 1.6–2.3(–2.7) µm; frequently branched near apex. **Medullary excipulum** subhyaline, 30 µm thick, of dense textura intricata with many inflated cells, sharply delimited only at flanks. **Ectal excipulum** hyaline, of thin-walled († slightly gelatinized), ± vertically oriented t. angularis from base to margin, 30 µm thick near base, cells *7–11 × 5–8(–10) µm; 20 µm thick at flanks and margin, at upper margin of t. prismatica-angularis oriented at a 40–70° angle to the surface, marginal cortical cells *5–7 × 3–4 µm, (†) thin-walled; **glassy processes** absent. **Anchoring hyphae** sparse, †2–3 µm wide, walls †0.2–0.4 µm thick. **SCBs** globose, in paraphyses 0.8–1.7 µm diam., in ectal excipulum (near margin) 1.7–2.7 µm. **Exudate** over paraphyses 0.5–2(–3) µm thick, continuous, hyaline, loosely attached; over margin and flanks granular to cloddy, rather thin, ± scattered. — **ANAMORPH**: unknown.

Habitat: collected 0.5–1 m above the ground, ± decorticated, 15 mm thick branch of *Purshia stansburyana*, on 0.1 mm deep strongly decayed wood, in a broad and shallow beetle gallery close to a deep longitudinal cleft and remnants of bark, greyed, algae very sparse. **Associated**: *Durella* sp., *Mellitiosporiella pulchella*, *Orbilia macrodelphinus*, *O. maeandrina*, *O. microsoma*, *Propolis farinosa*, *Teichosporella dura*, indet. black pycnidia. **Desiccation tolerance**: fully viable for at least 28 months. **Altitude**: 2433 m a.s.l. **Geology**: Quaternary alluvial sandy deposits from granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia stansburyanae* is characterized by ± fusoid(-clavate), rather large ascospores with obtuse to acute apices, large, ± globose spore bodies closely attached to the apex, and 16-spored asci. The species might be related to *O. geijerae* which differs in narrower spores with a less tapered apex, and smaller SBs. It also resembles *O. ponderosae*, which differs in shorter spores with a rounded apex, SBs with a more distinct short filum, and in a textura porrecta at the margin.

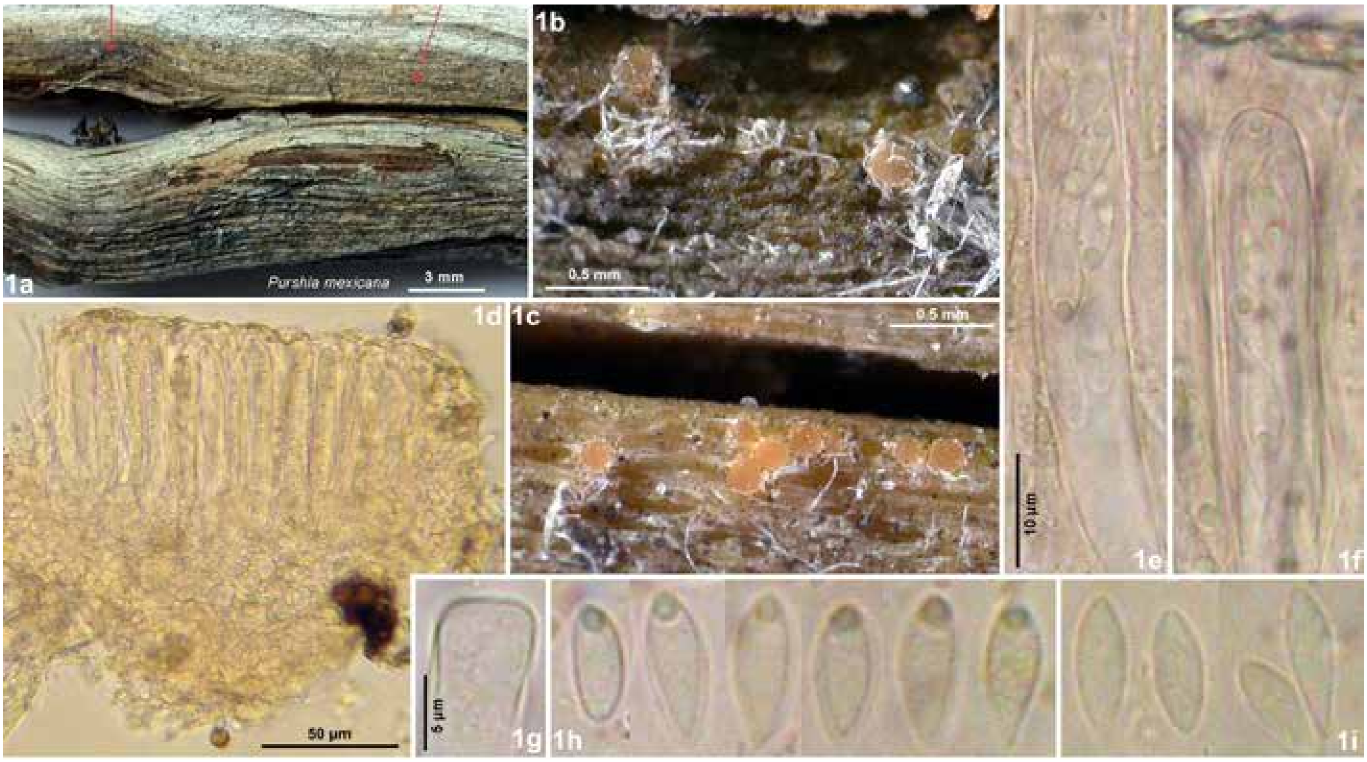

Plate 783. **1**: *Orbilia stansburyanae*. – **1a**. decorticated xeric branch of *Purshia stansburyana*; **1b–c**. rehydrated apothecia; **1d**. apothecium in median section; **1e–f**. mature asci and paraphyses; **1g**. ascus apex; **1h–i**. ascospores. – Living state, except for **1g**, **i** (in KOH). — **1a–h**. H.B. 7918a (holotype): USA, Utah.

The more cylindrical spores of *O. pleiocreosoteris* (Pl. 785) likewise differ from *O. stansburyanae* in rounded apices, and the SBs have a more distinct, ± broad triangular connecting part, also the paraphyses tend to a strongly capitate apex. In the marginal excipulum *O. ponderosae* sharply differs from *O. stansburyanae*, but this feature was not studied in *O. pleiocreosoteris*.

Ecology. *O. stansburyanae* was collected on rotten wood of a xeric branch of *Purshia stansburyana* in a scrub with *Purshia stansburyana* and *Amelanchier utahensis* on a south-exposed mountain slope in a cold-temperate subhumid pinyon-juniper woodland in the Dixie Forest of Utah Mountains in western North America.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 29 km NNE of Escalante, 10 km N of Boulder, 3.5 km W of Deer Mt., 2433 m, branch of *Purshia stansburyana*, on wood, 11.VI.2003, G. Marson (ex H.B. 7918a, M-0276512, **holotype**).

Orbilia geijerae Baral, **sp. nov.**, MB 813918 — Pl. 784

Etymology: named after the substrate, *Geijera parviflora*.

Typification: Australia, Queensland, Banana, branches of *Geijera parviflora*, 22.X.1998, G. Marson (ex H.B. 6279c, BRI AQ799179, holotype).

Latin diagnosis: *Similis* Orbiliae atriplicis *et* O. multicreosoteris *sed asci 16-spori, ascosporae leniter longiores. Habitat ad corticem putridum ramorum siccorum* Geijerae parviflorae *in zona tropica subhumida Australiae orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3 mm diam., 0.08–0.1 mm high, pale rose-cream(-orange), round, ± scattered; disc slightly concave to flat, margin distinct, not protruding, smooth; broadly sessile, superficial or immersed in small cracks, dry light orange-cream. **Asci** *(45–)50–63 × 7.3–8.2 µm, †30–40(–55?) × 6.2–7.3 µm, 16-spored, spores *4–5-seriate, 8 lower spores inverted (scarcely mixed), pars sporifera *27–32 → 21–28 µm long; **apex** (†) medium (to strongly) truncate (not indented, laterally not inflated), thin-walled; **base** with short, thick, slightly flexuous stalk, L- to Y-shaped. **Ascospores** *(7.5–)8.5–10(–11) × 2–2.5(–2.8) µm, †6–8 × 2–2.3(–2.5) µm, subcylindric-clavate (to fusoid-clavate), apex rounded to sometimes obtuse, base slightly to medium attenuated, straight to slightly inequilateral, rarely slightly curved near base; **SBs** *1.1–1.5 × 1–1.3 µm, broadly tear- to almost plug-shaped, apically narrowed to a ± wide point or not narrowed. **Paraphyses** apically slightly clavate-capitate, terminal cells *6–15 × 2.3–3 µm, lower cells *8–11 × 1.7–2.4 µm; unbranched at upper septum. **Medullary excipulum** 20 µm thick, of dense textura intricata with inflated cells, medium sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. angularis from base to mid flanks, 15 µm thick near base, cells †~5–8 × 4–5 µm; 15 µm thick near margin, of t. porrecta oriented at a 10–30° angle to the surface, marginal cortical cells *6–9 × 2.1–2.8 µm, ± undulating, (†) thin-walled; **glassy processes** absent. **Anchoring hyphae** sparse, †1.5–2 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and marginal excipulum globose, in paraphyses 0.8–1.6 µm diam. **Exudate** over paraphyses 0.3–1(–2) µm thick, granular-cloddy, hyaline, loosely attached; over margin and flanks 0.5–1.5 µm thick, rough-cloddy, firmly attached. — **ANAMORPH**: unknown.

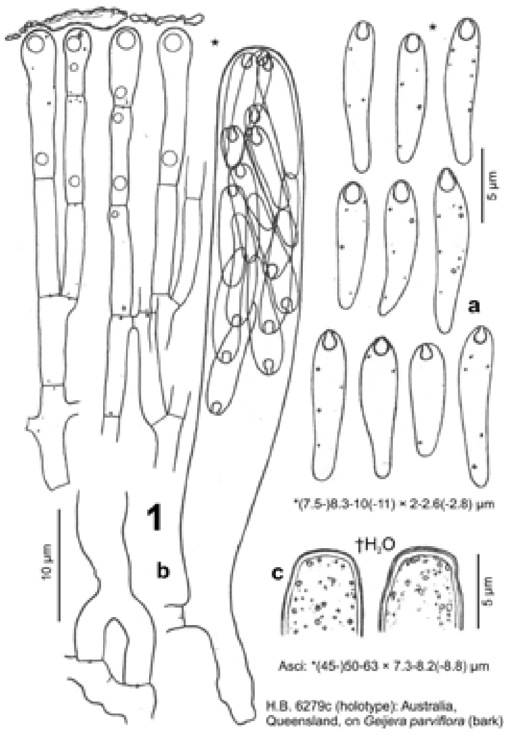

Plate 784. **1**: *Orbilia geijerae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices.

Habitat: collected 0.5–2 m above the ground, corticated, 6–9 mm thick branches of *Geijera parviflora*, on strongly decayed, eroded outer surface of detached bark (bast), greyed, green algae very sparse. **Associated**: *Orbilia acaciae*, *O. corculispora*, *Rhytidhysteron* sp., *Schizoxylon* sp., *Thyronectria* sp. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 136 m a.s.l. **Geology**: Permian sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia geijerae* is characterized by subcylindric- to fusoid-clavate, medium-sized ascospores with large, closely attached SBs, and by 16-spored asci. Rarely 8-spored asci with up to 15 µm long spores were seen among the 16-spored ones. The North American *O. multicreosoteris* and Australian *O. atriplicis* differ mainly in 32-spored asci. The Australian *O. pleioaustrocylindrica* (section *Orbilia*) differs in smaller spores, SBs with a distinct but short filum, and more inflated paraphysis apices.

Ecology. *O. geijerae* was found on rotten bark of xeric branches of *Geijera parviflora* in a narrow strip of eucalypt open woodland between road and pasture in tropical subhumid eastern Australia (west of the Great Dividing Range).

Specimens included. **AUSTRALIA**: **Queensland**, Brigalow Belt South, 138 km SSW of Rockhampton, 11 km SW of Banana, 136 m, branches of *Geijera parviflora*, on bark, 22.X.1998, G. Marson (ex H.B. 6279c, BRI AQ799179, **holotype**).

Orbilia pleiocreosoteris G. Marson, **nom. prov.** — Pl. 785

Etymology: named after the host, *Larrea tridentata* (creosote bush).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.45 mm diam., light orange. **Asci** *85–122 × 8–8.8 µm, 16-spored, spores *3–4-seriate, lower spores inverted; **base** with short, thick, slightly

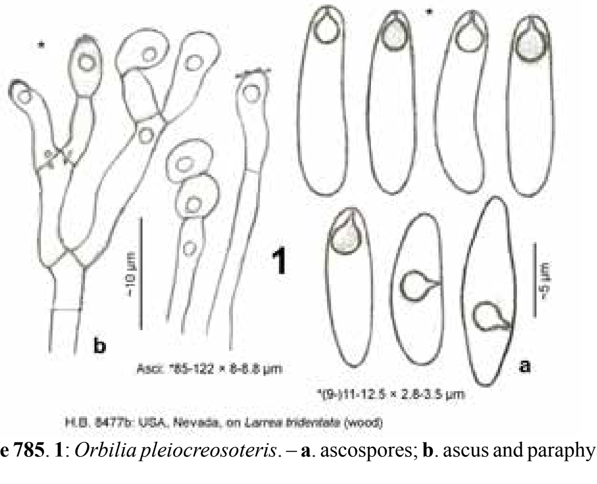

Plate 785. **1**: *Orbilia pleiocreosoteris*. – **a**. ascospores; **b**. ascus and paraphyses.

flexuous stalk, L- to Y-shaped. **Ascospores** *(8.8–)11.2–12.5 × 2.8–3.6 µm, ± subcylindric, apex rounded to sometimes obtuse, base not or rarely slightly attenuated, straight to rarely slightly curved; **SBs** apically or rarely laterally attached to spore wall, *2–2.5 × 1.7–2 µm, broadly tear-shaped, apically narrowed to small point. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells short, often branched at upper septum. **SCBs** in paraphyses globose. **Exudate** over paraphyses thin, granular-cloddy. **— ANAMORPH**: unknown.

Habitat: decorticated, 10–11 mm thick branches of *Larrea tridentata*, on strongly rotten and greyed wood. **Associated**: *Carestiella schizoxyloides*, *Orbilia ?flexisoma*, *O. lentiformis*, *O. sonorensis*, *Symbiotaphrina desertorum*, indet. hyphomycete. **Desiccation tolerance**: Probably highly tolerating drought. **Altitude**: 960 m a.s.l. **Geology**: Mississippian & Permian carbonate and clastic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiocreosoteris* resembles *O. multicreosoteris*, especially the collection illustrated in Pl. 786: 2, but differs in 16-spored asci and distinctly larger ascospores. *O. geijerae* differs in narrower, basally tapered spores with much smaller and more broadly attached SBs, much shorter asci, and apically less inflated paraphyses. From *O. ponderosae* this species differs in longer spores. For the differences to *O. stansburyanae* see p. 1274. The occasional lateral SB attachment is reminiscent of *O. myrioauris* (section *Hemiorbilia*).

When still alive, the sparse material was sketchily studied by one of us (G.M.), but later no apothecia could be discovered on the branch fragments. We therefore refrained from validly publishing this species.

Ecology. *O. pleiocreosoteris* was found on decayed wood of a xeric branch of *Larrea tridentata* in a warm-temperate arid Mojave creosotebush desert scrub in western North America.

Specimens included. **USA**: **Nevada**, Mojave Desert, 18.5 km WSW of Las Vegas, 4.5 km ESE of Blue Diamond, 960 m, branch of *Larrea tridentata*, on wood, 1.V.1995, G. Marson (H.B. 8477b ø).

Orbilia multicreosoteris Baral & G. Marson, **sp. nov.**, MB 813919 — Pl. 786

Etymology: according to the similarity to *O. pleiocreosoteris* which grew on *Larrea tridentata* (creosote bush).

Typification: USA, Arizona, Tucson, branch of *Olneya tesota*, 30.V.2003, G. Marson (ex H.B. 8085f, M-0276519, holotype).

Latin diagnosis: *Similis* Orbiliae atriplicis *sed ascosporae latiores, rectae, corpuscula refringentia latiora, partim perlate ad apicem affixa. Habitat ad corticem putridum ramorum siccorum* Olneyae tesotae *et* Sarcobati *in zona subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.34 mm diam., 0.1–0.11 mm high, pale to light (dirty) orange(-ochraceous), round, scattered; disc slightly concave to flat, margin distinct, not protruding, smooth; broadly sessile, slightly immersed. **Asci** *75–77 × 8.8–9.2 µm {1}, †45–60 × (6–)7–9(–9.5) µm {2}, 32-spored (26–30 spores counted), spores *4-seriate, lower spores inverted (strongly mixed); **apex** (†) slightly to strongly truncate (not distinctly indented, laterally not inflated), thin-walled (rarely immature slightly thick-walled); **base** without or with short, thick stalk, Y- to h-shaped. **Ascospores** *(5–)6–8.5(–9.5) × (2–)2.5–3 µm {2}, †5.5–8.5 × (2.3–)2.5–3(–3.2) µm {2}, subcylindrical to ellipsoid- (rarely fusoid-)clavate, apex rounded to obtuse, base not or often slightly to medium attenuated, straight to sometimes slightly curved at base; **SBs** *(0.8–)1.2–1.5 × 1.1–1.3 µm {2}, globose to broadly tear-shaped, also broadly plug-, rarely lens-shaped, apically closely attached or narrowed to a small point, with or without a very short filum, also broadly attached. **Paraphyses** apically uninflated to slightly clavate-capitate, rarely moniliform, terminal cells *6–9 × 2.3–2.6 µm {1}, †3.5–11 × 2–2.7 µm {T}, lower cells †(4–)6–9 × 1.3–1.8 µm {T}; frequently branched at upper septum. **Medullary excipulum** 15 µm thick, of dense textura intricata with many inflated cells, indistinctly delimited. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. angularis from base to mid flanks, 15–20 µm thick near base, cells †8–10 × 5–8 µm {T}; 10–15 µm thick near margin, oriented at a 10° angle to the surface, marginal cortical cells †~7–8 × 2–3 µm {T}, ± thin-walled; **glassy processes** absent. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2 µm thick {T}. **SCBs** in paraphyses globose (rarely crystalloid?) {1}. **Exudate** over paraphyses 0.2 µm thick, continuous, also 2–3 µm thick, hyaline, loosely attached; over margin and flanks 0.2–0.7 µm, granular-cloddy. **— ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, partially to almost entirely decorticated, 8–13 mm thick branches of *Olneya tesota* {1}, *Sarcobatus vermiculatus* {1}, on strongly decayed bark (bast) {2}, eroded, strongly greyed, no algae. **Associated**: *Orbilia ?barrowensis* {1}, *O. maeandrina* {2}, *O. multigambelii* {1}, *O. myrioolneyae* {2}, *O. myriourosperma* {1}, *Patellaria 'andina'* {1}. **Desiccation tolerance**: some paraphyses still viable after 2 years, spores still alive after 34 months. **Altitude**: 710–745 m a.s.l. **Geology**: Holocene alluvial sand, silt & clay; felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multicreosoteris* is characterized by 32-spored asci and cylindric-ellipsoid spores with rather large, ± isodiametric SBs of quite a variable shape. The species is similar to the Australian *O. atriplicis*, from which it differs in straight and wider, more ellipsoid spores with more attenuated bases, and in larger, broadly attached SBs. However, when the paratype was first examined by one of us (GM), the spores were found to be narrower, more cylindrical and with often untapered bases, with globose SBs being apically narrowed to a small point (Pl. 786: 2a$_2$). Therefore, the species is not sharply separated from *O. atriplicis*. *O. multicreosoteris* closely resembles *O. pleiocreosoteris*, which deviates in 16-spored asci

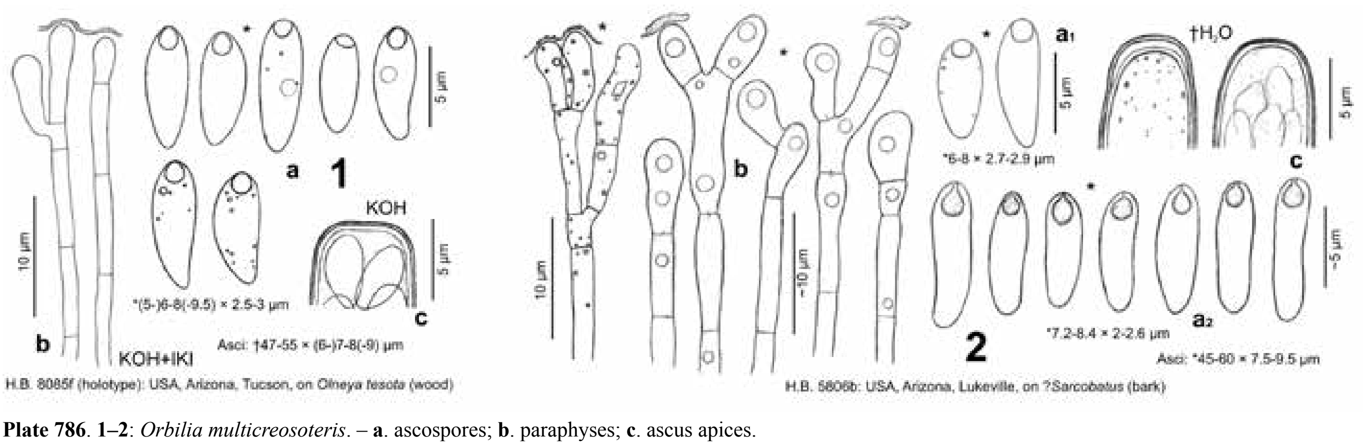

Plate 786. **1–2**: *Orbilia multicreosoteris*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices.

and larger spores. *O. flavida* (section *Lentiformes*) resembles *O. multicreosoteris* in spore size and shape but differs in consistently lens-shaped SBs being always wider than high.

Ecology. *O. multicreosoteris* was detected on rotten bark of xeric branches of two different angiosperm shrubs in subtropical semiarid (almost arid) Sonoran paloverde-mixed cacti desert scrubs in the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 25 km WNW of Tucson, 5 km S of Picture Rocks, Saguaro, 745 m, branch of *Olneya tesota*, on bark, 30.V.2003, G. Marson (ex H.B. 8085f, M-0276519, **holotype**). – 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branch of *Sarcobatus vermiculatus*, on bark, 5.V.1995, G. Marson (H.B. 5806b).

Orbilia atriplicis Baral, **sp. nov.**, MB 813920 — Pls 787–788

Etymology: named after the substrate, *Atriplex nummularia*.

Typification: Australia, Northern Territories, Alice Springs, branches of *Atriplex nummularia*, 9.X.1998, G. Marson (ex H.B. 6569a, MEL 2389209, holotype).

Latin diagnosis: *Apothecia rehydratata 0.12–0.22 mm diam., pallide aurantiaca, sessilia, margine laevi. Asci 32-spori. Ascosporae *5–7.8 × 1.7–2.3 µm, plus minusve cylindricae, apice rotundatae, partim leniter vel valde curvatae, corpusculum refringens globosum ad late lacrimiformem, ad apicem confertim affixum continentes. Excipulum marginale absque processis vitreis. Habitat ad corticem putridum ramulorum vel ramorum siccorum* Atriplicis nummulariae *in zona subtropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.12–0.22 mm diam., 0.1 mm high (receptacle 0.07–0.09 mm), pale to light (rose-)orange, round, very scattered to subgregarious; disc flat, margin not protruding, smooth; sessile, superficial. **Asci** *48–68 × 7.5–8(–8.5) µm, †42–58 × 6–7.5 µm, 32-spored, spores *4–5-seriate, lower spores inverted (strongly mixed), pars sporifera *33–42 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not inflated), thin-walled; **base** with very short to medium long, ± thick, flexuous stalk, L- to Y-shaped. **Ascospores** *5–7.8 × (1.7–)1.8–2.3(–3) µm, (sub) cylindrical (rarely slightly clavate), sometimes slightly dumbbell-shaped, rarely ± ellipsoid-(ob)ovoid (then 2.7–3 µm wide), apex rounded (to obtuse), base sometimes slightly attenuated, straight to slightly, sometimes strongly curved (geniculate) in middle or lower part; **SBs** *1–1.2 × 0.8–1 µm, globose to very broadly tear-shaped, closely attached to spore wall. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells *7–13(–16) × 2–3.5(–4.2) µm, lower cells *10–13 × 1.5–2(–3) µm [near base *5–10 × 2–2.7(–3) µm]; sometimes or frequently branched at upper septum. **Medullary excipulum** 25 µm thick, of medium dense textura intricata-angularis, indistinctly delimited. **Ectal excipulum** of (†) thin-walled, ± vertically oriented t. angularis from base to mid flanks, 20–30 µm thick near base, cells †5–9 × 4–7 µm; 15 µm thick near margin, of t. prismatica oriented at a 50–80° angle to the surface (t. porrecta at upper margin), marginal cortical cells †6–9 × 2.5–3.5 µm, thin-walled; **glassy processes** absent. **Anchoring hyphae** medium abundant, */†2–3 µm wide, walls 0.2(–0.3) µm thick. **SCBs** in paraphyses globose, 1–2.7 µm diam. **Exudate** over paraphyses 0.5–2 µm thick, cloddy, hyaline, ± firmly attached; over margin and flanks 0.5–1 µm thick, smooth, firmly attached, pale yellowish. **— ANAMORPH**: unknown.

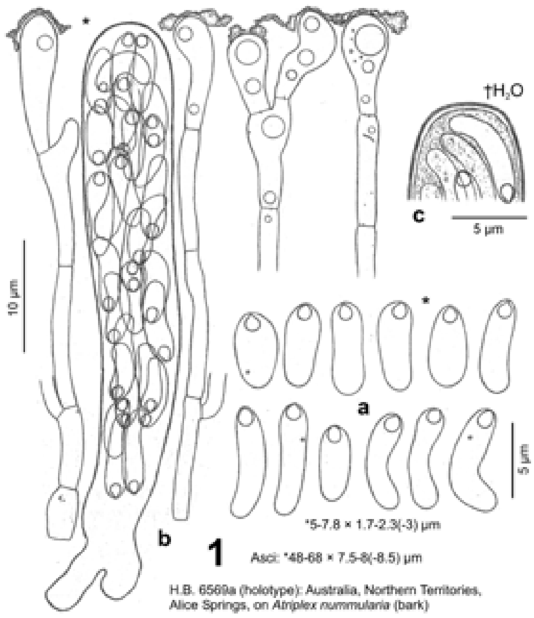

Plate 787. **1**: *Orbilia atriplicis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Habitat: collected 0.5–1 m above the ground, decorticated on 1 side, 4–18 mm thick twigs and branches of *Atriplex nummularia*, on medium to strongly decayed bark, slightly to strongly greyed, without algae. **Associated**: *Dothideales*, *Orbilia bicknellensis*, *O. lentiformis*, *O. ?multitrapezoidea*, *O. myriostomachia*, *O. pluristomachia*. **Desiccation tolerance**: fully viable for at least 16.5 months. **Altitude**: 586 m a.s.l. **Geology**: Neoproterozoic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia atriplicis* is characterized by 32-spored asci and cylindrical, partly curved ascospores with ±

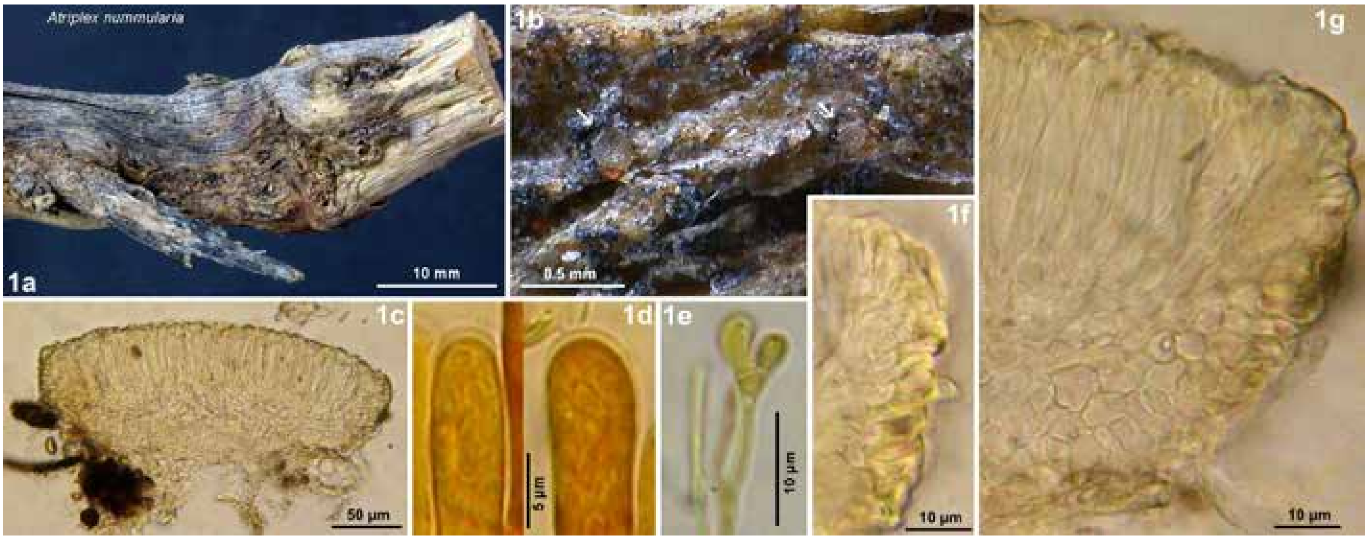

Plate 788. **1**: *Orbilia atriplicis*. – **1a**. partly decorticated xeric branch of *Atriplex nummularia*; **1b**. rehydrated apothecia (after 8 years); **1c**. apothecium in median section; **1f–g**. id., marginal ectal excipulum; **1d**. ascus apices; **1e**. upper part of paraphysis. – Dead state: **1c**, **f–g** in KOH; **1d–e** in KOH+IKI. — **1a–g**. H.B. 6569a (holotype): Australia, Northern Territories, Alice Springs, on *Atriplex*.

globose SBs. *O. multiaustrocylindrica* (section *Orbilia*) differs merely in narrower spores and SBs but these values overlap and the species is doubtfully distinct, as it grew on the same host genus in a similar ecological region though in 200 km distance. For the similar North American *O. multicreosoteris* see above. The 16-spored *O. geijerae* differs in longer spores with more attenuated bases.

Ecology. *O. atriplicis* was detected on ± rotten bark of xeric twigs and branches of *Atriplex nummularia* in a subtropical arid acacia open shrubland in a flat depression northeast of Macdonnell Ranges in central Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, MacDonnell Ranges, 15 km WNW of Alice Springs, N of Honey Moon Gap, S of Simpson Gap, 586 m, branches of *Atriplex nummularia*, on bark, 9.X.1998, G. Marson (ex H.B. 6569a, MEL 2389209, **holotype**).

Orbilia subcylindrospora Baral & E. Weber, **sp. nov.**, MB 813935 — Pls 789–790

Etymology: referring to the similarity with *O. cylindrospora*.

Typification: France, Neffiès, branches of *Erica arborea*, 6.V.2005, G. Garcia (ex H.B. 7843, M-0276594, holotype).

Latin diagnosis: *Similis* Orbiliae cylindrosporae *sed ascosporae leniter majores, saepe leniter vel valde curvatae, paraphyses ad apicem magis capitatae, apothecia magis intense rosea. Habitat ad lignum putridum ramorum siccorum arborum coniferarum et angiospermarum in zona orosub- ad mesosubmediterranea humida ad semihumida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5 mm diam., 0.1–0.2 mm high (receptacle 0.07–0.11 mm), pale to light rose to pink, slightly to rather strongly translucent, round (to elliptical) or slightly undulating, scattered to gregarious in smaller or larger groups; disc flat, margin distinct, thin, not protruding, smooth to finely rough; on a narrowed base or an indistinct stipe, superficial to slightly erumpent, partly deeply immersed in biofilm; dry light to bright rose- or orange-red. **Asci** *36–53 × 4.3–5.3 µm {2}, †(28–)33–45(–48) × (3.3–)3.7–4.3(–4.6) µm {3}, 8-spored, spores *2-seriate, (2–)3–5 lower spores inverted {3} (often mixed), pars sporifera *24–30 → 16.5 µm long; **apex** (†) slightly to medium (rarely strongly) truncate (not indented, laterally not inflated), thin-walled; **base** with short to long, ± thick and flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(4–)5–7.2 {3} × 1.3–1.6 {1} or 1.6–1.8(–2.2) {2} µm, †(4.5–)5–6 {2} × 1.2–1.4 {1} or 1.6–1.8 µm {1}, subcylindrical to slightly or sometimes strongly (fusoid-)clavate, apex rounded to obtuse, base not or slightly, sometimes strongly attenuated, slightly to strongly curved (often geniculate in middle or lower part), exceptionally straight; **SBs** *0.6–1.2 × 0.5–0.8 µm {3}, globose to broadly tear-shaped, apically closely attached, partly narrowed to a small point, sometimes with a very short, sometimes invisible filum. **Paraphyses** apically (slightly) medium to strongly capitate, terminal cells *(9–)12–19(–23.5) × (2.3–)2.8–4 µm {3}, †2.3–4 µm wide, lower cells *8–12 × 1.8–2 µm {T}, †1.2–1.8 µm wide; sometimes branched at upper septum. **Medullary excipulum** pale rose or yellow, 25–70 µm thick, of dense textura intricata with many inflated cells, medium to sharply delimited from ectal excipulum mainly at flanks by a 12–15 µm thick layer of t. porrecta. **Ectal excipulum** of hyaline, (†) slightly gelatinized, vertically oriented t. (globulosa-)angularis(-prismatica) from base to mid flanks, 20–60 µm thick near base, cells *10–18(–25) × 6–14(–18) µm {3}, †6–14 × 5–7 µm {1}; 20–40 µm thick at lower flanks, 15–25 µm at mid flanks, 10–30 µm near margin, at submargin of t. globulosa-prismatica oriented at a 50–90° angle to the surface, at upper margin of t. (angularis-)prismatica(-porrecta) oriented at 10–50°, marginal cortical cells *9–12 × 3–5 µm {1}, †6–12 × 3–4.2 µm {2}, (†) slightly thick-walled {3}; **glassy processes** absent. **Anchoring hyphae** sparse to abundant, */†2.3–3.7(–4.3) µm wide, walls (0.2–)0.3–0.5(–1) µm thick {3}. **SCBs** globose {2}, in paraphyses 1.3–2.2 µm diam., in ectal excipulum near margin 2–2.5(–3.5) µm. **Exudate** over paraphyses 0.3–1.5(–2) µm

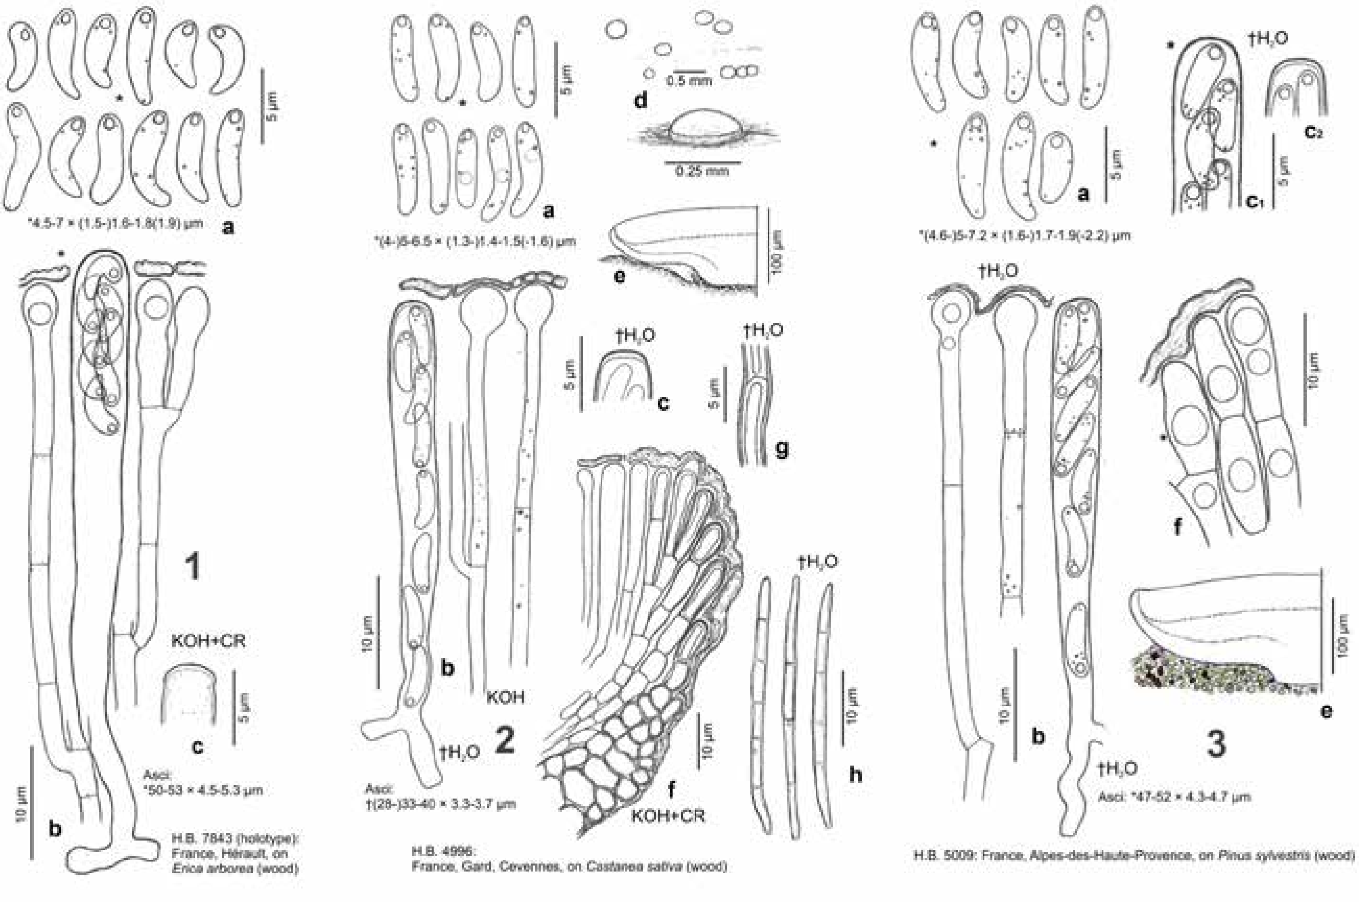

Plate 789. **1–3**: *Orbilia subcylindrospora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum at margin and mid flanks; **g**. anchoring hypha; **h**. conidia from substrate.

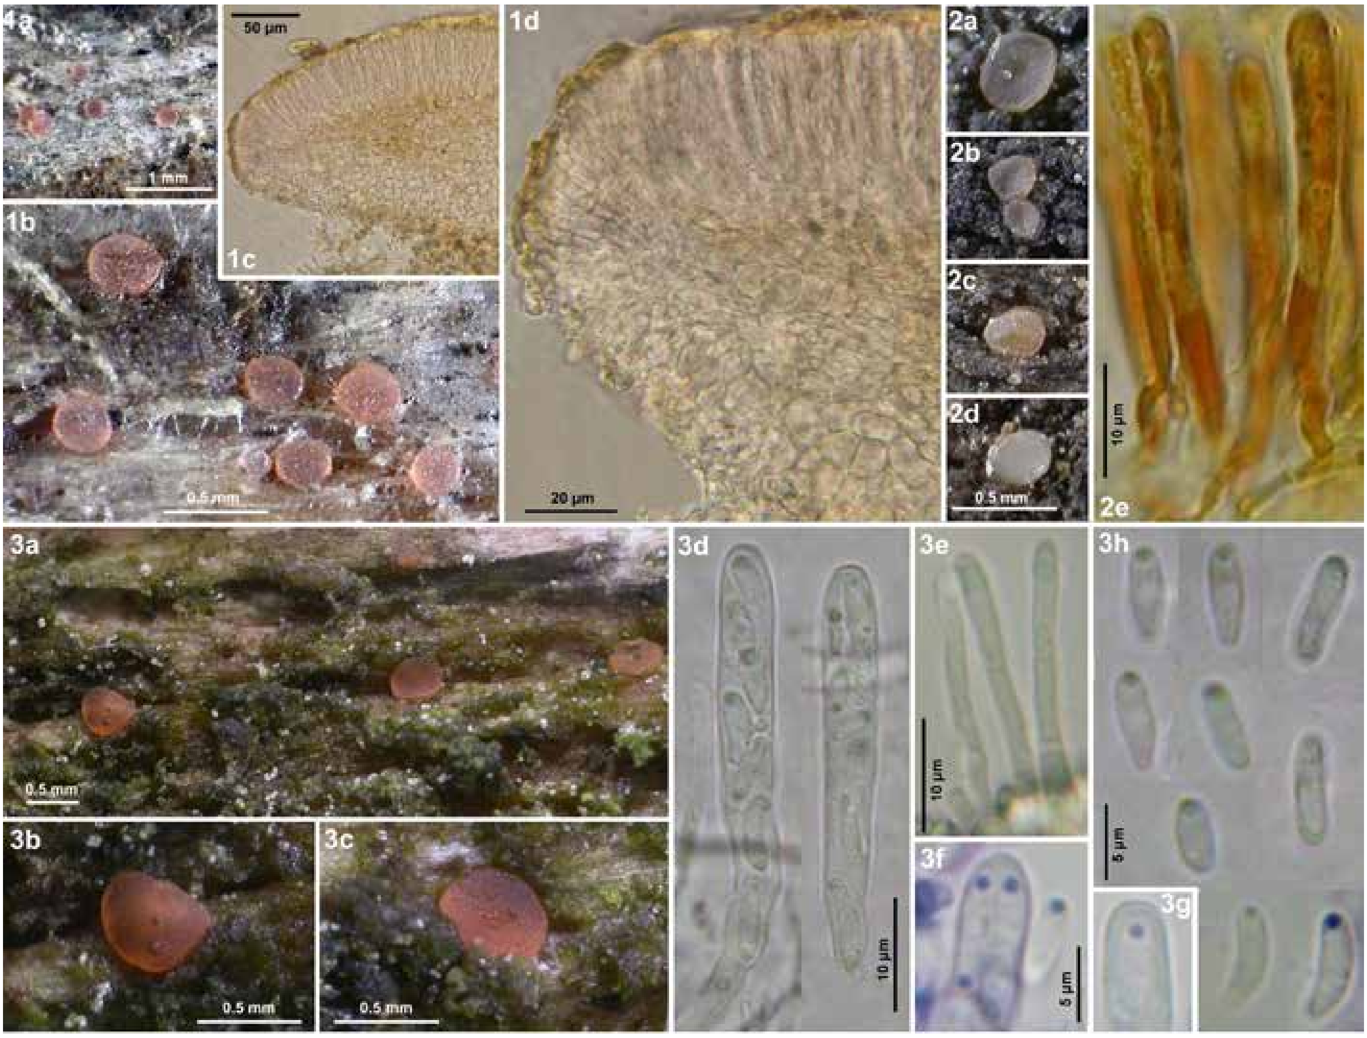

Plate 790. **1–2**: *Orbilia subcylindrospora*; **3**: *O.* cf. *subcylindrospora*. – **1a–b**, **2a–d**, **3a–c**. rehydrated apothecia (**1**: after 2 months, **2**: after 13 years); **1c–d**. apothecia in median section; **2e**, **3d–e**. asci and paraphyses; **3f–g**. ascus apices (in CBR); **3h**. ascospores (1 in CRB). – Living state, except for **2e** (in KOH+IKI), asci in **3d**. – **3e–g**, **3h** 2 spores below: phot. G. Friebes. — **1a–d**. H.B. 7843 (holotype): France, Hérault, on *Erica*; **2a–e**. H.B. 5009: France, Alpes-de-Haute-Provence, on *Pinus*; **3a–h**. H.B. 10019: Austria, Steiermark, on *Juniperus*.

thick, cloddy-continuous, ± loosely attached, ± hyaline; over margin and flanks (1–)1.5–3(–5) µm thick, rough-cloddy(-granular), hyaline to pale yellow-orange. — **ANAMORPH**: unknown (but see below).

Habitat: collected ~1.5 m above the ground, entirely decorticated, 15–25 mm thick branches of *Castanea sativa* {1}, *Erica arborea* {1}, *Pinus* (?)*sylvestris* {1}, on 0.2–0.4 mm up to 2–5 mm deep strongly decayed wood {3}, slightly to strongly greyed, green algae sparse to abundant. **Associated**: *Dacrymyces* sp. {1}, *Gloniopsis smilacis* {1}, *Orbilia patellarioides* {1}, *O. sphaerospora* {2}, *O. subvinosa* {1}, *Phragmiticola* sp. {1}, crustose and foliose lichens. **Desiccation tolerance**: fully viable for at least 2 months, some excipular cells still viable after 5 months. **Altitude**: 235–1080 m a.s.l. **Geology**: Austria: Mesozoic dolomite; Provence: Upper Cretaceous marl; Languedoc: mica schist, basalt. **Phenology**: V, IX–X (but long-lived).

Taxonomic remarks. *Orbilia subcylindrospora* is characterized by subcylindrical (sometimes clavate), medium-sized, generally more or less curved to geniculate ascospores and globose to broadly tear-shaped spore bodies, also by medium to strongly capitate paraphyses and rose-coloured apothecia. The taxonomic position of *O. subcylindrospora* is not clear. The closest relatives appear to be *O. cylindrospora* and *O. austrocylindrica*, which differ in smaller, ± straight spores, the former also in less inflated paraphyses, the latter in shorter asci. However, the spores of *O. subcylindrospora*, especially in the specimen on *Erica*, also resemble *O. basiflexa* and members of sections *Arthrobotrys* (*O. cupressi*) and *Aurantiorubrae* (some species of series *Regales*). Some of these differ in possessing glassy processes, others in having ± spathulate paraphyses, e.g., *O. pseudocylindrospora* (series *Regales*) which further differs in a thin exudate individually attached to each paraphysis, slightly longer spores, and SBs with a more distinct, partly apically widened filum. Also *O. cupressi* differs from *O. subcylindrospora* in slightly longer spores and in SBs with a short filum. Narrow-spored collections of *O. subovoidea* differ from *O. subcylindrospora* only gradually in their wider spores. *O.* aff. *dixiensis* (on *Arctostaphylos*, Pl. 699: 4) differs in a tendency to elongate SBs, for which reason we assume its relationship to section *Habrostictis*.

Variation. The three included collections show a rather high variation in several features, especially in the spores. The one on *Castanea* has distinctly narrower spores than the other two, and in that on *Erica* the spores are partly more curved and tapered at the base. The size of the SBs varies remarkably between the three collections, ranging from 0.6–0.8 × 0.5–0.6 µm (*Castanea*) over 0.8–1 × 0.6–0.8 µm (*Pinus*) to 0.8–1.2 × 0.6–0.8 µm (*Erica*). The paraphyses show a stronger apical inflation in the collection on *Castanea*.

Not included collection. The sample on *Juniperus* (Pl. 790: 3) is not included because of its larger spores which approach narrow-spored populations of *O. subovoidea*. It closely resembles the sample on *Pinus* except for having uninflated paraphyses, spores of *5–7.5(–8.5) × 1.8–2.3(–2.5) µm with wider SBs (1–1.2 × 1–1.2 µm), and longer asci (*50–60 × 5.3 µm). The ascus base was partly H-shaped.

Anamorph. In one collection we observed narrow phragmoconidia (†31–35 × 1–1.2 µm, Pl. 789: 2h) similar as in *O. cylindrospora*. At present we consider these conidia as doubtful. The presumed anamorph of the possibly distantly related *O. cupressi* (section *Arthrobotrys*) has very long, fusoid, multiseptate conidia similar as in *Dactylella oxyspora*.

Phylogeny. A sequence was taken from apothecia of the not included specimen from Steiermark (H.B. 10019), comprising ITS and LSU (D1–D2); the S1506 intron is absent. This strain deviates in the ITS and available LSU from *O. sphaerospora* by 5.2/1.8% and from *O. subovoidea* by 5.5/~1.8%, respectively. These distances and the presence of the S1506 intron in *O. subovoidea* suggest that H.B. 10019 is specifically distinct hereof.

Ecology. *O. subcylindrospora* was found on rotten wood of xeric branches of both gymno- and angiosperms. The species is so far only known from southern France and eastern Austria. The holotype on *Erica* is from a mesosubmediterranean semihumid shrubland with *Cheilanthes tinaei*, those on *Castanea* and *Pinus* from a suprasubmediterranean semihumid open chestnut forest and an orosubmediterranean humid pine forests. The not included collection on *Juniperus* was in an orotemperate humid pine forest with *Picea* and *Fagus* etc. and abundant *Cypripedium* in the eastern Alps.

Specimens included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Alpes-de-Haute-Provence**, 6.5 km SE of Castellane, 0.8 km NW of La Bâtie, Col de Luens, 1080 m, branch of *Pinus* (?)*sylvestris*, on wood, 5.X.1993, G. Marson (H.B. 5009). – **Languedoc-Roussillon**, **Gard** (border to Lozère), Massif central, 10 km WNW of St.-Jean-du-Gard, 2.3 km N of Saumane, SW of St.-Roman-de-la-Tousque, 500 m, branch of *Castanea sativa*, on wood, 25.IX.1993, G. Marson (H.B. 4996). – **Hérault**, 18 km SE of Bédarieux, 2 km ENE of Neffiès, Les Baumes, 235 m, branches of *Erica arborea*, on wood, 6.V.2005, G. Garcia (ex G.G. 05050605/H.B. 7843, M-0276594, **holotype**).

Not included. **AUSTRIA**: **Steiermark**, 20 km NNW of Bruck an der Mur, 3 km NNW of St. Ilgen, Karlschütt, 890 m, branch of *Juniperus communis*, on wood, 6.VIII.2016, G. Friebes (ex G.F. 20160171, H.B. 10019; sq.: MK493136).

Orbilia basiflexa Baral, **sp. nov.**, MB 813746
— Pls 791–792

Etymology: named after the spores having a tapered, geniculate base.
Typification: Mongolia, Dayan lake, branch of *Lonicera microphylla*, 16.VIII.2005, P. Karasch (ex H.B. 7897c, M-0276439, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–0.35 mm diam.*, *aurantiaca*, *sessilia*, *margine laevi vel subcrenulato. Ascosporae *7.3–9.5 × 2–2.4 µm*, *fusoideo-clavatae*, *apice obtusae*, *basaliter valde curvatae*, *in statu vivo corpusculum refringens globosum*, *ad apicem filo brevissime affixum continentes. Paraphyses ad apicem leniter vel modice capitato-clavatae. Habitat ad corticem putridum rami sicci* Lonicerae microphyllae *in zona subhumida continentali subalpina Asiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.35 mm diam., 0.12–0.22 mm high (receptacle 0.08 mm), pale to light orange, translucent, round, subgregarious; disc slightly concave to flat, margin thin, not protruding, smooth or very indistinctly crenulate; with a broad, 20 µm high stipe, superficial. **Asci** *44–56 × 6–6.4(–6.7) µm, †35–51 × 5.2–5.7 µm, 8-spored, spores (*) obliquely biseriate, 2–6 lower spores inverted (scarcely mixed), pars sporifera *20–27 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not inflated), thin-walled; **base** unstalked or with a short to medium long, thick stalk, T-, L- or Y-shaped. **Ascospores** *7.3–9.5 × 2–2.3(–2.4) µm, †8–9 × 2–2.2 µm, fusoid-clavate, apex rounded to obtuse, base medium to strongly attenuated in a tail-like end, here always medium to strongly curved (geniculate); **SBs** *1.2–1.4 × 0.9–1.2 µm, globose (to broadly tear-shaped). **Paraphyses** apically (uninflated to) slightly or medium clavate-capitate, sometimes moniliform, terminal cells *(5–)8–15(–20) × (2–)2.5–4(–4.5) µm, lower cells *7–11.5 × 1.6–2.5(–3.5) µm; sometimes branched at upper septum. **Medullary excipulum** subhyaline, 70–80 µm thick, of medium loose textura intricata with many inflated cells, rather sharply delimited. **Ectal excipulum** pale rose, of (†) distinctly gelatinized, indistinctly vertically oriented t. globulosa-angularis(-prismatica) from base to margin, 50–100 µm thick near base, cells *10–36 × 8–18 µm; 18 µm thick near margin, oriented at a high angle to the surface, marginal cortical cells *6–12 × 3–4.5 µm, thin-walled, somewhat free, converging to form minute teeth; **glassy processes** absent. **Anchoring hyphae** rather abundant, †2–3.3 µm wide, walls 0.2–0.3 µm thick. **SCBs** globose, in paraphyses (0.7–)1.5–2.3(–2.6) µm diam., in ectal excipulum (near margin) 1.5–3.7 µm. **Exudate** over paraphyses and excipulum 0.5–1.5 µm thick, cloddy(-continuous), loosely, later firmly attached, partly rough, hyaline. — **ANAMORPH**: unknown.

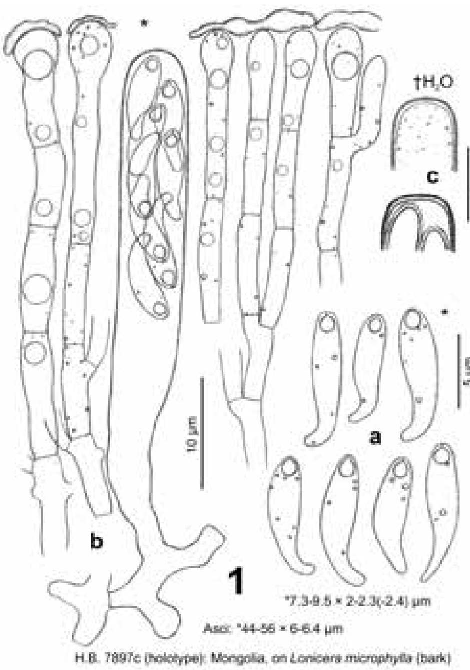

Plate 791. **1**: *Orbilia basiflexa*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Habitat: collected 0.5–1.5 m above the ground, corticated, 9–10 mm thick branch of *Lonicera microphylla*, on medium decayed bark detaching in thin layers, strongly greyed, green algae medium abundant. **Associated**: *Caloplaca* sp., *Durella* ?*atrocyanea*, *Lecanora* sp., *Orbilia concoloris*, *O. delphinus*, *O. maeandrina*, *Parmelia* sp., *Stenocybe* sp., ?*Teichospora* sp. **Desiccation tolerance**: fully viable for at least 1 month. **Altitude**: 2095 m a.s.l. **Geology**: Paleozoic sediment. **Phenology**: VIII (but rather long-lived).

Taxonomic remarks. *Orbilia basiflexa* is characterized by medium-sized, fusoid-clavate ascospores with rather strongly tapered and geniculate bases, and large, ± globose spore bodies in the apex. Its taxonomic position is difficult to determine. The large SBs appear to indicate a relation to section *Ovoideae*, especially to *O. subovoidea* or to *O. subcylindrospora*, whereas the basally curved spores recall members of section *Aurantiorubrae* (especially *O. comma* and *O. mali*). *O. comma* differs in smaller, helicoid, more fusiform spores and in the presence of crystalloid SCBs, *O. mali* in smaller, especially narrower spores and more elongate, tear-shaped to pyriform SBs. *O. subcylindrospora* differs in smaller spores and SBs, and less tapered, usually less curved spore bases.

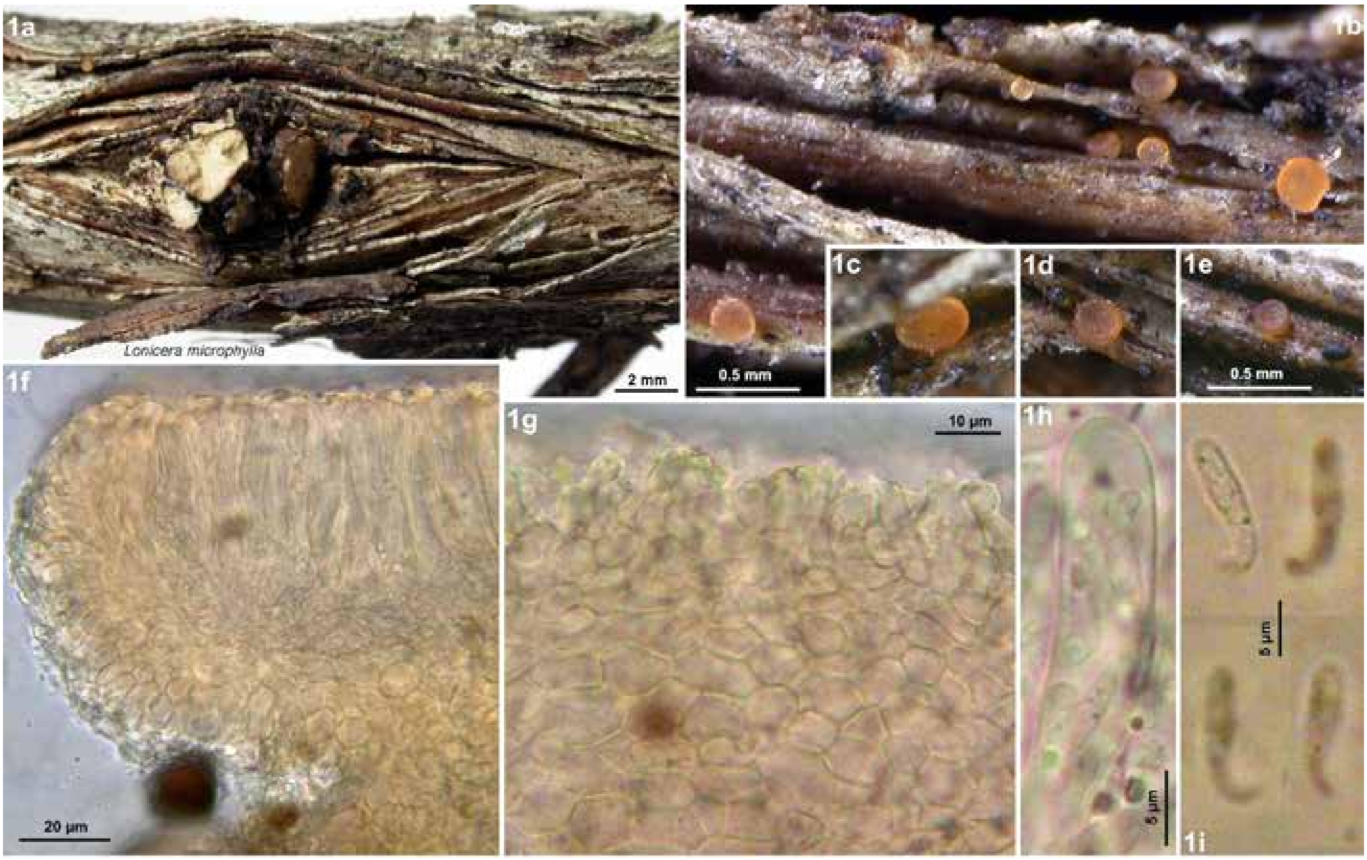

Plate 792. **1**: *Orbilia basiflexa*. – **1a**. corticated xeric branch of *Lonicera microphylla*; **1b–e**. rehydrated apothecia; **1f**. apothecium in median section; **1g**. marginal ectal excipulum in external view; **1h**. mature ascus; **1i**. ascospores. – Living state, except for **1i** (in H_2O). — **1a–i**. H.B. 7897c (holotype): Mongolia, Altay, on *Lonicera*.

Ecology. *O. basiflexa* was found on medium rotten bark of a xeric branch of *Lonicera microphylla* in a continental, orotemperate subhumid (winter-dry), subalpine shrub vegetation (*Spiraea alpina*, *Ribes nigrum*, *Juniperus sabina*) on a south-exposed slope in central Asia.

Specimens included. **MONGOLIA**: **Bayan Ölgii**, Sagsai, Altay Mts., S-part of Tavan Bogd, 20 km SE of Dayan lake, 8 km NE of Chinese border, Songino Gol river valley, 2095 m, branch of *Lonicera microphylla*, on bark, 16.VIII.2005, P. Karasch (ex H.B. 7897c, M-0276439, **holotype**).

Orbilia octosporoides Baral & G. Marson, **sp. nov.**,

MB 813937 — Pls 793–794

Etymology: referring to the genus *Octospora* Hedw. to which the *Orbilia* has several striking similarities.

Typification: USA, Utah, Cedar City, branch of *Juniperus osteosperma*, 24.VIII.1994, G. Marson (ex H.B. 5175b, M-0276542, holotype).

Latin diagnosis: *Apothecia rehydratata 0.3–2 mm diam., aurantio-rosea, substipitata, margine exigue albo-fimbriata vel dentata. Asci 8-spori, in statu emortuo modice truncati, tenuitunicati. Ascosporae *5–9 × 3.7–4.8 µm, ellipsoideo-ovoideae, corpusculum refringens magnum, late lacrimiformem, ad apicem cuspide brevi affixum continentes. Paraphyses saepe moniliformes, ad apicem non vel leniter capitatae, cellulis vivis corpuscula crystalloidea continentibus. Excipulum marginale pilis longis praeditum, partim processis vitreis brevibus terminatis. Habitat ad corticem putridum rami sicci* Juniperi osteospermae *in zona orotemperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.5–0.8(–2) mm diam. (including hairs), in total 0.3(–0.4) mm high [receptacle 0.19(–0.28) mm], light to bright orange-rose, round or laterally compressed, subgregarious in small groups; disc concave, finally flat, margin and flanks with white, prominent hairy teeth, strongly protruding at margin (~100–150 µm incl. hairs); with a distinct stipe 0.1–0.14 × 0.18–0.25 mm, stipe base very slightly immersed, apothecia sometimes entirely hidden beneath detaching thin periderm. **Asci** *65–88 × 6–7.2 µm, †60–75 × 5–6 µm, 8-spored, spores uniseriate, 1–6 lower spores inversely oriented (often mixed), pars sporifera *36–43 µm long; **apex** (†) slightly to medium truncate or hemispherical depending on the viewing direction (not indented, laterally not inflated), thin-walled; **base** with short to long, thick, flexuous stalk, L- or Y-shaped. **Ascospores** *(5–)5.7–7.6(–9) × (3.7–)4–4.8 µm, †5–7 × 3.8–4.6 µm, broadly ellipsoid-obovoid, apex rounded to obtuse, base exceptionally with a short tail-like end; **SBs** *(1.8–)2–2.8 × (1.2–)1.4–1.8 µm, broadly tear-shaped (globose with triangular upper part), apically narrowed to a very short filum. **Paraphyses** apically uninflated or only slightly clavate-capitate, often somewhat moniliform or sublageniform, terminal cells *13–40 × 3–4(–5.2) µm, scarcely exceeding the dead asci, lower cells *7.5–20 × 1.7–3(–3.4) µm, branched only near base. **Medullary excipulum** 30–100 µm thick in receptacle, of medium dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a distinct, 10–35 µm thick layer of t. porrecta. **Ectal excipulum** pale rose, of (*) thin-walled († slightly gelatinized, common walls 0.5–1.2 µm), vertically oriented t. angularis from base to lower flanks, 30–80 µm thick, cells *10–24 × 8–16 µm, †9–16 × 6–10 µm, 25–30 µm thick at mid flanks, of t. prismatica-angularis oriented at a 50–80° angle to the surface, 15 µm thick at margin, of t. porrecta oriented at ~0–20°, marginal cortical cells †10–15 × 3–4.5 µm, **hairs** at margin ± agglutinate, *50–110 × 4–6.5(–8) µm, 3–5-celled, cylindrical, slightly moniliform, terminal cells *8.5–22(–45) µm long, apex obtuse, partly covered by low warts, without glassy caps, basal cells 12–18 µm long, gradually emerging from ectal excipulum, wall *0.3–0.5(–0.8) µm thick, hairs at flanks always dead and ± collapsed, †2–4 µm wide, mostly tipped by high-refractive, hyaline, partly stratified **glassy processes** (2–)6–20 × 3.5–5.5 µm, sometimes instead with glassy lateral walls up to †1.8 µm thick. **Anchoring hyphae** forming an up to 80–100 µm thick, ± gelatinized layer of t. intricata, gradually passing over into hairs at flanks, hyphae *(2–)3–4.5 µm wide, walls *0.2–0.3(–0.5) µm thick (†0.3–0.7 µm), interspersed from base to margin with many small extracellular crystals. **SCBs** in paraphyses globose, 1–1.5 µm diam.,

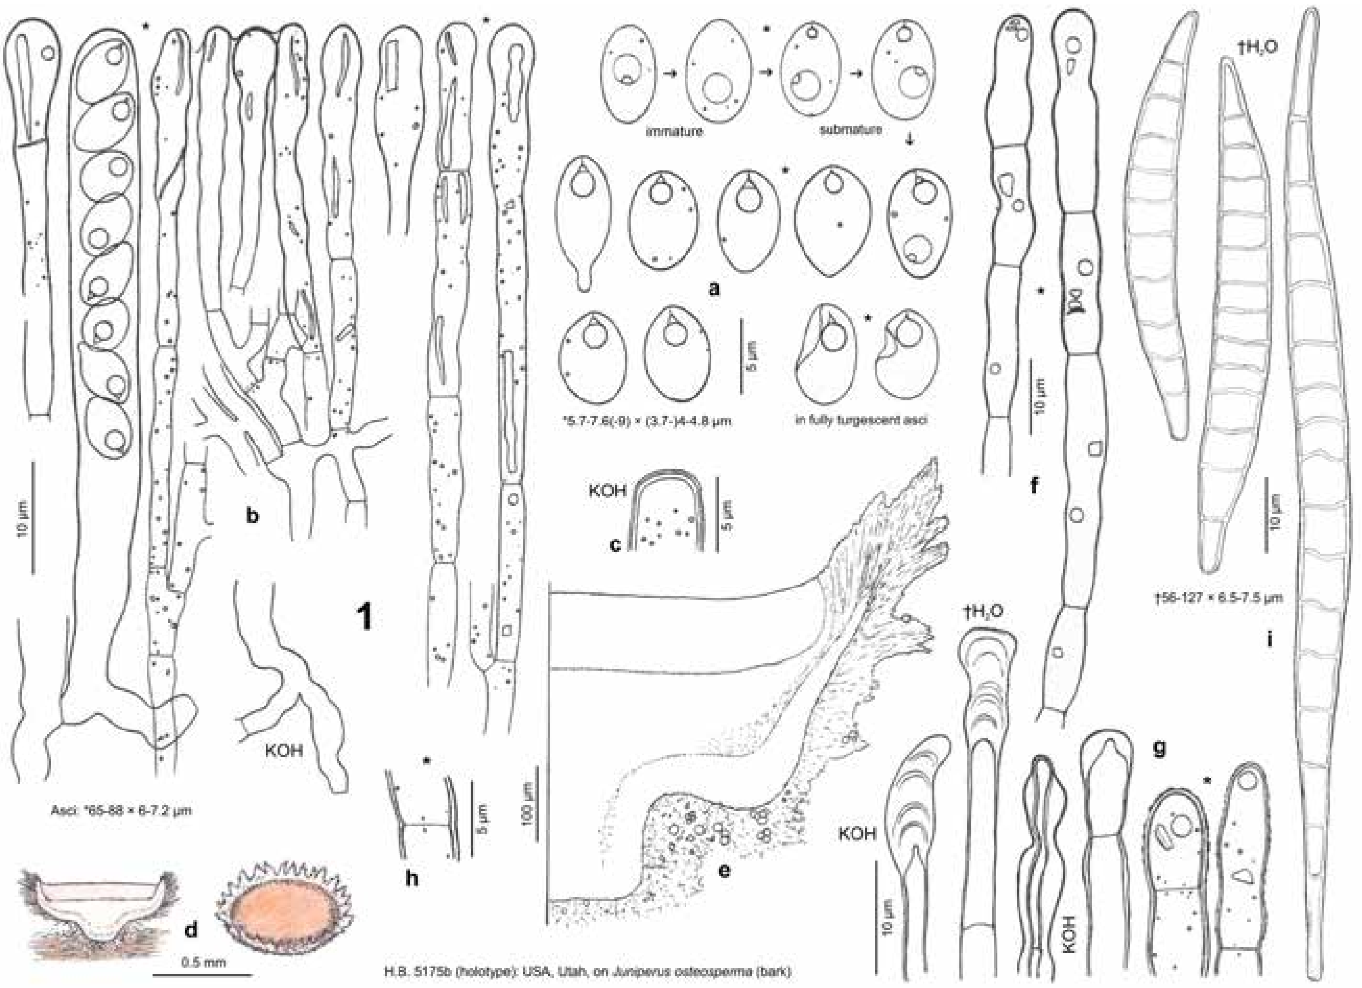

Plate 793. **1**: *Orbilia octosporoides*. – **a**. ascospores (nucleus figured in 5 immature and submature spores); **b**. ascus and paraphyses; **c**. ascus apex; d. rehydrated apothecium with dentate-hairy margin, left in median section; **e**. apothecium in median section; **f**. marginal hairs; **g**. tips of hairs, those at flanks with apical glassy processes or with lateral wall thickenings; **h**. detail of anchoring hypha; i. conidia from substrate.

mixed with 1–3 filiform or rectangular, crystalloid ones of (1.5–)2–7.5(–11) × 0.3–1.2 µm; in ectal excipulum globose (1 per cell, 1.3–2.2 µm diam.) and filiform to angular (1–2 per cell); **LBs** in paraphyses towards base abundant, small, orange, (carotenoids). **Exudate** over paraphyses absent, apices covered by inconspicuous gel; exudate only present near base of apothecia, light yellow-ochraceous, continuous. — **ANAMORPH**: vermispora-(to dactylella-) like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** unbranched, gradually strongly attenuated towards both ends, almost straight to slightly curved, †56–127 × 6–7 µm, 10–17-septate.

Habitat: lying in a dry riverbed, on corticated, 9–17 mm thick branch of *Juniperus osteosperma*, on medium decayed, detaching bark (periderm and bast), somewhat greyed, with some green algae. **Associated**: *Carestiella schizoxyloides*, *Orbilia cucumispora*, *O.* ?*maeandrina*, *O. multidelphinus*, *O. multihamulata*, *O. ophiosoma*, *O. osteospermae*, *O. pisciculus*. **Desiccation tolerance**: fully viable for at least 2 months, but completely dead (including the spores) after 1½ years. **Altitude**: 1815 m a.s.l. **Geology**: Upper Cretaceous sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia octosporoides* is quite outstanding within section *Ovoideae* due to a series of characteristics. The apothecia have long, septate hairs forming large broad teeth at margin and flanks. Short glassy processes occurred only at the tips

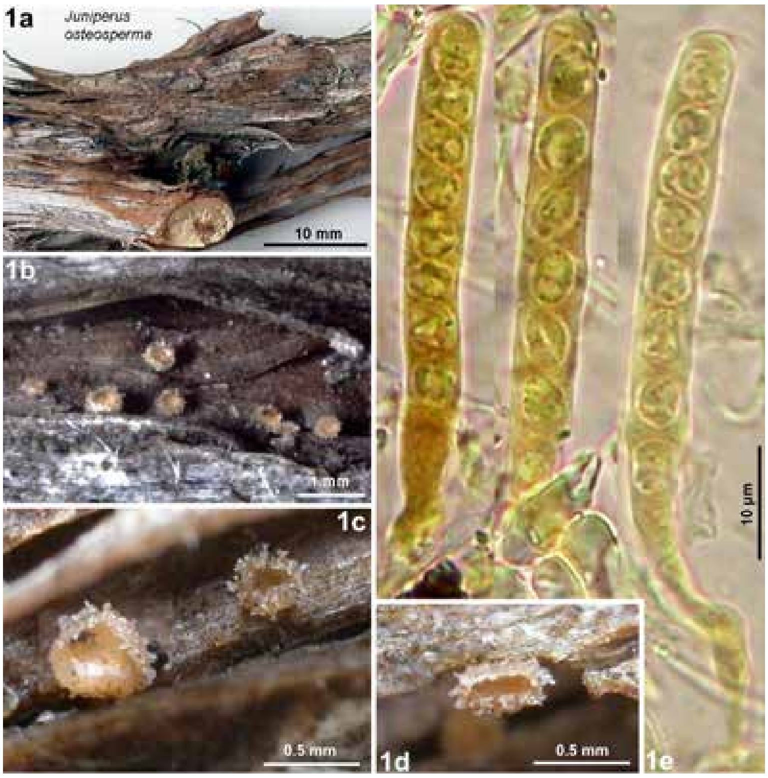

Plate 794. **1**: *Orbilia octosporoides*. – **1a**. dead corticated xeric branch of *Juniperus osteosperma*; **1b–d**. rehydrated apothecia (1b: after a few months, **1c–d**: after 10 years); **1e**. mature asci (in KOH+IKI). — **1a–e**. H.B. 5175b (holotype): USA, Utah, on *Juniperus*.

of the flank hairs. Also the presence of crystalloid SCBs is unique within this section. The large, ellipsoid-obovoid ascospores with large, globose to broadly tear-shaped spore bodies are typical of the group but resemble also spores of pezizalean taxa such as *Octospora*, with the difference that spore guttules in *Pezizales* are composed of lipid and are, therefore, KOH-resistant. We assume that *O. octosporoides* occupies a marginal position within section *Ovoideae*. A possible relationship to *O. arizonensis* (series *Hesperideae*) which has very similar spores and SBs cannot be excluded, although in that series the asci consistently have distinct apical domes.

