Matsushima (1981) considered ***Dicranidion argentinense*** (on bark of *Eucalyptus* from Buenos Aires, Pl. 858: 11) as a possible synonym of *D. fragile*. Indeed, according to Spegazzini's (1911) drawing of the conidia the identity with *D. fragile* seems probable (size ~12–16 × 5.5–8 µm, arms 10–12 × 3–4 µm, from drawing 8–12 × 2.5–3.5 µm). The arms form a convex, elliptical outline, the basal cell is partly elongated, very similar to Y. Zhang's Chinese isolate (Pl. 859: 16d). Spegazzini figured the conidiophores aggregated in fascicles by forming cushion-shaped, white, pruinose sporodochia of 0.25–0.5 mm diam., in concordance with Peek & Solheim (l.c.) and Matsushima (1975, 1981: fig. 72) who described *D. fragile* as 'effuse or aggregated into sporodochium-like units'. Also Seifert et al. (2011, pl. 300A) provided a drawing of these fructifications, but referred to them as synnemata, a possibly more appropriate term. A Canadian specimen without teleomorph (DAOM 152586), identified as *D. fragile* by S.J. Hughes, was studied by K. Seifert (pers. comm.), who kindly supplied his documentation (Pl. 860: 10). However, such synnemata have so far never been seen by us in association with the teleomorph of *O. eucalypti*, although the exact origin of the conidia on the natural substrate was mostly unclear in our

Table 75. Available sequences of the different genotypes of *Orbilia eucalypti* and *Dicranidion fragile* (A–D), and of the similar *O. plurivacuolata* s.l., *O. tremulae*, and *D. inaequale*. Abbreviations for apothecial colour: carn = carneous, ywsh = yellowish; S1506: intron length (number of nt), 0 = intron absent; DNA isolation: ap. = from apothecia, cult. = from ascospore isolate, con. = from conidial isolate, env. = environmental isolate from wood. Identity of NBRC 6886 and CBS 217.59 as belonging to the same strain of *D. fragile* is assumed based on identical ITS data and K. Tubaki as collector.

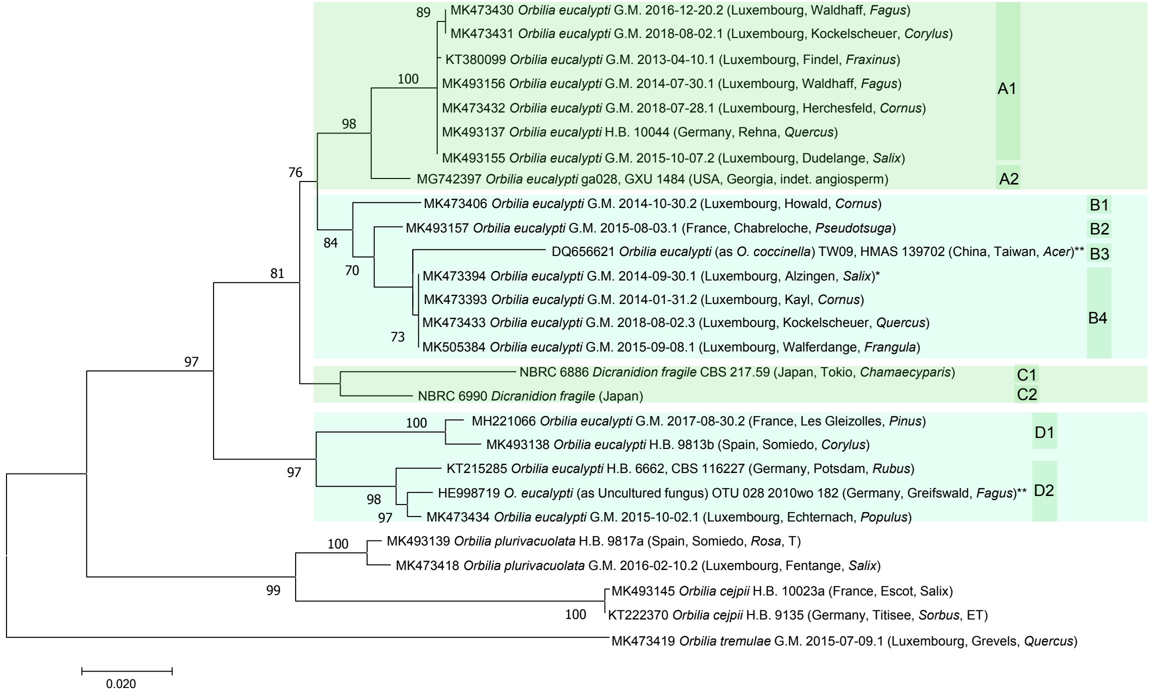
samples. In any case, also in our pure cultures the conidiophores emerged always singly (Pls 857: 1–2; 858: 3–4).

A recent record from subtropical humid Mexico (Xalapa, 1400 m) identified as *D. fragile* (López et al. 2013) likewise formed cushion-shaped synnemata. Yet, the conidia are larger ('22–30 × 7–9 µm', but the given width is too low when considering the length:width relation on the photo) and have arms with 3–6 septa. They fit quite well *D. amazonense* Matsush., a species described without aggregated conidiophores.

The 'conidial state' obtained in an agar culture by Bell (2005, fig. 32 F) from an ascospore isolate of '*O. alnea*' looks like chlamydospores. Yang & Liu (2005) observed in a CBS-strain under the name *O. coccinella* (CBS 916.72) a phragmosporous anamorph which they described accordingly as *Dactylella coccinella*. However, its molecular data are very different from those now available for *O. eucalypti* (for further details see under *O. dryadum*, p. 1390).

Phylogeny. Sequences were gained in the present study from 17 European samples here referred to *O. eucalypti*, all from xeric or sometimes recently fallen branches, comprising ITS and



Phylogenetic analysis 24. Phylogram of *O. eucalypti* s.l. inferred from combined ML analysis of ITS+LSU (D1–D2) rDNA dataset (27 sequences, 1214 positions, aligned with MUSCLE) using the K2+G+I model in MEGA7 (500 replicates). The tree is rooted with *O. tremulae*. Asci 8-spored in all taxa; ET = epitype, * = without partial ITS2, ** = without LSU.

LSU, six also SSU (Tab. 75). Two were from ascospore isolates, the remaining from apothecia. An ITS sequence in GenBank that matches *O. eucalypti* was obtained by Unterseher et al. (2013) from a pure culture isolated from a dead attached branch of *Fagus* in Greifswald (Germany), but apothecia and conidia were not observed (M. Unterseher pers. comm.). A North American ascospore isolate (ITS+LSU) was referred to *O. eucalypti* by Shao et al. (2018), and a Taiwanese ascospore isolate (ITS) to *O. coccinella* by B. Liu (pers. comm.). Finally, sequences exist of two anamorphic Japanese strains under the name *Dicranidion fragile* (ITS+LSU). The S1506 intron in present in 16 of these strains and clearly absent in four.

All these sequences clustered in analyses of SSU+ITS+LSU, ITS+LSU, or ITS in a medium to strongly supported clade (Phyls 22, 24, S28) which, however, comprises four subclades (A–D) with 10 different genotypes. Among the four subclades a distance of 4–11.5 % (ITS, Phyl. S28) or 1.3–4.3 % (LSU D1–D2 domain, S27) is observed, which suggests that different taxa are involved. When analysing the intron, *O. eucalypti* even appears polyphyletic by forming three strongly supported clades that clustered distantly and unresolved among other taxa of series *Orbilia* (S26). Subclades A and D received strong support in Phyls 22, 24, D also in S27, S28; subclade B received only medium support (Phyl. 24), and subclade C only low support (S28).

Although our two European ascospore isolates (G.M. 2013-04-10.1, H.B. 6662) coincide in conidial as well as ascospore size and shape, they clustered in different subclades (A1 and D2). Based on the available data, the morphology of ascospores and conidia seems to play a subordinate role at the molecular level, also apothecial colour varied within each subclade (Tab. 75, subclade C was without teleomorph). Regrettably, apothecial colours and micromorphology were partly not documented in the specimens treated by molecular methods.

A high genetical homogeneity in the ITS region is noted within the genotypes A1 (0–0.4 %, 7 of our samples) and B4 (0 %, 4 of our samples). Despite this homogeneity, the inhabited substrate covers a wide range of woody angiosperms, with two genera occurring in both subclades. In contrast to A1 and B4, subclade D, which includes five of our samples with a likewise very wide host range, shows ITS heterogeneity in both genotypes (2 % in D1, 1.5–2.7 % in D2), although only 0–0.2 % variation is observed in the LSU. Finally, two of our samples represent genotypes B1 and B2, each containing only one strain, and four extra-European samples (USA, Japan, Taiwan) represent other four distinct genotypes (A2, B3, C1, C2). Gymnosperms occurred as hosts in three genotypes (B2, C1, D1).

The two genotypes of subclade A differ from each other in the ITS/LSU by 3/1.6 %, those of subclade B by 2.3–5/0.6–1.1 %, Japanese *D. fragile* (C1 and C2) by 6.5/1.6 %, and subclade D1 from D2 by 7–7.5/1.3–1.8 %. Among the subclades, the distance between A and B is 4–6/1.5–3 %, C differs from A and B by 5–9/1.3–3 %, and D from A–C by 9–11.5/2–4.3 %.

Even in the SSU V8 the six available sequences belonging to three genotypes (4 strains of A1, 2 strains of D1 & D2) differ at pos. 61 (A1: TG**G**CC, D1 & D2: TG**A**CC) and 90 (A1: AC**T**CT, D1 & D2: AC**C**CT).

Also the intron shows a high distance of up to 8–26 % among the 14 strains which have it. A similarly high distance is observed to other species of series *Orbilia* which possess the intron, the minimum being between the Potsdam strain (D2) and *D. inaequale* (14 %). Phylogenetically the intron behaves different from ITS and LSU: particularly subclades A and B clustered very distant from each other (S26). In accordance with the ITS region, genotypes A1 (6 strains) and B4 (4 strains) each possesses ± identical intron data. However, a 7th strain (from Howald) unexpectedly clustered with genotype A1 with only 3 nt and 2 gaps deviation, although it deviates in the ITS by 5.5–5.8 % and clustered in the analysis of that region in subclade B (B1, Phyls 24, S28). In this strain the intron has a much larger size (1233 nt) compared to the other strains of *O. eucalypti* (381–390 nt). Its long 3'-end aligns with the similarly large introns of *D. fragile* (NBRC 6990, ~1290 nt) and *O. frangulae* (1266, see Tab. 24), whereas *D. fragile* (NBRC 6886) appears to have an intron of normal length (below 400 nt). As a further surprise, the two *D. fragile* strains clustered in two very distant, partly strongly supported clades, C2 with A1, and C1 with B4 and D1, while genotype D2 clustered unresolved and distant from D1.

In Liu et al.'s (2006a) separate analyses of ITS an LSU, sequences of seven strains (5× ITS, 4× LSU) were included under the name *O. coccinella*, all of which showing high distances among each other. The heterogeneity of his species concept becomes apparent from the very different clades in which they clustered. Morphological data were available to us only for two of the seven strains (anamorph: B.L. 748, teleomorph: B.L. 6176). Among these seven strains, only that from Taiwan (B.L. TW09, ITS, genotype B3) fell in the *O. eucalypti* clade (Phyls 23, 24, S28) by showing a minimum distance of 4% to genotype B4. Two from Beijing (B.L. 6578, LSU; B.L. 6176, ITS) clustered in the medium supported *cejpii-frangulae* clade (Phyls 23, S27), whereby B.L. 6578 concurs with *O. cejpii* on *Fagus*. Two samples not treated in Liu (2006) clustered with low support and high distance with *O. renispora* and could belong to the same species: B.L. 6179 (Beijing, ITS, in Liu's unpublished list as *O. coccinella*) and B.L. 747 (unlocalized, LSU) (Phyls 23, S27). Among the remaining two Chinese strains, one from Qinghai (B.L. Q132, ITS+LSU) is found here to belong to *O. tremulae*, and B.L. 748 (Hunan, ITS+LSU) clustered unresolved in series *Orbilia* very distant from any other sequence (Phyls 22, 23, S27). This latter strain closely resembles *O. eucalypti* based on conidial morphology from culture (Liu 2006: 64, fig. 21), though deviating in rather long, predominantly 3-celled conidial arms.

A sample from Massachusetts (bhi-F948), reminiscent of *O. eucalypti* s.l., is named *O.* aff. *plurivacuolata* because of its multiguttulate paraphyses. Its sequence clustered distantly and unresolved between the *O. eucalypti* clade and the *cejpii-frangulae* clade, to which *O. plurivacuolata* belongs (Phyl. 23). It also deviates at the 5'-end of ITS2 by ATTA in contrast to ATTG in most other sequences of ellipsoid-spored members of series *Orbilia*, or ATGT in *O. renispora*, *O. fissilis*, and the *leucostigma-xanthostigma* clade (Tab. 20).

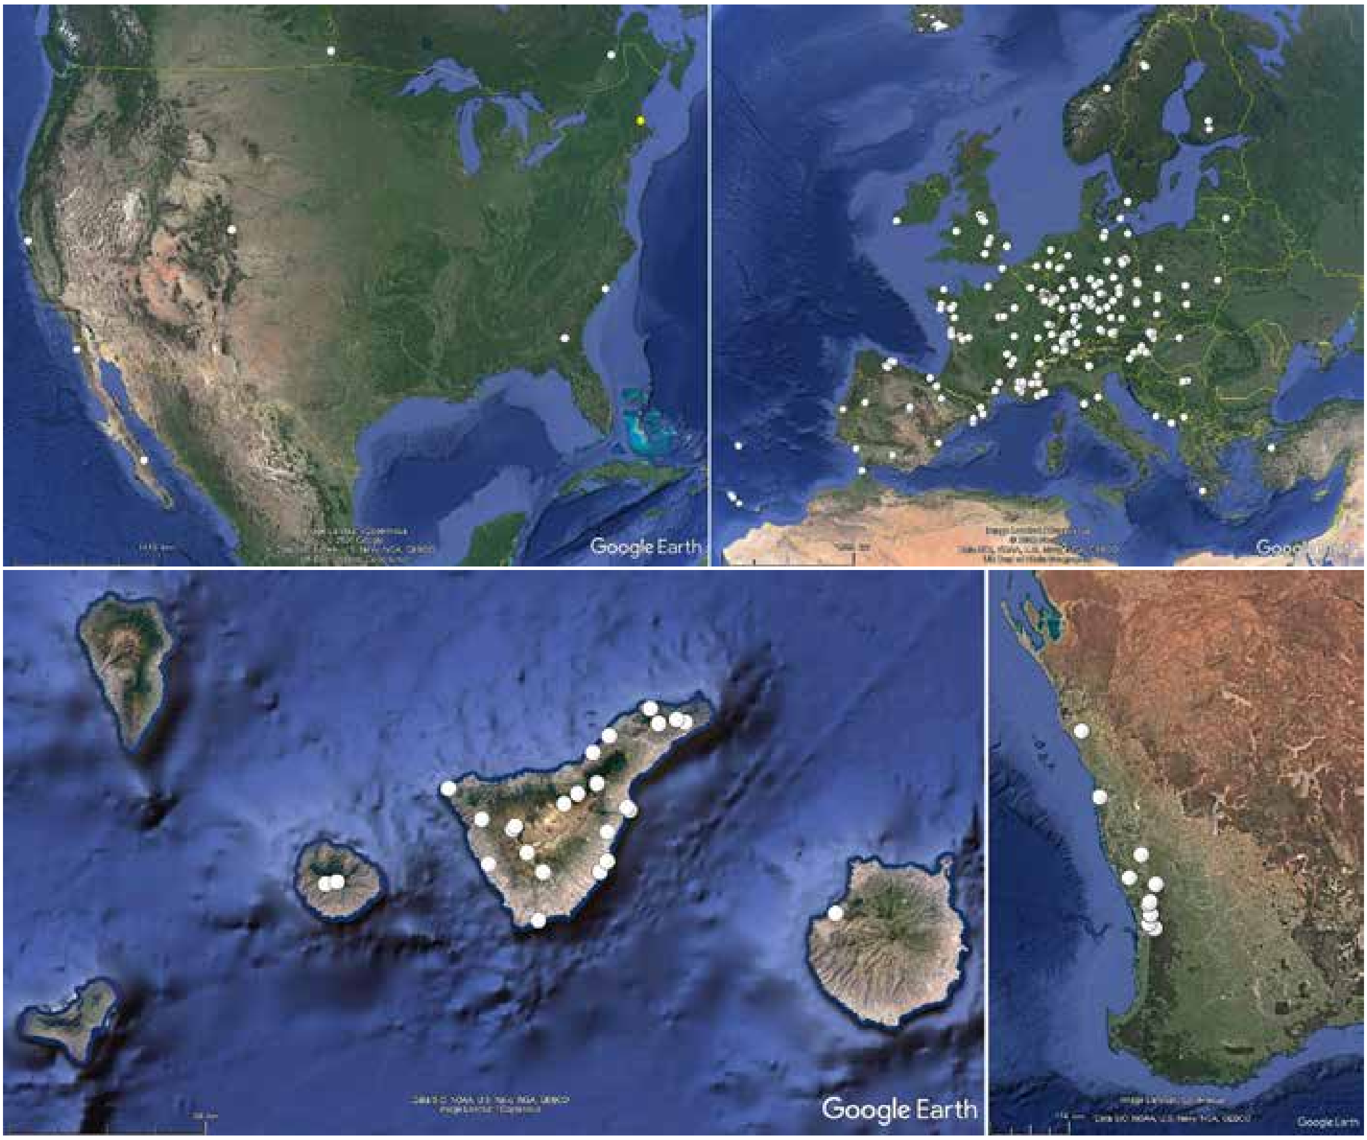
Due to the high molecular variation among strains of the *O. eucalypti* clade, we conclude that our present concept of *O. eucalypti* is heterogeneous. Even in the here presented narrow sense which excludes the similar *O. tremulae* and *O. plurivacuolata*, *O. eucalypti* includes within Europe six different genotypes that possibly represent six cryptic species. Remarkable is that even in the 5.8S two paired positions of stem-loop B8 differ in genotype D1 from the rest of *O. eucalypti* (see p. 1327). The future will show whether further, possibly intermediate genotypes exist within Europe, and also how many genotypes occur outside Europe and whether any of them concurs with the European ones.

Although *O. eucalypti* is morphologically not easily separable from *O. tremulae* and *O. plurivacuolata*, the ITS distance between these species ranges at 17–18.5% and 13–23%, respectively, and similar distances are observed to *O. fissilis* and *O. cejpii* s.l.

Ecology. *Orbilia eucalypti* is one of the commonest species of the genus. A total of about 400 collections are assigned to it here, including doubtful samples, and over 440 collections would be involved when including the similar *O. tremulae*. *O. eucalypti* occurs on ± rotten wood and bark of mainly xeric but also hygric twigs, branches and trunks of various angio-, rarely gymnosperm trees and shrubs, also on branches of succulents, stems of *Rubus fruticosus*, petioles of *Macrozamia*, and fruitbodies of aphyllophoralean basidiomycetes. Populations on herbaceous stems have almost never been encountered, with the exception of slightly woody stems of the perennial *Astragalus lusitanicus*, *Euphorbia characias* and *E. palustris*. Extraordinary substrates are bamboo (Liu et al. 2006b, as *O. coccinella*) and dung (Bell 2005, as *O. alnea*). Favourite hosts were *Quercus* {69} and *Salix* {60}, followed by *Carpinus* {22}, *Corylus* {19}, *Fagus* {12}, *Ulex* {11}, and *Pinus* {10}. Bark and wood were quite equally often recorded as substrate.

O. eucalypti shows a worldwide distribution, being recorded from Europe, Asia, Australia, North and South America, and Africa. Within Europe the species occurs in a wide range of climatic zones, from atlantic to continental, thermomediterranean semihumid to cold-temperate humid and even thermo- to oroboreal regions from planar up to subalpine altitudes. In Macaronesia and Morocco (northwestern Africa) it occurs in thermo- to inframediterranean semihumid to arid as well as meso- to supra(sub)mediterranean semihumid xerophytic scrublands, also (sub)humid cloud forests (Quijada et al. 2016), and a single sample from Réunion (Mascarene islands east of Madagascar) was from a temperate humid (winter-dry) forest. Collections from Australia were so far exclusively from the southwest of the continent in subtropical semihumid banksia-eucalypt or acacia (open) woodlands from the Geraldton Sandplains, Swan Coastal Plain, and Jarrah Forest in the northern part of Darling Range. The few records from North America are from humid hemiboreal forests in the north and northeast (Canada, *D. fragile* synnemata) and from the subarctic tundra in western Greenland, from the midwest in the cold-temperate humid Douglas fir mixed forest of the Southern Rocky Mountains and from the southwest in a subtropical semihumid chaparral and semiarid desert scrubs of the Sonoran Desert of Baja California. Two old records from the pacific west represent the types of *O. eucalypti* and *D. fragile* which were in a mediterranean, mild-maritime semihumid region of California. A record of *D. fragile* by Butterfield (1973) was from the humid subtropical coastal region of South Carolina. Two samples from South America were in warm-temperate altimontane and subtropical planar (type of *D. argentinense*) humid regions.

The fact that this omnipresent species was not recorded by Dennis (1978) for Great Britain indicates that collectors of the 20th century have ignored dry attached branches on which a majority of the present about 400 collections were made, whereas a small part derives more or less from the moist ground. Under the names *O. coccinella*, *O. alnea* and *O. microclava*, the species was reported for North America by Seaver (1951), for arctic Alaska by Korf (in Kobayasi et al. 1967, on *Salix alaxensis*), for Macaronesia by Korf (1992, on bark and palm leaves) and Quijada (2010, on phylloclades of *Euphorbia* spp.), for mediterranean southwestern Europe by Sierra López (1987, on wood of *Pinus halepensis*, *Cistus* sp., *Quercus ilex* and *Spartium junceum*), for the Far East of Russia by Raitviir (1991), for Tibet by Liu et al. (2006b), for southeastern Asia by Liu (2006), Z.F. Yu, Y. Zhang and H. Su (pers. comm.), and for southeastern Australia by Bell (2005).



Map 137. Known distribution of *O. eucalypti* in North America, Europe, Macaronesia, and southwestern Australia (yellow = not included collection).

Specimens included. **GREENLAND**: **Qeqqata**, 13 km WSW of Kangerlussuaq, close to Lake Helen, 200 m, branch of *Salix glauca*, on wood, 14.VIII.2000, A. Raitviir (TAAM 137783, H.B. 6828). — **IRELAND**: **Cork**, 12.5 km WSW of Glengariff, 1.5 km N of Adrigole, 65 m, branch of *Ulex europaeus*, on bark, 7.V.2016, J.P. Priou (J.P.P. 16149, doc. vid.). — **GREAT BRITAIN**: **Yorkshire**, **West Yorkshire**, 8.5 km SSE of Halifax, 1.8 km NW of Huddersfield, Edgerton, 150 m, branch of *Quercus*, on old *Colpoma*, 5.I.2013, C. Yeates (C.Y. F/2272, doc. vid.). – **South Yorkshire**, 7.5 km NNW of Sheffield, 1 km NW of Grenoside, Wharncliffe Wood, 245 m, branch of *Quercus petraea*, on wood, 18.V.2011, H.O. Baral (ø). – 18 km ESE of Sheffield, 1.5 km SE of South Anston, Anston Stones Wood, 95 m, branch of *Ulmus glabra*, on bark, 16.V.2011, T. Læssøe (ø). – 8 km NNW of Barnsley, 6.5 km S of Wakefield, Seckar Wood, 75 m, branch of *Quercus*, on bark, 19.V.2011, H.O. Baral (ø). – 3.5 km S of Barnsley, 1.3 km SW of Worsbrough, Worsbrough Country Park, 70 m, branch of *Salix cinerea*, on bark, 20.V.2011, H.O. Baral & S. Rogerson (ø). – ibid., branch of *Salix*, on *Schizopora paradoxa*, T. Læssøe (K(M)70825). – 3.5 km SW of Barnsley, ENE of Wentworth Castle, 140 m, branch of *Quercus petraea*, on wood, 16.V.2011, H.O. Baral (ø). – **East England**, **Suffolk**, 3.7 km ENE of Halesworth, 2.5 km N of Wenhaston, Blyford wood, 35 m, branch of *Quercus robur*, on wood, 5. VIII.2004, E. Batten (E.B. 4547, K(M) 158855, doc. vid.). – ibid., branch of *Carpinus betulus*, on wood, 22.VI.2005, E. Batten (H.B. 7831 ø). – 0.4 km NNW of Wenhaston, Bicker's Heath, 15 m, branches of *Ulex europaeus*, on bark, 10.I.2004, S.M. Francis & E. Batten (ø). – ibid., branch of *U. europaeus*, on bark, 3.II.2004 (ø). – ibid., 10.I.2006, E. Batten & S.M. Francis (H.B. 8045b, anam. only). – ibid., branch of *Cytisus scoparius*, on bark, 24.XI.2006, S.M. Francis (ø). – ibid., Blyford Lane, Garden Hill Cottage, 12 m, branch of *Ulex europaeus*, on bark, 3.II.2005, S.M. Francis (E.B. 4584, anam. substr., doc. vid.). – 5.5 km SW of Southwold, 2.3 km NNW of Dunwich, Dunwich Forest, 7 m, branches of *Lonicera periclymenum*, on wood, 13. & 31.I.2006, E. Batten (E.B. 4665, H.B. 8052 ø, anam. substr.). – 1 km NW of Dunwich, 16 m, branch of *Ulmus minor*, on bark, 13.XII.2005, E. Batten (E.B. 4657, K(M) 227386, doc. vid.). – 1 km W of Dunwich, 14 m, branch of *Salix cinerea*, on bark, 21.VIII.2004, E. Batten & S.M. Francis (E.B. 4554, K(M) 159077, doc. vid.). – 1.5 km WSW of Dunwich, Dunwich Forest, 10 m, branch of *Quercus robur*, on wood, 28.VII.2004, E. Batten (E.B. 4546, K(M) 227419, doc. vid.). – ibid., branch of *Q. robur*, on wood, 14.VIII.2004, E. Batten (E.B. 4550, doc. vid.). – 12.5 km SSW of Southwold, 2.5 km NE of Leiston, NW of Sizewell, Kenton Hills, 4 m, branch of *Salix cinerea*, on bark, 23.XII.2005, E. Batten (E.B. 4658, doc. vid.). – **Cambridgeshire**, 11 km N of Huntingdon, 6 km E of Sawtry, Woodwalton Fen, branch of *Quercus robur*, on bark (old *Vuilleminia*), 7 m, 17.IV.2017, H.O. Orbilia tremulae Velen., Monogr. Discom. Bohem.: 92, pl. 11 fig. 10 (1934) — Pls 861–862, Map 138

?= *Orbilia coccinella* var. *versicolor* Grelet & Croz., Bull. Trimest. Soc. Mycol. Fr. 44: 336 (1928)
= *Orbilia coccinella* var. *abietina* Velen., Monogr. Discom. Bohem.: 92 (1934)
= *Orbilia xanthostigma* s. Svrček (1954: 12) p.p.
?= *Dicranidion inaequale* Tubaki & T. Yokoyama [as '*inaequalis*'], Trans. Mycol. Soc. Jpn. 12(1): 22, fig. 4 (1971)

Etymology: *tremulae*, *abietina*: referring to the substrate (*Abies alba*, *Populus tremula*); *inaequale*: referring to the conidia having an often asymmetrical basal cell; *versicolor* = changing in colour.

Typification: Czechia, Hrusice, Hubáčov, branch of *Prunus spinosa*, VII.1931, J. Velenovský (PRM 152382, lectotype of ***Orbilia tremulae***, designated here, MBT202381); Germany, Bayreuth, Heinersreuth, branch of *Frangula alnus*, 29.IV.2001, W. Beyer (ex H.B. 6963a, M-0276602, epitype, designated here, MBT202382, ex-epitype culture: CBS 116232; sq.: KT215283) — France, Savigné, branch of *Quercus*, VI.1913, L.J. Grelet (PC 0001042, holotype of ***O. coccinella*** var. ***versicolor***). — Czechia, Třemblat, log of *Abies alba*, X.1931, J. Velenovský (PRM 152389, holotype of ***O. coccinella*** var. ***abietina***). — Japan, Ōtsu, on diaporthe-like fungus, VI.1969, T. Yokoyama (IFOH-11610, holotype of ***Dicranidion inaequale***; ex-type cultures: NBRC IFO-9366, ATCC 22517, IMI 158983, CBS 564.71 etc.; sq.: LC146731).

Misapplied names: Karsten (1861, 1869 p.p.), as *Peziza*/*Orbilia coccinella*; Velenovský (1934:92, pl. 11 fig. 7, p.p.), as *O. coccinella*; Berthet (1964a: 126, 1964b: 23), as *O. xanthostigma*; Liu (2006, p.p.), as *O. coccinella*.

Description: — **TELEOMORPH**: **Apothecia** fresh (0.13–)0.2–1.3 mm diam., (0.09–)0.12–0.16(–0.22) mm high (receptacle 0.08–0.1 → 0.05–0.075 mm), whitish-greyish to light (or bright) (honey-)yellow-amber to yellow-orange(-rosaceous) or cream to ochraceous-yellow, or whitish with irregular pale yellow colours, translucent, ± round to slightly undulating, subgregarious to densely gregarious; disc medium concave to flat or slightly convex, margin indistinct or distinct, thin, 0–5 µm protruding, smooth; broadly sessile or with an indistinct obconical stipe 0.04–0.1 × 0.15–0.25 mm, superficial; dry yellow-orange to honey-yellow. **Asci** *(34–)38–50(–56) × 3.4–4.2(–4.4) µm {9} → 4.1–4.5 µm, †(25–)30–45(–51) × 2.8–3.5(–4) µm {10}, 4–8 µm protruding at full turgescence, 8-spored, spores (*) obliquely uniseriate or subbiseriate in upper part, (2–)3–5(–7) lower spores inverted {6} (often mixed), pars sporifera *14–25 → 10–13 µm long; **apex** (†) (medium to) strongly truncate (sometimes indented, laterally hardly inflated); **base** with absent to long, thin or thick, ± flexuous stalk, h- to H-shaped. **Ascospores** *(2.7–)3–4.2(–4.5)((–4.8)) × (1.5–)1.7–2(–2.2) µm {31}, †(2.8–)3–4(–4.2) × (1.5–)1.6–1.9(–2.1) µm {10}, subcylindric to ellipsoid, sometimes fusoid(-clavate), both ends rounded or obtuse, straight, rarely slightly inequilateral, exceptionally slightly curved at base; **SBs** consistently present, *(0.3–)0.4–0.5(–0.7) µm diam. {8} (0.5–1 µm total length), globose, with or without very short, indistinct filum, LBs absent or 1–3(–5) minute droplets especially close to SB. **Paraphyses** apically slightly to mostly medium to (very) strongly capitate(-clavate), sometimes asymmetrical, terminal cells *(14–)18–24(–27) × (2.5–)3–5(–6) µm {7}, †(2–)2.5–4(–5.3) µm wide {3}, lower cells *6–10(–15) × 1.3–2.4 µm {3}; sometimes branched at upper septum, subhymenium and lower part of hymenium pale yellow(-orange). **Medullary excipulum** subhyaline to pale yellow, 35–80 µm thick, of loose to dense, horizontally oriented textura intricata with many inflated cells, very sharply delimited from ectal excipulum, especially at flanks, partly by a thin t. porrecta. **Ectal excipulum** hyaline, towards margin pale yellow, of (†) thin-walled, vertically oriented t. angularis-prismatica from base to margin, (20–)40–70(–90) µm thick near base, cells at first *4–8 × 3–6 µm, later */†10–30(–36) × (6–)8–17(–20) µm {7}; 10–30 µm thick at flanks, 6–20 µm at margin, oriented at a 45–80° angle to the surface, marginal cortical cells */†(2.5–)5–10(–16) {4} × (2.5–)4–7(–9) µm {5}; **glassy processes** absent. **Anchoring hyphae** medium to very abundant, †1.5–3(–4) µm wide, walls 0.2(–0.3) µm thick {4}, non-gelatinized, forming a 15–50 µm thick t. intricata(-angularis). **SCBs** globose, in paraphyses near apex 0.8–1 µm diam., in ectal excipulum at margin absent {3} or ~1–2 {3} up to 3–4 µm {1} diam.; **VBs** absent {4} or slightly to medium refractive, hyaline or very pale yellowish {2}; **LBs** at septa of paraphyses and marginal excipulum minute, often yellow-orange (carotenoids). **Exudate** over paraphyses absent or minutely granular, loosely attached, over margin and flanks very scattered, thin, granular, 0.2–0.5 µm thick. **— ANAMORPH**: dicranidion-like (from ascospore isolate {2}. **Conidiophores** reduced (integrated), ~2.5–5 × 2 µm. **Conidia** 2-armed, U-shaped without stipe, ± rounded-truncate below, with small nodulous scar, *(8–)9–14(–16) × (5.8–)6–6.8(–7.2) µm {2}, arms *(5–)7–12.5 × 2.5–3 µm, (0–)1–2(–3)-septate, basal cell mostly asymmetrical (with only 1 oblique to almost vertical basal septum), rarely symmetrical (then all septa horizontal); unbranched conidia infrequent (~8%), *(8–)12–15 × 2.5–3 µm {2}, 1(–2)-septate.

Habitat: usually lying on moist ground or on a pile, partly on underside, sometimes 0.5–3 m above the ground, corticated to decorticated, 8–80 mm thick branches or logs of *Abies alba* {1}, ?*Alnus* sp.{1}, *A. alnobetula* subsp. *alnobetula* {6}, *A. alnobetula* subsp. *fruticosa* {1}, *Betula* sp. {1/1}, *B. pubescens* {1}, *Buddleja* sp. {1}, *Carpinus betulus* {11/3}, *Corylus avellana* {2/1}, *Cotoneaster* sp. {2}, *Fagus*

Phenology of *O. tremulae*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
3	0	4	4	10	2	10	11	4	2	1	0

Taxonomic remarks. *Orbilia tremulae* is difficult to distinguish from *O. eucalypti* and *O. cejpii*. It is treated here as a separate species especially because of the distinctive dicranidion-like anamorph and deviating molecular data. Further features that differentiate it from *O. eucalypti* are the often yellow-ochraceous-amber-coloured apothecia, comparatively small (< 4–4.5 µm), especially narrow (< 2–2.2 µm) ascospores, often very strongly inflated and sometimes asymmetrical paraphysis apices, a tendency of the ectal excipulum to larger, vertically elongated basal cells and slightly wider marginal cortical cells, and a predominantly hygric habitat.

O. cejpii (and *O. fissilis*) differ from *O. tremulae* in slightly shorter, more broadly ellipsoid to subglobose or sometimes ovoid spores. The spores of *O. eucalypti* are usually larger than in *O. tremulae* and often tend to be fusoid or fusoid-clavate, the paraphysis heads are only rarely asymmetrical, and the apothecia mostly bright orange or rose and grow on xeric substrate. However, all these features are too variable to permit a clear distinction in every case based on the teleomorph alone. Therefore, many of the here reported collections are only tentatively included in either of these four species.

A rather sharp separation was observed between *O. tremulae* and *O. dryadum*, the latter differing in narrower ascospores but also in consistently unbranched conidia. Also *O. paracylindrospora* deviates from *O. tremulae* in narrower spores, light rose-orange, desiccation-tolerant apothecia, and less inflated paraphysis apices, but its anamorph is unknown.

Variation. A typical colour of fresh apothecia seems to be a pale to light yellow(-orange) (Pl. 862: 3, 5, 7), but many collections had whitish-greyish or cream apothecia or showed a varying and irregular degree of yellowish (Pl. 862: 2a–b, 6a–b). A (yellowish-)orange colour was also noted in, e. g., H.B. 9879 (holotype of *O. coccinella* var. *abietina*) and E.B. 4558.

Ascospore shape varies between cylindric-ellipsoid (Pl. 861: 1) ellipsoid (4) and ellipsoid-fusoid (5–6). The globose SCBs in the marginal excipular cells strongly vary in size among the populations, being largest in the epitype on *Frangula* (3–4 µm) but usually smaller (1–2 µm) or even lacking (Pl. 861: 5e, 6e).

Type studies. Velenovský (1934) described ***O. tremulae*** based on populations on damp, shaded wood of '*Tremula*, *Populus*, *Aesculus* etc.', with glassy-translucent, colourless or pale yellowish apothecia 1–2 mm diam., asci 25 µm long (excluding stipe), [paraphyses] strongly clavate, 5–6 µm wide, marginal ('external') paraphyses uninflated, and ovate spores 2–4 µm long. He stated to have frequently found this species during summer on various substrates. Three collections are described on his two manuscript plates, one as *O. tremulae* (on *Populus tremula*, 13.VI.1923, Hrusice) and two as *O. ektophysa* (on *Populus tremula*, 21.VII.1926, Mnichovice; on *Prunus spinosa*, VII.1931, Hubáčov). Both plates contain cross-references which appear to indicate that he considered the three samples to be conspecific. *O. ektophysa* is an unpublished name, whereas the similar name *O. ektophysata* was published for a collection on stems of *Cirsium* which is considered here to belong to *O. oxyspora* (section *Arthrobotrys*).

Two specimens were studied by Svrček (1954: 21), whereas the third (21.VII.1926) does not appear to have been preserved. Svrček designated the collection labelled *O. tremulae* (PRM 149390, 13.VI.1923) as lectotype. Yet, in our opinion Svrček's lectotypification is against the Code (ICN Art. 9.19), for two reasons:

(1) The data on Velenovský's manuscript plate of this collection ('*Orbilia Tremulae* sp. n.', apothecia 3–4 mm diam., pale amber, asci 30–40 × 4 µm, drawn without bifurcate base, paraphyses medium capitate-clavate, spores 2–3 µm long, ovoid) were only used by him in the protologue of *O. tremulae* regarding the spores. Moreover, the protologue says 'on wood' whereas this sample as here reexamined is on bark. Instead, the protologue data are a compilation of those two collections illustrated on his manuscript plate under the name '*Orbilia ektophysa* sp. n.'. This name is derived from the 'external' (probably marginal) paraphyses being filiform, a feature which he illustrated for the two specimens and mentioned in the protologue of *O. tremulae*. One of them (on *Prunus spinosa*, asci 25 × 3–4 µm excluding stipe, spores 2–3 µm long, narrowly ellipsoid, paraphyses strongly capitate, 5–6 µm wide) has predominantly influenced the protologue and seems to have been the basis of his pl. XI fig. 10. The other, unpreserved sample (on *Populus tremula*, apothecia 0.3–0.6 mm diam., amber-coloured, asci 25–30 × 3–4 µm, spores 3–4 µm long) influenced the protologue merely concerning the spore size of '2–4 µm'. The apothecial size of 1–2 mm in the protologue is in conflict with this sample as well as to PRM 149390.

(2) The lectotype designated by Svrček must have been a mixture or a mistake. This now contains an *Orbilia* with completely different, arcuate spores which Svrček identified as *O. curvatispora* (= *O. auricolor*). The present reexamination confirms that it belongs to section *Arthrobotrys*, though it deviates from typical *O. auricolor* in the margin having 2–12 × 3.5–5 µm large glassy processes, therefore, a relation to a species of series *Dactylellina*, e. g., *O. rubrovacuolata* or *O. mammillata*, cannot be excluded. Velenovský's manuscript drawing of this specimen shows ovoid spores which are also figured inside an ascus, hence Velenovský very probably studied a species of series *Orbilia*, possibly *O. cejpii*. For this reason and because the original data of this record were not included in the protologue, the preserved material cannot be used as lectotype.

Plate 862. **1–7**: *Orbilia tremulae*; **8**: *O.* cf. *tremulae*. – **1c**. corticated branch of *Frangula alnus*; **2a–b**, **3a–b**, **5**, **6a–b**, **7a–b**. fresh apothecia; **1a–b**, **4b**, **8a–b**. rehydrated apothecia (**1**. after 6 years, **4**. after 33 years, **8**. after 3/4 year); **1d**. apothecium in median section; **1e**. id., ectal excipulum from base to margin; **1f**. do, at lower flanks; **3c**, **4a**, **8c**. id., marginal ectal excipulum; **2c**. ascospores. – Living state, except for **1d–f**, **4a** (in KOH). – **5–6**: phot. J.P. Priou, **7**: phot. I. Wagner. — **1a–d**. H.B. 6963a (epitype): Germany, Bayreuth, on *Frangula*; **2a–c**. H.B. 8262: Switzerland, Uri, on *Sorbus*; **3a–c**. H.B. 8258: ibid., on *Alnus*; **4a–b**. H.B. 2337: Germany, Tübingen, on *Fagus*; **5**. J.P.P.13064: France, Morbihan, on *Cotoneaster*; **6a–b**. J.P.P.13010: ibid., on *Cotoneaster*; **7a–b**. I.W. 130628: Germany, Thüringen/Hessen, on ?*Carpinus*; **8a–c**. H.B. 8497a: Australia, Queensland, Daintree Forest, on *Bambusa*.

The other specimen studied by Svrček (on *Prunus spinosa*, PRM 152382) was apparently thought by him to be without apothecia, because he relied on Velenovský's description when he concluded that it belongs to *O. xanthostigma* s. Svrček. A small number of apothecia indeed occurred in this specimen, and their reexamination revealed that they closely match, e.g., the here designated epitype of *O. tremulae* (Pl. 861: 1). We here designate PRM 152382 as **lectotype** of *O. tremulae*, because it has predominantly influenced the protologue.

In mounts of H_2O as well as KOH the spore body could be discerned as a transparent region in the lectotype (Pl. 861: 7). Although we did not find any conidia in this specimen, we conclude that it is conspecific with the collection of W. Beyer from Germany (Bayreuth, on *Frangula*, ex H.B. 6963a, M-0276602), from which an ascospore isolate (CBS 116232) and a sequence were gained, and which we here designate as **epitype** of *Orbilia tremulae*.

Velenovský (1934: 92) separated from his concept of *O. coccinella* a collection on log of *Abies* as ***O. coccinella* var. *abietina***, with smaller, orange, hardly lobate apothecia, without giving any microscopic details. This taxon is mentioned but not described or figured on his manuscript plate. Svrček (1954: 12) reexamined the holotype and stated that it represented typical *O. xanthostigma* s. Svrček, but also he did not provide microscopic features. The present reexamination revealed asci †37–45 × 3 µm, spores †3–3.5 × 1.5–1.8 µm, and medium to strongly clavate-capitate paraphyses, which well fit *O. tremulae* (the apothecia were described by Velenovský as orange but are now whitish-cream when rehydrated, 0.3–0.6 mm diam., IVV: H.B. 9879).

Because of a deviating colour of the apothecia (brownish, then brown-bloodred; in contrast to scarlet red in *O. coccinella* s.auct.), and more regularly shaped, eguttulate spores, Grelet & Crozals (1928) described ***O. coccinella* var. *versicolor*** based on a French collection (Poitou-Charentes). A single apothecium was detected in the holotype from PC (Pl. 861: 9) which grew on the periderm of a fallen, 9 mm thick, corticated branch of *Quercus* (associated with *Capitotricha bicolor*). The spores are found somewhat smaller, especially narrower compared to the protologue which gives *4–5 × 2.5 µm. From the original drawing a size of *4.3–4.8 × 2.4–2.6 µm can be evaluated for the 3 free spores, while those inside the ascus measure only *3–3.5 × 1.5–1.8 µm. The asci are found here to measure †42–50 × 3–3.3 µm including the long and thin stipe, while the authors gave a size of *35–45 × 5 µm (*48 × 4.7 µm evaluated from drawing) and described and figured them as hardly attenuated towards the bifurcate base. The figured ascus is obviously in the living state according to its width and ample lumen below the spores. The taxon seems to fit the present concept of *O. eucalypti*, e.g., the small-celled basal ectal excipulum, but the brownish colour and the partly small size and symmetrical shape of the spores are more reminiscent of *O. tremulae*.

Misapplication. A specimen from eastern Lapland (Kola Peninsula, on wood of *Salix*, 27.VII.1861, herb. P.A. Karsten 3192) was examined and tentatively included in the description of *O. tremulae* because of its small ellipsoid spores (Pl. 861: 8). Some unbranched, 1-septate conidia (†9.5 × 3.3–3.5 µm) were observed in the squash mount, but their affiliation is not clear. Although referred by Karsten and W. Nylander to *P.*/*O. leucostigma* on the label, Karsten (1861: 36, 1869: 173) apparently reported the same specimen under the name *O. coccinella*. As substrate he gave in 1861 wood and bark of *Salix*, but included also a specimen on a polypore (both from Kola), and in 1869 he included a lignicolous specimen of Nylander from Lake Onega. Karsten described the apothecia in 1861 as obscurely rose, disc yellowish, and in 1869 as moist rose-coloured, dry translucent red, but could not find any spores. A possibility would be that this specimen represents a member of series *Drechslerella*, e.g., *O. yunnanensis* or *O. tonghaiensis*, which possess very similar didymosporous microconidia.

Velenovský (1934: 92, pl. 11 fig. 7) applied the name *O. coccinella* to populations with amber-yellowish apothecia 2–4 mm diam., becoming strongly lobate with age, a large-celled basal excipulum, strongly capitate paraphyses, and (narrowly) ellipsoid, 3–5 µm long spores. His collections derive from damp logs of gymnosperms (*Pinus* and *Picea*) from planar to montane areas throughout Bohemia. A manuscript plate on them exists, but Velenovský did not state the localities and apparently did not preserve material. His description appears to match *O. tremulae* very well, apart from the large apothecial diameter and the possibly inexact spore length (the figured spores do not show such variation). Also Liu's (2006) concept of *O. coccinella* includes *O. tremulae*. Judging from conidial morphology (Pl. 861: 3), Berthet (1964a, b) applied the name *O. xanthostigma* in a sense as already favoured by Svrček (1954), which predominantly matches the present concept of *O. tremulae*.

Not included collections. Various doubtful records with intermediate spore size and orange or reddish apothecia growing predominantly on xeric substrates are not included in the description (see Pls 861: 2, 8–9; 862: 8; IVV). For the type of the anamorphic *Dicranidion inaequale* see under Anamorph, and for *O. coccinella* var. *versicolor* see under Type studies.

Anamorph. Conidia were only observed in two of the included records. Both were gained from ascospore isolates, from samples from Rhône-Alpes (P. Berthet) and Bayern (W. Beyer, epitype of *O. tremulae*). Morphologically both fit very well the type culture of *Dicranidion inaequale*: in all three strains the conidia lack a stipe-like base, and most of them possess only 1 oblique to almost vertical basal septum (Pl. 861: 1g, 2g, 3g). In contrast to this, a majority of conidia of *O. eucalypti* (*D. fragile*) show 2 oblique basal septa (e.g., Pls 856: 5, 6, 7c; Pl. 858: 9f, 10f). The single septum in *O. tremulae* provokes an asymmetry of the basal cell, whereas the 2 septa in *O. eucalypti* result in a symmetrical conidial base. The epithet *inaequale* was introduced by Tubaki & Yokoyama (1971) according to this asymmetry. because the conidial base of *O. eucalypti* is more conical instead of rounded-truncate, the nodulous basal scar characteristic of *O. tremulae* is less pronounced in *O. eucalypti*.

Compared to the type of *D. inaequale*, the bilobed conidia in the epitype of *O. tremulae* are slightly shorter, while those obtained by Berthet are distinctly shorter. The conidial arms are mainly 2–3-septate in the type, but 0–2-septate in the other two isolates (rarely 3-septate in the epitype). In addition to the branched conidia, Berthet observed also unbranched, 1-septate conidia (8–15 × 2–3 µm) in his culture, and also we have seen them in our epitype culture in ~8% of the conidia (1–2-septate, *13–14.5 × 2.6–3 µm). Also Tubaki & Yokoyama and Butterfield found unbranched conidia in the type culture of *D. inaequale* (12–19 × 2.3–3 and 11–26.5 × 3–4 µm, respectively), whereas on the natural substrate Tubaki & Yokoyama saw purely bilobed conidia. Yet, Butterfield's rather large phragmoconidia possessed 3–7 septa, while Tubaki & Yokoyama did not illustrate phragmoconidia, nor did they mention the number of septa.

Butterfield (1973), followed by Matsushima (1981), synonymised *D. inaequale* with *D. fragile*, because in the type culture of *D. inaequale* conidia with symmetrical basal cells also occurred. However, in Butterfield's study only 26–32% of the bilobed conidia of *D. inaequale* showed symmetrical basal cells, whereas in *D. fragile* 94–99% did so. Moreover, 0–55% of the conidia of *D. inaequale* were unbranched, depending on the culture medium, whereas in *D. fragile* only 1–12% were unbranched. The bilobed conidia illustrated by Butterfield from the type culture of *D. inaequale* (ATCC 22517) are very different from the protologue but resemble instead those of *O. cejpii* in having partly a 1-septate stipe. Conidial size is difficult to evaluate from Butterfield's fig. 1 since the given photos are said to have six different magnifications, some of which appearing to be untrustworthy.

In summary, the type strain of *D. inaequale* shows slightly longer bilobed conidia, and phragmoconidia with more septa. Also the reduced conidiophores illustrated by Berthet are in contrast to the comparatively long, sympodially proliferating conidiophores in the type of *D. inaequale*. Because of the rather high molecular distance between Japanese and European strains (see below), we consider *D. inaequale* as specifically distinct from *O. tremulae* and give here a modified version of the protologue of ***D. inaequale*** by Tubaki & Yokoyama (1971): Conidiophores 20–50 µm long, 1.5–2.6 µm wide at base, septate, unbranched, straight to zigzag-shaped, sympodial, conidia terminally formed and from lateral, 0.5–1 µm wide pegs. Bilobed conidia 12–17 × 6–7 µm, arms 7–12 × 2.5–3.5 µm, 2–3-septate, basal cell mostly very asymmetrical (one arm 2-septate, the other 3-septate), but in 26–32% of conidia symmetrical, rarely with a stipe-like 1-septate base or with more than two arms.

Phylogeny. Available sequences of *O. tremulae* derive from four European ascospore isolates. In two of them the substrate was mesic to xeric (branches 0.5–1.5 m above the ground), while one (epitype) was more hygric and one (Berthet's) is unclear in this respect. They all comprise S1506 intron, ITS, and LSU (1 also SSU). In the ITS region the four are highly concordant: the strain from Bretagne on *Cotoneaster* fully matches Berthet's strain from Haute-Savoie on *Alnus* (NBRC 9521), whereas the isolate from Bayreuth on *Frangula* merely deviates by 1 gap in the ITS2 region. A Chinese strain under the name *O. coccinella* from Qinghai on undetermined wood (B.L. Q132) differs by only 3 nt (0.6%) in the ITS region and obviously belongs to *O. tremulae*. A sequence of the type culture of *Dicranidion inaequale* in NBRC 9366 comprises S1506 intron, ITS, and LSU and turned out to be very distantly related to *O. tremulae*. On the other hand, an LSU sequence under the name *D. fragile* (CBS 467.73, France, unlocalized) fully concurs with *O. tremulae* in the D1–D2 but differs by 2 nt and 1 gap in the D3 domain.

The almost absent variation in the ITS region among the available sequences of *O. tremulae* is astonishing since the ascospores in the Bretagne strain are shorter and wider than in that from Bayreuth (microscopic data of the Haute-Savoie strain were not taken and the material was lost, P. Berthet pers. comm.), and morphologically similar taxa, which are very difficult to distinguish from *O. tremulae*, are highly distant in that region: *O. eucalypti* and *O. fissilis* differ from *O. tremulae* by 17–19%, *O. cejpii* s.l. by 15.5–19.5%, and also *O. paracylindrospora* and *O. frangulae* show similar distances, depending on the alignment.

The overlapping parts of LSU (558 nt) are identical between the four strains of *O. tremulae* (except for 1 gap in H.B. 6963a). In this region the distance to other members of series *Orbilia* ranges at 5–8%. The three European sequences contain the S1506 intron of 414 nucleotides, while the Chinese strain does not cover this region. Also this intron is highly concordant, differing only by 1 nt, whereas other members of series *Orbilia* show high distances of ~14–20% or more.

O. tremulae clustered in the weakly supported *xanthostigma-tremulae* clade (Phyl. 22). Despite its very similar conidia, *D. inaequale* is from a molecular point of view very different from any other strain of series *Orbilia* (intron and ITS min. 15–16%, LSU min. 4%). It did not cluster with *O. tremulae* in all our analyses, but unsupported with *O. fissilis* (Phyls 22–23) or *O. eucalypti* (S27). The distance to *O. tremulae* is 16.5% in the ITS and 5% in the LSU D1–D2. In the D1 domain, *D. inaequale* concurs at pos. 129–137 with *O. eucalypti* p.p.maj. and *O. fissilis* (CTTT**GG**T**G**C) while *O. tremulae* has 5 deletions (----**AA**-**G**C) in concordance with other members of the *xanthostigma-tremulae* clade, to which *D. inaequale* does not belong. Further Asian records should be studied in order to clarify this surprising result.

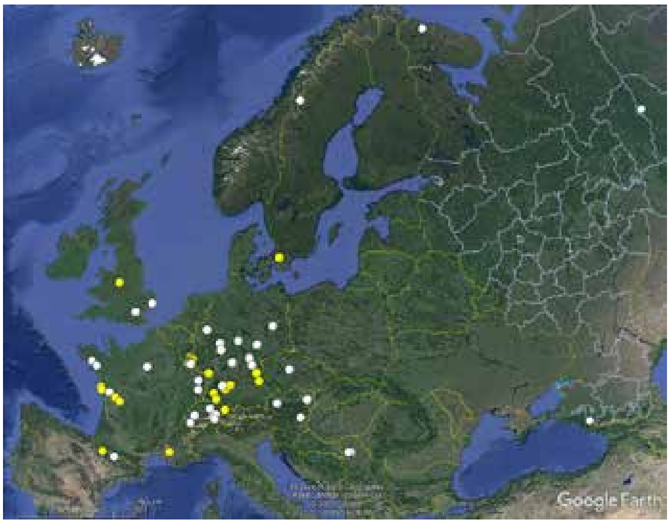
Ecology. *O. tremulae* was found on rotten wood, less often on bark, of hygric but also xeric branches and logs of various angiosperm trees and shrubs. Favourite hosts were *Carpinus* {11}, *Alnus* {6}, *Quercus* {6}, *Fagus* {6}, and *Salix* {5}. Rarely the species was found on gymnosperms or on fungi (resupinate basidiomycetes, pyrenomycetes). *O. tremulae* appears to be predominantly a desiccation-sensitive species, with the substrate lying on moist or wet ground, but some of the included collections were on projecting branches and such populations are assumed to tolerate drought for some time.

O. tremulae is reported here from Europe and Asia. Collections derive from planar to montane and subalpine-boreal, atlantic to subcontinental, humid regions of Europe. The climate types include cold- and orotemperate, also sometimes warm-temperate and orosub- to suprasubmediterranean, and in Scandinavia supra- to oroboreal. It occurs also in orotemperate to boreal eastern Russia. The vegetation includes *Querco-Carpinetum*, *Galio-Carpinetum*, *Crataego-Prunetum*, *Salicetum*, *Alnetum glutinosae*, *Alnetum viridis*, acidic *Sphagnum*-rich peat bogs, and many others. The Chinese sample was in an orotemperate humid (winter-dry) forest at the eastern edge of the Qinghai-Tibet Plateau.

Among the sequenced European strains, the epitype of *O. tremulae* grew on an old corticioid basidiomycete that covers the periderm of a hygric branch of *Frangula alnus* in a boggy *Frangula* plantation along a rivulet in a colline subcontinental area in Oberfranken (northern Bayern), while Berthet's strain was on *Alnus alnobetula* in a subalpine alder shrub in Haute-Savoie in eastern France (P. Berthet pers. comm.), and that from western France on bast and periderm of a mesic branch of *Cotoneaster* in atlantic lowlands of Bretagne.

In a not included collection from Luxembourg the apothecia grew on xeric bark of a vital trunk of *Fagus*, but also in the three included ones from Luxembourg (5.V.1999, H.B. 4833, G.M. 2015-07-09.1) the branches were attached 0.5–3 m above the ground (the sequence of the latter concurs with the hygric and mesic samples).

The not included holotype of *D. inaequale* grew on a decaying fruitbody of a diaporthe-like fungus in the subtropical humid more southern part of Honshu (Shiga Pref., Japan). Not included are also the two Australian collections, which grew



Map 138. Known distribution of *O. tremulae* in Europe (yellow = not included collections).

on xeric *Xanthorrhoea* fruits on a sand dune in the subtropical semihumid southwest and on xeric bamboo in the tropical humid northeast, both showing a much higher drought tolerance of up to 9 months regarding the excipular cells.

Specimens included. **RUSSIA (West)**: **Murmansk**, **Kola Peninsula**, Lapponia tulomensis, unlocalized, branch of *Salix*, on wood, 27.VII.1861, P.A. Karsten (Karsten 3192, H-6008812, as *Peziza leucostigma* or *O. coccinella*). – **Adygea**, ~63 km NE of Sochi, ~7 km NE of Guzeripl, Tsornõi Shahan, 700–1300 m, log of *Quercus*, on wood, 16.VII.1975, M. Murdvee (TAAM 69733). — **RUSSIA (East)**: **Sverdlovsk**, Ural Mts., ~75 km WSW of Serov, ~NE of Kytlym, 334 m, branch of *Sorbus*, on wood, 20.VII.1973, E. Parmasto & A. Raitviir (TAAM 62980, H.B. 8709 ø). – **Irkutsk**, Sayan Mts., ~SW of Baykalsk, S-end of lake Baykal, ~1000 m, branch of *Alnus alnobetula* subsp. *fruticosa*, on wood, 17. VIII.1975, E. Parmasto (TAAM 96057, H.B. 8710a ø). — **SWEDEN**: **Jämtland**, 60 km WSW of Saxnäs, 3 km SW of Leipikvattnet, Bjurälven, Lillälven waterfall, 500 m, stump of *Betula pubescens*, on bark, 27.VII.2010, S. Orbilia guyanensis Baral, **sp. nov.**, MB 813961 — Pls 863–864

Etymology: named after the origin of the holotype, French Guiana.

Typification: French Guiana, Cayenne, branch of indet. angiosperm, 1.III.2007, C. Lechat (ex H.B. 8453, M-0276490, holotype; sq.: KT222432).

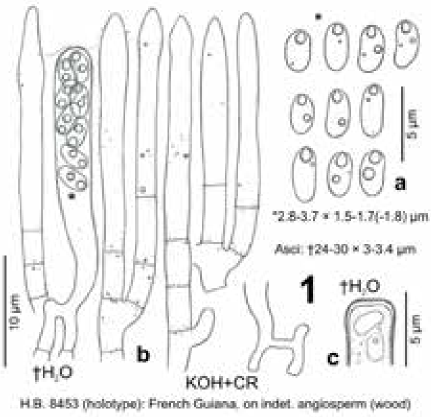

Plate 863. **1**: *Orbilia guyanensis*. – **a**. ascospores; **b**. ascus and paraphyses, ascus base; **c**. ascus apex.

Latin diagnosis: *Apothecia rehydratata 0.3–1.4 mm diam., pallide vel subvivide lutea, breviter stipitata, margine elevata, laevi. Ascosporae *2.8–3.7 × 1.5–1.8 µm, (ellipsoideo-)subcylindricae, rectae vel paulo curvatae, corpuscula refringentia 0.6–1 × 0.5–0.8 µm. Paraphyses ad apicem leniter vel modice obtuse lanceolatae, paulo protrudentes, exsudato nullo. Excipulum marginale absque processis vitreis. Habitat ad lignum putridum uvidum angiospermae in zona tropica humida Americae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.5–1.4 mm diam., 0.3 mm high (receptacle 0.09–0.13 → 0.06 mm), pale to light yellow, semitranslucent, round, scattered to subgregarious in small groups; disc slightly to medium concave, finally flat with raised margin, margin thin, 5 µm protruding, smooth; with a cylindrical to obconical stipe 0.1–0.2 × 0.15–0.35 mm, superficial; dry pale to bright yellow, receptacle partly strongly inrolled. **Asci** †24–30 × 3–3.4 µm, 8-spored, spores †(1–)2-seriate, 2–6 lower spores inverted (very strongly mixed); **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to medium long and thin, flexuous stalk, T- or often h- to H-shaped. **Ascospores** *2.8–3.7 × 1.5–1.7(–1.8) µm, subcylindric(-ellipsoid), both ends rounded to slightly obtuse, straight to slightly inequilateral or curved; **SBs** *0.6–1 × 0.5–0.8 µm, broadly tear-shaped to almost plug-shaped, apically narrowed to a ± wide point, often with a lateral LB of 0.4–0.8 µm diam. **Paraphyses** slightly to medium lanceolate, apex obtuse to acute, terminal cells †(12–)15–20(–22) × 1.6–2.5 µm, exceeding the dead asci by 2–4 µm, lower cells †3.5–7 × 1.8–2.6 µm; unbranched at upper septum. **Medullary excipulum** hyaline, 170 µm thick in centre, 40–70 µm in receptacle, of dense textura porrecta, horizontally oriented in receptacle, upwards in stipe, without inflated cells but with many solid (glassy), 2–4 µm wide elements mainly in upper part, very sharply delimited. **Ectal excipulum** hyaline, of vertically oriented t. angularis from base to margin, (†) medium gelatinized (common walls 1–1.5 µm thick, cortical wall 1–2 µm), 30–45 µm thick in stipe, 15–35 µm at flanks, cells †(9–)15–25 × (6–)10–18 µm; 15 µm thick near margin, oriented at a 70–90° angle to the surface, marginal cortical cells †6–10 × 5–7 µm, firm-walled; **glassy processes** absent. **Anchoring hyphae** abundant at base of stipe, †2.5–4.3 µm wide, walls 0.2–0.3 µm thick, forming a loose t. intricata. **SCBs** & **VBs** no data available. **Exudate** over paraphyses and excipulum absent. — **ANAMORPH**: unknown.

Habitat: lying on moist ground, decorticated, 2–4 cm thick piece of timber from an unidentified broad-leaved tree, on 0.2–0.5 mm deep strongly decayed wood, eroded, partially blackened, no algae. **Associated**: none observed. **Desiccation tolerance**: desiccation-sensitive, but many spores still viable after 4 weeks. **Altitude**: 23 m a.s.l. **Phenology**: III (tropical belt).

Taxonomic remarks. In the lanceolate paraphyses and smooth apothecia *Orbilia guyanensis* is similar to *O. umbilicata*, but also *O. alba* (series *Gamsylella*). It differs in distinctly shorter and wider, only very slightly curved ascospores, larger, apically

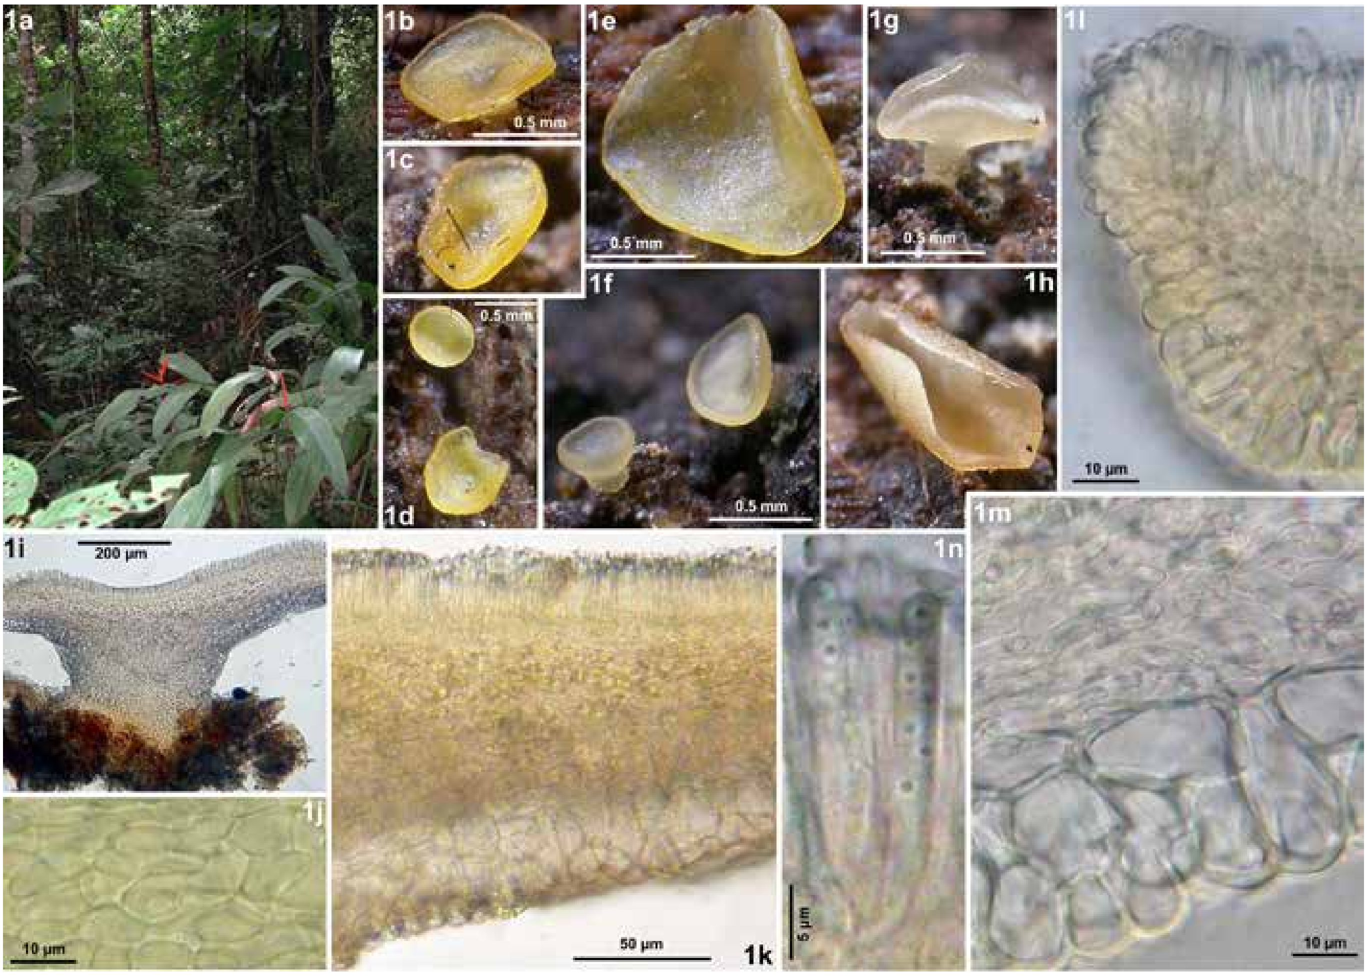

Plate 864. **1**: *Orbilia guyanensis*. – **1a**. tropical rainforest at the type locality; **1b–h**. rehydrated apothecia; **1i**. apothecium in median section; **1k**, m. id., at lower flanks; **1l**. id., marginal region; **1j**. external view on ectal excipulum at mid flanks, cells horizontally elongated; **1n**. mature asci and paraphysis. – Dead state (**1k**, **n** in H_2O; **1i–j**, **l–m** in KOH), except for ascospores in asci of **1n** (with SBs or LBs). – **1a**: phot. C. Lechat. — **1a–n**. H.B. 8453 (holotype): French Guiana, Cayenne, on indet. angiosperm.

more broadly attached SBs, and in thick-walled excipular cells. A Chinese collection mentioned under *O. umbilicata* differs from *O. guyanensis* in slightly longer and narrower spores and longer asci; yet, the shape of the SBs is unknown. *O. dryadum* and *O. gaillardii* have similar spores but differ in capitate paraphyses, globose SBs with a very fine, usually invisibly filum (unknown in *O. gaillardii*), and an ectal excipulum with thinner walls. Also species around *O. orientalis* (series *Drechslerella*) have similar spores but differ in smaller, ± rod-shaped, often eccentric SBs attached by a thin filum, in the frequent presence of glassy processes, and in uninflated to capitate paraphyses.

Phylogeny. A sequence was gained from apothecia of the holotype, comprising SSU (without S1506 intron), ITS, and LSU. In our analyses of SSU+ITS+LSU, ITS, or LSU (Phyls 7, 22–23, S27), *O. guyanensis* clustered in section *Orbilia* with a very high distance to any other species, ranging between 23 and over 30% depending on the alignment. Even the 5.8S differs by a minimum of 4 nt from *O. dryadum* p.p. and by 5 nt from various other members of *Orbiliomycetes*. The lowest distance in the LSU D1–D2 is 10% to the *xanthostigma-leucostigma* complex and *Dicranidion inaequale*. These results support an isolated position of *O. guyanensis*.

However, in Phyls 22 and S27, *O. guyanensis* clustered weakly or unsupported in the *xanthostigma-tremulae* clade, and molecular motifs in the LSU D1 domain strongly suggest that it belongs in this group (see p. 1327).

Ecology. *O. guyanensis* was found on rotten wood of a hygric piece of timber of an unidentified angiosperm tree in a tropical humid coastal rainforest in northeastern South America.

Specimens included. **FRENCH GUIANA**: 7 km WSW of Cayenne, Secteur Crique Macouria, N of Pont du Larivot and Rivière de Montsinéry, 23 m, branch of indet. angiosperm, on wood, 1.III.2007, C. Lechat (ex H.B. 8453, M-0276490, **holotype**; sq.: KT222432).

Orbilia umbilicata Baral, Ying Zhang & K.Q. Zhang, in Zhang et al., Fungal Diversity 36: 146 (2009) — Pls 865–866

Etymology: referring to the depressed centre of the apothecial disc.
Typification: Japan, Sugadaira, branch of indet. angiosperm, 13.VIII.1997, W. Gams (ex H.B. 5903, M-0140895, holotype)

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–1.4 mm diam., 0.12–0.17 mm thick (receptacle 0.07–0.1 → 0.06–0.07 mm), whitish to pale cream-chlorinaceous (light honey-yellow with age), translucent (partly dark brownish in centre), round to slightly undulating, scattered or often gregarious over small to large areas; disc slightly to medium concave, flattened to slightly convex when large but still distinctly depressed and concave in centre, margin thin, 5 µm protruding, smooth; subsessile or often with distinct obconical stipe 0.1–0.15 × 0.35–0.5 mm, superficial; dry light chlorinaceous-yellowish-ochraceous. **Asci** †(25–)28–35 × 2.8–3.5(–3.8) µm {2}, 8-spored, spores 3-seriate, lower spores inverted, pars sporifera †9.5–16 µm long; **apex** (†) medium to strongly truncate (rarely very slightly indented, laterally not distinctly widened); **base** with very short to

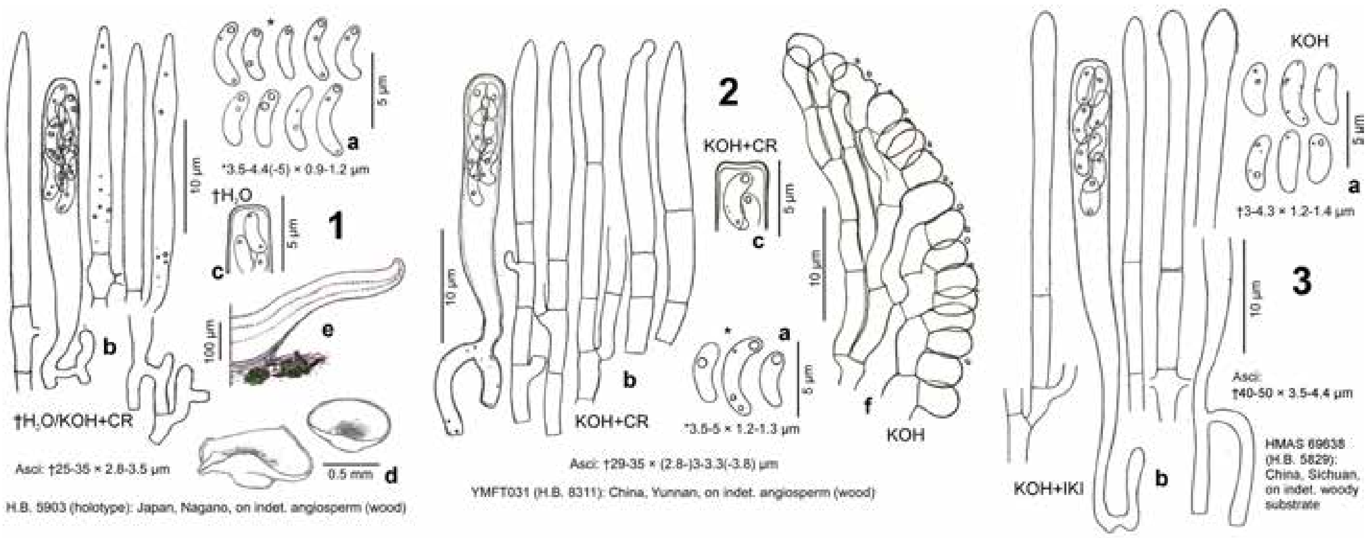

Plate 865. **1–2**: *Orbilia umbilicata*; **3**. *O.* aff. *umbilicata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum.

medium long, thick or thin, flexuous stalk, h- to H-shaped. **Ascospores** *(3–)3.5–4.5(–5) × (0.9–)1–1.2(–1.4) µm {2}, †3–5 × 1 µm {1}, cylindrical, both ends rounded, slightly to strongly curved (allantoid or sometimes slightly helicoid); **SBs** *0.3–0.5(–0.6) µm diam., globose, a short distance from apex, attachment not seen (total length 0.6–0.7(–1) µm). **Paraphyses** (narrowly) lanceolate, terminal cells †(10–)20–28 × (1.5–)2–2.5(–2.8) µm {2}, exceeding the asci by 2–4(–5) µm, lower cells †(3–)4–6 × 1.3–2.5 µm {2}. **Medullary excipulum** 25–70 µm thick, of dense or medium loose, partly horizontally oriented, not or slightly gelatinized textura intricata(-porrecta), very sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, vertically oriented t. angularis(-prismatica) from base to margin, 50–70 µm thick near base, cells †10–18 × 8–15 µm {T} or †12–30(–40) × 10–20(–25) µm {1}; 15–30 µm thick at lower flanks, 10 µm towards mid flanks, 5–8 µm near margin, here oriented at a 10–80° angle, marginal cortical cells †(4–)6–11(–13) × 2.5–3.5 {1} or 3.5–6 µm {T}, thin-walled (0.2 µm), **glassy processes** absent. **Anchoring hyphae** abundant, forming a dense, medium gelatinized t. intricata-porrecta 40–60 µm thick, hyphae †1.5–3 µm wide, walls 0.2 µm thick (common walls 0.4–1.3 µm) {2}. **SCBs** and **VBs** no data available. **Exudate** over paraphyses absent; over margin and flanks 0.2–0.5 µm thick, continuous and smooth, or as scattered granules. — **ANAMORPH**: unknown.

Habitat: branches or logs of indet. angiosperm trees {2}, lying on ground, decorticated, on entirely strongly decayed wood {2}, soaked with water, upperside, without or with many green algae. **Associated**: leafy liverwort {1}. **Desiccation tolerance**: only ascospores were viable after 6 weeks. **Altitude**: 1250–2550 m a.s.l. **Geology**: Jurassic sedimentary rock; mafic volcanic rock. **Phenology**: VII–VIII.

Taxonomic remarks. *Orbilia umbilicata* is characterized by allantoid ascospores and lanceolate paraphyses. The species seems to be related to *O. guyanensis* (for the differences see p. 1380), although a possible relationship could instead exist to *O. pilosa* (section *Arthrobotrys*) which has similarly shaped spores and paraphyses. *O. epipora* (section *Arthrobotrys*) and *O. dryadum* differ from *O. umbilicata* in cylindrical to capitate paraphyses and straight or only slightly curved spores. *O. fraxini* (section *Arthrobotrys*) differs in hair-like marginal cortical cells tipped by 1–4 µm thick exudate caps and in wider and less curved, more ellipsoid to clavate spores.

Variation. *O. umbilicata* s.l. was so far only studied in the dead state, except for the spores which were still alive in the two included samples. The abundant Japanese holotype (Pls 865–866: 1) fits very well the Chinese paratype (Pls 865–866: 2) in many respects, though it differs in longer terminal cells of paraphyses, smaller basal excipular cells, and wider marginal cortical cells, and in flat to convex, centrally depressed (umbilicate) apothecia.

Not included collections. Two samples from Primorje (Russian Far East, Pl. 866: 3) and Nara (Japan, IVV: H.B. 9982) differ from *O. umbilicata* in cylindrical to narrowly lanceolate paraphyses, slightly longer asci (†30–42 × 3.3–3.8 µm), and wider, less curved spores (†3.2–5 × 1.2–1.4 µm). A collection from Daba Mts. in Chongqing (before 1997 a part of Sichuan) (Pl. 865: 3) deviates from *O. umbilicata* in somewhat shorter and wider, distinctly less curved spores, less acute, ± spathulate paraphyses, and distinctly longer asci, and seems to be intermediate to *O. guyanensis*. A similarity exists also with *O. fraxini*, but regrettably the marginal excipulum of the single received apothecium was not studied. This and another sample from the same site (HMAS 69639) were reported by Zhuang (1997: 9) under the name '*O. xanthostigma* s. Svrček 1954', with flat, sessile, very thin, cream white, semitranslucent apothecia 1–3 mm in diam., ellipsoid to rod-shaped spores 3.5–4.5 × 1.2–1.5 µm, and asci 27–32 × 3.7–4 µm (probably excluding stipe). Liu (2006) erroneously included both Sichuan samples in his concept of *O. epipora* (spores 2.5–3 × 1.2–1.3 µm, straight to sometimes slightly curved), which otherwise comprised *O. dryadum* and an unidentified taxon.

Ecology. *O. umbilicata* s.l. was found on deeply rotten wood of hygric decorticated logs of angiosperm trees in continental, cold- to warm-temperate humid (winter-dry) forests of the Far East of Russia and the large central island of Japan, but also in subtropical humid (winter-dry), montane evergreen forests of central and southern China. In the sample from Primorje the forest was composed of *Abies holophylla*, *Acer* spp., *Fraxinus mandshurica*, *Quercus mongolica*, *Tilia mandshurica*, and *T. amurensis* (E.S. Popov pers. comm.), in that from Sugadaira (holotype) it was a montane forest with a rivulet in a ravine.

Specimens included. **JAPAN**: **Honshu**, **Nagano**, Chiisagata-gun, 12 km NE of Ueda, 9.5 km SSE of Sugadaira, Kakuma Valley, 1250 m, branch of indet. angiosperm, on wood, 13.VIII.1997, W. Gams (M-0140895, **holotype**; **isotype** in H.B. 5903). — **CHINA**: **Yunnan**, **Dali**, Yongping, ~38 km ENE of Baoshan, Jinguangsi virgin forest, 2550 m (erron. as 863 m in Zhang et al. 2009b, Z.F. Yu pers. comm.), log of indet. angiosperm, on wood, 14.VII.2006, Y. Zhang (Y.Z. yp-2, YMFT 031, H.B. 8311).

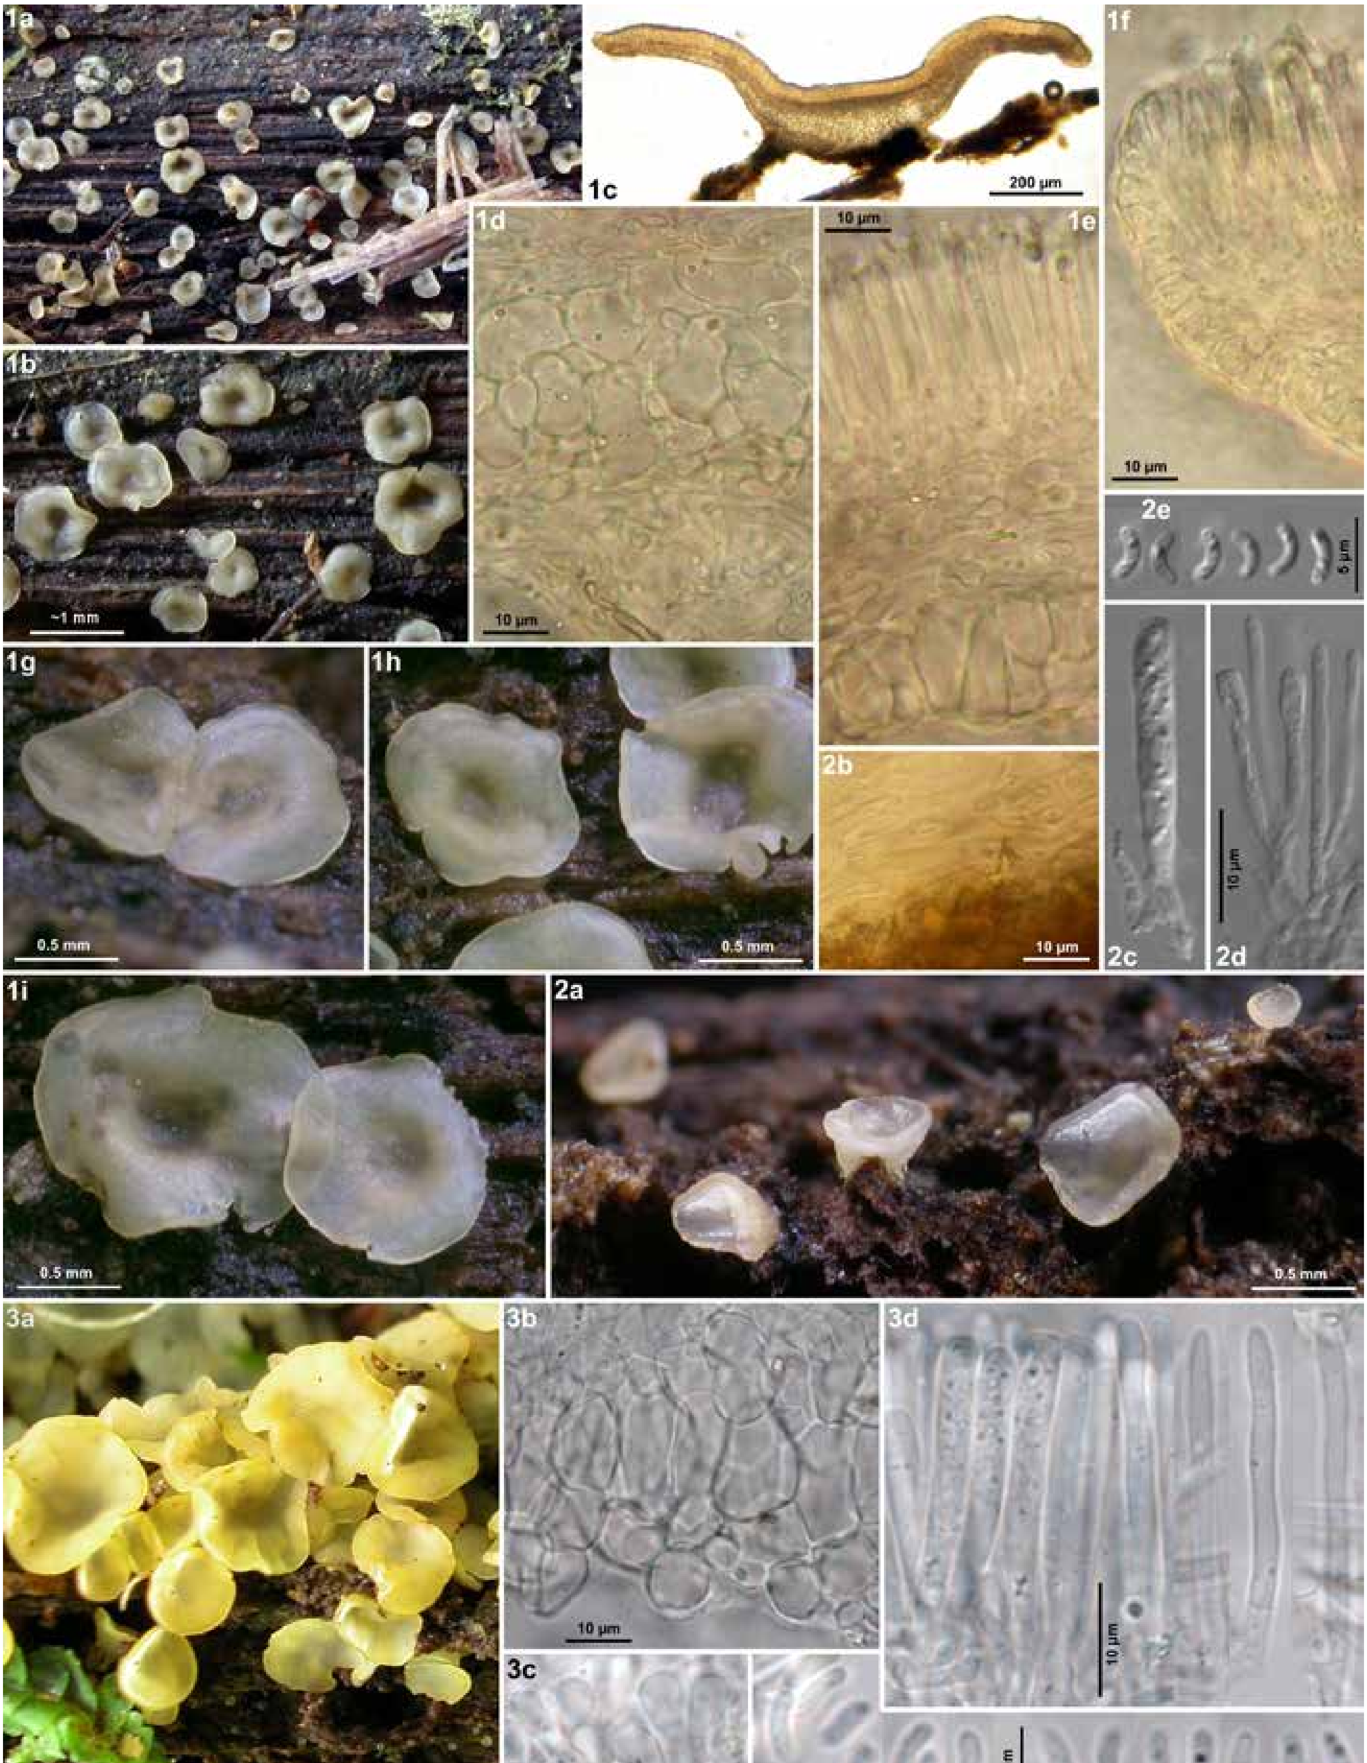

Plate 866. **1–2**: *Orbilia umbilicata*; **3**. *O.* cf. *umbilicata*. – **1a–b**, **g–i**, **2a**. rehydrated apothecia; **1c**. apothecium in median section; **1d**. id., basal ectal excipulum with anchoring hyphae; **1e**, **3b**. id., at lower flanks; **1f**. id., marginal region; **3c**., marginal cells in external view; **2b**. gelatinized anchoring hyphae; **2c–d**, **3d**. paraphyses and asci; **2e**, **3e**. ascospores. – Dead state: **1c**, **2c–e** (in H_2O, except for spores); **1d–f**, **2b**, **3b–e** (in KOH). – **2c–e**: from Zhang et al. (2009b, DIC); **3a–e**: phot. E.S. Popov. — **1a–f**. H.B. 5903 (holo/isotype): Japan, Nagano, on indet. angiosperm; **2a–e**. Orbilia spirospora Baral & E. Weber, **sp. nov.**,

MB 813960 — Pls 867–868

Etymology: named after the strongly twisted, *Spirillum*-like ascospores.

Typification: Japan, Kōchi, log of indet. angiosperm, VII.1994, Kawasaki et al. (TNS-F-56764, holotype).

Latin diagnosis: *Apothecia rehydratata 0.3–0.9 mm diam.*, *pallide cremea*, *subsessilia*, *margine laevi. Ascosporae †3.5–4.5 × 0.7–0.9 µm*, *cylindricae*, *basi raro parum attenuatae*, *valde helicoideae*, *sinistrorsum convolutae. Paraphyses ad apicem modice vel valde obtuse lanceolatae*, *distincte protrudentes*, *exsudato nullo. Excipulum marginale absque processis vitreis*, *excipulum medullare percrassum*, *valde gelatinosum*, *hyphae basales muco circumdatae. Habitat ad lignum putridum trunci uvidi angiospermae in zona subtropica humida Japoniae meridionalis.*

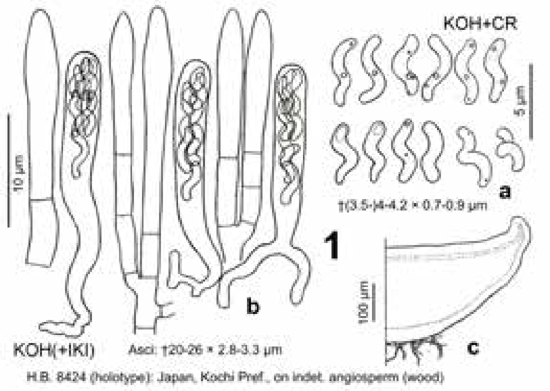

Plate 867. **1**: *Orbilia spirospora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. apothecium in median section.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.9 mm diam., 0.25–0.33 mm high, now pale cream, medium translucent, round, somewhat gelatinous, subgregarious; disc slightly concave to flat, margin medium thick, distinctly raised, not protruding, smooth; with an ill-defined, short, obconical stipe, superficial; dry light yellowish-cream. **Asci** †20–26 × (2.8–)3–3.3(–3.7) µm, 8-spored, spores †3–4-seriate, inversion not clearly seen, pars sporifera †10.5–12.5 µm long; **apex** (†) slightly to medium truncate (never indented, laterally not inflated); **base** with short to medium long, gradually tapered, somewhat flexuous stalk, L-, Y-, h- or H-shaped. **Ascospores** †(3.5–)4–4.2(–4.5) × 0.7–0.9 µm, cylindrical, rarely slightly clavate, both ends rounded or base sometimes slightly attenuated, strongly helicoid (always twisted like a left-hand thread); **SBs** rarely seen as transparent subglobose region near 1 end. **Paraphyses** medium to broadly lanceolate with ± obtuse apex, terminal cells †12.5–20 × 2–3.2 µm wide, exceeding the dead asci by 2–5 µm, lower cells †3–7 × 1.5–2.3 µm; unbranched at upper septum. **Subhymenium** very pale cream, 10 µm thick, of non-gelatinized, dense horizontal textura prismatica-porrecta. **Medullary excipulum** hyaline, 150–230 µm thick, of very loose t. intricata with abundant medium refractive intercellular gel, without inflated cells, very sharply delimited. **Ectal excipulum** hyaline, of slightly gelatinized, irregularly oriented t. (globulosa-)angularis from base to margin, 30–40 µm thick near base, cells †10–18 × 7–12 µm; 15–20 µm thick at flanks and margin, marginal cortical cells †6–7 × 3–5 µm; **glassy processes** absent. **Anchoring hyphae** rather sparse, only at base, projecting, †1.8–3 µm wide (excluding gel sheath), walls 0.2 µm thick, covered by a gel sheath that swells in KOH to a thickness of 1–1.5 µm (in water much thinner and more refractive). **SCBs** & **VBs** no data available. **Exudate** over paraphyses and excipulum absent. **— ANAMORPH**: unknown.

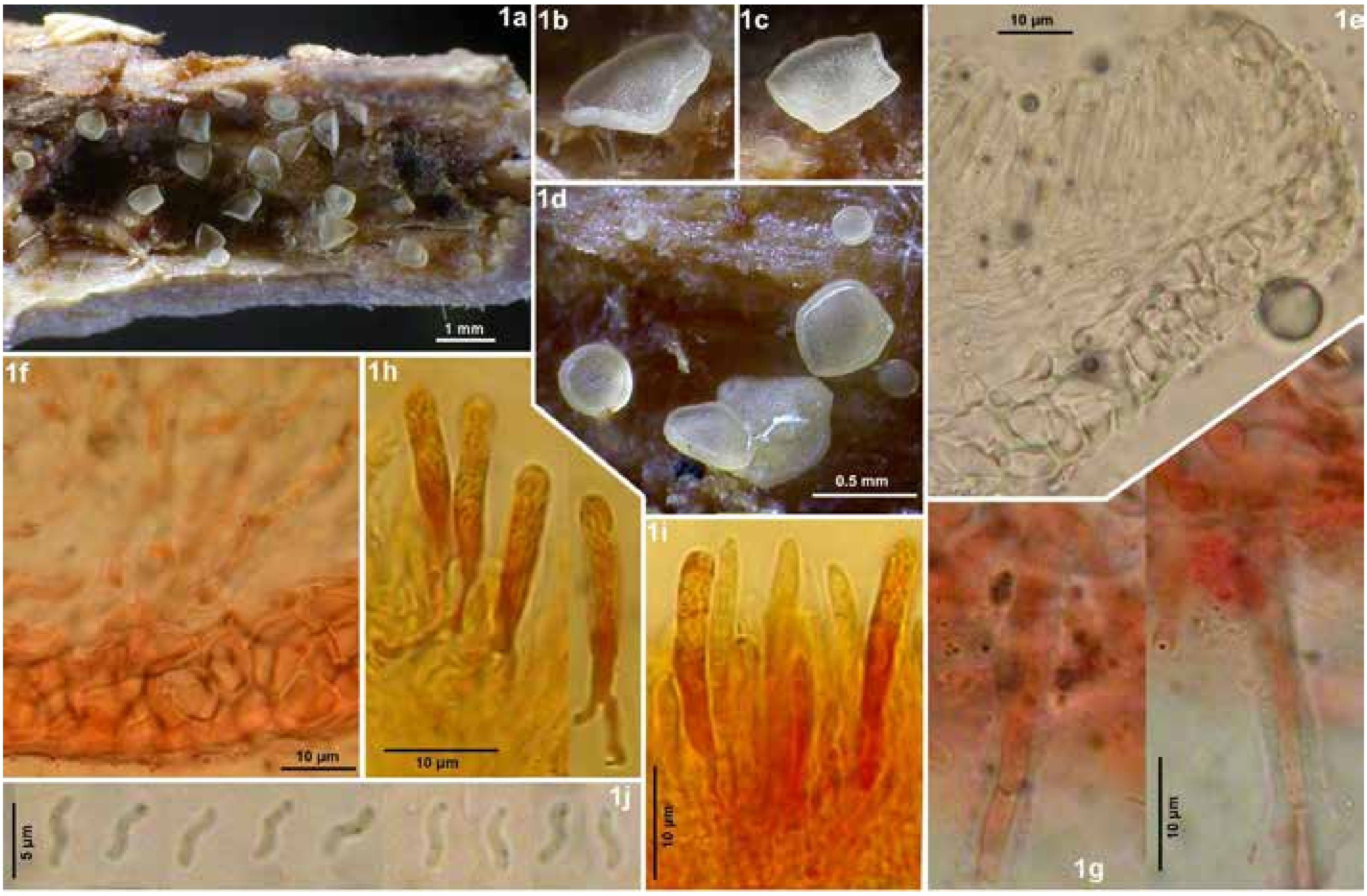

Plate 868. **1**: *Orbilia spirospora*. – **1a–d**. rehydrated apothecia; **1e**. median section of marginal region; **1f**. id., ectal and gelatinized medullary excipulum at flanks; **1g**. anchoring hyphae with gel sheath; **1h–i**. asci and paraphyses; **1j**. ascospores. – Dead state (**1e**, **j** in KOH; **1f–g** in KOH+CR; **1h–i** in KOH+IKI). — **1a–h**. TNS-F-56764 (H.B. 8424, holotype): Japan, on indet. angiosperm.

Habitat: on uneven decorticated surface of a probably thick log of unidentified broad-leaved tree on the moist ground, on deeply medium decayed wood, ungreyed, no algae. **Associated**: none observed. **Desiccation tolerance**: unknown (probably desiccation-sensitive). **Altitude**: ~100 m a.s.l. **Phenology**: VII.

Taxonomic remarks. *Orbilia spirospora* is characterized by small, cylindrical, strongly helicoid ascospores and obtusely lanceolate paraphyses, also by a very thick, strongly gelatinized medullary excipulum, and anchoring hyphae with a thick gel sheath (in KOH). *O. umbilicata* resembles *O. spirospora* in the paraphyses, but differs in wider, allantoid spores, longer asci, and a much less gelatinized, thinner medullary excipulum.

The spores of *O. spirospora* are consistently twisted like a left-hand thread. This is a rare feature of taxa of *Orbiliomycetes* with helicoid spores, being otherwise noted only in a few species of some other sections of *Orbilia* (*O. bomiensis*, *O. curvatiobliqua*, *O. helicoobliqua*, *O. helicovinosa*).

Ecology. *O. spirospora* occurred on medium rotten wood of a hygric log of an unidentified angiosperm tree in a subtropical humid (winter-dry) floodplain rainforest in southern Japan.

Specimens included. **JAPAN**: **Shikoku**, **Kōchi**, Shimanto River, ~100 m, log of indet. angiosperm, on wood, VII.1994, Kawasaki et al. (TRL 1072, TNS-F-56764, **holotype**, H.B. 8424 ø).

Orbilia minutispora Velen., Monogr. Discom. Bohem.: 98, pl. 11 fig. 40 (1934) — Pl. 869

Etymology: named according to the small spores.
Typification: Czechia, Mělník, stems and leaves of *Cirsium palustre*, 14.VIII.1924, J. Velenovský (PRM 149655, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1 mm diam., thin, light honey-yellowish-ochraceous (Velenovský: white), translucent, round to slightly undulating, gregarious; disc flat, margin thin, scarcely protruding, smooth; broadly sessile, superficial. **Asci** †18–26 × 2.4–2.7 µm, 8-spored, spores biseriate, orientation unclear, pars sporifera †11.5–12.5 µm; **apex** (†) hemispherical to slightly truncate; **base** with very short stalk, h- to H-shaped. **Ascospores** †2.7–3.6 × 0.9–1.1 µm, subcylindrical to narrowly ellipsoid, ends rounded to obtuse, straight (rarely slightly curved); **SBs** invisible in dead state. **Paraphyses** narrowly to mostly broadly lanceolate, with ± obtuse tips, terminal cells †15.5–21 × (1.8–)2.2–3 µm, exceeding the dead asci by 2.5–3.5 µm, lower cells †4–6 × 1.7–2.5 µm. **Medullary excipulum** not studied. **Ectal excipulum** of very thin-walled textura globulosa-angularis from base to lower flanks, cells †11–19 × 10–12 µm, 15 thick near margin, of t. prismatica oriented at a 60–90° angle to the surface, marginal cortical cells †10–14 × 4–5.5 µm, clavate, **glassy processes** absent. **Anchoring hyphae** not observed. **SCBs** & **VBs** no data available. **Exudate** granular, ~0.2–1 µm thick, hyaline, scattered between tips of paraphyses; on margin and flanks more abundant. — **ANAMORPH**: unknown.

Habitat: 4–5 mm thick stem and ?petiole of *Cirsium palustre*, medium decayed, with a rose-red stain. **Associated**: none observed. **Desiccation tolerance**: unknown (possibly intolerant). **Altitude**: ~180 m a.s.l. **Geology**: Upper Cretaceous clay- & marlstone. **Phenology**: VIII.

Taxonomic remarks. *Orbilia minutispora* is characterized by lanceolate, protruding paraphyses, and very small asci and ascospores. Also Svrček emphasized the paraphysis shape as most characteristic. Apart from this feature the microanatomy of *O. minutispora* recalls *O. epipora* or *O. atlantis* (section *Arthrobotrys*), the latter deviating also in much longer spores. The species might also be related to the more tropical *Orbilia alba* and *O. pilosa* (section *Arthrobotrys*). From the former it differs, e. g., in shorter spores and smaller apothecia, from the latter in broadly sessile apothecia and the complete absence of hairs.

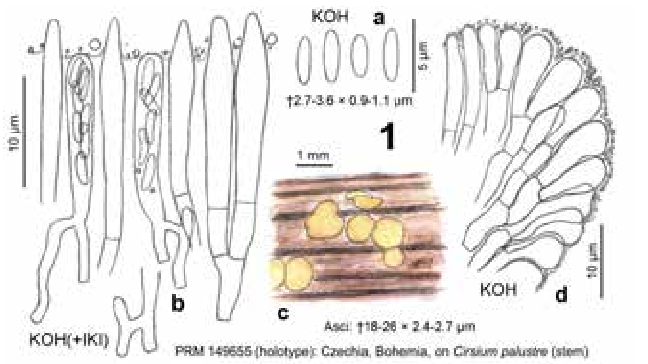

Plate 869. **1**: *Orbilia minutispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. rehydrated apothecia; **d**. marginal ectal excipulum in median section.

Type studies. Velenovský described and figured the paraphyses as filiform, apically obtuse, hardly inflated, covered by a 'vanishing epithecium', whereas Svrček found them to be mostly narrowly lanceolate and without exudate. In the present study small scattered granules were found lying over inconspicuous gel which is penetrated by the protruding parts of the distinctly lanceolate paraphyses. Only a few free straight spores were encountered; yet, within the asci they were also slightly curved. Svrček found them 'rather abundant, 2.5–4 × 0.8–1 µm, short acicular, straight or nearly so'. Also Velenovský described the spores as 'narrowly linear, often very slightly curved', 1–2.5 µm long (manuscript). He reported the fresh apothecia as translucent, white, 1–1.5 mm diam., whereas the rehydrated apothecia were found to be pale yellow (Svrček) or light honey-yellowish-ochraceous (present study).

Ecology. *O. minutispora* is only known from the holotype on hygric 'stems and leaves' (petioles?) of *Cirsium palustre* in a marsh with *Geoglossum fechtneri* in cold-temperate humid, subcontinental central Bohemia (eastern Europe).

Specimens included. **CZECHIA**: **Central Bohemia**, ~11 km SE of Mělník, Všetaty, ~180 m, stem & ?petiole of *Cirsium palustre*, 14.VIII.1924, J. Velenovský (PRM 149655, **holotype**, H.B. 6184 ø).

Orbilia dryadum (Velen.) Baral & E. Weber, in Quijada et al., Phytotaxa 284(4): 245 (2016) — Pls 870–872, Map 139

Basionym: *Orbilia alnea* var. *dryadum* Velen., Monogr. Discomyc. Bohem.: 93 (1934)

Etymology: named after the dryads (tree nymphs) who are said to dance at night under the waterfalls, referring to the type locality, Bubovické vodopady.
Typification: Czechia, Karlštejn, log of *Tilia*, X.1926, J. Velenovský (PRM 151745, holotype); Germany, Tübingen-Pfrondorf, branch & log of *Fagus sylvatica*, 16.VII.2006, E. Weber & H.O. Baral (ex H.B. 8224a, M-0291769, epitype, designated here, MBT385131; sq.: KT222358).
Misapplied names: Bachman (1909: 58), as *O. xanthostigma*; Beaton & Weste (1979), as *O. epipora*, Spooner (1987: 166, fig. 20), as *O. cunninghamii* (?= *O. dryadum*); Korf (1992, p.p.), as *O. epipora*; Liu (2006: 76, p.p.), as *O. epipora*; Pfister (1997: fig. 6, D.H.P. 184), as *O. ?alnea*; Spooner (in Kirk & Spooner 1984: 573, fig. 9 A), as *O.* cf. *acuum*.

Description: — **TELEOMORPH**: **Apothecia** fresh (0.25–)0.3–1(–1.5) mm diam., 0.12–0.25 mm high (receptacle 0.07–0.13 → 0.05–0.1 mm), white or usually pale to light carneous-cream, yellowish or (isabelline-)rosaceous(-lilaceous), translucent, round, sometimes strongly undulating-lobate when large, scattered to subgregarious, sometimes densely gregarious in small groups; disc slightly (to medium) concave, finally flat, margin distinct, thin or thick, somewhat raised, 0–5 µm protruding, smooth; subsessile or often with a broad obconical stipe 0.05–0.1(–0.13) × 0.2–0.4 mm, superficial, sometimes with white subiculum; dry light to bright cream to rose or apricot.

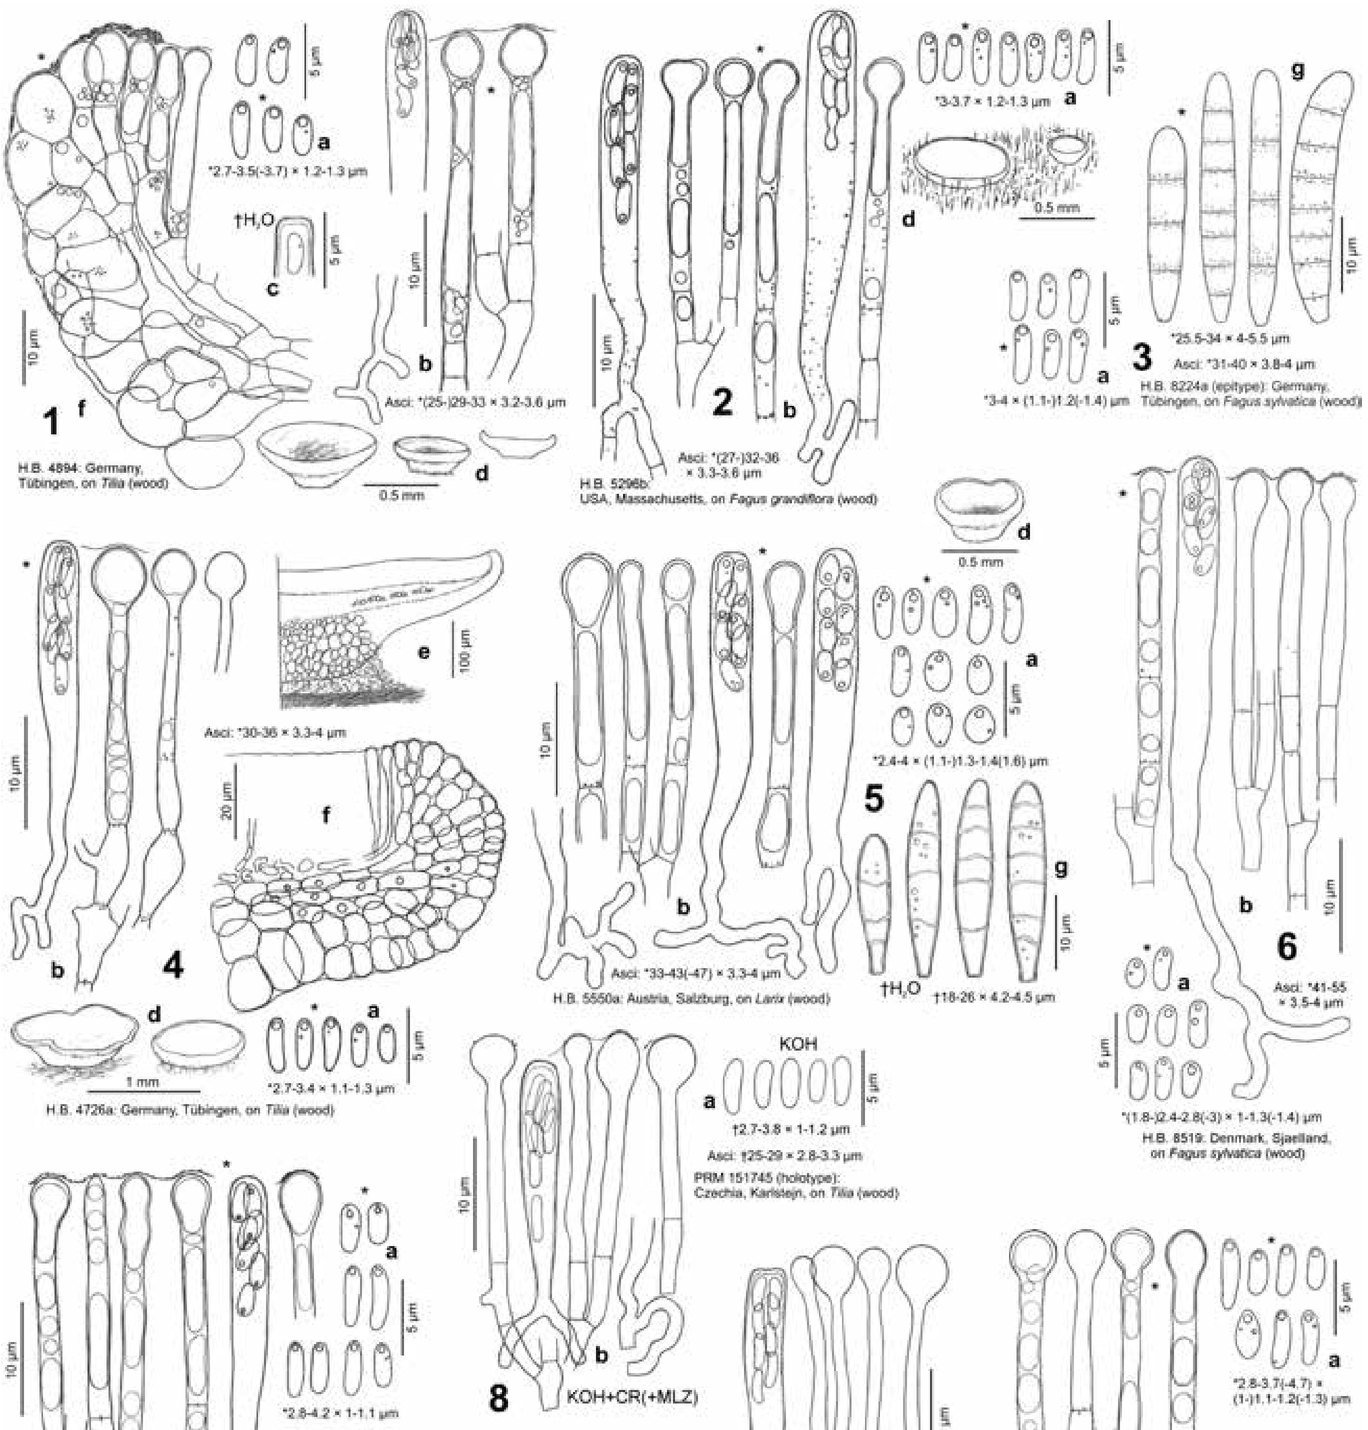

Plate 870. **1–6**, **8–10**: *Orbilia dryadum*; **7**: *O.* aff. *dryadum*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. fresh apothecia; **e**. apothecium in median section; **f**. id., ectal excipulum at margin and flanks; **g**. conidia from substrate.

Asci *((24–))(25–)29–41(–45)((–55)) × (2.8–)3.2–4(–4.5) µm {17}, †(22–)23–33(–41) × (2.3–)2.7–3.3(–3.8) µm {14}, 8-spored, spores *2–3-seriate, ((1–))(2–)3–5(–6)((–7)) lower spores inverted {15} (often mixed), pars sporifera *(8–)10–14(–16) µm long; **apex** (†) medium or mostly strongly truncate (not or rarely slightly indented, laterally not widened); **base** mostly with short to long, thin, flexuous stalk, T-, L-, Y- or often h- to H- shaped. **Ascospores** *((1.8–))(2.3–)2.7–3.9(–4.2)((–4.7)) × (1–)1.1–1.3(–1.5) µm {29}, †(2–)2.5–3.5(–4) {12} × 0.8–1 {3} or (0.8–)1–1.2(–1.3) µm {9}, (sub)cylindrical, some slightly cuneate (wedge-shaped), rarely ellipsoid, both ends rounded, straight to (very) slightly inequilateral or curved; **SBs** *(0.2–)0.3–0.6(–0.8) µm diam. {15}, total length (0.4–)0.5–0.8(–0.9) µm, globose, sometimes with a thin, very short filum, with a few minute **LBs**. **Paraphyses** apically slightly or usually medium to (very) strongly capitate, terminal cells *(15–)16–24(–28) {12} × (2–)2.5–4.5((–5)) µm {16}, †13–22 {2} × (2.2–)3–4.2(–4.5) µm {3}, lower cells *(3–)4–8(–10) × (1.3–)1.5–2.8(–3.5) µm {8}, †3–7 × 1.3–1.9 µm {2}; sometimes branched at upper septum. **Medullary excipulum** hyaline, 30–50 µm thick, of medium dense textura globulosa-prismatica-intricata, ± horizontally oriented, medium sharply delimited from ectal excipulum only at flanks by a 5–10 µm thick layer of t. porrecta. **Ectal excipulum** hyaline, of thin-walled (to slightly gelatinized), vertically oriented t. globulosa-angularis(-prismatica) from base to margin, 40–120 µm thick near base, cells */†9–20 {6} or 20–35(–45) {5} × 7–15 {6} or 10–26 {7} µm; 15–40 µm thick at flanks, 10–20 µm near margin, oriented at a 30–70 {5} or 90° {2} angle to the surface, marginal cortical cells *(3–)4–9(–12) × (2.7–)4–6(–8) µm {7}; **glassy processes** absent. **Anchoring hyphae** medium (to very) abundant, */†(1.5–)2–4(–5)((–6)) µm wide, walls 0.2(–0.3) µm thick {7}, forming a loose or dense, hyaline, 20–30 µm thick t. intricata. **SCBs** globose, in paraphyses 0.3–1 µm diam., inconspicuous between VBs, often in small groups, in marginal excipulum ~0.6–2 µm diam., in medullary excipulum exceptionally with globose, medium to strongly refractive guttules (?SCBs) 1–2.5 µm diam. {2}; **VBs** globose to strongly elongate, very low- to high-refractive, hyaline {13}, sometimes absent (especially in more mature paraphyses) {5}. **Exudate** over paraphyses absent, over margin 0.2–1 µm thick, sparse, granular to cloddy-continuous. — **ANAMORPH**: dactylella-like (from ascospore isolate {3} and natural substrate {9}). **Conidiophores** *10–105 × 2–3(–4) µm, (0–)1–3(–9)-septate, branched or unbranched, 1.3–1.7 µm wide above, conidia formed terminally {including data from Liu 2006, Pfister 1997, and M. Bemmann pers. comm.}. **Conidia** cylindric-ellipsoid to fusoid, straight; in pure culture 23–33 × 5–6.3 µm, 3–4(–6)-septate {Pfister 1997}, 22.5–56 × 4–6.5 µm, 2–8-septate {Liu 2006}, *(16–)24–30 × (3.2–)3.5–4 µm, (0–)1–3-septate {H.B. 8223}; on natural substrate *(16–)22–35(–42) × (2.8–)3.2–5(–5.5) µm {9}, †18–26 × 4.2–4.5 {1} µm, (1–)3–6-septate {10}.

(temperate Europe), 1750 m (subalpine, Austria, on *Larix*), 850–1520 m (Macaronesia). **Geology**: Cambrian & Ordovician siltstone & quartzitic wacke, Silurian & Devonian sedimentary rock, Buntsandstein, Keuper (marl & sandstone), Cretaceous, Paleogene & Miocene sand- & limestone, till & tuff; granite, migmatite, gneiss; tephritic, phonolitic and basaltic flows or pyroclasts. **Phenology**: IV–X(–XII) (in Macaronesia I, III–IV, VI, IX).

Phenology of *O. dryadum* (temperate northern hemisphere)											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0	0	0	3	2	4	9	6	4	7	0	2

Taxonomic remarks. *Orbilia dryadum* is characterized by cylindrical to somewhat cuneate (wedge-shaped), almost straight, small, comparatively wide ascospores with globose SBs very close to the apex, and medium to mostly strongly capitate paraphyses without exudate. The similar *O. epipora* (section *Arthrobotrys*) is separated by slightly longer and narrower spores, somewhat shorter asci, never strongly capitate paraphyses (in the living state), consistently white apothecia which often grow densely gregarious over large areas (a feature never seen in *O. dryadum*), and in distinctly smaller, especially narrower conidia with fewer septa. *O. cunninghamii* from New Zealand differs from *O. dryadum* in longer spores that tend to be slightly curved.

The tropical *O. gaillardii* resembles *O. dryadum*, but differs in shorter and wider, more ellipsoid spores, and bright (yellow-) orange apothecia. *O. eucalypti* differs in more ellipsoid and distinctly wider spores and in its dicranidion-like anamorph. *O. battenii* differs in shorter spores and branched conidia, but two samples included in *O. dryadum* (Denmark, Sjælland, Pl. 870: 6; France, Finistère, IVV: 6.XII.2013, spores *2.2–2.7 × 1–1.2 µm) have a spore size as in *O. battenii*, but are treated under *O. dryadum* because of the associated unbranched conidia. *O. acuum* (tentatively assigned to section *Arthrobotrys*) differs in longer spores with apparently tear-shaped SBs. *O. orientalis* (section *Arthrobotrys*) differs, e.g., in wider spores with very different SBs, and usually also in the presence of glassy processes, in addition to its drechslerella-like anamorph.

Variation. Apothecial colour varied among the collections from white to often light isabelline-rosaceous-lilaceous or rosaceous-carneous-cream. Apothecial size ranged between (hydrated) 0.25–0.45 and 0.5–1.5 mm diam. (in the type 0.4–1.2 mm). This variation in size was even observed within a collection (Pl. 871: 2a–d vs. 2e), though on different branches. At a single site near El Pico (Asturias) a population of light yellow-ochraceous apothecia grew on *Salix* (IVV: E.R.D. 5978) while another of white apothecia grew a year later on the same host genus (IVV: E.R.D. 6172). In their microscopy no clear differences could be found (E. Rubio pers. comm.), but because of the strong macroscopic resemblance of the white population with *O. epipora* (section *Arthrobotrys*) and the absence of clear microscopic differences to that species, we tentatively placed E.R.D. 6172 in *O. epipora*.

The asci were mainly around *30–40 µm long, but in a sample from Denmark (Pl. 870: 6) they were much longer (*41–55 µm), and a few samples had extraordinarily short asci (*24–30 µm, e. g., Pl. 870: 10). Great variation in the size of the basal and marginal excipular cells was noted among the populations, partly even at the same collection site, but this was hardly correlated with other features. Ascospore length varied between *2.4–3 (Pl. 870: 6) and *3–4 µm (Pl. 870: 3), and intermediate values were also frequent. Irrespective of spore length, spore width varied between *1–1.1 and *1.2–1.4 µm. The presence of rather long and narrow spores thereby complicated delimitation from *O. epipora*.

Collections from Tenerife (Macaronesia) are somewhat intermediate between *O. dryadum* and *O. epipora*. They show a spore width at the lower end of the range of *O. dryadum*, but fit this species better because spore length is below that of *O. epipora* and the paraphyses more capitate. For instance, in

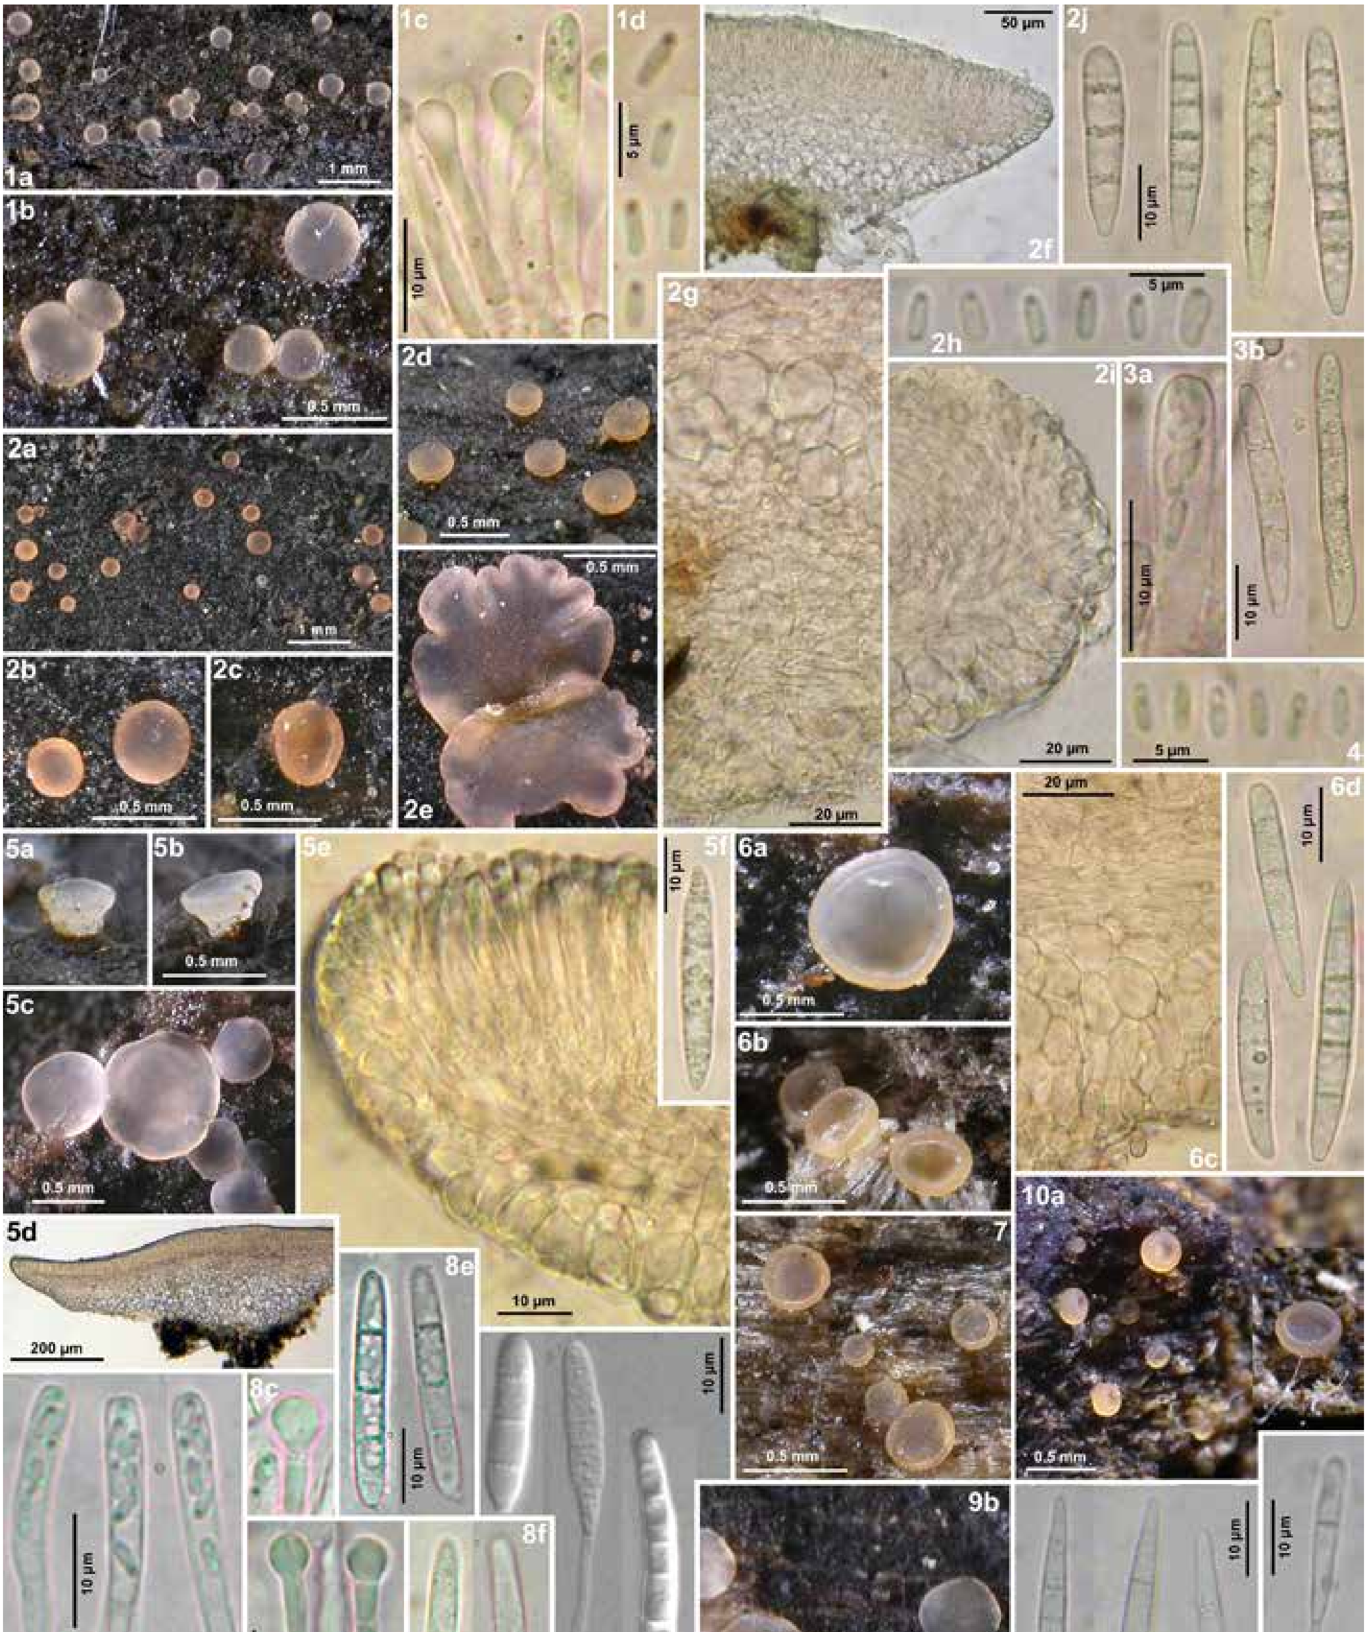

Plate 871. **1–10**: *Orbilia dryadum*. – **1a–b**, **2a–e**, **5a–c**, **6a–b**, **10a**. fresh apothecia; **7**, **9b**. rehydrated apothecia; **2f**, **5d**. apothecia in median section; **2i**, **5e**. id., ectal excipulum at margin and flanks; **2g**, **6c**. id., near base (**2g** with anchoring hyphae); **1c**, **3a**, **8a**, **c–d**. asci and paraphyses (**3a** fully turgescent); **1d**, **2h**, **4**, **8b**. ascospores; **2j**, **3b**, **6d**, **8e–f**, **10b–c**. conidia from substrate, partly on conidiophores; **5f**, **9a**. conidia & conidiophore from culture. – Living state, except for **4**, **9a** right conidium (in H_2O). – **8a–f**: phot. H.B. 6876a: France, Bretagne, Glénac, on *Ulex*; **4a–c**: H.B. 6878: id., Talhuart, on *Ulex*.

CUP-MM-000245 (on angiosperm wood) the spores measured †2.7–3.5 × 0.8–1 µm, and in three samples on wood of *Pinus* (H.B. 6904a = A.H. 7349), *Ocotea* and *Chamaecytisus* *2.3–3.2(–3.8) × 1–1.2(–1.3) µm. In their gross morphology in the living state the three latter samples do not differ from typical European specimens. Also ascus size fits *O. dryadum* (*27–41 × 2.7–3.5 µm, Quijada et al. 2016), though ascus width is at the lower end of the range of European samples of that species, whereas asci of *O. epipora* are with *22–29(–32.5) × 2.8–3.5 µm distinctly shorter.

In some European collections (Pl. 870: 5, wood of *Larix*; 870: 7, bark of *Ulex*; IVV: 6.XII.2013, wood of *Carpinus*) the paraphyses are only slightly to medium capitate, reminiscent of *O. epipora*. Yet, the degree of apical inflation generally varies rather strongly within an apothecium. The collection on *Larix* represents the only known subalpine record referred by us to *O. dryadum*. Here some of the asci contained distinctly broader, often ellipsoid spores of *2.2–3 × 1.6–2 µm. Such anomalous ellipsoid spores inside living mature asci were exceptionally also seen in a colline specimen from Tübingen on *Fraxinus* (H.B. 8223, Pl. 870: 10).

Conspicuous globose ?SCBs in the medullary excipulum were seen in two collections (H.B. 4726a, Pl. 870: 4f; H.B. 4894a) which both originate from the same trunk of *Tilia* though gathered in different years. No other collection was noted in which such cell contents were seen.

Type studies. Velenovský's very brief description of *O. alnea* var. *dryadum* includes 1–1.5 mm large apothecia with a rose tint, and ochraceous, thick-walled, 15–17 µm large 'corpuscules'. The latter are spores of an unknown fungus (Svrček 1954: 9). On Velenovský's manuscript plate these spores are drawn ellipsoid and non-septate. In the present reexamination of the holotype they could not be found, instead dark brown setae and medium red-brown, 2-septate pyriform conidia of *Brachysporium obovatum* occur in association.

The rather rich holotype (Pl. 870: 8) fits well Velenovský's manuscript plate on which the spores are depicted cylindrical to narrowly ellipsoid, 2–3 µm long, with 2 rather large globose drops, one at each end. These drops are very probably SBs, and it seems likely that Velenovský was incorrect in placing them at both ends of the spore. Svrček (1954: 9) identified this taxon as *O. xanthostigma* s. Svrček (= *O. eucalypti* or *O. tremulae*).

A specimen from Germany (Tübingen-Pfrondorf, on *Fagus*, ex H.B. 8224a, Pls 870: 3; 871: 2) from which a sequence was gained, is designated here as **epitype** of *O. dryadum*.

Misapplication and literature reports. Kirk & Spooner (1984: 573, fig. 9A, erroneously as 'B' in legend and text) reported under the name *O.* cf. *acuum* a collection on decorticated wood from Scotland (Isle of Arran, 8.IX.1980, P. Kirk) with consistently 'cylindric-clavate' (wedge-shaped) ascospores (2.5–3 × 0.8–1 µm, from scale 2.7–3 × 1–1.2 µm). This appears to fit very well our concept of *O. dryadum*. The same is true regarding the teleomorph of Pfister's (1997: fig. 6) *Dactylella* sp. from Maine (as *O. ?alnea*), which shows predominantly slightly wedge-shaped spores according to our reexamination (Pl. 870: 9). Likewise, Bachman's (1909: 58, pl. IV figs 9–12) report of two samples under the name *O. xanthostigma* (from Ohio, on old logs, apothecia 1–3 mm, reddish-yellowish, spores 3–4 × 1.5 µm, cylindric-clavate, paraphyses capitate) probably represents *O. dryadum*, judging from the illustration.

Under the name *O. cunninghamii*, Spooner (1987: 166) redescribed a collection from Australia that was first identified as *O. epipora* by Beaton & Weste (1979). However, it resembles also *O. dryadum*, to which it perhaps better fits (for more details see p. 1393). Under the name *O. epipora* Liu (2006: 74) reported several collections from China with spores 2.5–3 × 1.2–1.3 µm. One of them (from Xinjiang, B.L. 6516, Pl. 871: 9) was found to fit well European *O. dryadum* (spores †2.5–3.2 × 1.1–1.3 µm), including its anamorph and molecular data (see below), whereas a strain from Guangxi (B.L. 6195, not illustrated in Liu l.c.) is genetically very distant and of unclear identity (Phyl. 22), and at least one of the samples from Chongqing (earlier Sichuan) belongs with its slightly curved spores and ± spathulate paraphyses more in vicinity of *O. umbilicata* (Pl. 865: 3).

Not included collections. Four samples from Bretagne on bark of *Ulex* represent the only records of *O. dryadum* on bark known to us (Pls 870: 7; 872: 3–4). The microscopic features are quite the same as in those on wood [spores *(2.5–)3–3.5(–4.2) × 1–1.2(–1.3) µm]. The paraphyses were often only medium capitate, but strongly capitate apices also partly occurred. However, differences in conidial length and sequence data of one of them were observed (see below). The two samples from subtropical Yunnan and Jiangxi (Pl. 872: 1–2) differ in extraordinarily long spores of */†3.5–4.5(–4.8) × 1–1.4 µm. For the not included Australian specimen see under Misapplication and literature reports.

Anamorph. Pfister (1997, fig. 6) reported a *Dactylella* sp. which he obtained from an ascospore isolate of '*O. ?alnea*' (D.H.P. 184, = D.H.P. 107 fide Pfister pers. comm., USA, Maine, on wood of *Alnus*) which was here reidentified as *O. dryadum* (see above). Also its subcylindrical conidia as figured by Pfister fit quite well in size, shape and septation those conidia we have found in some of our collections on the natural substrate (e. g., Pls 870: 3g; 871: 2j, 3b, 6d, 8e–f, 10b), except that Pfister's conidia are slightly wider, and conidia observed by us sometimes tend to be fusoid. From the mentioned collection from Xinjiang (B.L. 6516, on wood of *Betula*), Liu (2006) obtained a very similar anamorph in culture (as *Dactylella* cf. *coccinella*, Pl. 871: 9a), with conidia as wide as in Pfister's strain, though partly longer and with more septa.

In a subalpine collection on wood of *Larix*, conidia were observed on the natural substrate (Pl. 870: 5g) which differ from planar to montane records on angiosperm substrates, including Pfister's and Liu's strains, in being rather short and consistently fusoid in shape. Also in pure culture of a specimen collected in Tübingen (on wood of *Fraxinus*, same site as Pl. 870: 3), a few rather narrow, ± fusoid conidia with a moderate to high lipid content were formed (Pl. 871: 5f). Similar fusoid conidia with a moderate lipid content were found close to apothecia on wood of *Corylus* (IVV: J.N. 06-228, †32–34.5 × 3.4–3.9 µm, ~3-septate), and on bark of *Ulex* (Pl. 872: 3b), while in one on *Alnus* from northern Germany the fusoid and rather narrow conidia are with a low lipid content (Pl. 871: 10a–b). In the *Ulex* specimen conidial length was at the upper end of the range (*37–52 × 3.5–4 µm, 6-septate), and also its molecular data deviate (see below), therefore, we refrained from including records on bark in the description of *O. dryadum*.

The conidiophores varied in length: they were rather short on the natural substrate (10–33 µm, Pl. 871: 8f, 10c), but partly rather long in pure culture (10–105 µm, Liu 2006). Also in Pfister's (1997) culture they tend to be long.

Yang & Liu (2005) observed a dactylella-like anamorph in a strain (CBS 916.72, CCRC/BCRC 33148) that was isolated by R.G. Benedict in or before 1972. It was probably gained from ascospores and was misidentified at that time as *Orbilia coccinella*, probably by the finder. The geographical origin of this strain could not be clarified. Probably it derives from USA, since Benedict worked at that time at the University of Washington in Seattle (the same applies to a strain which was named *O. vinosa*, see under *O. sinensis*, section *Helicoon*., p. 1006).

Yang & Liu (2005) described Benedict's strain as a new anamorph-typified species which they named after the specific epithet of the teleomorph as *Dactylella coccinella* Ying Yang & Xing Z. Liu (holotype HMAS 87787, dried culture). The figured conidia are very similar to those reported by Pfister (1997) and Liu (2006), showing a (sub)cylindrical shape and a size of *22.5–32.5 × 5–6.5 µm, with (1–)3–6(–7) septa. The features of the teleomorph are unknown, however. Judging from its anamorph, Benedict's strain is certainly not conspecific with *O. coccinella* s.auct. (= *O. eucalypti* or *O. tremulae*, with a dicranidion-like anamorph), and most probably also not with the type of *O. coccinella*, a rare fungus known only from the type collection from northern Norway (see p. 1427). For its molecular data see below.

Phylogeny. Sequences of *O. dryadum* were available from five strains. Four derive from ascospore isolates: USA, Maine, wood of *Alnus* (D.H.P. 107 = 184, ITS); China, Xinjiang, on wood of *Betula* (B.L. 6516, ITS+LSU); Germany, Gießen, wood of ?*Carpinus* (F.P. 390, ITS); Germany, Mönchengladbach, wood of *Alnus* (G.M. 2014-04-23, ITS+LSU), and one from apothecia: Germany, Tübingen, wood of *Fagus* (H.B. 8224a, ITS). A further sequence was gained from an ascospore isolate from France, Morbihan, bark of *Ulex* (H.B. 6876a, SSU+ITS+LSU), here referred to as *O.* aff. *dryadum*. The S1506 intron is absent in the strains from *Fagus* and *Ulex*, but present in the German strain from *Alnus*. The strains D.H.P., F.P., and B.L. do not cover the intron region.

In our analysis of ITS (Phyl. 23) the six strains of *O. dryadum* s.l. clustered together in a strongly supported clade which nested in our combined analysis (Phyl. 22) weakly supported in the *xanthostigma-tremulae* clade. *O. dryadum* s.str. falls into two close groups which differ in the ITS by 1.4% (7 nt): thereby, the Chinese strain fully concurs with German strains on *Fagus* and ?*Carpinus*, and the German strain on *Alnus* completely matches Pfister's strain on the same host. This is very surprising, considering the high geographical distance between the strains with identical ITS data and comparatively low distance (180–340 km) among the three German strains. Despite the observed 1.4% deviation, the five strains, which all were from apothecia on decorticated wood, are considered by us to represent typical *O. dryadum*.

The collection on *Ulex* bark shows a distance of 6.5–6.7% in the ITS region to *O. dryadum* s.str., which indicates that two species are involved. In the LSU (D1–D2) *O. dryadum* varies by 1 nt (0.2%) but differs from the *Ulex* strain by 1.4–1.6%. Compared to these distances, European *O. epipora* differs from *O. dryadum* s.l. by ~23–26% in the ITS and 9–9.5% in the LSU, and from another Chinese strain under the name *O. epipora* (B.L. 6195) by 22.5% in the ITS and 5–6% in the LSU; it clustered in Phyl. 22–23 unsupported near *O. guyanensis* but in S27 weakly supported sister to *O. leucostigma*). *O. cunninghamii* differs from *O. dryadum* by 18–18.5% (17.5% from *O.* aff. *dryadum* on *Ulex* bark).

In Yang & Liu's (2005) molecular analysis of the ITS region, Benedict's strain of '*Orbilia*/*Dactylella coccinella*' (CBS 916.72) clustered together with Pfister's North American strain of *O. dryadum* (as *O. alnea*). Also in our ITS analysis (Phyl. 23) *O. dryadum* clustered with Benedict's strain, though unsupported. Yang & Liu concluded that this indicates a close relationship between *O. coccinella* and *O. alnea*, with 3 nt difference in the 5.8S rDNA. However, this gene region is very conservative. When comparing the complete ITS region, the two strains show a distance of 17%, as was also stated by Liu (2006: 75), hence their conspecificity can be excluded. Due to this distance, Liu (2006) named the anamorph of his Chinese strain B.L. 6516 *Dactylella* cf. *coccinella*. *O.* aff. *dryadum* on *Ulex* is only slightly closer to Benedict's strain, differing by 15.3%.

Ecology. *O. dryadum* is known from rotten decorticated wood of hygric branches and logs of various angiosperm trees and shrubs, exceptionally gymnosperms or resupinate basidiomycetes. The species was mainly recorded from humid, cold-temperate, rarely suprasubmediterranean or orotemperate (subalpine), subcontinental but also warm-temperate atlantic Europe. The recorded vegetation includes shady forests (*Querco-Fagetum*, *Aceri-Fraxinetum*), partly close to rivulets or forest ponds, the substrate being sometimes flooded. The observed drought tolerance in two samples from Denmark is surprising since the apothecia grew on the underside of logs lying on the moist ground.

Collections from Macaronesia include lower mesomediterranean (sub)humid laurel forest (*Lauro novocanariensis-Perseetum indicae*), and subhumid and pine forest (*Sideritido solutae-Pinetum canariensis*). Two samples from central Asia (Sayan and Altay Mountains) represent an altimontane cold-continental humid climate. Records from a tropical humid (winter-dry) region in Taiwan and an altimontane site in central Honshu in Japan, together with collections from (north) eastern North America from cold-temperate humid lowland forests suggest a worldwide distribution of *O. dryadum*.

Among the not included samples, those on hygric bark of *Ulex* are from atlantic, warm-temperate humid lowlands of northwestern France, one on hygric angiosperm bark from subtropical humid (winter-dry) montane evergreen forests in southern China, and one on hygric wood from an oceanic, warm-temperate humid eucalypt tall open forest in the southernmost part of southeastern Australia.

Map 139. Known distribution of *O. dryadum* in Europe and Tenerife (Macaronesia, cyan = *O.* aff. *dryadum* on *Ulex* bark).

Specimens included. **GREAT BRITAIN**: **Scotland**, **North Ayrshire**, Isle of Arran, 3 km NNE of Brodick, Merkland Point, near old quay, ~5 m, indet. wood, 8.IX.1980, P. Kirk (K, as *O.* cf. *acuum*, Kirk & Spooner 1984: 573). — **DENMARK**: **Sjælland**, 6.5 km S of Sorø, 4 km S of Frederiksberg, Suserup Skov, 30 m, log of *Fagus sylvatica*, on wood, 25.V.2007, H.O. Baral (H.B. 8519, T.L. 13057 [in C and S], anam. substr.). – 6 km S of Sorø, 3 km S of Frederiksberg, N of Suserup, 33 m, branch of *Salix*, on wood, 28.V.2007, J.G.B. Nielsen (H.B. 8530). – Falster, 11 km WNW of Nørre Alslev, 4 km W of Vålse, Resle Skov, 14 m, branch of *Corylus avellana*, on wood, 30.X.2006, J.G.B. ***Orbilia* sp.**: **CHINA**: **Guangxi**, **Xishan**, Guiping, 180 m, indet. wood, 2.VIII.2002, B. Liu (B.L. 6195, HMAS 139540, as *O. epipora*, non vid.; sq.: DQ656619).

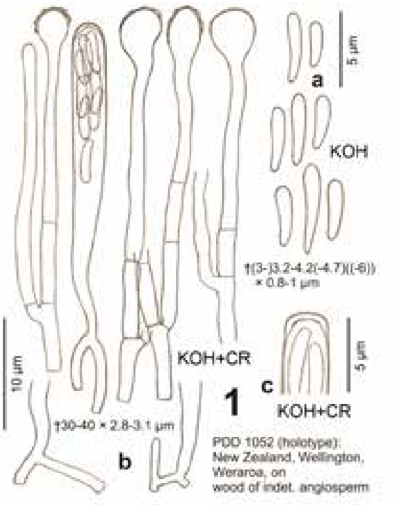
Orbilia cunninghamii Syd., Ann. Mycol. 22: 308 (1924) — Pls 873–874, Map 140

Etymology: after the collector G.H. Cunningham, a New Zealand mycologist.
Typification: New Zealand, Wellington, Weraroa, branch of indet. angiosperm, 16.IX.1919, G.H. Cunningham (PDD 1052, holotype).
Misinterpretation of *O. cunninghamii*: Spooner (1987: 166 fig. 20), ?= *O. dryadum*; Liu et al. (2002, cited in Zhang & Mo 2006: 20), = *Orbilia quercus*.
Misapplication: Dennis (1956: 296, as *O. epipora*), ?= *O. cunninghamii*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.5–)0.8–1.3(–1.6) mm diam., 0.15–0.25 mm high (receptacle 0.2 → 0.1 mm), white when fresh (Sydow: rehydrated yellow-ochraceous to egg-yellow), medium translucent, round, to slightly undulating, (sub) gregarious; disc young medium concave to flat, with a slight to distinct central depression, margin somewhat thickened, 10–20 µm protruding, smooth; with an indistinct stipe 0.04–0.8 × 0.25–0.5 mm, superficial; dry almost orange (Sydow). **Asci** †30–40 × 2.8–3.1 µm {2}, 8-spored, spores 3–4-seriate above, lower spores inverted {1}, pars sporifera †14–15 µm; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to long, thin, flexuous stalk, L-, Y-, h- or H-shaped. **Ascospores** †(3–)3.3–4.2(–4.7)((–6)) × 0.8–1((–1.1)) µm {3}, narrowly cylindric-clavate, apex rounded, slightly to distinctly tapered towards base (cuneate), straight to often slightly curved; **SBs** unknown, **LBs** not seen. **Paraphyses** apically (medium) strongly (very strongly) capitate-clavate, terminal cells †15–20 × 2.2–3.5(–4) µm {T}, lower cells *4–7 × 1.2–1.5(–1.7) µm {T}; never branched at upper septum. **Medullary excipulum** 70–90 µm thick, of dense, horizontal textura intricata with many slightly inflated cells, sharply delimited from ectal excipulum, towards margin with or without a 5–10 µm thick layer of loose t. porrecta. **Ectal excipulum** of (†) thin-walled, slightly gelatinized in basal cortex and especially near medullary excipulum, vertically oriented t. globulosa-angularis-prismatica from base to margin, 60–80(–90) µm thick near base, cells †(8–)10–21(–26) × 8–17 µm {2}, 25–30 µm thick near margin, oriented at a 40–60° angle to the surface, marginal cortical cells †5–9 × 4–5.5 µm {T}; **glassy processes** absent {T} or as ~0.5–1 µm thick caps {1}. **Anchoring hyphae** abundant near base, †1.5–3 µm wide, walls 0.15–0.2 µm thick {2}, forming a 10–60 µm thick, dense t. intricata. **SCBs** and **VBs** no data available. **Exudate** over paraphyses absent or 0.2–0.4 µm thick, rough, firmly attached, over margin and flanks ± absent. — **ANAMORPH**: dicranidion- & dactylella-like (from ascospore isolate {1}, P.R. Johnston pers. comm.). **Conidiophores** unbranched. **Conidia** of 2 types: (1) unbranched, cylindric-clavate, 2–4-septate, straight; (2) branched, with parallel, 1–2-septate arms and a basal nodulous scar [measurements not given].

Habitat: lying on ground, branches and logs of *Beilschmiedia tawa* {2}, *Weinmannia racemosa* {1}, indet. angiosperms {3}, indet. woody plant {13}, on medium rotten wood {15} and bark {2}, pores of ?*Phellinus* {1}. **Associated**: *Hyalorbilia* ?*ulicicola* {1}, *Rhizodiscina lignyota* {1}. **Desiccation tolerance**: unknown (probably intolerant). **Altitude**: 47–790 m a.s.l. **Phenology**: IX–VI (southern hemisphere).



Pl. **873**. **1**: *Orbilia cunninghamii* (holotype). – **a**. ascospores; **b**. ascus and paraphyses, ascus bases; **c**. ascus apex

Taxonomic remarks. *Orbilia cunninghamii* was so far studied only in the dead state. It resembles *O. epipora* (section *Arthrobotrys*) and *O. dryadum* in ascospore morphology, but differs in longer asci and basally consistently gradually tapered spores. Typical *O. epipora* further deviates from *O. cunninghamii* by paraphyses with only slightly inflated apex and rather wide lower part, and *O. dryadum* by shorter and wider spores. The genetically related *O. tremulae* differs from *O. cunninghamii* in much wider, more ellipsoid spores. Within series *Neodactylella* of section *Arthrobotrys*, *O.* cf. *atlantis* (on *Phragmites* in Australia) and *O. acuum* resemble *O. cunninghamii* but have larger spores with a more tapered (obtuse) apex.

Type studies. *O. cunninghamii* was described by Sydow (1924) for a specimen collected on 16.IX.1919 by G.H. Cunningham on unidentified [angiosperm] wood near Wellington (New Zealand). Sydow characterized it by asci 32–38 × 2.5–3 µm, paraphyses hardly 1 µm wide, apically capitate, 3 µm wide, spores bacilliform, straight, 3–3.5 × 0.75 µm, minutely biguttulate. The present reexamination of the holotype (Pl. 873, Pl. 874: 1) concurs quite well except for slightly larger spores. Apothecial colour was yellow-ochraceous to egg-yellow in the type when rehydrated by Sydow a few years after it was collected, and when dry it was almost orange (Sydow 1924). In the present reexamination this colour was not clearly perceptible anymore.

During 1989–2006 P.R. Johnston (pers. comm.) collected in New Zealand six specimens, which he cultured and identified as *O. cunninghamii*. In the fresh state the apothecia were (greyish-) white. two of them (Pl. 874: 2–3) were here reexamined and found to match the holotype very well (asci †30–39 × 2.8–3 µm, spores †3.3–4 × 0.8–1.1 µm). Their apothecia displayed a light chlorinaceous-ochraceous colour when rehydrated 9 and 22 years after they have been collected.

A North American collection mentioned under *O. epipora* (Pl. 901: 7) fits the holotype of *O. cunninghamii* except for shorter asci and ± homopolar spores. When studied almost 70 years after it was collected, it displayed pale yellowish-ochraceous (dry deep ochre) apothecia unlike *O. epipora* (the previous identification as *O. xanthostigma* suggests that they were yellow when fresh). Also samples reported as O. *epipora*

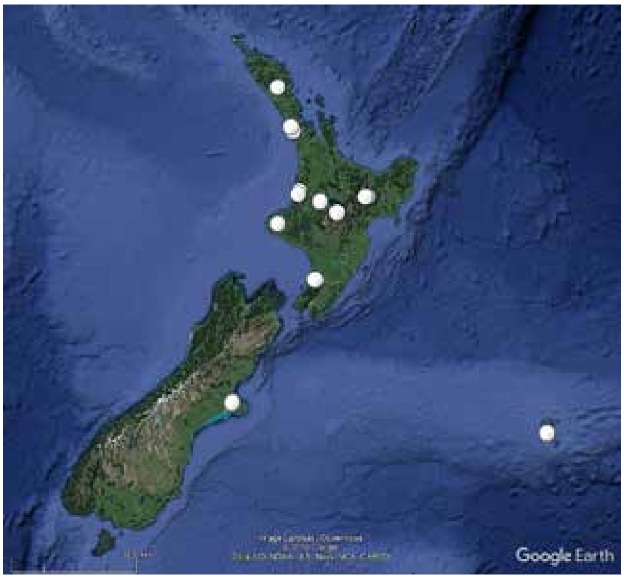
Pl. 874. 1–3: *Orbilia cunninghamii*. – **1a–c**, **2b–c**, **3a–b**. rehydrated apothecia; **2a**. dry apothecia; **3c**. median section of apothecium; **1d**. id., basal ectal excipulum and anchoring hyphae; **1e**. id., lower flanks; **3d**. id., margin region; **1f**. ascospores. – Dead state (**1d–f** in KOH, **3c–d** in H_2O). — **1**. PDD 1052 (holotype): New Zealand, Wellington, Weraroa, on indet. angiosperm; **2**. PDD 93943: Bay of Plenty, Ruatahuna, on indet. angiosperm; **3a–d**: PDD 60056: Auckland, Cornwallis, on ?*Phellinus*.

by Dennis (1956: 296) from Panama and Cuba might belong to *O. cunninghamii* because of their partly basally tapered spores of '3–4.5 × 0.5 µm'.

Because he was unable to locate holotype material, Spooner (1987: 166, fig. 20) described a specimen collected by G. Beaton in Australia (Victoria, near Laver's Hill, Hordern Vale road, on dead wood, 17.XI.1962, G. Beaton 43, as *O. epipora*, Beaton & Weste 1979). Spooner referred this sample to *O. cunninghamii* and thought that it 'agrees in all respects with the original description'. His description includes pale amber to orange-yellow apothecia, asci 32–40 × ~3 µm, and spores 3–4(–4.5) × 0.8(–1) µm, slightly curved, gradually tapered towards the rounded base (wedge-shaped). The given spore size would fit the here redescribed lectotype of *O. epipora*, but the spores are too wide when evaluating their size from Spooner's drawing (3.3–4.3 × 1–1.2 µm), and also the yellow colour and the longer asci exclude *O. epipora* but are in the range of *O. dryadum*, to which Beaton's specimen possibly belongs.

Spooner believed that *O. epipora* deviated from *O. cunninghamii*, besides apothecial colour and smaller asci, also by smaller apothecia (< 0.5 mm diam.), slightly longer and narrower spores (3.5–5 × 0.6–0.8 µm), and paraphyses usually immersed in a 'thin encrusting epithecium'. This conclusion was based on a specimen of *O. epipora* in Lundell & Nannfeldt, F. exs. Suecici 1780, with extraordinarily long spores, whereas the present restudy of the types revealed that *O. epipora* actually has spores of equal or even very slightly shorter length compared to *O. cunninghamii*. A sparse granular exudate ('epithecium') was only occasionally seen in the present study of both *O. dryadum* and *O. epipora*.

Anamorph. In one isolate (PDD 60056) P.R. Johnston (pers. comm.) observed an anamorph which he briefly illustrated with one dicranidion- and three dactylella-like conidia, the former resembling *Dicranidion fragile*. *Monacrosporium parvicolle* was



Map 140. Known distribution of *O. cunninghamii* in New Zealand.

reported by Liu et al. (2002) as anamorph of *O. cunninghamii*, but this refers to the type collection of *O. quercus*/*Dactylellina quercus* (B. Liu pers. comm.).

Phylogeny. ITS sequences were taken by P.R. Johnston (pers. comm.) from all of his six ascospore isolates of *O. cunninghamii*. Five of them cover the 3'-end of SSU, which always lacks the S1506 intron. In the ITS region they show a high molecular concordance, varying by only 0.2–0.4% (0–2 nt), which confirms that they belong to a single species (4 are shown in Phyl. 23). The closest species appear to be *O. tremulae*, *O. cejpii*, and the morphologically similar *O. dryadum* s.l., showing a rather high distance (15.5–16%, ~15–20%, and 17.5–18.5%, respectively), whereas *O. epipora* is distinctly more distant (23–23.5%). In our analysis of the ITS region, *O. cunninghamii* clustered with *O. dryadum* and *O. tremulae* in an unsupported clade, the latter two forming in Phyl. 24 the weakly supported *xanthostigma-tremulae* clade.

Ecology. *O. cunninghamii* is so far only known with certainty from New Zealand. It was collected on ± rotten, hygric wood or rarely bark of branches of different angiosperms, mostly unidentified (in the holotype the wood shows rather broad radial rays). Four collections were on identified hosts: *Beilschmiedia* (*Lauraceae*) and *Weinmannia* (*Cuneaceae*). The substrate appears to have always been lying on the moist ground. The species was especially collected in various regions of the North Island, from which all sequenced and studied strains derive, but also from the South Island and Chatham Island. The vegetation comprises cold-temperate to subtropical humid, oceanic (marine), indigenous forests and scrubs of *Nothofagus* or mainly of *Podocarpus*, sometimes mixed with *Agathis*, at colline to montane altitudes.

Specimens included. **NEW ZEALAND**: **North Island**, Northland, 23 km SW of Whangarei, Tangihua Forest, 260 m, indet. wood, 23.V.1992, P.R. Misapplied names: Feltgen (1899: 53, 1901: 35, 1903: 41, p.p.maj.), as *O. coccinella*; (1899: 54, p.p.), as *O. luteorubella*.

Misinterpretation of *O. leucostigma*: Ginko (1986), ?= *O. cejpii*; Nylander (1869) and Karsten (1869 p.p., as *P. leucostigma*), = *O. eucalypti*; Ekanayaka et al. (2018), = *Orbilia* sp. (mentioned under *O.* aff. *renispora*).

Misinterpretation of *O. xanthostigma* (selected cases): Bachman (1909: 58), ?= *O. dryadum*; Berthet (1964a: 126, 1964b: 23), = *O. tremulae*; Feltgen (1901: 35 p.p., on *Sorbus*), = *Hyalorbilia inflatula*; Fries and Bommer & Rousseau (in sched., as *P. xanthostigma*), = *O. auricolor*; Persoon (1796, 1801, 1822, p.p., as *P. aurea*), = *O. comma*; Svrček (1954: 23), = *O. eucalypti*; Thind & Sharma (1980), ?= *O.* aff. *luteorubella*; Zhuang (1997: 9), = *O.* cf. *umbilicata*; Guo et al. (2014b), = *Orbilia* sp. (?section *Arthrobotrys*).

Anamorph synonyms:

?= *Dicranidion gracile* Matsush., Microfungi of the Solomon Islands and Papua-New Guinea (Osaka): 24, fig. 47 (1971)

?= *Dicranidion tenue* Matsush., Matsush. Mycol. Mem. **7**: 49, fig. 725 (1993)

?= *Dicranidion dactylopagum* (Drechsler) Peek & Solheim, in Peek, University of Wyoming Publ. Sci., Bot. 19: 92 (1955)

≡ *Pedilospora dactylopaga* Drechsler, Journ. Washington Acad. Sci. 24(9): 400 (1934)

Etymology: *gracile* and *tenue*: according to the slender conidia, *dactylopaga*: after the finger-shaped conidia and the ability to trap rhizopods.

Typification: Solomon Islands, Honiara, wood of indet. angiosperm, 5.I.1970, T. Matsushima (MFC 2894, holotype of ***Dicranidion gracile***). — Peru, Rio Negro, palm petioles, XI.1990, T. Matsushima (MFC OP-460, holotype of ***D. tenue***). — USA, Washington D.C., decaying rootlets, undated, C. Drechsler (holotype of ***Pedilospora dactylopaga***, illustration in Drechsler 1934: fig. 1).

Combined description of *O. leucostigma* and *O. xanthostigma* (including extra-European specimens): — **TELEOMORPH**: **Apothecia** fresh (0.2–)0.35–2(–4.5) mm diam., 0.14–0.35 mm high (receptacle 0.11–0.2 mm), mostly pale to bright golden yellow-orange, yellow-ochraceous, or honey-yellow(-amber) {> 150}, more rarely (glassy) watery-white, pale chlorinaceous to yellowish-cream, or even pale isabelline to rosaceous-lilaceous-carneous {> 50}, centre often translucent (pale to light olivaceous), round to ± lobate when large, then sometimes with translucent concentric rings, often densely gregarious; disc slightly concave to flat, finally sometimes convex, margin thin or ± thick, 0–10 µm protruding, smooth; sessile or with an obconical base, also with a short and broad stipe of 0.02–0.2 × 0.15–0.8 mm, superficial; dry light to deep golden- or honey-yellow (with dark grey-brown centre), rose-orange-red or cream-ochraceous-isabellinea, margin not or often somewhat inrolled, colour fading in the herbarium. **Asci** *(25–)30–45(–53) × 3.2–4.3 {18} → 40–55 × (3.8–)4–4.8(–5.3) µm {3}, 0–5 → 3–10 µm projecting beyond asci, †(24–)27–41(–45) {36} or 45–52 {1} × (2.5–)2.7–3.7(–4.3) µm {37}, 8-spored, spores uniseriate, some of the 8 spores inverted (sometimes the basal ones, often oriented in various directions), pars sporifera *12–16(–19) → (8–)9–12(–15) µm long; **apex** (†) strongly truncate (sometimes slightly to distinctly indented, laterally indistinctly inflated); **base** with short to long, thin, flexuous stalk, h- to often H-shaped, rarely T- or L-shaped. **Ascospores** *((2–))(2.2–)2.4–3(–3.3) × (1–)1.1–1.4(–1.6) µm in situ (excluding warts) {~60} (~3.5–4.2 µm actual length), †((2–))(2.2–)2.3–2.8(–3) × ((0.8–))(0.9–)1–1.3(–1.5) µm {~37}, (reniform to) cashew-shaped, curved by ~(90–)120–180° (± semicircular), ends rounded to obtuse, basal end rarely slightly more tapered, dorsal side (and also laterally) with a row of ± distinct warts {> 200}, very rarely ± smooth {4}; **SBs** *(0.4–)0.5–0.7(–0.9) µm diam. {11}, globose, rarely broadly tear-shaped, attachment invisible, rarely a short fine filum seen (total length 0.8–1 µm). **Paraphyses** apically slightly or mostly medium to very strongly capitate (rarely clavate or moniliform), terminal cells *15–25(–28) {5} × (2–)2.5–4.4(–4.7) µm {7}, †14–23(–25) × (1.3–)2.2–4(–4.5) µm {10}, below inflated apex *(1–)1.2–1.5 µm wide (†0.8–1.4 µm), lower cells *4.5–10 × 1.7–2.3(–2.8) µm {5}, †4–10 × (1–)1.5–2.1 µm {4}; unbranched at upper septum; contents hyaline or in lower part and near apex light to bright yellow. **Medullary excipulum** 35–80(–150) µm thick, of a dense, somewhat horizontally oriented, hyaline or pale yellow textura globulosa-angularis-prismatica with some prismatic-hyphoid cells, sometimes with a lower part of loose t. intricata, sharply delimited from ectal excipulum only towards margin by a 10–20 µm thick layer of t. porrecta. **Ectal excipulum** hyaline to light yellow, of (†) thin-walled to slightly gelatinized, vertically oriented t. globulosa-angularis(-prismatica) from base to margin, 40–120(–150) µm thick at base, cells */(/†) (9–)12–45(–75) × (8–)10–30(–40) µm {10}; 15–60 µm thick at lower flanks, 10–15 µm at mid flanks and margin, oriented at a (50–)70–90° angle, marginal cortical cells *6–11(–15) × 4–7(–9) µm {4}, **glassy processes** absent. **Anchoring hyphae** sparse to abundant, */†2–3.5 µm wide, walls 0.2(–0.3) µm thick {4}, sometimes forming a compact, hyaline, small-celled, up to 50–60 µm thick (rarely 100–200 µm) t. intricata-porrecta or t. angularis at base. **SCBs** in paraphyses apparently sometimes present, globose, up to 1 µm diam.; in ectal

Taxonomic remarks. Species of the *xanthostigma-leucostigma* complex are readily recognized under the microscope (oil immersion) by small, cashew-shaped, semicircular ascospores of about 2.5–3 µm length (in situ), with distinct warts on the rounded dorsal side (see also Fig. 55) and a single globose SB at one of the two ends. However, this species complex varies in apothecial colour between whitish to pale chlorinaceous or pale rosaceous-lilaceous and pale to bright yellow(-orange). Strong molecular differences among populations with such spores resulted in a number of well-defined clades which tend to include only one of the two main colour variants. The '*xanthostigma-leucostigma* complex' is applied in a morphological sense here, comprising species with curved and warted ascospores related to *O. xanthostigma* s.l. and *O. leucostigma* s.l. Included in this complex is the very similar tropical *O. aureocrenulata*, which can macroscopically be recognized by a notched margin and a distinct stipe. The North American *O. xanthoflexa* which genetically falls in the *leucostigma-xanthostigma* clade, and *O. renispora* which appears to be related to it but also to *O. tremulae*, are excluded from the *xanthostigma-leucostigma* complex because of larger, often less curved ascospores which are consistently completely smooth.

Based on very strong molecular differences among European samples, which correlate with apothecial colour, we are forced to distinguish two here neotypified taxa: *O. leucostigma* s.str. with colourless or pale rosaceous-lilaceous apothecia, and *O. xanthostigma* s.str. with pale to bright yellow(-orange) apothecia. A further, so far unnamed and apparently rare European variant is genetically close to *O. xanthostigma* but differs in growing on xeric branches. Molecular data from Tenerife (Canary Islands) recently gained by L. Quijada indicate that *O. xanthostigma* s.str. occurs also in the Macaronesian archipelago (Baral et al. in prep.). On other continents, however, some further cryptic species with mainly yellow pigmented apothecia exist. Therefore, and because we did not recognize any micromorphological differences between specimens from Europe, North America, Asia, and New Zealand, we refrained from presenting separate descriptions for these cryptic taxa at the present stage (see also Baral et al. in prep.).

To recognize population identity within Europe proved difficult in various cases of freshly photographed samples which showed intermediate, pale yellow to almost white apothecial colours (e.g., Pl. 877: 4–5; IVV: H.B. 9451). Since our experience was that both pale and bright yellow apothecia belong genetically to *O. xanthostigma*, only those populations were identified as *O. leucostigma* which lack any yellow tints. Together with the frequent occurrence of mixed populations of both colour variants, identification based on colour alone was often problematic.

In addition to this, the bright yellow pigment fades away in the herbarium with the decades by getting more or less cream-ochraceous, while colourless apothecia appear to attain a similar colour. Thus, striking colour differences in the fresh state eventually become obscure in the preserved specimens, while notes on the colour of fresh samples are often lacking. As a consequence, older specimens cannot be identified in such a case, and mixed populations with originally very different colours (Pl. 877: 7a–b) later caused problems in recognizing the individual populations, for instance in the type of *O. faginea* (see also Baral et al. in prep.). Identification was possible in those old specimens for which a single apothecial colour was noted by the collector or could be assumed based on the applied name (e.g., yellow to orange in *xanthostigma* or *coccinella*). In order to provide an idea of the possible identity of each sample, abbreviations are used in the below list of specimens examined which are, however, to be used with caution.

Taxa related to the *xanthostigma-leucostigma* complex but with completely smooth spores are, *O. xanthoflexa*, *O. renispora* s.l., *O. fabacearum*, *O. subfabacearum*, and *O. coccinella*. Their spores are partly larger and more variable in shape, with a tendency of some spores to be less curved. Additionally, in *O. fabacearum* the SBs are inserted at the dorsal side of the spores, and the paraphyses are apically only slightly inflated. *O. subfabacearum* differs in sometimes having glassy caps on the marginal excipular cells and in a distinct exudate over the paraphyses, also in a tendency of the spores to be curved by over 180°. Also *O. coccinella* has small glassy processes at the margin but deviates from all mentioned species in 16-spored asci.

Variation. Size and also shape of the spores in the *xanthostigma-leucostigma* complex was quite constant in the many collections examined, irrespective of apothecial colour. Spore length was always within the limits of *(2.2–)2.4–3(–3.3) × 1–1.6 µm (in situ). The spores were found to shrink only very slightly in the dead state to a size of †2.2–3 × 0.9–1.5 µm. As an exception from this, Quijada et al. (2016) observed in collections from Macaronesia slightly shorter spores of *(1.9–)2.2–2.5(–2.7) × 1–1.4 µm (†2.1–2.3 × 1.1–1.2 µm) (measurements from four collections, L. Quijada pers. comm.). Also in one of the studied collections from New Zealand (PDD 59160) the spores measured only †2.2–2.5 × 0.8–1 µm.

The warts on the spores were consistently present in the numerous European, African, Asian, Australasian, and American specimens, with very few exceptions: smooth or almost smooth spores were observed in the small-spored collection from New Zealand (PDD 59160) and in three collections from Bayern with a normal spore size (München-Allach, Pl. 875: 5; Salzburg-Sam, 9.VIII.1990, 20.VII.1991), but at the Salzburg site also records with slightly (10.IV.1991) or distinctly (24.VIII. & 24.X.1990) warted spores occurred. A few unpreserved collections from Germany and Austria studied between 1975–77 were recorded as smooth-spored, but here the warts were probably overlooked. The same applies to some further records documented by others.

The shape of the paraphysis apex did not markedly differ among the specimens, whereas ascus length strongly varied between the extremes of †24–31 and †35–42 µm (Pl. 875: 3, 7) or even †38–45 µm (5). The remarkably long asci of the latter sample measured in the living state *45–53 × 3.2–3.6 µm, or *50–55 × 4–4.4 µm when fully turgescent; also the terminal cells of paraphyses were here extraordinarily long (*18–28 µm). In spite of this and the almost smooth spores we have included this specimen in the description. Even longer asci of †45–52 µm were found in a specimen from Chile (Pl. 875: 3, 7, 12) which is, therefore, included only with hesitation. Rather strong variation was noted in size and thickness of the apothecia and also in thickness of the basal tissue formed by the anchoring hyphae.

Variation in colour is most remarkable, but is not correlated with micromorphological features. The frequent *O. xanthostigma* with pale to mostly bright yellow-ochraceous to golden yellow-orange apothecia, illustrated, e. g., in Breitenbach & Kränzlin (1981, fig. 253), can be recognized within Europe even in the field with rather high certitude. When pale chlorinaceous, *O. leucostigma* may easily be confused with *Hyalorbilia inflatula*, and when pale rose-lilaceous it strongly resembles *O. sarraziniana* or *O. rosea*. Completely hyaline (whitish) populations of *O. leucostigma* do not markedly differ macroscopically from species such as *O. epipora* or whitish populations of *O. auricolor*. *O. leucostigma* is distinctly less frequent in Europe than *O. xanthostigma*. About 250 European collections with yellow apothecia are recorded in the present study, but only ca. 75 with whitish ones.

Boudier (1904–10: 266, pl. 460) described the apothecia of *O. xanthostigma* as bright orange-reddish, but his illustration shows the typical yellow(-orange) colour. Liu (2006) described the apothecia of his *O. delicatula* from China as 'dark orange or orange-grey, the colour lighter after rehydration', so that all of his many specimens listed appear to have had a more or less orange or perhaps yellow colour when fresh. Among them are also those two for which sequences were available.

In at least 25 collections listed below, whitish and pale to bright yellow apothecia occurred in close association, either in separate populations on the same piece of substrate or more or less densely aggregated or even intermingled. Although *O. xanthostigma* predominantly forms its apothecia on the upper and lateral sides of the branches and logs and *O. leucostigma* preferably on the shadowed underside, colourless and bright yellow apothecia grew sometimes together on the exposed upper side (Pl. 877: 7a–b), being sharply separated by their colour. This was also the case in two of the samples with rDNA data (H.B. 6810c, G.M. 2015-08-15.4a/b). The exposed growth of colourless apothecia allows to conclude that the absence of the yellow pigment is not a result of low intensity of illumination but has a genetical basis.

The yellow pigment occurs in the paraphyses, subhymenium, medullary and ectal excipulum (Pl. 877: 12b). It originates from two apparently very different chemical compounds, one being lipid-soluble, the other water-soluble. The predominant part of the pigment locates as carotenoids in small LBs which occur especially near the septa, e. g., in the lower part of the paraphyses (Pl. 875: 5b, 9b, 15b). These yellowish LBs are KOH-resistant including their pigmentation which stains blue-green with iodine. The water-soluble pigment occurs more in the centre of the cells, e. g., in the inflated paraphysis apices and in the excipular cells, often as a pale yellow vacuolar sap. This vacuolar pigment may also precipitate during maturation to form bright yellow, more or less strongly trembling groups of small granules located in the vacuoles (Pls 875: 9b; 877: 7f; 878: 1c). In fully developed apothecia these granules are especially found in cells of the medullary and ectal excipulum at the flanks, but also in the paraphysis apices. The granules instantly disappear in KOH whereas their pigment is stable and again forms a homogeneous yellowish sap inside the dead cells in that medium.

Literature reports on the *xanthostigma-leucostigma* complex. *O. leucostigma* with whitish apothecia and *O. xanthostigma* with yellow-orange apothecia represent one of the most often reported species of *Orbiliomycetes* in the literature. Judging from the reported microscopic features, many of these records clearly refer to one of these two species, for which the name *O. delicatula* has been adopted by Spooner (1987). Records under the name *O. xanthostigma* in this sense are those of Boudier (1904–10), Bayliss Elliott (1920), Moser (1963), Dennis (1978), Ellis & Ellis (1985), Breitenbach & Kränzlin (1981: 212), Huhtinen (1985b: 496), Schmid-Heckel (1985: 62), Baral & Krieglsteiner (1985: 28), and Grauwinkel (1987: 128). However, a couple of other reports under the name *O. xanthostigma* clearly do not represent *O. xanthostigma* as neotypified in the present study (see below).

Mainly because of the absence of the yellow pigment, the more rare whitish populations have been separated as *O. leucostigma*, e.g., by Dennis (1978) and Ellis & Ellis (1985) at the species level. Other authors like Karsten (1869: 174, 1870, 1871: 99), Rehm (1891: 455), Massee (1895: 148), and Grelet (1948a: 54) recognized the yellow taxon only at different infrageneric levels, and Seaver (1951: 154) took it even as a synonym of *O. leucostigma*. All of these latter authors report the spores as ellipsoid, which leaves the question open whether they overlooked the curvature of the spores or described a truly ellipsoid-spored species such as *O. eucalypti*. Also Feltgen (1899: 53) overlooked spore curvature when stating that *O. leucostigma* and its var. *xanthostigma* differed from *O. eucalypti* (as *O. coccinella*) mainly in colour.

During the present study, reexamination of various herbarium specimens revealed that *O. leucostigma* and *O. xanthostigma* in the here neotypified sense have been deposited under the epithets *leucostigma* (Petrak, Killermann, Bommer & Rousseau) and *xanthostigma* (W. Phillips 130, J. B. Ellis Reliqu. Farlow. 912, H. Schmid 2141, F. Kränzlin NMLU 2507-75, F. Doveri 193) but also *coccinella* (F. Höhnel A 4945, H. Rehm 71b, A. Allescher, J. Poelt, 6 specimens of J. Feltgen) and other names. Feltgen's material may serve as an example of the high confusion concerning these taxa: he subsumed under the epithet *coccinella* frequently members of the *xanthostigma-leucostigma* complex but also *O. eucalypti*, and under the epithets *leucostigma*/*xanthostigma* taxa here referred to *O. crenatomarginata*, the *xanthostigma-leucostigma* complex, and *Hyalorbilia inflatula*.

Although spore shape and ornamentation in the *xanthostigma-leucostigma* complex are quite easily seen under oil immersion at 1000×, these characters are frequently overlooked even in recent times. Boudier (1904–10: pl. 460), Bayliss Elliott (1920), and Velenovský (1934: pl. 11 fig. 4, as *O. paradoxa*) correctly illustrated deeply reniform or cashew-shaped spores. Also Höhnel (1907a) and Svrček (1954: 7) appropriately described the shape of the spores of *O. botulispora* as 'allantoid, nearly semicircular'. Bayliss Elliott drew attention to the fact that the strongly curved spores mislead to describe them as ellipsoid when seen in dorsal view and as two circles when seen in ventral view. Nevertheless, all these authors overlooked the warts on the spores.

Others, like Grelet (1948a: 54), Dennis (1978: 187, pl. XXV A), Chacón & Guzmán (1984), Ellis & Ellis (1985) and Korf (1992), reported the spores as only slightly curved or slightly

kidney-shaped, therefore, some uncertainty remains about the identity of the treated material. Doubtful are those reports of Karsten (1869: 174), Phillips (1887: 329), Massee (1895: 147), and Rehm (1891: 454) who described the spores as globose-ellipsoid, (elongate-)ellipsoid, or egg-shaped. Some reports suggest a gradual variation from straight to strongly curved spores which led some authors (e. g., Bayliss Elliott 1920: 264), especially in the case of yellow to orange apothecia, to consider *O. coccinella* and *O. leucostigma* var. *xanthostigma* as possible synonyms. Due to the small spore size, reports of ellipsoid spores are often doubtful, particularly in the older literature. As an example, Velenovský erroneously described globose or ellipsoid spores in *O. alnea* var. *vesiculosa*, *O. faginea*, *O. hypothallosa*, *O. microspora*, *O. millispora* and *O. vitrea*. When Svrček (1954) revised the types of these taxa, he found allantoid, cashew-shaped spores and referred all of them (except for *Orbilia alnea* var. *vesiculosa*, see below) to synonymy with *O. botulispora* (= *O. xanthostigma*). A recent report of *O. xanthostigma* by Akata & Doğan (2015: fig. 3d) figures cylindrical straight spores, but reexamination of this sample revealed strongly cashew-shaped warted spores, thus fig. 3d shows alien spores.

Spore size of *O. leucostigma* and its synonyms (in a wide sense) as stated in the literature lies in the range of (1.5–)2–3(–4) × 1–2(–3) µm. Although in the present study the spores almost never exceeded 3 µm in length (in situ), Dennis (1978: 187), Breitenbach & Kränzlin (1981: pl. 253), and Ellis & Ellis (1985: 12) uniformly give a spores size of 3–4 × 1–1.5 µm for *O. xanthostigma*. Similarly, Boudier (l.c.: 266), followed by Grelet (1948a: 54), gave the spore size for *O. xanthostigma* as 3–4 × 2–3 µm (3–3.7 × 1.1–1.7 µm when evaluated from Boudier's plate; the value of 2–3 µm obviously refers to the total width of the curved spore). Reexamination of the material figured by Breitenbach & Kränzlin revealed a size of 2.5–2.7 × 1 µm, therefore, it can be assumed that values of 3–4 µm refer to the actual spore length (measured along the curvature).

Svrček (1954) gave for *O. xanthostigma* a spore size of 2.5–5 × 1.5–3 µm because his interpretation of this name concerns *O. eucalypti* and includes perhaps also *O. tremulae* (see below, also under these two species), while he used the name *O. botulispora* with spores of 2.5–3.5 × 1–1.5 µm for the present concept of *O. xanthostigma*. A report under the name *O. xanthostigma* by Zhuang (1997: 9), with cream-white apothecia and ellipsoid to rod-shaped spores (3.5–4.5 × 1.2–1.5 µm) was restudied and found to have slightly curved spores; it is referred to as *O.* aff. *umbilicata* here (Pl. 865: 3). Three collections reported by Thind & Sharma (1980) from temperate to tropical India under the name *O. xanthostigma*, with golden yellow apothecia, suggests a relation to section *Helicoon* because of fusoid, straight to slightly curved spores of 3–6.5(–7.5) × 1–2.5 µm. Guo et al. (2014b) used the name *O. xanthostigma* for a collection of unclear identity from subtropical China, with reddish or whitish apothecia and falcate spores of *6–8.5(–10) × 1–1.4 µm, reminiscent of section *Arthrobotrys*, although the strongly refractive VBs in the paraphyses would be a rare case in that group; alternatively it could be a member of series *Xanthoguttulatae*, in which VBs occur in *O. nemaspora*.

It was in the holotype of *O. delicatula* when Spooner (1987, fig. 21 A–C) reported for the first time the warts on the ascospores. In the present study this characteristic feature could indeed be seen, e. g., in all of Velenovský's type specimens here referred to synonymy with *O. leucostigma* or *O. xanthostigma* (Pl. 875: 3–4, 6–8). The warts are visible in every mature, living or dead spore, both inside or outside living or dead asci, not only on some spores as Spooner's drawing might mislead to think. The warts are also clearly visible on LM photographs (Pls 877: 3c; 878: 3, 4b, 8). In several specimens from Argentina, Romero (1994, fig. 15 M) confirmed Spooner's observation. Also Liu (2006: 69, fig. 23) reported the spores to be warted in all of his many Chinese specimens, although the warts are not clearly visible on his photos. Matočec & Focht (2000) described and figured the spores of a specimen from Montenegro as 'finely punctate at dorsal part, readily visible in water mount under oil immersion', and likewise Matočec et al. (2005: 324) found spores with ornamented dorsal part in an Austrian sample.

SEM micrographs (Pfister 1997, fig. 2; Wang & Pei 2001, fig. 2b; see Fig. 55: c–d) showed that these warts also occur on the sides of the spores, and a TEM study (Müller 1998, fig. 21c; Fig. 55: a–b) revealed that they are protrusions of the spore wall rather than deposits on the wall, and this appears to be the reason why they are not stainable by dyes.

Although the mature living spores always contain a single globose spore body at one end, literature reports do not account for this feature. Either the spores are described as empty, mainly because of herbarium studies but also by vital taxonomists like Boudier, or they are reported to contain 2 drops, one at each end (e. g., in the type of *O. paradoxa* by Velenovský 1934: 102, pl. XI fig. 4 and Svrček 1954: 18, or under *O. xanthostigma* by Bride & Caillet 1975: 72 and Dennis 1978: 187). Velenovský undoubtedly saw the spore bodies, but it seems to have been a matter of imagination that he depicted two at each spore end (in profile view). Although 1–3 small LBs frequently accompany the SBs, the LBs are nearly always much smaller and not strictly near the poles. When viewing the spores in front view, the two spore ends may simulate drops which could be the case in Dennis' drawing (1978: pl. XXV A) and also in Velenovský's (1934: pl. XI figs 9, 16) report of oblong-ellipsoid spores in *O. alnea* var. *vesiculosa* and *O. microspora* (p.p.).

Nomenclature and type studies. The brief protologues of the four oldest epithets *aurea* (Persoon 1796), *leucostigma* and *xanthostigma* (Fries 1815), and *rufula* (Schweinitz 1832) present only macroscopical characters which do not even allow to decide whether an asco- or basidiomycete was described. Because of the unclarified identity and/or inconsistent application of these names, Spooner (1987: 167) selected the epithet *delicatula* (Karsten 1869) to replace the currently applied epithet *xanthostigma*. He rejected the two Friesian taxa as nomina ambigua because, according to Nannfeldt (1932: 253), no authentic material of them has been preserved.

During the present study, several authentic specimens of *Peziza aurea* and the presumed holotype of *P. rufula* were examined. Moreover, an authentic non-type specimen of *Peziza xanthostigma* could be studied, while no specimen identified as *P. leucostigma* by Fries could be located. Accordingly, *P. rufula* and *P. aurea* p.p. were found to have cashew-shaped warted

spores, but *P. aurea* was heterogeneous and comprised also *O. comma* and *Dacrymyces chrysocomus*. The authentic specimen of *P. xanthostigma* represents *O. auricolor*, but this specimen was probably collected after the sanctioning protologue was published by Fries and cannot, therefore, be considered as type material.

The here proposed neotypification of *O. leucostigma* and *O. xanthostigma* is based on two recent European collections with cashew-shaped, warted ascospores, and with white or yellow apothecia, respectively, from which molecular data were gained. With this neotypification we believe to have found an acceptable solution for the necessary name change of *O. delicatula* (because of the priority of *P. aurea* and *P. rufula*) and the necessary clarification of the identity of *O. xanthostigma* (the lectotype of the genus *Orbilia*). The reintroduction of the commonly used epithet *xanthostigma* as the correct name for *O. delicatula* was possible because *O. leucostigma* as here neotypified was molecular-biologically very different. Would the result have been that the two taxa were conspecific, Seaver (1951) had to be followed who gave *O. leucostigma* priority at the species level by listing *O. xanthostigma* as a synonym (ICN Art. 11.5, Turland et al. 2018). Because the oldest name, *Peziza aurea* Pers., was not sanctioned by Fries, but listed as a synonym of *Dacrymyces chrysocomus*, its reintroduction in the here lectotypified sense of *O. xanthostigma* would only be possible if *P. xanthostigma* (which has priority over *P. aurea*) would have been redefined in a sense different from *P. aurea*, or retained as a nomen ambiguum.

Peziza leucostigma is one of the two species that Fries included when erecting the genus *Orbilia*. The taxon was designated as lectotype of *Orbilia* by Clements & Shear (1931), but these authors were unaware of the earlier lectotypification on *O. xanthostigma* by Bachman (1909). Authentic material of *P. leucostigma* in GH and UPS could not be traced. In the absence of a type specimen, Nannfeldt (1932: 253), followed by Spooner (1987: 161), referred to the interpretation of *P. leucostigma* by Nylander (1869) when suggesting *P. leucostigma* [sensu] Nyl.

as ‘neotypus’ of the genus *Orbilia*. Nannfeldt obviously did not examine Nylander’s material himself, but relied on Nylander’s description which is likewise too brief to allow recognition of the species, though including microscopic characters.

The original description of *Peziza leucostigma* provided by Fries (1815, 1822) refers to a fungus with the following macroscopic characters (Pl. 879): gregarious, sessile, whitish-hyaline with a slightly greyish disc, ¾–1¼ lin. (= ~1.5–2.5 mm) diam. (1815) or scarcely over ½ lin. (= ~1.2 mm) large (1822), concave, then nearly flat, submembranaceous, coriaceous, margin smooth, growing on blackened, very rotten wood of *Fagus* in autumn and spring in Sweden.

The interpretation of *P. leucostigma* by later authors is highly heterogeneous, as it was mainly based on the whitish colour of the apothecia. For instance, five specimens from P.A. Karsten’s herbarium in H bearing the epithet *leucostigma* were examined and found to belong to four different species. Nylander (1869: 54) partly detected this confusion when reviewing Karsten’s specimens. Three of them turned out to have narrowly cylindrical spores and became syntypes of *P. epipora* (however, Nylander overlooked that one of them represents *Hyalorbilia inflatula*, see p. 1449).

The remaining two specimens Nylander found to be ellipsoid-spored, so he continued to assign it to *O. leucostigma*. The descriptions in Nylander (l.c.) and Karsten (1869: 174) run about as follows: fresh whitish-hyaline, dry yellowish, paraphyses ~1 µm wide, with a subglobose apical inflation 2–2.5 µm wide, spores ellipsoid or oblong, 3–4 × 1–1.5 µm, asci narrowly clavate, 30–35 × 3–3.5 µm. The described shape of the paraphyses excludes a short-spored member of *Hyalorbilia*, and the spores are suggestive of *O. dryadum* or a pale-coloured specimen of *O. tremulae*. Reexamination of these two specimens revealed that they belong to two different species: *O. tremulae* (Kola Peninsula, *Salix* wood, 27.VII.1861, Karsten 3192) with ellipsoid spores (Pl. 861: 8), and *O. leucostigma* in the here neotypified sense (Turku, Merimasku, coniferous wood, 21.VI.1860, Karsten 3193), with cashew-shaped, dorsally warted spores of †2.6–2.9 × 1–1.2 µm (Pl. 875: 10a). Although now pale cream-ochraceous(-orange) when dry, the fresh colour was whitish-hyaline fide Nylander and Karsten (l.c.). A further, apparently duplicate specimen in H bearing the same collection data (Karsten 3193) is from Nylander’s herbarium and was not received. This specimen was identified by Svrček (1989, in sched.) as *O. epipora*, therefore, it seems unlikely to be conspecific with *O. leucostigma* as neotypified here.

When Karsten (1869) separated *Peziza delicatula* from *P. leucostigma*, he saw not only a difference in apothecial colour (golden-yellow vs. whitish), but also in spore size and shape (1–2.5 µm long, ellipsoid-subglobose vs. 3–4 µm long, ellipsoid-oblong). However, reexamination of the holotype of *P. delicatula* by Spooner (1987) revealed cashew-shaped, dorsally warted spores, indistinguishable from those here seen in Karsten 3193. Hence, both Karsten and Nylander overlooked the curvature and ornamentation of the spores, while the reported spore size of 3–4 µm seems to refer to *O. tremulae* rather than *O. leucostigma*.

Many later authors adopted the name *O. leucostigma*. However, their diagnoses are often more or less exact copies of those of Nylander and Karsten (Saccardo 1889: 629, Rehm 1891: 454, Grelet 1948a: 53, Seaver 1951: 154, Ahmad 1978: 210), which permits to conclude that they did not perform personal studies. Rehm suggested that *O. leucostigma* was possibly only a small-spored form of *O. coccinella* (in the sense of *O. eucalypti* s.l.), whereas Feltgen (1899: 53) saw only differences in colour between the two taxa. Regrettably, the three collections reported by Feltgen under the name *O. leucostigma* in his herbarium in LUX were found to be devoid of apothecia, whereas those reported under the name *O. coccinella* mainly belong to *O. xanthostigma* and sometimes to *O. eucalypti*. The two specimens in the herbarium of E.C. Bommer & M.H. Rousseau (Belgium, BR) under the name *O. leucostigma* also contained different species, *O. leucostigma* (IX.1884, wood of *Quercus*) and *O. auricolor* (VI.1913, bark of *Fraxinus*). Specimens named *O. leucostigma* in the herbaria of Petrak (VIII.1934, U.S.A, New York, Old Forge, wood of ?*Fagus*, M) and Killermann (15. VI.1918, Bayern, Regensburg, Pfatter, wood of *Quercus*, M) are confirmed here.

Clear microscopic differences between *O. leucostigma*, *O. xanthostigma* and *O. eucalypti* are quite wanting in the older literature. For instance, Phillips’ (1887: 330) diagnoses define these three taxa mainly by their colour (white, yellow, or flesh-red, respectively) whereas the microscopic features differ only slightly. Often the statement can be found that *O. leucostigma* is merely a colourless form of *O. xanthostigma* (Karsten l.c., Saccardo 1889: 629, Grelet l.c., Dennis 1978: 188). Also Ellis & Ellis (1985: 11) distinguish the two taxa only by colour. A similar opinion is expressed by Karsten (1869) who reduced *O. xanthostigma* to a subspecies, and later (1871) to a variety of *O. leucostigma*. Seaver (1951) even synonymised *O. xanthostigma* under *O. leucostigma*.

Almost all consulted authors prior to 1960 who provided microscopic data, but also Ginko (1986: 201), reported under the epithet *leucostigma* ellipsoid-oblong or globose-ellipsoid spores. Those who did not merely copy Karsten’s description might likewise have overlooked the curvature of the spores, but Ginko’s

Plate 879. Left: protologue of *Peziza xanthostigma and P. leucostigma* in Observationes Mycologicae (Fries 1815: 165–167). Right: redescription in Symbolae Mycologicae (Fries 1822: 146).

illustration of ellipsoid spores suggests that he was dealing with *O. cejpii* or a similar species. Contrary to the situation before 1960, Dennis (1960, 1978) and Ellis & Ellis (1985) reported under the name *O. leucostigma* British specimens with consistently slightly curved (allantoid) spores. These records obviously refer to *O. leucostigma* although the spores are described as smooth and too long, perhaps by referring to the actual length.

Some further interpretations of *Peziza leucostigma* are mentioned in the following. Although described by Fries as having a plane hymenium, Cooke (1871: 703) reported the young apothecia of *P. leucostigma* as cupulate and with a visible subiculum which suggests a *Hyalorbilia* (no microscopic data are given). Also Karsten identified a polyporicolous collection (Tampere, Ruovesi, 4.VIII.1859, H) as *P. leucostigma* (and later as *O. epipora*) which represents *H. inflatula*. Schulzer (1878) referred a collection on wood of an old *Quercus* stump to *P. leucostigma*. The ascospores are described as cylindrical, 5 µm long, and the conidiophores and conidia (24–26 × 6 µm, 1–5-septate) emerging from the hymenium obviously belonging to a *Dactylella*, which suggests that the species under study might belong to series *Neodactylella.* A specimen on wood of *Fagus* (Höhnel A 4946, Wienerwald, Großer Stiefelberg, 1906, M) was reexamined and found to represent *O. epipora*. A specimen on *Phylica* (*Rhamnaceae*) from Tristan da Cunha (south Atlantic Ocean), identified as *O. leucostigma* by Dennis (1955: 1), was described with yellowish apothecia (when soaked up), cylindrical, straight to slightly allantoid spores of 3 × 0.75 µm, truncate ascus apices, capitate paraphyses, cortical cells with a yellow oily matter, and 4–5 µm wide anchoring hyphae. The spores suggest identity with *O. epipora*, but the yellow cortical pigment points to a different species. A report of *O. leucostigma* from Bayern (Berchtesgaden Nr. 2509, *Alnus alnobetula*, 28.IX.1982, H. Schmid-Heckel, M) was found to be *O. sarraziniana*.

In order to settle the identity of *O. leucostigma*, a neotype needs to be chosen. In our opinion, a solution with the lowest nomenclatural changes would be gained by neotypifying *P. leucostigma* based on a European population with white apothecia and cashew-shaped warted spores. This selection would partly concur with Nylander's interpretation of the epithet, and would also be in accordance with the general use of the name *O. leucostigma* since 1960. We here designate a specimen from Germany (Tübingen, on *Fagus*, ex H.B. 9958a, M-0276499), from which a sequence was gained, as **neotype** of *O. leucostigma*. A documentation of this collection will be given in a separate paper (Baral et al. in prep.).

Peziza xanthostigma is the other of the two species on which Fries (1835) based the genus *Orbilia*. The taxon was designated as lectotype of *Orbilia* by Bachman (1909). Although the epithet *xanthostigma* has been used over more than a century for the common species with small cashew-shaped spores, e.g., by Boudier (1904–10: pl. 460), Dennis (1978: pl. XXV A), and Breitenbach & Kränzlin (1981: pl. 253), Spooner (1987) abandoned the name as a nomen dubium because no type material could be located and the epithet has not consistently been applied by older authors due to inexact microscopic data. Our search for authentic material in GH and UPS revealed a single specimen in the Fries Herbarium (see below).

Actually, the name *O. xanthostigma* has been applied in different ways. A frequent interpretation concerns *Orbilia eucalypti* or *O. tremulae*, 2 common taxa with ellipsoid spores, although the name *xanthostigma* (= yellow) is in contrast to the often orange- to rose-red or cream to almost whitish, but sometimes also yellow-orange apothecia of *O. eucalypti*. For instance, Velenovský (1934: 92, apothecia pale rose), Svrček (1954: 23, 1987b: 93, apothecia yellow), and Korf & Zhuang (1985: 503) favoured this interpretation of *O. xanthostigma.* The cashew-spored species was reported by these authors under various new (Velenovský 1934, 1947) or established names such as *O. botulispora* Höhn. (Svrček 1954) or *O. delicatula* (Korf 1992). A North-American specimen labelled *O. xanthostigma* (X.1925, herb. Petrak, M) appears to belong to *O. epipora* (Pl. 901: 7).

A surprise was the identity of the only authentic specimen of *P. xanthostigma* that we have received ('Tyskland, Sauter', undated, herb. E. Fries, F–015650, UPS 247614), on bark of a branch of ?*Salix*. This contains three apothecia which belong to *O. auricolor* (see Pl. 951: 2), a species which has often whitish apothecia but may occur in a more or less bright golden yellow, somewhat desiccation-tolerant form to which the epithet '*auricolor*' better fits. A.E. Sauter (1800–1881) started to publish on fungi around 1841 (Keißler 1917). Hence, this collection probably dates later than 1815 (or 1822, the sanctioning description) and, therefore, cannot be considered as type material of *O. xanthostigma*.

In the protologue of *Peziza xanthostigma*, Fries (1815: 166) described the apothecia as 'minute, subgregarious, round, concave, golden yellowish, coriaceous, glabrous', growing on wood of *Abies alba* ('in ligno *Pini Abietis*') in Poland (Pl. 879 left). Later, Fries (1822: 146) emended the description to 'sessile, minute, soft-membranaceous though quite tough, smooth, excavated (cupulate), round, golden yellow, gregarious, on rotten wood of *Abies* etc. in summer and autumn' (Pl. 879 right). In 1815 Fries believed that the species differed from *Peziza leucostigma* in its colour and more concave discs, and from *P. aurea* in smaller and thinner, coriaceous apothecia with an even margin, whereas in 1822 he stated *P. umbonata* and *P. leucostigma* to be somewhat similar to *P. xanthostigma*.

Fries' concept of *Peziza xanthostigma* was purely based on macroscopy, therefore, it might have comprised several, rather distant though macroscopically similar species. Among those European *Orbiliomycetes* with comparatively large apothecia and a partly more or less yellow pigmentation, at least six possible candidates must be considered: *Orbilia xanthostigma* in the here adopted sense, *O. eucalypti*, *O. tremulae*, *O. auricolor*, *O. xanthoguttulata*, and *Hyalorbilia inflatula*. Fries' (1836) statement of moniliform asci in the protologue of *Orbilia* indicates, however, that he was not dealing with a member of section *Arthrobotrys* (*O. auricolor*), nor with 1 of section *Aurantiorubrae* (*O. xanthoguttulata*) or *Hyalorbilia*: due to the falcate, helicoid, or rod-shaped spores in these taxa, the dead, overmature asci never attain a moniliform shape.

When leaving ascus shape aside, the original description of *Peziza xanthostigma* appears to fit *Hyalorbilia inflatula*, a common species with rod-shaped spores and membranaceous apothecia with often concave disc and yellowish colour, which becomes even more intense in the dry state but also under more bluish illumination. No doubt, Fries must have known this common species which has comparatively large apothecia. Actually, the discrepancy between Fries' description and Boudier's interpretation of *O. xanthostigma* concerning the apothecial shape and thickness was also noted by Nannfeldt (in sched., fide Spooner 1987: 172). The *xanthostigma-leucostigma* complex and *O. eucalypti* are more fleshy instead of membranaceous, mainly near the margin, and never have distinctly concave discs in the hydrated state (except for a depression in the centre), although in the dry state *O. eucalypti* gets shallowly cupulate. However, the words 'tough' and 'coriaceous' in Fries' descriptions hardly match the fragile consistency of *H. inflatula*.

Both the cashew-spored species (*O. xanthostigma*) and the ellipsoid-spored species (*O. eucalypti*/*O. tremulae*) are fungi which Fries should have seen. According to Spooner (1987: 172), the cashew-spored species was stated by Nannfeldt to be common in Sweden. Spooner concluded that 'it is therefore one with which Fries must have been familiar'. Actually, this species represents roughly half of the specimens of *Orbiliomycetes* deposited in the consulted public herbaria. As this is the only known common European species which frequently forms bright yellow(-orange) apothecia, we may assume that Fries used the name *xanthostigma* for it. *O. eucalypti* is surely also frequent there, but whether Fries became familiar with it depends on his collection methods since bright-coloured *O. eucalypti* is more or less restricted to xeric substrate. The helicoid-spored *O. xanthoguttulata* with its bright yellow to orange colour would also fit, but seems unlikely to have met Fries' attention because of its comparative rarity in addition to growing on xeric substrate.

As already stated above, Boudier (1904–10: 266, pl. 460), followed by most British authors, applied the name *O. xanthostigma* to the cashew-spored species, whereas Velenovský (1934) and Svrček (1954) used it for species with ellipsoid ascospores, and named the cashew-spored taxon *O. paradoxa* or *O. botulispora*, respectively. Because of different apothecial colours, Spooner (1987: 172) believed that 'the fungus [with ellipsoid spores] to which Svrček applied the name [*O. xanthostigma*] has been variously described as amber to pink and thus seems unlikely to be that described by Fries'. Probably, Spooner referred to Boudier's (l.c.: pl. 461) plate of *O. coccinella* which shows bright pink apothecia. However, Spooner seems to have been unaware of collections of *O. eucalypti* from xeric habitats with often bright yellow-orange to orange-red apothecia (Pls 856, 859, 860). Svrček (1987: 93) considered a yellow pigmentation even as typical of the ellipsoid-spored taxon.

In order to conserve the current usage, we consider selection of the *O. auricolor* specimen as neotype of *O. xanthostigma* as counterproductive, since we are unaware of any later usage of the name in that sense. *H. inflatula* was at least a single time identified as *O. xanthostigma* by Feltgen, according to our revision of Feltgen's specimens, but no further report of *O. xanthostigma* in that sense came to our notice. Fries' generic diagnosis of *Orbilia* in regard to moniliform asci excludes these two species. Among the remaining taxa, *O. xanthostigma* was distinctly more often attached to the cashew-spored species than to the ellipsoid-spored species. We here designate a specimen from Germany (Tübingen, on *Fagus*, ex H.B. 6749, M-0177061), from which an ascospore isolate (CBS 116210) and a sequence (CBS ined.) were gained, as **neotype** of *O. xanthostigma*. For the anamorph obtained in pure culture of this collection see Pl. 876: 3. A documentation of the teleomorph based on a reexamination from the herbarium specimen is given in a separate paper (Baral et al. in prep.).

Persoon (1796: 41) briefly described the apothecia of ***Peziza aurea*** as: 'crowded, minute, sessile, flat, subgelatinous, shining yellowish-brown (fulvo nitido). Habitat frequently on logs of various trees; of fleshy-gelatinous consistency, therefore slightly wrinkled and less fleshy when dry, from *Peziza lenticularis* Bull. sufficiently different by the submarginate fruitbodies when flattened. Scarcely 1 line [ca. 2 mm] wide'. Later, Persoon (1801: 635, 1822: 304) considered *P. aurea* to be a possible synonym of *P. chrysocoma* Bull. Apparently therefore, Fries (1822: 140, 1874: 699) listed *P. aurea* Pers. as a synonym of *P. chrysocoma* or *Dacrymyces chrysocomus*, respectively, and this opinion was followed also by Sommerfelt (1826), Saccardo (1888: 799), and Mussat (1901: 246).

During a revision of specimens under the epithets *aurea* and *chrysocoma* in Persoon's herbarium, Donk (1964: 97) revealed that one (L 910.261-259, labelled '*Peziza chrysocoma* Fries / *P. aurea* ? Pers.') represents the basidiomycete *Dacrymyces chrysocomus* (Bull.) Tul. in the sense of Fries (see *P. chrysocoma*, p. 1665). Among the remaining five specimens bearing the epithet *aurea*, Donk found four to contain members of the superficially similar genus *Orbilia*, while one contained hardly any fruitbodies. For three of these specimens (including the latter) Persoon applied the name *aurea* without question mark. Among these, Donk designated the specimen L 910.261-29 (labelled '*Peziza aurea.* Syn. fung. / – *chrysocoma* Bull.') as lectotype of *Peziza aurea*. Reexamination of this specimen (Pl. 422: 1) revealed identity with *Orbilia comma*. The abundant apothecia grew on bark, obviously of *Ulmus*, judging from the appearance of the inner bark surface. However, examination of the other specimen which was available for selection (L 910.261-262) turned out to be *O. xanthostigma* (Pl. 875: 16). Also a specimen labelled '*Peziza chrysocoma*' by Persoon (L 910.261-249) was examined and found to represent *O. xanthostigma* (IVV: H.B. 7709); this collection was obviously not studied by Donk. Both collections have cashew-shaped warted ascospores and, because of the attached names *aurea* and *chrysocoma*, they are assumed here to represent European *O. xanthostigma* with pale to bright golden yellow apothecia.

The protologue of *P. aurea* provides features which appear to refer to a *Dacrymyces*, especially a fleshy-gelatinous consistency and a wrinkled hymenium in the dry state. This is no surprise as microscopes with immersion objectives did not yet exist when Persoon studied these collections, therefore, he confused *Dacrymyces* and *Orbilia*. In our opinion, Donk's selection was unfortunate, however, because apothecial colour in the numerous recent specimens of *O. comma* studied in the present work was never with a distinct yellow component. Instead, it varied from rose over orange to amber-coloured (Pl. 422: 1). Art. 9A.2 (ICN) recommends that designation of a lectotype should be undertaken only in the light of an understanding of the group concerned. According to ICN Art. 9.19, the choice of a lectotype is superseded if it is in serious conflict with the protologue and another element is available that is not in conflict with the protologue. *P. aurea* was described as yellowish-brown, and the specific epithet suggests a golden-yellow colour, therefore, we here designate L 910.261-262 (Pl. 875: 16) as **lectotype** of *Peziza aurea* Pers. The fragment of substrate appears to be *Ulmus* bark where it abundantly grew on its inner surface, partly in beetle galleries (IVV: H.B. 8776).

According to ICN Art. F.3.2 and F.3.4, the combination *Peziza aurea* Persoon (1796) is not illegitimate but nevertheless unavailable for use, because Fries (1822) sanctioned the homonym *Peziza aurea* (Pers.) Fr. The former taxon may, therefore, be made available by a nomen novum or new combination based on the here designated lectotype, if arguments were presented that it is not conspecific with *O. xanthostigma* (Art. F.3.4 ICN). Such a combination was made long ago in the genus *Helotium*, as *H. persoonii* (see below).

The sanctioned homonym of *Peziza aurea* Pers., *P. aurea* (Pers.) Fr. is based on a different binomial, *Helotium aureum* Pers. (Persoon 1801: 678), and represents a stipitate anamorphic fungus connected to '*Bisporella*' *resinicola* as teleomorph (Seifert & Carpenter 1987). *Peziza aurea* (Bolton) Sowerby is a further homonym. Bolton's fungus, originally published as *Helvella aurea* Bolton, refers to ?*Hymenoscyphus serotinus* (see Fries 1822: 119, Saccardo 1889: 222) while Sowerby's interpretation concerns *Calycina citrina* (see Saccardo 1889: 224). *Calycina aurea* (Bolton) Kuntze published by Kuntze (1898: 448) is another combination of this taxon.

Montagne (1853) described under the name ***Helotium persoonii*** a collection on ligneous substrate (indet. angiosperm) from Chile, with brownish-yellow to reddish apothecia. He observed asci and paraphyses but could not clearly see any spores. Dumont (1981: 358) stated that 'the description is suggestive of an *Orbilia*', but 'the holotype specimen cannot now be located at PC'. When ordered by us, 2 well-preserved authentic specimens were received from PC, with 'Chili' as the only collection data, obviously duplicates of the same collection on wood of indet. angiosperm. This collection fits the *xanthostigma-leucostigma* complex in most respects (Pl. 875: 12), but deviates by unusually long asci (†45–52 × 3.5–3.8 µm).

Helotium persoonii was believed by Dumont (1981) to have been published as a new species. Saccardo does not seem to have mentioned this binomial at all. Montagne (1853) listed *Peziza aurea* Pers. as a synonym of *H. persoonii*, hence we conclude that *H. persoonii* was intended as a nomen novum to avoid homonymy with *Helotium aureum* Pers. [≡ *Eustilbum aureum*]. Although he had not clearly seen any spores, Montagne was sure about the identity of his collection with Persoon's *Peziza aurea*, based on examination of an authentic specimen of Persoon under that name. He was also sure about the identity of *P. aurea* and *P. chrysocoma* s. Sowerby, but he felt uncertain concerning *P. chrysocoma* s. Bulliard in the lack of a type specimen.

Schweinitz (1832) briefly described ***Peziza rufula*** for a collection on ligneous substrate from Pennsylvania (USA), with reddish ('e rubro rufa') apothecia but with a more whitish margin, and compared it with *P. rubella* (= *Orbilia rubella*). A single specimen labelled 'type' (probably holotype) could be located at K and is found here to fit *O. xanthostigma* s.l. in every respect (Pl. 875: 1). The taxon was accepted by Cooke & Ellis (1877: 91) who referred to it a collection on a log of *Quercus* from New Jersey (USA). Based upon this latter report, Saccardo (1889: 621) combined it as *O. rubella* var. *rufula*, with a reference to p. 283 where he recombined the same taxon in *Pezizella*. Such 'alternative names' are considered to be valid when published before 1953 (Art. 36.3 ICN). Massee (1894b: 99) placed *P. rufula* and several other taxa in synonymy with *O. cruenta* Schwein., for which he described the spores as cylindric-oblong (see p. 1668). As he stated that he studied the 'specimens from Schweinitz' which comprise *P. citrinella*, *P. cruenta* and *P. rufula*, it can be assumed that he saw type material of all of them.

A reddish apothecial colour without a yellow component is unusual for *O. xanthostigma* s.l. When the presumed holotype was reexamined in 1997 during the present study, the apothecia were dry orange-brownish and rehydrated very pale ochraceous-yellowish. The unidentified host resembles a member of *Quercus*, judging from the ring-pored wood with broad radial rays.

Karsten (1869) described ***Peziza delicatula*** based on a collection on moulded wood of *Betula* from Finland (P.A. Karsten 2351) with golden yellow apothecia 1–2 mm diam., and 'short ellipsoid to subglobose' spores 1–2.5 µm long. He separated this species from the also yellow *O. leucostigma* subsp. *xanthostigma* by much larger apothecia and smaller, subglobose spores. Later, Karsten (1871) considered *P. delicatula* as a subspecies of *O. coccinella*, because of seemingly similar spores. Spooner (1987, fig. 21 A–C) reexamined the holotype, and his detailed documentation includes cashew-shaped, dorsally warted spores of †2.3–2.9 × 0.9–1.2 µm when evaluated from his drawing (2.5–3 × ~1 µm in the description which includes further collections). Spooner's description leaves no doubt about the conspecificity with *O. xanthostigma* in the present sense, therefore, this collection was not restudied here.

O. coccinella* f. *undulata was described by Feltgen (1901) from Luxembourg (Bridel, on rotten wood), based on apothecia with an undulating margin (colour not stated), but without any microscopic characters. The holotype in LUX was reexamined and found to have the typical cashew-shaped, warted spores. As Feltgen assigned this as a form of *O. coccinella*, it can be assumed that the apothecia were of some yellow-orange colour, therefore, we treat it as a synonym of *O. xanthostigma*.

Höhnel (1907a) described ***O. botulispora*** for a specimen with egg-yellow apothecia on wood of *Fagus* from Austria (Wienerwald). Höhnel correctly reported the cashew-like shape of the spores (2–3 × 1 µm) but did not see the warts on them which were demonstrated from the holotype in the present study (Pl. 875: 2). Based on apothecial colour, *O. botulispora* is a synonym of *O. xanthostigma*.

Velenovský (1934) described ***O. millispora*** for a collection from Rokycany (Czechia) on log of *Abies*, with pale yellow, strongly lobate apothecia 3–10 mm diam., and globose to ovate, 1–2 µm long spores. The holotype consists of a few apothecia of very different size (rehydrated 0.5–4.5 mm diam., now light yellowish-ochraceous). The asci were found to be 28–38 × 2.7–3.2 µm, and the spores 2.3–2.6 × 1.1–1.3 µm, cashew-shaped, with distinct warts. Svrček (1954: 17) correctly referred the taxon to synonymy with *O. botulispora* (= *O. xanthostigma*).

O. alnea* var. *vesiculosa was described by Velenovský (1934) for several Czech collections (on *Fraxinus*, *Alnus*, *Carpinus*, and *Quercus*), with egg-yellow apothecia and 4 µm long, oblong-ellipsoid spores with 1 quite large drop at each end. Without providing a description, Svrček (1954: 9) designated the *Fraxinus* specimen from Mnichovice as lectotype and assigned it to *O. xanthostigma*, a name applied by him to collections with ellipsoid, smooth spores here referred to *O. eucalypti* or *O. tremulae*. However, the present reexamination of this material revealed cashew-shaped, warted spores (Pl. 875: 7). Furthermore, the substrate is not *Fraxinus* as indicated by Velenovský but the wood anatomy fits *Alnus*. Velenovský's (l.c., pl. 11 fig. 9) illustration clearly refers to this collection, following his manuscript plate. The corpuscules on the excipulum, from which the name of the taxon is derived, represent conidia of a hyphomycete (fide Svrček). They were also seen in the present study and belong to *Haplotrichum* Link, the anamorph of a species of *Botryobasidium* Donk.

Velenovský (1934) described ***O. microspora*** based on two samples from different forests in the Transcarpathians (now Ukraine), both on wood of *Corylus* logs (according to the wood anatomy), collected by A. Pilát in VIII.1929. The two specimens contain abundant apothecia and now exist under the numbers PRM 151768 and 899283. When Svrček (1954: 17) concluded that they contain typical *O. botulispora* (= *O. xanthostigma*), the two specimens have been merged in one convolute under a single number 151768, labelled 'holotype'. Svrček's identification is confirmed here for PRM 151768, which originally had lemon-yellow apothecia, whereas PRM 899283 appears to contain *O. leucostigma* based on its originally wine-reddish apothecia (colours according to Velenovský's manuscript plates). When the 'holotype' was reexamined in 1998, it still carried only one number, PRM 151768, and no distinction was made between the two convolutes. Both were examined, but regrettably it is now impossible to say from which PRM number the drawing in Pl. 875: 3 was made. In one of the convolutes (PRM 899283) also four apothecia of *O. polybrocha* were found, which Velenovský seems to have overlooked (see Pl. 1006: 2).

Because of differences in apothecial colour and microscopic features, Velenovský (1934: pl. XI fig. 16 & 43) made two sketches. These can also be found on two separate manuscript plates which carry two different diagnoses. These two diagnoses can be assigned to the two convolutes, but only because of different notes for the (misidentified) substrate, as the apothecial colour is now uniformly pale yellowish-chlorinaceous in both: one convolute is labelled 'Habr', which means *Carpinus*, and corresponds to the plate with the note 'Na habrovém dřevě' (= on wood of *Carpinus*), whereas the other does not indicate the substrate and thus seems to correspond to the plate with the note 'Na listn. dřevu' (= on wood of broad-leaf tree). The former was from a montane virgin forest ('v pralesích horských') and the latter from an alpine virgin forest ('v alpin. pralesích'). Due to these circumstances, the two convolutes were now given two different numbers.

Although Velenovský's sketches on the two manuscript plates hardly suggest a single species, he merged them under one, and also Svrček (l.c.) did not comment on the strong divergences between the sketches. PRM 151768 (Velenovský 1934, pl. 11 fig. 16) relates to lemon-yellow ('citrónově žluté') apothecia of 1 mm diam., non-furcate asci 25 × 2 µm, distinctly capitate paraphyses, and broadly ellipsoid, biguttulate spores up to 1 µm long and PRM 899283 (pl. 11 fig. 43) to 'wine-reddish apothecia of 1 mm diam., bifurcate asci 20–24 × 2 µm, apically uninflated paraphyses, and narrowly ellipsoid, eguttulate spores 1–1.5 µm long'. The protologue contains data from both diagnoses: the apothecia are described as 'wine-reddish, yellow', and also the spore data are a mixture of both ('ellipsoid, 1–1.5 µm, biguttulate'). However, data on asci and paraphyses are solely taken from the wine-reddish specimen.

The depicted biguttulate spores are apparently a misinterpretation of the cashew-shaped spores of *O. xanthostigma* when seen in front view. Apothecia with uninflated paraphyses could not be found in the present examination of both convolutes, also a thick exudate ('epithecium') as mentioned in the protologue could not be seen. In both samples the mostly strongly capitate paraphysis apices (2.5–3.7 µm wide) are covered only by a very thin refractive exudate. Because of the capitate paraphyses and cashew-shaped spores (as 'biguttulate') reported only for the 'lemon-yellow' fungus, we here designate the specimen PRM 151768 as **lectotype** of *O. microspora*, which becomes a synonym of *O. xanthostigma*.

Four apothecia of *Orbilia polybrocha*, with rehydrated dark brown, crenulate margins and ochraceous-greyish discs, occur in association in PRM 899283 (see Pl. 1003: 4). However, this can hardly be the typifying taxon on account of the apothecial margin and the much more elongated spores (6–6.5 × 1–1.1 µm).

O. paradoxa was described by Velenovský (1934) for several Czech and Slovakian collections (mainly on wood of *Fagus*, one on log of *Abies*), with 'sulphur or pale or egg-yellow' apothecia and 1.5–2.2 µm long, ± semicircular spores ('resembling a horseshoe'), with one quite large drop at each end. Svrček (1954: 18) designated the *Abies* collection from Mnichovice as lectotype, which he correctly referred to synonymy with *O. botulispora*. The present reexamination of the lectotype (unillustrated) revealed cashew-shaped, warted spores 2.5 × 1 µm (Svrček: 2–2.5 × 1–1.5 µm). Here the apothecia are distinctly larger (up to 2 mm diam. fide Svrček, in present study dry 1–2.5 mm, ochre honey-brown) than Velenovský indicated in the protologue (0.4–1 mm). That size derives from the first collection from 13.VI.1925, according to Velenovský's manuscript plate, which shows illustrations for this and the lectotype. Velenovský placed *O. paradoxa* in a subgroup of its own, named *Soleina* after the horseshoe-like spores which he sketched with a curvature of partly over 180° in both populations.

O. hypothallosa was described by Velenovský (1947) from Mnichovice (Czechia, on wood of *Robinia*), with amber-yellow apothecia and globose spores 2–3 µm in diam. Svrček (1954: 15) found allantoid spores in the holotype and correctly referred it to synonymy with *O. botulispora*. Distinctly warted spores were seen in the present study (Pl. 875: 6). *O. hypothallosa* was named after the presence of very thick hyphae (8–10 µm) which were thought to emerge from the basal ectal excipulum. However, Svrček discovered conidia formed on them and referred this to a hyphomycete which is identified in the present study as the anamorph (*Haplotrichum*) of a species of *Botryobasidium*.

O. faginea was described by Velenovský (1947) from Jevany (Czechia, on log of *Fagus*), with white or pale lemon-yellow ('alba vel citrinella') apothecia and short ellipsoid spores scarcely 2 µm long. Svrček (1954: 14) correctly referred it to synonymy with *O. botulispora*. Again, the present study revealed warted spores (Pl. 875: 8). The asci are distinctly larger than indicated in the protologue ('25–27 µm including the bifurcate stipe'), and the capitate paraphysis apices 2.5–4 µm wide (Velenovský: '2.5 µm'). Based on the original colour, it seems that *O. faginea* represents a mixture of *O. leucostigma* and *O. xanthostigma*. A lectotypification on a part of the population is impossible because the very abundant and densely aggregated apothecia are now uniformly light yellowish-cream (when rehydrated). DNA extracts would be necessary to clarify the identity of individual apothecia of this collection. Velenovský's manuscript plate of *O. faginea* does not show the type but 2 much older collections with the note that he considered them as synonymous with *O. alnea*.

O. vitrea Velenovský (1947) was described from Mnichovice (Czechia, on rotten wood of *Juniperus communis*), with subhyaline apothecia of 1–2 mm diam. and globose-ellipsoid to globose spores 1–2 µm diam. Although the holotype was stated to be empty by Svrček (1954: 23), a single apothecium with now ochre(-orange) colour when dry could be found, which contained mature asci with cashew-shaped, warted spores

(Pl. 875: 4). Because of the apothecia originally described as subhyaline, *O. vitrea* is considered here to be a synonym of *O. leucostigma*. A manuscript plate with a brief sketch and a Latin diagnosis exists, which corresponds to the protologue except for ascus size (20–25 × 2.5 µm) which is erroneously given as 20–35 × 2.5 µm in the protologue.

Anamorph. From two different ascospore isolates under the name *O. delicatula*, Pfister (1997: fig. 7) and Liu (2006, fig. 24, see Pl. 878: 5) presented illustrations of a dicranidion-like anamorph, which Pfister referred to as '*Dicranidion* sp. of the gracile type' (D.H.P. 111 = 105), and Liu as *D. tenue* (HMAS 139665). On his fig. 8, Pfister considered an anamorph isolated from '*O. alnea*' (D.H.P. 81) as of the 'fragile type', although the conidia possess a distinct stalk contrary to *D. fragile* (note that Pfister erroneously applied on p. 13 the epithets '*fragile*' and '*gracile*' in contradiction to the legends under his figs 7 and 8). Pfister's fig. 8 resembles the anamorphs of *O. cejpii* or less so *O. renispora* but could instead belong to *O.* cf. *xanthoflexa* (see p. 1423). For another sample under the name *O. alnea* (D.H.P. 91) from another county in Massachusetts a sequence exists which clustered distant from the topotype of *O. xanthoflexa* (D.H.P. 130, as *Orbilia* sp.) and is named *O.* cf. *xanthoflexa* here. D.H.P. 91 and D.H.P. 130 formed a dicranidion-like anamorph with undocumented morphology, and clustered in a supported clade with European *O. leucostigma* and North American *O.* cf. *leucostigma* (see Phyl. 23). It appears possible that the illustrated D.H.P. 81 represents also *O.* cf. *xanthoflexa*.

In our two ascospore isolates of *O. xanthostigma* (neotype, Pl. 876: 3) and *O. leucostigma* (H.B. 6810c) we obtained dicranidion-like conidia (in H.B. 6810c without documentation), but we observed them also rather frequently on the natural substrate in close association with the apothecia or even on their margin and hymenium (Pls 876: 1–2; 878: 1d). Similarly, Arnaud (1952, fig. 7A) figured an anamorph found on an *Orbilia* sp. growing on a *Pinus* log, which he referred to *Pedilospora parasitans* (as *P.* '*parasitica*'). This is very probably not a parasite but a dicranidion-like anamorph that belongs to the apothecia on which it grows, and the conidial morphology fits the anamorph of *O. xanthostigma*. Conidia were also obtained by P.R. Johnston (pers. comm.) in ascospore isolates of two collections from New Zealand (PDD 58571, PDD 64847). They occur in the dried culture of PDD 58571, but we found them also on the natural substrate in PDD 59160. Sequences of these three strains clustered in three different clades (I–III, see below).

Some differences in conidial size and shape among the observed anamorphs were noted, even between populations from the very same geographical area. Conidia formed in our pure culture of *O. xanthostigma* showed a tendency to shorter, ± parallel arms with fewer septa similar as those cultured by Liu (2006, fig. 24), whereas conidia from the natural substrate in both *O. xanthostigma* and *O. leucostigma* generally had longer and mostly diverging arms (V-shaped). However, the conidia in one of Pfister's (1997: fig. 7, D.H.P. 111) cultures predominantly resemble those larger conidia with diverging arms, and only some conidia had ± parallel arms. The latter type of conidia, especially in Liu's and our strain, resemble more *Dicranidion tenue*, whereas those on the natural substrate and in D.H.P. 111 better fit *D. gracile*. *D. gracile* as described by Matsushima (1971, fig. 47; 1975: pl. 344 fig. 3; 1981, fig. 73) somewhat deviates from the anamorph of *O. xanthostigma* s.l. in having 0–5-septate conidiophores of 5–23 × (2–)3 µm, with 1–5 conical denticles (sympodial proliferation, see Pl. 11: g), whereas, in contrast, the conidiophores of *O. xanthostigma* s.l. on the natural substrate (Pl. 876: 1) and in culture (Pl. 878: 5b) were unbranched, 0–3 septate, with only terminally formed conidia. However, in Pfister's culture D.H.P. 111 sympodial proliferation also occurred.

For the type of *D. tenue* 3-septate conidiophores of 45–100 × 2–3 µm are reported (Matsushima 1993: 49, fig. 725), which rarely proliferate at the apex. *D. dactylopagum* was described with slightly longer, unbranched, only basally septate conidiophores (75–125 × 2–3 µm) with strictly terminally formed conidia. Apart from conidiophore length, this matches the anamorph of *O. xanthostigma* s.l. quite well. In the presence of testaceous rhizopods, the species produced adhesive protuberances on the mycelium which capture these invertebrates (Drechsler 1934). No rhizopods were added to our two ascospore isolates (H.B. 6810c, *O. leucostigma*; H.B. 6749, *O. xanthostigma*), but only nematodes which did not induce trapping organs.

Due to the similarity of the anamorphs observed in association with *O. leucostigma*, *O. xanthostigma*, and *O. xanthoflexa*, and the absence of sequence data in the types of *D. dactylopagum* and the similar *D. gracile* and *D. tenue*, these three anamorph-typified taxa are treated here as possible synonyms of the *xanthostigma-leucostigma* complex and require further investigation, particularly a molecular analysis of their type cultures. The predacious capabilities of *D. dactylopagum* are reminiscent of anamorphs of *Hyalorbilia*. However, in this genus dicranidion-like anamorphs and long, unbranched conidiophores are unknown at present, although similar staurosporous anamorphs do occur.

Phylogeny. Sequences of the ITS region were available for 36 samples of the *xanthostigma-leucostigma* complex (with warted ascospores, including *O. aureocrenulata* s.l.), which represent no less than 14 different genotypes and derive from five different continents (15 from New Zealand, 13 from Europe, 3 from USA, 2 from China, 1 from Brazil; see Baral et al. in prep.). Within Europe three genotypes have so far been observed: *O. xanthostigma* from nine samples, *O.* cf. *xanthostigma* from one sample (on a xeric branch), and *O. leucostigma* from three samples.

No other gene region was available for most of these 36 samples, except for 10 from Europe, which include also LSU D1–D2(–D12) (6× *xanthostigma*, 1× cf. *xanthostigma*, 3× *leucostigma*) and partly SSU (V1–)V8–V9 (1 × *xanthostigma*, 2 × *leucostigma*). For a further North American sample (D.H.P. 111) only SSU (V1–V8) was available in GenBank, but for it exists also unpublished LSU, and for about a dozen additional North American samples ITS and/or LSU (R. Healy pers. comm.).

In the present ML analysis of the ITS region (Phyl 24) we have used a reduced data set for *O. xanthostigma* (4 out of 9 sequences) and for *O.* cf. *xanthostigma* from New Zealand (5 out of 15 sequences, representing 5 different genotypes). The only environmental sequence, a DNA isolate from a *Picea* log from Sweden, which falls in this group, belongs to *O. xanthostigma* (Phyl 24). A comprehensive study on all sequences, including those from North America, will be published in a separate paper (Baral et al. in prep.).

The reduced data set of overall 20 strains formed together with three samples of the smooth-spored *O. xanthoflexa* s.l. a monophyletic group, the *leucostigma-xanthostigma* clade, which received medium support in our ITS analysis (Phyl. 23) and strong support in the ITS+LSU tree (Phyl. 22), whereas it was paraphyletic when analysing solely LSU (S27). Another species with smooth spores, *O. renispora*, clustered unsupported sister to this clade in Phyl. 22–23 but sister to the *xanthostigma* subclade (= *O. xanthostigma* s.l.) in S27. Its relationship with the *leucostigma-xanthostigma* clade is supported by characteristic motifs in the LSU D1 domain (see p. 1327). Based on these motifs we here use the name *xanthostigma-renispora* clade for the entire group.

Despite the high micromorphological homogeneity within the *xanthostigma-leucostigma* complex, a remarkable diversity in the rDNA is observed among these 36 samples. The *leucostigma-xanthostigma* clade consists of two medium (ITS) or strongly (ITS+LSU) supported subclades with about 16 genotypes, which represent four recognized species (*O. aureocrenulata*, *O. leucostigma*, *O. xanthostigma*, *O. xanthoflexa*) and 12 unnamed genotypes ('cf.'). Among the many synonyms listed under *O. leucostigma* and particularly *O. xanthostigma*, only one is of extra-European origin, *Peziza rufula* from Pennsylvania, and could represent an available name for one of the unnamed North American genotypes with pigmented apothecia.

Neither in the teleomorph nor the anamorph we have observed notable morphological deviations among the 14 genotypes of the *xanthostigma-leucostigma* complex, except for differences in pigmentation between *O. leucostigma* and *O. xanthostigma* within Europe and a different apothecial shape in *O. aureocrenulata*. A majority of available sequences derive from more or less yellow apothecia, but notes on the fresh colour were not available in every case. In the three European strains of *O. leucostigma* with sequence data the colour was whitish or sometimes pale violaceous-rosaceous, whereas in *O. aureocrenulata* s.str. and the nine European sequenced strains of *O. xanthostigma* it was pale to bright yellow. In samples from New Zealand the apothecia varied from pale chlorinaceous to bright golden yellow(-orange) when fresh (P.R. Johnston & J.A. Cooper pers. comm.), and in those from North America they were either white with sometimes pink tinge, pale to bright yellow, or orange (R. Healy pers. comm.).

According to Phyls 22 & 23), the *xanthostigma* subclade, as we call one of the two main clades of the *xanthostigma-leucostigma* complex, includes at present European (and Macaronesian, not shown) *O. xanthostigma*, European *O.* cf. *xanthostigma*, and different clades of *O.* cf. *xanthostigma* from New Zealand and North America. The other clade includes the tropical *O. aureocrenulata* and the *leucostigma-xanthoflexa* subclade which consists of two subgroups: (1) European *O. leucostigma* and two genotypes from USA and China (*O. leucostigma* s.l.), and (2) North American taxa with smooth spores (*O. xanthoflexa* s.l.). A strong correlation with the geographical origin is seen at the moment when focusing on all 14 genotypes of the *xanthostigma-leucostigma* complex: five genotypes are Australasian (New Zealand), three European, four North American (northeastern USA), one South American, and two eastern Asian. According to unpublished phylogenetic analyses (R. Healy pers. comm.), a majority of North American samples with white to yellow or orange apothecia represent two genotypes in the *xanthostigma* subclade, one of which including strain bhi-F037 from Massachusetts in Phyl. 23. Two samples with white apothecia belong with D.H.P. 108 from Maine to a genotype in the *O. leucostigma-xanthoflexa* subclade (for a comprehensive analysis see Baral et al. in prep.).

The affiliation of *O. xanthoflexa* s.l. from North America with *O. leucostigma* (ITS distance 7–8%) was unexpected, because this somewhat heterogeneous species sharply differs from the *xanthostigma-leucostigma* complex in longer, partly less curved, smooth ascospores. Its placement near *O. leucostigma* is surprising, considering the high ITS distance of 16.5% between *O. leucostigma* s.str. and *O. xanthostigma* s.str.

In the LSU D1–D2 the distance between *O. leucostigma* s.str. and *O. xanthostigma* s.str. lies at 3.5% and in the SSU V8–V9 at 0.8%. An overview of the ITS distances among the various genotypes within the *leucostigma-xanthostigma* clade is given in Baral et al. (in prep.).

The **S1506 intron** is present within the *leucostigma-xanthoflexa* subclade in *O.* cf. *xanthoflexa* (ga026b) and the three samples of European *O. leucostigma*, and within the *xanthostigma* subclade in 10 samples from New Zealand (4 shown in Phyl. S26), one from Luxembourg (G.M. 2018-04-28.1) and one from Massachusetts (bhi-F037). The intron is absent in nine European *O. xanthostigma* samples, two from Macaronesia, one from New Zealand (D2007), and in *O. aureocrenulata*. Some sequences are unclear in this respect as they were gained with the ITS1 primer or with the ITS4 primer alone. In conclusion, the presence/absence of the S1506 intron and its phylogenetic analysis permit distinction among the different genotypes, except that in one genotype from New Zealand with seven strains (including D660) the intron was 6× present and 1× absent (D2007).

When analysing the intron phylogenetically (Phyl. S26), strains bhi-F037 and G.M. 2015-12-12.1, members of the *xanthostigma* subclade, clustered with strong support sister to *O. leucostigma*, although other members of the *xanthostigma* subclade (i.e., samples from New Zealand) formed with unresolved relationship a strongly supported clade of their own (for more details see Baral et al. in prep.).

Three **group I introns** occur in the LSU D9–D11 domain (see Tab. 28) in both *O. xanthostigma* and *O. leucostigma*. The L1921 intron was not obtained in *O. leucostigma*, but appears to exist according to the PCR product on the agarose gel (sequencing of the D9 domain so far failed). The other two introns differ between *O. xanthostigma* and *O. leucostigma* by 23% (L2449) and 7% (L2563). The high distance in the L2449 intron is accompanied by numerous gaps in both sequences.

A correlation between molecular data and conidial shape seems unlikely. The conidia seen in two collections from New Zealand (IVV: PDD 58571, PDD 59160) did not differ from those observed in Europe. Regrettably, DNA data were unavailable for Liu's HMAS 139665, therefore, a molecular comparison of the samples with different conidial shapes was impossible. The inofficial LSU of D.H.P. 111 ('gracile type') belongs to one of the two mentioned unique North American genotypes of *O.* cf. *xanthostigma*, according to an unpublished phylogenetic analysis by R. Healy (pers. comm.).

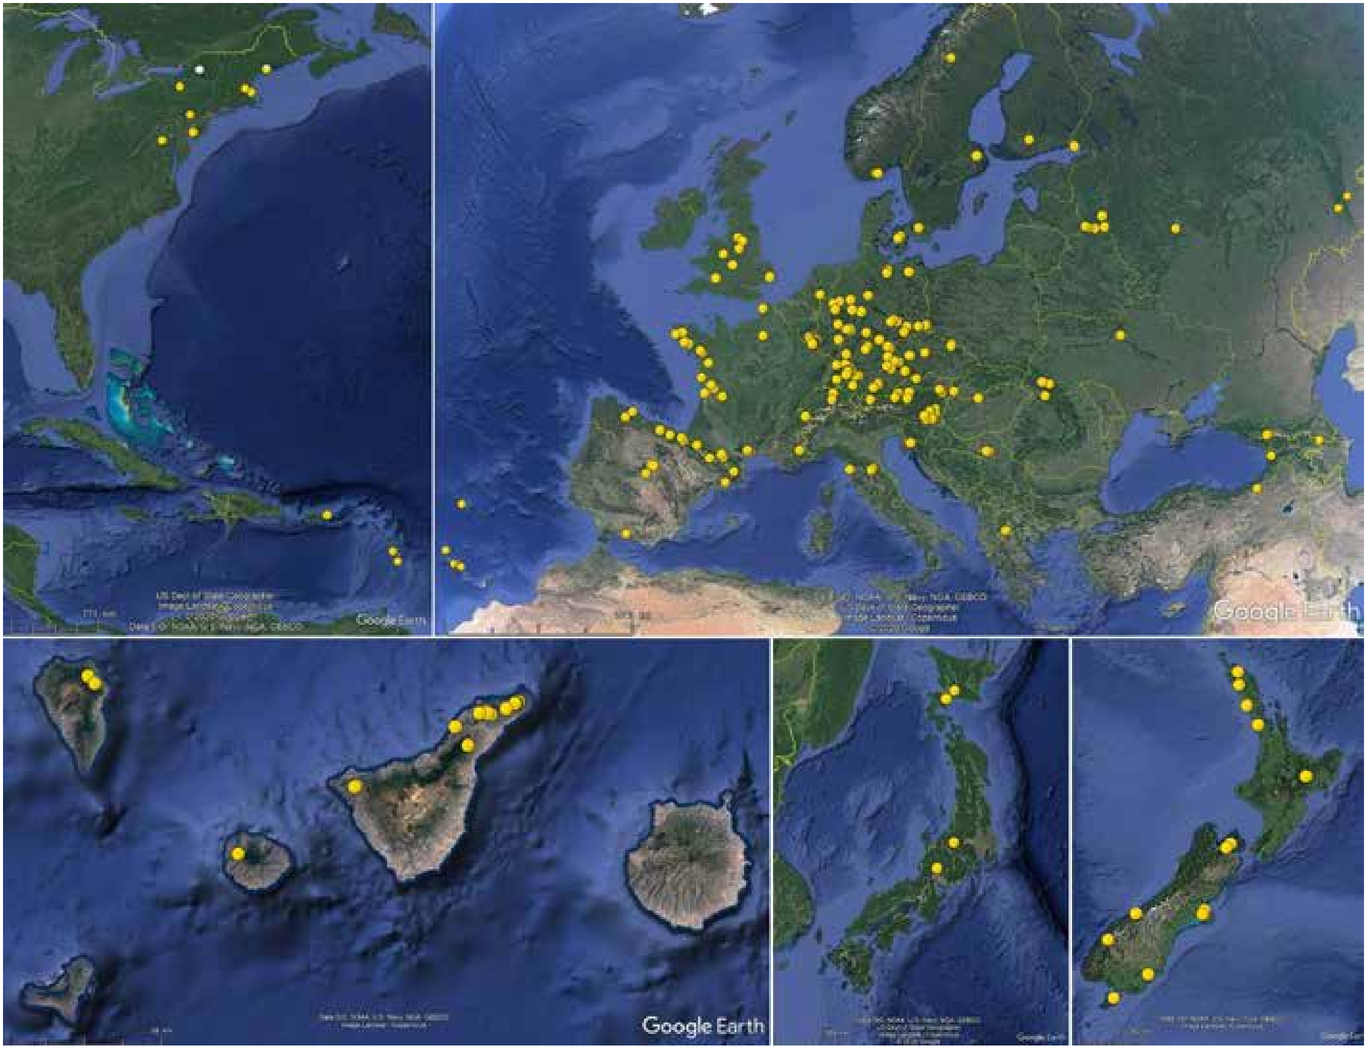
In view of the high distances observed in the ITS region within the *leucostigma-xanthostigma* clade, it appears that a couple of different cryptic species will need to be segregated in the future. Only *O. aureocrenulata* we have segregated here because of its macroscopic differences, although the hymenial features do not differ.

***O.** leucostigma* and O. *xanthostigma* possibly differ in the **relative DNA content**. In her study on the DNA content of nuclei, Weber (1992) found one of the three studied collections of

'*O. delicatula*' (from Wunsiedel, REG 143) to be heterogeneous within a single population, showing fruitbodies with the lowest relative DNA content (1 ×) and others with the double content (2 ×), whereas in the other two samples (REG 134, 138) she observed only the double content. No micromorphological differences were observed between the fruitbodies. Regrettably the apothecial colour was not noted, though she remembers mainly yellow apothecia. A possible explanation would be that REG 143 contained both *O. leucostigma* and O. *xanthostigma*, and the rarer *O. leucostigma* had the 1 × content.

Ecology. Judging from the literature and the consulted herbaria, the *xanthostigma-leucostigma* complex is among the most frequently collected species of *Orbilia*. A total of over 450 collections are assigned here to this complex. Within *xanthostigma-leucostigma complex*, yellow populations (marked by 'xan') were much more frequently encountered than white populations (marked by 'leu'). Among the European specimens listed below, 246 samples were assigned to *O. xanthostigma* and 74 to *O. leucostigma*. However, this distinction is based in most cases on apothecial colour alone, which was in *O. xanthostigma* partly only a faint yellow. Further 38 collections remained unclarified because notes on colour were lacking.

Species of the cosmopolitan and plurivorous *xanthostigma-leucostigma* complex grow on rotten wood, rarely bark (~6.5 %) of ± hygric to mesic branches or mainly on trunks/logs and stumps of both gymno- and angiosperm trees (rarely shrubs), rarely (~1 %) on xeric branches. Exceptionally it grew on cones of *Pinus*, perennial basidiomycetes, or pyrenomycetes. Favourite host genera can hardly be determined. Within Europe the species aggregate was predominantly recorded on *Fagus* {73 [43/25/5]}, followed by *Quercus* {51 [37/12/2]}, *Alnus* {32 [24/4/4]}, *Betula* {31 [23/3/5]}, *Carpinus* {22 [12/5/5]}, and *Salix* {17 [11/5/1]} (by omitting uncertain hosts, numbers in square brackets refer to *O. xanthostigma*/*O. leucostigma*/ undetermined). However, coniferous host genera (mainly *Pinus*) were also very frequently recorded {63 [47/8/8]}. The observed frequency of *O. xanthostigma* and comparative rareness of *O. leucostigma* on gymnosperms is in conflict with observations



Map 141. Known distribution of *O. xanthostigma* s.l. (yellow) and *O. leucostigma* (white) in Northern America, Europe (including Macaronesia and eastern Asia), Japan, and New Zealand.

by Ellis & Ellis (1985) who reported *O. leucostigma* mainly on coniferous wood (*Pinus nigra* var. *maritima* = Corsican Pine, a commonly planted forest tree in the lowlands of Britain), whereas they found *O. xanthostigma* to be more common on deciduous trees and only occasionally on conifers (*Pinus radiata*). In Macaronesia *O. xanthostigma* (and rarely *O. leucostigma*) were quite frequently collected by L. Quijada and J.P. Priou in the mesosub- to mesomediterranean semihumid to humid laurel forest and *Erica platycodon* ridge-crest evergreen forest, also in the humid pine forest, and the identified hosts include *Lauraceae* (*Laurus* 13 ×, *Ocotea* 3 ×, *Apollonias* 1 ×), *Ericaceae* (*Erica* 10 ×), *Myricaceae* (*Myrica* [= *Morella*] 8 ×), *Rosaceae* (*Prunus* 6 ×), and *Aquifoliaceae* (*Ilex* 6 ×) (for the list of collections see Quijada et al. 2016).

In about 15 of the European collections (~ 10 %) the inhabited region of the branches, trunks or logs was without contact to the soil. However, when growing on deeply rotten wood of standing, dead, ± decorticated trunks, the apothecia need not to be desiccation-tolerant since their water supply is provided by the substrate over a long time (marked below by 'mes'), similar as on the upper side of logs lying tightly on the ground. Only when growing on thin branches up to 0.5–3 m above the ground, the substrate is periodically dry and the apothecia should expectedly be drought-tolerant (marked below by 'xer'). This situation was only exceptionally observed, e. g., in a collection from Oberpfalz (H.B. 4929a) made in August 1993, in which ca. 25 bright honey-yellow apothecia of *O. xanthostigma* and *Brachysporium nigrum* grew closely together with the desiccation-tolerant *O. vinosa* on a 13 mm thick, partially decorticated, attached branch of *Quercus* in 1–2 m above the ground at the base of a south-exposed slope in a shady forest. However, all asci were dead when the dry specimen was examined a few days later. In another collection (H.B. 6396a, Oberbayern) 14 bright yellow(-orange) apothecia grew 0.5 m above the ground in association with the desiccation-tolerant *Claussenomyces atrovirens* on an arm-thick branch attached to a fallen tree, and here the rare case of nearly smooth spores was observed (Pl. 875: 5).

Whether members of the *xanthostigma-leucostigma* complex are able to trap invertebrates, in particular testaceous rhizopods, remains to be clarified. This behaviour was reported by Drechsler (1934) in *Pedilospora dactylopaga* (≡ *Dicranidion dactylopagum*), which might be a member of this group.

The *xanthostigma-leucostigma* complex appears to occur in all climatic regions that provide sufficient and prolonged humidity (humid to subhumid or semihumid) and woody substrate of a minimum thickness of (1–)3 cm. The altitude includes all levels from planar to subalpine. The species aggregate occurs from oroboreal to tropical, and from maritime to continental climates. Within Europe, a rather dense distribution is reported, e. g., for the Netherlands (http://www.verspreidingsatlas.nl/657030), Great Britain (http://www.fieldmycology.net/GBCHKLST/gbchklst.asp), Germany (Krieglsteiner 1993), Austria (http://www.austria.mykodata.net), and Switzerland (http://www.wsl.ch/dienstleistungen/inventare/pilze_flechten/swissfungi/verbreitungsatlas/index_DE). Outside of Europe its distribution includes eastern Asia (Raitviir 1991: 357, Liu 2006: 69, Wu 1998), southeastern Australia and New Zealand (Spooner 1987), Northern America (e. g., Schweinitz 1832, Pfister 1997), Middle America (present study), South America (Montagne 1853), Macaronesia (Quijada et al. 2016), and southeastern Africa (present study).

The occurrence within Europe mainly includes nemoral, cold-temperate to hemiboreal humid regions, with forests like *Querco-Fagetea*, *Alno-Fraxinetea*, and *Salicetea*, but also conifer forests, on calcareous as well as acidic soils. Collections are also known from warm-temperate to mesomediterranean regions of southern Europe (map). Within Macaronesia the known records are from the north-exposed thermomediterranean (sub)humid laurel forest and *Erica platycodon* ridge-crest forest but also the humid pine forest (map).

In (north)eastern North America the *xanthostigma-leucostigma* complex was recorded from cold- to warm-temperate humid forests, and in the northwest from a mild-maritime humid mixed evergreen forest. A few collections were studied from the tropical humid rainforests of the Antilles archipelago (map). Asia. In Australia and New Zealand (map) the vegetation mainly includes warm-temperate to subtropical humid *Nothofagus* forests. The single record from Africa was from a subtropical humid (winter-dry) broad-leaved forest in a ravine of a savannah plateau in the Drakensberg Mountains.

Specimens included (xan = *O. xanthostigma* s.l., with very pale to bright yellow apothecia [or clade genetically determined], leu = *O. leucostigma* s.l., with whitish or wine-reddish apothecia, leu & xan: mixed population of both colours, *leu = no information on apothecial colour available; xer = xeric, mes = mesic, no remark = hygric or unknown): **NORWAY**: **Aust-Agder**, 4 km N of Arendal, 2.7 km N of Vrengen, Sørsvann, 52 m, *Betula*, 19.X.2008, T.H. Dahl (xan, K.H. 161/08, doc. vid.). – 5 km ENE of Arendal, Tromøy, Alvekilen, 20 m, *Betula*, 3.V.2008, T.H. Dahl (xan, K.H. 95/08, doc. vid.). — **SWEDEN**: **Västerbotten**, 21 km NW of Saxnäs, NE of Grundfors, S of Kraejhpiesvaerie, ~620 m, log of *Betula pubescens*, on wood, 25.VII.2010, T. Læssøe (xan, ø). – **Uppsala**, 35 km WNW of Uppsala, around Knutby, ~30 m, log of *Picea abies*, before 2011, M.T. Banik (xan, 0521Banik_04G_31, uncultured clone; sq.: HQ611325). – **Skåne**, Söderåsen, 4.5 km NW of Röstånga, NW of Lierna, Lia mad, 120 m, log of ?*Carpinus betulus*, on wood, 4.VI.2006, J.G.B. Nielsen (xan, ø). – unlocalized, *Fagus sylvatica*, on wood, autumn and spring, ?E.M. Fries (leu, **type** of *Peziza leucostigma*, non vid., unlocated). — **FINLAND**: **Varsinais-Suomi**, 21 km W of Turku (Abo), Merimasku, ~10 m, log of indet. gymnosperm, on wood, 21. VI.1860, P.A. Karsten (leu, herb. Karsten 3193 & W. Nylander, H-6051956, as *Peziza leucostigma*). – **Kanta-Häme**, ~8 km E of Forssa, N of Tammela, Mustiala, 110 m, wood of *Betula*, 1.X.1868, P.A. Karsten (xan, Karsten 2351, H-6051979, **holotype** of *O. delicatula*, doc. vid.). — **ESTONIA**: **Tartumaa**, ~7 km SW of Tartu, Ropka Forest, 80 m, log of *Picea abies*, on wood, 30.VIII.1976, B. Kullman (*leu, TAAM 68861). — **DENMARK**: **Sjælland**, 6.5 km S of Sorø, 4 km S of Frederiksberg, Suserup Skov, 30 m, log of *Fagus sylvatica*, on wood, 25.V.2007, H.O. Baral (leu, H.B. 8513 ø). – ibid., shore of Tystrup Lake, 15 m, branch of *Alnus glutinosa*, on bark, 25.V.2007, W. Orbilia aureocrenulata Baral, **sp**. **nov**., MB 813962 — Pls 880–881

Etymology: named after the golden yellow colour and the notched margin.
Typification: Puerto Rico, El Yunque, trunk of indet. angiosperm, 18.I.1996, D.H. Pfister & F.A. Harrington (ex D.H.P. PR 42, FH 00458097, holotype).

Latin diagnosis: *Apothecia rehydratata 1–3 mm diam.*, *vivide aureo-lutea*, *distincte abrupte stipitata*, *margine exigue crenulato. Ascosporae †2.5–3 × 1.1–1.3 µm*, *valde curvatae (semicirculares)*, *dorsaliter minute verrucosae. Paraphyses ad apicem modice ad valde capitatae*, *exsudato nullo. Excipulum in parte basali cellulis paulo crassitunicatis*, *margine absque processis vitreis. Habitat ad lignum putridum truncorum uvidorum angiospermarum in zona tropica (per)humida Americae centralis et australis.*

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated (0.5–)1–2.2(–3) mm diam., (0.3–)0.5–0.9 mm high (receptacle 0.15–0.2 → 0.1 mm), light to bright golden yellow(-ochraceous), rarely pale yellowish to chlorinaceous, medium translucent, hygrophanous, round to slightly undulating, distinctly gelatinous, scattered or subgregarious to gregarious in small groups; disc slightly concave to flat or finally

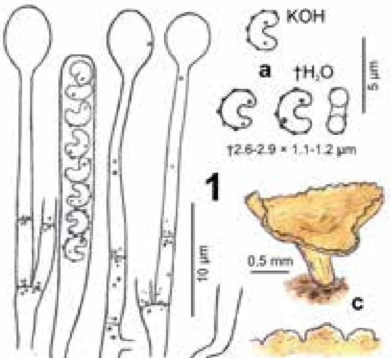

Plate 880. **1**: *Orbilia aureocrenulata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. apothecium (rehydrated 21 months after collecting); **d**. dentate margin.

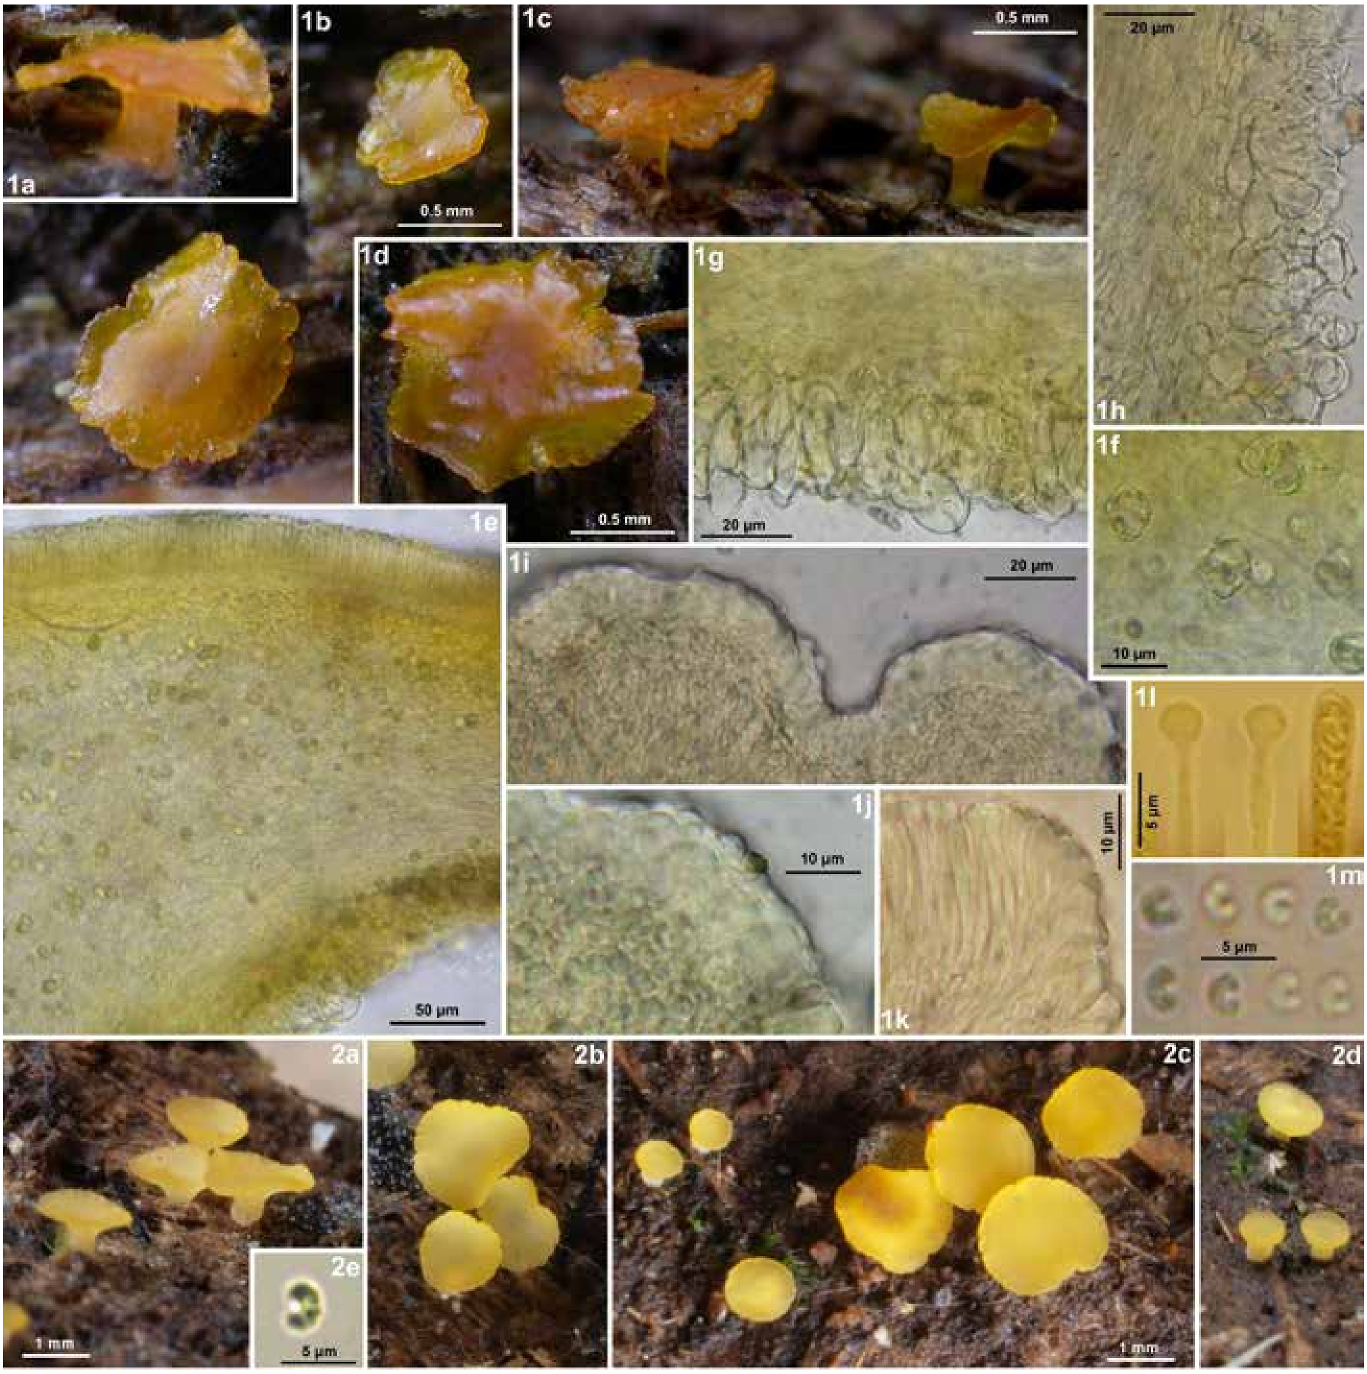

Plate 881. **1–2**: *Orbilia aureocrenulata*. – **2a–d**. fresh apothecia; **1a–d**. rehydrated apothecia (1 month after collecting); **1e**. apothecium in median section near stipe; **1f**. closeup of medullary excipulum in **1e**, with druses-like exudate; **1g**. median section of ectal excipulum at lower flanks; **1h**. id., in stipe; **1i–j**. marginal lobes in top view; **1k**. margin in median section; **1l**. apices of ascus and paraphyses; **1m**, **2e**. ascospores. – Dead state (**1e–f** in H_2O; **1g–j**, **m** in KOH, **1l** in KOH+IKI), except for **2e**. – **2a–e**: phot. M. Mann. — **1a–m**. H.B. 8027: Lesser Antilles, Martinique, on indet. angiosperm (wood); **2a–e**. H.B. 9672: Brazil, Rio de Janeiro, on indet. angiosperm (bark).

± convex, margin not protruding, regularly notched by forming small, obtuse yellow lobes; always with an abrupt, ± cylindrical, sometimes slightly eccentric, whitish to pale yellow stipe (0.1–)0.3–0.8 × 0.2–0.7 mm, superficial; dry bright yellow-ochre. **Asci** †(26–)30–38 × (2.7–)3–3.3(–3.5) µm {3}, 8-spored, spores †uniseriate, irregularly oriented; **apex** (†) strongly truncate (not or sometimes slightly indented, laterally not inflated); **base** with short to medium long, thin or thick, ± flexuous stalk, Y-, h- or H-shaped. **Ascospores** †2.4–3 × 1–1.3 µm {4}, cashew-shaped, very strongly curved (± semicircular, for ~160–200°), both ends rounded to obtuse, dorsal side with 4–7 minute warts {6}; **SBs** probably near 1 end, globose. **Paraphyses** apically medium to very strongly capitate, terminal cells †19–25 × (2–)2.5–4.2 µm {2} (0.7–1.5 µm below head), lower cells †5–7.5 × 1.2–1.7 µm {2}; unbranched at upper septum, lower part of hymenium light yellow. **Medullary excipulum** subhyaline, ~100–200 µm thick in receptacle, of dense textura intricata with a few inflated cells, sometimes with intercellular druses-like balls of pale yellowish exudate, sharply delimited from ectal excipulum, upper 20–30 µm (subhymenium) light yellow. **Ectal excipulum** hyaline to pale yellow, of (†) slightly gelatinized, vertically oriented t. globulosa-angularis(-prismatica) from stipe to flanks, 40–90 µm thick near base, cells †19–25 × 10–19 µm {1}; at flanks 35–40 µm thick, at margin 10 µm, of t. globulosa-prismatica oriented at a (20–)40–70° angle to the surface, marginal cortical cells †7–10 × 3–6 µm {1}, thin-walled; **glassy processes** absent. **Anchoring hyphae** abundant, †1–3 µm wide, walls 0.2 µm thick {1}, forming a dense, hyaline t. intricata-porrecta 50–70 µm thick below base of stipe. **SCBs** no data available. **Exudate** over paraphyses, margin and flanks absent. — **ANAMORPH**: unknown (but see below).

Habitat: lying on ground, on the underside of decorticated or corticated, ~8 cm thick branches or thick logs of indet. angiosperm trees {6}, on deeply strongly decayed wood {4} or bark {2}, no algae. **Associated**: *Ascocoryne* sp. {2}, ?*Dicranum* sp. {1}, *O. martinicensis* (on different branch) {1}, indet. pleurocarpous moss {3}, black setae of hyphomycete. **Desiccation tolerance**: not tested, probably desiccation-sensitive. **Altitude**: 15–1475 m a.s.l. **Phenology**: X, XII–I, IV (tropical belt and southern hemisphere).

Taxonomic remarks. *Orbilia aureocrenulata* differs from the remaining members of the *xanthostigma-leucostigma* complex in apothecia with a comparatively long, cylindrical stipe (at least about as long as wide), and a distinctly and regularly notched margin, also in a tendency to more thick-walled cells of the ectal excipulum, finally in the tropical distribution. The only documented living spore of *O. aureocrenulata* (Pl. 881: 2e) suggests that 2 globose SBs occur, one at each end, but we assume that one of them represents an oil drop.

Most of the seven studied collections of *O. aureocrenulata* showed a golden yellow colour very similar to *O. xanthostigma*. Since also the microscopic characters perfectly concur in the two species, the delimitation from tropical records here included in the *xanthostigma-leucostigma* complex requires further molecular research. For instance, in the El Yunque National Forest in Puerto Rico, besides *O. aureocrenulata* (D.H.P. PR 42, 58, 76) also *O. xanthostigma* s.l. with sessile, yellow apothecia was collected (D.H.P. PR 10), according to brief notes by the first author, but this remained without sequence.

Not included collection. The sample from tropical China (B. Liu, IVV: B.L. 6212) concurs with *O. aureocrenulata* in spore characters, but its yellow, apparently sessile apothecia have a smooth margin and its molecular data strongly deviate.

Anamorph. An ascospore isolate of the not included collection from tropical China formed dicranidion tenue-like conidia in culture (B. Liu pers. comm.) but we did not see photos of them.

Phylogeny. An ITS sequence from apothecia of the Brazilian specimen clustered strongly or medium supported but unresolved in the *leucostigma-xanthostigma* clade (Phyls 22–23), with a minimum distance of 13.5% to *O. leucostigma* and 15.5% to *O. xanthostigma*. This result and an unavailable LSU sequence of the holotype of *O. aureocrenulata* (D. Pfister pers. comm.) support the taxonomic distance of this species. However, the various, morphologically indistinguishable unnamed clades within the *leucostigma-xanthostigma* clade show similar distances among each other which lie in the range of 5–18%. The S1506 intron is absent in concordance with *O. xanthostigma* s.str., whereas it is present in European *O. leucostigma* and some American and New Zealand strains of this aggregate. An ITS sequence of a sample from tropical southern China under the name *O. delicatula* (B.L. 6212) clustered strongly supported but with ~17% distance with *O. aureocrenulata* (Phyl. 23).

Ecology. *O. aureocrenulata* was found on rotten wood of hygric mossy branches or logs of broad-leaved trees. All six known records studied by the first author are from tropical humid (wet and dry) atlantic rainforests in Middle and South America. A recent collection examined by L. Quijada (pers. comm.) was from a subtropical humid (mesophilic) rainforest in Mexico. Also the not included Chinese sample was made in a tropical humid rainforest.

Specimens included. **COSTA RICA**: **Cartago**, Canton de Paraíso, 19 km km SE of Cartago, 9 km SE of Orosi, Tapantí, Sendero Oropendola, ~1290 m, on wood of indet. angiosperm, 14.IV.1992, G. Kost (G.K. 7559). — **PUERTO RICO**: Sierra de Luquillo Mts., El Yunque, trail from Sierra Palm to Mt. Britton, ~650 m, trunk of indet. angiosperm, on wood, 18.I.1996, D.H. Pfister & F.A. Harrington (D.H.P. PR 42, FH 00458097, **holotype**, H.B. 5944 ø, sq.: ined.). – El Yunque, 30 km ESE of St. Juan, Rio Grande, El Verde Field Station, 15 m, log of indet. angiosperm, on wood, 20.I.1996, D.H. Pfister, F.A. Harrington, M. Liftik & D. Potter (D.H.P. PR 76, FH). – ibid., log of indet. angiosperm, on bark, 20.I.1996, S.M. Hundorf (D.H.P. Lechat (C.L.L. 5537, H.B. 8027). — **MEXICO**: **Veracruz**, 8.5 km WSW of Xalapa, 1 km SW of Rancho Viejo, Rancho Agüita Fría, 1475 m, branch of indet. angiosperm, on ?wood, 22.X.2018, L. Quijada & R. Medel (doc. vid.). — **BRAZIL**: **Rio de Janeiro**, ~145 km WNW of Rio de Janeiro, 9.5 km N of Itatiai, N of Penedo, 690 m, branch of indet. angiosperm, on bark, 9.X.2011, M. Mann (H.B. 9672; sq.: KT222359).

Not included. **CHINA**: **Yunnan**, **Xishuangbanna**, 19 km NNE of Jinghong, 10 km NNW of Mengyangzhen, Wild Elephant Valley, 1000 m, branches of indet. tree, 9.XI.2002, B. Liu, Y. Yang & B. Wang (B.L. 6212, HMAS 139670, as *O. delicatula*, anam. cult., doc. vid.; sq.: DQ656622).

Orbilia renispora Y.Y. Shao, Quijada, Baral, Haelew. & Bin Liu, in Shao et al., Mycol. Progr. 17(11): 1229 (2018) — Pls 882–883

Etymology: according to the reniform ascospore shape.

Typification: USA, Georgia, Fargo, Stephen C. Foster Park, branch of indet. angiosperm, 24.IX.2015, Y.Y. Shao & H.F. Zheng (UGA ga038, GXU 1487; sq.: MG742403, MG742404).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.25–)0.4–0.8(–1.1) or sometimes 0.8–1.6 mm diam., 0.16–0.32 mm high (receptacle 0.11–0.25 → 0.08 mm), whitish to often bright yellow to yellow-orange, medium translucent, round, subgregarious to gregarious; disc slightly concave, finally flat with umbilicate centre, margin distinct, smooth, thin or thick, not protruding; sessile on a broad base, superficial; dry slightly contracted, yellow-orange or pale cream. **Asci** *28–38 × 3.1–3.6 µm {2}, †(24–)28–35(–39) × 2.7–3.5(–3.8) µm {6}, 8-spored, spores ± 1-seriate, ~3–5 lower spores inverted (often strongly mixed) {~4 }, pars sporifera *9–10.5 µm long, †16–20 µm; **apex** (†) strongly truncate (often distinctly indented, laterally not widened); **base** with very short to long, flexuous stalk, L-, Y- or often h- to H-shaped. **Ascospores** *(2.4–)2.6–3(–3.5) × (1.1–)1.2–1.4 µm {2} or *2.8–3.7 × 1.6–1.8 µm {2}, †(2.8–)3–3.6(–3.9) × 1.5–1.8(–2) µm {3}, ellipsoid-clavate, upper end rounded to obtuse, lower end not or slightly to medium, rarely strongly attenuated, smooth, slightly to medium, rarely strongly curved (reniform); **SBs** 0.3–0.5(–0.6) µm diam., globose, in the upper end close to the wall; **Paraphyses** apically uninflated to mostly slightly to strongly capitate(-clavate), terminal cell */†14–21 × (1.7–)2–3.3 µm {3}, lower cells */†4–8 × (1.2–)1.5–2.2 µm {3}, unbranched in upper part. **Medullary excipulum** 40–70 µm thick, of ± loose t. intricata with ± inflated cells, sharply delimited. **Ectal excipulum** (†) thin-walled to slightly gelatinized, of vertically oriented textura globulosa-angularis (to t. prismatica) from base to mid flanks, 35–55 µm thick near base, cells *(8–)12–21(–28) × (5–)10–14(–18) µm {3}, at margin 15 µm thick, oriented at 0–20°, marginal cortical cells *5–7 × 2.5–3.5 µm {1}; **glassy processes** absent. **Anchoring hyphae** sparse to medium abundant, 2–3 µm wide, walls ~0.2–0.3 µm thick {1}. **SCBs** in apex of paraphyses not seen for sure; **VBs** roundish to elongate, partly strongly divided, slightly to medium refractive, hyaline {4}; small golden yellow-orange **LBs** present at septa of paraphyses, also in ectal excipular cells at margin and flanks {3}, or absent {2}. **Exudate** overall absent or thin (0.1–0.2 µm), granular, firmly attached. — **ANAMORPH** (dicranidion-like, from pure culture {1}): **Conidiophores** unbranched, erect, *3.5 × 1–2.8 µm, 1.0–1.5 µm wide at apex. **Conidia** Y-shaped, with 2 straight, parallel or distinctly diverging arms of ± equal length, total size *9.3–12.3 × 4–5.8 µm, stipe *1.5–3 × 1.4–1.6 µm, obconical, aseptate, arms *5.5–8.5 × 1.8–2.2 µm, cylindrical but slightly tapering above, 1–2-septate; some conidia unbranched, narrowly fusoid, e.g., *15.5 × 2.6 µm, 3-septate {1}.

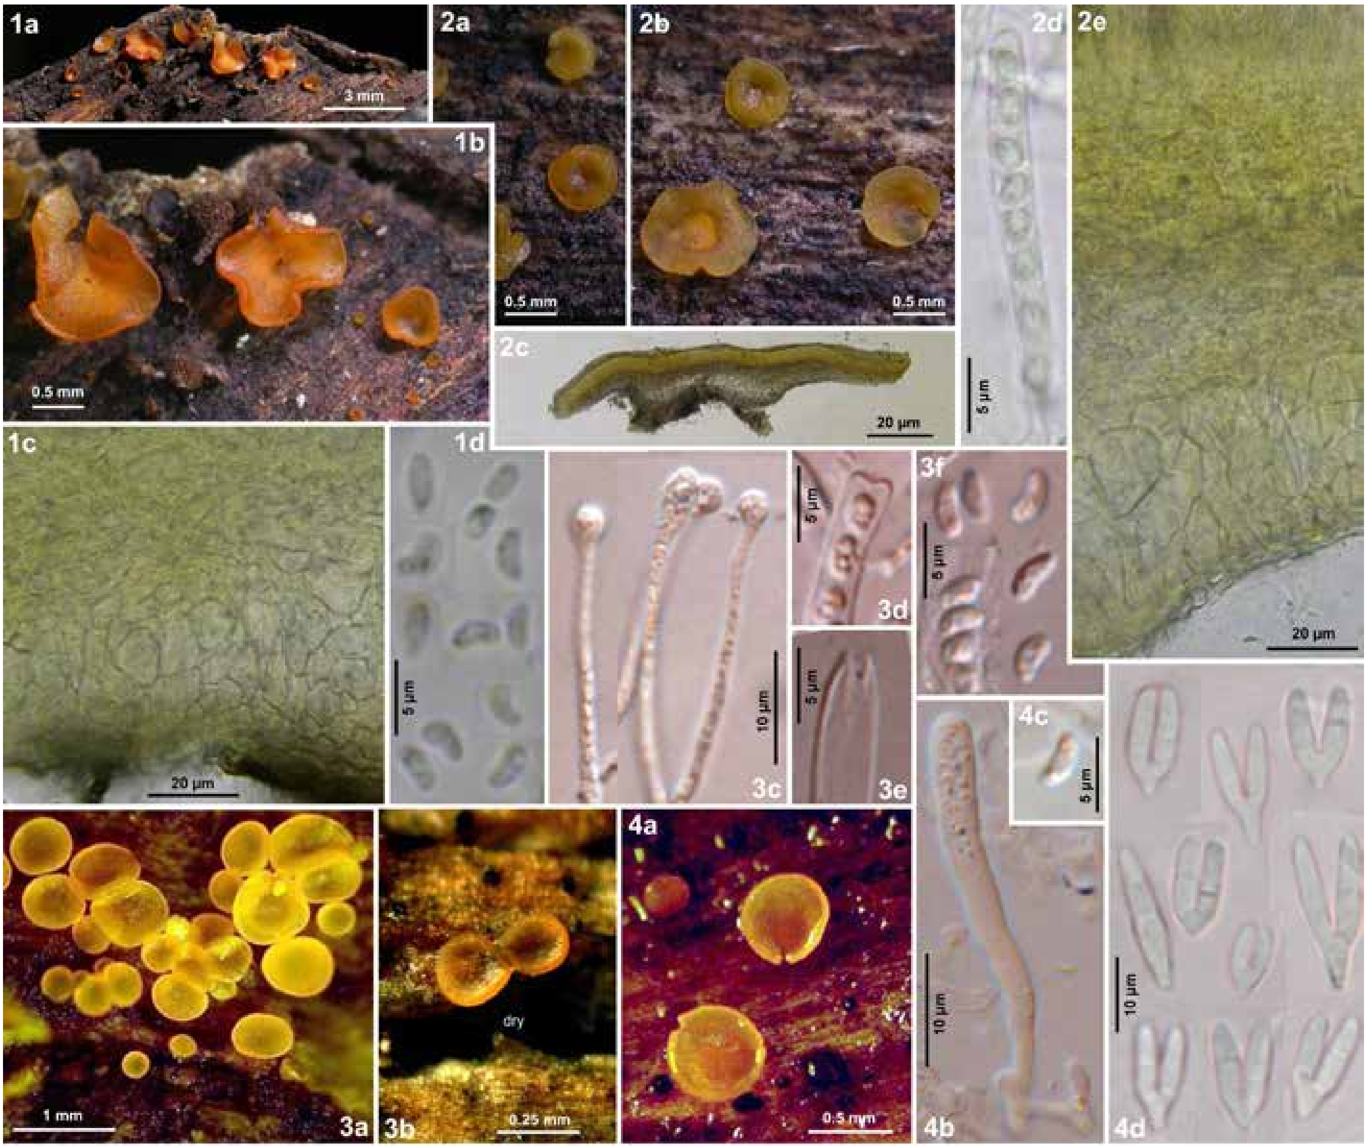

Plate 882. **1–4**: *Orbilia renispora*. – **3a**, **4a**. fresh apothecia; **1a–b**, **2a–b**. rehydrated apothecia; **3b**. dry apothecia; **2c**. apothecium in median section; **1c**. id., ectal and medullary excipulum in central part of apothecium; **2e**. id., at lower flanks; **2d**, **4b**. asci; **3d**. ascus apex in front view; **3e**. apex of emptied ascus with slit-like opening; **3c**. paraphyses; **1d**, **2d**, **3f**, **4c**. ascospores; **4d**. conidia. – Dead state (in H_2O), except for **2d** (spores), **4c–d**. – **3–4**: phot. Y.Y. Shao. — **1a–d**. H.B. 9997: USA, Massachusetts, Boston Harbor Islands, on *Quercus*; **2a–e**. H.B. 9998: id., on *Acer*; **3a–f**. ga031: USA, Georgia, Douglas, on indet. angiosperm; **4a–d**. ga038: id.