Anamorph. Large multiseptate conidia similar to those of *O. ovoidea* and similar species were observed on the substrate near the apothecia of *O. octosporoides*.

Ecology. *O. octosporoides* was found on medium rotten bark of a xeric branch of *Juniperus osteosperma* in a cold-temperate subhumid pinyon-juniper woodland of Dixie Forest, a part of the Utah Mountains in western North America. The species is only known from the holotype which contained about 20 apothecia.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 1.5 km ESE of Cedar City, 1815 m, branch of *Juniperus osteosperma*, on bark, 24.VIII.1994, G. Marson (ex H.B. 5175b, M-0276542, **holotype**, anam. substr.).

Orbilia pisciculus Baral & G. Marson, **sp. nov.**,
MB 813938 — Pl. 795

Etymology: named after the spores resembling young fishes.

Typification: USA, Utah, Cedar City, branch of *Juniperus osteosperma*, 24.VIII.1994, G. Marson (ex H.B. 5175e, M-0276555, holotype).

Latin diagnosis: *Apothecia rehydratata 0.15–0.28 mm diam., aurantiaca, sessilia, margine laevi. Asci 8-spori, in statu emortuo modice truncati, plerumque tenuitunicati. Ascosporae *5.2–10.8 × 2.8–4 µm, fusoideo-ellipsoideae, basi cauda 2–5 × 0.9–1.7 µm partim basaliter inflata, corpusculum refringens magnum, globosum vel late lacrimiformem, ad apicem cuspide brevi affixum continentes. Paraphyses ad apicem leniter vel modice capitato-clavatae. Excipulum marginale absque processis vitreis. Habitat ad corticem putridum rami sicci* Juniperi osteospermae *in zona orotemperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.28 mm diam., 0.1–0.11 mm high, light orange(-ochraceous), round, scattered; disc flat, margin distinct, 10–15 µm protruding, smooth; broadly sessile, slightly erumpent. **Asci** *48–64 × 5.5–6.5 µm, †44–55 × 4.3–5.5(–6) µm, 8-spored, spores *2–3-seriate, (1–)2–3(–4) lower spores inverted (not mixed), pars sporifera *26 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not inflated), thin-walled, rarely with a 0.8 µm thick dome; **base** with short to long, thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(5.2–)8–10.8 × (2.8–)3–3.3(–4) µm, †6–10.8 × 2.5–3 µm, divided into a broadly ellipsoid-fusoid head and a thick, basally partly swollen tail */†2–5 × 0.9–1.2(–1.7) µm, apex rounded to obtuse, tail straight to slightly, rarely strongly curved or flexuous, exceptionally absent; **SBs** *1.3–1.6 × 1–1.5 µm, globose to broadly tear-shaped, apically narrowed to a small point, mostly with a very short filum. **Paraphyses** apically slightly to medium clavate-capitate, terminal cells †13–19 × 2–3.3 µm, lower cells †5.5–15 × 1.1–1.4 µm; unbranched at upper septum. **Medullary excipulum** hyaline, 30 µm thick, of medium dense textura intricata with many inflated cells. **Ectal excipulum** pale orange, of (†) slightly gelatinized, 25 µm thick t. angularis-prismatica from base to mid flanks, cell size not measured (but in inflated cells in medulla *5–13 × 6–8.5 µm); at flanks oriented at a 45° angle to the surface, 20 µm thick near margin, of t. prismatica-porrecta oriented at 10–40°, marginal cortical cells †10–15 × 2–3 µm, thin-walled; **glassy processes** absent. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2–0.5 µm thick. **SCBs** in paraphyses globose, (0.5–)1–1.8 µm diam. **Exudate** over paraphyses 0.1–0.3 µm thick, continuous, very finely rough, loosely attached, also 2–3 µm thick, cloddy; over margin and flanks 0.5–1.5 µm thick, continuous to cloddy. **— ANAMORPH**: unknown.

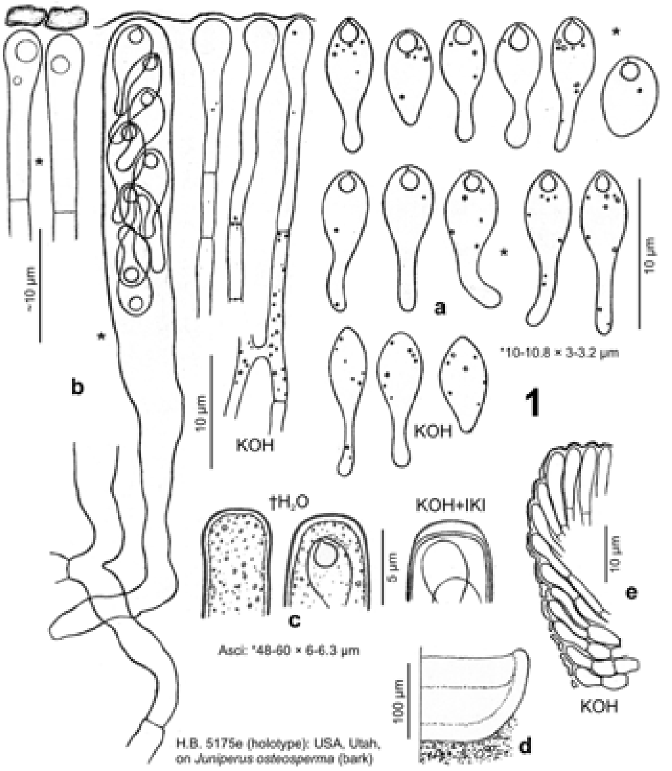

Plate 795. **1**: *Orbilia pisciculus*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Habitat: ± corticated, 10–15 mm thick branch of *Juniperus osteosperma*, on medium decayed outer surface of bark, strongly greyed, without or with a few green algae. **Associated**: *Carestiella ?schizoxyloides*, *Orbilia cucumispora*, *O. ?maeandrina*, *O. multidelphinus*, *O. multihamulata*, *O. octosporoides*, *O. ophiosoma*, *O. osteospermae*. **Desiccation tolerance**: mature asci remain viable over at least 2 months. **Altitude**: 1815 m a.s.l. **Geology**: Upper Cretaceous sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pisciculus* is easily recognized by its ascospores having a thick, partly basally swollen tail and ± globose spore bodies in their ellipsoid head. The tail was present in almost all of the spores, whereas especially inside the asci a few spores were without a tail.

The species is obviously very closely related to *O. clavipisca*, which differs in spores almost always without a tail, the spore body with a distinctly longer filum, asci mostly with an apical thickening, finally in much larger and thicker apothecia. *O. gregorii* differs from *O. pisciculus* in narrower, more fusoid spores with longer SBs and only ± tail-like bases. Likewise, the Macaronesian *O. pisciformis* (section *Aurantiorubrae*) differs in much narrower, more fusiform spores with longer, tear-shaped SBs, while the spores have similar though shorter tails.

Further sections of the genus *Orbilia* include species with a similar spore shape. *O. clavuliformis* and allied taxa (section *Hemiorbilia*) differ from *O. pisciculus* in strongly elongated SBs and thick-walled ascus apices. Species of section *Habrostictis* with tailed spores (e. g., *O. quercus-ilicis*, *O. caudimaeandrina*) have vermiform to filiform SBs. In the type of *O. caudata* (section *Aurantiorubrae*) spore shape is very similar to *O. pisciculus* but spore size much smaller, the SBs more tear-shaped, and the apothecia possibly desiccation-sensitive.

Ecology. The sparse collection of *O. pisciculus* (~6–10 apothecia) was detected on medium rotten bark of a xeric branch of *Juniperus osteosperma* lying in a dry riverbed in the

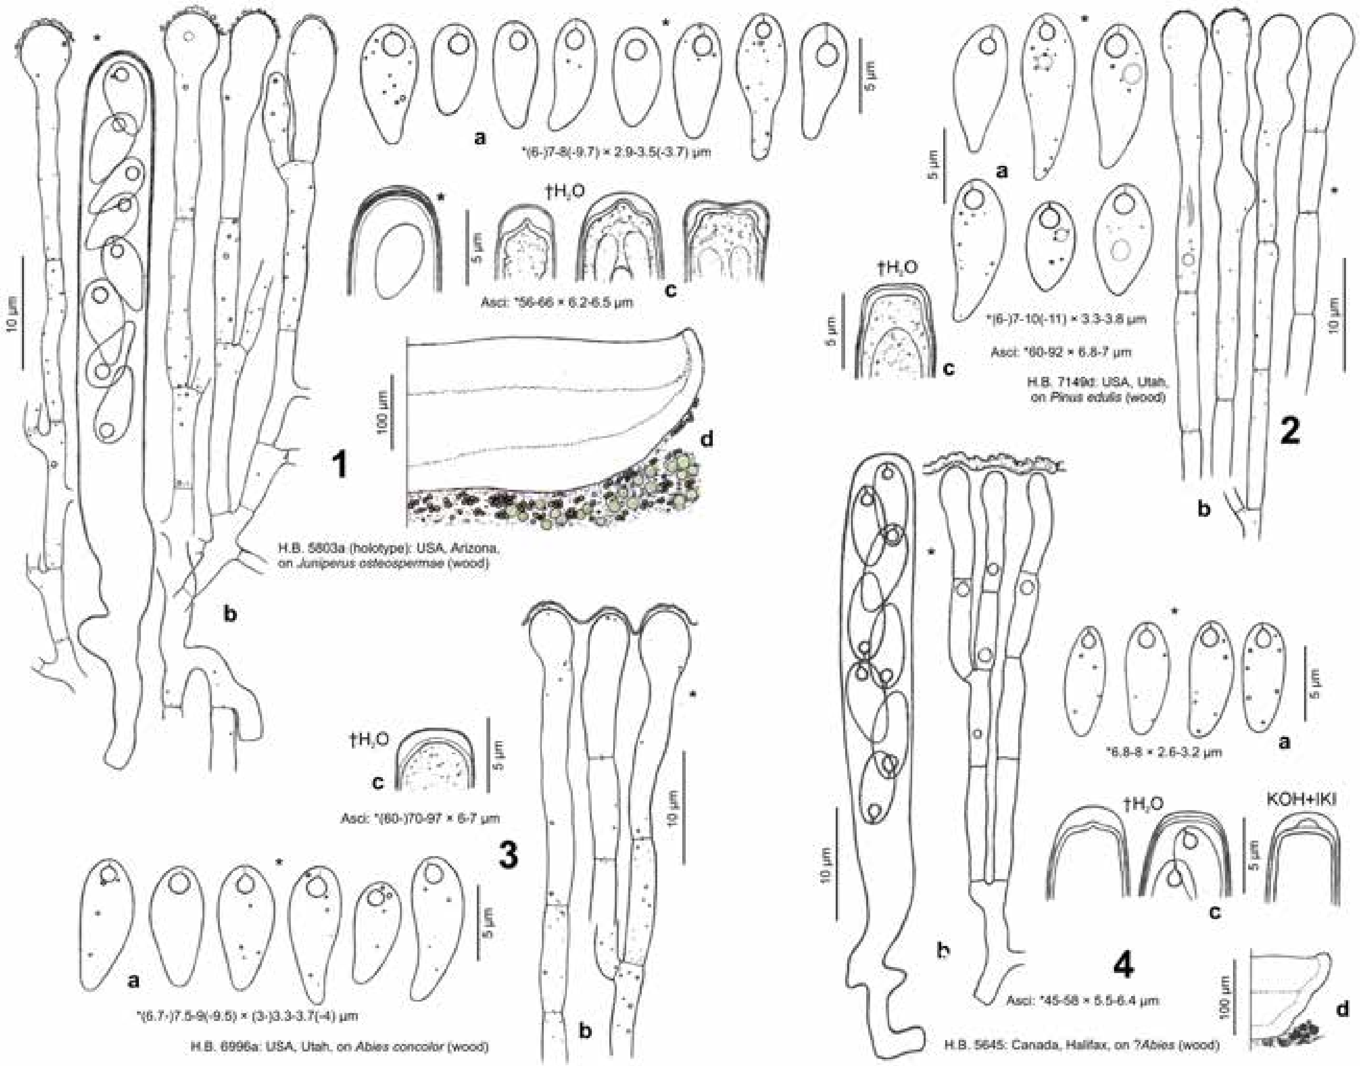

Plate 796. **1–3**: *Orbilia clavipisca*; **4**: *O.* aff. *clavipisca*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section.

cold-temperate subhumid pinyon-juniper woodland of Dixie Forest, part of the Utah Mountains in western North America. The holotype appears to be empty after the seemingly last apothecium was used up during a later reexamination.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 1.5 km ESE of Cedar City, 1815 m, branch of *Juniperus osteosperma*, on bark, 24.VIII.1994, G. Marson (ex H.B. 5175e, M-0276555, **holotype**).

Orbilia clavipisca Baral & G. Marson, **sp. nov.**, MB 813939 — Pls 796–797

Etymology: referring to the clavate, somewhat fish-like ascospores and the resemblance to *O. pisciculus*.

Typification: USA, Arizona, Flagstaff, branch of *Juniperus osteosperma*, 9.V.1995, G. Marson (ex H.B. 5803a, M-0276455, holotype).

Latin diagnosis: *Similis* Orbiliae ovoideae *sed excipulum marginale cellulis tenuitunicatis*, *multo brevioribus compositum*, *in statu vivo absque corpusculis globosis magnis*, *asci apice in statu emortuo plerumque crassitunicati, etiam tenuitunicati. Habitat ad lignum putridum ramorum siccorum arborum coniferarum in zona boreale ad temperata (sub)humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–1(–1.2) mm diam., 0.15–0.3 mm high, (light to) bright orange(-ochraceous), ± translucent or not, round to elliptical, slightly lobate when large, scattered or in small groups; disc slightly concave to flat, margin distinct, thick when young, (0–)5–20 µm protruding, smooth; broadly sessile or with a hidden stipe-like base, nearly superficial. **Asci** *55–66 {1} or 60–97 {2} × 6–7.5(–8) µm {3}, †(55–)60–80(–90) × 5–6.2(–6.5) µm {3}, 8-spored, spores subbiseriate, (1–)2–3(–5) lower spores inversely oriented {4} (never or very rarely mixed), pars sporifera *(25–)30–39(–42) µm long; **apex** (†) slightly to strongly truncate (rarely slightly indented and laterally inflated), thin-walled {1} or with †0.8–1.4 → 0.5–1 µm thick dome {3}, with or without apical chamber; **base** with short to long, thin or thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(6–)7–10(–11) × (2.9–)3.2–3.8(–4) µm {4}, ellipsoid-obovoid(-fusoid) to often ellipsoid- to obovoid-clavate, apex rounded to obtuse, base mostly medium to strongly attenuated, exceptionally tail-like, straight to slightly curved near base; **SBs** *(1.6–)1.8–2.2(–2.8) × (1–)1.2–1.4(–1.6) µm {3}, globose, apically abruptly narrowed to a fine, ± short filum. **Paraphyses** apically cylindrical or mostly slightly to medium (rarely strongly) clavate-capitate, sometimes moniliform, rarely spathulate, terminal cells *(8–)11–26(–34.5) × (2.3–)3–4.5(–5.2) µm {3}, lower cells *(6–)8–15(–18) × 1.4–2.5(–3.3) µm {3}; rarely branched near apex; hymenium subhyaline to pale rose-orange. **Medullary excipulum** subhyaline to pale rose-orange, 50–130 µm thick, of medium dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** pale rose-orange, of thin-walled († slightly gelatinized), vertically oriented t. angularis(-prismatica) from base to mid flanks or submargin, 30–70 µm thick near base, cells *(7–)10–22(–27) × (5–)6–15(–19) µm {4}; 30–70 µm thick at lower flanks, 15–30 µm at mid flanks, 15–20 µm near margin, of t. porrecta-prismatica or t. prismatica-angularis oriented at a 10–45° angle to the surface, slightly gelatinized at submargin, marginal cortical cells */†6–15 × 2–4 µm {4}, (†) ± thin-walled, **glassy processes** absent. **Anchoring hyphae** very abundant, †2–3(–3.7) µm wide, walls (0.1–)0.2–0.4(–0.6) µm thick {3}, sometimes forming a compact 10–20

Plate 797. **1**: *Orbilia clavipisca*. – **1a**. conifer forest in the Douglas fir mixed forest, young and old *Abies concolor* (also *Pinus ponderosa*, *Pseudotsuga menziesii* and *Quercus gambelii*); **1b–f**. rehydrated apothecia; **1i–j**. apothecia in median section; **1g**. id., marginal ectal excipulum; **1h**. id., basal ectal excipulum. – Living state, except for **1g** (in H_2O). — **1a–j**. H.B. 8095c: USA, Utah, on *Abies*.

µm thick gelatinized layer near base. **SCBs** in paraphyses absent, rarely a few globose, up to 1 µm diam.; in excipular cells absent. **Exudate** over paraphyses 0.2–0.8 µm thick, continuous to granular, ± firmly attached; over margin and flanks 0.2–1 µm thick, granular or cloddy. — **ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, decorticated, 10–30 mm thick branches of *Abies concolor* {2}, *Juniperus osteosperma* {1}, *Pinus edulis* {1}, on 0.2–0.5 mm deep strongly decayed, eroded wood {4}, strongly greyed, with sparse to abundant green algae. **Associated**: ?*Amandinea* sp. {1}, *Caloplaca* sp. {2}, *Hypogymnia* sp. {1}, *Lecanorales* {2}, ?*Melanelia* sp. {1}, *Melaspilea emergens* {1}, *Mellitiosporiella pulchella* {1}, *Orbilia coniferarum* {1}, *O. delphinus* {1}, *O. edulis* {1}, *O. maeandrina* {1}, *O. multitrapezoidea* {1}, *O. ophiosoma* {1}, *Ostropales* {1}, *Parmelia* sp. {1}, *Tryblidaria* ?*fenestrata* {1}. **Desiccation tolerance**: fully viable for at least 2 years, after 33 months still many excipular cells and some spores alive. **Altitude**: 1965–2778 m a.s.l. **Geology**: Cambrian-Ordovician, Permian and Cretaceous to Miocene carbonate sandstone; lava flow of rhyolite and andesite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia clavipisca* is very similar to the European *O. ovoidea*, from which it differs in thin-walled, much shorter marginal cortical cells, the absence of large globose SCBs, and (regarding three of the four included specimens) in consistently thick-walled ascus apices. The Australian *O. gregorii* differs in narrower spores, shorter terminal cells of paraphyses which regularly contain globose SCBs, and in the absence of apical domes. For the similar North American *O. pisciculus* and Australian *O. eremaeae* see above and below.

O. ponderosae differs in 16-spored asci and rarely tapered spore bases. In the shape of its spores and SBs *O. clavipisca* shows also similarities to the 64-spored *O. myriosphaera* of section *Lentiformes*. Even the hyphoid marginal cortical cells of *O. myriosphaera* which are thick-walled in the dead state resemble those of typical representatives of section *Ovoideae*.

Variation. *O. clavipisca* varies among the collections in the thickness of the apical dome. In the collection on *Pinus* (Pl. 796: 2) the asci were without a distinctly thickened apical wall, whereas in the holotype the apical domes were thickest.

Not included collection. A sample from Canada (Pl. 796: 4) deviates in narrower spores with smaller SBs, smaller asci, and much smaller apothecia (0.15–0.22 mm), besides apically hardly inflated paraphyses that contain globose SCBs.

Ecology. *O. clavipisca* was found on rotten wood of xeric branches of different gymnosperm trees and shrubs in cold-temperate to boreal humid ponderosa pine and Douglas fir mixed forests or once subhumid pinyon-juniper woodland in the Colorado Plateau (Utah Mountains, Canyonlands section, Mogollon Rim) in the southwest of Northern America. The not included Canadian collection was from the cold-temperate humid Atlantic Coast of northeastern North America.

Specimens included. **USA**: **Utah**, Utah Mts., Bryce Canyon, 32 km SE of Panguitch, 13 km WSW of Tropic, near Trough Spring, 2500 m, branch of *Abies concolor*, on wood, 13.VI.2003, G. Marson (H.B. 8095c). – 42 km SSE of Panguitch, Rainbow Point, 2778 m, branch of *A. concolor*, on wood, 20.VI.2000, G. Marson (H.B. 6996a). – Canyonlands, 16 km NNW of Mexican Hat, 1 km N of Mokee Dugway, Cedar Mesa, 1965 m, branch of *Pinus edulis*, on wood, 14.VI.2000, G. Marson (H.B. 7149d). – **Arizona**, Mogollon Rim, 9 km NW of Flagstaff, 9 km SSW of Humphreys Peak, Rte. 180, 2250 m, branch of *Juniperus osteosperma*, on wood, 9.V.1995, G. Marson (ex H.B. 5803a, M-0276455, **holotype**).

Not included. **CANADA**: **Nova Scotia**, 81 km ENE of Halifax, Taylor Head, Provincial Park, ~20 m, twig of ?*Abies*, on wood, X.1996, C. Peller (H.B. 5645).

Orbilia eremaeae Baral, **sp. nov.**, MB 813940
— Pls 798–799

Etymology: named after the host genus, *Eremaea* (*Myrtaceae*).
Typification: Western Australia, Cowalla, branch of *Eremaea pauciflora*, 23.X.2007, G. Marson (ex H.B. 8775b, MEL 2389259B, holotype).

Latin diagnosis: *Similis* Orbiliae clavipiscae *sed apothecia minora, ascosporae cylindricae ad ellipsoideae, basi non vel leniter attenuatae, paraphyses apice haud inflatae. Habitat ad corticem putridum ramuli sicci* Eremaeae pauciflorae *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.27 mm diam., 0.1–0.17 mm high, light orange, slightly translucent, round, scattered; disc flat, margin distinct, 5–10 µm protruding, smooth; sessile on a narrowed base, ± immersed in biofilm. **Asci** *48–60 × 7–7.3 µm, †43–52 × 6–6.3 µm, 8-spored, spores */†1–2-seriate, 3–5 lower spores inverted (often mixed, laterally sometimes oriented); **apex** (†) (very) slightly truncate, dome †1–1.2 → 0.8–1 µm thick, without or with shallow apical chamber; **base** with short to long, ± thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(6–)6.5–8.5(–10.5) × 3.2–4(–4.3) µm, cylindric-ellipsoid to broadly-ellipsoid, apex rounded, base sometimes slightly attenuated, straight to distinctly inequilateral; **SBs** *1.8–2.2(–2.5) × 1.2–1.6 µm, ± globose to broadly tear-shaped, apically partly narrowed to a short filum. **Paraphyses** apically uninflated to sometimes slightly clavate, terminal cells *7–20 × 2.3–3 µm, lower cells *(6.5–)8–11.5 × 1.7–2.6 µm; never branched at upper septum. **Medullary excipulum** pale orange, 30–80 µm thick, of dense textura intricata with many inflated cells, not sharply delimited. **Ectal excipulum** very pale orange, of (†) ± thin-walled, indistinctly oriented t. angularis from base to mid flanks, 20 µm thick near base, cells *8–13 × 6–10 µm; 15–20 µm thick near margin, of t. prismatica-porrecta oriented at a 0–20(–50)° angle to the surface, marginal cortical cells *6–13 × 2.5–3.5 µm, (†) thin-walled; **glassy processes** absent. **Anchoring hyphae** sparse to medium abundant, */†2–2.8 µm wide, walls 0.2–0.4(–0.6) µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2 µm diam. **Exudate** over paraphyses 0.3–1.5 µm thick, cloddy-continuous, hyaline, ± loosely attached, over margin and flanks 1.5–3 µm thick, rough-cloddy. **— ANAMORPH**: unknown.

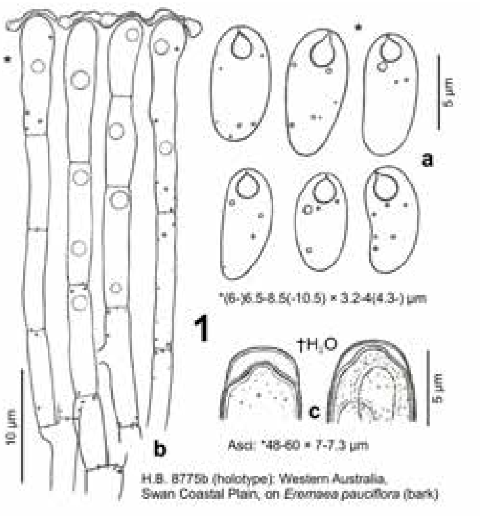

Plate 798. **1**: *Orbilia eremaeae*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices.

Habitat: collected 0–50 cm above the ground, corticated, 8 mm thick branch of *Eremaea pauciflora*, on strongly decayed bark (periderm), strongly greyed, green algae sparse. **Associated**: *Durella* aff. *connivens*, ?*Eutypa* sp., *Gloniopsis praelonga*, *Orbilia austrocylindrica*, *O. multicurvula*, *O. pleistovitalbae*, *Proliferodiscus olivaceoviridis*, *Rhizodiscina lignyota*. **Desiccation tolerance**: fully viable for at least 4 months. **Altitude**: 77 m a.s.l. **Geology**: Cretaceous sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia eremaeae* resembles the conifericolous North American *O. clavipisca* in many respects, but differs in smaller apothecia, cylindric-ellipsoid ascospores with not or only slightly attenuated bases, spore bodies with a very short filum or a small triangular connecting part, apically

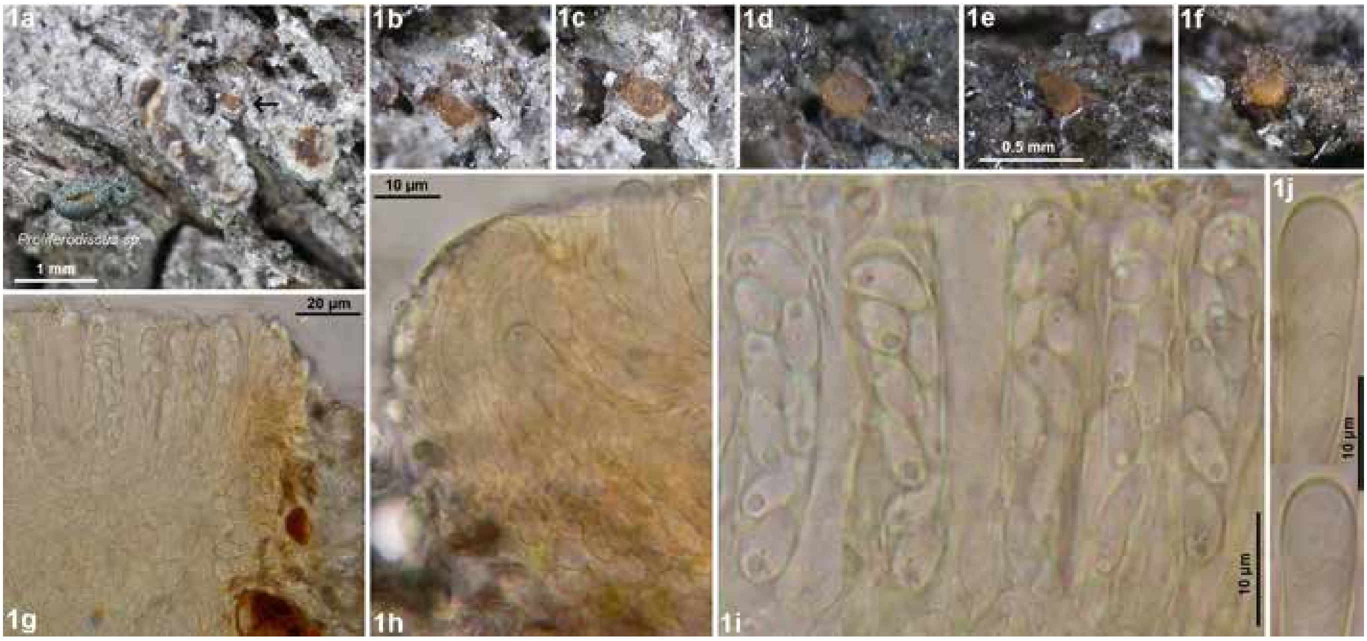

Plate 799. **1**: *Orbilia eremaeae*. – **1a–f**. rehydrated apothecia (**1a** with *Proliferodiscus olivaceoviridis*); **1g**. apothecium in median section; **1h**. id., marginal ectal excipulum; **1i**. mature asci with ascospores; **1j**. apices of submature asci. – Living state, except for marginal cells in **1g** and asci in **1i**. — **1a–j**. H.B. 8775b (holotype): Western Australia, Moora, on *Eremaea*.

not or only slightly inflated paraphyses, the abundant presence of medium-sized globose SCBs, and the occurrence on angiosperm bark in Australia.

Not included collections. A specimen with very similar spores grew on a branch of *Carya* in Massachusetts (USA) and was only seen from a microphoto made by B. Liu (IVV: ~VIII.2011). With its small, presumably orange apothecia (0.1–0.3 mm diam) it would fit *O. eremaeae*, but the spores are broader and more ellipsoid-ovoid (*~7–8.5 × 4–4.5 µm), also the SBs are broader (~2.3–2.6 × 1.6–1.8 µm). In a similar sample on bark of *Arbutus* in British Columbia (O. & A. Ceska, IVV: 30.IV.2017) the orange apothecia measure up to 0.53 mm diam. and have whitish marginal teeth composed of glassy processes. In the spores (*7–8 × 4–5 µm) and SBs (~2.5 × 1.5 µm) this would quite perfectly fit the sample on *Carya*.

Ecology. *O. eremaeae* was found on decayed bark of a xeric branch of *Eremaea pauciflora* in a subtropical semihumid banksia-eucalypt-acacia open wood- and shrubland in southwestern Australia. The not included North American collections were on *Carya* in a cold-temperate humid deciduous forest on granite in the Northeastern Coastal Forests, and on *Arbutus* in a mild-maritime humid mixed evergreen forest in the Pacific west (southern end of Coast Mountains).

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 59 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Rd, 77 m, branch of *Eremaea pauciflora*, on bark, 23.X.2007, G. Marson (ex H.B. 8775b, MEL 2389259B, **holotype**).

Not included. **CANADA**: **British Columbia**, 11 km NNW of Victoria, Observatory Hill, 140 m SE of planetarium, 195 m, branch of *Arbutus menziesii*, on bark 30.IV.2017, O. & A. Ceska (O.C. 2170430, doc. vid.). — **USA**: **Massachusetts**, ~4 km S of Concord, ~4 km W of Lincoln, Mt. Misery, ~40 m, branch of *Carya*, on ?wood, ?VIII.2011, B. Liu (B.L., doc. vid.).

Orbilia ponderosae Baral & G. Marson, **sp. nov.**, MB 813941 — Pls 800–801

Etymology: named after the substrate of the type, *Pinus ponderosa*.

Typification: USA, Arizona, Flagstaff, branches of *Pinus ponderosa*, 12.VI.2000, G. Marson (ex H.B. 6997a, M-0276568, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–0.33 mm diam., aurantiaca, subsessilia, margine laevi. Asci 16-spori, in statu emortuo modice truncati, tenuitunicati. Ascosporae *5–8.7 × 2.8–3.6 µm, subcylindrico-ellipsoideae, corpusculum refringens magnum, globosum, ad apicem cuspide interdum incrassata affixum continentes. Paraphyses ad apicem non vel modice capitato-clavatae, exsudato valido tectae. Excipulum marginale textura porrecta sub angulo acuto orientata, absque processis vitreis. Habitat ad corticem putridum ramorum siccorum* Pini ponderosae *in zona orotemperata humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.33 mm diam., 0.16 mm high, light orange, round, (very) scattered; disc slightly to medium concave, margin thin, scarcely protruding, smooth; subsessile, superficial; dry deep orange(-apricot). **Asci** *60–89 × (6.7–)7.3–8(–9) µm, †56–85 × 6.4–7.7 µm, 16-spored, spores 2–4-seriate, lower 7–13 spores inversely oriented (strongly mixed), pars sporifera *45–58 µm long; **apex** (†) medium truncate (laterally not or slightly inflated), thin-walled, rarely young with 1.2 µm thick apical dome; **base** with short to medium long, thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(5–)6.5–8(–8.7) × (2.8–)3–3.4(–3.6) µm, subcylindric-ellipsoid(-clavate), ends rounded, base rarely slightly to medium attenuated, straight to slightly inequilateral; **SBs** *(1.5–)1.8–2 × (1–)1.2–1.4 µm, globose to broadly tear-shaped (to ampulliform), apically narrowed to a ± small point, with a very short

H.B. 6997a (holotype): USA, Arizona, on *Pinus*.

thick or sometimes thin, cylindrical or tapering connecting part. **Paraphyses** apically uninflated or slightly to medium (rarely strongly) clavate-capitate, sometimes slightly (obtusely) lanceolate, terminal cells *(10–)13–19(–22) × (1.6–)2–3.7(–4.3) µm, lower cells *8–16 × 1.5–2.5(–3.5) µm, finally sometimes branched near apex; hymenium very pale rose. **Medullary excipulum** 60 µm thick, of medium loose textura intricata with a few inflated cells, medium sharply delimited from ectal excipulum, at flanks forming a t. porrecta. **Ectal excipulum** pale rose, of thin-walled, irregularly oriented t. angularis from base to lower flanks, 20–25 µm thick near base, cells *6–13 × 4–10 µm; 15–20 µm thick from lower flanks up to margin, at mid flanks and margin (upper 100 µm) of t. porrecta, oriented at a 10–30° angle to the surface, cells *(2–)7–13 × 2–3(–4) µm, (*) thin-walled, marginal cortical cells *10–23 × 2.5–3 µm, **glassy processes** absent. **Anchoring hyphae** abundant, †2–3(–4) µm wide, walls 0.2–1.2 µm thick. **SCBs** in paraphyses globose, 1–2.7 µm diam.; in excipular cells absent. **Exudate** over paraphyses 0.3–2 µm thick, continuous to cloddy, hyaline, loosely attached; over margin and mid flanks continuous, ± rough, 0.5–2 µm thick, at lower flanks forming ~5 µm thick large clods. **— ANAMORPH**: unknown.

Habitat: collected 1.5–3 m above the ground, partially decorticated, 14–19 mm thick branches of *Pinus ponderosa*, on medium decayed, small, ± detaching squamules of the outer bark (periderm and bast, on surface, edges and lower side), greyed, many green algae. **Associated**: ?*Stictis* sp., crustose and foliose lichens. **Desiccation tolerance**: fully viable for at least 13 months. **Altitude**: 2250 m a.s.l. **Geology**: Triassic-Jurassic sedimentary rock; lava flows of rhyolite and andesite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia ponderosae* appears to be closely related to *O. eremaeae*, from which it differs in 16-spored asci, and predominantly absent ascus apical thickenings. For the similar *O. stansburyanae* and *O. sarcobati* see p. 1272 and p. 1287. *O. ponderosae* also resembles *O. canadensis*, from which it differs in larger, more elongate spores and a thin-walled textura porrecta at margin and mid flanks.

Not included collection. A collection on *Cercocarpus* (Pl. 800: 2) differs in larger apothecia, longer, perhaps also wider spores with partly obtuse apices and apparently larger SBs, and paraphyses with somewhat shorter and thicker terminal cells. Regrettably, the marginal excipulum was not studied, therefore, a possibly close relationship to *O. stansburyanae* cannot be excluded.

Ecology. *O. ponderosae* was found on medium rotten bark of xeric branches of *Pinus ponderosa* in a cold-temperate humid ponderosa pine forest of the Mogollon Rim in the southwest of Northern America. The not included collection on *Cercocarpus* was in a cold-temperate subhumid pinyon-juniper woodland at the eastern end of the Uinta Basin.

Specimens included. **USA**: **Arizona**, Mogollon Rim, 9 km NW of Flagstaff, San Francisco Peaks, 9 km SSW of Humphreys Peak, Rte. 180, 2250 m, branches of *Pinus ponderosa*, on bark, 12.VI.2000, G. Marson (M-0276568, **holotype**; **isotype** in H.B. 6997a).

Not included. **USA**: **Colorado**, Uinta Basin, 50 km ESE of Vernal, 6 km NE of Dinosaur, 2100 m, on *Cercocarpus intricatus*, 12.VI.1996, G. Marson (ø).

Orbilia sarcobati Baral & G. Marson, **sp. nov.**, MB 813942 — Pls 802–803

Etymology: referring to the substrate, *Sarcobatus vermiculatus*.

Typification: USA, Utah, Blanding, branches of *Sarcobatus vermiculatus*, 14.V.1995, G. Marson (ex H.B. 5400a, M-0276582, holotype).

Latin diagnosis: *Similis* Orbiliae ponderosae *sed excipulum marginale textura globulosa-prismatica, cellulis multo brevioribus compositum, cellulae terminales paraphysium breviores et magis inflatae, corpuscula refringentia ascosporarum leniter angustiora, partim ampulliformia. Habitat ad corticem vel lignum leniter putridum ramorum siccorum* Sarcobati vermiculati *in zona temperata semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.25(–0.3) mm diam., 0.09–0.125 mm high, pale to light (yellowish-) orange(-rose), round, very scattered to medium gregarious; disc flat to slightly convex, margin thin, 0–5 µm protruding, smooth; sessile or with ill-defined hidden stipe 0.02 × 0.03 mm, superficial or somewhat erumpent between fibres. **Asci** *50–65 × (8–)8.5–9.5(–10.5) µm {3}, †39–58 × 6.7–8.5 µm {2}, 16-spored, spores ± biseriate, ~7–10 lower spores inversely oriented {2} (rather mixed, especially in upper part,

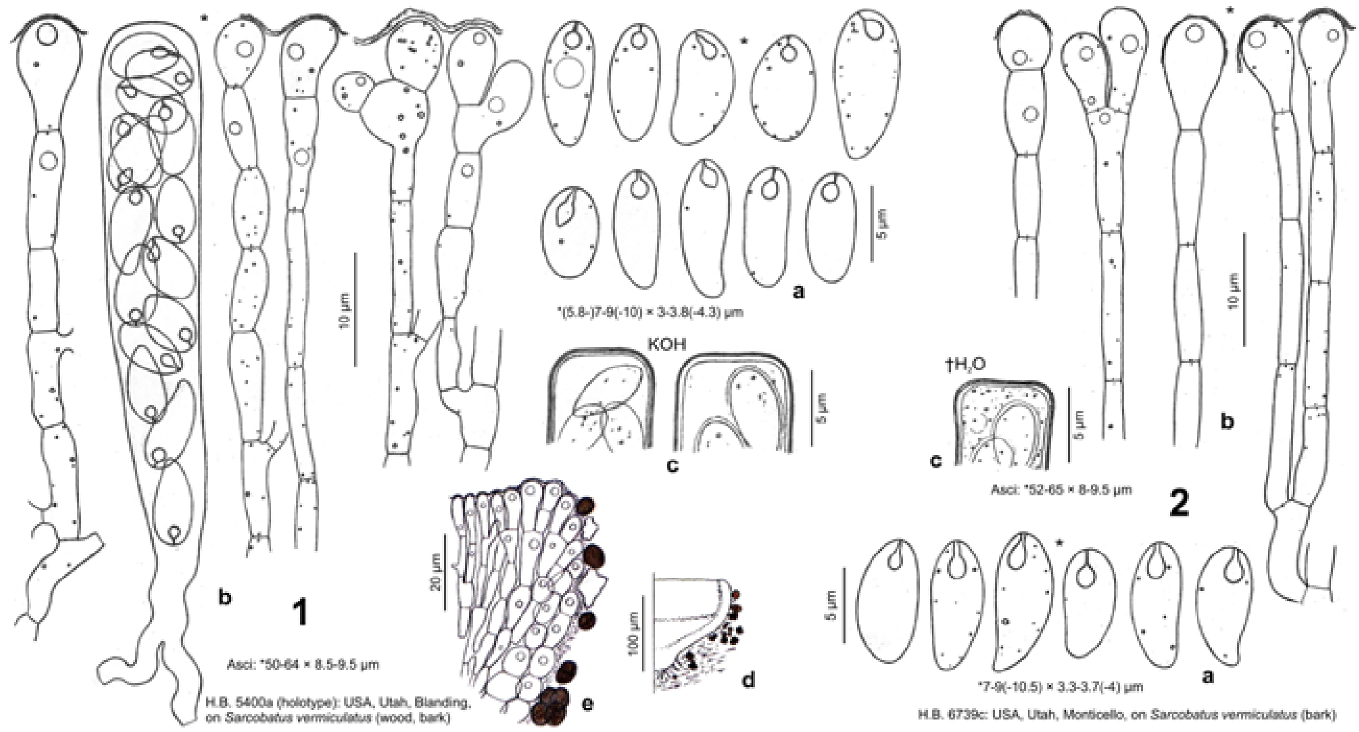

Plate 802. **1–2**: *Orbilia sarcobati*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum (with dark brown cells of black yeasts).

here partly laterally oriented), pars sporifera *33–47 µm long, †45–50 µm; **apex** (†) medium to strongly truncate (scarcely indented, laterally sometimes inflated), thin-walled; **base** with short, thick, flexuous stalk, L-, T-, h-, sometimes H-shaped. **Ascospores** *(5.8–)7–10(–11) × (2.8–)3–3.8(–4.3) µm {3}, †6.2–9 × 3.3–3.8 µm {1}, subcylindric-ellipsoid, sometimes obovoid-clavate, apex rounded, base often slightly (rarely strongly) tapered, straight to slightly curved near base; **SBs** *(1.3–)1.7–2.5 × (0.7–)0.9–1.2(–1.4) µm {3}, (sub)globose to tear- or pear-shaped, more rarely ampulliform, apically narrowed to a small, more rarely wide point, often with a short filum. **Paraphyses** apically slightly or mostly medium to strongly capitate-clavate, sometimes moniliform, terminal cells *(3–)5–14(–17) × 3–5.7 µm {3}, †3–5 µm wide, lower cells *(4.5–)7–14 × 1.8–3(–3.7) µm {2}; sometimes branched near apex. **Medullary excipulum** hyaline, 15–25 µm thick, of medium dense textura intricata with a few inflated cells, indistinctly or sharply delimited. **Ectal excipulum** very pale reddish, of thin-walled, ± horizontally oriented t. globulosa-angularis from base to mid flanks, 12–20 µm thick near base, cells *5–11 × 5–10 µm {2}; 12–15 µm thick at mid flanks and margin, of t. globulosa-prismatica oriented at a 10–40° angle, marginal cortical cells *5–14 × 3.7–6 µm {2}, **glassy processes** absent. **Anchoring hyphae** very sparse, 3–4 µm wide, walls 0.3–0.4 µm thick {1}. **SCBs** globose {3}, in paraphyses 0.8–2 µm diam., in ectal excipulum 1.4–2.2 µm. **Exudate** over paraphyses 0.2–0.5(–1) µm thick, continuous, loosely attached; over margin and flanks granular. **— ANAMORPH**: unknown.

Habitat: collected 0.05–0.1 m above the ground, ± corticated, 6–18 mm thick branches of *Sarcobatus vermiculatus* {3}, on slightly to medium decayed wood {1} or bark (periderm) {3}, slightly to medium greyed, sometimes in old wound, green algae present or absent. **Associated**: *Orbilia bicknellensis* {1}, *O. vermiculati* {2}, *Schizoxylon* ?*argentinum* {1}, *Teichospora* sp. {1}, *T. obducens* {1}, *Xanthoria* sp. {2}, various crustose lichens. **Desiccation tolerance**: fully viable for at least 8 months, some mature asci still alive after 26 months. **Altitude**: 1602–1905 m a.s.l. **Geology**: Triassic to Cretaceous red sand- & mudstone. **Phenology**: long-lived.

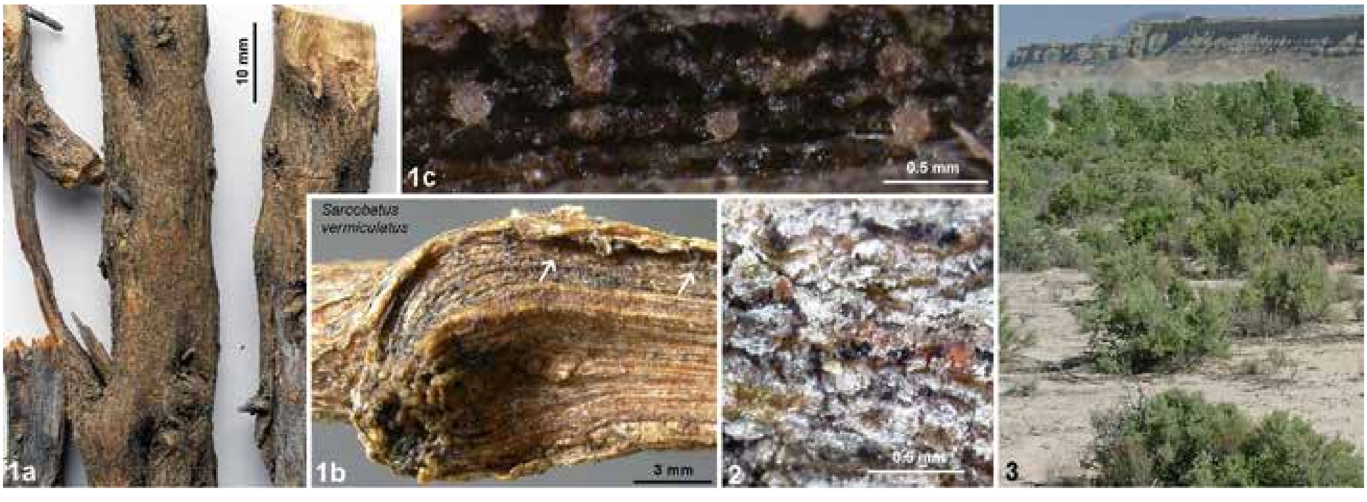

Plate 803. **1–3**: *Orbilia sarcobati*. – **3**. River plain with semiarid shrubland of *Sarcobatus vermiculatus*; **1a–b**. dead, undecayed, corticated xeric branches of *S. vermiculatus*; **1c**, **2**. rehydrated apothecia (**1c**: after 11 years, **2**: after 4.5 years). — **1a–c**. H.B. 5400a (holotype): USA, Utah, Blanding, on *Sarcobatus*; **2**. H.B. 6739c: ibid., Monticello, on *Sarcobatus*; **3**. 7 km W of Hanksville (phot. 10.VI.2003), showing a habitat similar as around Blanding.

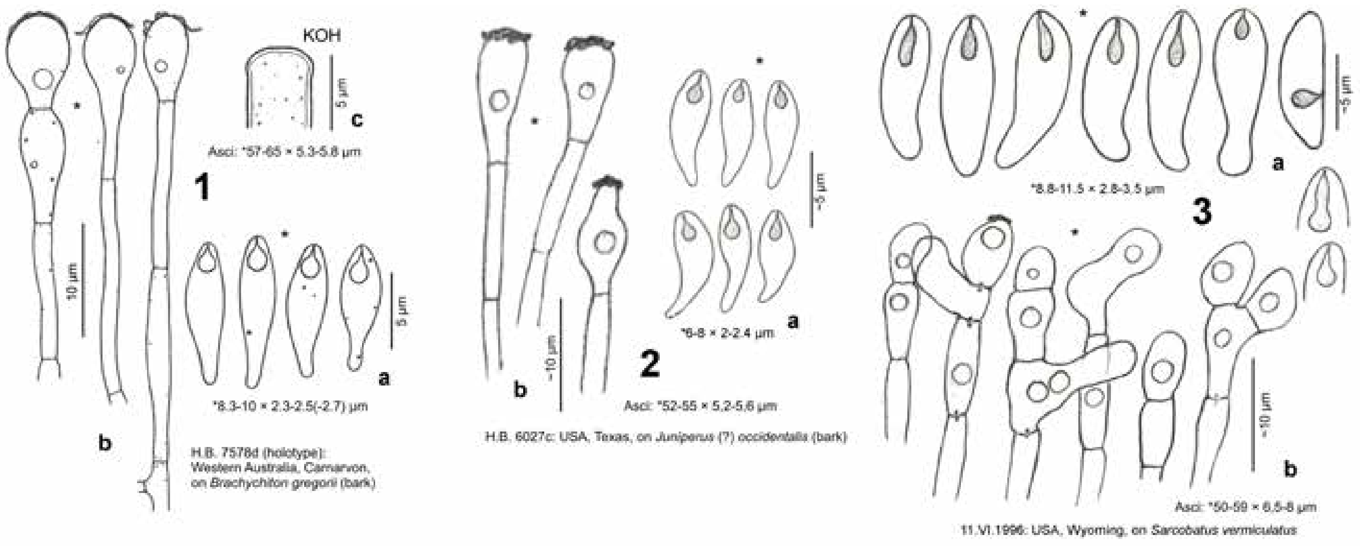

Plate 804. **1**: *Orbilia gregorii*; **2–3**: *O.* aff. *gregorii*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

Taxonomic remarks. *Orbilia sarcobati* is characterized by 16-spored asci with ± ellipsoid ascospores containing rather large, globose to tear-shaped SBs, paraphyses with short, distinctly capitate-clavate terminal cells, minute apothecia, and in a seeming restriction to *Sarcobatus*. A collection on the same host mentioned under *O. gregorii* (Pl. 804: 3) differs in 8-spored, narrower asci and slightly longer spores with more elongate SBs. Also *O. vermiculati* (section *Habrostictis*) appears to prefer the same host and has partly similar ascospores (particularly H.B. 7163a), but differs in much longer SBs and longer, basally more attenuated spores. In overmature spores, however, the SBs get tear-shaped, very similar as in *O. sarcobati*. *O. ponderosae* (on bark of *Pinus*) differs in a marginal ectal excipulum of t. porrecta, longer terminal cells of paraphyses being rarely inflated at the apex, and somewhat narrower, partly ampulliform SBs.

Ecology. *O. sarcobati* grows on ± undecayed bark (rarely wood) of xeric branches of *Sarcobatus vermiculatus* (greasewood), to which it might be restricted. It is so far only known from cold-temperate to warm-continental semiarid saltbush desert scrubs at the base of the Abajo Mountains in the Canyonlands section of the Colorado Plateau in the southwest of Northern America.

Specimens included. **USA**: **Utah**, Canyonlands, 45 km NNE of Blanding, 16 km N of Monticello, Peters Canyon, 1905 m, branch of *Sarcobatus vermiculatus*, on bark, 15.VI.2000, G. Marson (H.B. 6739c). – ~16 km WNW of Blanding, ~1795 m, branches of *S. vermiculatus*, on wood & bark, 14.V.1995, G. Marson (M-0276582, **holotype**; **isotype** in H.B. 5400a). – 15 km WSW of Blanding, Cottonwood Road, Brushy Basin Wash, 1602 m, branch of *S. vermiculatus*, on bark, 15.VI.2000, G. Marson (ø).

Orbilia gregorii Baral, **sp**. **nov**.,
MB 813943 — Pls 804–805

Etymology: after the substrate, *Brachychiton gregorii*.

Typification: Western Australia, Peron Peninsula, branch of *Brachychiton gregorii*, 8.XII.2001, G. Marson (ex H.B. 7578d, MEL 2389238, holotype).

Latin diagnosis: *Similis* Orbiliae sarcobati *sed ascosporae angustiores, fusiformes, asci octospori, excipulum ectale multo crassius. Habitat ad corticem rami sicci* Brachychitonis gregorii *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4 mm diam., 0.2 mm high, light orange; margin finely rough; superficial. **Asci** *57–65 × 5.3–5.8 µm, 8-spored, spores *biseriate, 2–6 lower spores inverted (not mixed), pars sporifera *27–34 µm long; **apex** (†) slightly to medium truncate (laterally not or only very slightly inflated), hemispherical in side view, thin-walled; **base** with short to medium long, thin or thick, slightly flexuous stalk. **Ascospores** *8.3–10 × 2.3–2.5(–2.7) µm, fusiform to fusiform-clavate, apex rounded to obtuse, base tail-like or with a short tail 1.3–1.7 × 0.8–1 µm, straight to slightly inequilateral; **SBs** *2–2.5 × 1–1.3 µm, tear-shaped, apically narrowed, ending in a very short filum. **Paraphyses** apically medium to (very) strongly capitate to broadly ellipsoid, terminal cells *6–16.5 × 3.5–5.5 µm, lower cells *10–19 × 1.5–2 µm (below terminal cells also up tp 4 µm wide); unbranched at upper septum. **Medullary excipulum** 20–30 µm thick, of ± dense textura globulosa-intricata, sharply delimited only towards margin. **Ectal excipulum** of (*) ± firm-walled t. globulosa from base to margin, 100 µm thick near base, cells *9–14 × 6.5–10 µm; 25 µm thick near margin, of t. angularis oriented at a 45° angle to the surface, marginal cortical cells elongate, †7–10 × 3–4 µm; **glassy processes** absent. **Anchoring hyphae** medium abundant, †2–3 µm wide, walls 0.2–0.3(–0.4) µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, (0.6–)1–1.8 µm diam. **Exudate** over

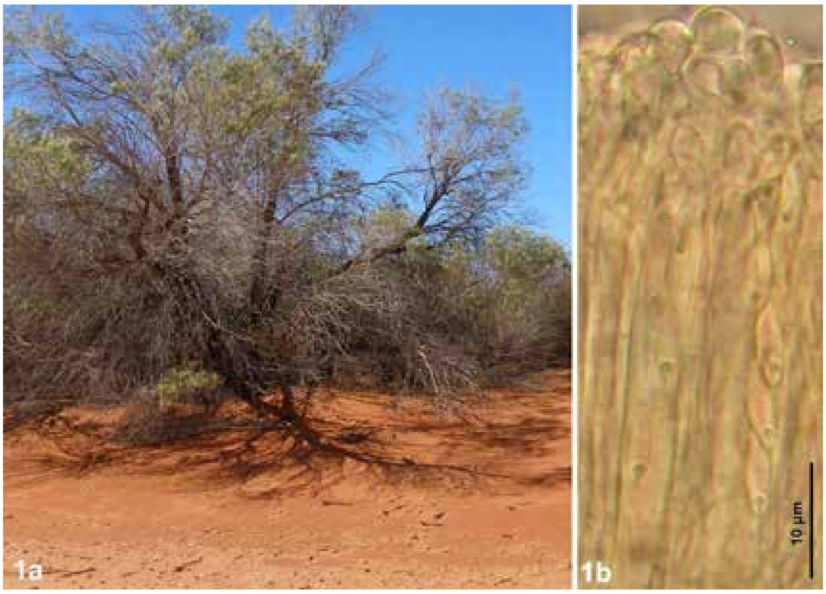

Plate 805. **1**: *Orbilia gregorii*. – **1a**. arid acacia shrubland with *Pittosporum phillyreoides* (*Brachychiton* also occurs here); **1b**. asci with spores, paraphyses. – Living state, except for ascus on the right. — **1**. H.B. 7578d (holotype): Western Australia, Carnarvon, on *Brachychiton*.

paraphyses and margin 0.3–1 µm thick, granular, firmly attached. — **ANAMORPH**: unknown.

Habitat: collected 2.5 m above the ground, corticated, 10–12 mm thick branch of *Brachychiton gregorii*, on medium decayed bark (periderm and bast). **Associated**: *Hysterographium fraxini*, *Orbilia brachychitonis*, *O.* ?*multigambelii*, *Patellaria* ?*andina*. **Desiccation tolerance**: fully viable after 33 months. **Altitude**: 41 m a.s.l. **Geology**: Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia gregorii* resembles *O. sarcobati* in the short terminal cells of paraphyses, but differs in narrower, fusiform ascospores with short and thick tails, and in 8-spored asci, also in larger apothecia with a much thicker ectal excipulum. *O. pilifera* (section *Aurantiorubrae*) resembles *O. gregorii* in the spores, but differs in much larger, ochraceous, hairy apothecia and lageniform to mammiform paraphyses.

Not included collections. Two North American samples (Pl. 804: 2–3) differ from *O. gregorii* in the spores: the one on *Juniperus* has shorter spores and that on *Sarcobatus* wider spores with much wider tail-like bases. In both samples the asci are thin-walled and truncate at the apex. The sample on *Sarcobatus* could be closely related to 16-spored *O. sarcobati*.

Ecology. *O. gregorii* was collected on medium rotten bark of a xeric branch of *Brachychiton* in a subtropical semiarid acacia shrubland in western Australia. The sparse holotype originally consisted of only two apothecia which were used up during examination. The two not included North American collections were from a cold-temperate subhumid saltbush desert scrub adjacent to a ponderosa pine forest in the Wyoming Basin (*Sarcobatus*), and a warm-temperate subhumid *Quercus virginia* forest on Cretaceous limestone in the Edwards Plateau in southern USA (*Juniperus*).

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 165 km SSE of Carnarvon, Peron Peninsula, 24 km SE of Shell Beach, Denham-Hamelin Rd, 41 m, branch of *Brachychiton gregorii*, on bark, 8.XII.2001, G. Marson (ex H.B. 7578d, MEL 2389238, **holotype**).

Not included. **USA**: **Texas**, Oaks and Prairies, Edwards Plateau, 65 km W of Austin, ~2 km WSW of Johnson City, 380 m, branch of *Juniperus* (?) *occidentalis*, on bark, 18.VI.1996, G. Marson (H.B. 6027c ø). – **Utah**, Wyoming Basin (adjacent to Uinta Mts.), ~2.5 km SW of Dutch John, Rte. 191 S, ~1900 m, on *Sarcobatus vermiculatus*, 11.VI.1996, G. Marson (ø).

Orbilia olivacea Baral & G. Marson, **sp. nov.**, MB 813944 — Pls 806–807

Etymology: named according to the dark olivaceous colour of the apothecial exudate.

Typification: France, Firminy, branch of *Pinus*, 21.IX.1990, G. Marson (ex H.B. 4232, M-0276543, holotype).

Latin diagnosis: *Apothecia rehydratata 0.15–0.35 mm diam., atro-olivacea, substipitata, margine laevi. Asci 8-spori, apice in statu emortuo hemisphaerici, tenuitunicati. Ascosporae *5–8.5 × 2.3–3.2 µm, subcylindrico-ellipsoideae, corpusculum refringens ellipsoideo-ovoideum, ad apicem indistincte affixum continentes. Paraphyses ad apicem non vel leniter inflatae. Excipulum marginale textura prismatica-angulari, absque processis vitreis, exsudato valido atroolivaceo tectum. Habitat ad corticem leniter putridum ramorum siccorum* Pini *in zona temperata ad orosubmediterranea humida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.35 mm diam., 0.13–0.2 mm high (receptacle 0.07 mm), blackish-blue-green to blackish-olivaceous, round, scattered; disc flat, margin thin, not protruding, smooth; often distinctly stipitate, with a cylindrical to obconical stipe up to 0.1 × 0.1–0.14 mm, superficial; dry black. **Asci** *43–62 × 5.8–7 µm {3}, †41–55(–65) × 5.2–6 µm {2}, (6–)8-spored, spores 2–3-seriate, upper (2–)3–5 spores inversely oriented {3} (sometimes mixed, rarely some asci with inverted lower spores and upper spores not inverted {1}), pars sporifera *20–29 µm long; **apex** (†) hemispherical to very slightly truncate, thin-walled (†0.2–0.25 µm); **base** with short, thick, flexuous stalk, h-shaped. **Ascospores** *(5–)5.5–7.5(–8.5) × 2.3–2.8(–3.2) µm {3}, †5–7 × 2.2–2.6 µm {2}, subcylindric to ellipsoid, also fusoid or obovoid-clavate, apex rounded to obtuse, base sometimes ± attenuated, straight or slightly inequilateral; **SBs** *1.1–1.8 × 0.8–1.2 µm {3}, (subcylindric-)ellipsoid-ovoid(-subglobose), either closely attached or a short distance below apex (invisibly connected). **Paraphyses** apically uninflated to very slightly clavate or sublageniform, sometimes flexuous, terminal cells *8–19(–28) × 2–2.5(–3) µm {3}, †1.8–2.3(–3) µm wide, lower cells

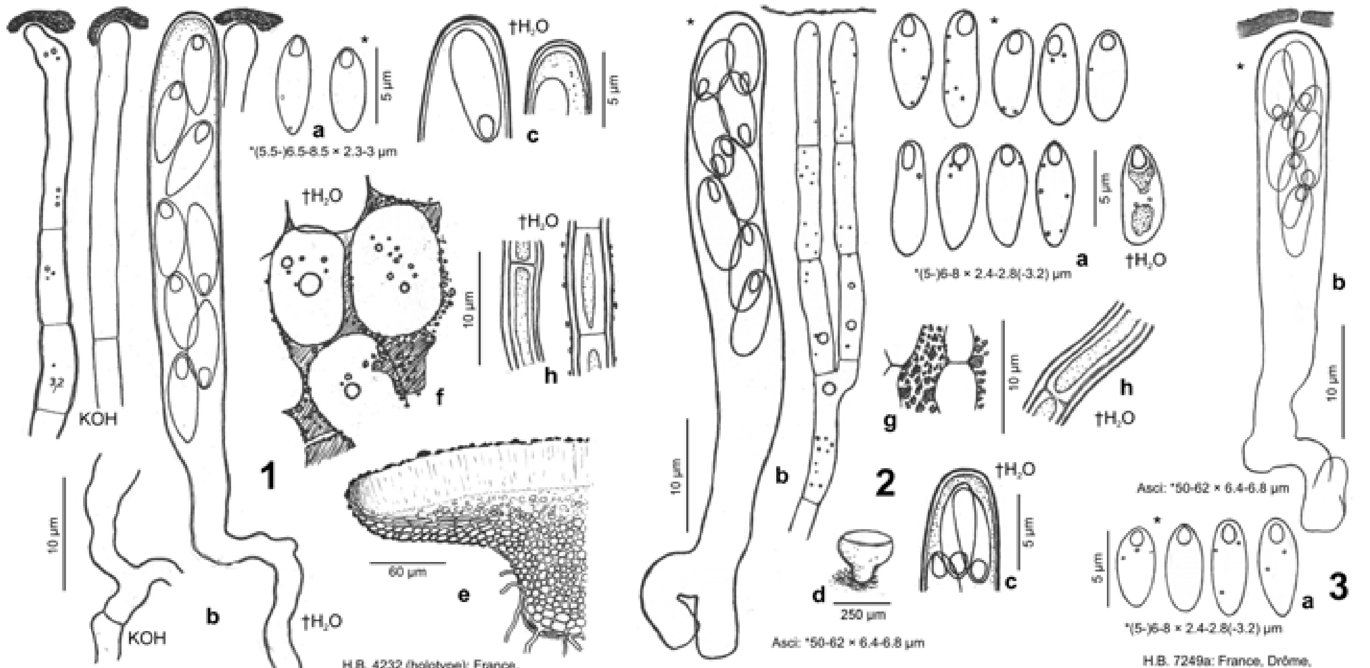

Plate 806. **1–3**: *Orbilia olivacea*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium; **e**. apothecium in median section; **f**. ectal excipulum in surface view at lower flanks, with granular exudate and LBs in the cells; **g**. id., near margin; h. anchoring hyphae.

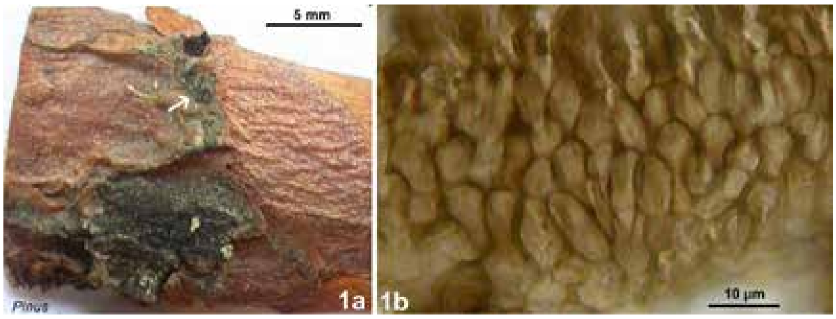

Plate 807. **1**: *Orbilia olivacea*. – **1a**. dead xeric corticated branch of *Pinus*, undecayed, with blackened resinous areas; **1b**. marginal ectal excipulum in external view (dead state, in H_2O). — **1a–b**. H.B. 4232 (holotype): France, Haute-Loire, Massif central, on *Pinus*.

*7–14 × 1.6–2.3(–3.2) µm {3}; unbranched near apex, lateral wall hyaline to pale olivaceous. **Medullary excipulum** hyaline with very few pale olivaceous patches, ~60–120 µm thick in centre, of dense t. globulosa-angularis, upwards of t. intricata, sharply delimited from ectal excipulum at flanks by a ~10 µm thick layer of pale olivaceous-brown t. porrecta. **Ectal excipulum** 30–40 µm thick at base, of (†) slightly gelatinized, indistinctly or vertically oriented t. globulosa-angularis-prismatica, cells †6–17 × 6–10 µm {2}; 15–20 µm thick at lower flanks, of t. prismatica-angularis oriented at a 20–30° angle to the surface, 10–15 µm thick near margin, of t. prismatica-porrecta oriented at 10°, marginal cortical cells †7–10 × 3–4.5 µm {1}, **glassy processes** absent. **Anchoring hyphae** sparse to abundant, projecting, hyaline, †3.5–4.5(–5.5) µm wide, walls 0.4–1.5 µm thick {3}, distinctly 3-layered (mid layer non-refractive). **SCBs** in paraphyses sparse, small, globose. **VBs** absent {3}; **LBs** in excipular cells distinct, ~0.3–2 µm diam. {1}. **Exudate** over paraphyses 0.3–2 µm thick, continuous to cloddy, dark olive(-brown), reddish-brown in KOH, loosely attached; over margin and flanks granular to cloddy or continuous, dark olive-brown, 2–3 µm thick, in KOH (brass-)ochre-brown, near base light olive(-ochre). — **ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). A single **conidium** seen to emerge from anchoring hypha: *85 × 9.8 µm, 14-septate, thick-walled (*~0.5 µm), with gradually tapered ends, slightly flexuous.

Habitat: collected 1.5–3.5 m above the ground, corticated, recently dead, 20–55 mm thick branches of *Pinus* sp. {1}, *P. sylvestris* {2}, directly at the border of small to very large open resinous wounds, or somewhat remote from them, on little decayed bark {3} (thin detaching squamules of periderm), partly on old, dark brown resin {1}, strongly greyed or blackened, green algae partly abundant. **Associated**: *Amphosoma atroolivaceum* {2}, *Ciliolarina pinicola* {1}, *Claussenomyces olivaceus* {1}, *Hypogymnia physodes* {1}, *Orbilia cylindrospora* {1}, *O. vinosa* {1}, *Pseudohelotium sordidulum* {1}, *Resinomyces kirschsteinianus* {2}, *Sarea difformis* {2}, *S. resinae* {1}. **Desiccation tolerance**: fully viable for at least 2 months, ascospores still alive after 22 months. **Altitude**: 700–1405 m a.s.l. **Geology**: Southern French Alps: Upper Jurassic & lower Cretaceous marl- & limestone; Auvergne: granite. **Phenology**: IX–X (but long-lived).

Taxonomic remarks. *Orbilia olivacea* resembles *O. clavipisca* or *O. subovoidea* in the ascospores and is, therefore, tentatively placed in section *Ovoideae*, despite the asci being only slightly truncate at their apices. *O. olivacea* is very exceptional in this section on account of its deep black apothecia, particularly in the dry state, due to a dark olivaceous exudate. Other species with black apothecia (mainly in section *Lentiformes* but also in the genus *Amphosoma*) differ in the SBs being broadly attached to the spore apex, and in a ± thick-walled ascus apex. *Amphosoma atroolivaceum* resembles *O. olivacea* in spore shape but differs in having 2 SBs, one at each end, also in showing strongly refractive globose VBs in the living paraphyses.

Anamorph. On the substrate a single unbranched, multiseptate conidium was seen to emerge from an anchoring hypha of *O. olivacea* (IVV: H.B. 7249a). This was similar in size and shape to conidia observed in some other species of section *Ovoideae*.

Ecology. *O. olivacea* was found on rather undecayed bark more or less close to wounds of xeric, recently dead branches of *Pinus* in cold-temperate (holotype) to orosubmediterranean humid pine forests of very different age in the Massif central and Southern French Alps in southern Europe. The vegetation was either an open woodland of rather young pine trees on ± south-exposed slopes, or the west-exposed border of a pine forest (Col de Soubeyrand).

Specimens included. **FRANCE**: **Auvergne**, **Haute-Loire**, Massif central, 50 km SW of Lyon, ~9 km SW of Firminy, La Chapelle-d'Aurec, 700 m, branch of *Pinus*, on bark, 21.IX.1990, G. Marson (ex H.B. 4232, M-0276543, **holotype**). – **Rhône-Alpes**, **Drôme**, 17 km E of Nyons, 4.5 km S of Rémuzat, Col de Soubeyrand, 1005 m, branch of *P. sylvestris*, on bark & resin, 10.X.2002, G. Marson (H.B. 7249a ø, anam. substr.). – **Provence-Alpes-Côte d'Azur**, **Alpes Maritimes**, 19 km NNE of Grasse, 4 km NNE of Gréolières, Gréolières les Neiges, 1405 m, branch of *P. sylvestris*, on bark, 1.X.1993, G. Marson (H.B. 4999 ø).

Orbilia yuccae Baral & G. Marson, **sp. nov.**, MB 813945 — Pls 808–809

Etymology: referring to the host plant, *Yucca elata*.

Typification: USA, New Mexico, Artesia, inflorescence stem of *Yucca elata*, 25.V.1996, G. Marson (ex H.B. 5655a, M-0276609, holotype).

Latin diagnosis: *Apothecia rehydratata 0.1–0.22 mm diam., subhyalina vel dilute luteo-ochracea, sessilia vel substipitata, margine laevi. Asci 8-spori, apice in statu emortuo hemisphaerici vel conici, leniter crassitunicati. Ascosporae *4–5.6 × 2.5–3 µm, ellipsoideae(-ovoideae), corpusculum refringens (sub)globosum vel crasse lentiformem, ad apicem confertim vel perlate affixum continentes. Paraphyses ad apicem plerumque valde clavato-capitatae. Excipulum marginale textura prismatica sub angulo acuto orientata, cellulae terminales vesiculosae, absque processis vitreis. Habitat ad caulem putridum siccum inflorescentiae* Yuccae elatae *in zona temperata semiarida Americae septentrionalis.*

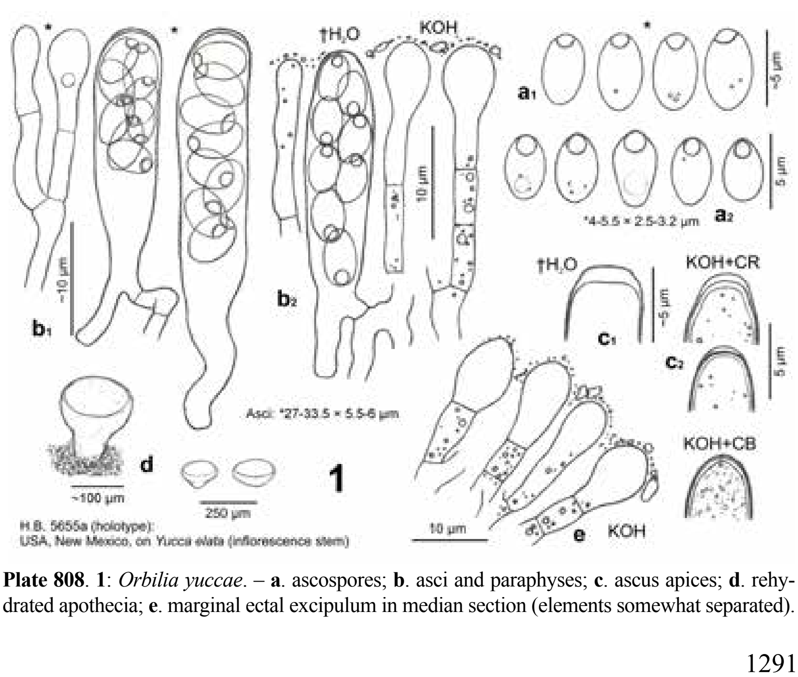

Plate 808. **1**: *Orbilia yuccae*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. marginal ectal excipulum in median section (elements somewhat separated).

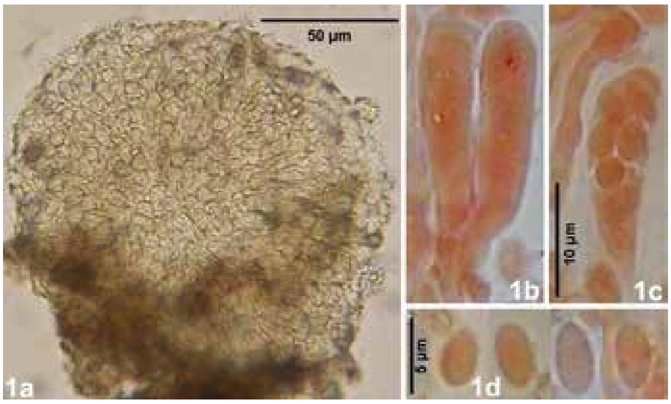

Plate 809. **1**: *Orbilia yuccae*. – **1a**. apothecium from below; **1b–c**. asci and paraphysis; **1d**. ascospores. – Dead state (**1a** in KOH, **1b–d** in KOH+CR). — **1a–d**. H.B. 5655a (holotype): USA, New Mexico, on *Yucca*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.22 mm diam., subhyaline to pale yellowish-ochraceous-amber, translucent, round, ± scattered; disc flat to slightly convex, margin thin, indistinct, not protruding, smooth; sessile or with a distinct short stipe ~0.03 × 0.06 mm, superficial. **Asci** *27–33.5 × 5.5–6 µm, †24–30 × (4–)4.7–5.6 µm, 8-spored, spores (*) biseriate († uni- or biseriate), ~4 lower spores inversely oriented (often mixed, laterally sometimes oriented); **apex** (†) hemispherical to slightly (truncate-) conical, apically very slightly thickened to †0.3–0.4 → 0.2 µm; **base** without or with short to medium long, ± thick, flexuous stalk, Y- to h-shaped. **Ascospores** *4–5(–5.6) × 2.5–3 µm, †3.5–4.8 × (2–)2.3–2.8 µm, broadly ellipsoid(-ovoid), rarely fusoid-clavate, apex rounded to obtuse; **SBs** *1.2–1.5 × (1–)1.2–1.4 µm, (sub)globose, closely but narrowly attached at apex (Pl. 808: 1a$_2$); in other apothecium lens-shaped and broadly attached (1a$_1$). **Paraphyses** apically uninflated to mostly medium to strongly clavate-capitate, terminal cells †(?9–)11–14 × (2–)3–5 µm, lower cells †6–8 × 1.5–2.2 µm; unbranched at upper septum. **Medullary excipulum** not examined. **Ectal excipulum** of (†) thin-walled to slightly gelatinized textura angularis from base to mid flanks, cells *13–20 × 10–15 µm; 5–10 µm thick near margin, of t. prismatica oriented at a ~10–30° angle, marginal cortical cells capitate-vesiculous, †10–19 × 5–7 µm, thin-walled, **glassy processes** absent. **Anchoring hyphae** very sparse, †3–3.5 µm wide, walls 0.2–0.5 µm thick. **SCBs** in paraphyses globose, sparse. **Exudate** over paraphyses and marginal excipulum granular to cloddy, 0.2–2 µm thick, hyaline, loosely attached. **— ANAMORPH**: unknown.

Habitat: 28 mm thick, decorticated inflorescence stem of *Yucca elata*, in a small old wound (depression), slightly to strongly decayed, very greyed (blackish), no algae. **Associated**: *Cyathicula ?nigrofusca*, *Orbilia bicknellensis*, *O. macrotrapeziformis*, *O. multigambelii*, *O. serpentina*, *Patellaria atrata*, *Teichosporella dura*. **Desiccation tolerance**: fully viable for at least 1.5 month, some ascospores and excipular cells alive after 5 months. **Altitude**: 1120 m a.s.l. **Geology**: Quaternary sediment. **Phenology**: probably long-lived.

Taxonomic remarks. *Orbilia yuccae* is characterized by ellipsoid-ovoid ascospores with large, closely or broadly attached, globose to lens-shaped SBs, small asci with indistinctly truncate apices, paraphyses with strongly capitate-clavate apices, thin-walled marginal cortical cells, and small subhyaline apothecia. The species appears to occupy a somewhat isolated position within *Orbilia* and is only tentatively placed in section *Ovoideae*. The spores resemble a bit those of *O. subovoidea* and particularly *O. amberina*, but the strongly inflated marginal cortical cells, the much smaller asci, and the unpigmented apothecia sharply distinguish *O. yuccae* from these species.

Another possible relationship might be with *Hyalorbilia*, particularly *H. erythrostigma*, because of the small asci and the structure of the ascus apex. However, the asci of *Hyalorbilia* always arise from croziers though these are often provided with a small or large perforation, whereas in *O. yuccae* the branches do not form a crozier and the ascus stalk, if present, is more flexuous than in *Hyalorbilia*. Also the genus *Lecophagus* resembles *O. yuccae* but has never a bifurcate ascus base and differs also in much wider anchoring hyphae.

Variation. When one of us (G.M.) examined the species about 1.5 months after collecting, he observed the SBs as a lens-shaped organelle that was broadly attached to the spore apex (Pl. 808: 1a$_1$). When the sample was reexamined 3.5 months later, the first author found subglobose narrowly attached SBs (1a$_2$). Such variation in SB morphology was also observed, e. g., in *O. multicreosoteris*.

Ecology. *O. yuccae* is only known from the sparse holotype collection. The species was found on a rotten, decorticated, xeric inflorescence stem of *Yucca elata* in a warm-temperate semiarid saltbush desert scrub at the northeastern end of Chihuahuan Desert (western North America).

Specimens included. **USA**: **New Mexico**, Chihuahuan Desert, ~13 km W of Artesia, 1120 m, inflorescence stem of *Yucca elata*, on wood, 25.V.1996, G. Marson (ex H.B. 5655a, M-0276609, **holotype**).

Section *Orbilia*

Orbilia Fr. subgenus ***Orbilia*** section ***Orbilia*** – Lectotype species: *Orbilia xanthostigma* (Fr.) Fr.

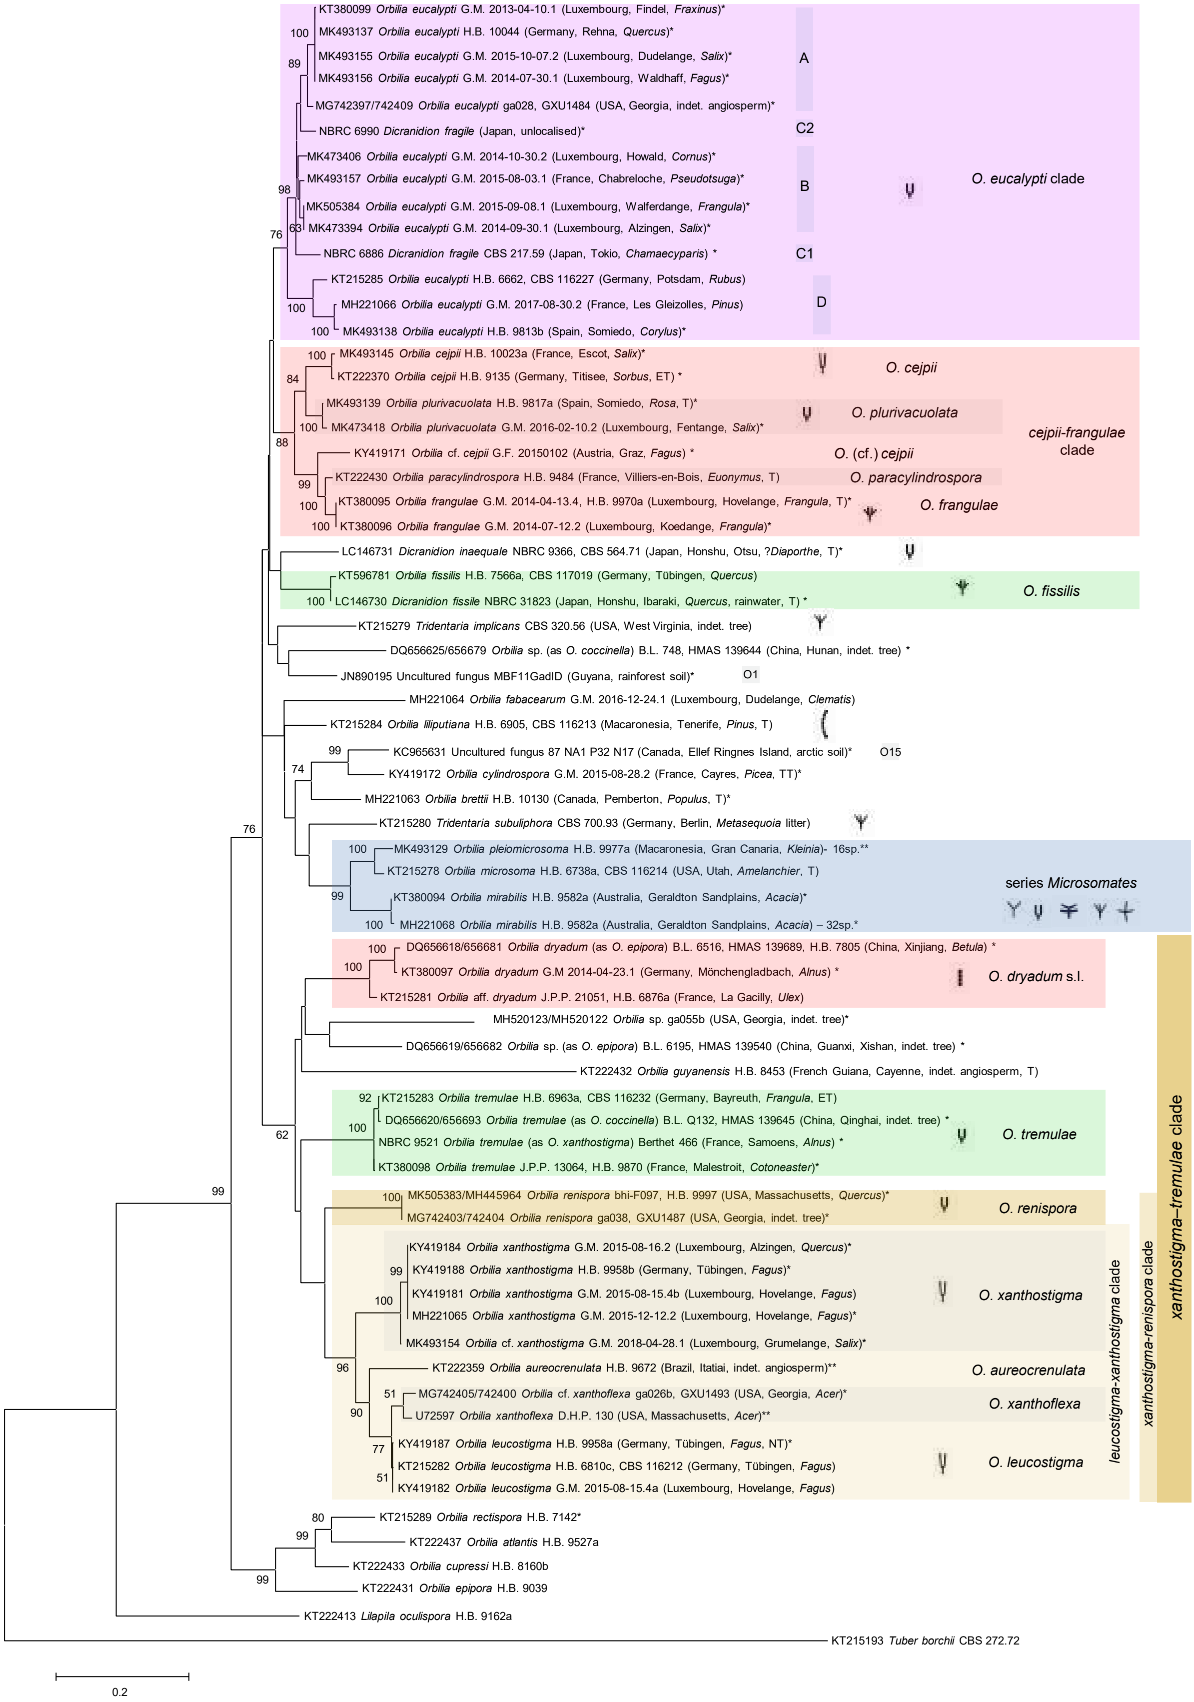
Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–2(–4.5) mm diam., white or pale to bright yellow, orange, or rose(-lilaceous), margin smooth or finely rough to crenulate, also with prominent teeth or notched by small lobes, sessile or with a ± distinct stipe. **Asci** *(22–)27–70(–78) × (2.8–)3–7.7 µm, 8- up to 64-spored, (2–)3–5(–6) lower spores inverted (but often oriented in all directions); **apex** (†) slightly to often medium to strongly truncate, not to distinctly indented and/or laterally inflated, hemispherical in profile view, thin-walled; **base** T-, L-, Y-, h-, or H-shaped. **Ascospores** *(1.8–)2.2–11.5(–14) × (0.8–)1–2.5(–3) µm, subglobose, ovoid, ellipsoid(-clavate), cylindric(-fusoid) or fusoid-clavate, apex rounded to obtuse (exceptionally subacute), straight to very strongly curved (cashew-shaped, rarely helicoid); **SBs** apically (rarely laterally) affixed to spore wall, 0.3–1.2(–1.4) × (0.2–)0.3–0.8(–1.2) µm, globose to tear-shaped, also plug-shaped, dumbbell-shaped or ampulliform, rarely lens-shaped, ± broadly affixed or narrowed to a small point, with or without a short filum, attachment visible or not. **Paraphyses** uninflated or slightly to strongly capitate-clavate, ± spathulate(-mammiform), lageniform or lanceolate at the apex, terminal cells (1–)2–4(–6)× longer than lower cells, unbranched or very rarely branched near apex. **Ectal excipulum** of vertically or indistinctly oriented textura globulosa-angularis-prismatica, **glassy processes** near margin absent or 1–15 µm up to sometimes 10–120 µm long, **hairs** absent. **SCBs** globose or mixed with crystalloid ones, also absent; **VBs** absent or low- to high-refractive, hyaline to yellowish; **carotenoids** in **LBs** observed in some species. **— ANAMORPH**: dactylella-like, descalsia-like, dicranidion-like, dwayaangam-like, trinacrium-like, vermispora-like, also arthropod-like. **Conidiophores** reduced to rather long (1.5–105 µm), unbranched or branched. **Conidiogenous cells** monoblastic or sympodial. **Conidia** either unbranched, phragmosporous, straight or ± curved; or often branched, with or without a stipe and with 2–9 arms). **Trapping organs**: only known in *Tridentaria implicans* and *Dicranidion dactylopagum* (taxa of uncertain relationship).

Habitat: on wood and bark, rarely herbaceous stems or leaves, of gymno- and angiosperms, rarely on polypores, semiarid to humid, boreal to tropical, desiccation-tolerant or -sensitive.

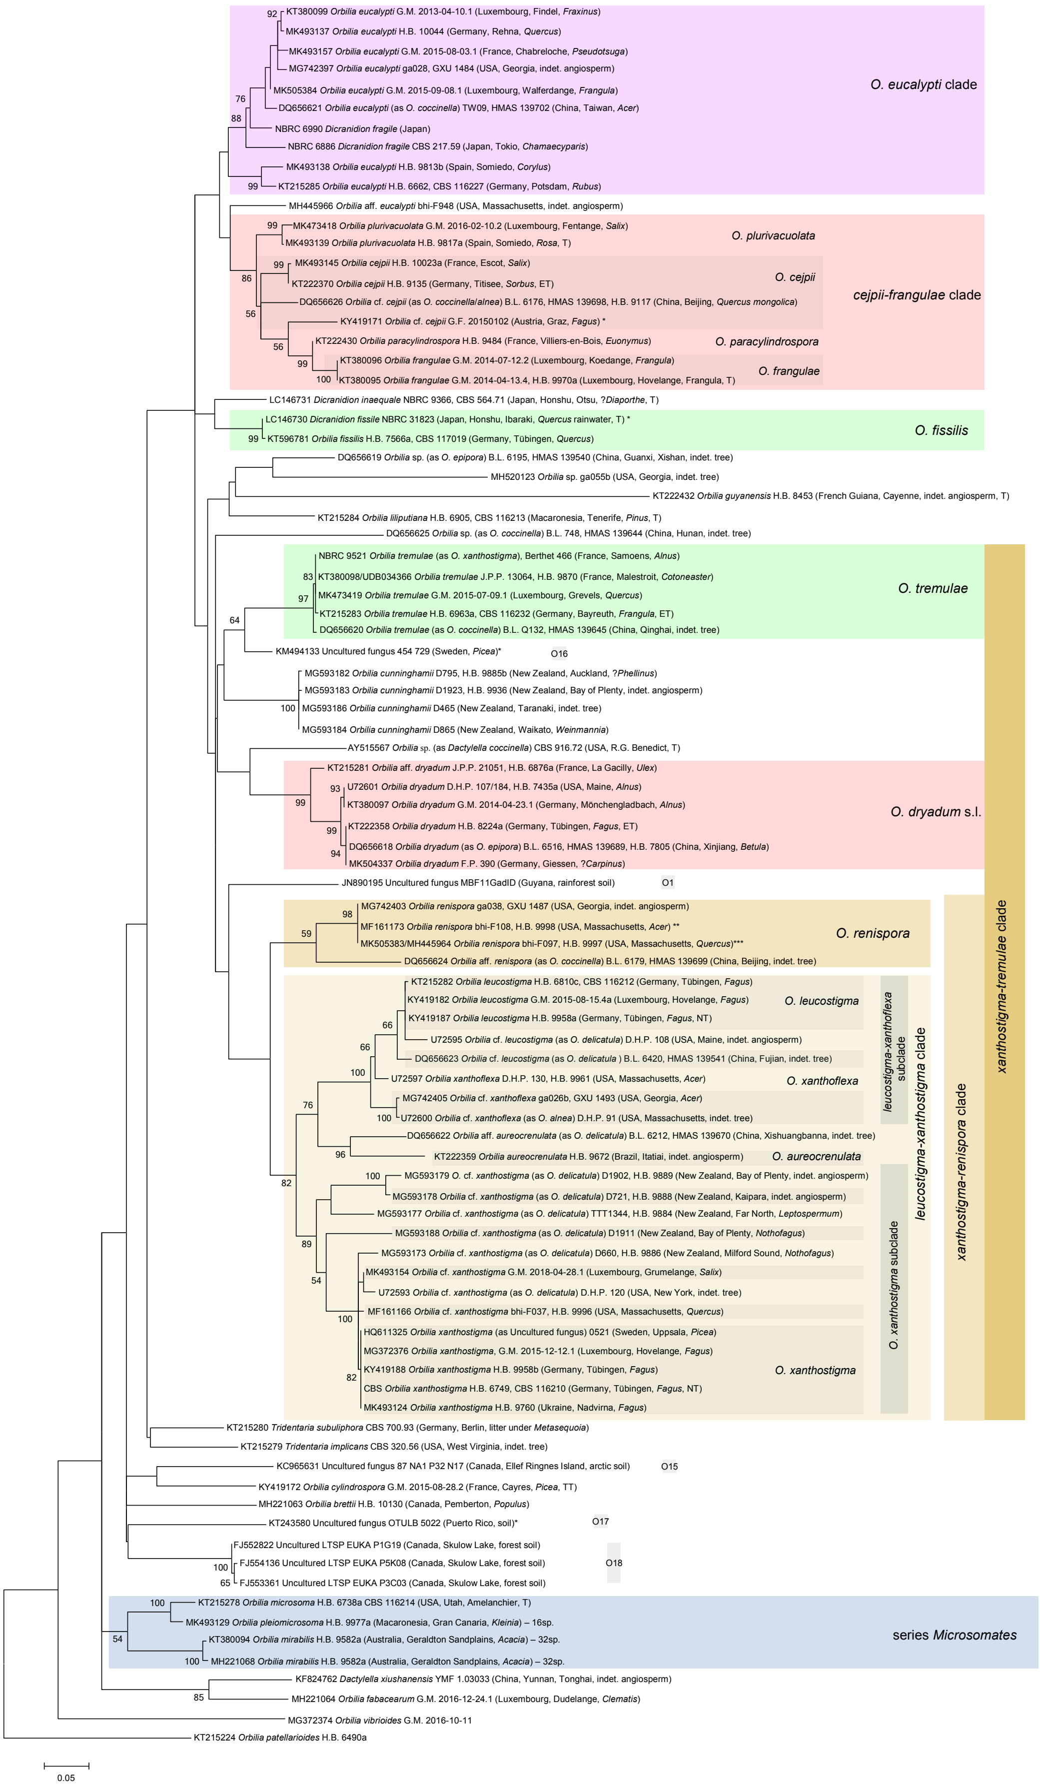
Recognized series: *Microsomates* and *Orbilia*, with 35 recognized species plus 6 unnamed ('affinis') and 7 species with uncertain affinity.

Taxonomic remarks. Members of section *Orbilia* are placed in two series, *Microsomates* and *Orbilia*, and the intermediate *O. cylindrospora* group. They have rather small ascospores of various shape and curvature, but mostly with a rounded to obtuse apex. Spore bodies are small and never strongly elongated.

Section *Orbilia* is morphologically difficult to separate



Phylogenetic analysis 22. Phylogram of section *Orbilia* inferred from combined ML analysis of SSU (V8–V9)+ITS+LSU (D1–D2) rDNA dataset (67 sequences, 1830 positions, aligned with MUSCLE) using the GTR+G+I model in MEGA6 (500 replicates). 2 environmental strains from GenBank are included representing unidentified species (O1, O15). The tree is rooted with *Tuber borchii*, *Lilapila oculispora*, and 4 species of section *Arthrobotrys*. Asci 8-spored if not otherwise stated; T = type, ET = epitype, NT = neotype, TT = topotype, * = SSU incomplete or absent, ** = without SSU and LSU.



Phylogenetic analysis 23. Phylogram of section *Orbilia* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (90 sequences, 872 positions, aligned with MAFFT) using the GTR+G+I model in MEGA6 (500 replicates). 8 environmental strains from GenBank are included, 1 belonging to *O. xanthostigma* and 7 representing 5 unidentified species (O1, O15–O18). O18 includes 6 Canadian environmental strains (only 3 are included in phylogram) showing affinities with section *Orbilia* according to ITS BLAST results. All of them possess also SSU (V8–V9) and lack the S1506 intron, but only 3 (P5K08, P3C03, P1P24) appear to be correct in the SSU whereas the other 3 (P1G19, P5K09, P2K09) yield *Lecanorales* in SSU BLAST searches, suggesting a chimere. The tree is rooted with *O. patellarioides* and *O. vibrioides*. Asci 8-spored if not otherwise stated; T = type, ET = epitype, NT = neotype, TT = topotype. * = without ITS1 and partial 5.8S, ** = without partial 5.8S and ITS2, *** = without ITS2.

Key to series of section *Orbilia*

1. SBs plug- to tear-shaped, broadly or narrowly attached to apex, 0.3–1.2 µm long; spores narrowly cylindrical to fusoid-clavate, *(4–)5–11.5(–13) × (1–)1.2–2.5(–2.7) µm, ± straight in upper part, partly slightly or sometimes strongly curved near base; paraphyses with thin to thick refractive caps of exudate, often ± spathulate (to lageniform); SCBs globose, sometimes crystalloid; upper margin of. textura prismatica or t. porrecta, oriented at a ± low angle (0–45°), usually terminated by short to very long glassy processes; asci 8–64-spored; apothecia reddish, always desiccation-tolerant .... **series *Microsomates***, p. 1295

1. SBs globose to broadly tear-shaped, narrowly attached by a fine filum which is mostly invisible, rarely more broadly attached (*O. guyanensis*), 0.2–0.9 µm long (including invisible filum); spores cylindrical to ellipsoid or globose, straight to strongly curved, *(1.8–)2.2–6(–7) × 0.8–2.5(–2.8) µm; paraphyses rarely with refractive caps of exudate; SCBs globose or absent, never crystalloid; upper margin of t. globulosa-angularis or t. prismatica, oriented at a medium to high angle (40–80°), rarely at 10–30°, usually without glassy processes (rarely up to 7 µm long); asci 8(–16)-spored; apothecia variously coloured, desiccation-tolerant or -sensitive.....................**series *Orbilia***, p. 1325

from other groups, especially from sections *Ovoideae* and *Arthrobotrys*, based on the teleomorph. This difficulty mainly relates to species with straight, rod-shaped spores (*O. dryadum*, *O. paracylindrospora*, *O. umbilicata*, *O. cylindrospora* group), which resemble those here assigned to section *Ovoideae* (*O. subcylindrospora* and related species) or series *Neodactylella* (*O. atlantis*, *O. cardui*, *O. cupressi*, *O. epipora*, *O. fraxini*, *O. lamarcheae*, *O. rhamni*, *O. rectispora*). Species of section *Ovoideae* with ± cylindrical spores have always desiccation-tolerant, orange to reddish apothecia with abundant exudate and often rather short terminal cells of the paraphyses. Some of those species included in *Neodactylella* deviate by SBs situated more distant from the spore apex, unlike members of series *Orbilia* and section *Ovoideae*.

Members of the rather distant series *Regales* (section *Aurantiorubrae*) may easily be confused with those of series *Microsomates*. They differ from typical representatives of that series in tear-shaped to globose SBs which are mostly narrowly attached, often with a very short filum, and in vermispora-like anamorphs. Another species included in section *Aurantiorubrae* (*O. gemma*) resembles series *Microsomates* in spore shape, but seems better included in series *Albovinosae* based on molecular data.

Series delimitation. The morphological limits between series *Orbilia* and *Microsomates* are not very sharp. Especially series *Orbilia* in the present circumscription is morphologically very diverse and cannot be clearly circumscribed by available molecular data. Some species are only tentatively assigned here. Species of the *O. cylindrospora* group appear to be somewhat intermediate between series *Orbilia* and *Microsomates*. *O. flexispora* is only tentatively included in series *Orbilia* because of the absence of molecular data and the lack of characters in the living state. Also the relationship of three species with lanceolate paraphyses (*O. umbilicata*, *O. spirospora*, and *O. minutispora*) which lack molecular data remains unclear.

Anamorph. The conidiophores within section *Orbilia* vary from very short to rather long, with conidiogenous cells often monoblastic but also sympodial. The conidia are septate, unbranched (dactylella-like) or branched but never with one cell distinctly inflated. Trapping capabilities are not known with certainty (the two taxa for which they have been reported need confirmation regarding their phylogenetic relationship).

Phylogeny. Section *Orbilia* formed a strongly supported monophyletic group in the SSU+ITS+LSU analysis of *Orbiliomycetes* in Baral et al. (2017b). However, its affiliation in the genus *Orbilia* remained unresolved. Contrary to this, in the present analysis of the genus *Orbilia* regarding the same gene region, the section is paraphyletic by falling into two groups, the group with *O. xanthostigma* forming a medium supported clade with series *Hyalinia* of section *Aurantiorubrae* (Phyl. 7). Within section *Orbilia*, series *Orbilia* is also paraphyletic, as the other of the two groups includes the strongly supported monophyletic clade of series *Microsomates*, besides some taxa of unclear relationship.

Specific nucleotide positions. Characteristic motifs are observed in the 5.8S region: all members of section *Orbilia* (but also section *Ovoideae*, section *Hemiorbilia* p.p.maj., and some series of section *Aurantiorubrae*) have at pos. 132–133 CC**GA**C or CC**GA**T, whereas different groups of *Orbiliaceae* and many species of series *Neodactylella* and *Arthrobotrys* have CC**TT**T, CC**AT**T, or CC**GG**T (see Tab. 18); at pos. 140 members of section *Orbilia* (but also series *Abutilones*, *Poitevinicae*, series *Hemiorbilia* p.p.maj., the *aprilis-crenatovinosa* clade, and *Hyalorbilia*) have GCA**C**G, whereas all members of section *Arthrobotrys* and many of other groups have GCA**T**G. Also in the LSU D1 domain, section *Orbilia* shows some characteristic motifs: pos. 13–17 is consistently C**AGACG**A, but this occurs within the genus *Orbilia* also in series *Hemiorbilia* s.str., *O. poitevinica*, and the *aprilis-crenatovinosa* clade; at pos. 162–163 section *Orbilia* has TG**CC**T, rarely TG**CT**T (*O. brettii*, *Tridentaria implicans*) as in section *Ovoideae*, or TG**TC**A (*O. dryadum*), whereas section *Arthrobotrys* has TG**TT**T (rarely TG**CT**T), and also most members of subgenus *Habrostictis* and *Hemiorbilia* have TG**TT**T or TG**CT**T, but TG**CC**T occurs in some members of section *Hemiorbilia*; at pos. 252–254 a strong predominance is seen for TG**TGG**CT, rarely TG**TGA**CT or TG**AGG**CT, but in other groups of *Orbilia* TG**AAA**CT, TG**TAA**CT, TG**TAG**CT, or TG**AAG**CT.

Ecology. Section *Orbilia* occurs worldwide and includes desiccation-tolerant and -sensitive taxa at about equal proportion. Most of the taxa occur on wood and bark, whereas herbaceous stems, leaves, and perennial basidiomycetes were rarely recorded as substrate.

Series *Microsomates*

Orbilia subgenus ***Orbilia*** section ***Orbilia*** series ***Microsomates*** Baral & E. Weber, **ser**. **nov**., MB 815022

– Type species: *Orbilia microsoma* Baral & G. Marson

Etymology: named after the small spore bodies.

Latin diagnosis: *Apothecia aurantiaca* ad *rosea, margine laevi vel dentata. Asci 8- ad 64-spori, apice in statu emortuo plerumque modice vel valde truncati, tenuitunicati. Ascosporae plerumque *(4–)5–11.5(–14) × (1–)1.2–2.5(–2.7) µm, anguste ellipsoideae ad subcylindricae vel fusoideo-clavatae, apice rotundato ad obtuso, raro subacuto, rectae vel prope basin leniter ad valde curvatae, in statu*

Key to species of series *Microsomates*

1. Asci 32–64-spored; paraphyses tipped by thin refractive caps or continuous exudate 2
1. Asci 8–16-spored; paraphyses often tipped by thick refractive caps 7

2. Without glassy processes; asci 32-spored; spores *4–7.7 × 1.5–1.7(–2) µm, ± subcylindrical; SBs ± broadly tear-shaped; branch of *Atriplex*, subtropical arid central Australia ..... ***O. multiaustrocylindrica*** (inc. sed.), p. 1321
2. With 2–120 µm long glassy processes 3

3. Glassy processes 2–15 µm long, not forming teeth; spores straight to slightly curved; SBs 0.3–0.8 µm long 4
3. Glassy processes 10–120 µm long, forming discrete teeth; spores straight to strongly curved; SBs 0.8–1.2 µm long 5

4. Asci 64-spored; spores *(4.3–)5–7.5(–8.4) × (1.4–)1.5–1.6(–1.8) µm; paraphyses with globose and crystalloid SCBs; bark of *Acacia*, subtropical semiarid western Australia ..... ***O. myrionanosoma***, p. 1309
4. Asci 32-spored; spores *4.5–5.7 × 1.3–1.5 µm; paraphyses with globose SCBs; bark of *Eucalyptus*, subtropical subhumid eastern Australia ..... ***O. multinanosoma***, p. 1308

5. Spores *(8–)9.5–11(–14) × (1.5–)1.6–1.7 µm, predominantly medium to strongly curved or geniculate; asci 32-spored; bark of *Acacia*, subtropical semihumid western Australia ..... ***O. mirabilis***, p. 1311
5. Spores *(4–)5–6.5(–8) × (1–)1.1–1.4(–1.7) µm, ± straight 6

6. Apothecia with rose-pink disc, teeth ± straight; asci 32-spored; SBs close to apex, globose; bark of *Lamarchea*; subtropical semiarid western Australia ..... ***O. gemma*** (series *Albovinosae*, section *Aurantiorubrae*), p. 934
6. Apothecia with orange disc, teeth curved downwards; asci 64-spored; SBs with a distinct short filum; bark of *Acacia*, subtropical arid western Australia ..... ***O. myriopseudoregalis***, p. 1313

7. Asci 16-spored 8
7. Asci 8-spored 10

8. Without glassy processes, spores *6.5–8.8 × (1.4–)1.5–1.6(–1.7) µm, subcylindrical to (fusoid-)clavate, straight to often slightly to strongly curved below; SBs broadly tear-shaped; wood of *Acacia* and *Eucalyptus*; subtropical semiarid to semihumid western Australia ..... ***O. pleioaustrocylindrica*** (inc. sed.), p. 1319
8. With (0–)1–9(–16) µm long glassy processes 9

9. Spores *(4–)5–9(–10) × (1.3–)1.6–2.1(–2.4) µm, cylindrical to ellipsoid-fusoid-clavate; SBs plug- or tear-shaped; paraphyses rarely with crystalloid SCBs in apex; wood of various angiosperms, warm-temperate humid to inframediterranean arid southern Europe, Macaronesia, western North America ..... ***O. pleiomicrosoma***, p. 1301
9. Spores *(6–)7–12(–13) × (1.8–)2–2.4(–2.7) µm, cylindric(-clavate); SBs always plug-shaped; paraphyses often with crystalloid SCBs in apex; wood of *Acacia* & *Eucalyptus*, subtropical subhumid to arid Australia ..... ***O. austropleiomicrosoma***, p. 1304

10. SB laterally attached to spore wall, ± globose; spores *(4.5–)5–6(–6.5) × 1.2–1.4(–1.5) µm, (sub)cylindrical, straight; bark of *Quercus*, suprasubmediterranean semihumid southern Europe ..... ***O. beatricis*** (inc. sed.), p. 1322
10. Attachment of SBs terminally 11

11. Without glassy processes 12
11. With (0–)1–9(–16) up to 20–35 µm long glassy processes 13

12. Spores 4–7(–8) × (1–)1.1–1.3(–1.5) µm, ± subcylindrical, straight; SBs globose to broadly tear-shaped, rarely ampulliform; mainly on wood of conifers; boreal to suprasubmediterranean humid Europe ..... ***O. cylindrospora*** (inc. sed.), p. 1314
12. Spores *(4–)4.5–7.5(–8) × (1.1–)1.3–1.7(–1.9) µm, cylindrical to narrowly fusoid, ± straight; SBs globose to broadly tear-shaped;bark of angiosperm trees and shrubs; subtropical humid to semiarid western & eastern Australia ..... ***O. austrocylindrica*** (inc. sed.), p. 1317

13. Glassy processes 20–35 µm long; spores *(5–)6–7.3(–8) × (2.5–)2.8–3.5(–4) µm, ellipsoid; SBs *1–1.3 × 0.5–0.8 µm, indistinctly ampulliform (keyhole-shaped); wood of *Populus*, cold-temperate humid western North America ..... ***O. brettii*** (inc. sed.), p. 1323
13. Glassy processes (0–)1–9(–16) µm long; spores *1.4–2.7 µm wide, elongate ellipsoid to cylindrical 14

14. SBs *0.3–0.8 × 0.7–1.2 µm, subglobose to lens-shaped, (very) broadly attached; spores *5.7–12.3 × (1.7–)1.9–2.2(–2.4) µm; cone of *Pinus halepensis*, mesomediterranean semihumid southern Europe ..... ***O. microlentiformis***, p. 1300
14. SBs *0.3–1.1 × 0.3–0.8 µm, plug- (to tear-)shaped, broadly to narrowly attached 15
If SBs globose see under *O. austrocylindrica*.

15. Spores *8–11.5 × 1.4–1.8 µm; SBs 0.5–0.8 × 0.3–0.6 µm; asci *(30–)36–44 µm long; conidia (presumed) arthropod-like, with 4–8 arms; wood & bark of *Acacia* & *Eucalyptus*, (sub)tropical subhumid northern and eastern Australia ..... ***O. arachnopus***, p. 1305
15. Spores *(4–)6–10(–12) × (1.7–)1.8–2.4(–2.7) µm; conidia Y-, ┼- or ¥-shaped, with 2–4 arms 16

16. SBs 0.7–1.1 × 0.5–0.8 µm; asci *40–64 µm long; margin with 1–9 µm long glassy processes; wood of angiosperm trees & shrubs, orotemperate to mesomediterranean, humid to semiarid western North America, Macaronesia & southern Europe ..... ***O. microsoma***, p. 1298
16. SBs 0.3–0.7(–1) × 0.3–0.4 µm; asci *38–40 µm long; margin without glassy processes; wood of *Pinus ponderosa*; orotemperate humid western North America ..... ***O.* cf. *microsoma***, p. 1300

vivo corpusculum refringens minutum, plerumque obturamentiformem, sed etiam lacrimi- vel ampulliformem continentes. Paraphyses non vel leniter ad modice, raro valde inflatae, clavato-capitatae vel saepe spathulatae ad lageniformes vel mammiformes. Excipulum marginale processis vitreis brevibus vel longis praeditum. Habitat ad lignum vel corticem putridum ramorum gymno- vel angiospermarum, in aere prominentium, in zona subtropica, arida ad humida.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.6(–1.2) mm diam., light to bright orange to rose, margin smooth or finely crenulate, also with prominent teeth; sessile or sometimes with a distinct short stipe. **Asci** *(30–)40–70(–78) × 4.6–7.7 µm, 8- up to 64-spored, lower spores inverted (~1/4–2/3 of total number), **apex** (†) slightly to mostly medium to strongly truncate, not or rarely slightly indented and laterally inflated; **base** T-, L-, Y- or h-, sometimes H-shaped. **Ascospores** *(4–)5–11.5(–14) × (1–)1.2–2.5(–2.7) µm, narrowly ellipsoid to subcylindrical or fusoid-clavate, apex rounded to obtuse (exceptionally subacute), straight to slightly, sometimes strongly curved, particularly near base; **SBs** 0.3–1.2(–1.4) × 0.25–0.8(–1.2) µm, plug-shaped, also tear- to dumbbell-shaped or ampulliform, rarely subglobose with a filum, or lens-shaped, ± broadly affixed to apical wall but sometimes narrowed to a small point. **Paraphyses** uninflated or slightly to medium, rarely strongly clavate-capitate or often ± spathulate(-mammiform) or lageniform at the apex, cells of ± equal length but terminal cells also often ~1.5–2 × longer than lower cells, near apex unbranched or rarely branched. **Ectal excipulum** of (†) thin-walled or sometimes slightly to medium gelatinized (common walls †0.3–1.5 µm), vertically or indistinctly oriented textura (globulosa -)angularis(-prismatica), cells near base *(6–)8–20(–24) × (5–)7–13(–15) µm, (upper) margin of t. prismatica-porrecta oriented at a 0–50° angle, with 1–15 or sometimes 10–120 µm long **glassy processes** (absent in *O.* cf. *microsoma*, H.B. 7518). **SCBs** globose, sometimes mixed with crystalloid ones; **VBs** consistently absent. **Exudate** 0.1–0.3 µm up to 0.5–3(–5) µm thick, granular to cloddy, often forming firmly attached caps on tips of paraphyses, hyaline or light yellow to ochraceous. **— ANAMORPH**: trinacrium-like, descalsia-like, arthropod-like. **Conidiophores** reduced. **Stauroconidia** *6.5–32 × 17.5–56 µm, 2–9-armed, partly associated with phragmoconidia. **Trapping organs**: unknown.

Habitat: on wood and bark of both gymno- and angiosperms, subtropical to orotemperate including (sub)mediterranean, arid to humid climates, all species desiccation-tolerant.

Recognized species: 9, plus 1 unnamed species ('affinis'), and 6 species with uncertain affinity.

Taxonomic remarks. Series *Microsomates* is characterized by very small, plug- to tear-shaped, usually broadly but also narrowly attached SBs, and more or less cylindric-ellipsoid, partly basally curved ascospores. The paraphyses tend to be spathulate and tipped by firmly attached glassy caps of exudate. Glassy processes are quite consistently present at the margin but are usually comparatively short. The apothecia are consistently reddish and desiccation-tolerant.

O. myrionanosoma, *O. mirabilis*, and *O. myriopseudoregalis* differ from typical members of series *Microsomates* in a rather thin exudate, the latter two species also in very long glassy processes forming discrete teeth, and *O. myriopseudoregalis* in tear-shaped SBs with a very short filum. *O. microlentiformis* is extraordinary because of its ± lens-shaped SBs. It might belong to series *Lentiformes*, but we prefer to place it here because of short glassy processes at the margin and exudate caps on the partly lageniform paraphyses. Also the strongly truncate, thin-walled ascus apex fits series *Microsomates* much better. The rather small SBs partly tend to be plug-shaped, and the taxon otherwise hardly differs from *O. microsoma*.

Similar as in series *Regales*, the glassy caps of exudate on the paraphyses in the present series closely resemble the glassy processes on the marginal cortical cells, which suggest that both are composed of cell wall material which is covered by yellowish exudate. Although exudate and cell walls behave very different in their staining properties, the question whether true glassy processes occur on the paraphyses could not be clarified (see also p. 99).

Species delimitation. Rather high variability in spore and SB shape and size is observed within *O. microsoma*, even within a population, and *O. microlentiformis* is only tentatively separated from it. Similarly, the Australian *O. austropleiomicrosoma* is proposed with hesitation as distinct from European *O. pleiomicrosoma*, based mainly on its larger spores. The remaining species are all Australian and appear to be well-defined, but are only known from one or a few records.

Anamorph. Different types of variously branched multiseptate conidia are known in some species of series *Microsomates*. They represent mere variations in the type of branching, therefore, they certainly do not indicate heterogeneity of the group, all the more as three of them occur even within a single isolate (*O. microsoma*). The observed spectrum comprises dichotomously branched, Y-shaped or multiarmed conidia with a single central cell (trinacrium-like), ┼-shaped conidia with either 1 central cell or 2 such cells with an oblique septum (descalsia-like), and characteristic ¥-shaped, arthropod-like conidia with a monopodial branching type with a septate main axis of 2 or more cells, from which lateral arms emerge on each side, besides unbranched phragomoconidia. The conidial arms are straight or slightly curved, septate, and usually ± attenuated at their apex.

Phylogeny. Sequences of three species were available, one comprising SSU+ITS+LSU (*O. microsoma*), one ITS+LSU (*O. mirabilis*), and one ITS (*O. pleiomicrosoma*). In all of them the S1506 intron at the 3'-end of SSU is absent. In phylogenetic analyses of SSU+ITS+LSU (Baral et al. 2017b, Phyls 7, 22) or LSU (S27), series *Microsomates* formed a strongly supported group. In Phyls 7 and 22 it clustered in an unsupported clade with *O. cylindrospora*, *O. brettii*, and *Tridentaria subuliphora*. The three species of series *Microsomates* show a high ITS distance to members of series *Orbilia*, the lowest percentage to *O. brettii*, *O. cylindrospora*, *O. liliputiana* and *O. eucalypti* (~16–20%). In the LSU (D1–D2, 613 nt) the lowest distance was 4.2–6% to *O. fissilis* and 5–7% to *O. liliputiana*, *O. brettii* and allied taxa. In comparison, the distance between the three available sequences of series *Microsomates* is 6–12.5% in the ITS region and 3.5% in the LSU.

Specific nucleotide positions. At pos. 175 in the LSU D1 domain, *O. microsoma* and *O. mirabilis* deviate by T (GT**T**C) from all members of series *Orbilia*, including *Tridentaria implicans* and *T. subuliphora*, which have GT**C**A, GT**C**C, GC**C**C, GC**C**A, GC**C**T, AC**C**C etc. Yet, various other sections (particularly *Lentiformes*, *Aurantiorubrae*, and *Arthrobotrys*) have also members with **T**. At pos. 181 *O. microsoma* and *O. mirabilis* deviate by GC**A**TA or GC**G**TA from other members of *Orbiliomycetes* having **C** or rarely **T**, exceptionally **A** (*O. atlantis*).

Ecology. Species of series *Microsomates* grow on exposed, xeric branches, rarely conifer cones, but were so far not observed on herbaceous substrate. Species derive from humid to arid regions but are absent in temperate humid central Europe. Records are known from North America, Europe, Macaronesia, and Australia.

Orbilia microsoma Baral, G. Marson & E. Weber, **sp. nov.**, MB 814373 — Pls 810–811, Map 131

Etymology: named after the small plug-shaped spore body.

Typification: USA, Utah, Monticello, branch of *Amelanchier utahensis*, 15.VI.2000, G. Marson (ex H.B. 6738a, M-0276515, holotype; ex-type culture: CBS 116214; sq.: KT215278).

Latin diagnosis: *Apothecia rehydratata 0.2–0.7 mm diam., salmonea vel aurantiaca, sessilia vel substipitata, margine laevi ad minute crenulato. Asci 8-spori. Ascosporae *4–12 × 1.8–2.7 µm, cylindricae vel cylindrico-clavatae, rectae vel leniter curvatae corpusculum refringens minutum, obturamenti- vel ampulliformem, ad apicem plus minusve late affixum continentes. Paraphyses ad apicem leniter vel valde capitatae ad spathulatae, pileis vitreis tectae. Excipulum marginale processis vitreis brevibus, pallide luteis praeditum. Habitat ad lignum leniter vel valde putridum ramorum siccorum fruticorum vel arborum angiospermarum in zona orotemperata ad mesomediterranea humida ad semiarida Americae septentrionalis, Macaronesiae et Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.6(–0.8) mm diam., 0.12–0.22 mm high (receptacle 0.1–0.14 mm), light to bright salmon-rose (or orange), slightly to strongly translucent, round, subgregarious to gregarious in ± small groups; disc slightly concave to flat, margin indistinct or distinct, smooth or finely crenulate, 5–10 µm protruding; broadly sessile or with a distinct stipe 0.05–0.1 × 0.2–0.3 mm, superficial, sometimes half immersed in biofilm, dry deep orange-red. **Asci** *(40–)43–58(–64) × 4.8–6(–6.3) µm {5}, †40–50(–55) × (4–)4.3–5(–5.2) µm {3}, 8-spored, spores 2–4-seriate, 2–5 lower spores inverted {5} (not or ± mixed), pars sporifera *20–27(–29) µm long; **apex** (†) medium to strongly truncate (never indented, laterally scarcely inflated); **base** with short to medium long, medium thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(4–)5.5–10(–12) × (1.7–)1.9–2.4(–2.7)((–3)) µm {6}, (sub)cylindrical, also cylindric-clavate (to clavate) or sometimes ellipsoid- to fusoid-clavate, apex rounded, rarely obtuse, base not or slightly (rarely medium) attenuated, straight or slightly inequilateral, some slightly (rarely medium) curved in middle or lower part; **SBs** *0.7–1.1 × 0.5–0.8(–0.9) µm {5}, plug-shaped or ampulliform,

Plate 811. **1–3**: *Orbilia microsoma*; **4**: *O.* cf. *microsoma*. – **3a**. mesomediterranean semihumid summit broom scrub (*Spartocytisetum supranubii*) with dead *Adenocarpus viscosus* in front of Teide; **1a–e**, **2a–c**, **3b**, **4a–d**. rehydrated apothecia; **3c**. dry apothecia; **3d**. ascus apex; **1f–g**, **3e**. apices of paraphyses covered by exudate; **3f**. ascospores. – Living state, except for **3e** above (in CR), ascus in **3d**. – **3a–f**: phot. rarely tear- or ± lens-shaped, apically broadly attached or narrowed to a ± wide point. **Paraphyses** apically slightly to strongly capitate(-clavate) to spathulate, rarely moniliform or sublageniform, terminal cells *7.5–20(–25) × (2–)3–4(–4.7) µm {5}, lower cells *7–11(–14) × 1.5–2(–2.5) µm {4} (4–9 µm long near base); branched only near base. **Medullary excipulum** subhyaline, 20–80 µm thick, of medium dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** very pale rose, of thin-walled, vertically oriented t. angularis(-prismatica) from base to mid flanks, 30–80 µm thick at base, cells *9–21 × (5.5–)8–13 µm {2}, †7–15 × 6–9 µm {1}; 30–40 µm thick at lower flanks, 15–20 µm near margin, of t. porrecta oriented at a 30–45° angle to the surface, marginal cortical cells *5–12 × 3–3.5(–4) µm {2}, †9–12 × 3–5 µm {1}; **glassy processes** present, 1–9 × (2–)2.5–3.5 µm {5}, strongly refractive, partly stratified, pale yellowish-chlorinaceous. **Anchoring hyphae** ± abundant, *2–3.5 µm wide (~1.5–2.5 µm), walls */†0.2–0.3(–0.7) µm thick {2}, forming a dense t. intricata up to 30–40 µm thick, covering the flanks as a thin network in surface view. **SCBs** in tips of paraphyses globose, 1–3 µm diam. {5}, also in ectal excipulum present {1}. **Exudate** forming firmly attached glassy caps (0.5–)1–3(–5) µm thick on tips of paraphyses, conical or tuberculate, pale yellowish-chlorinaceous; on marginal glassy processes thin, rarely with some clods. — **ANAMORPH**: conidia Y-shaped (trinarium-like), ┼-shaped (descalsia-like) and ¥-shaped (arthropod-like) (from ascospore isolate {1}). **Conidiophores** reduced. **Conidiogenous cells** integrated. **Conidia** of very diverse shape, 2–4-armed, total size *15–32 × 17.5–36 µm, stipe *5–16 × 2.6–3.3 µm, (1–)2–3-septate, arms *7–16 × 3.7–4.5 µm, (1–)2–4-septate; Y-, ┼- and ¥-shaped conidia in more or less equal frequency, also unbranched conidia present but less frequent, *27.5–35 × 4.3–4.4 µm, 7-septate, ± straight.

Habitat: collected 0–3 m above the ground, decorticated, 15–35 mm thick branches of (?)*Acer* sp. {1}, *Adenocarpus viscosus* {1}, *Amelanchier utahensis* {1}, *Laburnum anagyroides* {1}, *Populus tremuloides* {1}, *Purshia stansburyana* {1}, on ~0.5 mm deep slightly to strongly decayed wood {6}, ± strongly eroded, with or without internal beetle galleries, also on boring dust of bark beetles, strongly greyed, green algae present or not. **Associated**: *Durella* sp. {1}, *Hysterium* sp. {1/1}, *Hysteropatella* sp. {1}, *Mellitiosporiella macrospora* {2}, *M. pulchella* {3}, *Odontotrema oregonensis* {1}, *Orbilia aprilis* {1}, *O. cupularis* {1}, *O. delphinus* {1}, *O. gambelii* {1}, *O. macrodelphinus* {1}, *O. maeandrina* {1}, *O. montigena* {1}, *O. multimaeandrina* {1}, *O. navajoana* {2}, *O. pleiomicrosoma* {1}, *O. stansburyanae* {1}, *O. tremuloidis* {1}, *Phragmiticola* sp. {1}, *Propolis farinosa* {1}, *Teichosporella dura* {1}. **Desiccation tolerance**: fully viable for at least 18 months. **Altitude**: 1250 m a.s.l. (southern Europe), 2055–2450 m (North America, Macaronesia). **Geology**: Cretaceous limestone; basaltic lava & cinders, andesite & rhyolite, phonolitic flow. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia microsoma* is characterized by subcylindrical to slightly clavate, medium-sized ascospores with a small, ± plug-shaped spore body, paraphyses tipped by glassy caps of exudate, and marginal cells tipped by glassy processes. The Australian *O. arachnopus* differs in longer and narrower spores and in conidial shape. *O. pleiomicrosoma* differs in 16-spored asci and a slight tendency to narrower spores. The only European sample of *O. microsoma* was mixed with *O. pleiomicrosoma*, which here differed from *O. microsoma* in shorter and wider asci and shorter spores. The European *O. microlentiformis* differs in slightly longer spores with much wider, broadly plug- to mostly lens-shaped SBs.

Variation. Rather great variation is noted within *O. microsoma* concerning length and shape of the spores and spore bodies, even within an apothecium. Ellipsoid, apparently atypical spores were observed in several collections (especially inside dead asci), which resemble those of *O. ovalis* (section *Lentiformes*). In the sample from Macaronesia the glassy processes were very short (1–2 µm), while the unpreserved and sparse European record was not examined in this respect.

Not included collection. A North American sample on *Pinus ponderosa* (Pls 810: 2; 811: 4) deviates by rather long and narrow spores with distinctly narrower SBs (similar to *O. arachnopus*), absence of glassy processes at the margin, rather short asci, and the coniferous host.

Anamorph. The conidia of *O. microsoma* show a remarkably high diversity in shape due to different branching types: unbranched (multiseptate), 2-armed (Y-shaped), 3-armed (┼-shaped), and 4-armed (¥-shaped). In this respect the anamorph resembles, e. g., that of *O. aristata*, in which triradiate and higher-branched conidia simultaneously occur (see also p. 113: Drechsler 1938 und Ando 1992).

Phylogeny. A sequence from an ascospore isolate of the holotype from Utah (H.B. 6738a) comprises SSU, ITS, and LSU. In the ITS region, *O. microsoma* differs from *O. pleiomicrosoma* by 6% and from *O. mirabilis* by 12.5% (3% in the LSU D1–D2).

Ecology. *O. microsoma* was found on ± rotten wood of xeric branches of different angiosperm trees and shrubs. Most collections derive from cold-temperate semiarid to subhumid pinyon-juniper woodlands and subhumid to humid ponderosa pine forests of the Colorado Plateau (Utah Mountains, Canyonlands section, Mogollon Rim) in the southwest of Northern America. The site in the French southern Prealps is a south-exposed mountain flank with an orotemperate humid deciduous woodland with *Corylus avellana* and *Laburnum anagyroides*, and that in Macaronesia a *Spartocytisetum supranubii* in the mesomediterranean semihumid caldera of the volcano Teide in Tenerife.

Map 131. Known distribution of *O. microsoma* in North America (yellow = not included collection).

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 29 km NNE of Escalante, 10 km N of Boulder, 3.5 km W of Deer Mt., 2433 m, branch of *Purshia stansburyana*, on wood, 11.VI.2003, G. Marson (H.B. 7918c). – Bryce Canyon, 33 km SE of Panguitch, 8 km WSW of Tropic, Navajo Trail SE of Sunset Point, 2300 m, branch of (?)*Acer*, on wood, 25.VIII.1994, G. Marson (H.B. 5164d ø). – Canyonlands, 42 km NNE of Blanding, 13 km N of Monticello, Peters Canyon, 2055 m, branch of *Amelanchier utahensis*, on wood, 15.VI.2000, G. Marson (H.B. 7158d ø). — **MACARONESIA**: **Canary Islands**, **Tenerife**, La Orotava, Las Cañadas del Teide, 3.5 km SSE of Teide, Callao, Tabonal Negro, 2230 m, branches of *Adenocarpus viscosus*, on wood, 20.II.2009, E. Beltrán-Tejera, L. Quijada & J. Díaz Armas (TFC Mic. 21528, doc. vid.).

Not included. **USA**: **Arizona**, Mogollon Rim, 16 km NW of Flagstaff, San Francisco Peaks, 6 km WSW of Humphreys Peak, 2550 m, branches of *Pinus ponderosa*, on wood, 17.VI.2003, G. Marson (H.B. 7518).

Orbilia microlentiformis Baral, **sp. nov.**, MB 813946 — Pl. 812

Etymology: named after the small lens-shaped spore body.

Typification: France, Narbonne, cones of *Pinus halepensis*, 1.IX.1999, H.O. Baral (ex H.B. 6523c, M-0276513, holotype).

Latin diagnosis: *Similis* Orbiliae microsomati *sed corpuscula refringentia ascosporarum breviora et latiora, crasse lentiformia. Habitat ad strobilum putridum siccum* Pini halepensis *in zona mesomediterranea semihumida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.19–0.2 mm diam., 0.11 mm high, light amber-reddish, round, scattered; disc flat, margin indistinct, ± smooth, not protruding; broadly sessile, superficial. **Asci** *55–60 × 4.6–5 µm, †45 × 5.3 µm, 8-spored, spores (*) obliquely biseriate, 5–8 lower spores inverted but sometimes also only 4 upper spores inverted, pars sporifera up to *29 µm long; **apex** (†) strongly truncate (very slightly indented, laterally hardly inflated); **base** with medium long, thick, flexuous stalk, L- to h-shaped. **Ascospores** *5.7–12.3 × (1.7–)1.9–2.2(–2.4) µm, †5–7 × 2–2.2 µm, narrowly ellipsoid to subcylindric(-clavate), apex obtuse, base hardly or sometimes rather strongly attenuated, straight to medium curved, especially near base (somewhat helicoid?); **SBs** *0.3–0.8 × 0.7–1.2 µm, lens- to broadly plug-shaped, apically broadly attached. **Paraphyses** apically uninflated to slightly clavate-capitate, also sublageniform (to moniliform), terminal cells *8–15 × 2.5–3.4 µm, lower cells *5–

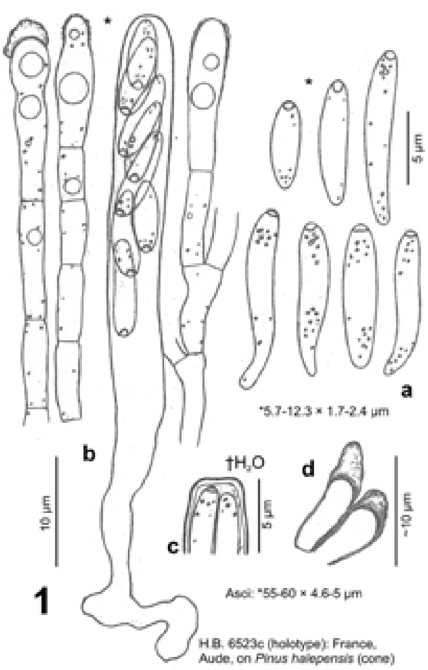

Plate 812. **1**: *Orbilia microlentiformis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal cortical cells with short glassy processes.

11 × 1.8–2.7 µm; unbranched at upper septum. **Medullary excipulum** not clearly seen, ~30 µm thick. **Ectal excipulum** of (†) thin-walled, indistinctly oriented textura angularis(-prismatica) from base to mid flanks, ~20 µm thick near base, cells †5–10 × 4–5 µm; 15 µm thick near margin, of t. prismatica-porrecta oriented at a 20–30° angle to the surface, marginal cortical cells †6–10 × 3–4 µm; tipped by **glassy processes** 1–5 × 2.5–4 µm, high-refractive, not stratified, pale chlorinaceous-yellow. **Anchoring hyphae** sparse, †1.5–2 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose, 0.8–2.6 µm diam. **Exudate** over paraphyses 0.1–2 µm thick, finely granular or as cloddy caps, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected ~1.5–2 m above the ground, still-attached cone of *Pinus halepensis*, on medium decayed scales, greyed, green algae absent to medium abundant. **Associated**: *Naemacyclus fimbriatus*, *Orbilia hesperidea*, *Propolis viridis*. **Desiccation tolerance**: fully viable for at least 1 week. **Altitude**: 9 m a.s.l. **Geology**: Lower Miocene marine limestone. **Phenology**: probably long-lived.

Taxonomic remarks. *Orbilia microlentiformis* closely resembles the mainly North American *O. microsoma* in size and shape of the ascospores, in shape and contents of paraphyses, in the glassy caps on them, and in the presence of short yellowish glassy processes on the margin. Yet, the spore bodies are distinctly wider and predominantly lens-shaped, and the paraphyses are apically less inflated. Size and shape of the spores showed a high variability within this sparse collection.

O. microlentiformis resembles members of series *Lentiformes* in the lens-shaped SBs. However, glassy processes are so far unknown in that series. Moreover, remnants of SBs in the dead spores are easily seen in series *Lentiformes*, but could not be discerned in *O. microlentiformis*. Due to these findings and the similarity with *O. microsoma* we place the species in series *Microsomates*.

Ecology. Only four apothecia could be discovered in the holotype collection. They grew in association with two apothecia of *O. hesperidea* and abundant *Naemacyclus fimbriatus* and *Propolis viridis* on dead cones still-attached to a living tree of *Pinus halepensis* in a sun-exposed open woodland strip with *Pinus halepensis* in mesomediterranean semihumid coastal lowland of southern Europe.

Specimens included. **FRANCE**: **Languedoc-Roussillon**, **Aude**, Languedoc, 15 km SSW of Narbonne, 3.7 km WNW of Sigean, Reserve africaine, 9 m, cones of *Pinus halepensis*, 1.IX.1999, H.O. Baral (ex H.B. 6523c, M-0276513, **holotype**).

Orbilia pleiomicrosoma Baral & G. Marson, **sp. nov.**, MB 814433 — Pls 813–814, Map 132

Etymology: named after the 16-spored asci and the spores similar as in *O. microsoma*.

Typification: Spain, Tarragona, branch of *Robinia pseudoacacia*, 27.IX.1999, H.O. Baral & G. Marson (ex H.B. 6494b, M-0276561, holotype).

Latin diagnosis: *Similis* Orbiliae microsomati *sed asci 16-spori. Habitat ad lignum putridum ramorum siccorum fruticum vel arborum coniferarum vel angiospermarum in zona temperata ad subtropica humida ad arida Europae meridionalis, Macaronesiae et Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.3–0.5(–1) mm diam., 0.11–0.23 mm high (receptacle 0.11–0.14 mm), pale to light rose to mostly (rose-)orange(-ochraceous), semitranslucent, ± round (to elliptical), scattered to sub- or densely gregarious; disc slightly concave to flat, margin distinct, thin or ± thick, 0–10 µm protruding, smooth to finely crenulate; broadly sessile or with an obconical base, superficial or erumpent between fibres, often immersed in biofilm; dry light orange. **Asci** *(40–)50–70(–74) × (4.7–)5.5–7(–7.5) µm {6}, †(33–)40–55(–60) × 4.7–5.5(–6.2) µm {3}, 16-spored, spores *3–4-seriate, 8–10 lower spores inverted {2} (± mixed), pars sporifera *19–32 µm long; **apex** (†) medium to strongly truncate (sometimes slightly indented, laterally rarely slightly inflated); **base** with short to long, thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(4–)5–9(–10) {10} × 1.3–1.6 {1} or (1.6–)1.7–2.1(–2.4) {9}, †(5–)6–8(–9) × 1.7–2(–2.2) µm {2}, subcylindrical to narrowly ellipsoid-clavate, also cylindric-, fusoid- or ovoid-clavate, or fusoid to fusiform, apex rounded, sometimes obtuse, rarely subacute, base not or often slightly to strongly attenuated, straight to slightly, also medium, rarely strongly curved (± geniculate) near base; **SBs** *(0.5–)0.7–1(–1.2) × (0.4–)0.5–0.8 µm {7}, plug- to tear-shaped, apically broadly attached, or narrowed to a wide to small point. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate to spathulate, rarely lageniform, terminal cells *(8–)10–20(–22) × (2–)2.5–3.7(–4.2) µm {7}, lower cells *(4.5–)6–12(–13.5) × 1.5–2.5(–3) {6} µm; not or rarely branched at upper septum. **Medullary excipulum** 40–50 µm thick, of medium dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a layer of t. porrecta at flanks. **Ectal excipulum** of thin-walled, indistinctly vertically oriented t. angularis(-globulosa) from base to mid flanks, 35–80 µm thick near base, cells *9–19 × 6–11.5 µm {2}; 20–30 µm thick near margin, of t. prismatica-angularis oriented at an 80° angle to the surface, upper margin of t. prismatica-porrecta orieneted at 30°, marginal cortical cells *(7–)10–15(–19) × 2.5–4.5(–5.5) µm {3}; **glassy processes** on margin and flanks 1–9(–16) {7} × 2.5–3.5 {4} or 3–6 {2} µm, ± high-refractive, stratified, pale to light yellowish-chlorinaceous. **Anchoring hyphae** medium abundant, */†1.5–2.5(–3) µm wide, walls 0.2 µm thick {2}. **SCBs** in paraphyses and marginal cortical cells globose, 1–3 µm diam. {7}, exceptionally with a rod-shaped SCB in paraphysis tip {2}. **Exudate** over paraphyses 0.2–3(–4.5) µm thick, forming 1 or more variously shaped caps on a single tip, firmly attached, hyaline to pale or light yellowish-chlorinaceous. **— ANAMORPH**: unknown, but see below.

Habitat: collected 0–4 m above the ground, (±) decorticated, 10–150 mm thick branches of *Aeonium lindleyi* {1}, *Baccharis sarothroides* {1}, *Euphorbia atropurpurea* {1}, *E. lamarckii* {1}, *Kleinia neriifolia* {1}, *Laburnum anagyroides* {1}, *Periploca laevigata* {1}, *Quercus rotundifolia* {1}, *Robinia pseudoacacia* {1}, *Rumex lunaria* {1}, *Pinus brutia* {1}, *P. halepensis* {2}, *Spartium junceum* {1}, on 0.1–1 mm deep slightly to often strongly decayed wood {11}, partly in beetle galleries, also on splitted wood, ± greyed, without or with many green algae. **Associated**: *Claussenomyces* sp. {1}, *Dacrymyces* sp. {2},

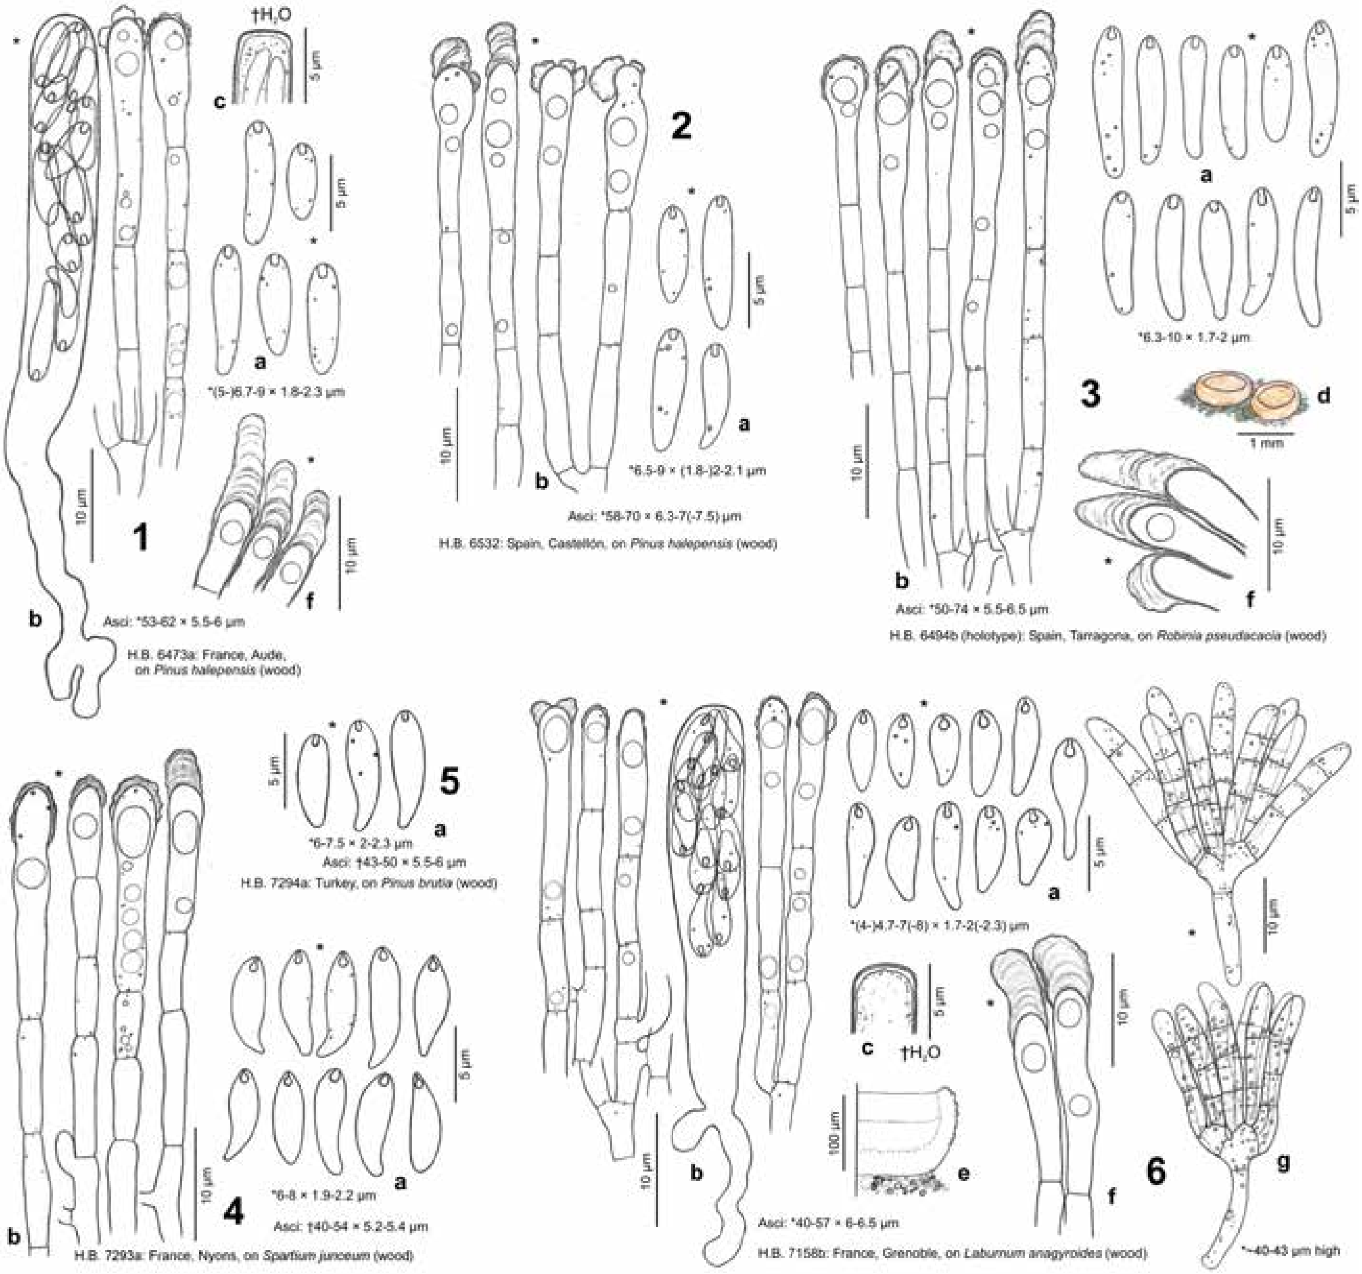

Plate 813. **1–6**: *Orbilia pleiomicrosoma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal cortical cells with glassy processes; **g**. conidia from substrate.

Durella ?*atrocyanea* {1}, *Orbilia aprilis* {1}, *O. bicknellensis* {2}, *O. corculispora* {1}, *O. eucalypti* {2}, *O. euonymi* {1}, *O. microsoma* {1}, *O. montigena* {1}, *O. pleistoeuonymi* {1}, *O. polyspora* {1}, *O. serpentina* {1}, *O. subaristata* {1}, *O. subvinosa* {1}, *O. vinosa* {3}, *Propolis viridis* {1}. **Desiccation tolerance**: fully viable after 3 (Gran Canaria) but also 23 months. **Altitude**: 9–1250 m a.s.l. **Geology**: Cretaceous & Miocene clay, lime- & sandstone; basaltic and trachybasaltic flows, mafic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiomicrosoma* is very similar to *O. microsoma*, from which it is easily distinguished by its 16-spored asci. Due to infraspecific variation, differences in ascus and ascospore size between the two species were only noted when selected populations were compared.

Variation. *O. pleiomicrosoma* is rather variable in size and shape of ascospores and spore bodies. In typical collections the spores are cylindric-ellipsoid to sometimes clavate and contain plug-shaped SBs (Pl. 813: 1–3). The collections on *Laburnum* and *Spartium* from France and those on *Quercus* from Spain and *Pinus* from Turkey differ in rather short spores which tend to be more fusoid-clavate with a more strongly attenuated base (Pl. 813: 4–6). The SBs are here often tear- instead of plug-shaped. In the *Pinus* collection from Turkey the smallest SBs were observed (Pl. 813: 5).

The only North American collection of *O. pleiomicrosoma* (IVV: 27.V.1996) showed rather short and wide, cylindric-ellipsoid spores of *6–6.8 × 2–2.4 µm. A 16-spored Australian collection on *Banksia* is mentioned under the 8-spored *O. arachnopus* because of its narrow spores. In other Australian collections the spores distinctly exceed those of *O. pleiomicrosoma* in length, therefore, they are treated below as a separate species.

Anamorph. Multi-armed dicranidion-like conidia were observed in association with *O. pleiomicrosoma* in four collections (Pls 813: 6; 814: 1, 6, 8). At least in the three latter samples the conidia emerged from the hymenium or margin of the apothecia. Additionally, such conidia were once found in association with *O.*

Plate 814. **1–8**: *Orbilia pleiomicrosoma* (with doubtful anamorph). – **1a**. decorticated xeric branch of *Spartium junceum*, with beetle galleries; **1b–c**, **2a**, **3a–c**, **6a**, **8a**. rehydrated apothecia; **5d**. marginal ectal excipulum in median section; **3d**. glassy processes at margin (squash mount); **4**. mature asci; 5c. ascus apex; **1d**, **5a–b**, **8c**. apices of paraphyses; **2b**, **5e**, **8b**. ascospores; **1e–f**, **6b**, **7**, **8d**. conidia formed on hymenium or margin of *O. pleiomicrosoma* (except for **7**). – Living state (**8b**: 4 spores in CRB), except for **1d** (in KOH+IKI), **1e** (in KOH), **8d** (in H_2O). – **4**, **5a–e**: phot. L. Quijada, **6a**, **7**: phot. T. Askun, **8a**: phot. J. Ormad, **8b–d**: phot. R. Tena. — **1a–f**. H.B. 7293a: France, Nyons, on *Spartium*; **2a–b**. H.B. 9977a: Gran Canaria, on *Kleinia*; **3a–d**. H.B. 7158b: France, Grenoble, on *Laburnum*; **4**. 5.II.2010: Tenerife, Güimar, on *Euphorbia*; **5a–e**. 6.XII.2009: Tenerife, Vera de Erques, on *Euphorbia*; **6a–b**. H.B. 7294a: Turkey, Ivrindi, on *Pinus brutia*; **7**. T.A. 38b, ibid., on *Quercus* (conidium near *O. subaristata*); **8a–d**. 2.XI.2011: Spain, Utiel, on *Quercus*.

subaristata (Pl. 814: 7). They resemble *Dicranidion incarnatum* or *Tridentaria fertilis* but differ in a longer stipe and, in the case of *D. incarnatum*, shorter arms. The charcters are as follows: conidia repeatedly dichotomously branched, with (4–)6–8(–12?)

fasciculate arms, total size */†(25–)35–43.5 × ~(7–)20–45 µm {5}, stipe */†(5–)7–15 × 1.5–3 µm, 1-septate, arms */†13–29 × 2.5–3.5 µm, 2–5-septate, conidiophores short, not clearly seen.