Habitat: on moist ground, ± decorticated, ~2–10 cm thick branches and logs or stumps of *Acer* {1}, *Quercus* {4}, indet. angiosperm {3}, indet. tree {1}, on slightly to strongly decayed wood {8}, sometimes below detaching bark, partially blackened, no algae seen. **Associated**: *Hyalorbilia japonica* {1}. **Desiccation tolerance**: probably intolerant but some ascospores survived for 2.5 years. **Altitude**: 5–70 m a.s.l. **Geology**: Miocene to Quaternary sediments; granite. **Phenology**: V–X.

Taxonomic remarks. In its ascospore shape and size and the dicranidion-like anamorph, *Orbilia renispora* somewhat resembles *O. xanthostigma*, *O. leucostigma*, *O. xanthoflexa*, and *O. eucalypti*. From the former two species it differs in larger, much less curved, smooth spores, and from the latter in slightly smaller, predominantly curved spores. *O. xanthoflexa* differs in much longer and narrower spores and in strongly capitate paraphyses. Macroscopically, *O. renispora* appears to be hardly distinguishable from these species. The Asian *O.* aff. *renispora* (Pls 884–885) differs in shorter, more strongly curved spores with a higher lipid content and more strongly inflated paraphyses. In Haelewaters et al.'s (2018) checklist of fungi at the Boston Harbor Islands *O. renispora* is referred to as *Orbilia* sp. 2.

Variation. In the four recent samples from Boston the spores are slightly shorter and especially narrower, and also the asci are shorter and narrower than in the two earlier samples from Boston and in those from Georgia.

Phylogeny. Sequences were available for three samples from Boston (bhi-F097, F108, F880a), one from Georgia (ga038, type), and one from Florida (FLAS-F-61526). All comprise S1506 intron, whereas the ITS is only complete in ga038 (ITS2 lacks in the others). For bhi-F097 and ga038 also LSU exists. In the intron the variance is 0.3–1 % (1–3 nt out of 348 nt) among the five samples. In the ITS1 four strains are identical, and bhi-F108 deviates by 1 nt. In the LSU D1–D2 the two available sequences are identical.

O. renispora clustered weakly supported with two unillustrated Chinese samples under the name *O. coccinella* (here referred to as *O.* aff. *renispora*). For one of them only ITS exists (B.L. 6179, Phyl. 23) and for the other only LSU (B.L. 747, Phyl. S27). The distance to *O. renispora* was in the ITS 17 % and in the LSU D1–D2 4.6–4.8 % (4.8–4.9 % to *O. leucostigma*). Whether they belong to the same genotype is unclear. In our

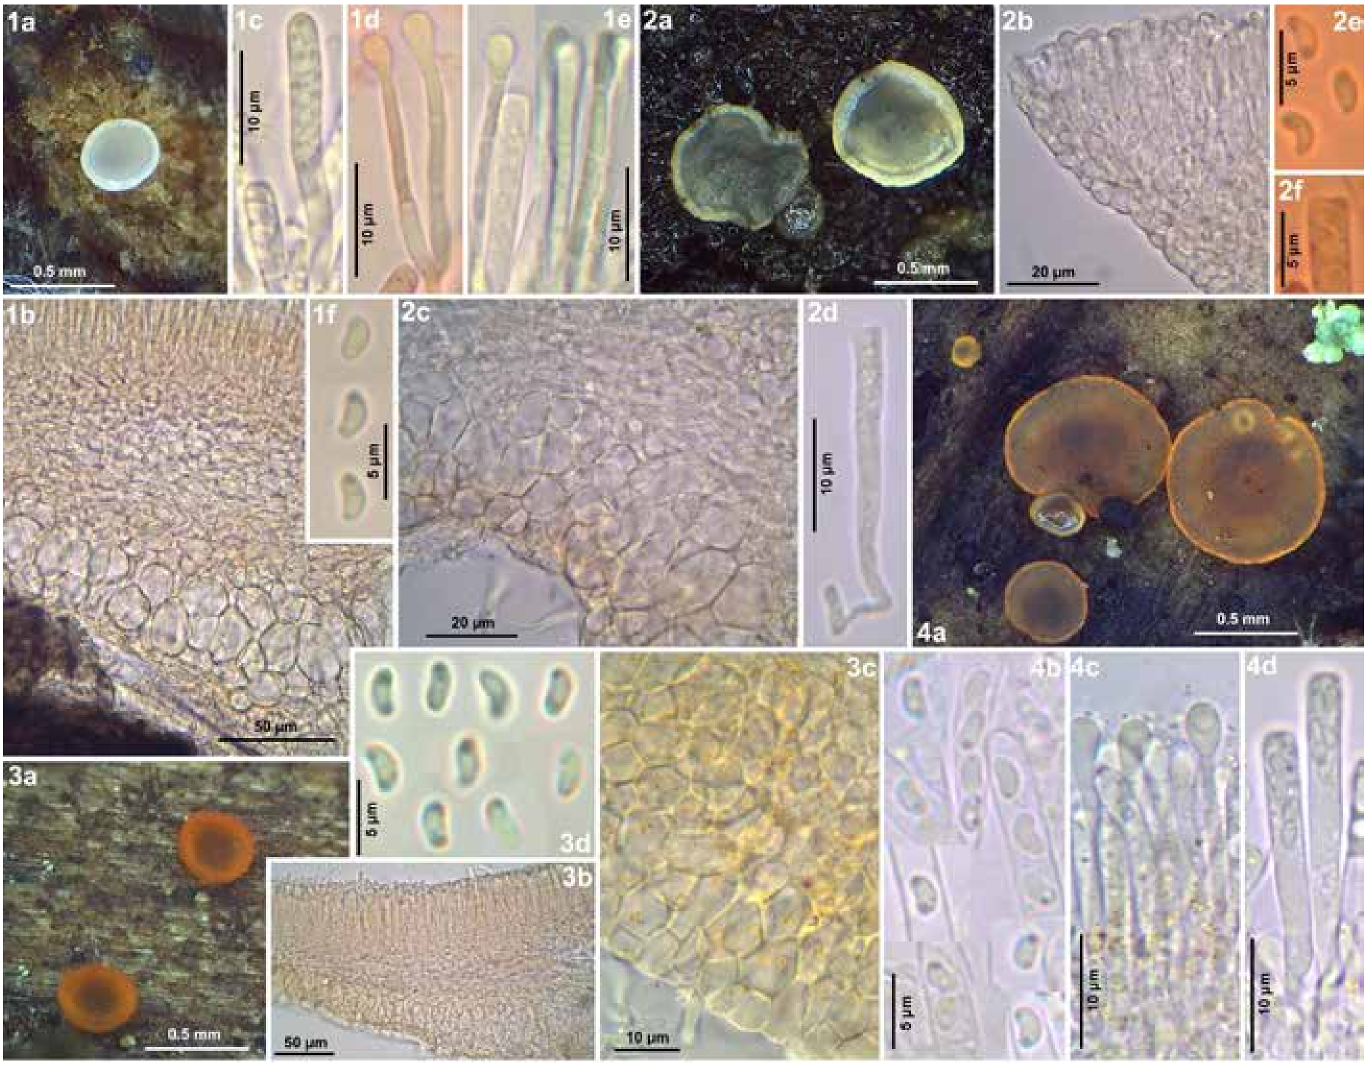

Plate 883. **1–4**: *Orbilia renispora*. – **1a**, **2a**, **3a**, **4a**. fresh apothecia; **3b**. apothecium in median section; **2b**. id., marginal region; **1b**, **2c**, **3c**. id., ectal (and medullary) excipulum at lower flanks (**3c** with carotenoids); **1c**, **2d**, **4d**. asci; **2f**. ascus apex in front view; **1d–e**, **4c**. paraphyses; **1f**, **2e**, **3d**, **4b**. ascospores. – Living state (**1d**, **2e** in CR) except for **2d** (in H_2O), **1d** (upper left cell) and **2f** (in CR). – phot. L. Quijada. — **1a–e**. bhi-F905a: USA, Massachusetts, Boston, Thompson Island, on *Quercus*; **2a–f**. bhi-F880a: id., World's End, on indet. angiosperm; **3a–e**. bhi-F943: id., on indet. angiosperm; **4a–d**. bhi-F1000.2: id., Thompson Island, on *Quercus*.

combined analysis (Phyl. 22) a chimeric combination of both sequences received distinctly less support for the *O. renispora* s.l. clade (not shown).

In our analyses of ITS+LSU and ITS (Phyls 22–23), *O. renispora* s.l. clustered unsupported sister to the *leucostigma-xanthostigma* clade and unresolved when analysing LSU (Phyl. S27). When comparing the intron region, *O. renispora* showed a very high distance of min. 20 % to any other *Orbilia* species. Because of a characteristic motif in the LSU (see p. 1327), we consider *O. renispora* s.l. as belonging in a monophyletic clade which we call *xanthostigma-renispora* clade.

Ecology. *O. renispora* was found on hygric, little to strongly rotten wood of *Quercus* but also *Acer* and other, unidentified angiosperms. In Massachusetts the species occurred in cold-temperate humid lowland forests with *Quercus alba*, *Q. rubra*, *Q. velutina*, *Acer rubrum*, *Carya cordiformis*, *Ostrya virginiana* etc., but in Georgia and Florida in subtropical humid lowland forests (in Florida *Quercus-Acer-Liquidambar* dominated).

Specimens included. **USA**: **Massachusetts**, Boston Harbor Islands, 19 km SE of Boston, 2.5 km NNE of Hingham, World's End peninsula, 5 m, stump of *Quercus*, on wood, 29.IX.2013, D. Orbilia* aff. *renispora — Pls 884–885

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1 mm diam., up to 0.19 mm high (receptacle 0.1–0.13 mm), whitish to pale yellowish-cream, subgregarious; disc flat or finally slightly convex, margin distinct, thin, smooth, not protruding; sessile. **Asci** *32–39(–41) × 4–4.5 µm, †29–35 × 3.3–3.8 µm, 8-spored, spores *subbiseriate, †uniseriate, irregularly oriented, pars sporifera *12–15 → 9–11 µm long; **apex** (†) strongly truncate (not or slightly indented, laterally

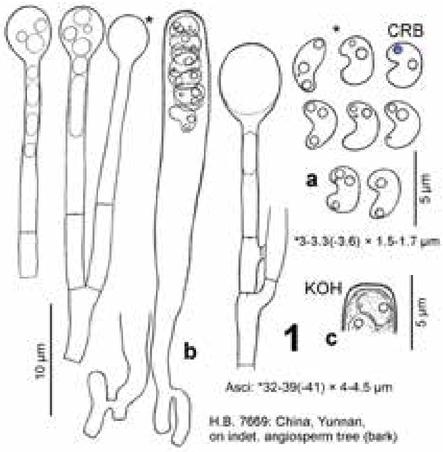

Plate 884. **1**: *Orbilia* aff. *renispora* (with smooth ascospores). – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

not inflated); **base** with short to medium long, ± flexuous stalk, L-, h- or H-shaped. **Ascospores** *3–3.3(–3.6) × 1.5–1.7 µm, cashew-shaped, strongly to very strongly curved (by ~100–180°), both ends rounded to obtuse, smooth; in front view ellipsoid to ovoid, 1.7–2 µm wide; **SBs** *0.4–0.6 µm diam., globose, close to 1 spore end, only seen in some spores, indistinguishable from LBs without staining, containing 1–3 **LBs** 0.4–0.8 µm diam. (KOH-resistant). **Paraphyses** apically (very) strongly capitate, terminal cells *(10–)16–21 × 3–4.7(–5.5) µm, lower cells *4–8 × 1.4–2 µm; rarely branched at upper septum. **Medullary excipulum** ~30–40 µm thick in receptacle, of dense textura angularis-intricata, at base unsharply delimited, at flanks very sharply delimited by a 10–15 µm thick t. porrecta. **Ectal excipulum** hyaline, of (†) thin-walled to slightly gelatinized, vertically or irregularly oriented t. globulosa from base to flanks, 100 µm thick near base, cells *12–22 × 8–17 µm; at lower flanks 50 µm thick, at submargin of t. globulosa-angularis oriented at a 70–90° angle to the surface, at margin 15 µm thick, of t. globulosa-prismatica oriented at 40–70°, marginal cortical cells *7–11 × 3–5 µm; **glassy processes** absent. **Anchoring hyphae** abundant, †2–4 µm wide, walls 0.2–0.4 µm thick. **SCBs** absent; **VBs** in paraphyses slightly to medium refractive or absent; many cells of ectal excipulum at flanks and margin contain small groups of pale to light golden-yellow granules (?LBs). **Exudate** over paraphyses absent, over margin 0.3–1 µm thick, pale yellowish, continuous. — **ANAMORPH**: unknown.

Habitat: lying on ground, on corticated, ~2 cm thick branch of indet. angiosperm tree, on strongly decayed bark (periderm), no algae. **Associated**: brown hyphomycete. **Desiccation tolerance**: not tested, probably desiccation-sensitive. **Altitude**: ?1300 m a.s.l. **Phenology**: X.

Taxonomic remarks. A small portion of the Chinese collection from Yunnan on hygric bark (Pls. 884; 885: 1) was received in the living state, showing whitish to very pale yellowish apothecia. It possibly represents a species distinct from North American *O. renispora*, while from the *xanthostigma-leucostigma* complex it appears to differ by rather large, smooth ascospores containing medium-sized LBs. Regrettably, neither cultural nor molecular data were available, therefore, we refrain from describing a new species. *O. subfabacearum* and *O. fabacearum* differ in spores with a dorsal SB and less inflated paraphyses.

Not included collections. A sample from Japan differs in larger, partly less curved, cashew-shaped spores (†3–4.3 × 1.7–2 µm, Pl. 885: 2) and herein appears to be intermediate to *O. renispora*. The asci measured †50 × 3–3.5 µm and the apothecia rehydrated 0.3–0.7 mm, being now rather pale while the original colour was not stated. A collection from northern Thailand on bark of unidentified angiosperm twig reported by Ekanayaka et al. (2018) under the name *O. leucostigma* concurs with *O. renispora* and the sample from Japan in spore size (†3–3.5 × 1.2–1.6 µm), but differs in more strongly curved (~180–270°) and basally partly much thinner spores, and in much wider asci (†35–45 × 5.5–6.5 µm, 5–6 µm according to scale in their fig. 6g–h). The apothecia are described as yellow, 0.35–0.4 mm diam., with smooth margin. In spore shape this collection resembles the 16-spored *O. coccinella*. The author's fig. 6 contains erroneous scales (d: ~15 instead of 35 µm, e–f: ~10 instead of 5 µm).

No documentation was available for two Chinese samples of which sequences exist in GenBank. They were originally identified by B. Liu as *O. coccinella*, which suggests that their spores were ellipsoid. Nevertheless, they clustered with low support near *O. renispora* (for further data see p. 1419).

Ecology. The South Chinese collection of *O.* aff. *renispora* grew on rotten bark of a hygric branch of an unidentified angiosperm in a montane, subtropical humid (monsoonal) evergreen forest, that from Thailand in a monsoonal tropical forest, and that from Japan in a cold-temperate humid forest with *Quercus*.

Specimens included. **CHINA**: **Yunnan**, **Pu'er**, Ning'er, ~64 km N of Puér, ?25 km SE of Jinggu, Xiaoheijiang, ?1300 m, branch of indet. angiosperm, on bark, 15.X.2004, Y. Zhang & M. Qiao (Y.Z. pe-1, YMFT, H.B. 7669).

Not included. **JAPAN**: **Honshu**, **Nagano**, Chiisagata-gun, 11.5 km NE of Ueda, 9 km SSE of Sugadaira, Kakuma Valley, 1245 m, branch of *Quercus*, on bark, 21.VI.1991, T. Hosoya & A. Nakagiri (TRL 337, TNS-F-56036, H.B. 9986 ø). — **THAILAND**: **Northern Thailand**, **Chiang Rai**, 16 km NNE of Chiang Rai, Mae Fah Luang University, ~460 m, twig of indet. angiosperm, on bark (as 'wood'), 20.IV.2015, A.H. Ekanayaka (hd035, MFLU 16-1861, as *O. leucostigma*, doc. vid.). — **CHINA**: **Beijing**, data unavailable (B.L. 6179, HMAS 139699, as *O. coccinella*, non vid.; sq.: DQ656624). – unlocalized (B.L. 747, as *O. coccinella*, non vid.; sq.: DQ656680).

Orbilia xanthoflexa Baral, Pfister & Healy, **sp. nov.**, MB 813957 — Pls 886–887

Etymology: referring to the yellow carotenoids in the oil drops, and the flexuous shape of the ascospores.

Typification: USA, Massachusetts, Concord, log of *Acer*, 1.X.1994, D.H. Pfister (ex D.H.P. O.109 & ex H.B. 5162, M-0276608, holotype).

Latin diagnosis: *Apothecia rehydratata 0.18–0.5 mm diam.*, *vivide aureo-lutea*, *subsessilia*, *margine laevi. Ascosporae †3.8–5.7 × 0.9–1.1 µm*, *cylindricae*, *apice rotundatae*, *basi interdum leniter attenuatae*, *modice ad valde curvatae vel geniculatae*, *in statu vivo corpusculum refringens globosum continentes. Paraphyses ad apicem valde capitatae. Cellulae viventes excipuli marginalis et paraphysium guttulas minutas luteas oleosas*, *modice abundantes continentes. Margo excipuli absque processis vitreis. Habitat ad lignum putridum in trunco uvido* Aceris *in zona temperata vel subtropica humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.7 mm diam., 0.11 mm thick (receptacle 0.08–0.09 mm), deep golden yellow(-orange), ± translucent, ± round, scattered to subgregarious; disc flat, margin thin, scarcely protruding, smooth; sessile or with an indistinct, short and thick stipe 0.02 × 0.12 mm, superficial. **Asci** †25–36 × 3–3.7 µm {2}, 8-spored, spores †~3-seriate, ~4 lower spores inverted (sometimes mixed) {2}, pars sporifera †12.5–15 µm long; **apex** (†) strongly truncate (partly distinctly indented, laterally not or scarcely widened); **base** with short to medium long, thick stalk, h- to H-shaped. **Ascospores** *(2.8–)4–5.3(–6) × 1.1–1.6 µm {2}, †(3.3–)3.8–5.3(–5.7) × 0.9–1.3 µm {2}, cylindric(-clavate), apex rounded to obtuse, base (very) slightly (to medium) attenuated, medium to strongly curved (falcate) or geniculate, often slightly helicoid, smooth; inflated to a width of *~1.7–2 µm during germination; **SBs** *0.7–0.8(–1) µm diam. {2}, globose, close to apex, attachment invisible (but clearly visible under TEM, total length ~0.8–1 µm), with a few minute **LBs**. **Paraphyses** apically strongly capitate(-clavate), terminal cells *10.5–17 × 3.5–4.4 µm {T}, †2–4.2 µm wide {2}, lower cells *4.5–6 × 1.5–2 µm {T}, †1–1.8 µm wide {2}; unbranched at upper septum, hymenium bright yellow-orange. **Medullary excipulum** hyaline to pale yellow, 20–30 µm thick, of loose to dense textura intricata with many inflated cells, sharply delimited from ectal excipulum near margin by a layer of t. porrecta. **Ectal excipulum** hyaline, of thin-walled, indistinctly vertically oriented t. globulosa-angularis from base to margin, 30–50 µm thick near base, cells †8–18 × 7–13 µm {2}; 15–25 µm thick at lower flanks, 8–12 µm near margin, oriented at a 40–60° angle to the surface, marginal cortical cells †6–10 × (3–)4–5(–6) µm {2}; **glassy processes** absent. **Anchoring hyphae** sparse, †1.8–2.7 µm wide, walls 0.3 µm thick {T}. **SCBs** in apex of paraphyses globose, 1–1.4 µm diam. {T}; **VBs** not seen; small golden yellow-orange **LBs** medium abundant in terminal and lower cells of paraphyses, also in marginal medullary excipulum and partly in ectal excipular cells on margin and flanks {T}. **Exudate** minute (0.1–0.2 µm), granular, firmly attached; over margin absent. **— ANAMORPH**: dicranidion-like (no further data available).

Habitat: lying on rather wet ground, decorticated, ?15 cm thick logs of *Acer* sp. {2}, indet. tree {1}, on deeply very rotten wood {3}, partly darkened, with some green algae (including *Gloeocapsa*). **Associated**: dark setose conidiophores of hyphomycete {1}, *Gloeocapsa* sp. {1}. **Desiccation tolerance**: a few paraphyses and spores survived for ~1 week. **Altitude**: 40–65 m a.s.l. **Geology**: Ordovician & Miocene sedimentary rock, Quaternary sediment; granite. **Phenology**: VI–VII, X.

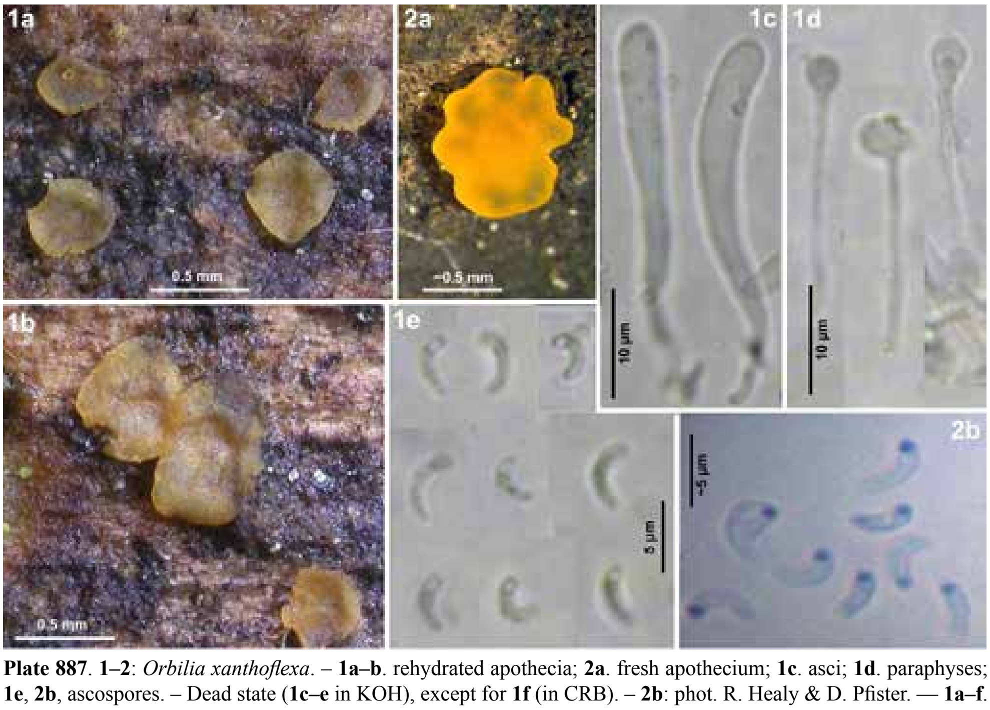

Plate 887. **1–2**: *Orbilia xanthoflexa*. – **1a–b**. rehydrated apothecia; **2a**. fresh apothecium; **1c**. asci; **1d**. paraphyses; **1e**, **2b**, ascospores. – Dead state (**1c–e** in KOH), except for **1f** (in CRB). – **2b**: phot. R. Healy & D. Pfister. — **1a–f**. D.H.P. 130, H.B. 9961: USA, Massachusetts, on *Acer*; **2a–b**. V.R. 13 (FH 00458182): ibid., on indet. tree.

Taxonomic remarks. *Orbilia xanthoflexa* is characterized by abundant yellow-orange LBs in paraphyses and marginal excipular cells, in combination with small, cylindric(-clavate), allantoid to helicoid ascospores containing a comparatively large, globose SB at the broader end. The spore features suggest a relation to the *xanthostigma-leucostigma* complex. However, the species resembles also *O. flexispora* in having similarly sized and curved spores, though differing in several respects (see p. 1430). *O. renispora* mainly deviates in shorter and wider spores and less strongly capitate paraphyses. *O. comma* and *O. neocomma* (section *Aurantiorubrae*) somewhat resemble *O. xanthoflexa* in the spores which are, however, helicoid with a tail-like base, and the paraphyses are covered by much thicker exudate. *O. epipora* (section *Arthrobotrys*) differs in ± straight spores, less inflated paraphyses, and white apothecia (however, a North American collection referred to *O. epipora* has capitate paraphyses and a yellow pigmentation, Pl. 901: 7).

Variation. In the holotype the spores are slightly narrower than in the other two included samples, also the paraphyses are wider in their lower part, but otherwise they concur quite well. Whether all of them contained yellow LBs in the living vegetative cells was not examined. Only a few spores and paraphyses could be studied in the living state because the specimen was received in dry condition. In other samples, R. Healy and D.H. Pfister (pers. comm.) observed a rather high variation in spore size, particularly in width (Pl. 887: 2b), which was always larger than in the holotype.

Not included collections. Three samples from USA are without teleomorph data. Two of them possess molecular data and cluster distantly from the topotype of *O. xanthoflexa*. For the third (D.H.P. 81) the anamorph was documented and its close relationship to the former two is assumed here.

Anamorph. Pfister (1997) listed the species (as *Orbilia* sp., D.H.P. 130) with a dicranidion-like anamorph, but did not provide an illustration or description. His illustration of D.H.P. 81 (Pfister 1997: fig. 8, as *Dicranidion* sp. of the 'fragile type') is assumed here to represent the anamorph of *O.* cf. *xanthoflexa* (see under *O. xanthostigma*, p. 1408), but molecular data were not available for it.

Phylogeny. An ITS sequence of a paratype of *O. xanthoflexa* in GenBank (D.H.P. 130) fully concurs with the unpublished sequence of a more recent sample of this species from the same region (V.R. 13, D.H. Pfister pers. comm., not shown in phylotree). The S1506 intron region is not covered in D.H.P. 130. In our phylogenetic analysis (Phyl. 23) the species is part of the strongly supported *leucostigma-xanthoflexa* subclade, which comprises *O. leucostigma* s.l. (including D.H.P. 108 and B.L. 6420) and *O. xanthoflexa* s.l. (including D.H.P. 91 and ga026b).

Regrettably, no morphological data exist for *O.* cf. *xanthoflexa* (D.H.P. 91 and ga026b), which deviate by only 0.7% in the ITS, whereas *O. xanthoflexa* (D.H.P. 130) differs from them by 5.3–6%. D.H.P. 91 probably had smooth ascospores, because it was named '*O. alnea*' by Pfister (1997). D.H.P. 108 possessed the typical cashew-shaped warted spores (D.H. Pfister pers. comm.), and also for B.L. 6420 this is probable. Strain ga026b was gained from an ascospore isolate of an overlooked mixture with *O. georgiana* and its apothecia might therefore be unpreserved. The ITS distance between *O. xanthoflexa* and *O.* cf. *xanthoflexa* lies at 5.3–6.1%, whereas *O. leucostigma* s.l. differs from them by 6.5–8.3%.

Ecology. *O. xanthoflexa* is only known from two localities near Concord (Massachusetts) in the lowlands of northeastern North America. It was repeatedly collected on rotten wood of decorticated hygric logs of *Acer* and unidentified trees at rather wet places, along a rivulet or near a pond, in a cold-temperate humid mixed forests (Hutchins Pond: *Quercus-Acer* dominated with *Fagus grandifolia* and *Pinus strobus* on acidic soil). The not included samples come from the same region (including the type locality), but also from the subtropical humid southeast.

Specimens included. **USA**: **Massachusetts**, Middlesex, 28.5 km NW of Boston, 4.3 km N of Concord, Estabrook Woods, 65 m, log of *Acer*, on wood, 1.X.1994, D.H. Pfister (ex H.B. 5162, M-0276608, **holotype**; D.H.P. O.109, FH 00458344, **isotype**). – ibid., log of *Acer*, on wood, 20.VI.1995, D.H. Pfister (D.H.P. 130 [O.115], FH, H.B. 9961, anam. cult.; sq.: U72597, **topotype**). – 2.8 km NNE of Concord, Punkatasset Hill, Hutchins Pond, 40 m, ?log of indet. tree, on wood, 10.VII.2014, V. Rodriguez & R. Healy (V.R. 13, FH 00458182, doc. vid., sq.: ined.).

Not included. **USA**: **Massachusetts**, Norfolk, 17 km SW of Boston, 3 km NE of Westwood, Purgatory Tract Area, 60 m, indet. tree, 14.VII.1994, D.H. Pfister (D.H.P. 91, FH 00304898, as *O. alnea*, anam. cult., non vid.; sq.: U72600). – Middlesex, 28.5 km NW of Boston, 4.3 km N of Concord, Estabrook Woods, 65 m, wood of indet. tree, 7.VII.1994, D.H. Pfister (D.H.P. 81, as *O. alnea*, anam. cult., doc. vid.). – **Georgia**, 88 km NW of Jacksonville, ~25 km NE of Fargo, Stephen C. Foster Park, 40 m, branch of *Acer*, on wood, 24.IX.2015, Y.Y. Orbilia fabacearum Baral & G. Marson, **sp. nov.**, MB 813963 — Pls 888–889, Map 142

Etymology: named after the predominant substrate, *Fabaceae*.

Typification: France, Annot, branch of *Laburnum alpinum*, 17.VIII.2001, G. Marson (ex H.B. 7025b, M-0276479, holotype).

Latin diagnosis: *Apothecia rehydratata 0.15–0.9 mm diam., dilute cremeo-rosea ad rosea, raro albida, sessilia, margine laevi. Ascosporae *2.3–4.2 × 1.1–1.6 µm, valde curvatae (semicirculares), laeves, corpusculum refringens globosum, tunicam dorsalem cuspide brevi affixum continentes. Paraphyses ad apicem non vel paulo clavato-capitatae, cellulae vivae absque vacuolis refringentibus. Excipulum marginale absque processis vitreis, exsudato tenui ad valido tectum. Habitat ad lignum vel corticem putridum ramorum vel truncorum siccorum, raro uvidorum fruticum vel arborum angiospermarum, plerumque* Fabacearum, *raro coniferarum, plerumque in zona atlantica temperata ad submediterranea (semi)humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** fresh (0.15–)0.2–0.7(–0.9) mm diam., 0.1–0.17 mm high (receptacle 0.1–0.11 mm), (very) pale to light cream-rose(-orange) or pure rose, rarely whitish, translucent, round, very scattered to subgregarious or gregarious in small groups; disc flat (to slightly convex), margin medium thick, 0–5 µm protruding, smooth; broadly sessile or with ill-defined, obconical, hidden stipe up to 0.06 × 0.18 mm, superficial or half immersed in biofilm; dry light to bright rose-orange(-apricot). **Asci** *(29–)32–38(–43) {6} or 43–48 {1} × 3.2–4 {7} → 3.5–4.3 µm, †24–36 × 2.8–3.5 µm {4}, 8-spored, spores (*) ± uniseriate, SBs mostly laterally oriented, pars sporifera *11–23 → 7–18 µm long; **apex** (†) slightly to strongly truncate (indistinctly indented, laterally not widened); **base** with short to medium long, medium thick, flexuous stalk, L-, h- to H-shaped. **Ascospores** *(2.3–)2.5–3.7(–4.2) × (1.1–)1.2–1.5(–1.6) µm {8}, cashew-shaped, (very) strongly curved (± semicircular, exceptionally only slightly curved), ~(70–)90–180(–220)°, sometimes somewhat geniculate (V- or L-shaped) or slightly to distinctly helicoid, ends rounded, rarely obtuse, smooth; **SBs** *0.6–1 × 0.4–0.7 µm {4}, globose to broadly tear-shaped, narrowed to a small point, often with a very short filum, attached to the dorsal side of the spore {8}, usually ± in the middle, also more towards 1 end. **Paraphyses** apically uninflated to slightly clavate-capitate, sometimes sublageniform, terminal cells *10–22 × (1.7–)2–3(–3.5) µm {6}, lower cells *6–12 × 1.7–2.5(–3) µm {6}, 4–8 µm long at base; never or rarely branched at upper septum. **Medullary excipulum** subhyaline, 30–60 µm thick in centre, of dense textura globulosa-prismatica-intricata, very indistinctly to rather sharply delimited. **Ectal excipulum** hyaline to very pale rose, of (†) thin-walled, irregularly to vertically oriented t. globulosa-angularis(-prismatica) from base to margin, 25–80 µm thick near base, cells *(5–)10–20(–25) × (3–)7–15 µm {5}; 20–60 µm thick at flanks, 15–40 µm near margin, here of t. prismatica(-angularis) oriented at a 30–80° angle, marginal cortical cells *4–10 × (2–)3–5(–7.5) µm {5}, **glassy processes** absent. **Anchoring hyphae** sparse to abundant, */†1.7–3(–5) µm wide (short-celled if 4–5 µm wide), walls 0.2(–0.3) µm thick {4}. **SCBs** absent or infrequently present, globose, (very) low-refractive, in paraphyses 0.8–2.2 µm diam., sometimes elongate; in excipular cells 1.5–3(–4) µm, globose; **VBs** absent {8}. **Exudate** (very) pale yellowish-chlorinaceous, over paraphyses 0.2–1(–2) µm thick, continuous to cloddy or granular, also sparse to absent, loosely or firmly attached; over margin and flanks (0.3–)1–3(–4) µm thick, granular to cloddy. **— ANAMORPH**: unknown (but see below).

Habitat: 0.3–4 m above the ground, also lying on ground under grass, moss or herbaceous vegetation (on underside), corticated or rather decorticated, 12–40 mm thick branches, also cut exposed wood of ~50 cm thick stump, of *Clematis vitalba* {1}, *Laburnum alpinum* {1},

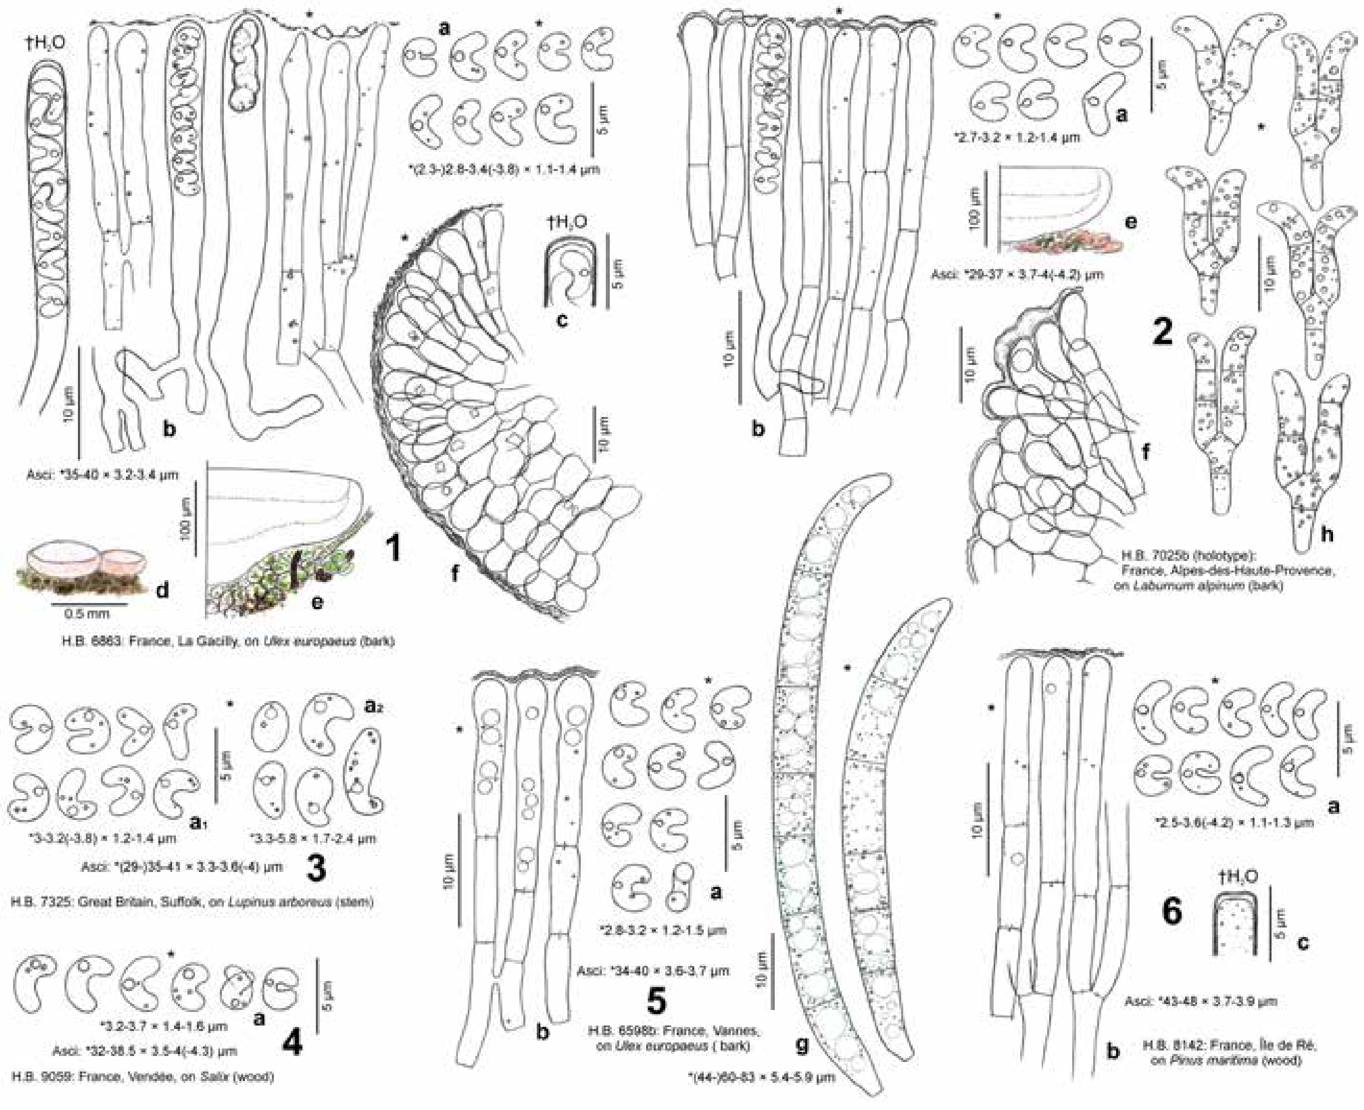

Plate 888. **1–6**: *Orbilia fabacearum*. – **a**. ascospores (5 spores in **3a$_2$** abnormally oversized, partly from 6-spored asci); **b**. asci and paraphyses (1 ascus in **1b** fully turgescent); **c**. ascus apices; **d**. fresh apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum at margin and mid flanks; **g–h**. 2 types of conidia of uncertain relationship from substrate.

Lupinus arboreus {1}, *Pinus pinaster* {1}, *Quercus* sp. {1}, *Salix* sp. {1}, *S.* ?*alba* {1}, *Ulex europaeus* {3}, *Ulmus* sp. {1}, on medium to very decayed wood (7) and bark {5} (periderm and bast), not or slightly greyed, with a few or many green algae. **Associated**: *Chaetosphaerella phaeostroma* {1}, *Hymenoscyphus infarciens* {1}, *Orbilia aristata* {1}, *O. cejpii* {1}, *O. rubrovacuolata* {1}, *O. subtrapeziformis* {1}, *Parmelia sulcata* {1}, ?*Stictis* sp. {1}, pleurocarpous moss {1}. **Desiccation tolerance**: fully viable for at least 1 month. **Altitude**: 1–87 m a.s.l. (western Europe), 290–475 m (central Europe), 1475 m (southern Europe). **Geology**: Cambrian silt, sandstone & quartzitic wacke, Lower Jurassic shale, Upper Cretaceous lime-, clay- & marlstone, Quaternary marine clay, silt & sand; granite, gneiss. **Phenology**: XII–V, VII–VIII (probably throughout the year, rather long-lived).

Taxonomic remarks. *Orbilia fabacearum* closely resembles members of the *xanthostigma-leucostigma* complex in the shape of ascospores which are, however, consistently smooth and have the SBs inserted ± in the middle of the spore away from the ends (similar as in the very distant *O. corculispora*), also the spores tend to be longer and the paraphyses have only slightly inflated apices.

The similar extra-European *O. subfabacearum* (Pls 890–891) is only tentatively separated from *O. fabacearum* by more strongly curved spores (often for > 180°), more capitate paraphyses, and in the type by the partial presence of glassy caps on the marginal cortical cells. Collections from southeastern Asia with smooth spores described here as *O.* aff. *renispora* (Pls 884–885) differ from both species in the partial presence of a spore body at one end of the spores which contain 1–2 rather large LBs, also in strongly capitate paraphyses and in whitish to yellowish apothecia.

Variation. Apothecia vary in size between 0.2–0.3 mm (*Laburnum*, Pl. 888: 2, type) and 0.5–0.9 mm (*Lupinus*, Pl. 889: 1). The specimen on *Pinus* (Pl. 888: 6) well concurs with those on angiosperm hosts, except that it showed distinctly longer asci when compared in the living state. However, the size of dead asci was with †33–36 × 3–3.5 µm quite the same as in H.B. 6863 (on *Ulex*, †31–36 × 2.9–3.3).

Anamorph. The anamorph of *O. fabacearum* is unclear. In two collections we observed very different types of conidia on the natural substrate. In the collection on *Ulex*, vermispora-like phragmoconidia occurred in great number near the apothecia (Pl. 888: 5g); similar but shorter and much narrower, less curved conidia were obtained in pure culture of Chinese *O.* cf. *subfabacearum* by Z.F. Yu (pers. comm., Pl. 891: 2f). In the holotype on *Laburnum*, lyra-shaped dicranidion-like conidia occurred (Pl. 888: 2h) together with T-shaped trinacrium-like

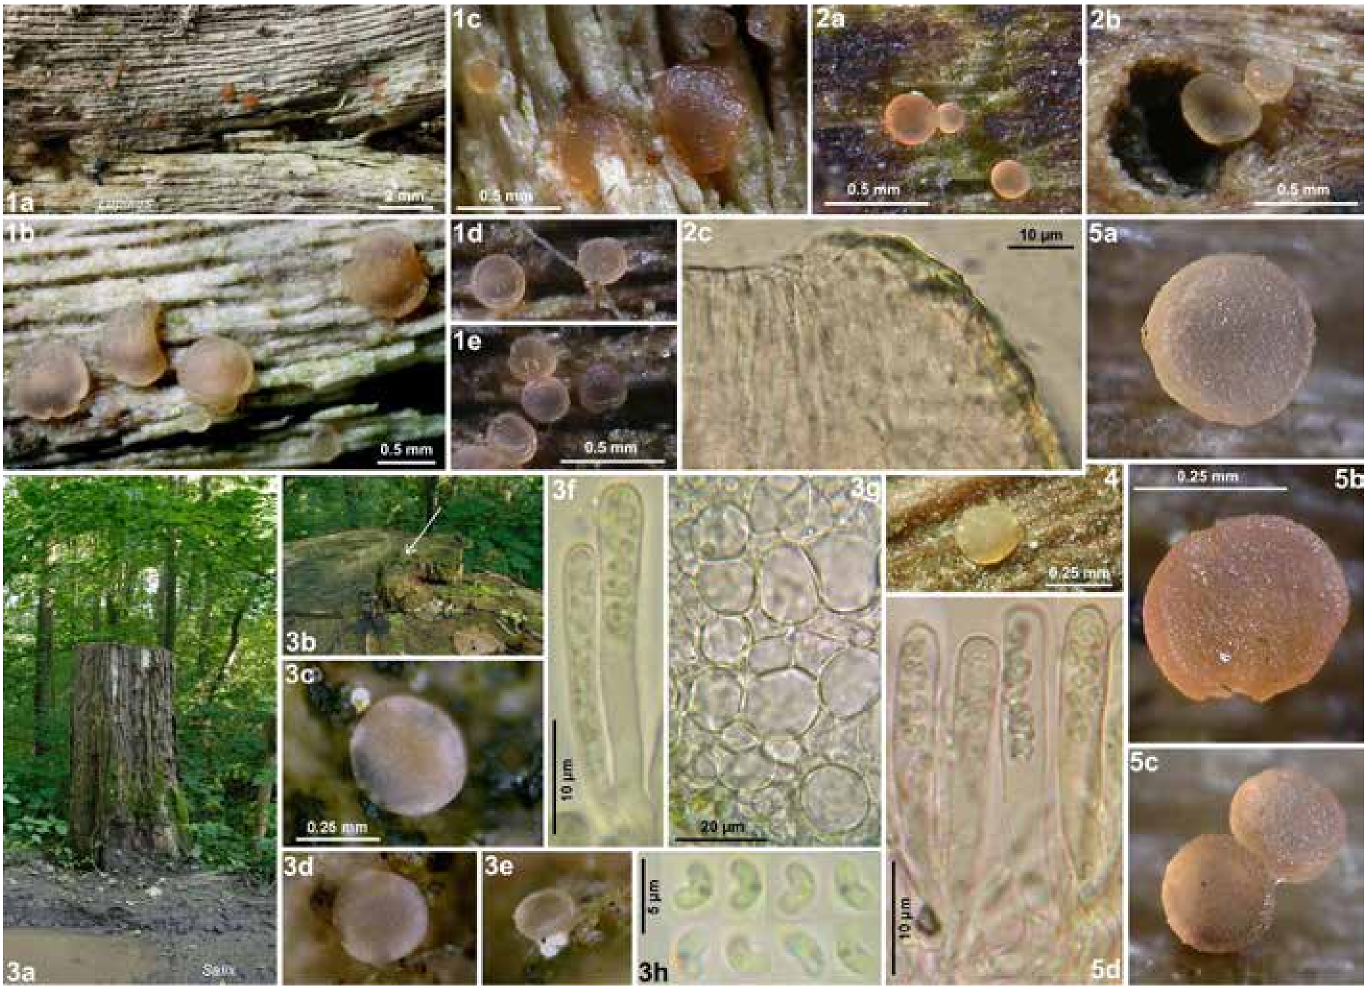

Plate 889. **1–5**: *Orbilia fabacearum*. – **3a–b**. cut *Salix* stump in a forest with *Acer* and *Fagus*; **1a–e**, **2a–b**, **3c–e**, **4**, **5a–c**. fresh or rehydrated apothecia; **2c**. marginal ectal excipulum in median section; **3g**. id., basal ectal excipulum; **3f**, **5d**. mature asci; **3h**. ascospores. – Living state, except for left ascus in **3f**. – **3a–h**: phot. P. Perz; **4**: phot. J.P. Priou. — **1a–e**. H.B. 7325: Great Britain, Suffolk, on *Lupinus*; **2a–c**. H.B. 8142: France, Île de Ré, on *Pinus*; **3a–h**. P.P. 20080720: Poland, Kłodzko, on *Salix*; **4**. J.P.P. 24011: France, Morbihan, on *Quercus*; **5a–d**. H.B. 9059a: France, Vendée, on *Salix*.

conidia and many 5-septate vermispora-like C-shaped conidia. The latter are with *28–32 × 2.8–3.3 µm much smaller than those on *Ulex*, and much more curved than those from China. Dicranidion-like anamorphs are rather frequent in series *Orbilia* and occur, e. g., in the closely related *xanthostigma-leucostigma* complex, whereas vermispora-like conidia resemble the anamorph of *O. liliputiana*.

The genetically distantly related anamorph-typified ***Orbilia xiushanensis*** Z.F. Yu & M. Qiao nom. prov. (Zhang et al. ined., IVV: YMF 1.03033) possesses similar vermispora-like conidia with curved ends formed on very short conidiophores. Its teleomorph is unknown because the ascospore isolate was erroneously thought to originate from a *Hyalorbilia*, *H. japonica* s.l. (IVV, 15.VIII.2008), a species with straight fusiform conidia which clusters in the core clade of *Hyalorbilia*.

Phylogeny. A sequence comprising SSU (without S1506 intron), ITS, and LSU was gained from apothecia of *O. fabacearum*. When analysing SSU+ITS+LSU or LSU (Phyl. 22. S27), the species clustered unsupported and with high distance in a clade containing, e. g., *Tridentaria subuliphora* and series *Microsomates*. When analysing ITS (Phyl. 23) it formed with *O. xiushanensis* a medium supported clade (ITS distance 16 %).

Ecology. *O. fabacearum* grew on ± decayed bark and wood of xeric, rarely hygric branches and stumps of trees and shrubs of *Faboideae* (*Fabaceae*) {5} but also non-fabaceous angiosperms {5} and even gymnosperms {1}. The species was repeatedly found in humid or rarely semihumid, warm-temperate or rarely mesosubmediterranean atlantic western Europe, e. g., in coastal *Ulex* shrubs or a pine forest. It occurred also in an

Map 142. Known distribution of *O. fabacearum* in Europe

orosubmediterranean mixed conifer forest with *Laburnum* and *Lavandula* in the Southern French Alps and in two supratemperate subcontinental sites in central Europe: a colline *Prunus spinosa* shrub with *Clematis* (Luxembourg) and a submontane deciduous forest with *Fagus*, *Acer*, and *Salix* (Poland).

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, 4.5 km NE of Leiston, Minsmere Haven, S of Sluice Chapel, 1 m, stem of *Lupinus arboreus*, on wood, 31.III.2003, E. Batten (E.B. 4399, K(M) 145648, H.B. 7325). — **LUXEMBOURG**: **Gutland**, 2 km SE of Dudelange, Bloklapp, 290 m, branches of *Clematis vitalba*, on wood & bark, 24.XII.2016, G. Marson (G.M. 2016-12-24.1; sq.: MH221064). — **FRANCE**: **Bretagne**, **Ille-et-Vilaine**, 7 km E of Rennes, 2.2 km SE of Cesson-Sévigné, Forgé, 47 m, branch of *Ulmus*, on wood, 24.V.2013, J.P. Priou (J.P.P. 13122, doc. vid.). – **Morbihan**, 8.7 km W of Ploërmel, 3.7 km SE of Josselin, NE of St.-Gobrien, Écluse de Clan, 26 m, branch of *Quercus*, on wood, 9.I.2004, J.P. Priou (J.P.P. 24011, doc. vid.). – 7.5 km NNE of La Gacilly, 3 km ENE of Carentoir, Le Gouta, 87 m, branch of *Ulex europaeus*, on bark, 3.III.2004, J.P. Priou (J.P.P. 24080, doc. vid.). – 4.5 km NW of La Gacilly, 3 km SW of Carentoir, NNE of l'Hôtel Portier, 25 m, branch of *Ulex europaeus*, on bark, 17.II.2001, J.P. Priou (J.P.P. 2088 ø, H.B. 6598b, anam. substr.). – **Pays-de-la-Loire**, **Vendée**, 8 km NNE of Fontenay-le-Comte, 1.7 km NW of Mervent, near Pont du Diet, along Mère river, 50 m, branch of *Salix*, on wood, 12.V.2009, N. Van Vooren (N.V. 2009.05.25, H.B. 9059a). – **Poitou-Charentes**, **Charente-Maritime**, Île de Ré, 2.5 km NNE of St.-Clément-des-Baleines, Forêt de St.-Clément, around parking area, 7 m, branch of *Pinus pinaster*, on wood, 26.IV.2006, S. Helleman (H.B. 8142). – **Provence-Alpes-Côte d'Azur**, **Alpes-de-Haute-Provence**, 9.7 km ESE of St.-André-les-Alpes, 3.2 km WSW of Annot, Colle Basse NE of Col de l'Iscle, 1475 m, branch of *Laburnum alpinum*, on bark, 17.VIII.2001, G. Marson (ex H.B. 7025b, M-0276479, **holotype**, anam. substr.). — **POLAND**: **Lower Silesia**, Kłodzko, 15.5 km S of Bystrzyca Kłodzka, 1.7 km NW of Miedzylesie, 475 m, stump of *Salix ?alba*, on wood, 20.VII.2008, P. Perz (P.P. 20080720-4, doc. vid.).

Not included. **CHINA**: **Yunnan**, **Yuxi**, Tonghai, 35 km SE of Yuxi, ~2 km S of Tonghai, Xiushan Forest Park, ~1900 m, twigs of indet. angiosperm, 15.VIII.2008, Z.F. Yu & S.F. Li (YMFT 1.03033, proposed holotype of *O. xiushanensis*, sq.: KF824762/MF948538, as *Hyalorbilia* sp./*Dactylella* sp.; reported teleomorph belongs to *Hyalorbilia japonica* s.l.).

Orbilia subfabacearum Baral & G. Marson, **sp. nov.**, MB 813964 — Pls 890–891

Etymology: named after the close resemblance to *O. fabacearum*.
Typification: Australia, Queensland, Mingela, branches of indet. climber, 17.X.1998, G. Marson (ex H.B. 6280e, BRI AQ799181, holotype).

Latin diagnosis: *Similis* Orbiliae fabacearum *sed paraphyses ad apicem modice ad valde capitatae, excipulum marginale processis vitreis brevibus praeditum. Habitat ad lignum vel corticem putridum rami sicci volubilis angiospermae in zona tropica subhumida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5 mm diam., 0.08–0.13 mm high, pale to light rose, round, subgregarious; disc flat, margin thin, not protruding, smooth; sessile to substipitate, slightly immersed in biofilm. **Asci** †27–35 × 3–3.5(–4) µm, 8-spored, spores (†) uniseriate, irregularly oriented; **apex** (†) strongly truncate (not indented, laterally sometimes inflated); **base** with medium long and thick, flexuous stalk, h- to H-shaped. **Ascospores** *2.5–3.5 × (0.9–)1–1.3(–1.5) µm, ± semicircular, very strongly curved [for ~(120–)160–270°], ends rounded; **SBs** apparently absent, often 1 small **LB** in middle part and 1–2 further LBs. **Paraphyses** apically medium to strongly capitate, terminal cells †9–18 × 2.5–4.5 µm, lower cells †6–9 × 1–1.8 µm; unbranched at upper septum. **Medullary excipulum** 25 µm thick, of medium dense textura intricata-angularis, medium sharply delimited. **Ectal excipulum** of thin-walled, indistinctly vertically oriented t. angularis at base and lower flanks, 25–70 µm thick near base, cells †8–17 × 7–11 µm; 15 µm thick at mid flanks and margin, oriented at a 60–70° angle to the surface, marginal cortical cells †6–10 × (2–)3–4(–5) µm, with ± conical ?**glassy processes** 1–4 × 2.5–4 µm, strongly refractive, not stratified, with a rough surface, partly completely absent. **SCBs & VBs** no data available. **Anchoring hyphae** sparse, †1.8–2.3 µm wide, walls 0.2 µm thick. **Exudate** over paraphyses 0.2–0.5(–1) µm thick, granular-cloddy, hyaline, firmly attached; on margin and flanks unclear (perhaps the entire processes represent exudate). — **ANAMORPH**: unknown (but see below).

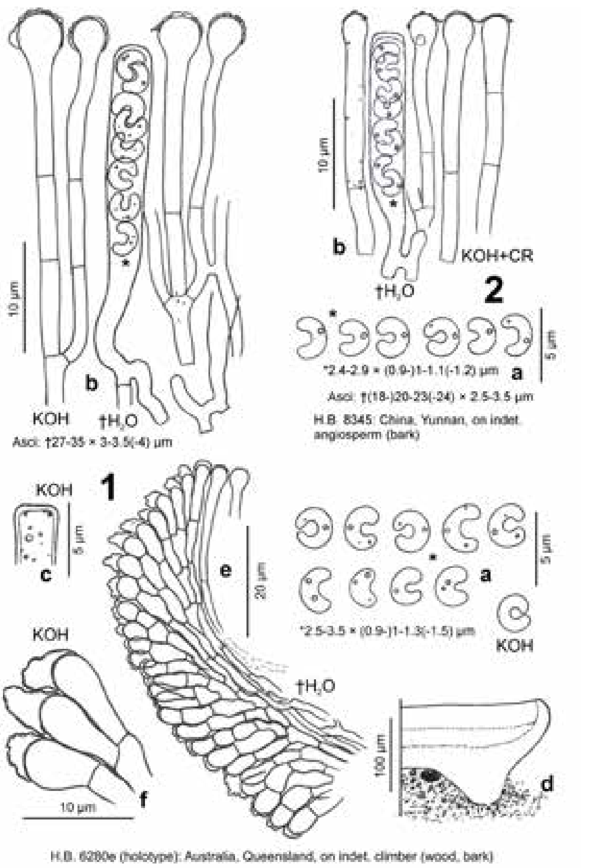

Plate 890. **1**: *Orbilia subfabacearum*; **2**: *O.* cf. *subfabacearum*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., ectal excipulum at margin and flanks; **f**. id., marginal cortical cells with short glassy processes.

Habitat: collected 0.5–3 m above the ground, partially corticated to decorticated, 9–13 mm thick branches of indet. climber, on 1 mm deep strongly decayed wood, also on bark (periderm), scarcely greyed, with very few green algae. **Associated** (remotely or on separate branches): *Hysteropatella ?prostii* {1}, *Orbilia mammifera* {1}, *O. neocomma* {1}, *O. paracaudata* {1}, *O. scandens* {1}, *Rhytidhysteron ?rufulum* {1}. **Desiccation tolerance**: unknown (probably desiccation-tolerant), ascospores survive for at least 2 months. **Altitude**: 286 m a.s.l. **Geology**: granite. **Phenology**: X (possibly long-lived).

Taxonomic remarks. *Orbilia subfabacearum* resembles *O. fabacearum* but also the *xanthostigma-leucostigma* complex in the cashew-shaped ascospores. It differs in the presence of refractive caps on the marginal excipular cells and in the absence of distinct SBs in the spores, from the *xanthostigma-leucostigma* complex also in smooth spores and from *O. fabacearum* in more capitate paraphyses.

When the type specimen was examined, merely the spores in numerous asci were viable. Their abundance suggests that the spores were mature. They apparently lack a spore body, contrary to the similar *O. fabacearum*. Often a small droplet was seen at their dorsal side which, however, did not stain in CRB and was apparently always KOH-resistant. The short glassy processes at the margin stained turquoise in CRB and rose in CR, therefore they consist at least in their outer region of exudate.

Not included collections: A Chinese collection (Pls 890: 2; 891: 2) differs from the type of *O. subfabacearum* in distinctly

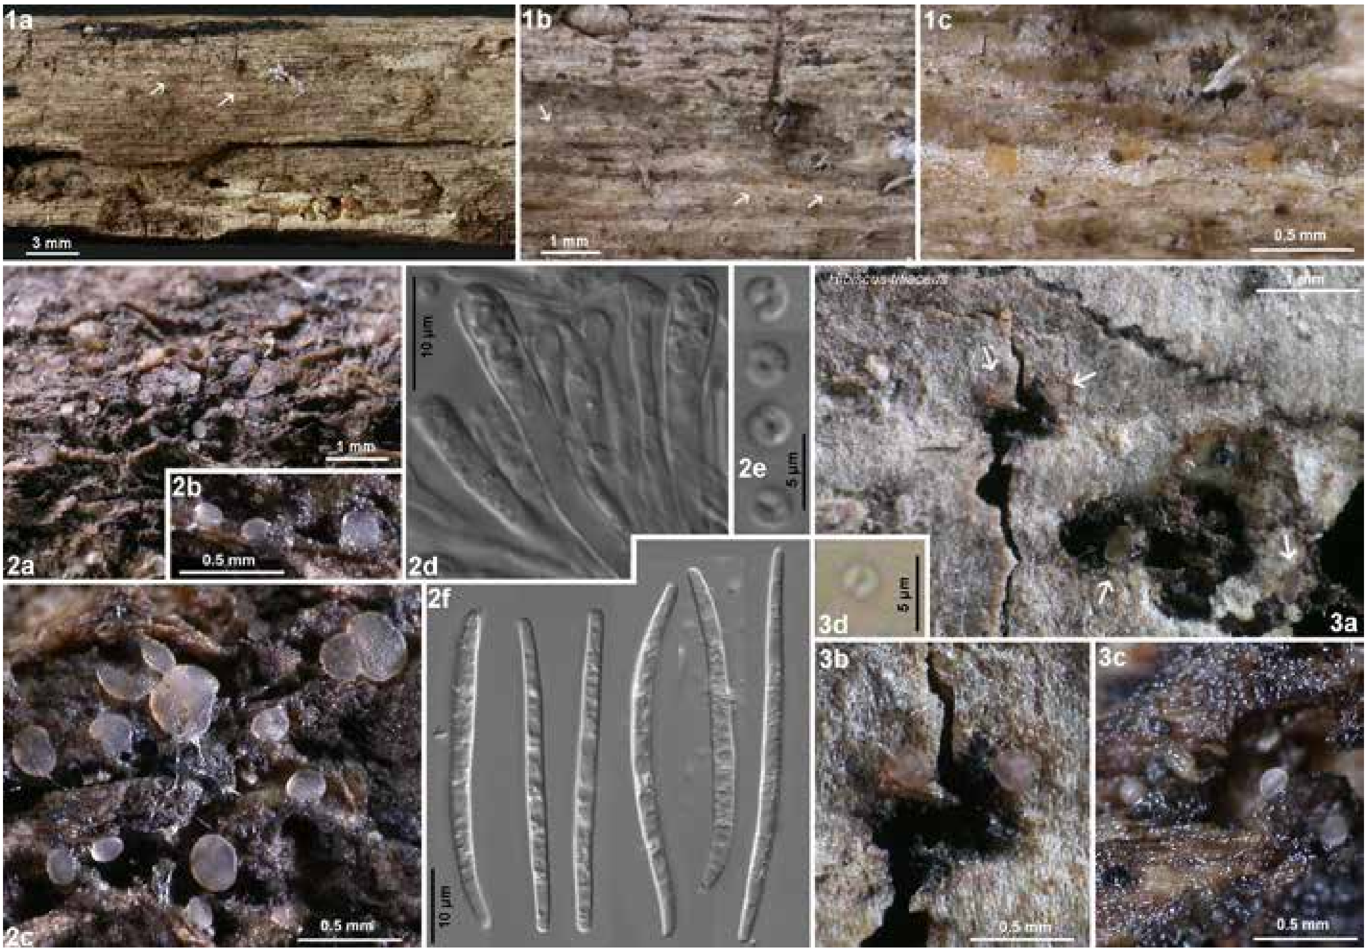

Plate 891. **1**: *Orbilia subfabacearum*; **2–3**: *O.* cf. *subfabacearum*. – **1a**, **2a**, **3a**. dead corticated (**2–3**) or decorticated (**1**) xeric (**1**, **3**) or hygric (**2**) branches; **1b–c**, **2a–c**, **3a–c**. rehydrated apothecia; **2d**. asci and paraphyses; **2e**, **3d**. ascospores; **2f**. conidia from culture. – Living state, except for **3d** (in H_2O). – **2d–f**: phot. Z.F. Yu (DIC). — **1a–c**. H.B. 6280e (holotype): Australia, Queensland, Einasleigh Uplands, on indet. climber; **2a–f**. H.B. 8345: China, Yunnan, on indet. angiosperm; **3a–d**. H.B. 8487b: Australia, Queensland, Daintree Forest, on *Hibiscus*.

shorter asci, and especially in the spores containing SBs at their dorsal side which disappear in KOH. An Australian sample (Pl. 891: 3) closely resembles the Chinese one, but here only dead spores could be studied, and the asci were narrower (†22 × 2.3–2.6 µm). Both differ from the type of *O. subfabacearum* also in less inflated paraphyses and in the cortical cells being consistently without refractive caps. From *O. fabacearum* the two differ in shorter asci, and in smaller, a bit more strongly curved spores. For the time being, these two samples are not included in either description.

A sample from Vietnam with sparse, ochraceous apothecia (0.15–0.3 mm) growing on angiosperm bark was briefly studied (IVV: H.B. 5256a). Only some spores were still alive, but SBs could not be seen. The sample appears to fit best *O. subfabacearum* in spore size and shape (*2.8–3 × 1 µm, asci †28–38 × 2.8–3.5 µm) but its correct identity remains uncertain.

Anamorph. Unbranched, straight to slightly curved vermispora-like phragmoconidia were obtained in pure culture of the Chinese collection (Pl. 891: 2f, *41–53 × 2.4–3 µm, 4–5-septate). Data about the conidiophores was not available.

Ecology. The sparse holotype was collected on rotten bark and wood of a xeric branch of an unidentified climber in a dry riverbed in a tropical subhumid (winter-dry savannah climate) eucalypt open woodland in northeastern Australia east of Great Dividing Range. The not included collections were on rotten bark of xeric or hygric branches of *Hibiscus tiliaceus* (Cottonwood) on Devonian sedimentary rock and an indetermined angiosperm in subtropical to tropical humid (winterdry), monsoon-dominated evergreen forests in northeastern Australia and southern China. The sample from Vietnam is from a tropical humid (wet and dry) rainforest.

Specimens included. **AUSTRALIA**: **Queensland**, Einasleigh Uplands, 75 km SSW of Townsville, 2 km WSW of Mingela, 286 m, branch of indet. climber, on bark & wood, 17.X.1998, G. Marson (ex H.B. 6280e, BRI AQ 799181, **holotype**).

Not included. **AUSTRALIA**: **Queensland**, Wet Tropics, 47 km N of Port Douglas, 5 km N of Cape Tribulation, 15 m, branch of *Hibiscus tiliaceus*, on bark, 30.VIII.2006, G. Marson (ex H.B. 8487b, in BRI AQ799192, H.B. 8487a, type of *O. spirillospora*). — **CHINA**, **Yunnan**, **Yuxi**, Yimen, 54 km NW of Yuxi, 3 km NW of Fangtunxiang, Dalongkou, 1750 m, branch of indet. angiosperm, on bark, VIII.2006, Z.F. Yu (Z.F.Y. ym-25, YMFT, H.B. 8345). — **VIETNAM**: **Phú Quốc island**, 14.5 km NNE of Dương Đông, 5.5 km ESE of Rạch Vẹm, 40 m, branch of indet. angiosperm, on bark, I.1995, N. Petit (H.B. 5256a).

Orbilia coccinella Fr., Summa Veg. Scand.: 357 (1849) — Pls 892–893

≡ *Peziza coccinella* Sommerf., Suppl. Fl. Lapp.: 296 (1826), nom. illegit., ICN Art. 53.1; – Fr., Elenchus Fung. 2: 12 (1828), nom. illegit., ICN Art. F.3.3 – [non *Peziza coccinella* Fr. 1822, ≡ *Helotium coccinellum* (Fr.) Boud. 1907, see below and p. 1666]
≡ *Mollisia coccinella* (Fr.) Gillet, Champ. Fr., Discomyc.: 129 (1882)
≡ *Calloria coccinella* (Fr.) W. Phillips, Man. Brit. Discomyc.: 328 (1887)

Etymology: a diminutive of scarlet red (*coccinea*), referring to the colour of the dry apothecia, perhaps also in comparison to the ladybird beetle genus *Coccinella*.

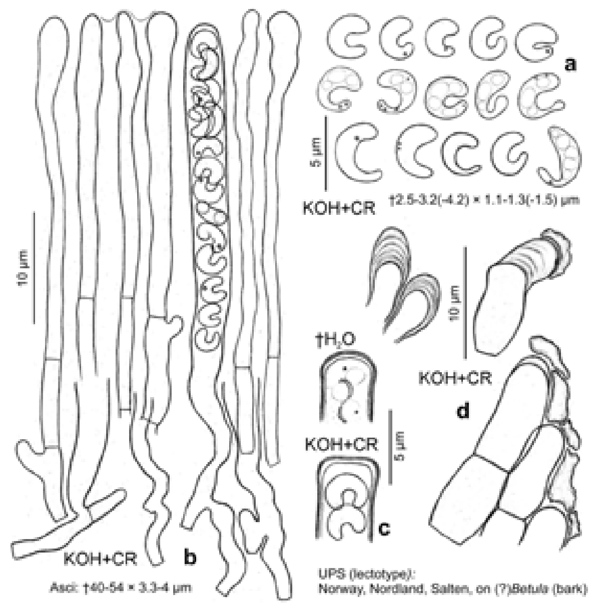

Plate 892. **1**: *Orbilia coccinella*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal cortical cells with short glassy processes.

Typification: Norway, Nordland, Salten, bark of (?)*Betula*, undated, S.C. Sommerfelt (herb. E. Fries, UPS, lectotype, designated here, MBT202386).

Misapplied name: Nannfeldt (1932: 252), as very closely related to *Hyalinia rubella* or perhaps even conspecific.

Misinterpretation of *O. coccinella*: Nylander (1869), Karsten (1869) and most later authors, = *O. eucalypti* or *O. tremulae*; Bachman (1909: 58), ?= *O. eucalypti*; Crouan (in sched.), = *O. rubrovacuolata*; Feltgen (1899: 53, 1901: 35, 1903: 41), = *O. xanthostigma* and *O. eucalypti*; Yang & Liu (2005), ?= *O. dryadum*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.8 mm diam., bright rose (protologue), now pale yellowish-cream, ± translucent, round to laterally compressed, scattered or in small groups; disc slightly concave to flat, margin distinct, finely rough or crenulate; sessile, superficial or immersed in clefts; dry translucent red (fide Sommerfelt). **Asci** †40–54 × 3.3–4 µm, 16-spored (~14–16 spores counted, sometimes apparently only 8-spored), spores (†) biseriate above, uniseriate below, oriented in all directions, pars sporifera †25–33 µm long; **apex** (†) medium, rarely strongly truncate (not indented, laterally not or rarely slightly inflated); **base** with short to long, thin or thick, ± flexuous stalk, T-, L- or h-, rarely H- or M-shaped. **Ascospores** †2.5–3.2 or rarely 3.3–4.2 × 1.1–1.3(–1.5) µm [4.5–6.5(–7) µm actual length], very strongly curved (± semicircular, curved by ~160–270°), not or partly somewhat helicoid, apex rounded to obtuse, below often slightly to strongly narrowed to a short tail that is rarely bulbous at the end; **SBs** not observed. **Paraphyses** apically uninflated or often slightly to rather strongly clavate or ± moniliform, also somewhat spathulate to lageniform, terminal cells †20–32 × 1.5–3 µm, hardly exceeding the dead asci, lower cells †6–12 × 1.2–2.2 µm; usually unbranched at upper septum. **Medullary excipulum** not examined. **Ectal excipulum** only examined near margin, here of textura prismatica oriented at a 40° angle, cortical cells †8–10 × 3–4.5 µm; **glassy processes** 1–5 × 3–4 µm, cap-like, ± high-refractive, stratified. **Anchoring hyphae** not examined. **SCBs & VBs** no data available. **Exudate** over paraphyses ± absent, over margin 1–2 µm thick, cloddy. **— ANAMORPH**: unknown.

Habitat: on apparently xeric bark of (?)*Betula*, outer surface of medium decayed bast being fragmented in scales, also at edges and below, partly darkened. **Associated**: *Hysterium angustatum*. **Desiccation tolerance**: probably drought-tolerant. **Altitude**: unknown (0–700 m). **Geology**: sand, wacke, mica schist, granitoid. **Phenology**: unknown.

Taxonomic remarks. *Orbilia coccinella* in its original sense is easily recognized by 16-spored asci and small, very strongly curved (cashew-shaped), smooth ascospores which are partly strongly attenuated at the lower end by often forming a short tail. The marginal cortical cells carry short glassy processes, which cause the finely rough or crenulate margin.

O. coccinella somewhat resembles the 8-spored *O. fabacearum* and *O. subfabacearum* which have similarly shaped spores, though never as heteropolar as in *O. coccinella*. No trace of the spore body could be discerned in *O. coccinella*. A few oversized spores were seen (3.3–4.2 × 1.3–1.5 µm) which might originate from asci with a reduced spore number. Following the protologue (see below), the epithet *coccinella* refers to the colour of the dry fruitbodies, which is generally much more intense than in the hydrated state.

Nomenclature and type studies. When Sommerfelt described *Peziza coccinella* in 1826, he appears to have been unaware of *Peziza coccinella* Fries (1822: 125), an obviously cyphelloid fungus (see p. 1666), although he compared his fungus with *P. xanthostigma* described in the same work (Fries 1822: 146). Even Fries (1828: 12) himself did not mention *Peziza coccinella* Fr. when he sanctioned Sommerfelt's *Peziza coccinella*, hence he seems to have overlooked this homonymy as well. Therefore, Fries' combination *Orbilia coccinella* is to be considered as a nomen novum (ICN Art. 58.1), and to be cited as *O. coccinella* Fr. instead of *O. coccinella* (Sommerf.) Fr. as was currently done.

Nannfeldt (1932: 252) appears to be the first and only person

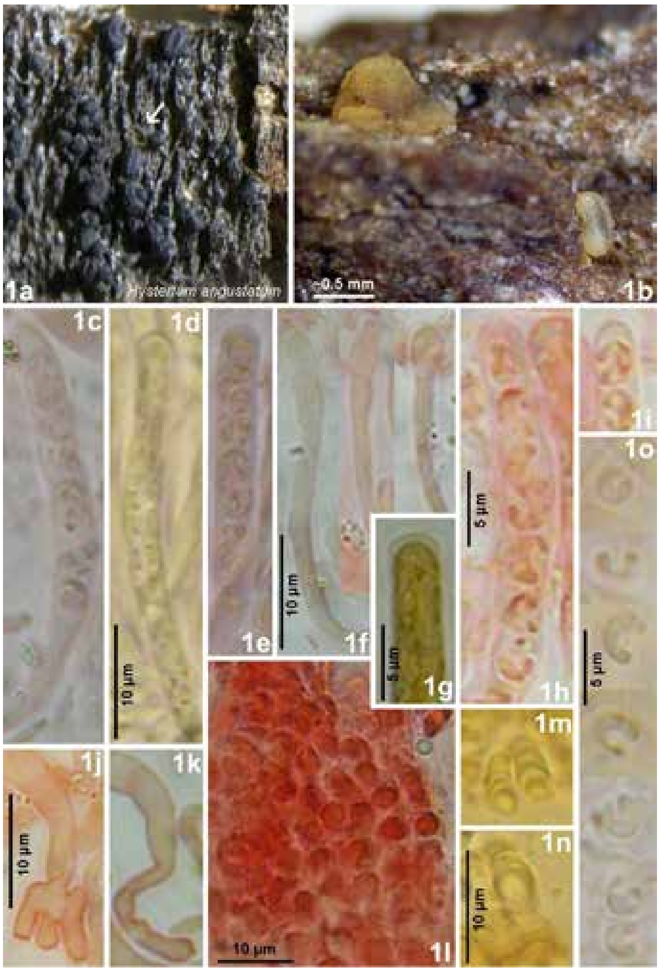

Plate 893. **1**: *Orbilia coccinella*. – **1a**. outer surface of bark of (?)*Betula*, with *Hysterium angustatum* and one destroyed apothecium; **1b**. rehydrated apothecia at edge of bark; **1c–e**. mature asci; **1f**. paraphyses; **1g**, **i**. ascus apices; **1j–k**. ascus bases; **1h–i**, **o**. ascospores; **1l**. glassy processes covering marginal ectal excipulum (external view); **1m–n**. glassy processes. – Dead state (**1d** in H_2O; **1m–n** in KOH; **1g**. KOH+IKI; **1c**, **e–f**, **h–l**, **o** in KOH+CR). — **1a–o**. UPS (lectotype): Norway, Nordland, on (?)*Betula*.

who ever reexamined authentic material of *Peziza coccinella* Sommerf. in herb. E. Fries (UPS). He found this species to differ greatly from the current concept of *Orbilia coccinella* (= *O. eucalypti*) as introduced by 'Nylander, Karsten, Rehm, Boudier and others'. Instead, he believed it to be 'very close to and perhaps even conspecific with *Hyalinia rubella*'. However, the latter species (= *Orbilia rubella*) and the similar *O. phragmotricha*, which Nannfeldt merged with *O. rubella*, sharply differ from the types of *O. coccinella* and *O. eucalypti* in having very distinctive, thick-walled hairs at the margin, and narrowly fusoid-clavate, only slightly curved ascospores. Regrettably, Nannfeldt did not provide any diagnostic features of Sommerfelt's material, therefore, the reasons for his conclusion remain obscure.

When asking in 2002 for authentic material of *O. coccinella* at UPS (and also at C, O, GH, GB, E), no such material was said to exist in all these herbaria. Later (2010) the specimen was rediscovered at UPS (S. Ryman pers. comm.), and it was studied in July 2010 by the first author during a mycological meeting in Saxnäs (Lapland). The label bears a note by Arendholz (in sched.) who had examined it in 1980, albeit only macroscopically because of the paucity of apothecia. The single envelope contains a few pieces of bark, probably of *Betula*, with a total of about 7 apothecia.

The present reexamination of two of them was a surprise: the asci were found to be 16-spored, the spores cashew-shaped, and the marginal cortical cells provided with short glassy processes, features being previously unreported as characteristics of Sommerfelt's fungus. Undoubtedly, Nannfeldt did not see the spores when he proposed a similarity to *Hyalinia rubella*, but he should have noticed the absence of distinct hairs in this material.

Peziza coccinella was originally described with glabrous apothecia. The translation of Sommerfelt's (1826) protologue reads as follows: '1722 *Peziza coccinella*: sessile, minute, submembranaceous, glabrous, flat, suboblong, bright rose, dry translucent red ('*coccinea*'), margin thin. ?*P. xanthostigma* Fr. Syst. [Mycol.] II[(1)] p. 146, Observ. [Mycol.] 1 p. 166? Habitat on bark of *Betula* being fragmented in scales, and on dead branches of *Populus*, widespread in the district Salten in Nordland county. Scarcely 1 line [~2 mm] diam. Sometimes in summer subirregular [possibly referring to an irregular occurrence]. Very closely related to *Dacrymyces urticae* [= *Calloria neglecta*], but this more gelatinous.' No illustration was supplied by Sommerfelt to his diagnosis.

Fries (1828: 12) merely copied Sommerfelt's description, but he added two German taxa which he considered as synonymous: *Peziza diluta* γ. *fungorum* Albertini & Schweinitz (1805: 338), on rotten *Boletus sistotremoides* (= *Phaeolus schweinitzii*) in Saxonia, and *P. dispersa* Wallroth (1833: 469), on *Sphaeria stigma* (= *Diatrype stigma*) in Thüringen. Fries stated that the colour of Sommerfelt's *P. coccinella* strikingly differed from his *P. xanthostigma*, and referred Swedish collections on rotten polypores to *P. coccinella*. Saccardo (1889: 628) followed Fries in citing *P. dispersa* Wallr. Crypt. N. 2503 as a synonym of *O. coccinella* and mentioned in the habitat also Fries's polypores, besides Italia and Galicia.

Since Sommerfelt reported his taxon on two different substrates, and also Fries cited Sommerfelt's fungus as growing on 'bark of *Betula* and *Populus*', the present material, which seems to contain remnants of a single host tree only, is not automatically the holotype. Therefore, the specimen in herb. Fries (UPS) labelled '*Peziza coccinella* Somf.', leg. Sommerfelt, is designated here as **lectotype** of *Orbilia coccinella* Fr.

Ecology. *O. coccinella* is so far only known with certainty from the sparse type collection on rotten xeric bark of a possibly standing trunk of (?)*Betula*. Judging from the rose-red colour of the apothecia and the polysporous asci, the species is most probably a desiccation-tolerant fungus. This is confirmed by the coexistence with *Hysterium angustatum*, but also by the appearance of the decayed bark. The species was collected in in the traditional district Salten, a prefecture at Sommerfelt's time which comprised also Ofoten (K. Homble pers. comm.), with the municipality Saltdal (with the main village Rognan) where Sommerfelt operated as a parson in his early years (1818–1824). Here, Sommerfelt most probably collected primarily in the chalk-rich Saltdal area, with the well known species-rich Junkerdal (K. Homble pers. comm.). Saltdal is just north of the arctic circle and represents one of the driest areas of Norway because it lies in a valley in the rainshadow of the surrounding mountains. Nevertheless, its oroboreal summer-warm forests are to be considered as humid. It seems probable that *O. coccinella* was collected in the widespread *Betula* forests of that area.

Specimens included. **NORWAY**: **Nordland**, Salten, ?Saltdal, unlocalized, 0–500 m, branch of (?)*Betula*, on bark, undated, S.C. Sommerfelt (herb. Fries, UPS, **lectotype**, H.B. 9402a ø).

Incertae sedis

Orbilia flexispora Spooner, Bibl. Mycol. 116: 173 (1987) — Pls 894–895

Etymology: referring to the flexuous shape of the ascospores.
Typification: Australia, Victoria, Colac, branch of *Melaleuca*, 6.IX.1964, G. & K. Beaton (K(M) 48775, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.85 mm diam., 0.18 mm thick (receptacle 0.1–0.12 mm), whitish to pale yellowish (Spooner: whitish), slightly translucent, ± round, superficial, scattered or a few densely aggregated; disc strongly concave, margin distinct, smooth, ~10 µm protruding, with a ± indistinct, short and thick stipe; dry light chlorinaceous (Spooner: pale orange). **Asci** †30–41 × 2.9–3.1 µm, 8-spored, spores †~3-seriate, usually lower (e.g., 5) spores inverted (± mixed), pars sporifera †12.5–14 µm

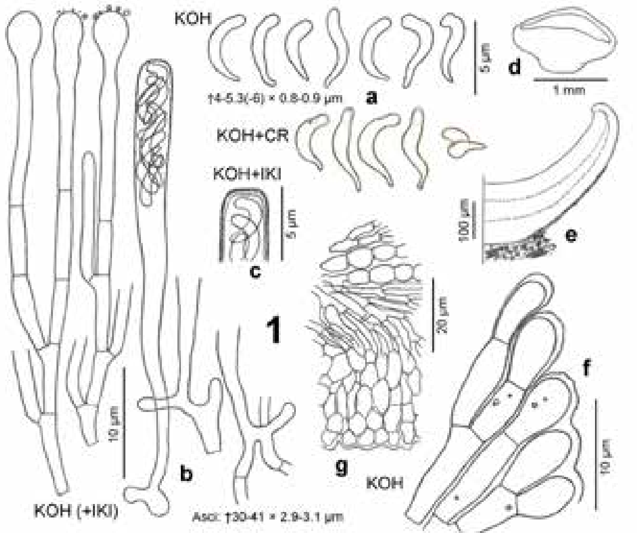

Plate 894. **1**: *Orbilia flexispora*. – **a**. ascospores (1 in bottom view); **b**. ascus and paraphyses; **c**. ascus apex; **d**. rehydrated apothecium; **e**. apothecium in median section; **f**. median section of marginal ectal excipulum; **g**. id., ectal and medullary excipulum at lower flanks.

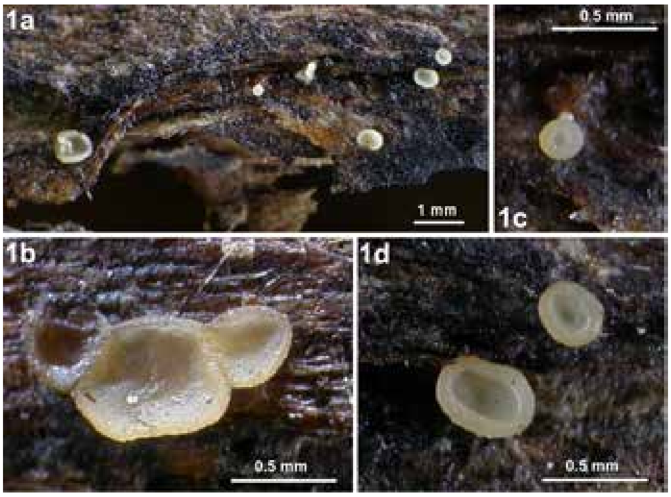

Plate 895. **1**: *Orbilia flexispora*. – **1a–d**. rehydrated apothecia. — **1a–d**. K(M) 48775 (holotype): Australia, Victoria, on *Melaleuca*.

long; **apex** (†) strongly truncate (not distinctly indented, laterally not widened); **base** with medium to very long, thin, flexuous stalk, T-, Y- or H-shaped. **Ascospores** †4–5.3(–6) × 0.8–0.9 µm, narrowly cylindric- to fusoid-clavate (subulate), apex rounded, not or slightly tapered, often subapically slightly constricted to form a knob-like end, base strongly attenuated (often tail-like), strongly curved (falcate to distinctly helicoid); **SBs** visible as a very faint, broadly ellipsoid area in the broad spore end. **Paraphyses** apically medium to strongly clavate-capitate, rarely moniliform, terminal cells †16–20 × 2–3.3 µm, lower cells †3.5–7.5 × 1–1.5 µm; unbranched at upper septum. **Medullary excipulum** hyaline, 50 µm thick, of medium loose horizontal textura porrecta-intricata with many inflated cells, sharply delimited from ectal excipulum by a layer of t. porrecta. **Ectal excipulum** hyaline, of thin-walled, vertically oriented t. angularis(-prismatica) from base to mid flanks, 50 µm thick near base, cells †5–15 × 4–10 µm; 30–35 µm thick at lower flanks, 15–20 µm near margin, of t. prismatica oriented at a 40–60° angle to the surface, marginal cortical cells †6–8 × 2.5–4 µm; **glassy processes** absent. **SCBs** & **VBs** no data available. **Anchoring hyphae** abundant, 1.5–2.7 µm wide, walls 0.2–0.3 µm thick, forming a dense, 5–15 µm thick layer at lower flanks. **Exudate** over paraphyses mostly absent, sometimes as scattered, loosely attached granules; over lower flanks up to margin ∼0.5–1 µm thick, continuous, firmly attached. **— ANAMORPH**: unknown.

Habitat: probably lying on ground, corticated, ∼20 mm thick branch of *Melaleuca* sp., on medium decayed bark (periderm), indistinctly greyed, with some algae. **Associated**: none observed. **Desiccation tolerance**: unknown (possibly intolerant). **Altitude**: ?230 m a.s.l. **Geology**: Cenozoic regolith. **Phenology**: IX (southern hemisphere).

Taxonomic remarks. *Orbilia flexispora* is characterized by comparatively small, rather strongly falcate to helicoid ascospores with one end rounded and the other strongly tapered and acute to acuminate. The SBs appear to be located in the rounded end, judging from the few spores in which a faint, transparent, broadly ellipsoid area could be discerned (Pl. 894: 1a below row).

A slight constriction is frequently seen near the rounded spore end, resulting in a knob-like spore apex, a feature which is quite unusual in *Orbilia*. Actually, this knob-like spore end is reminiscent of the basal spore ends in, e. g., *O. milinana* (series *Abutilones*), but a slight constriction near the spore apex is also seen in some members of section *Arthrobotrys*, e. g., in *O. elegans* (Pl. 961: 1a), and the flexuous shape of the tapered end indicates that it can hardly represent the spore apex.

O. xanthoflexa has a similar spore size and curvature, but deviates in having only slightly tapered spore bases, smaller asci, and bright yellow apothecia with a flat disc. *O. neocomma* (series *Commatoideae* of section *Aurantiorubrae*) resembles *O. flexispora* in spore shape and might be closely related. It differs in longer and especially wider, more fusoid spores with more tapered apices without subapical constriction, also in the presence of exudate caps on the paraphyses, furthermore in the absence of H-shaped ascus bases and in flatter apothecia. The presence of H-shaped ascus bases in *O. flexispora* supports its position within section *Orbilia*, though section *Arthrobotrys* would be another possibility for this species. Because of this uncertainty we did not include this species in the description of series *Orbilia*.

The thick and refractive walls of the cortical excipular cells are apparently made up of exudate, since this layer stains deep rose-red in CR. However, the possibility cannot be excluded that the rose-red stain is restricted to the surface, whereas the matrix is composed of a gel or a glassy wall substance.

Type studies. The present redescription fits quite well the protologue (Spooner 1987: apothecia 0.5–1 mm diam., asci 30–36 × 2.5–3 µm, spores 4.5–6 × 0.6–1 µm, paraphyses not encrusted). Spooner described the asci as apically rounded, although his illustration shows ± distinctly truncate apices. The original colour of the apothecia was not noted by the finder, and the material was restudied by Spooner maybe 20 years after the specimen was collected.

Ecology. *O. flexispora* is only known from the holotype. It grew on medium rotten, probably hygric bark of a *Melaleuca* branch in southeastern Australia. The collection site was given as 'Victoria, Pipeline Road'. There are several Pipeline Roads in Victoria, but it seems quite probable that the one not far from Cape Otway was meant, the southernmost part of southeastern Australia. The natural vegetation around this road appears to be an oceanic, warm-temperate humid eucalypt tall open forest which lies in the South East Coastal Plain ecoregion.

Specimens included. **AUSTRALIA**, **Victoria**, **South East Coastal Plain**, ?95 km WSW of Geelong, ?27 km SW of Colac, Pipeline Road, ?230 m, branch of *Melaleuca*, on bark, 6.IX.1964, G. & K. Beaton (Beaton 258, K(M) 48775, **holotype**, H.B. 5752 ø).

Unidentified psammina-like anamorphs with possible relationship with series *Orbilia*:

Collections from Europe and North America: **Conidiophores** not observed. **Conidia** hyaline, */†19–31 µm diam., with 8–13 arms of */†(6–)8–30 × 2–3.5 µm, each arm with 0–3 septa.

Collections from Australia: **Conidiophores** not observed. **Conidia** hyaline, */†43.5–58 × 47.5–71 µm, with 16–21 arms of */†6–13 × 2–3.5(–4) µm, each arm with 3–7 septa.

Taxonomic remarks. Psammina-like conidia seem to represent a multibranched variant of the genus *Dicranidion*. We have observed them on xeric wood and bark of different gymno- and angiosperms, partly in association with *Orbilia* spp. They resemble some members of the genus *Psammina* as surveyed by Lee & Crous (2003) and Earland-Bennett & Hawksworth (2005) who provided a dichotomous key. This genus is listed in Index Fungorum and Species Fungorum with nine species which occur saprobic on monocots or more or less parasitic on lichens and in close association with green coccoid algae on xeric wood and bark of angiosperms. One species, *P. palmatum* Earl.-Benn. & D. Hawksw., was considered to be lichenized

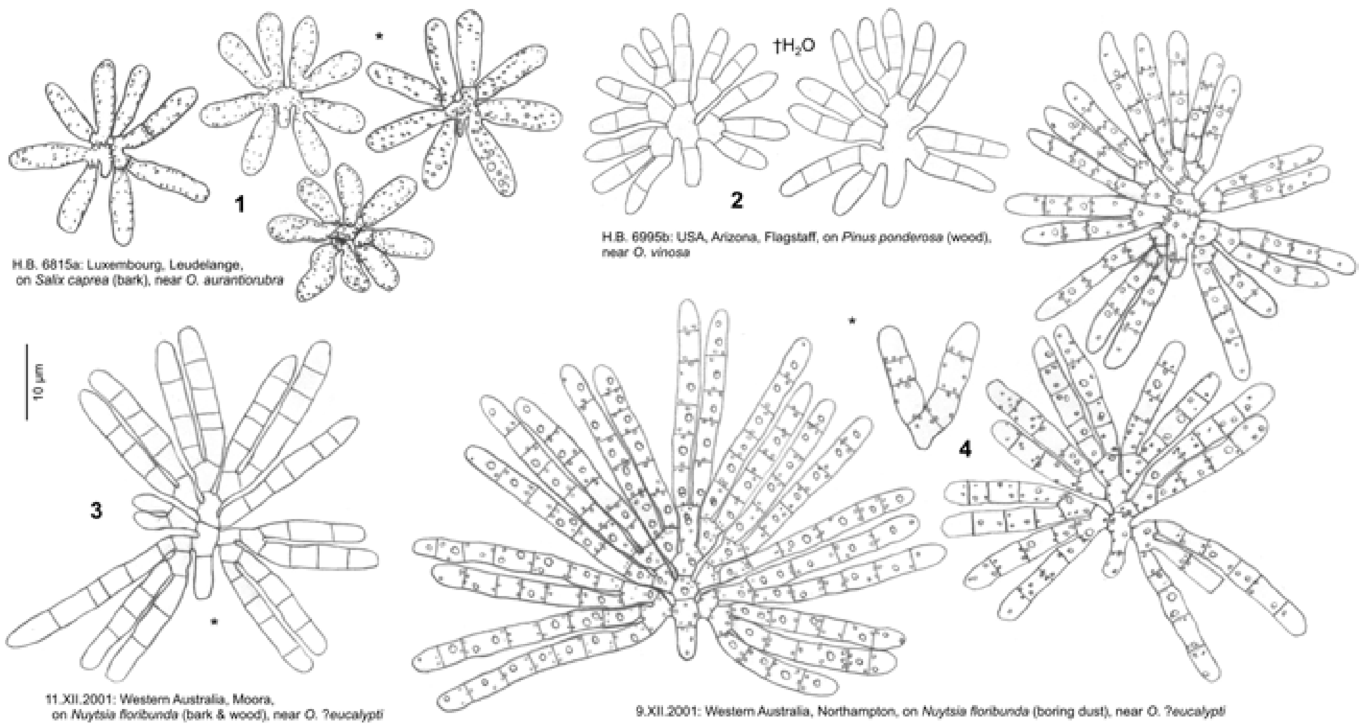

Plate 896. Psammina-like conidia from natural substrate (in **4** also dicranidion-like).

(Earland-Bennett & Hawksworth 2005). Conidia are hyaline or pale brown and are formed on short monoblastic conidiophores in dispersed colonies or within conidiomata.

The specimens studied here differed from each other in conidial size and number of septa. The smaller ones have been collected in Europe (with few septa) and North America (with many septa), the larger multiseptate ones in Australia. The latter resemble *Dicranidion incarnatum* which regularly forms conidia with 3–8 arms (see Pl. 11: l) except that the arms point in all directions. In the material from Luxembourg and France, septa occurred mainly at the base of the arms, possibly because these conidia are juvenile. In the collection on *Nuytsia* rarely 2-armed dicranidion-like conidia occurred with the multiarmed ones (Pl. 896: 4), which resemble those of *O. eucalypti* and allied species.

Different species of *Orbilia* with different anamorphs grew in association with our samples of psammina-like conidia but all are excluded as teleomorph of them because they produce different conidia in pure culture: in one from Luxembourg it was *O. aurantiorubra* with vermispora-like conidia, in one from USA it was *O. vinosa* which has trinacrium-like conidia, and in two from Australia *O. ?eucalypti* (9.XII.2001 with oversized spores) and *O. ?tremulae* (11.XII.2001) occurred, which both typically have dicranidion-like conidia. Only within the species complex of ellipsoid-spored taxa around *O. eucalypti* and *O. tremulae* it seems possible that psammina-like conidia belong to the associated teleomorph.

Phylogeny. An LSU sequence of the type species, *P. bommeriae* Sacc. & M. Rousseau (with hyaline conidia), was available in GenBank (MH878435), which refers this species near *Torula* Pers. and *Corynespora* Güssow in the *Pleosporales*, *Dothideomycetes*. Further molecular studies are unknown to us.

Specimens included (all without presumed teleomorph): **AUSTRALIA**: **Western Australia**, Jarrah Forest, 56 km NNE of Perth, 14 km NNE of Muchea, Great Northern Hwy, 230 m, branch of *Pinus radiata*, on boring dust, 23.XI.2001, G. Marson (ø) – Geraldton Sandplains, 60 km N of Geraldton, 12 km N of Northampton, 278 m, branch of *Nuytsia floribunda*, on boring dust near *O. ?eucalypti*, 9.XII.2001, G. Marson (ø), – 145 km NNW of Perth, 48 km WSW of Moora, 2.5 km NW of Cataby, Brand Hwy, branch of *Nuytsia floribunda*, on bark & wood with *O. ?eucalypti*, G. Marson, 11.XII.2001 (ø), — **LUXEMBOURG**: **Gutland**, 4.5 km SW of Luxembourg, 1.5 km SW of Cessange, Bois de Cessange, 305 m, branch of *Salix caprea*, on bark near *O. aurantiorubra*, 5.XI.2000, G. Baral (H.B. 8136d). — **USA**: **Arizona**, Mogollon Rim, 9 km NW of Flagstaff, San Francisco Peaks, 9 km SSW of Humphreys Peak, Rte. 180, 2250 m, branch of *Pinus ponderosa*, on wood near *O. vinosa*, 12.VI.2000, G. Marson (H.B. 6995b).

Section *Arthrobotrys*

Orbilia subgenus ***Orbilia*** section ***Arthrobotrys*** (Corda) Baral, E. Weber & Hagedorn, **comb. & stat. nov.**, MB 814997 – Type species: *A. superbus* Corda [= *Orbilia* ?*auricolor* (A. Bloxam) Sacc.]

Basionym: *Arthrobotrys* Corda, Pracht-Fl. Eur. Schimmelbild.: 43 (1839)

Emended diagnosis: **TELEOMORPH**: Apothecia with smooth or denticulate to hairy margin, sessile or stipitate, desiccation-sensitive or -tolerant. Asci 8-spored, apex (†) ± truncate, thin-walled, base furcate, often H-shaped. Ascospores ellipsoid, fusoid, narrowly cylindrical or subulate, straight to strongly curved; spore bodies globose to filiform. **— ANAMORPH**: Conidiophores usually ± long, unbranched or branched in upper part (sympodial), conidiogenous loci apical, singly, or on aggregated denticles or nodules (multiple). Conidia straight or sometimes curved, exceptionally branched, 0–multiseptate, with or without inflated middle cells. Trapping organs present or absent.

TELEOMORPH: **Apothecia** moist/rehydrated (0.15–)0.25–2(–6) mm diam., whitish or pale to bright rosaceous or yellow-orange to blood-red or purplish-brownish, margin smooth or finely to distinctly crenulate or denticulate, sessile or with a short to comparatively long stipe. **Asci** *24–67 × 3–5(–6) µm, 8-spored, lower or upper (1–)3–5(–6) spores inverted; **apex** (†) slightly to strongly truncate in front view, not or ± distinctly indented and laterally inflated, hemispherical in profile view, thin-walled; **base** generally H-shaped in a part of the asci. **Ascospores** *(2.7–)5–14(–17)((–20.5)) × (0.6–)0.8–1.7(–2.3)((–3.5)) µm, ellipsoid-ovoid to subcylindrical or often narrowly fusiform to fusoid-clavate (subulate), apex rounded to obtuse or subacute to acuminate, base not or slightly to strongly tapered, sometimes with a tail, straight or slightly to strongly curved (falcate), usually strongest near base; **SBs** apically affixed to spore wall, central or ± eccentrical, (0.4–)0.8–2(–3) × 0.15–1 µm, globose to tear-shaped or subulate to rod-shaped, narrowed to a small to wide point, with or without short filum, attachment visible or not. **Paraphyses** not or slightly to strongly inflated at apex, clavate-capitate, sometimes obtusely lanceolate, terminal cells (1–)2–5(–6)× longer than lower cells, unbranched near apex. **Ectal excipulum** of vertically oriented textura globulosa-angularis-prismatica; **glassy processes** absent or 1–5 µm up to 50–70 µm long, **hairs** absent, rarely 12–110 µm long, thick-walled, septate. **SCBs** absent or globose, never crystalloid (exception: strain from *O. senegalensis* in series *Neodactylella*); **VBs** absent or slightly to medium, rarely strongly refractive; **LBs** without **carotenoids** (very pale yellowish in *O. terrestris*). **Exudate** (0.1–)0.3–2(–8) µm thick, continuous to cloddy-granular, loosely or firmly attached, hyaline to bright yellowish, rarely reddish or brownish, sometimes absent. **— ANAMORPH**: arthrobotrys-like, dactylella-like, dactylellina-like, drechslerella-like, gamsylella-like, presumably also anguillospora- or vermispora-like. **Conidiomata** absent, rarely synnematous (*Roigiella*). **Conidiophores** erect, medium long to very long (30–600 µm), apically unbranched, with a single acrogenous conidium, or sympodially branched (geniculate, candelabrelloid or arthrobotryoid). **Conidiogenous cells** monoblastic or sympodial, or aggregated as denticles or nodules. **Conidia** unbranched, exceptionally trinacrium-like, cylindric-ellipsoid, clavate, obovoid, fusiform, or top-shaped, aseptate or usually oligo- to multiseptate, straight or sometimes curved; **conidial dimorphism** present or absent. **Trapping organs** formed or not formed in the presence of nematodes (or other invertebrates), including adhesive knobs, adhesive columns and bridges, adhesive nets, non-constricting rings, and constricting rings. **Habitat**: on wood and bark, herbaceous stems, leaves or fruits of both gymno- and angiosperms, sometimes fungicolous or on dung, temperate to tropical, humid to semihumid, sometimes semiarid to arid, desiccation-sensitive or sometimes -tolerant.

Recognized series: *Arthrobotrys*, *Dactylellina*, *Drechslerella*, *Gamsylella*, and *Neodactylella*, with 88 recognized species (35 of them without known teleomorph) plus 1 with a provisional name, 18 unnamed species ('affinis'), and 6 species of uncertain affinity (2 of them unnamed); further ~67 anamorphic species not treated here.

Taxonomic remarks. Section *Arthrobotrys* includes five series: *Neodactylella*, *Arthrobotrys*, *Dactylellina*, *Gamsylella*, and *Drechslerella*, which have been treated as different anamorph-typified genera before the ICN came into effect in 2012. It is circumscribed here for species with predominantly desiccation-sensitive apothecia, often narrowly falcate but also rod-shaped or ellipsoid ascospores, often very long conidiophores, and almost exclusively unbranched, often rather broad conidia. Except for series *Neodactylella*, all members form trapping organs on their mycelia, which are able to catch nematodes and other invertebrates.

Anamorph, **series delimitation**. Various molecular studies indicate that the type of trapping organ (or its absence) represents the key character of each of the five recognized groups (see below). To classify a species into a series solely by the teleomorph proved difficult if not impossible, and even the conidiophores and conidia observed on the natural substrate or in pure culture usually do not provide enough characteristics, unless the trapping organs are unequivocally detected as belonging to the fungus.

Earlier classification systems to distinguish anamorph-typified genera of nematophagous fungi have been based on conidiophore (Fig. 103) but also conidial morphology (for a review of the generic names see Baral et al. 2017b). However, these morphological traits were largely not supported by molecular data. In fact, three of the four main conidiophore types that occur within section *Arthrobotrys* are found in all of the five recognized series. Merely the arthrobotryoid type is exclusively observed in series *Arthrobotrys*, with one exception, *Dactylellina ferox*, which is tentatively placed here in series *Gamsylella*. Yet, series *Arthrobotrys* comprises also the candelabrelloid, geniculate, and acrogenous type.

Although four series with predacious capabilities are recognized, the observed trapping organs can be classified into five main types: adhesive sessile or stalked knobs (*Gamsylella*, *Dactylellina*), adhesive columns and bridges (*Gamsylella*), adhesive nets (*Arthrobotrys*), non-constricting rings (*Dactylellina*), and constricting rings (*Drechslerella*), the latter two being non-adhesive. Except for adhesive nets and constricting rings, these trap types may sometimes occur together within a strain: adhesive knobs and non-constricting rings occur in several species of series *Dactylellina*, and adhesive knobs and columns or bridges in some of series *Gamsylella* (and *Dactylellina*). Non-constricting rings appear never to occur alone in a species.

Species concept. Numerous misidentifications were discovered within section *Arthrobotrys* when comparing morphology-based species concepts with those inferred from rDNA sequences. Such misidentified strains generally clustered very distant from the correct clades, their molecular deviation being far beyond the accepted, often rather high infraspecific variability of frequently studied taxa. Nevertheless, species delimitation remained unsettled in some taxa with strong variability, such as *O. oligospora*, *O. elegans*, and *G. cionopaga*, in which different, closely related cryptic taxa appear to exist. For further details see under the series.

Nomenclature. From 1839 until recently the name *Arthrobotrys* has been attributed a feminine gender. However, the traditional usage of the suffix *-aster* is masculine [see ICN Art. 62.2 (a)], therefore, all names with a different feminine final epithet had to be corrected to masculine. According to ICN Art. 62.1 'A generic name retains the gender assigned by nomenclatural tradition, irrespective of classical usage or the author's original usage'.

Phylogeny. The first four molecular phylogenetic studies on nematode-trapping orbiliaceous fungi based on rDNA (Liou & Tzean 1997, Ahrén et al. 1998, Tanabe et al. 1999, Hagedorn & Scholler 1999, Scholler et al. 1999) provided striking evidence for a high taxonomic value of trapping organs, which have earlier been underestimated. The two main conidiophore types (arthrobotryoid vs. acrogenous/genicularioid/candelabrelloid) turned out to have a polyphyletic origin in various clades.

Based on the five main types of trapping devices, Scholler et al. (1999) distinguished four anamorph-typified genera: *Arthrobotrys*, *Dactylellina* (with two types of traps), *Drechslerella*, and *Gamsylella*. We here adopt these four taxa but reduce them to series level and include the non-predacious genus *Dactylella* as a further series (*Neodactylella*) of section *Arthrobotrys*.

Three exceptions in which the molecular result was contradictory to the trapping organs are possibly due to a mistake. *Dactylellina multiseptata* and *D. varietas* were described as having stalked adhesive knobs, but the sequences of the ex-type strains clustered in series *Neodactylella* (see *Neodactylella* without teleomorph, p. 1513). Similarly, the ex-type strain of *Dactylella zhongdianensis* was described with adhesive networks but clustered in series *Neodactylella* (see p. 1472). A case of misidentifications concerns *Dactylellina asthenopaga*: some strains under this name fell in series *Neodactylella* and actually do not form adhesive knobs, whereas others clustered in series *Dactylellina* (see *Dactylellina* without teleomorph, p. 1607).

In various published phylogenetic analyses, the four predacious series of section *Arthrobotrys* formed four monophyletic clades, which predominantly included isolates of the anamorph state. In our combined phylogenetic analysis of the entire *Orbiliomycetes* (Baral et al. 2017b, SSU+ITS+LSU), series *Arthrobotrys* and *Drechslerella* received very high but series *Dactylellina* and *Gamsylella* only low support. Series *Neodactylella* formed a paraphyletic basal sister clade to the four predacious series, with *O. epipora* positioned sister to all of them. When restricting the analysis of the same gene region to section *Arthrobotrys*, *O. epipora* clustered unresolved, and series *Drechslerella* received only low support (Phyl. 25).

The monophyly of the two series *Arthrobotrys* and *Drechslerella* already becomes evident when restricting the analysis to one gene region, such as ITS, LSU, *TUBB*, or the S1506 intron. Even when analysing merely the SSU V8–V9 region, some of the five series can more or less be differentiated. When inferring a phylogeny from the 5.8S region, only series *Arthrobotrys* was sharply recognized, based on the combination of a few deviating nucleotides.

The position of the five series within section *Arthrobotrys* varied among different analyses, nevertheless, strong tendencies can be observed. In the combined analysis of rDNA in Baral et al. (2017b), series *Dactylellina* clustered in a monophyletic but unsupported clade with the morphologically similar series *Gamsylella*. Series *Arthrobotrys* clustered as a sister group of them, and the three series formed a medium supported monophyletic clade for all taxa with adhesive traps. Series *Drechslerella* appeared in sister position of the adhesive trap formers and formed with them a strongly supported clade for all predacious taxa. The non-predacious series *Neodactylella* nested in a paraphyletic basal sister position to them, supporting its ancestral status to the predacious series.

In Phyl. 25, taxa with adhesive traps clustered in an unsupported monophyletic group, with series *Drechslerella* forming a sister clade to them. Two nucleotides in the SSU V8 region (109, 126, Tab. 76) underline the result of a common ancestor of the three series with adhesive traps and also suggest a link between series *Neodactylella* and *Drechslerella*, in concordance with the analysis in Baral et al. (2017b).

A basal position of series *Drechslerella* within the nematode-trapping taxa appears to indicate that constricting rings were an early evolved morphological trait. This was also suggested by various previous single gene analyses of ITS (Hagedorn & Scholler 1999, Liu et al. 2006a, Wang et al. 2011, Yang & Liu 2006, Yang et al. 2007, Yu et al. 2009a, Li et al. 2016), SSU (Ahrén et al. 1998, Tanabe et al. 1999), LSU (Liu et al. 2006a, Wang et al. 2011), *TUBB* (Li et al. 2005), and *MAD1* (Li et al. 2016), and in combined analyses of ITS, *RPB2*, *TEF1*, and *TUBB* (Yang & Liu 2006, Yang et al. 2007). In all those studies which include members of series *Neodactylella*, series *Drechslerella* diverged either directly after it (Hagedorn & Scholler l.c., Liu et al. 2006a, Wang et al. l.c.), or even before (Ahrén et al. 1998, Zhang et al. 2010, Li et al. 2005) or within the paraphyletic *Neodactylella* clade (Tanabe et al. 1999). Yet, these branching points have partly low or no bootstrap support, which was also emphasized by Hagedorn & Scholler. In any case, different authors concluded from their analyses that 'no secondary loss of predacity could be detected', which is confirmed by our analyses.

In any case, the basal position of constricting rings does not imply that the other types of trapping devices evolved from it. Their common ancestor could as well have been adhesive, and trapping devices intermediate to constricting rings have not been found. A somewhat different result was obtained by Li et al. (2005, 5.8S+LSU and 5.8S+LSU+*TUBB*), Yu et al. (2007a, ITS), and Swe et al. (2008b, LSU, ITS, ITS+*TUBB*). Their phylogenetic analyses suggest that adhesive traps evolved prior to non-constricting rings and constricting rings, a phylogenetic concept presented by Li et al. (2005) in their fig. 4. In Li et al.'s (2005: fig. 3) combined analysis of rDNA and *TUBB*, series *Drechslerella* and *Neodactylella* (partly as *Dactylellina*) formed a monophyletic sister clade to series *Dactylellina*, while series *Arthrobotrys* and *Gamsylella* (also as *Arthrobotrys*) diverged prior to them.

The entire section *Arthrobotrys* formed in the combined analyses of Baral et al. (2017b) and in Phyl. 7 a strongly or medium supported monophyletic group, but its position within the genus *Orbilia* varied among different analyses and never received bootstrap support. Despite the high support that the clade received, its morphological separation is not sharp. Members with straight, rod-shaped or ellipsoid ascospores

Table 76. Nucleotide positions in SSU (V8–V9), 5.8S, ITS2, and LSU (D1) within section *Arthrobotrys* found to be specific at the series level (in bold). Ambiguous nucleotides: Y = C/T, R = A/G, V = A/C/G, M = A/C, B = C/G/T. Position numbers evaluated by starting with CCTTAGAT (SSU), AAAACTTT (5.8S), after GAGCGTC (ITS2), and with TGACCT (LSU) by omitting predominant gaps in alignment of all groups of *Orbiliomycetes*. * = also in *Arthrobotrys nonseptatus*, ** = also in *A. reticulatus* (6 strains) and *O.* aff. *auricolor* (H.B. 10024/denovo367, G.M. 2017-09-25.1/2018-11-27.1).

closely resemble taxa of series *Orbilia* in the teleomorph and partly also anamorph. For instance, *O. epipora* and *O. atlantis* (series *Neodactylella*) can easily be confused with *O. dryadum* and *O. cylindrospora*, or *O. orientalis* (series *Drechslerella*) can be confused with ellipsoid-spored taxa of series *Orbilia*. However, available molecular data, and in *O. orientalis* also the trapping organs, suggest that they belong in section *Arthrobotrys*.

In summary, the present molecular data provide valuable hints on the evolutionary lineages for the different trapping organs (see also p. 121, Phylogeny of trapping organs). The predominant basal position of series *Neodactylella* within section *Arthrobotrys* suggests that taxa with trapping organs evolved from non-predacious ancestors of that series. On the other hand, it appears easier to conceive that all these taxa forming trapping organs have an ancestor with predacious capabilities in common with the predacious genera *Lecophagus* and *Hyalorbilia*. In this case, members of series *Neodactylella* should have lost the ability of trap formation, or got adapted to trap animals other than nematodes. Constricting rings show a high grade of complexity, and a regression to non-constricting rings or adhesive networks appears improbable. Possibly, constricting rings evolved from adhesive ring- or peg-like structures typical of series *Gamsylella* by losing their adhesive properties.

Specific nucleotide positions. A unique nucleotide for the entire section *Arthrobotrys* or for taxa that form trapping organs within that section could hardly be found. There exists in the LSU D1 domain a single position (326, TAAATA**T**TGG) which is quite consistent within this section, but it occurs also in some other groups of *Orbiliomycetes*, such as *Lilapila* and *Hyalorbilia* p.p. Most of the remaining *Orbiliomycetes* have instead TAAATA**C**TGG, and a few show some further variants: TAAATA**CC**GG (e.g., *Amphosoma*, *Lecophagus*, *Hyalorbilia*, *Orbilia aprilis*), rarely TAAATA**C**A**G**G (*Amphosoma*) or TAAATA**TC**TG (*Vermispora*). Another motif is at pos. 162–163: TG**TT**T in section *Arthrobotrys* (rarely TG**CT**T), in contrast to TG**CC**T (rarely TG**TC**A or TG**CT**T) in section *Orbilia*; yet, TG**TT**T occurs also in many members of subgenus *Habrostictis* and some of subgenus *Hemiorbilia*.

A search for series-specific nucleotides of frequently recorded regions of the rDNA within section *Arthrobotrys* yielded the following result (Tab. 76):

(1) Series *Neodactylella* can unequivocally be recognized by T vs. C at pos. 30 of 5.8S (except for a few *Drechslerella* spp. that have T) and by A vs. G at pos. 332 of LSU (D1).

(2) In the SSU (V8–V9) series *Drechslerella* and *Neodactylella* share 2 positions (109 A, 126 T) with all other members of *Orbilia* outside section *Arthrobotrys*, whereas taxa with adhesive traps (series *Arthrobotrys*, *Dactylellina*, *Gamsylella*) consistently deviate in having at pos. 109 G and at pos. 126 C, by which they concur with members of *Hyalorbilia* (see Tab. 60)

Table 77. Nucleotide positions in stem-loop B8 of 5.8S rDNA within section *Arthrobotrys* (series *Neodactylella*, *Arthrobotrys*, *Dactylellina*, *Gamsylella*, *Drechslerella*): eight symmetric positions (120–123, 132–135, in bold) form different motifs within the otherwise conservative loop. # = concurring with two taxa of section *Aurantiorubrae*, *O. jugulospora* (China) and *O. rubella*; § = coinciding with three taxa of section *Aurantiorubrae* (*O. aurantiorubra*, *O. jugulospora* from Ethiopia, *O. phragmotricha)*; * = coinciding with series *Xanthoguttulatae*, series *Regales*, section *Hemiorbilia* p.p. and others; ssp./str. = number of species/strains.

Phylogenetic analysis 25. Phylogram of section *Arthrobotrys* inferred from combined ML analysis of SSU (V8–V9)+ITS+LSU (D1–D2) rDNA dataset (77 sequences, 1881 positions, aligned with MAFFT) using the GTR+G+I model in MEGA6 (500 replicates). The tree is rooted with *Lilapila oculispora* and *O. patellarioides*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, NT = neotype, * = without SSU.

Key to series of section *Arthrobotrys* based mainly on the teleomorph

1. Spores distinctly helicoid; without trapping organs .... **series *Hyalinia*** (p. 868) ***& Xanthoguttulatae*** (p, 845, section *Aurantiorubrae*)
1. Spores straight or slightly to strongly falcate, never distinctly helicoid 2

2. Spores *(11.5–)14–17.5(–20.5) × (2.4–)2.6–3(–3.5) µm, almost straight; SBs completely absent .. ***O. asomatica*** (series *Neodactylella*), p. 1487
2. Spores not exceeding 13 × 1.7 µm; SBs present near apex 3

3. Spores always distinctly (slightly to strongly) curved, rather long and narrow, length/width ratio > (7–)8 based on actual length [e. g., 10 × 1–1.3 µm] 4
3. Spores straight or curved, shorter and wider, length/width ratio < 7(–8) based on actual length [e. g., 10 × 1.4–1.5 µm] 7

4. Ectal excipulum near margin oriented at a ± low angle (10–50°) to the surface, at least in the outermost region, cells here often forming distinct cell rows; cortical cells partly protruding to form small teeth or short hairs; without trapping organs .... **series *Neodactylella***, p. 1437
4. Ectal excipulum near margin oriented at a high angle (60–90°) to the surface, even in the outermost region; margin ± smooth, rarely finely crenulate, never forming distinct cell rows 5

5. Apothecia usually bright red (rarely whitish); SBs consistently rod-shaped, 0.2–0.6 µm wide, apical attachment broad or narrow but never with a filum; paraphyses never lanceolate; with stalked adhesive knobs as trapping organs .... ***O. rubrovacuolata*** (series *Dactylellina*), p. 1587
5. Apothecia never bright red; SBs globose to oblong, rarely rod-shaped, 0.5–0.8 µm wide, attached by a mostly invisible, very fine filum of about the length of the inflated part 6

6. With adhesive networks as trapping organs .... **series *Arthrobotrys***, p. 1513
6. Without trapping organs .... ***Orbilia* sp. XJ-2009** (series *Neodactylella*), p. 1500

7. Spores medium to strongly curved, mostly gradually and strongly tapered below 8
7. Spores straight to strongly curved, only slightly to medium (or only infrequently strongly) tapered below 9

8. Ectal excipulum near margin oriented at a high angle (50–90°), not forming distinct cell rows ....
O. terrestris (p. 1583), ***O. multiformis*** (p. 1547), ***O. neglecta*** (p. 1568, series *Arthrobotrys*) or ***O. cocois*** (p. 1474, series *Neodactylella*)
8. Ectal excipulum near margin oriented at a 10–60° angle in the outermost region, forming distinct cell rows ....
.... ***O. desertorum*** (p. 1507, series *Neodactylella*) or ***O. javanica*** (p. 1550, series *Arthrobotrys*)

9. Apothecial margin with 12–45 µm up to 70–100 × 5–9 µm large, septate, thick-walled hairs; apothecia ± stipitate; spores *3.5–5 × 1–1.4 µm, cylindrical, straight to very slightly curved; SBs globose; with constricting rings as trapping organs .... ***O. pilosa*** (series *Drechslerella*), p. 1629
9. Apothecial margin without prominent septate hairs; spores *2.7–10 × 0.8–2 µm 10

10. SBs partly distinctly eccentrical (± adjacent to lateral spore wall, depending on the viewing direction), shortly rod- to tear-shaped, rarely subglobose, filum often invisible; spores straight or rarely slightly curved near base 11
10. SBs central at the spore apex, globose or ± tear- to rod-shaped 12
If spores subglobose see *A. nonseptatus*, Pl. 960.

11. With constricting rings as trapping organs (as far as known) .... **series *Drechslerella***, p. 1623
11. With stalked adhesive knobs covered by thick gel being able to swell .... **series *Gamsylella*** (p.p.), p. 1610
See also two unidentified taxa without known trapping organs: Pls 1021 (H.B. 8963) & 1023 (H.B. 8749).

12. SBs rod- to tear-shaped, apically narrowed to a smaller or larger point, never with a filum; with stalked adhesive knobs as trapping organs (or unknown) .... **series *Dactylellina***, p. 1584
12. SBs globose to tear-shaped, with a distinct or invisible filum (length ½–1 × as long as inflated part); without trapping organs
.... **series *Neodactylella***, p. 1437

Key to series of section *Arthrobotrys* based mainly on the trapping organs

1. Not forming trapping organs upon contact with nematodes .... **series *Neodactylella***, p. 1437
1. Capturing nematodes (or arthropods) by various trapping organs 2

2. With knobs or columns, capturing nematodes or arthropods 3
2. With ring- to net-like structures (scalariform bridges, arches, rings, ladders, networks), capturing nematodes 5

3. With sessile knobs, superimposed (proliferating) knobs, or columns, capturing nematodes .... **series *Gamsylella***, p. 1610
3. With stalked knobs 4

4. Knobs covered by thin invisible gel, capturing mainly nematodes .... **series *Dactylellina***, p. 1584
4. Knobs covered by thick gel being able to strongly swell, capturing arthropods .... **series *Gamsylella***, p. 1610

5. Rings ± circular, 3- (very rarely 4–5-)celled, singly at the tip of a 1–3-celled stalk **6**
5. Rings circular to rectangular, without a stalk, branched by repeated ring formation or by bridges between columns, partly forming 3-dimensional networks **7**

6. Rings actively constricting, inner wall with triangular wall thickenings at the septa, individual cells ± fusoid, narrowed near septa, instantly swelling, stipe 2.5–6.5 µm wide, above with 2 septa connected to 2 adjacent ring cells .... **series *Drechslerella***, p. 1623
6. Rings non-constricting, without triangular wall thickenings at the septa, individual cells cylindrical, unable to swell, stipe 1.5–2.5 µm wide, above with a single septum connected to a ring cell .... **series *Dactylellina***, p. 1584

7. Rings ± circular, repeatedly branched to form a 3-dimensional network .... **series *Arthrobotrys***, p. 1513
7. Rings ± rectangular, formed by bridges between columns .... **series *Gamsylella***, p. 1610

and two environmental strains of unclear relationship.

(3) A majority of *Drechslerella* spp. deviate from all other members of section *Arthrobotrys* at position 111 of 5.8S (T vs. C), but a minority (*D. bembicodes*, *D. stenobrocha*, *D. coelobrocha*, *D. doedycoides*), being phylogenetically positioned more at the base of that series, concur here with the other series.

(4) Position 14 of the variable ITS2 region behaves extraordinarily stable and informative: All investigated *Gamsylella* sequences and most of *Drechslerella* have here the character A, whereas all members of *Dactylellina*, *Arthrobotrys* and *Neodactylella*, but also the aberrant *Drechslerella bembicodes* (4 strains) have G. This position represents one of the 3 ITS positions found to be variable among three strains of *O. anigozanthi* (Tab. 91), one species having the character G (not shown in Tab. 76) but two the character A.

(5) Position 13 concurs in *Neodactylella* and *Arthrobotrys* (A) and in *Dactylellina* and *Gamsylella* (G), while *Drechslerella* shows mainly G but also A.

(6) Position 15 is mostly C, but T in all *Dactylellina* sequences, except for the two critical Chinese strains of *D.* aff. *phymatopaga* which do not clearly cluster in a series.

The two nucleotide positions mentioned under (1) and (2) remarkably correlate with other *Orbiliomycetes*: (1) the combination T+A is characteristic of *Neodactylella* but also occurs in most other groups of the class, whereas C+G, which characterizes the nematode-trapping taxa of section *Arthrobotrys*, is also consistently found in all strains of series *Abutilones*, section *Ovoideae*, and the genus *Hyalorbilia*. However, three exceptions were observed: in some species of series *Drechslerella* the rare combination T+G occurs, and within series *Orbilia O. dryadum* shows the combination C+G and *O. cunninghamii* the very unusual combination C+A, whereas all other taxa have T+A. (2) the combination G+C is characteristic of those species of section *Arthrobotrys* with adhesive traps, but is also consistently observed within the genus *Hyalorbilia*, whereas all other groups of *Orbiliomycetes* without known adhesive traps, but also *Lecophagus*, have the combination A+T (see Tab. 60).

The motif ATTA at the 5'-end of ITS2 (pos. 1–4) occurs in most members of section *Arthrobotrys* but is frequent also in various other *Orbiliomycetes*. The deviation ATTT occurs in *Drechslerella* p.p. (not correlated with pos. 11–15) und ATCA in *Gamsylella gephyropaga* (Tab. 20.

Ecology. Section *Arthrobotrys* occurs worldwide, with a significant preference for a hygric environment. This preference seems to be due to the fact that many nematodes, the predominant prey of predacious members of this section, are adapted to a more or less stable water supply. Some taxa of series *Neodactylella* and one of *Gamsylella* (*O. anigozanthi*) are restricted to xeric substrate, some of them being adapted to semihumid and arid zones. Yet, also the predacious *O. auricolor* is sometimes found on exposed xeric substrate.

Series *Neodactylella*

Orbilia subgenus ***Orbilia*** section ***Arthrobotrys*** series ***Neodactylella*** Baral & E. Weber, **ser. nov.**, MB 814993 – Type species: *Monacrosporium oxysporum* Sacc. & Marchal [≡ *Orbilia oxyspora* (Sacc. & Marchal) E. Weber & Baral]

?= *Dactylella* Grove, J. Bot. 22: 199 (1884) – Type species: *D. minuta* Grove

= *Drechsleromyces* Subram., Kavaka 5: 93 (1978, '1977') – Type species: *Dactylella atractoides* Drechsler

= *Gangliophragma* Subram., Kavaka 5: 94 (1978, '1977') – Type species: *Dactylella rhopalota* Drechsler

Etymology: *Neodactylella*: named after the anamorph-typified genus *Dactylella*; *Dactylella*: referring to the conidia at the conidiophore apex resembling fingers; *Drechsleromyces*: named after the mycologist Charles Drechsler; *Gangliophragma*: referring to the holoblastic, septate conidia.

Latin diagnosis: *Apothecia margine laevi vel crenulato, siccitatem tolerantia vel non tolerantia. Ascosporae subcylindricae ad fusoideo-clavatae vel subulatae, rectae ad valde falcatae, in statu vivo corpusculum refringens globosum ad lacrimiformem, non excentricum continentes. Paraphyses non vel leniter ad valde clavato-capitatae. Conidia ellipsoidea vel cylindrico- ad fusoideo-clavata vel fusiformia, recta vel raro curvata, 1–14-septata, numquam dimorpha, cellulis numquam inflatis. Hyphae laqueos non formantes.*

TELEOMORPH: **Apothecia** hydrated (0.1–)0.3–1.5(–2.3) mm diam., white to pale rose, yellow-ochraceous, orange, or brownish, margin smooth or finely rough to crenulate, sometimes with distinct teeth, sessile or with a ± indistinct short stipe. **Asci** *(26–)30–60(–67) × (2.7–)3–5(–6) µm, 8-spored, lower (2–)3–5(–7) spores inverted; **apex** (†) slightly to strongly truncate, not or slightly indented and laterally inflated; **base** usually partly H-shaped. **Ascospores** *(3.5–)5–12(–13.2) × (0.8–)1–1.8(–2.3) µm (rarely 11.5–20.5 × 2.4–3.5 µm), broadly or narrowly subcylindrical to fusoid-clavate or subulate, apex rounded to obtuse (exceptionally subacute), base sometimes with indistinct or distinct tail, straight to strongly curved (falcate) or only curved below; **SBs** never distinctly eccentrical, (0.6–)0.8–1.7(–1.9) × 0.3–1 µm (rarely absent), globose to tear-shaped, mostly with a fine, short, often invisible filum. **Paraphyses** uninflated or slightly to strongly clavate-capitate at apex, sometimes spathulate-lageniform, terminal cells about (1–)2–4(–6)× longer than lower cells. **Ectal excipulum** of (†) thin-walled or rarely slightly gelatinized (common walls 0.3–1 µm thick), vertically or indistinctly oriented textura globulosa-angularis(-prismatica), cells near base *(4–)8–30(–40) × (3–)6–23(–30) µm, at margin either of t. globulosa-angularis oriented at a (40–)60–90° angle or of t. angularis or t. prismatica(-porrecta) oriented at a 0–30(–60)° angle by forming rows of often thick-walled cells; **glassy processes** absent or 2–18, rarely 50–70 µm long. **SCBs** globose or absent, exceptionally crystalloid (*O. senegalensis* in series *Neodactylella*); **VBs** absent or slightly to sometimes medium or strongly refractive. **Exudate** 0.1–3(–5) µm thick, continuous to cloddy or granular, loosely or firmly attached, hyaline to bright yellow. — **ANAMORPH**: dactylella-like, rarely vermispora- to anguillospora-like. **Conidiophores** ((10–))(40–)60–200(–300) µm long, 2–4 µm wide near base, 1.5–2.5 µm at the tip, conidia arising singly at the unbranched tip, rarely in clusters of 2–4 at the sympodially proliferating tip (geniculate to candelabrelloid). **Conidia** *(16–)25–100(–143) × 3.5–11(–13) µm, ellipsoid or often cylindrical or cylindric- to fusoid-clavate or fusiform, rarely rostrate above, straight, rarely curved, (1–)3–14(–21)-septate, never with 1 cell much larger than the others; **conidial dimorphism** not observed. **Trapping organs**: absent.

Habitat: on hygric or sometimes xeric, rarely semiaquatic wood and bark (rarely fruits) of angiosperms (rarely gymnosperms), herbaceous stems and leaves of mono- and dicotyledons, also on dung, isolated also from rhizosphere of herbs, boreal to tropical, humid to arid, desiccation-sensitive or often ± -tolerant.

Recognized species: 25 (3 of them without a known teleomorph), plus 1 species with a provisional name and 3 unnamed species ('affinis'); for further 20 species see Tabs 45 and S8.

Taxonomic remarks. Series *Neodactylella* cannot with certainty be recognized by the teleomorph alone, but requires cultural studies and/or molecular data. Yet, in six species (*O. oxyspora*, *O. dorsalis*, *O. clavispora*, *O.* aff. *clavispora*, *O. desertorum*, *O. tenuissima*) the marginal cortical cells of the ectal excipulum form more or less striking rows of quadrate to prismatic cells with often slightly thickened walls, running under a more or less low angle to the surface. These were generally not observed in the other series of section *Arthrobotrys*, with the exception of *O. bambusina* p.p. (incertae sedis) and *O. javanica* (series *Arthrobotrys*). These cell rows are sometimes terminated by glassy processes (see, e.g., Pls 933, 942, 946) and produce a minutely crenulate apothecial margin. Similar hair-like marginal hyphae are observed in *O. fraxini*, *O. lamarcheae*, and *O. asomatica*. Webster et al. (1998) erroneously believed that the whole *O. auricolor* complex possessed such cell rows (see also under *O. oxyspora*, p. 1494).

The six mentioned species with marginal cell rows further deviate from the remaining members of series *Neodactylella* in longer and more curved (falcate) ascospores with a higher length/width ratio. Since they are also phylogenetically related by forming a supported clade (except for *O. tenuissima*, see p. 1511), they are referred to as *oxyspora-heptameres* clade here. The hair-like marginal hyphae of *O. fraxini* resemble the cell rows of this group, but the ascospores are very different and the species does not cluster in this clade. *O. cocois* is somewhat exceptional within section *Arthrobotrys* in its terminal cells of paraphyses being not always longer than the lower cells. Some species show similarities to sections *Aurantiorubrae* or *Habrostictis* (*O. pseudeuphorbiae*, *O. asomatica*) and were placed by us in series *Neodactylella* mainly because of their molecular data.

Anamorph (see also p. 220–223 and Tab. S8). Members of series *Neodactylella* have a dactylella-like anamorph which is characterized in pure culture by not forming trapping organs upon treatment with nematodes. Conidia are unbranched, straight, cylindrical, clavate, or fusiform, rarely apically with a short to long rostrum, mostly 3- to multiseptate, usually medium- to large-sized. More or less curved, multiseptate conidia occur in *O. fraxini* (vermispora-like) and *O. rhamni* (anguillospora-like), but these anamorphs are not confirmed by pure culture. Microconidia have so far not been observed in this series. A single observation of small, 1-septate conidia on very short conidiophores formed on the anchoring hyphae in a collection mentioned under *O. clavispora* (Pl. 941: 2) requires confirmation. Conidiophores are usually very long, but their length strongly varies within a culture. Rarely they measured only 40–50 µm (*O. epipora*, 15–30 µm in the possible synonym *D. polyctona*). Also the recently described South African, possibly drought-tolerant *D. bolusanthi* (Crous 2019) has only 10–50 µm long conidiophores (the reported phialidic conidiogenesis is an error since the micrographs clearly show a holoblastic development).

Conidial shape shows a remarkable conformity within series *Neodactylella*, being cylindrical or often cylindric-clavate, except for fusiform conidia which exclusively occur in the *oxyspora-heptameres* clade. Anamorphs of series *Neodactylella* with cylindric-clavate conidia appear to be indistinguishable from those connected to members of series *Xanthoguttulatae* p.p. and *Hyalinia* of section *Aurantiorubrae*, and also from some of series *Orbilia*. Molecular data are lacking for several species described in *Dactylella* (including the type) and their relationship within *Orbilia* remained unsettled.