A parasitic infestation rather than a true anamorph cannot be excluded. Similar though less branched conidia found on apothecia of *O. vinosa* (section *Hemiorbilia*) are assumed here to be the anamorph of *Hyalorbilia hergiswiliana* (Pls 137–138). Also on apothecia of *O. cylindrospora* (incertae sedis) and *O. vibrioides* (section *Hemiorbilia*, Pls 370–371) we found similar conidia, which could likewise represent a parasite. However, similar conidia but with more diverging arms, observed on the substrate in association with *O. frangulae*, are presumed here to represent the anamorph of *O. frangulae* (series *Orbilia*, Pl. 850).

Phylogeny. An ITS sequence of *O. pleiomicrosoma* was taken from apothecia of a sample from Gran Canaria (H.B. 9977a), differing from *O. microsoma* by 6% and from *O. mirabilis* by 12.5%.

Ecology. *O. pleiomicrosoma* was collected on ± rotten wood of xeric branches of angiosperm trees, shrubs, and succulents, also of gymnosperms, in thermo- to supramediterranean or mesosub- and orosubmediterranean semihumid to humid scrubs and woodlands in southern Europe, subtropical (infra- to thermo-mediterranean) semihumid to arid desert scrubs in Macaronesia, and a warm-temperate semiarid Sonoran riparian mixed desert scrub near to the Mogollon Rim in western North America.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Drôme**, Vercors, 45 km SW of Grenoble, 8.3 km N of Die, 2.5 km SW of Col de Rousset, 1250 m, branch of *Laburnum anagyroides*, on wood, 22.VIII.2000, G. Marson (H.B. 7158b, anam. substr.). – Préalpes du Dauphiné, 1 km N of Nyons, Col du Pontias, 460 m, branch of *Spartium junceum*, on wood, 11.X.2002, G. Marson (ø).

Map 132. Known distribution of *O. pleiomicrosoma* in Europe, Macaronesia, and Turkey.

Not included. **Turkey**: **Marmara**, **Balıkesir**, 50 km WSW of Balıkesir, 17 km SW of Ivrindi, 1km SW of Korucu, 410 m, branch of *Quercus ilex*, in vicinity of *O. subaristata*, 1.XI.2002, T. Askun (T.A. 38b, anam. only).

Orbilia austropleiomicrosoma Baral & G. Marson, **sp. nov.**, MB 813947 — Pls 815–816

Etymology: named after the close resemblance to *O. pleiomicrosoma* and the Australian origin.

Typification: Australia, Northern Territories, Curtin Springs Roadhouse, twigs and branches of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277a, MEL 2389198, holotype).

Latin diagnosis: Orbiliae pleiomicrosomati *similis sed ascosporae longiores et latiores, paraphyses apice saepe corpusculis crystalloideis continentes. Habitat ad lignum putridum siccum* Acaciae *et* Eucalypti *in zona subtropica arida ad subhumida Australiae occidentalis, centralis et meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.25–0.5(–0.8) mm diam., 0.13–0.19 mm high, (pale to) light to bright pink-rose to orange or brick-red, rarely subhyaline, round (sometimes elliptical), (very) scattered or in small groups; disc slightly concave to flat, margin distinct, thin or thick, 0–15 µm protruding, nearly smooth; broadly sessile, superficial to entirely immersed; dry pale to deep orange or (rose-)red. **Asci** *60–78 × 6–7.2 {3} → 7.7 µm, †50–60 × 5–6 µm {T}, 16-spored, spores 3–5-seriate, ± half of spores inverted (strongly mixed), pars sporifera *35–45 → 34 µm long; **apex** (†) strongly truncate (partly very slightly indented, laterally not or slightly widened); **base** with short, thick stalk, L- to h-, sometimes H-shaped. **Ascospores** *(6–)7–12(–13) × (1.8–)2–2.4(–2.7) µm {3}, †(6.5–)8–12(–13) × 1.8–2.4 µm {T}, (sub)cylindrical to cylindric-clavate, apex rounded, base not or slightly to medium attenuated (sometimes tail-like), straight to often slightly to medium, rarely strongly curved near base (± geniculate); **SBs** *0.5–0.9 × 0.4–0.8(–1) µm {3}, plug-shaped, apically broadly attached; overmature generally getting 1-septate (SB thereby unchanged). **Paraphyses** apically slightly or mostly medium (rarely strongly) clavate-capitate to often spathulate (to mammiform) or obtusely lanceolate, terminal cells *(3–)7–18(–25) × (2–)3–4.5(–5.7) µm {3}, lower cells *7.5–14(–16) × 1.5–2.7(–3.5) µm {3}; branched only near base. **Medullary excipulum** 40–80 µm thick, of (medium) dense textura intricata with some or many inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, vertically oriented t. angularis-globulosa from base to mid flanks, 30–50 µm thick near base, cells *9–20(–24) × 6–14.5 µm {3}; 20–30 µm thick near margin, of t. prismatica-porrecta oriented at a 10–40° angle to the surface, marginal cortical cells *(6–)7–12 × 2.7–4 µm {3}; **glassy processes** 1–8 × 2.8–4 µm {3}, refractive, stratified or not, hyaline to pale golden yellowish-chlorinaceous, ± coherent to form small indistinct teeth. **Anchoring hyphae** (medium) abundant, *2.5–3.5 µm wide, walls 0.2–0.3 µm thick {2}. **SCBs** in paraphyses and ectal excipulum globose {3}, 1.3–2.8 µm diam., in paraphysis apices also rod-shaped {2}. **Exudate** over paraphyses 0.1–3 µm thick, cloddy, hyaline to light yellow, partly absent, firmly individually attached, also on lateral parts of terminal cells, over margin 0.2–0.5 µm thick. — **ANAMORPH**: unknown.

Habitat: lying on dry ground or 3 m above ground, decorticated, (3–)6–17 mm thick (twigs and) branches of *Acacia cheelii* {1}, *A. jennerae* {1}, *Eucalyptus* sp. {1}, on 0.5 mm deep strongly decayed wood {3}, strongly greyed, without green algae, mostly on the ungreyed underside among adhering red sand grains. **Associated**: *Baggea* sp. {1}, *Coccomycetella* sp. {1}, *Hysteropatella* sp. {1}, ?*Monodictys* sp. {1}, *Orbilia angustoaristata* {1}, *O. coronohesperidea* {1}, *O. multiaustraliensis* {1}, *O. multiserpens* {1/1}, *O. myriella* {1}, *O. myrionamibica* {1}, *O. pleioaustraliensis* {1/1}, *O. pleiocoronohesperidea* {1}, *O. velutina* {1}, *Ostropales* {1}, ?*Peniophora* sp. {1}, *Symbiotaphrina desertorum*

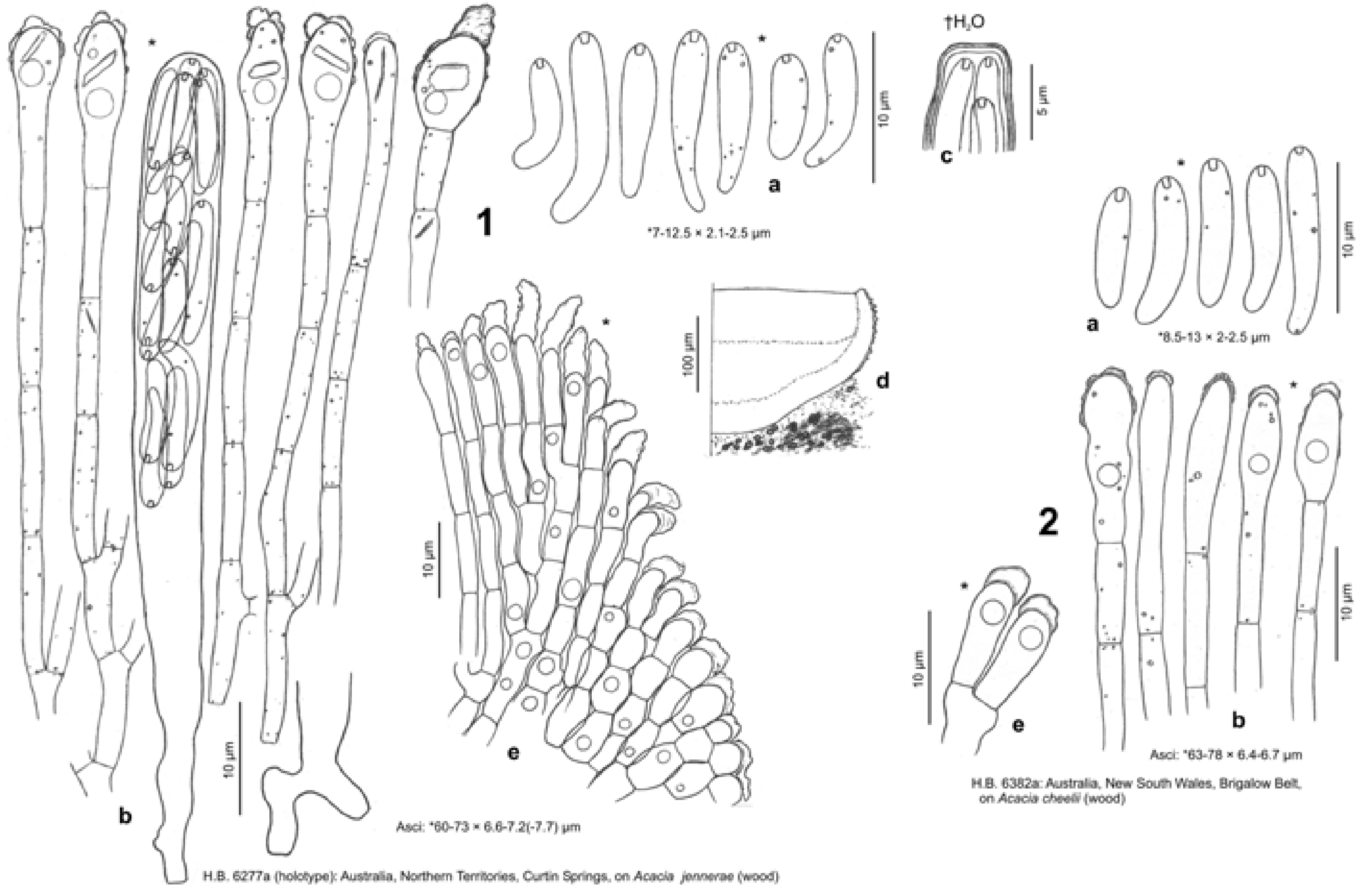

Plate 815. **1–2**: *Orbilia austropleiomicrosoma*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum, cortical cells with glassy processes.

{1}. **Desiccation tolerance**: fully viable for at least 7.5 months, a few paraphysis cells still alive after 45 months. **Altitude**: 480–540 m a.s.l. **Geology**: Mesoproterozoic and Jurassic sedimentary rock, Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia austropleiomicrosoma* is tentatively segregated from European *O. pleiomicrosoma* because of slightly longer and wider ascospores and slightly wider paraphysis apices which more frequently contain rod- to plate-shaped SCBs.

Variation. Within each collection spore shape varied rather strongly between ellipsoid or cylindrical, basally tapered or not, straight or curved, also spore length and width show great variation. Paraphysis shape was often clavate but a tendency to spathulate and rarely mammiform was noted. The exudate formed thick caps on the paraphysis tips only in the holotype, and here only on some of the paraphyses. Crystalloid SCBs were seen in two of the three samples but are partly very inconspicuous. In one sample (Pl. 815: 2) no crystalloid SCBs could be observed.

Ecology. *O. austropleiomicrosoma* was found on rotten wood of xeric branches of *Acacia* and *Eucalyptus* in a subtropical arid acacia open shrubland in central Australia (northern border of Musgrave Range, holotype), in a subtropical arid acacia open woodland with *Eucalyptus* in western Australia, and in a subtropical subhumid eucalypt woodland with *Acacia* and *Callitris glaucophylla* in sand dunes of southeastern Australia (west of Great Dividing Range). In two of the three samples, the inhabited branches were lying on the dry sandy ground, with plenty of attached red sand grains which complicated detection of the small, similar coloured apothecia.

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Eucalyptus*, on wood, 28.X.2007, G. Marson (ex H.B. 9772c, mixture in MEL 2389281 [type of *O. velutina*]). – **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 480 m, twigs & branches of *Acacia jennerae*, on wood, 10.X.1998, G. Marson (MEL 2389198, **holotype**; **isotype** in H.B. 6277a). – **New South Wales**, Brigalow Belt South, 16 km S of Coonabarabran, Mendooran Road, 514 m, branch of *Acacia cheelii*, on wood, 25.X.1998, G. Marson (H.B. 6382a).

Orbilia arachnopus Baral & G. Marson, **sp. nov.**, MB 813948 — Pls 817–818

Etymology: referring to the presumed anamorph with conidia having 4–9 arms resembling a spider.

Typification: Australia, New South Wales, Coonabarabran, branch of *Eucalyptus*, 25.X.1998, G. Marson (ex H.B. 6387b, MEL 2389206A, holotype).

Latin diagnosis: *Similis* Orbiliae microsomati *sed ascosporae angustiores*, *corpuscula refringentia minores*, *asci breviores*, *conidia corpori* Arthropodae *similes. Habitat ad lignum vel corticem putridum siccum* Eucalypti *in zona tropica vel subtropica subhumida Australiae septentrionalis et meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.6 mm diam., 0.11 mm thick, pale to light (yellowish-)orange-apricot, round, sometimes compressed, scattered; disc slightly concave, margin ± thick, 10 µm protruding, very finely rough; sessile, superficial to slightly erumpent. **Asci** *(30–)36–44 × 5–5.5(–6.4) µm {T}, †30–35 × 4.5 µm {1}, 8-spored, spores 4-seriate, 3–4 lower spores inverted {2}, pars sporifera *17–19 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not widened); **base** with short to medium long, flexuous stalk, T-, Y- or H-shaped. **Ascospores** *8–11.5 × 1.4–1.8 µm {2}, narrowly (fusoid-)subcylindric-clavate, apex rounded (to obtuse), base often slightly, also medium attenuated, ± slightly curved; **SBs** *0.5–0.8 × 0.3–0.6 µm {2}, plug- (to tear-)shaped, apically ± broadly attached, also narrowed to a wide point. **Paraphyses** apically uninflated or slightly (rarely medium) clavate to spathulate(-lageniform), terminal

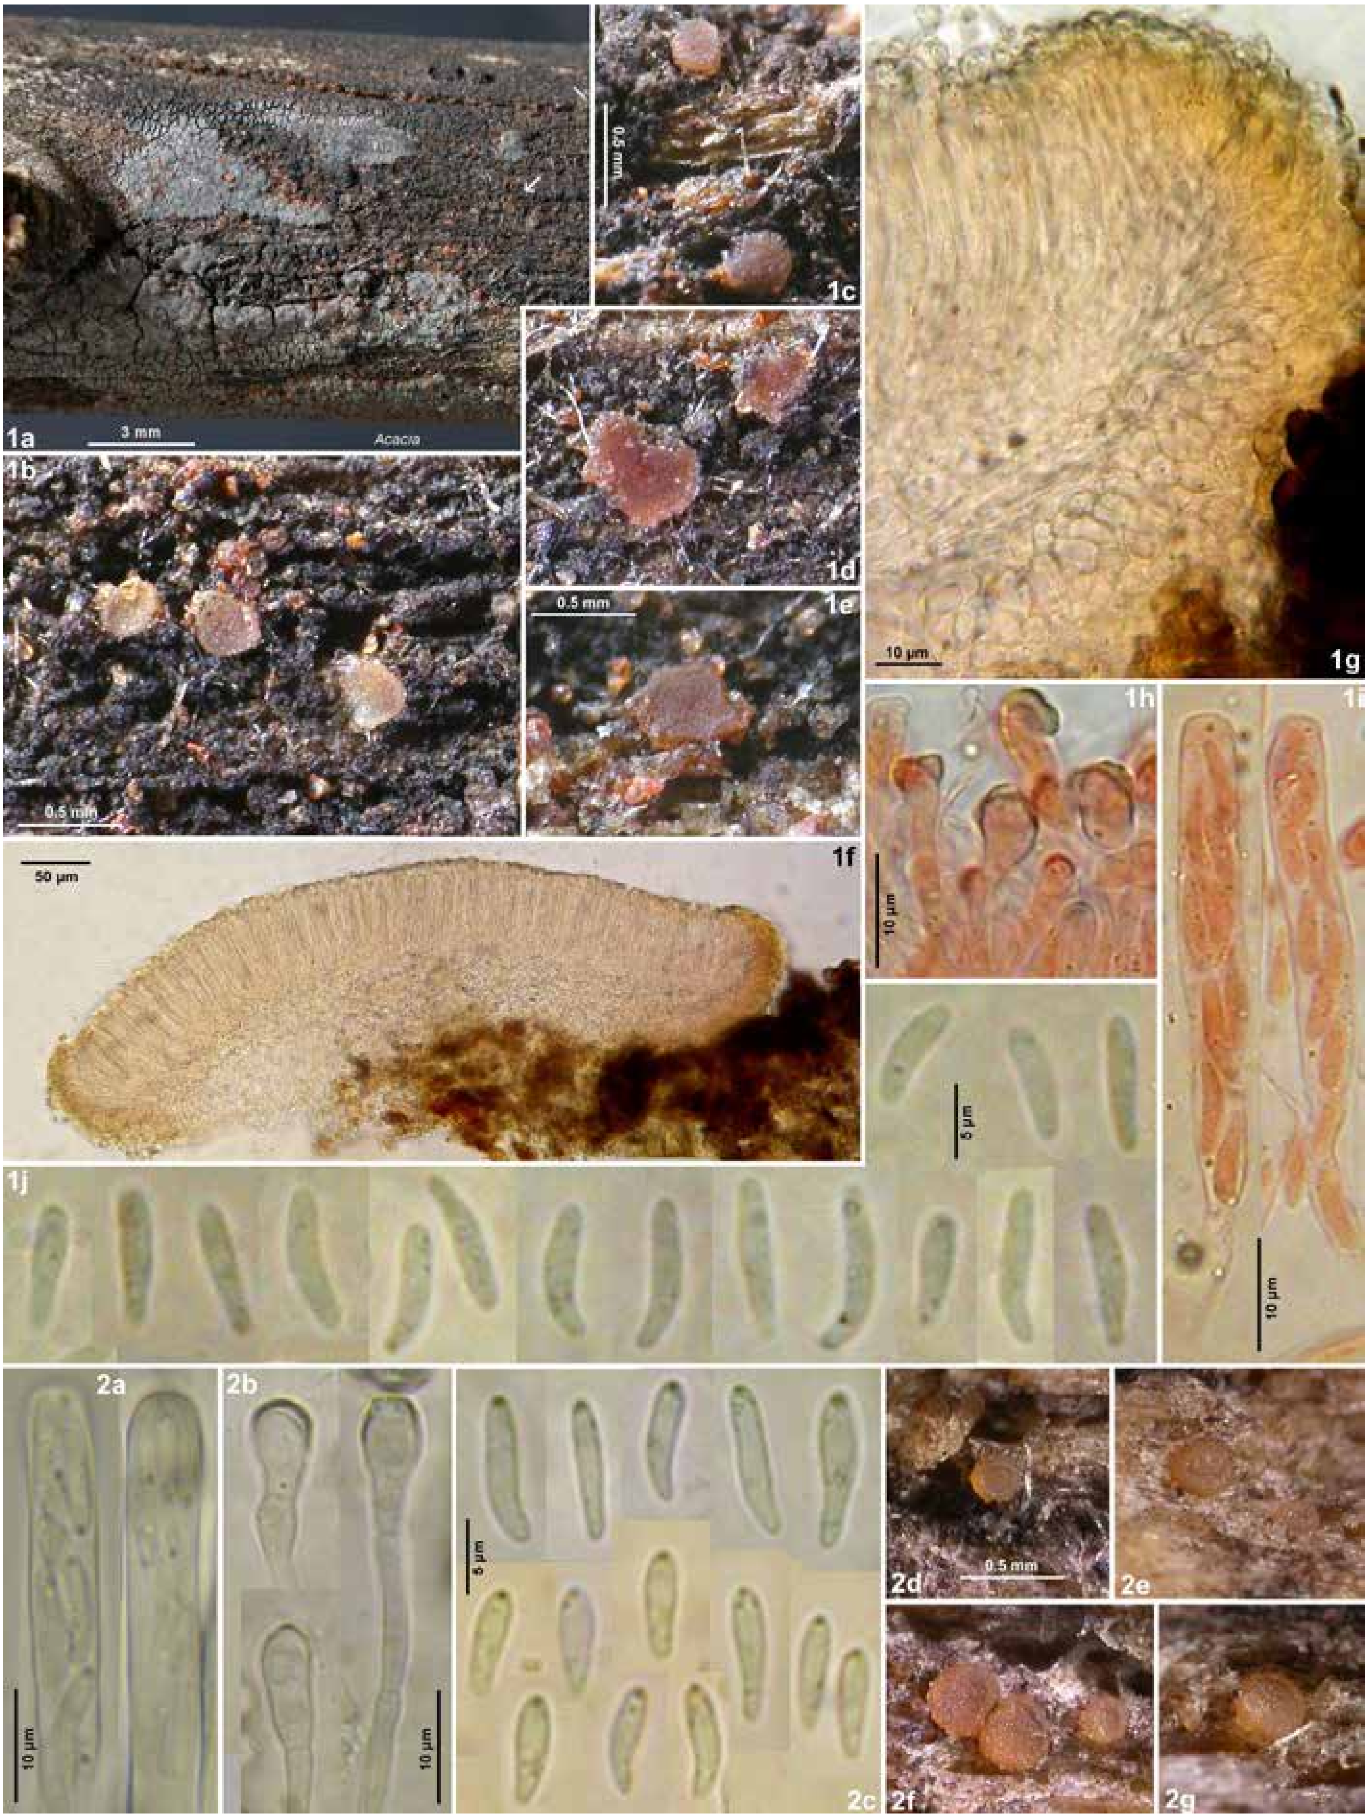

Plate 816. **1–2**: *Orbilia austropleiomicrosoma*. – **1a**. underside of xeric branch of *Acacia* lying on sandy ground; **1b–e**, **2d–g**. rehydrated apothecia (**1b–e**: after 8 years); **1f**. apothecium in median section; **1g**. id., marginal ectal excipulum; **1h**, **2b**. paraphyses; **1i**, **2a**. asci; **1j**, **2c**. ascospores. – Living state, except for **1h–i** (in KOH + CR), **1j** (KOH), **2a** (left ascus). — **1a–j**. H.B. 6277a (holotype): Australia, Northern Territories, Finke, on *Acacia*; **2a–g**. H.B. 9772c: Western Australia, Gascoyne, on *Eucalyptus*.

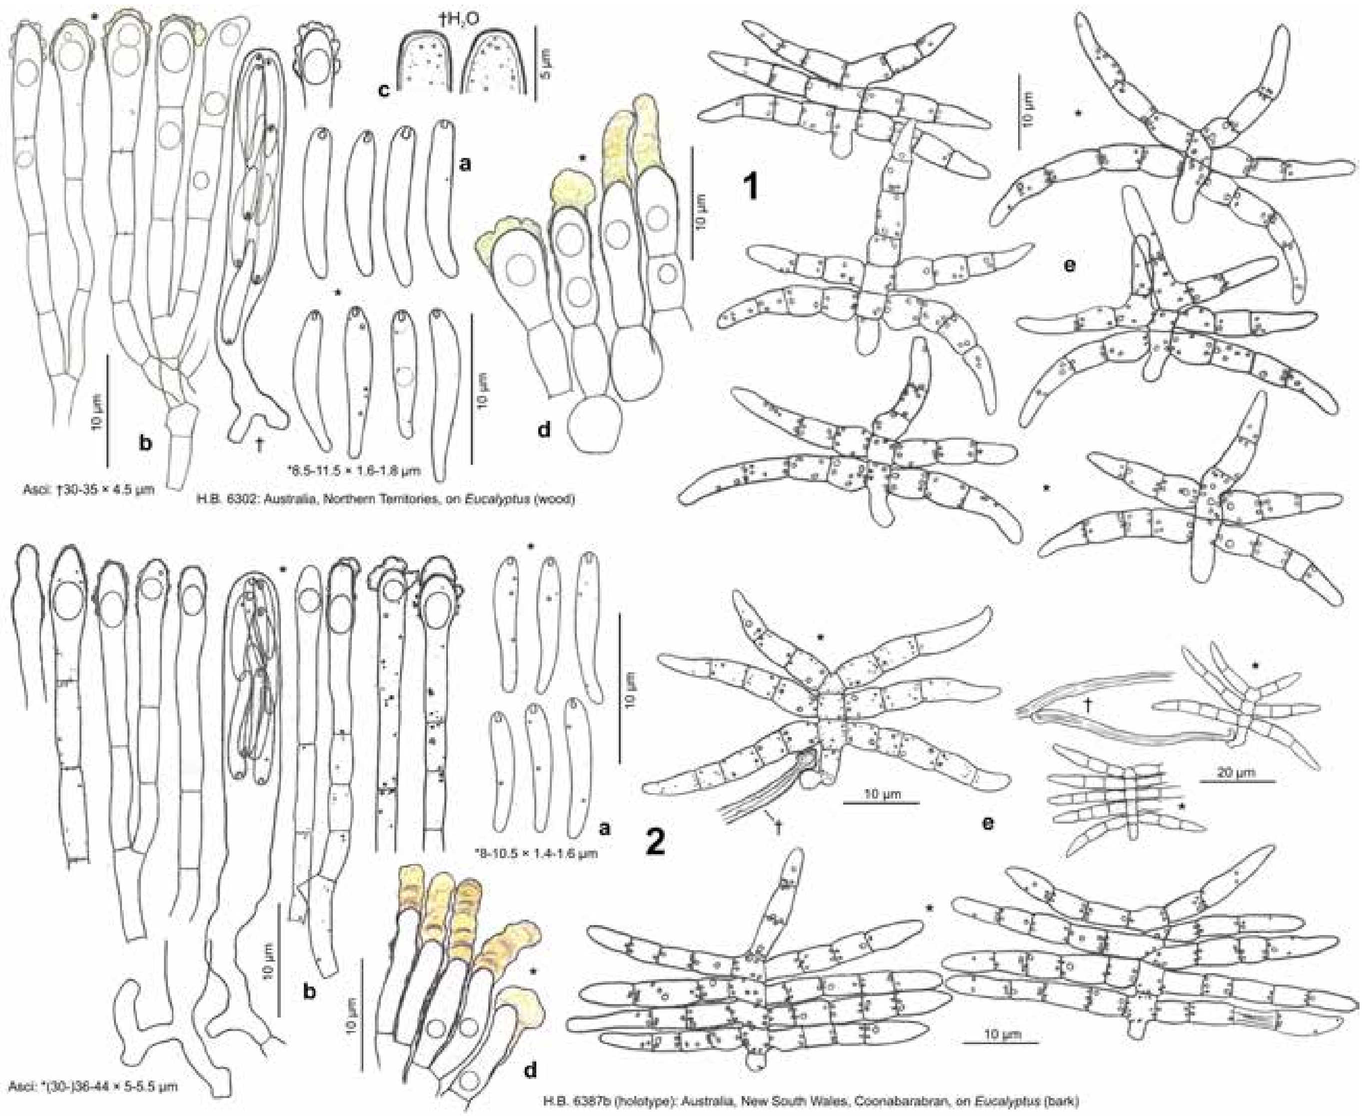

Plate 817. **1–2**: *Orbilia arachnopus*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum (median section), with glassy processes; **e**. conidia (from substrate).

cells *8–21 × 2.4–3.6 µm {2}, lower cells *4–10 × 1.7–2.5(–2.9) µm {2}; branched only near base. **Medullary excipulum** 40 µm thick, of dense textura intricata with some inflated cells, medium sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. angularis at base and flanks, 20 µm thick near base, cells †6–10 × 5–8 µm {1}; 10–15 µm thick near margin, of t. porrecta oriented at a 0–20° angle to the surface, marginal cortical cells *8–13 × 3–5 µm {2}; **glassy processes** (1–)4–9 × 2–3(–4) µm {2}, refractive, stratified, light golden yellow-chlorinaceous {2}, coherent to form small teeth. **Anchoring hyphae** abundant, *2–3.5 µm wide, walls 0.2–0.3 µm thick {2}. **SCBs** in paraphyses and ectal excipulum globose (or ellipsoid), 1.3–2.5 µm diam. {2}. **Exudate** over paraphyses 0.2–2 µm thick, rough to cloddy or cap-like, firmly attached, over glassy processes 0.2–1 µm thick, light yellow, cloddy-granular. **— ANAMORPH**: multiarmed conidia (arthropod-like, presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** with a short stipe and 4–9 arms, emerging laterally from the main axis like the legs of a spider or crab, mostly with 5–6 arms, at distal end often only one arm, sometimes 1–2 arms dichotomously branched, total size: *21–32 × 38–56 µm, stipe *3–6 × (2–)2.5–3 µm, 0–1-septate, arms *(8–)14–27 × 3–4.5 µm, (1–)3–5-septate, straight to medium curved {2}.

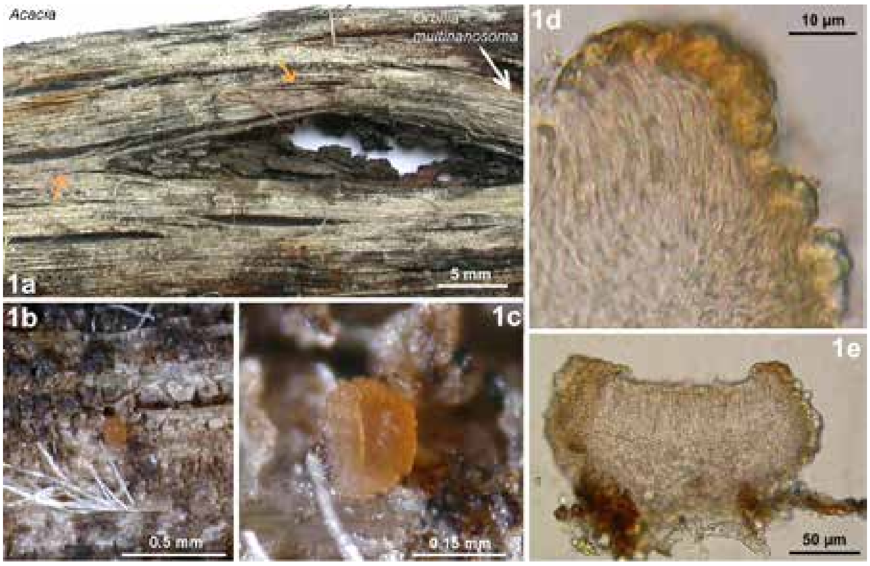

Plate 818. **1**: *Orbilia arachnopus*. – **1a**. outer surface of detached bark; **1b–c**. rehydrated apothecium; **1e**. apothecium in median section; **1d**. id., marginal ectal excipulum. – Dead state (in KOH). — **1a–e**. H.B. 6387b (holotype): Australia, New South Wales, on *Eucalyptus*.

Habitat: collected 2.5–3 m above the ground, corticated or partially decorticated, 15–17 mm thick branches of *Eucalyptus* {2}, on strongly decayed wood {1} or bark {1}, greyed, no algae. **Associated**: *Orbilia albidorosea* {1}, *O. multinanosoma* {1}, *Psiloglonium ?lineare* {1}. **Desiccation tolerance**: fully viable for at least 9.5 months, conidia viable for at least 6 months. **Altitude**: 193–540 m a.s.l. **Geology**: Jurassic sedimentary rock, Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. Within series *Microsomates*, *Orbilia arachnopus* is characterized by 8-spored asci with comparatively narrow ascospores. The similar *O. microsoma* differs in distinctly wider spores with larger SBs, longer asci, and particularly in differently shaped conidia. However, a deviating North American collection on *Pinus* mentioned under *O. microsoma* resembles *O. arachnopus* in the spores and asci, but lacks glassy processes.

O. euphorbiae (section *Aurantiorubrae*) shows some similarities to *O. arachnopus*, but differs in the always tear-shaped spore bodies (faintly visible also in the type material), a tendency to much larger apothecia, and in conidia of the *Vermispora*-type.

Not included collection. A sample on bark of *Banksia* (IVV: 18.XII.2001) fits *O. arachnopus* in the spores (*9–11 × 1.5–1.7 µm) and SBs but deviates in 16-spored asci. The specimen was only very briefly studied and not preserved and possibly it was only a narrow-spored variant of *O. austropleiomicrosoma*.

Anamorph. The staurosporous, multiarmed, arthropod-like conidia of the presumed anamorph of *O. arachnopus* somewhat resemble the 4-armed conidia of *O. microsoma* and *O. mirabilis*, but often develop more than 4 arms (up to 6–9) that emerge from a longer main axis with more septa.

Ecology. *O. arachnopus* was found on rotten wood and bark of xeric branches of *Eucalyptus* in a tropical subhumid (savannah) eucalypt open woodland in northern Australia (paratype) and a subtropical subhumid eucalypt woodland with *Acacia* and *Callitris glaucophylla* in sand dunes of southeastern Australia (west of Great Dividing Range, holotype). The not included 16-spored collection was from subtropical semihumid southwestern Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Stuart Plateau, 72 km N of Dunmarra Roadhouse, 26 km N of Daly Waters, 193 m, branch of *Eucalyptus*, on wood, 6.X.1998, G. Marson (H.B. 6302, anam. substr.). – **New South Wales**, Brigalow Belt South, 16 km S of Coonabarabran, Mendooran Road, 514 m, branch of *Eucalyptus*, on bark, 25.X.1998, G. Marson (ex H.B. 6387b, MEL 2389206A, **holotype**, anam. substr.).

Not included. **Western Australia**, Swan Coastal Plain, Perth, Kings Park, 45 m, on bark of *Banksia sessilis*, 18.XII.2001, G. Marson (ø).

Orbilia multinanosoma Baral, **sp. nov.**,

MB 813949 — Pl. 819

Etymology: named after the 32-spored asci and the ascospores containing very minute SBs.

Typification: Australia, New South Wales, Coonabarabran, branch of *Eucalyptus*, 25.X.1998, G. Marson (ex H.B. 6387a, MEL 2389206B, holotype).

Latin diagnosis: *Similis* Orbiliae myrionanosomati *sed asci 32-spori, cellulae vivae paraphysium absque corpusculis crystalloideis. Habitat ad corticem putridum rami sicci* Eucalypti *in zona subtropica subhumida Australiae meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25 mm diam., light orange-apricot, round; margin smooth; sessile. **Asci** *38–46 × 5.3–5.8 µm, 32-spored (28 counted), spores ~5–6-seriate, lower spores inverted (strongly mixed), pars sporifera *21–26 µm long; **apex** (†) strongly truncate (not indented, laterally not widened); **base** unstalked, h- (to H-)shaped. **Ascospores** *4.5–5.7 × 1.3–1.5 µm, subcylindric(-clavate) to fusoid, apex rounded to obtuse, base often slightly to medium attenuated, straight to slightly curved; **SBs** *0.4–0.5 × 0.25–0.3 µm, plug-shaped, apically broadly attached. **Paraphyses** apically medium (rarely strongly) clavate-capitate or often slightly spathulate (to sublageniform), terminal cells *(8–)10–18 × 3.3–4.8(–5.5) µm, lower cells *7–12 × 1.6–2.3(–2.6) µm; branched only near base. **Medullary excipulum** not examined. **Ectal excipulum** of thin-walled textura globulosa-angularis from base to mid flanks, at margin (upper 50 µm) of t. porrecta oriented at a low angle, marginal cortical cells †12–19 × 2.8–3.3 µm, slightly thick-walled; tipped by refractive stratified **glassy processes** 2–4 × 2–3.5 µm. **Anchoring hyphae** abundant, 2–4 µm wide, walls 0.3–1 µm thick, often slightly rough. **SCBs** in paraphyses globose, 1.2–2.3 µm wide. **Exudate** pale yellowish(-orange), over paraphyses 0.5–1.6 µm thick, cloddy, firmly attached; marginal cortical cells heavily encrusted by 0.3–1.3 µm thick yellow exudate. — **ANAMORPH**: unknown.

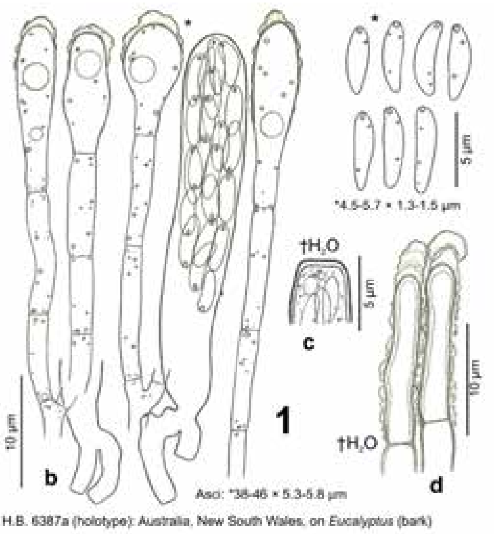

Plate 819. **1**: *Orbilia multinanosoma*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal cortical cells in surface view, with small glassy processes covered by exudate.

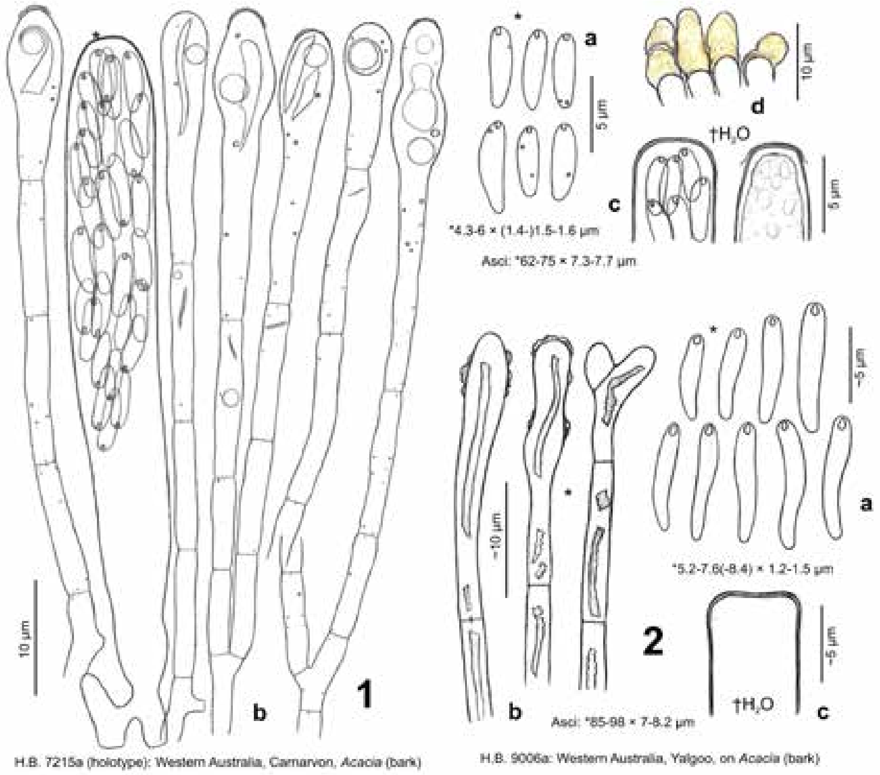
Habitat: on hanging, corticated, 17 mm thick branch of *Eucalyptus*, on outer surface of detached bark (bast), very decayed, on blackened parts around scar of broken side twig, no algae. **Associated**: *Orbilia albidorosea*, *O. arachnopus*, *Psiloglonium lineare*. **Desiccation tolerance**: fully viable for at least 7 months. **Altitude**: 514 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multinanosoma* and the similar *O. myrionanosoma* are well characterized within series *Microsomates* by comparatively small ascospores and SBs, and by multispored asci. *O. myrionanosoma* differs in much larger, 64-spored asci, slightly wider spores, and crystalloid SCBs in the paraphyses.

Ecology. The only known, very sparse collection of *O. multinanosoma* was made on rotten bark of a xeric branch of *Eucalyptus* in a subtropical subhumid eucalypt woodland with *Acacia* and *Callitris glaucophylla* in sand dunes of southeastern Australia west of Great Dividing Range.

Specimens included. **AUSTRALIA**: **New South Wales**, Brigalow Belt South, 16 km S of Coonabarabran, Mendooran Road, 514 m, branch of *Eucalyptus*, on bark, 25.X.1998, G. Marson (ex H.B. 6387a, MEL 2389206B, **holotype**).



H.B. 7215a (holotype): Western Australia, Carnarvon, *Acacia* (bark)

H.B. 9006a: Western Australia, Yalgoo, on *Acacia* (bark)

Plate 820. **1–2**: *Orbilia myrionanosoma*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal cortical cells in surface view, with glassy processes.

Orbilia myrionanosoma Baral & G. Marson, **sp. nov.**, MB 813950 — Pls 820–821

Etymology: named after the 64-spored asci and the ascospores containing very minute SBs.

Typification: Western Australia, Hamelin Pool, branch of *Acacia*, 7.XII.2001, G. Marson (ex H.B. 7215a, MEL 2389230A, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–0.65 mm diam., aurantiaca, sessilia, margine laevi vel minute aspero. Asci 64-spori. Ascosporae *4.3–8.4 × 1.2–1.6 µm, subcylindricae vel anguste ellipsoideae, basi interdum attenuatae, rectae vel leniter curvatae, corpusculum refringens minutissimum, obturamenti- vel lacrimiformem, ad apicem late vel anguste affixum continentes. Paraphyses ad apicem leniter vel modice capitato-clavatae ad spathulatae, exsudato tenui tectae. Excipulum marginale processis vitreis brevibus, hyalinis vel pallide luteis praeditum. Cellulae vivae paraphysium corpuscula globosa et crystalloidea continentes. Habitat ad corticem putridum ramorum siccorum* Acaciae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.65 mm diam., 0.25 mm thick (receptacle 0.14–0.17 mm), light (ochraceous-) orange(-rose), round to strongly compressed, scattered to subgregarious in small groups; disc slightly concave to flat, margin ± thick, 30–40 µm protruding, smooth to usually yellowish powdery rough or with minute dents; sessile, ± deeply immersed in clefts. **Asci** *62–75 {T} or 85–98 {1} × (7–)7.3–7.7(–8.2) µm {2}, †56–74 × 5.5–7.2 µm {2}, 64-spored (~40–58 spores counted), spores */†multiseriate, lower spores inverted (strongly mixed), pars sporifera *36–40 → 35 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not or distinctly widened); **base** without or with short to medium long, ± thick and flexuous stalk, h- or H-shaped. **Ascospores** *4.3–6 × (1.4–)1.5–1.6 {T} or *(4.7–)5.2–7.5(–8.4) × (1.2–)1.3–1.5 µm {2}, †4–6 × (1.1–)1.2–1.4 {T} or †(5–)6–7(–8.3) × 1.4–1.5(–1.8) µm {1}, ± subcylindrical to narrowly ellipsoid, also narrowly subcylindric-clavate, apex rounded to obtuse, base not or sometimes slightly to medium attenuated, straight to slightly curved; **SBs** *0.3–0.6 × 0.3 {T} or *0.5–0.8 × 0.3–0.4(–0.5) µm {2}, plug- {T} to tear-shaped, apically ± broadly {T} or narrowly attached. **Paraphyses** apically mostly slightly to medium clavate-capitate to often spathulate, sometimes lageniform to moniliform, terminal cells *(12.5–)14–27(–32) × (2.5–)3.5–5(–5.4) µm {T}, †14–30(–37) × (2–)2.5–4.5(–5) µm {2}, lower cells *7–15 × 1.8–2.5 µm {T}, †7–12 × 1.6–2 µm {1}; unbranched at upper septa, exceptionally branched at the very apex. **Medullary excipulum** 130 µm thick, of medium dense textura intricata with many ± distinctly inflated cells, sharply delimited at flanks. **Ectal excipulum** of (†) non- to medium gelatinized [common walls †0.5–1(–1.5) µm], vertically oriented t. angularis(-globulosa) from base to mid flanks, 30 µm thick near base, cells †6–14 × 4–10 µm {2}, hyaline, from flanks to margin light yellowish-ochraceous; 15–20 µm thick at lower flanks, of t. angularis(-prismatica) oriented at a 60–80° angle, 15 µm thick at mid flanks, of t. prismatica oriented at 30–50°, 25 µm thick at margin, of t. porrecta oriented at 0–20°, marginal cortical cells †8–15 × 2.2–4.3 µm {2}; **glassy processes** 2–15 × (2.3–)2.7–4(–5) µm {3}, low- to medium refractive in KOH, hyaline to pale or light amber-yellow, stratified, straight or often outwards curved, not forming discrete teeth. **Anchoring hyphae** (very) abundant, †(2–)2.5–2.8(–3) µm wide, walls 0.2–0.4 {T} or 0.3–0.8 µm thick {1}. **SCBs** in paraphyses globose, 1.5–2.5 µm diam., associated with low-refractive, large, hyaline crystalloid SCBs (rod- or ring-shaped) {3}. **Exudate** over paraphyses, margin and flanks 0.1–1 µm thick, finely rough, hyaline to pale yellowish, firmly attached, in ectal excipulum towards margin with yellowish-ochraceous intercellular exudate {2}. — **ANAMORPH**: unknown.

Habitat: collected 1–1.2 m above the ground, corticated, ~1–4 cm thick branches of *Acacia* sp. {3}, on outer or inner surface of attached or detached bark, sometimes immersed in clefts, on medium to strongly decayed bark {3} (bast), greyed, no algae. **Associated**: *Orbilia ?mirabilis* {1}, *O. ?multiserpens* {1}, *O. myriofusiclava* {1}, *O. myriohesperidea* {1}, *O. myriomuscula* {1}, *O. myriopseudoregalis* {1}, *O. pleioaustraliensis* {1}, *O. ?pleioserpens* {1}. **Desiccation tolerance**: fully viable after 33 months. **Altitude**: 67–540 m a.s.l. **Geology**: Mesoproterozoic and Cretaceous sedimentary rock (red-brown sand & gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myrionanosoma* resembles *O. myriopseudoregalis*, with which it grew in association, and even more closely the 32-spored *O. multinanosoma* (for the differences see under these species). The 64-spored *O. myriella* (section *Habrostictis*) has a spore size and shape similar to *O. myrionanosoma* but differs in filiform SBs which attain a length of ⅓ to ½ of the spore length, and in the absence of both glassy processes and crystalloid SCBs.

Variation. In the two paratype collections (Pls 820: 2; 821: 2–3) which are tentatively included in *O. myrionanosoma*, the SBs are slightly larger and a little tear-shaped, though closely connected to the spore apex and not by a short filum as in *O. myriopseudoregalis*. Further features by which these collections deviate from the holotype involve longer asci and spores, and a tendency to less inflated paraphyses. Spore size in one of them (Pl. 821: 3) is somewhat intermediate, however [*(4.7–)5.3–7.1 × 1.3–1.5 µm].

Ecology. The three known very sparse collections of *O. myrionanosoma* were made on medium decayed bark of xeric branches of *Acacia* in subtropical semiarid acacia (open) shrublands (mulga) and a subtropical semiarid acacia open woodland with *Eucalyptus* in a dry riverbed in the Gascoyne ecoregion of western Australia.

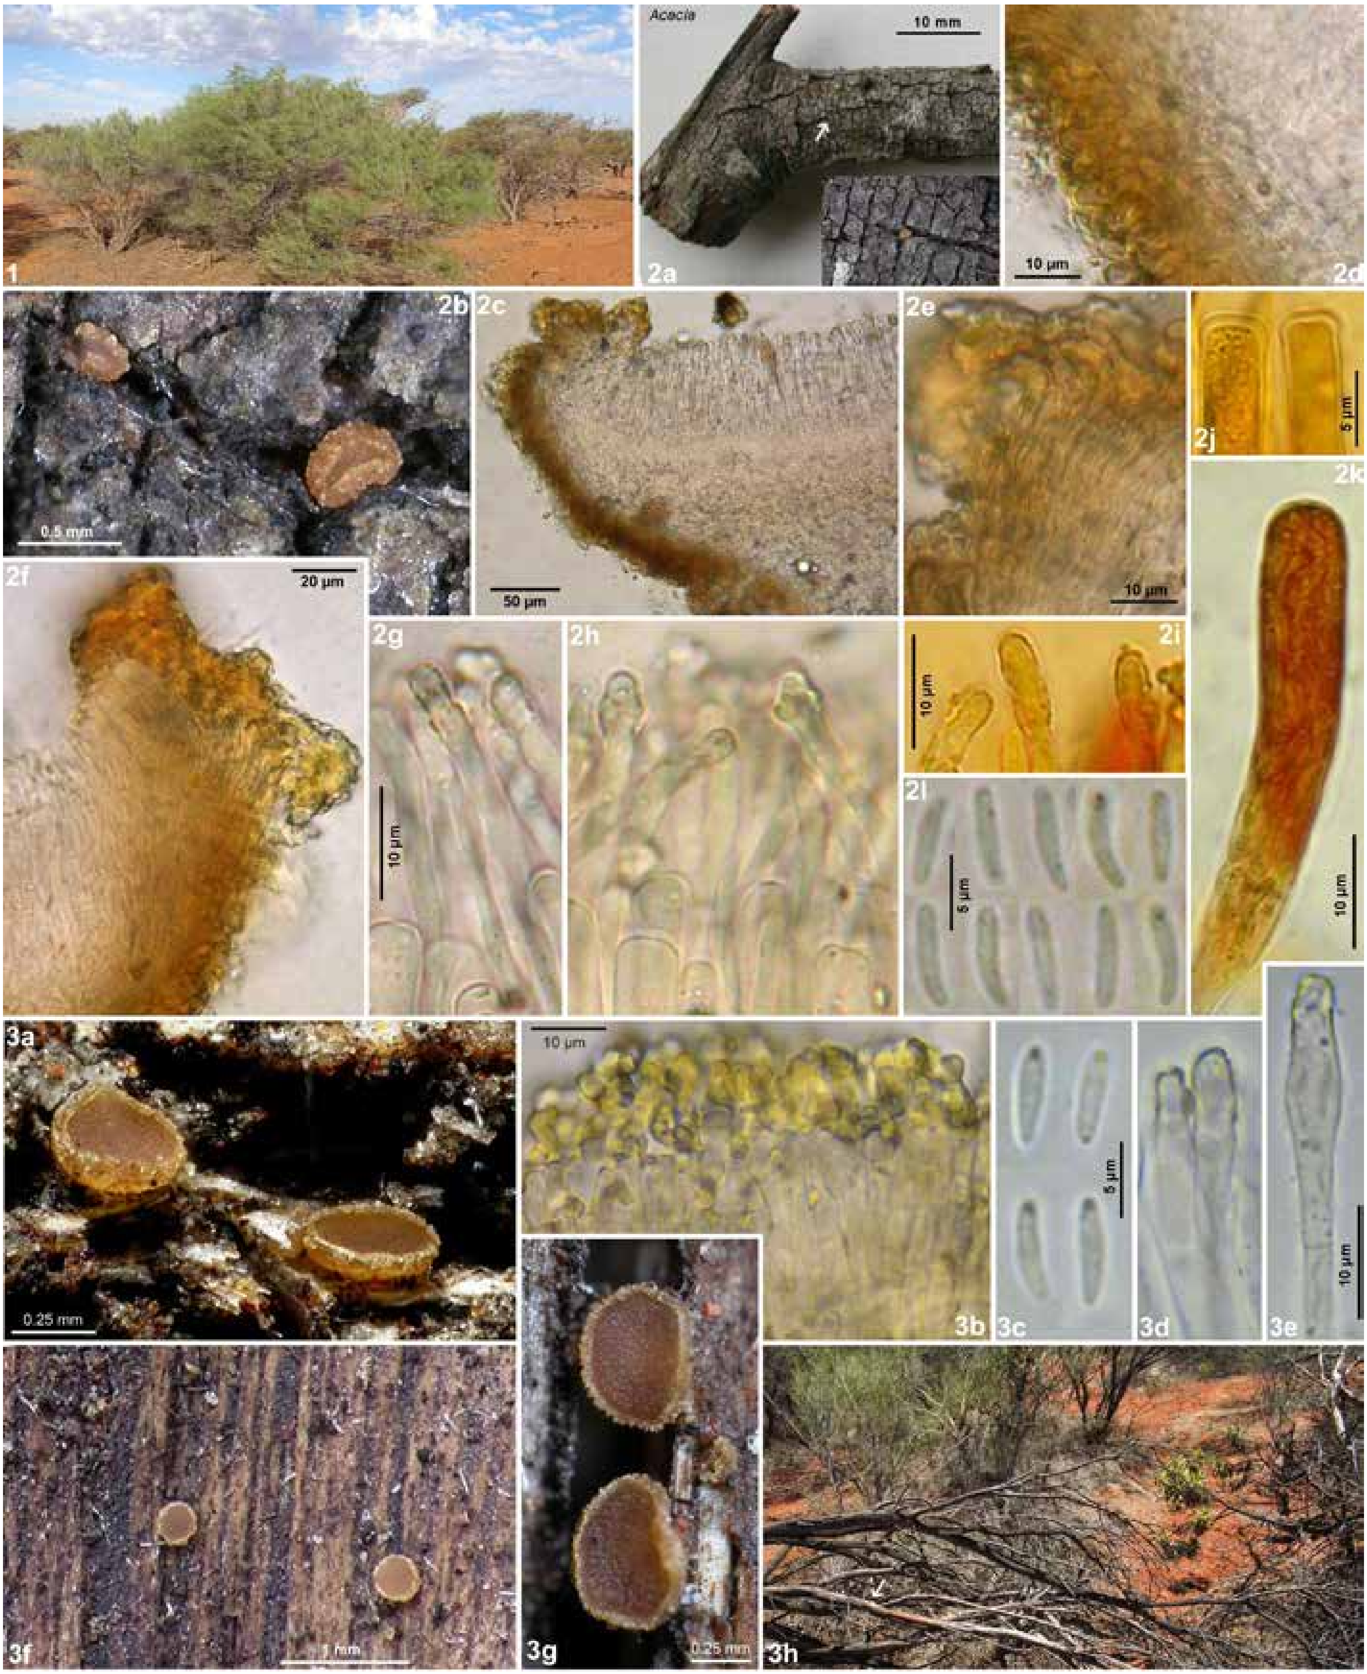


Plate 821. **1–3**: *Orbilia myrionanosoma*. – **1**. semiarid acacia shrubland (mulga); **3h**. arid acacia open woodland with dead parts of *Acacia* in a dry riverbed; **2a**. dead corticated xeric branch of *Acacia*; **2b**, **3a**, **f–g**. rehydrated apothecia (**2**: after > 7 years, **3**: after < 3 months); **2c**. apothecium in median section; **2e**, g. id., marginal ectal excipulum; **2d**. id., at flanks; **3b**. margin with glassy processes; **2k**. mature ascus; **2j**. apices of immature asci; **2g–i**, **3d–e**. apices of paraphyses (and asci); **2l**, **3c**. ascospores. – Living state, except for **2c–h**, **l** (in KOH), **2i–k** (in KOH+IKI). — **1**. Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, 67 m, branch of *Acacia*, on bark, 7.XII.2001, G. Marson (ex H.B. 7215a, MEL 2389230A, **holotype**). – Yalgoo, 200 km N of Geraldton, 15 km SSE of Wannoo Billabong Roadhouse, W of Toolonga, 157 m, branch of *Acacia*, on bark, 8.XII.2001, G. Marson (H.B. 9006a). – Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Acacia*, on bark, 28.X.2007, G. Marson (H.B. 9695k ø).

Orbilia mirabilis Baral, G. Marson & E. Weber, **sp. nov.**, MB 813951 — Pls 822–823

Etymology: referring to the appealing apothecia with prominent marginal teeth. **Typification**: Western Australia, Illawong, branches of *Acacia*, 9.XI.2007, G. Marson (ex H.B. 8996a, MEL 2389270, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–1.2 mm diam., lateritio-aurantia, (sub)sessilia, margine exigue albido-dentata. Asci 32-spori. Ascosporae *8–14 × 1.5–1.7 µm, (sub)cylindricae, ad basim vix attenuatae, leniter ad valde curvatae, corpusculum refringens minutum, obturamenti- vel ampulliformem, ad apicem subanguste affixum continentes. Paraphyses ad apicem lageniformes, exsudato tenui tectae. Excipulum marginale processis vitreis longis hyalinis agglutinatis, deorsum curvatis praeditum. Cellulae paraphysium in statu vivo corpuscula globosa et crystalloidea continentes. Habitat ad corticem separatum putridum ramorum siccorum* Acaciae *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.65(–1.2) × 0.2–0.4(–0.75) mm (incl. teeth), (0.12–)0.15–0.2 mm high (receptacle 0.11–0.16 mm), pale to mostly light to bright brick-red-orange, non-translucent, round to often elliptical, scattered or often subgregarious; disc slightly concave to flat, margin with prominent whitish teeth ~50–150 × 27–50 µm, always strongly outwards curved, protruding (30–)40–60 µm beyond disc; broadly sessile or with a short obconical stipe 0.07–0.15 × 0.16–0.2 mm, superficial or somewhat erumpent from cracks in bast; dry ± completely closed by the incurved margin and teeth (hysterioid). **Asci** *~65–80 × 6.3–6.7 µm {1}, †55–76 × (5.2–)5.5–6 µm {2}, 32-spored (25–28 spores counted), spores *~4–5-seriate, especially the lower spores inverted {very strongly mixed}, pars sporifera *43–45 µm long; **apex** (†) slightly to strongly (subconico-)truncate (never indented nor inflated), (subconico-) hemispherical in profile view; **base** with rather short and thick, flexuous stalk, L- to h-shaped. **Ascospores** *(8–)9.5–11(–14) × (1.5–)1.6–1.7(–1.8) µm {T}, †8–11(–12) × 1.4–1.6 µm {2}, (sub)cylindrical, apex rounded to obtuse, base not or only slightly attenuated, slightly to strongly curved (predominantly near base, partly geniculate); **SBs** *0.8–1.2(–1.4) × 0.4–0.5 µm {T}, rod- to dumbbell-shaped or ampulliform, apically attached by a ± wide point, straight. **Paraphyses** apically not or usually slightly to medium inflated (lageniform), with thick, short (sometimes long), often ± flexuous or slightly nodding beak, terminal cells *20–30(–36) × 3–4.7 µm {T}, †2.5–3.5(–4.7) µm wide {T}, exceeding the dead asci by 3–13 µm, lower cells *10–16 × 2–2.6 µm {T}; never branched at upper septum. **Medullary excipulum** hyaline, 40–80 µm thick, of medium loose textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** hyaline near base, of (†) ± thin-walled, ± vertically oriented t. globulosa(-prismatica), 30–60 µm thick, cells *10–19(–23) × 7–12 µm {T}; at lower and mid flanks of 15–20 µm thick vertically oriented t. angularis(-prismatica), bright yellow-ochre in outer part, cells *5–8(–13) × 3–5 µm, at submargin of t. prismatica oriented at a 30–40° angle, at upper margin of 20–30 µm thick t. porrecta oriented at 10–30°, marginal cortical cells *12–15 × 3–4 µm {T}; **glassy processes** (4–)10–65(–100) × 2.5–3.5(–5) µm {2}, high-refractive, stratified in KOH, strongly curved outwards under a rather wide arch, strongly coherent to form distinct teeth. **Anchoring hyphae** ± abundant, †2–3(–3.5) µm wide, walls 0.2–0.4 µm thick {T}. **SCBs** in paraphyses globose and often also rod-shaped to plate-like or angular {T}, low-refractive, hyaline, in ectal excipulum not observed; **LBs** in paraphyses sparse, pale yellow (carotenoids), 0.5–1 µm diam., especially near septa. **Exudate** over paraphyses 0.2–0.3 µm thick, finely rough, firmly attached, over glassy processes 0.2–2 µm thick, pale yellowish, at lower and mid flanks 1–2 µm thick, gel-like, bright yellow-ochre. — **ANAMORPH**: arthropod-like (presumed, from natural substrate {2}). **Conidiophores** not observed. **Conidia** ¥-shaped (like a 'K'), of the monopodial type, with 4 arms emerging from a central main axis with a very reduced central stipe, branching type monopodial, sometimes with a small nipple-like protrusion opposite to the stipe, total size *10–14(–17) × (24–)29–36 µm, stipe *1–2.2 × 2–3 µm (main axis 6.5–9 µm long), arms *(12–)14–17 × 3–3.5(–4) µm, straight, 2–4-septate, containing large LBs 1–1.5(–2) µm diam. {2}.

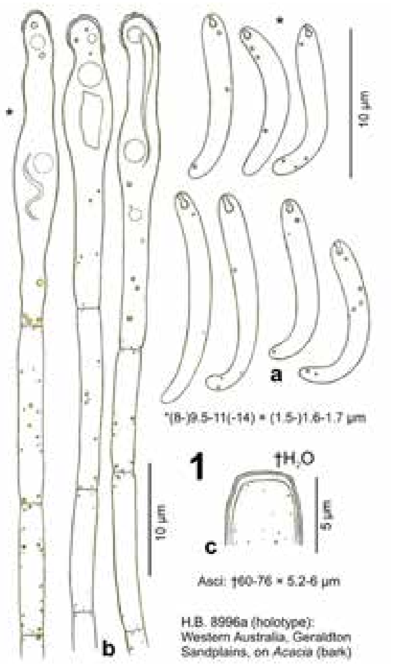

Plate 822. **1**: *Orbilia mirabilis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

Habitat: collected 0.8–2 m above the ground, ~30–45 mm thick branches of *Acacia* sp. {2}, on inner surface (rarely on edges or outer surface) of detached bark {2}, medium decayed, ± greyed, no algae. **Associated**: *Orbilia commarosa* {2}, *O. eucalypti* {1}. **Desiccation tolerance**: excipular cells, paraphyses, immature asci, ascospores and conidia still viable after 15 months. **Altitude**: 6–7 m a.s.l. **Geology**: Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia mirabilis* is easily recognized by its prominent, outwards curved, whitish teeth, 32-spored asci, and consistently curved ascospores. It differs from the 16-spored *O. austropleiomicrosoma* also in narrower spores and much longer glassy processes. In its spores, paraphyses and marginal glassy processes *Orbilia mirabilis* closely resembles species of series *Regales* (section *Aurantiorubrae*), e.g. *O. euphorbiae* or *O. carnegieae*. However, we have never seen members of that series with asci other than 8-spored. With its large outwards curved teeth *O. mirabilis* resembles the 64-spored *O. myriopseudoregalis* of the present series, whereas the marginal teeth within series *Regales* are more irregularly or indistinctly curved and usually also shorter.

Variation. The two included, geographically very close collections concurred quite well in their morphology.

Not included collection. A sample of the Australian midwest (Gascoyne) was only briefly examined in the dead state (IVV: 28.X.2007): apart from slightly shorter spores seen only inside the asci, its features are those of *O. mirabilis*, yet the shape of SBs and SCBs is unknown. It might instead be a 32-spored variant of *O. myriopseudoregalis*, but its paraphyses are predominantly lageniform.

Anamorph. The conidia associated with *O. mirabilis* resemble those 4-armed, ¥- or K-shaped conidia of *O. microsoma* but differ in much shorter, nearly reduced, aseptate stipes. With this presumed anamorph *O. mirabilis* fits very well series *Microsomates* but not series *Regales*.

Phylogeny. Sequences were gained from two different apothecia on the same piece of bark in the paratype, comprising ITS and LSU D1–D3 (the S1506 intron is absent). A few

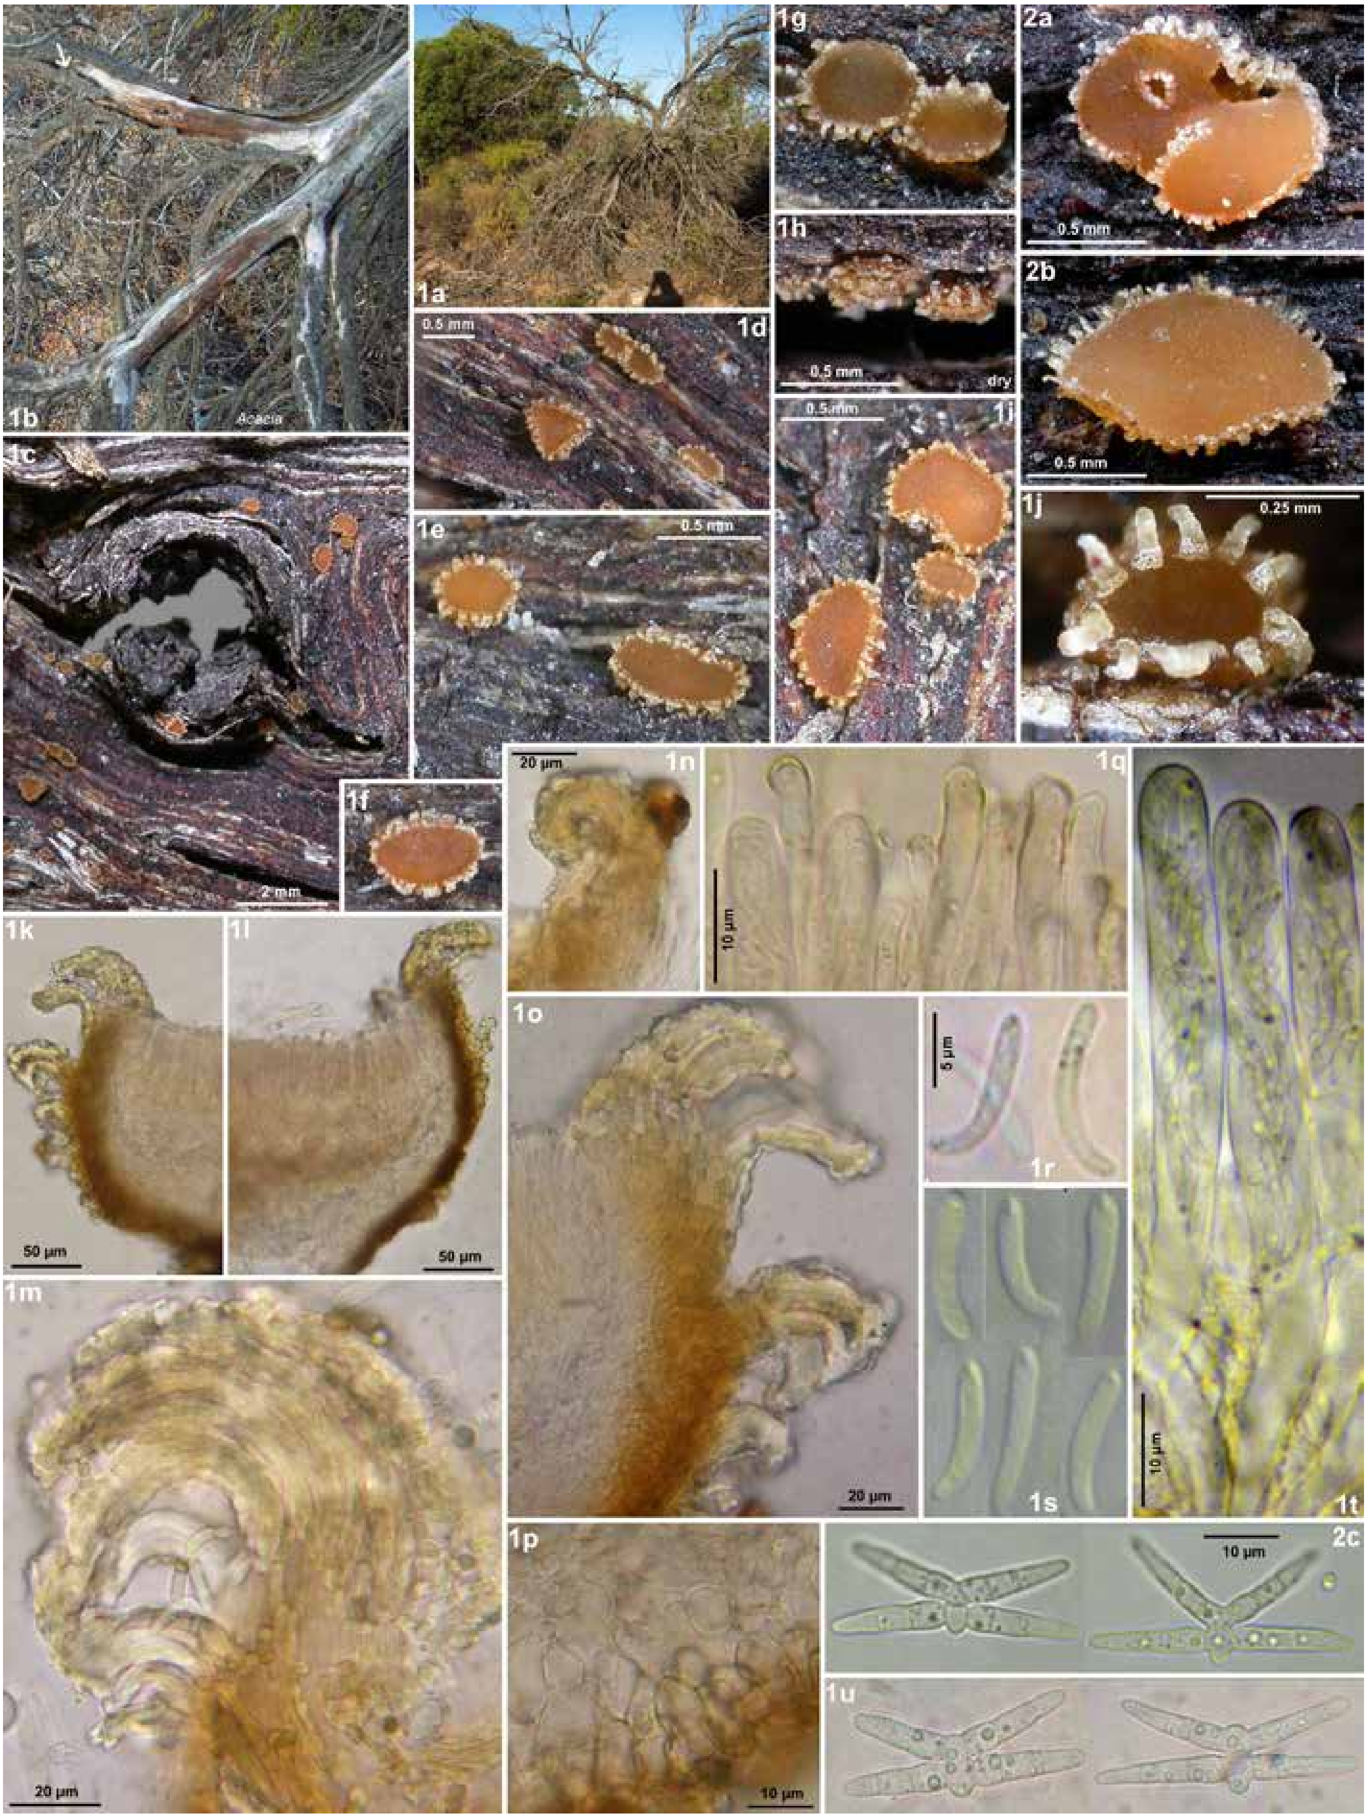

Plate 823. **1–2**: *Orbilia mirabilis*. – **1a**. semihumid acacia shrubland with dead *Acacia* shrub; **1b**. dead xeric branches of *Acacia* with loosely adhering bark; **1c–g**, **i–j**, **2a–b**. rehydrated apothecia on inner surface of bark; **1h**. dry apothecia; **1k–l**. apothecia in median section; **1m–o**. id., marginal ectal excipulum with outwards curved glassy processes; **1p**. id., lower flanks of ectal excipulum; **1q**. apices of paraphyses and asci; **1t**. mature asci; **1r–s**. ascospores; **1u**, **2c**. conidia from substrate. – Living state, except for **1q**, **r** (in H_2O). — **1a–u**. H.B. 8996a (holotype): Western Australia, Geraldton Sandplains, on *Acacia*; **2a–c**. H.B. 9582a: ibid., on *Acacia*.

deviating nucleotides were observed between the two sequences: in the ITS1 4 nt and 3 inserts, and in the LSU D1 domain 2 nt. Therefore, both sequences were uploaded. *O. mirabilis* differs in the ITS by 12–13 % from *O. microsoma* as well as *O. pleiomicrosoma*, and in the LSU D1–D2 by 3.3–3.6 % from *O. microsoma*.