The absence of trapping organs has previously been ascertained in a majority of taxa of *Dactylella* by adding nematodes to a pure culture, except for the type species. Among the species of series *Neodactylella* treated here, the absence of trapping organs was demonstrated, e.g., by Webster et al. (1998) for *O. fimicoloides* (= *O. oxyspora*), Rubner (1996: 114) for *Dactylella oxyspora*, Yu et al. (2007) for *O. dorsalis*, Z.F. Yu (pers. comm.) for *O.* aff. *clavispora* (Y.Z. bn1-14), and *O. cotoneastri* (H.B. 7241a).

Nomenclature. Because of the similar morphology of dactylella-like anamorphs in different sections of *Orbiliomycetes*, the phylogenetic relationship of the type species of *Dactylella*, *D. minuta*, which is only known from the old type collection, remains uncertain. Its holotype specimen is said to be located in K (Rubner 1996), consisting of a piece of dead wood without any trace of the fungus. A culture was probably not made by Grove, and unambiguous further records of this species are unknown.

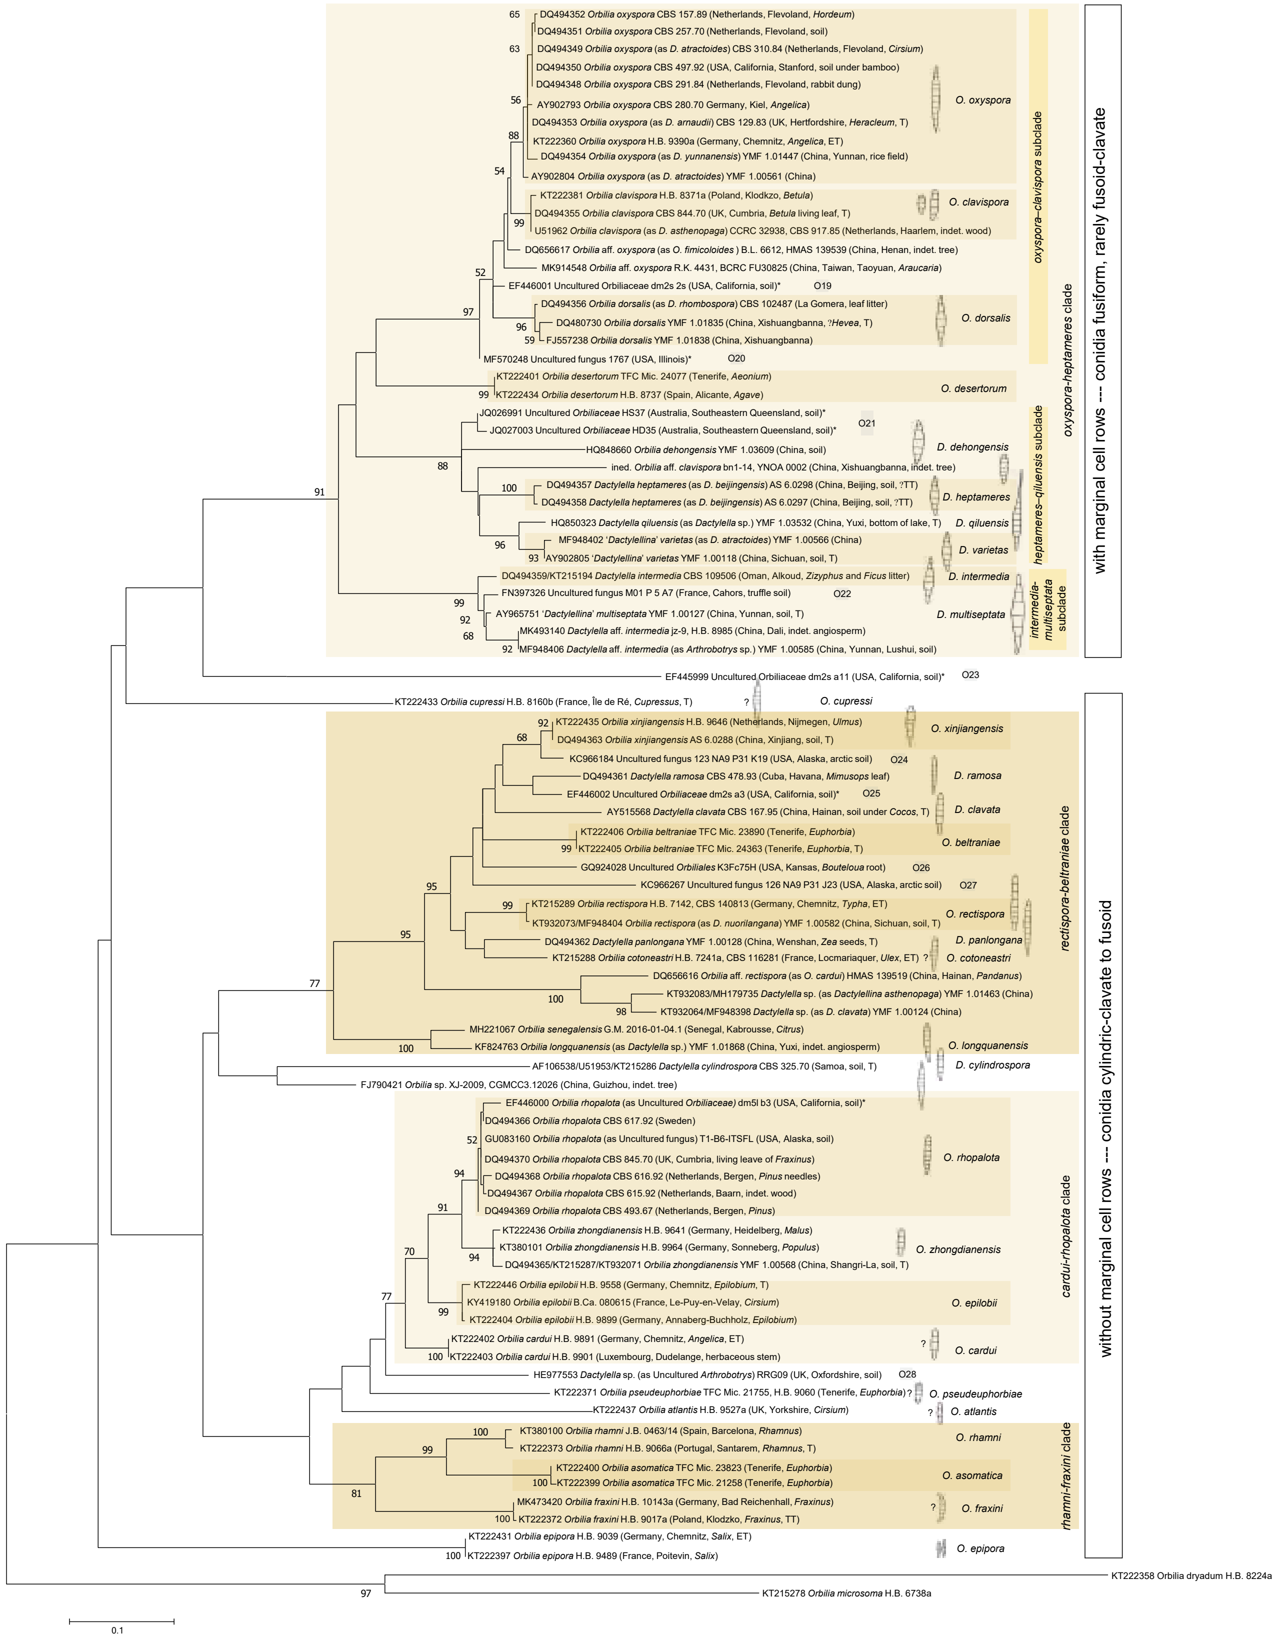
Therefore, the name *Neodactylella* is proposed here at the series level to include phylogenetically related, non-predacious taxa within section *Arthrobotrys*. Because no recent record was available that could be considered as conspecific with *D. minuta* and proposed as epitype, we here typify *Neodactylella* by *O. oxyspora*. We have based the new name *Neodactylella* on the well-established name *Dactylella* instead of resurrecting the rarely used alternative names *Drechsleromyces* or *Gangliophragma*.

Species delimitation. Although many of the included species appear to be recognizable from the teleomorph, some require conidial morphology and some DNA data to permit their recognition. For instance, *O. oxyspora* and *O. dorsalis* were thought by us to represent a single species, but DNA showed that they are distinct. *O. cardui*, *O. zhongdianensis*, and *O. xinjiangensis* are rather similar in both morphs, differing mainly in conidial shape. DNA data gained from European ascospore isolates enabled their separation and connection to two described Chinese anamorph-typified taxa. *O. cardui* and *O. rectispora* were considered as synonymous by earlier authors, but differ in ascospore width and presence/absence of short glassy processes, also they show a remarkable host specificity (dicots vs. monocots, although *O. luzularum* appears to belong to *O. cardui*) and differ in their DNA data. Quite a few species are only known from a single collection and their independency is, therefore, to be considered as more or less tentative.

Phylogeny. In phylogenetic analyses of (SSU)+ITS+LSU, series *Neodactylella* as here circumscribed formed a paraphyletic group (Baral et al. 2017b, Phyls 7, 25) which clustered with medium support in a monophyletic clade with the nematode-trapping taxa. Its position was usually at the base of section *Arthrobotrys*, where it formed a sister group of the remaining series (see p. 1433). In the ITS analysis of Chen et al. (2007a), series *Neodactylella* formed a monophyletic group, but in this work only members of *Hyalorbilia* and *Vermispora* but no predacious taxa were compared (except for '*Dactylella tenuis*', a member of series *Drechslerella*). A monophyletic group, though without support, is also obtained when analysing the S1506 intron (S30).

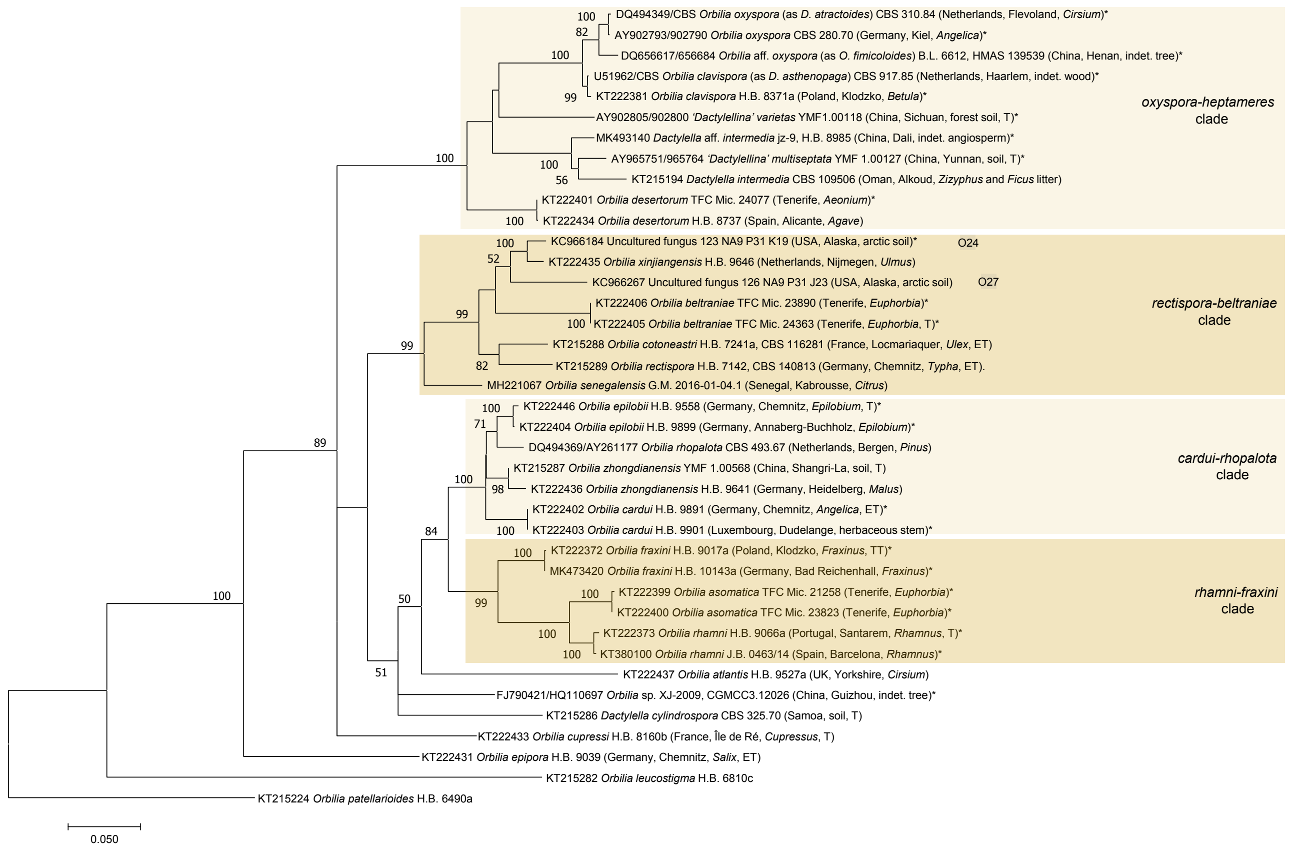
In our combined analysis (Phyl. 27) four strongly supported clades can be recognized within series *Neodactylella*: the *oxyspora-heptameres* clade, the *cardui-rhopalota* clade, the *rhamni-fraxini* clade, and the *rectispora-beltraniae* clade. Yet, six species (*Dactylella bolusanthi*, *O. cupressi*, *D. cylindrospora*, *Orbilia* sp. XJ-2009, *O. atlantis*, *O. epipora*) did not cluster in either of them. When separately analysing ITS (Phyl. 26) only the *oxyspora-heptameres* clade received strong support. When analysing LSU (S31) only the *rhamni-fraxini* clade received strong support while the *cardui-rhopalota* clade and *rectispora-beltraniae* clade were paraphyletic.

The *oxyspora-heptameres* clade comprises taxa with marginal cell rows, rather long and narrow, falcate ascospores, and large, fusiform but also cylindric-clavate conidia. In



Phylogenetic analysis 26. Phylogram of series *Neodactylella* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (88 sequences, 663 positions, aligned with MAFFT) using the GTR+G+I model in MEGA7 (500 replicates). Thirteen environmental strains from GenBank are included, 11 of them representing 10 unidentified species (O19–O28). The tree is rooted with *O. microsoma* and *O. dryadum*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, TT = topotype, * = without ITS1 and partial 5.8S.

the analysis of the ITS region it formed two subclades, the strongly supported *oxyspora-clavispora* subclade and the weakly supported *heptameres-qiluensis* subclade, besides two smaller subclades for *Dactylella intermedia* (?= ‘*Dactylellina*’ *multiseptata*, *intermedia-multiseptata* subclade) and *O. desertorum*. The *cardui-rhopalota* clade and *rectispora-beltraniae* clade include taxa without marginal cell rows, rather short, partly straight ascospores, and cylindric-clavate or only slightly fusoid conidia, which seemingly cannot morphologically be differentiated. Taxa of the *rhamni-fraxini*



Phylogenetic analysis 27. Phylogram of series *Neodactylella* inferred from combined ML analysis of SSU (V8–V9)+ITS+LSU (D1–D2) rDNA dataset (39 sequences, 1614 positions, aligned with MAFFT) using the GTR+G+I model in MEGA7 (500 replicates). The tree is rooted with *O. patellarioides* and *O. leucostigma*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, TT = topotype. * = SSU incomplete or absent.

Key to species of series *Neodactylella* with known teleomorph

(for a key based on anamorphs see Chen et al. 2007b)

1. Spores *(11.5–)14–17.5(–20.5) × (2.4–)2.6–3(–3.5) µm, almost straight; SBs completely absent; xeric wood of *Euphorbia*, thermo- to mainly inframediterranean semi- to hyperarid Macaronesia ...... ***O. asomatica***, p. 1487
1. Spores not exceeding 13 × 1.8(–2.3) µm; SBs always present in apex of living mature spores 2

2. Spores always distinctly (slightly to strongly) curved, rather long and narrow, length/width ratio > (7–)8 based on actual length [e.g., 10 × 1–1.3 µm] 3
2. Spores straight to slightly (rarely medium) curved, shorter and wider, length/width ratio < 7(–8) based on actual length [e.g., 10 × 1.4–1.5 µm] 8

3. Excipular cells near margin oriented at a high angle (80–90°), not forming distinct cell rows, cortical cells without glassy processes; spores strongly arcuate, *7.2–13 × 1.1–1.4 µm; conidia narrowly fusoid, attenuated in a long and narrow apical part, *47–87(–100) × 4.3–6.5 µm, 8–19-septate; hygric bark, subtropical humid eastern Asia ...... ***Orbilia* sp. XJ-2009**, p. 1500
Compare also *O. fimicola* on dung, with short glass processes and spores of †8–10 × 1.2–1.4 µm (anamorph unknown, see under *O. oxyspora*, p. 1493).
3. Excipular cells at mid flanks and margin oriented at a low angle (0–50°), at least in outermost region, here usually forming ± distinct cell rows 4

4. Spores †(7–)7.5–10.5(–11) × 0.8–1.1 µm, mostly strongly tapered at base; no SB data available; asci †22–35 × 2.5–3.4 µm; apothecia light yellow-chlorinaceous; hygric petioles, fruits of woody plants, stems of bamboo, (sub)tropical (semi)humid America, Africa, ?Macaronesia, ?eastern Asia ...... ***O. tenuissima***, p. 1510
4. Spores †(1–)1.1–1.3(–1.4) µm wide [*1.1–1.5(–1.7) µm], slightly to strongly tapered towards base; asci †28–45 × 3–4.2 µm 5

5. SBs with distinct filum; spores *(6–)8–10(–11.5) × (1.1–)1.2–1.5(–1.7) µm; apothecia pale orange-ochraceous; xeric branches & stems of *Aeonium*, *Agave*, *Ferocactus*, *Yucca*, thermomediterranean semiarid or rarely warm-continental subhumid southwestern North America, southern Europe, Macaronesia ...... ***O. desertorum***, p. 1507
5. SBs mostly without visible filum; spores *(7–)8–11(–12) × (1–)1.2–1.4(–1.6) µm 6

6. Spores strongly tapered towards base, often with a distinct tail; apothecia whitish to light amber-brownish; conidia cylindric-ellipsoid-clavate, *22–40 × 6.5–9.5 µm, 2–4-septate; ± hygric wood & bark of *Betula* & *Tilia*, cold-temperate humid, atlantic to subcontinental Europe ...... ***O. clavispora***, p. 1501
6. Spores slightly to strongly tapered towards base but never tail-like; conidia fusiform, *40–110 × (6.3–)8–10(–13) µm, 4–12-septate 7

7. Apothecia whitish, rarely yellowish; conidia *(45–)50–95(–110) µm long, (5–)7–11(–12)-septate; hygric herbaceous stems, angiosperm wood & bark, dung, hemiboreal to subtropical humid to semihumid Europe & North America, cool-continental to tropical humid eastern Asia, Australasia .... ***O. oxyspora***, p. 1489

7. Apothecia cream to yellowish; conidia *(40–)50–75(–85) µm long, (4–)5–8(–9)-septate; hygric angiosperm wood & bark, (sub)tropical humid eastern Asia, Macaronesia .... ***O. dorsalis***, p. 1498

8. Paraphyses apically cylindrical to ± lanceolate-lageniform (though with obtuse tip), distinctly protruding 9

8. Paraphyses apically cylindrical to capitate-clavate but not tapered, not distinctly protruding 14

9. Spores *(5–)6–7.5(–8) × 1.3–1.7 µm, straight to slightly curved; apothecia whitish to pale cream; hygric stems of *Epilobium* & *Cirsium*, (oro)temperate humid Europe .... ***O. epilobii***, p. 1468

9. On xeric bark or wood; apothecia pale cream to ochraceous or orange 10

10. Spores *4.5–6.5 × (1–)1.1–1.6(–1.7) µm, cylindrical, ± allantoid; marginal cortical cells not forming cell rows 11

10. Spores longer or wider, partly distinctly tapered and often slightly to medium curved below; marginal cortical cells tending to form cell rows with exudate caps or glassy processes 13

11. Margin with short protruding thin-walled hairs; SBs 0.7–0.9 µm wide; conidia unknown; xeric bark of *Lamarchea*, subtropical semiarid Australia .... ***O. lamarcheae***, p. 1485

11. Margin hairless; SBs 0.3–0.9 µm wide 12

12. Margin smooth or finely powdered by small glassy caps; spores *4.5–6 × 1–1.5 µm, straight to strongly curved; SBs 0.3–0.5 µm wide; conidia anguillospora-like (presumed), *85–127 × 3.6–4.3 µm; xeric bark (& wood) of *Rhamnus*, *Ficus*, mesomediterranean semihumid southern Europe .... ***O. rhamni***, p. 1483

12. Margin smooth, without glassy caps; spores *4.7–7 × 1.2–1.7 µm, straight to slightly curved; SBs 0.6–0.9 µm wide; conidia unknown; xeric wood of *Euphorbia canariensis*, inframediterranean semi- to hyperarid Macaronesia .... ***O. beltraniae***, p. 1466

13. Spores *(6.3–)7–9(–10) × 1.3–1.9 µm, curved below, SBs 0.5–1 µm wide; conidia (presumed) straight, *24–26 × 5.3–7.5 µm; xeric wood of *Euphorbia*, inframediterranean semi- to hyperarid Macaronesia, ?Australia .... ***O. pseudeuphorbiae***, p. 1476

13. Spores *(3.5–)4.5–6.5(–7.5) × 1.6–2.1 µm, SBs 0.3–0.6 µm wide; conidia (presumed) curved at the ends, *35–45.5 × 4.3–5.5 µm; xeric bark of *Fraxinus*, cold- to warm-temperate humid Europe .... ***O. fraxini***, p. 1480

Similar European collections on xeric bark of *Populus* differ in only *(1.3–)1.4–1.6(–1.8) µm wide spores.

14. Marginal excipular cells oriented at a low angle (20–40°); spores *6.5–7.3(–8) × (1.3–)1.4–1.5 µm; conidia ellipsoid-clavate, *20–47.5 × 6.5–9.3 µm, 3–7-septate; hygric indet. bark, tropical humid China .... ***O*. aff. *clavispora***, p. 1506

O*. *senegalensis on xeric bark of *Citrus* from western Africa (Pl. 910) with spores */†5–6.5 × 1–1.4 µm keys out here but differs from all species of section *Arthrobotrys* known in the living state by excipular cells containing crystalloid SCBs (p. 1465).

14. Marginal excipular cells oriented at a ± high angle (50–90°) 15

15. Spores *0.8–1.2(–1.3) µm wide 16

15. Spores min. *(1.1–)1.2–1.4 µm wide 19

16. SBs rod- to tear-shaped, apically narrowed to a smaller or larger point, never with a filum; conidia broadly fusiform, *9–14.5 µm wide .... see ***O. mammillata*** (p. 1594, series *Dactylellina*) and ***O. bambusina*** **(**inc. sed., p. 1656)

16. SBs globose to tear-shaped, with a distinct or invisible filum (½–1 × the length of inflated part); conidia *2–8 µm wide 17

17. Spores *(5–)6.5–9.5(–11) × 1–1.2(–1.3) µm, often slightly curved; VBs in paraphyses hyaline; conidia *37–67 × 5.3–8 µm, 3–7-septate; semiaquatic leaves of monocots, oro- to mesotemperate humid Europe, eastern Asia .... ***O. rectispora***, p. 1451

17. Spores max. 6(–7) µm long, *0.8–1 µm wide; conidia *2.2–4.8 µm wide, ± straight 18

18. Spores *(2.8–)3.3–4.3(–5) × 0.8–1 µm; VBs in paraphyses hyaline; conidia *13.5–25 × 2.2–3.2 µm, (0–)1–3-septate; apothecia white, mostly densely gregarious; hygric wood of angiosperms, predominantly *Fagus* and *Salicaceae*, boreal to thermotemperate humid Europe, North America, Asia .... ***O. epipora***, p. 1446

The North American collection (on ?*Fraxinus* wood) differs from typical *O. epipora* in yellowish apothecia. An Australian collection on a xeric monocot culm mentioned under *O. acuum* differs from *O. epipora* in much smaller apothecia and a thicker exudate (p. 1659).

18. Spores *(4.5–)5–6(–7) × (0.8–)0.9–1 µm; VBs in paraphyses mostly yellowish; conidia (presumed) *24–47 × 4.2–4.8 µm, 2–4-septate; xeric to hygric herbaceous stems & leaves, bark of *Ilex*, cones of *Cupressus*, cold-temperate humid to submediterranean semihumid atlantic western Europe .... ***O. atlantis***, p. 1442

Two collections deviate in slightly wider spores (*1–1.2 µm): one on *Zea* from northwestern France also in whitish apothecia and absent VBs, and one on *Phragmites* from Australia in more ochraceous apothecia due to brownish VBs and in very short glassy caps at the margin (p. 1445).

19. Conidia (presumed) *60–74 × 5–6 µm, 8–14-septate, narrowly fusiform; apothecial margin lacking glassy processes; spores *(3.7–)5–8.5(–9.3) × (1.5–)1.8–2(–2.3) µm, ± curved; xeric wood of *Cupressus*, submediterranean semihumid western Europe .... ***O. cupressi***, p. 1479

19. Conidia max. 40–60 µm long, (3–)5–7-septate 20

20. Apothecial margin without glassy processes, conidia (3–)5–7-septate 21

20. Apothecial margin with short to long glassy processes, conidia (1–)3(–4)-, 4–5- or 5–7-septate 25

21. Paraphyses apically ± uninflated; spores *(4.8–)6–9(–10) × (1.1–)1.2–1.6(–1.7) µm, slightly to medium curved; conidia unknown; apothecia whitish; hygric stems of *Ranunculus*, leaves of *Carex*, orotemperate humid central Europe .... ***O*. cf. *epilobii***, p. 1469

21. Paraphyses apically slightly (to medium) capitate-clavate; mainly lignicolous (also on dung) 22

22. Conidia narrowly fusoid to fusiform with cylindrical middle part, *40–60.5 × 4–5.5 µm; spores *6–8.5 × 1.3–1.5 µm, slightly tapered at base, straight to slightly curved; apothecia yellowish; hygric bark of angiosperm, subtropical humid China .... ***O. longquanensis*** (see under *O. senegalensis*), p. 1465

22. Conidia cylindric-ellipsoid-clavate, min. *6.5–8 µm wide; apothecia whitish 23

23. Spores *6–9(–10) × (1.4–)1.6–2(–2.3) µm, often with tail-like base, straight to slightly curved; conidia *40–59 × 7–12 µm; hygric bark of *Ulmus*, cold-temperate humid atlantic western Europe and continental eastern Asia .... ***O. xinjiangensis***, p. 1456

23. Spores *1.3–1.6 µm wide, base partly tapered but not tail-like; conidia *(23–)31–45 × 6–8.2 µm 24

24. Exudate over paraphyses forming 0.3–1 µm thick caps; spores †(6–)7–8(–9.2) × 1.1–1.3(–1.4) µm, consistently tapered at base, slightly to medium curved; conidia 3–7-septate; on dung, temperate humid Europe .... ***O. leporina***, p. 1473

24. Exudate over paraphyses absent; spores *5.2–7.5 × 1.4–1.6 µm, only partly tapered at base, straight to slightly curved; conidia (4–)7-septate; hygric bark & wood of angiosperms, cold- to warm-temperate humid Europe .... ***O. cotoneastri***, p. 1462

A sample on bark of *Eucalyptus* in thermotemperate humid southern Europe deviates in more cylindric(-clavate), 3–5-septate conidia and in paraphyses covered by exudate (p. 1464).

25. Spores *(6.3–)7–9(–10) × 1.3–1.9 µm, curved below; paraphyses partly slightly spathulate-lageniform; conidia (presumed) cylindric-ellipsoid, *24–26 × 5.3–7.5 µm, 5–6-septate; xeric wood of *Euphorbia*, inframediterranean semi- to hyperarid Macaronesia, ?Australia .... ***O. pseudeuphorbiae***, p. 1476

25. Spores *(5–)6–7(–8) × (1.2–)1.3–1.5(–1.7) µm 26

26. Conidia cylindric(-clavate), *(17.5–)22–34(–37.5) × 5–7(–8) µm, (1–)3(–4)-septate; spores ± straight; hygric to mesic bark of angiosperms, cold-temperate to cold-continental humid Europe & eastern Asia .... ***O. zhongdianensis***, p. 1470

26. Conidia cylindric-clavate to clavate, *30–46 × (5–)6–8(–8.8) µm, 4–7-septate 27

27. Apothecia whitish to pale cream; spores straight or only very slightly curved; terminal cells of paraphyses (1.5–)2–3(–4)× longer than lower cells, with or without VBs, without SCBs, apices covered by cloddy exudate; conidia (presumed) cylindric- to ellipsoid-clavate, (3–)5–7-septate; ± hygric herbaceous stems & leaves, also bark & wood of gymno- & angiosperms, polypores, warm- to cold-temperate or oroboreal humid Europe, Asia .... ***O. cardui***, p. 1457

27. Apothecia bright yellow-orange; spores ± distinctly curved; terminal cells of paraphyses 1–2 × longer than lower cells, with small globose SCBs, apices with firmly attached glassy caps 0.3–1.5 µm thick; conidia (presumed) clavate, 4–5-septate; xeric petiole of *Cocos*, tropical humid Middle America .... ***O. cocois***, p. 1474

A sample on xeric leaf of *Zea* from thermotemperate (semi)humid Spain deviates by a very thick, gelatinized subiculum below the apothecia (p. 1476).

clade have also straight, short to long ascospores but deviate in lageniform paraphyses, often hair-like marginal projections, and anguillospora- or vermispora-like conidia.

Three of these clades were also obtained in Chen et al.'s (2007a: fig. 1) neighbour joining analysis of the ITS region. *D. cylindrospora* formed here with strong support a sister taxon to the *cardui-rhopalota* clade. '*Dactylella tenuis*' (AS6.0287, DQ494360) clustered unresolved among the three clades, but this strain appears to be misidentified as it belongs to series *Drechslerella* (near *O. brochopaga*).

Phylogenetic analyses of the entire *Orbiliomycetes* (Baral 2017b, Phyl. 7) suggest that the current morphological concept of the anamorph-typified genus *Dactylella*, being based on the absence of trapping organs and on straight phragmoconidia, is polyphyletic, as it includes also taxa which cluster in series *Xanthoguttulatae* and *Hyalinia* of section *Aurantiorubrae* (*Dactylella vermiformis*, *D. pseudobrevistipitata*) and series *Orbilia* (section *Orbilia*). Already Chen et al. (2007a) observed this polyphyly when referring some taxa to the genus *Brachyphoris* (= *Hyalorbilia*) which were previously assigned to *Dactylella*.

Specific nucleotide positions. As discussed under section *Arthrobotrys*, series *Neodactylella* shares with series *Drechslerella* 2 positions in the SSU and 1 in the 5.8S, and with series *Arthrobotrys* one in the ITS2; in the LSU pos. 332 is unique within the section while concurring with most other groups of non-predacious *Orbiliomycetes* (Tab. 76). Four symmetric nucleotide positions in stem-loop B8 of the 5.8S region vary to form six different variants which are diagnostic for different relationships within series *Neodactylella* (Tab. 77). Three of these variants are consistent within monophyletic clades (*cardui-rhopalota* clade, *oxyspora-heptameres* clade, *rhamni-fraxini* clade). The latter variant characterizes also a majority of series *Dactylellina* and *Drechslerella*. Two other variants represent the *rectispora-beltraniae* clade but also a majority of series *Arthrobotrys*.

Ecology. 17 out of ~25 species of series *Neodactylella* with a known teleomorph possess more or less desiccation-tolerant apothecia. These are *O. atlantis*, *O. asomatica*, *O. beltraniae*, *O. cardui*, *O. clavispora*, *O. cocois*, *O. cupressi*, *O. desertorum*, *O. dorsalis*, *O. fraxini*, *O. lamarcheae*, *O. oxyspora*, *O. pseudeuphorbiae*, *O. rhamni*, *O. senegalensis* nom. prov. *O. xinjiangensis*, and *O. zhongdianensis*. Depending on the species and habitat, this tolerance lasts a few days or many months. Some species are only known from moist or wet habitats and did not survive 1 day in the dry state: *O. cotoneastri*, *O. epilobii*, *O. epipora*, and *O. rectispora*. Series *Neodactylella* occurs worldwide, from boreal to tropical and from humid to arid regions. The substrate can be woody or herbaceous, or even dung.

1. Marginal excipular cells oriented at a high angle, usually not forming distinct cell rows, ascospores rod-shaped to allantoid, mostly < 8–9 µm long, conidia cylindric-clavate to fusoid

Orbilia atlantis Baral, Spooner & Hairaud, **sp. nov.**,
MB 813969 — Pls 898–900, Map 143

Etymology: named after the atlantic distribution of the so far known collections.

Typification: Great Britain, Farnham, branch of *Ilex aquifolium*, 27.X.2002, B.M. Spooner (ex H.B. 7239a, M-0276436, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–1.5 mm diam., pallide succineo-chlorina vel luteo-cremea, (sub)sessilia, margine laevi. Ascosporae *4.5–7 × 0.8–1 µm, anguste cylindricae, basi non vel parum attenuatae, subrectae, corpusculum refringens minutum globosum, sat distans ab apice continentes. Paraphyses ad apicem non vel modice capitatae, exsudato tenui tectae, in statu vivo vacuolas pallide-luteas continentes. Excipulum marginale absque processis vitreis. Habitat ad corticem* Ilicis, *strobilos* Cupressi, *caules vel folios herbarum, in aere prominens vel ad terram humidam, in zona atlantica temperata ad submediterranea (semi)humida Europae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.3–0.9(–1.4) mm diam., 0.08–0.14 mm high (receptacle 0.08–0.11 → 0.07–0.08 mm), pale amber-chlorinaceous to yellowish-cream, translucent, round, sometimes lobate when large, ± loosely gregarious,

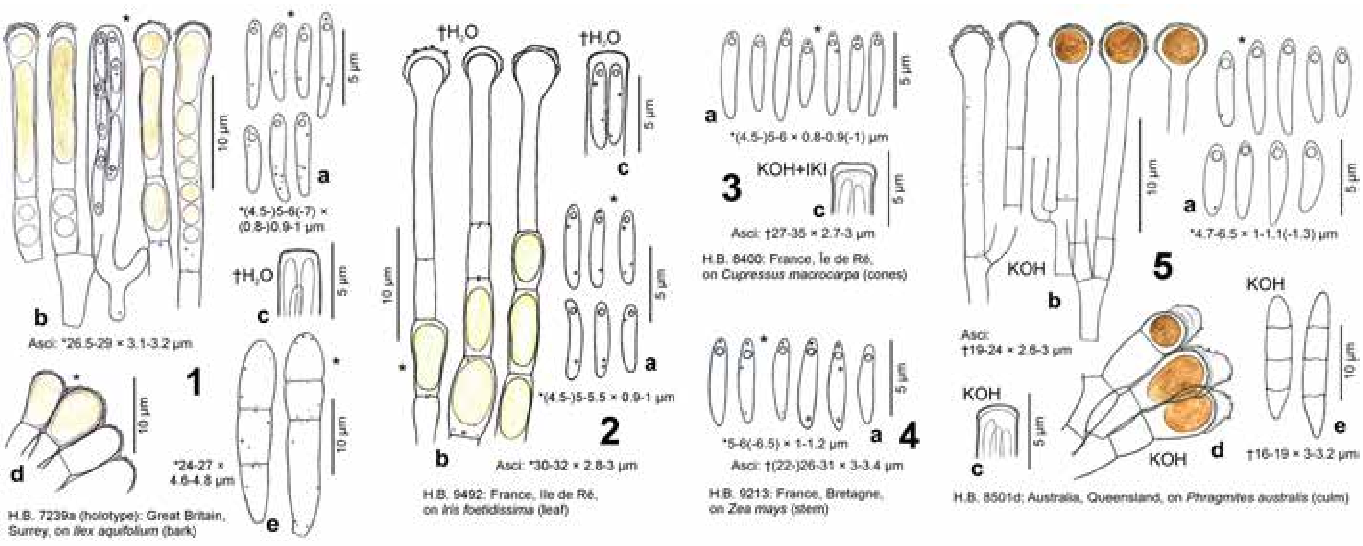


Plate 898. **1–3**: *Orbilia atlantis*; **4–5**: *O.* cf. *atlantis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section (**5d**: cortical cells with glassy caps); **e**. conidia from substrate.

sometimes in aggregated in small groups; disc flat to medium convex, margin thick or thin, 0–25 µm protruding, smooth; broadly sessile, or subsessile on a ± obconical stipe, superficial; dry light to bright yellow-amber to orange-ochraceous. **Asci** *26–32 × (2.7–)2.9–3.2(–3.6) µm {5}, †(22–)25–30(–35) × 2.4–3 µm {4}, 8-spored, spores *3–4-seriate, 4–5(–6) lower spores inverted {3} (± mixed), pars sporifera *17–18 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not or slightly inflated); **base** with short to long, thin or thick, flexuous stalk, Y-, h- or H-shaped. **Ascospores** *(4.5–)5–6(–7) × (0.8–)0.9–1 µm {9}, †4.5–5.5(–6) × 0.7–0.9(–1) µm {2}, narrowly cylindric(-fusoid), rarely cylindric-clavate, apex rounded to obtuse, base not or slightly attenuated, straight, sometimes slightly curved; **SBs** globose, *(0.25–)0.35–0.5(–0.7) µm diam., 0.4–0.8 µm away from apex, total length 0.7–1.5 µm (including invisible attachment) {5}. **Paraphyses** apically uninflated or mostly slightly to medium (rarely strongly) capitate, terminal cells *(13.5–)15–20(–22) × 2.2–3 µm {2}, †10–19 × 2–3.5 µm {2}, lower cells *4–8 × 2.2–2.7 µm {3}, †4–6 × 1.6–2.2 µm {1}, up to *3–4 µm wide near base; not branched at upper septum, hymenium pale chlorinaceous (in KOH hyaline). **Medullary excipulum** hyaline, 15–50 µm thick, of dense, horizontally oriented textura prismatica-angularis-globulosa or medium loose t. intricata with many inflated cells, indistinctly to very sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly to vertically oriented t. angularis-globulosa from base to margin, 30–70 µm thick near base, cells */†(8–)10–25(–32) × (6–)8–18(–21) µm {5}; 10–20 µm thick near margin, oriented at a 70–90° angle to the surface, marginal cortical cells */†5–8 × 3–6 µm {2}; **glassy processes** absent {6}. **Anchoring hyphae** sparse to abundant, *(1.5–)2–3(–4) ((–5)) {2} µm wide, †1.5–2(–2.5) µm {1}, walls */†0.1–0.2 µm thick {3}, forming either a 10–20 µm thick t. intricata below the basal excipulum, or sometimes a 60–90 µm thick layer of globose cells *5–13 µm diam. {2}. **SCBs** absent; **VBs** in paraphyses pale yellowish-chlorinaceous(-olivaceous), very low- to low-refractive {8}, globose to very elongate, also in upper part of medullary excipulum and/or in ectal excipulum at margin and flanks. **Exudate** over paraphyses and margin 0.1–0.3(–1) µm thick, pale yellowish, finely rough or granular, continuous, firmly attached, covering paraphyses like a hemispherical cap. — **ANAMORPH**: dactylella-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** unbranched, cylindric-ellipsoid-clavate, straight, *24–27(–47) × 4.2–4.8 µm, 2(–4)-septate {1}.

Habitat: on moist ground or 0.2–2.5 m above the ground, corticated, 9 mm thick branch of *Ilex aquifolium* {1} (on bark, mostly over narrow cracks in periderm formed by *Corynespora*, also on small periderm-free areas on bast), cones of *Cupressus sempervirens* {1}, standing or lying herbaceous stems of *Cirsium palustre* {2}, *Oenanthe crocata* {4}, leaves of *Helleborus niger* {1}, *Iris foetidissima* {1}, *I. pseudacorus* {1}; medium decayed, medium greyed, green algae sparse or absent. **Associated**: *Cistella grevillei* {2}, *Corynespora smithii* {1}, *Orbilia auricolor* {3}, *O. oxyspora* {1}, *Psilachnum rubicundum* {1}, *P. rubrotinctum* {1}, *Pyrenopeziza atrata* {2}, *P. ?imbricata* {1}. **Desiccation tolerance**: many medullary excipular cells, a few paraphyses and mature asci survived for 3–4 days, spores still viable after 3 weeks, conidia after 10 days. **Altitude**: 6–185 m a.s.l. **Geology**: Ordovician-Silurian-Devonian sand- & siltstone, Carboniferous lime-, sand- & mudstone and coal, Upper Cretaceous limestone, Quaternary marine sand; granite, mica schist & gneiss. **Phenology**: III–VI, X, XII (possibly throughout the year).

Taxonomic remarks. A number of species of section *Arthrobotrys* closely resemble *Orbilia atlantis* in spore size and shape and in the globose SBs situated a good distance from the apex, for instance, *O. rectispora* and *O. cardui*, from which it differs in smaller spores, pigmented VBs, from the former also in a drier habitat, and from the latter in the absence of glassy processes. *O. cotoneastri* resembles *O. atlantis* but differs in hyaline apothecia, longer asci, and wider spores with larger SBs. *O. bambusina* (incertae sedis) differs in tear-shaped, visibly attached SBs and short glassy processes. *O. acuum* (incertae sedis) differs in shorter, also partly wider spores, wider asci, and apparently narrowly tear-shaped SBs. *O. flavovacuolata* (series *Drechslerella*) is very similar especially regarding the yellowish VBs, but differs in distinctly wider asci, partly non-globose and eccentrical SBs, a tendency to basally tapered spores, paraphyses without exudate, and smaller apothecia. *O. quercus* (series *Dactylellina*) has slightly wider, more clavate spores with SBs close to the apex, and wider asci.

O. atlantis resembles also *O. epipora*, which mainly differs in distinctly shorter spores with SBs close to the apex, and in hyaline VBs. Also the Australasian *O. cunninghamii* (series *Orbilia*) differs in distinctly shorter spores, though the asci are longer (SBs are unknown since living spores were not studied). The desiccation-tolerant *O. cylindrospora* (section *Orbilia*) has a spore size and shape very similar to *O. atlantis*, but also here the SBs are much closer to the spore apex, and VBs are consistently absent.

Variation. The included collections show a rather high conformity, particularly in spore size and presence of yellowish VBs. However, SBs varied in size between 0.25–0.35 µm (on

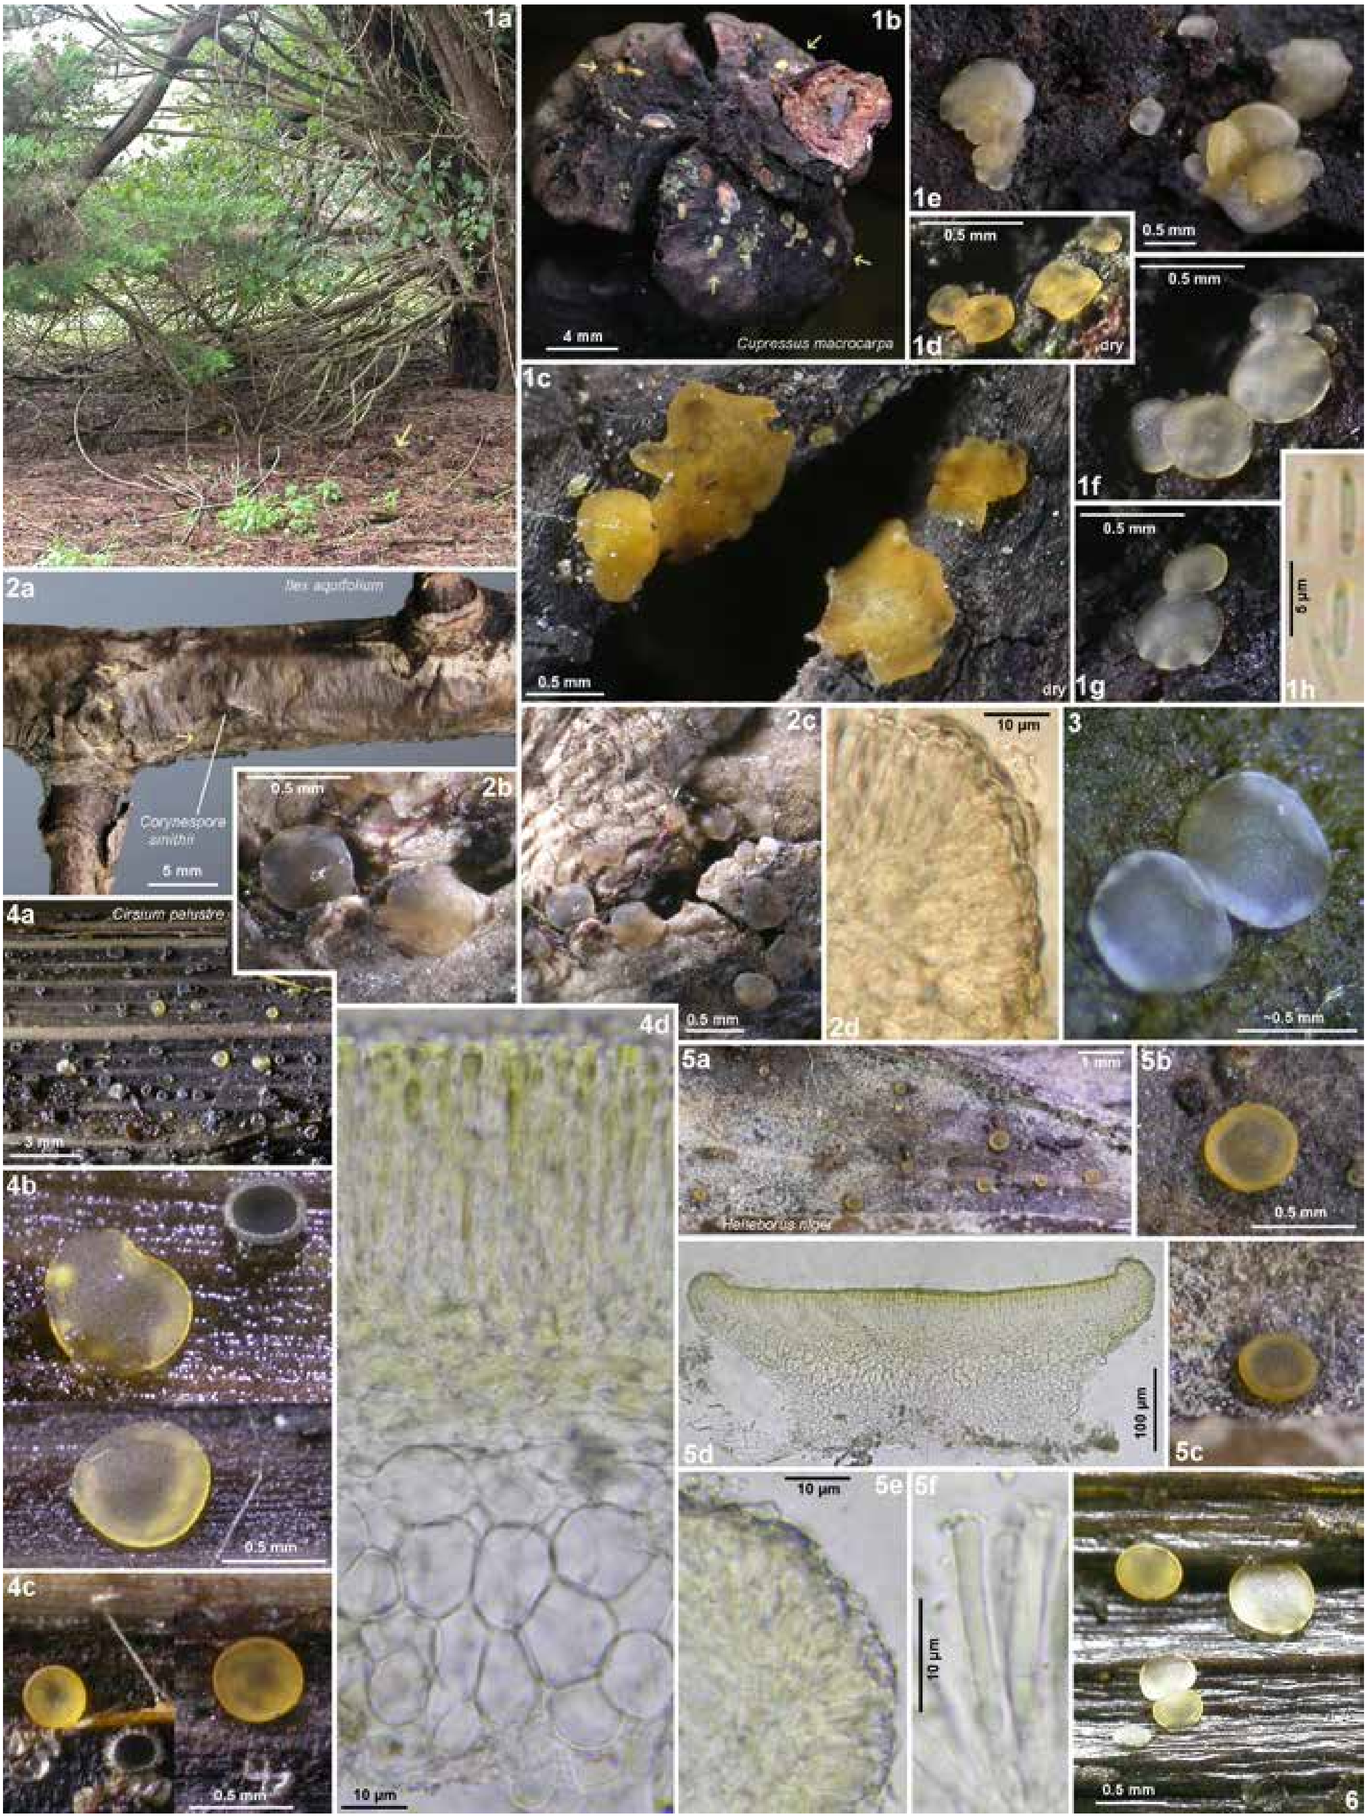

Plate 899. **1–2**, **4–6**: *Orbilia atlantis*; **3**: *O.* cf. *atlantis*. – **1a**. submediterranean coastal *Cupressus macrocarpa* woodland with cones lying in litter; **1b**. fallen cone with apothecia; **2a**. dead corticated xeric branch of *Ilex aquifolium*; **4a**. dead standing stem of *Cirsium palustre* (fresh); **5a**. underside of *Helleborus niger* leaf (fresh); **1e–g**, **2b–c**. rehydrated apothecia: **3**, **4a–c**, **5a–c**, **6** fresh apothecia (**4** with *Pyrenopeziza atrata*); **1c–d**. dry apothecia; **5d**. apothecium in median section; **2d**, **5e**. id., marginal region: **4d**. id., lower flanks; **5f**. paraphyses; **1h**. ascospores. – Living state, except for **2d** (in KOH). – **1a**: phot. M. Hairaud. **3**: phot. J.P. Priou. — **1a–h**. H.B. 8400: France, Île de Ré, on *Cupressus*; **2a–d**. H.B. 7239a (holotype): Great Britain, Surrey, on *Ilex*; **3**. H.B. 9213: France, Bretagne, on *Zea*; **4a–d**: H.B. 9527a: Great Britain, Barnsley, on *Cirsium*; **5a–f**. H.B. 9509: id., on *Helleborus*; **6**. H.B. 9492a: France, Saintes, on *Iris*.

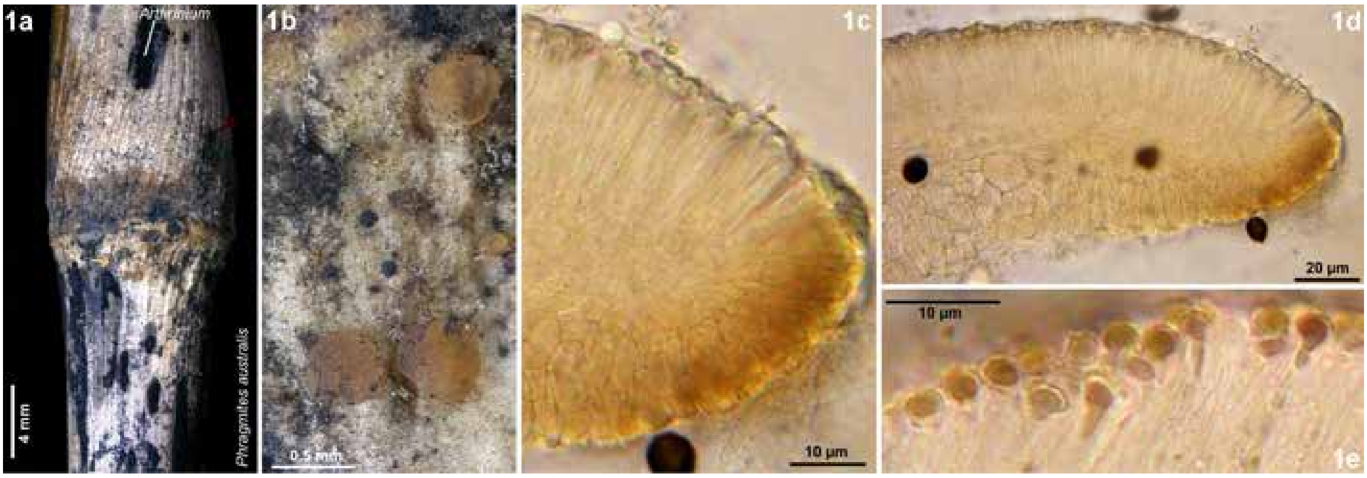

Plate 900. **1**: *Orbilia* cf. *atlantis*. – **1a**. dead xeric (standing) culm of *Phragmites australis*, with black mould (*Arthrinium arundinis*); **1b**. rehydrated apothecia: **1d**. apothecium in median section; **1c**. id., marginal region; **1e**. apices of paraphyses with brown contents. – Dead state (**1e**. in H_2O, **1c–d** in KOH). — **1a–e**. H.B. 8501d: Australia, Queensland.

Iris foetidissima) and 0.7 µm (on *Helleborus*), though being mainly 0.35–0.5 µm in diam. Further variation includes ascus width (from *2.7–2.8 µm up to 3.2–3.6 µm) and apical inflation of paraphyses. The collections on *Helleborus* and *Cirsium* from Barnsley differed from the others in a thick layer of basal textura globulosa that formed a pseudostipe below the ectal excipulum (Pl. 899: 5d), the *Helleborus* collection also in a thick protruding margin. The size of hydrated apothecia varied among the samples between 0.25–0.45 mm (*Helleborus*) and 0.6–1.2 mm (*Iris foetidissima*); in that on *Cupressus* an extremely wide range of (0.1–)0.3–1(–1.4) mm was observed.

Not included collections. Three caulicolous samples on *Poaceae* differ by slightly wider spores [*(0.9–)1–1.1(–1.3) µm] compared to typical *O. atlantis* [*(0.8–)0.9–1 µm]. Two from Europe (Pls 898: 4, 899: 3, on *Zea*; IVV: 11.VI.2019, on *Poaceae*) differ also in the lack of pigmented VBs and, therefore, more whitish apothecia, also by slightly wider asci (no data available for the latter sample). One from Australia (Pls 898: 5, 900, on *Phragmites*) differs in VBs that turn bright brown in the dead state (no living VB-containing cells seen), also in larger SBs with a partly visible fine filum, and in short glassy caps at the margin.

Anamorph. Only three phragmoconidia were seen on the natural substrate (in the holotype, Pl. 898: 1e); one was much longer than the other two and had 4 septa, but was damaged at the upper end. In the deviating Australian collection on *Phragmites* similar though smaller, 3-septate conidia were detected (Pl. 898: 5e).

Map 143. Known distribution of *O. atlantis* in Europe (yellow = not included collections on *Poaceae*).

Phylogeny. A sequence was gained from apothecia of a specimen from Yorkshire (H.B. 9527), which comprises SSU (without S1506 intron), ITS, and LSU. In our combined analyses (Phyls 25, 27), *O. atlantis* clustered unresolved in none of the four clades, with a minimum distance of 11.5 % to *O. pseudeuphorbiae* and 12 % to *O. rhopalota*, *O. zhongdianensis*, and *O. epilobii*. Species such as *O. rhamni*, *O. cotoneastri*, or *O. cardui* show a distance of ~ 12–18 %. In the LSU the lowest distance was 6.5 % to *O. xinjiangensis*, *O. cotoneastri*, *O. epilobii* etc.

Ecology. *O. atlantis* was found on a variety of different substrates: bark of an *Ilex* branch, cones of *Cupressus*, stems and leaves of herbaceous mono- and dicots. Some of the collections were made on hygric substrate close to the moist or wet ground (*Cirsium* from Sussex, *Cupressus*, *Helleborus*, *Iris*, *Oenanthe*), but two were on xeric substrate: on a standing stem in ~ 20–30 cm above the ground (*Cirsium* from Yorkshire), on a still-attached branch 2.5 m above the ground (holotype). *O. atlantis* is at least slightly desiccation-tolerant, since some asci survived for a few days in the dry state. *Corynespora smithii* occurred in abundance on the *Ilex* branches, though only sparsely on that branch which carried the *Orbilia* (B. Spooner pers. comm.). In the *Cupressus* collection the apothecia grew mainly over small cracks in the scales, on dark brown hyphae of unknown identity.

Collections were made in atlantic, cold- to warm-temperate humid northwestern and warm-temperate humid to mesosubmediterranean semihumid western Europe. The vegetation was quite diverse. The holotype locality in southern England was a damp shaded mixed woodland of *Quercus*, *Betula*, *Corylus* and *Ilex*, with some *Pinus* and *Castanea*. Samples from Île de Ré in western France were from coastal cypress woodlands and those on *Oenothera* from ± coastal wood-, shrub- and marshland in Wales and Bretagne, along ditches, rivers and lakes in a meadow among rocks or in wet *Salix* woodlands in a moist *Quercus* forest with *Buxus* and *Ruscus*. Collections from Yorkshire were on *Cirsium* in an ancient estate with *Rhododendron* in a moist *Alnus-Betula* forest and on *Helleborus* in a cultivated *Rhododendron* park.

The not included collection from northeastern Australia was on standing, dead, xeric culms of *Phragmites* being covered over large areas by a black conidial layer of *Arthrinium arundinis* in a tropical (semi)humid floodplain between savannah and rainforest on Devonian sedimentary rock, and that on *Zea* from western France was in a ditch in an atlantic, mesosubmediterranean humid forest, into which the substrate was transported by floodwater.

Specimens included. **GREAT BRITAIN**: **Yorkshire**, **South Yorkshire**, 4 km SW of Barnsley, W of Wentworth Castle, Stainborough Park, 185 m, leaves of *Helleborus niger*, 14.V.2011, T. Læssøe & J.H. Petersen (J.H.P. 11.095, H.B. 9509). – 8 km NNW of Barnsley, 6.5 km S of Wakefield, Seckar Wood, 70 m, stem of *Cirsium palustre*, 19.V.2011, H.O. Baral (H.B. 9527a, J.H.P. 11.177; sq.: KT222437). – **Wales**, **Pembrokeshire**, 7 km WNW of Pembroke, 3.3 km SSW of Waterston, Pwllcrochan Marsh, 10 m, stems of *Oenanthe crocata*, 9.V.2009, P. Thompson (K(M) 163314, doc. vid.). – **South East England**, **Surrey**, 55 km SW of London, 3 km NNW of Farnham, Rowhill, 135 m, branch of *Ilex aquifolium*, on bark, 27.X.2002, B.M. Spooner (K(M) 105703 **isotype**; ex H.B. 7239a, M-0276436, **holotype**, anam. substr.). – **West Sussex**, 6.5 km S of Crawley, SE of Handcross, 130 m, stem of *Cirsium palustre*, 25.V.2017, N. Aplin (N.A. 675, doc. vid.). — **FRANCE**: **Bretagne**, **Finistère**, 6.5 km WSW of Plouay, 1.7 km ENE of Arzano, Pont Kerlo, 35 m, stem of *Oenanthe crocata*, 12.V.2014, P.Y. Courio (P.Y.C. 14050, doc. vid.). – 6 km ESE of Quimperlé, 1 km WSW of Rédené, Rosbigot, 38 m, stem of *O. crocata*, 21.III.2020, P.Y. Courio (P.Y.C. 20041, doc. vid.). – **Morbihan**, Île de Groix, 2 km WSW of Le Bourg, WNW of Quéhello, Port St.-Nicolas, 17 m, stem of *O. crocata*, 6.VI.2015, J.P. Priou (J.P.P. 15135 ø, doc. vid.). – **Poitou-Charentes**, **Charente-Maritime**, Île de Ré, 1.7 km WNW of Ars-en-Ré, 1.5 km SSE of St.-Clément-des-Baleines, Forêt de la Combe à l'Eau, 6 m, leaves of *Iris foetidissima*, 28.IV.2011, B. Capoen (H.B. 9492a). – 2 km E of La-Flotte-en-Ré, SSW of L'Abbaye des Châteliers, 14 m, fruits of *Cupressus sempervirens*, 16.XII.2006, M. Hairaud & N. Van Vooren (H.B. 8400). – 2.5 km NE of Saintes, SE of Lormont, 20 m, stem of *Iris pseudacorus*, 26.V.2012, M. Hairaud & P. Tanchaud (M.H. 210512, H.B. 9686).

Not included. **FRANCE**: **Bretagne**, **Morbihan**, Bretagne, 1.7 km SSW of La Gacilly, 2.4 km WNW of Cournon, La Chevée, 7 m, culms of *Zea mays*, 4.IX.2009, J.P. Priou (J.P.P. 29163 ø, H.B. 9213). — **SERBIA**: **Vojvodina**, Fruška Gora, 13 km SSW of Novi Sad, 1 km E of Brankovac, 430 m, leaf of *Poaceae*, 11.VI.2019, D. Savić (doc. vid.). — **AUSTRALIA**: **Queensland**, Einasleigh Uplands, 22 km SSW of Mossman, 2 km N of Mount Molloy, Mossman Mt. Molloy Rd, 390 m, culms of *Phragmites australis*, 28.VIII.2006, G. Marson (ex H.B. 8501d, mixture in BRI AQ799195 [type of *O. stilbospora*]).

Orbilia epipora (Nyl.) P. Karst., Not. Sällsk. Fauna Fl. Fenn. Förh. 11: 248 (1870) — Pls 901–902, Map 144

≡ *Peziza epipora* Nyl., Not. Sällsk. Fauna Fl. Fenn. Förh. 10: 58 (1869)
= *Orbilia sericea* Henn., Hedwigia 45: 29 (1905)
= *Orbilia connata* Velen., Monogr. Discom. Bohem.: 95, pl. 11 fig. 13 (1934)
(?)= *Trichothecium polyctonum* Drechsler, Mycologia 44(4): 550 (1952)
≡ *Dactylella polyctona* (Drechsler) K.Q. Zhang, Xing Z. Liu & L. Cao, Mycosystema 7: 113 (1995) [1994]

Etymology: *epipora*: growing on the pores of *Phellinus igniarius*; *sericea*: from the silky appearance of the apothecia; *connata*: according to the densely gregarious apothecia; *polyctona*: referring to a wide scope of parasitism (literally: much slaying).

Typification: Finland, Ruovesi, on bark of indet. angiosperm tree and on *Phellinus igniarius*, 4.VIII.1859, P.A. Karsten (herb. Karsten 5278, H-6003825, as *Peziza leucostigma*, lectotype of ***Peziza epipora***, designated here, MBT202383); Germany, Chemnitz, branch of *Salix*, 20.IV.2009, B. Mühler (ex H.B. 9039, M-0291771, epitype, designated here, MBT385132; sq.: KT222431). — Russia (west), Podolsk, trunk of (?)*Populus*, VIII.1904, N.A. Mosolov (S, herb. Sydow, lectotype of ***Orbilia sericea***, designated here, MBT202384). — Ukraine, Swydiwec (Svitovec) mountain range, trunk of *Fagus sylvatica*, VIII.1930, A. Pilát (PRM 151704, holotype of ***O. connata***).

Misinterpretation of *O. epipora*: Beaton & Weste (1979), ?= *O. dryadum*; Korf (1992), = *O. dryadum* & *Hyalorbilia inflatula*; Liu (2006: 76 p.p.), = *O. dryadum*; Nylander (1869: 58 p.p.), = *H. inflatula*; Svrček (1954: 8 p.p.), ?= *Hyalorbilia* sp.; Dennis (1956: 296, as *O. epipora*), = *O.* ?*cunninghamii*.
Misapplied name: Otani (1990), as *Orbilia inflatula* [= *O.* ?*epipora*].

Description: — **TELEOMORPH**: **Apothecia** fresh (0.2–)0.3–1(–1.5) mm diam., (0.08–)0.11–0.16(–0.2) mm high (receptacle 0.07–0.12 → 0.05–0.06 mm), (greyish-)white, pale to light cream to yellowish-ochraceous with age, translucent, round, mostly densely gregarious in large numbers; disc young slightly to medium concave, later flat, rarely medium convex, margin thin, 0–5 µm protruding, smooth; with a broad obconical stipe 0.02–0.1 × 0.25–0.5 mm, superficial; dry pale to light or bright cream-yellowish(-chlorinaceous) or ochraceous. **Asci** *22–29(–32.5) × 2.8–3.5 µm {7}, †18.5–26((–28)) × (2.2–)2.4–2.8(–3) µm {5}, 8-spored, spores *4-seriate [†(1–)2(–4)-seriate], 3–5 lower spores inverted {6} (mostly mixed), pars sporifera *10–12 µm long (†9–18 µm); **apex** (†) medium to strongly truncate (not indented, laterally not or rarely slightly inflated); **base** with short to medium long, rather thin, somewhat flexuous stalk, T-, Y-, h- or H-shaped. **Ascospores** *(2.8–)3.3–4.3(–5) × 0.8–1((–1.2)) µm {17}, †(2.7–)3.2–4.3(–4.7) × (0.6–)0.7–0.9(–1) µm {8}, narrowly (sub)cylindrical, rarely slightly fusoid, ends rounded or obtuse, straight to often slightly curved; **SBs** *0.6–1 × 0.3–0.6 µm {4}, globose, apically abruptly narrowed to a minute, mostly invisible, very short filum, with a few minute LBs. **Paraphyses** apically uninflated or usually slightly to medium, only sometimes a few strongly capitate when in the dead state, terminal cells *13–22 × (2.2–)2.5–3.2(–3.5) µm {7}, †(11–)13–18(–20) × (2–)2.3–3(–3.4) µm {5}, lower cells *(2.5–)4–6(–7.5) × 2–3(–3.5) µm {6}, †3.5–6 × (1.3–)1.5–2.3(–2.6) µm {4}; sometimes branched at upper septum. **Medullary excipulum** 15–30 µm thick, of dense textura (intricata-)globulosa, indistinctly delimited from ectal excipulum, towards margin with or without a 5–10 µm thick layer of loose t. porrecta. **Ectal excipulum** of (†) not or very slightly gelatinized, indistinctly vertically oriented t. globulosa(-angularis) from base to margin, (25–)50–100(–150) µm thick near base, cells *10–32(–38) × 8–22(–30) µm {5}, †9–32 × 8–19 {4}; 10–15 µm thick near margin, oriented at a 45–90° angle to the surface, marginal cortical cells */†6–12(–15) × (4–)5–6(–7) µm {5}, at submargin 6–9 µm wide; **glassy processes** absent. **Anchoring hyphae** partly abundant at base, *2–5 µm wide, walls 0.2–0.3 µm thick {3}, forming a quite dense 10–50 µm thick texture of intricate hyphae, towards excipulum sometimes forming a paraplectenchyma of 6–8 µm wide cells, on stipe sometimes forming projecting hairs. **SCBs** not seen; **VBs** in paraphyses globose to mostly elongate, slightly to strongly refractive {18}. **Exudate** over paraphyses absent or as scattered, loosely attached, 0.1–0.5 µm thick granules, over margin and flanks ± absent. — **ANAMORPH**: dactylella-like (from ascospore isolate and natural substrate {1}). **Conidiophores** *~40–50 × 2–3 µm, branched or unbranched, conidia terminally formed, partly also on 1–3 lateral denticles (sympodial). **Conidia** unbranched, cylindrical to narrowly ellipsoidal, straight, *(13.5–)16–22(–25) × 2.2–3(–3.2) µm, (0–)1–3-septate {1}.

Habitat: mostly lying on the ground, corticated or decorticated, 3.5–30 cm thick branches and trunks, rarely a 3–4 mm thick twig, of *Acer* sp. {1}, *Betula obscura* {1}, *Buddleja davidii* {1}, *Carpinus betulus* {1}, *Fagus sylvatica* {8}, ?*Fraxinus* sp. {1}, *F. angustifolia* {1}, *Populus* sp. {5/1}, *P. tremula* {1}, *Salix* sp. {8}, *S. aurita* {1}, *S. fragilis* {1}, *Sambucus racemosa* {2}, *Tilia* sp. {2}, *Ulmus* sp. {1}, indet. angiosperms {4}, on lower side on 1–4 mm deep or entirely strongly decayed (white- or brown-rotten) wood {34}, rarely on bark {6}, often darkened, no algae, upper side partly covered by pleurocarpous mosses, often water-soaked, also on pores of old *Fomitiporia punctata* {1}, *Phellinus igniarius* {1}, indet. perennial basidiomycete {1}. **Associated**: *Hypnum cupressiforme* {1}, *Lasiosphaeria* sp. {1}, *L. hirsuta* {1}, *Lentomitella cirrhosa* {1}, *Orbilia crenatomarginata* {1}, *O. sinensis* {1}, *Pleurothecium* sp. {2}, *Pulvinula convexella* {1}. **Desiccation tolerance**: asci did not survive for 1 h in the dry state, but excipular and paraphysis cells survived sometimes 1 day (some cells even 3 days), and the ascospores were still viable after 1 month. **Altitude**: 3–595 m a.s.l. (atlantic to subcontinental Europe), 190–1020 m (continental Europe, Caucasus, central Asia). **Geology**: Ordovician & Carboniferous mud-, silt- & sandstone, Permian (Rotliegend), Middle Keuper & Lower Jurassic sandstone, Cretaceous limestone & flysch, Tertiary molasse, Quaternary loess, till, silt & sand; granite, pegmatite, serpentinite, gneiss, mica schist. **Phenology**: (III–)IV–X.

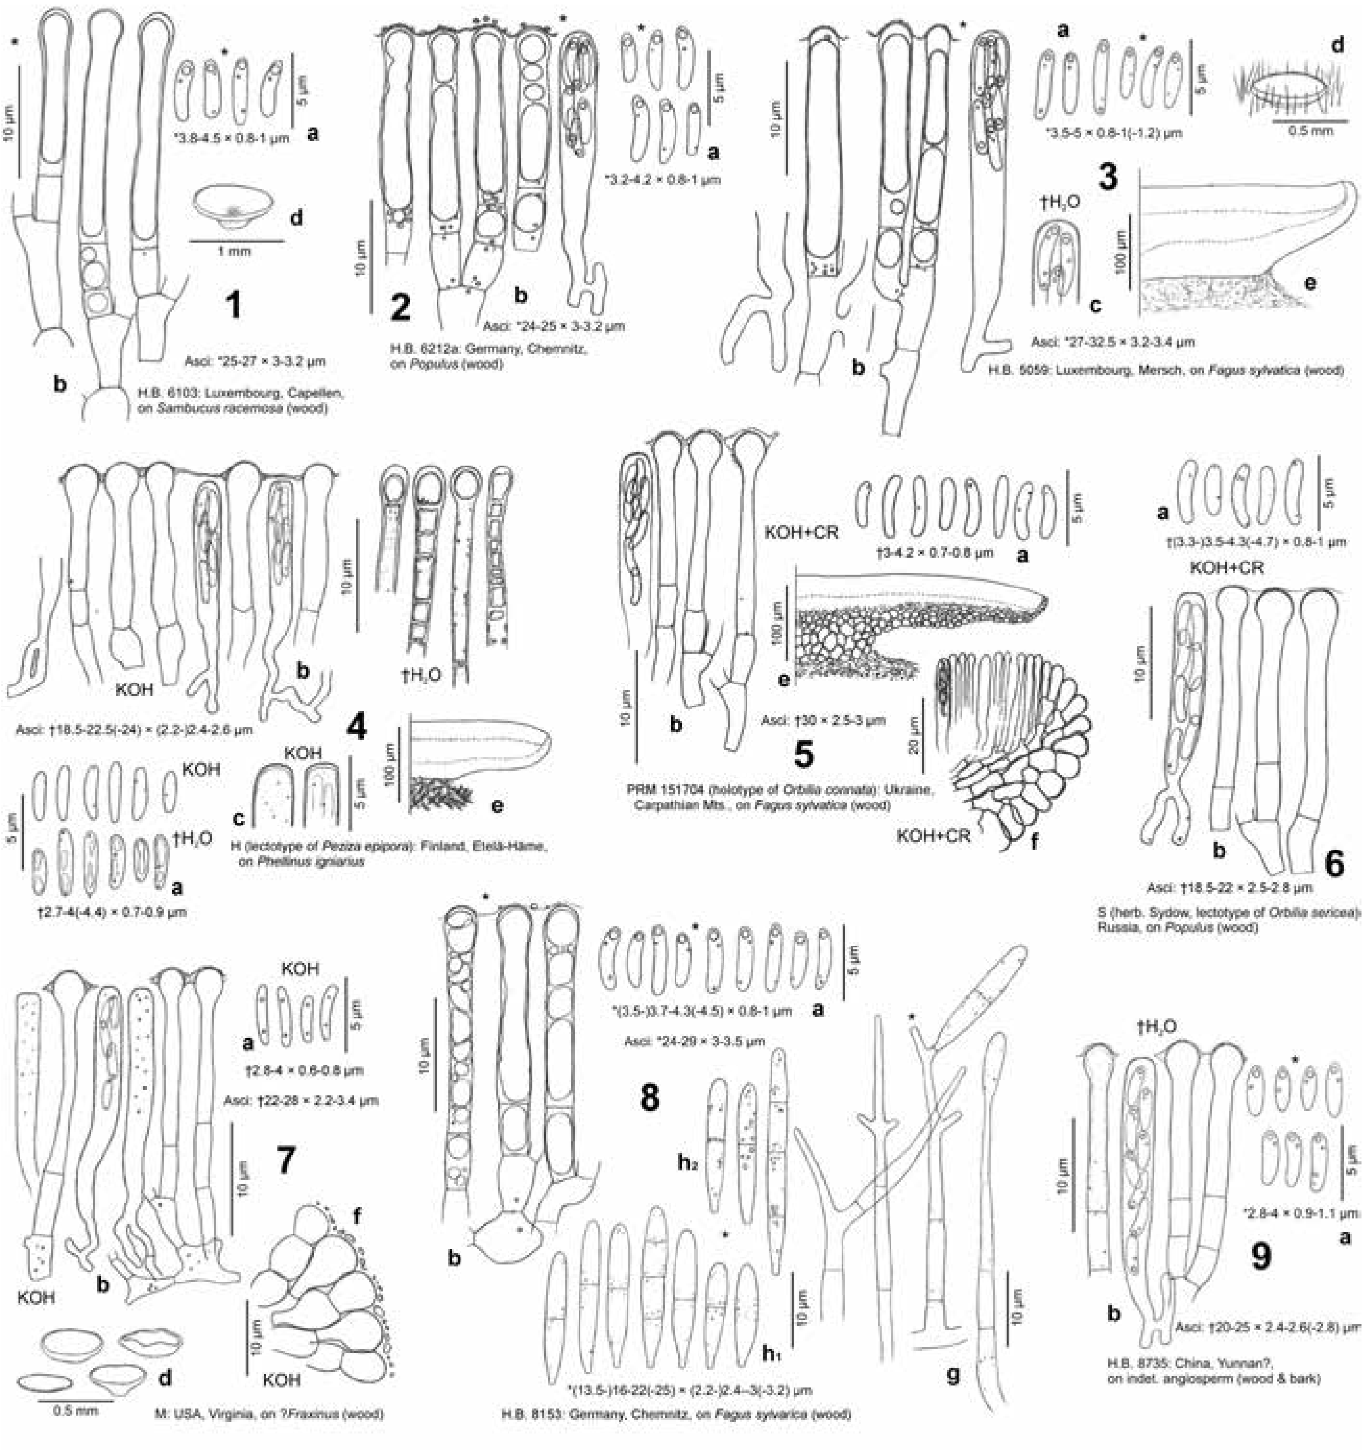

Plate 901. **1–9**: *Orbilia epipora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. fresh apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum at margin and mid flanks; **g**. conidiophores from substrate; **h**. conidia from substrate ($\mathbf{h_1}$) and culture ($\mathbf{h_2}$).

Phenology of *O. epipora*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0	0	1	10	8	3	4	6	2	3	0	0

Taxonomic remarks. *Orbilia epipora* is characterized by narrowly cylindrical, often slightly curved ascospores with a globose spore body at one end, and by whitish, translucent, desiccation-sensitive apothecia which grow mostly densely in large populations. *O. atlantis* differs in longer spores with the globose SBs more remote from the apex, in yellowish-chlorinaceous VBs and in apothecia growing in small groups, also in wider conidia. *O. cylindrospora* (section *Orbilia*) differs in longer and wider spores and asci, a thicker exudate, cells of the marginal ectal excipulum running under a lower angle, and in desiccation-tolerant, scattered apothecia often with a rose tint. *O. acuum* (incertae sedis) differs in larger asci and spores, and apparently in more tear-shaped spore bodies. The Australasian *O. cunninghamii* (section *Orbilia*) differs in much longer asci and in basally tapered spores. The Asian *O. yuanensis* (section *Helicoon*) has distinctly larger spores and tear-shaped SBs with a distinct filum.

Delimitation between *O. epipora* and the very similar *O. dryadum* (section *Orbilia*) was unclear in some intermediate populations, due to a pronounced variability in the latter species (see p. 1387).

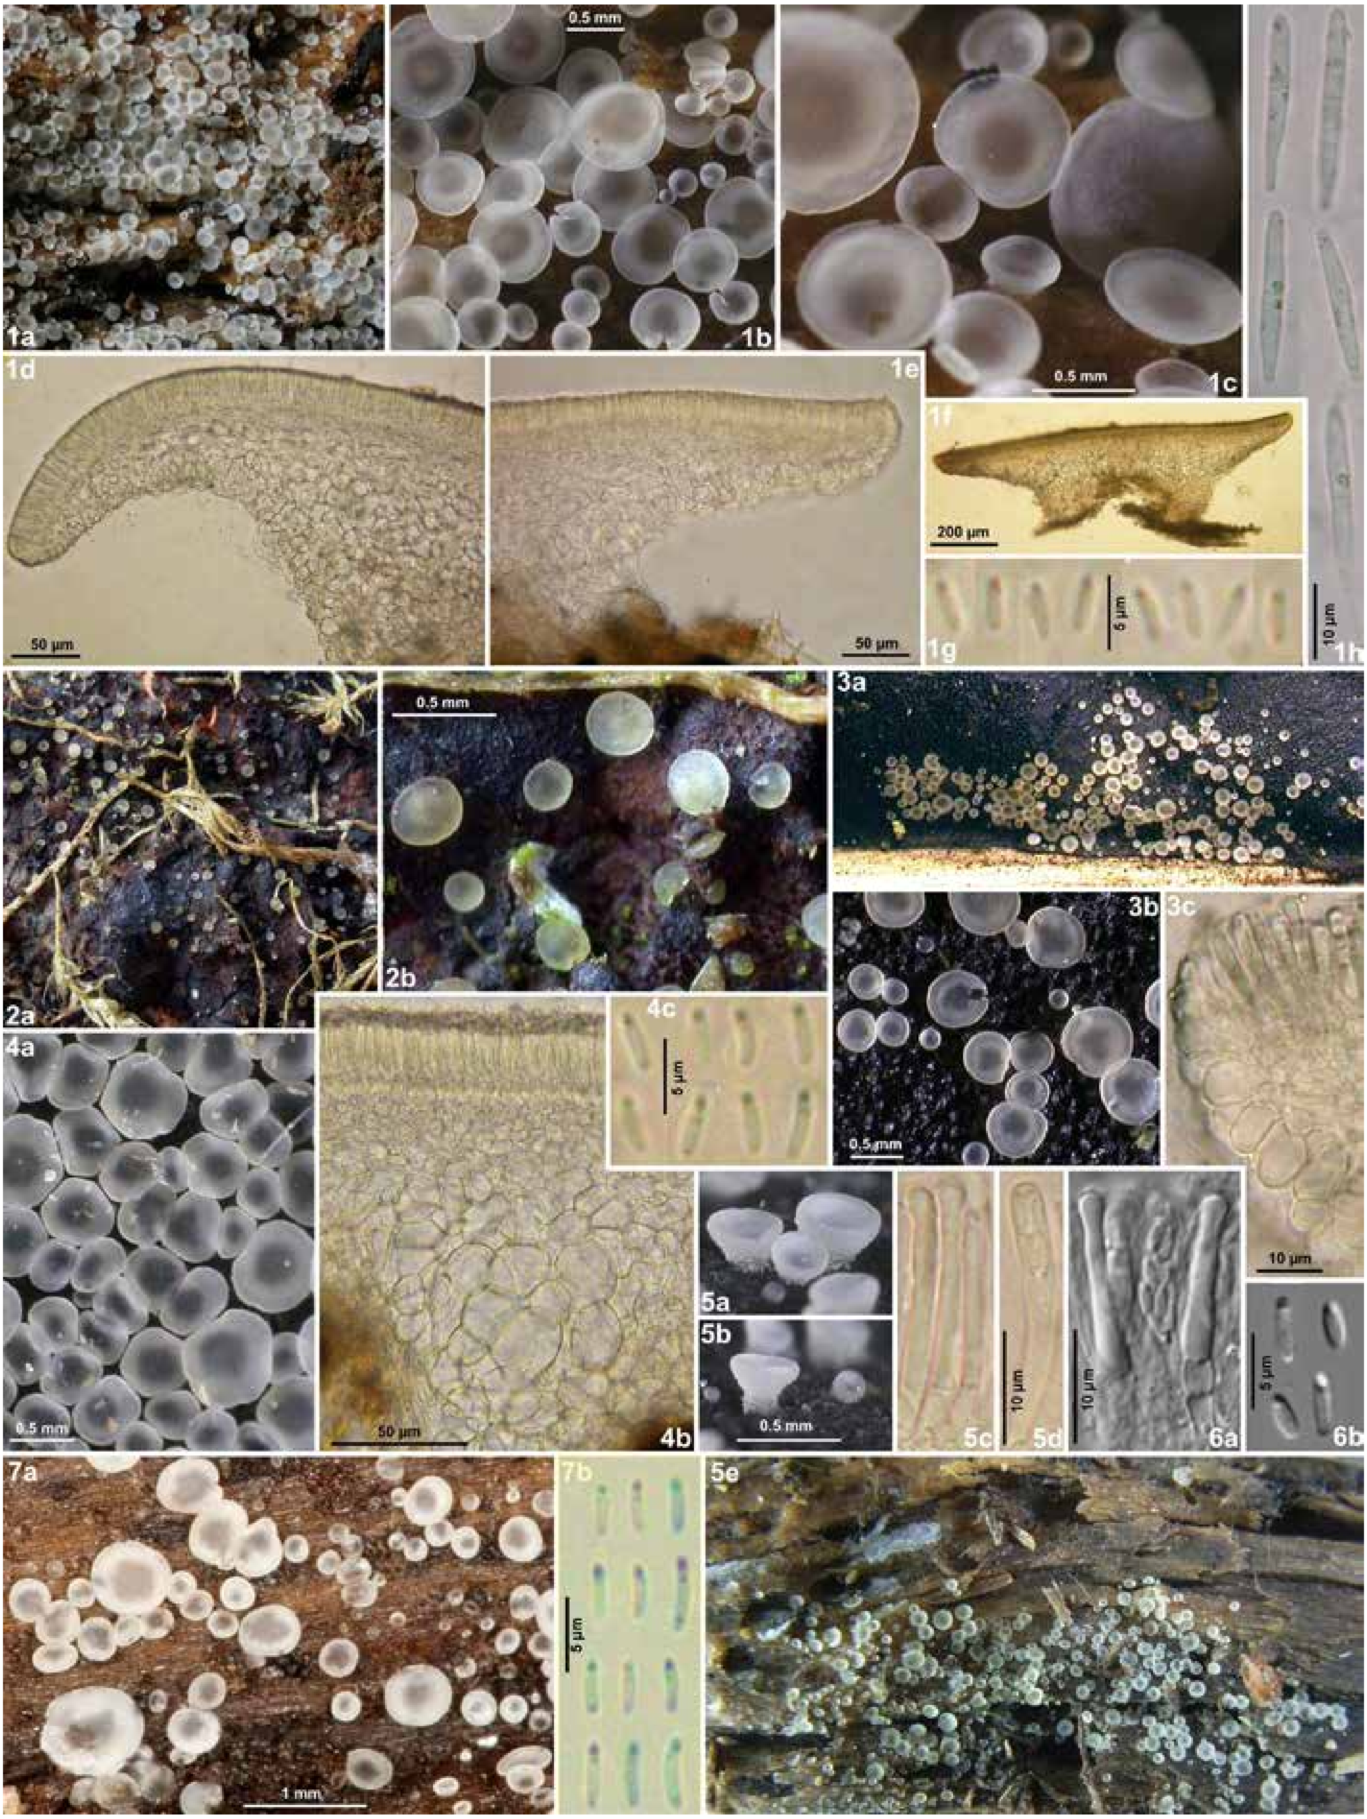

Plate 902. **1–6**: *Orbilia epipora*. – **1a–c**, **2a–b**, **3a–b**, **4a**, **5a–b, e**, **7a**. fresh apothecia; **1d–f**. apothecia in median section; **3c**. id., marginal ectal excipulum; **4b**. id., central part of apothecium; **5c–d**, **6a**. asci and paraphyses; **1g**, **4c**, **6b**, **7b**. ascospores; **1h**. conidia from culture. – Living state. – **6a–b**: phot. H.B. 8195b: Sweden, Skåne, on *Fagus*; **4a–c**. H.B. 8186: Germany, Chemnitz, on *Populus*; **5a–e**. H.B. 9039 (epitype): ibid., on *Salix*; **6a–b**. H.B. 8735: China, Sichuan, Jiuzhaigou, indet. angiosperm; **7a–b**. 20.VIII.2019: Serbia, Fruška Gora, on *Fagus*.

Variation. *O. epipora* seems to exhibit little variation in ascus and spore dimensions. The species varies mainly in the apical inflation of paraphyses between scarcely inflated to usually slightly to medium (types of *O. epipora* and *O. sericea*), rarely partly strongly capitate (type of *O. connata*). However, paraphysis shape appears to depend on the method: in recent specimens here depicted in the living state the paraphyses are apically not or only slightly inflated, whereas in herbarium specimens studied only in the dead state they are predominantly medium to rarely strongly inflated (Plate 901).

No difference between lignicolous and polyporicolous collections was observed. A specimen from mountainous central China (Pls 901: 9; 902: 6) fits well European samples, though the apothecia grew on a twig, and partly on bark, and the spores were slightly wider. Alternatively, this collection could belong to the narrow-spored *O.* aff. *dryadum* (e. g., Pl. 870: 7). A North American collection from Virginia (Pl 901: 7) fits rather well *O. epipora* but was only studied in the dead state. It shows pale yellowish-ochraceous apothecia (rehydrated, dry deep ochraceous) and might have been more intensely yellow in the fresh state as it was labelled by F. Petrak '*O. xanthostigma*', perhaps similar to *O. xanthoflexa*. The paraphyses are rather strongly capitate, similar as in the type of *O. connata*. From *O. cunninghamii* it seems to differ in shorter asci and in spores which are hardly tapered below.

Literature reports. Nannfeldt (1932: 254, fig. 40a–b) gave a description and illustration of the excipulum of a Swedish sample of *O. epipora* (on wood of *Populus tremula*, Lundell & Nannfeldt, F. exs. Suecici 1780), and Spooner (in Kirk & Spooner 1984: 573, fig. 9 C [as 'B']) added the hymenial characters of this sample, with asci 22–26 × 2.5 µm and slightly curved, basally ± tapered spores 3.5–5 × 0.6–0.8 µm (4.5–5.5 × 0.8–1 µm according to scale). The rather long, heteropolar spores would better fit *O. cunninghamii* (section *Orbilia*) from New Zealand, but the short asci exclude this species. Also Spooner (1987: 167) characterized *O. epipora* by small asci, but he saw a 'thin encrusting epithecium' over the paraphyses in F. exs. Suecici 1780, while in our studied collections of *O. epipora* no or only sparse and minutely granular exudate was present.

Also the reports by Seaver (1951: 155, as '*O. epispora*', eastern USA) and Raitviir (1991: 359, Far East of Russia) might fit the present concept of *O. epipora*, although Seaver's brief diagnosis (apothecia whitish-translucent) lacks data on paraphyses, and the Russian sample deviates by yellowish apothecia and strongly capitate paraphyses. Dennis (1954: 296, figs D–E) compared a collection made in Cuba (C. Wright 355, fig. E) with an authentic specimen from Finland (P.A. Karsten 725, fig. D, not examined by us), but his sketches show too narrow, partly basally tapered spores of '3–4.5 × 0.5 µm' in both samples, reminiscent of *O. cunninghamii*.

Type studies. ***O. epipora*** was described by Nylander (1869) for a polypore inhabiting fungus collected in August at Ruovesi (Tampere, Finland), with white, flat, gregarious apothecia 0.3–0.5 mm diam., clavate asci of 16–19 × 2–2.5 µm, bacilliform or acicular-fusiform spores of 3–6 × 0.5 µm, and clavate, apically flattened paraphyses. Three authentic specimens were received from H, all being collected by P.A. Karsten at Ruovesi at the same day (4.VIII.1859). Two of them are duplicates in which the apothecia grew on the pores of *Phellinus igniarius*, one bearing Nylander's handwriting, the other Karsten's. The third specimen is on an unidentified, apparently different polypore, and bears only Karsten's notes. Karsten (1861: 39) referred his two collections to *Peziza leucostigma* (see Karsten 1869: 174), whereas Nylander (1869) distinguished them by smaller apothecia, smaller asci, and narrower spores. Nylander appears to have also seen the specimen on unidentified polypore, judging from his statement in the protologue 'Supra *Polyporum igniarium* et alios'.

The present reexamination of the three specimens revealed that the two duplicates represent an *Orbilia* species with (rehydrated) flat apothecia of 0.2–0.55 mm diam., stipitate asci with a furcate base, cylindrical spores, and distinctly capitate paraphyses (Pl. 901: 4), whereas the specimen on unidentified polypore contained *Hyalorbilia inflatula*, with (rehydrated) cupulate apothecia 0.2–0.65 mm, non-stipitate asci 19–28 × 3.3–4 µm arising from croziers, cylindrical to subfusoid spores 6–7 × 0.8–1 µm, and uninflated paraphyses. Obviously, the original description predominantly refers to the *Orbilia* but appears to be also influenced by the *Hyalorbilia*, at least concerning spore length. In order to stabilize the application of Nylander's taxon, we here designate that part of the duplicate specimen which bears Nylander's notes (labelled 'In paroecia Ruovesi', H) as **lectotype** of *Peziza epipora*. The lectotype fits quite well the present concept of *O. epipora* which, however, comprises predominantly lignicolous collections. A specimen from Germany (Chemnitz, on *Salix*, ex H.B. 9039, Pl. 902: 5), from which a sequence was gained, is designated here as **epitype** of *O. epipora*.

In a syntype of ***O. sericea*** (on wood of *Populus*, Moscow, S) the apothecia measure (rehydrated) 0.3–0.8 mm diam., the paraphyses have a distinctly capitate, 2–3.3 µm wide apex, and the spores are cylindrical and slightly allantoid (Pl. 901: 6). Hennings reported the apothecia as 0.3–0.35 mm diam., the paraphyses as filiform, 0.5 µm wide, and the spores as 4–5 × 0.5 µm, fusoid. The abundant material looks homogeneous and well concurs with the type of *O. epipora*. Type material in B was destroyed during the Second World War, therefore, the examined specimen in S (herb. Sydow) is herewith designated as **lectotype** of *O. sericea* (ICN Art. 9.11, Turland et al. 2018).

Svrček (1954: 12) stated ***O. connata*** to be a synonym of *O. epipora*. This is confirmed here based on the reexamination of the holotype which contains about 1 thousand overmature apothecia growing densely gregarious on ± darkened wood of a decorticated log of *Fagus* among black setae of a hyphomycete. Although the apothecia were given by Velenovský as 1–1.5 mm diam. (rehydrated 0.3–1 mm in the present study), Svrček emphasized their 'very small' size (in the dry state), but did not provide values. He corrected Velenovský's too small spore measurements of 1–2 µm in the protologue (1–2.5 µm in the manuscript) to 3–4.5 × 0.5–0.8 µm which concurs with the present result (Pl. 901: 5).

Both Velenovský and Svrček reported the asci to be (very) coherent. Yet, this feature is due to apothecial senescence and results in the difficulty to clearly see the ascus base. Therefore, the available ascus measurements are uncertain (Svrček: †22–25 × 3 µm, 30 × 2.5–3 µm in present study). Velenovský's (1934) sketch of the asci shows long and thin, basally short bifurcate stalks but he gave too small values also here (16–20 × 2 µm). The ectal excipulum is of textura angularis up to the margin, whereas Svrček saw at the margin a t. prismatica. The paraphyses are always medium to strongly capitate, although Velenovský's protologue and sketch displays them as apically uninflated (Svrček did not clearly see them). The characters given by Svrček (1954: 8) in the key suggest that he used the name *O. epipora* in the sense of a *Hyalorbilia*.

Misapplication. *O. epipora* has repeatedly been confused with *Hyalorbilia inflatula* in the past, mainly because of its rod-shaped spores also based on the growth on a polypore. Already Nylander or Karsten confused the two species: in the protologue of *O. epipora*, Nylander cited a collection made by Karsten at the same day and site as the lectotype, but which represents *H. inflatula*. Also Saccardo (1889: 626) referred an Italian specimen on *Polyporus squamosus* to *O. epipora* which might be *H. inflatula* because of the long spores (7 × 0.75 µm). On the other hand, Otani's (1990: 260) report of *Orbilia inflatula* from Japan might refer to *O. epipora* base don the isodiametrical excipular cells, except for its wider spores.

The two Macaronesian specimens reported by Korf (1992) under the name *O. epipora* show very different spores in Korf's drawing. The present reexamination revealed that the sample with acicular spores (CUP-MM-001537, Madeira, on bark, erroneously as MM 1145 in the legend, S. Gruff pers. comm.) represents *Hyalorbilia inflatula*. The one with rod-shaped spores (CUP-MM-000245, Tenerife, on angiosperm wood) fits rather well *O. dryadum* in showing many strongly capitate paraphyses (sometimes asymmetrical) and a spore length typical of *O. dryadum* (†2.7–3.5 × 0.8–1 µm). Yet, spore width is unusually narrow and corresponds to recent records from Tenerife in being somewhat intermediate between *O. epipora* and *O. dryadum* but apparently better fitting *O. dryadum*. Also Beaton & Weste's (1979) and Liu's (2006) interpretation of *O. epipora* better fit *O. dryadum* (see p. 1389).

Not included collection. A sample on *Salix caprea* from Spain is intermediate to *O. dryadum* in having partly strongly capitate paraphyses and rather short spores of 3–3.7 × (0.9–)1 µm. For the not included type of *Dactylella polyctona* see under Anamorph.

Anamorph. The dactylella-like anamorph of *O. epipora* was so far only observed in a single collection, and here both in pure culture and on the natural substrate (Pls 901: 8g–h; 902: 1h). From the similar *O. dryadum* (section *Orbilia*) this deviates in smaller, especially narrower conidia with fewer septa.

This anamorph shows a very good match with *Dactylella polyctona* as described by Drechsler (1952, see Pl. 5: a). Conidial size and shape perfectly fit Drechsler's data (12.7–21 × 2.3–2.8 µm), also the conidiophores fit well except for being shorter in Drechsler's strain (15–30 × 2–3 µm).

Phylogeny. Two sequences of *O. epipora* were gained from apothecia: one comprising SSU (V7–V9), ITS, and LSU (D1–D2, Chemnitz, H.B. 9039), and one SSU (V9), ITS, and LSU (D1–D3, Deux-Sèvres, H.B. 9489). In their overlapping parts the two sequences are completely identical. In both the S1506 intron is absent.

The phylogenetic analyses of SSU+ITS+LSU in Baral et al. (2017b) and Phyl. 7 placed *O. epipora* with medium or low support sister to the rest of section *Arthrobotrys* and more distant from section *Orbilia*. The ITS distance to any other member of section *Arthrobotrys* is rather high, the lowest percentage being to 14.5% to *Orbilia* sp. XJ-2009, 15.5–16% to *O. cupressi* and *O. fraxini*, and 18% to *O. atlantis*. Unexpectedly high distances were noted to *O. dryadum* s.l. (~23–26%) and *O. cunninghamii* (23–23.5%). On the contrary, the minimum distance in the LSU is around 6–7% to members of series *Orbilia*, but 7–8% to those of series *Neodactylella*.

Map 144. Known distribution of *O. epipora* in Europe.

Specific nucleotide positions. When looking at characteristic nucleotide positions of the 5.8S region, *O. epipora* shows affinities to different groups of *Orbiliaceae* but not to section *Orbilia*: pos. 132–133 has CC**TT**T which is typical of many species of series *Neodactylella* and *Arthrobotrys* (besides CC**A**T**T** and CC**GG**T, see Tab. 18), whereas all members of section *Orbilia* have CC**GA**C or CC**GA**T; pos. 140 has GCA**T**G in concordance with all members of section *Arthrobotrys* and many of other groups, whereas all members of section *Orbilia*, some other groups of *Orbilia*, and *Hyalorbilia* p.p. have GCA**C**G.

Characteristic motifs also occur in the LSU D1–D2 domain, some of which being more or less unique to *O. epipora*. Further nucleotides support placement in section *Arthrobotrys*: (1) at pos. 163 *O. epipora* has **T** (GC**T**TC) in common with many other *Orbiliomycetes*, including all members of section *Arthrobotrys* (mostly GT**T**TC), whereas almost all of section *Orbilia* have **C** (mostly GC**C**TC); (2) at pos. 253 *O. epipora* has **A** (GA**A**GC) as many other *Orbiliomycetes*, including all members of section *Arthrobotrys* (which have mostly GA**A**AC), whereas section *Orbilia* has always **G** (mostly GT**G**GC).

Within section *Arthrobotrys*, *O. epipora* fulfils all specific nucleotide positions listed for series *Neodactylella* in Tab. 76. For example, at pos. 30 of 5.8S (TTC**T**CGC) and pos. 332 of LSU (G**A**GAGA) *O. epipora* concurs with series *Neodactylella* but differs from all nematophagous species of *Arthrobotrys* having TTC**C**CGC and G**G**GAGA. However, the 2 positions in *O. epipora* are also typical of series *Orbilia* and most other groups of *Orbiliomycetes*.

Ecology. *O. epipora* was found on rotten wood (rarely bark) of hygric branches and logs (rarely twigs) of predominantly *Salicaceae* {17} and *Fagus* {8}, also on polypores, in thermoboreal (type), atlantic to continental, planar to colline, cold- to warm-temperate humid Europe. The vegetation comprises (boreo) nemoral forests such as *Fagetea*, swampy forests with *Salix*, *Populus*, *Betula*, *Alnus* etc., or a *Pinus-Betula* forest in a quarry. *O. epipora* occurs also in warm-temperate humid eastern North America, orotemperate southeastern Europe (Caucasus, forest with *Tilia platyphyllos* and *Ulmus*), boreal (cold-continental) humid central Asia (Altay, *Pinus sibirica-Abies sibirica* forest), and in warm-temperate humid (monsoon-influenced) continental central China. Cash (1938) listed for Hawaii collections on *Artocarpus* and *Mangifera*, but these need reexamination.

D. polyctona was isolated from forest humus near Hermiston (Oregon, North America) and was found to parasitize testaceous rhizopods (*Arcella vulgaris*), oospores of *Pythium spinosum*, and cysts of a myxobacterium (*Polyangium* sp.).

Orbilia rectispora (Boud.) Baral, in Liu et al., Fungal Diversity 22: 116 (2006) — Pls 903–904, Map 145

≡ *Hyalinia rectispora* Boud., Hist. Class. Discom. Eur: 103 (1907)
≡ *Pezizella rectispora* (Boud. 1907) Sacc. & Traverso in Traverso, Syll. Fung. 20: 321 (1911)
= *Orbilia arundinacea* Velen., Monogr. Discomyc. Bohem.: 99, pl. 11 fig. 32 (1934)
?= *Orbilia arundinacea* var. *hypothallosa* Velen., Monogr. Discomyc. Bohem.: 99, pl. 11 fig. 33 (1934) (non *O. hypothallosa* Velen. 1947)
= *Dactylella nuorilangana* X.F. Liu & K.Q. Zhang, in Zhang & Mo, Fl. Fung. Sinicorum (Beijing) 33: 79 (2006)

Etymology: *rectispora*: referring to the straight ascospores; *arundinacea*: growing on reed; *hypothallosa*: after the hyphae around the apothecia; *nuorilangana*: referring to the Nuorilang waterfall in the north of Sichuan.

Typification: France, Paris, leaves of *Scirpus silvaticus*, VII., É. Boudier (holotype of ***Hyalinia rectispora***, illustration in Boudier 1909: pl. 467); Germany, Chemnitz, *Typha* leaves, 1.VI.2002, B. Mühler (ex H.B. 7142, M-0276578, epitype, designated here, MBT202388; ex-epitype culture: CBS 140813; sq.: KT215289, MH878185). — Czechia, Kosoř, *Phragmites australis* culms, VI.1927, J. Velenovský (PRM 151743, lectotype of ***Orbilia arundinacea***, designated by Svrček 1954: 10). — Czechia, Zvánovice, *Juncus communis*, V.1927, J. Velenovský (holotype of ***O. arundinacea* var. *hypothallosa***, illustration in Velenovský 1934). — China, Sichuan, Jiuzhaigou, Nuorilang, 7.VI.2003, soil isolate, X.F. Liu (type of ***Dactylella nuorilangana***, YMF 1.00582).

Misapplied names: Beyer (1998: 191), as *O. luzularum*; Svrček (1954: 11 p.p.), as *O. cardui*.

Misinterpretation of *O. rectispora*: Grelet (1948b: 107, as *Hyalinia rectispora* var. *majuscula*), = *Hyalorbilia inflatula*; Liu (2006: 102 p.p.), Liu et al. (2006b: 116 p.p.), Liu et al. (2006a p.p.), = *O. sinensis* & *O. tenuispora*.

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated (0.15–)0.3–1(–1.5)((–2.3)) mm diam., 0.08–0.25 mm high (receptacle 0.06–0.16 mm), whitish to pale cream to isabelline, medium to strongly translucent, round, somewhat lobate when large, medium scattered to densely gregarious; disc flat, slightly to medium convex with age, margin distinct, thin, not protruding, smooth; broadly sessile or with a (very) broad stipe ~0.02–0.04 × 0.1–0.27 mm, superficial; dry light cream to yellowish-ochre. **Asci** *(30–)33–41 × 3.3–4.2 µm {4}, †(24–)27–34(–38) × (2.7–)2.9–3.4(–3.8) µm {11}, 8-spored, spores *4-seriate, 3–4 lower spores inverted {5} (not or rarely mixed), pars sporifera *14–19 → 8–11 µm long; **apex** (†) slightly to strongly truncate (not or slightly indented, laterally not or slightly inflated); **base** with short to medium long, thin or thick, slightly flexuous stalk, Y- to h- or H-shaped. **Ascospores** *(5–)6.5–9.5(–11) × (0.9–)1–1.2(–1.3) µm {11}, †5–9 × (0.8–)0.9–1.2 µm {6}, narrowly (sub)cylindric(-clavate) to fusoid-clavate, apex rounded to obtuse, base not or slightly to medium (to strongly) attenuated, straight to often slightly (to medium) curved especially towards base, sometimes very slightly helicoid; **SBs** *0.5–0.9 µm diam. {7} (1–1.8 µm total length), globose, with a short and fine, mostly invisible filum. **Paraphyses** apically uninflated to mostly slightly (rarely medium) capitate(-clavate), terminal cell *14–23 × (2.5–)3–4(–5) µm {4}, †15–22 × 2–3.3 µm {3}, lower cells *(3.5–)4.5–7(–9) × (2–)2.5–3(–4.5) µm {4}, †(2.2–)3.5–6(–9) × 1.8–2.2(–2.5) µm {2}; unbranched at upper septum. **Medullary excipulum** 15–70 µm thick, of dense textura globulosa-angularis(-intricata),

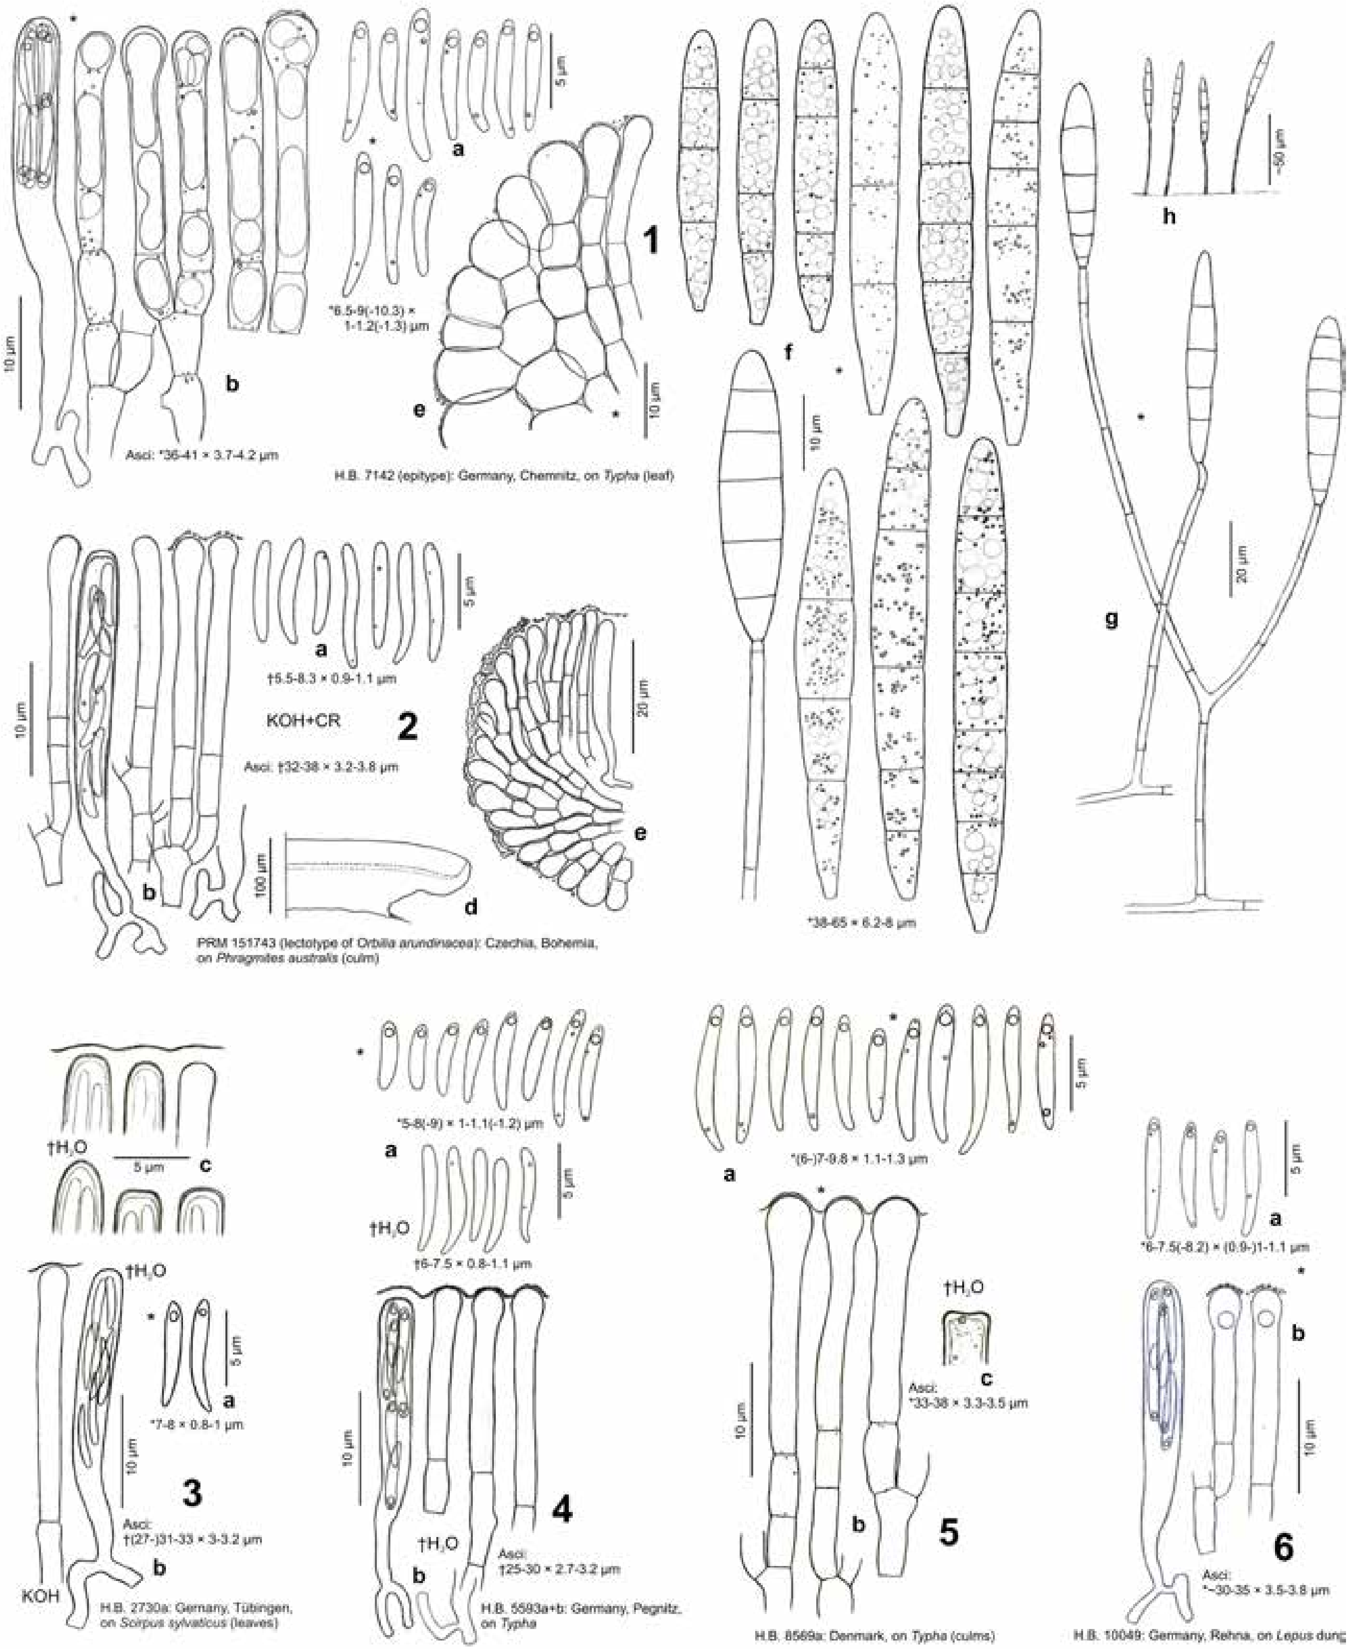

Plate 903. **1–6**: *Orbilia rectispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices (**3c** with 1 paraphysis apex); **d**. apothecium in median section; **e**. id., ectal excipulum at margin; **f–h**. conidia and conidiophores (all from culture; **h**: in situ on agar surface).

medium to sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled, vertically oriented t. globulosa-angularis(-prismatica) from base to margin, 25–150 µm thick near base, cells *10–30(–40) × (7–)10–25(–30) µm {4}, †(9–)13–25(–45) × (6–)10–20(–30) µm {2}, 10–20 µm thick near margin, oriented at a 45–90° angle to the surface, marginal cortical cells *7.5–16.5 {4} × 4–4.5(–6.5) {1} or 5–8(–9) µm {3}, †7–12 × (3–)4–5.5(–6.5) µm {2}; **glassy processes** absent {11}. **Anchoring hyphae** (very) abundant, */†1.5–3(–3.5) µm wide (4–5 µm near insertion), walls 0.2 µm thick {5}, forming a ± dense to very loose, slightly gelatinized t. intricata(-porrecta) 10–100 µm thick. **SCBs** not observed {3}; **VBs** (very) slightly refractive, globose to elongate {1}, or absent {3}; excipular cells near base often with some 1–3.5 µm large **LBs** in each cell {4} but also without. **Exudate** over paraphyses 0.1–0.3(–0.5) µm thick, finely granular to almost smooth, scattered to continuous, sometimes absent, loosely attached; over margin and flanks very sparse to contiuous, 0.2–2 µm thick, granular to cloddy or almost absent. — **ANAMORPH**: dactylella-like (from ascospore isolate {1} and natural substrate {4}). **Conidiophores** *85–170 {1, Europe} or 30–80 µm long {China}, 2–2.5 µm wide near base, 1.5–1.7 µm at the tip {1}, rarely branched in lower or middle part. **Conidia** phragmosporous, *37–67 × 5.3–8 µm {1, Europe}, 42–62 × 4.5–7.5 µm {1, China}, cylindric- to fusoid-clavate or often cylindric-fusoid, rounded to obtuse at the tip, (1–)3(–7)-septate {1, China}, 3–7-septate {3, Europe}.

Habitat: lying on wet ground or standing in water (above water level), on decayed previous year's leaves, leaf sheaths and culms of *Glyceria* sp. {1}, *Iris pseudacorus* {2}, *Phragmites communis* {1}, *Typha* sp. {7}, *T. angustifolia* {1}, *T. latifolia* {6}, *Scirpus silvaticus* {6}, *Sparganium erectum* {1}, dung of *Lepus europaeus* {1}, with or without blue and green algae and diatoms. **Associated**: *Acanthophiobolus helicosporus* {1}, *Cistella albidolutea* {1}, *Psilachnum lateritioalbum* {2}, *Pyrenopeziza inapiculata* {1}, *Rodwayella citrinula* {1}, *Scutellinia ?scutellata* {1}. **Desiccation tolerance**: drought-intolerant, ascospores still viable after 1 month. **Altitude**: 1–450 m a.s.l. (Europe), 2350 m (China). **Geology**: Devonian limestone & shale, Permian (Rotliegend), Buntsandstein, Keuper (gypsum & sandstone), Middle Jurassic & Cretaceous limestone, Tertiary & Quaternary marl, silt & sand; granite. **Phenology**: III–X (teleomorph).

Taxonomic remarks. *Orbilia rectispora* is characterized by narrowly cylindrical to fusoid-clavate, often slightly curved ascospores with a globose spore body somewhat below the apex, mostly only slightly capitate paraphyses with sparse exudate, and by the absence of glassy processes. For the closely related *O. xinjiangensis*, the plurivorous *O. cardui* and *O. atlantis*, and the coprophilous *O. leporina* see under these species. The lignicolous *O. longquanensis* (p. 1465) has similar conidia as *O. rectispora* but differs in yellowish apothecia and smaller, basally less tapered spores. The lignicolous *O. mammillata* (series *Dactylellina*) resembles *O. rectispora* in spore size and shape, but differs in elongate, visibly attached SBs which, however, may become subglobose with age, wider asci, presence of glassy processes, and in a dactylellina-like anamorph. *O. auricolor* (series *Arthrobotrys*) differs in longer, consistently curved spores and an arthrobotrys-like anamorph. An altimontane collection on *Carex* (Pl. 912: 3) differs from *O. rectispora*, e.g., in much longer asci and wider spores.

Variation. *O. rectispora* varies rather strongly in spore length, also in the strength of tapering and curvature of the spore bases, even within a collection. The lectotype of *O. arundinacea* differs from the other included specimens in rather abundant exudate on the margin, also it has rather thin apothecia and small basal excipular cells (†9–18 × 6–10 µm), whereas in collections with thicker apothecia, including the epitype, the cells showed often, though not always, about the double diameter. The collection on hare dung did not differ from those on monocots (Pl. 903: 6).

Type studies. Boudier (1907: 103) described ***O. rectispora*** based on a single collection (Paris, Bois d'Ecouen, base of rotten leaves of *Scirpus sylvaticus*, in July). Shortly later, Boudier (1909: 270, pl. 467) published a colour drawing showing the holotype collection. Here he mentioned to have found the species also in Forêt de Montmorency. Grelet (1948b: 106) merely copied Boudier's description. Regrettably, neither of Boudier's collections could be located at PC. In the absence of type material, Boudier's illustration (pl. 467) is considered here as **holotype** of *O. rectispora* (ICN Art. 8.1, 40.4, Turland et al. 2018).

Boudier described the species as follows: apothecia 0.3–0.6 mm diam., gregarious, flat then convex, pale greyish-yellowish, with indistinct smooth margin; asci 33–38 × 2.5–3 µm [30–32 × 3 µm when evaluated from his plate], with a truncate apex and a narrowed base with often 2 long and thin branches (bifurcate); spores cylindrical, 7–9 × 1.5 µm [7–9.5 × 1–1.4 µm according to his plate], both ends obtuse to subacute, straight or sometimes (very) slightly curved, rarely subflexuous, eguttulate; paraphyses uninflated at apex, 1–1.5 µm wide. Although the description does not provide information on the spore body and on the absence of glassy processes at the margin, the holotype appears to fit very well the present concept of the species as being already applied in Baral & Krieglsteiner (1985: 25). We here designate a recent collection from Sachsen (on *Typha*, H.B. 7142, M-0276578) as **epitype** of *Orbilia rectispora*. From this specimen a pure culture (CBS 140813) and a sequence was gained.

Velenovský (1934) described ***O. arundinacea*** for collections on various monocotyledonous plants (*Phragmites*, *Glyceria*, *Juncus*, *Sparganium*, *Acorus*, *Triticum*), with sparse, convex, white to rose or wine-yellowish apothecia of 1–5 mm diam., with an often slightly lobate margin and a large-celled excipulum, asci 25–30 × 5–6 µm, uninflated paraphyses covered by rather thick exudate, and straight, acicular spores of 6–10 µm. Except for that on *Sparganium*, Svrček examined all of them, which he considered to be conspecific with *O. cardui*. Apparently, Svrček did not compare Boudier's *Hyalinia rectispora*, the description of which much resembles *O. arundinacea*. The lectotype of *O. arundinacea* on *Phragmites* contains six mature apothecia (rehydrated 0.4–0.8 mm diam., Pl. 903: 2). It fits well the present concept of *O. rectispora*, except for the more abundant exudate on the margin. On his manuscript plate of that specimen Velenovský measured and depicted the spores much too narrow ('6–10 × 1/4 µm').

Under the name O. *arundinacea* Ellis & Ellis (1985) reported *O. rectispora* on *Typha*, with very large apothecia (1–5 mm) and narrow spores (6–10 × 0.5–1 mm). Except for spore width these data seem to be copied from Velenovský's protologue.

No material of ***O. arundinacea* var. *hypothallosa*** exists fide Svrček (1954). Velenovský separated this variety from *O. arundinacea* by an abundant subiculum and wider spores. According to his manuscript plate, the single collection was made in the valley of Zvánovice in May 1927 in a swamp on culms of *Juncus communis*. These data are lacking in the very brief protologue which contains the misprint 'in Juneo' instead of 'in Junco'. On his manuscript plate some paraphyses are figured with a row of distinct guttules (VBs), and the ascus bases as H-shaped. The question remains open whether this represents *O. rectispora* or perhaps *O. cardui* which was once found on a monocot (*Luzula*).

Misapplication. Previous authors have not distinguished between *O. rectispora*, which is adapted to monocots, and *O. cardui*, which almost exclusively growing on dicots. E. g., Svrček (1954, 1986b) considered *O. arundinacea*, a taxon here referred to synonymy with *O. rectispora*, to be (probably) conspecific with *O. cardui* (see p. 1460). Beyer (1998: 191) reported under the name *O. luzularum* a fungus on *Typha* (4 collections, all from the same locality, W. Beyer pers. comm), which is referred here to *O. rectispora*. Beyer illustrated and measured the spores unusually wide (*6–8 × 1.8–2 µm), contrary to the present examination of two of these specimens which yielded much narrower spores, although his ascus measurements (†25–32 × 3 µm) match those gained here (Pl. 903: 4).

Due to a similar size and shape of the spores, *O. rectispora* has sometimes been confused with *Hyalorbilia inflatula*. Grelet

Plate 904. **1–7**: *Orbilia rectispora*. – **2a**. *Phragmitetum* marshland with *Iris pseudacorus* (not on photo); **1a–c**, **2b–e**, **4**, **7a–b**. fresh apothecia; **1d**, **2f**. apothecia in median section; **1e**, **2h**, **6**. id., marginal ectal excipulum; **2g**. id., basal excipular cells; **1f**, **3b**, **5**, **7c**. ascospores; **3a**. ascus apices; **7e**. ascus with H-shaped base; **7d**. paraphysis; **1g**, **2i**. conidia from substrate. – Living state, except for **6** (KOH), asci in **3a**, **7e**. – **2a**: phot. H.B. 9554: Germany, Chemnitz, on *Typha*; **4**. H.B. 7142 (epitype): ibid., on *Typha*; **5**. H.B. 9549: Great Britain, Barnsley, on *Typha*; **6**. H.B. 2730a: Germany, Tübingen, on *Scirpus*; **7a–e**. E.R.D. 4770: Spain, Avilés, on *Typha*.

(1948b) described *Hyalinia rectispora* var. *majuscula* on the basis of several lignicolous specimens which bear the label '*Hyalinia rectispora*'. One of them shows the remark 'vidit Boudier'. Five such specimens identified by Grelet were received from PC, all of which belong to *Hyalorbilia inflatula* (see p. 345).

Liu (2006: 102) reported 10 Chinese collections under the name *O. rectispora* which grew mainly on wood and bark, a single time also on a polypore. Two of them are from Tibet and were separately desecribed in Liu et al. (2006b: 116). Based on a later reexamination of a few of them during the present study, and on molecular data gained by B. Liu, they belong to series *Pseudotripoconidium* of section *Helicoon*, either to *O. sinensis* or to *O. tenuispora* (see under these species).

Not included collections. A Chinese specimen growing on leaves of *Pandanus tectorius* was reported by Liu (2006: 62) and Liu et al. (2007a) under the name *O. cardui* (HMAS 139519). With its straight, basally slightly tapered spores (5.2–6.2 × 1.1–1.6 µm) it seems indeed to fit *O. cardui*, but it differs in much shorter asci (†21–28.2 × 3–4.2 µm), sparse exudate, and in the absence of glassy processes. *O. rectispora* resembles this collection but differs in longer and narrower spores, also *O. quercus* (series *Dactylellina*) and *O. bambusina* (incertae sedis) differ in narrower spores. No anamorph was obtained in pure culture. Based on its molecular data, this collection belongs neither to *O. rectispora* nor to *O. cardui* (see below). For the not included *O. rectispora* var. *hypothallosa* see under Type studies.

Anamorph. The dactylella-like anamorph of *O. rectispora* obtained in pure culture deviates from that of *O. cardui*, *O. cotoneastri*, and *O. crenatomarginata* in somewhat longer conidia of a more fusoid shape (Pl. 903: 1f–h). Similar conidia are found in two Chinese taxa, *Dactylella panlongana* Xing Z. Liu & K.Q. Zhang (from soil, Yunnan) and *D. nuorilangana* (from soil, Sichuan). The former has somewhat longer conidia with more septa (up to 11–12, mostly 8–9), while the latter matches the anamorph of *O. rectispora* quite well (see Pl. 5: o). The also similar *D. ramosa* Matsush. (on *Ficus* leaf, Solomon Islands) differs in slightly narrower conidia and much more branched conidiophores. *D. submersa* (Ingold) Sv. Nilsson (on *Quercus* leaves in streams, Great Britain) differs in conidia with less attenuated bases, being 0–1-septate when liberated.

Phylogeny. A sequence comprising SSU (with S1506 intron), ITS, and LSU was gained from the ex-epitype culture of *O. rectispora* (H.B. 7142). In the combined analysis in Baral et al. (2017b) *O. rectispora* clustered in a strongly supported clade with *O. cotoneastri* and *O. xinjiangensis*, which is referred to as *rectispora-beltraniae* clade here. In the present ITS and combined analyses which include more taxa (Phyls 26, 27), the *rectispora-beltraniae* clade received medium or strong support and comprises also *Dactylella panlongana*, *D. ramosa*, *D. clavata*, and *O. beltraniae*, and *O. longquanensis* and *O. senegalensis* in a sister-positioned subclade. When analysing LSU (S31), the *rectispora-beltraniae* clade was paraphyletic and included also *D. implexa*, for which only LSU was available.

Sequences also exist of the ex-type strain of *D. nuorilangana* (SSU V1–V3, S1506 intron, ITS, *MAD1*, *TEF1*, *RPB2*, mtLSU). In the ITS it differs from the epitype of *O. rectispora* by only 0.2 %, i. e., 1 nt in the ITS2 and 3 gaps or inserts. Hence, we consider both taxa as conspecific. An environmental sequence from soil of the Tibet Plateau (OTU138) differs by 1.6 % from the epitype and 1.8 % from *D. nuorilangana*. The next close match was *D. panlongana* with a 6 % distance, and the other taxa of the clade showed distances of 7–10 %. *D. rhopalota*, *O. cardui*, and *O. epilobii* clustered in a separate clade and show distinctly higher distances. No sequence of *D. submersa* exists.

In the S1506 intron, however, the distance between *D. nuorilangana* and the epitype of *O. rectispora* is 5 %. In this region *O. rectispora* differs from *O. cotoneastri* by 12.5–15 % and from other members of section *Arthrobotrys* by min. ~16 %. For OTU138 the intron is unavailable because of the used ITS1 primer. In the LSU (D1–D2) the lowest distance of *O. rectispora* was to *O. cotoneastri* (2.2 %), whereas other available strains differ by > 3.5 %.

Map 145. Known distribution of *O. rectispora* in Europe.

A sequence of the Chinese '*O. cardui*' specimen on *Pandanus* (HMAS 139519) comprises the ITS region (the S1506 intron is absent). It clustered in the phylogenetic analysis of Liu et al. (2006a) with the type of *Dactylella clavata*. In our analysis (Phyl. 26), both fall in the *rectispora-beltraniae* clade, HMAS 139519 forming with 7–8 % distance a strongly supported clade with 2 unnamed Chinese strains with incomplete ITS, the clade showing a 10–11.5 % distance to *O. rectispora*.

Ecology. *O. rectispora* appears to be restricted to monocotyledonous hosts at ponds and in marshes such as *Caricetea*, *Phragmitetea*, and *Filipendulion ulmariae*. The inhabited dead leaves and culms are soaked with the usually very near groundwater, and in swamps with standing water the apothecia occur just above the water level. Also the sample on hare dung was close to water and regularly flooded. The species was recorded from atlantic to subcontinental, supra- to thermotemperate humid Europe at planar to colline altitude. In contrast to this, the type of *D. nuorilangana* was isolated from soil below the Nuorilang water fall in a orotemperate humid, altimontane region of the Jiuzhaigou mountain range in northern Sichuan at the northeastern end of Himalaya (X.Z. Liu pers. comm.). Unpreserved and undocumented records of *O. rectispora* by Deny (2002) were also from an orotemperate region in central Europe (Vosges, on *Scirpus sylvaticus*, see also under *O. epilobii*, p. 1470). B. Liu's deviating Chinese collection on *Pandanus* is from a tropical humid (winter-dry) area in the southern part of the Hainan island which represents the southernmost part of China, and the Qinghai soil sample is from a continental subhumid tree- and shrubless grassland in a mountain steppe in eastern China.

Specimens included. **GREAT BRITAIN**: **Yorkshire**, **South Yorkshire**, 3.5 km S of Barnsley, 1.5 km SW of Worsbrough, Worsbrough Country Park, 72 m, leaves of *Typha latifolia*, 20.V.2011, H.O. Orbilia xinjiangensis (J. Chen, L.L. Xu, B. Liu & Xing Z. Liu) E. Weber, Baral & Helleman, **comb. nov.**, MB 831502 — Pl. 905

Basionym: *Dactylella xinjiangensis* J. Chen, L.L. Xu, B. Liu & Xing Z. Liu, Fungal Diversity 26(1): 113 (2007)

Etymology: named after the geographical origin of the type, Xinjiang province (China).

Typification: China, Xinjiang, Huocheng, soil isolate, VIII.2003, X.Z. Liu (HMAS 140511, holotype; ex-type culture: CGMCC (AS) 6.0288; sq.: DQ494363).

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated (0.3–)0.4–1(–1.3) mm diam., 0.2–0.25 mm high (receptacle 0.15–0.22 mm), whitish-greyish to pale yellowish-cream, medium translucent, ± round, slightly lobate when large, subgregarious; disc flat to medium convex, margin distinct, thin, 5 µm protruding, smooth; broadly sessile, superficial; dry flat, light ochraceous(-cream). **Asci** †(40–)45–55(–60) × 4–5 µm, 8-spored, spores †2-seriate, lower spores inverted; **apex** (†) medium truncate (not indented, laterally not inflated); **base** with short to long, thin to thick, ± flexuous stalk, L-, h- or H-shaped. **Ascospores** *6–9(–10)((–12.2)) × (1.4–)1.6–2(–2.3) µm, †7–9(–10) × 1.8–2(–2.2) µm, narrowly (ellipsoid-)clavate, apex obtuse, base medium to strongly attenuated, often tail-like, straight to (very) slightly curved; **SBs** *0.6–0.7 µm diam., globose, partly ± eccentric, attachment invisible (total length 1.1–1.5 µm). **Paraphyses** apically slightly to medium (clavate-)capitate, terminal cell †13–20 × 2–3.3(–4) µm, lower cells †9–12 × 1.5–2(–2.5) µm; sometimes branched at upper septum. **Medullary excipulum** 40–70 µm thick, of dense textura intricata with inflated cells, indistinctly or sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled, irregularly to vertically oriented t. globulosa-angularis from base to margin, 120–140 µm thick near base, cells *8–19 × 8–14 µm; 40–110 µm thick at lower flanks, cells *8–13 × 6–11 µm; 25–20 µm thick near margin, oriented at an 80–90° angle to the surface, marginal cortical cells *(6–)8–11(–13) × 4.5–7(–8) µm; **glassy processes** absent. **Anchoring hyphae** medium abundant, †1.7–3.5 µm wide, walls 0.2 µm thick. **SCBs** not observed; **VBs** absent. **Exudate** over paraphyses, margin and flanks 0.2–0.5(–1.5) µm thick, granular-cloddy, hyaline to pale yellowish, firmly attached. **— ANAMORPH**: dactylella-like (from soil isolate {1} and natural substrate {1}, connection proved by DNA). **Conidiophores** 60–132 µm long, 2.5–4.5 µm wide at base, 1–2 µm at apex, unbranched. **Conidia** unbranched, straight, ellipsoid-clavate, ± obtuse at apex, *(39.5–)45–54(–59) × (7–)8–11(–12) µm, ((3–))(5–)7-septate {2}. **Chlamydospores** often produced abundantly in culture.

Habitat: 15 cm thick cut stump of *Ulmus* sp. {1}, 10 cm above the ground, on detaching, slightly undecayed bark {1} (bast), on inner surface and on edge. **Associated**: none observed. **Desiccation tolerance**: after ~3 weeks excipular cells and a few ascospores viable. **Altitude**: 12–700 m a.s.l. **Geology**: Netherlands: Pleistocene fluviatile deposits. **Phenology**: XII (teleomorph).

Taxonomic remarks. *Orbilia xinjiangensis* resembles *O. zhongdianensis*, particularly in the shape of the basally tapered ascospores which contain near the apex a small, globose, partly eccentrical spore body. It differs in distinctly larger spores and larger conidia with more septa. In gross morphology the species is difficult to distinguish from other taxa of this group, such as *O. rectispora*, *O. cardui*, and *O. leporina* (including the type of *O. luteorubella* f. *charticola*). *O. cardui* differs in glassy processes at the margin and smaller, basally often untapered spores which contain larger SBs, and the other two in predominantly curved, partly narrower spores.

On the cut upper edge of bark a small population of immature apothecia occurred (Pl. 905: 1d) which undoubtedly belong to the same species. They differed mainly in a more intense, yellowish-cream colour when fresh, probably because they were more exposed to light.

Anamorph. Conidial size and shape in the sample from the Netherlands (*40–59 × 7.5–11.5 µm, mainly 5–7-septate, Pl. 905: 1g) fit quite well the type of *Dactylella xinjiangensis* (*39.5–54 × 7–12 µm, mainly 7-septate, Pl. 905: 2). The conidia were observed by S. Helleman on the natural substrate, but only in association with those immature apothecia growing on the edge of bark. On the plate of *D. xinjiangensis* in Chen et al. (2007b) we believe that fig. 18C and F have the same scale as E, though bearing the shorter scale of B and D which is only 83 % of that in E. Therefore, we have reduced in Pl. 905: 2 the image size of C and F accordingly.