Ecology. *Orbilia mirabilis* was detected on the medium rotten inner surface of xeric bark more or less detached from branches of dead, partly broken, large shrubs of *Acacia*. The two very close sites are located in the coastal subtropical semihumid acacia shrubland of Geraldton Sandplains in southwestern Australia, 330–340 m from the sea shore. The not included collection was in a subtropical semiarid acacia open woodland with *Eucalyptus* in a dry riverbed in the Gascoyne ecoregion in western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Geraldton Sandplains, 90 km SSE of Geraldton, 21 km N of Illawong, 6 m, branches of *Acacia*, on bark, 9.XI.2007, G. Marson (ex H.B. 8996a, MEL 2389270, **holotype**, anam. substr.). – 96 km SSE of Geraldton, 15 km N of Illawong, 7 m, branch of *Acacia*, on bark, 10.XI.2007, G. Marson (H.B. 9582a, anam. substr., sq.: KT380094, MH221068).

Not included. **Western Australia**, Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Acacia*, on bark, 28.X.2007, G. Marson (ø).

Orbilia myriopseudoregalis Baral & G. Marson, **sp. nov.**, MB 813952 — Pl. 824

Etymology: named after the crown-like marginal teeth and the spore body shape that are both reminiscent of a member of series *Regales*.
Typification: Western Australia, Hamelin Pool, branch of *Acacia*, 7.XII.2001, G. Marson (ex H.B. 7215b, MEL 2389230B, holotype).

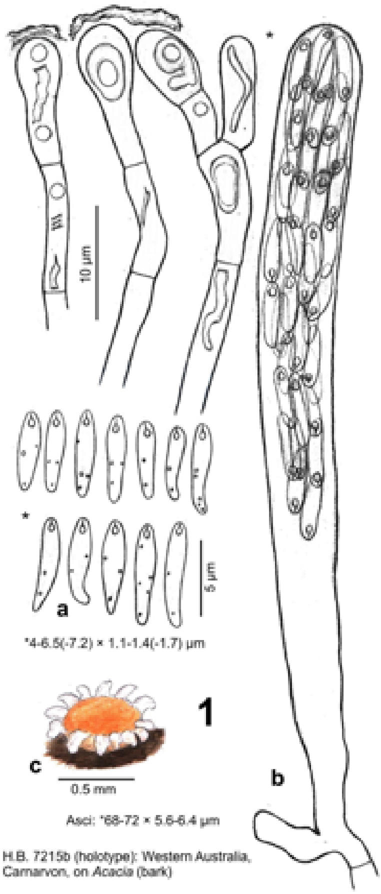

Plate 824. **1**: *Orbilia myriopseudoregalis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. apothecium (rehydrated).

Latin diagnosis: *Similis* Orbiliae myrionanosomati *sed corpuscula refringentia ascosporarum longiora, subglobosa ad lacrimiforme, filo brevi affixa, excipulum marginale processis vitreis perlongis, agglutinatis praeditum. Habitat ad corticem putridum rami sicci* Acaciae *in zona subtropica arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–0.6 mm diam. (0.6–0.7 mm incl. teeth), hardly translucent, round, scattered; disc light orange, slightly concave to flat, margin with prominent white teeth 100–150 × 40–80 µm, strongly protruding beyond hymenial surface; broadly sessile, superficial. **Asci** *68–72 × 5.5–6.5 µm, †4.3–4.8 µm wide, 64-spored (52–64 spores counted), spores (*) multiseriate, lower spores inverted (strongly mixed), pars sporifera *41 µm long; **apex** (†) strongly truncate (not distinctly indented, immature laterally distinctly inflated); **base** attenuated in a short stalk, T- or L-shaped. **Ascospores** *(4–)5–6.5(–7.2) × (1–)1.1–1.4(–1.7) µm, subcylindrical to often fusoid or fusoid-clavate, apex obtuse, base slightly to medium attenuated, straight to slightly or medium curved near base; **SBs** *0.8–1.2 × 0.3–0.5 µm, subglobose to tear-shaped, apically narrowed in a very short filum. **Paraphyses** apically uninflated or mostly slightly to medium clavate, also sublageniform, terminal cells *6.5–13 or 14–26 × 3–4.7 µm, †2–3 µm wide, lower cells *~(6–)8–15 × 1.8–3.3 µm; sometimes branched at upper septum. **Medullary excipulum** not studied. **Ectal excipulum** of textura angularis from base to mid flanks, (*) thin-walled, (†) slightly to medium gelatinized (common walls 0.5–1.5 µm thick), cells at flanks *5–9.5 × 5–8 µm, †5–8 × 4–6 µm, walls light ochre-yellow, near margin of t. porrecta oriented at a low angle to the surface, marginal cortical cells †7–15 × 2–3 µm; **glassy processes** 10–120 × 2.5–3.5(–4) µm, high-refractive, stratified in KOH, predominantly curved downwards (partly uncinate), coherent to form distinct teeth. **Anchoring hyphae** very abundant, †2–3.5 µm wide, walls 0.2–0.4(–0.8) µm thick, hyphae at flanks hair-like. **SCBs** in paraphyses and ectal excipulum (on margin an flanks) globose, 0.8–1 µm diam., and rod- or ring-shaped; in paraphyses with scattered pale yellowish **LBs** up to 1.5 µm diam. (carotenoids). **Exudate** over paraphyses ~0.5–1.3 µm thick, rough, loosely attached, on glassy processes absent but on hyphae at flanks rough cloddy, 0.5–1.5 µm thick, firmly attached. — **ANAMORPH**: unknown.

Habitat: corticated, ~4 cm thick xeric branch of *Acacia*, on inner surface of detached bark, on medium decayed bast, greyed, no algae. **Associated**: *Orbilia ?multiserpens*, *O. myriofusiclava*, *O. myrionanosoma*, *O. pleioaustraliensis*, *O. ?pleioserpens*. **Desiccation tolerance**: paraphyses still alive after 10 months. **Altitude**: 67 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriopseudoregalis* differs from *O. myrionanosoma*, which grew on the outer surface of the same piece of bark, in prominent marginal teeth made up of long glassy processes, and in slightly narrower ascospores containing longer tear-shaped SBs with a distinct short filum. The SBs resemble those in series *Regales*, but that group so far contains only members with 8-spored asci and shows never crystalloid SCBs. Since *O. myriopseudoregalis* otherwise closely matches *O. myrionanosoma*, we believe that it belongs to series *Microsomates*. In the marginal teeth and SB-shape *O. myriopseudoregalis* resembles *O. mirabilis.*

The very sparse apothecia in the holotype are predominantly strongly overmature, without hymenial elements. Apparently only the one apothecium studied in the living state was in good condition.

Ecology. *O. myriopseudoregalis* was only found a single time, on medium decayed bark of a xeric branch of *Acacia* in a subtropical arid acacia open shrubland of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, Denham-Hamelin Rd, 67 m, branch of *Acacia*, on bark, 7.XII.2001, G. Marson (ex H.B. 7215b, MEL 2389230B, **holotype**).

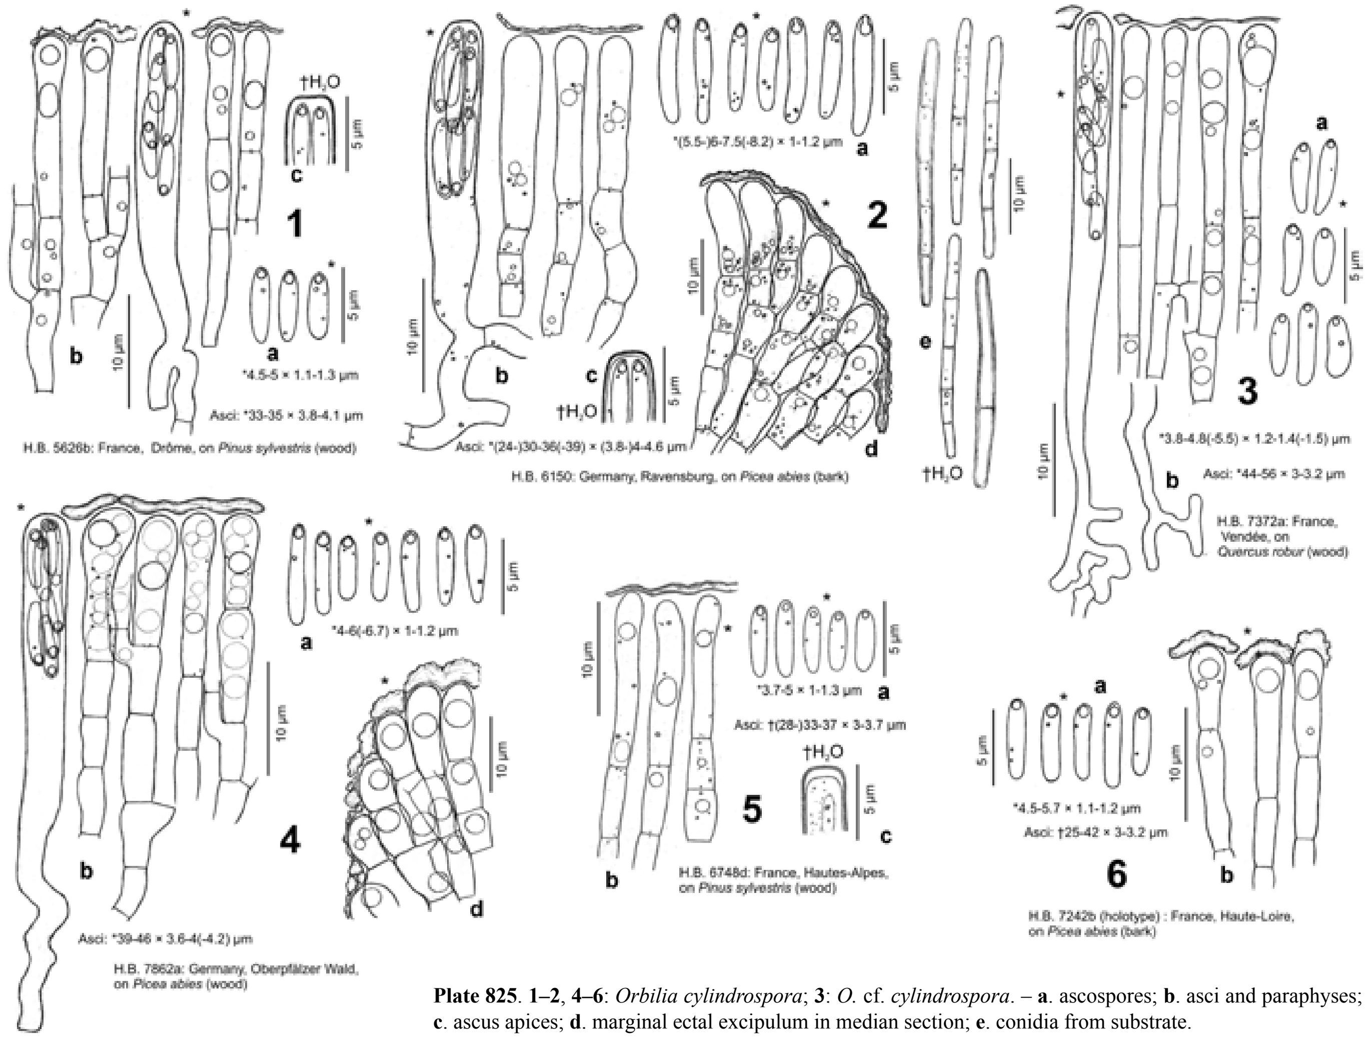

Plate 825. **1–2**, **4–6**: *Orbilia cylindrospora*; **3**: *O.* cf. *cylindrospora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section; **e**. conidia from substrate.

Incertae sedis (*O. cylindrospora* group)

Orbilia cylindrospora Baral, E. Weber & G. Marson, **sp. nov.**, MB 813921 — Pls 825–826, Map 133

Etymology: named after the cylindrical ascospores.

Typification: France, Le-Puy-en-Velay, Cayres, branches of *Picea abies*, 4.X.2002, G. Marson (ex H.B. 7242b, M-0276470, holotype).

Latin diagnosis: *Apothecia rehydratata 0.15–0.7 mm diam., pallide roseo-ad albido-cremea, sessilia, margine laevi vel leniter aspero. Asci 8-spori. Ascosporae *3.7–8.2 × 1–1.5 µm, plus minusve cylindricae, apice rotundatae ad obtusae, subrectae, corpusculum refringens globosum vel late lacrimiformem, ad apicem confertim affixum continentes. Paraphyses ad apicem non vel leniter clavato-capitatae. Excipulum marginale absque processis vitreis, exsudato valido tectum. Habitat ad lignum putridum, raro corticem, ramorum vel truncorum siccorum coniferarum, raro angiospermarum, in zona boreale ad orotemperata et orosub- vel suprasubmediterranea humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.12–)0.15–0.5(–0.65) mm diam., 0.09–0.14 mm high, pale to light rose, rose-cream, also whitish to cream-isabelline, ± translucent, round to slightly undulating, scattered to (sub)gregarious; disc flat, rarely up to medium convex, margin indistinct or thin, 0–5 µm protruding, smooth or finely rough; broadly sessile or sometimes with an obconical base, superficial; dry light orange(-rose) to pink. **Asci** *(24–)33–46 {5} × 3.4–4(–4.2) {3} or 4–4.6 {2} µm, †(24–)28–37(–42) × (2.8–)3–3.7(–4.2) µm {6}, 8-spored, spores *2–4-seriate, (1–)3–5(–6) lower spores inverted {4} (± mixed), pars sporifera *13–18 µm long; **apex** (†) (slightly to) medium to strongly truncate (never or sometimes very slightly indented, laterally not inflated); **base** with short to long, gradually tapered, flexuous stalk, L- to often h-shaped. **Ascospores** *3.7–5(–5.7) {5} or (4–)5–7(–8.2) {4} × (1–)1.1–1.3(–1.5) µm {9}, †(3–)4–5 {2} or 6–7.8 {1} × 0.8–1.2 µm {3}, (sub)cylindrical, rarely slightly (ob)clavate with slightly to medium attenuated base, apex rounded to obtuse, straight, sometimes (very) slightly curved; **SBs** *0.4–0.6 {1} or 0.6–0.8 {5} µm diam., total length ~0.5–0.7 {1} or 0.7–1(–1.3) {4} µm, globose to broadly tear-shaped, rarely ampulliform, closely attached to spore apex, partly apically narrowed to a small (exceptionally wide) point, or attachment invisible. **Paraphyses** apically uninflated or slightly (exceptionally medium) clavate-capitate, terminal cells *(7.5–)9–17 × 1.9–3.2(–4) µm {6}, lower cells *((2–))(3–)5–8(–11) × (1.8–)2–2.5(–3.2) µm {6}; rarely branched at upper septum. **Medullary excipulum** 35–50 µm thick, of medium dense textura intricata with many inflated cells, indistinctly delimited. **Ectal excipulum** of thin-walled, indistinctly, rarely vertically oriented t. globulosa-angularis from base to mid flanks, 20–35 µm up to 40–60 µm thick near base, cells *(6–)8–13(–16) × (4–)6–10(–14) µm {6}; 15–20 µm thick near margin, of t. prismatica(-porrecta), rarely t. prismatica-angularis, oriented at a 30–45° angle to the surface, marginal cortical cells */†6–10(–12) × (2–)2.5–4.5(–6) µm {4}; **glassy processes** absent. **Anchoring hyphae** mostly abundant, */†(1.7–)2–2.5(–3) µm wide, walls 0.2(–0.3) µm thick {2}. **SCBs** globose, in paraphyses (0.5–)1.3–2(–3) µm diam., in marginal excipulum 1.5–3.5 µm {7}; lower excipular cells sometimes with thin ring-shaped SCBs {1}. **Exudate** over paraphyses 0.5–1.5(–2) µm thick, hyaline, continuous-cloddy, loosely but finally firmly attached; over margin and flanks 0.5–4 µm thick, continuous-cloddy, usually rough. **— ANAMORPH**: unknown (but see below).

Habitat: collected 0.2–4 m above the ground, ± corticated or partially to often entirely decorticated, 7–20(–55) mm thick branches, also 35 cm thick log, of *Juniperus communis* {1}, *Larix* sp. {1}, *L.* ?*decidua* {1},

Picea abies {8}, *Pinus* sp. {1}, *P. sylvestris* {4}, on 0.05–0.3 or 0.5–1 mm deep medium to strongly decayed wood {14}, rarely bark (periderm) {1}, sometimes in beetle galleries or on resinous wounds {2}, slightly to strongly greyed, partly densely covered by green algae. **Associated**: *Amphosoma atroolivaceum* {1}, *Capronia* sp. {1}, *Chrysodisca peziculoides* {1}, *Ciliolarina* sp. {1}, *C. pinicola* {1}, ?*Cistella* sp. {1}, *Colpoma crispum* {1}, *Cryptodiscus pini* {2}, *Dacrymyces* sp. {1}, '*Helotium*' *uvidulum* {1}, *Hyaloscypha bulbopilosa* {1}, *Mellitiosporium propolidoides* {1}, *Mollisia* sp. {1}, *Mytilidion* sp. {1}, *Orbilia alpigena* {1}, *O. aprilis* {1}, *O. eucalypti* {2}, *O. euonymi* {3}, *O. olivacea* {1}, *O. patellarioides* {2}, *O. subvinosa* {2}, *O. vibrioides* {4}, *O. vinosa* {5}, *Propolis betulae* {1}, *P. rhodoleuca* {1}, *Pseudographis pinicola* {1}, *Resinomyces kirschsteinianus* {1}, *Sarea difformis* {1}, *S. resinae* {1}, *Stictis friabilis* {1}, *Unguiculariopsis* sp. {1}, crustose lichens {1}, pleurocarpous moss {1}. **Desiccation tolerance**: mature asci survive at least a few days, many paraphyses and excipular cells but scarcely any mature asci still viable after 1.5 months. **Altitude**: 510–1408 m a.s.l. (central and northern Europe), 812–1595 m (southern Europe). **Geology**: Muschelkalk, Middle & Upper Jurassic and Cretaceous marl- & limestone, Pleistocene moraine; granite, gneiss, mica schist, amphibolite, dolerite, basalt. **Phenology**: V–X (but probably throughout the year, long-lived).

Taxonomic remarks. The characters of *Orbilia cylindrospora* include small, straight, cylindrical ascospores with ± globose spore bodies close to the apex, 8-spored asci, and apically not or only slightly inflated paraphyses covered by a distinct layer of ± continuous exudate. *O. subcylindrospora* (section *Ovoideae*) is mainly separated by distinctly larger, often curved spores and often strongly capitate paraphyses. For the very similar *O. austrocylindrica* (p. 1317) and the distantly related *O. paracylindrospora* of series *Orbilia* (p. 1343) see there.

The more or less desiccation-sensitive *O. epipora* and *O. cardui* (series *Neodactylella*) differ in larger, whitish apothecia, the former also in smaller asci and spores and sparse to absent exudate, the latter in slightly larger spores with SBs distant from the spore apex. The type of *O. acuum* (section *Arthrobotrys*) appears to differ in a thin granular exudate and more tear-shaped SBs which were seen only in a few dead spores; the marginal excipulum is of t. globulosa oriented at a high angle, quite untypical for *O. cylindrospora*.

O. picea Velen., a dubious taxon found on a xeric *Picea* branch in Czechia, might be similar to *O. cylindrospora* but no type material exists (see p. 1682). The spores were described as '8–10 µm, very narrowly linear and acute', and the apothecia 1 mm diam., flesh-coloured.

Variation. The apothecial colour of *O. cylindrospora* varies from almost hyaline to light rose-orange depending on the

Map 133. Known distribution of *O. cylindrospora* in Europe (yellow = not included collection).

populations, the reddish colour occurring on the more xeric substrates. The oro- and (sub)mediterranean collections differ in having shorter spores and often distinctly smaller SBs, also smaller basal excipular cells, in comparison to the (sub)montane collections from central Europe. The sample on *Picea* log (Pl. 825: 2) deviates from the others in that the apothecia grew on bark; moreover, it shows the widest asci and longest spores. The terminal cells of paraphyses are usually distinctly longer than the lower cells, but in some collections terminal cells occur which are shorter than the penultimate cell (see 4 & 6).

Not included collection. The only sample on angiosperm substrate (Pl. 825: 3, attached branch of *Quercus*) differs from those on gymnosperms in extraordinarily long and narrow asci with a partly H-shaped base, a thicker marginal excipulum of t. prismatica-angularis oriented at a high angle, a sharply delimited medullary excipulum, slightly narrower paraphysis cells, and smaller SBs, though in the sample in Pl. 825: 5 the SBs were similarly small. Contrary to typical *O. cylindrospora*, it originates from an atlantic region at planar altitude. Therefore, it might well represent a different species.

Anamorph. Narrow phragmoconidia were seen in one collection (†27–35 × 1.2–2 µm, Pl. 825: 2e) similar to those observed in a sample of *O. subcylindrospora*. In both species we consider these conidia as possibly alien. In two further collections of *O. cylindrospora* we found tridentaria-like conidia emerging from the apothecia. In both samples *O. vibrioides* (section *Hemiorbilia*) grew in association, and it remained unclear whether the tridentaria-like conidia belong to one of the two or another species (see p. 749, Pls 370: 4g; 371: 5b).

Phylogeny. A sequence taken from apothecia of a topotype of *O. cylindrospora* (Pl. 826: 3) comprises S1506 intron, ITS, and LSU. In our combined analysis (Phyl. 7), the species clustered with low support within one of the two groups of section *Orbilia*. Within this section it formed with *O. brettii* a strongly (Phyls 7) or medium (22, S27) supported clade, and in the combined analyses also an unsupported clade with *Tridentaria subuliphora* and series *Microsomates*, whereas in analyses of ITS or the S1506 intron it clustered unresolved.

O. cylindrospora clustered strongly supported (Phyl. 22) with a 14% ITS distance with an environmental strain from Canadian arctic (Ellef Ringners Island, KC965631), while the distance to *O. brettii* is 19%. When analysing the S1506 intron, *O. cylindrospora* clustered in an unsupported clade which includes part of series *Orbilia* (*O. eucalypti*, *O. tremulae*, *O. renispora*) but also section *Ovoideae* (Phyl. S26). In the 5.8S region *O. cylindrospora* is identical with various members of sections *Hemiorbilia* and *Orbilia*, including *O. brettii* and *O. paracylindrospora*, but deviates by 3 nt from section *Ovoideae* (pos. 30 T vs. C, pos. 140 C vs. T, pos. 142 T vs. C). Also at the 3 LSU positions, which are characteristic of section *Ovoideae* (see p. 1245), *O. cylindrospora* deviates by showing the character typical of the remaining *Orbilia* species.

All these results suggest that *O. cylindrospora* belongs to section *Orbilia* and particularly to series *Orbilia*. However, DNA data are lacking for a large number of taxa here assigned to section *Ovoideae*, and also within the here tentatively established *O. cylindrospora* group, which comprises species with very similar ascospores, *O. cylindrospora* is the only for which a sequence was available, with the exception of *O. brettii* with ellipsoid spores.

Ecology. *O. cylindrospora* was collected on ± rotten wood (rarely bark) of xeric or mesic branches (rarely logs) of coniferous trees and shrubs. A single but doubtful collection was on wood of a xeric *Quercus* branch. Records are from oroboreal Scandinavia (Lapland), subcontinental, cold-temperate humid, montane central Europe (Hunsrück, Thüringer Schiefergebirge, Oberpfälzer Wald, Oberschwaben, High Tatras), and from orotemperate to orosub- or suprasubmediterranean humid southern Europe (Massif central, Southern French Alps). Mostly the apothecia grew on ± exposed xeric branches, but in some from central Europe they were on more mesic branches and logs in shady or open conifer forests, partly lying ± close to the ground. The not included collection is from an atlantic humid *Quercus robur*-*Castanea sativa* forest with *Ilex aquifolium* in the coastal lowland of western Europe.

Taxonomic remarks. *Orbilia austrocylindrica* is characterized by small, subcylindrical, straight ascospores with comparatively large, globose to broadly tear-shaped SBs. The European *O. cylindrospora* is tentatively separated by a tendency to narrower spores, apically less inflated paraphyses, and longer asci. For the similar *O. subcylindrospora* (section *Ovoideae*) see p. 1277. *O. pleioaustrocylindrica* and *O. multiaustrocylindrica* mainly differ in their polysporous asci and in shorter terminal cells of paraphyses, the former also in a more gelatinized ectal excipulum.

Variation. The collections varied in shape and size of spores and SBs, and in the apical inflation of paraphyses, often within a given sample. The holotype (Pls 827: 2; 828: 1) differs from the other samples in often bright orange apothecia, distinctly longer spores, and slightly longer SBs. Yet, it originates from the same site and substrate (*Eremaea*) as a collection from the year before, which showed shorter spores and paler apothecia (Pls 827: 1; 828: 4). A small group of apothecia that grew on a separate branch of *Eremaea* (Pl. 827: 1B) deviates in narrower, cylindrical to almost dumbbell-shaped spores with narrower SBs with a distinct, often thickened filum; in spore shape this population approaches European *O. cylindrospora*. In a sample on *Adenanthos*, some of the apothecia (Pls 827: 3A; 828: 5) differ from those on a thicker branch (Pls 827: 3B; 828: 2) in having prominent marginal teeth composed of glassy processes, also in shorter and wider spores. This is possibly only a variant of the same species, the more so as these processes vary among the apothecia in length (see Pl. 828: 5f–g). Similar spores were observed in a sparse sample on *Eucalyptus* with smooth apothecia (Pl. 827: 4) which deviates in apically ± uninflated paraphyses.

Ecology. *O. austrocylindrica* grew on rotten bark of xeric branches of different trees and shrubs belonging to *Myrtaceae*, *Proteaceae* and *Sapindaceae* in subtropical semihumid (banksia-)eucalypt woodlands (northeast of Muchea) or semiarid acacia shrublands (Yalgoo) in southwestern Australia, and in a cold-temperate humid eucalypt open forest of southeastern Australia (Great Dividing Range).

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, trunk of *Dodonaea viscosa* subsp. *angustissima*, on bark, 8.XI.2007, G. Marson (H.B. 8838h ø). – Swan Coastal Plain, 48 km NNE of Perth, 4.5 km NE of Muchea, Reserve Road, 97 m, branch of *Banksia menziesii*, 3.IX.2006, G. Marson (G.M. 2006-09-03.4 ø). – 59 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Rd, 77 m, branch of *Adenanthos sericeus*, on bark, 5.IX.2006, G. Marson (H.B. 8658c). – ibid., branches of *Eremaea pauciflora*, on bark, 5.IX.2006, G. Marson (H.B. 8643h). – ibid., branches of *E. pauciflora*, on bark, 23.X.2007, G. Marson (MEL 2389259A, **holotype**, **isotype** in H.B. 8775c). – 55 km SSW of Moora, 30 km NNE of Gin Gin, Moore River, 83 m, branch of ?*Myrtaceae*, on bark, 11.XI.2007, G. Marson (G.M. 2007-11-11.2 ø, doc. vid.). – **New South Wales**, Sydney Basin, 95 km WNW of Sydney, 11.5 km SE of Lithgow, Mt. York, 1073 m, branch of *Eucalyptus*, on bark, 26.X.1998, G. Marson (H.B. 6776 ø).

Orbilia pleioaustrocylindrica Baral, G. Marson & E. Weber, **sp. nov.**, MB 813933 — Pls 829–830

Etymology: named after the 16-spored asci and the resemblance to *O. austrocylindrica*.

Typification: Western Australia, Wubin, twig of *Acacia*, 24.XI.2001, G. Marson (ex H.B. 7204e, MEL 2389225, holotype).

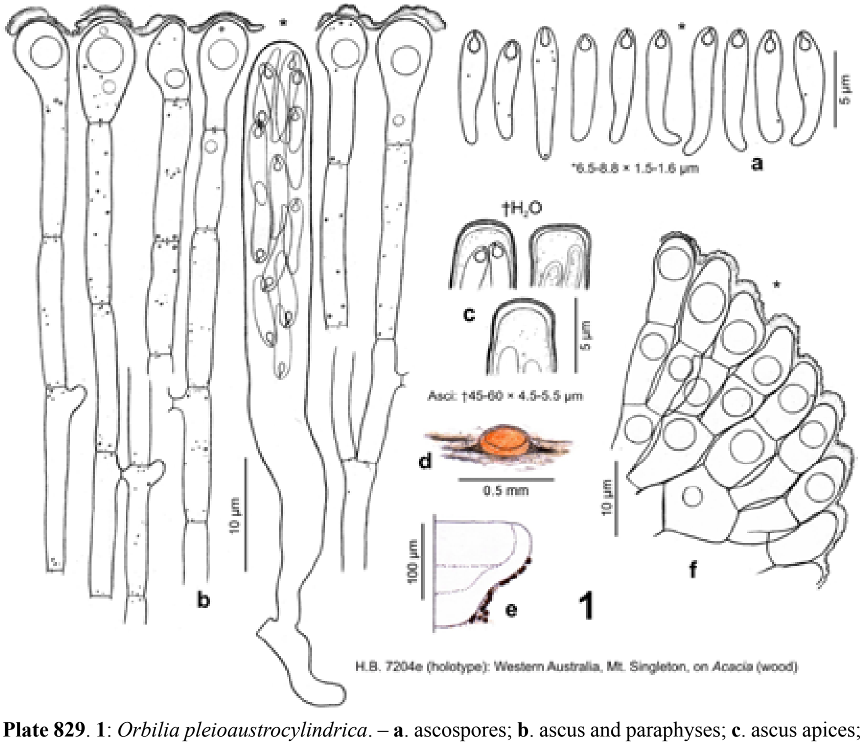

Plate 829. **1**: *Orbilia pleioaustrocylindrica*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium; **e**. apothecium in median section; **f**. id., marginal ectal excipulum.

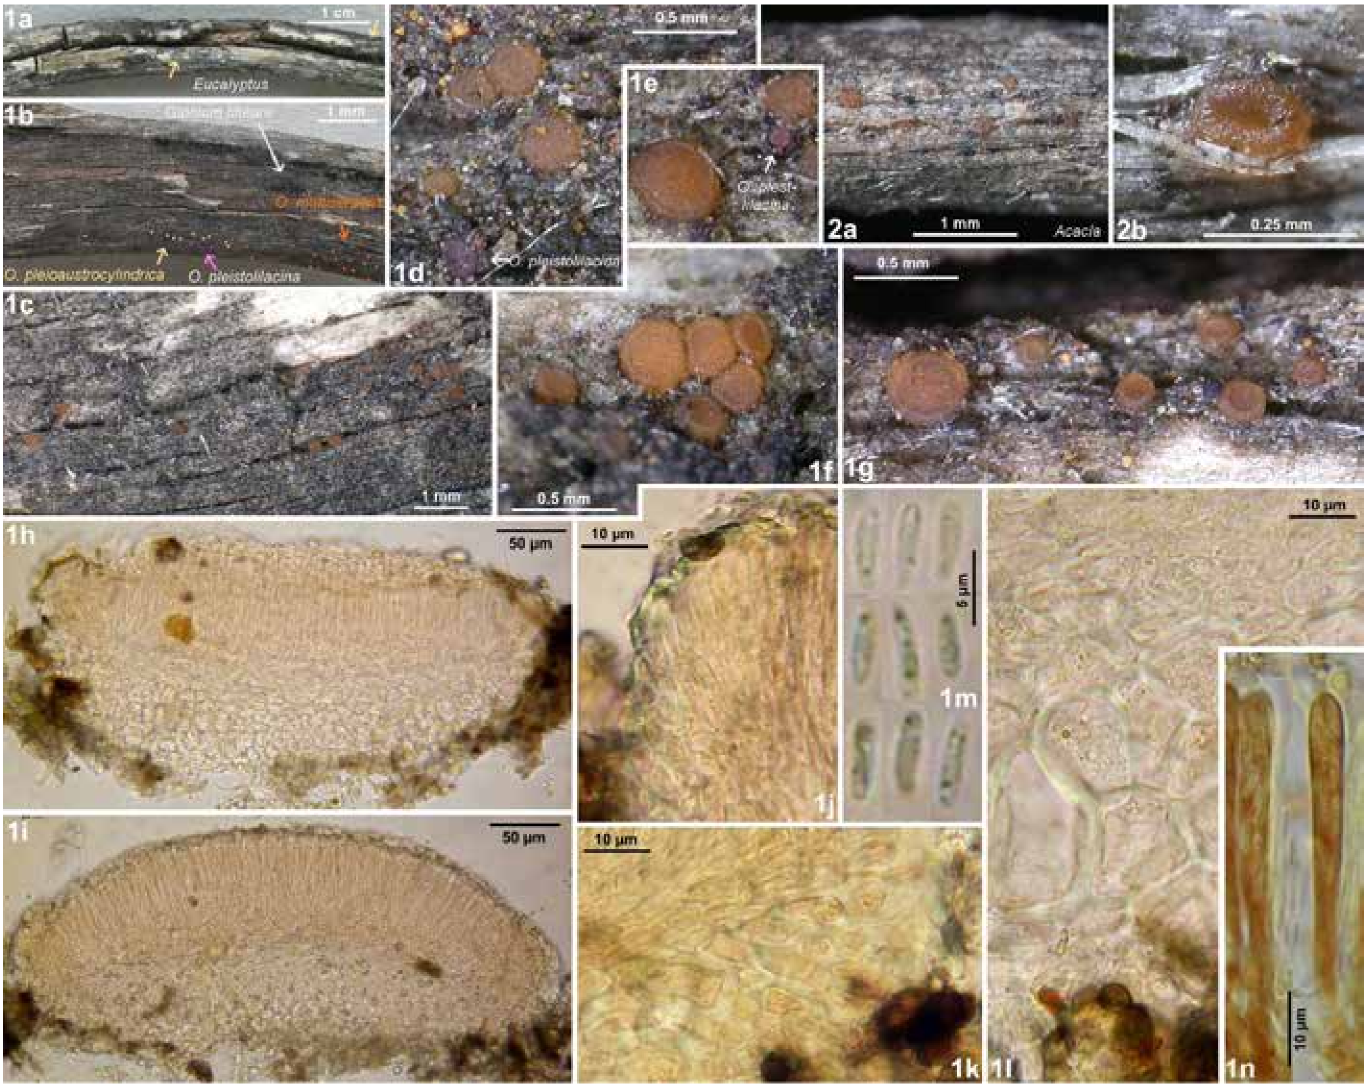

Plate 830. **1–2**: *Orbilia pleioaustrocylindrica*. – **1a–b**, **2a**. decorticated xeric twigs and branch; **1c–g**, **2a–b**. rehydrated apothecia; **1h–i**. apothecia in median section; **1j**. id., marginal ectal excipulum; **1k**. id., mid flanks; **1l**. id., lower flanks; **1m**. ascospores; **1n**. mature asci. – Dead state (**1h** in H_2O, **1i–m** in KOH, **1n** in KOH+IKI). — **1a–n**. H.B. 8641b: Western Australia, Kulin, on *Eucalyptus*; **2a–b**. H.B. 7204e (holotype): ibid., Mt. Singleton, on *Acacia*.

Latin diagnosis: *Similis* Orbiliae austrocylindricae *sed asci 16-spori*, *excipulum ectale basi crassitunicatum. Habitat ad lignum putridum ramulorum vel ramorum siccorum* Acaciae *et* Eucalypti *in zona subtropica semiarida et semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4(–0.6) mm diam., 0.14–0.2 mm high (receptacle 0.08–0.14 mm), light to bright orange, non-translucent, round, rarely broadly elliptical, scattered or ± densely gregarious in smaller or larger groups; disc flat, margin distinct, rather thick, not protruding, smooth; broadly sessile (sometimes with obconical base or with a hidden stipe), nearly superficial to entirely immersed, erumpent between fibres; dry bright orange to brick-red. **Asci** *55–67 × 5.8–6.8 µm {1}, †(38–)45–65(–70) × (4–)4.5–5(–5.5) µm {2}, 16-spored, spores *3–4-seriate, lower spores inverted (± mixed), pars sporifera *29–30 µm long; **apex** (†) medium to strongly truncate (not or slightly indented and laterally inflated); **base** with short to medium long, thin or thick, ± flexuous stalk, L- to h-shaped. **Ascospores** *6.5–8.8 × (1.4–)1.5–1.6(–1.7) µm {T}, †4.8–6.5(–7) × 1.2–1.5 µm {1}, subcylindrical to (fusoid-)clavate, apex rounded to obtuse, base mostly slightly to medium attenuated, straight to often slightly to strongly curved below; **SBs** *1–1.3 × 0.6–0.8 µm {1}, ± broadly tear-shaped, apically narrowed to a ± small point, mostly with a very short filum. **Paraphyses** apically (slightly to) medium to (very) strongly clavate-capitate, terminal cells */†8–19(–22) × 3–5 µm {2}, lower cells *9–17 × 1.8–2.5 µm {1}; never branched near apex. **Medullary excipulum** 20–40 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** (*) slightly gelatinized [† medium to strongly so, common walls 1–2(–3) µm thick], indistinctly to vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 40–70 µm thick near base, cells */†10–20(–33) × 7–15(–18) µm {2}; 20–30 µm thick near margin, of t. prismatica-angularis oriented at a 60–80° angle to the surface, marginal cortical cells *8–11 × 4–5.5 µm {T}, or t. prismatica(-porrecta) oriented at 40–50° {1}, cortical cells †8–17 × 3.5–6 µm {1}, slightly gelatinized; **glassy processes** absent. **Anchoring hyphae** sparse to medium abundant, */†2–3.5 µm wide, walls 0.2–0.3(–0.6) µm thick {2}. **SCBs** globose, in paraphyses 1.5–3 µm diam.; in ectal excipulum (near margin) 3–5 µm. **Exudate** over paraphyses and marginal excipulum 0.2–1.5(–2) µm thick, granular to cloddy-continuous, hyaline, ± firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, decorticated, 1.5–27 mm thick twigs and branches of *Eucalyptus* sp. {1}, *Acacia* sp.{1}, on 0.5 mm deep very decayed wood {2}, strongly greyed, green algae sparse or absent. **Associated**: *Capronia* sp. {1}, *Gloniopsis subrugosa* {1}, *Orbilia amberina* {2}, *O. australiensis* {2}, *O. austroobtusispora* {2}, *O. aviflagellata* {1}, *O. helicoobliqua* {2}, *O. hesperidea* {2}, *O. microserpens* {2}, *O. multiserpens* {2/1}, *O. myriolilacina* {2}, *O. myrioobliqua* {2}, *O. nothovinosa* {2}, *O. paraobliqua* {2}, *O. pleioaustraliensis* {2}, *O. pleioaustrocylindrica* {1}, *O. pleistolilacina* {1}, *Ostropales* {2}, *Patellaria* ?*andina* {2}, *Psiloglonium* ?*lineare* {1}, *Triblidium* spp. {3}, *Symbiotaphrina desertorum* {1}. **Desiccation**

tolerance: after 16 months paraphyses and excipulum, also some submature asci still viable. **Altitude**: 286–379 m a.s.l. **Geology**: Archean sedimentary rock, granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleioaustrocylindrica* resembles the European *O. subcylindrospora* (section *Ovoideae*) in having often curved ascospores, but differs in 16-spored asci and in a rather strongly gelatinized ectal excipulum. *O. multiaustrocylindrica*, *O. myriolilacina*, and *O. pleistolilacina* (both section *Ovoideae*) differ in higher-spored asci, in a more thin-walled ectal excipulum, and in slightly shorter and wider spores. The latter two species differ also in distinctly rose-lilaceous apothecia; both grew in close association with *O. pleioaustrocylindrica*, partly even strongly intermingled. *O. austrocylindrica* differs from the present species in 8-spored asci, shorter, less curved spores, and a more thin-walled ectal excipulum.

Variation. The very rich paratype collection on branches of *Eucalyptus* was studied in the dead state only, except that a living spore was sketchily documented earlier by the third author (IVV: H.B. 8641b). It deviates from the rather sparse holotype in larger and thicker apothecia, slightly smaller spores, a thinner exudate, and more elongate marginal cortical cells. Only in the holotype a short apothecial stipe was observed.

Ecology. *O. pleioaustrocylindrica* was found on very rotten wood of xeric twigs and branches of *Acacia* and *Eucalyptus* in a subtropical semiarid acacia shrubland and a semihumid small eucalypt forest in a cornfield in southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twig of *Acacia*, on wood, 24.XI.2001, G. Marson (ex H.B. 7204e, MEL 2389225, **holotype**). – Mallee, 14 km SSW of Kondinin, 9 km NE of Kulin, Fence Road, 286 m, branches of *Eucalyptus*, on wood, 14.XII.2001, G. Marson (H.B. 8641b).

Orbilia multiaustrocylindrica Baral, sp. nov.,

MB 813934 — Pl. 831

Etymology: named after the 32-spored asci and the resemblance to *O. austrocylindrica*.

Typification: Australia, Northern Territories, Wilora, branch of *Atriplex*, 8.X.1998, G. Marson (ex H.B. 6262b, MEL 2389195, holotype).

Latin diagnosis: *Similis* Orbiliae pleioaustrocylindricae *sed asci 32-spori, excipulum ectale tenuitunicatum. Habitat ad lignum putridum ramorum siccorum* Atriplicis *in zona subtropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4 mm diam., 0.12 mm high, pale to light (dirty) orange, round, scattered; disc flat, margin not protruding, smooth; broadly sessile, somewhat immersed. **Asci** *50–60 × 7–7.5 µm, †45–50 × 6–7 µm, 32-spored (28–29 spores counted), spores (*) multiseriate, part of spores inverted (mostly the lower spores, strongly mixed), pars sporifera *25–35 µm long; **apex** (†) medium to strongly truncate (not indented, laterally never inflated); **base** with short, thick stalk, Y-shaped. **Ascospores** *4–7.7 × 1.5–1.7(–2) µm, subcylindrical, rarely fusoid-clavate, apex rounded to obtuse, rarely subacute, base not or sometimes slightly attenuated, straight or slightly curved near base; **SBs** *0.9–1.3 × 0.6–0.9 µm, globose to mostly broadly tear-shaped, apically closely attached, with or without a very short filum. **Paraphyses** apically slightly to strongly capitate(-clavate), terminal cells *6.5–13 × 3–5 µm, lower cells *8–14 × 1.7–2.3 µm; sometimes branched at upper septum. **Medullary excipulum** hyaline, 25 µm thick, of dense textura angularis-intricata, indistinctly delimited. **Ectal excipulum** hyaline, of (*) thin-walled, indistinctly oriented t. angularis from base to mid flanks, 40 µm thick near base, cells *6–11 × 5–9 µm; 20 µm thick near margin, of t. prismatica oriented at a 30–45° angle to the surface, marginal cortical cells *6–12 × 3–4.5 µm; **glassy processes** absent. **Anchoring hyphae** sparse, 2–2.5 µm wide, walls 0.2 µm thick. **SCBs** globose, in paraphyses 1.5–2.7 µm diam., partly laterally more refractive (half-moon-like); in ectal excipulum (near margin) 2–3 µm. **Exudate** over paraphyses and marginal excipulum 0.5–2.5 µm thick, rough-cloddy, medium firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, ± decorticated, 15–18 mm thick branches of *Atriplex* sp., on 0.3 mm deep strongly decayed wood, very greyed, no algae. **Associated**: *Orbilia barrowensis*, *O. lanternae*, *O. ?livistonae*, *O. ?multigambelii*, *O. octocercocarpi*, *O. pleioaustraliensis*, *?Pleospora* sp. **Desiccation tolerance**: fully viable for at least 3 weeks. **Altitude**: 480 m a.s.l. **Geology**: Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multiaustrocylindrica* is characterized by rather small, subcylindrical, predominantly straight ascospores with broadly tear-shaped SBs, and by 32-spored asci. It is obviously closely related to the 64-spored

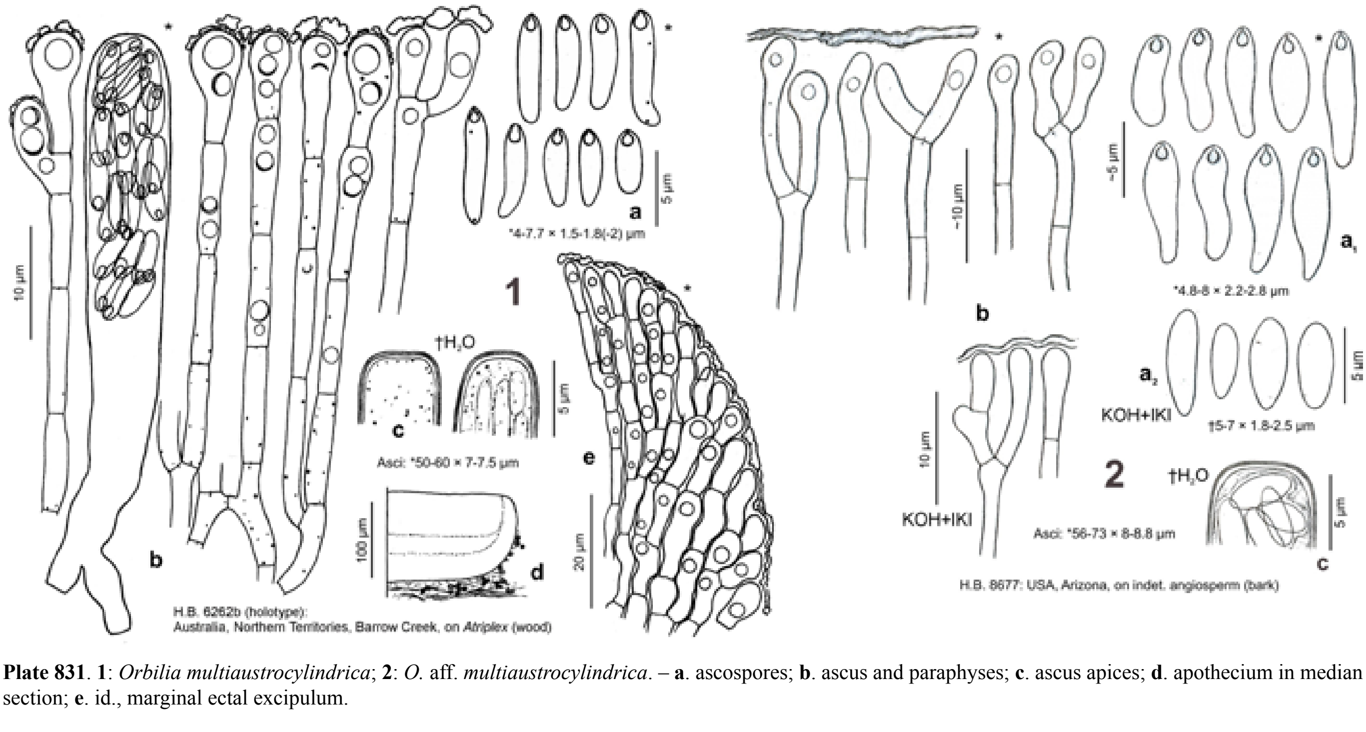

Plate 831. **1**: *Orbilia multiaustrocylindrica*; **2**: *O.* aff. *multiaustrocylindrica*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

O. myriolilacina (section *Ovoideae*) but also to the 16-spored *O. pleioaustrocylindrica*, the former differing further in rose-lilaceous apothecia, the latter in a gelatinized excipulum.

Not included collection. A very sparse North American sample on bark of unidentified angiosperm shrub (Pl. 831: 2) closely resembles *O. multiaustrocylindrica* except for somewhat larger asci and wider spores which are more often fusoid-clavate. Therefore, we have not included this specimen in the description. In its wider spores this closely resembles *O. atriplicis* (section *Ovoideae*), a taxon which we have only tentatively separated from *O. multiaustrocylindrica* because of wider spores and wider SBs, and which grew on the same host genus as the type, though on bark.

Two not included Australian collections each consisted of one apothecium only and were only briefly documented (IVV: H.B. 7213d, 9050d). Both might belong to *O. multiaustrocylindrica* though spore length was very different between them (*Acacia*: *7.5–8 × 1.5–2 µm; *Chamelaucium*: *4.7–5.5 × 1.8–1.9 µm). In the former the SBs were rather small, and the latter differed in bright rose-red apothecia.

Ecology. The type of *O. multiaustrocylindrica* represents a sparse collection on rotten wood of dead xeric branches of an unidentified species of *Atriplex* climbing up trees of *Acacia* in a subtropical arid acacia open shrubland north of Macdonnell Ranges in central Australia. The not included collections are from a subtropical semiarid Sonoran paloverde-mixed cacti desert scrub in the southwest of Northern America, and from a subtropical semiarid acacia shrubland and semihumid eucalypt low open forest in southwestern Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Burt Plain, 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, 480 m, branch of *Atriplex*, on wood, 8.X.1998, G. Marson (ex H.B. 6262b, MEL 2389195, **holotype**).

Not included. **USA**: **Arizona**, Sonoran Desert, 82 km NW of Phoenix, ~1.5 km SE of Wickenburg, 620 m, branch of indet. angiosperm, on bark, 4.V.1995, G. Marson (H.B. 8677). — **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, twig of *Acacia*, on bark, 8.XI.2007, G. Marson (H.B. 9050d ø). – Jarrah Forest, 47 km WNW of Albany, 13 km NNE of Denmark, Mount Lindesay, 75 m, branch of *Chamelaucium ciliatum*, on wood, 15.XII.2001, G. Marson (H.B. 7213d ø).

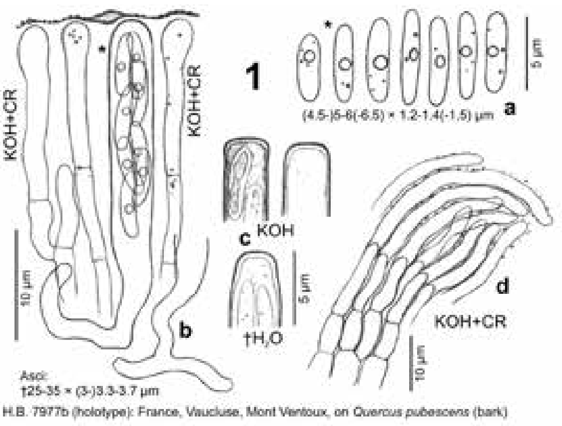

Plate 832. **1**: *Orbilia beatricis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum with glassy processes (median section).

Orbilia beatricis Baral, **sp**. **nov**., MB 813936 — Pls 832–833

Etymology: named after the collector, Beatrice Senn-Irlet.

Typification: France, Bédouin, trunk of *Quercus* ?*pubescens*, 19.X.2005, B. Senn-Irlet (ex H.B. 7977b, M-0276441, holotype).

Latin diagnosis: *Apothecia rehydratata 0.3–0.4 mm diam., dilute roseo-aurantiaca, sessilia, margine exigue albido-dentata. Ascosporae *4.5–6.5 × 1.2–1.5 µm, (sub)cylindricae, subrectae, corpusculum refringens globosum, ad tunicam mediam lateralem indistincte affixum continentes. Paraphyses ad apicem leniter clavato-capitatae, exsudato tenui tectae. Excipulum marginale processis vitreis longis agglutinatis praeditum. Habitat ad corticem putridum trunci sicci* Quercus ?pubescentis *in zona suprasubmediterranea semihumida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.4 mm diam., 140 mm high, light rose-orange, translucent, round, scattered; disc flat, margin with prominent, 20 µm protruding whitish teeth ~40 × 40 µm; broadly sessile but with a very indistinct, narrowed base, superficial. **Asci** *26–30 × 4 µm, †25–35 × (3–)3.3–3.7 µm, 8-spored, spores (*) obliquely biseriate, pars sporifera †19 µm long; **apex** (†) strongly truncate (not indented, laterally sometimes slightly inflated); **base** with short to medium long, ± thin, flexuous stalk, T- to L-shaped. **Ascospores** *(4.5–)5–6(–6.5) × 1.2–1.4(–1.5) µm, (sub) cylindrical, both ends rounded, straight to very slightly curved; **SBs**

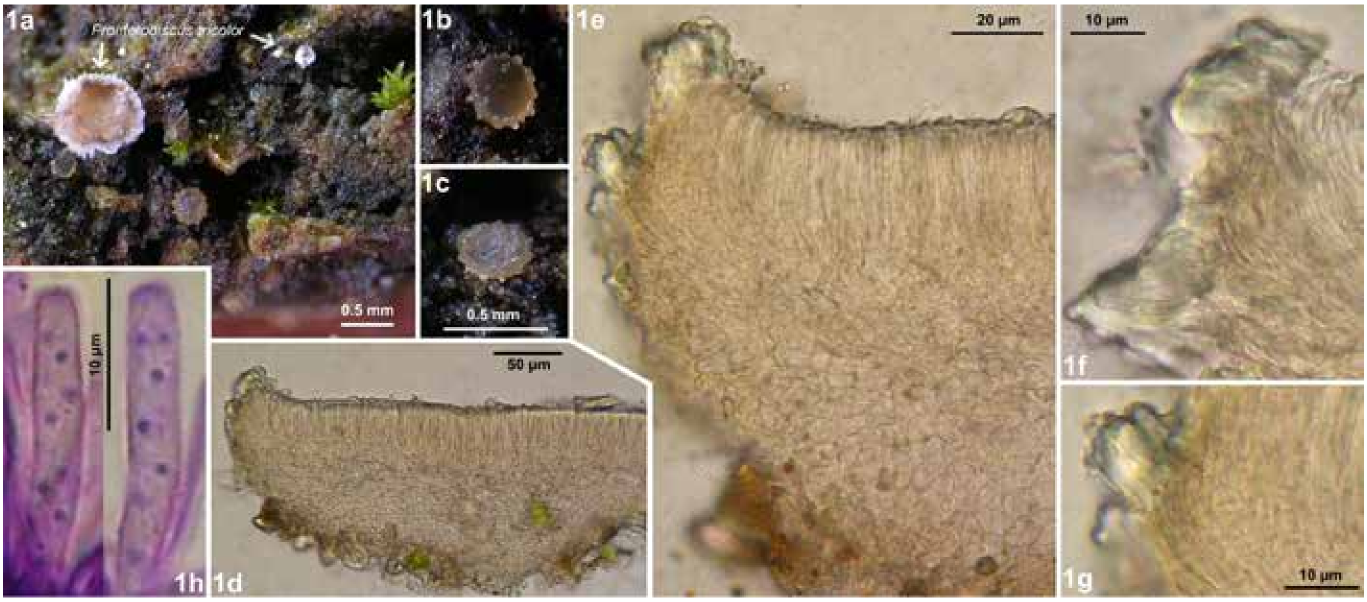

Plate 833. **1**: *Orbilia beatricis*. – **1a**. 2 rehydrated apothecia (with *Proliferodiscus tricolor*); **1b–c**. right apothecium of **1a**; **1d**. apothecium in median section; **1e–g**. id., marginal region, with glassy processes that form teeth; **1h**. mature asci (SBs in spores stained dark blue). – Living state, except for asci in **1h** (in CRB). — **1a–h**. H.B. 7977b (holotype): France, Vaucluse, Mont Ventoux, on *Quercus*.

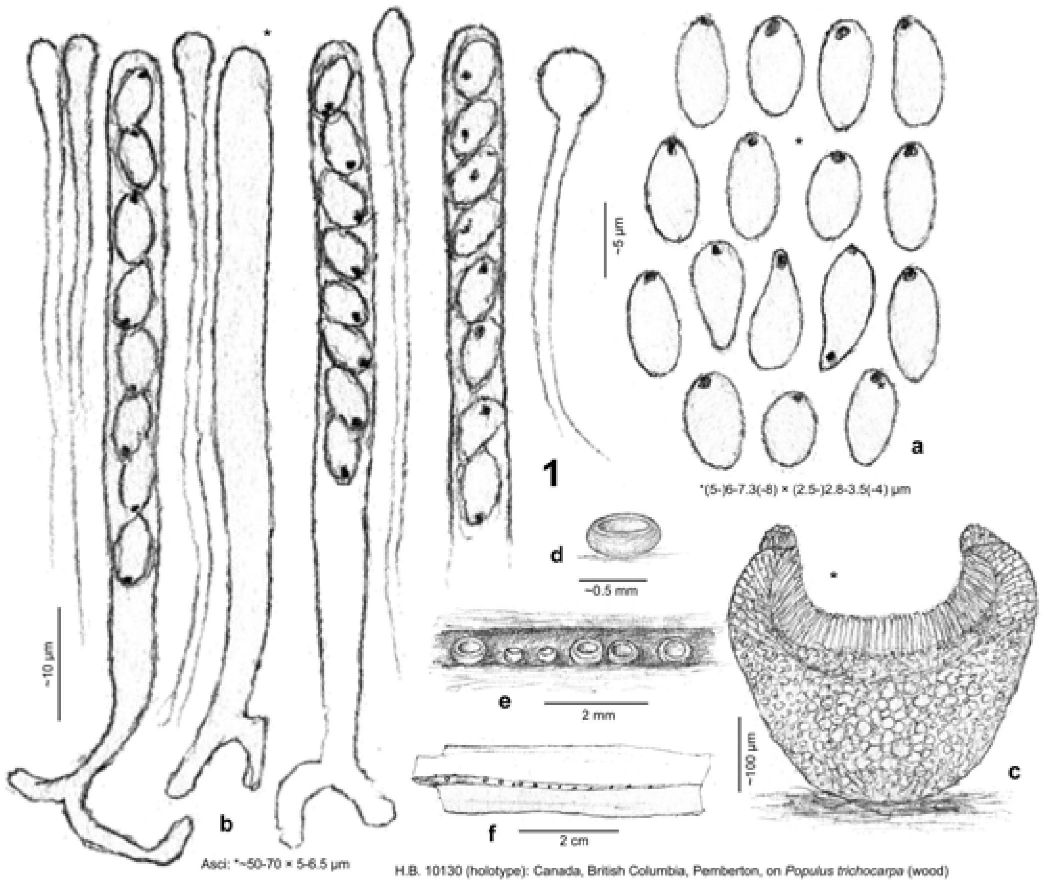

H.B. 10130 (holotype): Canada, British Columbia, Pemberton, on *Populus trichocarpa* (wood)

Plate 834. **1**: *Orbilia brettii*. – **1a**. ascospores; **1b**. asci and paraphyses; **1c**. apothecium in median section; **1d–e**. apothecia; **1e**. piece of *Populus trichocarpa* branch. – del. O. Ceska.

*0.7–1 × (0.5–)0.7–0.9 µm, globose to subglobose, positioned close to lateral wall ± in centre of spore, attachment to wall invisible (even in CRB). **Paraphyses** apically slightly clavate-capitate, terminal cells †13–17 × 1.5–2.6 µm, lower cells †5–9 × 1–2 µm; unbranched at upper septum. **Medullary excipulum** ~50 µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum only at flanks. **Ectal excipulum** of thin-walled, vertically oriented t. angularis from base to mid flanks, 50 µm thick near base, cells *5–12 × 4–7 µm; 30 µm thick at flanks and margin, at margin oriented at a 20–40° angle to the surface, marginal cortical cells †8–15 × 2–3 µm; **glassy processes** 10–40 × 2–3 µm, rather high-refractive, indistinctly stratified, coherent to form distinct teeth. **Anchoring hyphae** sparse, †2–2.5 µm wide, walls 0.2–0.3 µm thick. **SCBs/VBs** unknown. **Exudate** over paraphyses 0.1–0.2 µm thick, granular to continuous, locally up to 1.3 µm thick, loosely attached; over glassy processes forming small granules or clods. **— ANAMORPH**: unknown.

Habitat: collected 1.5 m above the ground, on living, 20 cm thick standing trunk of *Quercus ?pubescens*, on medium rotten surface of bark, greyed, with some green algae below apothecia. **Associated**: *Frullania ?dilatata*, *?Orthotrichum* sp., *Proliferodiscus tricolor*. **Desiccation tolerance**: Some mature asci survived for at least 4 weeks. **Altitude**: 800 m a.s.l. **Geology**: Lower Cretaceous (Urgonian) limestone. **Phenology**: X (but probably long-lived).

Taxonomic remarks. *Orbilia beatricis* is very extraordinary in its almost straight, cylindrical ascospores with a centrally positioned spore body. The small, desiccation-tolerant, light reddish apothecia possess long glassy processes at the margin that form distinct whitish teeth. Because of the small cylindrical spores with central SBs, a relationship was assumed with *O. fabacearum* (series *Orbilia*), which differs in strongly curved spores and in the absence of glassy processes. However, the absence of H-shaped ascus bases makes such placement improbable.

Species around *O. cylindrospora* differ from *O. beatricis* in the absence of glassy processes and in apically inserted SBs. Yet, the Australian *O. austrocylindrica* (H.B. 8658c) occurred in a variant with distinct teeth of glassy processes. In the dead state this variant differs from *O. beatricis* mainly in wider spores.

Ecology. The only two discovered apothecia of *O. beatricis* grew on medium rotten xeric bark of a living trunk of *Quercus ?pubescens* in a suprasubmediterranean semihumid *Quercus pubescens* woodland with planted *Cedrus atlantica* on the south-exposed slope of Mont Ventoux in French southern Prealps of southern Europe.

Specimens included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Vaucluse**, Préalpes du Dauphiné, Mont Ventoux, 5.7 km ENE of Bédouin, NE of St.-Estève, Forêt communale de Bédoin, 800 m, trunk of *Quercus ?pubescens*, on bark, 19.X.2005, B. Senn-Irlet (ex H.B. 7977b, M-0276441, **holotype**).

Orbilia brettii O. Ceska, Baral, G. Marson & E. Weber, **sp. nov.**, MB825638 — Pls 834–835

Etymology: in honour of M.Sc. Bob Brett, forest ecologist and environmental consultant in British Columbia.

Typification: Canada, British Columbia, Pemberton, branch of *Populus trichocarpa*, 3.VI.2017, O. & A. Ceska (ex H.B. 10130, M-0291755, holotype; sq.: MH221063).

Latin diagnosis: Orbiliae eucalypti *similis sed apothecia cupulata*, *margo leniter aspera vel coronata, excipulum marginale processis vitreis praeditum*, *ascosporae leniter latiores*, *corpusculum refringens ampulliforme, paraphyses ad apicem partim spathulatae. Habitat ad lignum putridum*, *rami sicci* Populi trichocarpae *in zona maritima humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.6 mm diam., ~0.2–0.25 mm thick, light rose(-orange), slightly translucent, round, scattered to subgregarious; disc ± deeply concave, margin raised, ~50–100 µm protruding, finely rough to indistinctly crenulate; sessile on an obconical base, superficial; dry bright rose-orange. **Asci** *~50–70 × 5–6.5 µm, †45–65 × (4–)4.5–5(–5.7) µm, 8-spored, spores uniseriate, ~4–8 lower spores inverted (sometimes strongly mixed), pars sporifera *~35–40 µm; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to long, thin or thick stalk, T- to Y- or h-shaped. **Ascospores** *(5–)6–7.3(–8) × (2.5–)2.8–3.5(–4) µm, †(3–)4–5 × 0.8–1.2 µm, ellipsoid, also fusoid or clavate, apex rounded to obtuse, base not or slightly to sometimes strongly attenuated, straight to slightly curved; **SBs** *1–1.3 × 0.5–0.8 µm, ampulliform (keyhole-shaped), attached to spore apex by a small point, usually in upper, wider end of spore (if heteropolar), also in narrower end or rarely at both ends. **Paraphyses** apically medium to strongly clavate-capitate or sometimes spathulate, apex †2.5–3(–4.5) µm wide.

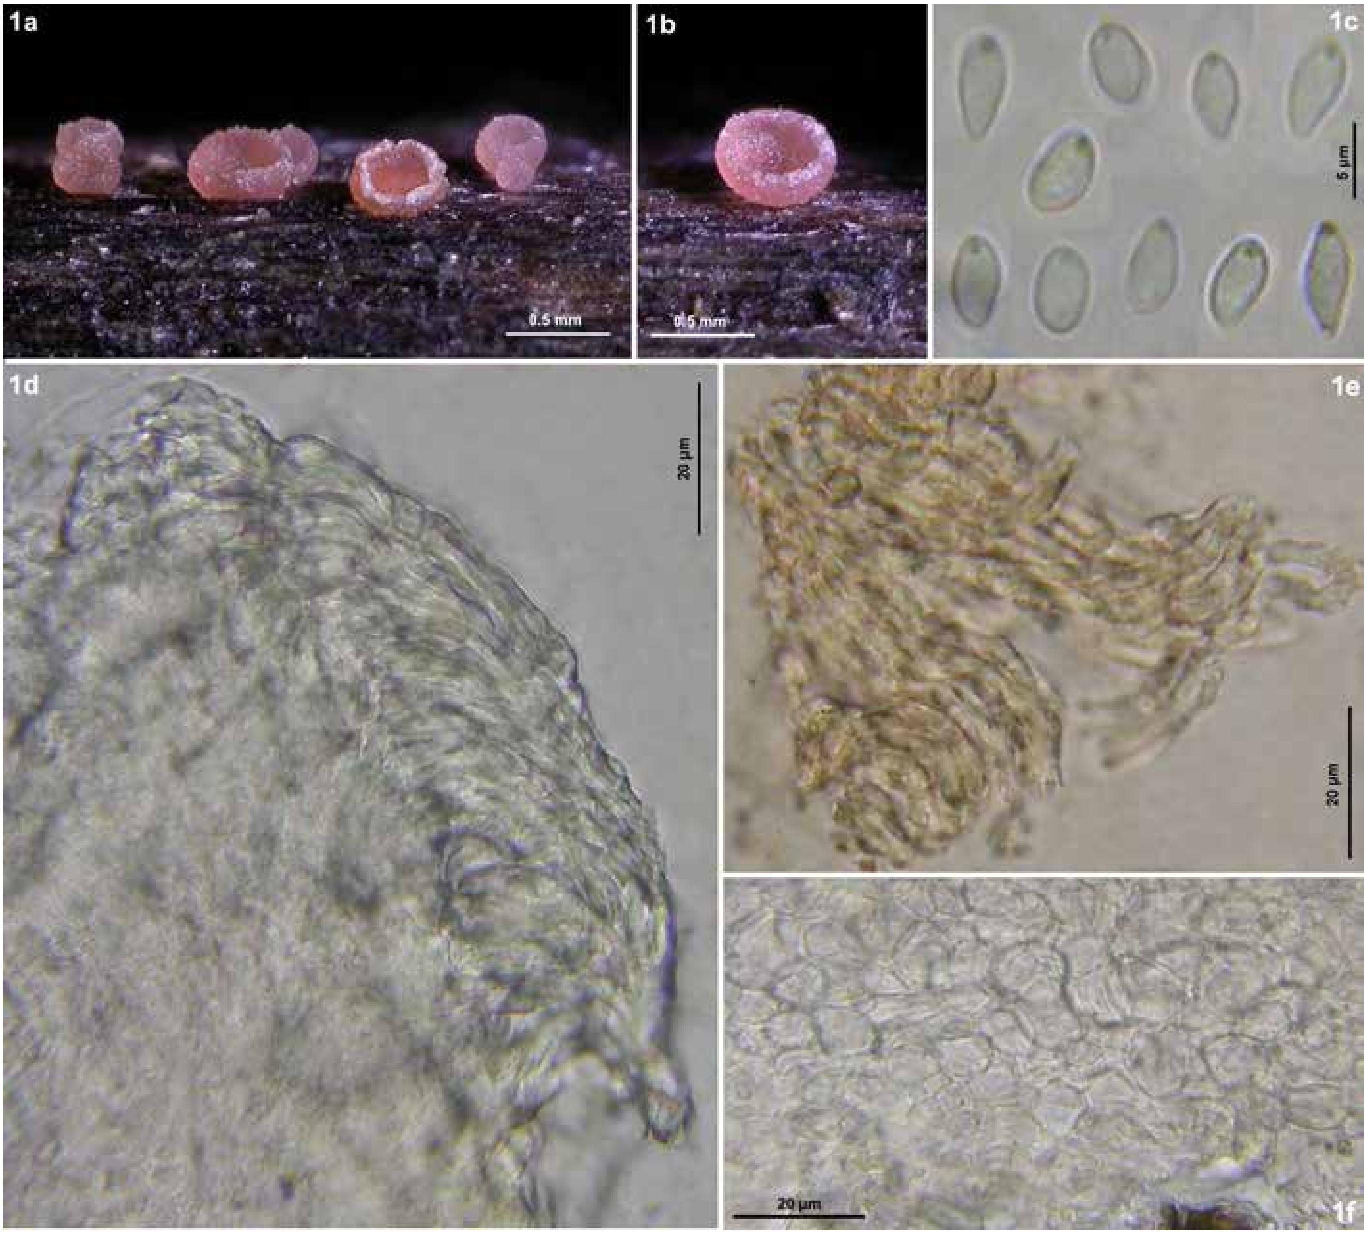

Plate 835. **1**: *Orbilia brettii*. – **1a–b**. rehydrated apothecia, **1c**. ascospores; **1d**. apothecium in median section, marginal ectal excipulum; **1f**. id., basal ectal excipulum; **1e**. glassy processes (in KOH +CR). – Living state, except for **1e**. — **1a–f**. H.B. 10130 (holotype): Canada, British Columbia, on *Populus*.

Medullary excipulum ~40–80 µm thick, of dense textura intricata with many small inflated cells, medium sharply delimited. **Ectal excipulum** of thin-walled, indistinctly oriented t. globulosa-angularis from base to margin, 50–150 µm thick near base, cells *~10–25 µm diam., †8–16 × 5–12 µm; ~20–50 µm thick at margin, indistinctly oriented at a ~40–90° angle to the surface, marginal cortical cells †~5–8 × 4–5 µm; **glassy processes** ~20–35 × (1.5–)2–2.5(–3) µm, medium refractive, rough, not dictinctly zonate, agglutinated but not forming distinct teeth, curved outwards. **Anchoring hyphae** medium abundant at base, †1.5–3(–4) µm wide, walls 0.2 µm thick, forming a 10–15 µm thick, dense layer of interwoven hyphae at flanks. **SCBs** no data available. **Exudate** over paraphyses and glassy processes ~0.2–0.5 µm thick, hyaline, granular, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 1.5 m above the ground, on decorticated, 14 mm thick, attached branch of *Populus trichocarpa*, on medium rotten, strongly greyed wood, at edge along longitudinal cleft, without algae. **Associated**: none observed. **Desiccation tolerance**: a few excipular cells and many ascospores still alive after 3 months. **Altitude**: 210 m. a.s.l. **Geology**: Cretaceous volcanic rock. **Phenology**: VI (but probably long-lived).

Taxonomic remarks. *Orbilia brettii* resembles under the microscope *O. eucalypti* at first glance in hymenial characters, but differs by cupulate apothecia with an often crown-like margin made up of prominent glassy processes, and paraphyses that partly tend to be spathulate, also by slightly larger, especially wider ascospores with minute ampulliform SBs. The species somewhat resembles members of series *Microsomates*, but our molecular analysis did not place it clearly in that series, but in the neighbourhood of *O. cylindrospora*, which differs from *O. brettii* in various morphological details.

Phylogeny. A sequence taken from apothecia of the holotype comprises a short part of SSU, S1506 intron, ITS, and LSU. In our combined analyses (Phyls 7, 22) or that of LSU (S27), *O. brettii* clustered in a strongly or medium supported clade with *O. cylindrospora*, and in the combined analyses also with unsupported connection to *Tridentaria subuliphora* and series *Microsomates*, whereas in analyses of ITS or the S1506 intron it clustered unresolved. The ITS distance to *O. cylindrospora* is 19 % and to the environmental Canadian strain 16 %. In the LSU

D1–D2 the distance is reverse: 3 % and 4.3 %, respectively.

Ecology. *O. brettii* is only known from the type collection on xeric wood of *Populus trichocarpa* in a cold-temperate humid alluvial forest with *Corylus cornuta* and mainly *Populus trichocarpa* in a valley of the Coast Mountains (Pacific Ranges) in the pacific maritime zone of southwestern Canada.

Specimens examined. **CANADA**: **British Columbia**, Coast Mountains, 26 km NNE of Whistler, 1 km NE of Pemberton, W of Mt. Currie, eastern bank of Lillooet river, 210 m, branch of *Populus trichocarpa*, on wood, 3.VI.2017, O. & A. Ceska (ex H.B. 10130, M-0291755, **holotype**; sq.: MH221063).

Series *Orbilia*

Orbilia Fr. subgenus ***Orbilia*** section ***Orbilia*** series ***Orbilia*** – Lectotype species: *Orbilia xanthostigma* (Fr.) Fr.

= *Dicranidion* Harkn., Bull. Calif. Acad. Sci. 1: 163 (1885) – Type species: *D. fragile* Harkn. [= *Orbilia eucalypti* (W. Phillips & Harkn.) Sacc.]

= *Pedilospora* Höhn., Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. 1, 111: 1047 [61 of repr.] (1902) – Type species: *P. parasitans* Höhn. [(?)= *O. eucalypti* (W. Phillips & Harkn.) Sacc.]

= *Orbilia* subgroup IV *Soleina* Velen., Mon. Discomyc. Bohem. p. 102 (1934, unranked) – Type species: *O. paradoxa* Velen. (= *O. xanthostigma*)

Etymology: *Dicranidion*: referring to the shape of conidia resembling a tuning fork; *Orbilia*: named after the orbicular shape of the apothecia; *Pedilospora*: apparently referring to the foot-shaped conidia; *Soleina*: because of the strongly curved ascospores (like a horseshoe).

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated (0.15–)0.25–2(–4.5) mm diam., white or pale to bright yellow, orange or rose(-lilaceous), margin smooth, rarely very finely rough or crenulate, or notched to form small lobes, sessile or with a sometimes distinct stipe. **Asci** *(22–)27–55(–70) × (2.8–)3–4.5(–5.3) µm, 8-, rarely 16-spored (*O. coccinella*), (2–)3–5(–6) lower spores inverted (but often oriented in all directions), **apex** (†) slightly to often strongly truncate, not or ± indented and/or laterally inflated; **base** T-, L-, Y-, h-, or H-shaped. **Ascospores** *(1.8–)2.2–6(–7)((–9)) × (0.8–)1–2.5(–3) µm, subglobose, ovoid, ellipsoid(-clavate) or cylindric(-fusoid), apex rounded to obtuse, base not or slightly tapered, rarely with a short tail (*O. coccinella*), straight to very strongly curved (cashew-shaped, rarely helicoid), sometimes warted on dorsal side; **SBs** usually present, 0.3–1 × (0.2–)0.3–0.8(–0.9) µm, globose, rarely broadly tear-shaped, attachment to apical or sometimes lateral wall usually invisible, sometimes a very fine and short filum seen, rarely more broadly attached (*O. guyanensis*). **Paraphyses** uninflated or slightly to strongly capitate(-clavate) or lanceolate-spathulate at the apex, terminal cells (1–)2–4(–6)× longer than lower cells, unbranched near apex. **Ectal excipulum** (†) thin-walled to slightly or rarely medium gelatinized [common walls 0.3–1.5(–2) µm], of vertically or indistinctly oriented textura globulosa-angularis-prismatica from base to margin, cells near base *(5–)8–25(–35)((–75)) × (4–)6–15(–25)((–40)) µm, margin of oriented at 10–90°, **glassy processes** absent or sometimes 1–7 µm long. **SCBs** globose or absent; **VBs** absent or low- to high-refractive, hyaline to yellowish. **Exudate** 0–1(–2)((–4)) µm thick, granular or cloddy to continuous, often sparse, loosely or firmly attached, hyaline or pale yellowish. — **ANAMORPH**: dactylella-like, dicranidion-like, vermispora-like. **Conidiophores** reduced to rather long (1.5–105 µm), unbranched or branched. **Conidiogenous cells** monoblastic or sympodial. **Conidia** phragmosporous: *(5–)12–45(–67) × (2.2–)3–5(–6.5) µm (actual length), (0–)1–9-septate, straight or slightly to strongly curved; dicranidion-like: 2-armed, *(4–)8–39 × 4.5–19 µm, also 3–8-armed, *15–47 × (8–)10–37(–43) µm. **Trapping organs**: only observed in 2 taxa of uncertain relationship (*Tridentaria implicans*: adhesive branches that encircle nematodes; *Dicranidion dactylopagum*: small, apparently adhesive protuberances that trap rhizopods).

Habitat: hygric to xeric wood and bark, rarely herbaceous stems, leaves of gymno- and angiosperms, rarely polypores, humid to semiarid, boreal to tropical, desiccation-sensitive or -tolerant.

Recognized species: 26, plus 6 unnamed species ('affinis') and 1 species with uncertain affinity.

Taxonomic remarks. Series *Orbilia* represents the core of the genus *Orbilia*; its members strongly vary in apothecial colour and tolerance to drought. The comparatively small ascospores contain small, mostly globose SBs. The asci are almost always 8-spored and, therefore, also rather small. The paraphyses are usually strongly capitate, but in some species they are lanceolate to spathulate and in others not or only slightly inflated at the apex. The exudate is often absent or rather sparse. Glassy processes are rarely present at the margin and then very short. The included species are arranged according to shape and curvature of the spores (ellipsoid vs. cylindrical, straight to curved under a wide arch vs. cashew-shaped) and paraphysis shape (capitate vs. lanceolate) (keys A–D). Six described species (*O. leucostigma*, *O. xanthostigma*, *O. aureocrenulata*, *O. fabacearum*, *O. subfabacearum*, *O. coccinella*) have strongly curved (often for ~180°), cashew-shaped spores. In the former three species (*xanthostigma-leucostigma* complex) the dorsal side is distinctly warted, a feature not seen in any other member of *Orbiliomycetes* (see Fig. 55). *O. fabacearum* forms with its somewhat irregularly curved spores a transition to *O. renispora*, *O. umbilicata*, and *O. xanthoflexa*, which have spores curved under a more or less wider arch, and these form a bridge to species with straight, cylindrical or ellipsoid spores. *O. spirospora* is exceptional in having helicoid spores. There is also no sharp limit between ellipsoid-spored taxa and those with cylindrical spores.

In *O. eucalypti* the SBs are impossible to recognize without vital staining whenever LBs of a similar size are associated, and in some collections they could not even be discerned with that method. In *O. fabacearum* and *O.* cf. *subfabacearum* the SBs are consistently attached at the dorsal side of the spores. In the type of *O. subfabacearum*, however, SBs could not be found, instead, the small drop at the dorsal side was KOH-resistant. *O. guyanensis* is remarkable in having broadly tear- to almost plug-shaped SBs.

Four species deviate from the remaining in having lanceolate to spathulate paraphyses (*O. guyanensis*, *O. minutispora*, *O. spirospora*, *O. umbilicata*). They are grouped together here but whether they form a natural relationship is uncertain. Sometimes, particularly in *O. subfabacearum* and *O. fabacearum* and in some collections mentioned under *O. liliputiana*, the terminal cells of paraphyses tend to be unusually short, i. e., not or only slightly longer than the lower cells.

The thickest exudate was noted in *O. fabacearum*. Three species (*O. coccinella*, *O. dalmatica*, *O. subfabacearum*) possess glassy processes which are always very short and provoke a finely rough to crenulate margin. *O. aureocrenulata* is exceptional in its golden yellow apothecia with a very distinct stipe and a notched margin. *O. flexispora* resembles *O. xanthoflexa*, but shows also morphological similarities to sections *Arthrobotrys* or *Aurantiorubrae*. Because anamorph and molecular data were unavailable, this species is placed with hesitation in series *Orbilia*.

Species delimitation. Problems at the species level arose in almost every included species. All of the ellipsoid-spored taxa are difficult to delimit from each other, and mainly their anamorph and/or molecular data indicate that they do not belong to a single species. *O. dryadum* is not always easy to separate from *O. epipora* (section *Arthrobotrys*) and *O. cunninghamii*. The *xanthostigma-leucostigma* complex poses an unsolved enigma because of an extraordinary molecular heterogeneity in spite of a highly concordant micromorphology. Our recent results support the earlier distinction between colourless (*O. leucostigma*) and yellow populations (*O. xanthostigma*). Also *O. fabacearum* and *O. subfabacearum* appear to form a complex of difficult taxa.

Anamorph. Three types of conidia have been observed in series *Orbilia*. The typical conidia are branched (staurosporous, dicranidion-like), but some species possess unbranched, phragmosporous conidia, either straight (dactylella-like) or curved (vermispora-like). However, species with dicranidion-like conidia may also form a varying percentage of dactylella-like conidia.

(1) Dicranidion-like conidia typically resemble a tuning fork, characterized by 2 parallel or somewhat diverging arms and a longer or shorter stipe which can also be absent. They are formed on short to rather long conidiophores, either singly at the tip or often sympodially. The two arms sometimes tend to diverge like a V or Y, therefore, a sharp morphological separation between dicranidion- and trinacrium-like conidia is impossible. In some species the conidia tend to form 4 or up to 8 arms.

Dicranidion-like conidia are so far known with certainty from 10 species of series *Orbilia* (*O. battenii*, *O. cejpii*, *O. cunninghamii*, *O. eucalypti*, *O. fissilis*, *O. leucostigma*, *O. renispora*, *O. tremulae*, *O. xanthoflexa*, *O. xanthostigma*). The type species *Dicranidion fragile* is the anamorph of the very common *O. eucalypti*, while *D. gracile* and *D. tenue* appear to belong to the likewise ubiquitous *O. xanthostigma* aggregate. The morphologically assumed conspecificity of *O. tremulae* and *D. inaequale* is disproved by a considerable molecular mismatch. In the anamorph of *O. fissilis* (≡ *D. fissile*) the conidia deviate in having also 4 arms in equal frequency. In *O. frangulae* we assume an anamorph with 4–8-armed dicranidion-like conidia.

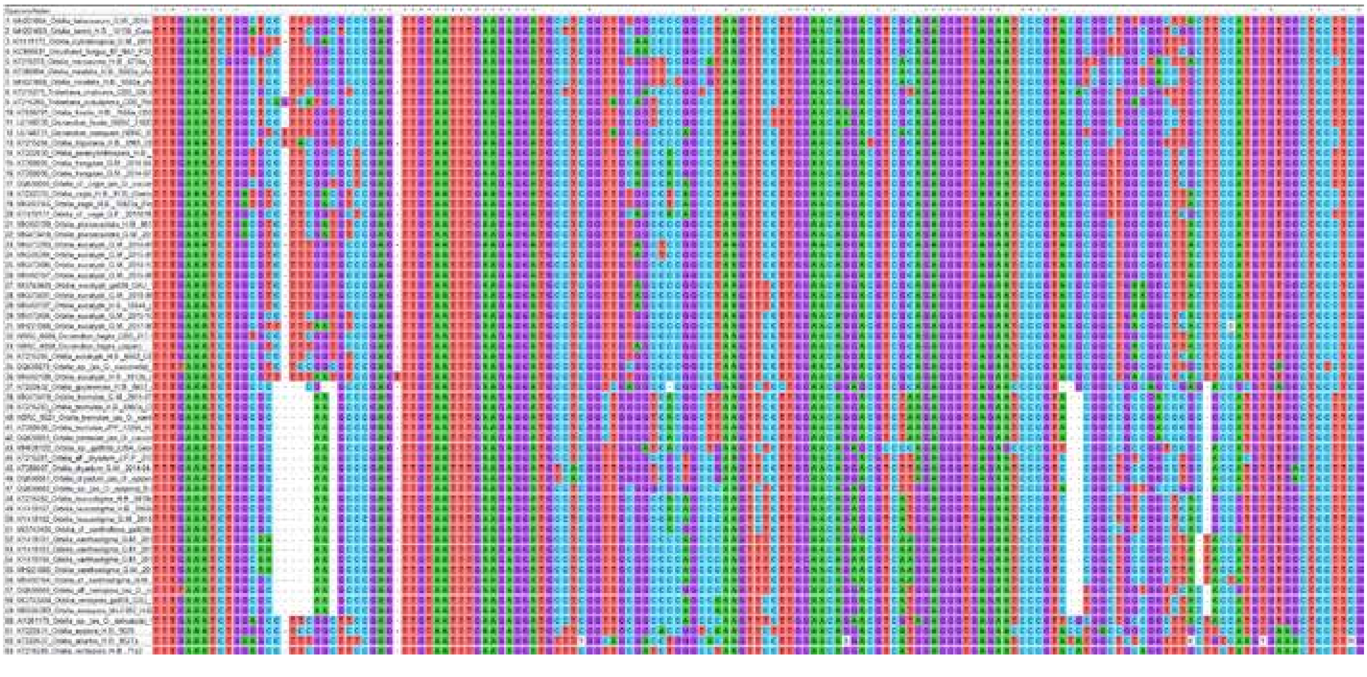
(2) The straight phragmoconidia of *O. dryadum* resemble those of *O. epipora* (series *Neodactylella*). Yet, molecular data suggest a relationship between *O. dryadum*, *O. tremulae* and *O. cunninghamii* (see Phyls 22–23). We conclude that the anamorph-typified genus *Dicranidion*, if used in a phylogenetic sense, should be enlarged to include also anamorphs which consistently lack branched conidia. This view is supported by the fact that in pure cultures unbranched and higher-branched conidia may simultaneously occur with 2-armed conidia. For example, conidia with 4 arms were rather frequently formed along with 2-armed ones in our and the type culture of *O. fissilis*, and unbranched conidia were rarely or frequently noted in the type culture of *D. inaequale* by Tubaki & Yokoyama (1971) and Butterfield (1973), depending on the agar medium. Also in the isolate of *O. cunninghamii* and the type culture of *D. fissile* dactylella-like conidia occurred along with dicranidion-like ones.

(3) Vermispora-like anamorphs were observed in pure culture of *O. liliputiana* and *O.* cf. *subfabacearum*, and on the natural substrate in *O. fabacearum*. Their phragmoconidia resemble dactylella-like conidia but are slightly to strongly curved. A sharp limit between type (2) and (3) does not exist. Within series *Orbilia*, data on conidiophores were so far unavailable for this type of conidia.

Dicranidion-like anamorphs very similar as in series *Orbilia* also occur in three quite distant groups: in series *Ovales* of section *Lentiformes* (subgenus *Hemiorbilia*), and in series *Xanthoguttulatae* and *Abutilones* of section *Aurantiorubrae* (subgenus *Habrostictis*). *Orbilia ovalis* of series *Ovales* resembles members of series *Orbilia* also in the teleomorph, including thin-walled, truncate ascus apices, but our molecular data from two different strains refer this species in section *Lentiformes*.

Phylogeny. According to our phylogenetic analyses of SSU+ITS+LSU, ITS, and LSU (Phyls 22, 23, S27), a division of series *Orbilia* according to ascospore and paraphysis shape as done in our keys A–D is not supported. In fact, various clades with more or less unresolved phylogenetic position are observed within series *Orbilia*. four of them contain at present more than one species or genotype: (1) the medium

Table 73. Alignment of LSU showing partial D1 domain (pos. 110–269) with three gappy regions, which appear to trace back to a common ancestor and mark the *xanthostigma-tremulae* clade.



(Phyl. 22) or weakly (S27) supported *O. eucalypti* clade (key A) includes the genetically variable *O. eucalypti*; (2) the medium (22, 23, S27) supported *cejpii-frangulae* clade includes four species with ellipsoid (key A) to subcylindrical (key B) spores (*O. cejpii*, *O. plurivacuolata*, *O. frangulae*, *O. paracylindrospora*); (3) *O. dryadum* and *O.* aff. *dryadum* have (sub)cylindrical spores (key B) and form a strongly supported clade (Phyls 22, 23, S27); (4) the strongly (22) or medium (23) supported *leucostigma-xanthostigma* clade comprises species with cashew-shaped, mostly warted spores (key D, spores smooth in *O. xanthoflexa*).

In the combined analysis in Baral et al. (2017b), *O.* aff. *dryadum* clustered with *O. tremulae* (spores ellipsoid, key A) and the *leucostigma-xanthostigma* clade in a strongly supported clade, and this clade is likewise seen in Phyls 7 and 22, though with only medium or weak support, respectively. *O. guyanensis* (with cylindric-ellipsoid spores and lanceolate paraphyses, key C) belongs here despite its high distance, and also *O. cunninghamii* with cylindric-clavate spores (key B), for which no LSU was available, might belong in this clade. This group, which is called *xanthostigma-tremulae* clade here, shares characteristic deletions in the LSU D1 domain which support its monophyly (see below).

O. eucalypti and the *cejpii-frangulae* clade clustered together in Phyls 22–23, but this clade did not receive support, and molecular motifs that would characterize the clade have not been found. Another association is observed for a group comprising *O. brettii*, *O. fissilis*, and *O. liliputiana* with ellipsoid to subglobose spores (key A), *O. cylindrospora* with cylindical spores (key B), *O. fabacearum* with smooth cashew-shaped spores (key D), *Tridentaria subuliphora*, and series *Microsomates*, but the clade did not receive support in our analyses (Phyls 22, S27), and in Baral et al. (2017b) it is paraphyletic.

Orbilia epipora and *O. atlantis*, both with rod-shaped spores similar as in *O. dryadum* or *O. cunninghamii*, clustered in series *Neodactylella* of section *Arthrobotrys*. Also *O. cupressi*, *O. fraxini*, and *O. rhamni*, which have cylindric to ellipsoid, partly allantoid spores, clustered in that series, although they resemble members of series *Orbilia* or section *Aurantiorubrae*.

Specific nucleotide positions. Characteristic positions in the rDNA which are unique for series *Orbilia* could only been found in the SSU V8 region: pos. 52 is CGAGT**TC** in most of the taxa, except for *O. liliputiana* and *Tridentaria subuliphora* which have CGAGT**AT** and herein concur with most other orbiliaceous groups which alternatively show the variants CGAGT**TT** and CGAGT**GT** (or rarely CGAGT**AC** in a few *Hyalorbilia* spp., *O. polyspora*, and clones U1–5).

Three positions in the 5.8S are informative within the series. Pos. 30 is usually TTC**T**CGC as in most remaining *Orbiliomycetes*, but in *O. dryadum* and *O. cunninghamii* it is TTC**C**CGC in concordance with *Hyalorbilia*, series *Abutilones*, section *Ovoideae*, and predacious members of section *Arthrobotrys*. Pos. 121 and 134, which belong to stem-loop B8, are correlated by base pairing (see Tab. 18) by providing two versions: G+C (mostly **G**TTGGTATTCCGA**C**) occurs in the *leucostigma-xanthostigma* clade and in *O. cunninghamii*, *O. dryadum*, *O. eucalypti* (subclade D1), *O. guyanensis*, *O. liliputiana*, *O. renispora*, *O. tremulae*, and *O. xiushanensis*, whereas A+T (mostly **A**TTGGTATTCCGA**T**) is observed in *O. brettii*, *O. cejpii*, *O. cylindrospora*, *O. eucalypti* (subclades A–C, D2), *O. fabacearum*, *O. fissilis*, *O. frangulae*, *O. paracylindrospora*, *O. plurivacuolata*, *D. inaequale*, and *Tridentaria* spp. Series *Microsomates* shows both versions, with *O. mirabilis* having G+C. A+T is also frequent, e. g., in sections *Ovoideae* (exception: *O. subovoidea* with G+C) and *Arthrobotrys* (including *O. epipora*).

The *xanthostigma-renispora* clade exhibits some characteristic motifs in the D1 domain of LSU: according to available LSU sequences (*xanthostigma-leucostigma* complex, *O.* cf. *xanthoflexa* ga026b, and the loosely associated *O. renispora* and *O.* aff. *renispora* B.L. 747), members of this aggregate differ at pos. 305 by **G** and after pos. 309 by a rare insert (**C**) from the rest of series *Orbilia*: GGTA**G**ATTT**C**CATC vs. GGTA**A**ATTT**-**CATC. Based on these 2 deviations, we include *O. renispora* s.l. in the *xanthostigma-renispora* clade, although their joint clade received no support (Phyl. 22). However, three exceptions occurred: *O. delicatula* YNUCC 6028 shows the latter variant although it clustered near *O. xanthostigma*; ‘*O. epipora*’ B.L. 6195 shows the combination GGTA**G**ATT**-C**CATC although it clustered near *O. leucostigma*; *O. fabacearum* deviates by GGTA**A**ATT**-C**CATC and shows an unresolved position outside the *xanthostigma-tremulae* clade. Of course, the exact position of the gap in these variants is not certain.

A relationship of the *xanthostigma-renispora* clade with *O. dryadum*, *O. tremulae*, *Orbilia* spp. (B.L. 6195 and ga055b), and *O. guyanensis* is supported in the D1 domain by 3 gappy regions that appear to trace back to a common ancestor (position of gaps ambiguous): (1) pos. 129–137 is **----AA-G**C (in *O. guyanensis* **---**C**G--G**C) vs. TTTT**AA**T**G**T, CTTT**GG**T**G**C, CTTC**GG**T**G**C, CTTC**GA**C**G**T, and some other variants in other taxa of section *Orbilia*; (2) 2 gaps between pos. 225 and 228; (3) 1 gap between pos. 243 and 245 (Tab. 73). These characteristic gaps suggest that the *xanthostigma-tremulae* clade is a monophyletic group, although its support in phylogenetic analyses was not strong.

Another motif which includes 4 gaps (LSU D2 domain at pos. 540–547, **--TC--GG**) occurs in the *xanthostigma-tremulae* clade but also in *O. eucalypti* and the *cejpii-frangulae* clade, the remaining species lack these gaps (CT**TC**GG**GG**, CC**TC**GG**GG**) or have only 2 gaps (*O. mirabilis*, *Tridentaria implicans*, YY**-C-**G**GG**).

Undoubtedly, also *O. xanthoflexa* and possibly *O. cunninghamii* (both without LSU) belong in this *xanthostigma-tremulae* clade which appears, e. g., in Phyl. 22 as a weakly supported clade. This clade is supported by stem-loop 8 of 5.8S, except that here also *O. liliputiana* shares the motif. In conclusion, cashew-shaped spores probably developed from cylindric-ellipsoid spores in two independent lineages, 1 represented by *O. fabacearum* with medium curved smooth spores, and the other by *O. renispora* and *O. xanthoflexa* as ancestral taxa with slightly to medium curved smooth spores, and the *xanthostigma-leucostigma* complex as an advanced group with strongly curved warted spores.

Ecology. Series *Orbilia* occurs worldwide, with a significant preference for hygric environments. As an exception, the very common *O. eucalypti* and some rarely collected taxa prefer more or less exposed (xeric) substrate. Most of the species were recorded in temperate to subalpine-boreal regions, but some in tropical (sub)humid and some in semihumid to semiarid, rarely arid zones.

Key to species of series *Orbilia*

1. Exudate over paraphyses often 1–2 µm thick, cloddy to continuous; SBs min. (0.8–)0.9 µm diam.; asci 8- up to 64-spored; apothecia always desiccation-tolerant ... see **section *Ovoideae***, p. 1241

1. Exudate over paraphyses absent or thin (0.2–0.5 µm), rarely 1(–2) µm thick, often sparse and finely granular; SBs max. 0.8(–0.9) µm diam.; asci 8-, rarely 16-spored; apothecia desiccation-sensitive or -tolerant ... 2

2. Paraphyses consistently slightly to distinctly spathulate-lanceolate or lageniform ... KEY C

2. Paraphyses clavate-capitate or uninflated, only exceptionally narrowed above ... 3

3. Spores cylindrical, always (very) strongly curved (by ~90–270°) under a narrow arch (C-shaped), *2.3–3.5(–4.5) µm long in situ, in some species warted ... KEY D

3. Spores straight or only slightly to medium curved, exceptionally strongly curved (over 90°) but under a wide arch (C- to L-shaped, also helicoid) and then *3.5–6 µm long in situ, always smooth ... 4

4. Spores ellipsoid(-fusoid) to ellipsoid-clavate, ovoid or (sub)globose, rarely some spores cylindrical(-ellipsoid), length/width ratio predominantly < 2.5(–3) ... KEY A

4. Spores cylindrical to cylindric(-ellipsoid) or cylindric(-clavate), length/width ratio mostly > 2.5 ... KEY B

If spores with ± eccentrical SBs see series *Drechslerella* and *Gamsylella* of section *Arthrobotrys*

KEY A (spores ellipsoid-ovoid, paraphyses uninflated to clavate-capitate)

1. Spores *(1.8–)2–2.5(–3) × (1–)1.2–1.4 µm; paraphyses capitate; apothecia 0.4–0.8 mm diam., pale yellowish; wood of *Pinus*, cold-temperate humid atlantic western Europe ... ***O. battenii***, p. 1333

1. Spores > *2.5 µm long and/or > *1.4 µm wide ... 2

2. Spores subglobose to broadly ellipsoid, max. *3.5(–4) µm long and min. *(1.6–)1.7 µm wide, length/width ratio ~(1–)1.3–1.6 ... 3

2. Spores ellipsoid(-subfusoid), length/width ratio ~1.6–3 ... 7

3. Marginal cortical cells with glassy processes (1–7 × 2.5–4.5 µm); paraphyses with firmly attached cap-like exudate; spores *(2.8–)3–3.5(–4) × 2–2.5 µm, with rather large SBs; apothecia bright orange; bark of *Juniperus*, mesomediterranean semihumid southern Europe ... ***O. dalmatica***, p. 1332

3. Marginal cortical cells without glassy processes; paraphyses without prominent cap-like exudate ... 4

4. Paraphyses uninflated to medium clavate, generally ± bent or hooked; spores *2–2.8 × 1.6–1.9 µm; SBs 0.3–0.4 µm wide; conidia vermispora-like; apothecia light to bright orange; wood of *Pinus*, mesomediterranean sub- to semihumid Macaronesia ... ***O. liliputiana***, p. 1331

4. Paraphyses slightly to strongly capitate, straight, if curved then spores distinctly > *3 µm in length; conidia dicranidion-like ... 5

5. Asci *(3.3–)3.8–4.5(–5.3) µm wide (†3–4.7 µm); spores *3–4.5 × 2–3 µm (†1.7–2.8 µm wide), broadly ellipsoid to (sub)globose; SBs often absent; apothecia desiccation-tolerant; wood & bark of angio- and gymnosperms, temperate humid to submediterranean semihumid Europe ... aberrant form of ***O. eucalypti*** with subglobose spores, p. 1357

5. Asci *3.2–4 µm wide (†2.5–3.5 µm); spores *2.5–3.5(–4) × 1.6–2.3 µm (†1.2–2 µm wide); SBs often present, 0.3–0.6 µm wide ... 6

6. Spores *(2–)2.3–3(–3.4) × (1.7–)1.9–2.3(–2.5) µm (†1.7–2 µm wide), broadly ellipsoid to subglobose, often with a few LBs 0.5–0.8 µm diam.; conidia with a distinct stipe and 2–4 arms that slightly to usually strongly diverge; paraphyses rarely strongly capitate; apothecia pale to light rose-orange, desiccation-sensitive; wood & bark of angiosperms, boreal to temperate humid Europe, subtropical humid eastern Asia ... ***O. fissilis***, p. 1350

Similar collections on xeric substrates without known anamorph are treated as *O.* (cf.) *cejpii* (p. 1340). Compare also '*Orbilia* sp.' with the anamorph *Arthrobotrys nonseptatus* (series *Arthrobotrys*, p. 1551) and species around *O. orientalis* (series *Drechslerella*, e. g., *O. tonghaiensis*, p. 1653)

6. Spores *1.6–2 µm wide (†1.2–2 µm), LBs sparse and minute or absent; conidia with 2 (exceptionally 4) arms that are parallel or diverge only slightly or sometimes moderately; paraphyses often very strongly capitate ... (try under 7)

7. Spores *1.3–1.6 µm wide ... 8

7. Spores predominantly > *1.7 µm wide ... 10

8. Spores †2.3–3.3 × (1.1–)1.2–1.5(–1.6) µm; SBs †0.7–0.9 µm wide; paraphyses strongly capitate, straight; apothecia 0.5–3 mm diam., bright orange; ?hygric wood of angiosperm trees, tropical humid South America ... ***O. gaillardii***, p. 1335

8. Spores *2.8–3.8 × 1.3–1.6 µm; SBs *0.3–0.4 µm wide; paraphyses slightly to medium capitate, often apically bent or hooked; apothecia (0.15–)0.3–1(–2) mm diam., whitish or pale to bright yellow or rose-orange; xeric wood or bark, Europe ... 9

If spores inequilateral to slightly curved, compare *O. renispora* (key D).

9. Spores *2.8–3.8(–4) × 1.3–1.6(–1.8) µm, ellipsoid to subcylindrical; apothecia pale cream-rose; wood of *Frangula*, warm- to cold-temperate humid western and central Europe ... ***O. frangulae***, p. 1345

9. Spores *(3–)3.7–4.5(–5) × 1.3–1.4(–1.6) µm, mainly subcylindrical; apothecia rose-orange; wood of *Euonymus*, warm-temperate humid western Europe ... ***O. paracylindrospora***, p. 1343

A collection on bark of *Corema* in thermomediterranean semihumid atlantic southwestern Europe deviates in wider SBs (0.4–0.6 vs. 0.3 µm, p. 1344).

10. Asci partly arising from croziers; apothecia 0.17–0.3 mm diam., pale greyish(-rosaceous) to cream; spores *3.2–4.4 × 1.7–2.1 µm; SBs absent; conidia (presumed) with diverging arms and long stipe; xeric wood of *Acer* & *Cornus*, oro- to cold-temperate (thermophilous) humid central Europe ... ***Hyalorbilia hergiswiliana***, p. 433

10. Asci consistently arising from simple septa; apothecia usually larger; spores *2.2–8 × 1.6–4 µm; SBs usually present, 0.3–0.8 µm wide; conidia with or without short stipe ... 11

11. Margin with 20–35 µm long glassy processes; spores *(5–)6–7.3(–8) × (2.5–)2.8–3.5(–4) µm; wood of *Populus*, cold-temperate humid western North America .... ***O. brettii*** (inc. sed.), p. 1323

11. Margin without glassy processes; spores *(1.6–)1.7–2.5(–3) µm wide 12

12. Conidia with truncate/rounded base without stipe, with small nodular scar, oblique basal septa absent or only singly (asymmetrical), arms parallel; spores *(2.7–)3–4.2(–4.5) × (1.5–)1.7–2(–2.2) µm, (subcylindric-)ellipsoid, sometimes fusoid(-clavate); SBs consistently present, *0.3–0.6 µm diam.; apothecia whitish, yellow-ochraceous, or yellow-orange; hygric, rarely xeric bark & wood of angiosperms, boreal to suprasubmediterranean humid Europe .... ***O. tremulae***, p. 1373

12. Conidia with a conical base or a distinct stipe, mostly 2 oblique basal septa present; apothecia whitish, yellow-orange, orange-rose, or pinkish........ 13

13. Spores *(2.2–)2.4–3.5(–4) × (1.4–)1.5–2(–2.2) µm, ellipsoid to ovoid or almost subglobose, sometimes ovoid; with 0.3–0.5(–0.6) µm wide SBs; conidia with distinct, partly septate stipe, arms diverging or not; apothecia white to yellowish-orange-rosaceous; hygric or xeric wood & bark of angiosperms, also gymnosperms, orotemperate to subtropical humid to semihumid Europe, Macaronesia, North America, eastern Asia, eastern Australia .... ***O. cejpii***, p. 1337

13. Spores *(3–)3.5–6(–8) × 1.8–2.5(–3) µm, ellipsoid- to fusoid(-clavate); with or without (0.4–)0.5–0.7(–0.8) µm wide SBs; conidia with conical base or rudimentary stipe, arms usually parallel, sometimes diverging; apothecia orange or rose, rarely whitish 14

14. Paraphyses containing many small to large (0.5–3 µm wide), globose to elongate, non- or slightly refractive vacuoles (sometimes also 1 globose SCB in apex); xeric (rarely hygric) wood & bark of angiosperms, also gymnosperms, oroboreal to thermomediterranean humid to arid, worldwide .... ***O. eucalypti***, p. 1352

14. Paraphyses containing numerous small (0.3–0.8 µm wide), globose, slightly to strongly refractive, hyaline vacuoles (VBs) but never SCBs; xeric bark & wood of *Salix* & *Rosa*, thermoboreal to mesosubmediterranean (semi)humid Europe ..... ***O. plurivacuolata***, p. 1347

KEY B (spores cylindrical, cylindric-clavate, straight to strongly curved under a wide arch, paraphyses uninflated to clavate-capitate) [compare also cylindric-spored species of section *Arthrobotrys*]

1. Spores mostly medium to strongly curved 2

1. Spores straight to slightly curved 3

2. Spores ± falcate, with obtuse base, subapically not constricted, †(3–)3.8–5.3(–5.7) × 0.9–1.3 µm (in situ); apothecia yellow, 0.18–0.7 mm diam.; paraphyses strongly capitate, with small yellow LBs; hygric wood of *Acer*, temperate to subtropical humid eastern North America .... ***O. xanthoflexa***, p. 1422

2. Spores falcate to helicoid, with acute base, often subapically slightly constricted, †4–5.3(–6) × 0.8–0.9 µm (in situ); hygric bark of *Melaleuca*, warm-temperate humid eastern Australia .... ***O. flexispora*** (inc. sed.), p. 1429

3. SBs in middle of spores; spores *(4.5–)5–6(–6.5) × 1.2–1.5 µm; apothecia rose-orange, margin distinctly dentate by glassy processes; xeric bark of *Quercus*, suprasubmediterranean semihumid southern Europe .... ***O. beatricis*** (inc. sed.), p. 1322

3. SBs near spore apex; apothecia with a smooth margin 4

4. Spores 4–8 µm long........ 5

4. Spores predominantly < 4.5(–5) µm long (in *O. acuum* rarely up to 6 µm); SBs close to apex 7

5. SBs globose, 0.3–0.5 µm diam., 0.4–0.8 µm away from apex, attachment invisible; Spores *(4.5–)5–6(–7) × (0.8–)0.9–1 µm, ± straight; asci †22–35 µm long; apothecia pale yellowish-chlorinaceous; paraphyses with chlorinaceous VBs; xeric to hygric bark of *Ilex*, cones of *Cupressus*, herbaceous stems, temperate to submediterranean atlantic Europe .... ***O. atlantis*** (section *Arthrobotrys*), p. 1442

5. SBs globose to broadly tear-shaped, rarely ampulliform, close to apex........ 6

6. Spores 4–7(–8) × (1–)1.1–1.3(–1.5) µm, ± subcylindrical, straight; mainly on wood of conifers; oroboreal to suprasubmediterranean humid Europe........ ***O. cylindrospora*** (inc. sed.), p. 1314

6. Spores *(4–)4.5–7.5(–8) × (1.1–)1.3–1.7(–1.9) µm, cylindrical to narrowly fusoid, ± straight; bark of angiosperm trees and shrubs, temperate humid western and subtropical semihumid to semiarid eastern Australia........ ***O. austrocylindrica*** (inc. sed.), p. 1317

7. SBs †1.2–1.8 µm long, elongate tear-shaped; spores †(3–)3.5–5(–6) × 0.8–1.2 µm; paraphyses uninflated to medium capitate; apothecia fresh whitish........ 8

7. SBs *0.4–1 µm long (total length), globose, attachment ± invisible; spores max. *4.3(–5) µm long 9

8. Spores mainly subcylindrical, straight; asci †27–31 µm long; needles and bark of *Pinus*, temperate humid central Europe .... ***O. acuum*** (section *Arthrobotrys*), p. 1658

8. Spores mainly cylindric-clavate, slightly curved; asci †30–40 µm long; stems of *Euphorbia*, temperate humid central Europe .... ***O. cyparissias*** (section *Arthrobotrys*), p. 1659

9. Spores gradually ± tapered towards base (cuneate), †(3–)3.3–4.2(–4.7) × 0.8–1 µm; SBs invisible in dead state; asci †30–40 µm long; paraphyses strongly capitate; apothecia fresh white or yellowish; hygric wood (rarely bark) of angiosperms, temperate to subtropical humid New Zealand .... ***O. cunninghamii***, p. 1392

9. Spores ± subcylindrical........ 10

10. Spores *(3–)3.7–4.5(–5) × 1.3–1.4(–1.6) µm; paraphyses without refractive VBs, apex uninflated to medium clavate-capitate; asci †32–38 µm long; apothecia light rose-orange or pale rose-cream; xeric wood & bark (*Euonymus*, *Corema*), warm-temperate humid western and thermomediterranean semihumid southern Europe........ ***O. paracylindrospora***, p. 1343

10. Spores max. *1.3(–1.5) µm wide; paraphyses containing ± refractive VBs; hygric wood........ 11

11. Spores *(1.8–)2–2.5(–3) × (1–)1.2–1.4 µm, subcylindric to ellipsoid; conidia dicranidion-like; wood of *Pinus*, cold-temperate humid atlantic western Europe ... ***O. battenii***, p. 1333
For small-spored samples on angiosperm wood see under *O. dryadum*.

11. Spores *(2.3–)2.7–4.3(–5) µm long, (sub)cylindric; conidia unbranched ... 12

12. Spores *(2.3–)2.7–3.9(–4.2) × (1–)1.1–1.3(–1.5) µm (l:w ratio around 3); paraphyses usually medium to very strongly capitate; asci †22–41 µm long; apothecia white to yellowish or often cream-rosaceous, scattered to gregarious in small groups; conidia *(16–)20–35(–56) × (3–)3.5–5.5(–6.5) µm, 3–7-septate; wood of angiosperms, rarely gymnosperms, orotemperate to mesomediterranean (sub)humid, worldwide ... ***O. dryadum***, p. 1385
Samples on bark of *Ulex* in cold-temperate atlantic Europe deviate in rather narrow spores (*1–1.2(–1.3) µm) and long conidia (*37–52 µm, p. 1389).

12. Spores *(2.8–)3.3–4.3(–5) × 0.8–1 µm (l:w ratio around 4); paraphyses mostly only slightly capitate; asci †18.5–26 µm long; apothecia white, often densely gregarious in large number; conidia *(13.5–)16–22(–25) × 2.2–3(–3.2) µm, 1–3-septate; wood of angiosperms, especially *Fagus* and *Salicaceae*, oro- to thermotemperate humid Europe, North America, western Asia ... ***O. epipora*** (series *Neodactylella* of section *Arthrobotrys*), p. 1446

KEY C (spores cylindrical, straight to strongly curved under a wide arch, paraphyses spathulate to lanceolate-lageniform, distinctly protruding)

1. Spores straight, rarely slightly curved, †2.7–3.6 × 0.9–1.1 µm; asci †18–26 × 2.4–2.7 µm; paraphyses lanceolate; apothecia flat, sessile, yellowish, 0.5–1 mm diam.; stem of *Cirsium*, temperate humid Europe ... ***O. minutispora***, p. 1385

1. Spores very slightly to distinctly curved, if straight then longer or wider; asci †20–35(–42) × 2.8–3.8 µm; apothecia ± saucer-shaped or umbilicate and/or margin ± distinctly protruding ... 2
If apothecia hairy and spores with ± eccentrical SBs see *O. pilosa* (section *Arthrobotrys*, p. 1629); if asci exceeding †35 µm in length and marginal cortical cells with short glassy caps compare *O. fraxini* (section *Arthrobotrys*, p. 1480).

2. Spores *1.2–1.8 µm wide, straight to slightly curved; Europe & America ... 3

2. Spores *0.8–1.2 µm wide, medium to strongly curved; eastern Asia ... 4

3. Spores *2.8–3.7 × 1.5–1.7(–1.8) µm; SBs 0.5–0.8 µm wide, subglobose to broadly tear-shaped, ± broadly attached, often with large LBs; paraphyses ± lanceolate; apothecia white; hygric angiosperm wood, tropical humid South America ... ***O. guyanensis***, p. 1380
A collection on ?wood from montane Asia (Sichuan, H.B. 5829) mentioned under *O. umbilicata* differs in larger asci (†40–50 × 3.5–4.4 µm), spathulate paraphyses, and longer spores (†3–4.3 × 1.2–1.4 µm, p. 1382).

3. Spores *4.5–6 × (1–)1.2–1.3(–1.5) µm; SBs 0.3–0.5 µm wide, globose with very fine filum, without large LBs; paraphyses ± lageniform; apothecia ± orange; xeric bark (& wood) of *Rhamnus* & *Ficus*, mesomediterranean semihumid Europe. ... ***O. rhamni*** (section *Arthrobotrys*), p. 1483

4. Spores allantoid, *(3–)3.5–4.5(–5) × (0.9–)1–1.2(–1.4) µm; asci †25–42 µm long; medullary excipulum 25–70 µm thick, of dense, not or only slightly gelatinized t. intricata; hygric angiosperm wood, temperate to subtropical humid eastern Asia ... ***O. umbilicata***, p. 1381

4. Spores helicoid, †(3.5–)4–4.2(–4.5) × 0.7–0.9 µm; asci †20–26 µm long; medullary excipulum 150–230 µm thick, of loose, strongly gelatinized t. intricata; hygric angiosperm wood, subtropical humid Japan ... ***O. spirospora***, p. 1384

KEY D (spores cashew-shaped, paraphyses uninflated to clavate-capitate)

1. Spores predominantly 4–5(–6) µm long (in situ), ± falcate ... see ***O. flexispora*** (p. 1429) & ***O. xanthoflexa***, (p. 1422)

1. Spores predominantly 2.5–3.5(–4) µm long (in situ), ± cashew-shaped ... 2

2. Asci predominantly 16-spored; spores smooth, †2.5–3.2(–4.5) × 1.1–1.3(–1.5) µm; marginal cortical cells with glassy caps; xeric bark of *Betula*, oroboreal humid Europe ... ***O. coccinella***, p. 1427

2. Asci 8-spored; marginal cortical cells usually without glassy caps (except for *O. subfabacearum*) ... 3

3. Spores distinctly warted on the curved dorsal side (exceptionally smooth), */†(2.2–)2.4–3(–3.3) × 1–1.6 µm, curved by ~(120–)160–180(–200)°; SBs globose, near one spore end; apothecia (0.2–)0.5–2(–4.5) mm diam. ... 4

3. Spores consistently smooth; apothecia 0.15–1.1 mm diam. ... 6

4. Apothecia ± gelatinous (excipular walls slightly gelatinized), with a well-defined cylindrical stipe which is usually about as long as wide; margin regularly notched by forming obtuse lobes, disc bright golden-yellow; hygric angiosperm wood; tropical humid Middle & South America ... ***O. aureocrenulata***, p. 1416

4. Apothecia non-gelatinous, sessile or with short thick, partly obconical stipe ~2–10× wider than long; margin even, in large apothecia sometimes lobate, disc whitish-rosaceous to yellow-orange; hygric, rarely xeric angio- and gymnosperm wood (rarely bark), boreal to warm-temperate humid but also mediterranean (semi)humid or tropical humid, worldwide ... 5

5. Apothecia whitish to very pale rosaceous-violaceous (usually growing on underside) ... ***O. leucostigma***, p. 1394

5. Apothecia pale to bright yellow-orange (growing ± exposed). ... ***O. xanthostigma***, p. 1394
Heterogenous complex of taxa with very different molecular characters. Within Europe the 2 above species are known which merely differ by colour and sometimes even grow intermingled. Extra-European records are frequently with yellow colours and represent different unnamed taxa.

6. SBs always situated at one end of the spore, globose (but partly also with 1–2 LBs); hygric wood & bark ... 7

6. SBs consistently situated at the dorsal side in the middle of the spore, globose to broadly tear-shaped; paraphyses uninflated to slightly capitate; apothecia whitish to rose-cream; mainly on xeric bark & wood ... 8

7. Spores slightly to medium curved, with or without 1-2 small LBs, *(2.4–)2.6–3.5(–3.7) × 1.1–1.8 µm; paraphyses slightly to strongly capitate; apothecia mostly bright yellow; hygric wood of angiosperms, cold-temperate to subtropical humid eastern North America ..... ***O. renispora***, p. 1418

7. Spores strongly to very strongly curved, with 1-2 large LBs, *3–3.3(–3.6) × 1.5–1.7 µm; paraphyses strongly capitate; apothecia yellowish; hygric bark of indet. angiosperm, subtropical humid eastern & southeastern Asia.......................... ***O*. aff. *renispora***, p. 1420

8. Spores curved by (70–)90–180(–220)°, *(2.3–)2.5–3.7(–4.2) × 1.1–1.6 µm; asci †24–36 µm long; apothecia (cream-)rose, 0.15–0.9 mm diam.; margin without glassy caps; bark & wood of *Faboideae* and other angiosperms, rarely gymnosperms, cold-temperate humid to mesosubmediterranean semihumid, mainly atlantic Europe .... ***O. fabacearum***, p. 1423

8. Spores curved by (120–)160–270° (often > 180°); apothecia 0.15–0.5 mm diam...9

9. Asci †27–35 µm long; margin with or without short glassy caps; spores *2.5–3.5 × 0.9–1.5 µm; apothecia pale rose; bark & wood of climber, subtropical subhumid Australia .... ***O. subfabacearum***, p. 1426

9. Asci †18–24 µm long; margin without glassy caps; spores *2.4–2.9 × 0.9–1.2 µm; apothecia whitish; bark of *Hibiscus* etc., (sub)tropical humid Australia and eastern Asia .... ***O*. cf. *subfabacearum***, p. 1427

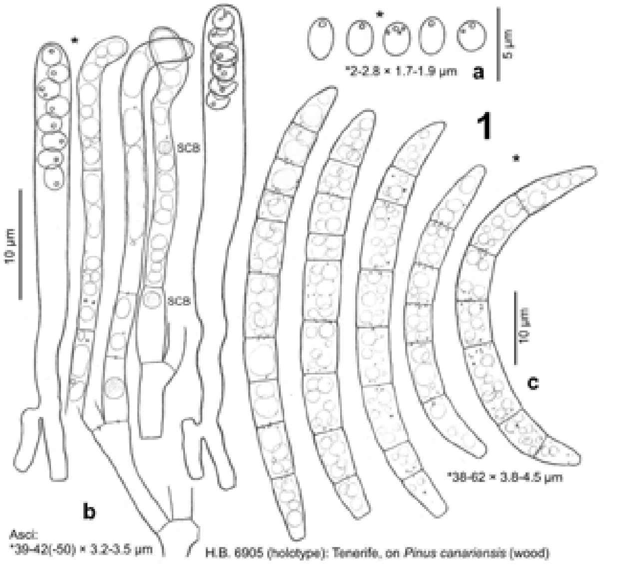


Plate 836. **1**: *Orbilia liliputiana*. – **a**. ascospores; **b**. asci and paraphyses; **c**. conidia from culture.

Orbilia liliputiana Baral, Quijada & E. Weber, **sp. nov.**, MB 814372 — Pls 836–837

Etymology: named after the small ascospores.

Typification: Macaronesia, Tenerife, La Esperanza, branch of *Pinus canariensis*, 31.III.2001, R. Galán (ex H.B. 6905, M-0276500, holotype; ex-type culture: CBS 116213; sq.: KT215284).

Latin diagnosis: *Apothecia hydratata 0.3–1.1 mm diam., dilute luteola vel salmonea, subsessilia, margine laevi. Ascosporae *2–2.8 × 1.6–1.9 µm, late ellipsoideae vel subglobosae, corpusculum refringens minutissimum, globosum ad apicem continentes. Paraphyses ad apicem non inflatae vel modice clavatae, plerumque curvatae vel uncinatae, exsudato nullo. Excipulum marginale absque processis vitreis. Status anamorphicus conidiis non ramosis, *38–62 × 3.8–4.5 µm, 5–9-septatis, leniter vel valde curvatis. Habitat ad lignum leniter putridum rami uvidi* Pini canariensis, *in zona mesomediterranea sub- ad semihumida Macaronesiae.*

Description: — **TELEOMORPH**: **Apothecia** fresh 0.3–1.1 mm diam., 0.15–0.2 mm high (receptacle 0.1–0.12 mm), whitish-yellowish or pale to light (cream-)salmon-rose when fresh, semitranslucent, round to slightly undulating, (sub)gregarious in small groups; disc flat, margin ± distinct, thin, 0–5 µm protruding, smooth; subsessile, superficial. **Asci** *37–44(–50) × 3–3.5 {2} → 37–46 × 3.6–4 µm {T}, †31–42 {2} × 2.3–2.6 {1} or 2.6–3.1 µm {T}, 8-spored, spores (*) uni- or subbiseriate († uniseriate), some lower spores inverted but often

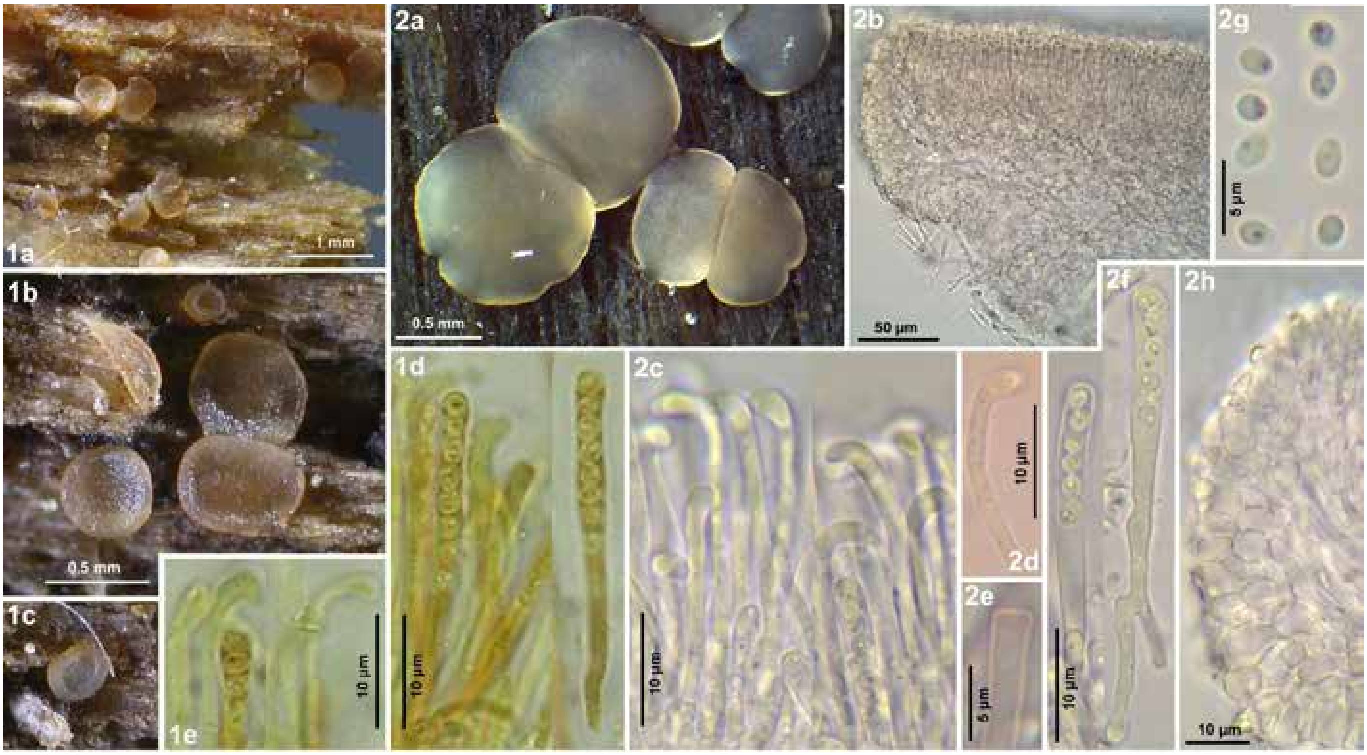

Plate 837. **1–2**: *Orbilia liliputiana*. – **1a–c**, **2a**. rehydrated apothecia; **2b**. apothecium in median section; **2h**. id., marginal ectal excipulum; **1d–e**, **2c–f**. asci and paraphyses; **2e**. ascus apex; **2g**. ascospores. – Living state except for **1d–e** (in KOH+IKI) and **2d–e** (in CR_{SDS}). – **2a–h**: phot. L. Quijada. — **1a–c**. H.B. 6905 (holotype): Tenerife, El Rosario, on *Pinus*; **2a–h**. TFC Mic. 24384: ibid., La Matanza de Ajentejo, on *Pinus*.

laterally oriented {2}, pars sporifera *12–15 → 9–10 µm long; **apex** (†) slightly to medium truncate (not indented, laterally hardly inflated); **base** with short to medium long, thick († thin), slightly flexuous stalk, L-, Y-, h- to H-shaped. **Ascospores** *(2–)2.2–2.6(–2.8) × 1.6–1.9 µm {2}, †2–2.3(–2.5) × 1.6–1.8 µm {T}, broadly ellipsoid to subglobose, exceptionally globose; **SBs** globose, *0.3–0.4 µm wide {T}, total length ~0.5–0.6 µm, quite close to wall but attachment invisible, with a few ± small LBs. **Paraphyses** apically uninflated or slightly to medium clavate, very often slightly to strongly bent, sometimes {T} or often {1} uncinate (~40–140°), terminal cells *(12–)17–24.5 {T} × 1.8–3 µm {2}, lower cells *6–10(–15) × 1.6–2.8 µm {T}; unbranched at upper septum. **Medullary excipulum** 50–100 µm thick, of medium dense textura porrecta-intricata with many inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, vertically oriented t. globulosa-angularis from base to margin, 30–60 µm thick near base, cells *8–22 × 5–11 µm {2}; 15 µm thick near margin, oriented at an 80–90° angle to the surface, marginal cortical cells *6–12 × 4–7.5 µm {2}; **glassy processes** absent. **Anchoring hyphae** sparse, *2–2.5 µm wide, walls 0.2 µm thick {T}. **SCBs** in paraphyses globose, 1.3–2 µm diam., low-refractive, 0–1 per cell, in ectal excipulum absent; **VBs** absent (vacuoles in paraphyses non-refractive) {T}, or medium refractive, roundish to elongate {1}. **Exudate** over paraphyses absent, over margin with 1 µm thick, scattered small clods. **— ANAMORPH**: vermispora-like (from ascospore isolate {T}). **Conidiophores** not seen. **Conidia** unbranched, slightly to strongly curved, ± attenuated at the ends, *38–62 × 3.8–4.5 µm (in situ, actual length ~45–67 µm), 5–9-septate.

Habitat: lying tightly close to very wet ground, on upperside of decorticated, 3 cm thick branch of *Pinus canariensis* {2}, on slightly decayed wood {2}, partly splitted, medium greyed or darkened, no algae. **Associated**: *Hyaloscypha aureliella*. **Desiccation tolerance**: not tested but possibly tolerant. **Altitude**: 1300–1433 m a.s.l. **Geology**: pyroclasts of basalt & trachybasalt and mafic phonolite. **Phenology**: III, IX (perhaps long-lived).

Taxonomic remarks. *Orbilia liliputiana* resembles *O. cejpii* in the small ascospores with distinct though small, globose spore bodies, but differs in paraphyses with often curved apices and a vermispora-like anamorph. *O. frangulae* resembles *O. liliputiana* in the paraphyses, but has longer and somewhat narrower spores and a presumed anamorph with multiarmed conidia. *O. dalmatica* differs in larger spores and SBs, and in having glassy processes, and *O. battenii* in smaller spores and a dicranidion-like anamorph, both also in straight paraphyses. *O. tremulae* differs in longer, more elongate-ellipsoid spores, capitate paraphyses, and a dicranidion-like anamorph.

Several specimens mentioned under *O. cejpii* are not included in either description though possibly belonging to *O. liliputiana*. In most of them the paraphysis apices are more capitate and partly tend to be asymmetrical to almost hooked, and the SBs and partly also the spores are slightly larger than in *O. liliputiana* (Pls 844: 8–11; 846: 5). An Australian collection of *O. cejpii* (Pl. 844: 7) likewise differs from *O. liliputiana* in slightly larger spores and SBs; it has straight, not or only slightly inflated paraphysis apices, narrower marginal cortical cells (*7–10 × 3–4), and a presumed dicranidion-like anamorph. The spores in three North American collections mentioned under *O. cejpii* (Pl. 844: 6, IVV: H.B. 5644, 23.X.2017) are similar to *O. liliputiana* in size and small droplets, but the paraphyses are ± straight and partly rather strongly capitate.

A collection described in detail in Quijada et al. (2016) under the name *O. cejpii* (TFC Mic. 23631) occurred at a distance of only 1 km from the second locality of *O. liliputiana* but on another host (*Adenocarpus*, *Faboideae*). Its straight and partly rather strongly capitate paraphyses deviate from *O. liliputiana*, also its larger SBs (0.4–0.6 µm diam.). The apothecia were light yellow to medium orange. In spore size it is at the lower range of *O. cejpii*, under which name we have treated it. No anamorph was observed on the substrate.

Variation. The two collections concur rather well, particularly in the size of asci and ascospores, but a few deviations are worth mentioning: the fresh apothecial colour was salmon-rose in the holotype but whitish-yellowish in the paratype, and VBs were absent in the holotype but present in the paratype.

Anamorph. The vermispora-like phragmoconidia in the holotype of *O. liliputiana* were only obtained when the culture was flooded by water. This type of conidia is so far exceptional within series *Orbilia*. The only other species within this series with such an anamorph obtained in pure culture is *O.* cf. *subfabacearum* from China (Pl. 891: 2).

Phylogeny. A sequence of the extype-culture comprises SSU (without S1506 intron), ITS, and LSU. In the ITS region the distance to other members of series *Orbilia* lies in the range of 17–19%, except for *O. eucalypti* and *O. fissilis* (13–14.5%). To series *Microsomates* the distance is 16–17%. In the LSU D1–D2 a 3.8% distance to *O. fissilis* and 5% or more to the remaining species is noted.

Ecology. The two collections included in *O. liliputiana* were on slightly decayed wood at the upperside of hygric branches of *Pinus canariensis* in the north- and south-exposed slopes of the lower mesomediterranean subhumid to semihumid pine forest (*Sideritido solutae-Pinetum canariensis ericetosum arboreae*) in Monte de la Esperanza of Tenerife (Macaronesia). The two sites are only 2.7 km from each other. Though the branch of the holotype was lying on very wet ground, the reddish colour of the apothecia together with the partly rather long lower cells of paraphyses appear to indicate that *O. liliputiana* is a desiccation-tolerant species. It seems possible that apothecia were already present on the branch when it was still-attached. However, the second collection showed whitish apothecia and grew likewise on a hygric branch.

Specimens included. **MACARONESIA**: **Canary Islands**, **Tenerife**, El Rosario, 14 km WSW of Santa Cruz de Tenerife, 3.5 km SW of La Esperanza, Pico de las Flores, 1300 m, branch of *Pinus canariensis*, on wood, 31.III.2001, R. Galán-Marquez (AH 7350, **isotype**; ex H.B. 6905, M-0276500, **holotype**, CBS 116213, anam. cult., sq.: KT215284). – La Matanza de Ajentejo, 6 km SW of La Esperanza, Lomo Colorado, 1433 m, branch of *Pinus canariensis*, on wood, 30.XI.2013, L. & C. Quijada (TFC Mic. 24384, doc. vid.).

Orbilia dalmatica Baral, **sp. nov.**, MB 813953

— Pls 838–839

Etymology: named after the geographical origin, Dalmatia.

Typification: Croatia, Korčula island, Kočje, branch of *Juniperus macrocarpa*, 3.VI.2000, N. Matočec & H.O. Baral (ex H.B. 6676a, M-0276471, holotype).

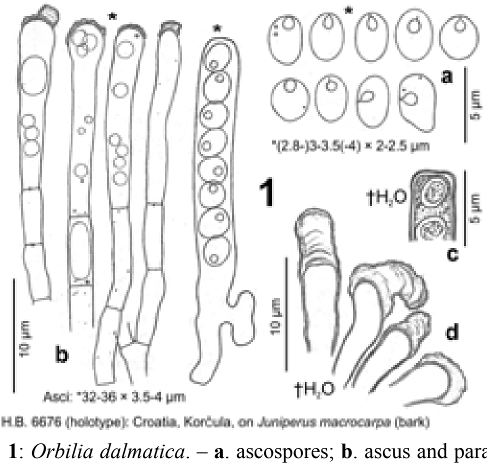

Plate 838. **1**: *Orbilia dalmatica*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal ectal excipulum in median section, cortical cells with glassy processes.

Plate 839. **1**: *Orbilia dalmatica*. – **1a**. mediterranean maquis, *Juniperus macrocarpa* shrub with dead branches; **1b**. corticated xeric branch with apothecia, associated with (?)*Peniophora* sp.; **1c–h**. rehydrated apothecia, with *Frullania dilatata* (phot. after 7 years). — **1a–h**. H.B. 6676a (holotype): Croatia, Korčula, on *Juniperus*.

Latin diagnosis: *Apothecia rehydratata 0.2–0.5 mm diam., aurantio-rosea, sessilia, margine laevi vel subtiliter aspera. Ascosporae *2.8–4 × 2–2.5 µm, late ellipsoideae vel subglobosae, corpusculum refringens submagnum, subglobosum, ad apicem cuspide brevi affixum continentes. Paraphyses ad apicem non inflatae vel leniter capitatae, pileis vitreis tectae, in statu vivo vacuolis refringentibus carentes. Excipulum marginale processis vitreis brevibus, pallide luteis praeditum. Habitat ad corticem putridum rami sicci* Juniperi macrocarpae, *in zona mesomediterranea semihumida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5 mm diam., 0.11 mm high, bright orange-rose, semitranslucent, round to elliptical, scattered; disc slightly concave, margin distinct, very slightly protruding, smooth to very finely rough; broadly sessile, superficial. **Asci** *32–36 × 3.5–4 µm, †31–32 × 2.8–3.2(–3.7) µm, 8-spored, spores (*) uni- or subbiseriate, some spores inverted (very strongly mixed, laterally sometimes oriented); **apex** (†) medium to strongly truncate (scarcely indented and laterally inflated); **base** unstalked or with short, thin, subflexuous stalk, Y- or H-shaped. **Ascospores** *(2.8–)3–3.5(–4) × 2–2.5 µm, †2.2–3.2 × 1.8–2.1 µm, broadly ellipsoid to subglobose, rarely with a tapered base; **SBs** *0.8–1 × 0.5–0.8 µm, subglobose to broadly tear-shaped, apically (rarely laterally) attached either closely or narrowed to a very short filum; with or without a few minute LBs. **Paraphyses** apically uninflated or slightly (rarely medium) capitate(-clavate), terminal cells *14–17 × 1.7–3.2 µm, lower cells *5–9 × 1.5–2.3 µm; unbranched at upper septum. **Medullary excipulum** 40 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** of thin-walled, irregularly oriented t. angularis-prismatica from base to mid flanks, 30 µm thick near base, cells †6–10 × 4–7 µm; at flanks and margin oriented at a 40–60° angle to the surface, 15 µm thick near margin, of t. prismatica, marginal cortical cells †7–10 × 2.5–4 µm; **glassy processes** 1–7 × 2.5–4.5 µm, high-refractive, stratified, pale yellowish. **Anchoring hyphae** rather sparse, †1.3–2 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose to ellipsoid, 0.6–2.3 µm diam., in ectal excipulum not examined; **VBs** absent. **Exudate** over paraphyses 0.3–2 µm thick, forming firmly attached caps, over glassy processes only as a firmly attached thin layer. **— ANAMORPH**: unknown.

Habitat: collected 1.5 m above the ground, corticated, 10 mm thick branch of *Juniperus macrocarpa*, on medium decayed bark (bast) in ± small holes of periderm, medium greyed, with many green algae. **Associated**: *Caloplaca* sp., *Frullania dilatata*, *Hysterium angustatum*, *Parmelia* ?*sulcata*, (?)*Peniophora* sp., *Sclerococcum* sp. **Desiccation tolerance**: asci still alive after 2 weeks (probably also after a much longer time). **Altitude**: 190 m a.s.l. **Geology**: Cretaceous limestone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia dalmatica* is recognized by small subglobose ascospores with comparatively large, broadly tear-shaped SBs, also by short glassy processes at the margin and small refractive caps on the paraphyses. Other species with subglobose spores such as *O. liliputiana*, *O. cejpii*, or *O. fissilis* have smaller, more globose SBs and are devoid of glassy processes and refractive caps. These species also differ in having less pigmented and probably much less desiccation-tolerant apothecia. *O. dalmatica* also resembles *O. ovalis* (section *Lentiformes*), particularly the collection on *Prunus* (Pl. 181: 5), which differs in larger spores with partly ampulliform SBs and in the absence of glassy processes. A collection from Canada mentioned under *O. cejpii* (Pl. 844: 8) has slightly smaller spores but similar SBs as in *O. dalmatica*.

Ecology. *O. dalmatica* was collected on medium decayed bark of a xeric branch of *Juniperus macrocarpa* in the mesomediterranean semihumid maquis in Dalmatia (southeastern Europe).

Specimens included. **CROATIA**: **Dubrovnik-Neretva**, **Korčula**, 3.5 km WSW of Korčula, 1.8 km NW of Žrnovo, Kočje, 190 m, branch of *Juniperus macrocarpa*, on bark, 3.VI.2000, N. Matočec & H.O. Baral (ex H.B. 6676a, M-0276471, **holotype**).

Orbilia battenii Baral & E. Weber, **sp. nov.**, MB 813954 — Pls 840–841

Etymology: *battenii*: named after Edward Batten who collected and studied this species.

Typification: Great Britain, Suffolk, Westleston, branch of *Pinus sylvestris*, 24.XI.2005, E. Batten (ex E.B. 4649 & ex H.B. 8004, M-0276440, holotype).

Latin diagnosis: *Apothecia hydratata 0.2–1 mm diam., albida ad pallide chlorinaceo-lutea, subsessilia, margine laevi. Ascosporae *1.8–3 × 1–1.4 µm, ellipsoideae vel (clavato-)subcylindricae, corpusculum refringens globosum, ad apicem cuspide brevi affixum continentes. Paraphyses ad apicem modice ad valde capitatae, rectae, in statu vivo vacuolas refringentes hyalinas continentes, exsudato nullo. Excipulum marginale absque processis vitreis. Status anamorphicus* Orbiliae cejpii *similis sed conidiophorae multo longiores et conidia multo longiora, stipitibus et ramis conidiorum longioribus. Habitat ad lignum putridum rami in aere prominentis* Pini sylvestris, *in zona temperata humida atlantica Europae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** fresh (0.2–)0.4–0.8(–1) mm diam., 0.18–0.19 mm high (receptacle 0.1–0.11 mm), whitish to pale yellowish-chlorinaceous, turning light cream-yellowish or partly orange-brown with age, semitranslucent, round to slightly undulating,

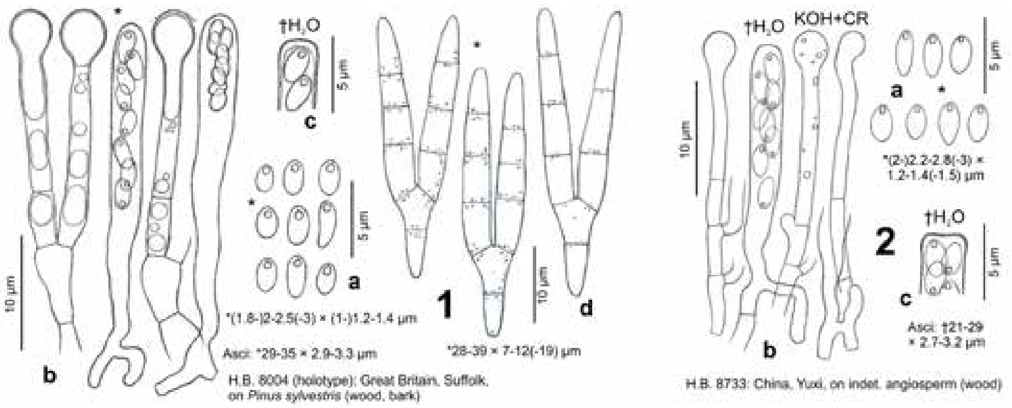

Plate 840. **1**: *Orbilia battenii*; **2**: *O.* cf. *battenii*. – **a**. ascospores; **b**. asci and paraphyses (right ascus fully turgescent); **c**. ascus apices; **d**. conidia from culture.

scattered to gregarious in rather small groups; disc flat to slightly convex, margin thin, not protruding, smooth; with a broad obconical stipe 0.08–0.09 × 0.2–0.3 mm, superficial. **Asci** *29–35 × 2.9–3.3 → 3.3–3.5 µm, 8-spored, spores (*) uni- or apically subbiseriate, 3–4 lower spores inverted (strongly mixed), pars sporifera *10–15(–18) → 7–8 µm long; **apex** (†) strongly truncate (never indented, laterally not or scarcely inflated); **base** with medium long, ± thick, slightly flexuous stalk, L- to h-shaped. **Ascospores** *(1.8–)2–2.5(–3) × (1–)1.2–1.4 µm, ellipsoid(-ovoid) to subcylindric(-clavate), apex rounded to obtuse, base sometimes slightly tapered, straight or rarely slightly inequilateral; **SBs** *0.7–0.8 × 0.4–0.6 µm, globose (to broadly tear-shaped), apically abruptly narrowed to a very short and fine, sometimes invisible filum, LBs not seen. **Paraphyses** apically medium to very strongly capitate, straight, terminal cells *14–20 × 3–4.5(–5) µm, lower cells *4.5–7 × 2–3.3 µm; sometimes branched at upper septum. **Medullary excipulum** 30–50 µm thick, of dense textura globulosa-angularis, very indistinctly delimited from ectal excipulum (or distinctly so by a narrow t. porrecta). **Ectal excipulum** of thin-walled, irregularly oriented t. globulosa from base to margin, 100 µm thick near base, cells *10–23 × 8–16 µm; 15 µm thick near margin, cells at mid flanks *8–12 × 7–9 µm, at margin oriented at an 80° angle to the surface, marginal cortical cells *5–8 × 3.5–5.5 µm; **glassy processes** absent. **Anchoring hyphae** medium abundant, †2–3.5 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses small, globose, in ectal excipulum at margin and flanks

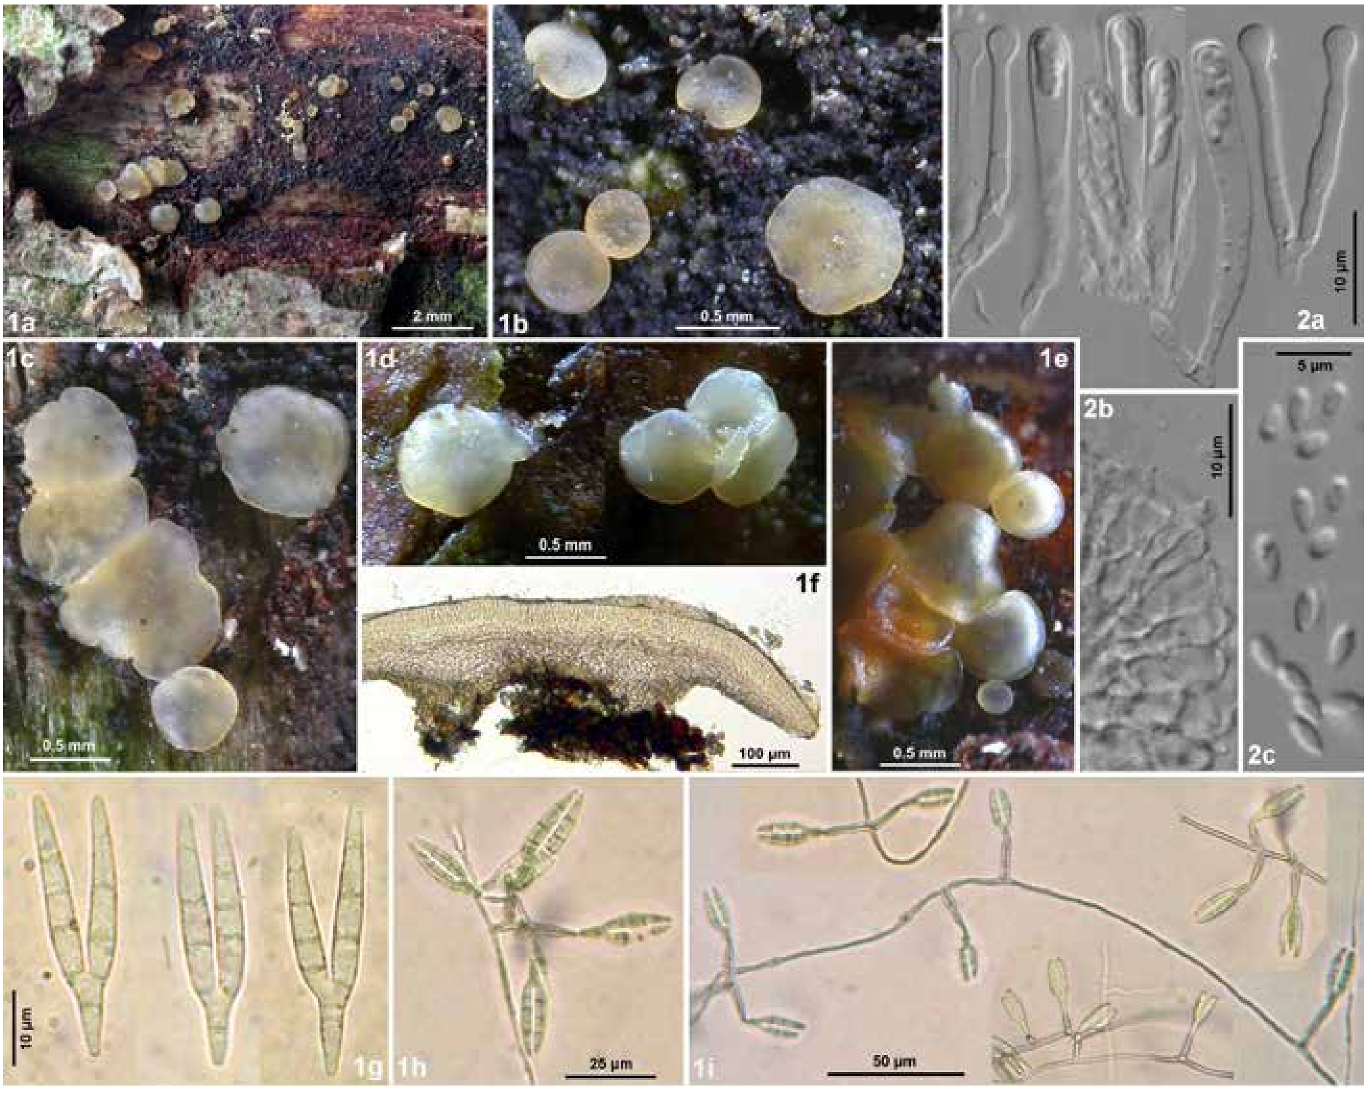

Plate 841. **1**: *Orbilia battenii*; **2**: *O.* cf. *battenii*. – **1a–e**. fresh apothecia; **1f**. apothecium in median section; **2b**. id., marginal ectal excipulum; **2c**. ascospores; **1g–i**. conidia and conidiophores. – Living state (**2a**: 3 asci fully turgescent), except for **2b** (in H_2O). – **2a–c**: phot. Z.F. Yu (DIC). — **1a–i**. H.B. 8004 (holotype): Great Britain, Suffolk, on *Pinus*; **2a–c**. Y.Z. jz-34: China, Yunnan, Dali, indet. ?angiosperm.

globose, 1–1.7 µm diam.; **VBs** medium refractive, mostly elongate, hyaline. **Exudate** over paraphyses absent or nearly so, over margin and flanks scattered granules 0.2–0.5 µm thick. — **ANAMORPH**: dicranidion-like (from ascospore isolate). **Conidiophores** *~7–18 × 3 µm, branched or unbranched, conidia formed terminally. **Conidia** 2-armed, *(28–)34–37(–39) × 7–12(–19) µm, stipe *8–11 × 2.6–3.5 µm, 1-septate, arms *16–26 × 3–4 µm, (2–)4(–6)-septate.