Phylogeny. Sequences were available for the ex-type strain from soil (ITS, presence of S1506 intron unclear because of the used ITS1 primer) and for the *Ulmus* specimen (from apothecia; SSU without S1506 intron, ITS, LSU). In the ITS region the ex-type strain fully matches the collection from the Netherlands by only 1 gap difference. Strain CBS 232.51 under the unpublished name *Dactylella horrida* (Vu et al. 2019: suppl. 1) or *Dactylella* sp. (GenBank) differs by 2 nt and 1 gap (0.4 %). The minimum distance to other species is 6.3 % to *O. beltraniae*, 7 % to *D. clavata*, and 8–9 % to *O. cotoneastri*, *D. panlongana*, *D. ramosa*, and *O. rectispora*. Although morphologically similar to *O. xinjiangensis*, *O. zhongdianensis*

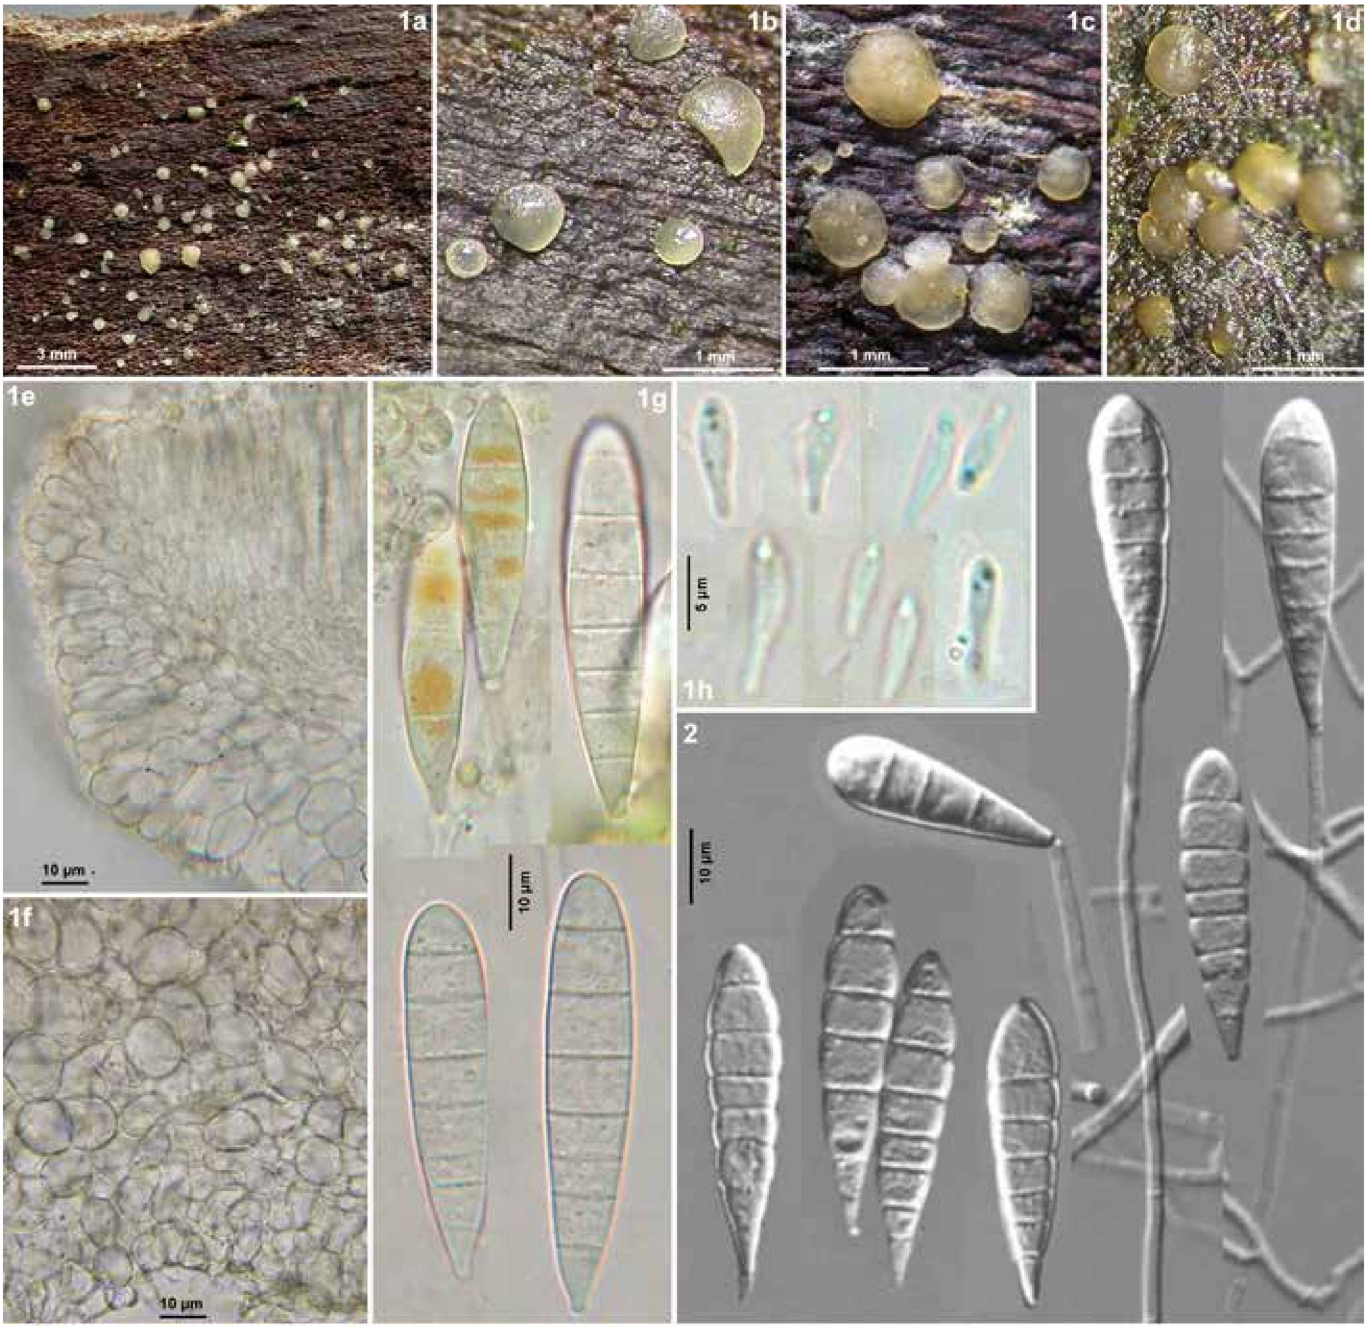

Plate 905. **1–2**: *Orbilia xinjiangensis*. – **1a**. inner surface of *Ulmus* bark with rehydrated apothecia; **1b–d**. fresh or rehydrated apothecia; **1e**. marginal ectal excipulum in median section; **1f**. id., ectal excipulum at base; **1h**. ascospores; **1g**, **2**. conidia and conidiophores (**1g** from substrate, **2** from soil isolate). – Living state. – **1b**, **d–e**, **g–h**: phot. S. Helleman, **2**: from Chen et al. (2007b). — **1a–h**. H.B. 9646: Netherlands, Nijmegen, on *Ulmus*; **2**. HMAS 140511 (holotype): China, Xinjiang, from soil.

and *O. epilobii* clustered in the *cardui-rhopalota* clade by showing a high distance to *O. xinjiangensis*. When analysing LSU, *O. xinjiangensis* shows to *D. implexa* and *D. clavata* a distance of 3.2–3.4 % in the overlapping region of D1–D2 (533 nt), and 5.3 % (584 nt) to *O. zhongdianensis*. *O. xinjiangensis* clustered in the *rectispora-beltraniae* clade (Phyls 25–27).

Ecology. Apothecia of *O. xinjiangensis* were found on slightly decayed, hygric bark of an *Ulmus* stump in an open park vegetation in subatlantic, cold-temperate humid northwestern Europe. The type was isolated from soil at the continental, cold-temperate (sub)humid northern foothills of the Tian Shan mountain range in eastern Xinjiang not far from the border to Kazakhstan in central Asia.

Specimens included. **CHINA**: **Xinjiang**, **Ili Kazakh**, Tian Shan Mts., 18 km NNW of Huocheng, Qingshuihezhen, 700 m, soil isolate, VIII.2003, X.Z. Liu (HMAS 140511, **holotype**; CGMCC (AS) 6.0288 ex-type culture [erron. as 6.0287 in Chen et al. 2007b: 113, J. Chen pers. comm.], conid. isol., doc. vid.; sq.: DQ494363). — **NETHERLANDS**: **Gelderland**, 5.5 km SW of Nijmegen, W of Meijhorst, Staddijkpark, 12 m, stump of *Ulmus*, on bark, 18.XII.2011, S. Helleman (H.B. 9646, anam. substr.; sq.: KT222435). — **GREAT BRITAIN**: unlocalized, 1948, collector unknown (CBS 232.51, IMI 24480, as *Dactylella horrida*, see Vu et al. 2019, sq.: MH856835, MH868351).

Misinterpretation of *O. cardui*: Beyer (1998: 191, as *O. luzularum*), = *O. rectispora*; Liu et al. (2006: 62, 2007a), = *O.* aff. *rectispora*; Raitviir (1991: 359 p.p.), = *O. cookei*; Svrček (1954: 11 p.p.), = *O. rectispora* & *O. oxyspora*.

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated (0.3–)0.5–1.5(–2.3) mm diam., 0.17–0.35(–0.5) mm high (receptacle 0.18–0.2 → 0.09–0.13 mm), whitish to very pale (yellowish-) cream(-isabelline), slightly to medium translucent, round, slightly lobate when large, scattered to subgregarious; disc flat to slightly (to medium) convex, margin distinct, not or slightly protruding, smooth or often rough to finely crenulate; broadly sessile, superficial; dry light yellowish-ochraceous(-orange). **Asci** *34–45 × 3.6–4.3 µm {2}, †31–44((–54)) × (3–)3.3–3.5(–3.7) µm {6}, 8-spored, spores *3–5-seriate, (2–)3–4 lower spores inverted {3} (sometimes mixed), pars sporifera *12.5–21 µm long (†17–20 µm); **apex** (†) slightly to medium (rarely strongly) truncate (rarely very slightly indented and laterally inflated); **base** mostly with short to long, thin, flexuous stalk, L-, Y-, h- or H-shaped. **Ascospores** *(5–)5.5–7.5 × (1.2–)1.3–1.5(–1.7) µm {5}, †(4–)5–7.3(–7.8) × (1–)1.2–1.3(–1.5) µm {4}, subcylindric to sometimes fusoid-clavate, apex rounded to obtuse, base not or slightly to medium attenuated, straight to very slightly curved; **SBs** *1.2–1.7 × 0.4–0.9 µm {3}, globose to tear-shaped, apically narrowed to a (very) short filum. **Paraphyses** apically uninflated or (very) slightly (exceptionally medium) clavate-capitate, terminal cell *16–21(–26) × 2.3–3.5 µm {2}, †(10–)13–20(–24) × (1.7–)2–3.4 µm {4}, lower cells *4.5–9 × 1.8–2.5(–2.8) µm {2}, †(2.5–)4–8(–10) × 1.6–2.2(–2.7) µm {3}; rarely branched at upper septum. **Medullary excipulum** 30–100(–300) µm thick, of dense textura globulosa-angularis(-prismatica), distinctly delimited from ectal excipulum mainly at flanks by a horizontal t. prismatica-porrecta, towards hymenium of a sharply delimited, 20–30 µm thick horizontal t. porrecta-intricata. **Ectal excipulum** of thin-walled, vertically oriented t. globulosa-prismatica from base to margin, 70–150 µm thick near base, cells *13–31 × 11–23 µm {2}; 50–60 µm thick at lower flanks, cells †6–18 × 5–11 µm {2}; 15–30(–60) µm thick near margin, oriented at a 40–90° angle to the surface, marginal cortical cells */†(5–)6–13(–15) × 3–7 µm {7}; **glassy processes** 2–15 × (3–)4–5(–6) µm {8}, or only 1–2 µm long {2}, low- to highly-refractive, stratified, ± coherent, straight to ± outwards curved. **Anchoring hyphae** ± abundant, */†1.5–4 µm wide (at insertion up to 4 µm), walls (0.15–)0.2(–0.3) µm thick {5}, forming a 15–35 µm thick, loose or dense, partly slightly gelatinized t. intricata(-porrecta). **SCBs** not observed; **VBs** absent {2} or slightly to medium or sometimes strongly refractive, hyaline, multiguttulate to elongate {2}. **Exudate** over paraphyses (0.2–)0.5–2(–3) µm thick, granular-cloddy, hyaline, firmly to loosely attached, over margin and flanks dense or scattered granular clods. — **ANAMORPH**: dactylella-like (presumed, from natural substrate {3}). **Conidiophores** not seen. **Conidia** unbranched, straight, (fusoid-)ellipsoid- to cylindric-clavate, rounded to obtuse at apex, *34–46 × (5–)6–8 µm, (3–)5–7-septate {3}.

Habitat: lying on ± moist ground or at base of standing stems, corticated, 5–8 mm thick twigs of *Juniperus communis* {1}, *Salix* sp. {1}, *Suaeda vera* {1}, on very undecayed to medium decayed bark {3} (periderm) or wood {1}; stems of *Angelica sylvestris* {1}, ?*Asteraceae* {1}, *Rubus fruticosus* agg. {2}, *Thalictrum flavum* {1}, rhizomes of *Tussilago farfara* {1}, leaves of *Luzula pilosa* {1}, *L. sylvatica* {1}; on upper side of basidiocarp of *Fomitopsis betulina* {1}; green algae absent or sparse. **Associated**: *Calycellina luzulae* {1}, *Mollisia* sp. {1}, *Orbilia sarraziniana* {1}, *Pirottaea* sp. {1}, *Pyrenopeziza* ?*atrata* {1}. **Desiccation tolerance**: nearly fully viable after 1 day dry (or almost all cells dead), after 1 week only ascospores viable, also conidia survive drying for at least 1 day. **Altitude**: 2–460 m a.s.l. (central Europe), 30 m (central Russia). **Geology**: Cambrian-Ordovician silt, shale & sandstone, Permian (Rotliegend), Lower Jurassic shale, Cretaceous flysch, Quaternary loess and marine sand; biotite-amphibolite & quartz diorite. **Phenology**: III, VI–XI.

Taxonomic remarks. *Orbilia cardui* resembles *O. rectispora* in its rather large, whitish-cream apothecia and narrowly cylindrical ascospores. Besides different hosts (dicots vs. monocots), *O. cardui* differs in more straight, somewhat shorter ascospores, but particularly in the quite consistent presence of short glassy processes at the margin and ± thick exudate over paraphyses and glassy processes, also in thicker apothecia due to a more bulky medullary excipulum. Their anamorphs slightly deviate in conidial shape (see below). For the similar *O. atlantis*, *O. cocois*, *O. cotoneastri*, *O. epilobii*, *O. leporina*, *O. xinjiangensis*, and *O. zhongdianensis* see there.

O. quercus (series *Dactylellina*) differs from *O. cardui* in smaller asci and spores, absent glassy processes, and a dactylellina-like anamorph. Likewise, species of series *Drechslerella* (*O. polybrocha*, *O. flavovacuolata*) may have spores similar to *O. cardui*, but differ in eccentrical, often rod-shaped SBs, also in short stipitate apothecia with often brown or yellow pigmentation. With herbarium material, however, most of these characters become very obscure and delimitation from *O. cardui* problematic.

O. epipora, *O. cylindrospora* (section *Orbilia*), and some species of sections *Aurantiorubrae* (*O. pseudocylindrospora*, *O. caulicola*) and *Helicoon* (*O. yuanensis*) differ in the absence of glassy processes at the margin, and (as far as known) in the anamorph having narrower or longer conidia. The spores of *O. epipora* are distinctly smaller than in *O. cardui*. *O. cylindrospora* and *O. pseudocylindrospora* differ in more desiccation-tolerant apothecia, the former also in spores with SBs positioned at the very apex. *O. yuanensis* much resembles *O. cardui* in the spores, but differs in somewhat longer and narrower SBs, paraphyses with strongly refractive VBs, and much longer conidia. *O. caulicola* differs in more tapered spore apices and smaller, pale reddish, desiccation-tolerant apothecia.

The caulicolous *O. rosella* (section *Aurantiorubrae*) also resembles *O. cardui*, e.g., in the crenulate margin. It differs in marginal cells oriented at a rather low angle to the surface by forming hair-like structures, also in capitate paraphyses and broader spores. The apothecia deviate by their reddish colour and are possibly desiccation-tolerant. The unclear *O. rubella* s. Beyer (1994, 1998) on *Rumex* resembles in the spores *O. cardui* or rather *O. rectispora* but was described with up to 50 × 5 µm large ?thin-walled or perhaps glassy hairs.

No clear microscopical differences between the lectotypes of *O. pellucida* (on *Juniperus*, Pl. 906: 2) and *O. cardui* (on *Rubus*, Pl. 906: 6) could be detected, according to the present reexamination, therefore, they are treated here as synonymous. Velenovský (1934) separated them mainly because of the ligneous vs. herbaceous substrate, and this seems also to have been one reason for Svrček (1954) to keep them apart. Yet, Svrček believed that *O. pellucida* was very closely related to *O. luteorubella*, from which it differed in apically less inflated paraphyses covered by a thick exudate ('epithecium'). For this reason he regarded it as a form of *O. luteorubella*. Svrček actually included a specimen in his concept of f. *pellucida* which is referred here to *O. sarraziniana* (see under *O. carpathica*, p. 1664). The characteristics which distinguish *O. cardui* (= *O. pellucida*) from *O. luteorubella* and *O. sarraziniana* are: (1) rather short SBs which are (2) located in the more obtuse spore end, (3) less truncate ascus apices (never indented), and (4) glassy caps on the marginal cells. Both Velenovský and Svrček were unaware of the very different spore bodies in these two groups of taxa.

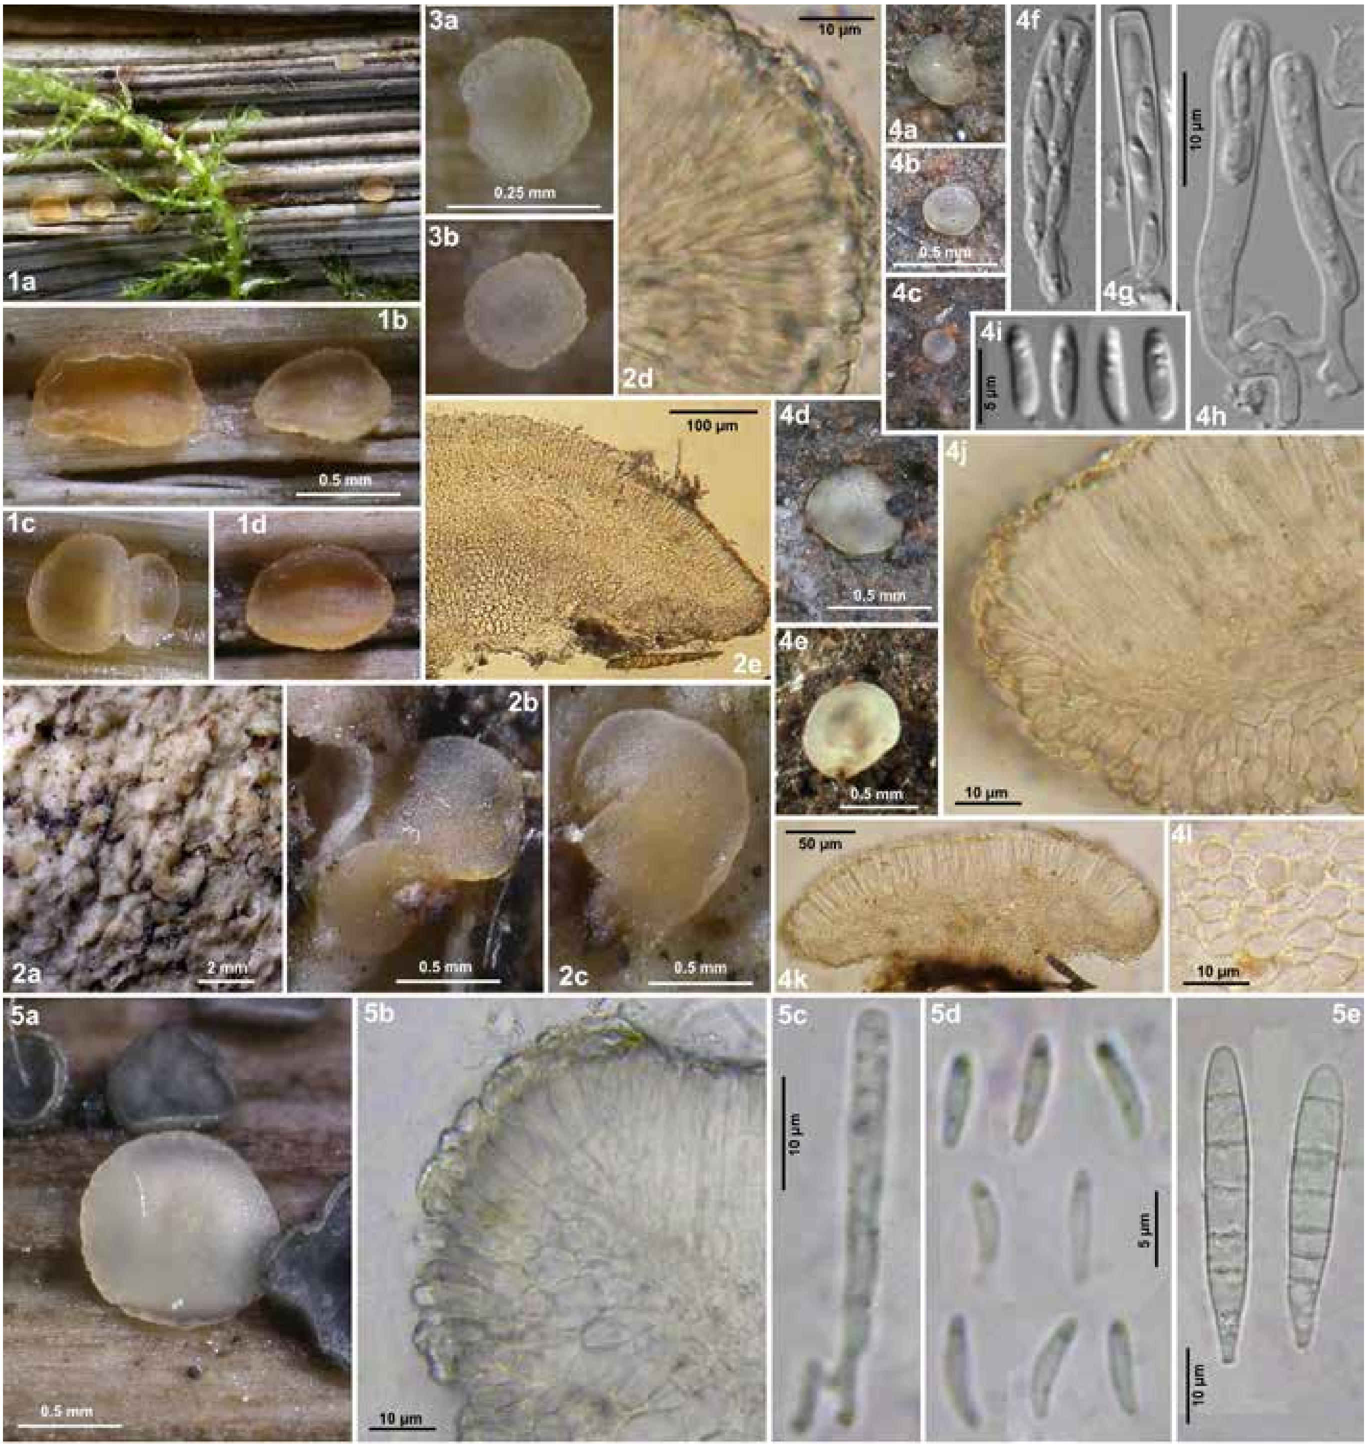

Plate 907. **1–3**, **5**: *Orbilia cardui*; **4**: *O.* cf. *cardui*. – **4e**, **5a**. fresh apothecium; **1a–d**, **2a–c**, **3a–b**, **4a–d**. rehydrated apothecia (**1–3**: after 5–31 years, **4**: after 2 months); **2e**, **4k**. apothecia in median section; **2d**, **4j**, **5b**. id., marginal ectal excipulum; **4l**. margin in external view; **4f–h**, **5c**. asci; **4i**, **5d**. ascospores; **5e**. conidia from substrate. – Living state, except for **2d–e** (in KOH), **4j–l**, **5c** (in H_2O), asci in **4f–g**, **4h** right ascus. – **4e–i**: phot. H.Y. Su (DIC). — **1a–d**. H.B. 7115a: France, Loire-Atlantique, on *Rubus*; **2a–e**. H.B. 6245: Germany, Tübingen, on *Fomitopsis*; **3a–b**. H.B. 8721b: Russia, Yamalia, on *Salix*; **4a–n**. H.B. 8964: China, Yunnan, on indet. woody angiosperm; **5a–e**. H.B. 9891 (epitype): Germany, Chemnitz, on *Angelica*.

Svrček (1954) accepted *O. cardui* in a rather broad sense, including Velenovský's *O. arundinacea* (= *O. rectispora*), *O. lupini* (?= *O. oxyspora*), *O. sambuci* (= *O. oxyspora*), and *O. luzularum* (= *O. cardui*), but excluded *O. pellucida*. Also Raitviir (1991: 359) accepted *O. cardui* in a broad sense by including *Peziza exigua* Cooke. For the latter species, which we consider to be distant from *O. cardui* but very close to *O. caulicola* (series *Commatoideae*), we here establish the new name *O. cookei* (see p. 807). We here consider *O. pellucida*, *O. cardui*, and *O. luzularum* as belonging to a single species, and adopt the more often used name *O. cardui*, which herewith receives priority over the other two (ICN Art. 11.5).

Variation. *O. cardui* varies somewhat in the ascospore bases from slightly to strongly tapered, though often within a collection, whereas spore size is rather consistent. Only three collections were documented in the living state (Pls 906: 1, 4; 907: 5): they differ in SB shape (lower part tear-shaped vs. globose) and in the absence vs. presence of VBs in the paraphyses. Possibly, the visibility of a short filum is characteristic for SBs of *O. cardui*. In two collections (Luxembourg, H.B. 9901; France, J.P.P. 27121) glassy processes were only 1–2 µm long and, therefore, easily overlooked. Yet, H.B. 9901 fully concurs in the ITS region with H.B. 9891 with 4–9 µm long processes, hence, the length of these processes is taxonomically unimportant (see below).

Type studies. Velenovský (1934: 98) described ***O. cardui*** from herbaceous stems of various plant genera (*Carduus*, *Cirsium*, *Sarothamnus*, *Rubus*, *Tussilago*, *Galeopsis*, *Verbascum*, *Papaver*), with 'mainly wax-golden but also rose, brick-coloured or white' apothecia. The indicated wide range in spore length (6–12 µm) is due to variation among the included collections but apparently also due to a measuring error. In his 'Additamenta' (Velenovský 1934: 401) he reduced his concept of *O. cardui* to specimens with 4–7 × 1–2 µm large spores growing on *Carduus*, *Cirsium*, *Sarothamnus*, *Rubus*, and *Caltha*, by excluding three varieties: *O. cardui* var. *rutae* on *Ruta graveolens* (spores 3–5 µm, see p. 1684), *O. cardui* var. *farfarae* on *Tussilago farfara* and *Galeopsis* (spores 4–5 × 3 µm, but on manuscript plate ~1–1.5 µm wide), and *O. cardui* var. *verbasci* on *Verbascum* (spores 6–10 × 2 µm).

Svrček (1954: 11) designated as lectotype of *O. cardui* the collection on stem of *Rubus* which contains about 10 mature apothecia (the other syntype collections were stated by Svrček to be immature and were not reexamined here). In the reexamined lectotype (Pl. 906: 6) the rehydrated light yellowish(-ochraceous) apothecia measure 0.7–1.5 mm diam. and possess medium refractive glassy caps 2–6 × 4–5.7 µm on the marginal excipular cells. Ascospore length was found to concur exactly with Svrček's data, whereas width was larger (Tab. 38). Svrček described the paraphyses as apically 'gradually clavate', a character which he used in his key, although they are 'not inflated' in Velenovský's and hardly so in the present study.

A specimen from Germany (Chemnitz, on *Angelica*, ex H.B. 9891, M-0291778, Pl. 907: 5, spores *(5–)6–7.5 × 1.4–1.7 µm), from which a sequence was gained, is designated here as **epitype** of *O. cardui*.

The lectotype of ***O. cardui* var. *farfarae*** (on rhizomes of *Tussilago farfara*) was stated to be empty by Svrček (1954). A single mature apothecium could be discovered, however. Velenovský's very brief diagnosis is quite incorrect: the short-cylindrical spores ('4–5 × 3 µm') actually have a width of only ~1–1.3 µm when estimated from his manuscript plate. The present reexamination (Pl. 906: 3) revealed distinctly longer spores which are partly attenuated at the base. The microscopic characters, including the glassy caps at the margin, fit well the present concept of *O. cardui*. Velenovský (1934 and manuscript plate) reported this variety also from *Galeopsis versicolor* and stated a 'clear identity' with *Pezizella orbilioides* Feltgen (see p. 1681). The '*Galeopsis*' sample (PRM 824943) was not mentioned by Svrček (1954) and is found to be empty here; the substrate is likely a twig of a broad-leaved tree. Svrček (1954) incorrectly referred to the specimen on *Tussilago* as 'holotype'. We here designate the collection on *Tussilago farfara* (PRM 149600) as **lectotype** of *O. cardui* var. *farfarae*.

Velenovský (1932) separated ***O. cardui* var. *verbasci*** from typical *O. cardui* by longer, often slightly curved, basally more tapered spores (8–10 µm; in manuscript plate 5–8–10 × 0.9–1.2 µm, width estimated from drawing). His illustration of the single collection well corresponds in the spores with the present reexamination of the holotype (Pl. 906: 8). Together with milky-white apothecia in the fresh state and a partly very finely crenulate margin due to the here observed glassy processes, the taxon might be conspecific with *O. oxyspora*. Since the marginal cells are oriented at a high angle to the surface and the spores rather short and only slightly curved, we doubt such identity. *O. cardui* var. *verbasci* could perhaps be a synonym of *O. fimicola*, if that taxon is considered to be different from *O. oxyspora*. Svrček (1954) saw a high conformity between *O. cardui* var. *verbasci* and *O. cardui*, but mentioned its longer spores as deviating.

Three localities and at least four collections are cited in the protologue of ***O. pellucida*** (on 'wood of broad-leaved trees' and *Juniperus*). Among Velenovský's manuscript plates, the oldest (VII.1924, Mnichovice, on decayed trunk of *Malus*) is entitled '*Orbilia pellucida* sp. n.' and is said to have translucent, hyaline, umbilicate apothecia 1–2 mm diam., and unstalked, non-furcate asci. In IX.1933 he added the remark '= *cyathea*' (= *Hyalorbilia inflatula*) to this plate, and actually his illustration shows a *Hyalorbilia*, possibly *H. inflatula*. Velenovský (1934) did not clearly cite this *Malus* collection under *O. cyathea*, but he also did not include its characters in the protologue of *O. pellucida* for which he reports the apothecia as '0.3–1 mm' and the asci 'with a thin bifurcate stalk'. Obviously Velenovský decided to use the name *pellucida* for a different species, and for this reason Svrček (1954: 18) designated the *Juniperus* specimen (as *Orbilia juniperina* [*nom. ined.*] on Velenovský's manuscript plate) among the remaining collections as lectotype.

The rather abundant apothecia in this lectotype (Pl. 906: 2) grew on very undecayed periderm of an 8 mm thick branch (Svrček: 'on rotten branch') of an old trunk of *Juniperus* in a moist and shady young spruce forest, according to the manuscript plate. Svrček gave smaller values for the spore width (5.5–7 × 0.5–0.8 µm, but 0.8–1 µm on the lectotype label) than measured here. Velenovský (1934) described the apothecia of *O. pellucida* as 'wine-red, violaceous, rarely uncoloured'. The latter statement obviously refers to the sample on *Juniperus*, since his manuscript plate reads 'apothecia gregarious, 0.5–1 mm diam., ..., glassy-translucent, white'. Later, Velenovský (1947: 104) referred to *O. pellucida* a collection on *Salix aurita* with red apothecia. Svrček obviously designated as lectotype of *O. pellucida* a hyaline fungus which Velenovský mentioned in the protologue as exceptional. Since Svrček did not cite further authentic material of *O. pellucida* we assume that none existed. Svrček's synonymisation of *O. silvatica* with *O. pellucida* is doubtful (see under *O. rosea*, p. 965). A possible identity of *O. pellucida* with *D. rhopalota* is considered under that species.

The holotype of ***O. luzularum*** contained only two mature apothecia (Pl. 906: 5). The asci are much longer than indicated by Velenovský and Svrček, and the marginal cortical cells bear 3–10 × 5–6 µm large, high-refractive glassy processes. Svrček's synonymisation with *O. cardui* is confirmed here. The monocot substrate and the rather narrow spores would suggest identity with *O. rectispora*, but glassy processes have never been seen in that species.

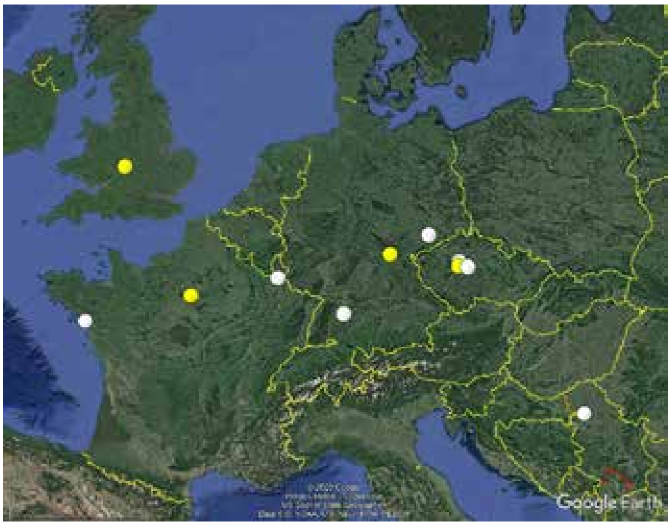
Not included collections. In a French sample on *Pinus* cone, glassy processes were very distinct, but we did not include it in the description because of larger conidia (see below). Also we did not include a German sample on *Solidago* with short glassy processes because it deviates by longer spores (*7–10 × 1.3–1.5 µm) and larger conidia (see below). An immature sample from altimontane central Asia (Kyrgyzstan) seemed to be *O. cardui* because of its short glassy processes, but the single observed conidium appears to exclude this species (see below).

In a Chinese sample (Pls 906: 7; 907: 4) the spores are slightly wider and more fusoid, and glassy processes are absent; the globose SBs are without visible filum and slightly eccentrical. This collection resembles a specimen from dung treated as an unclear taxon (*Orbilia* sp. H.B. 8749, incertae sedis, Pls 1023–1024), whereas a Chinese specimen on *Bambusa* (*Orbilia* sp. H.B. 8963, incertae sedis, Pls 1021–1022) differs in distinctly narrower spores. In the two latter specimens the SBs tend to be slightly elongated and more eccentrical, however.

No documentation of the British sample under the name *O. luzularum* reported by Clark (1980a: 79) was seen. For the not included *O. cardui* var. *verbasci* see under Type studies.

Anamorph. Ellipsoid- to cylindric-clavate conidia were observed in three of the included specimens of *O. cardui* (Pls 906: 1g, 4g; 907: 5e, all from natural substrate). These conidia seem to be indistinguishable from those of *O. cotoneastri*, but are clearly different from those of *O. rectispora* which are longer and more ellipsoid-fusoid. On the other hand, conidia of the presumed anamorph of *O. crenatomarginata* (section *Aurantiorubrae*) resemble those of *O. cardui*, though being larger, especially wider, and more clavate. Also the so far purely anamorphic *Dactylella rhopalota* shows hardly any morphological differences to the anamorph of *O. cardui*, except that its conidia tend to be longer, but molecular data support its distinction. Also *D. clavata* (from soil under *Cocos*, Xisha islands, China) matches *D. rhopalota* in conidiophore and conidial morphology but is divergent from both species by its molecular data. The three not included collections on *Pinus* from France (unillustrated), *Solidago* from Germany (IVV: 29.VI.2015), and indet. dicot from Kyrgyzstan (unillustrated) showed distinctly larger conidia (*50–53 × 8.3 µm, 7-septate, †50–68 × 7–10 µm, 7–9-septate, and †52 × 6 µm, ~10-septate, respectively) in comparison to the other three records of anamorphs in *O. cardui*, and might instead belong to *D. rhopalota.* The conidia of *D. xinjiangensis* show about the size of these aberrant samples, but never possess more than 7 septa. The conidia of *D. cylindrospora* resemble those of typical *O. cardui* (and *O. cotoneastri*) in size (22.5–45 × 6.5–8.5 µm) and shape, but have only 1–4 septa and the conidiophore tips are strongly branched (candelabrelloid).

Phylogeny. Molecular data (ITS and LSU) were obtained from apothecia of two collections (Chemnitz, H.B. 9891; Luxembourg, H.B. 9901). In both the S1506 intron is absent. The two sequences are completely identical in the entire overlapping part. *O. cardui* clustered in the *cardui-rhopalota* clade (Phyls 25–27, S31). The distance to morphologically similar species is 5.5–6% to *O. epilobii*, 7% to *O. zhongdianensis*, and 7.5% to *D. rhopalota* 7.5%, whereas the similar *O. atlantis*, *O. cotoneastri*, *O. rectispora,* and *O. beltraniae* show a 12.5–17.5% distance. In the LSU (D1–D2) the distance to *O. zhongdianensis* is 1% and to *O. epilobii* 1.5%.



Map 146. Known distribution of *O. cardui* in Europe (yellow = not included collections).

Ecology. A broad range of substrates is inhabited by *O. cardui*, including bark and wood of trees and shrubs, herbaceous stems and leaves of both mono- and dicotyledonous plants, and polypores. Contrary to *O. rectispora*, *O. cardui* is not confined to swamps and shows a slight desiccation tolerance. The vegetation includes shady forests, ruderal places (railway), wetlands (*Filipenduletum*, meadow with *Thalictrum*), and salt marshes. Clark (1980a: 79) and Ellis & Ellis (1985: 553) reported *O. cardui* on leaf bases of *Luzula sylvatica* in central England (as *O. luzularum*), and Raitviir (1991: 359, as *O. cardui*) on stems of larger herbs from the Far East of Russia, but these records require reexamination. The examined collections of *O. cardui* range from atlantic to subcontinental, warm- to cold-temperate humid Europe at planar to colline altitudes. One included collection is from continental oroboreal northern Asia and two not included ones are from orotemperate (altimontane) humid, continental central and subtropical humid (winter-dry) eastern Asia.

Specimens included. **LUXEMBOURG**: **Gutland**, **Esch-sur-Alzette**, 2 km NNE of Dudelange, 1.5 km S of Bettembourg, Triage, 275 m, stem of ?*Asteraceae*, 25.VII.2014, G. Marson (H.B. 9901; sq.: KT222403). — **FRANCE**: **Pays-de-la-Loire**, **Loire-Atlantique**, 2.3 km NE of Mesquer, l'Île de Rostu, 2 m, twigs & branches of *Suaeda vera*, on bark, 9.XI.2007, J.P. Priou (J.P.P. 27121, doc. vid.). – ibid., stem of *Rubus fruticosus*, 23.III.2002, J.P. Priou (H.B. 7115a, anam. substr.) — **GERMANY**: **Sachsen**, 6 km NNE of Chemnitz, 1 km E of Glösa, Indianerteich, 325 m, stem of *Angelica sylvestris*, 15.VI.2014, B. Mühler (ex H.B. 9891, M-0291778, **epitype**, anam. substr.; sq.: KT222402). – **Baden-Württemberg**, 6.5 km NE of Tübingen, 1.5 km NNE of Pfrondorf, Brand, 460 m, on *Fomitopsis betulina*, 3.X.1998, H.O. Baral (H.B. 6245, anam. substr.). — **CZECHIA**: **Central Bohemia**, 23 km SE of Praha, 2.5 km NNW of Mnichovice, near Menčice, 400 m, stem of *Rubus fruticosus*, on bark, VII.1929, J. Velenovský (PRM 152452, **lectotype** of *O. cardui*; H.B. 6059 ø). – Mnichovice, ~370 m, twig of *Juniperus communis*, on bark, IX.1925, J. Velenovský (PRM 147662, **lectotype** of *O. pellucida*, H.B. 6269 ø). – 3 km SE of Mnichovice, near Hrusice, 360 m, leaves of *Luzula pilosa*, 18.VIII.1924, J. Orbilia cotoneastri Velen. [as '*cotoneastris*'], Monogr. Discom. Bohem.: 401 (1934) — Pls 908–909

Etymology: referring to the type substrate.

Typification: Czechia, Praha, St. Prokop, branch of *Cotoneaster integerrima*, 24.X.1925, J. Velenovský (PRM 148957, holotype); France, Locmariaquer, branch of *Ulex europaeus*, 3.XI.2002, J.P. Priou (ex J.P.P. 22122 & H.B. 7241a,

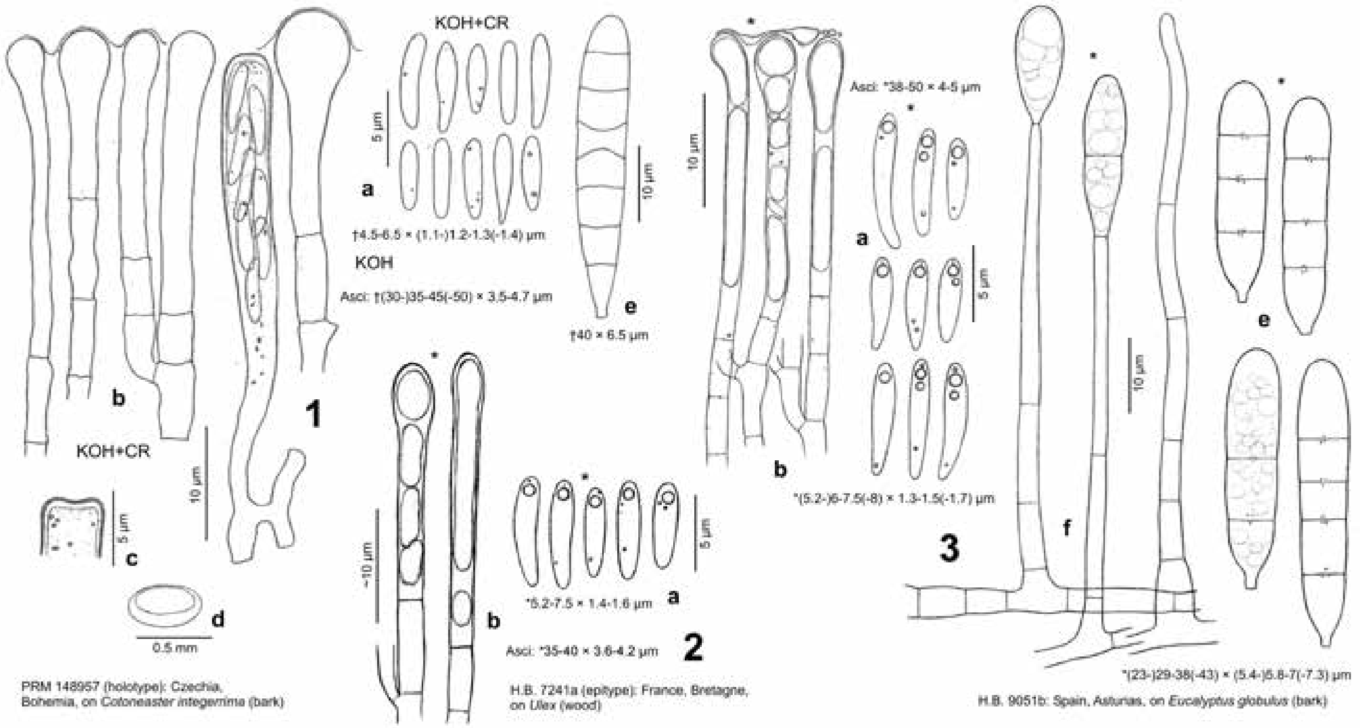

Plate 908. **1–2**: *Orbilia cotoneastri*; **3**: *O.* cf. *cotoneastri*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. rehydrated apothecium; **e**. conidia; **f**. conidiophores with young conidia (**1e** from substrate, **2e–f** from culture).

M-0177060, epitype, designated here, MBT382108, ex-epitype culture: CBS 116281; sq.: KT215288).
Misapplied name: Svrček (1954: 13), as *O. inflatula*.

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated 0.5–1 mm diam., 0.12 mm high, whitish with pale cream-isabelline or yellowish-chlorinaceous tint, medium translucent, round to somewhat lobate, gregarious; disc flat to slightly convex, margin distinct, thin or thick, not protruding, smooth; broadly sessile, superficial. **Asci** *35–40 × 3.6–4.2 µm {1}, †(30–)35–40(–50) × 3.5–4.3(–4.7) µm {2}, 8-spored, (1–)2–4 lower spores inverted {2} (mixed or not); apex strongly truncate (sometimes indented, laterally hardly inflated), thin-walled; **base** with short to long, thin stalk, T-, Y-, h- or H-shaped. **Ascospores** *5.2–7.5 × 1.4–1.6 µm {1}, †(4.5–)5.5–6.8(–7.8) × (1.1–)1.2–1.3(–1.4) µm {2}, cylindric- to fusoid-clavate, apex (rounded to) obtuse, base hardly or slightly to strongly attenuated, straight to slightly curved; **SBs** *1.3–1.5 × 0.6–0.8 µm {1}, globose, apically with a hardly visible filum. **Paraphyses** apically uninflated or slightly to medium, rarely strongly capitate-clavate, terminal cell *22–30 × 2.5–3.8 µm {1}, †15–28 × 3–5(–7) µm {T}, lower cells †4–9(–11) × 2–4 µm {T}; unbranched at upper septum. **Medullary excipulum** 40 µm thick, sharply delimited. **Ectal excipulum** of thin-walled, vertically oriented t. globulosa-angularis-prismatica from base to margin, 35 µm thick near base, cells *9–16 × 6–10 µm {1}, †15–24 × 13–19 µm {T}; ~25 µm thick at lower flanks, cells †9–13 µm wide {T}, 10–15 µm thick near margin, oriented at an 70–80° angle to the surface, marginal cortical cells †7–15 × 3.5–6 µm {T}, thin-walled; **glassy processes** absent {T} or up to 1 µm thick {1}. **Anchoring hyphae** */†(2–)2.5–4(–5) µm wide, walls 0.2(–0.3) µm thick {2}. **SCBs** not observed; **VBs** present or absent, slightly refractive, hyaline, globose to elongate {1}. **Exudate** over paraphyses, margin and flanks absent or 0.1–0.2 µm thick, smooth or finely granular {2}. — **ANAMORPH**: dactylella-like (from natural substrate {2} and ascospore isolate {1, not studied in detail}). **Conidiophores** not seen. **Conidia** unbranched, straight, (cylindric- to) ellipsoid-clavate, obtuse at apex, */†37–40 × 6.5–8.2 µm, (4–)7-septate {2}.

Habitat: on corticated or decorticated, ~15–20 mm thick branches of *Cotoneaster integerrima* {T}, *Ulex europaeus* {1} lying on moist ground (partly buried), on medium to very rotten bark (bast) (1) and wood (1). **Associated**: ?*Hyaloscyphaceae* {1}. **Desiccation tolerance**: not tested, possibly intolerant. **Altitude**: 2–250 m a.s.l. **Geology**: Czechia: Devonian limestone & calcareous shale, silt- & sandstone; France: granite. **Phenology**: X–XI.

Taxonomic remarks. *Orbilia cotoneastri* differs from *O. cardui* in the absence of glassy processes at the margin and in a much thinner or absent exudate over the partly more inflated, capitate-clavate paraphyses. The sparse records of *O. cotoneastri* were on woody substrates, except for a not included sample on *Reynoutria*. *O. senegalensis* on bark of *Citrus* differs by prominent crystalloid SCBs in the excipular cells (Pl. 910).

Variation. The collection on *Ulex* (Pls 908: 2, 909: 1) fits rather well the holotype of *O. cotoneastri* but their conspecificity is not certain due to lack of molecular data of the holotype. In the spores the two are very similar when considering the shrinking effect, whereas the dead asci in the holotype are slightly larger than the living asci in the *Ulex* sample. The marginal excipular cells show thick glassy walls in the *Ulex* sample, while they are thin-walled in the holotype. Despite these differences we feel justified to designate the collection on *Ulex* (France, Locmariaquer, ex J.P.P. 22122 & H.B. 7241a, M-0177060) for which a pure culture (CBS 116281) and sequence exists, as **epitype** of *O. cotoneastri*.

Type studies. The sparse holotype of ***O. cotoneastri*** was thought by Svrček (1954: 13) to represent typical *O. inflatula* (≡ *Hyalorbilia inflatula*). However, both the protologue and Velenovský's unpublished manuscript plate describe the asci with a thin, 2–3-furcate stalk. This clearly indicates that *O. cotoneastri* does not belong to *Hyalorbilia*. Velenovský actually compared *O. cotoneastri* with *O. pellucida* (= *O. cardui*), from which he appears to have distinguished it mainly because of wider asci (5 and 3–4 µm, respectively) and more inflated paraphyses without exudate.

According to the present reexamination of the holotype (Pl.

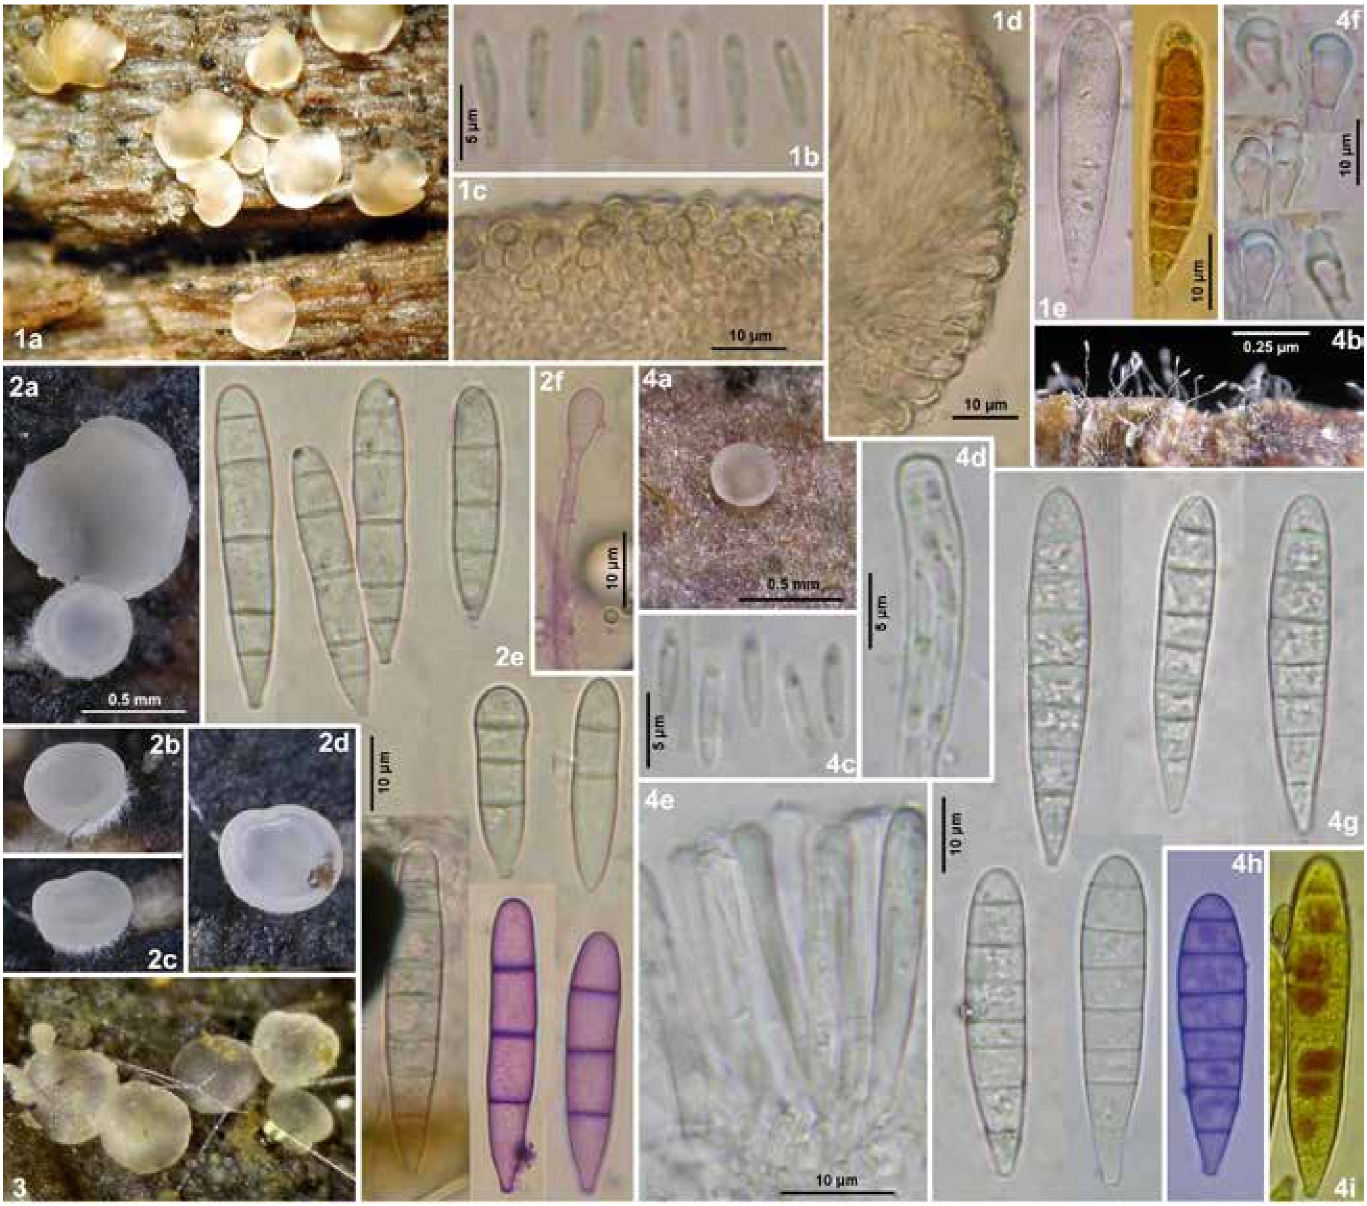

Plate 909. **1**: *Orbilia cotoneastri*; **2–4**: *O*. cf. *cotoneastri*. – **1a**, **2a–d**, **3**, **4a**. fresh apothecia; **1c**. marginal cortical cells in top view; **1d**. marginal ectal excipulum in median section; **4f**. short glassy processes on marginal cortical cells; **4d–e**. asci and paraphyses; **1b**, **4c**. ascospores; **2f**. conidiophore with young conidium; **4b**. conidiophores with mature conidia on bark; **1e**, **2e**, **4g–i**. conidia (**1** & **4** from substrate, **2** from culture). – Living state (**4i** in IKI, **2e** below and **4h** in CRB), except for **1b–d**, **1e** left (KOH), **1e** right (KOH+IKI). – **1a**, **3**: phot. J.P. Priou. — **1a–e**. H.B. 7241a (epitype): France, Bretagne, on *Ulex*; **2a–f**. H.B. 9051b: Spain, Asturias, on *Eucalyptus*; **3**. J.P.P. 28122: France, Bretagne, on *Reynoutria*; **4a–i**: H.B. 9645b: Spain, Galicia, on *Quercus*.

908: 1), *O. cotoneastri* resembles *O. cardui* in its short and wide, straight spores. However, no glassy caps could be found on the marginal cells, also the paraphysis apices are very variable in this specimen, ranging from slightly to strongly clavate, 3–5(–7) µm wide. Moreover, both paraphyses and excipulum are devoid of exudate. The entire ectal excipulum is composed of a rather large-celled, thin-walled textura angularis. The asci are much longer and the spores wider than indicated by Velenovský (25–30 × 5 and 4–5 × 0.8–1 µm, spore width estimated from his drawing) as well as Svrček (30 × 4–4.5 µm and 5–5.5 × 1 µm). However, the ascus length in the protologue was obviously taken by exclusion of the stalk, judging from Velenovský's free-hand drawing, which shows narrowly ellipsoid-fusoid spores with a medium-sized drop near each end similar as drawn for *O. pellucida*.

Not included collections. Some samples more or less resemble *O. cotoneastri*. Two from Spain (Asturias: on *Eucalyptus*, spores *6–7.5 × 1.3–1.5 µm, Pls 908: 3; 909: 2; Galicia: on *Quercus*, spores *6–6.7 × 1.1–1.3 µm, Pl. 909: 4) both grew in association with the rare *Orbilia alba*, but slightly differ from each other in spore width and anamorph (see below). That on *Eucalyptus* lacks glassy processes but shows 1–1.5 µm thick exudate; that on *Quercus* has only 0.2–0.4 µm thick exudate as a maximum but possesses glassy processes of 2–6 × 4–6.5 µm (Pl. 909: 4). The *Quercus* sample might in fact represent a narrow-spored lignicolous population of *O. cardui* with rather short glassy processes. Two further samples were studied by J.P. Priou (Valenciana, on *Eucalyptus*, IVV: J.P.P. 27143; Bretagne, on *Reynoutria*, IVV: J.P.P. 28122), and another by N. Matočec (Croatia, on cardboard, IVV: N.M. 3800) which all lack glassy processes but show distinct exudate over the paraphyses.

Anamorph: The anamorph of *O. cotoneastri* closely concurs with that of *O. cardui* and *Dactylella rhopalota*. Ellipsoid- to cylindric-clavate conidia were observed on the natural substrate in the holotype of *O. cotoneastri* (Pl. 908: 1e, 1 conidium seen) and in the epitype (Pl. 909: 1e, */†35–38 × 7–8.2 µm, 4–7-septate). Conidia developed in the latter sample also in pure culture, but the anamorph was not studied in detail.

Conidia were also observed in some of the not included collections, either on the natural substrate (Galicia, Pl. 909: 4b, g–i; Valenciana, IVV: J.P.P. 27143) or in pure culture (Asturias, Pls 908: 3e–f; 909: 2e–f). The conidia from Asturias are mainly cylindrical, rather narrow and with only (2–)3–5(–7) septa, compared to those from Galicia which measured *(30–)35–48.5 × (7.5–)8–8.5(–9) µm and were ((4–6–))7((–8))-septate. Therefore, these two samples might be specifically distinct. The single clavate conidium seen in the sample from Andalucía measured 40 × 10 µm and was 5-septate.

Phylogeny. A sequence from pure culture of the epitype on *Ulex* comprises SSU (with S1506 intron), ITS, and LSU. *O. cotoneastri* formed with *O. rectispora* a strongly to medium supported clade (Phyls 25, 27, S31), with a distance of 6.7–7% in the ITS region to *D. panlongana*, *D. ramosa*, and *O. rectispora* (all these species have more fusoid conidia), 8% to *D. xinjiangensis*, and 9–9.5% to *O. beltraniae* and *D. clavata*. Species of the *cardui-rhopalota* clade show much higher distances, e.g., 14.5% to *O. cardui*. In the intron the lowest distance was 12.5% to *O. rectispora*.

Ecology. *O. cotoneastri* grew on rotten hygric branches of angiosperm shrubs. The holotype was on bark of *Cotoneaster* in cold-temperate humid subcontinental Europe (Bohemia), and the epitype on wood of *Ulex* in a warm-temperate humid coastal open shrubland in atlantic Europe (Bretagne). The not included collections were, besides a further sample from Bretagne (on herbaceous stems of *Reynoutria*), from atlantic, thermotemperate humid coastal forests in northern Spain (with *Castanea sativa*, *Laurus nobilis*, *Quercus robur*, *Eucalyptus*), from a thermomediterranean semiarid coastal saline shrubland in southern Spain, and from a mesomediterranean semihumid shrubland in a depression of an ancient lake in the Dalmatic islands.

Specimens included. **CZECHIA**: **Central Bohemia**, 7 km SW of Praha, St. Prokop (Prokopské údolí, Prokop valley), ~250 m, branch of *Cotoneaster integerrima*, on bark, 24.X.1925, J. Velenovský (PRM 148957, **holotype**, H.B. 6132 ø, anam. substr.). — **FRANCE**: **Bretagne**, **Morbihan**, 12 km S of Auray, 1.6 km SW of Locmariaquer, Breneguy, 2 m, branch of *Ulex europaeus*, on wood, 3.XI.2002, J.P. Orbilia senegalensis Baral, G. Marson & E. Weber, **nom. prov.** — Pl. 910

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.25 mm diam., 0.1 mm thick (receptacle 0.06–0.07 mm), whitish-greyish to light cream-brownish, medium translucent, round to somewhat undulating, gregarious in small groups; disc flat, margin thin, ± smooth, not protruding, sessile on a broad base, superficial. **Asci** †(27.5–)33–35(–43) × 3.7–4.2 µm, 8-spored, 4–6 lower spores inverted {4}, pars sporifera *16–20 → 15–16.5 µm long; **apex** strongly truncate (not indented, not inflated), thin-walled; **base** with short to medium long stalk, h- or H-shaped. **Ascospores** */†5–6.5 × 1–1.4 µm, cylindrical to slightly fusoid-clavate, with rounded to obtuse ends, only slightly (rarely medium) tapered below, straight or slightly curved; **SBs** *0.7 × 0.4 µm, globose, often ± eccentrical, sometimes with distinct filum (total SB length 1.5 µm). **Paraphyses** uninflated to often slightly to medium lanceolate-lageniform with rounded tip, terminal cell *(13.5–)17.5–19.5(–25) × 2–3 µm {5}, 3–5 µm protruding beyond living asci, lower cells *(4.5–)7–9.5(–10.5) × 1.5–2.5(–2.8) µm {5}, unbranched at upper septum, rarely with a bifurcate apex. **Medullary excipulum** 20–45 µm thick, of dense textura intricata with inflated cells, sharply delimited. **Ectal excipulum** of indistinctly vertically oriented, thin-walled t. globulosa-angularis, at base 30 µm thick, cells *7–12.5 × 5–9.5 µm, at margin 12–15 µm thick, oriented at a high angle, marginal cortical cells †4–5.5 × 3.5–5 µm, at upper margin with or without hair-like outgrowths ~14 × 3.5 µm oriented at a ~20–45° angle; **glassy processes** absent. **Anchoring hyphae** sparse, ~1.5–2.5 µm diam., wall ~0.2 µm thick. Crystalloid **SCBs** in excipular cells at flanks, 2.5–5 × 0.5–2.5 µm, refractive, spool- to C-shaped, very pale rose. **VBs** probably absent. **Exudate** 0.3–1.5 µm thick, cloddy, firmly attached, over paraphyses and marginal excipulum. — **ANAMORPH**: unknown.

Habitat: on corticated, xeric, 12–14 mm thick branch of *Citrus* × *limon*, on medium rotten bark (bast). **Associated**: none observed. **Desiccation tolerance**: only excipular cells survived at least 1 week. **Altitude**: 15 m a.s.l. **Phenology**: I.

Taxonomic remarks. This species differs from all other species of series *Neodactylella* studied in the living state by very distinct crystalloid SCBs in the excipular cells (Pl. 910: 1k–n), a so far unique character within the entire section *Arthrobotrys*. However, because the specimen was lost after study, this exceptional feature could later not be confirmed in order to exclude a mixture or confusion. Otherwise the species resembles *O. cardui* and *O. cotoneastri* in its rod-shaped spores, which are partly somewhat attenuated and curved below and contain a minute, globose SB attached to the apex by a short filum.

The genetically close south Chinese ***Orbilia longquanensis*** M. Qiao & Z.F. Yu nom. prov. (Zhang et al. ined., IVV: YMF 1.01868) differs in much larger (0.5–1 mm diam.), yellow, gregarious, possibly drought-intolerant apothecia which lack any exudate, and in slightly larger ascospores; whether its excipular cells contained SCBs is unknown.

Anamorph. No conidia were found on the natural substrate. The closely allied *O. longquanensis* possesses fusiform, (3–)6–7 septate conidia of *40–60.5 × 4–5.5 µm with cylindrical middle part, formed at the tip of 50–150 µm long, simple or basally branched conidiophores.

Phylogeny. A sequence was gained comprising SSU V3, V6–V9, S1506 intron, ITS, and LSU D1–D8. The species formed with *O. longquanensis* a strongly supported clade with a distance of 5% (ITS) or ~6.5% (intron). This clade clustered with medium or strong support sister to the remaining species of the *rectispora-beltraniae* clade, to which it shows a high distance (Phyls 26–27, S31).

Ecology. The species was found on bark of a xeric branch of *Citrus* in the tropical monsoon climate of northwestern Africa, with strong change between humid (summer) and arid (winter). *O. longquanensis* grew on bark of a hygric angiosperm twig in subtropical humid (monsoon-influenced) eastern Asia.

Specimens included. **SENEGAL**: **Ziguinchor**, 55 km WSW of Ziguinchor, 2.5 km NW of Kabrousse, Cap Skirring, 15 m, branch of *Citrus* × *limon*, on bark, 4.I.2016, R. Reuter (G.M. 2016-01-04.1; sq.: MH221067).

Not included. **CHINA**, **Yunnan**, **Yuxi**, Yimen, ~2.5 km WNW of Yimen, Longquan, 1750 m, twig of broad-leaved tree, on bark, 26.VI.2009, Z. F. Yu & S. F. Li (YMFT1.01868, proposed holotype of *O. longquanensis*, ex-type culture YMF1.01868, CGMCC3.18831, sq.: KF824763/MF948419.

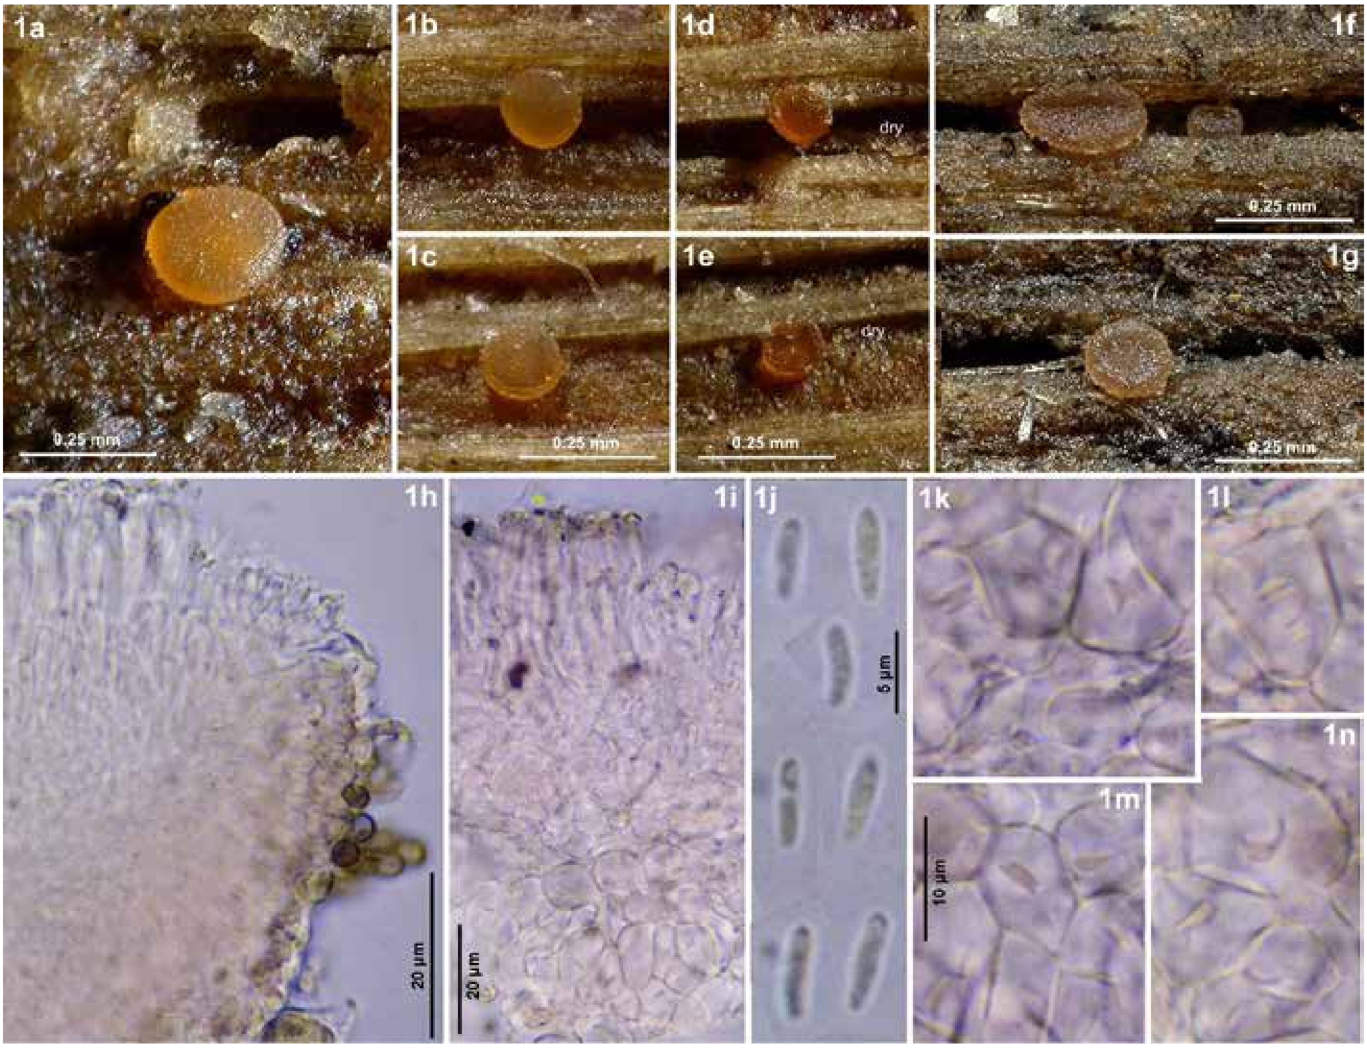

Plate 910. **1**: *Orbilia senegalensis*. – **1a–c**, **f–g**. rehydrated apothecia; **1d–e**. dry apothecia; **1h**. apothecium in median section, marginal ectal excipulum; **1i**. hymenium, medullary and ectal excipulum, flank region; **1j**. ascospores; **1k–n**. crystalloid SCBs in cells of ectal excipulum at flanks. – Dead state, except for ectal excipulum at flanks. — **1a–n**. G.M. 2016-01-04.1: Senegal, Kabrousse, on *Citrus*.

Orbilia beltraniae Quijada, Baral & G. Marson, in Quijada & Baral MycoKeys 25: 6 (2017) — Pl. 911, Map 147

Etymology: referring to the mycologist Esperanza Beltrán-Tejera.

Typification: Macaronesia, Tenerife, Mesa del Mar, branch of *Euphorbia canariensis*, 30.X.2013, L. Quijada (TFC Mic. 24363, holotype; sq.: KT222405).

Description: — **TELEOMORPH** (from Quijada et al. 2017, modified): **Apothecia** moist 0.4–1.2(–1.5) mm diam., 0.1–0.2 mm thick (receptacle 0.06–0.07 mm), whitish-greyish to light cream-brownish, medium translucent, round to somewhat undulating, gregarious in small groups; disc flat, margin thin, ± smooth, not protruding, sessile on a broad base, superficial. **Asci** *(32–)38–43(–46) × (3–)3.5–4(–4.5) µm {6}, †(27.5–)33–35(–43) × 3–3.7 µm {6}, 8-spored, 4–6 lower spores inverted {4}, pars sporifera *16–20 → 15–16.5 µm long; **apex** strongly truncate (not indented, not inflated), thin-walled; **base** with short to medium long stalk, h- or H-shaped. **Ascospores** *(4.5–)5–6.5(–7) × (1.2–)1.4–1.6(–1.7)((–1.9)) µm {6}, †(4–)4.5–5.2 × 1–1.4 µm {3}, cylindrical to slightly fusoid-clavate, with rounded to obtuse ends, straight or slightly curved, only slightly (rarely medium) tapered below; **SBs** *(1–)1.5–2 × 0.6–0.9 µm {5}, globose, often ± eccentrical, sometimes with distinct filum. **Paraphyses** uninflated to often slightly to medium lanceolate-lageniform with rounded tip, terminal cell *(13.5–)17.5–19.5(–25) × 2–3 µm {5}, 3–5 µm protruding beyond living asci, lower cells *(4.5–)7–9.5(–10.5) × 1.5–2.5(–2.8) µm {5}, unbranched at upper septum, rarely with a bifurcate apex. **Medullary excipulum** 20–45 µm thick, of dense textura intricata with inflated cells, sharply delimited. **Ectal excipulum** of indistinctly vertically oriented, thin-walled t. globulosa-angularis, at base 40–70(–105) µm thick, cells *(7.5–)11–13(–18) × (4.5–)8–9.5(–13) µm, at margin 10–28 µm thick, oriented at a 40–80° angle, marginal cortical cells *(5.5–)7.5–8.5(–12.5) × (2.5–)3.5–4.5(–7) µm {5}, not forming distinct cell rows; **glassy processes** absent {6}. **Anchoring hyphae** rather sparse, *1.5–3.5 µm diam., wall 0.2 µm thick {2}. Many globose, very low- to low-refractive globose (?)**SCBs** filling terminal cells of paraphyses {5}, **VBs** absent. **Exudate** forming a 0.2–0.3(–1) µm thick, firmly attached layer over paraphyses and marginal excipulum. **— ANAMORPH**: unknown.

Habitat: lying on the ground or semierect, 2–6 cm thick, partially corticated branches of *Euphorbia canariensis* {7}, on medium to very decayed wood {7}. **Associated**: *Orbilia amarilla* {1}, *O. asomatica* {1}, *O.* aff. *farnesianae* {1}, *O. pisciformis* {1}. **Desiccation tolerance**: fully alive for at least ~1 week. **Phenology**: X–V, but possibly throughout the year. **Altitude**: 35–345 m a.s.l. **Geology**: basaltic flows. **Phenology**: III, V, X, XII (apparently throughout the year).

Taxonomic remarks. *Orbilia beltraniae* was collected and studied by L. Quijada. The species resembles *O. rhamni* in the lanceolate-lageniform paraphyses but differs in the ascospores (see p. 1483). *O. epilobii* resembles *O. beltraniae* in similar spores and partly lanceolate paraphyses, but differs in paraphyses not covered by exudate and mostly containing VBs, and in thicker apothecia. Also *O. cardui*, *O. cotoneastri*, *O. rectispora*, and *O. zhongdianensis* resemble *O. beltraniae*

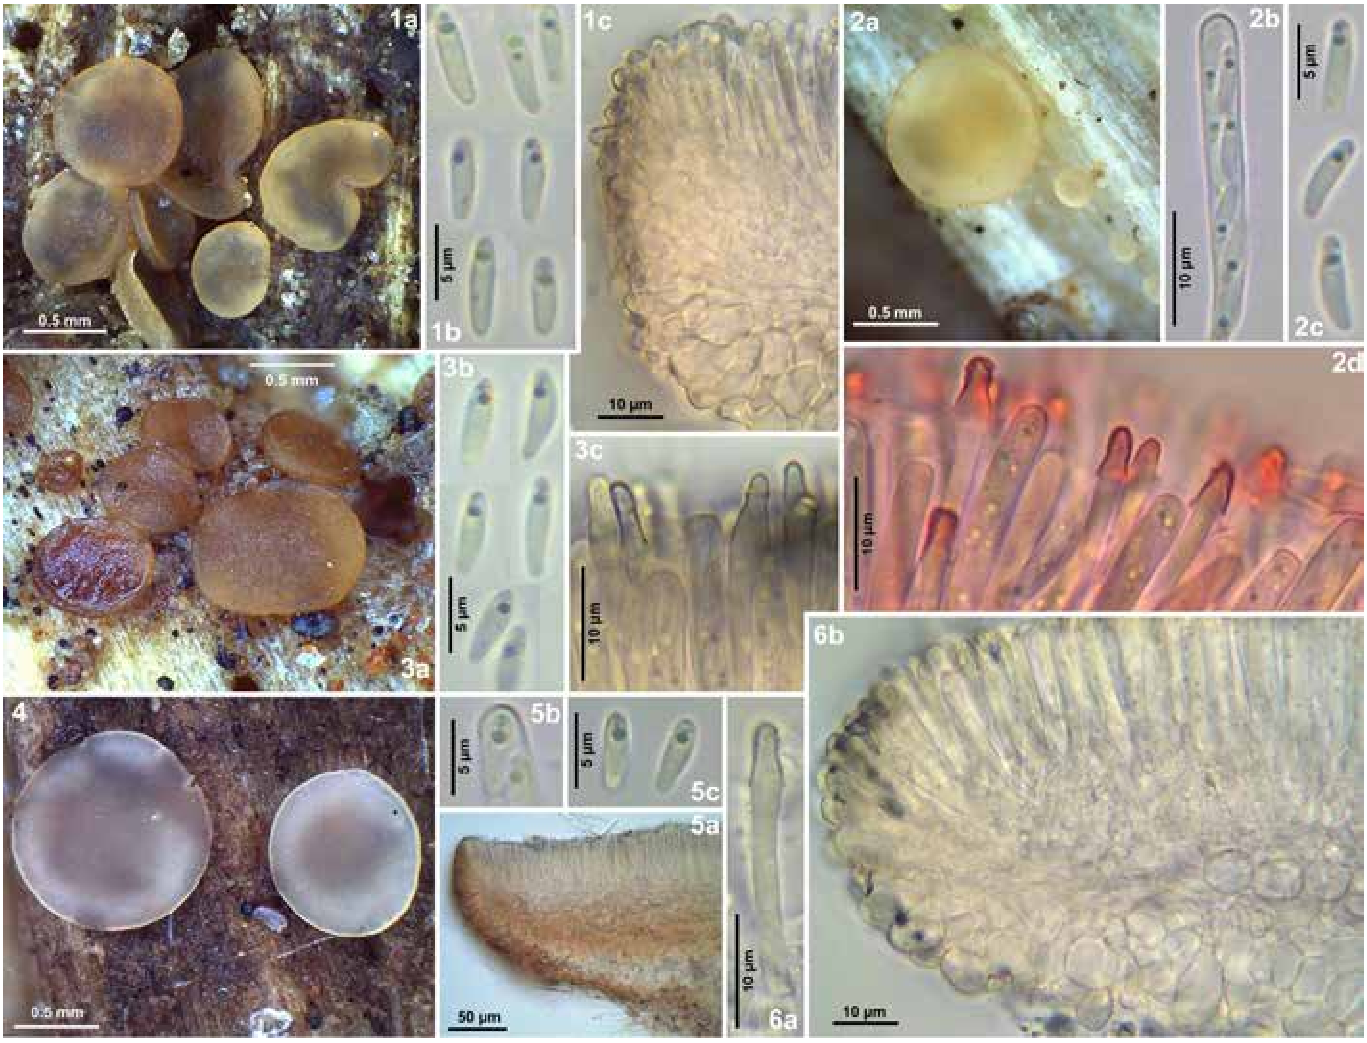

Plate 911. **1–6**: *Orbilia beltraniae* (all from Tenerife on *E. canariensis*). – **1a**, **2a**, **3a**, **4**. apothecia rehydrated after 1–2 weeks; **5a**. apothecium in median section; **1c**, **6b**. id., marginal region; **2b**, **d**, **3c**, **6a**. asci and paraphyses; **5b**. ascus apex in profile view; **1b**, **2c**, **3b**, **5b–c**. ascospores. – Living state. – **1–6**: phot. L. Quijada (**1a**, **3a**, **4**, **6a**: from Quijada & Baral 2017). — **1a–c**. TFC 24363 (holotype): Mesa del Mar; **2a–d**. TFC 23836: Punta de Teno; **3a–c**. TFC 23771: Montaña Amarilla; **4a–c**. TFC 24449: Punta de Hidalgo; **5a–c**. TFC 23902: Hoya el Laurel; **6a–b**. TFC 24231: Punta de Hidalgo.

in the spores but differ in cylindrical to capitate paraphyses, *O. rectispora* also in longer and narrower spores, and *O. zhongdianensis* in smaller SBs. Especially the spores of *O.* cf. *cardui* (Pl. 906: 7) with their globose, slightly eccentrical SBs without a visible filum match well those of *O. beltraniae*. For the similar *O. pseudeuphorbiae* see p. 1476.

Phylogeny. Sequences were gained from apothecia of two collections of *O. beltraniae*, comprising ITS and LSU (D1–D4, the S1506 intron is absent in both). The two sequences are completely identical in their overlapping part. In our phylogenetic analyses (Phyls 25–27) *O. beltraniae* clustered in the *rectispora-beltraniae* clade, though showing a minimum ITS distance of 6.3% to *O. xinjiangensis*, 8.5% to *O. rectispora* and *D. panlongana*, and 9% to *O. cotoneastri*, but 17.5% to *O. cardui*. In the LSU (D1–D2) the lowest distance is 5% to *O. rectispora* and 6% to *O. xinjiangensis*, and here *O. beltraniae* clustered separate from the rest of the *rectispora-beltraniae* clade (S31).

Ecology. *O. beltraniae* was recorded from xerophytic succulent scrublands at six different sites of Tenerife (L. Quijada & E. Beltrán-Tejera pers. comm.). It grew always on ± decayed wood of dead, xeric branches of *Euphorbia canariensis*. The sites are mainly located in the northern part of the island in the inframediterranean semiarid to arid cardonal vegetation (*Periploco laevigatae-Euphorbietum canariensis*), but one is from the very south in the hyperarid tabaibal dulce (*Ceropegio fuscae-Euphorbietum balsamiferae*).

Specimens included (all on wood of *Euphorbia canariensis* branches): **MACARONESIA**: **Canary Islands**, **Tenerife**, San Cristóbal de La Laguna, Anaga, 6 km NE of Tegueste, 2.3 km E of Punta de Hidalgo, NW of Chinamada, 345 m, 20.V.2013, L. Quijada (TFC Mic. 24231, doc. vid.). – ibid., 29.XII.2013, L. Quijada (TFC Mic. 24449, doc. vid.). – Santa Cruz de Tenerife, 3 km NNW of San Andrés, Hoya el Laurel, 307 m, 5.III.2013, L. Quijada (TFC Mic. 23902,

Castro (TFC Mic. 23771, doc. vid.).

Orbilia epilobii Baral & E. Weber, **sp. nov.**, MB 813973 — Pls 912–913

Etymology: referring to the substrate, stems of *Epilobium*.

Typification: Germany, Chemnitz, stem of *Epilobium hirsutum*, 15.VI.2011, B. Mühler (ex H.B. 9558, M-0276478, holotype; sq.: KT222450, KT222446).

Latin diagnosis*: Similis* Orbiliae cardui *sed paraphyses ad apicem haud inflatae, sublanceolatae, excipulum marginale absque processis vitreis. Habitat ad caules uvidos* Epilobii *et* Cirsii *in zona (oro)temperata humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** fresh 0.3–2(–2.4) mm diam., ~0.2–0.4 mm high (receptacle ~0.15–0.2 mm), whitish to pale cream, finally light ochraceous, not or slightly translucent, round to slightly lobate, scattered to gregarious; disc flat, finally medium convex, margin distinct, not or up to 50–60 µm protruding, smooth; broadly sessile, superficial. **Asci** *40–48(–53) × (3.5–)3.8–4.5 µm {3}, †30–44 × 3–4.2 µm {2}, 8-spored, 3–5 lower spores inverted {2} (often mixed), pars sporifera *14–17 µm long; **base** with short to long, thin, flexuous stalk, h- or H-shaped. **Ascospores** *(5–)6–8(–9) × (1.2–)1.4–1.7(–1.8)((–2)) µm {3}, †5.5–7.5 × 1.3–1.5 µm {1}, cylindrical to sometimes slightly fusoid(-clavate), apex rounded to obtuse, base not or slightly to medium attenuated, straight to slightly curved; **SBs** *1–1.5(–1.7) × 0.5–0.8 µm {2}, globose, apically with a hardly visible filum. **Paraphyses** apically uninflated {3} or often slightly to distinctly lanceolate-lageniform or subspathulate-submammiform {3}, terminal cell *(14–)18–21(–27) × 2.5–3.2(–3.5) µm {2}, 1–5 µm longer than living asci, lower cells *4–9(–12) × (2–)2.5–3.5(–4.2) µm {3}; unbranched at upper septum. **Medullary excipulum** 90–150 µm thick, of ± dense textura intricata with many large globose cells especially in upper part, medium sharply delimited. **Ectal excipulum** of thin-walled, vertically oriented t. globulosa-prismatica from base to margin, 120–250 µm thick near base, cells *11–30(–40) × 8–20(–25) µm {3}; 40–90 µm thick at lower flanks, cells *(5–)7–12(–14) × 5–11 µm {3}, 25–60 µm thick near margin, oriented at an 80–90° angle to the surface, marginal cortical cells *9–17 × 4–6(–7) µm {3}, thin-walled; **glassy processes** absent {4}. **Anchoring hyphae** abundant, *(2–)2.5–3.5(–5) µm wide, walls 0.2 µm thick {2}, forming a 20–100 µm thick, ± dense, non-gelatinized t. intricata. **SCBs** not observed; **VBs** in terminal (and lower) cells of paraphyses mostly present, slightly to medium (to strongly) refractive, hyaline, globose to elongate {3}. **Exudate** over paraphyses, margin and flanks absent or 0.1–0.2 µm thick, ± smooth, hyaline to pale yellowish {3}. **— ANAMORPH**: dactylella-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** unbranched, straight, ellipsoid-clavate, obtuse at apex, *25 × 6 µm, 3-septate or *~48 × 7 µm, 6-septate {only 2 conidia seen, 1 per sample}.

Habitat: on previous year's herbaceous stems of *Cirsium palustre* {1}, *Epilobium* sp. {1}, *E. hirsutum* {3}, lying on damp to wet ground or at the base of standing stems. **Associated**: *Pyrenopeziza carduorum* {1}, *P. chamaenerii* {2}. **Desiccation tolerance**: asci and paraphyses do not survive half a day. **Altitude**: 153–193 m a.s.l. (England), 325–520 m a.s.l. (Germany), 1115 m (Auvergne). **Geology**: Cambrian, Silurian & Carboniferous lime-, sand- & mudstone, Permian (Rotliegend), Pleistocene sand & gravel; mica schist. **Phenology**: V–VII.

Taxonomic remarks. *Orbilia epilobii* differs from the similar *O. cardui*, *O. cotoneastri*, and *O. zhongdianensis* in the paraphyses having uninflated to slightly tapered (sublanceolate

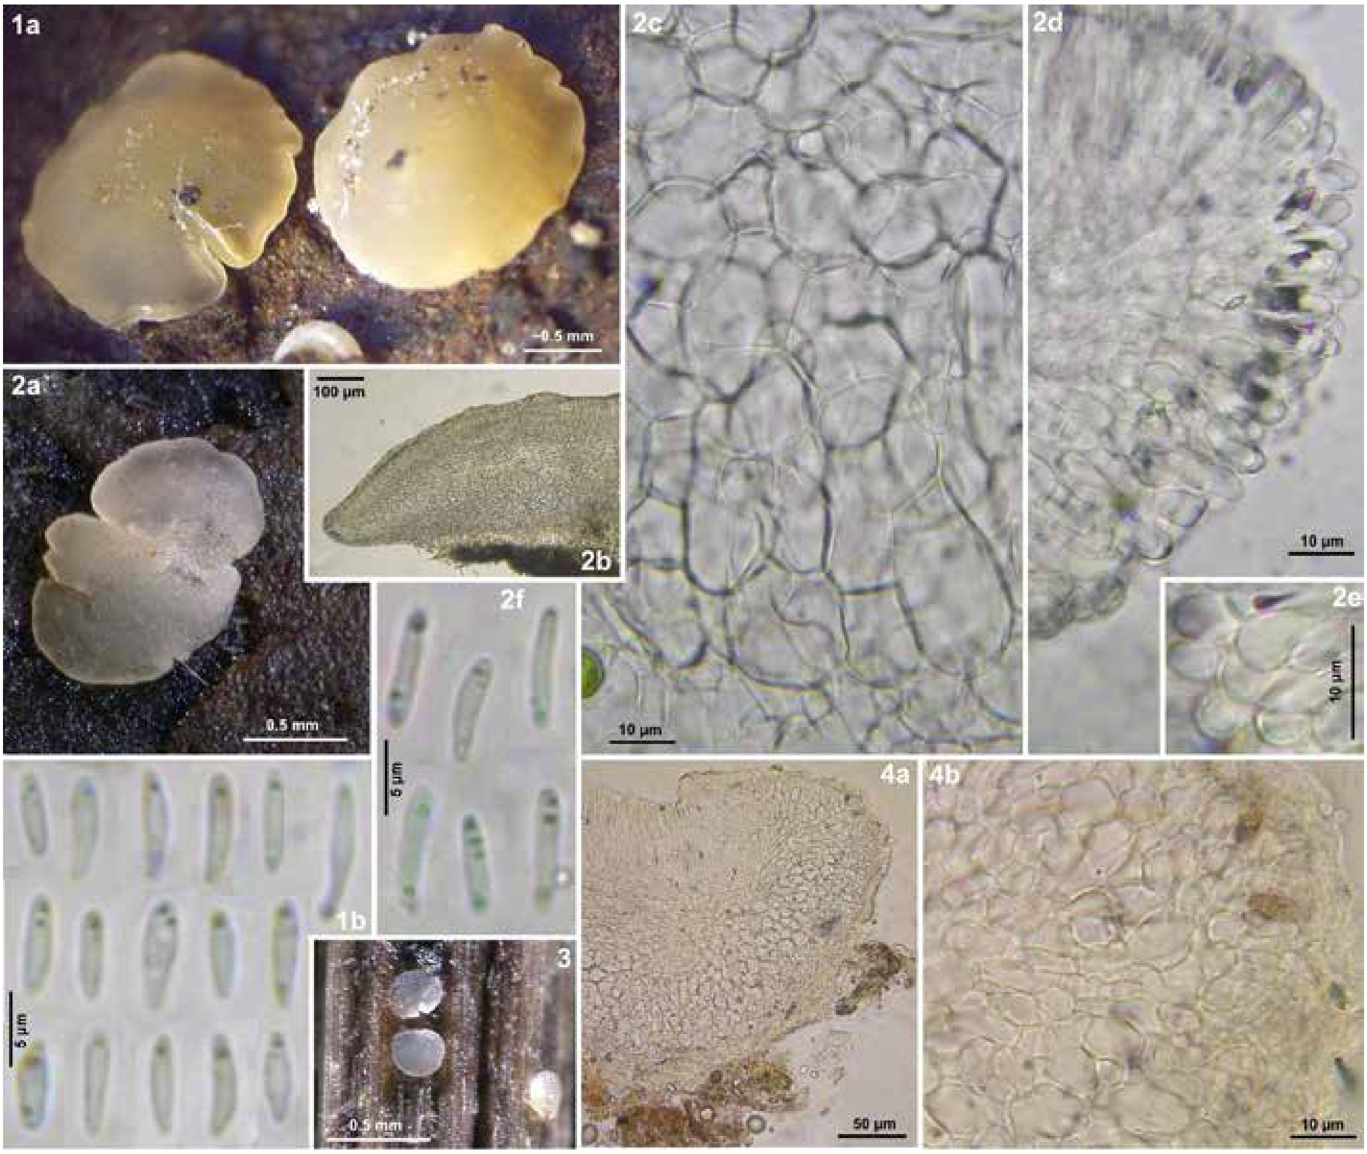

Plate 913. **1–2**: *Orbilia epilobii*; **3–4**: *O.* cf. *epilobii*. – **1a**, **2a**, **3**. apothecia (**1a**, **2a** fresh, **3** rehydrated); **2b**, **4a**. apothecium in median section, **2c**. id., ectal excipulum at flanks; **2d**, **4b**. id., at margin; **2e**. marginal cortical cells; **1b**, **2f**. ascospores. – Living state, except for **4a–b** (in KOH). – **1a**: phot. B. Mühler. – **1a–b**. H.B. 9558 (holotype): Germany, Chemnitz, on *Epilobium*; **2a–f**. H.B. 9899: Annaberg-Buchholz, on *Epilobium*; **3**. H.B. 5530: France, Vosges, on *Ranunculus*; **4a–b**. H.B. 5883: ibid., on *Carex*.

to sublageniform) but never distinctly capitate apices, from *O. cardui* and *O. zhongdianensis* also in the absence of glassy processes. When the paraphyses are tapered, they overtop the living submature asci distinctly more than in the latter three species, while the lower cells tend to be broader than there. However, no tapered paraphyses were seen in the collection on *Cirsium*, and here a morphological distinction from the lignicolous *O. cotoneastri* is problematic. Ascus and spore size as well as spore and SB shape are very similar in all four species. *O. epilobii* is proposed here as a new species because of the sublanceolate paraphyses but mainly for molecular reasons.

At the type locality of *O. epilobii* (on *Epilobium*) also *O. cardui* (on *Angelica*) and *O. rectispora* (on *Typha*) occurred. Because of their similarity one might think that these three hosts carry one and the same *Orbilia* species, but this is disproved by the different sequence data gained for the former two species from this locality. These findings suggest also a certain host specificity within this group of fungi, particularly in that *O. rectispora* is restricted to monocots.

Variation. The four included collections are very similar, although the paraphyses differ in shape, those from Annaberg and Auvergne being partly cylindrical, those of the holotype more lageniform, and those from England more spathulate-lanceolate. In the collection on *Cirsium* the asci and spores were rather narrow (*3.5 and *1.2 µm, respectively).

Not included collections. Two orotemperate (altimontane) samples from a single site near Les Vazenées (Gérardmer, Vosges, on *Ranunculus* and *Carex*, Pls 912: 2–3; 913: 3–4) resemble *O. epilobii* in their consistently uninflated paraphyses and paucity of exudate. The one on *Ranunculus* resembles also *O. cardui*, particularly when comparing the sample on *Fomitopsis* (Pl. 906: 1), both sharing somewhat tear-shaped SBs with a visible filum. The *Carex* collection differs from that on *Ranunculus* in much longer asci and longer spores, much larger apothecia (0.8–2.5 vs. 0.25–0.6 mm), and in showing hyphoid elements covering the marginal cortical cells (Pl. 913: 4a–b). Because of its rather wide spores this sample cannot belong to *O. rectispora*. Also three samples on *Oenanthe* from two sites in Bretagne (IVV: J.P.P. 13123, 15154, 15155) resemble *O. epilobii*, but also the montane collection on *Ranunculus*. They might well belong to *O. epilobii*, but molecular data were not avaiable. From *O. atlantis* they differ in larger, basally ± curved and more tapered spores and whitish apothecia (but in J.P.P. 15155 the spores match *O. atlantis* except for their length of *5.2–8 µm).

Three unpreserved records from Les Vazenées but on *Scirpus sylvaticus*, the type substrate of *O. rectispora*, were only studied by J. Deny (pers. comm., see also Deny 2002). They were said to have rather short asci and spores, but since all typical European records of *O. rectispora* so far showed a planar to colline occurrence, those from altimontane areas need to be recollected and documented (note that the type of *D. nuorilangana*, a synonym of *O. rectispora*, derives from altimontane central China).

Anamorph. A rather short, 3-septate conidium seen in the sample from Annaberg (IVV: H.B. 9899) would fit in the scope of *O. zhongdianensis*, whereas a rather long, 7-septate conidium in an apothecium of the sample from Walsall (IVV: 29.VI.2017) would fit *O. rhopalota*. A few fusoid-clavate conidia of *32–44 × 6.7–7.2 µm with 3–6 septa were seen in one of the not included collections on *Oenanthe* (IVV: J.P.P. 15155), while in the other on that host a larger broken conidium with min. 7 septa occurred (IVV: J.P.P. 15154). Whether all these conidia belong to *O. epilobii* and how representative they are remains unclear.

Phylogeny. Sequences were gained from apothecial fragments of the two sparse German records on *Epilobium* and the abundant French one on *Cirsium*, comprising ITS and LSU, in the holotype also SSU. The S1506 intron is absent in the sample from Annaberg, but present in the other two. Between the two strains on *Epilobium* an ITS distance of 0.8 % is observed, while the *Cirsium* collection differs by only 0.2–0.4 % from them. In the LSU D1–D2 the three strains differ from each other by 1 nt or 1 gap.

O. epilobii clusters in the *cardui-rhopalota* clade (Phyls 25–27, S31). The closest distance in the ITS/LSU (D1–D2) was to *D. rhopalota* (4.5–5.8/0.4–0.7 %), *O. zhongdianensis* (5.8–6.5/0.8–0.9 %), and *O. cardui* (5.5–6/1.5–1.8 %), whereas *O. cotoneastri* and *O. rectispora* show distances of 15.5–16/4.3 % and 19/3.9 %, respectively. A different result is obtained in the SSU (V7–V9), with 0.4 % (*Dactylella cylindrospora*) and 0.7 % (*O. desertorum*, *O. cupressi*, *D. intermedia*) as closest match, while this region was not available for *D. rhopalota*. In the S1506 intron *O. epilobii* shows a high distance to other members of series *Dactylella*, the lowest percentage being to European *O. zhongdianensis* (14 %).

Ecology. *O. epilobii* is so far with certainty known from five locations in cold- to orotemperate humid, atlantic to subcontinental Europe, where it was found on hygric herbaceous stems of *Epilobium*, once also *Cirsium*. The type locality near Chemnitz is a colline wet meadow (abundant *Filipenduletum ulmariae* with *Typha*) surrounded by oak and poplar trees. That from Erzgebirge (ca. 35 km south of the type locality) is a montane, periodically dry pond between a pasture and small woods, and that from Auvergne a dense altimontane forest on moist ground. The two colline sites in England include a marshy place with *Filipendula ulmaria* at a small pond, surrounded by a deciduous forest with, e. g., *Ulmus glabra*, *Acer campestris*, *Fraxinus excelsior*, *Crataegus monogyna*, *Juncus effusus*, *Carex remota* etc. (Fishpool Valley), and a ditch with only *Epilobium hirsutum* at a pond in a forest (Merrions Wood). Perhaps all these locations are flooded during heavier rainfalls, e. g., in winter.

Specimens included. **GREAT BRITAIN**: **West Midlands**, 8.7 km NNW of Birmingham, 4.5 km SE of Walsall, Merrions Wood, 153 m, stem of *Epilobium hirsutum*, 29.VI.2017, P. Thompson (ø, anam. substr., doc. vid.). – **Herefordshire**, 10.5 km SW of Ludlow, 8.5 km NNW of Leominster, N of Croft Castle, Fishpool Valley, 193 m, stem of *E. hirsutum*, 4.V.2017, P. Thompson (H.B. 10079a). – ibid., 8.VII.2017 (ø, non vid.). — **GERMANY**: **Schleswig-Holstein**, 13.5 km SE of Ratzeburg, NNW of Groß Zecher, Küchensee, 40 m, stem of *E. hirsutum*, 26.VI.2018, T. Richter (H.B. 10167). – **Sachsen**, 6 km NNE of Chemnitz, 1 km E of Glösa, Indianerteich, 325 m, stem of *E. hirsutum*, 15.VI.2011, B. Mühler (ex H.B. 9558, M-0276478, **holotype**; sq.: KT222450, KT222446). – Erzgebirge, 31 km S of Chemnitz, 10 km WSW of Annaberg-Buchholz, 2.5 km S of Elterlein, 520 m, stem of *Epilobium* sp., 23.VII.2014, B. Orbilia zhongdianensis (J. Zhang & K.Q. Zhang) Baral, E. Weber & M. Bemmann, **comb. nov.**, MB 813974 — Pls 914–915

Basionym: *Dactylella zhongdianensis* J. Zhang & K.Q. Zhang, Mycotaxon 92: 290 (2005)

Etymology: in reference to the geographical origin of the type, Zhongdian (= Shangri-La), Yunnan province, China.

Typification: China, Yunnan, Shangri-La, soil isolate, 7.IX.2003, J. Zhang (YMF 1.00568, holotype; sq.: DQ494365, KT215287).

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated 0.5–1.7 mm diam., 0.23–0.32 mm high (receptacle 0.18–0.24 → 0.1–0.13 mm), milky-white to light cream-isabelline(-apricot), ± translucent, round, subgregarious; disc flat, margin distinct, thin or thick, 0–10 µm protruding, smooth to very finely crenulate; sessile on a broad or narrow base, superficial; dry bright dull orange, with thick protruding margin. **Asci** *35–46 × 3.6–4.3 µm {1}, †32–45 × 3.1–4 µm {2}, 8-spored, spores *2–3-seriate, lower ~4 spores inverted {2}, pars sporifera → 9–14 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to long, thin or thick, flexuous stalk, Y-, h- or H-shaped. **Ascospores** *(5–)5.7–7(–8) × (1.2–)1.3–1.5(–1.7) µm {2}, cylindrical to ellipsoid-fusoid(-clavate), apex rounded to obtuse, base partly medium to strongly attenuated, sometimes with a tail, straight to slightly inequilateral; **SBs** *0.3–0.6 µm diam., ± globose, partly ± eccentrical, attachment invisible (total length 0.8–1.5 µm) {2}. **Paraphyses** apically not or slightly capitate, terminal cell *16–24 × 2–3.5 µm, lower cells *5–11 × 2–2.5(–3) µm. **Medullary excipulum** 30–40 µm thick, of dense textura intricata horizontally oriented, with inflated cells, medium or sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled, indistinctly oriented t. globulosa from base to margin, 110–150 µm thick near base, cells *13–28 × 11–19(–24) µm {2}; 50–80 µm thick at lower flanks, *7–15 × 6–12 µm, 30–40 µm thick near margin, oriented at an 80–90° angle to the surface, marginal cortical cells *(5–)6–11(–13) × 3.5–6 µm {2}; **glassy processes** 2–17 × 4–6 µm {2}, strongly refractive, stratified, ± straight. **Anchoring hyphae** medium abundant, †1.7–2.5(–3) µm wide, walls 0.2(–0.3) µm thick {1}. **SCBs** not observed; **VBs** medium refractive, globose to elongate, filling entire terminal cell. **Exudate** over paraphyses, margin and flanks 0.2–1 µm thick, granular

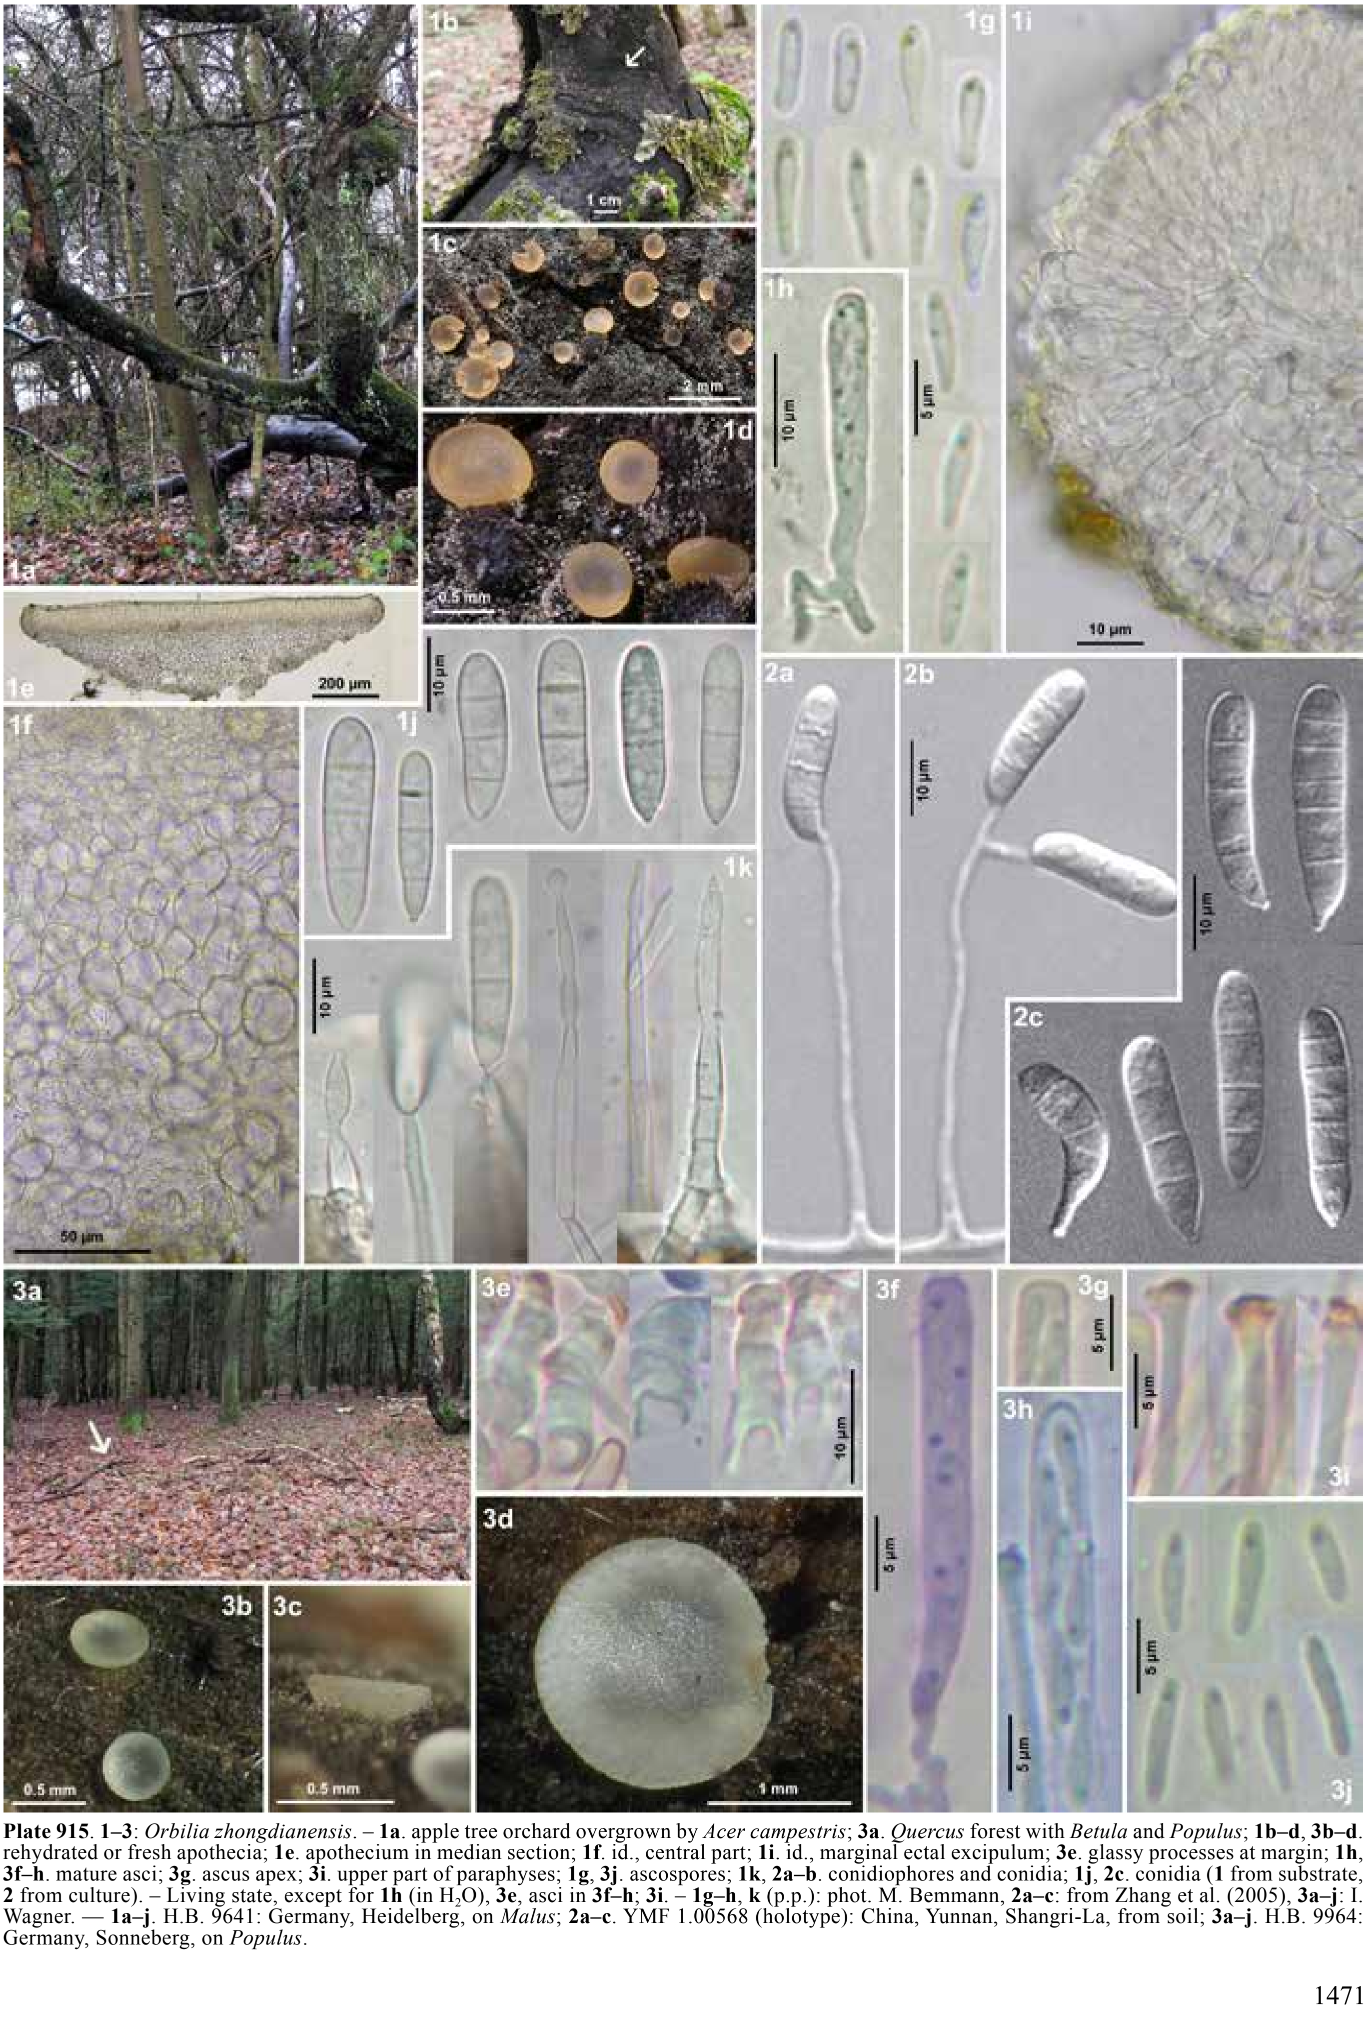

Plate 915. **1–3**: *Orbilia zhongdianensis*. – **1a**. apple tree orchard overgrown by *Acer campestris*; **3a**. *Quercus* forest with *Betula* and *Populus*; **1b–d**, **3b–d**. rehydrated or fresh apothecia; **1e**. apothecium in median section; **1f**. id., central part; **1i**. id., marginal ectal excipulum; **3e**. glassy processes at margin; **1h**, **3f–h**. mature asci; **3g**. ascus apex; **3i**. upper part of paraphyses; **1g**, **3j**. ascospores; **1k**, **2a–b**. conidiophores and conidia; **1j**, **2c**. conidia (**1** from substrate, **2** from culture). – Living state, except for **1h** (in H_2O), **3e**, asci in **3f–h**; **3i**. – **1g–h**, **k** (p.p.): phot. to cloddy, hyaline, ± firmly attached. — **ANAMORPH**: dactylella-like (from soil isolate {1} and natural substrate {1}, connection proved by DNA). **Conidiophores** *(20–)40–118(–132) µm {T} or *50–75 µm {1} long, 2.5–5 wide at base, 1–2 µm at apex, unbranched or sometimes branched in middle or upper part. **Conidiogenous cells** monoblastic, rarely sympodial. **Conidia** unbranched, straight to slightly or sometimes strongly curved near base, cylindric(-ellipsoid) to cylindric(-clavate), rounded (to obtuse) at apex, base often with a small basal protrusion, *(17.5–)22–34(–37.5) × (5–)5.7–7(–8) µm, (2–)3(–4)((–6))-septate {T}, or *22.5–27 × 5–6.7 µm, (1–)3(–4)-septate {1}.

Habitat: lying on ground or 1.5 m above, 17–90 mm thick branches of *Malus* sp. {1}, *Populus tremula* {1}, on outer surface of ± detaching, medium decayed remnants of bark (bast) {2}. **Associated**: *Hypnum cupressiforme* {1}, anamorph of *Thaxteriella pezizula* {2}. **Desiccation tolerance**: asci do not survive a few days, after ~3 weeks excipular cells and a few ascospores still viable. **Altitude**: 128–480 m a.s.l. (Germany), 3538 m (Yunnan). **Geology**: Germany: Lower Carboniferous sediment, Upper Buntsandstein; China: mafic volcanic rock. **Phenology**: XI–XII (teleomorph).

Taxonomic remarks. *Orbilia zhongdianensis* resembles the herbicolous *O. cardui*, from which it differs in the ascospores containing smaller, ± eccentrical, invisibly attached SBs (Pls 914: 1a; 915: 1g, 3j), also in shorter conidia with fewer septa. In spore characters the species resembles *O. xinjiangensis* which, however, has larger spores and much larger conidia. *O. clavispora* resembles *O. zhongdianensis* in its anamorph but differs in longer, curved ascospores and a marginal ectal excipulum of distinct, obliquely oriented cell rows.

Anamorph. Zhang et al. (2005) described *Dactylella zhongdianensis* as a 'new predacious antagonist of nematodes', with a 3-dimensional adhesive network. Nevertheless, the authors placed it in *Dactylella* following the generic concept of Subramanian (1964) based on conidial morphology and simple conidiophores. However, Chen et al. (2007b) did not find trapping organs in the type isolate when challenged with nematodes, and also the obtained molecular data support placement in *Dactylella* in the modern sense. The anamorph observed on the natural substrate in the sample from Heidelberg (Pl. 915: 1j–k) concurs very well with the ex-type strain (2a–c).

Zhang et al. (2005) gave a conidial size of 17.5–35 × 5–10 µm, with an average of 28.3 × 7.2 µm. From their scale, however, the conidia measure *17.5–33.5 × 5–7 µm. Chen et al. (2007) measured them as 22–37.5 × 5–8 µm (average 28 × 7 µm), therefore, we have restricted conidial width to a maximum of *8 µm.

Dactylella cylindrospora, isolated from soil under cocoa in Samoa, resembles *O. zhongdianensis* and *O. cotoneastri* in conidial morphology (22.5–45 × 6.5–8.5 µm, (1–)3(–4)-septate) but differs in forming 6–12 conidia at the candelabrelloid conidiophore tip. However, in Chen et al.'s (2007b) redescription of the type strain the conidia are 3(–7)-septate and measure 29–51 × 8.5–13 µm.

Phylogeny. Sequences were gained in the present study from the Chinese ex-type culture (soil isolate) and the two German samples (from apothecia), comprising S1506 intron, ITS, LSU, and in two strains also SSU. The ex-type culture was also sequenced by Chen et al. (2007a) for the ITS region, and their sequence fully agrees with ours, and also the German samples correspond quite well to them (0.8 % distance), except for a few gaps in the ITS1 and particularly a deviating motif at its 5'-end (AAA**TTT**AT vs. AAA**C--**AT). However, the *Malus* sample was incompletely sequenced in the ITS1, with some uncertain and ~83 missing nt). In the available parts of SSU (V8–V9) and LSU (D1–D2) the German samples do not differ at all from the type. Obviously, the three strains are conspecific. However, in the S1506 intron the Chinese strain differs from the two from Germany by 15.3 % in the overlapping region, while the two latter are completely identical, also the length is 1565 nt in the ex-type strain but only 385 in the German strains.

In our analysis of ITS (Phyl. 26), but not in the LSU and combined tree (Phyl. 27, S31), *O. zhongdianensis* formed with *D. rhopalota* a strongly supported clade, showing an ITS distance of only 2.9–3.7 % (LSU D1–D2 1.5 %). Although *O. cardui* and *O. epilobii* show to *O. zhongdianensis* a lower LSU distance of 0.8–1 %, a much higher ITS distance of 5.8–7 % is observed. *D. cylindrospora* clustered unresolved and with high distance to other species of series *Neodactylella*.

Ecology. The type strain was isolated from soil in a highland forest (probably coniferous with *Rhododendron*) in the eastern Himalaya near Zhongdian in northwestern Yunnan (China), which shows a orotemperate humid (winter-dry), continental climate. The two European collections were on rotten, hygric or mesic angiosperm bark in colline, subcontinental, cold-temperate humid shady forests on acidic soil. In the sample on *Malus* the apothecia occurred on the main trunk of a standing dead tree 1.5 m above the ground. The orchard was overgrown by *Acer campestris*, which possibly caused the death of the *Malus* tree. The apothecia grew amongst conidiophores of *Thaxteriella pezizula*, and the anchoring hyphae of *O. zhongdianensis* seemed to be parasitic on the conidiophores. Also in the sample on a branch of *Populus* lying on the ground in a *Quercus* forest with *Betula* and *Populus*, numerous sigmoid conidia occurred which might belong to *T. pezizula*.

Specimens included. **GERMANY**: **Thüringen**, 2.3 km NW of Sonneberg, 1 km NNE of Bettelhecken, Wehd, 480 m, branch of *Populus tremula*, on bark, 9.XI.2014, I. Wagner (H.B. 9964; sq.: KT380101). – **Baden-Württemberg**, 12.5 km E of Heidelberg, 1 km SE of Neckarsteinach, 128 m, branch of *Malus domestica*, on bark, 30.XII.2011, M. Bemmann (H.B. 9641, anam. substr.; sq.: KT222436). — **CHINA**: **Yunnan**, **Dêqên**, 32 km E of Shangri-La (Zhongdian), Bitahai, 3538 m, soil isolate, 7.IX.2003, J. Zhang (YMF 1.00568, **holotype**, conid. isol., doc. vid.; sq.: DQ494365, KT215287).

Orbilia rhopalota (Drechsler) Baral & E. Weber, **comb. nov.**, MB 813975 — Pl. 5: q

Basionym: *Dactylella rhopalota* Drechsler, Mycologia 35: 357 (1943)
≡ *Gangliophragma rhopalota* (Drechsler) Subram., Kavaka 5: 94 (1977)

Etymology: *rhopalota*: named after the clavate conidial shape.
Typification: USA, Maryland, Beltsville, forest litter, I.1938, C. Drechsler (holotype, illustration in Drechsler 1943: fig. 3 H–O).

Description: — **TELEOMORPH**: unknown. **ANAMORPH** (from Drechsler 1943 and Rubner 1996): dactylella-like (from environmental isolates). **Conidiophores** unbranched or sympodially branched, 50–200 µm long, 2.5–4 µm wide at base, 1–2 µm at apex. **Conidia** unbranched, straight, cylindric-clavate, rounded to obtuse at apex, *36–60 × (6–)7.5–8.5(–9.5) µm, (3–)7(–10)-septate.

Taxonomic remarks. Thakur & Zachariah (1989) isolated from the rhizosphere of soybeans in Ontario a dactylella-like anamorph which they identified with Drechsler (1943b) as *Dactylella rhopalota*. The culture produced in the presence of bacteria apothecia of an *Orbilia* which the authors could not identify at the species level. Although the description of the teleomorph is too inaccurate to recognize the species, we believe that it was a member of series *Neodactylella*, based on the †~4.5–6 × 0.8 µm large, rod-shaped ascospores (evaluated from scale) that are sometimes slightly tapered and bent at the base, and the apparently H-shaped ascus base, together with the anamorph. An earlier assumption that it could be *Hyalorbilia inflatula* (Baral in Rubner 1996: 22, as *O. inflatula*) is obviously unfounded. Thakur & Zachariah's photo shows clavate conidia with a stipe-like basal protrusion, which are seemingly surrounded by a halo. The authors measured them as 42.5–55 × 5–6.5 µm and observed 8 septa, whereas in the type of *D. rhopalota* Drechsler (1943b) gave distinctly wider conidia (*36–60 × 6.7–9.6 µm) with mainly 7 septa. Rubner (1996) examined and identified several CBS cultures as *D. rhopalota* (e. g., CBS 493.67 and 615.92), most of which were first named *D. minuta* and erroneously thought to be nematophagous. Her conidial data are similar to Drechsler's: 36–60 × 6–8.5 µm, (3–)7(–10)-septate.

In conidial shape and number of septa, these *D. rhopalota* strains resemble the anamorphs of *Orbilia cardui* and *O. cotoneastri*, except that these species have smaller, especially shorter conidia on average, and septal numbers higher than 7 were not encountered. An unpreserved, submature specimen from France, identified as *O.* cf. *cardui* (26.I.1997, on *Pinus* cone, with 3–12 µm long glassy processes), would fit well the type of *D. rhopalota* based on the distinctly larger conidia (*50–53 × 8.3 µm, 7-septate, clavate-cigar-shaped, not illustrated) found in association with the teleomorph. Possibly, this record represents *D. rhopalota*, especially when considering the repeated isolation of *D. rhopalota* from coniferous substrate. It seems further possible that the type of *O. pellucida* represents *D. rhopalota*, because it grew on a twig of *Juniperus*. *D. rhopalota* also resembles the presumed anamorph of *O. crenatomarginata* (section *Aurantiorubrae*, see p. 872). Based on our broad concept of *Orbilia*, and because it will be difficult to clarify the identity of *O. pellucida* which would have priority over *D. rhopalota*, we here propose a new combination for *D. rhopalota* into *Orbilia*.

Phylogeny. For the North American holotype of *O. rhopalota* no culture or sequence seem to exist. Six European strains, mostly isolated from plant substrate, were identified as *D. rhopalota* by Rubner (1987). Except for that from UK, all carried the name *D. minuta*. Five were sequenced by Chen et al. (2007a) for the ITS region, and one (CBS 664.75) exists only inofficially at CBS. All of them agree by a 0.2–0.6% distance. Whether any of them possesses the S1506 intron is unclear because the ITS1 primer was used.

Sequences from two uncultured soil isolates from Alaska (GU083160, ITS) and California (dm5l_b3, ITS2+LSU) are obviously conspecific with those, the former differing by 0–0.4% in the entire ITS, the latter by 2–4 nt in the ITS2. *O. rhopalota* clustered strongly supported with *O. zhongdianensis* (Phyl. 26), with an ITS distance of 2.9–3.7%. *O. epilobii* deviates by 4.5–5.8% and *O. cardui* by 7.5%. One of the European strains (CBS 493.67) comprises also SSU V1–V9 (lacking the 3'-end with the S1506 position) and LSU. In the LSU D1–D2 the distance is 0.7% to *O. epilobii*, 1.5 % to *O. zhongdianensis*, and 2.5% to *O. cardui*.

Ecology. *O. rhopalota* was isolated from not further specified forest litter near Beltsville (type, warm-temperate humid eastern North America), but DNA extracts indicate occurrence in boreal and mild-maritime humid western North America. The CBS strains studied by Rubner (1996) were from subatlantic Netherlands, atlantic England, and from Sweden, and include decaying wood and leaf litter of *Juniperus* and *Pinus*, and living leaves of *Fraxinus*.

Specimens included. **USA**: **Maryland**, Beltsville, forest litter, I.1938, C. Drechsler (**holotype** [illustration], conid. isol., doc. vid.). – **Alaska**, unlocalized, from soil, undated (K.M.E. Stone et al., T1-B6-ITSFL, mol. extr.; sq.: GU083160). – **California**, ~30 km WSW of Santa Rosa, Bodega Bay, ~30 m, soil under *Lupinus arboreus* (Smith & Jaffee 2009, dm5l_b3, sq.: EF446000). — **NETHERLANDS**: **Noord-Holland**, Bergen, on wood of *Pinus sylvestris*, 8.X.1967, W. Gams, vid. A. Rubner (CBS 493.67, conid. isol., non vid.; sq.: AJ001992, DQ494369, AY261177, MH870756). – ibid., from needle of *Pinus* sp., 1968, W. Gams, vid. A. Rubner (CBS 616.92, conid. isol., non vid.; sq.: DQ494368). – **Drenthe**, Lheedorp near Wijster, from litter of *Juniperus communis*, XI.1975, W. Gams, vid. A. Rubner (CBS 664.75, as *D. minuta*, conid. isol., non vid., sq.: CBS ined.). – **Utrecht**, Baarn, from decaying wood, X.1967, W. Gams, vid. A. Rubner (CBS 615.92, as *D. minuta*, conid. isol., doc. vid.; sq.: DQ494367). — **SWEDEN**, unlocalized, X.1975, G.L. Hennebert, vid. A. Rubner (CBS 617.92, as *D. minuta*, conid. isol., non vid.; sq.: DQ494366). — **GREAT BRITAIN**: **North West England**, **Cumbria**, Meathop Wood, Intern. Biol. Programme site, Westmoreland, on a living leaf of *Fraxinus excelsior*, VIII.1970, J.C. Frankland, vid. A. Rubner (CBS 845.70 [as 'CBS 475.70' in Rubner 1996], conid. isol., non vid.; sq.: DQ494370, MH871769).

Orbilia leporina Velen., Opera Bot. Čech. 4: 103 (1947) — Pl. 916

?= *Orbilia leucostigma* var. *charticola* Feltgen, Rec. Mém. Trav. Soc. Bot. G.-D. Luxemb. 14: 54 (1899)
≡ *Orbilia luteorubella* f. *charticola* (Feltgen) Feltgen, Rec. Mém. Trav. Soc. Bot. G.-D. Luxemb. 15: 36 (1901).

Etymology: *leporina*: named after the substrate, hare droppings, *charticola*: after its growing on a cardboard.

Typification: Czechia, Mnichovice, dung of *Lepus*, 6.VIII.1941, J. Velenovský (PRM 152419, holotype of ***Orbilia leporina***). — Luxembourg, Mersch, on cardboard, 29.VI.1896, J. Feltgen (LUX 042447, holotype of ***O. luteorubella* f. *charticola***).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.5 mm diam. (Velenovský: 0.5–1 mm), 0.14 mm high, now pale yellowish-cream (Velenovský: yellowish), translucent, round; disc slightly concave then flat, margin indistinct, not protruding, smooth; broadly sessile, superficial. **Asci** †32–45 × 3.5–3.7 µm, 8-spored, spores †2–3-seriate, 4 lower spores inverted (not mixed); **apex** (†) strongly truncate (not indented, laterally hardly inflated); **base** with medium long, thin, flexuous stalk, L- to Y-shaped (rarely seen). **Ascospores** †(6–)7–8(–9.2) × 1.1–1.3(–1.4) µm, narrowly fusoid-clavate (to fusoid), apex rounded to obtuse (rarely subacute), base medium to strongly attenuated, slightly curved to geniculate, especially in lower part; **SBs** very indistinctly seen in dead spores. **Paraphyses** apically uninflated to medium capitate, terminal cell †12.5–15 × 2–3.3 µm, lower cells †4–8.5 × 1.4–1.9 µm; unbranched at upper septum. **Medullary excipulum** 60 µm thick. **Ectal excipulum** of (†) thin-walled, vertically oriented textura globulosa-angularis from base to margin, 35–40 µm thick near base, cells †8–12 × 8–10 µm; 30 µm thick near margin, outer part of t. prismatica oriented at a 80–90° angle to the surface, marginal cortical cells †6–14 × 3–4.5 µm; **glassy processes** absent. **Anchoring hyphae** sparse, †2.2.7 µm wide, walls 0.2–0.25 µm thick. **SCBs** and **VBs** no data available. **Exudate** over paraphyses 0.3–1 µm thick, rough, firmly attached, over margin and flanks ~0.2–0.5 µm thick, granular. — **ANAMORPH**: dactylella-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** ellipsoid-clavate, straight, †31–45 × 7.5–7.7 µm, 3–7-septate.

Habitat: collected on the forest floor, on droppings of *Lepus europaeus*. **Associated**: *Coprotus sexdecimsporus*, *Saccobolus dilutellus*, *Sporormiella australis*, *S. octomera*. **Desiccation tolerance**: unknown. **Altitude**: 360 m a.s.l. **Geology**: amphibole biotite & tonalite, quartz diorite. **Phenology**: VIII.

Taxonomic remarks. *Orbilia leporina* seems to be closely related to *O. cardui* and *O. cotoneastri*, from which it is tentatively separated here by basally more attenuated and curved ascospores and the occurrence on dung, from *O. cardui* also in the absence of glassy processes. *O. leporina* differs

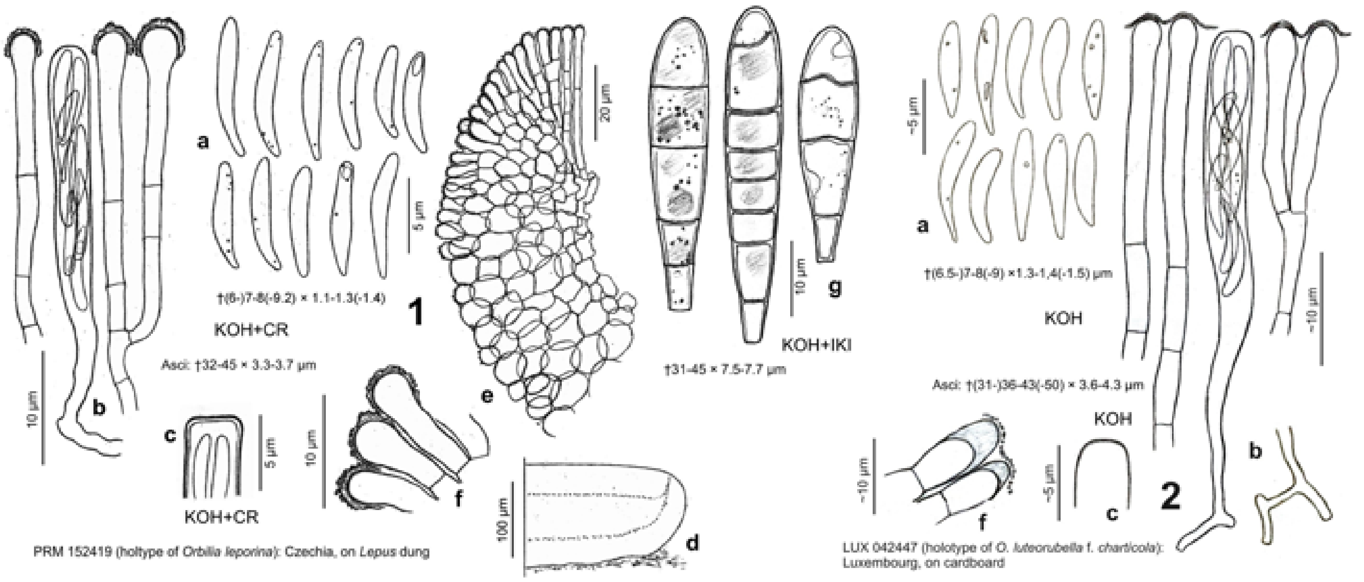

Plate 916. **1**: *Orbilia leporina*; **2**: *Orbilia* cf. *leporina*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., ectal excipulum at margin and mid flanks; **f**. id., marginal cortical cells, with or without glassy processes; **g**. conidia from substrate.

from the caulicolous *O. rectispora* in slightly longer asci and wider spores, also in an exudate forming individual caps on the paraphyses, finally in conidial shape (see below). The lignicolous *O. mammillata* differs from *O. leporina* in slightly longer and narrower spores, shorter asci, short glassy processes at the margin, and especially in very differently shaped conidia. The tropical *O. cocois* is only tentatively separated from *O. leporina* (see p. 1474).

Type studies. Contrary to Svrček (1954), the holotype of ***O. leporina*** is not empty. In the present study two apothecia could be found which belong to *Orbilia* section *Arthrobotrys*, not to *Hyalorbilia* as suggested by Svrček (as *O. inflatula*) based on Velenovský's brief description. In fact, the spores are much longer than Velenovský indicated, and also at least slightly curved (Velenovský described them as '3–5 × 1 µm, narrowly linear, straight'). Velenovský saw also the associated conidia (see below).

The holotype of ***O. luteorubella* var. *charticola*** (on rotten cardboard, Pl. 916: 2) resembles *O. leporina* in many respects. The ascospores are slightly (to medium) curved, apically obtuse and basally often strongly tapered. Feltgen (1899) reported them as 'straight to slightly flexuous, rod-shaped, 6–8 × 1–1.5 µm'. The apothecia were described as whitish-yellowish, 0.2–0.5 mm diam., but in the present study they were rehydrated 0.3–1 mm diam., finally convex and up to 350 µm thick, white to light yellow-ochraceous. The cells of the marginal excipulum are oriented at a 60–70° angle and terminated by glassy caps of 3–6 × 3.5–4.5 µm (Pl. 916: 2f). These and the scarcely inflated paraphysis apices are covered by a thin granular exudate. The taxon is clearly not related to section *Helicoon* but resembles *O. leporina* and also *O. cocois* and *O. cardui*, from which it deviates in a ± gelatinized basal ectal excipulum and abundant anchoring hyphae forming a gelatinized layer, from *O. leporina* also in the presence of cap-like glassy processes at the margin, from *O. cardui* in longer, more attenuated and curved ascospores, and from *O. cocois* in, e. g., longer terminal cells of paraphyses.

Anamorph. The conidia found on the substrate of *O. leporina* were also seen by Velenovský who described them as 'cylindrical corpuscules 50 × 8 µm, attenuated at both ends, 6–8-septate, emerging from the yellowish anchoring hyphae'. They fit well those of other members of series *Neodactylella*, such as *O. cardui* and *O. cotoneastri*, but also in *O. cocois* we found very similar conidia. Identity with the coprophilous '*Monacrosporium*' *subtile* Oud. seems to be excluded, because this taxon was described with longer conidia (45–70 × 5–7 µm) with up to 13 septa. Type material of '*M.*' *subtile* could not be located (Rubner 1996).

Ecology. *O. leporina* was collected in a colline *Picea* forest on droppings of *Lepus europaeus* ('ad excrementa leporina') in subcontinental, cold-temperate humid eastern Europe. *O. leucostigma* var. *charticola* grew on cardboard lying in a moist wastewater gutter in a comparable, almost subatlantic climate.

Specimens included. **CZECHIA**: **Central Bohemia**, 26 km SE of Praha, W of Mnichovice, above Zítův mlýn (ancient mill), 360 m, dung of *Lepus europaeus*, 6.VIII.1941, J. Velenovský (PRM 152419, **holotype** of *O. leporina*, H.B. 6187 ø, anam. substr.).

Not included. **LUXEMBOURG**: **Gutland**, 15 km N of Luxembourg, Mersch, 230 m, cardboard, 29.VI.1896, J. Feltgen (LUX 042447, **holotype** of *O. luteorubella* f. *charticola*; H.B. 5359 ø).

Orbilia cocois Baral, **sp. nov.**, MB 813976 — Pls 917–918

Etymology: named after the host, *Cocos nucifera*.

Typification: Mexico, Cancun, petiole of *Cocos nucifera*, 16.II.2004, M. Eckel (ex H.B. 7647, M-0276458, holotype).

Latin diagnosis: *Similis* Orbiliae leporinae *sed ascosporae leniter breviores et latiores, paraphyses ad apicem haud inflatae, cellulae terminales partim non longiores quam cellulis aliis, excipulum marginale processis vitreis, apothecia aurantio-lutea. Habitat ad petiolum* Cocois *in zona tropica humida Americae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.75(–1) mm diam., 0.11–0.19 mm high (receptacle near margin 0.07–0.08 mm), light to bright yellowish-orange, medium translucent, round, subgregarious; disc slightly concave to flat, margin thick, slightly raised but not protruding, smooth; sessile on a narrow or broad base, superficial; dry bright to deep orange(-red). **Asci** †37–46 × (3.6–)3.8–4 µm, 8-spored, spores †2–3-seriate, 3–4 lower spores inverted (sometimes mixed); **apex** (†) medium to strongly truncate (not indented, laterally not or scarcely inflated); **base** with short to medium long, ± thin and flexuous stalk, L- to h- (?and H-)shaped.

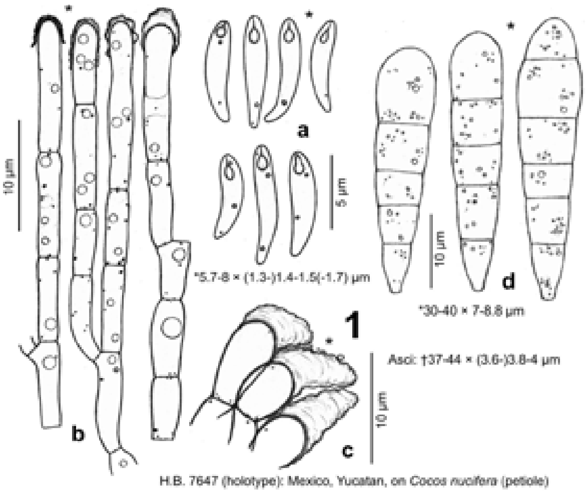

Plate 917. **1**. *Orbilia cocois*. – **a**. ascospores; **b**. paraphyses; **c**. marginal cortical cells of ectal excipulum in median section, tipped by glassy processes; **d**. conidia from substrate.

Ascospores *5.7–8 × (1.3–)1.4–1.5(–1.7) µm, †6–7.8 × 1.3–1.5 µm, cylindric- to fusoid-clavate, apex (rounded to) obtuse, base slightly to often ± strongly attenuated, entirely or towards base slightly to medium curved; **SBs** *(1.3–)1.5–1.7(–1.9) × (0.4–)0.5–0.7 µm, nearly globose to mostly tear- (to pear–)shaped, apically narrowed to a fine, (very) short filum. **Paraphyses** apically uninflated or sometimes very slightly clavate, terminal cell *(7.5–)12–17 × 2–2.5(–3) µm, †3–5 µm longer than asci, lower cells *6.5–12(–14) × 2–2.5 µm, near base also *4–7 × 3.3 µm; unbranched at upper septum, hymenium hyaline. **Medullary excipulum** hyaline to pale orange, 25–30 µm thick, of dense textura globulosa-intricata, medium sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled, vertically oriented t. angularis(-prismatica) from base to mid flanks, 30–60(–110) µm thick near base, cells *8–23 × 7–15 µm; 20–30 µm thick at flanks, 20–25 µm thick near margin, of t. (angularis-)prismatica-porrecta oriented at a 50–80° angle to the surface, marginal cortical cells *6–10 × 3.5–4 µm; **glassy processes** 4–6 × 4–5 µm, medium refractive and stratified, at margin often only 0–2 µm long. **Anchoring hyphae** quite abundant, *1.5–2.3 µm wide, at insertion up to 3(–4) µm, walls 0.2 µm thick, partly forming projecting strands. **SCBs** in paraphyses globose, 0.6–1.8 µm diam.; **VBs** absent. **Exudate** over paraphyses 0.2–1.5 µm thick, forming rough, firmly attached caps on each tip, mostly also laterally (4–7 µm from tip), sometimes loosely attached, pale yellowish; over margin and flanks more scattered, cloddy-granular. — **ANAMORPH**: dactylella-like (presumed, from natural substrate). **Conidiophores** not observed. **Conidia** *30–40 × 7–8.8 µm, (cylindric-)clavate, 4–5-septate.

Habitat: lying on ground, on inner surface of petiole of *Cocos nucifera*, slightly decayed, on white layer of fibrous hairs covering the epidermis,

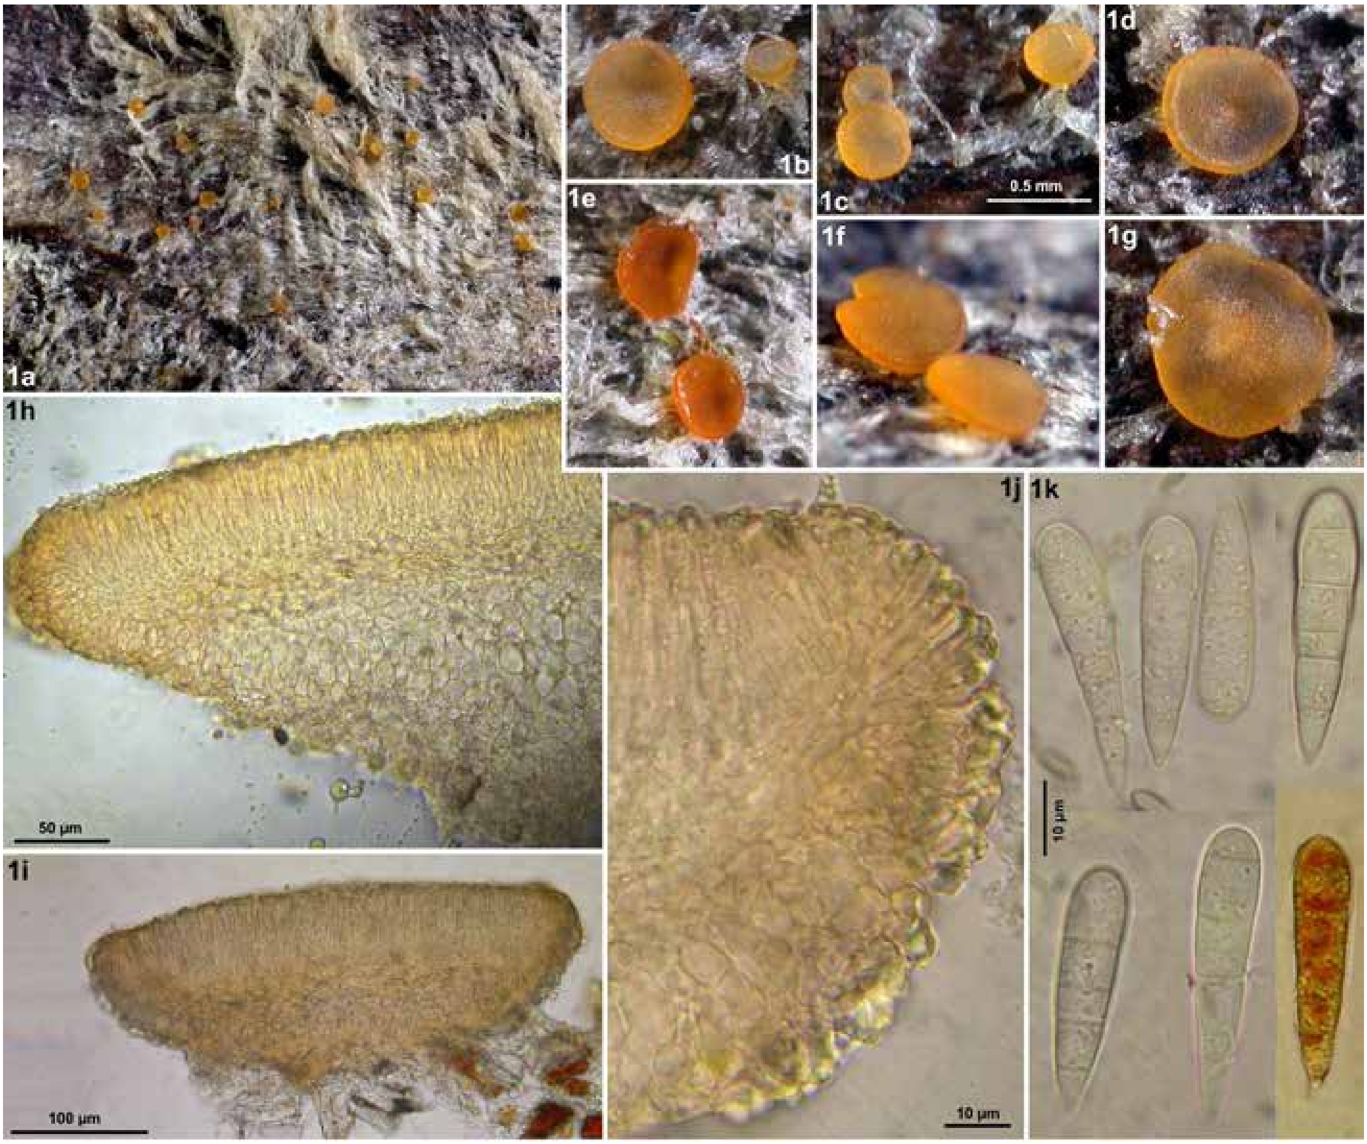

Plate 918. **1**: *Orbilia cocois*. – **1a–d**, **f–g**. rehydrated apothecia; **1e**. dry; **1h–i**. apothecia in median section; **1j**. id., marginal region of ectal excipulum; **1k**. conidia from substrate. – Most cells in the living state (including the conidium stained in IKI). — **1a–k**. H.B. 7647 (holotype): Mexico, on petioles of *Cocos*.

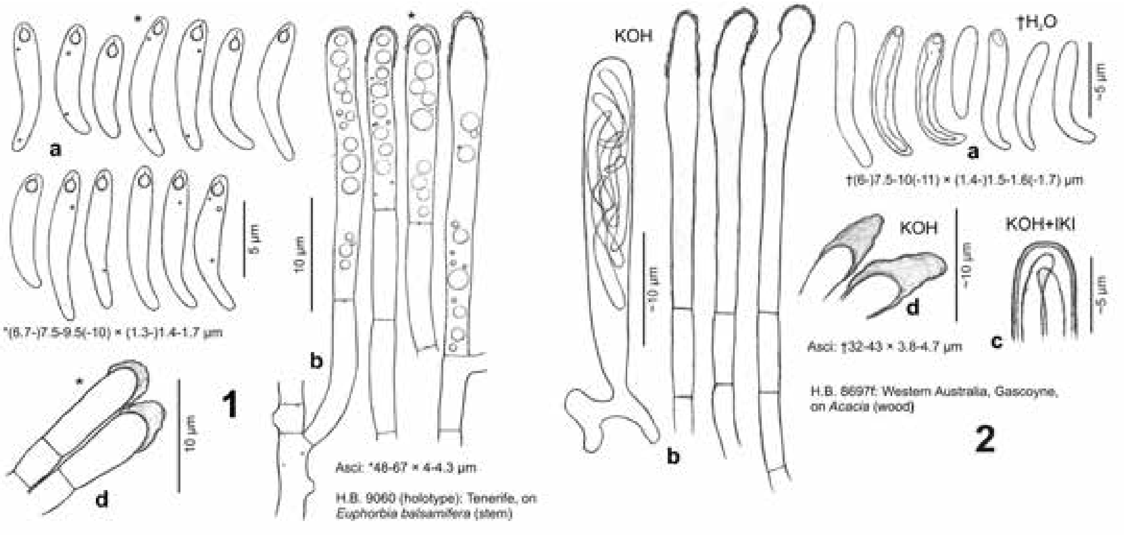

Plate 919. **1**: *Orbilia pseudeuphorbiae*; **2**: *O.* cf. *pseudeuphorbiae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal cortical cells with glassy processes in median section.

slightly greyed, green algae sparse (on outer surface very sparse). **Associated**: none observed. **Desiccation tolerance**: spores and cells of ectal and medullary excipulum still viable after 11 months, after 25 months a few excipular cells still viable. **Altitude**: 5 m a.s.l. **Phenology**: II (tropical belt).

Taxonomic remarks. *Orbilia cocois* is tentatively separated from *O. leporina* because of slightly shorter and wider ascospores, short glassy processes at the margin, paraphyses with less inflated apices and more equally distributed septa, and more orange apothecia, also because of a very different ecology. However, the associated conidia hardly differ from those of *O. leporina*.

O. cocois strongly resembles *O. cardui* and especially the type of *O. luteorubella* f. *charticola* in the spores, but deviates in shorter terminal cells of paraphyses, light orange apothecia, a pronounced desiccation tolerance, and a tropical occurrence, from the former also in more curved spores. The similar *O. desertorum* differs in longer, more curved spores, and in smaller, less clavate conidia with fewer septa.

O. cocois shows some similarity with members of series *Regales* (section *Aurantiorubrae*), e. g., the European *O. aradi*, which differs in spores with globose SBs and in the associated vermispora-like anamorph, or the Australian *O. kingsiana* which differs in wider SBs with a thicker filum, much longer terminal cells of paraphyses with more inflated apices covered by thicker glassy caps, and in apothecial colour.

Not included collection. A sample on leaf sheaths of *Zea* in Galicia (IVV: H.B. 10189) has basally less tapered spores of *~6.2–7.5 × 1–1.2 µm (J. Castillo pers. comm.). Its dry bright orange apothecia are seated on a very thick (100–180 µm), strongly gelatinized subiculum which is restricted to the area below each apothecium.

Ecology. *O. cocois* was found on a slightly decayed xeric petiole of *Cocos nucifera* close to the coastline of the tropical humid (dry in late winter) Caribbean Sea in Middle America.

Specimens included. **MEXICO**: **Yucatán peninsula**, Cancun, Riviera Maya, ~2 km from coastline, near golf course, 5 m, petiole of *Cocos nucifera*, 16.II.2004, M. Eckel (ex H.B. 7647, M-0276458, **holotype**, anam. substr.).

Not included. **SPAIN**: **Galicia**, 2.5 km SW of O Grove, WSW of Estonllo, 15 m, on leaves of *Zea mays*, 18.II.2019, M.A. Delgado, vid. J. Castillo (H.B. 10189).

Orbilia pseudeuphorbiae Baral, Quijada & Beltrán-Tej., **sp. nov.**, MB 813977 — Pls 919–920, Map 148

Etymology: after the similarity to *O. euphorbiae* (section *Aurantiorubrae*).

Typification: Macaronesia, Tenerife, Arico, branches of *Euphorbia balsamifera*, 22.III.2009, L. Quijada, R. Castro & F. Rodríguez (ex H.B. 9060, M-0276569, holotype; sq.: KT222371).

Latin diagnosis: *Similis* Orbiliae euphorbiae *sed corpuscula refringentia ascosporarum latiora, paraphyses ad apicem haud lageniformes, excipulum marginale processis vitreis brevioribus, apothecia pallide colorata. Habitat ad lignum putridum ramulorum siccorum* Euphorbiarum *in zona inframediterranea (semi)arida Macaronesiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.4–)0.6–1.3(–1.6) mm diam., 0.15–0.22(–0.27) mm high (receptacle 0.13–0.15 → 0.06–0.09 mm), whitish to pale or light cream-ochre to chestnut-brownish, slightly to medium translucent, round, finally slightly lobate, scattered to gregarious in ± small groups; disc slightly concave, margin rather thick, 5–10 µm protruding, smooth to very finely rough; broadly sessile or with very short and broad stipe, superficial; dry bright cream-ochre to brownish-orange, strongly contracted, with inrolled margin. **Asci** *(42–)45–60(–67) × (3.5–)3.8–4.3 µm {3}, 8-spored, spores *2-seriate, 3–6 lower spores inverted {3} (± strongly mixed), pars sporifera *(22–)26–30(–40) µm long; **apex** (†) medium to strongly truncate (not or only very slightly indented and laterally widened); **base** with a very short to medium long, thin or thick, flexuous stalk, L-, Y-, h- or H-shaped. **Ascospores** *(6.3–)7–9(–10) × (1.3–)1.4–1.7(–1.9) µm {3}, narrowly cylindric- to fusoid-clavate, apex rounded to obtuse, base slightly to medium attenuated, often tail-like, slightly to medium curved or geniculate at lower third of spore; **SBs** *(1.1–)1.2–1.5(–1.8) × (0.5–)0.6–0.8(–1) µm {3}, globose to broadly tear-shaped, apically abruptly narrowed to a short, sometimes invisible filum, usually slightly eccentrical; with a few minute LBs. **Paraphyses** uninflated or very slightly spathulate-lageniform, terminal cells *16–22(–36) × (2–)2.3–3(–3.7) µm {3}, ± equalling the living, not fully turgescent asci, exceeding the dead asci by ~1–3 µm, lower cells *6–14 × 1.7–2.5 µm {3}; exceptionally branched at upper septum. **Medullary excipulum** hyaline, 30–60 µm thick (up to 130 µm in centre), of dense textura intricata with many inflated cells, sharply delimited by a 10 µm thick layer of t. porrecta. **Ectal excipulum** pale ochraceous, of thin-walled, vertically oriented t. globulosa-angularis(-prismatica), 50–90 µm thick near base, cells *(4–)7–18 × (3–)6–12(–15) µm {3}; 20–30 µm thick at flanks and margin, at margin of t. prismatica-angularis oriented at a 60–80° angle to the surface, sometimes forming indistinct cell rows, marginal cortical cells *(6–)8–12(–14) × 2.7–4 µm {2} (5–9 µm long at submargin); **glassy processes** 1–3(–10) × 3–4(–5) µm {3}, strongly refractive, ± stratified. **Anchoring hyphae** abundant, *1.5–3 µm wide {1}, walls 0.2

Plate 920. **1–3**: *Orbilia pseudeuphorbiae* (on *E. balsamifera*); **4**: *O.* cf. *pseudeuphorbiae* (on *Acacia*). – **1a**. tabaibal dulce (with *Astydamia* and *Salsola*, in foreground large shrub of *Euphorbia balsamifera*); **1b**. dead *E. balsamifera*; **1c–e**, **4a–c**. rehydrated apothecia; **1f**. dry apothecia; **1g**. apothecium in median section; **3a–b**. id., ectal excipulum at lower and mid flanks; **3c**. id., at margin; **1h**. id., at base; **1i**. upper part of paraphyses; **2a–b**. asci and paraphyses; **1j**, **2c**, **3d**. ascospores; **3e**. conidia (from substrate). – Living state, except for left ascus in **2b**, some cells in **3a–b**. – **1a–b**, **d–f**, **i**, **2a–c**, **3a–e**: phot. L. Quijada. — **1a–n**. H.B. 9060 = TFC 21755 (holotype): Tenerife, Arico; **2a–c**. TFC 22852: Tenerife, Montaña Amarilla, on *E. balsamifera*; **3a–e**. TFC 22646–8: Tenerife, Tejina, on *E. balsamifera*; **4a–c**. H.B. 8697f: Western Australia, Meekatharra.

µm thick {1}, forming a loose t. intricata(-porrecta) 30–60 µm thick at base, embedded in non-refractive gel. **SCBs** in paraphyses and marginal excipulum globose, 0.7–2 µm diam. {2}, singly or sometimes densely filled (partly VBs?). **Exudate** over paraphyses 0.3–0.7 µm thick, rough to granular-cloddy, hyaline, firmly attached, covering also the sides of the tips; over margin and flanks 0.2–1(–2) µm thick, very pale yellowish to bright honey-yellow. — **ANAMORPH** dactylella-like (presumed, from natural substrate {1}): **Conidiophores** not seen. **Conidia** *24–26 × 5.3–7.5 µm {1}, straight, cylindric-ellipsoid, with rounded apex and hardly tapered base, 5–6-septate, containing a few minute LBs.

Habitat: lying on dry ground, on 10–140 mm thick branches of *Euphorbia balsamifera* {14}, *E. canariensis* {7}, *E. lamarckii* {1}, on medium decayed wood {22}, ± ungreyed, no algae. **Associated** (L. Quijada pers. comm.): *Orbilia eucalypti* {2}, *O. pisciformis* {4}, ?*Hysteropatella* sp. {2}, *Patellaria atrata* {6}, ?*Unguiculella* sp. {1}. **Desiccation tolerance**: fully alive for at least 2 months. **Altitude**: 6–225 m a.s.l. **Geology**: basaltic & trachybasaltic and phonolitic flows and pyroclasts, ignimbrite. **Phenology**: X–VI (possibly throughout the year, long-lived).

Taxonomic remarks. *Orbilia pseudeuphorbiae* resembles *O. leporina* in the ascospores but deviates in uninflated to spathulate instead of capitate paraphyses and a different substrate. *O. cocois* mainly differs in shorter terminal cells of paraphyses and marginal excipulum, and in shorter spores, and *O. cupressi* in wider spores. All these species differ from *O. pseudeuphorbiae* in the conidia of the presumed anamorph. *O. pseudeuphorbiae* and *O. cupressi* were at first tentatively included by us in

O. euphorbiae (series *Regales* of section *Aurantiorubrae*), a species with bright yellowish-orange apothecia with a distinctly crenulate, more protruding margin due to longer glassy processes, paraphyses with a more inflated, lageniform to mammiform apex without SCBs, thicker-walled anchoring hyphae, and particularly spores with a distinctly narrower, 0.3–0.5(–0.6) µm wide spore body. In contrast to *O. euphorbiae* the ascus base in *O. pseudeuphorbiae* is often H-shaped, which supports its placement in section *Arthrobotrys*. *O. arachnopus* (series *Microsomates* of series *Orbilia*) remarkably resembles *O. pseudeuphorbiae* in microscopic features, but differs, e. g., in much smaller, usually broadly attached SBs.

O. beltraniae, which also grows on *Euphorbia canariensis* in Macaronesia and is macroscopically quite similar (Pl. 911), differs in shorter asci (*32–46 × 3–4.3 µm) and shorter, more or less straight, basally only slightly tapered ascospores (*4.7–7 × 1.2–1.7 µm). As in *O. pseudeuphorbiae*, the spores contain rather large, globose, more distinctly eccentrical SBs with a fine filum. The paraphyses are partly more sublanceolate to lageniform and usually protrude 2–4 µm beyond the living, not fully turgescent asci, and the marginal cortical cells are without glassy wall thickenings.

A collection on *Aeonium pseudourbicum* at high altitude in Tenerife referred to *O. desertorum* differs from *O. pseudeuphorbiae* in much larger basal excipular cells [*11–25(–28) × 10–22(–25) µm], equally curved spores reminiscent of *O. oxyspora* though smaller (*6.5–8 × 1.3–1.4 µm), slightly capitate paraphyses, and in more round and flat, yellowish-brownish-orange apothecia with a thinner margin (see Pl. 945: 4).

Variation. *O. pseudeuphorbiae* seems to be rather constant in its microscopical features, varying only slightly in spore length between *6.3–8 and 7–9 µm and in width between *1.3–1.4 and 1.4–1.7 µm.

Not included collection. An Australian sample on *Acacia* (Pl. 919: 2) resembles *O. pseudeuphorbiae* in most features, including pale-coloured, ± smooth apothecia, spore size, and indistinctly spathulate paraphyses, but it was studied only in the dead state. Its spores tend to be slightly longer and more strongly curved, the asci shorter and wider, and the apothecia smaller (0.25–0.7 mm). In some spores SBs could be discerned, which seem to be smaller than in Macaronesian specimens and do not with certainty exclude an identity with *O. arachnopus* (series *Microsomates* of section *Orbilia*) or a member of series *Regales*.

Anamorph. Straight, dactylella-like conidia were found near the apothecia of *O. pseudeuphorbiae* (Pl. 920: 3e). They resemble those of *Dactylella coccinella* and *D. pulchra*, being wider than the former and smaller than the latter. *O. euphorbiae* sharply differs in the anamorph having straight to strongly curved (C-shaped), longer and narrower, vermispora-like conidia.

Phylogeny. A sequence taken from apothecia of the holotype of *O. pseudeuphorbiae* comprises the S1506 intron and the ITS region. In our ITS analysis (Phyl. 26) it clustered in series *Neodactylella*, but unresolved among the main clades and with rather high distance, the lowest percentage being 10.5–11.5 % to *O. epilobii*, *D. rhopalota*, *O. atlantis*, and *O. zhongdianensis*. Also an analysis of the intron shows *O. pseudeuphorbiae* in the unsupported *Neodactylella* clade, but with high distance to other species. Also when analysing the entire section *Arthrobotrys*, *O. pseudeuphorbiae* clustered within this clade (not shown).

Ecology. *O. pseudeuphorbiae* is so far only known with certainty from Tenerife (Macaronesia), where it was recorded at 12 main collection sites on rotten wood of ± xeric branches of different *Euphorbia* species in inframediterranean, semi- to hyperarid xerophytic scrublands around the island (Quijada 2010). The species mainly occurred in the sweet spurge scrub dominated by *Euphorbia balsamifera* (tabaibal dulce, *Ceropegio fuscae-Euphorbietum balsamiferae*), rarely also in the cardon scrub dominated by *E. canariensis* (cardonal, *Periploco laevigatae-Euphorbietum canariensis*) and the hyperarid *Frankenio ericifoliae-Zygophylletum fontanesii*, *Frankenio ericifoliae-Astydamietum latifoliae*, and *Launaeo arborescentis-Schizogynetum sericeae.* The not included sample was on rotten bark of a xeric branch of *Acacia* in a subtropical arid acacia open woodland (mulga) in northwestern Australia.

Map 148. Known distribution of *O. pseudeuphorbiae* in Tenerife (Macaronesia).

Specimens included (all on wood of branches of *Euphorbia*, leg. L. Quijada & E.V. Rodríguez if not otherwise stated): **MACARONESIA**: **Canary Islands**, **Tenerife**, La Matanza de Acentejo, 8.5 km NE of Puerto de la Cruz, 1.5 km WNW of La Matanza de Acentejo, NW of Jagre, Puntillo del Sol, 43 m, *E. canariensis*, 21.XI.2009 (TFC Mic. 22545, 22548, 22551–22552, 22555, 22559, non vid.). – St. Cristóbal de la Laguna, 2 km NNW of Valle Guerra, Playa de Arena, 6 m, *E. balsamifera*, 3.XI.2009, L. Not included. **AUSTRALIA**: **Western Australia**, Gascoyne, southern border of Collier Range, 175 km NE of Meekatharra, 41 km SW of Kumarina Roadhouse, Great Northern Hwy, 560 m, branch of *Acacia*, on bark, 26.XI.2001, G. Marson (H.B. 8697f).

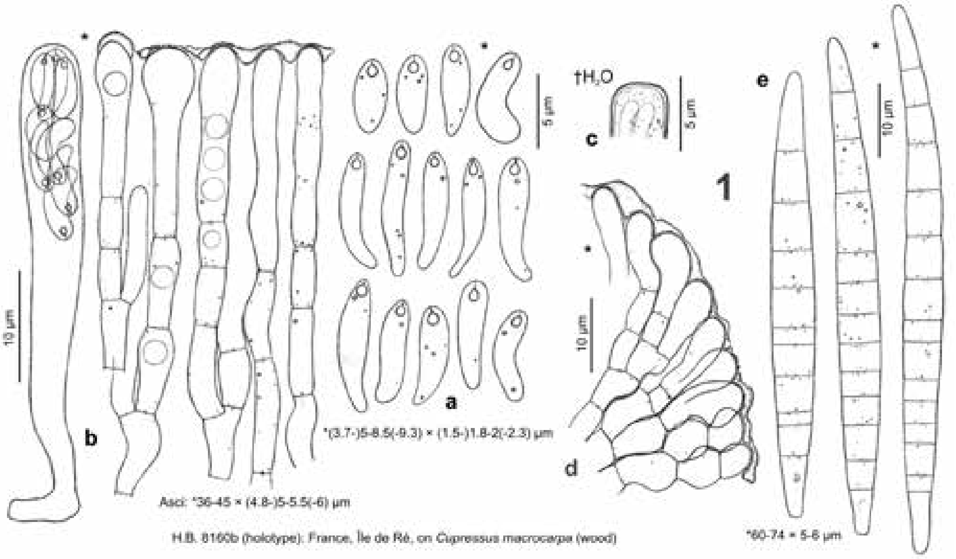

Plate 921. **1**: *Orbilia cupressi*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. ectal excipulum in median section (margin and mid flanks); **e**. conidia from substrate.

Orbilia cupressi Baral & E. Weber, **sp. nov.**, MB 813978 — Pls 921–922

Etymology: after the host, *Cupressus sempervirens*.

Typification: France, Île de Ré, branch of *Cupressus macrocarpa*, 26.IV.2006, S. Helleman & G. Marson (ex H.B. 8160b, M-0276466, holotype; sq.: KT222433).

Latin diagnosis: *Similis* Orbiliae pseudeuphorbiae *sed ascosporae breviores et latiores, paraphyses ad apicem magis inflatae, partim capitatae, excipulum marginale absque processis vitreis, apothecia minora. Habitat ad lignum putridum rami sicci* Cupressi *in zona mesosubmediterranea semihumida Europae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.8 mm diam., 0.11–0.17 mm high, pale cream-ochraceous(-orange), ± translucent, round or slightly undulating, scattered to subgregarious in small groups; disc flat to slightly convex, margin distinct, thin, not protruding, smooth; broadly sessile, superficial but partly deeply immersed in biofilm; dry also cream-brown. **Asci** *36–45 × (4.8–)5–5.5(–6) µm, †32–44 × 4–4.5 µm, 8-spored, spores *~3-seriate, 3–5(–7) lower spores inverted (often ± mixed), pars sporifera *16–18 µm long; **apex** (†) medium truncate (not indented, laterally not inflated); **base** with short to medium long, thick stalk, L-shaped. **Ascospores**

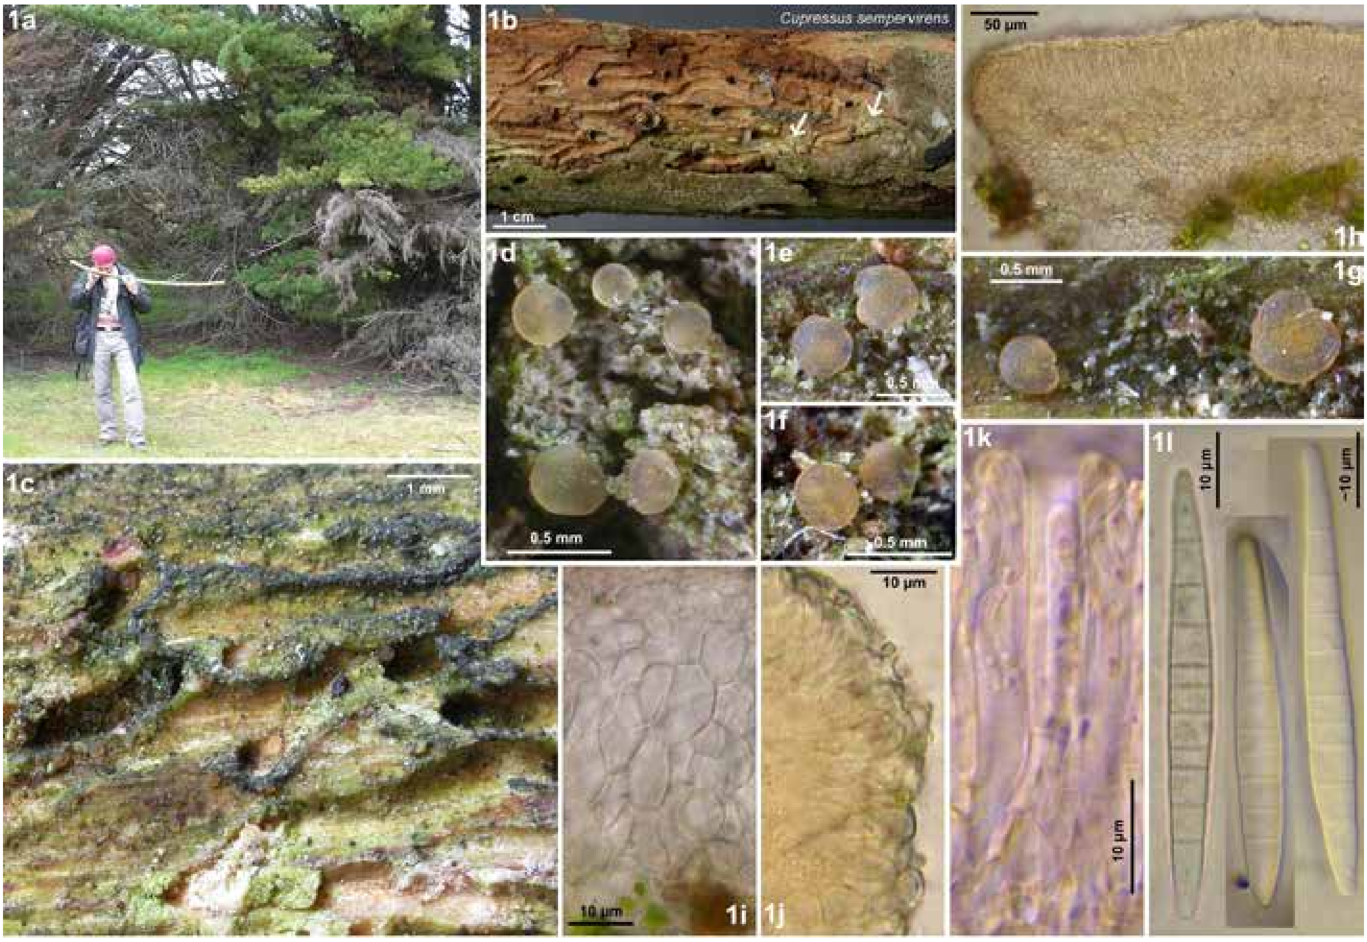

Plate 922. **1**: *Orbilia cupressi*. – **1a**. atlantic submediterranean open forest with *Cupressus macrocarpa*, decorticated xeric branch of holotype shortly after harvesting; **1b–c**. closeup of branch showing beetle galleries; **1d–g**. rehydrated apothecia (**1d**: on boring dust); **1h**. apothecium in median section; **1i**. id., basal ectal excipulum; **1j**. id., marginal ectal excipulum; **1k**. asci; **1l**. conidia. – Living state, except for **1j** (in KOH). — **1a–l**. H.B. 8160b (holotype): France, Île de Ré, on *Cupressus*.

*(3.7–)5–8.5(–9.3) × (1.5–)1.8–2(–2.3) µm, †5.7–7.7 × 1.7–1.8 µm, subcylindrical to fusoid-clavate, rarely ± ellipsoid, apex rounded to obtuse, sometimes subacute, base not or slightly to strongly attenuated, straight or mostly slightly to strongly curved (often geniculate in lower part); **SBs** *1–1.4 × 0.6–0.8 µm diam., globose to broadly tear-shaped, with a short, thin or thick filum. **Paraphyses** apically uninflated or slightly, sometimes medium inflated, clavate-capitate to ellipsoid, terminal cells *13–20 × 2.3–5 µm, lower cells *3.5–10 × 2–3 µm; unbranched at upper septum. **Medullary excipulum** hyaline to pale yellowish-cream, 25–35 µm thick, of dense textura intricata-angularis, sharply delimited from ectal excipulum. **Ectal excipulum** of hyaline, thin-walled, vertically oriented t. globulosa-angularis from base to margin, 30–70 µm thick near base, cells *8–19 × 6–14 µm; 20 µm thick near margin, of t. globulosa-prismatica oriented at a 45–90° angle to the surface, marginal cortical cells *5–12 × 3–6 µm; **glassy processes** absent. **Anchoring hyphae** ± abundant, †1.5–2.5(–3) µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose, very faintly refractive, 1.5–2.2 µm diam.; in ectal excipulum not seen. **Exudate** over paraphyses 0.2–1.5 µm thick, cloddy-continuous, ± loosely attached; over margin and flanks (0.2–)1–3(–5) µm thick, hyaline. — **ANAMORPH**: dactylella-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** straight to (very) slightly curved, narrowly fusiform, gradually tapered towards the ends, *60–74 × 5–6 µm, 8–14-septate.

Habitat: collected ~1–1.5 m above the ground, 27 mm thick branch of *Cupressus macrocarpa*, one side partially corticated, on 0.1–0.2 mm deep strongly decayed wood, in galleries or on boring dust of a bark beetle, somewhat greyed, with abundant green algae. **Associated**: *Orbilia subdelphinus* {1}. **Desiccation tolerance**: fully viable for at least 3 weeks. **Altitude**: 19 m a.s.l. **Geology**: Quaternary marine sand over Upper Jurassic limestone. **Phenology**: IV (but rather long-lived).

Taxonomic remarks. *Orbilia cupressi* resembles *O. cardui* s.l., *O. pseudeuphorbiae*, or *O. cocois*, from which it differs, e.g., in wider ascospores and/or non-spathulate paraphyses, smaller apothecia, and particularly in the presumed anamorph. *O. cupressi* differs from *O. subcylindrospora* (section *Ovoideae*) in longer SBs with a short filum, paraphyses being never strongly capitate, and apothecia without a rose colour. *O. oxyspora* matches *O. cupressi* in the anamorph, but differs in much longer and narrower spores and in the marginal excipulum forming distinct cell rows.

Variation. Size and shape of the spores vary rather strongly within the only known collection. The observed short and wide, ellipsoid spores are to be considered as more or less abnormal, while elongate spores with a curved lower part represent the typical spores.

Anamorph. The conidia of the presumed anamorph of *O. cupressi* closely resemble those of *O. oxyspora*, but are narrower and tend to have more septa. *Orbilia* sp. XJ-2009 is very similar to *O. cupressi* in size and shape of conidia which exceed those of *O. cupressi* in the number of septa (8–19), but sharply differs in much longer and narrower, strongly falcate ascospores. Species related to *O. cardui* differ in shorter, cylindric-clavate conidia with fewer septa.

Phylogeny. A sequence from apothecia of the holotype comprises SSU (without S1506 intron), ITS, and LSU. In our combined analyses (Phyls 25, 27), *O. cupressi* clustered unresolved within the paraphyletic series *Neodactylella*, without connection to the four main clades. Also when analysing ITS or LSU separately, the result is similar (Phyls 26, S31). To all other species it shows a high distance, the lowest to the *cardui-rhopalota* clade (ITS 15.5–16.5 %, LSU 3–3.3 %).

Ecology. *O. cupressi* was found in beetle galleries on rotten wood of an attached xeric branch of *Cupressus sempervirens* in a coastal atlantic, mesosubmediterranean semihumid open cypress woodland in coastal western Europe.

Specimens included. **FRANCE**: **Poitou-Charentes**, **Charente-Maritime**, Île de Ré, 2 km SE of St.-Martin-de-Ré, 1.8 km W of La Flotte, Les Maraises, 19 m, branch of *Cupressus macrocarpa*, on wood, 26.IV.2006, S. Helleman & G. Marson (M-0276466, **holotype**; **isotype** in H.B. 8160b, anam. substr.; sq.: KT222433).

Orbilia fraxini Baral & P. Perz, **sp. nov.**, MB 813979 — Pls 923–925

Etymology: named after the host, *Fraxinus excelsior*.

Typification: Poland, Miedzylesie, branches of *Fraxinus excelsior*, 3.II.2008, P. Perz (ex H.B. 8754, M-0276486, holotype).

Latin diagnosis: *Apothecia rehydratata 0.5–2 mm diam., ochraceo-aurantiaca, (sub)sessilia, margine glabro vel subtiliter aspero. Ascosporae *3.5–7.5 × 1.6–*

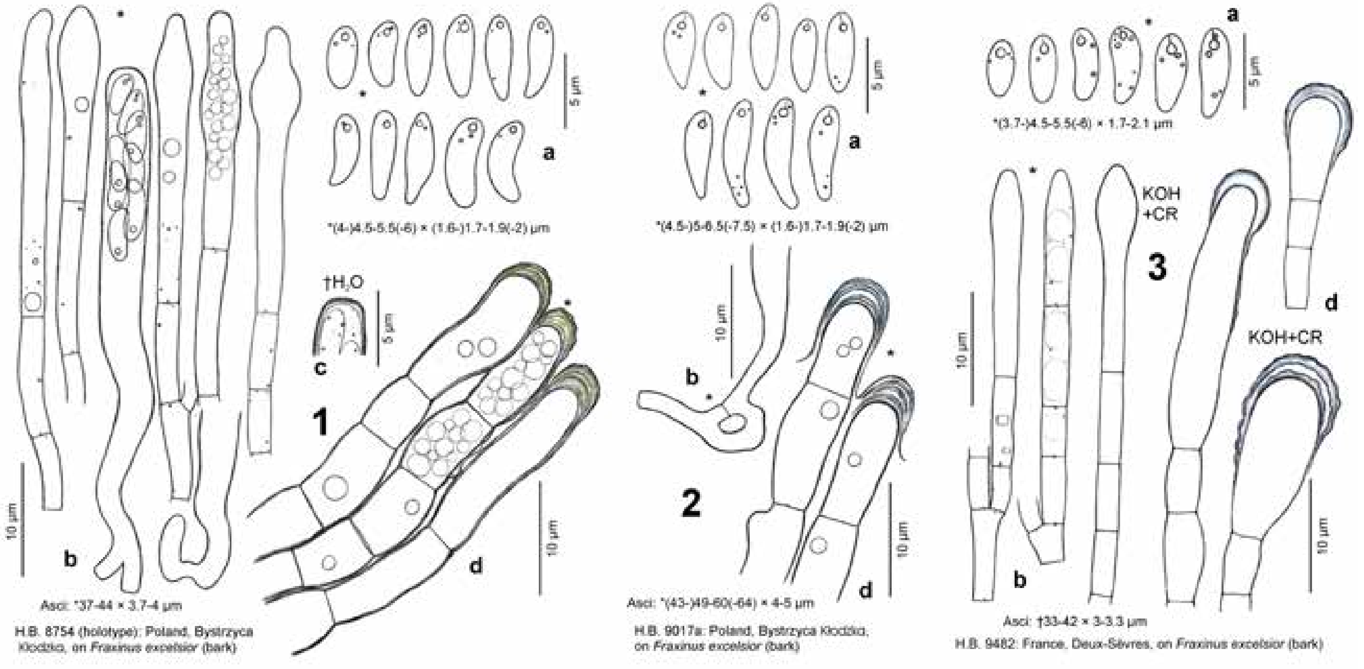

Plate 923. **1–3**: *Orbilia fraxini*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal ectal excipulum composed of hair-like cells, in median section.

2 µm, subcylindrico-ellipsoideae, apice obtusae, ad basim plus minusve attenuatae, rectae vel basi leniter curvatae, in statu vivo corpusculum refringens minutum globosum, ad apicem filo breve affixum continentes. Paraphyses ad apicem distincte spathulatae vel lageniformes. Margo excipuli pilis agglutinatis, septatis, subcrassitunicatis compositus, absque processis vitreis. Habitat ad corticem putridum ramorum Fraxini excelsioris, *leniter in aere prominulum, in zona atlantica ad subcontinentale temperata humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1.5(–2.2) mm diam., 0.12–0.22 mm high (receptacle 0.12–0.16 → 0.09–0.12 mm), very pale to light (rose-)orange- to yellow-ochraceous, non- or medium translucent, round to slightly, rarely strongly undulating, subgregarious to gregarious; disc medium concave to flat, eventually medium convex, margin 10–25 µm protruding, almost smooth to finely rough; broadly sessile or on a narrow, stipe-like base 0.05–0.07 × 0.35 mm, superficial; dry light orange-ochraceous. **Asci** *(37–)40–60(–64) × (3.7–)4–4.5(–5) µm {2}, †31–42 {2} or 46–58 {2} × (2.5–)3–3.8(–4.2) µm {4}, 8-spored, spores (*) obliquely biseriate, (1–)3–5(–6) lower spores inverted {4} (strongly mixed or not), pars sporifera *16–23 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not inflated); **base** with short to long, ± thin, flexuous stalk, Y-, h- or H-shaped, rarely with perforated croziers. **Ascospores** *(3.5–)4.5–6.5(–7.5) × (1.6–)1.7–1.9(–2.1) µm {7}, subcylindric-ellipsoid to fusoid-clavate, apex (rounded to) obtuse (rarely subacute), base not or slightly to strongly attenuated, rarely tail-like, straight to ± inequilateral or slightly (to medium) curved below; **SBs** *0.8–1.4 × (0.3–)0.4–0.5(–0.6) µm diam. {3}, globose, with a fine, short, sometimes invisible filum, inflated part sometimes ± eccentrical. **Paraphyses** apically slightly or mostly distinctly spathulate to usually lageniform-lanceolate with rounded to obtuse apex, terminal cells *12–27 × (2–)2.7–3.7(–4.3) µm {5}, †15–19 × 2–2.5(–3.6) µm {1}, exceeding the living asci by 3–7 µm (the dead asci by 2–4 or 4–10 µm), lower cells *4–13.5 × 1.6–2.8 µm {4}; unbranched at upper septum, with scattered minute yellowish LBs in the cells (hymenium very pale orange). **Medullary excipulum**, 20–100 µm thick, very pale orange or cream, of dense or loose textura intricata with many inflated cells, sharply delimited from ectal excipulum (partly by a ± distinct, 10 µm thick t. porrecta). **Ectal excipulum** hyaline, of (†) thin-walled to slightly gelatinized (common walls 0.3–1 µm thick), vertically oriented t. angularis-prismatica from base to mid flanks, 40–80 µm thick near base, cells *9–20(–33) × 7–15(–19) µm {3}; 15–20 µm thick near margin, of t. prismatica(–globulosa) oriented at a 45–70° angle to the surface; running out into ~20–30 µm long, ± agglutinated or ± free, (1–)2(–4)-celled rows of **hair**-like hyphae oriented at 10–80°, lateral wall */†0.2–0.4 µm thick (0.5–0.8 including exudate), terminal cells */†6–19 × (3–)3.5–6(–7.5) µm {4}; **glassy processes** apparently absent, but hairs tipped by exudate caps {3}. **Anchoring hyphae** medium to very abundant, *(1.5–)2–3(–4) µm wide, walls 0.1–0.2 µm thick {3}, forming a loose hyaline textura intricata 10–100 µm thick, embedded in non-refractive gel. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.2–2 µm diam. {5}, low-refractive, usually solitary but in some paraphyses and marginal hairs densely filling the cells; **VBs** absent. **Exudate** over paraphyses absent, on hair tips 1–4 µm thick {3}, cap-like, composed of several 0.2–0.7 µm thick refractive layers. **— ANAMORPH**: vermispora-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** phragmosporous, slightly to often strongly curved at the ends, with straight (to slightly curved) middle part, *(35–)38–45.5 × (4.3–)4.5–5.2(–5.5) µm {2} (in situ and actual length), (5–)6–8(–9)-septate {2}.

Habitat: 0–3 m above the ground, corticated, 8–50 mm thick branches or 15–20 cm thick trunks of *Fraxinus excelsior* {8}, on outer and inner side of ± strongly decayed, sometimes detaching bark {8} (periderm {1} and bast {7}), often over small or large holes or cracks in periderm or on periderm-free areas, at edge of bark, in beetle galleries when on inner surface, greyed (bast dark brown to blackish), without or with some green algae, sometimes close to old pyrenomycete {1}. **Associated**: *Lecanora* sp. {2}, *L. ?argentata* {1}, *Lecidella elaeochroma* {1}, *Melanomma* (?)*pulvis-pyrius* {1}, *Orbilia aristata* {1}, *O. xanthoguttulata* {1}, *Physcia adscendens* {2}, *Sclerencoelia fraxinicola* {1}, *Xanthoria parietina* {2}. **Desiccation tolerance**: immature asci survive for 3 weeks, ectal and medullary excipulum, paraphyses and spores still alive after 4 months. **Altitude**: 5–610 m a.s.l. **Geology**: Upper Cretaceous calcareous clay- & marlstone and flysch, Pleistocene moraine, peat over Jurassic. **Phenology**: I–VIII (but rather long-lived).

Taxonomic remarks. *Orbilia fraxini* resembles *O. cupressi* in ascospore morphology, but differs in larger apothecia, spathulate to lageniform paraphyses, and the presumed anamorph forming curved conidia. Similar paraphyses are found in *O. rhamni* which differs in narrower spores and thin-walled marginal excipular cells. A certain similarity is also seen with *O. phragmotricha* (section *Aurantiorubrae*), from which *O. fraxini* differs in shorter and wider spores without tails, smaller, globose SBs with a fine filiform attachment, shorter, thin-walled, ± agglutinated hairs, and in the absence of crystalloid SCBs. *O. pseudocylindrospora* (on *Salix*, section *Aurantiorubrae*) differs in slightly longer spores and SBs, only sometimes spathulate-lageniform paraphyses, marginal cortical cells tipped by thinner exudate, and pinkish apothecia. The short-haired form of *O. pilosa* (section *Arthrobotrys* series *Drechslerella*) differs in smaller spores, more thick-walled hairs, larger, isodiametric, thick-walled excipular cells, and white apothecia. *O. fraxini* may also be confused with *O. eucalypti* (section *Orbilia*) which differs, e. g., in capitate paraphyses and in lacking thick-walled, protruding marginal cells.

The layered refractive caps on the hair tips of *O. fraxini* are stained by CR or CRB and are, therefore, apparently exudate rather than glassy processes.

Variation. A high difference in ascus length was noted between the two samples from Poland (Pl. 923). Also the ascospores show a high variability in length and shape within the collections. Apothecial colour varied between orange, ochre, yellow, and fawn, sometimes within a collection. Nevertheless, the samples from the four collection sites concur very well in most respects.

Not included collections. Two samples on *Populus* bark from Austria and Serbia differ in slightly longer and particularly narrower spores of *(4.8–)5.2–6.5(–7.2) × (1.3–)1.4–1.6(–1.8) µm.

Anamorph. We found two times curved, vermispora-like phragmoconidia near apothecia of *O. fraxini* (Pls 924: 2j; 925: 1d). Due to their curved ends this type of conidia is reminiscent of members of section *Aurantiorubrae* (series *Regales*) or section *Orbilia* (*O. xiushanensis*) rather than section *Arthrobotrys*.

Phylogeny. Sequences comprising ITS and LSU D1–D2 were gained from apothecia of the topotype from Lower Silesia and the sample from Oberbayern. The S1506 intron is absent in both. The two sequences are identical, except for 1 deviating nucleotide in the ITS1.

In spite of its presumed vermispora-like anamorph, *O. fraxini* clustered in our analyses (Phyls 25–27, S31) with *O. rhamni* and *O. asomatica* in a medium to strongly supported clade (here called *rhamni-fraxini* clade) within series *Neodactylella*. *O. fraxini* shows an ITS/LSU distance of 11/1.6–1.8 % to *O. rhamni*, and 12/2.1 % to *O. asomatica*, but the distance to species of the *cardui-rhopalota* clade is also only 9–12/2.5–3 %.

Ecology. *O. fraxini* is so far only known from rotten bark of hygric and xeric branches and trunks of *Fraxinus excelsior* at four very remote sites of Europe. In the type collection from southern Poland the inhabited branches were deposited in a ditch between road and pasture, when large alley trees were pruned in their lower part about 2–3 years ago. Although the apothecia developed on branches close to the ground, they are desiccation-tolerant. In the samples from France and Luxembourg the fungus grew on still-attached branches and in that from Germany on detaching bark of standing isolated trunks. The climate is subcontinental cold-temperate humid, but in western France atlantic warm-temperate humid. The vegetation in Luxembourg was a forest bordered to a farmland in the south by *Fraxinus* trees, that in France a large marshy forest area with many ash trees at very low altitude, and that in Germany a row of ash and willow trees along a small rivulet bordered by a pasture and farmland. The two not included samples grew under a similar subcontinental climate on xeric, very rotten, ± detaching bark (bast) of corticated attached branches or fallen trunks of *Populus* in association with various lichens, including *Xanthoria parietina*, in Austria on crystalline rock (mica schist) and in Serbia on Cretaceous flysch.

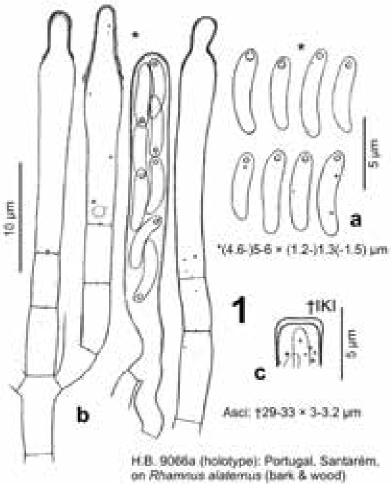

Plate 926. **1**: *Orbilia rhamni*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Specimens included. **POLAND**: **Lower Silesia**, Kłodzko, 11.5 km S of Bystrzyca Kłodzka, 6 km NNW of Miedzylesie, ESE of Gniewoszów, 437 m, branches of *Fraxinus excelsior*, on bark, 3.II.2008, P. Perz (ex H.B. 8754, M-0276486, **holotype**; P.P. 20030203-6, **isotype**). – ibid., branches of *F. excelsior*, on bark, 7.III.2009, P. Perz (H.B. 9017a, **topotype**, anam. substr.; sq.: KT222372). — **GERMANY**: **Bayern**, **Oberbayern**, 5.5 km N of Bad Reichenhall, S of Aufham, Reitweg, 505 m, trunk of *F. excelsior*, on bark, 20.I.2018, I. Rößl (doc. vid.). – ibid., 7.III.2018 (H.B. 10143a; sq.: MK473420). – ibid., 17.III.2018, I. Rößl & T.R. Lohmeyer (T.R.L. 2018-006, doc. vid.). – ibid., 13.VIII.2018, H.O. Roffler (U.R. 1227, doc. vid., sq.: ined.). — **LUXEMBOURG**: **Gutland**, 4.3 km ENE of Luxembourg, S of Kalchesbrück, between Cents & Findel, 355 m, branch of *F. excelsior*, on bark, 9.V.2011, G. Marson (G.M. 2011-05-09, anam. substr.). — **FRANCE**: **Poitou-Charentes**, **Deux-Sèvres**, 14.5 km WSW of Niort, 1.5 km NNW of Amur, Marais Poitevin, Port Goron, 5 m, branch of *F. excelsior*, on bark, 26.IV.2011, E. Weber (H.B. 9482a).

Not included. **AUSTRIA**: **Steiermark**, 14.5 km WSW of Hartberg, NW of Herberstein castle, Buchberg, 512 m, trunk of *Populus ?tremula*, on bark, 8.XII.2018, G. Friebes (G.F. 20180348, doc. vid.). – **SERBIA**: **Vojvodina**, Fruška Gora, 12.5 km S of Novi Sad, 6 km NNW of Irig, Iriški venac, W of WWII memorial, 415 m, branch of *Populus alba*, on bark, 12. & 15.VII.2019, D. Savić (doc. vid.).

Orbilia rhamni Baral & Priou, sp. nov., MB 813980 — Pls 926–927

Etymology: named after the type host genus.

Typification: Portugal, Santarém, twigs of *Rhamnus alaternus*, 6.V.2009, J.P. Priou (ex H.B. 9066a, M-0276579, holotype; sq.: KT222373).

Latin diagnosis: *Apothecia rehydratata 0.25–1 mm diam., aurantiaca, sessilia, margine glabro vel subtiliter aspero. Ascosporae *4.5–6 × 1–1.5 µm, (sub) cylindricae, apice rotundatae ad obtusae, basi non vel indistincte attenuatae, leniter curvatae, in statu vivo corpusculum refringens minutum globosum, filo brevissime affixum continentes. Paraphyses ad apicem leniter inflatae, distincte lageniformes. Cellulae excipuli marginalis et paraphysium guttulas paucas minutas luteas oleosas continentes. Margo excipuli processis vitreis brevissimis praeditus. Habitat ad lignum vel corticem putridum ramulorum siccorum* Rhamni alaterni *in zona mesomediterranea semihumida Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.7(–1) mm diam., 0.1–0.13 mm high (receptacle 0.08 → 0.06 mm), pale to bright (yellowish-)orange(-ochraceous), slightly translucent, round to ellipsoid or somewhat undulating, scattered to subgregarious; disc flat or somewhat concave near margin, margin thin or thick, 5–20 µm protruding, smooth to finely rough or powdered; sessile on a narrowed base, superficial or slightly erumpent from cracks; dry slightly contracted, bright orange-ochraceous. **Asci** *~35 × 3.7–4 µm {T}, †25–34 × 3–3.8 µm {3}, 8-spored, spores (†) biseriate, ~3–4 lower spores inverted {T} (strongly mixed), pars sporifera †22.5 µm long; **apex** (†) medium to strongly truncate (hardly indented or laterally inflated); **base** with short, flexuous stalk, h-shaped. **Ascospores** *4.5–6 × (1–)1.1–1.3(–1.5) µm {3}, (sub)cylindrical, homopolar, apex rounded to obtuse, base not or indistinctly attenuated, slightly but also medium to strongly curved (entirely or only near base), sometimes slightly

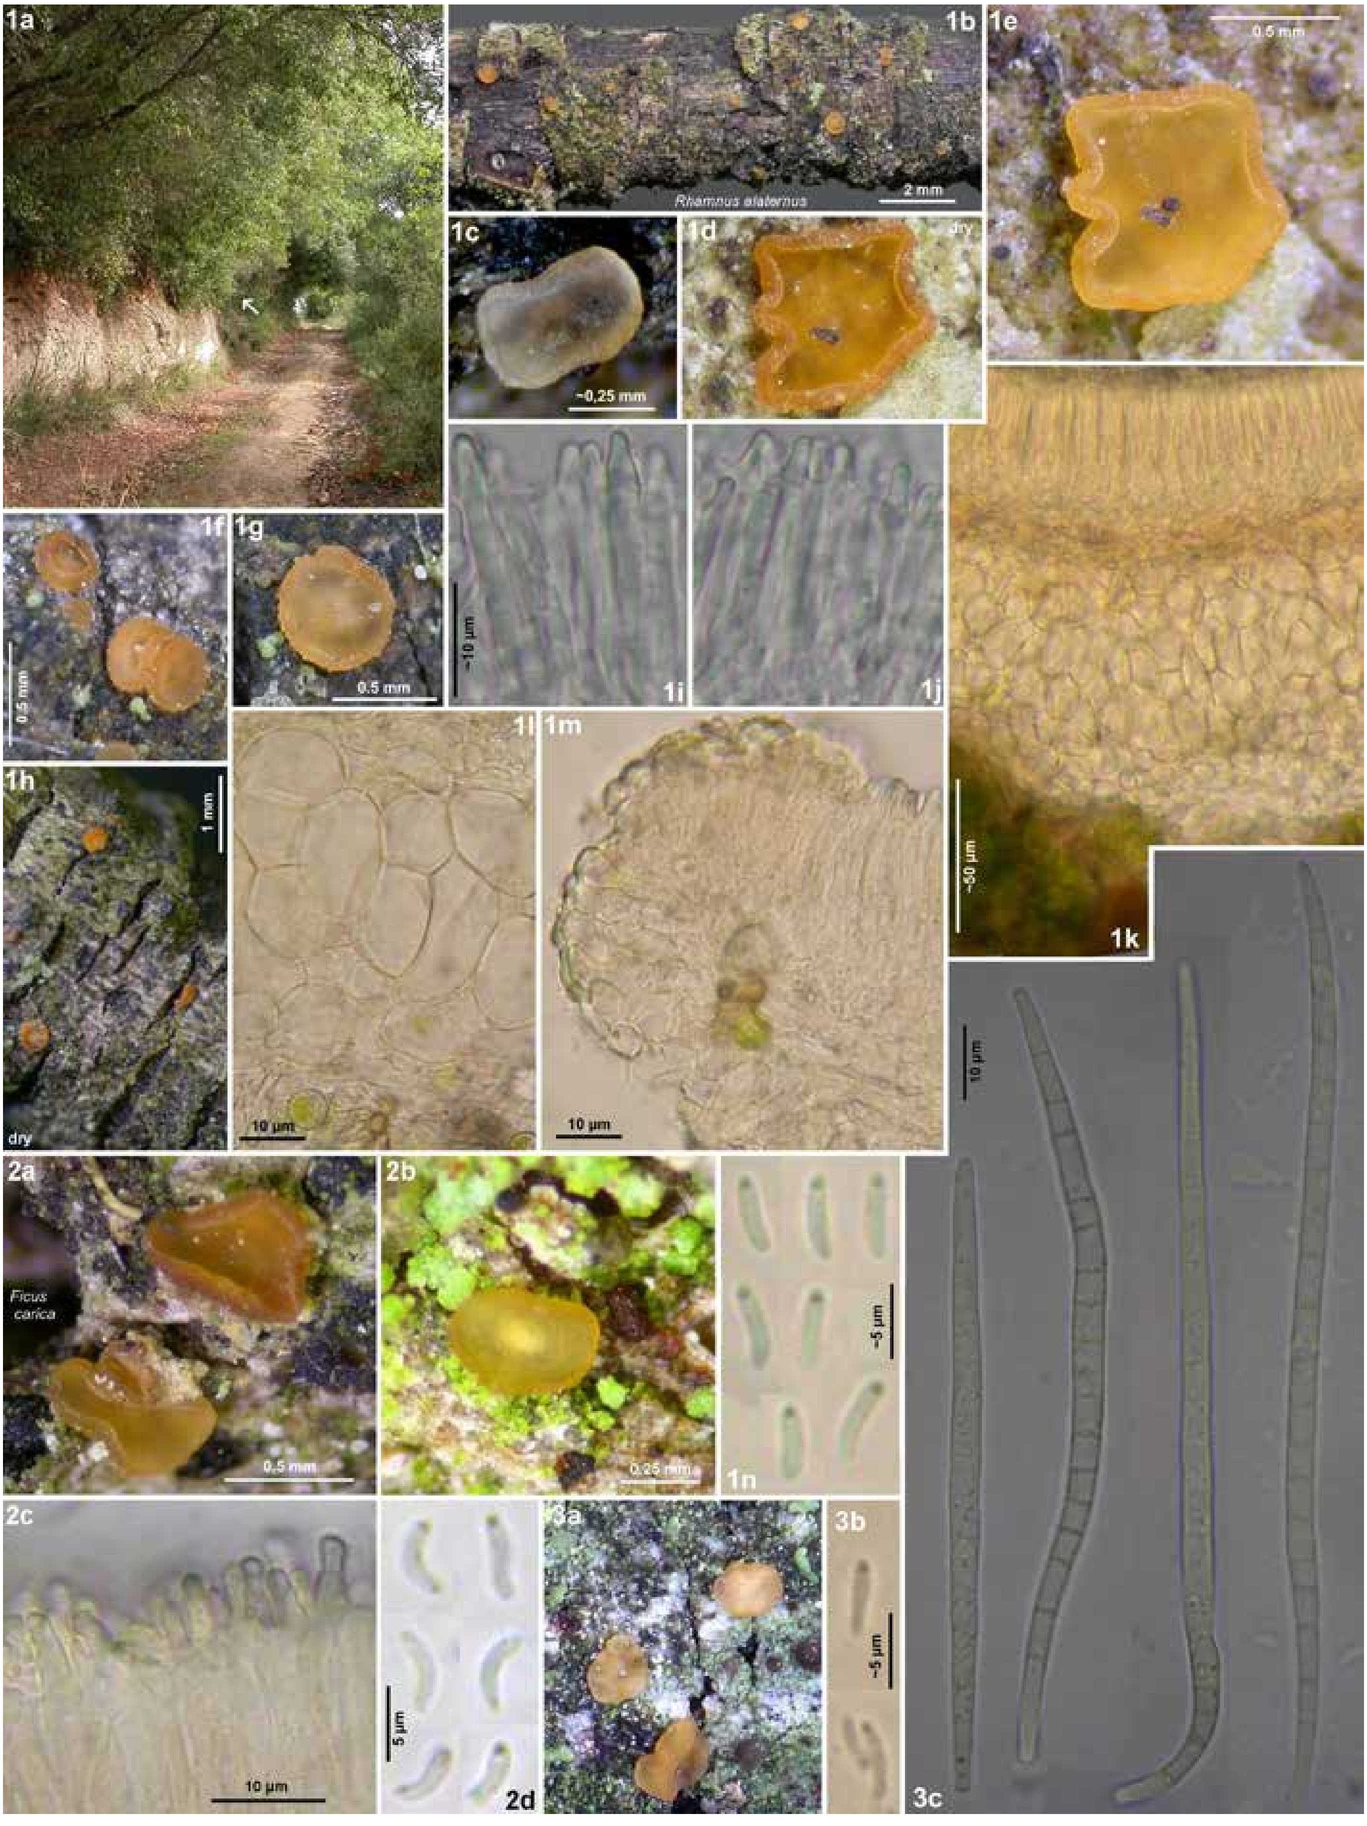

Plate 927. **1–3**: *Orbilia rhamni*. – **1a**. mediterranean woodland with *Quercus rotundifolia* trees and *Rhamnus alaternus* shrubs at edge of slope above forest track; **1b–c**, **e–h**, **2a–b**, **3a**. rehydrated apothecia; **1d**, **h**. dry apothecia; **1k**. central part of apothecium in median section; **1l**. id., basal ectal excipulum; **1m**. id., marginal region; **1i–j**, **2c**. (asci and) paraphyses; **3c**. conidia from substrate; **1n**, **2d**, **3b**. ascospores. – Living state, except for **2c** (in H_2O), 2 middle spores in **2d**. – **1a**, **c–e**, **h–k**, **n**, **2a–b**: phot. J.B. 0463/14: Spain, Cataluña, on *Rhamnus*.

helicoid; **SBs** *0.7–0.8 × 0.3–0.5 µm {2}, globose to indistinctly tear-shaped, with a very short and fine, often invisible filum. **Paraphyses** apically (vry) slightly inflated, consistently lageniform or lanceolate with rounded tips, terminal cells *15–24 × 2.5–3.5 µm {T}, †(14–)19–24 × 2.2–2.8 µm {1}, exceeding the dead asci by (3–)5–7 µm, lower cells *5–7 × 2–2.7 µm {T}, †3.5–6 × 1.5–2.4 µm {1}; unbranched at upper septum. **Medullary excipulum** pale orange, 15–40 µm thick, of dense or loose textura intricata with some or many inflated cells, sharply delimited. **Ectal excipulum** hyaline to very pale orange, of (†) thin-walled, vertically oriented t. globulosa-angularis-prismatica from base to margin, 30–60 µm thick near base, cells *(8–)10–20(–24) × (7–)8–13(–15) µm {2}; 12–20 µm thick near margin, of pale orange t. prismatica oriented at a 70–80° angle to the surface, marginal cortical cells †6–15 × 3.5–6 µm {2}; **glassy processes** 0–5 × 3–5 µm {2}, high-refractive, forming broad caps. **Anchoring hyphae** sparse to abundant, *2–3 µm wide, walls 0.2(–0.3) µm thick {2}, forming a dense t. intricata up to 25 µm thick. **SCBs** in paraphyses and ectal excipulum absent, exceptionally globose. **Exudate** over paraphyses 0.1–0.3 µm thick, finely rough, hyaline to pale yellow, firmly attached on tapered part of apex, over margin and flanks forming a thin layer over glassy caps (hardly differentiated from glassy matrix). — **ANAMORPH**: anguillospora-like (presumed, from natural substrate {1}). **Conidiophores** not observed. **Conidia** *85–127 × 3.6–4.3 µm (actual length), 16–21-septate, narrowly cylindric-fusoid, straight to slightly and irregularly curved, rarely strongly bent at base, with some minute LBs especially at septa.

Habitat: collected 0–1.8 m above the ground, ± corticated, 4–43 mm thick twigs and branches of *Rhamnus alaternus* {3}, *Ficus carica* {2}, on strongly decayed bark {4} (periderm), rarely wood {1}, slightly to strongly greyed, with some to many green algae. **Associated**: *Lophiostoma quadrinucleatum* {1}, *Trichopeziza perrotioides* {1}. **Desiccation tolerance**: almost fully viable for at least 1 month (but only a few living asci seen). **Altitude**: 50–340 m a.s.l. **Geology**: Portugal: Miocene schist, sand- & limestone, marl & gypsum; Spain: alluvial deposits from siltstone. **Phenology**: IV–VI (but long-lived).

Taxonomic remarks. The distinctly lanceolate-lageniform paraphyses in combination with small, slightly or sometimes distinctly allantoid ascospores allow to recognize *Orbilia rhamni* easily. For the similar *O. fraxini* (p. 1480) and the Australian *O. lamarcheae* (p. 1485) see there. With its cylindrical spores with globose SBs, *O. rhamni* also resembles *O. cylindrospora* (section *Orbilia*) and *O. subcylindrospora* (section *Ovoideae*) or some species of series *Microsomates*. *O. umbilicata* (series *Orbilia*) is also similar, differing in desiccation-sensitive, hyaline apothecia, and lanceolate paraphyses which are completely devoid of exudate.

O. beltraniae from Macaronesia (on *Euphorbia canariensis*) is similar but has slightly larger, ± straight spores (*4.5–7 × 1.2–1.7 µm) containing much larger (0.6–0.9 µm wide, total length 1–2 µm), distinctly eccentrical SBs (Pl. 911).

Variation. The specimen on *Ficus* differs from the two on *Rhamnus* in more strongly curved, allantoid ascospores.

Anamorph. The anguillospora-like conidia observed on the natural substrate near the apothecia are narrower and much longer than those of *O. fraxini*, and only exceptionally bent at the ends. They resemble those of *O. caulicola* (section *Aurantiorubrae*).

Phylogeny. Sequences comprising the S1506 intron, ITS, and LSU were gained from apothecia of the holotype and from pure culture of the Spanish sample. They differ by 1 % in the ITS (4 nt in ITS1, 1 nt in ITS2) and by 1 nt in the D2 domain of LSU. In the intron they differ by 1.3 % in the overlapping 320 nt, whereas the distances among species of series *Neodactylella* lie in the range of 8–28 %.

O. rhamni clustered in all analyses with *O. asomatica* and *O. fraxini* in a supported clade (for the molecular distances see under these species), but only in the combined and LSU analyses the *rhamni-fraxini* clade received high support (Phyls 27, S31).

Ecology. The five known collections of *O. rhamni* grew on bark (& wood) of xeric twigs and branches of *Rhamnus alaternus* and *Ficus carica* in southwestern Europe. The samples from Portugal were in a mesomediterranean semihumid *Quercetum ilicis* woodland on a west-exposed slope with planted *Olea europaea* and *Pinus pinea*, that from Barcelona was a similar woodland with *Quercus coccifera* and *Pinus halepensis*.

Specimens included. **PORTUGAL**: **Santarém**, Ribatejo, 10 km NNW of Santarém, 2.3 km NE of Romeira, Val de Flores, 60 m, twigs of *Rhamnus alaternus*, on bark & wood, 6.V.2009, J.P. Priou (ex H.B. 9066a, M-0276579, **holotype**; **isotype** in J.P.P. 29098; sq.: KT222373). – ibid., 50 m, branch of *Ficus carica*, on bark, 1.V.2012, J.P. Priou (J.P.P. 12100, H.B. 9683). – ibid., 56 m, branch of *F. carica*, 12.VI.2017, J.P. Priou (J.P.P. 17145, non vid.). — **SPAIN**: **Cataluña**, **Barcelona**, 27 km NW of Barcelona, 3 km NW of Terrassa, Torrent de Gaià, 340 m, branches of *Rhamnus alaternus*, on bark, 5. & 21.IV.2014, J. Bometón (J.B. 0463/14, anam. substr.; sq.: KT380100). – 19 km NW of Barcelona, 5.5 km SSE of Terrassa, 175 m, branch of *R. alaternus*, on bark, 30.V.2020, J. Bometón (doc. vid.).

Orbilia lamarcheae Baral, sp. nov., MB 813981 — Pls 928–929

Etymology: named after the host, *Lamarchea hakeifolia*.

Typification: Western Australia, Nerren Nerren, trunk of *Lamarchea hakeifolia*, 8.XI.2007, G. Marson (ex H.B. 9020g, MEL 2389276, holotype).

Latin diagnosis: *Similis* Orbiliae rhamni *sed apothecia margine breviter pilosa, ascosporae corpusculum refringens multo majorem continentes. Habitat ad corticem separatum putridum siccum trunci vivi* Lamarcheae hakeifoliae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.4 mm diam., 0.14–0.2 mm high, light yellowish-ochraceous, slightly translucent, round, very scattered; disc strongly concave, margin thick, 20–40 µm protruding, finely whitish pubescent; sessile on a narrowed base, ± superficial. **Asci** *38–45 × 3.7–4(–4.5) µm, 8-spored, spores *1–2-seriate, 3–5 lower spores inverted (sometimes strongly mixed, rarely upper spores inverted), pars sporifera *18–26 µm long; **apex** (†) strongly truncate (slightly indented and laterally inflated); **base** with short to medium long, flexuous stalk, h- to H-shaped. **Ascospores** *5.2–6 × 1.2–1.4 µm, subcylindrical, homopolar, apex rounded to obtuse, base not or indistinctly attenuated, slightly (to medium) curved, often only near base; **SBs** *1–1.2 × 0.7–0.9 µm, globose, apically narrowed to a very short, indistinct filum. **Paraphyses** apically cylindrical or often spathulate to lageniform, terminal cells *19–27 × 2.6–3.6 µm, exceeding the living asci by ~1–3 µm, lower cells *4.5–9 × 2–3 µm; unbranched at upper septum. **Medullary excipulum** 50–70 µm thick, of medium dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** pale ochraceous-orange, of (†) thin-walled, vertically oriented t. (globulosa-)angularis-prismatica from base to mid flanks, 50–70 µm thick

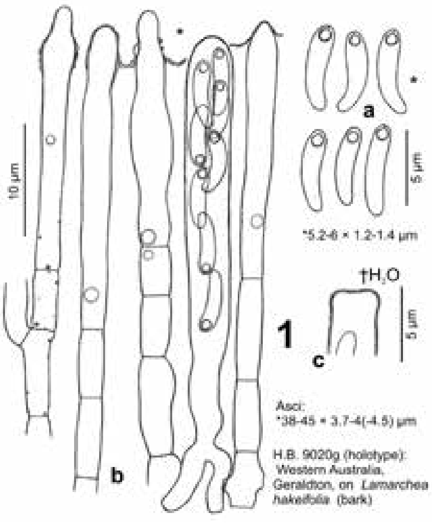

Plate 928. **1**: *Orbilia lamarcheae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

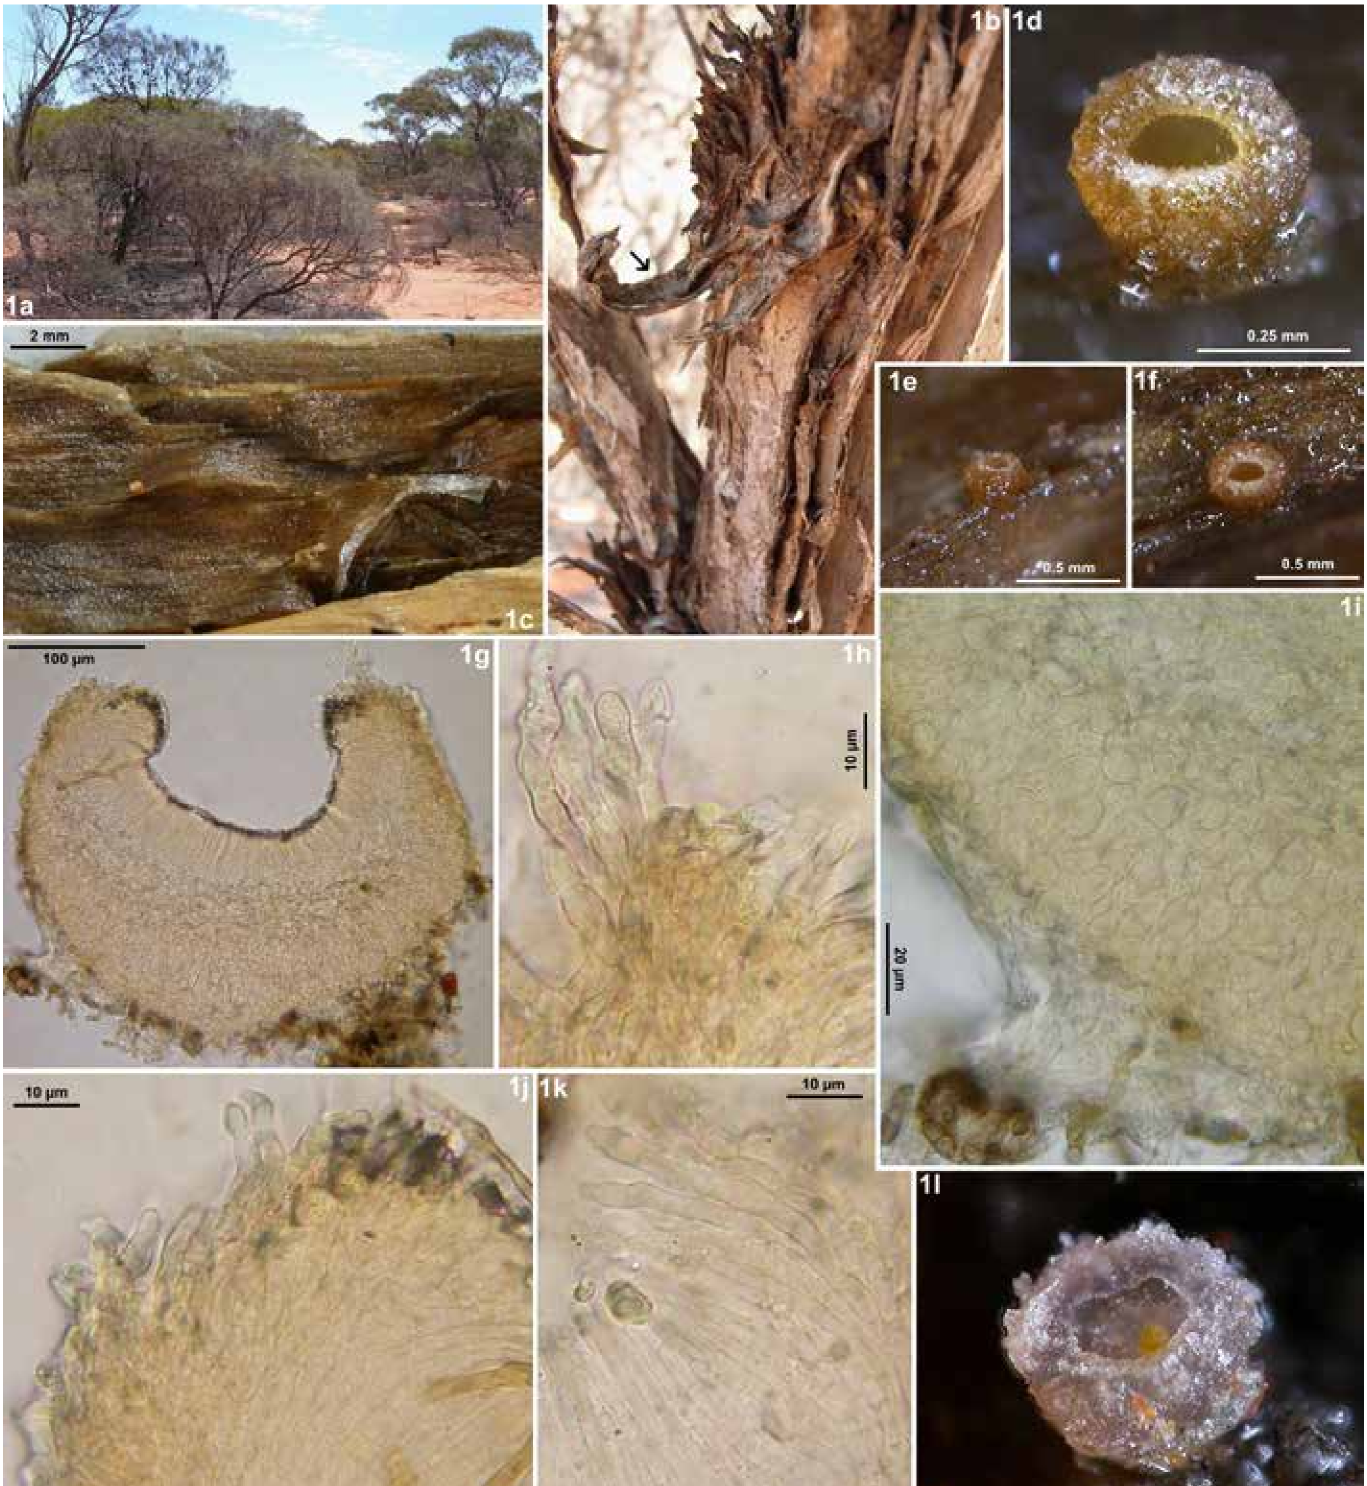

Plate 929. **1a–j**: *Orbilia lamarcheae*; **1k–l**: *O.* cf. *lamarcheae*. – **1a**. semiarid *Acacia* shrubland with *Lamarchea* (left, with fruits), *Acacia*, *Dodonaea*, *Callitris*; **1b**. living trunk with detaching paper-like bark; **1c**. bark with scattered rehydrated apothecia; **1d–f**, **l**. rehydrated apothecia; **1g**. apothecium in median section; **1h**, **j–k**. id., marginal ectal excipulum; **1i**. id., basal ectal excipulum. – Living state. — **1a–j**. H.B. 9020g (holotype): Western Australia, Yalgoo, on *Lamarchea*; **1k–l**. H.B. 9020o: ibid.

near base, cells *(8–)10–18(–22) × 7–12 µm; 20–25 µm thick near margin, of pale orange t. prismatica oriented at a 30–50° angle to the surface, marginal cortical cells *6–10 × 3–4 µm, terminating in thin-walled (†0.3–0.4 µm), irregularly flexuous, ~1–3-septate free **hairs** of */†20–45 × (3–)3.5–5(–6) µm; glassy processes absent. **Anchoring hyphae** not observed. **SCBs** in paraphyses globose, in ectal excipulum not observed. **Exudate** over paraphyses 0.1–0.3 µm thick, indistinctly granular, continuous, firmly attached, on marginal cells among hairs 0.5–3 µm thick, pale yellow. — **ANAMORPH**: unknown.

Habitat: collected 0.5–1.5 m above the ground, corticated, ~10–18 cm thick, standing, living trunk of *Lamarchea hakeifolia*, on strongly decayed, almost entirely detached, paper-like bark, ± greyed, without algae. **Associated**: *Capronia* spp. {2}, *Claussenomyces* sp., *Hyalorbilia pleioerythrostigma*, *Orbilia austroobtusispora*, *O. gemma*, *O. kingsiana*, *O. myriolilacina*, *O. pseudoflagellispora*, *O.* ?*pubescens*, *Ostropales*, *Symbiotaphrina desertorum*, ?*Xerotrema* sp. **Desiccation tolerance**: fully viable for at least 20 months. **Altitude**: 190 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia lamarcheae* is very similar to the south European *O. rhamni*, from which it differs in the presence of distinct, short marginal hairs, much larger SBs, also in thicker apothecia, the latter feature being, however, perhaps an accidental difference.

Not included collection. A single immature apothecium associated with *O. lamarcheae* in ~2 cm distance differs in a distinct pale rose colour, also a partly thicker exudate over paraphysis and hair apices (Pl. 929: 1k–l). It belongs only doubtfully here and is, therefore, not included in the description.

Ecology. *O. lamarcheae* grew very sparsely on loose bark of a xeric trunk of *Lamarchea hakeifolia* in a subtropical semiarid open acacia shrubland in western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, NW Coastal Hwy, 190 m, trunk of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (ex H.B. 9020g, MEL 2389276, **holotype**).

Not included. ibid. (H.B. 9020o).

Orbilia asomatica Baral, Quijada & Beltrán-Tej., in Quijada et al., Nova Hedwigia 96: 241 (2012) — Pls 930–931, Map 149

Etymology: named after the absence of a spore body.

Typification: Macaronesia, Tenerife, Abades, branch of *Euphorbia canariensis*, 5.VI.2009, L. Quijada, R. Castro & E.V. Rodríguez (TFC Mic. 22165, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.9 {T} or 0.8–1.5(–1.9) mm diam., 0.13–0.2 or 0.3–0.4 mm high (receptacle 0.13–0.18 → 0.09–0.13 mm), light ochre-orange, hardly translucent, round, slightly gelatinous, subgregarious; disc medium to strongly concave, margin thin, concolorous or more reddish-brown, rough to distinctly crenulate or fimbriate by whitish, ± conglutinate or free hairs, ~5–50 µm protruding (incl. hairs); broadly sessile or with an obconical stipe, superficial to slightly erumpent; dry strongly contracted, bright dirty (olivaceous- to maroon-)brown, externally covered with dirty whitish granules. **Asci** *(48–)60–72(–76) × 5.5–6.5 µm {2}, †54–67 × 5–6 µm {T}, (5–)8-spored, spores *2–3-seriate, ~3–5 lower spores inverted {T}, pars sporifera *(30–)33–42(–47) µm long; **apex** (†) medium to strongly truncate (partly very slightly indented, laterally not or hardly inflated); **base** with short to medium long, thin or thick, flexuous stalk, L-, h- to H-shaped. **Ascospores** *(11.5–)14–18(–21.5) × (2.4–)2.6–3.2(–3.5) µm {3}, †13–15 × 2.2–2.7(–3) µm {T}, subcylindrical to narrowly fusoid to fusoid-clavate, apex obtuse, base slightly to rather strongly attenuated, sometimes with a short and thick tail, inequilateral to slightly curved, especially near base, rarely 1-septate (apparently freshly ejected) {2}; **SBs** absent at all stages of development. **Paraphyses** apically slightly to medium inflated, consistently lageniform, sometimes lanceolate, terminal cells *(16.5–)22–31(–38) × 2.3–3.8 µm {2}, beak *2–4.5 × 1.7–2.3 µm, partly ± flexuous, exceeding the dead asci by 3–7 µm, lower cells *(6.5–)9–15(–19) × (1.5–)2–2.5(–3) µm {2}; unbranched at upper septum. **Medullary excipulum** 40–80 µm thick, of ± dense textura intricata, horizontally oriented, with many inflated cells, sharply delimited. **Ectal excipulum** of (†) slightly gelatinized, ± vertically oriented t. angularis(-prismatica) near base, 30–60 µm thick, cells *10–22 × 7–14 µm {T}; 15–20 µm thick at flanks and margin, of t. globulosa-angularis up to mid flanks, at upper margin of t. prismatica-porrecta oriented at a 0–10° angle to the surface, marginal cortical cells *8.5–12 × (2.3–)3.5–4.5 µm {1}, †5–10 × 2.5–3 µm {T}, partly terminating in thin-walled hairs *13–22 (0-septate) or 35–45(–54) (2-septate) × (2–)3–5 µm {2}; **glassy processes** absent. **Anchoring hyphae** abundant, *2–3 µm wide, walls 0.2 µm thick {T}. **SCBs** in paraphyses and ectal excipulum not observed; **VBs** in terminal cells of paraphyses globose, 0.5–1.8(–2.2) µm diam., abundant, very low- to low-refractive {T}, dead plasma turning pale amber-yellow. **Exudate** over paraphyses 0.1–0.2(–0.5) µm thick, smooth to somewhat rough, firmly attached, over margin and flanks 0.2–0.5 µm up to ~1–2 µm thick, continuous, smooth to rough, hyaline to bright maroon-yellow. **— ANAMORPH**: unknown.

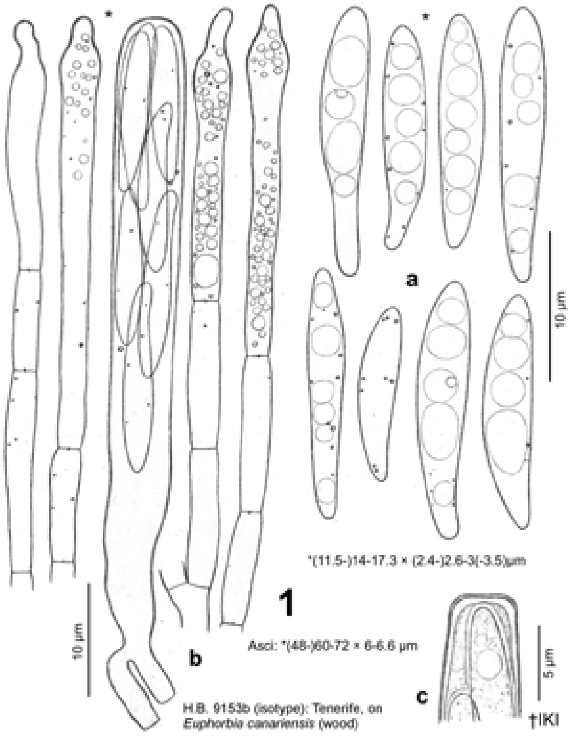

Plate 930. **1**: *Orbilia asomatica*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Habitat: close to the ground with contact to soil or up to 1 m above the ground, ± decorticated, terminal and hollow branches of *Euphorbia canariensis* {6}, *E. lamarckii* {1}, on strongly decayed wood {4}, usually on underside, very slightly greyed, no algae. **Associated**: *Orbilia acaciae* {1}, L. Quijada (pers. comm.): especially *O. pisciformis*, also *O. amarilla*, *O. beltraniae*, *O. eucalypti*, *O.* aff. *farnesianae*, *O. succulenticola*, ?*Unguiculella* sp. **Desiccation tolerance**: fully tolerant for at least 8 weeks (but not tolerating repeated rewetting), mature asci still alive after 2.5 months and spores after 3 months. **Altitude**: 15–640 m a.s.l. **Geology**: basaltic and trachybasaltic flows. **Phenology**: IV–VI, X, XII (probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia asomatica* is very exceptional within the *Orbiliomycetes* because it entirely lacks a spore body. When the holotype was studied by the first author 8 weeks after collecting, the apothecia were viable concerning most of their elements, even many of the mature asci were alive and also a single fully turgescent ascus was seen (Pl. 931: 1l). All spores inside the living asci and also many viable free spores were consistently without any trace of a spore body. Several further collections have been studied by L. Quijada who confirmed the consistent absence of SBs in this species (Quijada et al. 2012).

With its large ascospore size *O. asomatica* exceeds all the other species of section *Arthrobotrys*. Recognition of this discomycete as orbiliaceous was possible due to the structure of the ascus apex and base, whereas placement in a section of *Orbilia* was quite impossible by morphology alone because of the lack of SBs. Only its molecular data permitted to place this species in series *Neodactylella*, while the lageniform paraphyses and concave, cup-shaped apothecia suggested a relationship to series *Habrostictis* or *Piliferae*. Three trinacrium robustum-like conidia were detected near the apothecia, but they might rather belong to the associated *O. acaciae*. Because of the absence of

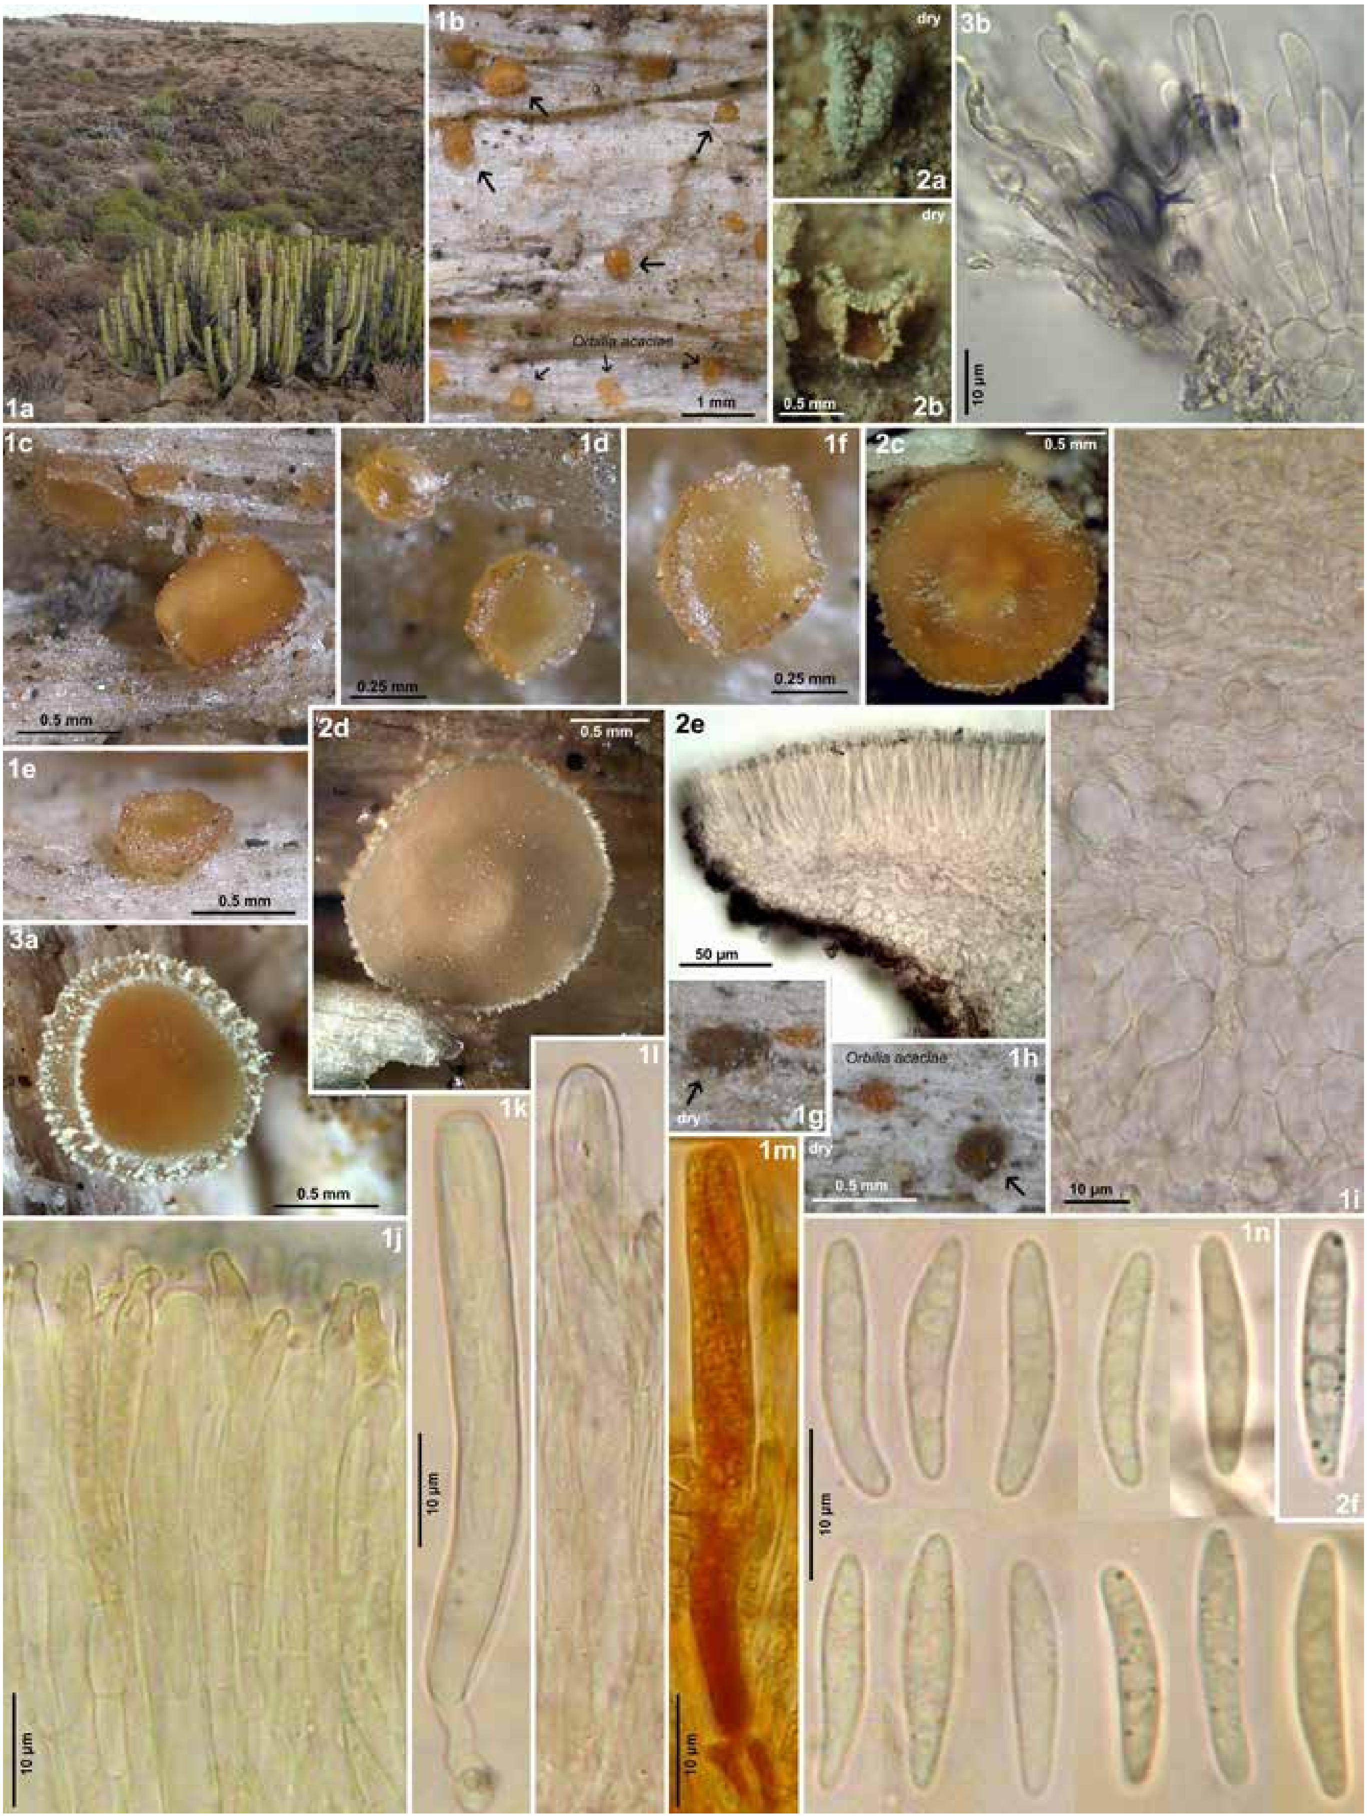

Plate 931. **1–3**: *Orbilia asomatica*. – **1a**. tabaibal dulce (*Ceropegio fuscae-Euphorbietum balsamiferae*) with *Euphorbia canariensis* in foreground; **1b–f**, **2c–d**, **3a**. rehydrated apothecia (light orange apothecia with smooth margin in **1b** belong to *O. acaciae*, marked by smaller arrows); **1g–h**, **2a–b**. dry apothecia (in **1** with orange apothecia of *O. acaciae*); **2e**. apothecium in median section; **3b**. id., marginal ectal excipulum; **1i**. id., basal ectal excipulum; **1j–m**. asci and paraphyses; **1n**, **2f**. ascospores. – Living state, except for **1m** (in IKI) (terminal cells), **3b** (outer hairs on left). – **1a**, **2a–f**, **3a–b**: phot. L. Quijada (**2e**: from Quijada et al. 2012, **3a**: from Quijada et al. 2016). — **1a–n**. H.B. 9153b (isotype): Tenerife, Abades, on *Euphorbia canariensis*; **2a–f**. TFC 22052, 22054: Montaña Amarilla, on *E. canariensis*; **3a–b**. TFC 23823: Punta de Teno, on *E. canariensis*.

Map 149. Known distribution of *O. asomatica* in Tenerife (Macaronesia).

a spore body the species was first classified by the finder as a possible member of the *Hyaloscyphaceae* (*Helotiales*).

Variation was mainly observed in apothecial size, being rather small in the holotype, while the microscopic features were rather concordant among the collections. Some extreme values in the protologue were not included in the above description, for instance *1.5 µm wide terminal cells refer to young paraphyses, or *5.7 × 3.3 µm large basal excipular cells concern rare, often external, very small elements that were consistently omitted in the present study.

Phylogeny. Sequences (ITS+LSU) were taken from apothecia of two specimens. Both lack the S1506 intron. Phylogenetic analyses provide strong evidence for a relationship with series *Neodactylella*, particularly with *O. rhamni*, with which it formed a supported clade irrespective of analysing ITS or LSU (Phyls 25–27, S31), with *O. fraxini* as sister clade. In the ITS region the two *O. asomatica* strains differ by 0.4 % (2 nt), while the distance to *O. rhamni* is 7 % and to *O. fraxini* 12 %. In the LSU (D1–D2) the two *O. asomatica* strains are identical, and the distance to *O. rhamni* is 0.7–0.9 % and to *O. fraxini* 2.1 %.

Ecology. *O. asomatica* was repeatedly encountered between 2009–2014 by L. Quijada (pers. comm.) on rotten wood of xeric branches of *Euphorbia* spp. in infra- to rarely thermomediterranean xerophytic scrublands at four sites in Tenerife (Macaronesia). The vegetation includes the semiarid cardonal (*Periploco laevigatae-Euphorbietum canariensis*) in the northwest of the island, a semiarid juniper woodland in the west, and an arid tabaibal dulce (*Ceropegio fuscae-Euphorbietum balsamiferae*) and hyperarid *Frankenio ericifoliae-Zygophylletum fontanesii* in the south. Although the inhabited branches were often more or less lying on the shaded ground, they are nevertheless dry for most time of the year.

Specimens included. **MACARONESIA**: **Canary Islands**, **Tenerife**, Buenavista del Norte, 5 km WSW of Buenavista del Norte, 3 km NW of Teno Alto, Punta de Teno, Lomo las Toldas, 190 m, branch of *Euphorbia canariensis*, on wood, 27.XII.2012, L. & C. Quijada (TFC Mic. 23823, doc. vid.; sq.: KT222400). – Guía de Isora, 5 km NNW of Guía de Isora, 1.7 km NW of Chío, Los Corchos, 640 m, branch of *E. lamarckii*, on wood, 24.X.2014, L. Quijada, C. Quijada & J. Kout (TFC Mic. 21258, non vid.; sq.: KT222399). – **Arico**, 1 km WSW of Abades, Baranco la Vera, 50 m, branch of *E. canariensis*, on wood, 5.VI.2009, L. Quijada, R. Castro & E.V. Rodríguez (TFC Mic. 22165, **holotype**; H.B. 9153b, **isotype**). – ibid., 5.V.2009 (TFC Mic. 22158, non vid.). – ibid., 12.VI.2009 (TFC Mic. 22233, doc. vid.). – San Miguel de Abona, 4.5 km SSW of Las Chafiras, 1.2 km ENE of Costa del Silencio, Montaña Amarilla, 15 m, branch of *E. canariensis*, on wood, 16.IV.2009, L. Quijada, J. Diaz Armas & E.V. Rodríguez (TFC Mic.22052, 22054, 22055, doc. vid.). – ibid. 11.VI.2009 (TFC Mic.22175, 22180, doc. vid.). – ibid., 35 m, branch of *E. canariensis*, 16.XII.2012, L. Quijada & R. Castro (TFC Mic. 23770).

2. Marginal excipular cells oriented at a low angle, forming distinct cell rows, ascospores generally falcate and mostly > 8 µm long, conidia fusiform, rarely fusoid-clavate

Habitat: lying at the moist ground or often at base of standing stems or in 0.5–2 m above the ground, corticated or decorticated, 1–15 cm thick branches and trunks of *Corylus avellana* {1}, *Fagus sylvatica* {2}, *Sambucus nigra* {1}, on slightly to strongly, partly deeply decayed wood {1} and bark {3} (periderm {3} and bast {2}, bark ± detached), hardly to strongly greyed or darkened, without or with a few green algae; herbaceous stems (rarely leaves) of *Angelica* sp. {1}, *A. archangelica* {1}, *A. sylvestris* {3}, *Arctium minus* {1}, *Cirsium arvense* {1}, *C. vulgare* {1}, *Foeniculum vulgare* {1}, ?*Helianthus tuberosus* {1}, *Heracleum* sp. {1}, *H. sphondylium* {1}, *Hordeum vulgare* {1}, *Impatiens glandulifera* {1}, *Oenanthe crocata* {2}, *Pastinaca sativa* {1}, *Smyrnium olusatrum* {1}, *Symphytum officinale* {1}, *Urtica dioica* {2}; on dung of *Equus caballus* {1}, *Oryctolagus cuniculus* {1}, ?mice {1}, caterpillar {1}; soil/forest litter isolates {3}. **Associated**: *Cistella* ?*aconiti* {1}, *C. grevillei* {1}, *Hyalorbilia fagi* {1}, *Urceolella* ?*pani* {1}, *Leptospora rubella* {1}, *Mollisia revincta* {1}, *Orbilia atlantis* {1}, *O. auricolor* {1/1}, *Pyrenopeziza atrata* {1}, *Trichosphaeria notabilis* {1}. **Desiccation tolerance**: paraphyses, immature asci, and conidia survive for at least 2 days. **Altitude**: -4–1175 m a.s.l. (Europe), 1100 m (Papua New Guinea). **Geology**: Cambrian, Ordovician & Carboniferous shale, silt- & sandstone, quartzitic & carbonaceous greywacke, Permian (Rotliegend), Keuper (sandstone & marl), Lower Jurassic sandstone, Upper Cretaceous clayey sand, Quaternary sand, marl & till; granite, quartzite, amphibolite, phyllite, mica schist, sericitic shale, gneiss. **Phenology**: II–X (teleomorph).

Taxonomic remarks. *Orbilia oxyspora* is characterized by its marginal excipular cells that form distinct rows oriented at a low angle to the surface, in combination with a dactylella-like anamorph with large, fusiform, multiseptate conidia. With its falcate ascospores the species resembles *O. auricolor* (series *Arthrobotrys*), which differs in the absence of marginal cell rows and an arthrobotrys-like anamorph with 1-septate conidia. However, there are other species with marginal cell rows: *O. dorsalis* hardly differs morphologically, except for its anamorph showing a slight tendency to shorter conidia with fewer septa; this species is accepted here as separate mainly for molecular reasons and a subtropical to tropical distribution. *O. clavispora* differs in subcylindrical conidia with obtuse ends and in strongly, often abruptly attenuated spore bases that form distinct tails. *O. tenuissima* differs in distinctly narrower ascospores, more yellow apothecia, and a tropical distribution, and *O. desertorum* in slightly wider spores, in the presumed anamorph having smaller, subcylindrical conidia with fewer septa, and in occurring in semiarid subtropical areas. Narrow spore tails were occasionally also seen in *O. oxyspora*, namely in the type of *O. ektophysata* (Pl. 932: 2a), but so far only in dead spores. Finally, a member of series *Arthrobotrys* (*O. javanica*, see p. 1550) strongly resembles *O. oxyspora* in the teleomorph characters but has a very different anamorph. For the possibly synonymous but not included *O. fimicola* and *O. lupini* see below.

Variation. The collections here included in the description of *O. oxyspora* show variation in some features. The exudate is rather thin in the specimens from Tübingen and Salzburg, and thickest in the type of *O. sambuci*. The latter shows also the highest ascus width and deviates in fresh vinaceous-yellowish apothecia. In the specimen from Luxembourg and the type of *O. sambuci* the glassy processes are ± absent, whereas the type of *O. ektophysata* belongs to those with the longest processes. In the specimen from Salzburg they form rather broad caps, and this is apparently also the case in the type of *O. fimicoloides*, which Webster et al. (1998) described as 'the apical cell often with greatly thickened refractive walls'. Perhaps because it was not fully mature, a sample from Bretagne (IVV: J.P.P. 15134, on *Ulex*) had straight to slightly curved living spores; it is included as it showed the typical conidia.

Type studies (teleomorph). Velenovský (1934) described ***O. sambuci*** based on two collections (on *Sambucus nigra* and *Rosa canina*). Svrček redescribed the *Sambucus* specimen (as 'holotype'), but he did not mention that on *Rosa*, probably because it could not be found at PRM. Since two collections are mentioned in the protologue and since the epithet *sambuci* does not automatically imply that the *Sambucus* collection is the holotype (ICN Art. 9A.2), we here designate the collection on *Sambucus* (PRM 148826) as **lectotype**.

This lectotype (Pl. 932: 3) consists of ~22 scattered apothecia which are rehydrated 0.25–0.55 mm in diam., now pale cream (Velenovský: vinaceous-yellowish, according to his manuscript plate which treats mainly the *Sambucus* sample). Svrček placed the taxon in synonymy with *O. curvatispora* (= *O. auricolor*), with the remark that the exudate ('epithecium') over the paraphyses is strongly developed (up to 5.5 µm thick, 1.5–3 µm in the present study). In the present reexamination the spores were wider than reported by Velenovský (8–10 × 0.7–1 µm, width evaluated from manuscript plate) and Svrček (9–11 × 0.8 µm). Velenovský's drawing shows much more curved (arcuate) spores than here observed, but this discrepancy seems to be due to the living vs. dead state. The marginal excipulum forms rather distinct, somewhat free rows of prismatic cells oriented at a 30–40° angle to the surface. This and the rather narrow anchoring hyphae of 2–2.5(–4) µm exclude *O. auricolor*. Although conidia were not found on the substrate, *O. sambuci* is considered here to be conspecific, e.g., with *O. fimicoloides*.

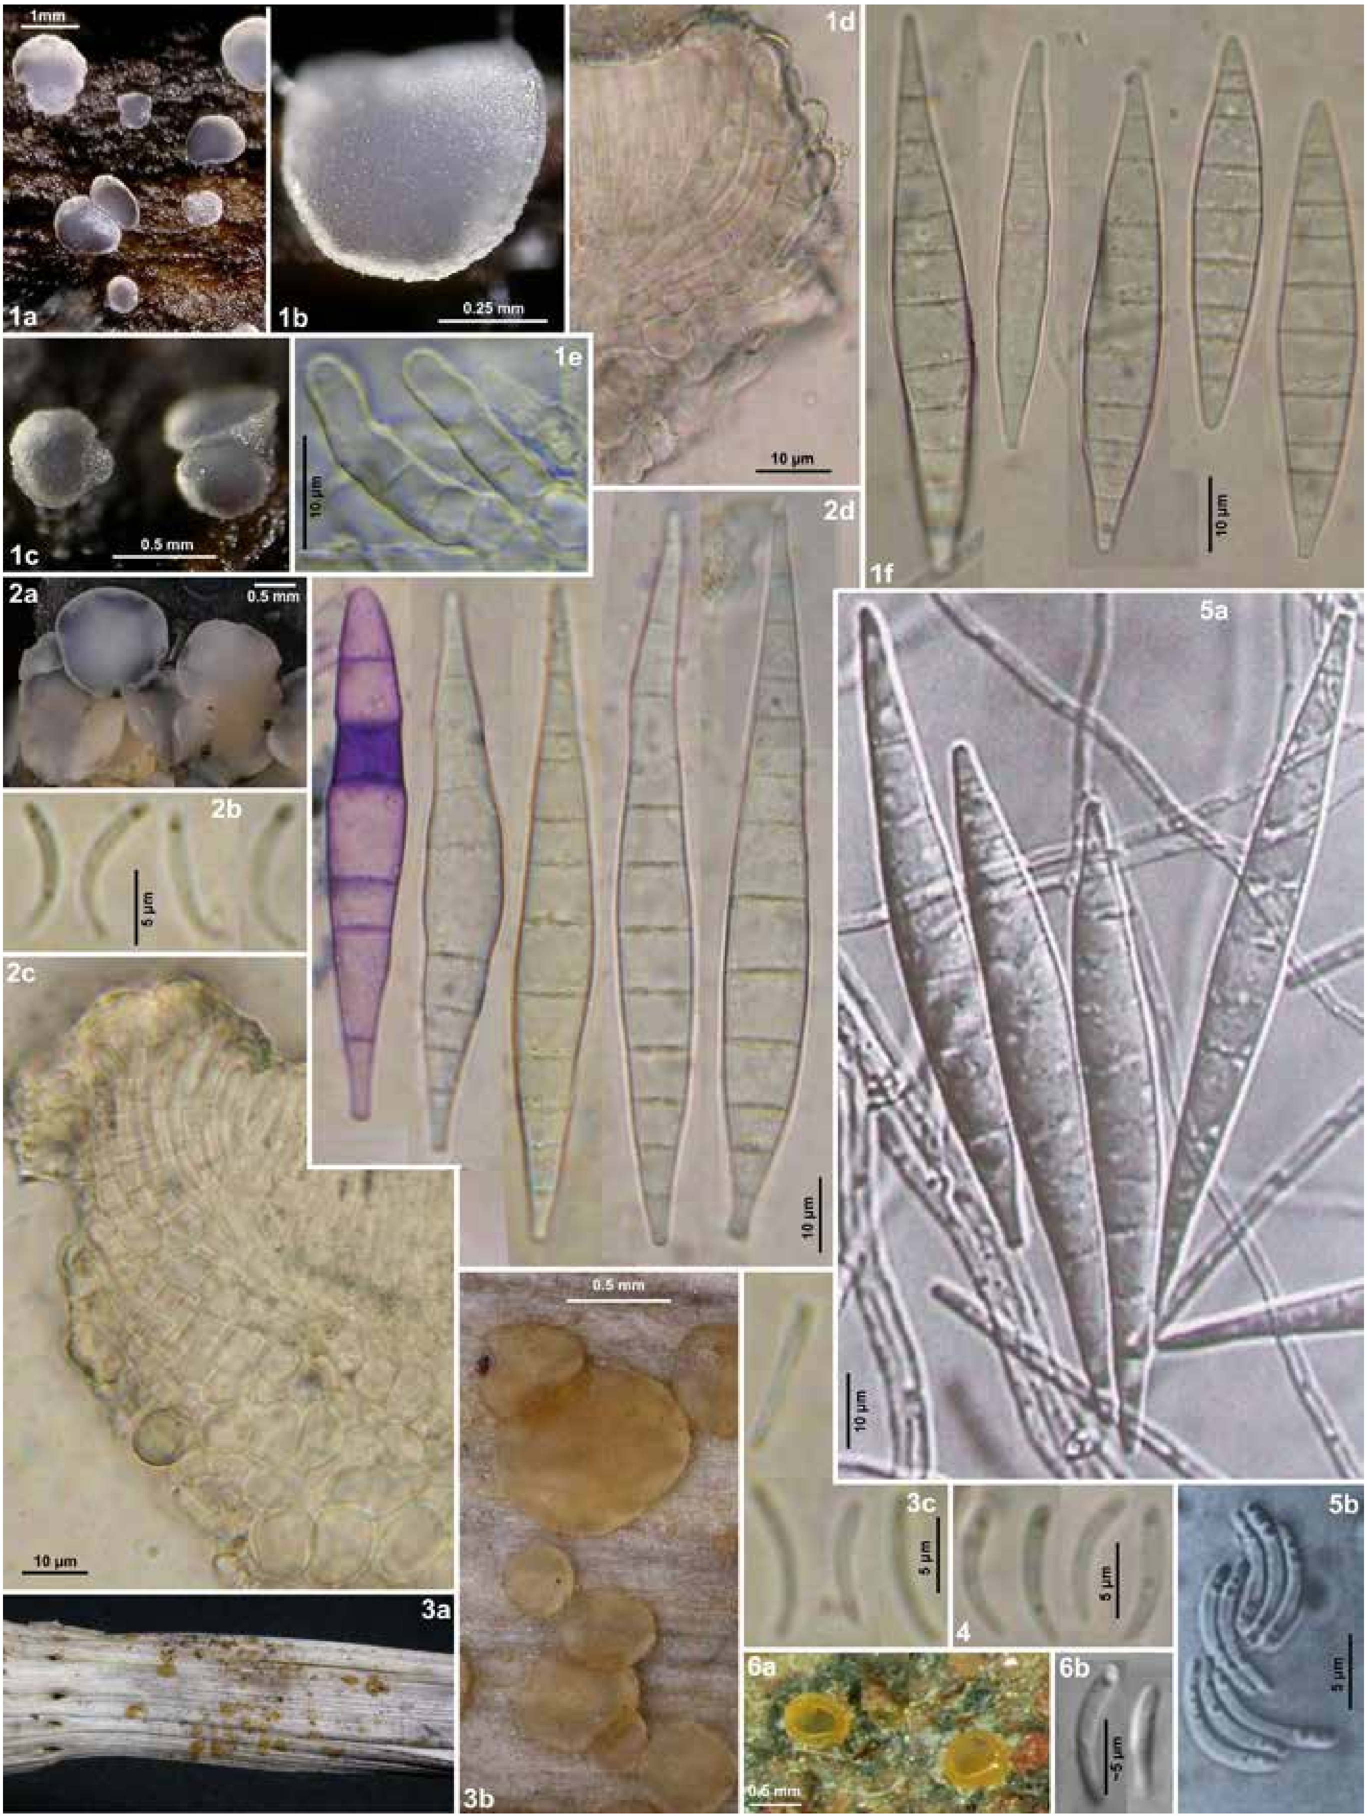

Plate 933. **1–5**: *Orbilia oxyspora*; **6**: *O.* aff. *oxyspora*. – **1a–c**, **2a**. fresh apothecia (**1a–c** grown in moist box); **3a–b**, **6a**. rehydrated apothecia; **1d**, **2c**, ectal excipulum in median section at mid flanks and margin; **1e**. hair-like rows of marginal cortical cells; **2b**, **3c**, **4**, **5b**, **6b**. ascospores; **1f**, **2d**. conidia from substrate; **5a**. conidia from culture (DIC). – Living state, except for **3c** (in KOH) and **6b** p.p. —**1a–f**. H.B. 8428b: Luxembourg, Echternach, on *Fagus*; **2a–d**. H.B. 9390a (epitype): Germany, Chemnitz, on *Angelica*; **3a–c**. H.B. 5299: France, Ardennes, on *Angelica*; **4**. H.B. 9447: France, Morbihan, on *Oenanthe*; **5a–b**. 18.II.1996: England, Middlesex (type of *O. fimicoloides*, from Webster et al. 1998: fig. 4); **6a–b**. HMAS 139539: China, Henan, on indet. wood (from Liu 2006, as *O. fimicoloides*).

O. ektophysata remained a dubious species in Svrček's (1954) revision because the author failed to find spores in the 'only two apothecia' of the holotype. In the present reexamination (Pl. 932: 2), about 10 apothecia were discovered. Two of them were examined, which showed abundant mature asci but no free spores. Strong pressure on the cover slip broke some asci, and their spores became discernible. Velenovský (1947) described the spores as '1–2.5 µm long, narrowly ellipsoid, straight, eguttulate' and compared the species with *O. minutispora*. His spore description might refer to the spore body, but his false calibration in the case of small elements excludes this possibility. Svrček gave an ascus size of 28–30 × 2.5 µm, probably by omitting the stipe. The margin shows a very fine crenulation due to short, conglutinate, 1–4-celled hairs tipped by ca. 3–10 × 3–3.5 µm large glassy processes. The hair cells are partly isodiametric and closely resemble those cell rows described in the protologue of *O. fimicoloides*. In concordance with Velenovský the paraphyses have a cylindrical to only slightly clavate apex 1.7–2.3 µm wide, covered by 0.5–1.5 µm thick exudate. The rehydrated apothecia are 0.3–0.7 mm diam., now whitish to light cream-yellowish (Svrček: [?dry] lemon-yellow, Velenovský wax-coloured). The 'ektophyses' which Velenovský described as 'numerous, straight, 25–30 × 2–3 µm, fusoid, septate, very thick-walled' appear to refer to the very distinctly developed marginal cell rows. No conidia could be found in this specimen. It must be noted that Velenovský earlier used the name *O. ektophysa* (ined.) on a manuscript plate for two collections here referred to *O. tremulae* (see p. 1375).

The holotype of ***O. lupini*** (Pl. 932: 1) was found at an arid, sun-exposed site on the top of a hill, growing densely gregarious at the base of a stem of *Lupinus polyphyllus*. The apothecia were described by Velenovský (1947) as translucent white, 0.5–1.5 mm diam. and by Svrček (1954) as dry yellow. In the present reexamination ~8 apothecia were found, being rehydrated light yellow-ochraceous, 0.8–1.4 mm diam. Five of them were tested but, despite their size, all were immature by showing only a few young asci. The ascospores could only faintly be seen in a single ascus (Pl. 932: 1b). They seem to be curved, with a size of about 8 × 0.7 µm. The ~100 µm thick basal excipulum is large-celled (15–25 × 10–17 µm) and the marginal cells form a textura prismatica-porrecta at a ~20° angle, with cortical cells 5–12 × 3–4 µm and glassy caps 2–7 × 3–4.5 µm. 2 fusiform conidia of the presumed anamorph were encountered close to the apothecia (see also below).

Svrček discovered a few straight spores 5.5–6 × 1 µm, whereas Velenovský (1947 and manuscript plate) reported them as 2–2.5 × 0.3 µm, cylindrical, often slightly to medium curved, with 3–4 rather large guttules. Even when considering an error of 50% in Velenovský's calibration, the length of these spores would better fit Svrček's than our data. Velenovský described the asci as 25 × 2.5 µm, with truncate unstalked base, and the paraphyses as filiform, features suggestive of a *Hyalorbilia*, but Svrček found the asci 30 × 2.5–3 µm, stipitate, and the paraphyses apically clavate, features suggestive of an *Orbilia*. The projecting hyphae at the apothecial base (6–9 µm wide, thick-walled, yellowish) illustrated by Velenovský support the former idea though the excipulum of isodiametric cells as stated by Svrček fits better an *Orbilia*. Possibly *O. lupini* was a mixture of two species.

Velenovský compared *O. lupini* with *O. cardui*, and Svrček even synonymised the two taxa because he found full concordance between them. Velenovský's report of 'erect, hyaline, subcylindrical, multiseptate tentacles (120–150 × 8–10 µm)' might represent the conidia of *O. lupini*, though those two ones discovered here are much shorter and fusiform. Based on the present reexamination, *O. lupini* is not conspecific with *O. cardui* but might well belong to *O. oxyspora* because of the marginal excipulum oriented at a low angle. Since spore morphology could not clearly be studied, we refrain from including this material in the description of *O. oxyspora*.

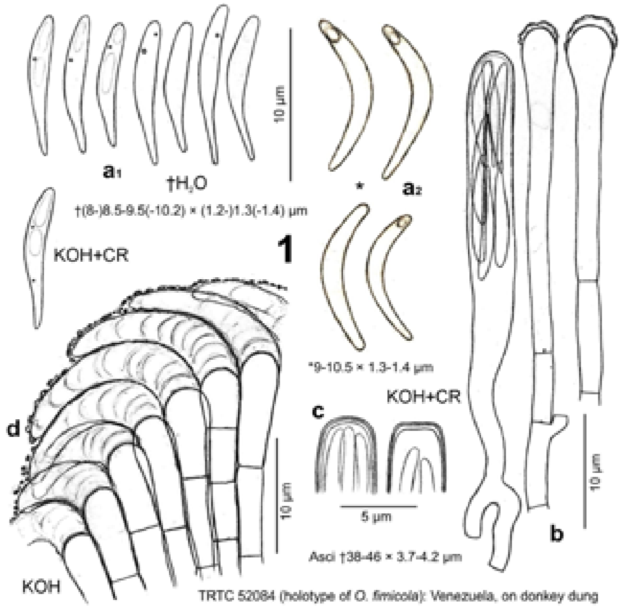

Plate 934. **1**: *Orbilia* cf. *oxyspora*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal cortical cells tipped by glassy processes, (living spores redrawn from photo in Jeng & Krug 1977: fig. 5).

O. fimicola (Pl. 934–935) was reported by Jeng & Krug (1977) for apothecia found on donkey dung in Venezuela. It was described as a new species mainly because of its coprophilous habitat. Though the given microscopic features somewhat resemble those of *O. auricolor*, Jeng & Krug compared it only with *O. leporina* which was described from hare dung. The authors believed that *O. leporina* differed in much smaller, straight spores, and in apically hardly inflated paraphyses covered by more abundant exudate. However, according to the present revision of the holotype of *O. leporina*, the spores are distinctly curved, basally attenuated, and only slightly shorter than in *O. fimicola*, also the paraphyses are apically distinctly inflated (Pl. 916: 1).

The present reexamination of the holotype of *O. fimicola* revealed that the protruding marginal ectal excipulum forms a textura prismatica oriented at a ca. 45° angle (also illustrated by Jeng & Krug), and the cortical cells are tipped by prominent glassy processes (Pls 934: 1d; 935: 1l). In conclusion, *O. fimicola* seems indeed not conspecific with *O. leporina*, in which the marginal cells are oriented at a high angle and without glassy processes, though the other features are very similar.

O. fimicola could well be a synonym of *O. oxyspora* or perhaps *O. clavispora*. The prominently arcuate and subulate spores on Jeng & Krug's photograph (redrawn in Pl. 934: 1a$_2$) resemble those of *O. oxyspora* quite well. Spore size is reported as 7–8.5 × 1.2–1.8 µm, but from the photo a size of *~9–10.5 × 1.3–1.4 µm (in situ) can be evaluated, also a globose (or tear-shaped?) spore body can be discerned in some spores. In the present reexamination (1a$_1$), the spores were distinctly less curved, which is obviously a consequence of the dead state.

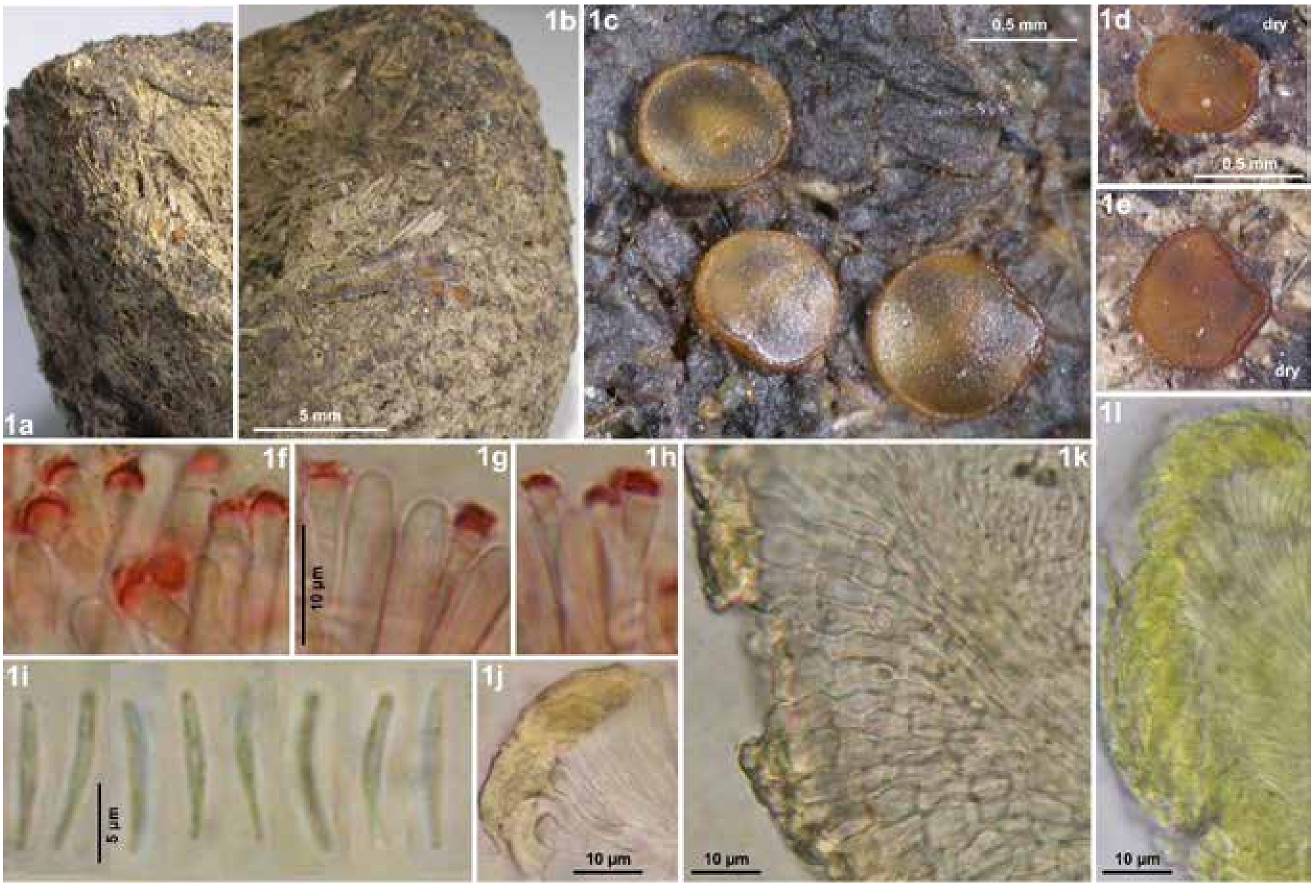

Plate 935. **1**: *Orbilia* cf. *oxyspora*. – **1a–b**. dung of donkey (in dry state); **1c**. rehydrated apothecia; **1d–e**. dry apothecia; **1f–h**. tips of asci and paraphyses (exudate stained red in CR); **1i**. ascospores; **1j–l**. marginal ectal excipulum in median section, cortical cells with glassy processes (yellow in **1l**). – Dead state (**1i–l** in H_2O, **1l** illuminated with Luxeon-LED, **1f–h** in KOH+CR-SDS). — **1a–l**. TRTC 52084 (holotype of *O. fimicola*): Venezuela, on donkey dung.

No anamorph was originally reported for *O. fimicola*, and no conidia could be detected on the substrate, therefore, synonymy with *O. clavispora* cannot be excluded. A sequence taken from the type material would help in clarifying the identity of *O. fimicola*. Pfister (1994) obtained an arthrobotrys-like anamorph in a collection which he identified as *O. fimicola*. The teleomorph of this strain was reexamined (Pl. 949: 2) and found to belong to the scope of *O. auricolor* (series *Arthrobotrys*) because of a vertically oriented marginal excipulum and longer spores, a result which is confirmed by molecular data.

O*. *fimicoloides was described by Webster et al. (1998) from droppings of probably mice from Great Britain. The type was not reexamined here, but the characteristics of the anamorph and teleomorph leave little doubt about its conspecificity with the here assigned, mainly lignicolous and herbicolous collections. Due to the coprophilous habitat, Webster et al. compared their taxon with *O. leporina* and *O. fimicola*. The authors described the apothecial margin as being composed of rows of short (quadrate), somewhat thick-walled cells which extend as free hair-like structures (15–35 × 6–8 µm), their apical cell often bearing a hyaline refractive cap, producing a minutely crenulate margin. However, Webster et al. erroneously believed that also *O. auricolor* possessed this feature. Like in *O. fimicola*, the authors of *O. fimicoloides* thought that *O. leporina* has much smaller, straight spores. In fact, the spores of *O. leporina* are rather similar to those of *O. fimicoloides*, but the marginal excipulum of *O. leporina* is different, and the conidia found on the substrate are shorter and distinctly heteropolar (ellipsoid-clavate, see Pl. 916).

Webster et al. concluded that *O. fimicola* differs from *O. fimicoloides* in light brown vs. white to yellow apothecia, shorter and much wider spores (7–8.5 × 1.2–1.8 µm vs. 8–10.5 × 0.9–1 µm), paraphyses apically inflated (2.8–3 µm wide) vs. non-inflated (1–1.5 µm wide), and a different anamorph (*Arthrobotrys superbus* vs. *Dactylella oxyspora*). However, when evaluating spore size from the photos in Jeng & Krug and Webster et al., the differences become quite vague. In fact, the corrected spore values of *O. fimicoloides* according to the given magnification (*8.8–10.7 × 1.1–1.4 µm) concur quite well with the corrected values of *O. fimicola* (*9–10.5 × 1.3–1.4 µm). The given width of 1–1.5 µm at the paraphysis apices is perhaps incorrect, and the difference in the anamorph is obsolete since the arthrobotrys-like anamorph originates from a misidentified collection.

Not included collections. An unillustrated sample from Tübingen (on *Ononis*) deviates by narrow spores [*8–10.5(–12.5) × 0.8–1.1 µm]. Liu (2006: 80) and Liu et al. (2007a) reported under the name *O. fimicoloides* two collections on unidentified wood from a single site and date in temperate humid China (Jigongshan, Henan, Pl. 933: 6), with yellow apothecia 0.6–1.5 mm diam. with a smooth margin. Although the texture of the marginal excipulum was not studied, a close relationship to *O. oxyspora* or *O. dorsalis* is quite certain because the typical fusiform conidia were found on the substrate (see below). Liu (l.c.) gave the spore size as 9.2–12 × 1–1.4 µm, but his spore photo suggests a lower l:w ratio, while from his scale the spores measure 7–9.5 × 1.2–1.3 µm. For the types of *O. fimicola* and *O. lupini* see under Type studies, *Dactylella atractoides*, *D. minuta* var. *fusiformis*, and *D. yunnanensis* see under Anamorph.