Habitat: collected 1.8 m above the ground, ± corticated, 18 mm thick branch of *Pinus sylvestris*, at small decorticated areas on 0.1 mm deep (rarely deeply) medium to strongly decayed wood, especially beneath bark, exceptionally on bark (periderm), slightly greyed, among blackish and red unidentified remains, sometimes close to abundant green algae. **Associated**: none observed. **Desiccation tolerance**: after 5 days only some cells of medullary excipulum and many spores still alive. **Altitude**: 10 m a.s.l. **Geology**: Pleistocene glaciofluvial sand and gravel. **Phenology**: XI.

Taxonomic remarks. The very small (subcylindric-)ellipsoid ascospores with a globose spore body in combination with a staurosporous dicranidion-like anamorph are the most striking features of *Orbilia battenii*. *O. cejpii* differs in distinctly larger, especially wider spores. The tropical *O. gaillardii* differs in larger, bright orange apothecia and slightly larger spores. *O. dryadum* differs in longer, more cylindrical spores, but two short-spored collections from Denmark (on *Fagus*, Pl. 870: 6, 871: 6) and Bretagne (on *Carpinus*, IVV: 6.XII.2013) closely resemble *O. battenii* except for the unbranched conidia observed near the apothecia and much longer asci in the Danish sample.

Not included collections. Two Chinese samples (Pls 840: 2; 841: 2) are not included in the description because of their geographical origin and deviating substrate (probably from angiosperms), also because of smaller SBs (0.3–0.5 × 0.25–0.35 µm) in the one from Yuxi. Likewise, a sample from Japan deviates in growing on angiosperm bark (*Tilia*, IVV: H.B. 9989); it fits well *O. battenii* in ascus (†22–25 × 2.4–2.8 µm) and spore size (†2.3–2.8 × 1.1–1.3 µm), but was only studied in the dead state and is without anamorph data. A specimen from tropical Australia included in *O. cejpii* (Pls 844: 3; 846: 1) closely resembles the Yuxi sample in ascospore shape whereas the larger ascospore size fits better *O. cejpii*. The same is true for a sample from subtropical North America (IVV: H.B. 5552a).

Anamorph. The dicranidion-like conidia of *O. battenii* grown in pure culture are of the 'gracile type' very similar to those of *O. cejpii* and the *xanthostigma-leucostigma* complex. For the difficulty to name this anamorph see under *O. xanthostigma*, p. 1408. The conidia of *O. cejpii* differ in having distinctly shorter arms and stipes, the arms being predominantly parallel. However, the mentioned Australian and North American collections showed conidia very similar to *O. battenii* (Pl. 846: 1n, 2a–b). *O. dryadum* sharply differs in unbranched conidia. The anamorphs of *O. gaillardii* and the Chinese samples are unknown.

Ecology. *O. battenii* grew on ± rotten wood (exceptionally bark) of a xeric branch of *Pinus sylvestris* in the cold-temperate humid atlantic lowlands of eastern England. Despite the exposed growth, the asci and paraphyses did not survive 5 days of drought. The not included collections were from subtropical humid (winter-dry) evergreen forests in southeastern Asia and continental temperate humid Japan.

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, ~7.5 km SW of Southwold, ~2.5 km NE of Westleston, Dunwich Forest (southwestern part), 10 m, branch of *Pinus sylvestris*, on wood & bark, 24.XI.2005, E. Batten (ex H.B. 8004, M-0276440, **holotype**, anam. cult.; E.B. 4649, K(M) 145642, **isotype**).

Not included. **CHINA**: **Yunnan**, **Dali**, Binchuan, ~42 km NNE of Dali, ~25 km NW of Binchuan, Jizushan, ~2400 m, on indet. wood (?angiosperm), IX.2005, Y. Zhang & M. Qiao (Y.Z. jz-34, YMFT, doc. vid.). – **Yuxi**, Yimen, 54 km NW of Yuxi, 3 km NW of Fangtunxiang, Dalongkou, Longquan, 1750 m, branch of indet. angiosperm, on wood, VI.2007, S.F. Li & J.W. Guo (J.W.G. lq2-35, YMFT, H.B. 8733). — **JAPAN**: **Hokkaido**, ~20 km NW of Tomakomai, Shikotsu lake, ~300 m, branch of *Tilia*, on bark, 28.VII.1990, T. Hosoya (TRL 146, TNS-F-55850, H.B. 9989 ø).

Orbilia gaillardii Sacc., Syll. Fung. 8: 629 (1889, as *O. gaillardi*, ICN Art. 60.8) — Pls 842–843

≡ *Orbilia tenuissima* Pat. & Gaillard, Bull. Soc. Mycol. Fr. 4: 99 (1889, '1888'), nom. illegit., ICN Art. 53.1 [non *Orbilia tenuissima* Speg.]

Etymology: named after the collector, Albert Gaillard.

Typification: Venezuela, Fortin El Zamuro, branch of indet. angiosperm, 28.V.1887, A. Gaillard (herb. Patouillard, FH 00304811, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–3.2 mm diam., 0.12–0.35 mm high (receptacle 0.1–0.26 → 0.06–0.08 mm), fresh bright yellow-orange {T}, recently rehydrated bright orange(-ochraceous) {1}, pale to light cream-ochraceous(-chlorinaceous) when rehydrated after 8 or > 100 years, ± translucent, round or often undulating, subgregarious to densely gregarious; disc flat but always with a central depression (umbilicate), margin distinct, thin, slightly raised but not protruding, smooth; with a distinct broad stipe 0.02–0.2 × 0.25–0.7 mm, superficial; dry bright yellowish-ochre to orange-red (bright amber-brown with yellowish-ochre margin when old). **Asci** †30–41(–46) × 2.8–3.3 µm {2}, 8-spored, spores †1–2-seriate, especially the lower spores (e. g., 3) inverted {T} (mixed), pars sporifera

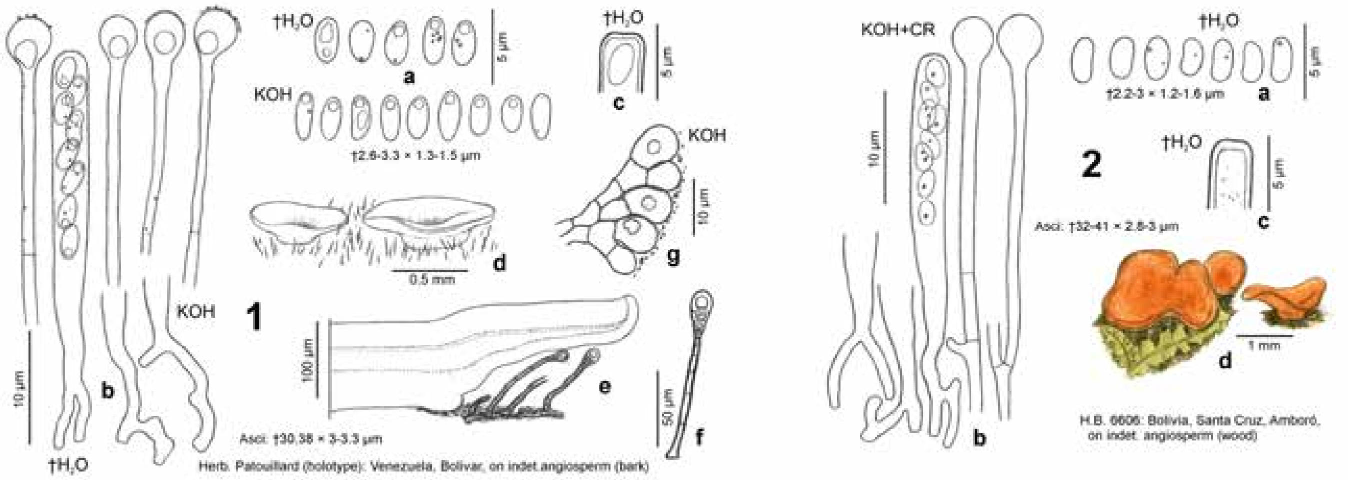

Plate 842. **1–2**: *Orbilia gaillardii*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia (rehydrated, **2d** with *Lophocolea* sp.); **e**. apothecium in median section; **f**. associated *Brachysporiella* ?*gayana*; **g**. marginal ectal excipulum in median section.

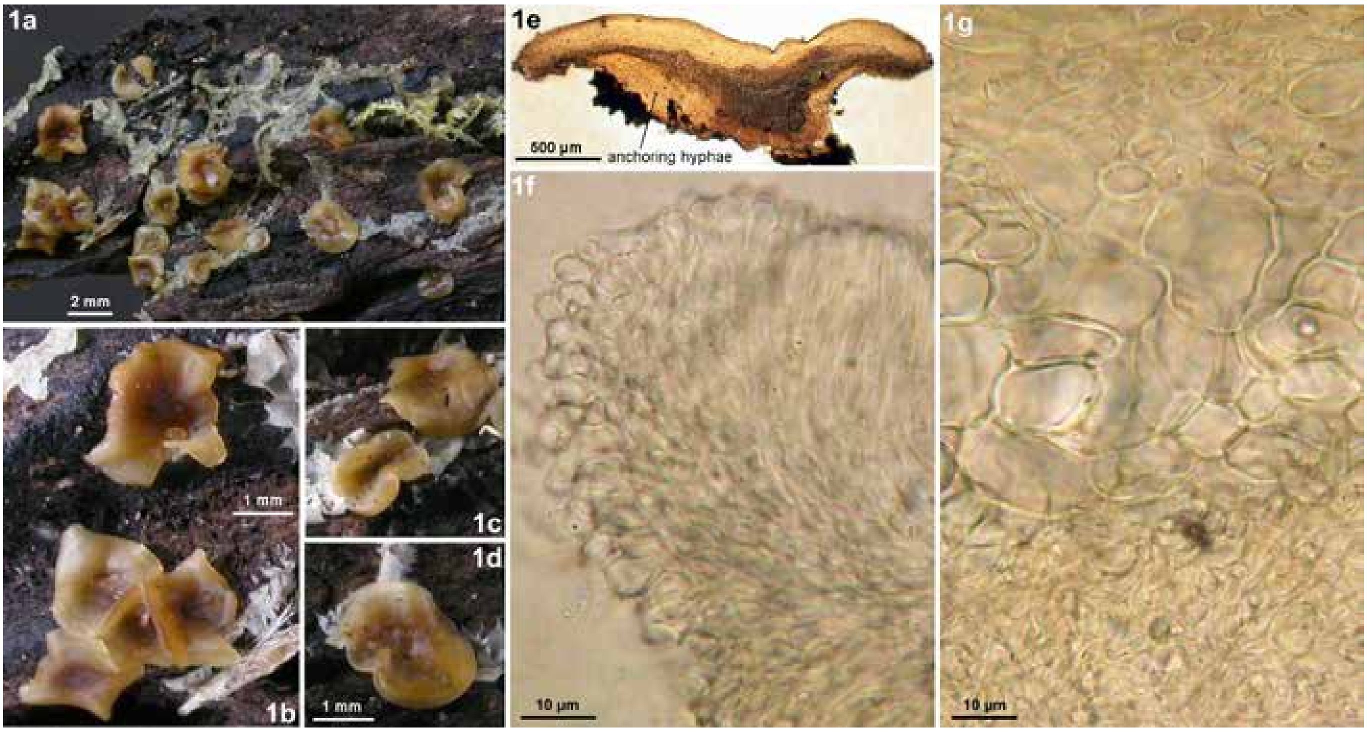

Plate 843. **1**: *Orbilia gaillardii*. – **1a–d**. rehydrated apothecia (with *Lophocolea*, after 8 years); **1e**. apothecium in median section; **1f**. id., marginal ectal excipulum; **1g**. id., basal ectal excipulum (below with thick compact tissue of anchoring hyphae). – Dead state (in KOH). — **1a–f**. H.B. 6606: Bolivia, on indet. angiosperm.

†15–20 µm long; **apex** (†) strongly truncate (not or distinctly indented, laterally not or very slightly inflated); **base** with short (to medium long), thin, flexuous stalk, Y-, h- or H-shaped. **Ascospores** †2.3–3.3 × (1.1–)1.2–1.5(–1.6) µm {2}, subcylindric to ellipsoid, sometimes (ob)ovoid, apex rounded to obtuse, straight to slightly inequilateral or curved; **SBs** †0.7–0.9 µm diam. {T} (~0.8–1 µm total length), visible as a globose transparent region a short distance from the apex, with a few minute LBs. **Paraphyses** apically medium or mostly strongly to very strongly capitate, terminal cells †(18–)20–25(–30) × (2–)3–4.2 µm {2} (septa difficult to see), lower cells †5–8 × 1–1.3 µm {1}; rarely branched at upper septum, lower part of hymenium and subhymenium pale orange. **Medullary excipulum** hyaline, 30–200 µm thick in centre, of medium dense horizontal textura porrecta with many inflated cells, very sharply delimited from ectal excipulum especially at flanks, near margin slightly gelatinized. **Ectal excipulum** hyaline, of (†) slightly gelatinized [common walls 0.8–1.5(–2) µm thick], irregularly, at flanks vertically oriented t. (globulosa-)angularis from base to margin, 50–100 µm thick near base, cells †10–30(–35) × 10–18(–25) µm {2}; 20–80 µm thick at lower flanks, 10–20 µm near margin, oriented at a 60–80° angle to the surface, cortical cells at flanks and margin †7–10 × 4–8 µm {2}; **glassy processes** absent. **Anchoring hyphae** abundant, †1.5–2.5(–3) µm wide, walls 0.2 µm thick {1}, forming a dense, slightly gelatinized t. intricata-porrecta 30–280 µm thick near base, partly covering also lower flanks as a 40–70 µm thick layer. **SCBs** no data available, in KOH globose ?SCBs in paraphysis apices seen, 1.5–1.8 µm diam. {T}. **Exudate** over paraphyses and margin absent or sparse, minutely granular, 0.1–0.2 µm thick. **— ANAMORPH**: unknown.

Habitat: lying on ground, corticated or decorticated, ?5–8 cm thick branches of indet. angiosperms {2}, on 1–2 mm deep strongly brown-rotten wood {1} or medium decayed bark (periderm) {T}, partially blackened, green algae sometimes present among anchoring hyphae. **Associated**: *Brachysporiella* ?*gayana* {T}, *Lophocolea* sp. {1}, pleurocarpous moss {1}. **Desiccation tolerance**: unknown, possibly desiccation-sensitive. **Altitude**: 45–1050 m a.s.l. **Phenology**: V (tropical belt).

Taxonomic remarks. *Orbilia gaillardii* is characterized by bright yellowish-orange apothecia, small subcylindric-ellipsoid ascospores and strongly capitate paraphyses. The orange colour is obviously located in minute LBs in the subhymenium and lower part of the paraphyses, and strongly fades in herbarium material within a few years. *O. dryadum* (with narrower, more cylindrical spores and less pigmented apothecia) and *O. eucalypti* (with larger spores) may be confused with *O. gaillardii* (see under these species). *O. tonghaiensis*, a member of series *Drechslerella* of section *Arthrobotrys*, has similar spores but more whitish apothecia. Among the species with small ellipsoid to subglobose spores (length/width ratio 1.3–1.6), *O. battenii* (with smaller spores) and *O. cejpii* are very similar to *O. gaillardii* but likewise differ in a pale colour of the apothecia. For the tropical *O. guyanensis* see p. 1380.

Variation. The Bolivian collection here referred to *O. gaillardii* differs from the type from Venezuela in somewhat more cylindrical, very slightly curved spores, and larger apothecia with larger excipular cells. The abundant tissue of densely interwoven anchoring hyphae at the apothecial base was not seen in the holotype.

Nomenclature and type studies. Patouillard & Gaillard (1889) described *O. gaillardii* under the illegitimate name *O. tenuissima*, with subglobose spores 0.25–0.5 µm diam., being uniseriately arranged in the asci. Due to the existence of the older *O. tenuissima* Speg., Saccardo (1889) introduced the new name *O. gaillardii* (ICN Art. 53.1, Turland et al. 2018). He and Dennis (1954: 297) copied Patouillard & Gaillard's wrong description of the spores, whereas Dennis later (VIII.1965, in sched.) examined the holotype (FH) and found the spores to be elliptical, 2 × 1 µm, 1–2-seriate, an observation which he used in his key (Dennis 1970: 352). Spooner (1987: 167, pers. comm.) examined a slide of this collection deposited in K, and found the spores 2.5–3 × (0.8–)1 µm. He believed that *O. gaillardii* was very closely related to *O. cunninghamii*, but the Australian specimen that he considered to be *O. cunninghamii* was perhaps *O. dryadum*.

The present examination of the holotype (FH) confirmed the spore length given by Spooner but revealed distinctly wider spores (Pl. 842: 1a). Possibly, Patouillard & Gaillard saw living spores inside the asci and misinterpreted the spore bodies as spores. The apothecia in the holotype grew on bark, not wood as stated in the protologue. Whether duplicate specimens of the type exist remains unclear.

Ecology. *O. gaillardii* was found on ± rotten wood and bark of hygric branches of unidentified broad-leaved trees. The holotype was collected in a lowland floodplain forest with tropical humid (wet and dry) savannah climate at the Orinoco river in the north of South America. The sample from Bolivia was made under a tropical humid highland broad-leaved forest at the southern base of the Los Volcanes mountain range in the Bolivian Andes in the mid west of South America.

Specimens included. **VENEZUELA**: **Bolivar**, Ciudad Bolivar, Fortin El Zamuro (as 'Puerto Zamuro'), 45 m, branch of indet. angiosperm, on bark, 28.V.1887, A. Gaillard (herb. Patouillard, 2^e sér. No. 23, FH 00304811, **holotype**, H.B. 5453 ø). — **BOLIVIA**: **Santa Cruz**, Amboró, 55 km SW of Santa Cruz de la Sierra, 30 km ENE of Samaipata, 4.5 km NE of Bermejo, Refugio Los Volcanes, 1050 m, branch of indet. angiosperm, on wood, 10.V.1998, L. Beenken & C. Hahn (L.B. 1202, H.B. 6606).

Orbilia cejpii Velen., Monogr. Discom. Bohem.: 92, pl. 11 fig. 8 (1934, as *O. cejpi*, ICN Art. 60.8, Ex. 31) — Pls 844–846, Map 135

Etymology: named after the collector, Karel Cejp.

Typification: Slovakia, Brezno, branch of indet. angiosperm, VIII.1930, K. Cejp (PRM 151734, holotype); Germany, Titisee, branch of *Sorbus aucuparia*, 16.VIII.2009, B. Liu & H.O. Baral (ex H.B. 9135, M-0291774, epitype, designated here, MBT385130; sq.: KT222370).

Misapplied names: Ginko (1986), as *O. leucostigma*; Korf (1992, MM 502A), as *O. alnea*; Liu (2006: 64 p.p.), as *O. coccinella*.

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated 0.15–0.4 up to 0.4–1.5(–2) mm diam., 0.07–0.1 or 0.1–0.28(–0.45) mm high (receptacle 0.065–0.15 mm), whitish or pale yellow-cream or orange-rosaceous-lilaceous, translucent, round, slightly lobate when large, very scattered to gregarious; disc slightly concave to flat, margin distinct, 0–5 µm protruding, smooth; broadly sessile or with an indistinct or distinct stipe 0.03–0.17 × 0.15–0.3 mm, superficial; dry pale yellowish to light reddish-ochraceous. **Asci** *(29–)32–47(–51) × (3–)3.2–4(–4.3) {9} → 3.8–4.3 µm, †(20–)24–42(–45)((–54)) × (2.6–)2.8–3.3(–3.5) µm {11}, 8-spored, spores (*) uni- or apically subbiseriate, 2–6 lower spores inverted {3} (often mixed, often also laterally oriented), pars sporifera *15–20 → 9.5–11 µm long; **apex** (†) medium to often strongly truncate (not or distinctly indented and laterally inflated); **base** with short to medium long, thin or thick, flexuous stalk, L-, h- or H-shaped. **Ascospores** *(2–)2.3–3.5(–4) × (1.4–)1.5–2(–2.2) µm {19}, †(1.9–)2.3–3.3(–3.7) × (1.3–)1.7–1.9(–2)((–2.3)) µm {9}, ellipsoid to ovoid or almost subglobose, rarely fusoid or subcylindrical, apex rounded, sometimes obtuse, base rarely ± tapered, straight or rarely slightly inequilateral; **SBs** *0.3–0.5(–0.6) µm wide {7} (0.5–1 µm total length), consistently present, (sub)globose, apically closely attached or narrowed to a very short fine, often invisible filum, without or with a few minute or small LBs. **Paraphyses** slightly or often medium to (very) strongly (clavate-)capitate at the apex, sometimes asymmetrical, usually straight or only slightly curved at apex, terminal cells */†9–16 {2} or */†15–20 {4} or 19–31 {1} × (1.5–)2–4(–4.8) {9} µm, lower cells *4–9(–11)((–17.5)) × 1.5–2.3(–2.6) µm {4}, †6–10 × 1.1–1.5 µm {T}; sometimes branched at upper septum. **Medullary excipulum** 35–150 µm thick, of dense textura intricata-globulosa-prismatica, indistinctly to sharply delimited from ectal excipulum, at flanks by a 10–30 µm thick layer of t. porrecta. **Ectal excipulum** of thin-walled, indistinctly vertically oriented t. globulosa(-prismatica) from base to margin, 25–120 µm thick near base, cells */†(7–)10–20(–25) × (4–)6–14(–17) µm {6}; 10–25 µm thick near margin, oriented at a 30–90° angle to the surface, marginal cortical cells */†(5–)6–12(–14) × (3–)4–6(–7) µm {7}; **glassy processes** absent. **Anchoring hyphae** sparse to abundant, *(1.5–)2–3 µm wide, walls 0.2(–0.3) µm thick {2}, partly forming strands or a dense t. intricata 50–70 µm thick. **SCBs** globose, in paraphyses (0.7–)1–1.8 µm diam., in medullary and ectal excipulum (near margin) 1.5–2.3 µm); **VBs** absent. **Exudate** over paraphyses absent {4} or as ± sparse granules 0.2–0.6 µm thick, over margin and flanks 0.2–1(–2) µm {4}, more abundant, granular to rough-cloddy, hyaline to pale yellowish. — **ANAMORPH**: dicranidion-like (from ascospore isolate {4} and natural substrate {5}). **Conidiophores** *1.5–16 × 1.5–2 µm, unbranched, apically not attenuated and often irregularly bent, with or without short denticles. **Conidia** 2-armed (exceptionally 4-armed by twice dichotomous branching, B.L. 6578), European collections: *(12.5–)16–21(–27) × (5.5–)6–7(–8) µm {2} or *23–26 × 8–9.5 µm {1}, stipe *4.5–9 × 2.5–2.8 µm {1} or *3.8–4.8 × 3–3.3 µm {1}, 0–1-septate, arms *(5–)8–15(–18) × 2.5–3.2(–3.7) µm {2} or *17–20 × 3.6–4.3 µm {1}, (1–)2–3(–4)-septate {2} or 4-septate {1}, ± parallel, sometimes slightly diverging; extra-European collections: */†25–38 × 6–9(–11.5) µm (11–20 µm if diverging or 4-armed), stipe */†6.5–11 × 2.5–3.5 {5} or 3.8–44.5 {1} µm, 1-septate, arms */†(11–)17–28 × 3–4(–5) µm, (2–)4–6-septate, ± parallel to slightly or medium diverging {6}.

Habitat: corticated or decorticated, 1–20 cm thick branches and logs lying on ± moist ground or 0.3–2.5 m above the ground, of *Adenocarpus foliolosus* {1}, *Barringtonia racemosa* {1}, *Campsis* (?)*radicans* {1}, *Carpinus betulus* {1}, *Clematis vitalba* {1}, ?*Crataegus* sp. {1}, *Eucalyptus globulus* {1}, *Fagus sylvatica* {5}, *Lavandula canariensis* {1}, *Melaleuca* sp. {1}, *Pinus niga* {1}, *Quercus* sp. {3}, *Q. mongolica* {1},?*Rosaceae* {1}, *Salix* sp. {3}, *Sorbus aucuparia* {3}, *Ulex europaeus* {2}, indet. angiosperm trees {3}, on upperside or laterally, on 0.5–2 mm deep strongly decayed wood {30} or bark {10}, with or without beetle galleries, inner surface of detaching bark, or in emergency holes, on hymenium of *Hymenochaetopsis tabacina* (on branches of *Salix*) {1}, leaf of *Cocos nucifera* {1}, greyed or darkened, without or with sparse green algae. **Associated**: *Calocera cornea* {1}, *Calycina citrina* {1}, *C. claroflava* {1}, *Capronia* sp. {1}, ?*Chaetosphaeria myriocarpa* {1}, *Dematioscypha olivacea* {1}, *Gloniopsis* ?*praelonga* {1}, *Hyalorbilia arcuata* {1}, *H. helicospora* {1}, *H. texensis* {1}, *Lecophagus vermicola* {1}, *Metzgeria* sp. {1}, *Orbilia arachnovinosa* {1}, *O. acaciae* {1}, *O.* ?*australiensis* {1}, *O. bambusina* {1}, *O. euonymi* {1}, *O. fabacearum* {1}, *O.* ?*fusiformis* {1}, *O. hesperidea* {1}, *O. nothovinosa* {1}, *O. orientalis* {4}, *O. pleioeuonymi* {1}, *O. trapeziformis* {1}, *O. xanthostigma* {1}, *Parmelia* sp. {1}, *Rhizodiscina lignyota* {1}, *Spadicoides bina* {1}, *Sclerococcum* sp. {1}, ?*Stictis* sp. {1}, ?*Ulota* sp. {1}, *Usnea* sp. {1}. **Desiccation tolerance**: fully viable after 10 days (Sweden), many spores still alive after 8 (Europe), some mature asci and spores still alive after > 2 years (Australia, H.B. 6823d). **Altitude**: 50–1600 m a.s.l. (Europe), 43–1521 m (Macaronesia), 35–150 m (North America), 5–278 m (Australia), 750–850 m (northern China), 2400 m (southern China). **Geology**: Paleozoic calcareous greywacke, Buntsandstein, Keuper (gypsum), Lower Jurassic and Cretaceous limestone & flysch, Tertiary molasse, Pleistocene sand, clay, mud & till; granite, (migmatitic) gneiss, basaltic flows and pyroclasts. **Phenology**: V–XII (temperate northern hemisphere).

Taxonomic remarks. *Orbilia cejpii* is characterized by comparatively small, mostly broadly ellipsoid (to subglobose) ascospores, usually strongly capitate paraphyses, and particularly by a dicranidion-like anamorph in which the mostly 2-armed conidia possess an often 1-septate stipe. The species is very closely related to *O. battenii*, *O. eucalypti*, *O. fissilis*, *O. tremulae*, *O. liliputiana*, and *O. paracylindrospora*. *O. eucalypti* and *O. tremulae* differ from *O. cejpii* in slightly longer spores and in conidia without a distinct stipe, *O. fissilis* in slightly wider spores and the frequent presence of 4-armed conidia, and *O. liliputiana* mainly in unbranched, curved (vermispora-like) conidia. *O. battenii* has smaller, especially narrower spores, while in conidial morphology it is very similar to some extra-European specimens (Pl. 846: 1n, 2) which we refer to *O. cejpii* because

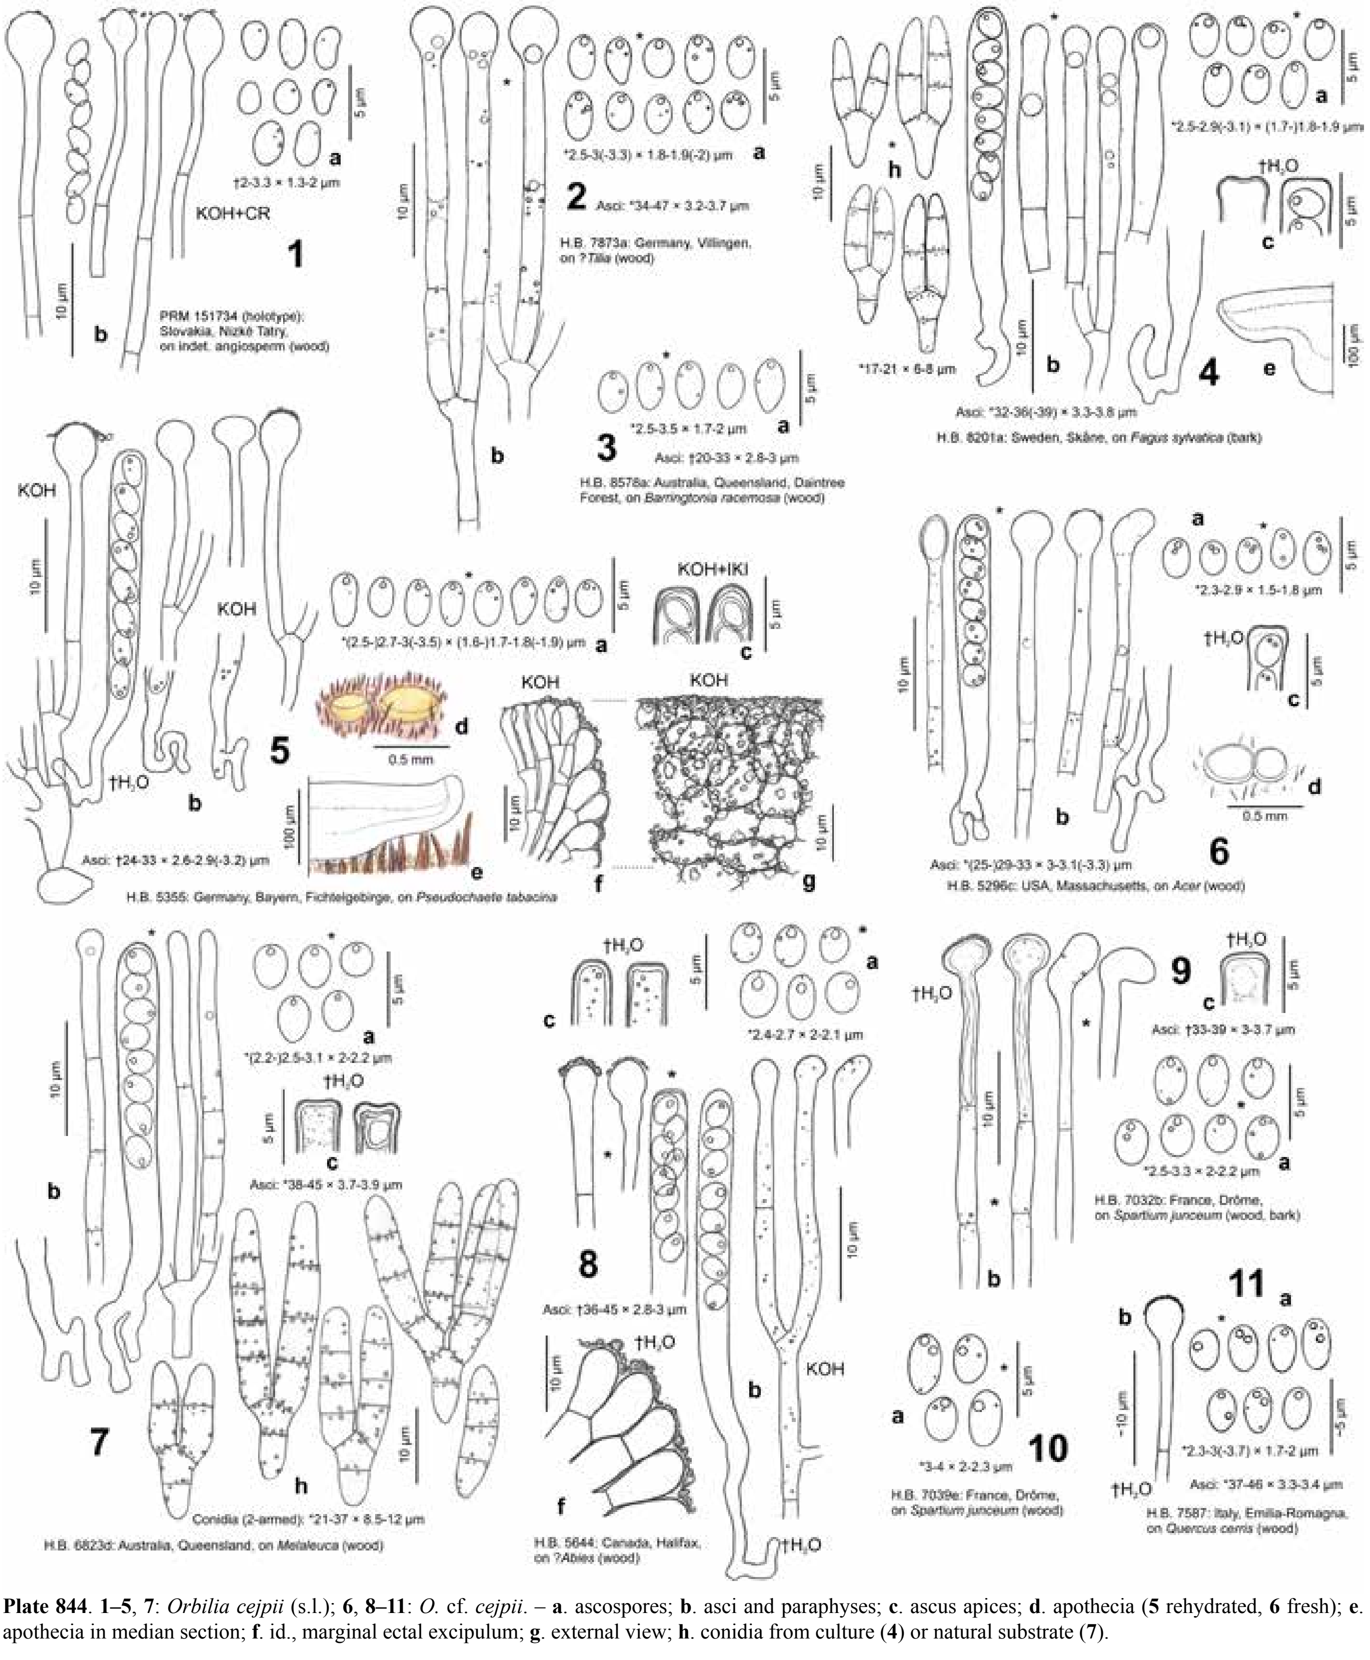

Plate 844. **1–5**, **7**: *Orbilia cejpii* (s.l.); **6**, **8–11**: *O.* cf. *cejpii*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia (**5** rehydrated, **6** fresh); **e**. apothecia in median section; **f**. id., marginal ectal excipulum; **g**. external view; **h**. conidia from culture (**4**) or natural substrate (**7**).

of larger, particularly wider spores. *O. gaillardii* is separated by its bright orange apothecia and a tropical distribution, while its anamorph is unknown. *O. paracylindrospora* is closely related to *O. cejpii* by molecular data, but differs in more cylindrical, distinctly narrower and slightly longer spores which exceed 4 µm in length, also in a thicker exudate over the paraphyses. Also *O. plurivacuolata* is closely related but differs in longer spores (*3.5–5.5 µm) and multiguttulate paraphyses (living state).

A sharp limit between *O. cejpii* and collections of *O. tremulae* with comparatively small spores is difficult to draw, but only if no anamorph data exist. Confusion with short-spored *O. frangulae* and even *Hyalorbilia hergiswiliana* is easily possible because of a similar spore size and shape (for the differences see there).

A collection from Massachusetts (IVV: H.B. 9998) would fit *O. cejpii* or *O. gaillardii* in the short spores (*2.8–3 × 1.6–1.8 µm), but it features bright yellow apothecia, and its molecular

data refer it to *O. renispora* which normally has distinctly reniform spores.

Variation. Five sub- to altimontane samples on *Sorbus* and indet. ?*Rosaceae* from Schwarzwald (Villingen and Titisee), Massif central (St.-Étienne) and Somiedo, and one on *Salix* from Pyrenees (Escot) (Pls 844: 2; 845: 1, 3, 6) are characterized by ± rosaceous(-cream) apothecia (white in Somiedo) of 0.3–2 mm diam., slightly to strongly capitate paraphyses, and rather minute SBs, whereas four temperate to submontane samples on *Fagus* from Skåne, Heidelberg and Graz, and one on *Clematis* from Bratislava have whitish-greyish to ochraceous apothecia of 0.25–0.8 mm diam. (Pl. 844: 4), paraphyses with only slightly to medium inflated apex (in spite of being fully mature), and slightly larger, more distinct SBs.

The differences between the two groups are unsharp, however. Ascus and ascospore size is virtually the same, although the majority of spores in the *Fagus* and *Clematis* samples tend to be longer (often *3–3.8 µm), except for the one from Skåne which fits with *2.5–3 µm in the other group. The group with often rose colour shows perhaps a higher tolerance to drought judging from the more exposed apothecia growing 1–2.5 m above the ground, although those from Villingen and Somiedo grew on branches on the moist ground.

According to the six available European sequences, *O. cejpii* belong to two distinct taxa which appear to represent these two groups (see below). Yet, we refrained from splitting the species because many of the samples are without DNA data and difficult to assign based on their morphological and ecological data alone. For instance, a montane sample on *Pseudochaete* on *Salix* (Pl. 844: 5) has rather small, yellowish apothecia but in its strongly capitate paraphyses and minute SBs it appears to fit more the *Salix-Sorbus* group. Here a fine connection of the SBs to the spore wall could be seen.

In the *Fagus* sample from near Graz the apothecia were 0.2–0.4 mm diam. and the spores measured *(2.7–)3.3–3.7 × 1.9–2.2 µm (G. Friebes pers. comm., Pl. 845: 4). Apothecia were recollected from the same log by I. Wendelin 22 days later, and here the apothecia were 0.5–0.85 mm diam. and the spores only †2.5–3 × 1.5–2 µm (IVV: 24.VIII.2015). The sequence was taken from the latter collection under the assumption that both samples were conspecific. Among the four sequences of the *Salix-Sorbus* group, the Somiedo sample shows rather short and broad, subglobose spores of *(2–)2.2–2.5(–2.7) × (1.8–)2–2.2(–2.4) µm compared to *2.5–3 × (1.6–)1.7–1.9(–2) µm in the other three.

The paraphyses of *O. cejpii* are generally straight at the apex. Strongly curved apices were noted in a sample from Texas (IVV: H.B. 5552a). Occasionally or often ± curved or asymmetrical apices occurred especially in one of the not included samples from southern France (on *Spartium*, Pl. 844: 9), but also in the *Fagus* sample from Graz (IVV: G.F. 20150102) and that from Bratislava (on *Clematis*, A.P. 19/21), and more or less in the not included ones from North America.

Two collections from tropical northeastern Australia (Pls 844: 3; 846: 1, on *Barringtonia* branch; IVV: H.B. 8494b, on *Cocos* leaves) also fit well *O. cejpii*, except for the small (0.15–0.4 mm) and thin (0.07–0.1 mm) apothecia growing on more xeric substrate, and the paraphyses having shorter terminal cells (10–17 µm). The sample on *Melaleuca* from eastern Australia (Pls 844: 7) shows the widest ascospores. However, differences are also noted in the conidia (see below). A Chinese collection from Yunnan (Pl. 846: 4, on indet. ?angiosperm, Z.F. Yu pers. comm.) shows spores (*~3–4 × 1.8–2 µm) with rather large LBs, but the conidia obtained in culture fit well those of what we consider to be typical *O. cejpii* (Pl. 845: 2).

Type studies. *O. cejpii* was described by Velenovský with 0.2–0.3 mm large, glassy-translucent, colourless apothecia, asci with long and thin, flexuous, Y-shaped stalk, 2 µm large, subglobose spores, and paraphyses 5–6 µm wide at the very strongly capitate apex. Only a single, very senescent apothecium could be found in the present reexamination of the holotype which consists of a minute fragment of an unidentified angiosperm tree. The ascus walls have disappeared, but paraphyses and spores (some still in a row of 8) were visible (Pl. 844: 1). The spores are found to be distinctly larger than indicated by Velenovský, but also larger than given by Svrček (1954: 12) who measured them as †1.7–2.3 × 1.2–1.5 µm and the asci as †22–30 × 2.3–3 µm. Svrček described the apothecia on the small wood fragment as solitary, only visible under a lens, dry yellowish, thin-membranaceous.

Based on Rehm (1891: 454), Svrček believed that a small-spored form of *O. xanthostigma* s. Svrček (= *O. eucalypti*) existed, '*O. xanthostigma* f. *delicatula* Karst. (sensu Rehm)', and that *O. cejpii* represents this small-spored fungus.

Misapplication. A collection from Macaronesia reported by Korf (1992, CUP-MM-000502A, as *O. alnea*) appears to fit *O. cejpii* because of the small ascospores (†~2.5–3 × 1.2–1.5 µm, evaluated from scale) and the figured conidium. Other collections treated by Korf as *O. alnea* (CUP-MM-002675, 002726) might belong to *O. eucalypti*. Also Ginko's (1986) collection from Poland (as *O. leucostigma*, spores ellipsoid, 2.4–3 × 1–1.8 µm) could belong to *O. cejpii*.

Two samples from Beijing on indet. angiosperms, referred by Liu (2006) to *O. coccinella*, were reexamined (Pl. 846: 3; IVV: H.B. 9117). The former was assigned to *O. cejpii* because of its small spores (†2.7–3.3 × 1.7–1.8 µm) and the characteristic anamorph obtained in culture by B. Liu (pers. comm.). The latter has larger spores, but both clustered in the *cejpii-frangulae* clade and are considered here to be conspecific with *O. cejpii*.

Not included collections. Various samples are not included in the description. Some unillustrated, sparsely documented records from Germany and Luxembourg, also one from France (H.B. 6461b), mostly on xeric substrates, showed spores of about 3–3.5(–3.7) × 1.7–2 µm and thus fit *O. cejpii*, although a relationship to *O. tremulae* cannot be excluded. Also a record from Czechia by Velenovský under the name *O. tremulae* is not included. It might belong to *O. cejpii* according to his unpublished sketch showing broadly ellipsoid, 2–3 µm long spores, but the corresponding material preserved in PRM 149390 contains a species of section *Arthrobotrys* with arcuate spores (see also under *O. tremulae*, p. 1375).

Collections from (sub)mediterranean France and Italy (on *Spartium junceum*, *Quercus cerris*, Pls 844: 9–11; 846: 5) are somewhat intermediate to *O. liliputiana* but differ in slightly larger spores and SBs and more capitate paraphyses. In three collections from Massachusetts (Pl. 844: 6, IVV: H.B. 10001, 23.X.2017, anamorph unknown) the living spores are slightly smaller than in typical *O. cejpii* and seemingly only LBs could be found in them. The other features appear to concur with *O. cejpii*, while *O. battenii* differs in narrower spores with distinct SBs. A Canadian collection (Pl. 844: 8) deviates in rather large SBs, with or without a visible filum, only slightly capitate paraphyses, and in growing on conifer wood. Also a sample from Japan is exceptional in growing on coniferous wood; it fits

well *O. cejpii* in ascus and spore size (IVV: TNS-F-55791), but was studied in the dead state only and is without anamorph data.

Anamorph. The conidia of *O. cejpii* resemble those of the closely related *O. eucalypti*, but differ in usually longer arms and a comparatively long and cylindrical instead of very short and conical stipe. In our two European culture isolates we consider the conidial state as being rather young with partly very small conidia: in the German sample only two conidia were found emerging from mycelium growing out from an apothecium fixed on the lid of a Petri dish (Pl. 845: 1k), while in the Swedish sample the conidia were sparsely formed in pure culture on agar (Pls 844: 4h; 845: 2d–e). In the sample from St.-Étienne (IVV: 13.IX.2018) the conidia from natural substrate had shorter, nonseptate stipes and longer and wider, mainly 4-septate arms.

Korf's (1992) report of a *Dicranidion* sp. associated with a teleomorph which he named *O. alnea* is considered here to represent *O. cejpii*, according to the figured conidium of †18.5 × 5 µm, with parallel, 1-septate arms and long, 1-septate stipe, along with small ascospores.

The conidia from pure culture of two Chinese collections (Pl. 846: 3d–e, 4d) fit well those of the European samples, except for their slightly longer arms. In the one from Beijing, B. Liu (pers. comm.) rarely observed 4-armed conidia (Pl. 846: 3e) reminiscent of *O. fissilis*, but with only slightly diverging arms. Distinctly wider arms and stipes (*3.8–5 µm) occurred on the natural substrate of the Australian sample on *Melaleuca* (Pl. 844: 7); these conidia were found in closer association with *O. ?livistonae*, and also here one of the conidia was 4-armed. In the tropical Australian sample on *Barringtonia* and subtropical North American on *Campsis* (Pl. 846: 1–2) the dicranidion-like conidia on the substrate have longer, more diverging arms with mostly 4–6 septa, which strongly resemble the anamorphs of *O. battenii* or the *xanthostigma-leucostigma* complex For the difficulty to name this type of anamorph see under *O. xanthostigma*, p. 1408.

No conidia were seen in the holotype of *O. cejpii*, therefore, the here assumed identity with the more recent collections is mainly based on spore size and shape. The mostly strongly capitate paraphyses in the holotype and its origin in the subalpine zone with *Pinus mugo* suggest conspecificity with the group on *Sorbus* and *Salix* rather than with that on *Fagus*. We here designate the sample from Titisee (on *Sorbus aucuparia*, ex H.B. 9135) as **epitype** of *O. cejpii*. Future research must clarify the morphological and ecological amplitude of the aberrant taxon on *Fagus*.

Phylogeny. Sequences were obtained from apothecia of three collections on *Sorbus aucuparia* (Titisee, Pl. 845: 3; St.-Étienne, IVV: 13.IX.2018; Somiedo, IVV: E.R.D. 7924), one on *Salix* (Escot, Pl. 845: 6), one on *Fagus* (Graz, Pl. 845: 4), and one on *Clematis* (Slovakia, IVV: 18.V.2019). They comprise ITS and often also LSU, that from St.-Étienne also SSU V8–V9. The four samples on *Salix* and *Sorbus* vary by only 0–0.4% in the ITS and lack the S1506 intron (in the LSU D1–D2 they are fully identical). In contrast, the samples on *Fagus* and *Clematis* possess the S1506 intron where they fully concur, while varying by only 0.2% in the ITS. Surprisingly, the two groups deviate by 16–16.5% (ITS) and 4% (LSU). Sequences were also available from two strains from Beijing: one (Yanqing, as *O. coccinella*, B.L. 6578, H.B. 9116, LSU) matches that on *Fagus* with a distance of only 0.3% (2 nt in D1–D2), suggesting conspecificity, while another (Huairou, B.L. 6176, as *O. coccinella*, H.B. 9117, ITS) clustered within the supported *cejpii-frangulae* clade but with a distance of 14–16% to the six European samples of *O. cejpii* s.l.

In analyses of SSU+ITS+LSU or LSU (Phyls 22, S27), *O. cejpii* on *Salix* and *Sorbus* clustered with *O. plurivacuolata* in a medium supported subclade, whereas *O.* cf. *cejpii* on *Fagus* and *Clematis* and the sample from Yanqing formed with *O. paracylindrospora* and *O. frangulae* a strongly supported subclade which forms a supported sister group to the former. In the SSU (not shown), *O. cejpii* on *Sorbus* clustered with *O. paracylindrospora* by a deviation of 1 nt.

In the ITS/LSU D1–D2, the two European genotypes of *O. cejpii* s.l. differ from *O. paracylindrospora* by 10/3.5% and 8/1.7%, respectively, and from *O. frangulae* by 12.7/3% and 10/1.3%, which are among the lowest distances of *O. cejpii* within series *Orbilia*. *O. plurivacuolata* is much more distant from the *Fagus*/*Clematis* taxon (16.5/4.5%) than from samples on *Salix* and *Sorbus* (9/2.8%). In comparison, *O. cejpii* s.l. differs from *O. eucalypti*, *O. fissilis*, *O. tremulae*, and *O. liliputiana* in the LSU by 4.5–7.5%. In the S1506 intron *O.* cf. *cejpii* shows a high distance to any other taxa of series *Orbilia* which possess it (16.5–17% to *O. plurivacuolata* with which it clustered in Phyl. S26).

In Liu et al.'s (2006a) analysis of LSU, the *O. cejpii* ('*O. coccinella*') strain from Yanqing clustered with rather high distance with a strain from Hunan uploaded under the same name *O. coccinella* (B.L. 748, ITS+LSU). This latter strain represents morphologically typical *O. eucalypti*, but it strongly deviates in the ITS from available sequences of European *O. eucalypti* and nested rather unresolved in our combined analysis (Phyl. 22).

Ecology. *O. cejpii* s.l. was recorded on ± rotten wood and bark of hygric but also xeric branches and trunks of different angiosperm trees and shrubs (particularly *Fagus*, *Quercus*, *Sorbus*, *Salix*), rarely on gymnosperms or perennial basidiomycetes (*Pseudochaete*). Within Europe the sites show an atlantic to subcontinental, cold- to warm-temperate humid climate at colline to altimontane altitudes. The holotype derives from a continental subalpine (orotemperate) *Pinus mugo* belt in the northwestern part of Carpathian Mountains in eastern Europe. In contrast, the two samples from the south of Northern America on *Campsis* and *?Crataegus* derive from the subtropical (sub)humid Oak and Coastal Prairies, and also the three eastern Australian records are from a tropical humid rainforest region (on *Barringtonia* and *Cocos*) and a subtropical subhumid eucalypt open woodland (on a xeric branch of *Melaleuca*); in the latter some mature asci were still viable after 25 months in the herbarium. Also the two Chinese collections include temperate to subtropical humid (winter-dry) climates. Within Macaronesia, the collections from Tenerife were in a lower mesomediterranean humid *Pinus canariensis* forest or fayal-brezal (*Myrica fayae-Ericetorum arboreae*), and at low altitude in an inframediterranean lower semiarid Euphorbia scrub (*Periploco laevigatae-Euphorbietum canariensis*); the sample from Madeira was in a mesosubmediterranean semihumid eucalypt forest.

Among the not included European samples are some from (sub)mediterranean regions on xeric branches of *Spartium junceum* and *Quercus cerris*. Those from northeastern North America were from cold-temperate to boreal humid areas. One of those from Massachusetts (H.B. 5296c) grew among abundant algae (*?Gloeocapsa*) on a water-soaked, decorticated, rotten, 30 cm thick log of *Acer* in association with *O. dryadum* and *O. polybrocha*. In contrast, that from Nova Scotia was on a

Map 135. Known distribution of *O. cejpii* in Europe (yellow = not included collections).

xeric, 4 mm thick coniferous twig, and also a sample from Japan was on coniferous wood.

Specimens included. **SWEDEN**: **Skåne**, Riseberga, Söderåsen, 4.7 km NW of Röstånga, WSW of Skäralid, Skärâns ravin, 75 m, trunk of *Fagus sylvatica*, on bark, 4.VI.2006, H.O. Baral (H.B. 8201a, anam. cult.). — **GERMANY**: **Baden-Württemberg**, 7 km E of Heidelberg, 1.5 km ESE of Ziegelhausen, Bärenbach, 175 m, branch of *Fagus sylvatica*, on wood, 31.VII.2010, M. Orbilia paracylindrospora Baral & E. Weber, **sp. nov.**, MB 813958 — Pls 847–848

Etymology: named after the ascospores resembling those of *O. cylindrospora*.
Typification: France, Villiers-en-Bois, twig of *Euonymus europaeus*, 27.IV.2011, H.O. Baral (ex H.B. 9484, M-0276550, holotype; sq.: KT222430).

Latin diagnosis: Orbiliae cylindrosporae *similis sed apothecia distincte roseo-aurantia, ascosporae latiores, corpusculum refringens minus, ad apicem filo breve affixum, paraphyses apice saepe curvatae. Habitat ad lignum putridum rami sicci* Euonymi europaei, *in zona temperata humida atlantica in Europae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.4 mm diam., 0.1–0.12 mm high, light rose-orange, medium translucent, ± round, subgregarious; disc flat, margin distinct, thick, 10 µm protruding, smooth; broadly sessile, superficial; dry light rose-cream. **Asci** *36 × 3.5 µm, †32–38 × 2.8–3 µm, 8-spored, ~4 lower spores inverted (± strongly mixed); **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with medium to long, thin, flexuous stalk, L-shaped. **Ascospores** *(3–)3.7–4.5(–5) × 1.3–1.4(–

1.6) µm, subcylindric(-ellipsoid), apex rounded to obtuse, straight to (very) slightly curved; **SBs** *0.5–0.8 × 0.3 µm diam., globose, apically with a very delicate filum (or attachment invisible), with 1–2 minute **LBs**. **Paraphyses** apically uninflated or slightly to medium clavate-capitate, often asymmetrical or curved (sometimes hooked), terminal cells *14–20 × 1.6–3 µm, lower cells *4.5–8(–10) × 1.6–2 µm; rarely branched at upper septum. **Medullary excipulum** very pale cream-rose, 25–30 µm thick, of dense, horizontally oriented textura porrecta-prismatica with many inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled, vertically oriented t. angularis-prismatica from base to margin, 25–33 µm thick near base, cells *6–12(–15) × 6–10(–12) µm; 20 µm thick at margin, oriented at a 70–80° angle to the surface, marginal cortical cells *7–10 × 3–3.5 µm; **glassy processes** absent. **Anchoring hyphae** abundant, *2–3 µm wide, walls 0.2 µm thick, forming strands. **SCBs** not observed. **Exudate** over paraphyses and margin 0.2–1.5(–2) µm thick, hyaline, granular-cloddy, firmly attached. **— ANAMORPH**: unknown.

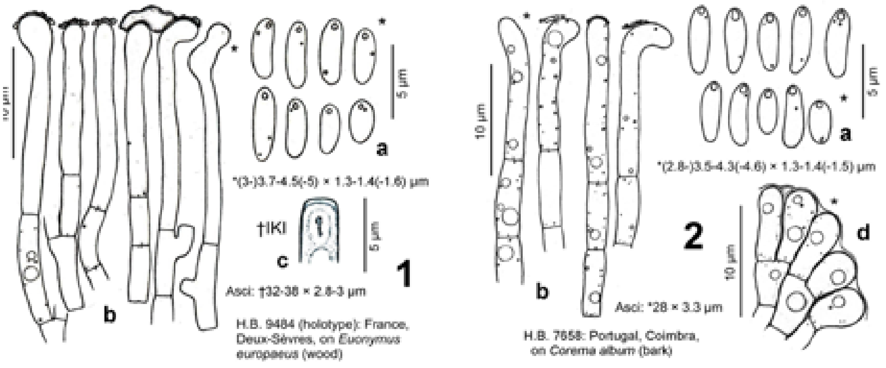

Plate 847. **1**. *Orbilia paracylindrospora*; **2**. *O.* cf. *paracylindrospora*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. marginal ectal excipulum in median section.

Habitat: collected 1.5 m above the ground, partially to often entirely decorticated, 4 mm thick twig of *Euonymus europaeus*, on 0.1–0.3 mm deep strongly decayed wood, slightly greyed, with some green algae. **Associated**: none observed. **Desiccation tolerance**: some paraphyses and ascospores still viable after 2 weeks. **Altitude**: 72 m a.s.l. **Geology**: Upper Jurassic clayey lime- & marlstone. **Phenology**: IV.

Taxonomic remarks. *Orbilia paracylindrospora* closely resembles *O. cylindrospora* (incertae sedis) in the cylindrical ascospores which are, however, slightly shorter and wider (though partly almost identical), and contain much smaller spore bodies (but small SBs were also observed in one of the specimens referred to *O. cylindrospora*). It further differs in the paraphyses being apically often curved and in the broad-leaved substrate. *O. tremulae* differs from *O. paracylindrospora* in wider spores, strongly capitate paraphyses, and usually yellowish apothecia.

Not included collection: A collection from Portugal on *Corema* (Pl. 847: 2) closely resembles *O. paracylindrospora*, e.g., in spore size and shape and in curved paraphyses. It deviates in wider SBs (0.4–0.6 µm) being more directly attached to the apex, and very pale rosaceous-cream apothecia with a thin margin. Very similar spores and SBs occurred in the single sample on angiosperm substrate (*Quercus*) tentatively included in *O. cylindrospora* (Pl. 825: 3): this concurs with *O. paracylindrospora* in the rose(-orange) apothecia with a thick margin and in the atlantic habitat, also in the short and wide spores. However, the asci are much longer and the paraphyses straight. Globose SCBs were seen in these specimens on *Corema* and *Quercus*, but not in the holotype on *Euonymus*. It cannot be excluded that all three specimens are conspecific.

Phylogeny. A sequence was gained from apothecia of the holotype, comprising SSU (with S1506 intron), ITS, and LSU. The lowest distance was observed to *O. frangulae*: 4.2 % in the ITS and 3 nt (0.6 %) in the LSU (D1–D2). *O. paracylindrospora* further deviates from *O. frangulae* by an insert of 44 nt in the ITS2, which is also ± absent in other species of series *Orbilia*. To *O. cejpii* the distances are 8–10 % (ITS) and 3.5 % (LSU), and to *O. tremulae* 14.5 % (ITS) and 6–7 % (LSU). In the intron *O. paracylindrospora* shows a very high distance to any other species, except for *O. frangulae* (1.8–1.9 %).

O. paracylindrospora clustered with *O. frangulae* and *O. cejpii* (on *Fagus*) in a strongly supported subclade of the *cejpii-frangulae* clade (Phyls 22, S27).

Ecology. *O. paracylindrospora* was collected on rotten wood of an attached, xeric twig of *Euonymus* (spindle tree) in a shady warm-temperate to mesosubmediterranean humid, atlantic *Querco-Carpinetum* (with *Lithospermum* and *Melittis melissophyllum*) in the lowlands of western Europe. The not included collection on bark of *Corema* (Portuguese crowberry) was from a thermomediterranean semihumid low shrubland

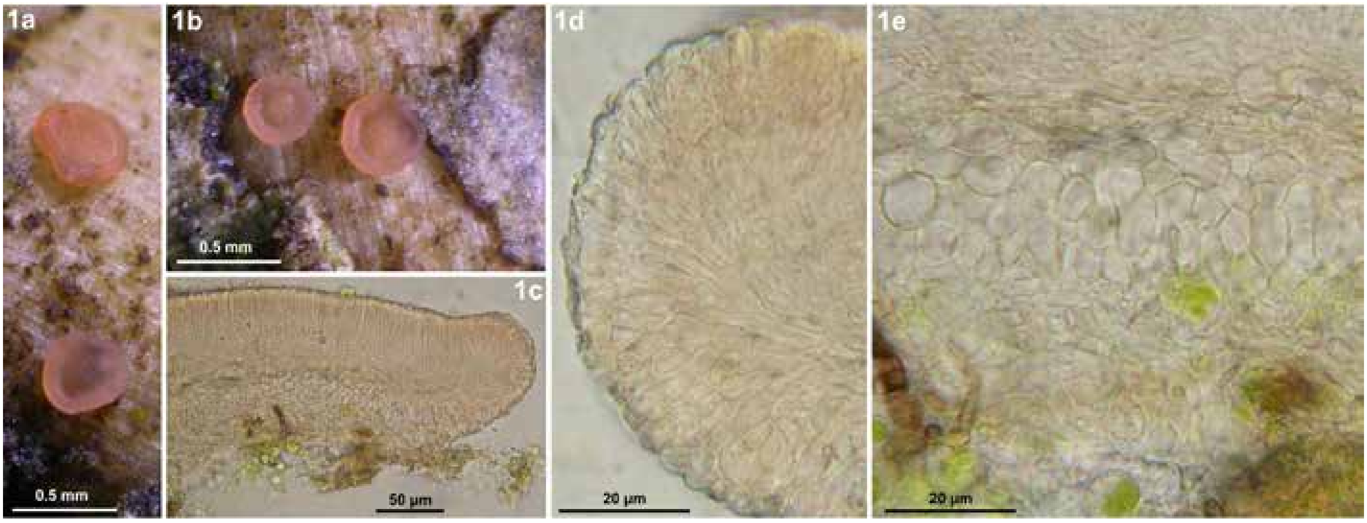

Plate 848. **1**: *Orbilia paracylindrospora*. – **1a–b**. rehydrated apothecia **1c**. apothecium in median section; **1d**. id., marginal ectal excipulum; **1d**. id., ectal excipulum, with medullary excipulum and anchoring hyphae. – Living state. — **1a–e**. H.B. 9484 (holotype): France, Deux-Sèvres, on *Euonymus*.

ahead of the pine forest at the atlantic coastal dune of the Iberian peninsula (southwestern Europe).

Specimens included. **FRANCE**: **Poitou-Charentes**, **Deux-Sèvres**, 4.5 km NW of Chizé, 1.3 km SSE of Villiers-en-Bois, Forêt de Chizé, 72 m, twig of *Euonymus europaeus*, on wood, 27.IV.2011, H.O. Baral (ex H.B. 9484, M-0276550, **holotype**; sq.: KT222430).

Not included. **PORTUGAL**: **Leiria**, Baixo Mondego, Beira, 47 km SW of Coimbra, 17 km SSW of Figueira da Foz, Osso da Baleia, 6 m, branch of *Corema album*, on bark, 26.XII.2004, J.P. Priou (J.P.P. 24285, H.B. 7658 ø).

Orbilia frangulae G. Marson, Baral & E. Weber, **sp. nov.**, MB 814008 — Pls 849–850

Etymology: named after the host tree, *Frangula alnus*.

Typification: Luxembourg, Mersch, Hovelange, on twigs & branches of *Frangula alnus*, 13.IV.2014, G. Marson (ex G.M. 2014-04-13.4 & ex H.B. 9970a, M-0276485, holotype; sq.: KT380095).

Latin diagnosis: Orbiliae paracylindrosporae *persimilis sed ascosporae leniter breviores et latiores, magis ellipsoideae. Habitat ad lignum et corticem putridum ramorum siccorum* Frangulae alni, *in zona* temperata humida *atlantica vel subcontinentale Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.6(–0.7) mm diam., 0.12–0.14 mm high (receptacle 0.1–0.12 mm), whitish-cream to pale or light rose(-orange), medium translucent, round to elongate or undulating, scattered to subgregarious in small groups; disc flat to slightly convex, margin distinct, thick, 0–10 µm protruding, smooth; broadly sessile, with obconical base, somewhat immersed in biofilm or rotten wood; dry pale bright rose-orange. **Asci** *37 × 3.4–3.7 µm {1}, †30–40 × 2.4–3 µm {T}, 8-spored, spores (*) ± obliquely (sub)biseriate, lower spores inverted (± strongly mixed), pars sporifera *11–13 µm long; **apex** (†) medium to strongly truncate, not indented, laterally not inflated; **base** with ± long, thin, flexuous stalk, L- to Y- or H-shaped. **Ascospores** *(2.7–)3–3.8(–4) × (1.1–)1.3–1.6(–1.8) µm {3}, ellipsoid to subcylindrical or subclavate, straight, apex rounded to obtuse; **SBs** globose, *0.3–0.4 µm diam. {1}, attachment invisible, total length 0.5–0.6 µm, with a few minute **LBs**. **Paraphyses** apically uninflated or mostly slightly to medium or (very) strongly capitate-clavate, often asymmetrical, also moniliform, sometimes or frequently hooked, terminal cells *10–15 × 2–3.5 µm {2}, 2–4(–5) µm wide {T}, lower cells †6–8 × 1.3–1.6 µm {1}, unbranched at upper septum. **Medullary excipulum** hyaline, 30–50 µm thick in centre (30 µm at flanks), of dense textura intricata-angularis, sharply delimited by a ~10 µm thick t. porrecta. **Ectal excipulum** of (†) thin-walled, vertically oriented t. angularis-prismatica from base to margin, 35–45 µm thick near base, cells *10–19 × 7–10(–13) µm {T}; 30 µm thick at flanks, 15–20 µm at margin, oriented at an 80–90° angle to the surface, marginal cortical cells †5–10 × 3–4.5 µm {T}; **glassy processes** absent. **Anchoring hyphae** rather sparse, *2,3–2,7 µm wide, walls 0.2–0.4 µm thick {T}. **SCBs** not observed. **Exudate** over paraphyses 0–0.2 µm thick, firmly attached, over margin continuous or cap-like, 0.2–0.8 µm thick. — **ANAMORPH**: dicranidion-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** *33–47 × (9–)23–37(–43) µm {2}, stipe *7–18 × 2–2.5 µm, (0–)1–2-septate {2}; 2–3 × dichotomously branched, with 4–8 ± diverging arms of *15–24 × 3–3.5(–4.2) µm, 3–5(–6)-celled {2}.

Habitat: collected 1–3 m above the ground, partially or entirely decorticated, 5–20 mm thick twigs and branches of *Frangula alnus* {4}, on 0.5–1 mm deep strongly decayed wood {3} or bark (bast and periderm) {4}, strongly greyed, green algae abundant. **Associated**: *Corticiaceae* {1}, *Helicogonium orbiliarum* (parasitic in *O. frangulae*) {1}, *Orbilia vinosa* {1}, *Parmelia sulcata* {1}. **Desiccation tolerance**: excipular cells, paraphyses and ascospores still viable after 17 months. **Altitude**: 45–405 m a.s.l. **Geology**: Bretagne: Cambrian siltstone & quartzitic wacke, Luxembourg: Lower Jurassic sandstone. **Phenology**: XII–I, IV, VII (probably throughout the year, rather long-lived).

Taxonomic remarks. *Orbilia frangulae* can hardly be distinguished morphologically from other taxa with small ellipsoid spores. From *O. paracylindrospora* it differs in slightly shorter and wider spores, and from *O. cejpii* and *O. tremulae* in slightly narrower spores. The paraphyses are frequently hooked, a remarkable feature which is usually not seen in *O. eucalypti*, *O. cejpii*, or *O. tremulae*, but which occurs in *O. paracylindrospora* and *O. liliputiana*, though less pronounced. Whether or not the pale cream-rose apothecial colour is a constant feature remains to be seen.

Variation. *O. frangulae* varied in ascospore size and shape between ellipsoid, *2.8–3.2 × 1.3–1.6(–1.8) µm (Koedange and La Gacilly, reminiscent of *O. cejpii*) and subcylindric-subclavate, *(3–)3.3–3.8(–4.2) × (1.1–)1.3–1.6 µm (Hovelange, holotype).

Not included collections. Five collections on hosts other than *Frangula* are not included in the description, mainly because of the taxonomic problems within this group of ellipsoid-spored taxa and the lack of molecular data: two from Luxembourg (on *Ulmus* and *Quercus*) fit very well *O. frangulae* in ascus and spore dimensions and in the often asymmetrical paraphysis apices [*Ulmus*: asci *41–44 × 3.4–3.8 µm, spores *2.5–3.8 × 1.5–1.8 µm; *Quercus*: Pl. 850: 4, spores *2.6–3.8 × 1.3–1.5(–1.7) µm]; a record from Ottawa on decayed *Fomitopsis* (*Piptoporus*) *betulinus* (J. Mack pers. comm., Pl. 850: 5), with often very strongly hooked paraphyses and pale pinkish to vivid pink apothecia, has broadly ellipsoid spores *~3 × 2 µm with larger LBs; a similar sample from Boston on a decayed ?*Schizopora* on *Acer* was only studied in the dead state (IVV: H.B. 10184); a sample from Japan (on *Salix*) has similar spores (†2.5–3.2 × 1.7–2 µm) though without LBs, and also here a majority of paraphyses is hooked at the inflated apex (IVV: H.B. 9988).

Anamorph. In the holo- and paratype from Luxembourg, 2–3 × dichotomously branched, dicranidion-like conidia occurred around the apothecia, which resemble the 2-armed conidia known from, e.g., *O. xanthostigma* and *O. battenii*, or *Hyalorbilia hergiswiliana*. Also in the not included *Ulmus* sample such conidia were observed (Pl. 849). With their 4–6–8 diverging arms and a narrow, medium long stipe they form a brush-like 3-dimensional structure. Similar conidia occurred in apothecia of *O. pleiomicrosoma*, (Pl. 814) but are there interpreted as parasitic.

Phylogeny. Sequences were taken from apothecia of two samples on *Frangula* (holo- and paratype from Luxembourg), comprising the S1506 intron, ITS, and LSU. In their entire overlapping part the two sequences are identical. In phylogenetic analyses of ITS, LSU, or (SSU+)ITS+LSU, *O. frangulae* always clustered with *O. paracylindrospora* and more distantly with *O. cejpii* on *Fagus* (Phyls 22–23, S27). Also when analysing the intron the two former species clustered with low distance

Table 74. Comparison between *O. frangulae* (2 strains) and *O. paracylindrospora* (1 strain) regarding 22 deviating nucleotides in the ITS1-5.8S-ITS2 and an insert of about 44 nt length in the ITS2 of *O. frangulae*, with which 2 nt of *O. paracylindrospora* ambiguously align. Position numbers starting after ATCATTA.

(1.8–1.9 %) in a strongly supported clade (S26), but very distant from any other species, including *O. cejpii* on *Fagus*. To *O. paracylindrospora* the distance in the ITS is 4.5 % (24 nt, Tab. 74; 0.6 % in LSU D1–D2), to *O. cejpii* 10–12.7 % (1.3–3 % in LSU), and to *O. tremulae* 17.3–18 % (6–7 % in LSU). The S1506 intron of *O. frangulae* is much longer than in *O. paracylindrospora*. An insert of about 44 nt occurs near the 5-end of ITS2 of *O. frangulae* in comparison to *O. paracylindrospora*, which also lacks in other species such as *O. cunninghamii*, *O. dryadum*, *O. fissilis*, *O. tremulae*, and *O. liliputiana* which are difficult to align with *O. frangulae* and *O. paracylindrospora* in this region.

Ecology. *O. frangulae* was collected on rotten wood and bark of xeric twigs and branches of *Frangula alnus*, in ± shady and moist, humid forests of warm-temperate atlantic western (Bretagne) and cold-temperate subcontinental central Europe (Luxembourg). The three sites in Luxembourg are on sandstone of lower lias, whereas that from Bretagne is on Cambrian (Brioverian) schist. One of the examined apothecia of the holotype was infected by *Helicogonium orbiliarum*. Not included collections were on branches of *Ulmus* and *Quercus* in Luxembourg, and on basidiocarps of *Fomitopsis* in cold-temperate to hemiboreal humid northeastern North America and northern Japan.

Specimens included. **LUXEMBOURG**: **Gutland**, 15 km WSW of Mersch, SSW of Hovelange, Haard, 350 m, twigs & branches of *Frangula alnus*, on wood & bark, 13.IV.2014, G. Marson (ex G.M. 2014-04-13.4 & H.B. 9970a, M-0276485, **holotype**, anam. substr.; sq.: KT380095). – 7 km ESE of Mersch, 1.2 km W of Koedange, NNE of Stuppicht, Breedschet, 405 m, branches of *F. alnus*, on wood & bark, 12.VII.2014, G. marginal excipular cells, containing carotenoids (light golden yellow-orange) {5}, LBs in pale-coloured apothecia sparse or subhyaline. **Exudate** over paraphyses absent or 0.2–0.3 µm thick, smooth to finely rough, firmly attached, over margin and flanks absent or 0.3–0.8(–2.5) µm thick, granular-cloddy to continuous. **— ANAMORPH**: dicranidion-like (presumed, from natural substrate {2}). **Conidiophores** not observed. **Conidia** 2-armed, the arms parallel, *14–18 × 6.5–8 µm {1}, base conical, with indistinct nodulous scar, basal cell ± deltoid, each arm delimited by a basal septum, the 2 septa forming a ~90° angle; arms *(7–)11–15 × 3–3.8 µm, 2–4-septate; rarely 3-armed, *9 µm wide.