Anamorph. *Dactylella oxyspora* was described in Marchal (1885) from excrements of caterpillars in Belgium. The type description and illustration shows 120–170 × 4–5 µm large conidiophores (1 unbranched conidiophore figured) and large, strongly fusiform conidia (2 conidia figured) which are very attenuated and sharply pointed at both ends. This taxon fits quite well the anamorph reported for *O. fimicoloides* from England by Webster et al. (1998). The latter grew on dung of a small mammal, probably field mouse (*Apodemus*) or field vole (*Microtus*), and its conidia measured in pure culture *63–112 × 9–10.5 µm, with 8–10 septa, but on the natural substrate 45–63 × 9–10 µm, with 7–10 septa (Pl. 933: 5a).

Webster et al. concluded that the anamorph of *O. fimicoloides* matches well *D. oxyspora* as described and illustrated by Matsushima (1971: 22, fig. 18) and Rubner (1996: fig. 58), but the authors did not explain why they named it '*D.* cf. *oxyspora*'. Differences actually exist in conidiophore branching. Matsushima and Rubner figured apically sympodially proliferating conidiophore tips, whereas Webster et al. reported the conidiophores with long and unbranched tips, below occasionally with 1–2 widely spaced branches, each bearing a single conidium at the tip. But also in Marchal's (l.c.) and Drechsler's (1937a: fig. 18 O–Q, as *D. rhombospora*) illustrations the conidia emerge singly on unbranched conidiophores. The only conidiophore seen by us (in H.B. 8428b, unillustrated) was also unbranched, with a single apical conidium.

In two of the studied collections we have seen conidia in abundance on the natural substrate near the apothecia (Pl. 933: 1f, 2d), but conidia were also seen by various collectors in their specimens. With their shape, size, and number of septa they fit well the reports in Tab. 78. In the type material of *O. lupini* two conidia were found on the substrate ~100 µm away from the apothecia. Both were 5-septate and somewhat too small to fit well into the present concept of *O. oxyspora* (Pl. 932: 1i).

Type material of *D. oxyspora* was not mentioned by Matsushima (1971), Rubner (1996), and Chen et al. (2007b), and appears never to have been located. In order to fix the name, an **epitype** is designated here: Germany, Chemnitz, on *Angelica*, ex H.B. 9390a, M-0276548 (Pl. 933: 2). In the ITS region this collection is virtually identical with the type of *D. arnaudii* (see below).

Liu (2006) and Liu et al. (2007a) applied the name *D. rhombospora* to an anamorph found on the natural substrate in one of Liu's collections from Henan (HMAS 139562, as *O. fimicoloides*), with 51.4 × 11 µm large, 7-septate conidia. Other possible synonyms of the anamorph of *O. oxyspora* are *Dactylella atractoides*, *D. heptameres*, *D. arnaudii*, *D. yunnanensis*, and *D. minuta* var. *fusiformis* (for illustrations see p. 223). According to Drechsler (1943b), *D. atractoides* and *D. heptameres* differ from *D. oxyspora* in considerably shorter conidia with more rounded ends, formed on strongly proliferating conidiophore tips. However, *D. heptameres* s. Drechsler is a dubious taxon which might belong instead to *Dactylellina* (see Rubner 1996: 111). *D. arnaudii* and *D. yunnanensis* were distinguished from *D. oxyspora* because of their apically often or consistently rostrate or at least strongly tapered conidia, with the widest part of the conidium below the middle (Chen et al. 2007b). Concerning *D. arnaudii*, Chen et al. believed that the observed variability in conidial shape was a specific character of that species. *D. minuta* var. *fusiformis* was separated by Grove (1886) from *D. minuta* by fusiform, 9–12 septate conidia of 60–75 × 7–9 µm and more aggregated hyphae (probably conidiophores). Based on Grove's illustration it might well belong in the scope of *O. oxyspora*.

Considering the morphological variation in the anamorph observed within a given population of this group of non-predacious species with fusiform conidia, we presume that too much emphasis has been put on features such as conidial size, shape and septation, and that the noted differences are partly also due to a different thoroughness of documentation.

In conclusion and based on the molecular data treated below, we believe that the type of *D. arnaudii* represents a clear synonym of *D. oxyspora* as currently interpreted, and also the Chinese strains of *D. atractoides* and *D. yunnanensis* can be considered as conspecific. Strains under these names often originated from herbaceous substrates but also from dung, and some of the here included samples of apothecia were also on such substrates. Conspecificity is supported by a high similarity in the ITS region of the available sequence data. We also conclude that the dung-inhabiting *O. fimicoloides* is a synonym of *O. oxyspora*, although molecular evidence is lacking here.

A collection of an anamorph on *Araucaria* twig from Taiwan fits *O. oxyspora* perfectly based on the drawing by R. Kirschner (IVV: R.K. 4431), with conidiophores 40–70 × 3–4 µm and strongly fusiform conidia (38–)48–72(–82) × 7–9 µm, with 8–11 septa. A culture from these conidia did not sporulate but gave a sequence distant from existing sequences of *O. oxyspora* (see below). Judging

Table 79. Diagnostic motifs in the ITS region which separate *O. oxyspora* s.l. from *O. clavispora* and *O. dorsalis*. Position numbers according to alignment of listed strains (*oxyspora-clavispora* subclade) by starting after ATCATTA and including rare inserts. ^{T} = ex-type strain, ^{ET} = ex-epitype strain.

from this, associated adhesive knobs and nematodes on the natural substrate appear not to be connected to this fungus.

Phylogeny. A number of sequences, mainly under the name *Dactylella oxyspora* but also *D. arnaudii*, *D. atractoides* and *D. yunnanensis*, can be found in GenBank, which belong in the scope of *O. oxyspora*. Most of them derive from European strains (mainly from Netherlands), but some from California and China. They were taken from culture isolates from soil, plant, or dung and mainly include the ITS region, a few also SSU and/or LSU. ITS was gained from apothecia of the here designated epitype from Chemnitz. The S1506 intron is present in the epitype and in strains from Kiel (CBS 280.70) and China (YMF 1.00561), but it is lacking in the Californian isolate (CBS 497.92) (the remaining sequences are unclear in this respect).

In the ITS region these sequences are either identical or show variation only at 1–5 positions (Phyl. 26). Even the two sequences from California gained from the same strain (CBS 497.92) deviate from two European strains (CBS 291.84, CBS 310.84) by only 1 gap or not at all, whereas three further European strains (CBS 257.70, CBS 157.89, CBS 280.70) deviate hereof at 1–3 positions. Strain CBS 280.70 was originally named *D. rhombospora* by W. Gams, then reidentified as *D. oxyspora* by Rubner (1996: 115), but retained as *D. rhombospora* by Liu et al. (2006a). Also the ex-type strain of *D. arnaudii* deviates merely by 2 nt from some of the *O. oxyspora* sequences.

Several of these records were made on herbaceous stems, including the epitype of *O. oxyspora*. The epitype sequence matches the above strains very well: it shows full identity in the ITS region with the ex-type strain of *D. arnaudii*, except for 2 uncertain gaps. Two Chinese strains (YMF 1.00561, as *D. atractoides*; YMF 1.01447, as *D. yunnanensis*) also deviate from the *D. oxyspora* sequences only by 2–5 nt. This close match of a 0–1% distance in the ITS region supports, in our opinion, conspecificity of all these strains. In the region of the intron, the epitype of *O. oxyspora* shows a 1.4% distance to the strain from Kiel (CBS 280.70) and 2.2% to *D. atractoides* (YMF 1.125), while the latter two deviate by 1.9%. LSU was available for two Chinese strains (*D. oxyspora*, YMF 1.10000; *D. atractoides*, YMF 1.125) and that from Kiel, which fully match each other in the D1–D3 domain, except for 1 nt in the *D. atractoides* strain.

The high molecular homogeneity in the ITS region in *D. arnaudii*, *D. yunnanensis*, and *D. oxyspora* is also obvious in Chen et al.'s (2007a) phylogenetic analysis. Nevertheless, Chen et al. (2007b) accepted them as three different species, although they synonymised *D. atractoides* with *D. oxyspora*. The authors based their opinion about *D. atractoides* on strain CBS 310.84 from Flevoland, which was deposited under that name by W. Gams. Its sequence indeed shows full ITS identity with other strains of *O. oxyspora*. However, Chen et al. did not mention a Chinese strain named *D. atractoides* in GenBank (YMF 1.00561) which shows a deviation of 6 nt and 1 gap in the ITS region to typical *O. oxyspora* strains. Regrettably, sequences of the ex-type strains of *D. atractoides*, *D. yunnanensis*, and *O. fimicoloides* were not available.

In our analysis of ITS or SSU+ITS+LSU (Phyls 25–27, S31), *O. oxyspora* formed with *O. dorsalis* and *O. clavispora* a strongly supported clade, here called *oxyspora-clavispora* subclade (no LSU was available for *O. dorsalis*). This group forms together with *O. desertorum*, the *heptameres-qiluensis* subclade and the *intermedia-multiseptata* subclade the strongly supported *oxyspora-heptameres* clade (Phyls 25–27).

Sequences of *O. oxyspora* in the present circumscription deviate in the ITS region from *O. clavispora* by 2.2–3.6% and from *O. dorsalis* (including *D. rhombospora* s. Chen et al.) by 4.3–6.2%. In the S1506 intron the lowest distance between *O. oxyspora* and other species of series *Neodactylella* is 7.5–9.5% to *D. intermedia* (CBS 109506) and 10.5–12% to *O. clavispora*. In the LSU D1–D2 domain (590 nt) the lowest distance is 1.6% to *O. clavispora*, and one of the next close species is *O. desertorum* with a 3.7–3.9%.

In a phylogenetic analysis of ITS or LSU by Liu et al. (2006a), a Chinese collection identified by Liu (2006) as *O. fimicoloides* (Henan, HMAS 139539, Pl. 31 Fig. 6, with anamorph '*D. rhombospora*' from natural substrate) clustered with *O. oxyspora* from Kiel (as *D. rhombospora*) and *D. oxyspora* from China (YMF 1.10000), respectively. In our ITS analysis (Phyl. 26) it clustered unsupported close to *O. oxyspora*, to which it shows a distance of 1.8–2.8%. HMAS 139539 differs from *O. dorsalis* by 4.2–4.8%, but from the morphologically more deviating *O. clavispora* only by 2.6–3%. In the LSU D1–D2 it differs from *O. oxyspora* by 5 nt and 3 gaps. Placement near *O. oxyspora* is supported by 4 diagnostic motifs in the ITS region (Tab. 79).

Besides Liu's *O.* '*fimicoloides*', three further strains clustered distinct from *O. oxyspora*, *O. clavispora*, and *O. dorsalis* though without forming a joint clade (Phyl. 26): the anamorphic isolate of *O.* aff. *oxyspora* from Taiwan, and two uncultured soil isolates without ITS1 (clone dm2s_2s from California: ITS2, LSU; clone 1767 from Illinois: ITS2). In the diagnostic motifs of Tab. 79, *O.* '*fimicoloides*' and the Taiwanese strain are closer to *O. oxyspora* but share 1 position (127) with *O. clavispora* and *O. dorsalis*, although *D. yunnanensis* (= *O. oxyspora*) shows this deviation as well. The Taiwanese strain shows at pos. 80–89 and 383–385 considerable deviations, which were unambiguously verified from the chromatogram. Due to the missing ITS1 the two uncultured clones were not included in the table. In the ITS2 clone dm2s_2s fits *O.* '*fimicoloides*' and *O. oxyspora* regarding pos. 375–376 (A**CT**TCTG), whereas clone 1767 matches *D. clavispora* (A**TC**TCTG).

Ecology. *O. oxyspora* is a plurivorous species which occurs on hygric and mesic, slightly to strongly rotten wood and bark of angiosperm trees and shrubs but particularly on herbaceous stems of dicots, rarely monocots, also on dung. Previous hypotheses on the restriction of some orbiliaceous fungi to coprophilous habitats could not be confirmed in the present case.

O. oxyspora s.l. was mainly recorded from warm- to cold-temperate regions of atlantic to subcontinental humid, rarely also hemiboreal, or mesosubmediterranean semihumid Europe. A few collections were made in the cool-continental humid (winter-dry) Far East of Russia, in subtropical humid (winter-dry) southern China, in tropical humid Papua New Guinea and northern South America, also in subtropical semihumid California (probably irrigated during summer) and warm-temperate humid eastern North America.

Map 150. Known distribution of *O. oxyspora* in Europe (yellow = not included collections).

Specimens included. **GREAT BRITAIN**: **East England**, **Hertfordshire**, ~30 km NNW of London, St. Albans, ~100 m, stems of *Heracleum sphondylium*, 25.VIII.1958, A.S. Yadav (IMI 77850, **holotype** of *D. arnaudii*, CBS 129.83, conid. isol., doc. vid.; sq.: DQ494353, MH873289). – **South East England**, **London**, 15 km WNW of London, N of Perivale, Perivale Wood, dung of ?mice, 30 m, 18.II.1996, A. Henrici (K(M) 48656, **holotype** of *O. fimicoloides*, anam. substr. & anam. cult., doc. vid.). – ibid., 10.VII.1997 (K, non vid.). — **NETHERLANDS**: **Flevoland**, 23 km E of Amsterdam, Almere, Bossen, 0 m, stems of *Cirsium arvense*, 31.III.1984, W. Gams (as *D. atractoides*, CBS 310.84, conid. isol., non vid.; sq.: DQ494349). – ~5 km SE of Almere, Almeerderhout F61, on dung of *Oryctolagus cuniculus*, 15.II.1984, H.A. van der Aa (CBS 291.84, conid. isol., non vid.; sq.: DQ494348). – ~60 km ENE of Amsterdam, Oostelijk (eastern Flevoland), 0 m, agricultural soil, 7.X.1969, J.W. Veenbaas-Rijks (CBS 257.70, conid. isol., non vid.; sq.: DQ494351). – Noordoostpolder, 8 km E of Emmeloord, ESE of Marknesse, Lovinkhoeve, -4 m, root of *Hordeum vulgare*, 1988, M. Barth (CBS 157.89, conid. isol., non vid.; sq.: DQ494352). – **Noord-Brabant**, 7 km NE of Tilburg, 1 km N of Udenhout, Nieuwe Tiend, 10 m, stem of *Angelica sylvestris*, 13.IX.2013, L. Rommelaars (L.R. 13-068, anam. substr., doc. vid.). — **BELGIUM**: **Vlaanderen**, **Vlaams-Brabant**, Brussels, dung of caterpillar, autumn 1884, E. Marchal (**holotype** of *D. oxyspora*, doc. vid.). — **LUXEMBOURG**: **Gutland**, **Echternach**, 10 km WNW of Echternach, 1.2 km SW of Beaufort, Längt, 340 m, trunk of *Fagus sylvatica*, on bark, 3.II.2007, G. Marson (H.B. 8428b, anam. substr.). — **FRANCE**: **Bretagne**, **Morbihan**, Île de Groix, 2 km WSW of Le Bourg, WNW of Quéhello, Port St.-Nicolas, 17 m, stem of *Oenanthe crocata*, 6.VI.2015, J.P. Priou (J.P.P. 15134 ø, anam. substr., doc. vid.). – 9.5 km SE of Malestroit, 2.7 km WNW of St.-Martin-sur-Oust, Beauvais, 8 m, stem of *O. crocata*, 28.X.2010, Y. Mourgues (J.P.P. 10180, H.B. 9447, anam. substr.). – 4.7 km SSE of La Gacilly, 1.2 km ESE of Glénac, Le Port Corbin, 12 m, stem of *Foeniculum vulgare*, 2.V.2013, J.P. Priou (J.P.P. 13096, anam. substr., doc. vid.). – **Poitou-Charentes**, **Charente-Maritime**, Île de Ré, 1.5 km WNW of Ars-en-Ré, 1.8 km SSE of St.-Clément-des-Baleines, Forêt de la Combe à l'Eau, 8 m, stem base of *Smyrnium olusatrum*, A. Brissard (H.B. 9495 ø). – **Champagne-Ardenne**, **Ardennes**, 10 km ENE of Vouziers, ~1.5 km WNW of Boult-aux-Bois, 240 m, stem of *Angelica*, 16.VI.1995, R. Collot (H.B. 5299, M.L. 95/06/16/1). — **SPAIN**: **Navarra**, 7.5 km SE of Irun, 3.5 km WNW of Bera, SE of Endarlatsa, 34 m, petioles of *Arctium minus*, 4.IX.2015, F.J. Balda (F.J.B. 40815, anam. substr., doc. vid.). – **Aragón**, **Huesca**, 2.8 km SSW of Benasque, S of Linsoles, 1175 m, branch of *Corylus avellana*, on bark, 1.VIII.2016, R. Blasco (ø, doc. vid.). — **GERMANY**: **Schleswig-Holstein**, ~5 km NE of Kiel, Kitzeberg, ~20 m, on *Angelica archangelica*, X.1965, W. Gams (CBS 280.70, as *D. rhombospora*, conid. isol., non vid.; sq.: AY902797, AY902793, AY902790). – **Nordrhein-Westfalen**, 4 km E of Mönchengladbach, Volksgarten, 45 m, stem of *Impatiens glandulifera*, 2.VI.2014, H. Orbilia dorsalis Ying Zhang, Z.F. Yu & K.Q. Zhang in Yu et al. [as '*dorsalia*'], Cryptog. Mycol. 28: 56 (2007) — Pls 936–937

= *Dactylella dorsalis* Ying Zhang, Z.F. Yu & K.Q. Zhang [as '*dorsalia*'], Cryptog. Mycol. 28: 58 (2007)

= *Dactylella rhombospora* s. Chen et al. (2007b: 108)

Etymology: *dorsalis*: according to the growth on the inner (reverse) side of bark; *rhombospora*: after the rhomboid conidia.

Typification: China, Yunnan, Jinghong, branch of ?*Hevea brasiliensis*, 5.VIII.2005, Y. Zhang (YMFT 1.01835, holotype of *Orbilia dorsalis*). — ibid. (YMFT 1.01835, holotype of *Dactylella dorsalis*; sq.: DQ480730).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.3–)0.6–1.4 mm diam., ~0.1–0.17 mm thick, subgregarious, pale to light cream or yellow, medium translucent; disc slightly concave to slightly convex, margin minutely denticulate; sessile on a narrow base, superficial. **Asci** †25–29 {T} or 31–37 {1} × 3–3.5(–3.8) µm {2}, 8-spored, lower ?3 spores inverted {2}; **apex** medium truncate, thin-walled; **base** with very short, thick stalk, h- to H-shaped. **Ascospores** *(7–)8–10(–10.5) × 1.1–1.4 µm (~9.5–12 µm actual length) {2}, subulate, apex rounded, base gradually slightly to medium tapered, strongly curved (falcate); **SBs** 0.8–1.3 × 0.7–0.8 µm {2}, globose to broadly ellipsoid, attachment invisible (total length 1.7–2 µm). **Paraphyses** not or very slightly inflated (capitate-clavate), terminal cells */†13–17 × 2–3 µm {2}; lower cells *4.5–6 × 2–2.2 µm. **Medullary excipulum** ~20–40 µm thick, of textura globulosa-intricata, indistinctly delimited. **Ectal excipulum** of non- or slightly gelatinized t. angularis, ~50–80 µm thick at base, cells †10–30(–35) × 6–15(–22) µm diam. {2}, at flanks oriented at 40–50°, at margin of t. prismatica oriented at 10–30°, cells forming distinct rows, marginal cortical cells †7–8 × 3–4 µm, thick-walled, ± protruding with their tips; **glassy processes** absent {T} or 10–14 × 4–5 µm {1}, pale yellowish, zonate, slightly curved outwards. **Anchoring hyphae** abundant, †2–3(–4) µm wide, wall 0.2–0.3 µm {1}. **SCBs** in paraphyses globose {2}. **Exudate** cloddy, ~0.5–3.5 µm thick, loosely attached. — **ANAMORPH**: dactylella-like (from ascospore isolate {2} and environmental isolate {1}. **Conidiophores** (50–)100–250(–300) µm long, erect, 3.5–4.5 µm wide at base, gradually tapered to (1–)1.5–2.5(–3) µm, apically with 1(–3) conidia on short sympodial branches (geniculate). **Conidia** fusiform, straight, *(40–)50–75(–85)((–93)) × (6.3–)8–10(–13) µm, ((2–))(4–)5–8(–9)-septate {3}, rarely clavate, *27–38 × 6.3–8 µm, 3-septate. **Chlamydospores** present in aged cultures, in chains or clusters, (sub)globose, ~6–8 µm wide {1}.

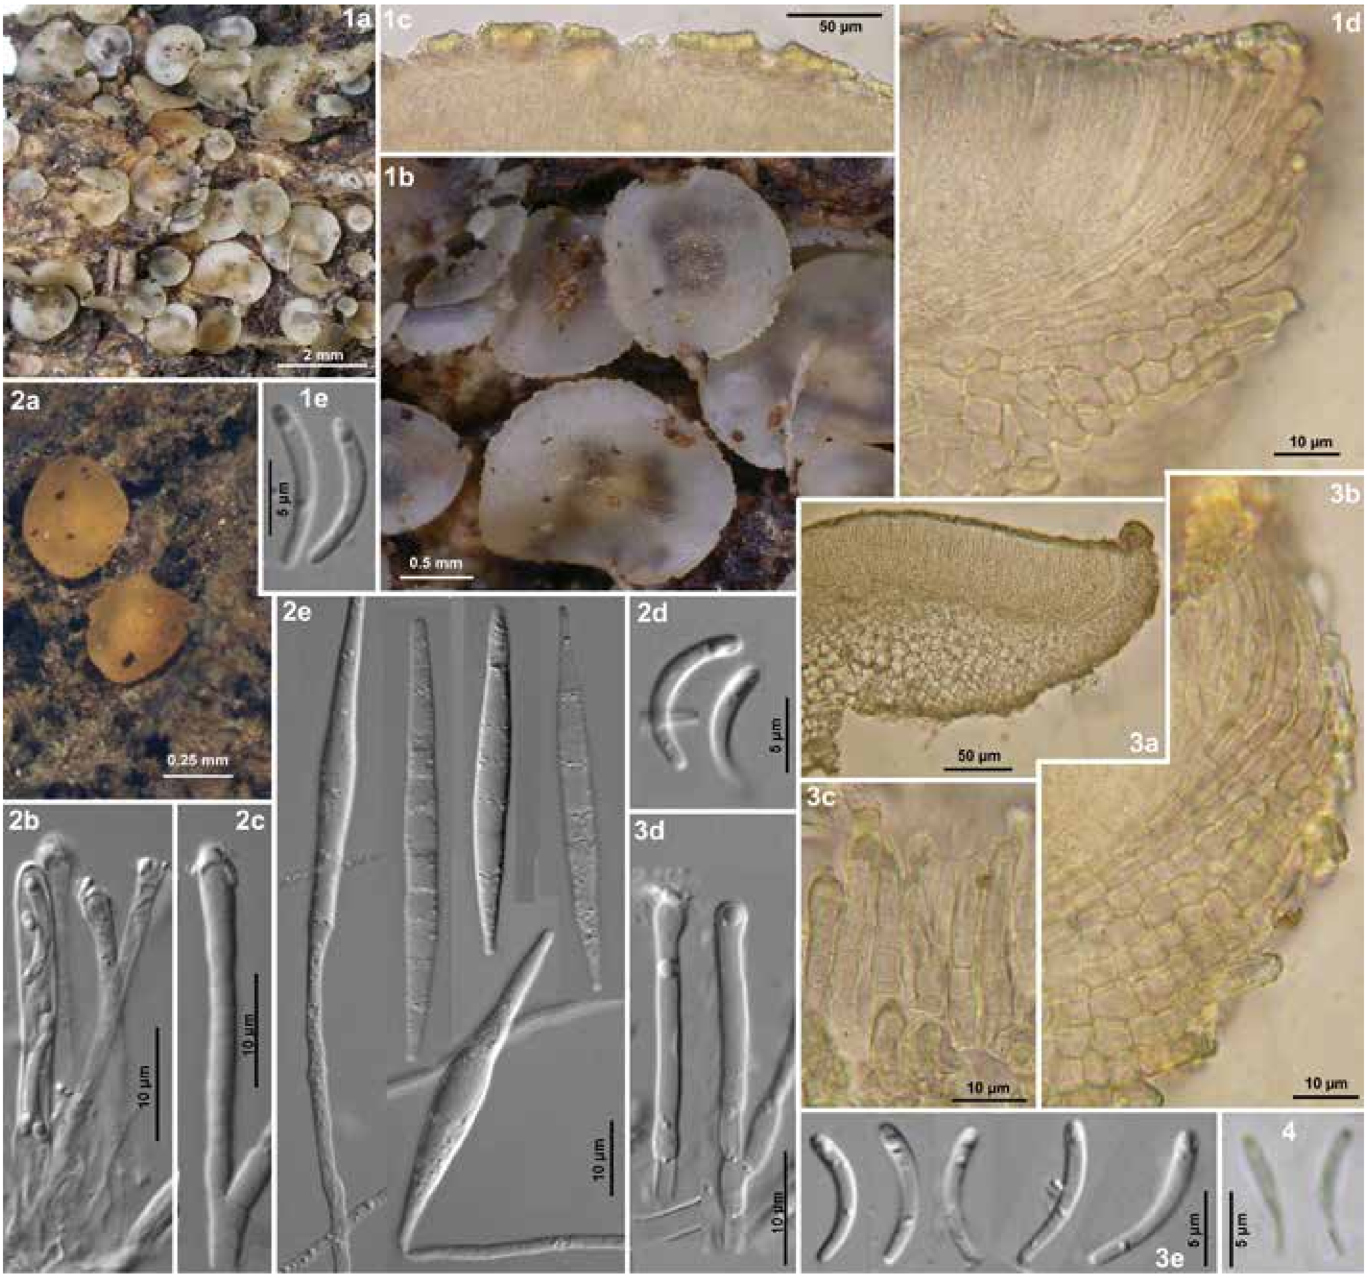

Plate 937. **1–4**. *D*. aff. *intermedia*/*dorsalis*. – **1a–b**. rehydrated apothecia; **2a**. fresh apothecia; **3a**. apothecium in median section; **1d**, **3b**. id., ectal excipulum at mid flanks and margin; **3c**. hair-like rows of marginal cortical cells, partly tipped by glassy processes; **1c**. crenulate margin in top view; **2b–c**, **3d**. ascus and paraphyses; **1e**, **2d**, **3e**, **4**. ascospores, **2e**. conidia and conidiophores (from culture). – Living state, except for **1c–d**, ascus and paraphyses in **2b**, **3a–c**, **4** (in H_2O), **2e** (p.p.). – **1e**, **2a–e**, **3d–e**: phot. Z.F. Yu (DIC). — **1a–e**. H.B. 8985 (H.Y.S. jz-9): China, Yunnan, Dali, on indet. angiosperm; **2a–e**. H.Y.S. jz-10: ibid.; **3a–d**. H.B. 8742 (J.W.G. ym3-62): Yunnan, Yuxi, on indet. angiosperm; **4**. H.B. 9536 (M.W. 990825T17): Taiwan, Taipei, on *Calamus*.

Habitat: lying at the moist ground, corticated or decorticated branches, 20–30 mm thick or more, of ?*Hevea brasiliensis* {1}, indet. angiosperms {3}, on very decayed wood {1} and bark {2}, partially blackened; leaf litter {anamorph}. **Desiccation tolerance**: Ectal excipular cells still alive after 4 months. **Altitude**: 550–2730 m (southern China). **Geology**: Jurassic to Cretaceous sedimentary rock. **Phenology**: VIII, XI (teleomorph).

Taxonomic remarks. The above description of *Orbilia dorsalis* and its anamorph *Dactylella dorsalis* is copied from that of the holotype from Xishuangbanna (Yu et al. 2007b) with some alterations, but includes also data from the teleomorph sample from Dali (H.B. 8782) and from the anamorph sample from La Gomera described by Chen et al. (2007b) as *Dactylella rhombospora*. *O. dorsalis* was proposed as a new species mainly because of its conidial dimensions which were thought to be much smaller than reported for the otherwise very similar *O. fimicoloides* (= *O. oxyspora*). Yet, conidial size in Yu et al. (2007b) was based on an erroneous calibration, and with the corrected values any clear biometrical differences to *O. oxyspora* disappeared. However, molecular data of *O. oxyspora* and *O. dorsalis* are sufficiently different in order to consider them as two distinct species (see below).

The teleomorph of *O. dorsalis* corresponds quite well to the protologue of *O. fimicoloides*, including marginal cell rows oriented at a low angle. Differences in spore width as indicated by Zhang et al. are eliminated when evaluating spore size from the plate in Webster et al. (1998), whereas the length of dead asci as stated for *O. dorsalis* is indeed below the values of dead asci as reported for *O. fimicoloides*, and below the values of all specimens assigned to *O. oxyspora* in the present study. However, the specimen from Dali here included in *O. dorsalis* has an ascus length typical of *O. oxyspora*, but no molecular data were available.

Nomenclature. The orignal specific epithet '*dorsalia*' is improper because the adjective *dorsalis* is unaltered in the masculine and feminine nominative singular case, whereas *dorsalia* would be the neuter plural in nominative and accusative case.

Not included collections. Two Chinese specimens are not included because one formed distinctly narrower conidia in culture (see below) and the other is without conidia but was from the same location. Two further Chinese specimens (H.B. 8742, Yuxi, Pl. 937: 3; H.B. 9536, Taiwan, 4) are uncertain because neither their anamorph nor molecular data were available. Another Chinese sample (*Orbilia* sp. XJ-2009, Guizhou, on unidentified bark, B. Liu, IVV: VII.2008) sharply differs from both *O. oxyspora* and *O. dorsalis* in marginal excipular cells oriented at a high angle and in differently shaped conidia (see also under Anamorph and Phylogeny).

Anamorph. *Dactylella dorsalis* was described with elongate fusiform conidia very similar to *O. oxyspora*, with (5–)6–8(–9) septa (mainly 7). In the protologue all conidia taken at high magnification (figs A–C, F–J) are wrongly calibrated, their 10 µm bars being 2.5 × too long, therefore, the values of 22–30.3(–32.5) × 3.3–4 µm given in the protologue are much too low. This becomes obvious when comparing figs D-E: according to the 50 µm bar the conidia here yield a size of 80–93 × 8–9 µm. After our request about this discrepancy, Z.F. Yu (pers. comm.) corrected the dimensions to 51.8–**66.5**–75.5 × 7.8–**10.3**–12.3 µm, which is about the 2.5-fold of the published values. When using the corrected data, *D. dorsalis* fits quite well the anamorph in the type of *O. fimicoloides*, particularly those conidia from natural substrate (45–63 × 9–10 µm, 7–10-septate), but also those observed in other specimens here referred to *O. oxyspora* (Pl. 933: 1f, 2d). Conidial length and number of septa in *O. oxyspora* partly exceed the values of *O. dorsalis*, but the data mainly overlap in the two taxa. A stronger tendency to fewer septa can be noted in the isolate from Dali (Pl. 936: 2), showing (2–)3–5(–8) septa, which is therefore thought to belong to *O. dorsalis*. On the photographs of the type of *D. dorsalis* the conidiophores are partly apically branched (Pl. 936: 1f–g), but this occurs also in *O. oxyspora*.

Based on Grove's (1885) insufficient description, the name *D. rhombospora* was applied with hesitation by different authors to isolates similar to *D. oxyspora*, for instance by Drechsler (1937a: 539), Liu (2006), and Liu et al. (2007a, see under *O. oxyspora*, p. 1495), but also to a strain from Germany (CBS 280.70) which was renamed to *D. oxyspora* by Rubner (1996). Chen et al. (2007b: 108) used the name *D. rhombospora* for the collection on leaf litter from La Gomera (CBS 102487), which was originally identified as *D. oxyspora*, but which the authors thought to be distinct from *D. oxyspora* because of shorter conidia (40–66 × 8.5–13 µm) with only (5–)7(–8) septa. very similar conidia occur in members of the *heptameres-qiluensis* clade (Phyl. 26).

In any case, the identity of *D. rhombospora* in its original sense remains doubtful. In Grove's (1885) protologue (on rotten wood and bark) the conidia are figured as 7-septate and with a pronounced rhomboid shape, and seem to have cells with an ocellate lumen enclosed by thick walls. Microscopical measurements were not given, but from the magnification indicated in the legend a size of 52 × 14.5–17 µm can be evaluated for the two conidia figured at 500 ×, but ~60–70 × 17–19 µm for the smaller, much less precise figure at 120 ×, with a conidiophore length of 95–190 µm. Rubner (1996) examined the holotype but could not detect elements of the fungus. We conclude that the large conidial width and the ocellate appearance of the cells exclude conspecificity with *O. oxyspora* or *O. dorsalis*, and the question is raised whether *D. rhombospora* was orbiliaceous at all.

Conidia similar to those of *O. dorsalis* (or *O. oxyspora*) though narrower were obtained in pure culture of a Chinese specimen from Dali (Pl. 937: 2): *37–89 × (3.6–)4–5(–8) µm, 4–5(–7)-septate. As in *O. dorsalis*, chlamydospores were formed in abundance. Due to the deviating conidial size the specimen is not included in either description. Another specimen from the same locality (Pl. 937: 1) is possibly conspecific but without data on its anamorph. Its sequence refers it in affinity with *D. intermedia* (see below). Conidia of a similar size were obtained in the sample from Guizhou (*Orbilia* sp. XJ-2009, *47–87(–101) × 4.3–6.6 µm), but with a fusoid-obclavate shape and 8–19 septa (B. Liu, IVV: VII.2008).

Phylogeny. Two sequences of Chinese *O. dorsalis* were available in GenBank. They derive from ascospore isolates of the holotype (YMF 1.01835) and a topotype (YMF 1.01838) which was not mentioned by Yu et al. (2007b). Both comprise the ITS region, the former also the 3'-end of SSU which lacks the S1506 intron. In the ITS region the two sequences differ by only 1 gap. *O. dorsalis* clustered in our analysis in a clade with *D. rhombospora* s. Chen et al. from La Gomera (CBS 102487), to which it differs by only 1 % (5 nt) and 2–3 gaps, suggesting conspecificity. Note, however, that in the CBS database an unofficial sequence of CBS 102487 exists which differs from the GenBank sequence of that strain by 3.5 % but also does not come closer to other sequences treated here.

The three sequences here referred to *O. dorsalis* clustered in the strongly supported *oxyspora-clavispora* subclade (Phyl. 26). They deviate from *O. oxyspora* by 4.3–6.2 % and from *O. clavispora* by 4.3–5 %. Also in the analysis of Chen et al. (2007a) a rather high distance between *D. oxyspora* and *D. rhombospora* is obvious, and two Chinese strains under the name *D. heptameres* (topotypes of *D. beijingensis*) likewise clustered in a clade distant from these taxa.

There are 4 diagnostic motifs in the ITS1 and ITS2 that are worth mentioning (Tab. 79): *O. clavispora* more or less concurs with *O. oxyspora* at 3 of these motifs, but it concurs with *O. dorsalis* at the remaining motif (pos. 79–90 of ITS1).

A sequence (S1506 intron, ITS, LSU) from apothecia of one of the not included samples (Yunnan, Dali, Jizushan, jz-9, H.B. 8985) clustered strongly supported with *D. intermedia*, though with a 4.7 % ITS distance. When assuming that it is conspecific with jz-10 from the same locality, which developed much narrower conidia (Pl. 937: 2e) than described for *D. intermedia* (Pl. 6: h), it cannot be conspecific with *D. intermedia*. A sequence from an unidentified *Dactylella* in pure culture (02SH140612-829-B, Y. Zhang pers. comm.) fully concurs with jz-9 in the S1506 intron and ITS, except for 2 gaps in the ITS (Phyl. 26). Its chromatogram (ab1) bears the number YMF 1.00585 and the name *Drechslerella inquisitor*, but this must be a confusion because YMF 1.00585, a soil isolate from Lushui, Yunnan, formed top-shaped conidia and constricting rings (Yu et al. 2014).

Orbilia sp. XJ-2009 from Guizhou (ITS+LSU) clustered in our combined analysis unsupported near *D. cylindrospora* outside the *oxyspora-heptameres* clade, with an ITS distance of 19–23 % to species of that clade (Phyls 25–27,). In the LSU analysis (S31) it clustered unsupported near the *cardui-rhopalota* clade and the *rhamni-fraxini* clade.

Ecology. *Orbilia dorsalis* is known from two collection sites in southern China, where it grew on rotten bark and wood of hygric branches of angiosperms in subtropical to tropical humid (winter-dry) evergreen forests. The holotype was at much lower altitude than the sample from Dali. The four not included collections were from a similar climate. The isolate from Macaronesia indicates a wider geographical range of the species.

Specimens included. **CHINA**: **Yunnan**, **Xishuangbanna**, Menglun, 47 km ESE of Jinghong, 1 km S of Menglun, Tropical Botanical Garden (Lushilin), 550 m, on bark of ?*Hevea brasiliensis*, 5.VIII.2005, Y. Zhang (Y.Z. bn1-7, YMFT 1.01835, **holotype** of *O. dorsalis*; YMFD 1.01835 permanent slide of culture, **holotype** of *D. dorsalis*, YMF 1.01835 culture, anam. cult.; sq.: DQ480730, doc. vid.). – ibid., date and substrate not stated (YMF 1.01838; sq.: FJ557238, non vid.). – **Dali**, Yongping, 35 km ENE of Baoshan, virgin forest around Golden Light temple (Jinguangsi), 2730 m, branch of indet. angiosperm, on wood, 18.XI.2007, H.Y. ***Orbilia* sp**. **XJ-2009**: **CHINA**: **Guizhou**, **Zunyi**, Suiyang, ~62 km NNE of Zunyi, ~38 km ENE of Tongzi, Kuankuoshui, 1420 m, bark of indet. tree, VII.2008, X.Z. Jiang (XJ-2009, CGMCC 3.12026; sq.: FJ790421, HQ110697).

Orbilia clavispora (J. Chen, L.L. Xu, B. Liu & Xing Z. Liu) Baral, E. Weber, P. Perz & G. Marson, **comb**. **nov**., MB 813983 — Pls 938–942, Map 151

Basionym: *Dactylella clavispora* J. Chen, L.L. Xu, B. Liu & Xing Z. Liu, Fungal Diversity 26(1): 93 (2007)

?= *Orbilia vestimenti* Velen., Monogr. Discom. Bohem.: 93, pl. 11 fig. 23 (1934)

Etymology: *clavispora*: referring to the clavate conidia; *vestimenti*: named after the substrate of the type, rotten textile.

Typification: Great Britain, Cumbria, Meathop Wood, leaf of *Betula*, VIII.1970, J.C. Frankland (HMAS 140510, holotype of ***Dactylella clavispora***, ex-type culture: CBS 844.70; sq.: DQ494355). — Czechia, Jevany, on textile, 10.X.1925, J. Velenovský (PRM 151613, lectotype of ***Orbilia vestimenti***, designated here, MBT382141).

Misapplied name: Rubner (1996: 50, CBS 917.85), as *Monacrosporium asthenopagum*.

Description: — **TELEOMORPH**: **Apothecia** fresh 0.5–1.2(–1.4) mm diam., (0.14–)0.2–0.3(–0.38) mm high (receptacle 0.11–0.2 → 0.08–0.12 mm), pale rose-cream to light yellowish-amber-brownish, medium translucent, round, densely gregarious; disc flat (to slightly convex), margin thin, 0–10 µm protruding, almost smooth to finely crenulate; sessile on a narrow or broad base or with an abrupt stipe 0.11–0.23 × 0.18–0.6 mm, superficial; dry light ochre to bright red-brown. **Asci** *35–50 × (3.7–)4–4.5(–4.8) µm {3}, †32–36 × 3.5–4 µm {1}, 8-spored, spores *4-seriate, ~4 lower spores inverted {2} (not mixed), pars sporifera *15–17 µm long; **apex** (†) strongly truncate (not indented, laterally not inflated); **base** with very short to medium long,

thin or thick, slightly flexuous stalk, L- to h- or H-shaped. **Ascospores** *(7.5–)8–11(–12) × (1.1–)1.2–1.4(–1.6) µm {3} (~9–14 µm actual length), †8.5–11 × 1.1–1.2 µm {2}, fusoid-subulate, apex obtuse (to subacute), base always strongly attenuated (often as distinct tail ~⅓ of spore length), (medium to) strongly (to very strongly) curved (falcate) when viable, slightly to medium curved in dead state; **SBs** globose, 0.4–0.7 µm diam. {2}, 0.5–1 µm away from apex, total length 1–1.5 µm, attachment invisible. **Paraphyses** apically (uninflated to) slightly to medium (to strongly) capitate-clavate, terminal cell *15–23 × 2.3–3.7 µm {2}, lower cells *(3–)4–8(–10) × 1.7–2.5 µm {2}; unbranched at upper septum. **Medullary excipulum** 10–100 µm thick, of medium-sized t. globulosa-angularis, rather sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled, indistinctly oriented textura globulosa-angularis(-intricata) at base and lower flanks, 50–110(–320) µm thick near base, cells *12–25(–30) × 10–23 µm {2}; 15–30 µm thick at mid flanks and margin, of t. globulosa-angularis, usually forming distinct moniliform cell rows oriented at a 10–40° angle to the surface, marginal cortical cells *4.5–11 × 2.7–4.5(–5.5) µm {3}, cylindrical to ± lageniform; **glassy processes** absent {1} or 1–4 {1} or 10–17 {1} × 3–4(–4.5) µm {2}, ± straight, low-refractive, slightly stratified, cell rows and processes forming indistinct minute teeth. **Anchoring hyphae** medium to very abundant, *2–3(–4) µm wide, walls 0.2(–0.3) µm thick {2}, with or without light honey-yellow gel, forming strands, sometimes with a 20–70 µm thick t. prismatica-globulosa near base. **SCBs** in paraphyses globose to ellipsoid, medium refractive, 0.8–1.5 µm diam., also in entire ectal excipulum, 1.5–3.3 µm diam.; **VBs** absent or low-refractive. **Exudate** over paraphyses 0.3–0.6(–1.8) µm thick, granular to continuous to cloddy, loosely to firmly attached; over margin and flanks 0.3–3 µm thick, continuous, rough, pale chlorinaceous-yellowish. — **ANAMORPH**: dactylella-like (from natural substrate {3}, from leaf isolate [type of *D. clavispora*, values in square brackets, after Chen et al. 2007b], connection proved by DNA): **Conidiophores** septate, unbranched (rarely 1 × branched above), *43–110 µm long [60–148 µm], (3.5–)4–5(–5.5) µm wide at base [2.5–5.5 µm], 2.2–2.6 µm at tip [1.5–2.5 µm], forming 1(–2) conidia. **Conidia** *(22–)26–35(–39.5) × (6.5–)7–8.5(–9.5) µm [*18–32.5 × 7.5–11 µm], cylindric-ellipsoid(-clavate), straight, sometimes slightly curved, (1–)3–4(–5)-septate {4} [(1–)3-septate].

Habitat: collected 0.5 m above the ground, corticated, ?5–20 cm thick cut branches or stumps of *Betula* sp. {2}, *Tilia cordata* {1}, on min. 2–3 mm deep medium to strongly decayed splitted wood {3}, also on inner surface of detaching bark {1}, blackened, with many green algae. **Associated**: *Cosmospora vilior* {1}, *Cryptodiscus foveolaris* {1}, *Hyalorbilia juliae* {1}, *Hysterium angustatum* {1}, *Orbilia eucalypti* {1}, *O. orientalis* {1}. **Desiccation tolerance**: many lower cells of paraphyses and some immature asci still alive when dry since 1 day, after 3 weeks many excipular cells and after 11 months some ascospores still viable. **Altitude**: 10–445 m a.s.l. **Geology**: Lower Carboniferous lime- & sandstone, Upper Cretaceous calcareous clay- & marlstone, Quaternary sand; mica schist & gneiss. **Phenology**: VIII, X–XI (teleomorph).

Taxonomic remarks. *Orbilia clavispora* resembles *O. oxyspora*, *O. dorsalis*, and *O. desertorum* in having more or less distinct marginal cell rows oriented at a ± low angle to the surface, strongly falcate ascospores (in the living state) which contain globose SBs, and a dactylella-like anamorph. It differs in spores with comparatively wide upper parts and strongly attenuated bases with partly distinct tails, apparently also in a brownish colour of the fresh apothecia. With *O. desertorum* it shares ellipsoid-oblong conidia, in contrast to *O. oxyspora* and *O. dorsalis* which have fusiform conidia. *O. auricolor* has similar falcate ascospores though without distinct tails, and further differs in the absence of marginal cell rows and an arthrobotrys-like anamorph with 1-septate conidia. *O. mammillata* differs from *O. clavispora* in less curved ascospores without distinct tails, rod-shaped SBs, wider and more short-stalked asci, and a dactylellina-like anamorph with broadly fusiform conidia. *O. cardui* resembles *O. clavispora* in the glassy processes but differs in ± straight spores without tails when compared in the living state. A montane specimen on *Carex* mentioned under *O. epilobii* (Pl. 912: 3) has spores similar to *O. clavispora*, but wider and less curved, and the marginal ectal excipulum is almost vertically oriented. *O.* aff. *clavispora* (Pl. 943) resembles *O. clavispora* in its marginal excipulum and conidia but its ascospores are similar as in *O. cardui*.

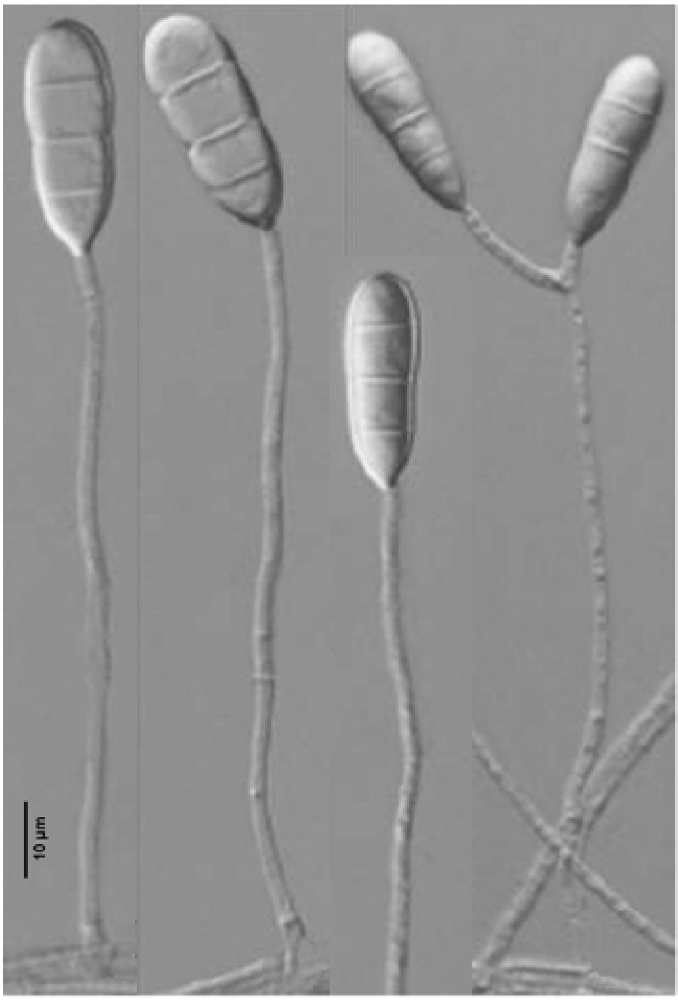

Plate 940. *Orbilia clavispora*. – Conidiophores and conidia, from pure culture (CBS 844.70, type of *Dactylella clavispora*, from Chen et al. 2006b).

Variation. Two collections from Poland were made on the very same stump of *Betula* but differ somewhat from each other: H.B. 8606 has slightly shorter spores and a thicker medullary excipulum than H.B. 8371a but, in contrast, a thinner basal ectal excipulum. Glassy caps or processes on the marginal cortical cells were absent in H.B. 8606, but were partly present in H.B. 8371a below the exudate at the uppermost margin (Pl. 938: 1e). In a third Polish record (on *Tilia*, Pl. 939: 3) the spores were at the lower end of the range (*8–9.5 × 1.1–1.2 µm) and the glassy processes 10–17 µm long.

Type studies. Velenovský (1934) described *O. vestimenti* based on two collections on moist ground (on textile and on stems of *Urtica*). No material on *Urtica* could be found at PRM, therefore, Svrček (1954) incorrectly referred to the other specimen as 'holotype'. In order to unequivocally fix the name to a specimen, the collection on textile (PRM 151613) is designated here as **lectotype** of *O. vestimenti*.

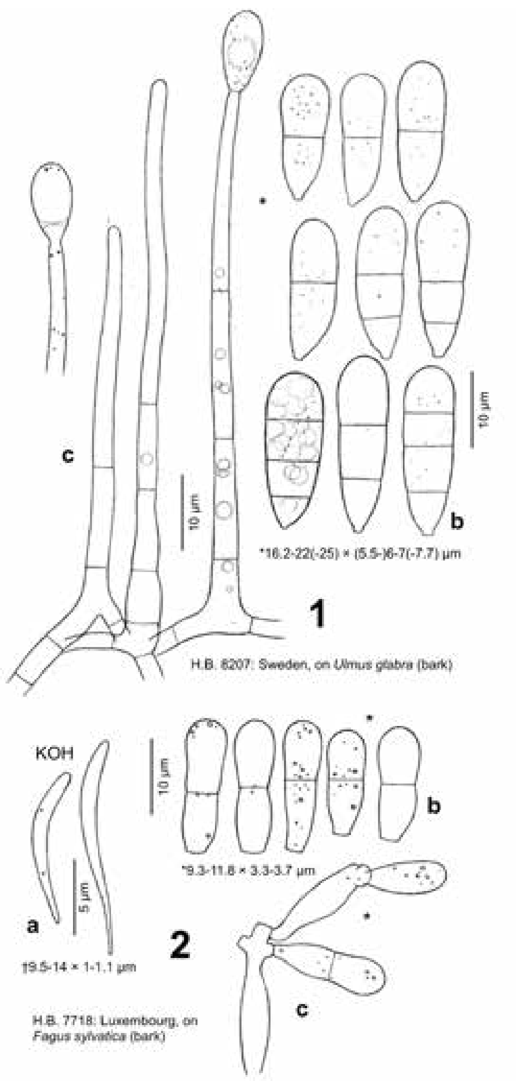

Plate 941. **1–2**: *Orbilia* cf. *clavispora*. – **a**. ascospores; **b**. conidia; **c**. conidiophores (**b–c** from substrate).

The apothecia of *O. vestimenti* were originally described as white and convex. They are now (rehydrated) cream-brownish, 0.3–1 mm diam., with a distinctly crenulate margin. Velenovský (1934 and manuscript plate) gave the spores as 10–15 × 0.7–1.2 µm (width estimated from drawing), and Svrček reported even narrower spores (10–12 × 0.5 µm). Though described as ‘straight to nearly straight’ by Svrček, the probably dead spores in Velenovský’s drawing show a partly distinct though slight curvature, and gradually taper towards an acute base.

Our reexamination revealed wider, straight or often slightly curved spores with an often distinct narrow tail. In the two Polish collections on *Betula*, the strongly curved living spores lose much of their curvature when losing turgor, in water (Pl. 938: 2a) as well as KOH (Pl. 939: 1j). Therefore, we may assume that the spores in the lectotype of *O. vestimenti* were also distinctly more curved in the living state. Velenovský described the asci with a very long and narrow stipe, but Svrček wrote ‘without elongate stipe’. In the present study only a few asci were found, and these had a thin and long stipe, the basis of which could not be discerned due to senescence of the material. The paraphysis apices were found to be narrower (†2–3.5 µm) than indicated by Velenovský (4–5 µm, probably in living state). Glassy processes have a length of 10–18 µm and are agglutinated as small teeth to form a distinctly crenulate margin. The ectal excipulum forms a textura globulosa up to the margin, and marginal cell rows oriented at a low angle were not observed. Yet, cell rows were also partly indistinct in the Polish sample on *Tilia*. The spores are ± straight or only slightly curved, i. e., less curved than in the Polish samples when compared in the dead state (Pl.938: 2a$_2$, 3a).

Svrček accepted *O. vestimenti* as distinct from *O. cardui* and *O. luteorubella* due to longer spores, coherent asci, and a deviating substrate, from the latter also because of encrusted paraphyses and hyaline apothecia. Conglutinate hymenial elements are confirmed in the present study of the lectotype, but certainly originate from senescence of the material. Although the features of *O. vestimenti* closely resemble those of *O. cardui*, including the glassy processes, we believe with Svrček that the spores are too different to consider the two taxa as conspecific. Because of the apparent absence of marginal cell rows, *O. vestimenti* might instead belong in the relationship of *O. rectispora* or *O. leporina*. Because of this uncertainty we refrained from including *O. vestimenti* in the description.

Not included collections. A sample from Serbia on *Betula* bark without conidia (IVV: 20.IX.2019) differs in a marginal excipulum of vertically oriented rows of roundish cells or, in another section, under a 45° angle, also in slightly shorter and wider (*7–9 × 1.3–1.6 µm), less curved spores. From *O. xinjiangensis* it differs in narrower, more curved spores.

Two collections on more xeric substrate (Sweden, bark of *Ulmus*; Luxembourg, bark of *Fagus*; Pls 941–942) are also not included in the description, especially because of smaller conidia. The abundant apothecia in the Swedish collection looked mature but spores could hardly be found inside the asci. A comparable collection with the very same ecology was made in Germany (Rhön, H.B. 7441, unillustrated, no conidia observed).

Anamorph. The conidia in the three specimens from Poland resemble in size and shape *Dactylella clavispora*, *D. cylindrospora*, *D. tenuis*, and *D. zhongdianensis*. The type of *D. clavispora* (from Great Britain) differs only insignificantly in having slightly shorter and wider conidia with max. 3 septa. Also *D. tenuis*, originally described from North America, concurs quite well with the Polish samples and might offer an earlier name for *O. clavispora*. *D. zhongdianensis* (from China) and *D. cylindrospora* (from Polynesia) have conidiophores with up to 3–5 branches, either in their middle part, or more apically (candelabrelloid), but apical branches were rarely also observed in the type of *D. clavispora*. *D. cylindrospora* is the only species that was compared with *D. clavispora* by Chen et al. (2007b). Compared to *O. cardui* or *O. rectispora*, *O. clavispora* possesses somewhat wider and shorter conidia but the other features of their anamorph are similar. No conidia have been found in the type of *O. vestimenti*.

The type of *D. clavispora* deviates from the anamorph observed in the Polish samples by slightly longer conidiophores and by shorter and wider conidia which were only 3-septate as a maximum. The conidia in the two not included, more xeric collections are distinctly smaller than in the specimens from Poland: in the Swedish sample (Pls 941: 1; 942: 1) the anamorph grew abundantly over the apothecia and the bark around. The medium-sized cylindric-clavate conidia were 1–2(–3)-septate; in the collection from Luxembourg (Pls 941: 2; 942: 2) some 1-septate small conidia were formed in small clusters at the tip of very short conidiophores which arose from the anchoring hyphae.

Phylogeny. A sequence which includes the S1506 intron, ITS, and LSU was gained from apothecia of one of the Polish collections. An ITS sequence that does not cover the intron region was obtained by Chen et al. (2007b) from the ex-type culture of *D. clavispora* from Great Britain, and an ITS sequence with S1506 intron was gained by Liou & Tzean from a strain under the name *D. asthenopaga* or *M. asthenopagum* from the Netherlands (CBS 917.85, Rubner 1996). That strain matches perfectly the type of *D. clavispora* in the ITS region except for a gap in the ITS1, and is thus obviously conspecific.

The Polish sample of *O. clavispora* differs from the two sequences with identical ITS by 1 nt in ITS1 and 1 nt in ITS2. Also in the available LSU it differs from CBS 917.85 by 2 nt in the D2 domain. We conclude that all three strains are conspecific. To *O. oxyspora* the ITS distance is 2.2–3.6% (1.6% in LSU) and to *O. dorsalis* 4.3–5%. In the S1506 intron the two available sequences of *O. clavispora* show a distance of 0.5% (2 nt and 1 gap), whereas *O. oxyspora* deviates here by 10.5–12% and *O.* aff. *clavispora* (Y.Z. bn1-14) by 19.5–20%. Other strains identified as *M. asthenopagum* belong to very different species (see p. 1607).

Map 151. Known distribution of *O. clavispora* in Europe (yellow = not included collections).

In our analyses of SSU+ITS+LSU, ITS, or LSU (Phyls 25–27, S31)*,* *O. clavispora* clustered with *O. oxyspora* and *O. dorsalis* in the strongly supported *oxyspora-clavispora* subclade. This is astonishing since its conidial morphology sharply differs from the fusiform conidia of these two species. *D. zhongdianensis* and *D. cylindrospora*, taxa with cylindric(-clavate) conidia, show a high molecular distance to *O. clavispora*, in accordance with shorter and straight ascospores in *D. zhongdianensis*. No

Plate 942. **1–2**: *Orbilia* cf. *clavispora*. – **1a**. *Fraxino-Aceretum pseudoplatani*, standing, probably dead *Ulmus* trunk with a large vertical slit in the partially detaching bark; **2a**. felled *Fagus* trunk with wounds with detaching bark; **1b–f**, **2b**. inner surface of detaching bark; **1c**, **e–f**, **2b**. rehydrated apothecia; **1d**. dry apothecia; **1g**, **2c**. marginal ectal excipulum in median section; **2d**. ascospores; **1i**. conidiophore with young conidium, **1j**. conidia (both from substrate). – Living state, except for **2c** (in KOH) and **2d** (left spore). — **1a–j**. sequence of the type of *D. tenuis* was available, since a Chinese strain under that name (DQ494360, from Xinjiang) obtained by Chen et al. (2007b) clustered in phylogenetic analyses in *Drechslerella* near *O. brochopaga*, although trapping organs were not observed.

Ecology. *O. clavispora* is so far only known from atlantic to subcontinental, cold-temperate humid Europe. The type was isolated from a living *Betula* leaf in a forest on a coastal limestone hill in atlantic northern England, and the strain under the name *M. asthenopagum* from decaying wood in subatlantic Netherlands. Apothecia have been collected on rotten, mesic wood and bark of a *Betula* stump and on hygric wood of a *Tilia* branch in subcontinental southern Poland. The lectotype of *O. vestimenti* grew on a hygric rotten textile in a moist place in Czechia. Further not included collections of apothecia were from temperate subcontinental Europe on xeric bark of standing trunks of *Fagus* in Luxembourg and of *Ulmus* in central Germany and southern Sweden, those on *Ulmus* being from nutrient-rich ravine forests (*Fraxino-Aceretum pseudoplatani*).

Specimens included. **GREAT BRITAIN**: **North West England**, **Cumbria**, ~2 km NE of Grange-over-Sands, Meathop Wood, ~50 m, isolated from living leaf of *Betula*, VIII.1970, J.C. Frankland (HMAS 140510, **holotype** of *D. clavispora*, CBS 844.70, conid. isol., doc. vid., sq.: DQ494355). — **NETHERLANDS**: **Noord-Holland**, 10 km SW of Haarlem, W of Vogelenzang, Waterleidingduinen, 10 m, isolated from decaying wood, IX.1985, W. Gams (CBS 917.85, G.S. de Hoog as *D. asthenopaga*, conid. isol., non vid.; sq.: U51962). — **POLAND**: **Lower Silesia**, 9 km S of Kłodzko, 2 km S of Żelazno, Bielica Mt., 420 m, stump of *Betula*, on wood & bark, 17.XI.2006, P. Perz (P.P. 20061117-1, H.B. 8371a, anam. substr.; sq.: KT222381). – ibid., stump of *Betula*, on wood, 18.VIII.2007, P. Savić (doc. vid.).

Orbilia aff. *clavispora* — Pl. 943

Description by Z.F. Yu (pers. comm., modified): — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1 mm diam., 0.11 mm thick (receptacle 0.09 → 0.07 mm), light yellow-amber, translucent, ± round, scattered to gregarious; disc flat to slightly convex, margin thin, smooth, not protruding; sessile, superficial. **Asci** †22.5–36.5 × 3–3.8 µm, 8-spored, spores *2–3-seriate, lower spores inverted (± mixed); **apex** (†) strongly truncate (not indented, laterally not widened); **base** with short, flexuous stalk, h-shaped. **Ascospores** *6.5–7.3(–8) × (1.3–)1.4–1.5 µm, subcylindrical to very slightly fusoid, apex rounded, base slightly (to medium) attenuated, slightly inequilateral to slightly, rarely medium curved; **SBs** globose, 0.8–1 µm diam., total length 1.5–1.7 µm but filum and attachment invisible. **Paraphyses** apically uninflated to slightly capitate-clavate, terminal cell †14–17 × 1.7–2 µm, lower cells †~5–7 × 1.2–1.7 µm. **Medullary excipulum** 15 µm thick. **Ectal excipulum** of thin-walled to slightly gelatinized textura angularis at base and flanks, 70 µm thick near base, cells †9–14 µm diam.; 30 µm thick near margin, of t. prismatica oriented at a 20–40° angle, marginal cortical cells †~5–8 × 2–3.5 µm; **glassy processes** absent. **Anchoring hyphae** not studied. **SCBs** and **VBs** no data available. **Exudate** over paraphyses 0.3–1 µm thick, cloddy, firmly attached. **— ANAMORPH**: dactylella-like (from ascospore isolate {1}). **Conidiophores** 50–210 µm high, 3.5–4 µm wide at base, gradually tapering upward to a width of 2.5–3µm at apex, initially with a single apical conidium, later often producing a few short branches near the apex, with 2–3(–5) conidia in sympodial arrangement. **Conidia** *(20–)24–43(–47.5) × (6.5–)7.5–8.5(–9.3) µm, (cylindric-)ellipsoid-clavate, obtuse at the distal end, slightly tapered at the ± truncate base, straight, rarely curved, with (3–)4–5(–7) septa. **Trapping organs** not produced when nematodes were added.

Habitat: on rotten bark of indet. tree. **Associated**: unknown. **Desiccation tolerance**: possibly intolerant. **Altitude**: 600 m a.s.l. **Phenology**: VIII.

Taxonomic remarks. *Orbilia* aff. *clavispora* resembles *O. cardui* in the morphology of ascospores and conidia, from which it differs in the apothecial margin composed of a textura porrecta

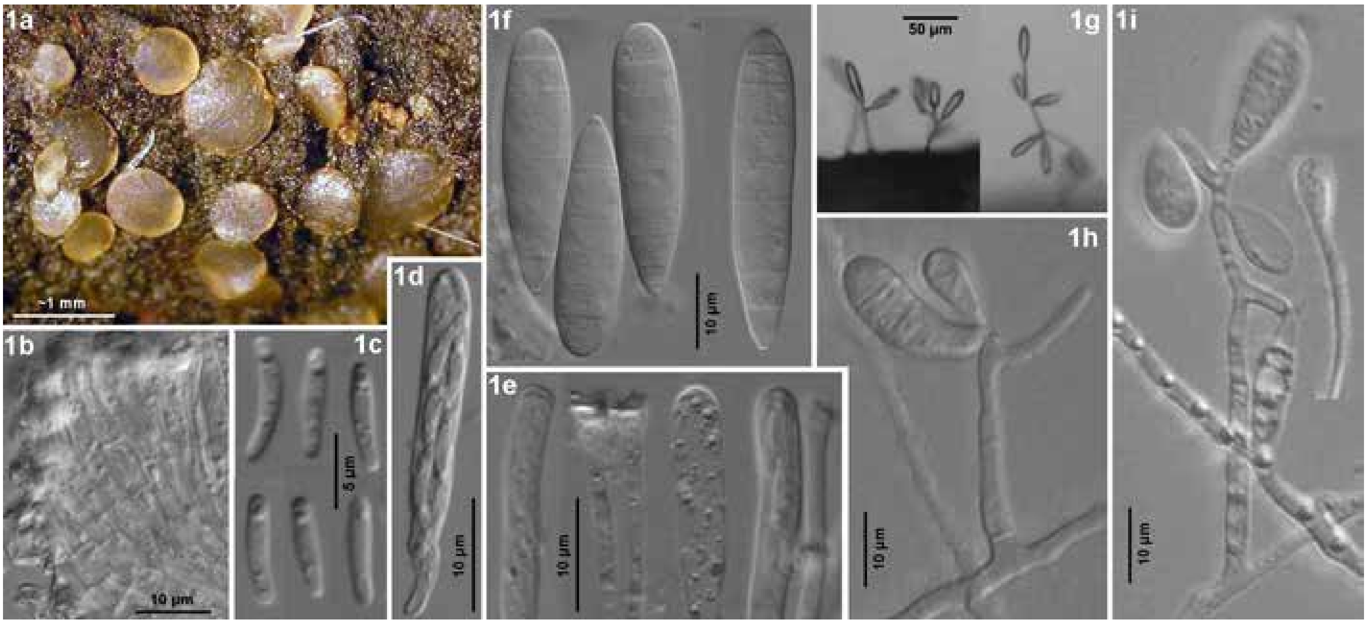

Plate 943. **1**: *Orbilia* aff. *clavispora*. – **1a**. fresh apothecia; **1b**. marginal ectal excipulum in median section; **1d–e**. asci and paraphyses; **1c**. ascospores; **1f**. conidia; **1g–i**. conidiophores with conidia. – Living state, except for **1b** (in H_2O), **1d** (ascus), **1f** (left asci and paraphyses). – phot. Z.F. Yu. — **1a–i**. Y.Z. bn1-14: China, Yunnan, on indet. tree.

oriented at a rather low angle to the surface. With this character the species resembles *O. clavispora*, which differs in always ± strongly curved and basally strongly attenuated ascospores, also in conidia with fewer septa and usually unbranched conidiophores.

Phylogeny. A sequence gained by Z.F. Yu (pers. comm.) from the ascospore isolate comprises ITS and the S1506 intron. In our analysis of the ITS region (Phyl. 26) it clustered in the medium supported *heptameres*-*qiluensis* subclade, though with a minimum distance of 6.5–7.5% to '*Dactylellina*' *varietas*, *Dactylella qiluensis*, and *D. heptameres*. When analysing the intron, it clustered in an unsupported clade with '*D.*' *varietas* (S30), with a distance of 12–14.5%.

Ecology. *Orbilia* aff. *clavispora* was collected on rotten bark, which was probably lying on the moist ground, in a tropical humid (winter-dry) rainforest in southern China.

Specimens included. **CHINA**: **Yunnan**, **Xishuangbanna**, 50 km ESE of Jinghong, 2 km SE of Menglun, Green Stone, 600 m, bark of indet. tree, 3.VIII.2005, M. Qiao & Y. Zhang (Y.Z. bn1-14, YNOA 0002, YMFT, permanent slide culture YNDA 0002, anam. cult., doc. vid.; sq.: ined.).

Orbilia desertorum Baral & Priou, **sp. nov.**, MB 813984 — Pls 944–945, Map 152

Etymology: named after the growth on xeric substrate in ± semiarid areas.

Typification: Spain, Torrevieja, leaves of *Agave americana*, 31.XII.2007, O. & J.P. Priou (ex H.B. 8737, M-0276474, holotype; sq.: KT222434).

Latin diagnosis: *Apothecia rehydratata 0.25–1.8 mm diam., dilute cremeo-(aurantio-)ochracea, sessilia, margine laevi vel minute crenulato. Ascosporae *6–11.5 × 1.1–1.6 µm, subulatae, apice rotundatae, basi attenuatae, interdum subcaudatae, modice ad valde arcuatae, corpusculum refringens (sub) globosum, ad apicem filo breve affixum continentes. Paraphyses ad apicem non vel leniter capitatae, exsudato valido luteolo tectae, cellulae vivae absque vacuolis refringentibus. Cellulae excipuli marginalis plerumque hyphas subcrassitunicatas sub angulo obliquo orientatas formantes et processis vitreis brevibus vel longis praeditae. Habitat ad folia putrida sicca* Agaves*, caules inflorescentiae* Yuccae*, ramos* Ferocacti*, plerumque in zona thermomediterranea semiarida Americae centralis, Macaronesiae et Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.4–1.3(–1.8) mm diam., 0.1–0.25 mm high, pale to light carneous or cream-ochraceous(-orange) to yellow-ochre, turning light to bright reddish-brownish with age, hardly to rather strongly translucent, round, slightly lobate if large, sub- to ± densely gregarious; disc slightly concave, soon flat, margin indistinct or distinct, thin, 0–10 µm protruding, smooth to

finely rough or crenulate, rarely with prominent whitish teeth; (broadly) sessile, superficial; dry dirty ochraceous, with inrolled margin. **Asci** *39–43 {2} or 45–57 {1} × 3.8–4.3 µm {3}, †31–45 × (3–)3.2–3.8(–4.2) µm {5}, 8-spored, spores 3–4-seriate, (2–)3–**5**(–6) lower spores inverted {5} (not mixed), pars sporifera *(20–)23–28(–32) → 17–20 µm long; **apex** (†) medium to strongly truncate (not or slightly indented, laterally sometimes inflated); **base** with short to medium long, thick, ± flexuous stalk, Y- to h- or H-shaped. **Ascospores** *(6–)7–10.5(–11.5) × (1.1–)1.2–1.5(–1.7) µm {8} [~(7–)9–12 µm actual length], †7–10.5 × 1.2–1.4 µm {2}, (sub)cylindric-clavate (subulate), apex rounded, base slightly to strongly attenuated, sometimes with indistinct tail-like base, medium to strongly curved (falcate, in KOH slightly to medium curved); **SBs** *(1.2–)1.3–1.6(–1.8) × (0.3–)0.5–0.9 µm {6}, divided into a (sub)globose or rarely tear-shaped lower part and a short, ± indistinctly visible filum, sometimes slightly eccentrical. **Paraphyses** apically uninflated to slightly (to medium) capitate(-clavate), terminal cell *(10–)17–27(–33) × 1.8–2.5 µm {2}, †13–16 × 2.5–3 µm {1}, lower cells *(2.5–)5–11(–15) × 1.4–2.1(–2.3) µm {4}; unbranched at upper septum. **Medullary excipulum** 20–40 µm thick, of ± dense textura globulosa(-prismatica), cells ± horizontally elongated, very indistinctly to sharply delimited from ectal excipulum. **Ectal excipulum** of (†) thin-walled, vertically or indistinctly oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 50–150 µm thick near base, cells *10–22(–28) × (6–)10–20(–25) µm {4}; 20–40 µm thick near margin, inner region of t. prismatica oriented at a 50–80° angle to the surface, outermost region of t. prismatica-porrecta at a 10–60° angle, cells of outer region usually forming ± distinct, free or agglutinated cell rows with yellowish, 0.2–0.3 or 0.3–0.8 µm thick lateral walls, terminal cells *(4–)6–10(–18) × (2.5–)3–5(–5.5) µm {4}; **glassy processes** absent {3} or present {5}, 1–6 {5}, 3–10 {1}, 5–20 {1}, or 50–70 {1} × (2–)3–4(–6) µm {4}, stratified, if long then curved outwards and coherent to form distinct teeth at margin and flanks. **Anchoring hyphae** ± abundant, */†2–3.5 µm wide, walls 0.2–0.5(–1) µm thick {3}, 4–5 µm wide near insertion, hyaline or pale yellowish, forming a dense t. intricata up to 50 µm thick. **SCBs** globose {5}, in paraphyses 1–2 µm diam., in ectal excipulum (at base and flanks, partly also up to margin) (1–)1.5–3(–4) µm diam.; **VBs** absent {4}, rarely present, multiguttulate {1}. **Exudate** pale to bright honey-yellow, over paraphyses cloddy, 1–3(–4.5) µm thick, loosely but also firmly attached; over margin and flanks continuous to rough-cloddy or granular, 1–5 µm thick. — **ANAMORPH**: dactylella-like (presumed, from natural substrate {3}). **Conidiophores** not seen. **Conidia** cylindric-ellipsoid, *23.5–26 × 4.5–5.3 µm, 3-sepatate {2}, or cylindric-clavate, *39 × 10.5 µm, 6-septate {1} (in each collection only 1 conidium seen).

Habitat: ± lying on sandy ground, xeric leaves, branches (2–4 cm thick) or inflorescence stems of *Aeonium pseudourbicum* {1}, *Agave americana* {4}, *A. shawii* {3}, *Ferocactus* sp. {1}, *Yucca* sp. {1}, on epidermis or epidermis-free regions, slightly to medium decayed, slightly to strongly blackened, without algae. **Associated**: *Badhamia affinis* {1}, *Didymium* sp. {1}, *Hyaloscyphaceae* sp. {1}, *Perichaena depressa* {1}. **Desiccation tolerance**: Mexican collections: fully viable for up to 5 months, ascospores, cells of ectal excipulum and some paraphyses still viable after 40 months; Spanish collections: some medullary and ectal excipular cells survived for at least 3 months, but asci and paraphyses did not survive for 3 weeks. **Altitude**: 10–18 m a.s.l. (Spain), 1050 m (Macaronesia), 100–1000 m (Mexico). **Geology**: Spain: marine sand near calcareous clay; Tenerife: tabular basaltic flow. **Phenology**: X–IV (but possibly throughout the year, long-lived).

Taxonomic remarks. *Orbilia desertorum* differs from most members of section *Arthrobotrys* in a rather high desiccation tolerance of the apothecia, also in the ability to form very long glassy processes, though this was only the case in the specimen from high altitude in Mexico. The species strongly resembles the temperate *O. oxyspora* and subtropical *O. dorsalis*, from which it differs in the globose SBs showing a more or less distinct filum, a tendency to wider spores, the occurrence on succulent desert plants in semiarid regions, apparently also in a distinctly different dactylella-like anamorph (though not proved in pure culture).

The temperate European *O. clavispora* differs from *O. desertorum* in the partial presence of ± distinct spore tails while its anamorph appears to be similar. *O. tenuissima* differs in narrower ascospores, shorter asci, and a tropical humid occurrence. *O. pseudeuphorbiae* differs in slightly spathulate-lageniform paraphyses, more geniculate instead of falcate spores, and less distinct cell rows at the margin. The Macaronesian sample on *Aeonium* was first compared with this species, but its molecular data refer it to *O. desertorum*.

O. auricolor and *O. terrestris* (series *Arthrobotrys*) differ from the former three taxa in an outer marginal excipulum of almost vertically oriented cells which do not form individual rows, and in a consistently smooth apothecial margin, *O. terrestris* also in wider spores with strongly attenuated spore bases and in more capitate paraphyses. However, a specimen reported by Liu (2006: fig. 13–14) under the name *O. auricolor* shows a marginal excipulum of textura porrecta running under a very low angle. Together with its rather short ascospores this specimen resembles *O. desertorum*, but it has a very different anamorph with 1-septate obpyriform conidia and adhesive networks which Liu identified as *Arthrobotrys javanicus* (see Pl. 959). Moreover, the habitat of this southern Chinese specimen was a subtropical semihumid montane forest.

Variation. The collections here included in *O. desertorum* show a remarkable variability in length of the glassy processes, which were very short or even absent in the samples on *Aeonium*, *Ferocactus* and *Yucca*, but strongly varied among those on *Agave* from ± absent over medium to very long. A correlation with the altitude was observed: the processes were 0–20 µm long at altitudes of 10–200 m (Spain and Mexico), but 50–70 µm at 1000 m (Mexico), but in the Macaronesian collection at 1050 m the glassy processes were absent to very short.

Further variation was noted in spore length and width, and in the paraphyses which are usually only very slightly inflated at the apex but predominantly medium capitate in the Mexican specimen with long glassy processes. In the *Aeonium* sample some paraphyses contain numerous medium-sized refractive guttules, which undoubtedly represent VBs and which were not seen in the other specimens. Apothecia in the collections from Torrevieja (Spain) showed a remarkable variation in their pigmentation, from flesh-coloured over light ochraceous or bright yellow-ochre to eventually bright reddish-brownish.

Anamorph. Only a single conidium was detected on the natural substrate in each of three collections. Based on their similarity to those of *O. clavispora*, we presume that they represent the anamorph of *O. desertorum*. However, in two of them (Pls 944: 5j; 945: 1k) the conidia were rather small and 3-septate, and resemble the type of *Dactylella tenuis*, which differs in wider conidia and in being isolated from leaf mould in deciduous woods, whereas in the third the conidium was larger and 6-septate (Pl. 944: 3g) and resembles *D. rhopalota*. The large conidium and one of the small ones occurred on the same host (*Agave*) at the same site in Spain. *D. clavispora* (= *O. clavispora*) as described by Chen et al. (2007b) has similar, (1–)3-septate conidia of *18–32.5 × 7.5–11 µm, which resemble in length and septation the small conidial type but in width the large conidial type observed in *O. desertorum*.

Phylogeny. Sequences were taken from apothecia of two samples (Com. Valenciana, on *Agave*, holotype; Tenerife, on

Map 152. Known distribution of *O. desertorum* in North America.

Aeonium), comprising the S1506 intron, ITS, and LSU, in the holotype also SSU. In the ITS region the two sequences are identical, whereas in the intron a deviation of 1 nt and 2 gaps occurs, and in the LSU (D1–D2) 1 nt deviates. In comparison, the distances among species of series *Neodactylella* lie in the range of 8–28% in the intron.

When analysing SSU+ITS+LSU or ITS (Phyls 25–27), *O. desertorum* clustered with strong support in the *oxyspora-heptameres* clade, with a minimum ITS distance of 8–9.5% to members of this clade. Also in the intron a high distance is noted among members of series *Neodactylella* (min. 12.5% to *O. clavispora*).

Ecology. *O. desertorum* grew on ± xeric, slightly to medium rotten branches, inflorescence stems, and succulent leaves of desert plants belonging to *Cactaceae* (*Caryophyllales*), *Crassulaceae* (*Saxifragales*), and *Agavaceae* (*Liliales*). The species was collected in the subtropical semiarid (summer-dry) southern mediterranean chaparral at 100–200 m a.s.l. in the Californian Coastal Sage and Chaparral and Baja California Desert and in a more warm-continental subhumid scrubland at 1000 m in the Sonoran Desert of southwestern North America. It also occurred in a thermomediterranean semiarid *Soncho-Aeonion* xerophytic scrubland with scattered *Juniperus* below the pine forest belt on a west-exposed slope of Tenerife (Macaronesia), and in thermomediterranean semiarid coastal sites with introduced *Agave* in southwestern Europe. It might well be that the fungus was introduced from North America to Spain with the *Agave* plants, but the occurrence on *Aeonium* in a natural vegetation in Tenerife might rather be native.

Specimens included. **SPAIN**: **Com**. **Valenciana**, **Alicante**, 6 km NNE of Torrevieja, E of Pinomar, Dunas de Guardamar, 10 m, leaves of *Agave americana*, 31.XII.2007, O. & J.P. (?) = *Orbilia prasina* Massee in sched.

Etymology: named according to the thin, membranaceous apothecia.
Typification: Paraguay, Yaguaron (Guarapi), leaves of *Epipremnum pinnatum*, IX.1883, B. Balansa (LPS 24449, holotype).
Misapplied name: Korf (1992), as *O. auricolor* (?= *O. tenuissima*).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–1.2 mm diam., 0.09–0.12 mm high (receptacle 0.09–0.1 → 0.07 µm), membranaceous, pale chlorinaceous or yellowish-cream-ochraceous, medium to strongly translucent, round, gregarious; disc flat to slightly convex, margin distinct, 0–10 µm protruding, very indistinctly rough to often finely to distinctly denticulate with pale yellowish teeth; broadly sessile, superficial; dry pale to light cream to chlorinaceous. **Asci** †(22–)25–32(–34.5) × 2.5–3.4 µm {5}, 8-spored, spores 4-seriate, 4 lower spores inverted {1}; **apex** (†) strongly truncate (not or slightly indented, laterally not or slightly inflated); **base** with very short to medium long, thin, ± flexuous stalk, Y- to h- or H-shaped. **Ascospores** †(7–)7.5–10.5(–11) × 0.8–1.1 µm {7} (~8.5–12 µm actual length), narrowly (subcylindric-)clavate (subulate), sometimes fusoid-clavate, apex rounded, sometimes obtuse, base ± strongly attenuated, medium (to strongly) curved (falcate); **SBs** not observed. **Paraphyses** apically slightly to strongly capitate-clavate, terminal cell †(12.5–)15–20 × (1.3–)2–3 µm {4}, lower cells †3–6.5(–9) × (1–)1.4–1.8 µm {4}; rarely branched at upper septum. **Medullary excipulum** hyaline, 10–15 µm thick, of dense textura globulosa-prismatica, medium sharply delimited from ectal excipulum. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. angularis at base and flanks, 50–70 µm thick near base, cells †10–25 × 7–18 µm {2}; towards mid flanks oriented at a 30–90° angle to the surface, 15–20 µm thick near margin, oriented at 0–45°, marginal cortical cells forming hair-like cell rows 8–35 µm long, †3.5–7.5 µm wide, (1–)3–10-celled, terminal cell †(3–)5–10(–12) × 3–4.5(–5.5) µm {5}, walls 0.2–0.5(–1) µm thick, tipped by **glassy processes** 1–10 × 3–5(–6) µm {7}, medium refractive, stratified, if cell rows long enough then ± coherent to form teeth which imbricately cover the marginal excipulum. **Anchoring hyphae** ± abundant, †1.5–3 µm wide, walls 0.2 µm thick {2}, forming a 10–20 µm thick t. porrecta-intricata. **SCBs** and **VBs** no data available. **Exudate** over paraphyses and margin 0.4–2.5(–4) µm thick, continuous to cloddy, (very) pale chlorinaceous, loosely or firmly attached; over outer excipulum granular, sparse. — **ANAMORPH**: unknown (but see below).

Habitat: lying on ground, ~2.5–30 mm thick, slightly to medium decayed stems of *Bambusa* {1}, petioles of *Cecropia* sp. {2}, *Epipremnum pinnatum* {1}, fruit pods of *Theobroma cacao* {1}, *Xylotheca kraussiana* {1}, decorticated log of indet. angiosperm {1}, corticated indet. woody plant {1}, on 1 mm deep strongly decayed wood {2}, or bark {1}, ungreyed but partly darkened, no algae. **Associated**: *Orbilia auricolor* {1}. **Desiccation tolerance**: unknown, possibly intolerant. **Altitude**: 15–500 m a.s.l. **Phenology**: XI, I, VI (tropical belt, possibly throughout the year).

Taxonomic remarks. *Orbilia tenuissima* was so far only be studied in the dead state. As in the former taxa (*O. oxyspora*, *O. dorsalis*, O. *clavispora*, *O. desertorum*), *O. tenuissima* possesses marginal cortical cells arranged in more or less free and distinct, hair-like rows oriented at a low to medium angle to the surface and tipped by short glassy processes, both causing the denticulate margin. *O. tenuissima* deviates from these four taxa in rather small asci and narrow ascospores, from *O. desertorum* also in presumably desiccation-sensitive apothecia. The rather thin apothecia of *O. tenuissima* are remarkable in usually showing a yellowish-cream to chlorinaceous colour.

O. auricolor (series *Arthrobotrys*) differs in lacking cell rows and in tending to larger asci and spores. However,

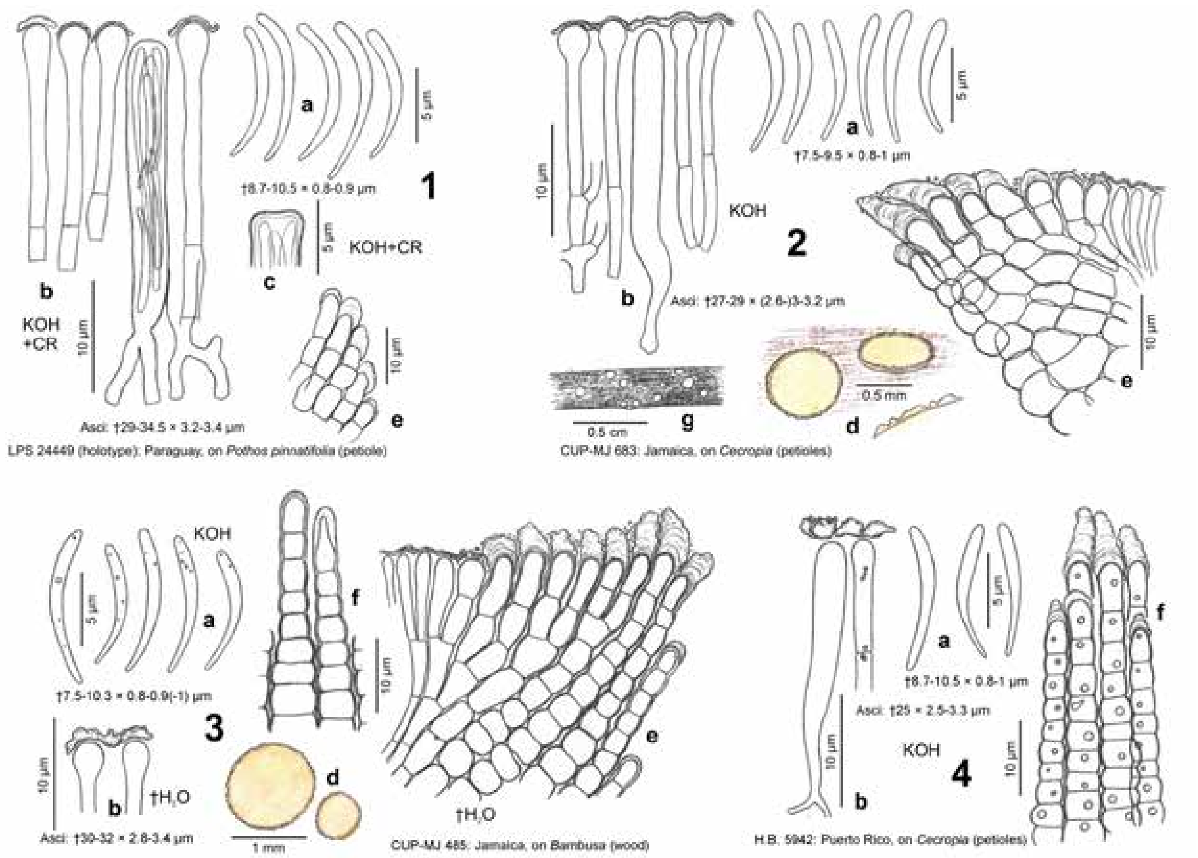

Plate 946. **1–4**: *Orbilia tenuissima*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia with dentate margin (closeup in **d**); **e**. marginal ectal excipulum with cell rows in median section; **f**. cell rows in surface view; **g**. petiole with apothecia.

the presence of cell rows was verified in a species of series *Arthrobotrys*, *O. javanica*, although morphological data of the teleomorph are sparse in the description of Liu (2006: 51, as *O. auricolor*, Pl. 959). No conidia were found in the examined collections of *O. tenuissima*, but an undocumented culture obtained in that from Puerto Rico and a sequence from a somewhat insufficiently studied south Chinese sample (HMAS 139520, Liu 2006: 112, Liu et al. 2007a, no data provided on the margin except for fine teeth) suggest its relationship with series *Arthrobotrys* (see below).

Variation. *O. tenuissima* appears to be a fairly constant species. Only the length of the marginal teeth and the distinctness of the cell rows was found to vary somewhat, even within a collection, resulting in variation from an indistinctly rough to distinctly denticulate margin.

Type studies. Spegazzini (1888) described *O. tenuissima* with pale amber-coloured, very thin, smooth apothecia 0.5–1 mm diam., asci 30 × 3–4 µm, and curved, cylindric-fusoid spores 8–11 × 0.5–1 µm. The holotype bears a microscopical sketch which fits very well the protologue and the data here evaluated from the type (Pl. 946: 1). Dennis (1954: 296, fig. 6F) briefly revised this material (see Fig. 159: F). Later, Dennis (1960b: 440, 1970: 352) referred a collection on *Espeletia spicata* from Venezuela (Sierra de Santo Domingo, S of Mucubaji, Edo. Merida, 5.VII.1958) to *O. tenuissima*.

Reid et al. (1981: 856) tentatively referred to *O. tenuissima* a collection from Galapagos Islands (Santa Cruz, near *Hypoxylon* sp. on bark and wood of a trunk of *Scalesia*, *Asteraceae*, without description), which was said to differ in shorter spores (6–8 × 0.5–1 µm). The unpublished herbarium name *O. prasina* for a collection on *Cecropia peltata* from Jamaica at K was compared with *O. fimicoloides* by Webster et al. (1998) and appears to represent *O. tenuissima* (B. Spooner pers. comm.), all the more as from the same country and substrate a more recent collection was restudied here (Pl. 946: 2).

Not included collections. A specimen from Tenerife (on wood of *Laurus*) was misidentified as *O. auricolor* by Korf (1992) and also by one of us (H.B.) when restudied in 1994. It fits *O. tenuissima* in its excipular structure of the margin and its narrow ascospores [†(9–)10.5–12(–12.7) × 0.9–1 µm in situ], according to a recent reexamination by L. Quijada (Quijada et al. 2016). Yet, it differs in rather long asci [†33–40 × (2.5–)3–3.5 µm], extraordinarily long spores, and thicker apothecia (150–160 µm), therefore, is not included in the description.

Liu (2006: 112) and Liu et al. (2007a) referred to *O. tenuissima* a collection from Hainan (tropical China), which deviates in larger asci and wider paraphyses: apothecia 0.5–2 mm diam., straw-yellow, with finely denticulate margin, asci †40–42 × 3.7–4 µm [but 35–40(–46?) × 3.5–4 µm according to scale], spores *9.2–12 × 0.9–1.2 µm, with globose SBs 0.5–0.8 µm diam., paraphyses †2–2.5 µm wide, with †4–5.5 µm wide, strongly capitate apex. It is not included in the scope of *O. tenuissima* here, mainly because clear evidence about marginal cell rows is missing and its DNA data refer it to series *Arthrobotrys*.

Anamorph. In an ascospore isolate of PR 11 an arthrobotrys-like anamorph was obtained by D.H. Pfister, but details of its morphology were apparently not documented and the culture does not exist anymore (Quijada et al. 2020).

Phylogeny. In the phylogenetic analysis of the ITS region by Liu et al. (2006a) the collection from Hainan (B.L. 271),

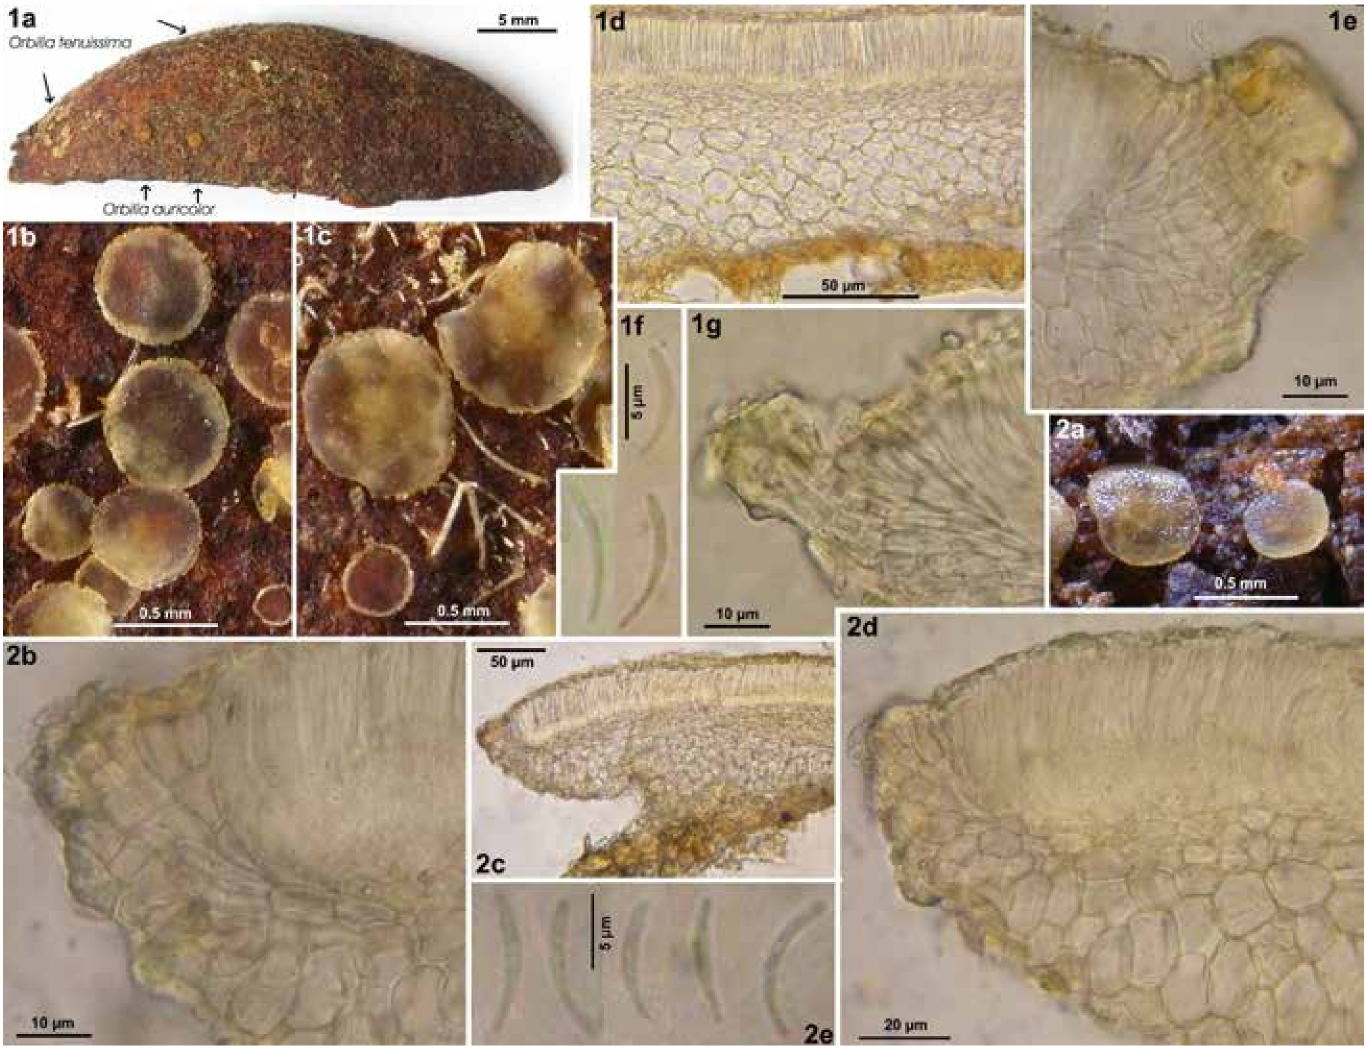

Plate 947. **1–2**. *Orbilia tenuissima*. – **1a**. outer surface of fruit pod; **1b–c**, **2a**. rehydrated apothecia (**1b–c** after 16 years, **2a** after 2 months); **2c**. apothecium in median section; **1d**. id., central part of apothecium; **1e**, **g**, **2b**, **d**. id., ectal excipulum at flanks and margin; **1f**, **2e**. ascospores. – Dead state (in KOH, except for **1d**: in H_2O). — **1a–g**. H.B. 5768b: South Africa, Durban, on *Xylotheca*; **2a–e**. H.B. 8414: Antilles, Guadeloupe, on indet. angiosperm.

from which only ITS was available (presence of S1506 intron uncertain), clustered in series *Arthrobotrys* near a strain identified by B. Liu as '*O. auricolor*' (with '*A. oligosporus*' as anamorph, B.L. 6225, Liu et al. 2006a). Also in our analysis it falls in *Arthrobotrys*, though rather unresolved and with high distance (min. 8 %) to other strains. This raises the question whether the Chinese strain actually represents *O. tenuissima*, or *O. tenuissima* as circumscribed here is better placed in series *Arthrobotrys*. Regrettably, no sequences of any of the specimens here included in *O. tenuissima* were available.

Map 153. Known distribution of *O. tenuissima* in Middle America.

An inofficial sequence from an unillustrated sample from Thailand (ITS, LSU, S1506 intron absent) formed with an ITS distance of 3.1 % a highly supported clade with B.L. 271 (Phyl. 28). It was at first confused by A.H. Ekanayaka (pers. comm.) with a documented sample of a *Hyalorbilia* (MFLU 15-0167), the trustworthy sequence of which clustered with *H. arcuata* (see there). Possibly both strains derive from the same piece of substrate and were mistaken as a single species. In our LSU analysis (Phyl. S32) the sequence of the unillustrated population clustered unsupported with *A. polycephalus*, and in the combined analysis (Phyl. S33) unsupported with *A. pyriformis*.

Ecology. *O. tenuissima* is apparently restricted to the (sub) tropical belt. Specimens are known from tropical humid rainforests in Middle America and a subtropical humid (± winter-dry) forests in South America and southeastern Africa. The not included collections were from the tropical humid (winter-dry) Hainan island in southernmost China and a mesomediterranean humid laurel forest in Tenerife (Macaronesia).

O. tenuissima is a polyphagous species that grows on hygric, slightly to medium decayed culms, leaves and fruits, but also strongly decayed wood and bark of trees. The hosts include various families of monocotyledons, such as *Poaceae* (*Bambus*) and *Araceae* (*Epipremnum*), and dicotyledons, such as *Urticaceae* (*Cecropia*), *Malvaceae* (*Theobroma*), and *Achariaceae* (*Xylotheca*).

Specimens included. **JAMAICA**: **Cornwall**, **Hanover**, ~6 km NNE of Grange Hill, Dolphin's Head, ?300 m, petioles of *Cecropia*, 22.I.1971, R.P. Korf et al. (CUP-MJ-000683, H.B. 5864 ø). – **Surrey**, **St**. **Thomas**, Morant Bay, above Bath Fountain Hotel, along Sulphur River, 170 m, stems of *Bambusa*, 14.I.1971, R.P. Korf et al. (CUP-MJ-000485; H.B. 5865 ø). — **PUERTO RICO**: 30 km ESE of St. Juan, El Yunque, Rio Grande, El Verde Field Station, 15 m, petioles of *Cecropia*, 16.I.1996, D.H. Pfister, F.A. Harrington & D.J. Lodge (D.H.P. PR 11, FH 00304902, anam. cult., H.B. 5942 ø). — **LESSER ANTILLES**: **Guadeloupe**, 3.5 km SW of Petit Bourg, Le Bois de Sergent, ~140 m, wood of indet. angiosperm, 23.XI.2006, C. Lechat (C.L.L. 6011(3), H.B. 8414). – **Dominica**, St. Paul, ~4 km NE of Roseau, Cochrane Estate, 500 m, fruit pods of *Theobroma cacao*, 28.VI.1970, R.P. Korf et al. (CUP-DO-000263). — **PARAGUAY**: **Paraguarí**, 35 km SE of Fernando de la Mora, Guarapi (today Yaguaron), leaves of *Epipremnum pinnatum* (as *Pothos pinnatifida*), on petioles, IX.1883, B. Balansa (LPS 24449, **holotype** of *O. tenuissima*; H.B. 6946 ø). — **SOUTH AFRICA**: **KwaZulu-Natal**, 20 km NW of Durban, 2.5 km E of Kloof, Kranskloof, near Molweni river, NW-exposed slope S of gorge, 400 m, fruit pods of *Xylotheca kraussiana*, 18.III.1990, D. Triebel & G. Rambold (G.R. 7216A, M-0229708, H.B. 5768b).

Not included. **CHINA**: **Hainan**, ~50 km N of Sanya, Wuzhishan, 900 m, bark of indet. tree, 14.XII.2003, B. Liu et al. (B.L. 271, HMAS 139520, doc. vid.; sq.: DQ656612). — **THAILAND**: **Northern Thailand**, **Chiang Rai**, Mae Fah Luang University, ~460 m, indet. tree, on ?bark, ?15.I.2015, A.H. Ekanayaka (unnumbered, non vid., sq.: ined.). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Anaga, Monte de las Mercedes, ?800 m, on wood of *Laurus novocanariensis*, 12.IV.1972, F.E. Eckblad (CUP-MM-001132 [duplicate in O], as *O. auricolor*).

Species without known teleomorph

'Dactylellina' multiseptata (H.Y. Su & K.Q. Zhang) Z.F. Yu, in Zhang & Hyde (eds), Nematode-trapping Fungi: 155 (2014) — Pl. 9: f

'Dactylellina' varietas Yan Li, K.D. Hyde & K.Q. Zhang, in Li, Jeewon, Hyde, Mo & Zhang, Mycol. Res. 110(7): 792 (2006) — Pl. 9: a

These two species have been ascribed to the genus *Dactylellina* because upon contact with nematodes they formed stalked adhesive knobs in pure culture, '*D.*' *varietas* also non-constricting rings. However, when comparing those 3 positions in the 5.8S, ITS2, and LSU at which series *Neodactylella* and *Dactylellina* differ (Tab. 76), the two ex-type strains clearly belong to *Neodactylella*. This finding could be interpreted as a molecular exception. Yet, also in our phylogenetic analysis of the entire ITS region the two species clustered strongly supported with species of *Neodactylella*: '*D.*' *varietas* with *Dactylella qiluensis* (*heptameres-qiluensis* subclade), and '*D.*' *multiseptata* forms with *Dactylella intermedia* (Phyl. 26) another subclade of the *oxyspora-heptameres* clade. Also in the analysis of the S1506 intron (S30) '*D.*' *varietas* clustered strongly supported in this clade, and in the LSU (S31) '*D.*' *multiseptata* clustered again strongly supported with *Dactylella intermedia*. Even the only 20 nt short fragment of the intron in '*D.*' *multiseptata* permits this conclusion because it fits exactly and exclusively the intron of *O. oxyspora* of series *Neodactylella*.

Also in Li et al.'s (2006) phylogenetic analyses of ITS, LSU, or *TUBB*, the two nematode-trapping taxa clustered in the *Dactylella* clade. With their elongate-fusiform conidia without a markedly larger middle cell and their simple conidiophores these species would actually fit the various taxa of *Neodactylella* with fusiform conidia, which also *Dactylella qiluensis* and *D. intermedia* have. We suspect that the mismatch between trapping organs and phylogeny originated from some confusion in the laboratory. A Chinese strain (YMF 1.00566) misidentified as *Dactylella atractoides* (= *O. oxyspora*) belongs to '*D.*' *varietas*, differing from the type by only 2 nt and 2 gaps in the ITS and 2 nt and 1 gap (besides differences at the incomplete 5'-end) in the S1506 intron.

The conidia of ***Orbilia dehongensis*** M. Qiao & Z.F. Yu nom. prov. (Zhang et al. ined., Yunnan, Dehong, forest soil, 10.XII.2012, Y. L. Bai, YMF 1.03609), which also clusters in the *heptameres-qiluensis* subclade (Phy. 27), tend to have a distinctly larger central cell, reminiscent of species of series *Dactylellina*. No teleomorph is known in any members of the *heptameres-qiluensis* and *intermedia-multiseptata* subclades.

Series *Arthrobotrys*

Orbilia subgenus ***Orbilia*** section ***Arthrobotrys*** series ***Arthrobotrys*** – Type species: *A. superbus* Corda [= *Orbilia* ?*auricolor* (A. Bloxam) Sacc.]

= *Monacrosporium* Oudem., Ned. Kruidk. Arch., Ser. 2,4: 250 (1885) – Lectotype species: *M. elegans* Oudem. [≡ *Orbilia elegans* (Oudem.) Baral et al.], designated by Clements & Shear (1931)

= *Orbiliella* Kirschst., Ann. Mycol. 36: 374 (1938) — Type species: *Orbiliella armeniaca* Kirschst. (= *Orbilia auriolor*)

= *Didymozoophaga* Soprunov & Galiulina, Mikrobiologiya 20: 493 (1951), nom. inval., ICN Art. 39.1 (Latin diagnosis missing), nom. illegit., ICN Art. 52.1 (nomenclaturally superfluous) – Lectotype species: *Arthrobotrys oligosporus* Fresen., designated by Schenck et al. (1977)

= *Candelabrella* Rifai & R.C. Cooke, Trans. Br. Mycol. Soc. 49(1): 160 (1966) – Type species: *C. javanica* Rifai & R. C. Cooke [≡ *Arthrobotrys javanicus* (Rifai & R.C. Cooke) Jarow.]

= *Duddingtonia* R.C. Cooke, Trans. Br. Mycol. Soc. 53: 316 (1969) – Type species: *Trichothecium flagrans* Dudd. [≡ *Arthrobotrys flagrans* (Dudd.) Mekht.]

= *Geniculifera* Rifai, Mycotaxon 2: 214 (1975) – Type species: *Trichothecium cystosporium* Dudd. [≡ *Arthrobotrys cystosporius* (Dudd.) Sidorova et al.]

≡ *Genicularia* Rifai & R.C. Cooke, Trans. Br. Mycol. Soc. 49: 153 (1966), nom. illegit., ICN Art. 53.1 (non *Genicularia* Rouss. 1806)

= *Nematophagus* Mekht., Mikol. Fitopatol. 9(2): 250 (1975) – Type species: *N. azerbaijanicus* Mekht. [≡ *Arthrobotrys azerbaijanicus* (Mekht.) Van Oorschot]

= *Monacrosporiella* Subram., Kavaka 5: 94 (1978, '1977') – Type species: *Dactylella megalospora* Drechsler [≡ *Arthrobotrys megalosporus* (Drechsler) M. Scholler et al.]

= *Woroninula* Mekht., Khishchnye Nematofagovye Griby – Gifomitsety: 109 (1979) – Type species: *Dactylella polycephala* Drechsler [≡ *Arthrobotrys polycephalus* (Drechsler) Rifai]

= *Roigiella* R.F. Castañeda, Revta Jardín bot. Nac., Univ. Habana 5(1): 62 (1984) – Type species: *R. lignicola* R.F. Castañeda (= *Arthrobotrys* sp. fide Seifert et al. 2011)

Etymology: *Arthrobotrys*: after the conidia formed in clusters and the chain-like arrangement of these clusters along the proliferating conidiophore; *Candelabrella*: used for species with pronounced denticles in a candelabrum-like terminal arrangement; *Didymozoophaga*: referring to the 2-celled conidia and the ability to trap nematodes; *Duddingtonia*: named after the British mycologist C.L. Duddington; *Genicularia* and *Geniculifera*: referring to the geniculate conidiophore apex; *Monacrosporiella* and *Monacrosporium*: based on conidiophores that produce a single acrogenous conidium; *Nematophagus*: referring to the ability to trap nematodes; *Orbiliella*: diminutive of *Orbilia*; *Woroninula*: named after the Russian botanist M.S. Woronin; *Roigiella*: named after the Cuban botanist J.T. Roig Mesa.

Emended diagnosis: **TELEOMORPH**: Apothecia with smooth or finely crenulate margin, desiccation-sensitive or slightly -tolerant. Ascospores subulate, gently to strongly curved; spore bodies globose to rod-shaped, never distinctly eccentrical. — **ANAMORPH**: Conidiogenous loci singly at apex of unbranched (acrogenous) or branched conidiophores (geniculate), or on prominent denticles (candelabrelloid) or indistinct nodules (arthrobotryoid). Conidia

0–4(–13)-septate, straight, exceptionally branched, microconidia present or absent. Forming 3-dimensional adhesive networks.

Description: — **TELEOMORPH**: **Apothecia** hydrated (0.3–)0.5–2(–5.5) mm diam., whitish to pale or light cream, yellow-orange or yellow-brown, margin smooth or sometimes finely crenulate, sessile or with a short and wide stipe. **Asci** *(30–)37–60 × 3.3–4.5 µm, 8-spored, lower (2–)3–5(–6) spores inverted; **apex** (†) slightly to strongly truncate, not or sometimes slightly indented, laterally not or rarely distinctly inflated; **base** often partly H-shaped. **Ascospores** *(6–)8–13(–15) × 1–1.4(–1.5) µm, subcylindric- to fusoid-clavate (subulate), apex rounded or sometimes subacute, base attenuated or sometimes with a distinct tail, slightly to usually ± strongly curved (falcate), rarely subglobose, *2.2–2.6 × 1.8–1.9 µm; **SBs** never distinctly eccentrical, (1–)1.5–2.5(–3) × 0.2–1 µm, globose, ellipsoid, tear-shaped or subulate to rod-shaped, apically narrowed to a small point, usually with a very fine filum, apically affixed to spore wall. **Paraphyses** (not or) slightly to medium (rarely strongly) inflated at apex, capitate(-clavate), also ellipsoid or lanceolate, terminal cells 2–5(–6)× longer than lower cells, lower cells 4–9(–11) µm long. **Ectal excipulum** of (†) thin-walled to slightly (to medium) gelatinized, vertically oriented t. globulosa-angularis(-prismatica) from base to margin, cells *(10–)15–40(–50)((–85)) × (8–)12–30(–35)((–48)) µm, at margin oriented at (40–)60–90°, rarely of t. prismatica at 0° (*O. javanica*); **glassy processes** absent or 0.5–8 µm long (rarely 8–30 µm: *O.* aff. *menageshae*). **SCBs** globose; **VBs** absent or low-refractive, hyaline. **Exudate** absent or (0.1–)0.3–2(–4) µm thick, continuous-granular to cloddy or cap-like, loosely to firmly attached, hyaline or pale yellowish. **— ANAMORPH**: arthrobotrys-like. **Conidiophores** *(75–)150–400(–600) × 3.5–9 µm, apically 2.5–4.5(–6.5) µm, conidia formed singly at the unbranched tip or sympodially (geniculate, candelabrelloid, or arthrobotryoid), conidia often in ± large clusters, partly several clusters at each conidiophore, either by apical branching or through proliferation by forming up to 10 nodes in a chain at intervals. **Conidia** *(11–)16–60(–86) × (3–)5–23(–26) µm, cylindric-ellipsoid to obpyriform-obovoid or clavate, also fusoid to top-shaped, with 0–4 septa, mostly with inflated cell when 2–4-septate; rarely 4–13-septate and partly apically branched; straight, rarely slightly curved; **conidial dimorphism** sometimes present (sharply differentiated or not). **Trapping organs**: adhesive, usually 3-dimensional networks, traps mainly formed when nematodes are present.

Habitat: on hygric or sometimes semiaquatic or mesic wood and bark (rarely fruits) of angiosperms (rarely gymnosperms), herbaceous stems (rarely leaves) of mono- and dicotyledonous plants, rarely fungicolous or on dung, isolated also from rhizosphere of herbs, capturing nematodes, temperate to tropical, humid to semihumid, perhaps also semiarid (?irrigated), desiccation-sensitive or sometimes slightly desiccation-tolerant.

Recognized species: 32 (19 of them without known teleomorph), plus ~7 unnamed species ('affinis') and 1 species of uncertain affinity; for further ~27 species see Tab. S7.

Taxonomic remarks. Members of series *Arthrobotrys* can hardly be recognized by the teleomorph as belonging to this series. Characteristic features are the narrow, subulate, slightly to strongly curved (falcate), apically rounded and basally tapered ascospores with small apical SBs (the connection of a teleomorph with subglobose ascospores to *A. nonseptatus* requires confirmation), a marginal ectal excipulum made up of cells oriented at a rather high angle to the surface (exception: *O. javanica*), and a smooth apothecial margin. This combination of characters is, however, also found in some species of series *Neodactylella* and *Dactylellina*.

In the present study, anamorph-teleomorph connections are accepted for 12 species of series *Arthrobotrys* (excluding the somewhat uncertain *A. nonseptatus*). Three of them can be recognized by their teleomorph: *O. blumenaviensis* by lanceolate paraphyses, *O. javanica* by a textura porrecta at the margin, and *O. latispora* s.l. by ascospores with rather abrupt tails. The remaning species (*O. auricolor*, *O. cladodes*, *O. elegans*, *O. menageshae*, *O. multiformis*, *A. musiformis*, *O. oligospora*, *O.* aff. *oligospora*, *O. scaphoides*) hardly show any reliable characteristics in their teleomorph, according to our investigations and those of Pfister (1994), Pfister & Liftik (1995), Webster et al. (1998), Mo et al. (2005a), Liu (2006: 49), H.Y. Su (ined.), and Z.F. Yu et al. (ined.). In these species the teleomorphs currently have been identified as *O. auricolor*, with the understanding that this morph represents an aggregate of rather uniform morphology but more or less diverse anamorphs in regard to their conidiophore types and conidial shapes.

O. terrestris is the only species with a known teleomorph treated here in series *Arthrobotrys*, for which an anamorph is unknown. We assume its relationship in this series because of morphological similarities to *O. auricolor*.

Anamorph (see also p. 216–217 and Tab. S7). Members of series *Arthrobotrys* are characterized by adhesive networks with a comparatively uniform morphology (see p. 118). These trapping devices are usually only observed in pure culture, particularly in the presence of nematodes, but probably also occur on the plant substrate, although they have never been observed in vicinity of apothecia during our study. Anamorphs with adhesive networks are referred to as arthrobotrys-like here.

The conidia are often formed in fascicles (clusters) at the tip of the conidiophore or, in addition, at intercalary position by forming clusters (whorls) in a chain. In other taxa the conidia are formed singly or 2–3 at the conidiophore tip. Four different main types of conidiophores can be distinguished in regard to conidiogenesis (see also p. 110): (1) conidia are formed singly at the tip (acrogenous), (2) conidia are formed on ± long apical branches (geniculate), (3) conidia are formed on short, ± aggregated denticles (candelabrelloid), (4) conidia are formed on nodules or very short denticles on often swollen, terminal or intercalary nodes (arthrobotryoid). The first two types are often found within a single species, and also the third is not sharply separated from the second. In the species treated here these types occur as follows: *O. menageshae* (acrogenous); *O. elegans*, *O. multiformis* (acrogenous and geniculate); *O. javanica* (candelabrelloid); *O. auricolor*, *O. blumenaviensis*, *O. latispora*, *A. nonseptatus*, *O. scaphoides* (arthrobotryoid).

Various further species are only known from their anamorph. One of them, *A. flagrans*, represents an aberrant type in which the 1-septate conidia are formed in small groups on non-protruding scars at the unbranched unswollen conidiophore tip, which is why they appear as rather broadly sessile (Duddington 1950, Cooke 1969, Rubner 1996: fig. 2f; see also Fig. 103: n). Because of this peculiarity the species has been placed in a separate genus *Duddingtonia*. It is considered here as belonging to series *Arthrobotrys* because it clusters in phylogenetic analyses with high support in a clade with *O. oligospora*.

In several species two different types of conidia are formed, macro- and microconidia. Macroconidial morphology comprises a series of different, species-specific shapes: cylindric-ellipsoid, pear-shaped, fusiform, and top-shaped. Usually the macroconidia are straight and unbranched, but in some species they are slightly curved and in *O. multiformis* partly branched (trinacrium-like). The number of septa varies between 1 and 2–4, rarely 0 or up to 13. Microconidia are cylindric-ellipsoid and 0–1(–2)-septate. Sometimes, a more or less pronounced variability in conidial

Table 80. Synonymies within series *Arthrobotrys* found by rDNA sequence similarity or (in *Orbilia blumenaviensis* and *O. fici*) by morphological reexamination, with indication of the year of the basionym. ^{T} = type material or ex-type strain, ^{ET} = ex-epitype strain, ^{TT} = ex-topotype strain.

size is observed within an isolate, the conidia varying gradually in size and/or shape, without a sharp limit between macro- and microconidia.

In many species only macroconidia are known, and in some others it seems that only microconidia have been observed. In one such strain which missed the characteristic macroconidia, molecular data demonstrated conspecificity with other strains which formed both conidial types: In the ex-type strains of *A. iridis*, *A. multiformis*, and *Dactylella ramiformis* large, multiseptate macroconidia and small, 0–1-septate, cylindric-clavate microconidia were reported, whereas in that of *A. yunnanensis* only small microconidia occurred. Based on identical ITS sequences in GenBank we have united all four taxa under the name *O. multiformis*, assuming that also *A. yunnanensis* is able to produce macroconidia.

Species delimitation. The morphology-based taxonomy of anamorphs within series *Arthrobotrys* is rather confusing. A vast number of species have been described in the literature, some of which are so similar that they are difficult to distinguish by their morphology, e.g., *A. superbus* and *A. cladodes*. Yu et al. (2014) listed a total of 53 accepted species. For most of them the connection to a teleomorph is as yet unknown. Species might exist that have lost the capacity to form a teleomorph, but we rather suppose that their teleomorph only awaits to be discovered. Because of the high diversity and often difficult species concepts we dispensed with a compilation of *Arthrobotrys* in the History of anamorph genera (see p. 216).

For a large number of isolates of various taxa of series *Arthrobotrys* molecular data were available in GenBank and other databases. Their analysis suggests that some of them represent synonyms and others are misidentified. Tab. 80 lists the synonymies that we observed based on sequence data originating either from the ex-type strain or from isolates being later considered to be conspecific with the type. These synonymies usually concur with a similar morphology of conidia and conidiophores, except for taxa which were described solely by their microconidial states (*A. pseudoclavatus*, *A. yunnanensis*) and were found to represent synonyms of their macroconidial states (*A. janus* and *A. multiformis*, respectively).

It appears that many of these synonyms are reported here for the first time, except for *A. multisecundarius* which was considered as a synonym of *A. microscaphoides* by Li et al. (2008) based on DNA data, and *Dactylella ramiformis* and *D. iridis* which were synonymised for morphological reasons under *A. multiformis* by Yu et al. (2014).

In addition to these synonymies, various misidentified strains exist in GenBank, which underline the limited taxonomic value of conidial morphology in series *Arthrobotrys*. Examples of the high confusion and doubtful identities in DNA databases are given under the respective species. On the other hand, the high molecular variation in the available ITS sequences observed at present in some species of series *Arthrobotrys* exceeds the currently accepted limits, and questions species concepts based on molecular data. For instance, *A. psychrophilus* is considered here as synonymous with *O. elegans* (≡ *A. oudemansii*) despite a 4.5% ITS distance based on the few available sequences. Likewise, the numerous sequences of *A. oligosporus* form different clades and subclades, which would permit splitting into at least three different cryptic species. From its molecular data, also *O. auricolor* exhibits a high diversity with several very distant clades, which will necessitate to split the morphologically rather homogeneous taxon into two different species. We here refrain from doing so because of the paucity of available molecular data and frequently absent data of its anamorph. Also *O. blumenaviensis*, *O. conoides*, *A. janus*, *O. latispora*, *O. menageshae*, *O. oligospora*, and *A. thaumasius* show strong molecular intraspecific variation which seems to indicate that in some of these taxa different species are involved. Other species show rather consistent ITS data (*O. multiformis*, *A. flagrans*). Irrespective of their molecular variation, the above-mentioned taxa are morphologically more or less homogeneous or show only gradual variation in conidial shape, except for *O. blumenaviensis* and *O. menageshae*, in which 1–2-septate clavate and 2–3-septate fusoid conidia occur, sometimes within a given strain.

Phylogeny. Within series *Arthrobotrys* a rather high number of clades that represent different species are observed in our ML analyses. The backbone phylogeny was generally not supported, however, and only a few clades which comprise clearly more than one species received support. In our combined analyses (Phyls 25 and S33) four groups were medium to mostly strongly supported: (1) the *scaphoides-botryosporus* clade which also includes *O. cladodes* (C1), *O. latispora* (C2+C3), *A. pravicovii*, and *A. macroides*; (2) the *mangrovisporus-sahelensis* clade; (3) the *elegans-gampsosporus* clade; (4) the *ellipsosporus-polycephalus* clade (in Phyl. 25 only weakly supported). The *oligospora-musiformis* clade with *A. amerosporus*, *A. conoides*, *A. flagrans*, *A. javanicus*, *A. musiformis*, and *O. oligospora* received medium support only in S33. In the LSU no medium or strongly supported clades with more than one species were observed, except for the *mangrovisporus-sahelensis* clade (S32).

Most of these clades were also obtained by Hagedorn & Scholler (1999: fig. 2, ITS, NJ) with high or medium support: the *elegans-gampsosporus* clade, the *scaphoides-botryosporus* clade, represented here by *A.* '*conoides*' (= *A. pravicovii*), *A. botryosporus*, and *O. cladodes* (D.H.P. 60 and 90), the *oligospora-musiformis* clade, still without *O. oligospora* since no ITS was available at that time. Their strongly supported clade with '*Monacrosporium eudermatum*' concerns the *mangrovisporus-sahelensis* clade (CBS 377.97) and *A. janus*

Phylogenetic analysis 28. Phylogram of series *Arthrobotrys* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (225 sequences, 765 positions, aligned with MUSCLE) using the GTR+G+I model in MEGA7 (500 replicates). 22 environmental strains from GenBank are included, 10 of them representing 5 unidentified species (O29–O33). The tree is rooted with *O. oxyspora* and *D. bembicodes*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, TT = topotype. * = without ITS1 and partial 5.8S, ** = without ITS2.

Key to species of series *Arthrobotrys* with known teleomorph

1. Spores subglobose, *2.2–2.6 × 1.8–1.9 µm; conidia non-septate, *11–16.5 × 5–6(–6.5) µm, formed in clusters (arthrobotryoid); subtropical humid southeastern Asia .... reported as teleomorph of ***Arthrobotrys nonseptatus***, p. 1551
1. Spores falcate or rarely helicoid, *6–15 × 1–1.5 µm 2

2. Spore base often or consistently narrowed to a ± abrupt tail of 1/3–1/2 × the total spore length; conidiogenesis arthrobotryoid, with unswollen nodes 3
2. Spores gradually attenuated towards base or only sometimes with a short tail; conidiogenesis arthrobotryoid or candelabrelloid 4

3. Paraphyses consistently lanceolate, non-furcate, without conspicuous exudate; conidiophores 113–500(–1500) µm long; conidia obpyriform to fusoid, *(16.5–)21–36(–40) × (10–)12.5–19(–21) µm, 1–3-septate; wood & bark of angiosperms, leaves of *Arecaceae*, thermotemperate to tropical humid America, worldwide .... ***O. blumenaviensis***, p. 1562
3. Paraphyses lageniform-mammiform, often bi- to trifurcate, with thin (sub)apical exudate that sometimes forms glassy caps on apex; conidiophores 90–200 µm long; conidia obovoid to obpyriform, *(14–)20–22(–26) × (7.5–)10–11(–13) µm, (0–)1-septate; wood of angiosperm, tropical humid Middle America .... ***O. jesu-laurae***, p. 1566

4. Spore base often or consistently narrowed to a ± abrupt tail of 1/3–1/2 × the total spore length 5
4. Spores gradually attenuated towards base or only sometimes with a short tail 7

5. Spores distinctly helicoid, †9–10 × 1.4–1.6 µm; leaves of monocots (*Arecales*), subtropical humid South America .... ***O. disseminata*** (series *Commatoideae*, section *Aurantiorubrae*), p. 818
5. Spores falcate 6

6. Spores †8–9.3 × 1.2–1.3 µm, always with abrupt, †0.15–0.2(–0.3) µm wide tails; anamorph unknown; leaves of *Elettaria* (*Zingiberales*), tropical humid Indonesia .... ***O. neglecta***, p. 1568
6. Spores *6.5–8.5(–9) × 1.3–1.5 µm, with abrupt, */†0.3–0.5 µm wide tails or sometimes tail-like or even gradually attenuated bases; conidia dimorphic, macroconidia *14.5–21.5 × 7.7–16.3 µm, (0–)1-septate, cylindric-ellipsoid to ± obpyriform, formed on ± swollen nodes in clusters (arthrobotryoid), microconidia 0-septate, ± clavate; wood & bark of angiosperms, orotemperate to subtropical humid eastern Asia .... ***O. latispora* s.l.**, p. 1569

7. Spores †9–11 × 1.4–1.7 µm, curved mainly near the strongly attenuated base, never with a distinct tail; SBs ?tear-shaped; asci †40–53 × 4.2–5.8 µm; marginal excipulum of t. prismatica oriented at a high angle; anamorph unknown; sandy soil, warm-continental semihumid mountainous Central Asia .... ***O. terrestris***, p. 1583
7. Spores *0.9–1.4(–1.5) µm wide (†0.8–1.3 µm), falcate 8

8. Macroconidia (0–)1-septate, mostly < 38 µm long, formed in groups of 3–15; microconidia unknown or rarely seen; glassy processes 0–3(–6) µm long 9
8. Macroconidia (0–)1–2(–3)- or multiseptate, mostly > 38 µm long, formed singly or in groups of 2–5 on ± distinct denticles or branches without swollen nodes (candelabrelloid or geniculate); microconidia present or absent; glassy processes 0–5(–30) µm long 12

9. Conidia formed on distinct denticles (candelabrelloid), cylindric-clavate to narrowly obpyriform, septum ± eccentrical; spores medium attenuated towards base 10
9. Conidia formed on ± swollen nodes (arthrobotryoid), obovoid, cylindric-ellipsoid, to ± obpyriform, *13–32 × 6–17 µm; spores ± strongly attenuated towards base, *(6–)7.5–12(–15) × (0.8–)1–1.3 µm; marginal excipulum oriented at a high angle 11

10. Conidia *25–42.5 × 9.5–15.5 µm, narrowly obpyriform, straight; spores *7–9 × 1.2–1.5 µm; marginal excipulum of t. prismatica oriented at a low angle; woody substrate, (sub)tropical humid (south)eastern Asia .... ***O. javanica***, p. 1550
10. Conidia *18.5–32.5 × 6–8.5 µm, cylindric-clavate, slightly curved; spores *7.7–10 × 1.1–1.2 µm; marginal excipulum of t. globulosa oriented at a high angle; woody substrate, temperate to tropical humid, worldwide .... ***A. musiformis* s.l.**, p. 1578

11. Conidia 6–13.5(–15) µm wide, cylindric-ellipsoid to ± obpyriform, septum median to slightly, exceptionally strongly eccentrical; woody substrate, herbaceous stems, dung etc., hemiboreal to tropical (semi)humid, worldwide .... ***O. auricolor***, p. 1520
11. Conidia 8.5–17 µm wide, obovoid to obpyriform, septum slightly to strongly eccentrical; woody & herbaceous, substrate, dung etc., temperate to subtropical humid to semiarid, worldwide .... ***O. oligospora***, p. 1539

12. Macroconidia narrowly fusiform, *60–198 × 7.5–21 µm, 4–13-septate, partly branched (Y-shaped); spores *8–10 × 1.3–1.4 µm, only slightly tapered towards base; isolated from monocot and conifer roots & stems, boreal to subtropical humid North America, Europe, Asia .... ***O. multiformis***, p. 1547
12. Macroconidia broadly fusiform or clavate, *32–63 × 12–26 µm, 1–3-septate; spores *(7.5–)9–13.5(–15) × (1–)1.1–1.4(–1.5) µm, ± strongly attenuated towards base 13

13. Macroconidia *33–57 × (16–)18–23(–26) µm, fusoid to top-shaped, (2–)3-septate, formed singly or 2–3 on long denticles at apex; glassy processes 2–8 µm long; spores *1–1.3 µm wide; herbaceous leaves & stems, dung, bark, cold-temperate to subtropical humid, worldwide .... ***O. elegans* s.l.**, p. 1552
13. Macroconidia *32–63 × (12–)14.5–18.3(–20.7) µm, obpyriform or fusoid, (1–)2(–3)-septate, formed singly at apex of conidiophores or on long branches; spores *1.2–1.5 µm wide; subtropical humid northeastern Africa 14

14. Paraphyses covered by firmly attached, 1–3(–4) µm thick exudate caps; glassy processes 0–5 µm long; bark of angiosperms .... ***O. menageshae***, p. 1558
14. Paraphyses covered by a thin layer of granular 0.2–0.5 µm thick exudate; glassy processes 2–30 µm long; herbaceous stems (*Solanecio*, *Euphorbia*) and bamboo .... ***O.* cf./aff. *menageshae***, p. 1558

clade (*A. eudermatus* is possibly conspecific with *A. janus*).

Morphological similarity was often not supported by molecular data: very similar taxa may cluster in very distant clades and, vice versa, morphologically different taxa may cluster in the same clade. A mismatch between phylogenetic analyses and earlier classification systems based on conidiophore and conidial morphology is often observed. For instance, the *O. auricolor* aggregate, characterized by ellipsoid-obpyriform conidia with 1 ± median septum formed on arthrobotryoid conidiophores, clustered with an ITS distance of 8–10 % in two clades, without clear morphological differences between the clades. The anamorphs of both clades can be referred to either *A. superbus* or *A. cladodes*, which are morphologically too similar and variable to enable safe distinction as two different species (see p. 1532).

However, one of these clades contains also *A. scaphoides* despite very differently shaped, fusiform, 2–4-septate conidia, whereas a species with *A. scaphoides*-like conidia, *A. gampsosporus*, clustered in a clade with *O. elegans*, which has shorter, more top-shaped conidia. The conidiophore type in the *elegans*-*gampsosporus* clade is acrogenous or candelabrelloid, suggesting that conidial types have a lower taxonomic relevance than conidiophore types. Likewise, species with 1-septate and non-septate conidia may cluster in a supported clade (*A. botryosporus* with *O. latispora*, *A. amerosporus* with *A. flagrans*). *A. amerosporus* has geniculate conidiophores, whereas *A. flagrans* lacks any nodules or denticles (similar as in *Trichothecium*), for which reason it was previously placed in a genus of its own (*Duddingtonia*). From all this follows that a subdivision of series *Arthrobotrys* into different groups based on conidiophore types turned out to be impossible.

In contrast to a high variation in the ITS region, the LSU is highly conservative and differs between closely related species often only at a few positions, resulting in a distance of often only 0.2–1 % in the D1–D2 domain. Therefore, the species are partly only indistinctly resolved in analyses of LSU.

Specific nucleotide positions. Specific nucleotide positions that characterize series *Arthrobotrys* have not been found (see Tab. 76). Position 13 in the ITS2 is CCTC**A** in series *Arthrobotrys* p.p.maj. and *Neodactylella*, and CCTC**G** in all other predacious series of section *Arthrobotrys*, but CCTC**A** also in *O. bembicodes* (series *Drechslerella*) and CCTC**G** also in *O.* aff. *auricolor* (H.B. 10024/denovo367 & G.M. 2017-09-25.1/2018-11-27.1), *A. nonseptatus*, and *A. reticulatus* (series *Arthrobotrys*). Two positions vary within series *Arthrobotrys* while being constant in the other series (Tab. 76): pos. 32 in 5.8S is mostly CCC**G**CAT as in the other series, but sometimes CCC**C**CAT (almost all strains of the *scaphoides-botryosporus* clade) and rarely CCC**A**CAT (*O. multiformis*); pos. 330 in the LSU D1 is mostly GG**C**GGG as in the other series (in series *Neodactylella* GG**C**GAG), but sometimes GG**G**GGG (all strains of the *scaphoides-botryosporus* clade) or GG**T**GGG (*O. multiformis* p.p. and a clade with *A.* '*superbus*' CBS 121.54 & 384.73 and *O.* '*auricolor*' B.L. 6225). Some further nucleotides at the few variable positions of LSU are species-specific and show interesting combinations.

Also pos. 123 of 5.8S varies between CAT**T**GGT and CAT**C**GGT, the latter being highly diagnostic for the *cladodes*-*botryosporus* clade and *A. koreensis*. This position is part of stem-loop B8 of 5.8S, in which series *Arthrobotrys* is otherwise highly conservative and concurs with two of the six variants observed in series *Neodactylella* (see Tab. 77).

Ecology. Members of series *Arthrobotrys* have predominantly desiccation-sensitive apothecia growing on a wide variety of woody and herbaceous substrates or are sometimes coprophilous or fungicolous. A certain desiccation tolerance was noted in *O. menageshae* and *O. auricolor* p.p. Species of this series occur worldwide, from boreal to tropical and from humid to semihumid regions.

Orbilia cladodes (Drechsler) E. Weber & Baral, **comb. nov.**, MB 829070 — Pls 949

Basionym: *Arthrobotrys cladodes* Drechsler, Mycologia 29(4): 463, fig. 2 (1937)

Etymology: *aranea*: referring to the web-like subiculum; *armeniaca*, *auricolor*, *vinosa*: referring to the golden-yellow, apricot, or wine-red colour of the apothecia; *curvatispora*, *drepanispora*: according to the curved spores; *brassicicola*, *daphnina*, *robiniae*: after the host genus; *caprina*: after the host *Salix caprea*; *cladodes*: in reference to the branching of the conidiophores; *irregularis*: after the variability of the node arrangement at the conidiophore apex; *karstenii*: in honour of the Finnish mycologist P.A. Karsten; *kirghizicus*: after the geographical origin, Kyrgyzstan; *superbus*: perhaps referring to the chain-like conidial clusters.

Typification: Great Britain, Leicestershire, Gopsall, branch of ?angiosperm, III.1854, A. Bloxam (K, lectotype of ***Peziza auricolor***, designated here, MBT202391); France, Gérardmer, Lac de Longemer, branch of *Alnus*, 25.IX.2000, J. Drechsler (holotype of ***A. cladodes***, illustration in Drechsler 1937a: fig. 2); USA, Wisconsin, *Pinus strobus* (CBS 297.84, CBS H-8895, RefSpec of *A. cladodes*, designated here). — Germany, Zootzen, trunk of *Quercus robur*, V.1908, W. Kirschstein (B, holotype of ***Orbiliella armeniaca***). — Czechia, Čimelice, branch of *Populus tremula*, 1.VIII.1969, M. Svrček (PRM 684767, holotype of ***Orbilia aranea***).