Habitat: ~1–3 m above the ground, corticated to partially decorticated, 7–30 mm thick twigs and branches, rarely trunks, of *Populus tremula* {1}, *Rosa* sp. {1}, *Salix* sp. {2}, *S. aurita* {1}, *S. caprea* {3}, on bark {7} (bast), more rarely wood {3}, in small to large holes of periderm, partly hidden below detaching periderm, or on decorticated areas, little to rather strongly decayed, algae absent, rarely abundant. **Associated**: *Hypogymnia physodes* {1}, *Merismodes* sp. {1}, *Mollisia rosae* {1}, *Parmelia* sp. {1}, *Sclerococcum* ?*stygia* {1}. **Desiccation tolerance**: fully viable for at least ~5 days, excipular cells, ascospores, and conidia viable after at least 4 weeks. **Altitude**: Scandinavia: 77 m a.s.l., central & southern Europe: 293–1600 m. **Geology**: Precambrian & Cambrian greywacke, silt- & sandstone, Devonian & Carboniferous clayey schist etc., Buntsandstein, Keuper (Rhätsandstein), Lower Jurassic sand- & limestone, dolomite; granite, gneiss, amphibolite, mica schist, phyllite. **Phenology**: XII–II, VI.

Taxonomic remarks. The here included eight collections of *Orbilia plurivacuolata* deviate from *O. eucalypti* in multiguttulate paraphyses (living state!) being filled with numerous small, globose, hyaline, medium to strongly refractive VBs. These VBs do not tremble by Brownian motion, apparently because each droplet represents a single vacuole. They stain distinctly turquoise in CRB and disappear in KOH or after longer storage in the herbarium. Except for slight differences in the presumed anamorph, *O. plurivacuolata* fits in the other features *O. eucalypti* which has paraphyses with larger, partly elongate, non- or rarely slightly refractive vacuoles.

In seven samples the ascospores contained in varying frequency LBs of 0.3–0.7 µm diam. Although such comparatively large LBs occur mainly in aberrant spores of *O. eucalypti*, they appear to be typical of normally developed spores of *O. plurivacuolata*, in which aberrant spores have as yet not been observed.

It cannot be excluded that teleomorphs described by Velenovský (*O. microclava*, on *Populus*; *O. alnea*, lectotype on *Salix*; *O. succinea*, on *Rosa*) or Svrček (*O. roseofuscella*, on *Picea*), here placed in synonymy with *O. eucalypti*, represent *O. plurivacuolata*. In any case, guttulate paraphyses were not reported by these authors and the spores contained only a few minute LBs in the present reexamination (Pl. 855: 1–3, 5).

Variation. In three of the German samples the paraphysis tips were partly to predominantly hooked like a walking stick, a feature typical of *O. frangulae*. Apothecial colour varied among the samples between light to deep yellow-orange, orange-pink, and rose. Within the collection from Finland, all these striking colour variants were observed intermingled, but the microscopical features were the same. In this specimen the hyaline VBs were present in all paraphyses of four apothecia examined (with either yellow-orange or rose colour). However, they were completely absent in two other, ± orange apothecia, although the paraphyses were fully alive in all 6 apothecia tested.

Ascospore size mostly ranged at *(3–)3.5–5(–5.5) × (1.8–)2–2.4(–2.6) µm, except for the unillustrated sample from Vosges (*5–6 × 2–2.3 µm). In the holotype the spores measured *3.5–4.5 × 2–2.4 µm and often contained two LBs.

Anamorph. The conidia observed in the sample from Finland emerged from the excipulum of the two apothecia with non-guttulate paraphyses. Whether these apothecia belong to *O. plurivacuolata* or *O. eucalypti* remains unclear, but the slightly larger conidia with 2–4-septate arms might indicate a morphological difference to *O. eucalypti*. Also in the sample from Luxembourg a few dicranidion-like conidia were observed but not documented. In conidial characters *O. plurivacuolata* does not differ from the type of *Dicranidion fragile* on *Nerium* from California. Even if the limits of the *O. eucalypti* complex is better understood in the future, clarification of the identity of *D. fragile* in its original sense will hardly be possible without molecular methods.

Map 136. Known distibution of *O. plurivacuolata* in Europe.

Not included collection: A sample from Massachusetts (IVV: bhi-F948) shows multiguttulate paraphyses reminiscent of *O. plurivacuolata*. It is named *O.* aff. *plurivacuolata* because of a high genetical distance.

Phylogeny. Sequences of two samples were available: H.B. 9817a (holotype, Spain, Somiedo, *Rosa*, apothecia rose-pink) and G.M. 2016-02-10.2 (Luxembourg, *Salix*, apothecia yellow-orange), both comprising S1506 intron+ITS+LSU. They differ in the ITS by 1.1% (5 nt, 4 gaps), in the intron by 0.9% (4 nt, 1 gap), and in the LSU D1–D2 by 0.5% (3 nt), suggesting conspecificity.

O. plurivacuolata clustered with a 9–10% ITS distance with *O. cejpii* (on *Sorbus* and *Salix*) in a medium supported subclade (Phyls 22, S27), whereas the distance to *O. cejpii* on *Fagus* lies at 13.5–16.5% and to *O. eucalypti* in the range of 13–23% (the lower values to subclade D). *O.* aff. *plurivacuolata*, for which only ITS was available (intron absent), clustered distantly and unresolved between the *O. eucalypti* clade and the *cejpii-frangulae* clade (Phyl. 23) by showing an ITS distance of 9.5% to *O. plurivacuolata*.

Ecology. Apothecia of *O. plurivacuolata* grew on xeric bark or more rarely wood of *Populus*, *Salix*, and *Rosa*. Seven of the eight collections were on *Salicaceae* in supra- to orotemperate and thermoboreal humid areas of Europe. The sample from Vosges was a boggy *Salicetum*, that from Lenggries the subalpine *Pinus mugo* belt with some *Salix* and *Fagus*, that from Sonneberg a narrow forest belt with *Salix* and *Betula*, also *Populus tremula*, *Acer*, and *Picea*, and that from Luxembourg a thermophilous *Querco-Carpinetum* with *Crataegus*, *Cornus*, *Prunus spinosa*, *Populus tremula* etc. The holotype on *Rosa* was from a *Quercus ilex* forest with *Corylus avellana* in mesosubmediterranean semihumid southwestern Europe. The not included sample is from a cold-temperate humid angiosperm (*Acer*) forest in eastern North America.

Specimens included. **FINLAND**: **Pirkanmaa**, 15 km WSW of Tampere, 3.5 km S of Nokia, S of Keho, Kehonnokka, 77 m, branch of *Salix*, on bark, 29.XII.1996, U. Söderholm (U.S. 2663, H.B. 5683, anam. substr.). — **GERMANY**: **Sachsen-Anhalt**, 14.5 km S of Quedlinburg, 2.2 km NNE of

Orbilia fissilis (K. Ando & Tubaki) E. Weber & Baral, in Baral et al., Mycol. Progr. 17 (1–2): 20 (2017) — Pls 853–854

Basionym: *Dicranidion fissile* K. Ando & Tubaki, Trans. Mycol. Soc. Japan 25(1): 39 (1984)

Etymology: referring to the conidia being split into arms.

Typification: Japan, Tsuchiura, isolated from rainwater from the intact canopy of *Quercus myrsinifolia*, 8.VII.1983, K. Ando (TKB-F-5079, holotype; ex-type culture: TKB-C-1362; sq.: LC146730).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.3–)0.4–1 mm diam., 0.1–0.28 mm high, pale to light rose-orange, ± translucent, round to slightly undulating, gregarious; disc flat to finally medium convex, margin thin, 0–5 µm protruding, smooth; subsessile or broadly sessile, superficial; dry light to bright pink-rose-orange. **Asci** 33–43(–50) × 3.3–4 → 3.8–4.4 µm {2}, †25–40 {4} or 35–45 {1} × 2.7–3.7(–4) µm {5}, 8-spored, spores (*) uniseriate, lower spores inverted (very strongly mixed), pars sporifera *17–20 → 12.5–15.5 µm long; **apex** (†) strongly truncate (not or slightly indented, laterally sometimes slightly inflated); **base** with short to medium long, thin or thick, flexuous stalk, T-, L-, Y- or h- to H-shaped. **Ascospores** *(2.1–)2.3–3(–3.4) × (1.8–)1.9–2.3(–2.5) µm {5}, †2.4–2.8 × 1.7–2 µm {1}, broadly ellipsoid to subglobose, ends rounded; **SBs** *0.3–0.5 µm diam., globose, attachment directly, or invisibly at a short distance, surrounded by a few large (0.5–0.8 µm) and small LBs. **Paraphyses** apically slightly to medium (rarely strongly) clavate-capitate, sometimes (sub)lageniform, terminal cells *(9.5–)15–20(–22.5) × 2.3–3.8(–4.5) µm {2}, lower cells *5–10 × 1.5–2.3 µm {2}; sometimes branched at upper septum, hymenium very pale rose. **Medullary excipulum** hyaline, 30–100 µm thick, of dense textura intricata-prismatica(-angularis), indistinctly to sharply delimited from ectal excipulum, partly by a 10–15 µm thick, pale greyish-rose layer of t. porrecta. **Ectal excipulum** hyaline, of thin-walled, vertically oriented t. globulosa-angularis(-prismatica) from base to margin, 25–130 µm thick near base, cells *8–25(–35) × 7–15(–17) µm {1}; cortical cells at submargin *6–22 × 5–9 µm, 20–30 µm thick near margin, oriented at a 60–80° angle to the surface, marginal cortical cells *5–9 × 4–5 µm {1}; **glassy processes** absent. **Anchoring hyphae** medium to very abundant, *1.8–2.8(–3.3) µm wide, walls *0.2(–0.3) µm thick (†0.2–0.4 µm) {1}. **SCBs** in paraphyses not observed, in medullary excipulum (near ectal excipulum) globose, 1.2–2 µm diam.; **VBs** sometimes present in paraphyses, elongate, hyaline, low-refractive. **Exudate** over paraphyses and exterior absent or sparse to abundant, ~0.2–0.5 µm thick, granular-cloddy. **— ANAMORPH**: dicranidion-like (from ascospore isolate {1} and natural substrate {1}). **Conidiophores** */†7–25 × (1–)2–3 µm {2}, unbranched, ± flexuous, conidia mainly terminally and sympodially formed. **Conidia** 1–2 × dichotomously branched (2- or 4-armed in about equal frequency, less often 3-armed), */†(12–)14–20(–22) µm long {3}, 2-armed conidia */†7–11 {2} or 10–16.5 {1, H.B. 9844} µm wide, 3-armed */†(8–)10–14 µm {2}, 4-armed */†(9–)11–19 µm {2}, stipe */†5–9.5(–11) × (1.6–)2–3 {3} [in Ando & Tubaki (1984b) as trunk (= main axis) of 7.5–10.5(–12) × 2.4–4 µm {T}], 0–1(–3)-septate, arms */†(2–)3.5–12(–15) × (1.7–)2–3(–3.5) {3} µm, (0–)1–3(–4)-septate, when 2-armed then arms parallel or diverging or only terminally curved outwards; rarely unbranched (T).

Habitat: collected 0–1 m above the ground, decorticated or corticated, 2.2–70 cm thick branches, stumps or logs of *Quercus* sp. {1}, *Q. myrsinifolia* {1}, indet. angiosperms {3}, on deeply strongly decayed wood {2} or bark {3} (outer and inner surface), somewhat greyed, with many green algae (especially *Gloeocapsa*). **Associated**: *Mollisia* ?*oblonga* {1}, *Gloeocapsa* sp. {1}, ?*Parmelia* sp. {1}. **Desiccation tolerance**: after 1 day only the cells of the ectal and medullary excipulum were still viable, but spores survived for at least 4 weeks. **Altitude**: 290–560 m a.s.l. (central Europe), 450 m (central Asia), 30 m (central Japan), 2700 m (southern China). **Geology**: France: Silurian-Devonian greywacke & ultrabasic olistolith; Germany: Keuper (Stubensandstein). **Phenology**: VII–X (teleomorph).

Taxonomic remarks. *Orbilia fissilis* strongly resembles *O. eucalypti* in characteristics of the teleomorph, but its ascospores tend to be subglobose, i.e., they are shorter and with a lower length/width ratio than is usually the case in *O. eucalypti*. *O. cejpii* differs from *O. fissilis* in slightly narrower spores with smaller LBs, but mainly in the anamorph.

A few collections of *O. eucalypti* showed a varying number of subglobose spores similar to those of *O. fissilis*, though with a tendency to being larger and sometimes fusoid or ovoid (see

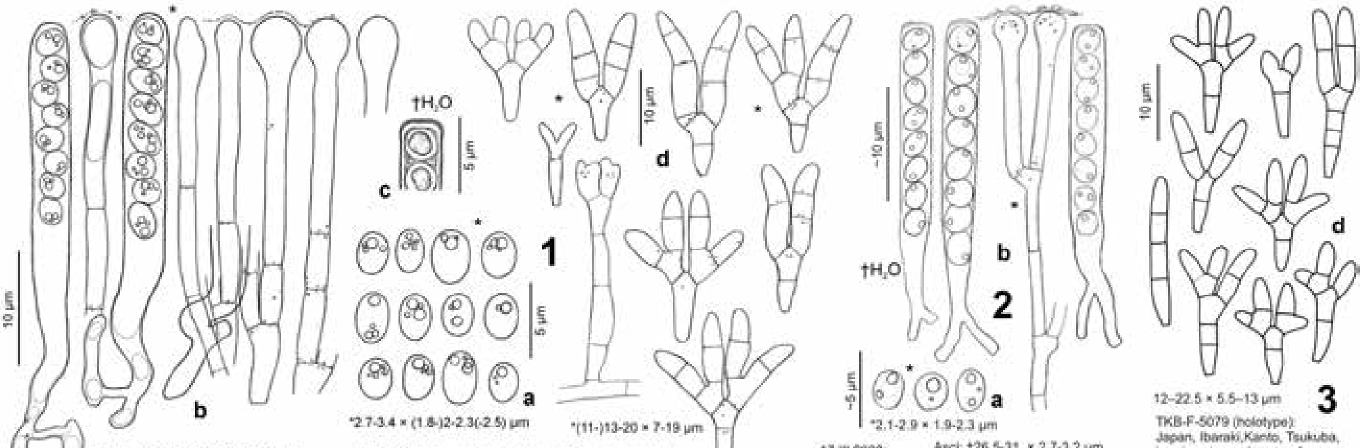

Plate 853. **1**: *Orbilia fissilis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. conidia from culture. – **2**: del. E.S. Popov, **3**: from Ando & Tubaki (1984b).

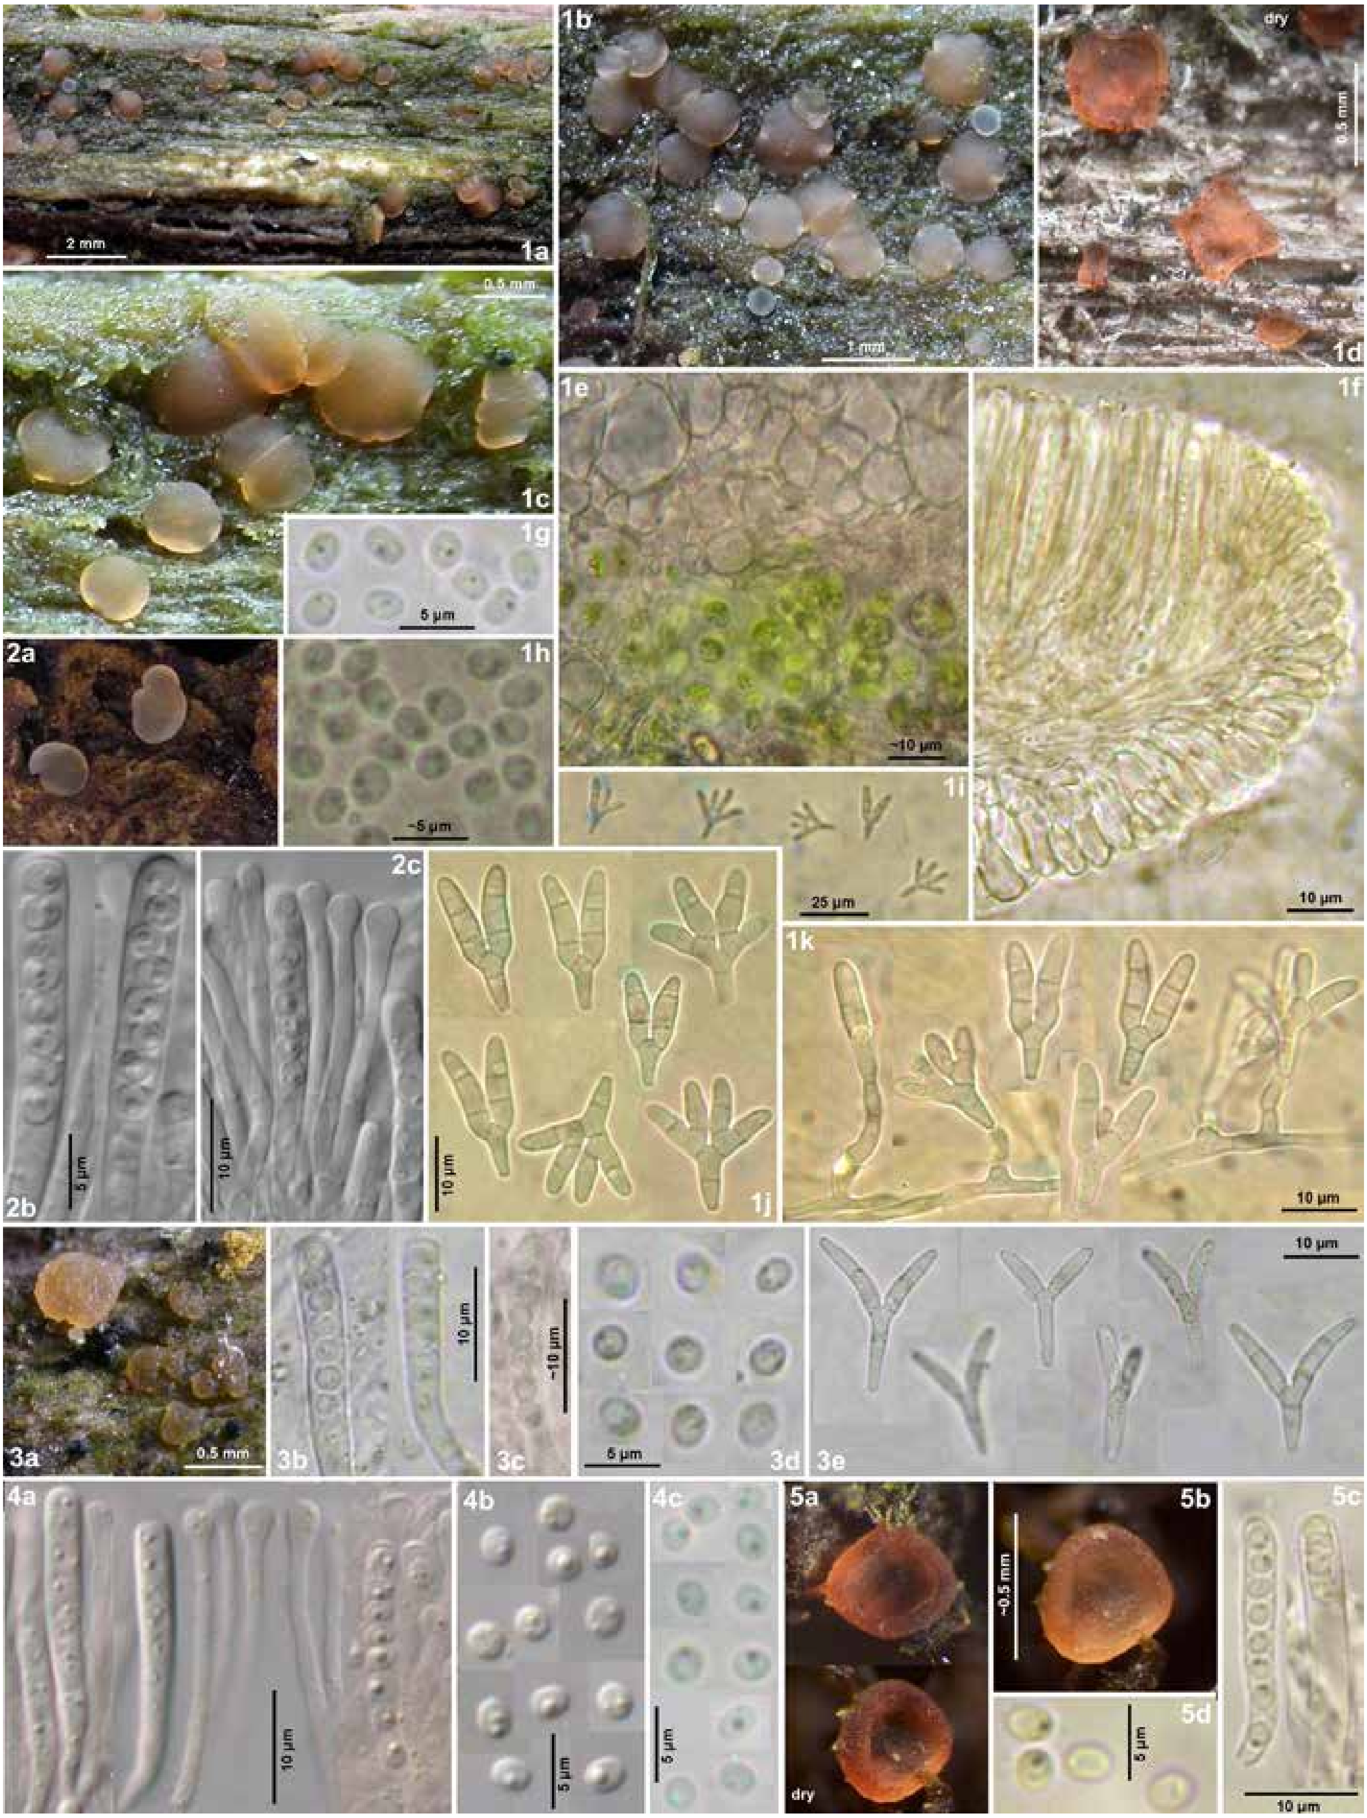

Plate 854. **1–4**: *Orbilia fissilis*; **5**: *O.* cf. *fissilis*. – **1a–c**, **2a**, **3a**, **5b**. fresh apothecia; **1d**, **5a**. dry apothecia; **1f**. ectal excipulum in median section (margin and mid flanks); **1e**. id. (near base, with *Gloeocapsa*); **2b–c**, **3b–c**, **4a**, **5c**. asci and paraphyses; **1g–h**, **3d**, **4b–c**, **5d**. ascospores; **1i–k**, **3e**. conidia and conidiophores (**1**: from culture, **3**: from natural substrate). – Living state, except for **1f–g** (in KOH), **3b–c** (asci), **4a** (asci & paraphyses), **5c** (left ascus). – **2a–c**: phot. Z.F. Yu (DIC), **3c**: N. Van Vooren, **4**: E.S. Popov (**4a–b**: DIC), **5**: G. Friebes. — **1a–j**. H.B. 7566a: Germany, Tübingen, on *Quercus*; **2a–c**. Y.Z. jz-36: China, Yunnan, Dali, indet. angiosperm; **3a–e**. H.B. 9844: France, Lyon, on ?*Salix*; **4a–c**. 17.VIII.2008: Russia, Altay, indet. angiosperm; **5a–d**. G.F. 20100313: Austria, Graz, on *Fagus*.

Pl. 858: 6–8). In contrast to *O. fissilis*, all these subglobose-spored variants of *O. eucalypti* grew on xeric substrate. In many collections here referred to *O. eucalypti* no associated anamorph could be found, therefore, especially those with small, broadly ellipsoid spores remain somewhat uncertain in their identity.

Variation. Although differing from the specimen from Tübingen in shorter asci, the other included collections are considered as conspecific because of a very similar ascospore size and shape containing large LBs, also because the apothecia grew on hygric substrate.

The SB in the spores of the specimen from Tübingen could only be distinguished from the surrounding LBs by a blue(-violet) stain in CRB, or by disappearing in KOH. However, this test was not applied to the drawn spores, therefore, the identity of each individual drop is not clear on the drawing. The presence of large LBs surrounding a smaller spore body was first thought to be characteristic of this species. However, E.S. Popov (pers. comm.) noted in his specimen that virtually all drops in the spores persist in KOH, whereas in G. Friebes' (pers. comm.) not included Austrian specimen a distinct SB is visible in the apex of each spore, while associated LBs are sparse. The Chinese specimen closely resembles the one from Tübingen in spore guttulation. A similar variation in spore guttulation between collections was frequently noted in *O. eucalypti*.

Not included collections: Two unillustrated records from Germany (ascospores 3–3.5 × 1.8–2.3 µm, on *Weigela*, 1.5 m above the ground) and France (orange apothecia, ascospores 3–3.3 × 2 µm, on *Fagus*, on the ground) are not included because of incomplete documentation, and a specimen from the Comoros (IVV: M.P. 13.167) because of bright chlorinaceous-yellow apothecia and rather small spores (2.2–2.4 µm diam.).

In the Austrian specimen large LBs in the ascospores did not occur, therefore, this could instead belong to *O. cejpii* in which, however, a light orange-red apothecial colour seems to be untypical. The asci were with *27.5–32.5 × 3.5–4 µm shorter than here reported for *O. fissilis* and *O. cejpii*, and the spores with *2–3.3 × 1.7–2.3 µm partly wider than in *O. cejpii*.

Anamorph. The dicranidion-like conidia of *O. fissilis* obtained in pure culture of the collection from Tübingen were frequently 4-armed, with ± diverging arms and a distinct, partly 1-septate stipe (Pls 853: 1d; 854: 1i–j). They herein sharply differ from the conidia of *O. eucalypti* with 2 (rarely 3) mostly not diverging arms and nearly absent or rather short stipe. The original description of *Dicranidion fissile* fits very well our strain in having 2-, 3- and 4-armed, though also unbranched conidia (Ando & Tubaki 1984b, Pl. 853: 3). The type differs from our strain in slightly longer conidiophores and conidial stipes, the latter with 1(–3) septa, also in narrower arms and stipes which might, however, be due to the dead state of the conidia. In the collection from Lyon 2-armed conidia were observed on the natural substrate (besides phragmoconidia which are of unclear relationship). They differ from the specimen from Tübingen in rather narrow arms and stipes (max. *2.2 µm), with the arms consistently diverging (Pl. 854: 3e), but they resemble those 2-armed conidia with diverging arms in the protologue. Also *O. cejpii*, *O. battenii* and *O. liliputiana* differ from *O. fissilis* in the anamorph (see there).

Phylogeny. A sequence taken from an ascospore isolate of the collection from Tübingen comprises SSU (with S1506 intron), ITS, and LSU. From the ex-type culture from Japan a sequence is deposited at NBRC and GenBank, which includes S1506 intron, ITS, and LSU. In the LSU the two sequences are identical, while in the ITS region the distance is 2.6% and in the intron 2.3%.

O. fissilis shows a high distance to any other species: in the LSU a minimum of 3.8% to *O. liliputiana* was noted, in the ITS min. 13.5% to *O. eucalypti,* and in the intron min. 18% to *O. leucostigma*. In the SSU V8–V9, however, it almost coincides with *Tridentaria implicans* and *O. tremulae*, showing to each a 1 nt deviation in the V8 (Phyl. S25). *D. inaequale* forms an unsupported clade with *O. fissilis* (Phyls 22–23), to which it shows a distance of 15%.

Ecology. *O. fissilis* is only known from a few records on hygric rotten wood and bark of angiosperms. The specimen from Tübingen grew on an old oak bench made of thick boards at a fireplace in a shady cold-temperate humid *Quercus-Fagus* forest. The Austrian sample on a *Fagus* stump originates from a probably similar forest. The specimen from France was on a recently fallen, completely rotten, corticated branch of an unidentified angiosperm in an almost warm-temperate *Quercus-Carpinus* forest, and that from Russia in an *Alnus fruticosa-Betula-Salix* forest in the boreal, cold-continental humid western Sayan Mountains. In contrast, the Chinese sample is from a subtropical humid (winter-dry) evergreen forest. The holotype of *D. fissile* was isolated from rainwater draining mainly from leaves of intact *Quercus myrsinifolia* trees in the subtropical humid central part of Honshu in Japan. Whether the conidia were formed on living leaves or on twig bark or dead wood in the canopy is unclear. The not included collection from southeastern Africa was in a tropical humid (wet & dry) rainforest in the Comoros.

Specimens included. **GERMANY**: **Baden-Württemberg**, 4.3 km WSW of Tübingen, NE of Hirschau, Spitzberg, Greut, 450 m, board of *Quercus*, on wood, 29.VIII.2004, E. Weber & H.O. = *Orbilia microclava* Velen., Monogr. Discom. Bohem.: 92 (1934)
= *Orbilia alnea* Velen., Monogr. Discom. Bohem.: 93 (1934)
= *Orbilia succinea* Velen., Opera Bot. Čech. 4: 101 (1947), nom. illegit., ICN Art. 53.1 [non *Orbilia succinea* (Fr.) Quél., ≡ *Siroscyphella succinea* (Fr.) Höhn., see p. 1687]
= *Orbilia xanthostigma* s. Svrček (1954) p.p.
= *Orbilia roseofuscella* Svrček, Česká Mykol. 41: 91 (1987)

Etymology: named after the apothecial colour (*roseofuscella* = pale rose-brown, *succinea* = amber) or the substrate (*alnea*, *eucalypti* – from *Alnus* and *Eucalyptus*); *microclava*: referring to the somewhat clavate paraphysis apices in the centre of the disc; *fragile*: apparently after the minute, pulvinate tufts formed by the conidiomata; *parasitans*: after the seemingly erroneous belief of the anamorph growing as a parasite on the here presumed teleomorph; *argentinense*: after the geographical origin, Argentina; *ramularioides*: after the sympodially proliferating conidiophores similar as in *Ramularia*; *episphaeria*: growing on a pyrenomycete (*Thyronectria cucurbitula*).

Typification: USA, California, unlocalized, branch of *Eucalyptus globulus*, 1882, H.W. Harkness (Harkn. 2872, K(M) 36053, holotype of ***Calloria eucalypti***). — California, Oakland, branch of *Nerium oleander*, II.1882, H.W. Phenology of *O. eucalypti* (temperate northern hemisphere)											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
39	33	39	53	22	21	23	23	27	25	25	21

Taxonomic remarks. *Orbilia eucalypti* is characterized by bright yellow-orange or rose-lilaceous but also whitish, desiccation-tolerant apothecia with smooth, often rather thick, ± raised margin, small to medium-sized, ellipsoid-fusoid ascospores, capitate paraphyses, and a dicranidion-like anamorph with deltoid basal cell with a conical base. However, delimitation from *O. tremulae* and *O. plurivacuolata* is problematic concerning both teleomorph and anamorph (see under these species), especially when studying herbarium material. *O. eucalypti* may also be confused with *O. battenii*, *O. cejpii*, *O. frangulae*, *O. gaillardii*, and *O. liliputiana*, which differ in shorter or narrower ascospores and a different anamorph (that of *O. gaillardii* is unknown). When studying dead herbarium material in which the spore bodies cannot be seen, large-spored collections of *O. eucalypti* may further be confused with some other species with orange apothecia on xeric wood and bark, e.g., *O. trapeziformis* and *O. vitalbae* (section *Habrostictis*), *O. ovalis* (section *Lentiformes*), and *O. subovoidea* (section *Ovoideae*). Collections of *O. eucalypti* with aberrant subglobose spores may be confused with *O. sphaerospora* (section *Ovoideae*) or *O. fissilis*. Yet, the spores of these species contain globose SBs whereas the aberrant spores of *O. eucalypti* possess merely KOH-resistant LBs.

Variation in colour. *O. eucalypti* has typically bright orange or sometimes yellow- or rose-orange apothecia, which misled earlier authors to identify a population as *O. coccinella*. However, the apothecial colour varies rather strongly in the present concept of *O. eucalypti*. Its typical colour is exclusively observed on exposed, xeric branches. Populations on branches and trunks on the moist ground are generally much paler rose or yellowish-cream, and then the distinction from *O. tremulae* becomes particularly problematic. Moreover, such pale colours were sometimes also observed on exposed xeric branches (e.g., Pl. 859: 4). In some collections on xeric or hygric substrates, closely associated or even intermingled populations strongly differ in colour between pale rose and bright orange (see Fig. 14: c), obviously due to a different concentration and composition of carotenoids inside LBs. Such colour variants of mixed populations of *O. eucalypti* have never been investigated by molecular methods.

Variation of ascospores. In the present concept of *O. eucalypti* great variation is noted in spore size and shape, also in content. This variation not only occurs among collections but sometimes also within a given population or even a single apothecium. We assume that these differences in spore size, shape, and content are not genetically fixed, but originate from some unknown environmental parameters, or perhaps the age of the apothecia. This assumption is based on the following phenomenon which includes the partial absence of SBs in living spores, and which seems to be rather exceptional within the *Orbiliomycetes*:

Living spores of *O. eucalypti* generally contain a globose spore body of ca. 0.5–0.7 µm diam., which is usually surrounded by a few similar-sized and refractive lipid bodies (Pls 855: 4, 6, 8; 856: 1f, 4b; 857: 7; 859: 6, 10; 860: 4a–b, 8d). The position of the SB and the associated LBs permits to recognize the upper spore end. However, LBs partly also occur at the lower spore end which results in a homopolar, sometimes biguttulate spore content. In *O. eucalypti* SBs and LBs can only be distinguished with certainty by vital staining (e.g., with Cresyl Blue, see Pl. 860: 4a) or by applying lethal agents such as KOH. This difficulty mainly concerns the case when LBs abundantly surround the SB at the spore apex (e.g., Pls 857: 1; 858: 2). In dead specimens usually only LBs can be seen when mounted in media such as H_2O or KOH. Exceptionally, SBs could unequivocally be discerned as a transparent region in the spore apex: in the holotype of *O. eucalypti* (in KOH or KOH+IKI, Pls 858: 1a; 860: 1c–d) and in some other collections, e.g., in an unillustrated sample which was reexamined 22 years later (H.B. 4653a, in H_2O).

However, particularly in desiccation-tolerant populations the spores are often without any trace of a spore body. Such seemingly aberrant spores tend to be larger, especially longer, and usually develop a higher number and/or larger size of lipid droplets which often attain a size of 1–1.5 µm. Aberrant spores with large LBs are shown in Pls 855: 7, right spore in 8; 857: 4–6; 858: 5a right; 859: 16a, c, but intermediate spores also occur (Pl. 857: 1–3). Sometimes the aberrant spores are only wider, or even of equal size with the normal spores. Wider, more ovoid to subglobose, rarely almost globose spores are illustrated in Pl. 858: 6–8 and where also observed in H.B. 4980, 5038b, and 5270 (unillustrated). They lie in the range of *3–4.5 × 2.2–3.5 µm, i.e., only the width exceeds the normal values. Ovoid to subglobose spores with a low lipid content and distinct SBs, have never been seen.

Although spores of the aberrant type have repeatedly been found inside living mature asci and are forcibly ejected like the normal spores, they might better be classified as overmature stages, contrary to the definition of maturity by Baral (1992: 375). This view is supported by the repeated observation within *Orbilia* that, during spore germination, the SBs gradually disappear while, contrary to the situation in many *Helotiales*, the number and size of LBs increases.

The observed differences in spore contents could reflect different strategies of colonization by giving more weight to either the formation of lipid bodies or a spore body (see p. 90). In several collections we have observed such aberrant lipid-rich spores together with the normal spores within an apothecium (sometimes even within a single ascus). Only exceptionally the asci contained less than 8 spores, hence the increased spore size is usually not a result of a reduced spore number. The percentage of aberrant spores strongly varies among the collections. A few or almost all asci of an apothecium may produce such spores, and this may affect the majority or only a few apothecia of a given collection.

Great variation in spore size is also noted among the normal spores when comparing different collections (Pls 855–860). Populations with smaller spores show a more or less ellipsoid spore shape and can hardly be delimited morphologically from

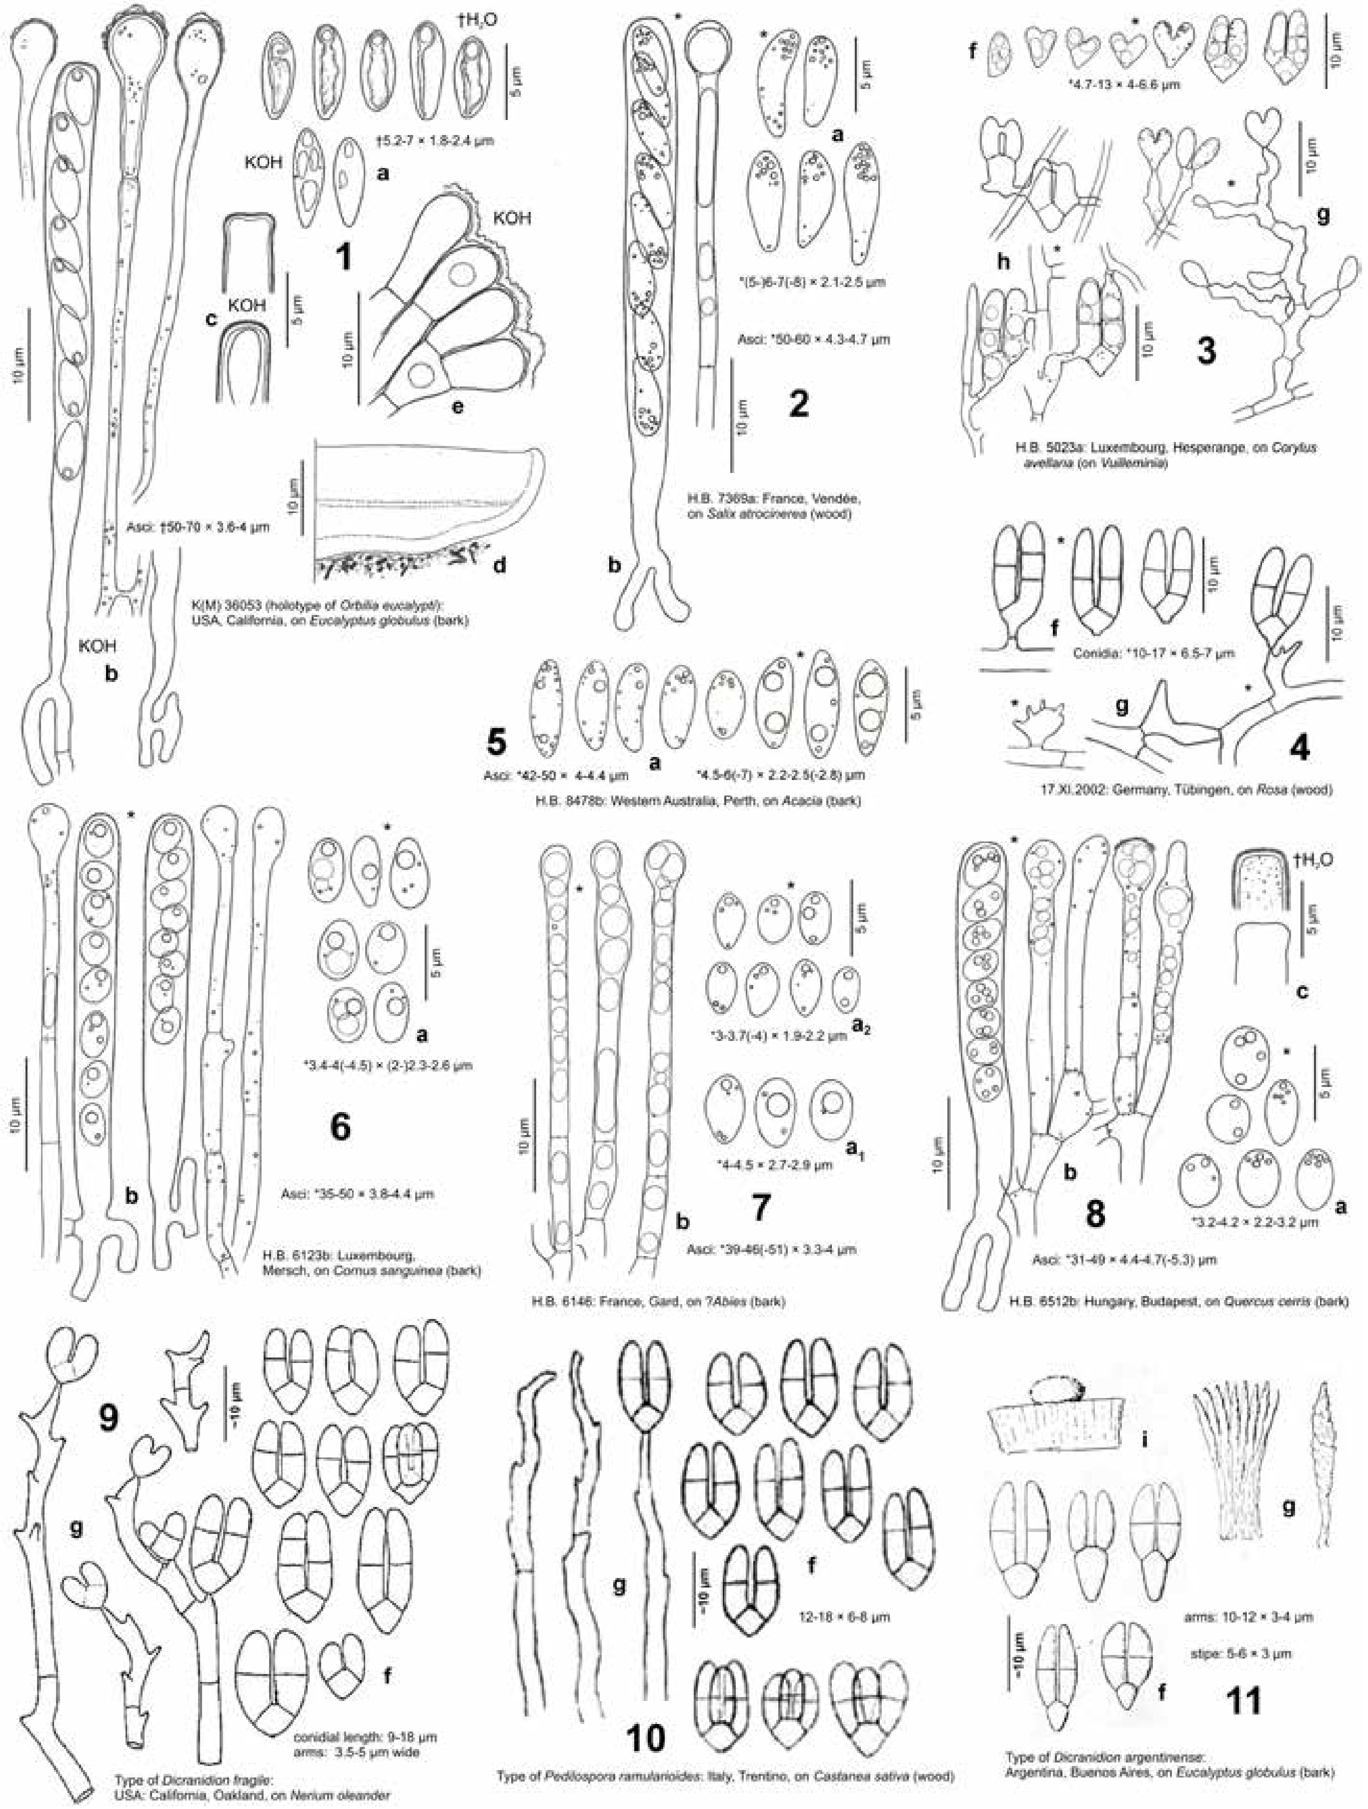

Plate 858. **1–8**: *Orbilia eucalypti*; **9–11**: *O.* cf. *eucalypti*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. detached conidia; **g**. conidiophores and conidia; **h**. germinated conidia; **i**. sporodochium (**3–4**, **9–10** from culture; **9**. from Hughes 1953, **10**. from Bubák 1916, **11**. from Spegazzini 1911).

O. tremulae without the anamorph, whereas those with larger spores tend to be more heteropolar (subclavate), i.e., slightly more attenuated and sometimes slightly curved at the base or more subglobose. The range of spore size within the smaller-spored populations lies at *3–4.5 × 1.7–2.2 µm, that of large-spored ones around *4–7(–8.5) × 2.1–2.8 µm. 2 western Australian collections on bark of *Acacia* deviate by extremely long spores [*(6–)7–9.5(–10.5) × 2.2–2.5(–2.8) µm, H.B. 8996c (Pl. 860: 6), 9.XII.2001], but also the holotype of *O. eucalypti* from California and three European records show rather long spores although containing only small LBs (Pls 857: 7; 858: 1–2, IVV: 24.V.2015).

This mixed occurrence of different spore sizes within an apothecium indicate that collections with aberrant spores are conspecific with those with normal spores. For instance, in a specimen with subglobose spores (Pl. 858: 7), the majority of asci contained normal spores while only some showed distinctly larger, more ovoid spores. In another sample, subglobose spores strongly prevailed in two of the three tested apothecia growing on wood (Pl. 858: 8), while the third apothecium showed consistently narrower, ellipsoid spores, and also in an adjacent population on bark (H.B. 6512c, not figured) only ellipsoid spores were found (*3.5–4 × 2 µm). In the rare case of asci containing less than 8 spores, subglobose spores with an extraordinary width (*5–5.5 × 4–4.3 µm) were seen in the mentioned unillustrated sample H.B. 5038b.

Also in those specimens with large elongate spores, apothecia with much shorter spores occurred in association. For instance, in the one with the largest spores observed (Pl. 857: 5), a rather large out of 6 apothecia examined deviated in exclusively much smaller spores (†3.5–5 × 2–2.2 µm) with a very low lipid content, and asci at the lowermost end of the range (†32–40 × 3.2–3.5 µm). Quite the same situation was observed in the type of *O. eucalypti*, but here also the large spores showed a low lipid content and possessed distinct SBs. In both cases the apothecia seemed to be sharply separated by their microscopical features, though macroscopically indistinguishable.

Variation of asci, **paraphyses and excipulum**. In the present concept of *O. eucalypti*, the length of the living mature asci (prior to full turgescence) considerably varies between 31–40 and 50–60 or even 60–70 µm. Also the ascus width varies at normal turgescence between 3.5–4 and 4.3–5.3 µm, with the longest asci often showing also the largest width. Thereby, ascus and spore size is correlated to a certain degree.

The paraphyses vary between slightly to strongly capitate or clavate, and some of them show strongly asymmetrical shapes which more or less resemble the upper end of a femur; however, such asymmetrical paraphysis heads are more typical of *O. tremulae*. A thin or medium thick, often granular exudate usually covers the paraphyses and also the cortical excipular cells at margin and flanks. This exudate often occurs only scattered and is sometimes completely absent, especially from the paraphyses.

The living paraphyses and marginal cortical cells contain non- or very low- to low-refractive vacuoles which are only partly illustrated here because of their inconspicuousness (Pls 857: 3, 7; 858: 2, 7, 8; 859: 2b, 16b). Globose SCBs of varying refractivity were sometimes observed in these cells (Pls 855: 6e, 7b; 859: 2b, 13a–c, 16b).

The size of the basal ectal excipular cells may vary between *(5–)8–14(–18) × (4–)6–11(–14) and *(8–)15–25(–33) × (7–)10–16(–19) µm. Those populations with large excipular cells are reminiscent of *O. tremulae*, but were not transferred there because of over 2 µm wide ascospores and/or bright orange apothecia. The excipular cells are usually thin-walled, but in an Australian collection (H.B. 8658a) the common wall was partly quite thick (*1–2.5 µm).

Variation reported in the literature. The strong variation in colour and size of the apothecia as well as in size of the spores is indicated in the literature. Rehm (1891: 454, as *O. coccinella*) emphasized the variability in apothecial colour and imagined that *O. leucostigma* (s. Karsten) with whitish apothecia and narrower spores might be conspecific, but tentatively included also Karsten's f. *delicatula* (= *O. xanthostigma*). Breitenbach & Kränzlin (1981: 210) reported two collections with a very different spore size (3–4 × 1.5–2.5 vs. 5–6.5 × 2–2.5 µm). The present revision of the specimens revealed that both grew on old ascomata of *Colpoma quercinum* on *Quercus*, contrary to the author's notes. The colour photo obviously does not belong to either of them, whereas the reported difference in spore measurements is confirmed, the small-spored one approaching *O. tremulae*. Ellis & Ellis (1985: 11) made a distinction among British specimens between *O. alnea* with (peachy) orange apothecia and narrowly ellipsoid spores 3–5 × 1–1.5 µm with polar guttules, and *O. coccinella* with red apothecia of a smaller size and biguttulate spores 4–5 × 2.5 µm, both on angiosperms. Also Clark (1980a: 79) recognized these two taxa as distinct, but referred a sample on conifer to *O. coccinella*. Similarly, Ginko (1986) distinguished among Polish material between *O. coccinella* with orange-red apothecia and subglobose spores 3–5 × 2–2.5 µm (*O. eucalypti*) and *O. leucostigma* with whitish apothecia and ellipsoid spores 2.4–3 × 1–1.8 µm (?= *O. cejpii*).

Grelet (1948a: 52) reported extraordinarily wide spores of 4–7 × 3–4 µm for two collections on coniferous wood. However, some of the reported spore measurements did not very well concur with the provided illustrations, according to the given scale. For instance, Boudier (1904–10: 266, pl. 461) gave the spores as 4–5 × 2.5–3 µm, but from his plate a size of 3.5–4.3 × (1.8–)2.2–2.5 µm can be evaluated. Bell (2005: 20, fig. 32 E–J, as *O. alnea*) reported pink-coloured apothecia obtained on dung from Australia. The broadly ellipsoid-clavate spores are stated to measure 3–4 × 2–3 µm in the key but on the plate they are 2.3–3.4 × 1.5–2 µm, with some minute drops only at one end. Judging from spore size this is possibly *O. cejpii* rather than *O. eucalypti*.

Nomenclature and type studies of teleomorph. The name ***Orbilia coccinella*** Fr., cited also as '(Sommerf.) Fr.', was in use for a considerably long time for collections with small ellipsoid ascospores, which in majority appear to fit the present concept of *O. eucalypti*. After a restudy of the type material, the name *O. coccinella* now has to be used for a very different species which is characterized by strongly curved, cashew-shaped spores and 16-spored asci (see p. 1427).

Though apothecial colours were given a higher taxonomic weight in earlier times, the concept of *O. coccinella* s.auct. comprises very different colours: pale to bright rose-red, yellow-orange, and even whitish. The usage for an ellipsoid-spored fungus started with Karsten (1861: 36, 1869: 173) and Nylander (1869: 55), and was followed over the next hundred years by Gillet (1882: 129, with unbelievably large apothecia of 5–8 mm diam.), Rehm (1891: 453), Phillips (1887: 328, with small subglobose spores), Saccardo (1889: 628), Schröter (1893: 121), Massee (1895: 144), Boudier (1904–10: 266, pl. 461),

Velenovský (1934: 92), Grelet (1948a: 52), and Seaver (1951: 157). The epithet *coccinella* was indeed only rarely applied in a different sense (see under Misapplication).

Even some recent authors retained this usage, although it was already Nannfeldt (1932: 252) who indicated in a footnote that the only authentic specimen of Sommerfelt in the UPS herbarium differed greatly from the current concept of *O. coccinella*. Nannfeldt's short note, which includes the erroneous assumption of an identity with *Hyalinia rubella*, was neglected in the following almost 50 years, perhaps because he did not mention any microscopic details of the type material. Clark (1980a: 79) appears to be the first to adopt the binomial *Orbilia alnea* Velen. for the ellipsoid-spored taxon (*O. coccinella* s.auct.), which he assumed to be the oldest available name. Clark's choice was followed by Ellis & Ellis (1985) and Korf (1992). Raitviir (1991: 357) erroneously believed that *O. microclava* Velen. had priority over *O. alnea* because it is described a page before *O. alnea* in Velenovský's (1934) monograph, and he consequently adopted that binomial to replace the misapplied name *O. coccinella*. However, all these authors overlooked a much earlier synonym, *O. eucalypti* (W. Phillips & Harkn.) Sacc., which was recognized in the present study as belonging in the current scope of *O. coccinella* s.auct.

Another solution was suggested by Svrček (1954: 12) who used for the ellipsoid-spored taxon (*O. coccinella* s.auct.) the name *O. xanthostigma*. Svrček's choice relies on the frequent occurrence of ellipsoid-spored collections with bright yellow-orange apothecia which differ only slightly in their macroscopy from yellow populations of the *xanthostigma-leucostigma* complex. Since there exists no syntype material of *O. xanthostigma*, one way of naming the ellipsoid-spored taxon would be to neotypify *O. xanthostigma* in Svrček's sense. When Svrček (1987b: 91) described his *O. roseofuscella*, he found that its 'microfeatures are similar to *Orbilia coccinella* sensu auct., a common *Orbilia* entirely different in its bright yellow colour and guttulate ascospores of another shape', but he did not mention the name *O. xanthostigma* here. On the other hand, it seems very unlikely that Fries never had yellow populations of *xanthostigma-leucostigma complex* in hand, and the frequent usage of the name *O. xanthostigma* in that sense argues against a neotypification in Svrček's sense (see under *O. leucostigma*, Nomenclature and type studies, p. 1401).

Another option to find a proper name for *O. coccinella* s.auct. would have been offered by the new rules of the Code (ICN) which attribute names of anamorphs equal priority rights. However, *O. eucalypti* antedates the oldest available name, *Dicranidion fragile* Harkn., by 1 year. As a consequence, we are forced to adopt the oldest available name *O. eucalypti*, despite the frequent usage of the name *O. coccinella* in the period of ~50–150 years ago.

Nylander's (1869: 55) report of *Peziza coccinella* concerns a collection with carneous-red ('carneo-coccinea') apothecia (on unidentified wood from Lake Onega), with asci 4–5 µm wide and short ellipsoid to subglobose spores. This record was not examined by us and its identity remains unclear. Nylander mentioned an externally similar, often corticolous 'var. *vinosella*' from 'central Europe (Germany, France)', which differed in narrower asci (generally 3 µm wide), based on a collection of Ravenel (Fung. Carol. IV: 19, as *P. vinosa*). It seems likely that Nylander referred to *P. vinosa* var. *vinosella* Fr., a taxon which we place in synonymy with *O. auricolor* based on the restudy of an authentic specimen of Fries (see p. 1528). However, Rehm (1891: 454) attributed 'O. *coccinella* var. *vinosella*' to Nylander, when he applied this name for an exsiccata cited under his specimens of *O. coccinella* (Sugenheim, wood of dead hanging branches of *Quercus*, 1871, H. Rehm, Ascomyc. 71). A restudy of this exsiccata revealed identity with *O. eucalypti*, with comparatively large asci (45–55 × 3.7–4.3 µm) and spores (4–5.3 × 2.2–2.8 µm). The collection is deposited in M and labelled '*Calloria coccinella* f. *vinosella* Nyl. Pez. Fen.: 55 = *Call. vinosa* Fckl. Symb. Mycol.: 283 sec. descript.'.

O. eucalypti was described by Phillips & Harkness (1884) as *Calloria eucalypti* based on a Californian collection on bark (periderm) of a thick branch of *Eucalyptus globulus*, with reddish flesh-coloured (on the watercolour drawing bright orange- or brick-red, Pl. 860: 1a), scattered apothecia with a paler, glabrous margin, ovate-ellipsoid spores 7 × 3.5 µm (an error for 7 × 2.5 µm, according to the sketch in the holotype convolute in K), and paraphyses with a pyriform apex. The present reexamination of the abundant specimen revealed extraordinarily long asci and spores (Pls 858: 1; 860: 1), which nevertheless more or less fit the large-spored collections of *O. coccinella* s.auct. The spores attain a size of max. 7 × 2.4 µm and contain rather well discernible SBs (as a transparent region ~0.5–0.8 µm diam., globose to tear-shaped) and no or only a few very minute LBs when viewed in water or KOH. The visibility of SBs is extraordinary because in most collections of this species they could not be seen in the dead state. Also the asci are with †60–70 µm extraordinarily long [max. †55(–60) µm in other collections examined]. Furthermore, the paraphyses are apically distinctly wider (in KOH 3.5–6 µm) than currently observed in this species (usually not over *4 or sometimes 4.5 µm). The widest paraphyses were otherwise seen in 1 aberrant collection from Germany with unusually large spores (Pl. 857: 5, paraphyses †2.5–4.8 µm wide) and in an Australian specimen in which the spores showed a normal size (Pl. 855: 4, paraphyses *4–5.5 µm wide, but only 2.5–3 µm when reexamined in KOH).

In a second examined, rather small apothecium in the holotype, the asci (†30–38 × 3–3.2 µm) and spores (†4 × 1.8 µm) were much smaller compared to the large, firstly examined apothecium, hence the type collection could represent a mixture of two different species. The small-spored one might represent *O. tremulae*, though it can be assumed that its apothecia have also been bright orange-red when fresh. Based on the spore size stated in the protologue, apothecia with small spores should not be regarded as part of the type, given that they belong to a different genotype. Apothecial size was given as 'minute' in the protologue, but on the watercolour drawing in the type convolute it is stated as '.1–.3 mm'. These values appear to refer to the dry state, in which the apothecia of both spore types are found to measure 0.2–0.35 mm here, while attaining a diameter of 0.2–0.5 mm when rehydrated. The substrate is erroneously declared as 'decorticated wood' in the protologue, although only bark is present in the holotype and no remnants of wood. Saccardo

(1889) and Seaver (1951: 158) merely repeated the protologue. Seaver gave the spore size in error as 7 × 3–5 µm (and 5–7 × 3 µm in his key p. 153), but added *Salix* as a further substrate.

Velenovský (1934) described ***O. microclava*** with blood-red (‘*sanguinea*’) apothecia 0.5–1 mm diam., asci 25 × 2.5 µm (including stipe), and ellipsoid, eguttulate, 2–3 µm long spores. The single collection was on a cut, dry, sun-exposed trunk of *Populus*, and a later collection referred here was on unidentified dry angiosperm branches in the canopy 10 m above the ground (Velenovský, 1947: 102). Velenovský characterized the species on account of the abundance of filiform, uninflated paraphyses towards the margin, whereas those near the centre of the disc have a small apical ‘clavula’. This ‘feature’ seems to indicate that he examined a submature apothecium. Indeed, the present reexamination of the holotype revealed that nearly all paraphyses in the only remaining apothecium had 2.5–4 µm wide, ± strongly capitate-clavate apices (Pl. 855: 5), and a similar result was reported by Svrček (1954). Moreover, the asci and spores (Svrček: 4–4.5 × 1.5–2 µm) were found to be much larger than indicated by Velenovský. Svrček found the apothecial colour as yellowish when dry and placed the taxon in synonymy with *O. xanthostigma* s. Svrček. The rather narrow, subcylindric-ellipsoid spores on Velenovský’s drawing are reminiscent of *O. tremulae*, but the blood-red colour and a spore length of up to †5.2 µm point to *O. eucalypti*.

Velenovský (1934) described ***O. alnea*** based on a collection on trunks of *Alnus* from near Mnichovice and some further samples on *Salix*, *Frangula*, and *Fagus* from near Jevany, with wine-rose or orange ('vinoso-rosea, aurantiaca') apothecia 0.2–0.5 mm diam., and oblong-ellipsoid, 3–4 µm long spores. The text of the protologue represents a mixture of different collections, including that on *Salix*, and unpublished sketches of the *Salix* collection and an unspecified one (probably that on *Alnus*) can be found on Velenovský's manuscript plate of *O. alnea*. Although Velenovský stressed the spores as containing 'always 2 polar guttules', he figured this feature only in the *Salix* collection, whereas in that on ?*Alnus* the spores are drawn slightly narrower and without guttules. Svrček (1954: 9) designated the *Salix* specimen (VII.1926) as lectotype and synonymised it with *O. xanthostigma* s. Svrček. The collections on *Alnus* (14.VII.1924), *Frangula* (3.VII.1925), and *Fagus* could apparently not be found in Velenovský's herbarium, at least Svrček did not comment on the presence of any syntype material. It must be mentioned that Velenovský's (1934, pl. 11 fig. 9) published illustration is misleadingly referenced under '*O. alnea* sp. n.', but in fact represents *O. alnea* var. *vesiculosa* (= *O. xanthostigma*).

In the present reexamination of the lectotype (Pl. 855: 3), about 25 scattered apothecia were seen growing on a thin, obviously xeric branch, densely intermingled with immature *Mollisia caespiticia*. The apothecial colour was not stated by Velenovský on his manuscript plate, but it is now yellowish-cream(-rose) when rehydrated and bright orange-ochraceous when dry. The asci are distinctly longer than indicated by Svrček. Actually, Svrček excluded the ascus stipe, according to his revision note. He also found the spores a bit shorter (3–3.5 × 1.5–2 µm) than evaluated in the present study, in which they contained only a few minute LBs. The paraphysis apices were found to be 2–3 µm wide (Svrček: 2.5–3 µm), the basal cells of the ectal excipulum measured 8–14 × 4–7 µm, and the marginal cortical cells 6–10 × 4–5 µm. Svrček reported the apothecia as 'immarginate' and the marginal excipulum made up of 'up to 30 µm long cells' which seem to refer to cells being intermediate to paraphyses.

The lectotype of *O. alnea* resembles *O. tremulae*, but the xeric habitat, the comparatively narrow paraphysis apices, and the small basal excipular cells in the lectotype, also the rose or orange colour in the protologue point more to *O. eucalypti*.

O. succinea was described by Velenovský (1947) for amber-coloured apothecia 0.5–0.8 mm diam. growing on a twig of *Rosa*, with globose-ellipsoid, biguttulate spores 1–2.5 µm diam., and paraphyses which are slightly clavate only in the centre of the disc (similar as in *O. microclava*). Yet, much larger spores were found in the rather abundant though not fully mature holotype. Svrček (1954: 21) found the apothecia orange to reddish and measured the spores as 3–4 × 2–2.5 µm, while the spores in the present study were even longer and instead narrower compared to Svrček's data (Pl. 855: 1a). Svrček correctly synonymised *O. succinea* with *O. xanthostigma* s. Svrček. The rather long, partly basally pointed spores and medium clavate paraphyses refer this taxon to *O. eucalypti*.

Svrček (1987b) described ***O. roseofuscella*** for a collection on bark of a fallen branch of *Picea*, as a 'very distinctive species readily recognized by the peculiar colour of the fresh apothecia (0.5–0.8 mm diam.) being pale brown with a rose tint or pale flesh-brownish, without any trace of yellow'. According to Svrček, 'the microfeatures are similar to *O. coccinella* sensu auct., a common *Orbilia* entirely different by its bright yellow colour and guttulate ascospores of another shape'.

Svrček's measurements of the asci (35–40 × 3.5–4 µm) and ovoid to (fusoid-)ellipsoid spores (3–4 × 1.8–2 µm) are confirmed in the present reexamination of the rich holotype, which did not reveal any clear difference to the present concept of *O. eucalypti*. The apothecia are now (rehydrated) pale cream and are seated on abundant aggregates of brown globose cells of a black yeast together with some green algae. The semitranslucent apothecia probably obtain their brownish colour from the black yeast beneath. The spores vary between narrowly (cylindric-) ellipsoid and subglobose (Pl. 855: 2a), the latter corresponding to those aberrant populations shown in Pl. 858: 6–8. Svrček also mentioned this variation in spore shape but he did not report subglobose spores. The question remains open which kind of 'entirely different' spore shape he had observed in his yellow-fruiting specimens of *O. xanthostigma* s. Svrček.

Misapplication. Though the name *O. coccinella* (s.auct.) has frequently been applied in a rather consistent way, reports by four older authors differ hereof. (1) A specimen of unknown geographical origin in the herbarium of C.F.P. v. Martius (BR), collected by F.M.J. Welwitsch on inner surface of '*Tilia*' bark in 1839, turned out to be *O. comma* and the substrate probably *Ulmus* bark. (2) Two specimens in the Crouan Herbarium (CO) labelled '*Helotium coccinellum* (Sommerf.) Crouan' in sched., on stems of *Rubus fruticosus* agg. (VIII.1865 and 12.VIII.1869), belong to *O. rubrovacuolata* (J.P. Priou pers. comm., see also under *Orbilia infixa*, p. 1675). (3) A revision of Feltgen's (1899: 53, 1901: 35, 1903: 41) specimens under the name *O. coccinella* revealed that his records mainly concern *O. xanthostigma* in the here neotypified sense, but sometimes also *O. eucalypti*, and a single time (unpublished specimen) *O.* cf. *luteorubella*. (4) Bachman's (1909: 58) report of *O. coccinella* from Ohio, with globose spores 2–3 µm diam., apically capitate paraphyses, and possibly desiccation-sensitive apothecia 1–2 mm diam., could refer to *O. fissilis*. The phragmosporous anamorph described by Yang & Liu (2005) from a CBS culture under the name *O. coccinella* resembles that of *O. dryadum* much better than the dicranidion-like state of *O. eucalypti* or *O. tremulae* (see under *O. dryadum*, p. 1390). Gremmen's (1960) report on pine branches under the name *O. luteorubella* might refer to *O. eucalypti*, but the spores which he reported as ellipsoid, 6 × 2 µm, are drawn partly subcylindrical.

Anamorph. The connection between *Dicranidion fragile* and *O. eucalypti* was reported for the first time by Brefeld (1891: 304, fig. 68, as *O. coccinella*, anamorph unnamed), and later by Liu (2006: 64, fig. 21, B.L. 748). *O. plurivacuolata* and also *O. tremulae* have a very similar anamorph, therefore, we treat *D. fragile* and further tentative synonyms as an uncertain synonym of *O. eucalypti* as the identity of the types of *D. fragile*, *O. eucalypti*, and *O. tremulae* remained unsettled.

We obtained this anamorph 6× in ascospore isolates of European samples. Also Y. Zhang (pers. comm.) obtained *D. fragile* in a Chinese ascospore isolate of *O. eucalypti* (Pl. 859: 16). A connection reported by Pfister (1997: fig. 8) under the names *Dicranidion* ?*fragile*/*O. alnea* might refer to *O.* cf. *xanthoflexa*. In various collections of *O. eucalypti* we observed conidia of *D. fragile* on the natural substrate near apothecia, but in two further samples the conidia occurred either in association with a very different *Orbilia* species (*O. corculispora*, H.B. 8045a) or without orbiliaceous teleomorphs (Pl. 859: 14).

The conidia of *O. eucalypti* are characterized by a deltoid central cell with a conical base and 2 oblique septa above which delimit it from the two arms. The arms are mostly parallel, rarely diverging, and each arm usually consists of 2 cells. Young conidia are initially subglobose to ellipsoid and later become heart-shaped. Before the arms develop, a septum is formed at one of the two arm initials, while the septum at the other arm initial appears later and usually symmetrical to the other (Pl. 857: 1i–j, see also Matsushima 1975: pl. 341). Conidia with diverging arms occasionally occurred among the normal ones in our samples from Italy and Germany (Pl. 859: 14–15), England (IVV: E.B. 4584), France (IVV: J.P.P. 16280), and Australia (IVV: 22.XI.2001).

When mature, conidial size ranged at *(6–)8–14.5(–17) × (4.7–)5.5–6.7(–7.3) µm and arm size at *(5–)6.5–11(–12.5) × 2.5–3.5(–3.7) µm. In the mentioned Australian sample the conidia are distinctly longer (*19–21 µm) and have longer and wider arms (*14–16 × 3.7–4 µm) which consistently diverge (conidial width 10–13 µm). This deviation appears to point to a species different from European samples. Also in *O. plurivacuolata* the conidia are slightly larger compared to *O. eucalypti* (*14–18 × 6.5–8 µm) and have larger arms of *(7–)11–15 × 3–3.8 µm.

Also the number of septa appears to serve as a character at the species level. *O. eucalypti* conidia (including the Australian sample) have 2-septate arms, rarely 1-septate and very exceptionally 3-septate (Pl. 857: 4), whereas in *O. plurivacuolata* the arms are 2–4-septate (Pl. 851), which is also the case in *D. fragile* from Japan and Peru (see below).

Dicranidion fragile was described by Harkness (1885a, b, without illustration) as forming minute, scattered, rosy-white acervuli on decaying *Nerium oleander*, collected in February 1882 in Oakland, California. In the same year, Harkness collected the holotype of *O. eucalypti* on bark of *Eucalyptus* in California, which was published 1 year earlier (Phillips & Harkness 1884). The brief description of *D. fragile* includes 12–16 µm long, 5-celled conidia with 4–5 µm wide branches. Both taxa originate from California, and the present study considers them as possibly conspecific, although some doubts remain. Hughes (1953: fig. 36) provided a detailed drawing of the type collection of *D. fragile* (Pl. 858: 9), regrettably without scale and measurements. Also Peek & Solheim (1958) studied the type by emending Harkness' description and supplying photomicrographs (fig. 6) and drawings (fig. 7 with erroneous scale, see Pl. 11: b, left). They stated the substrate to be wood and found several associated fungi, including a *Bispora*, partly serving as support for the pulvinate tufts of the *Dicranidion*.

According to the mentioned drawings of the *D. fragile* holotype, conidial shape is mainly ellipsoid because the arms more or less converge, whereas the photos by Peek & Solheim show straight, parallel arms. Conidial size was given by Peek & Solheim as †9–18 × 6–8 µm (†14–18 × 9 µm when evaluated from their fig. 6c, with arms †7–12 × 3.5–4 µm). Particularly Harkness' statement of 4–5 µm wide arms would exclude conspecificity with European *O. eucalypti*. Instead, the larger conidia with a higher number of septa would fit the presumed anamorph of *O. plurivacuolata* (see p. 1349).

Several authors reported *D. fragile* from different regions: Tubaki (1958) and Matsushima (1975) from Japan, Butterfield (1973) from South Carolina, and Matsushima (1981) from Peru. Matsushima's samples tend to have slightly larger conidia than *D. fragile*: summarized (12–)13.5–18(–22)((–25)) × (6.5–)7–9(–10) µm, arms 9–15(–19) × 3–4.5 µm, 2-septate but infrequently 3- and sometimes 4-septate. The larger size and wider arms with more septa questions conspecificity with European *O. eucalypti*, and we preferred to list them as not included collections. However, a recent ascospore isolate from Georgia, USA (Shao et al. 2018, conidia *10.5–15.5 × 6.3–7.5 µm, arms 5.5–10.5 × 2.7–3.7 µm, 1–2-septate) and 2 conidia found in association with apothecia of *O. eucalypti* in Mexico (†11.5–14 × 6–6.5 µm) suggest that American populations exist that do not differ from European ones in conidial size and septation.

The description and illustration of ***Pedilospora ramularioides*** in Bubák (1916) includes (12–)16–18 × 6–8 µm large conidia with 2 or sometimes 3 parallel, 2-septate arms, formed on minute denticles on ~60 long and 3–4 µm wide conidiophores. The species was said to grow parasitic on brown hyphae of *Bispora pusilla* (= *B. betulina*) on wood of *Castanea sativa* in Tirol (now Trentino, Italy) (Pl. 858: 10). We agree that it is a synonym of *D. fragile* as stated by Peek & Solheim (1958) and Matsushima (1981), and also with their belief that the unillustrated *P. parasitans* and *P. episphaeria* are with hesitation conspecific with *D. fragile*. Already Hughes (1953: 607) synonymised *Pedilospora* with *Dicranidion*, though without commenting on this.

Pedilospora parasitans was described by Höhnel (1902) as growing 'in *Helotio citrino* (?) parasitica' (≡ *Calycina citrina*) in Austria (Wienerwald) with 5-celled, ellipsoid, bilobed conidia of 13–16 × 5–6 µm. Possibly Höhnel confused this helotialean discomycete with *O. eucalypti*. Bubák stressed the sympodial, ramularia-like conidiogenesis on up to 8 teeth-like nodules along the elongated flexuous conidiophores and the conidia being larger and with arms that never touch each other, but he admitted that Höhnel's *P. parasitans* might lack these nodules due to a less advanced development stage.

Pedilospora episphaeria was described by Höhnel (1924) as growing on old *Thyronectria cucurbitula* on *Picea* bark in Austria (Wienerwald), with bi-, rarely trilobed conidia of 11–18 × 6–6.5 µm, with a biconical basal cell 3–3.5 × 3–3.5 µm and mostly 3-celled, mostly parallel arms of 8–15 × 2.5–3 µm, formed on teeth-like protrusions of 1.5–2.5 µm wide hyphae. Höhnel expressed his doubts whether these three *Pedilospora* taxa are specifically distinct or only forms of a single species.