Misapplied names: Feltgen (1901: 36, on *Fagus*), as *O. luteorubella*, (: 37, on *Angelica*), as *O. rosella*; Fries (in sched., UPS 247614), as *O. xanthostigma*; Pfister (1994), as *O. fimicola*; Phillips (1887: 333, pl. 10 fig. 63), as *Calloria vinosa*.

Misinterpretation of *O. auricolor*: Rehm (1891: 447, fig. 10, 1891: 458, as *O. curvatispora*), = *O. xanthoguttulata*; Korf (1992), = *O. ?tenuissima*; Pfister & Liftik (1995) p.p., = *O. oligospora* (anamorph *A. oligosporus*); Baral in Rubner (1996: 92), = *O. elegans* (anamorph *A. psychrophilus*/*A. elegans*); Liu (2006: 51), = *O. javanica* (anamorph *A. javanicus*); Mo et al. (2005a), = *O. multiformis* (anamorph *A. yunnanensis*). Most authors prior to 1987 used the name *O. auricolor* in the sense of *Hyalorbilia inflatula*, e. g., Massee (1895: 148), Nannfeldt (1939: 244), Dennis (1960a, 1970: 352, 1978), Moser (1963), Bride & Caillet (1975), Ahmad (1978), Thind & Sharma (1980: 303), Chmiel (1982: 80), Ellis & Ellis (1985).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.3–)0.5–1.5(–2.5)((–4)) mm diam., (0.15–)0.2–0.35(–0.4) mm high (receptacle 0.08–0.17 mm), greyish-white, also carneous, cream-rosaceous(-violaceous), or (orange-)yellowish-ochraceous-amber(-chlorinaceous), translucent, round, sometimes sinuate to lobate-crenate when large, gregarious to densely aggregated, rarely scattered; disc slightly (to medium) concave to flat, margin ± thick, 5–10 µm protruding, smooth, finally medium convex, immarginate; sessile or mostly with short and broad stipe 0.1–0.28(–0.7) × 0.25–0.8 mm, superficial (or slightly immersed); dry bright ochre, honey-yellow, yellowish-orange-apricot, or rose, in about half of the collections with a white subiculum covering ± large areas around each apothecium. **Asci** *(30–)37–51(–60) × (3.3–)3.5–4.3 µm {21}, †(26–)30–48(–55) × (2.8–)3–4(–4.5) µm {26}, 8-spored, spores 3–5-seriate, (2–)3–4(–5) lower spores inverted {18} (rarely mixed), pars sporifera *(15–)20–30(–36) µm long; **apex** (†) slightly to strongly truncate (rarely slightly indented and laterally inflated); **base** with short to medium long, thick, sometimes flexuous stalk, T-, Y-, h- or H-shaped. **Ascospores** *(6–)7.5–12(–13) × (0.8–)1–1.3 µm {38} [~(9–)10–14(–15) µm actual length], †((6–))(7.3–)8–13(–14.5) × (0.7–)0.8–1.2(–1.3) ((–1.4)) µm {40}, narrowly subcylindric-clavate (subulate) to fusoid-clavate, apex rounded, base medium to strongly attenuated, (slightly to) medium to (very) strongly curved (falcate), in dead state slightly to medium curved; **SBs** *0.5–1.3(–1.8) × (0.3–)0.5–0.7(–0.8)((–1)) µm {22}, globose to cylindric-ellipsoid or tear-shaped, sometimes rod-shaped, apically narrowed to a (very) short, fine, often invisible filum, total length (1–)1.5–2.3(–2.7) µm. **Paraphyses** apically (uninflated to) slightly to medium (to strongly) capitate(-clavate), terminal cell *14–30 × (2.5–)3–4.5(–5.5) µm {11}, †(14–)18–25(–26.5) {6} × (2–)2.5–4.5(–5) µm {8}, lower cells *4–10 × (1.7–)2–3(–3.5) µm {9}, †(3–)5–11(–13) × 1.5–2.5(–3.5) µm {4}; unbranched at upper septum. **Medullary excipulum** 20–50 µm thick, of ± loose or dense textura angularis-globulosa-intricata, sharply delimited from ectal excipulum partly only towards margin by a 10–20 µm thick layer of t. porrecta, not gelatinized but in KOH sometimes ± gelatinized. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, vertically oriented t. globulosa-angularis-prismatica from base to margin, (40–)65–150(–200) µm thick near base, cells */†10–35((–45)) × 9–30 µm {12}; 40–50 µm thick at lower flanks, 20–30 µm thick at mid flanks and margin, oriented at a (50–)60–90° angle to the surface, marginal cortical cells */†(6–)8–15(–17) × (3–)4–8(–9) µm {21}, never forming individual cell rows; **glassy processes** absent {32} or more rarely present {20}, 0.5–3(–6) × 3.5–7 µm, (low to) high refractive, partly distinctly stratified, sometimes entire cortical cells thick-walled. **Anchoring hyphae** abundant, rarely sparse, */†(2–)2.5–6(–7)((–10)) µm wide, walls 0.2–0.4(–1) µm thick {31}, sometimes short-celled and moniliform, sometimes forming a loose t. (porrecta-)intricata(-angularis) 10–60(–100) µm thick, rarely gelatinized (southern Africa, H.B. 5768a). **SCBs** globose, in paraphyses 0.5–2 µm diam., in ectal excipulum 1–4.5 µm; **VBs** in paraphyses sometimes seen, several large or many small ones, globose to angular, low-refractive, hyaline {11}. **Exudate** granular to cloddy, hyaline, rarely yellowish-ochraceous, over paraphyses (0.1–)0.3–2(–3) µm thick, loosely or firmly attached, forming individual caps, at margin and flanks as a 0.3–3(–4) µm thick layer. — **ANAMORPH**: arthrobotrys-like (from ascospore isolate {6}, conidial isolate {2}, or natural substrate {23}). **Conidiophores** *~(70–)100–250(–300) µm long {8}, 4.5–7 µm wide at base, *2.5–4.5 µm wide below nodes, unbranched or sometimes branched, at nodes often (sub)apically proliferating, conidia formed on nodules or short denticles on ± inflated nodes (arthrobotryoid), occasionally on elongated denticles (sometimes with a separating cell, Pl. 951: 1h), ~5–15 conidia per node. **Conidia** varying in size and shape, also in position of septum: either *(18–)21–28(–32) × ((7–))(9–)10–12.5(–13.5) µm {4}, †18–24.5 × 9.5–15 µm {1}, obpyriform, with the upper cell usually distinctly wider and partly also longer than lower cell {3}, often with ± distinct basal protrusion, 1-septate; or *(13–)15–20(–25) × (6–)7–10(–12) µm {14}, †(15–)16–22(–25) × (7–)7.5–9.5(–11) µm {6}, cylindric-ellipsoid to slightly obpyriform, the 2 cells of ± equal size, exceptionally upper cell larger; with or without basal protrusion, 1-septate or exceptionally non-septate; sometimes mixed with non-septate **microconidia** of *11–19 × 5.3–8 µm {5} or 1-septate conidia of intermediate size. Trapping nematodes by means of 3-dimensional **adhesive networks**, forming loops with an inner diameter of (10–)12–17(–20) µm, outer diam. ~(20–)25–35(–45) µm, loop cells *(5–)5.5–7.5(–8) µm wide {1}. **Chlamydospores** not observed (but reported by Pfister & Liftik 1995).

Habitat: on moist ground or up to 1–1.5 m above the ground, mostly corticated, 3–60 mm thick **branches** and up to min. 20 cm thick **trunks or logs** of *Acacia* sp. {1}, *A. saligna* {1}, *Aesculus hippocastanum* {1}, *Alnus* sp. {1}, *A. glutinosa* {1}, *A. incana* {1}, *Baccharis halimifolia* {1}, *Bambusoideae* {1}, *Clematis vitalba* {1}, *Corylus avellana* {1}, *Cyphomandra betacea* {1}, *Daphne mezereum* {1}, *Fagus sylvatica* {8}, *Fraxinus excelsior* {1}, *Genista* sp. {1}, *Hedera helix* {2}, *Lavatera arborea* {1}, *Picea abies* {2}, *P. glauca* {1}, *Pinus pinea* {1}, *P. strobus* {1}, *P. sylvestris* {1}, *Populus* sp. {3}, *P. tremula* {4}, *Pyrus pyraster* {1}, *Quercus* sp. {1/1}, *Q. robur* {1}, *Rhus laurina* {1}, *Salix* sp. {2/2}, *S. ?alba* {1}, *S. aurita* × *caprea* {1}, *S. caprea* {1}, *Sorbus aucuparia* {1/1}, *S. torminalis* {1}, *Tilia* sp. {2}, *T. platyphyllos* {2}, *Ulex europaeus* {5}, *Ulmus* sp. {4}, *U. glabra* {1}, *U. minor* {1/1}, *Vitis vinifera* {1}, indet. climber {1}, indet. angiosperm {7/1}, on slightly to medium, also strongly decayed bark {62} (bast {20} or periderm {17}), more rarely wood {16}, exceptionally coniferous leaves {1}, often in holes in periderm caused by pyrenomycetes or anamorphic fungi, or on inner surface of bark; not greyed, no green algae; on **fruits** of *Aesculus hippocastanum* {1}, *Cocos nucifera* {3}, *Theobroma cacao* {1}, *Xylotheca kraussiana* {1}; **inflorescence stems** of *Xanthorrhoea australis* {1}; on previous year's **herbaceous stems**, **leaves**, **petioles** of *Adenostyles alliariae* {1}, *Angelica* sp. {1}, *Arctium* sp. {4}, *A. lappa* {2/1}, *Brassica oleracea* {2}, *Carex* sp. {1}, *C. vesicaria* {1}, *Digitalis purpurea* {1}, *Equisetum* sp. {1}, *Helleborus foetidus* {3}, *Heracleum sphondylium* {1}, *Humulus lupulus* {1}, *Iris foetidissima* {1}, *Lavatera* sp. {1}, *Lupinus arboreus* {2}, *Oenanthe crocata* {1}, *Oenothera biennis* {1}, *Onopordum acanthium* {1}, *Pastinaca sativa* {1}, *Petasites hybridus* {1}, *Phalaris arundinacea* {1}, *Phragmites australis* {1}, *Phoenix* (?)*canariensis* {1}, *Ranunculus repens* {1}, *Scirpoides holoschoenus* {1}, *Triticum aestivum* {1}, *Typha latifolia* {1}, *Verbascum* sp. {1}, *Yucca* sp. {2}, lying on moist ground or often at moist base when still standing, on epidermis or on epidermis-free areas; on **textile**: cloth {2}, tennis ball {1}; on **fungi**: *Bionectria ralfsii* {1}, *Diatrype stigma* {2}, ?*Cryptodiaporthe* sp. {1}, *Orbilia comma* {1, anamorph}, *Rosellinia* sp. {1}, *Thelonectria discophora* {1}, indet. crustose lichen thallus {1}; on **bone** of *Sus scrofa* {1}, **excrements** of *Capreolus capreolus* {2}, *Lepus europaeus* {1}, *Oryctolagus cuniculus* {3}. **Further associated**: *Arnium apiculatum* {1}, *Bionectria ralfsii* {1}, *Cistella grevillei* {2}, *Claussenomyces* sp. {1}, *Coprinus* sp. {1}, *Cyathicula starbaeckii* {1}, *Diaporthe arctii* {1}, *Diatrype disciformis* {1}, *Endoxyla* sp. {1}, *Graphium calicioides* {1}, *Herpotrichia macrotricha* {1}, *Holwaya mucida* {2}, *Hyalorbilia*

inflatula {1}, *H. juliae* {1}, *H. rotifera* {1}, *Karstenia rhopaloides* {1}, *Licea fimicola* {1}, *Melanomma pulvis-pyrius* {1}, *Nectria* sp. {3}, *N. pseudopeziza* {2}, *Orbilia aristata* {1}, *O. atlantis* {2}, *O. aurantiorubra* {1}, *O. caulicola* {1}, *O. comma* {1}, *O. oxyspora* {3}, *O. phragmotricha* {1}, *O. pilifera* {1}, *O. rubrovacuolata* {1}, *O. tenuissima* {1}, *O.* ?*clavispora* {1}, *Physcia* sp. {1}, *Pyrenopeziza* sp. {1}, *P. atrata* {6}, *P. caespiticia* {1}, *P. ranunculi* {1}, *Sporidesmium* sp. {1}, *Trichoderma citrinum* {1}. **Desiccation tolerance**: all asci dead after 1 hour, but sometimes some paraphyses and submature asci alive after 1 month, excipular cells still alive after 1 month, some spores viable after 21 months but in other material all spores dead after 4 months; conidia viable for at least 2 months. **Altitude**: 1–1000 m a.s.l. (temperate Europe), 20–1700 m (southern Europe), 170–500 m (Middle America), 2000–3500 m (Himalaya). **Geology**: Cambrian, Ordovician, Silurian & Carboniferous quartzitic wacke, schist, silt-, sand- & limestone, Permian (Rotliegend), Buntsandstein, Muschelkalk, Keuper (clay, marl & sandstone), Lower to Upper Jurassic limestone & shale, Cretaceous & Tertiary sand-, marl- & limestone, flysch, dolomite, Quaternary till, marl, silt & sand, peat; granite, migmatite, biotite-amphibolite & quartz diorite, mica schist, gneiss. **Phenology**: throughout the year.

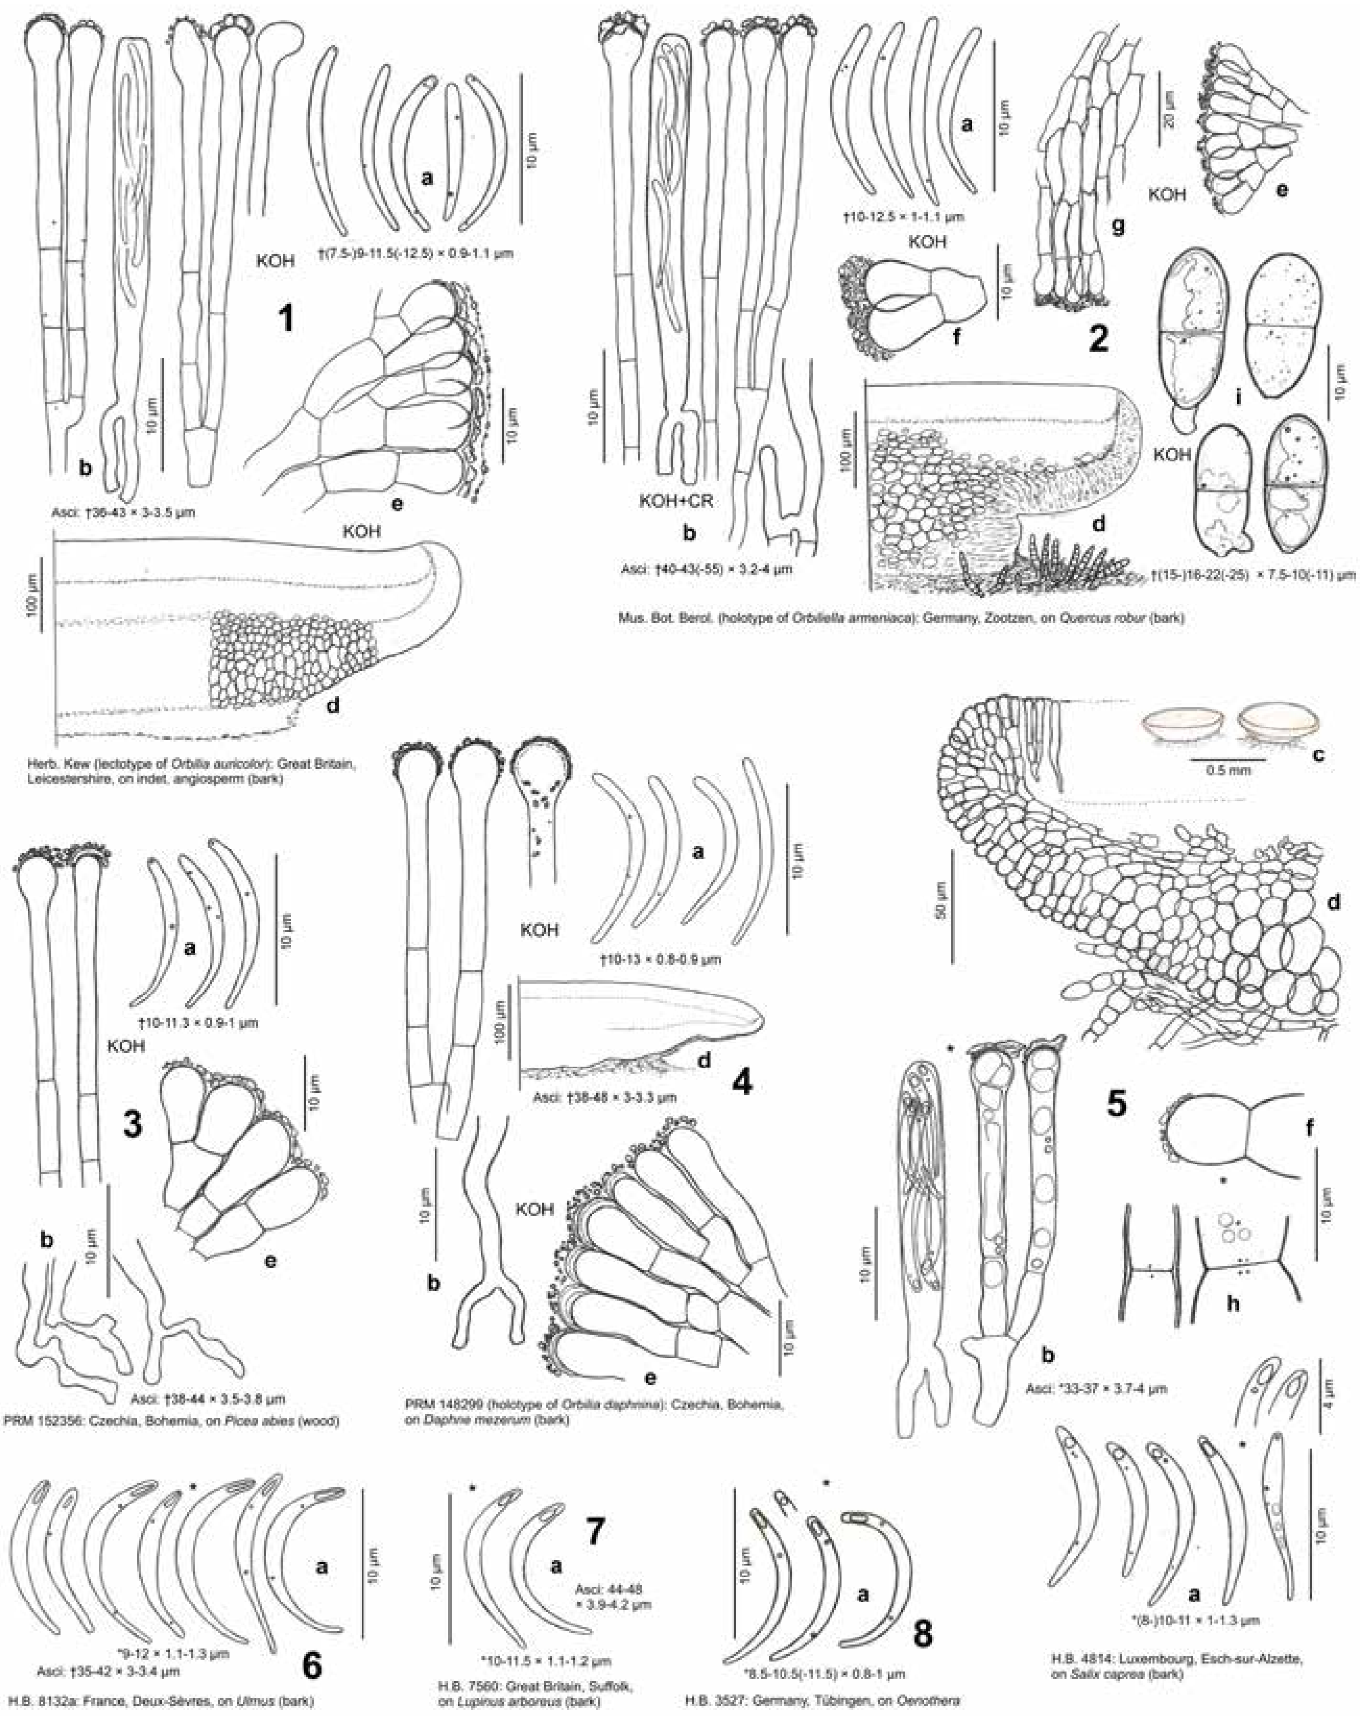
Phenology of *O. auricolor* s.l. (teleomorph, northern hemisphere, extra-tropical)											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
5	5	13	13	9	18	16	14	10	6	9	3

Taxonomic remarks. *Orbilia auricolor* s.l. (including *O. cladodes*) seems to be the most frequently collected species of series *Arthrobotrys* regarding the teleomorph, and also its anamorph was often isolated. In contrast, the teleomorph of the similar *O. oligospora*, of which many isolates of the anamorph exist, is known to us with certainty only from one record (Pfister & Liftik 1995).

The present concept of *Orbilia auricolor* s.l. includes specimens with the following characteristics of the teleomorph: ascospores *10–14 × 1–1.3 µm (actual length), medium to strongly falcate, distinctly tapered below, paraphyses ± capitate, marginal excipular cells oriented at a high angle to the surface, not forming distinct cell rows, glassy processes max. 3(–6) µm long, apothecial margin therefore smooth, anchoring hyphae comparatively wide (mostly 3–5 µm), conidiophores arthrobotryoid, conidia (0–)1-septate, *15–28 × 7–12.5 µm, with usually median to moderately eccentrical septum (length ratio of the upper/lower cell 1 : 1 up to 1.5 : 1, exceptionally > 2 : 1).

As a matter of fact, all taxa of series *Arthrobotrys*, for which a teleomorph is known, show more or less these characteristics in the teleomorph. Most of them can be recognized by their anamorph or by slight or clear differences in their teleomorph, while some appear to differ merely in their molecular data. Because conidia were not observed in the holotype of *O. auricolor*, the exact identity of this name remains unclear up to now. Possibly, future techniques will gain DNA from the type specimens of *O. auricolor*, *Orbiliella armeniaca*, and *Helotium karstenii*, or the authentic specimens of *O. curvatispora* and others.

For the time being, our concept of *O. auricolor* is undoubtedly heterogeneous from a molecular point of view. We here adopt the name *O. auricolor* s.str. in a restricted but still rather wide sense for the taxon being connected to an anamorph with arthrobotryoid conidiophores forming conidia that are reminiscent of *Arthrobotrys superbus*. For specimens with the very similar *A. cladodes*-like anamorph coupled with strongly deviating molecular data we use the name *O. cladodes*, and accordingly for specimens with an anamorph similar to *A. oligosporus* and corresponding molecular data we use the name *O. oligospora*. *A. macroides* appears to represent a further distinct taxon of this group, though without a known teleomorph at present (see p. 1576).



Herb. Kew (lectotype of *Orbilia auricolor*): Great Britain, Leicestershire, on indet. angiosperm (bark)

Mus. Bot. Berol. (holotype of *Orbiliella armeniaca*): Germany, Zootzen, on *Quercus robur* (bark)

PRM 152356: Czechia, Bohemia, on *Picea abies* (wood)

PRM 148299 (holotype of *Orbilia daphnina*): Czechia, Bohemia, on *Daphne mezerum* (bark)

H.B. 4814: Luxembourg, Esch-sur-Alzette, on *Salix caprea* (bark)

H.B. 8132a: France, Deux-Sèvres, on *Ulmus* (bark)

H.B. 7560: Great Britain, Suffolk, on *Lupinus arboreus* (bark)

H.B. 3527: Germany, Tübingen, on *Oenothera*

A clarification of this complex of taxa requires epitypification of *O. auricolor* and allied taxa, including *A. superbus*, *A. cladodes*, and *A. macroides*, together with a morphological and molecular study of these epitypes. In the following we propose reference specimens for *O. auricolor* and *O. cladodes* as a first step towards an epitypification. Only for *O. oligospora* we propose an epitype and provide a separate description, being aware that some collections

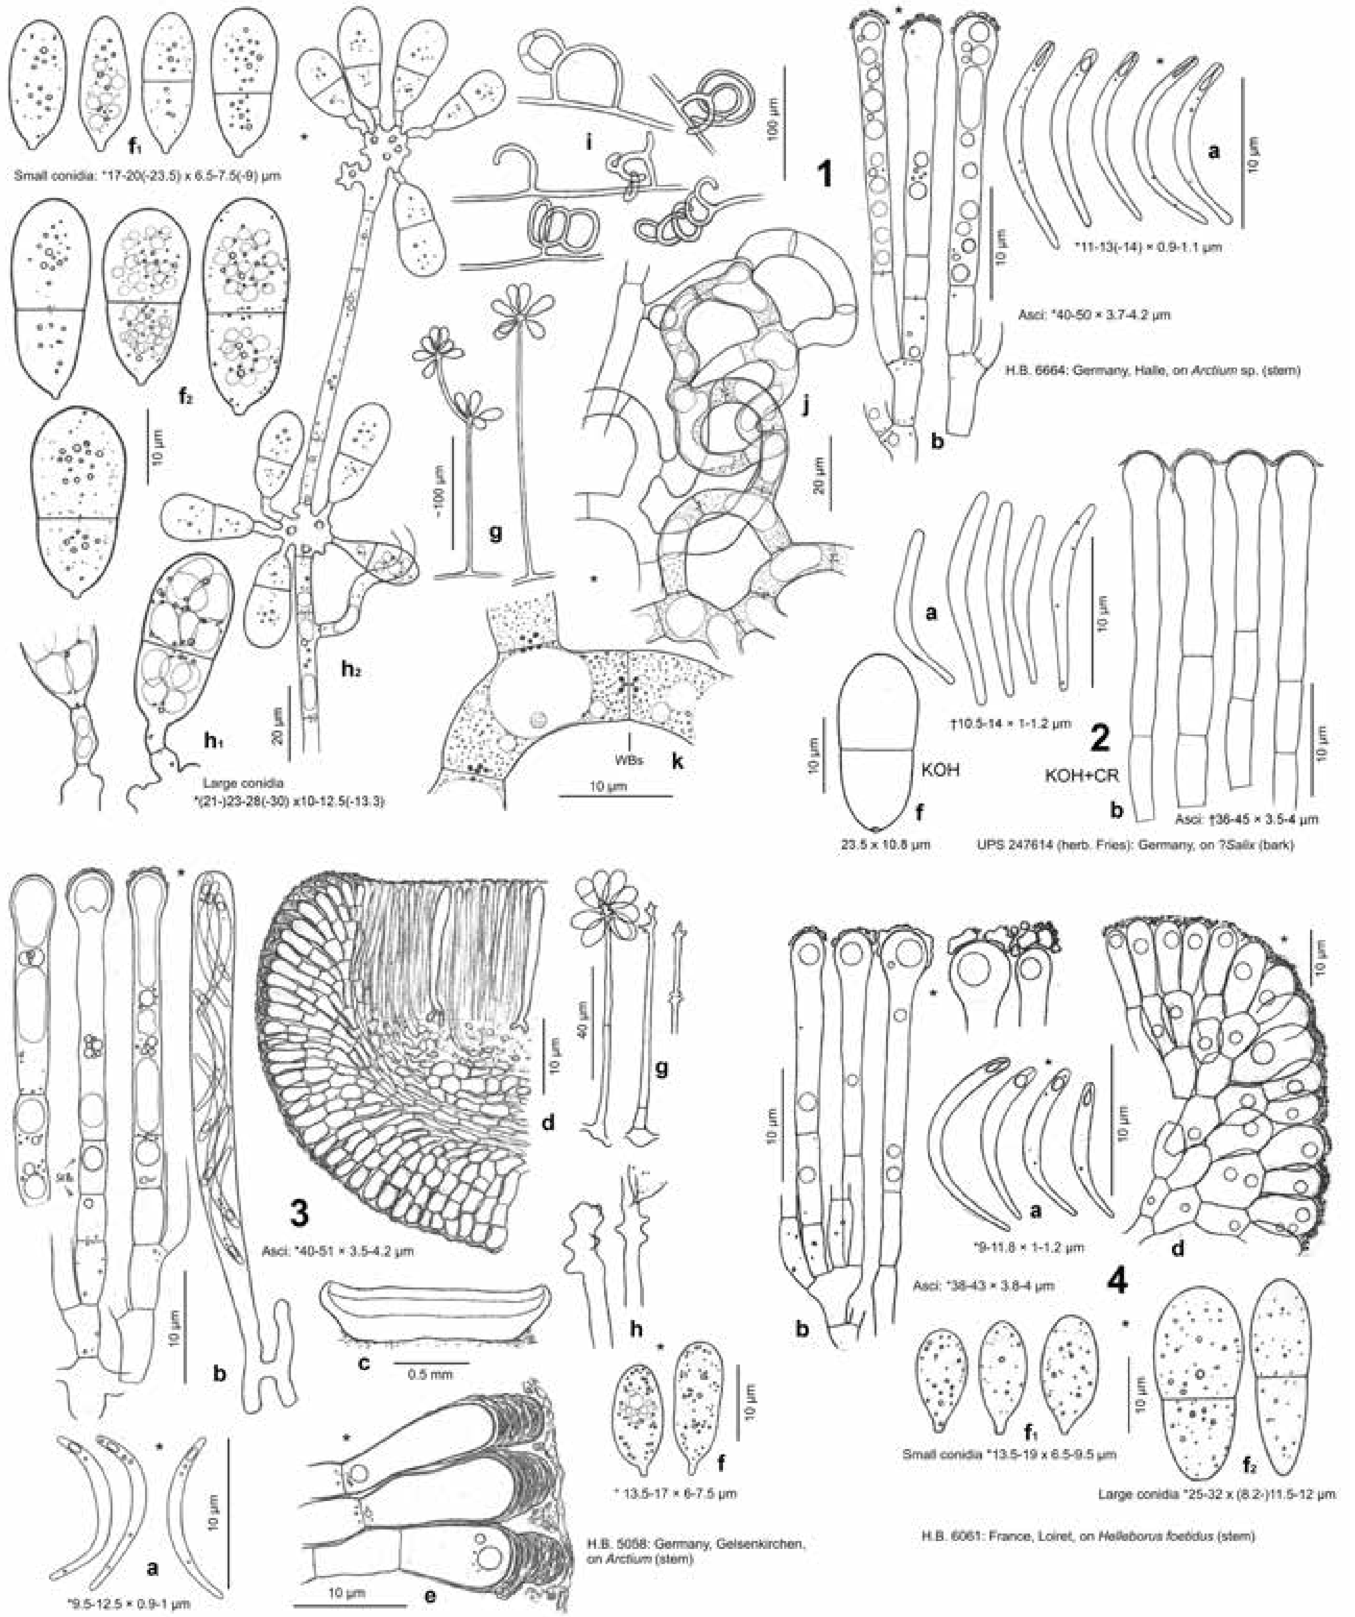

Plate 951. **1–4**: *Orbilia auricolor* s.l. – **a** ascospores; **b**. ascus and paraphyses; **c**. apothecium in median section; **d**. id., marginal region; **e**. id., marginal cortical cells with short glassy processes; **f**. conidia; **g**. conidiophores; **h**. conidiophore tips, arthrobotryoid conidiogenesis; **i–k**. adhesive networks (**k**. with WBs at septa) (**1f–k**. from culture; **3f–h**, **4f**. from substrate).

without anamorph and molecular data here included under *O. auricolor* possibly belong to *O. oligospora*.

Anamorphs within the *O. auricolor* aggregate, which corresponds more or less with the entire series *Arthrobotrys*, deviate in conidial shape and septation, type of conidiogenous loci and their aggregation at the conidiophore tip, and in branching and proliferation of conidiophores. *O. cladodes*, *O. elegans*, *O. menageshae*, and *O. oligospora* are virtually indistinguishable from *O. auricolor* as circumscribed here based on teleomorph characteristics alone, but more or less sharply differ in their anamorph. For instance, conidia of *O. oligospora* differ in having an eccentrical septum and a distinctly wider

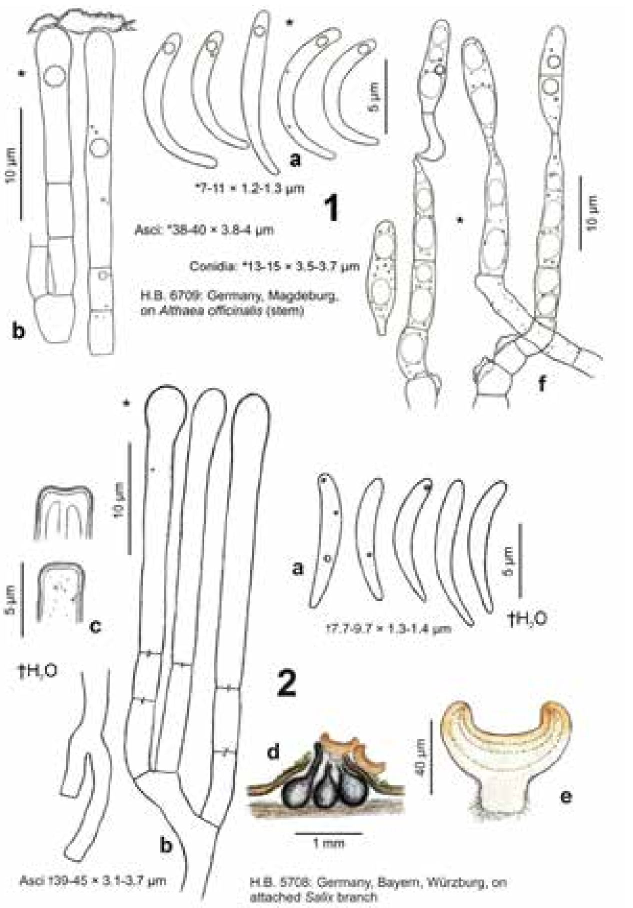

Plate 952. **1–2**: *Orbilia* cf. *auricolor*. – **a**. ascospores; **b**. paraphyses and ascus base; **c**. ascus apices; **d–e**. apothecia in median section, growing on ?*Cryptodiaporthe salicella*; **f**. conidiophores and conidia emerging from apothecia (perhaps a parasite?).

upper cell, but collections with intermediate conidia impede this distinction. *O. multiformis* differs from typical *O. auricolor* in slightly shorter, basally less tapered ascospores, but sharply differs in forming phragmo- and stauroconidia (Pl. 958). The ascospores of *O. javanica* as figured by Liu (2006) are short enough not to be confused with *O. auricolor*, also the marginal excipulum is oriented at a low angle, while the conidia are similar to *O. auricolor* but longer (Pl. 959). *O. latispora* s.l. differs in shorter and wider ascospores with basally tail-like ends and an anamorph similar to *O. cladodes* but with wider conidia (Pl. 971). *O. blumenaviensis* differs in protruding, ± lanceolate paraphyses without exudate, besides much larger, 1–3-septate conidia, and *O. terrestris* in much wider ascospores (anamorph unknown). Also for *O. scaphoides* (X.Z. Liu, BJ08-20) and *A. musiformis* (Z.F. Yu pers. comm.) a teleomorph was observed but the connection remained so far unpublished.

In a very broad sense, the *O. auricolor* aggregate comprises also taxa without an arthrobotrys-like anamorph. At least five species of series *Neodactylella*, viz. *O. oxyspora* (including *O. fimicola*), *O. dorsalis*, *O. clavispora*, *O. desertorum*, and *O. tenuissima* closely resemble *O. auricolor* in their hymenial characters. They differ in the marginal excipulum forming ± distinct cell rows oriented at a rather low angle to the surface, being often tipped by glassy processes. Their anamorphs, as far as known, are dactylella-like, i.e., without known trapping capabilities. Also two species of series *Dactylellina*, *O. rubrovacuolata* and *O. mammillata*, resemble *O. auricolor* but differ in consistently rod-shaped spore bodies without a filum, marginal cortical cells predominantly with glassy processes, and a dactylellina-like anamorph, the former also in usually bright red apothecia. Herbarium material of the teleomorph of these two species may easily be confused with *O. auricolor*. *O. leporina* and long-spored collections of *O. rectispora* or those mentioned under *O. epilobii* of series *Neodactylella* may also be confused due to their tendency to form slightly curved, basally tapered spores.

Variation in the teleomorph. The apothecial colour of *O. auricolor* s.l. is often whitish to pale cream-rosaceous but also yellow-ochraceous or even orange, especially in collections in which the apothecia are more light-exposed. Such stronger pigmented collections agree better with the species epithet '*auricolor*'. Collections with distinctly yellowish-ochraceous to apricot-orange apothecia were mainly encountered on bark (e.g., on *Ulmus* and *Tilia*), but rarely also on herbaceous stems (Pl. 953: 3) or on a bone (Pl. 953: 6, see also Fig. 116: a). Also one of the two North American samples treated by Pfister & Liftik (1995) and here referred to *O. cladodes* was described with yellow-orange apothecia (on bark, Pl. 949: 1). Svrček (1992) erected a new species *O. aranea* for samples on bark with yellowish-ochraceous apothecia and a conspicuous white subiculum. Possibly, the more yellow-orange populations tend to show a certain desiccation tolerance, but this could so far not be tested.

Sometimes, almost colourless and more intensely coloured apothecia occurred together, either in separate groups (Pl. 953: 9a–d) or intermingled (1a–b). In a specimen collected by O. Jaap (Pl. 953: 10) the pale cream apothecia had partly turned bright red due to some ageing process. Spooner observed a 'conspicuous yellowish to orange-yellow pigment' or 'yellowish sap' in many of the excipular cells in all specimens of *O. auricolor* examined, including the holotype. In the present study, however, no such intracellular pigment was ever clearly seen, neither in living nor dead material.

Although the ascospores with their subulate-falcate shape are quite characteristic, they show considerable variation in size, curvature, and strength of basal tapering. This variation is observed between populations, but generally also within an apothecium. A striking effect is that dead spores are less curved and consequently in situ slightly longer than living spores. The curvature of living spores varied in most collections between slight and very strong, therefore, the in situ length varies strongly within a collection. Nevertheless, the in situ length varied among the collections from *7–10 µm to *8.5–12 µm or rarely *10–13 µm. Spore bases varied from slightly to mostly medium to strongly attenuated, usually within a given collection.

Rather high variation was noted in the shape of the spore body, which is partly globose but often ellipsoid and sometimes tear- to rod-shaped. The attachment is generally by a short or longer, very fine or often invisible filum. The differences in SB shape possibly depend on the development stage, since globose and elongate SBs were partly observed in the same collection (e.g., Pl. 949: 1a, c).

Further variation occurs in the marginal cortical cells which are often ± short and broad and completely without glassy caps (e.g., in the types of *O. auricolor* and *Orbiliella armeniaca*, Pl. 950: 1–2, also in Pls 948: 1, 8; 949: 1–2; 940: 3, 5; 951 Fig. 4; and 953: 2). In other populations the cells are more elongate and narrow and often tipped by thinner or thicker glassy caps (e.g., in the types of *O. aranea* Pl. 948: 7 and *O. daphnina* Pl. 950: 4, also in Pl. 948: 4 and 951: 3), but sometimes they are without such caps (e.g., in the type of *Orbilia karstenii*, Pl. 948: 6). Although these glassy caps are quite conspicuous, their nature is not easy to determine because they are often covered by exudate or might consist of exudate instead.

The paraphysis apices usually vary within an apothecium from slightly to medium, sometimes strongly capitate, though in a few collections they are predominantly uninflated (e.g., Pl. 948: 3, 5). Also the exudate varies from nearly absent (e.g. Pls 948: 6; 949: 1–2; Pls 951: 2; 952: 2) to often thin-granular and firmly attached, or sometimes thick-cloddy and loosely attached (e.g., Pl. 948: 5, 7).

Misapplications. *Orbilia auricolor* belongs to the rather frequently misapplied names. The main misinterpretation lasted almost a hundred years when most authors prior to 1987 used the name *O. auricolor* in the sense of *Hyalorbilia inflatula* (see below). More recent reports concern the use of the name *O. auricolor* for teleomorphs connected with different anamorphs (see below). Misapplications of the name *O. auricolor* include also *Orbilia* spp. belonging to various other sections (*O. luteorubella*, *O. rosella*, *O. vinosa*, *O. xanthoguttulata*, *O. xanthostigma*, see under these species).

The only Macaronesian record of *O. auricolor* (Korf 1992, on ?*Laurus*) turned out to belong to a species of series *Neodactylella*, possibly *O. tenuissima*, according to a reexamination by L. Quijada (pers. comm.). No anamorph was detected, but the marginal excipulum of very distinct cell rows oriented at a very low angle clearly suggests such relationship (see Quijada et al. 2016).

Specimens treated by Pfister. Pfister (1994) and Pfister & Liftik (1995) investigated three collections from Massachusetts which they identified as two species, *O. fimicola* and *O. auricolor*, while they referred the obtained anamorphs to three different species of *Arthrobotrys*, *A.* cf. *superbus* (*O. fimicola*), *A. cladodes* var. *macroides* and *A. oligosporus* (*O. auricolor*). Reexamination of the teleomorphs of these three collections hardly revealed any differences worth mentioning (Pls 949: 1–2; 955: 1). All show the typical characters of *O. auricolor* as represented by the holotype from England (Pl. 950: 1). The latter (on a lichen, Pl. 955: 1) is treated here as *O. oligospora* according to its anamorph and DNA data, while the other two (on bark and dung) are considered to belong to *O. cladodes* based on their DNA data.

In the collection on deer dung (‘*O. fimicola*/*A.* cf. *superbus*’), the ascospores were longer and narrower (Pl. 949: 2) than can be evaluated from Pfister’s (1994) drawing: (6.4–)7.5–8.3 × (0.9–)1.1–1.2 µm (in situ), although both show about the same curvature (some of his spores might have been alive as he indicated SBs in two of them). This spore drawing would fit *O. latispora* (Pls 971–973), but our phylogenetic analysis shows *O. latispora* (clades C2/C3) to be specifically distinct from Pfister’s (clade C1), although both clustered in the *cladodes-botryosporus* clade (Phyl. 28). The paraphyses on Pfister’s drawing are abnormally inflated at the apex, quite untypical of *O. auricolor*, but they are much less inflated in the present reexamination (Pl. 949: 2b). The cells of the marginal excipulum are vertically oriented and not terminated by glassy processes (Pl. 949: 2f–g), unlike the type of *O. fimicola* (Pl. 934). Hence, Pfister’s specimen is obviously not conspecific with *O. fimicola*, which seems to belong to series *Neodactylella* close to *O. oxyspora*.

Unlike Pfister (1994), Pfister & Liftik (1995) described and illustrated the obtained anamorphs in detail, but hardly treated the microscopical features of the teleomorph, probably because of their close similarity. However, Pfister & Liftik saw slight differences in macroscopy: those apothecia growing on a lichen were fresh white to pale tan, broadly attached and broadly turbinate, whereas those on bark were fresh yellow to orange, centrally attached, lenticular. In the specimen on dung, Pfister (1994) illustrated ellipsoid SBs in two of the spores. When reexamined 21–29 months after collecting, only one of the three specimens (on bark, after 21 months) contained a few viable spores (Pl. 949: 1a, c) with partly globose, partly subulate SBs, the latter being only seen within the asci.

Nomenclature and Type studies. ***O. auricolor*** was described by A. Bloxam in a note published by Berkeley & Broome (1865), based on a single British collection on bark ‘on the underside of a fallen tree’ (in Saccardo 1889: 625 erroneously ‘on underside of fallen leaves’). The very brief protologue reads about as follows: apothecia soft, subgelatinous, orange, with a broad raised margin, springing from thin hyaline radiating filamentous layer of interwoven hairs, spores narrow. Both Nannfeldt (1939: 244) and Spooner (1987: 163) reexamined the type collection. Nannfeldt did not comment on the observed characters when he stated ‘*Orbilia inflatula* Karst.’ to be a synonym. Later (in Lundell & Nannfeldt 1946: no. 1388), he stated to have made a bad mistake when synonymising the two taxa, but did not specify the identity of *O. auricolor*. Based on Nannfeldt’s error, the epithet *auricolor* was continued to be misapplied over the next decades in the sense of *Hyalorbilia inflatula* (see also p. 342). It was only in 1987 when Spooner found that *O. auricolor* is conspecific with *O. curvatispora* based on curved spores and stipitate asci, but very different from *O. inflatula* which has straight spores and sessile asci.

The type material in K consists of six convolutes affixed to several sheets. All these convolutes bear a similar label and contain pieces of bark which undoubtedly belong to a single collection (B. Spooner pers. comm.). When ordered, one of them was received. This contained over 60 apothecia, and the present reexamination is based on this part of the collection. Spooner’s conclusion is fully confirmed. The spores were found to be wider (see Pl. 950: 1) than stated by him (10–11 × 0.5–0.8 µm), but concur with the measurements evaluated from his drawing (10–11.3 × 0.9–1.2 µm, in situ). Since only a single convolute is allowed to serve as nomenclatural type (ICN Art. 8.3, 9.1, Turland et al. 2018), we here designate specimen ‘AB [= A. Bloxam], March 1854, on the underside of a fallen tree. Gopsall Plantation’ **as lectotype** of *O. auricolor*.

Because of the molecular heterogeneity of *O. auricolor*, we here propose a European collection (H.B. 6763, CBS 116282, Pl. 948: 2), for which both a culture and sequence exists, as **Reference Specimen**, in order to give a first suggestion for the correct interpretation of the name in the future when the limits within this species complex will hopefully become clearer. This specimen was collected in a montane area of eastern France and grew like the lectotype from central England on angiosperm bark. It clustered in subclade A2 of our *O. auricolor* clade, to which also several British strains under names such as *A. superbus* and *A. pyriformis* belong (Phyl. 28).

Peziza vinosa in its original sense (non s. Albertini & Schweinitz 1805, see under *Orbilia vinosa*, p. 603) was proposed by Persoon (1801) for a caulicolous discomycete growing on 'rootstocks of larger herbs', with minute, round, sessile, subgelatinous, pale wine-coloured or rose, flat apothecia. Later, Persoon (1822: 303) changed the description by referring to a fungus on stems of *Urtica dioica*, with minute, round, subgelatinous, dull yellow-brown to flesh-coloured or rosaceous, shining, thin, flat, immarginate apothecia '½–¾ lin.' [ca. 1–1.5 mm] diam., fruiting in spring and at the end of summer, 'not to be confounded with *Tremella lacrymali*' [= *Dacrymyces sp.*].

In Persoon's herbarium in L two authentic specimens under the name *Peziza vinosa* (near Paris, VIII.1816, on herbaceous stem, 910.256–1356; on old cord, 910.261–343) exist. Both were examined in the present study and contained apothecia referable to *Orbilia auricolor* (with falcate, basally tapered spores †11–12 × 1.2–1.3 µm, IVV: H.B. 7702, 7703). From the date of the former and the substrate of the latter, both cannot be taken as lectotype material of *P. vinosa* Pers. (≡ *P. vinosa* var. *vinosella* Fr.), but it seems clear that Persoon (1822) included at least the caulicolous collection in his concept of *P. vinosa*. In the absence of older authentic material, it remains unclear whether Persoon had *O. auricolor* in hand when describing *P. vinosa* in 1801.

Fries (1822) changed the name *vinosa* to *vinosella* when treating Persoon's caulicolous taxon as a variety of Albertini & Schweinitz's lignicolous *Peziza vinosa* (see p. 604). No material under the name *Peziza vinosa* var. *vinosella* could be located in L, LG, and PC. A specimen in S labelled '?*Orbilia vinosella*' by Rehm (Italy, Südtirol, Bozen, Seis, *Aconitum napellus*, VIII.1907) was identified as *Laetinaevia carneopallida* by Hein (1976: 45). Grelet (1948a: 49) referred a collection on dead stem of *Lycopus europaeus* to *O. vinosa* var. *vinosella*. The detailed description appears to refer to *O. auricolor* or another member of section *Arthrobotrys*.

Helotium karstenii was described by Roumeguère (in sched.) to grow on rotten linen at Toulouse (France), with 1–5 mm large red apothecia with a partly undulating margin, turning light rusty-brown with age, and a 'pseudostipe' with a sparse whitish subiculum. The spores were said to be 'oblong, arcuate, ochre, 0.02 mm long, surrounded by a gelatinous substance'. Saccardo (1880: 78) examined a syntype specimen (probably from PAD) and found the spores to be 'bacilliform, 10–12 × 1 µm, slightly curved, hyaline'. He placed the taxon in synonymy with *O. luteorubella*, an opinion followed by Rehm (1882: 72, 1891: 455), Karsten (1885: 142), and Dennis (1964: 47). Dennis examined a syntype (probably from K) and described the spores as slender and rod-shaped, but appears to have seen them only within the asci, judging from his illustration.

In the two here examined syntype specimens of *H. karstenii* (from H and PC) the apothecia were rehydrated 0.5–1.5 mm diam., bright amber red-brown (PC) or pale cream (H). The microscopic features fit well *O. auricolor*: spore length is at the upper end of the range of *O. auricolor* and the marginal cortical cells of the narrow type. The original apothecial colour (concolorous red but getting paler ferruginous) suggests identity with *O. rubrovacuolata*. However, glassy processes could not be found, and the 1-septate conidia detected on the substrate fit well *O. auricolor*.

The protologue is handwritten but exists as copies (indelible autograph) in different herbaria, thus *H. karstenii* is validly published (ICN Art. 30.6, Turland et al. 2018). The specimen in PC (Pl. 948: 6) is designated here as **lectotype** of *H. karstenii.*

The holotype of ***O. curvatispora*** (Forêt de Montmorency, inner surface of *Quercus* bark, VII.1885, É. Boudier) could not be located in PC. The protologue and drawing (Boudier 1888) comprises white, hardly yellowish apothecia with smooth or scarcely subcrenulate margin, strongly capitate paraphyses, and strongly curved ('semicircular'), filiform, hardly tapering spores measuring 10 × (nearly) 1 µm but attaining 15 µm if stretched (actual length). In his Icones Fungorum Boudier (1904–10: 267, pl. 463) again illustrated the very same specimen on bark, but stated that he later found this species mainly on wood of *Quercus*. From his drawing a spore size of 8–12 × 0.9–1.1 µm (in situ) can be evaluated.

Two authentic specimens from Boudier's herbarium (PC) were examined and found to represent typical *O. auricolor*. One was collected in 1897 in Lyon, while the other is without collection data and also cannot be the holotype because the apothecia grew on the exterior of bark on detaching periderm, which does not look like *Quercus*. The very abundant apothecia are rehydrated 0.8–2 mm large (many over 1 mm, dry 0.7–1.7 mm) while in the protologue they are given as 0.6–1 mm. The spores in this undated collection have a size of 9–12 × 1 µm and are medium curved, the marginal cortical cells are clavate and without glassy caps, and do not form cell rows (IVV: H.B. 6896). A single arthrobotrys-like conidium (22 × 9.7 µm, 1-septate, cells nearly equal-sized) and some uninfected nematodes (partly still inside their eggs) were found on the subiculum of an apothecium.

In the absence of a type specimen, the illustration added to the protologue and the plate in Boudier's Icones Mycologicae must serve as holotype (Arts 8.1, 40.4 ICN). Future sequencing techniques might gain molecular data from the two authentic samples and permit selection of one as epitype of *O. curvatispora*.

For a collection from Himalaya (India) under the name *O. curvatispora*, Thind & Sharma (1980) figured straight or only slightly curved, fusoid, rather short and thick spores. Like in *H. karstenii*, the present reexamination of a duplicate in TAAM revealed typical spores of *O. auricolor* (distinctly sickle-shaped, basally tapered, †7.5–10 × 1–1.2 µm).

O. chrysocoma* var. *brassicicola from Luxembourg on stems of *Brassica oleracea* was at first invalidly described by Feltgen (1899: 55) as '?var. *brassicaecola*' under *O. chrysocoma*, with mostly curved spores of 10–15 × 1 µm. Later, Feltgen (1901) validly described this variety based on a reexamination of the same sample, with slightly curved, sometimes S-shaped spores of 8.5–10 × 0.75–1 µm. The present examination of the holotype revealed slightly to strongly falcate spores of 11–13 × 1–1.2 µm in situ (IVV: 7.IX.1896), and a marginal excipulum composed of broad cells oriented at a high angle, without glassy caps. No associated conidia could be found. The apothecia were described as 1–2 mm diam., yellowish, with undulating margin.

No type material of ***O. drepanispora*** could be located at B, H, L, and C. The taxon was described by Lindau (1904) without illustration. It was based on two collections from the Harz mountains in Germany: on naked wood of *Picea*, Kollieberg, Braunlage; on stumps of large *Picea*, Dicke Tannen, Hohegeiß. Lindau considered the taxon to be close to *O. curvatispora* (= *O. auricolor*), differing 'sharply' in the paraphyses terminated by a globose head and in the 'constantly more or less falcate spores' (7–12 × 1–1.5 µm). He compared his fungus with Rehm's description of *O. curvatispora*. Yet, Rehm (1891: 458) described the spores as worm-shaped (helicoid) and the paraphysis apices as egg-shaped inflated, with a yellowish oil drop. Rehm's interpretation clearly does not match the original concept of *O. curvatispora* but appears to refer to a specimen

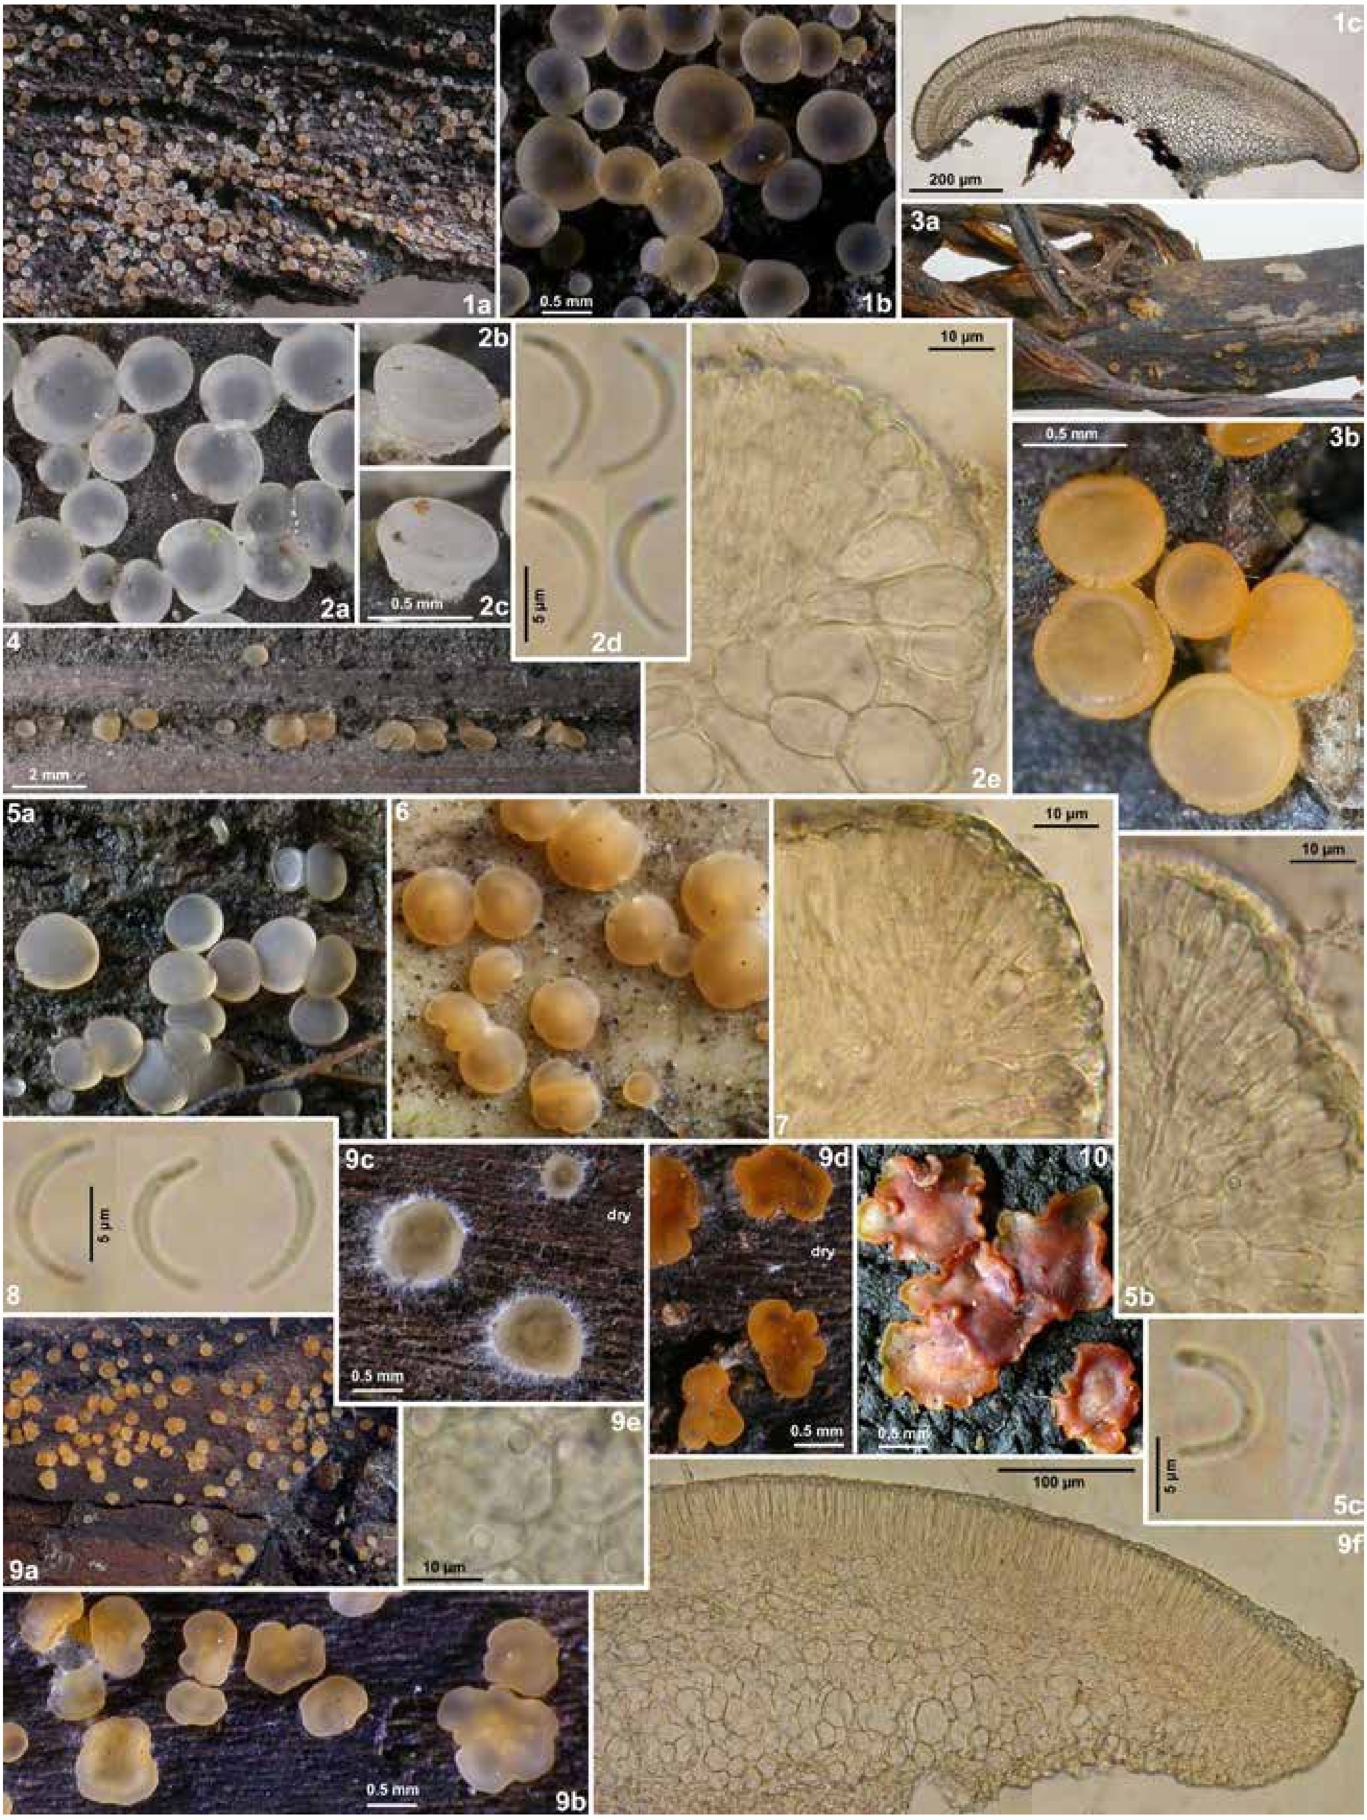

Plate 953. **1–10**: *Orbilia auricolor* s.l. – **2a–c**, **3a–b**, **5**. fresh apothecia; **1a–b**, **4**, **6**, **9a–b**, **10**. rehydrated apothecia; **9c–d**. dry apothecia; **1c**, **9f**. apothecia in median section; **2e**, **5b**, **7**. id., marginal ectal excipulum; **9e**. cells of ectal excipulum containing globose SCBs; **2d**, **5c**, **8**. ascospores. – Living state. – **6**: phot. of *O. xanthoguttulata* (see p. 851). Why Lindau asserted that Rehm reported a blue iodine reaction of the ascus tips remains mysterious. Lindau had obviously no access to Boudier (1888, 1904–10) and Saccardo (1889), where the spores of *O. curvatispora* are described as rather strongly curved (falcate) and the paraphyses distinctly capitate. These characteristics fit very well the protologue of *O. drepanispora*, which is tentatively placed here in synonymy with *O. auricolor*.

O. curvatispora* var. *robiniae was separated by Velenovský (1934) from the type variety solely by macroscopy ('apothecia 1–2 mm diam., ochraceous, scarcely lobate', no figure provided). No material exists of this taxon (Svrček 1954: 13) and no manuscript plate of Velenovský could be found (see also below under *O. aranea*). Similarly, Velenovský (l.c.) separated ***O. curvatispora* var. *caprina*** by wine-rose, not lobate apothecia of 0.5–1 mm diam. and spores of 5–8 µm, from the type variety for which he gave the spores as 8–15 µm. The spores are strongly arcuate on his manuscript plate, on which he also illustrated asci of 30–40 × 5 µm and medium clavate paraphyses. Also here no material could be found (Svrček l.c.).

O. daphnina was repeatedly collected by Velenovský on *Daphne mezereum* in his garden. Svrček (1954: 14) mentioned only one authentic collection in PRM. The rich material appears to have correctly been referred to *O. auricolor* (as *O. curvatispora*) by Svrček, according to the present reexamination (Pl. 950: 4), which revealed the apothecia to occur together with *Pyrenopeziza caespiticia*, often on old, black pycnidia erumpent beneath the periderm. The asci are larger than given by Velenovský (1934, 25–30 × 4 µm 'incl. stipe') and Svrček (35–37 × 4 µm) whereas the spores well concur with Svrček's (10–13 × 0.8–1 µm) or Velenovský's data (6–10 µm). The narrow marginal cells run under a vertical angle and are covered by very thin glassy cap. The abundant subiculum consists of comparatively broad hyphae (3.5–5 µm) with thick walls (0.3–1 µm), and covers the lower flanks as a 10–15 µm thick layer, but brown hyphae and small brown globose (?)conidia at the base of the apothecia as reported by Velenovský (1934) could not be found. The paraphyses are slightly to strongly capitate, each individual head being covered by rather small warts, in contrast to Velenovský ('slightly inflated, heavily covered by exudate').

Kirschstein (1938) described the new genus and species ***Orbiliella armeniaca*** (on bark of *Quercus*, northeastern Germany) mainly because of the whitish to very pale orange subiculum. Kirschstein seems to have overlooked the curvature of the spores which he described as filiform, 9–11 × 1 µm. The teleomorph features of the rich holotype (Pl. 950: 2), but also the associated anamorph (see below) clearly suggest conspecificity with *O. auricolor*.

Svrček (1992) described ***O. aranea*** because of the conspicuous white subiculum forming a dense mat up to 2 mm around the yellowish-ochraceous, 0.3–2 mm large apothecia, but did not discuss the differences to similar species. In addition to the holotype (on bark of fallen branches of *Populus tremula*, Czechia), Svrček identified as *O. aranea* also several samples 'on bark of accumulated branches of *Robinia*', which he earlier referred to *O. curvatispora* var. *robiniae*. The here examined holotype of *O. aranea* (Pl. 948: 7) well concurs with that of *O. auricolor*, except for the narrower marginal cortical cells (6–14 × 3–4.5 µm) which are tipped by 2–3 µm thick glassy caps. Svrček also mentioned these narrow marginal cells ('only 3–4 µm wide') but not the glassy caps. No conidia were found in association.

Svrček (1954) designated as lectotype of ***O. verrucosa*** a specimen on *Picea* from Mnichovice (PRM 152356) that represents *O. auricolor*. However, we found Svrček's selection to be against the Code, and here declare a specimen on *Pinus* from Vysoké Tatry (PRM 151737) as lectotype of *O. verrucosa* which appears to represent *O. rosea* (see p. 965).

Literature reports of anamorph-teleomorph connections. Three arthrobotrys-like anamorphs with didymosporous conidia and arthrobotryoid conidiophores have been obtained in ascospore isolates of *Orbilia auricolor* s.l. (incl. *O. cladodes*) in the here presented circumscription: Pfister (1994), as *Arthrobotrys superbus* s. Drechsler, from apothecia on dung, teleomorph misidentified as *O. fimicola* (Pl. 949: 2); Pfister & Liftik (1995), as *A. cladodes* var. *macroides*, from apothecia on bark, teleomorph as *O. auricolor* (Pl. 949: 1); Liu (2006: 52, pl. 11–12), as *A. cladodes*, from apothecia on wood, teleomorph as *O. auricolor* (IVV: HMAS 139635).

Other anamorphs reported as being connected to *O. auricolor* in a wider sense (*A. javanicus*, *A. oligosporus*, *A. psychrophilus* ?= *A. elegans*, *A. yunnanensis* = *A. multiformis*) are more easily recognizable. Three of them have acrogenous to candelabrelloid conidiophores and two have very differently shaped conidia. *A. javanicus* and *A. oligosporus* are not sharply delimited in conidial morphology from what we saw in our *O. auricolor* strains, nevertheless they strongly differ in their molecular data, the former also in candelabrelloid conidiophores.

The two anamorphs reported by Pfister (*A. superbus*) and Pfister & Liftik (*A. cladodes* var. *macroides*) resemble each other quite closely in conidial morphology when comparing Drechsler's drawings. Regrettably, Pfister did not describe *A. superbus* in detail. His photo shows a conidiophore with a single conidial cluster at the tip (Pl. 949: 1j), unlike *A. superbus* which is said to have typically a geniculate proliferation resulting in nodes in a chain (Drechsler 1937a: fig. 1). Perhaps therefore, Pfister identified the anamorph only 'tentatively' as *A. superbus*.

Two earlier observations already point to a conidial state of *O. auricolor*, though only on the natural substrate: Kirschstein (1938, on bark, type of *Orbiliella armeniaca*, Pl. 950: 2) reported 2-celled conidia of 18–20 × 8–9 µm formed on not further specified conidiophores that emerged from the subiculum. He regarded this as the anamorph and provisionally as belonging to the genus *Trichothecium*. Reexamination of the holotype suggests that these conidia might belong to *A. superbus*, but conidiophores were not observed. Velenovský described on an unpublished manuscript plate obpyriform conidia in association with '*Orbilia pyrifera*' (on stems of *Arctium*, 18.VI.1925; non *O. pyrifera* Velen. 1947 = *Hyalorbilia inflatula*). The teleomorph fits *O. auricolor*, but the 1-septate, 20–22 µm long conidia with the upper cell distinctly larger than the lower cell resemble those of *A. oligosporus* as described by Drechsler (1934a, see Pl. 955: 3), but also part of the conidia observed by us in some samples of *O. auricolor* (Pls 948: 5g; 951: 1f). Also here conidiophores were not described.

In a nematode-infested culture of *A. superbus*, Drechsler (1937a: 458, fig. 18 R) obtained apothecia of an unidentified discomycete, but he could not exclude a contamination. According to his figure showing inverse orientation of the lower spores within the asci, this fungus clearly belongs to *Orbilia*. With its short, clavate, slightly curved spores (~4.5–5.2 × 1–1.3 µm evaluated from scale) it resembles *O. flexispora* or *O. cyparissias* (incertae sedis).

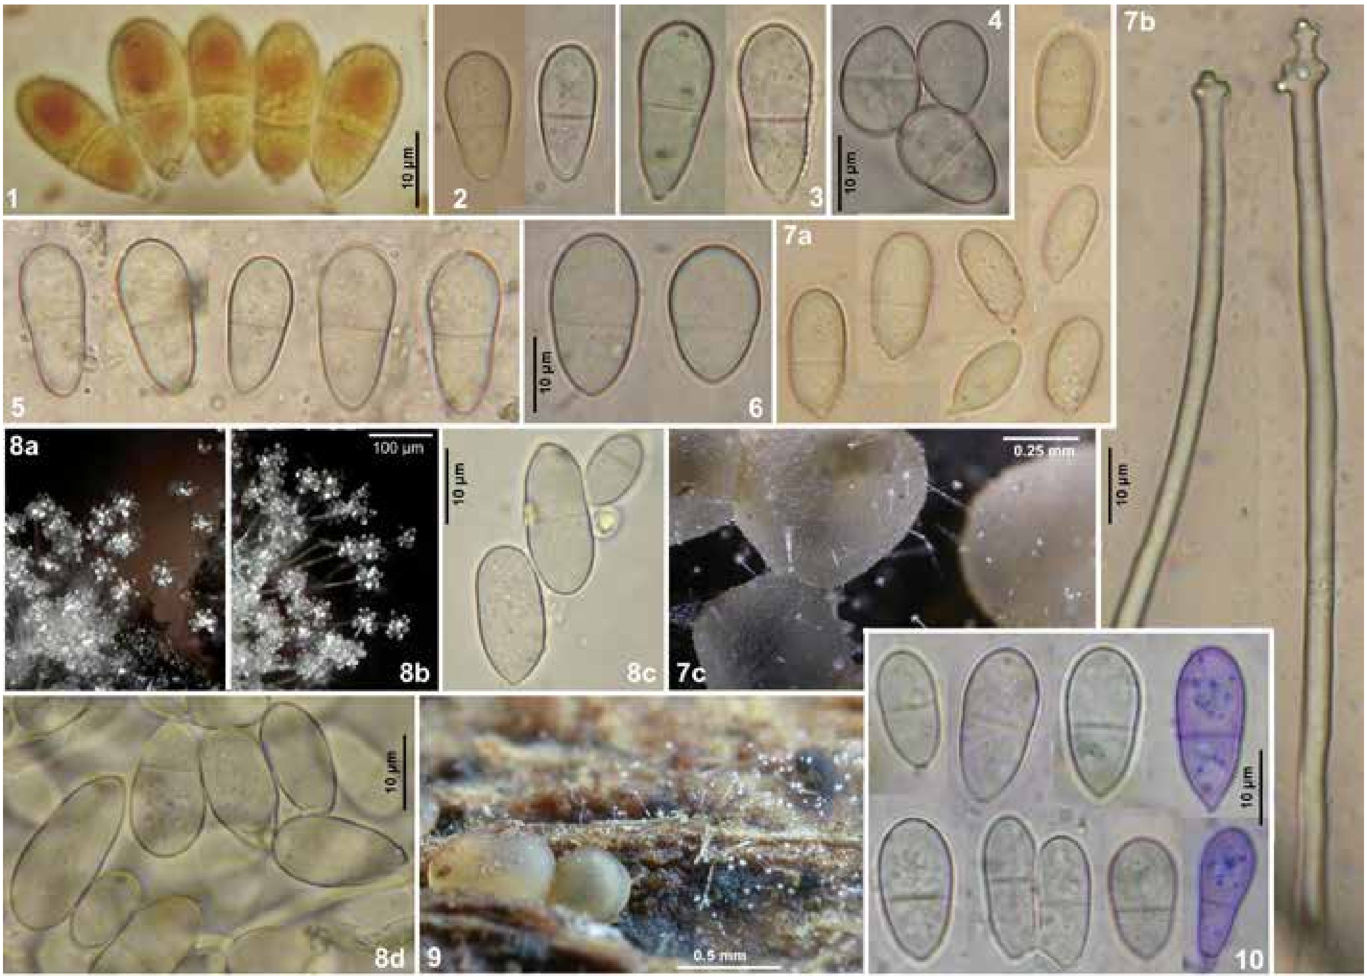

Plate 954. **1–10**: *Orbilia auricolor* s.l. – Conidia and conidiophores (**1–3**, **5–10**: from substrate, **4**: from culture, **9**: with two associated apothecia). – Living state (**10** p.p. in CRB), except for **1** (in IKI). — **1**. Anamorphs in present study. In 28 out of ca. 140 collections of the teleomorph here referred to *O. auricolor* s.l. an anamorph was observed, though often only some detached conidia. These anamorphs, which were either grown from ascospore isolates or mainly found on the natural substrate, varied more or less in conidial size, shape and septation among each other. Due to this variability and the ambiguous literature data, we were unable to decide to which of the described anamorph-typified taxa they can best be assigned. Our strains roughly fall into two morphological groups based mainly on conidial shape and size. Yet, no sharp border could be drawn among the two groups:

(1) three specimens with rather large, cylindric-ellipsoid to ± obpyriform conidia (Pls 948: 5; 951: 1, 4) resemble *Arthrobotrys oligosporus* var. *oligosporus*. However this taxon was described by Fresenius (1850) with much larger (up to ~36 × 18 µm), more strongly obpyriform or obovoid conidia, in which the upper cell is consistently larger than the lower cell (see p. 1540). Such conidia, albeit smaller, were only sometimes found in our specimens (e.g., Pl. 948: 5g, 4 larger conidia). The original description of *A. oligosporus* otherwise fits quite well our three specimens with rather large conidia. Based on conidial size and more equally sized cells, a further possible name for this anamorph is *A. arthrobotryoides* (Berl.) Lindau in the interpretation of Drechsler (1944a), Haard (1968), or Swe et al. (2008a), but Hoog & Van Oorschot (1985) regarded this species in the absence of type material as doubtful in its original sense.

(2) In the majority of our specimens we observed smaller, cylindric-ellipsoid or only slightly obpyriform conidia with ± equally sized cells (Pls 948: 2, 6, 8; 949: 2; 951: 3; 954: 1–3, 5, 7–10). These fit quite well *A. superbus* (but also *A. macroides*) as described by Drechsler (1937a, 1944a), Haard (1968), Jarowaja (1970), Van Oorschot (1985), or Swe et al. (2008a). Pfister & Liftik (1995) identified their collection as *A. cladodes* var. *macroides* apparently because of the presence of chlamydospores, size and predominantly median septation of conidia, and the kind of apical branching of the usually non-proliferating conidiophores. Drechsler distinguished his var. *macroides* also by conidia with a small basal protrusion, which is absent in typical *A. cladodes* but also in Pfister & Liftik's strain referred to var. *macroides*.

However, conidial size and shape varies within group (2). In some specimens the conidia were partly aseptate and comparatively small (Pls 951: 1, 3, 4; 954: 7). In such cases the conidia can usually be separated to some extent into a larger and a smaller type, the latter measuring *11–19 × 5.3–8 µm, but they are not sharply enough separated from the large ones to call them microconidia. Two types of conidia, though always 1-septate, were observed in the Italian sample on dung (Pl. 948: 5), the large ones resembling *O. oligospora*. Intermediate cases of short and wide, more obovoid conidia also occur (Pl. 954: 4, 6).

In a specimen on *Lupinus* (IVV: H.B. 7560) the aseptate conidia became larger and 1-septate after a few days in a moist chamber, whereas they remained small and non-septate under such conditions in the specimen on (?)*Sorbus* (Pl. 954: 7). Similarly, Drechsler (1937a) obtained in *A. oligosporus* only in nematode-infested cultures conidia typical of that species, whereas in cultures without nematodes smaller and less obpyriform conidia developed, comparable to ours.

Nomenclature of anamorph. The identity of the different anamorph-typified names that show morphological resemblance with the anamorphs observed within *O. auricolor* s.l. is difficult to determine. This difficulty originates from the observed morphological variability of the anamorph and the heterogeneous species concept of *O. auricolor* according to available DNA data. What makes classification within *Arthrobotrys* quite problematic is the fact that morphological data from the literature (Drechsler 1937a, 1944a, Haard 1968, Jarowaja 1970, Van Oorschot 1985) are often somewhat contradictory.

There are mainly three anamorph-typified names that come into consideration as the anamorph of *O. auricolor* s.l. as interpreted by us: ***Arthrobotrys superbus***, ***A. cladodes***, and ***A. macroides***. These are problematic in their morphological as well as molecular delimitation. Drechsler (1937a) cautiously distinguished between them, but he was aware of their close relationship.

Chain-like or geniculate proliferation and branching of conidiophores have currently been used as a key character to distinguish between ***A. superbus*** (with proliferation, unbranched) and ***A. cladodes*** or ***A. macroides*** (without proliferation, unbranched or branched), see Drechsler (1937a: figs 1–2, 1944a: fig. 1), Haard (1968), Van Oorschot (1985: figs 54, 61), and Swe et al. (2008a: figs 2, 6). Haard (1968) classified *A. superbus*, *A. oligosporus*, and *A. conoides* as unbranched. Yet, Van Oorschot found in cultures assigned to *A. superbus* that 'branching becomes increasingly evident with subculturing' compared to the natural substrate or fresh culture, and Jarowaja (1970: fig. 8) illustrated a Polish strain under the name *A. cladodes* var. *macroides* showing proliferation. Pfister (1994) and Pfister & Liftik (1995) figured only non-proliferating conidiophore tips in their strains referred to *A. superbus* and *A. cladodes* var. *macroides*, the latter with apical branches (Pl. 949: 1j, 2j). Proliferation occurred in five of the nine samples in which we observed conidiophores (see Pl. 948: 2; 951: 1g–h, 3g), but branching was generally not observed. In some other samples we only saw non-proliferating conidiophores (Pl. 954: 7b).

According to Drechsler (1937a, 1944a), Haard (1968), and Van Oorschot (1985), *A. cladodes* var. *macroides* has longer and narrower conidia with a small basal protrusion compared to *A. cladodes* var. *cladodes*, measuring *(13–)15–21(–26) × (5–)6–7(–8.2) µm vs. *(11–)13–16.5(–18) × (6.2–)7–8(–8.8) µm in var. *cladodes*, and also differs in the presence of chlamydospores. Confusion between the two taxa is exemplified by strain D.H.P. 90, which Pfister & Liftik (1995) identified as *A. cladodes* var. *macroides*, apparently because it formed chlamydospores in culture. Its sequence, however, falls in the clade of *O. cladodes* (Phyl. 28). This could mean that chlamydospores have been overestimated as a taxonomic character. Also it cannot even be excluded that Drechsler's two type strains represent a single species. Two further strains referred to *A. cladodes* var. *macroides* (CBS 120.54, 493.90) belong from their sequence data to the *O. auricolor* clade (see Phyl. S32 regarding CBS 120.54 which is the only strain studied by Van Oorschot under the name *A. cladodes* var. *macroides*).

Another taxon of relevance is *A. irregularis*, which was described by Matruchot (1892) as a variety of *A. superbus* and raised to species level by Mekhtieva. The illustrated conidiophore morphology suggests affinity with *A. conoides* and *A. macroides* rather than *A. superbus*. As conidial size he only gave a length of 25 µm and a maximum width of 12 µm for the upper cell and 8 µm for the lower cell. From the given magnification a size of ~18–31 × 8.5–11.5 µm can be evaluated, with the lower cell ~6.5–9.5 µm wide. This is larger than described in *A. conoides* and *A. macroides*.

A. superbus was described by Corda (1839) from the natural substrate with very long, unbranched conidiophores with 9–16 nodes with conidial clusters simultaneously formed at intervals along their entire length. Thereby, the conidiophore filament is apically hardly narrower than basally and seemingly unable to stay erect.

Jarowaja (1970) considered *A. superbus* as a species known only from the type collection, being non-predacious and characterized by conidia with double walls and strong constriction at the septa. However, her drawn copy of Corda's figure is rather inexact and incorrect, and the 'double wall' is merely a comparatively thick cell wall.

Van Oorschot's (1985) species concept of *A. superbus* is found to be rather heterogeneous when comparing available DNA data from 17 of a total of 18 strains studied by her. These data, which were obtained from alignment queries in the CBS database, suggest that she included in *A. superbus* mainly anamorphs referable to the *O. auricolor* clade (subclades A1–A2) and the *cladodes-botryosporus* clade (subclades C1, C3, see below and Phyl. 28), and two which are of unclear relationship (Tab. S7) Regrettably, she did not specify from which collections her drawings derive (Van Oorschot l.c.: fig. 61). Also the two strains of *A. cladodes* studied by her comprise both clades (CBS 297.84: subclade C1, CBS 433.81: subclade A1) (Phyl. 28, S32), and her single studied strain of *A. cladodes* var. *macroides* (CBS 120.54) belongs to the *O. auricolor* clade (subclade A1) (Phyl. S32, LSU). On the other hand, her concept of *A. pyriformis* also includes one species of *O. auricolor* (CBS 602.80, see Tab. 87).

A majority of Van Oorschot's *A. superbus* strains belong to subclade A2 of the *O. auricolor* clade, according to ITS data in the CBS database, but none with certainty to subclade A1, or they belong to the *cladodes-botryosporus* clade. In order to avoid more name changes than necessary, a reference specimen of *A. superbus* should be selected, perhaps among the CBS strains studied by Van Oorschot, preferably one of those European strains for which also ITS is available (Netherlands 263.83, 662.70; Belgium 507.83, 619.82). However, since we do not know any illustration that derives from one of these strains, we here refrain from proposing a reference specimen.

One of Van Oorschot's *A. cladodes* strains (CBS 297.84, USA, Wisconsin, *Pinus strobus*) belongs to the *cladodes-botryosporus* clade (subclade C1 = *O. cladodes*), and also two Chinese strains identified as *A. cladodes* are conspecific (HMAS 139635, Liu 2006: fig. 12; YMF 1.01839). The other of Van Oorschot's *A. cladodes* strains (CBS 433.81, UK) belongs in the *O. auricolor* clade (A1). Since *A. cladodes* was originally described from North America, we here designate CBS 297.84 (CBS H-8895) as **Reference Specimen** of *Arthrobotrys cladodes* (illustration: Van Oorschot 1985: fig. 54).

Not included collections. In a collection from Germany (on *Althaea*, H.B. 6709, Pl. 952: 1) the ascospores are only slightly (to medium) attenuated towards base, and an anamorph of unclear relationship was observed in association. The rather small, 0–1-septate conidia resemble microconidia and are formed singly at the tip of short conidiophores which appeared to have emerged from the marginal cortical cells. A further collection from Germany (on xeric *Salix* bark, Pl. 952: 2) and one from Algeria (on indet. bark, MPU, IVV: H.B. 5601) possess comparatively short and slightly curved ascospores (dead state) and their anamorph is unknown. A collection from Japan (on ?*Populus* bark, TNS-F-56841, IVV: H.B. 9991) is not included because of frequently slightly spathulate paraphyses.

In a collection from China, Guizhou (Z.F. Yu pers. comm., on indet. bark, IVV: gz-26) the teleomorph did not show any differences to typical *O. auricolor* (ascospores *8–11 × 1–1.2 µm, subulate, strongly tapered towards base, medium to strongly curved; marginal ectal excipulum vertically oriented, without glassy caps). In pure culture it formed 1-septate, cylindric-ellipsoid microconidia of *13.3–17.8 × 3.9–4.5 µm in brush-like arrangement on small nodules along the upper part of the microconidiophores, and 3-septate, cigar-shaped macroconidia of *23–28.5 × 4.8–5.5(–6) µm singly at the conidiophore tip. *Arthrobotrys iridis* resembles this isolate but has longer microconidia and much larger, partly branched macroconidia (see under *O. multiformis*, p. 1547).

The following three unidentified taxa lack anamorph data and are treated as ***O*. aff. *auricolor*** because their rDNA data place them very distant from *O. auricolor* and *O. cladodes*. (1) A collection from Serbia on *Iris* leaf (15.VI.2017, IVV) with whitish apothecia 0.6–1.5 mm diam. and medium curved ascospores (*9.3–10 × 1.1–1.2 µm) with tear-shaped SBs (*1.3–1.5 × 0.6 µm) clustered in vicinity of *A. pravicovii*. (2) Two collections from Luxembourg on xeric *Fagus* bark (IVV: 25.IX.2017, 27.XI.2018) have whitish apothecia 0.4–0.9 mm diam. and comparatively short, medium curved ascospores (*7–9 × 1.1–1.3 µm) with narrowly tear-shaped to almost filiform SBs (1–1.4 × 0.3–0.4 µm). They are phylogenetically related to (3) a collection from French Pyrenees on xeric *Fraxinus* bark (IVV: H.B. 10024) which has orange-ochraceous apothecia 1–2 mm diam. and comparatively short, strongly curved ascospores (7.5–8.5 × 1–1.3 µm) with ± tear-shaped SBs (~0.8 × 0.3–0.5 µm). No glassy caps occurred on the almost vertically oriented marginal excipular cells in all three taxa.

For the listed uncertain synonyms of *O. auricolor* see under Type studies and Anamorph. Their conspecificity with the here defined concept of *O. auricolor* s.str. cannot be ascertained without sequence data, but they are included in the description which comprises also *O. cladodes*.

Phylogeny. Sequences of the *O. auricolor* aggregate were available for a large number of samples (Tab. 81). Because of their high molecular and partly also morphological heterogeneity, the aggregate forms various clades across series *Arthrobotrys* (Phyl. 28). Two large clades, which are phylogenetically distant from each other, are called here *O. auricolor* clade (= *O. auricolor* s.str., with subclades A1–A2) and subclade C1 (= *O. cladodes*) of the *cladodes-botryosporus* clade. These clades include morphologically quite indistinguishable teleomorphs and anamorphs. Other clades in which *O. auricolor*-like teleomorphs occur, are the *scaphoides-pravicovii* clade, the *elegans-gampsosporus* clade, the *oligospora-musiformis* clade, *O. multiformis*, and *O. javanica*. Each of the former three clades is morphologically heterogeneous by including very different conidial types. Two unnamed clades clustered distant from the preceding: B.L. 6225 (as *O. auricolor*/*A. oligosporus*) appears to be related to two CBS strains: CBS 121.54 and 384.73 (as *A. superbus*); H.B. 10024 and G.M. 2017-09-25.1/2018-11-27.1 (all as *O. auricolor*, without anamorph data) form a supported clade.

When analysing SSU+ITS+LSU (Phyl. S33), two of the named clades received strong support (*O. auricolor*, *cladodes-botryosporus* clade) and two medium support (*oligospora-musiformis* clade, *scaphoides-pravicovii* clade). Besides *O. cladodes* (C1), the *cladodes-botryosporus* clade includes *O. latispora* s.l. (subclades C2–C3) and *A. botryosporus* (subclade C4), and the *scaphoides-pravicovii* clade includes also *A. macroides* (Phyl. 28). Characteristic nucleotides for these clades are listed in Tabs 82–83.

Table 81. Strains of *O. auricolor* s.l. (forming morphologically ± indistinguishable anamorphs and/or teleomorphs) with available rDNA data gained from apothecia (ap), ascospore isolates (ai), conidial isolates (ci). A = *O. auricolor* clade, C = *cladodes-botryosporus* clade, S = *scaphoides-pravicovii* clade, * = RefSpec of *O. auricolor*, # = teleomorph not observed. § = anamorph not observed; (+) = unavailable sequence at CBS, for H.B. 8898a only S1506 intron available. Note that present description of *O. auricolor* includes clades A1/2 and C1 because of paucity of molecular identifications.

Also when analysing the S1506 intron, *O. auricolor* (except CBS 109.52) and *O. latispora* s.l. of the *cladodes-botryosporus* clade formed two distant, strongly supported clades (S30). Surprisingly, *A. superbus* (CBS 109.52, subclade A2) and *A. botryosporus* (subclade C4) clustered, contrary to ITS and LSU analyses, in a separate, unsupported clade together with *O.* cf. *elegans* (subclade E2) and *O. multiformis*. CBS 109.52 nested with a 2.5% distance close to *O.* cf. *elegans* while differing by ~10.5–11.5% from the *O. auricolor* clade. In comparison, the distance between the *O. auricolor* clade and the *cladodes-botryosporus* clade, or between the latter and the *elegans-gampsosporus* clade lies around 11.5–18.5%. The intron of CBS 109.52 differs from other strains also in having about double length. This intron and the ITS region were twice sequenced (U51949, Liou & Tzean 1997; KT215210, G. Hagedorn), with almost the same result (1 nt and 2 gap deviation).

Cladodes-botryosporus **clade** (with subclades C1–C4). In Pfister's (1997: fig. 12) phylogenetic analysis of the ITS region, his two North American strains (D.H.P. 60 and 90) clustered in a strongly supported clade and their close morphological similarity is supported by a 0.8% distance (4 nt, 1 gap), hence we conclude that they are conspecific. In the analysis by Hagedorn & Scholler (1999: fig. 2), Pfister's two strains clustered with *A. botryosporus* (CBS 321.83) and *A. pravicovii* (as *A. conoides*, SBUG-M12) in a clade. In our analysis of ITS (Phyl. 28), *A. botryosporus* (subclade C4) clustered in the *cladodes-botryosporus* clade, whereas *A. pravicovii* formed with *O. scaphoides* the medium supported *scaphoides-pravicovii* clade which clustered in our combined analyses with strong support sister to the *cladodes-botryosporus* clade (Phyls 25, S33), although both *A. botryosporus* and *A. pravicovii* show a similar distance of 4–5% to Pfister's strains.

A. cladodes (subclade C1) comprises at present eight strains. The ITS region was available for seven of them: Pfister's two from Massachusetts (D.H.P. 60 & 90), two from China (Beijing, HMAS 139635; Yunnan, YMF 1.01839, both as *A. cladodes*), one from Lithuania (GU062287, as *Arthrobotrys* sp.), one from Finland (CBS 367.75, as *A. superbus*), and one from Wisconsin, USA (CBS 297.84, RefSpec of *A. cladodes*), but exists also for CBS 107.81 (from Belgium, as *A. superbus*). Their variance lies in the range of 0.2–1.5%, the closest (0.2%) between D.H.P. 60 and the Wisconsin strain. For D.H.P. 60 the intron is absent whereas for CBS 367.75 and CBS 107.81 the S1506 intron exists in the CBS database (Tab. 81).

Subclades C2 and C3 include seven strains of *O. latispora* s.l. which has characteristic, shorter and wider ascospores (Pls 971–973), and subclade C4 represents the ex-type strain of *A. botryosporus* with non-septate conidia (Phyl. 28). Subclades C2–C4 show an ITS distance of 3.3–5.5% to subclade C1. The *cladodes-botryosporus* clade comprises only taxa with 0–1-septate, ellipsoid-ovoid conidia, whereas the *scaphoides-pravicovii* clade includes 1-septate, ellipsoid-ovoid conidia (*A. pravicovii*, A. *macroides* SBUG 160) as well as much larger, 2–4-septate fusiform conidia (*O. scaphoides*, Pls 974–975). *A. koreensis* with 1-septate, obovoid conidia clustered unresolved in regard to these two clades (Phyl. 28). But even *O. scaphoides* and *A. koreensis* differ from subclade C1 by only 4.5–5%.

When analysing LSU, subclades C1–C4 are not clearly resolved (S32). Eight LSU sequences belonging to clade C were available in GenBank and two unofficial ones in the CBS database. They include four Chinese strains under the names *A. cladodes* (YNUCC 3528) and *O. auricolor*/*A. cladodes* (B.L. 6141, 6202, X087; Liu 2006: figs 11–12). Also the unofficial LSU sequence of the RefSpec strain of *A. cladodes* from Wisconsin (CBS 297.84) and a strain from Finland (CBS 367.75, as *A. superbus*, MH872670, not shown), clustered, besides a strain from Oman (CBS 109508, as *A. javanicus*), an environmental strain from USA, *A. botryosporus*, and *O. cf. latispora*, in the *cladodes-botryosporus* clade. Only three of these strains possess also ITS (B.L. 6202, CBS 297.84, 367.75) and permit recognition of the subclade. When assuming that pos. 541 of LSU D2 (Tab. 83) is characteristic for subclade C1 (C**TT**, vs. C**C**T in subclades C3, C4, and environmental strain O34), then the critical B.L. X087 and CBS 109508 belong to subclade C1.

In a phylogenetic analysis of the ITS+LSU region by X.Z. Liu and X.Z. Jiang (pers. comm.) presented in Amsterdam in 2012, in which many strains comprised only ITS and some only LSU, the three Chinese HMAS strains clustered in a clade with Pfister's strains (subclade C1). The four Chinese strains with LSU deviate from each other by 1–2% in the D1–D2 domain, whereas the available LSU sequences of the *O. auricolor* clade deviate from each other by only 0–2 nt and 0–1 gaps, including an unofficial one from Texas (CBS 349.76). However, the *cladodes-botryosporus* clade differs in this region from the *O. auricolor* clade merely by 1.2–2.5% and from *A. macroides* (SBUG 160) and *O. scaphoides* by 1.3–1.7%. Specific nucleotides that separate these clades are listed in Tab. 83.

The S1506 intron was available within the *cladodes-botryosporus* clade in three sequences of the Asian *O. latispora* s.l. (C2–C3) but in none of clade C1 (*O. cladodes*). However, the intron exists for two strains in the CBS database (Tab. 81), showing distant affinities to *O. latispora* s.l., particularly to subclade C3.

O. auricolor **clade** (with subclades A1–A2). This clade differs from the *cladodes-botryosporus* clade by 8–10% in the ITS and by 1.2–2.5% in the LSU. In Hagedorn & Scholler's analysis it includes two British strains isolated and identified by Duddington as *A. cladodes* (CBS 433.81, UK, with unknown ecology) and *A. superbus* (CBS 109.52, UK, Surrey, apparently the strain from horse dung named *A. conoides* by Duddington 1951). The two strains show an ITS distance of 2.3% to each other, hence could be conspecific. Our two central European ascospore isolates (H.B. 6664, Sachsen-Anhalt; H.B. 6763, Vosges) likewise deviate from each other by 2% (10 nt and 13 gaps) and each clustered with one of Duddington's strains by forming two supported subclades, A1 and A2 (Phyl. S33, see also Phyl. 28).

Subclade A1 includes four strains: H.B. 6664 and H.B. 9208 (Corse) with a 0.2% ITS distance and a characteristic deletion of 5 nt near the 3'-end of ITS2 where most other members of series *Arthrobotrys* have CCTAC, also *A. cladodes* (CBS 433.81) and *A. pyriformis* (CBS 340.94) with a 0.4–0.6% distance from those. Subclade A2 includes H.B. 6763 (RefSpec of *O. auricolor*) and G.M. 2014-10-11.3 (Luxembourg), which fully concur in the ITS, H.B. 8898a (Sachsen), for which only the fragmentary S1506 intron was available (not shown), four partly unofficial sequences under the names *A. superbus* (ATCC 96676, California; CBS 115.61, MH857992; Québec; CBS 619.82, Belgium) and *Geniculifera cystosporia* (CBS 130.83), which differ in the ITS by 0–0.4% from the former strains, and three environmental isolates. Duddington's *A. superbus* (CBS

Table 82. Nucleotide positions in the ITS1-5.8S-ITS2 region that separate different groups within the *O. auricolor* aggregate: 26 positions differ between the *cladodes-botryosporus* clade (C1–C4) and the *O. auricolor* clade (A1–A2), additional 6 positions between C1 (*A. cladodes*) and *O. auricolor (*A1–A2), and 11 positions between A1 and A2. Note frequent identity of subclades A, E, and O32, and likewise within clade C. – A1 = subclade with H.B. 6664, A2a = CBS 109.52 and isolate 2569, A2b = remaining strains (including H.B. 6763 = RefSpec of *O. auricolor*), C2 = *O. latispora*, C3 = *O.* cf. *latispora*, C4 = *A. botryosporus*, E1 = *O. elegans*, E2 = *O.* cf. *elegans*, E3 = *A. gampsosporus*, O32 = *Arthrobotrys* sp. 109.52) matches with only 1 gap difference an unidentified Chinese isolate from *Ophiocordyceps sinensis* (HM439570) by showing at least 1 % ITS distance to the other strains of subclade A2 (Phyl. 28). Further, apparently incomplete ITS sequences in the CBS database under the names *A. superbus* (CBS 507.83 Belgium; 662.70, Netherlands) or *A. cladodes* var. *macroides* (CBS 493.90, Tenerife) also show min. 1 % distance to the above sequences (not shown). Hence, *O. auricolor* s.str. is not restricted to the European continent, but occurs also in California, Canada, Macaronesia, and the Antarctic (all subclade A2), and similarly *O. cladodes* (subclade C1) includes strains from North America, eastern Asia, and Europe.

Two strains which were at first identified as *A. robustus* and later as *A. pyriformis* belong in the scope of the *O. auricolor* clade: CBS 340.94 (Berlin) to subclade A1 and CBS 602.80 (?UK) to subclade A2. The latter strain was said by Van Oorschot (1985) to have been isolated by Duddington (the CBS database says 'isolated by the Boots Pure Drug Co., 1963') and to belong to *A. pyriformis*, but its unofficial sequence deviates from other *A. pyriformis* strains while showing a 3.5 % ITS distance to *O. auricolor* (H.B. 6763) as closest match.

When analysing LSU, subclades A1–A2 are more or less recognizable (S32), differing by 1 nt (pos. 579: AG**T**CC vs. AG**C**CC). Within subclade A1, four strains are identical in the D1-D2, including CBS 120.54 ('*A. cladodes* var. *macroides*'), whereas CBS 340.94 deviates by 1 nt at pos. 565 (Tab. 83). Within subclade A2, 15 strains form two identical groups with 1 nt deviation at pos. 459 between them: CT**T**CC in 11 strains vs.

Table 83. Eight nucleotide positions in the LSU D1–D2 domain (16, 330, 511, 522, 567, 574, 585, 601) that separate within the *O. auricolor* aggregate the *cladodes-botryosporus* clade (C1–C4) from the *O. auricolor* clade (A1–A2), together with some other informative positions, in comparison with *O. scaphoides*, *A. pravicovii*, *A. macroides* (SBUG 160), *A. cystosporius*, *O. menageshae* s.l., the *elegans-gampsosporus* clade (E1–E3), *Arthrobotrys* sp. ATCC MYA-4125 (O32), '*A. superbus/oligosporus*' (CBS 121.54 & 384.73, B.L. 6225), *O. oligospora*, and *O.* aff. *auricolor* (G.M. 2017-09-25.1/2018-11-27.1, H.B. 10024). Note frequent identity of clades A, E, O32, and *A.* '*superbus/oligosporus*'. Pos. 522+523 characterize the *scaphoides-pravicovii* clade. – Position numbers starting with TGACCT by omitting predominant gaps in alignment of all groups of *Orbiliomycetes*. Column 'Str.' gives number of strains, whereby pos. 14–53 were not available in all strains of a clade, likewise two strains of the *elegans* clade do not cover pos. 601. * = variants of C1 occurring singly or in combination in B.L. 6262, B.L. X087, and YNUCC 3528.

Subclade	Str.	14–26	50–53	133–6	201–4	328–333	510–523	538–42	565–8	574–79	583–87	599–603

CT**C**CC in four strains (including H.B. 6763). The heterogeneity of the 11 strains in S32 is mainly due to incompleteness of some sequences.

The S1506 intron was available in two North American and six European strains. Two strains of subclade A1 and two of A2 each show full identity, while CBS 115.61 (not shown) and ATCC 96676 fall in subclade A1 with a 0.3 % and 2 % distance, respectively, and CBS 340.94 falls in subclade A2 with 0.8–1.1 % distance. The distance between subclades A1 and A2 lies at 4–6 %. A very fragmentary, unpublished sequence which only includes the fragmentary intron (H.B. 8898a) falls in subclade A1.

***O.* aff. auricolor**. A sequence from the Serbian collection on *Iris* (TU(M) 104916, ITS+LSU, presence of S1506 intron uncertain) clustered in the *scaphoides-pravicovii* clade (Phyl. 28) by showing an ITS distance of 1.9–2.3 % to *A. pravicovii* and 3.1 % to *O. scaphoides*. In the LSU it differs from *A. macroides* (SBUG 160) merely by 1 nt, although the ITS distance is 3.5 % here. We assume that it represents a species of its own related to monocotyledonous substrates, from which also *A. pravicovii* was once isolated (see p. 1577).

Sequences of the two mentioned samples from Luxembourg (on *Fagus* bark, G.M. 2017-09-25.1/2018-11-27.1) comprise SSU+ITS+LSU and possess the S1506 intron. They merely differ by 1 nt in the ITS and formed a strongly supported clade with the sample from French Pyrenees (on *Fraxinus* bark, H.B. 10024, S1506 intron absent), with an ITS distance of 7 % (1 % in LSU D1–D2). This clade clustered unsupported near *A. nonseptatus*, *A. polycephalus*/*A. ellipsosporus*, or *A. reticulatus* (Phyl. 25, 28, *Fagus* strains not shown), all representing basal species with unknown relationship within series *Arthrobotrys*, or even unsupported with *O. quercus* of series *Dactylellina* (S33).

It seems well possible that some other collections with yellow to orange apothecia and a more or less xeric habitat here accepted in *O. auricolor*, including the types of *O. aranea* and perhaps even *O. auricolor*, belong to H.B. 10024. Since variation from whitish to yellow-orange was observed within populations here referred to *O. auricolor* s.l. (e. g., Pl. 953: 9), macroscopic recognition of different genotypes appears to be impossible. A molecular extract (ITS2) from a *Picea* log in northwestern Russia (Karelia) matches H.B. 10024 except for 5 nt and 2 gaps (denovo367, Kazartsev et al. 2018). Almost identical with the two samples from Luxembourg in the ITS and fully so in the LSU is a strain in CBS which is visible only as a restricted item in the database, and which represents an isolate of W. Gams under the name *Arthrobotrys entomopagus* (G. Verkley pers. comm.).

Specific nucleotide positions. Characteristic motifs in the alignment of ITS1-5.8S-ITS2 distinguish the *O. auricolor* clade (A1–A2), the *cladodes-botryosporus* clade (C1–C4) and the *elegans-gampsosporus* clade (E1–E3) and their subclades (Tab. 82). *A. cladodes* (subclade C1, 7 strains) differs from the *O. auricolor* clade (14 strains) at 32 positions, 24 of them being consistent within the entire *cladodes-botryosporus* clade. One of these positions (326) belongs to 5.8S. The *elegans-gampsosporus* clade shares at these positions either the character of the *cladodes-botryosporus* clade (pos. 66, 477, partly also 145, 491–92, 542) or mainly that of the *O. auricolor* clade (16 positions) whose two subclades, represented by H.B. 6664 (A1, 4 strains) and H.B. 6763 (A2, 11 strains), are separated by 9 consistent nt in the ITS region. At six of them (22, 25, 60, 64, 114, 406) subclades A1 and C1 concur, and at two of them (506, 522) subclades A2 and C1 concur.

Characteristic positions in the LSU (D1–D2) that separate the *O. auricolor* clade from the *cladodes-botryosporus* clade are listed in Tab. 83. Also here the *elegans-gampsosporus* clade shares positions of one of the two clades, mainly those of the *O. auricolor* clade.

The two aberrant genotypes on *Fagus* and *Fraxinus* bark show at pos. 13–15 of ITS2 the exceptional motif CCTC**GGC** which otherwise occurred only in *A. reticulatus* (6 strains), *Dactylellina* aff. *phymatopaga* (3 strains), and Chinese *O. orientalis* (4 strains). The majority of series *Arthrobotrys* have here CCTC**AGC**, and members of *Dactylellina* (including *O. quercus*) CCTC**GGT** (see Tab. 77).

Conclusions. The above analyses of the ITS and LSU region and that of the S1506 intron suggest that our here presented narrow concept of *O. auricolor* is heterogeneous and comprises at least two phylogenetically different species, *O. auricolor* s.str. and *O. cladodes*, despite a very high morphological similarity in both anamorph and teleomorph. Difficult to understand is the fact that species with morphologically very different conidia (*O. scaphoides*, *O. elegans*/*A. gampsosporus*) cluster near members of these two clades and share their characteristic nucleotides. Remarkable is also the deviating result from the intron region in regard to *A. botryosporus* and the *A. superbus* strain CBS 109.52.

From all this we conclude that anamorphs of *Arthrobotrys* cannot safely be identified with existing morphological keys. Our analysis of the two investigated European ascospore isolates (H.B. 6763, H.B. 6664) indicate that differences in conidial size seem to be of subordinate value, although an ITS distance of 2 % and the formation of two rather well-defined subclades within *O. auricolor* s.str. seems remarkable. A more comprehensive morphological and molecular study on further collections of the *O. auricolor* aggregate is required, also an rDNA extraction of the type material of *O. auricolor* and its here suggested synonyms might question the here proposed reference specimens.

Ecology. *O. auricolor* s.l. is a plurivorous species which is obviously able to grow on all kinds of organic substrates, including bark and wood of twigs, branches, and trunks of angiosperm, rarely gymnosperm trees, shrubs and climbers, also coniferous leaves, fruits, herbaceous stems of various, predominantly dicotyledonous plants, sometimes also fungi such as stromata of pyrenomycetes or lichen thalli. Even dung, bones, and textile are colonized. two records were on a fern (*Angiopteris*, Wu et al. 1998) and a horsetail (*Equisetum*, E. Rubio pers. comm.), but the former was reported as *O.* cf. *auricolor* and inadequately described, and the latter remained undocumented and unpreserved. The strength of decomposition of the substrate also varies considerably. Regarding availability of moisture, *O. auricolor* is usually found on hygric substrate in close contact to the ground, but some collections were on mesic or xeric substrate.

O. auricolor s.l. occurs worldwide. The here examined collections are from various regions of Europe and northern Africa with an atlantic to continental, thermo- to hemiboreal or oro- to thermotemperate humid, but also suprasub- to mesosub- and supra- to inframediterranean semihumid climate, from planar to montane altitudes. Included extra-European collections are from hemiboreal warm-temperate and mild-maritime humid or subtropical subhumid Northern America, subtropical semiarid to tropical humid (partly winter-dry) Middle and South America, subtropical humid (winter-dry) southeastern Africa, cold-continental to warm-temperate humid (winter-dry) central and eastern Asia, and oceanic, warm-temperate humid southeastern Australia. The few unquestionable European and North American records of *O. cladodes* are all from supratemperate humid sites, whereas those from Asia include also a subtropical monsoon and cold-continental climate.

The high substrate diversity comes along with a high variety of plant associations in which *O. auricolor* was found. In addition to various *Querco-Fagetea* communities, it occurred in floodplain forests with *Alnus*, *Salix*, *Ulmus* etc., open wetlands (*Cirsio-Filipenduletum*, *Oenotheretum*, *Caricetea*), tall forb communities, dry grassland (*Gentiano-Koelerietum*), atlantic *Ulex* shrubs, mediterranean shrub- and woodland, and even halophytic vegetation at the sea shore.

European reports of *O. auricolor* s.l. (under the name *O. curvatispora*) are, e.g., those of Boudier (1904–10: 267), Velenovský (1934: 100), Grelet (1948a: 51), Dennis (1978: 188), Breitenbach & Kränzlin (1981: 210), Ginko (1988), and Pop (1994: 65, pl. 1 fig. 5). Extra-European reports (some as *O. curvatispora*) include Binyamini (1991: 367, Israel, *Eucalyptus* branch), Ahmad (1978: 210, Pakistan), Thind & Sharma (1980, India), Raitviir (1991: 360, eastern Russia), Zhuang & Korf (1989: 306, China), Liu (2006, HMAS 96824 Tibet, HMAS 139635 Beijing); Wu (1998, Taiwan, *Angiopteris lygodiifolia* petiole), Spooner (1987, southeastern Australia), and Seaver (1951: 155, northeastern America).

Two GenBank sequences gained from culture isolates from rotten timber in the maritime antarctic (subarctic) tundra region (Arenz & Blanchette 2009, Held & Blanchette 2013) belong to European *O. auricolor* (clade A). These wood isolates were taken from old British and Chilean research station buildings at Deception and Stonington Island, and the fungus could well have been introduced to this remote region.

Map 154. Known distribution of *O. auricolor* s.l. in Europe and northern Africa (yellow = not included collections).

Specimens included [A = *O. auricolor* s.str., C1 = *O. cladodes*]: **EUROPE**: unlocalized, on a rope, undated, collector unknown (herb. Persoon, L 910.261–343, as *Peziza vinosa*, H.B. 7702 ø). — **GREAT BRITAIN**: unlocalized, substrate unknown, 1963, C.L. Duddington (CBS 130.83, as *Geniculifera cystosporia*, conid. isol., non vid.; sq.: CBS ined. [A2]). – **East Midlands**, **Leicestershire**, 7 km NW of Market Bosworth, 2 km NNE of Twycross, Gopsall plantation, 100 m, branch of ?angiosperm, on bark, III.1854, A. Bloxam (K, **lectotype** of *O. auricolor*, H.B. 5348 ø). – **East England**, **Suffolk**, 5 km SW of Southwold, 1.8 km of Dunwich, Dunwich Forest, 15 m, stem of *Lupinus arboreus*, 7.III.2003, E. Batten & S.M. Francis (E.B. 4397, H.B. 7309). – 4 km ESE of Halesworth, NNE of Wenhaston, Blyford Lane, Hill Cottage, 12 m, branch of *Lupinus arboreus*, on bark, 13.VII.2004, E. Batten (E.B. 4539, K(M) 227390, H.B. 7560 ø, anam. substr.). – **South East England**, **London**, ~18 km SW of London, Kingston-upon-Thames, ~10 m, horse dung delivered as garden manure, XI.1949, C.L. Duddington (MUCL 1019, CBS 109.52, CCRC 32698, as *A. conoides* or *A. superbus*, conid. isol., doc. vid.; sq.: KT215210, U51949 [A2]; non AJ001983 = *O. oligospora* ?CBS 115.81). – unlocalized, substrate unknown, 1963, C.L. Duddington (IMI 101307, CBS 433.81, CCRC 32697, as *A. cladodes*, conid. isol., non vid.; sq.: U51945, U51952, KT215211 [A1]). — **SWEDEN**: **Uppsala**, 40 km NNE of Uppsala, 1.5 km W of Österbybruk, Sandgropen, 42 m, stem base of *Arctium*, 17.VII.1936, S. Lundell (Holm & Nannfeldt F. exs. Suec. 3450, as *O.* cf. *epipora*, UPS F-005012, H.B. 7330 ø). – **Blekinge**, 12 km E of Karlshamn, Åryd, Tjärö, 10 m, dung of *Oryctolagus cuniculus*, 11.VI.1962, I. Nordin, vid. I. Olariaga (UPS F-705224, as *Orbilia* sp., doc. vid.). — **DENMARK**: **Sjælland**, Falster, 11 km WNW of Nørre Alslev, Resle Skov, 2 m, branch of *Corylus avellana*, on wood, 10.VII.2006, J.G.B. Nielsen (J.N. 06–114). — **FINLAND**: **Kanta-Häme**, ~1 km N of Tammela, Mustiala, ~110 m, branch of *Salix*, on bark, IX.?1869, P.A. Karsten (FFE 834, H 6051957, in envelope of '*O. rubella*' = *O. phragmotricha*). – **Uusimaa**, Helsinki, unlocalized, ~10 m, stump of *Picea abies*, A.M. Hallakselä (CBS 367.75, as *A. superbus*, conid. isol., non vid.; sq.: CBS ined., MH872670 [A1]). – ibid., from house dust (M. Pitkaranta et al., BF-OTU265, mol. extr.; sq.: AM901709 [A2]). — **ESTONIA**: **Tartumaa**, 44 km NNW of Tartu, Jõgevamaa Sport Center, culms of *Phalaris arundinacea*, 80 m, 20.X.1982, K. Allik (TAAM, H.B. 8714 ø). — **RUSSIA (West)**: **Stavropol**, **Predgorny**, Caucasus region, ~3 km SSE of Zheleznovodsk, Beshtau Mt., ~1000 m, stump of indet. angiosperm, on wood, 29.VIII.1925, A.I. Lobik, vid. E.S. Popov (LE 142161, doc. vid.). — **POLAND**: **Lesser Poland**, 6 km E of Nowy Sącz, 1.8 km E of Piątkowa, NW of Paszyn, 380 m, bone of *Sus scrofa*, 27.VIII.2007, S. Misapplied name: Pfister & Liftik (1995, teleomorph), as *O. auricolor*.
Misinterpretation of anamorph: Loew (1867), = ?*A. cladodes*; Liu (2006: fig. 15, B.L. 6225), = *Arthrobotrys* sp.; den Belder (1994) (CBS 289.82), ?= *Arthrobotrys pravicovii*.

Description: — **TELEOMORPH** (from D.H.P. 45/55): **Apothecia** dry 0.4–1.6 mm diam., rehydrated 0.25–0.28 mm thick, white to pale brownish (tan); disc flat, margin smooth, not protruding; sessile on a very broad and short stipe; dry deep yellowish-ochre, with a white, radiating subiculum. **Asci** †40–44 × 3.2–4 µm, 8-spored, spores †~4-seriate, lower spores inverted, pars sporifera †20 µm long; **apex** (†) strongly truncate (slightly indented, laterally distinctly widened); **base** with medium thin stalk, h-shaped. **Ascospores** †8–12.5(–14.5) × 0.9–1.1 µm [~10–14(–16) µm actual length], narrowly subcylindric-clavate, apex rounded, base strongly attenuated into a thin or thick tail, medium to strongly curved (falcate); **SBs** no data available. **Paraphyses** apically medium clavate-capitate, terminal cell †19 × 2.7–3.7 µm, lower cells †6.5–8 × 1.4–2 µm, branched below. **Medullary excipulum** 20–50 µm thick, of small-celled textura angularis. **Ectal excipulum** of (†) thin-walled t. angularis at base and flanks, 150–200 µm thick at base, large-celled, marginal cortical cells oriented at a high angle, †9–12 × 3–6 µm; **glassy processes** forming refractive caps of 0.8–1.2 µm thickness. **Anchoring hyphae** very abundant, †3–5(–6.5) µm, wall 0.3–0.5 µm thick. **SCBs** and **VBs** no data available. **Exudate** over paraphyses 0.2–1 µm thick, granular to cloddy, firmly attached. — **ANAMORPH**: arthrobotrys-like (from ascospore isolate {1}; description compiled from Fresenius 1850, Drechsler 1937a, Duddington 1952, Soprunov 1958, Haard 1968, Jarowaja 1970, Mekhtieva 1979, Van Oorschot 1985, Pfister & Liftik 1995, and Swe et al. 2008a): **Conidiophores** erect, 180–800 µm long, 5–8.5 µm wide at base, 2–4(–5) µm wide below nodes, often proliferating repeatedly to form several nodes in a chain, unbranched or rarely branched, conidia formed on nodules or short denticles on ± 4–6 µm wide, swollen nodes (arthrobotryoid), ~5–20 conidia per node. **Conidia** ((12–))(16–)20–27(–30)((–36)) × ((6–))(8–)10–15(–17)((–20)) µm, consistently 1-septate (exceptionally 2-septate), often constricted at septum, obovoid to obpyriform, upper cell usually distinctly wider and mostly also longer than lower cell. Trapping nematodes by means of 3-dimensional **adhesive networks** with outer diameter of ~25–45 µm, loops 5–7 µm thick. **Chlamydospores** present, intercalary, usually singly, 8–30 µm diam.

Habitat: branch of *Fagus sylvatica* {1}, indet. trees {2}, on wood {3}, thallus of indet. *Lecanorales* {1}, dung of *Capreolus capreolus* {1} and *Equus caballus* {1}, various isolates from soil, fresh water, and mangroves. **Associated**: none reported. **Desiccation tolerance**: not tested, ?slightly tolerant. **Altitude**: 10–390 m a.s.l. (temperate Europe), 1–3000 m (northern China), 1–550 m (southern Asia). **Phenology**: IV (teleomorph).

Taxonomic remarks. *Orbilia oligospora* appears to be indistinguishable from *O. auricolor* when considering teleomorph morphology alone, for which reason Pfister & Liftik (1995) applied the name *O. auricolor* in a wide sense. Identification of *O. oligospora* by its anamorph is complicated by strains with variable, intermediate conidial characters. The main argument for its independency is supplied by molecular data, by which it sharply differs from closely related taxa. *C*onsequently, collections of *O. oligospora* without anamorph and without molecular data are easily misidentified as *O. auricolor*. Since many of our records of *O. auricolor* are without such data, some of them might in fact belong to *O. oligospora*. Some other species possess an anamorph reminiscent of *O. oligospora*, but differ in teleomorph characteristics: *O. latispora* s.l. has shorter and wider ascospores, and *O. blumenaviensis* lanceolate paraphyses.

Anamorph. The connection of *A. oligosporus* var. *oligosporus* to the teleomorph *O. auricolor* was reported by Pfister & Liftik (1995, D.H.P. 45/55) and Liu (2006: fig. 15, B.L. 6225, but see under Misinterpretation). Pfister & Liftik's anamorph was isolated from apothecia that were obtained during storage in a moist chamber, growing on a crustose lichen which was collected on a rock in a temperate area in Massachusetts (Pl. 955: 1), whereas Liu's (2006) apothecia grew on branches of an undetermined tree in a tropical botanical garden in Yunnan (for a spore photo see Pl. 957: 1). In the teleomorph both authors saw no difference to *O. auricolor*.

O. oligospora differs from *O. auricolor* in conidia with more or less obovoid to obpyriform shape and consistently more or less eccentrical septum. As a consequence, the upper cell is mostly distinctly larger than the lower cell [Pl. 955], 957). Conidial size is somewhat beyond that of *O. auricolor*, but varies strongly. Conidial length as given by Fresenius is at the upper range of *O. oligospora* and far beyond that of *O. auricolor*, but such a length never occurred in the here available documentations of *O. oligospora*.

Identification of *O. oligospora* is complicated by populations here referred to *O. auricolor*, in which the conidia tend to be asymmetrically septate (see, e.g., Pls 948: 5g; 949: 1i; 954: 6). The anamorph of *O. oligospora* may also be confused with

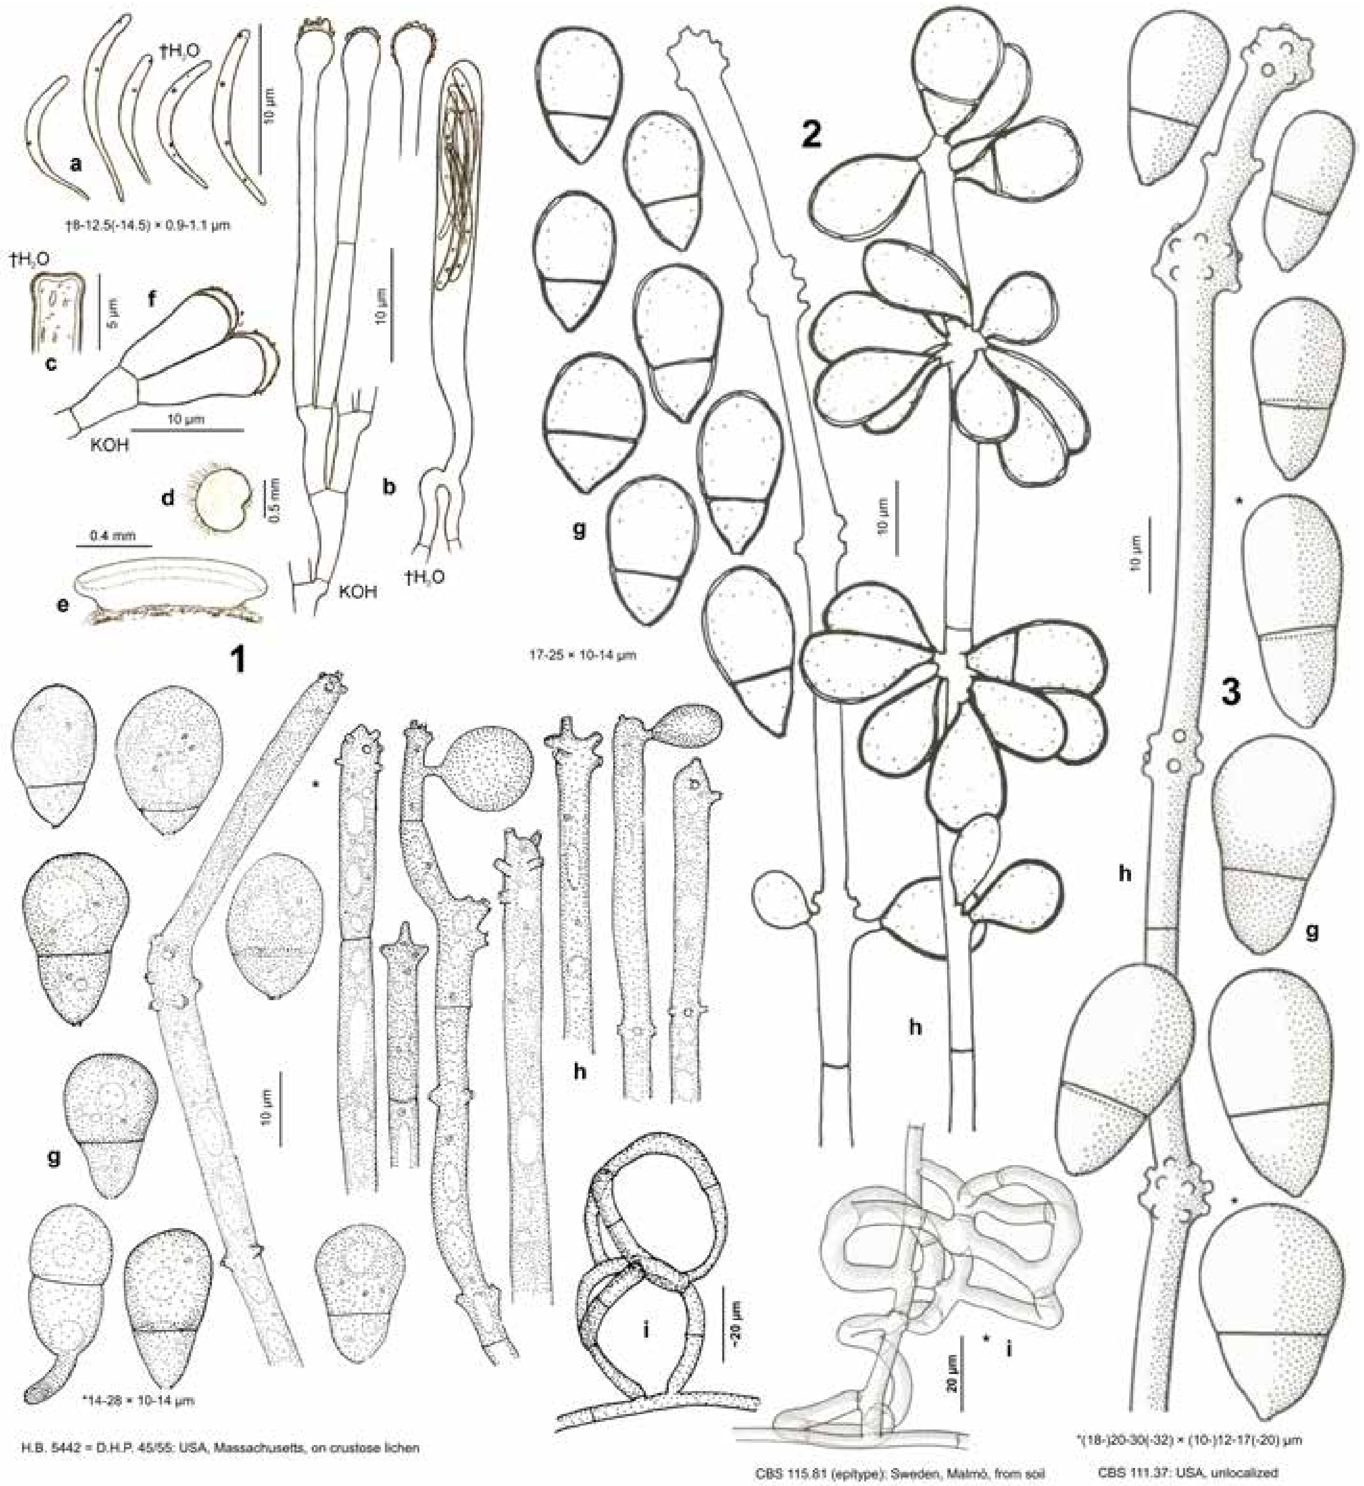

Plate 955. **1–3**: *Orbilia oligospora* (clade B). – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. fresh apothecium with subiculum; **e**. apothecium in median section; **f**. id., marginal cortical cells with thin glassy caps; **g–i**. anamorph (from culture); **g**. conidia; h. upper parts of conidiophores; **i**. adhesive networks. – **1a–f**. H.B. 5442 = D.H.P. 45/55; **1g–i**. D.H.P. 45 (from Pfister & Liftik 1995, as *A. oligosporus* var. *oligosporus*, scale for **1i** corrected, in Pfister & Liftik given as 16 instead of ~32 µm); **2**. CBS 115.81 (from Van Oorschot 1985, as *A. oligosporus* var. *oligosporus*, epitype, scale corrected [20 µm, as '10 µm']); **3**. CBS 111.37 (from Drechsler 1937a, as *A. oligosporus*).

that of *O. latispora* s.l. (= *Arthrobotrys latisporus*), in which the conidia are partly eccentrically septate, though often also more centrally (Pl. 973). A similar situation of partly eccentrical septation is observed in *O. blumenaviensis* (= *A. vermicola*), which differs from *O. oligospora* in larger conidia and in the simultaneous formation of fusoid, 2–3-septate conidia, though in a strongly varying frequency. *A. conoides* differs from *O. oligospora* in more elongate conidia, i. e., with a higher l:w ratio. *A. koreensis* Wu et al., *A. paucisporus* (R.C. Cooke) Jarow., *A. cystosporius* (Dudd.) Sidorova et al., and *A. perpastus* (R.C. Cooke) Jarow. have similar conidia, but rather sharply differ in the candelabrelloid or geniculate type of conidiogenesis (longer denticles, lack of swollen nodes) and in producing less conidia per conidiophore.

Arthrobotrys oligosporus was frequently investigated because of various peculiarities, such as the ability to effectively capture four different plant-parasitic nematode species (den Belder 1994: 27), the formation of simple adhesive rings directly on

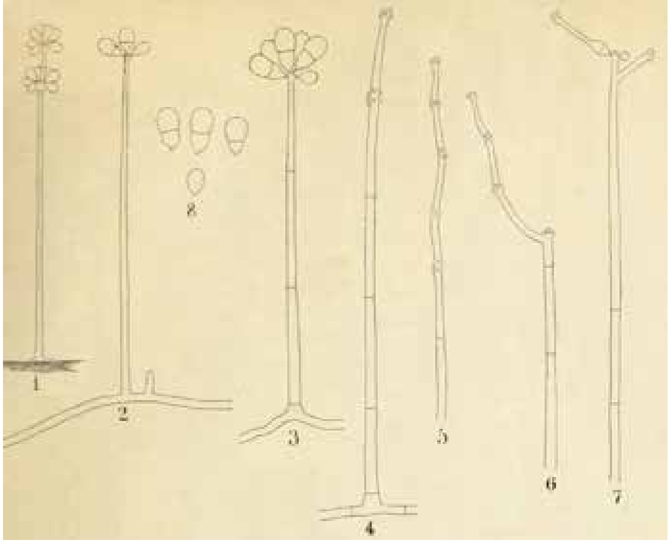

Plate 956. Type of *A. oligosporus*, original drawing by Fresenius (1850, published without scale).

the conidia ('conidial traps'), and mycoparasitism (formation of hyphal coils around hyphae of *Rhizoctonia*, Nordbring-Hertz 2004) Molecular studies involve the detection of active chemical compounds (e.g., Zhao et al. 2004), and the evaluation of population genetics (Zhang et al. 2011b).

Type studies. In the original description of *A*. ***oligosporus*** (Pl. 956), Fresenius (1850) described the conidia as pear-shaped, 1/28 mm long (= 35.7 µm, 18 µm wide when taking the longest conidium as 36 µm), with the septum somewhat below the centre, and the conidia less constricted at the septa compared to *A. superbus*. In the discussion, however, he emphasized that the septum occurs 'more in the lower third of the spore than in the middle'. His illustration (Pl. 956) shows both unequally and almost equally septate conidia, with the upper cell always distinctly wider than the lower cell, reminiscent of some collections here referred to *O. auricolor*. About 12 conidia as a maximum are said to be formed in a terminal cluster, more rarely also two conidial clusters or exceptionally up to 5 clusters in a row.

Since a pure culture of the type of *A. oligosporus* is lacking, an **epitype** (Sweden, Malmö, CBS 115.81) is designated here, which is well-documented (Pl. 955: 2), and for which sequences of different gene regions are available.

Massee (1885) was obviously unaware of *Arthrobotrys oligosporus* when he described *A*. ***roseus***. He did not give a conidial size, but from his drawing a size of ~21–27 × 14–17.5 µm can be evaluated. From *A. roseus* he distinguished *A. superbus* by equally septate conidia and pure white colonies. Duddington (1952) compared his *A*. ***robustus*** with *A. superbus* and *A. cladodes* s.l. regarding differences in conidiophore morphology, conidial size, and chlamydospores, but mentioned *A. oligosporus* only for its similar trapping organs. He described the spores with a nearly median septum, which appears to have mislead Van Oorschot (1985) and the CBS database to consider *A. robustus* to be a synonym of *A. pyriformis* or to compare it with *A. cladodes* var. *macroides*. However, Duddington's figure shows also conidia with the septum almost in the lower third and with always broader upper cell, reminiscent of *O. oligospora*. Conidial size is given as 18–27 × 8–12 µm, hence conidial width is at the lower range of *O. oligospora*. Molecular data from the ex-type strain (CBS 107.51), which was said by Van Oorschot to be now sterile, confirm synonymy with *O. oligospora* (see below).

A. ***globosporus*** **var**. ***globosporus*** was proposed by Soprunov (1958) and separated from *A. oligosporus* based on a denser arrangement of the clusters, with a maximum distance of 20–30 µm between the nodes, the terminal clusters being gradually more closely arranged and, therefore, confluent to form a single elongate cluster (in *A. oligosporus* all clusters separate at a distance of ~25–50 µm). Judging from the illustration we see no clear differences between the two taxa. Although Soprunov stated the colony colour to be light pink in his var. *globospora*, he separated *A*. ***globosporus*** **var**. ***roseus*** from the type variety merely by the intense rose-red colony colour. Mekhtieva (1979) compared *A*. ***compactus*** with *A. oligosporus*, from which she distinguished it, e.g., in larger conidial clusters, but her description and illustration concurs well with typical *A. oligosporus*. According to Van Oorschot (1985), *A*. ***globosporus*** **var**. ***microsporus*** has distinctly smaller conidia (Soprunov 1958: 15.2–19.6 × 6–11 µm) than *A. oligosporus*. A sequence from Japan under the name *A. oligosporus* var. *microsporus* falls in subclade A of the *O. oligospora* clade.

The descriptions and illustrations of ***Arthrobotrys oviformis*** in Soprunov & Galiulina (1951) and Soprunov (1958), a species accepted by Scholler et al. (1999), present obovoidal to pyriform conidia of 22.5–32.5 × 10–15.5 µm, with a strongly eccentrical septum, reminiscent of *A. oligosporus*, except that almost 1/4 of the conidia are 2-septate and of ellipsoid shape (note that in Soprunov & Galiulina l.c. the legends to Fig. 5 II and VI are confused). Van Oorschot (1985) and Yu et al. (2014) accepted *A. oviformis* as distinct from *A. oligosporus* based on branching of conidiophores and occasionally 2-septate conidia in *A. oviformis* as opposed to consistently unbranched conidiophores and consistently 1-septate conidia in *A. oligosporus*.

Only one of the six included Chinese samples bears a culture number (YMF 1.00121), and Yu et al. (l.c. fig. 3.34) illustrate the morphology of this strain. Its conidia measure from the scale 19–32 × 11–13.7 µm, which concurs with Soprunov (1958) but is about the double size of what their description tells (7.5–22.5 × 5–10 µm, note that the scales for conidiophores and conidia have the same length, although the former are reproduced at a smaller magnification). A sequence of YMF 1.00121 was uploaded in GenBank under the name *A. oligosporus* (MH179701). It belongs to clade A1 of *O. oligospora*, where it is fully identical in the ITS with, e.g., an *A. oligosporus* strain from Florida (KJ938573). This questions the taxonomic value of branching and additional spore septum in *A. oviformis*.

Jarowaja (1970) distinguished her *A*. ***oligosporus*** **var**. ***sarmaticus*** from *A. globosporus* var. *globosporus* by shorter conidiophores with only one or rarely two nodes at intervals, longer conidia of 20–34(–40) × 10–19 µm, and adhesive nets with thicker loop hyphae.

Variation in the anamorph. In Pfister & Liftik's strain the nodules at the conidiophore tips are uninflated (Pl. 955: 1h), whereas in Drechsler's strain they are distinctly inflated (3h). The position of the conidial septum and the volume relation between the two cells vary among conidia of a population, also the total size of conidia may vary considerably. This is particularly seen in Drechsler's (1937a: fig. 3) strain, in which, conidia on nematode-infested plates were distinctly larger than on non-infested ones.

Misinterpretation of ***A*. *oligosporus***. A few literature reports under the name *A. oligosporus* represent different species. Loew (1867) illustrated samples on rotten stems of *Apiaceae* and

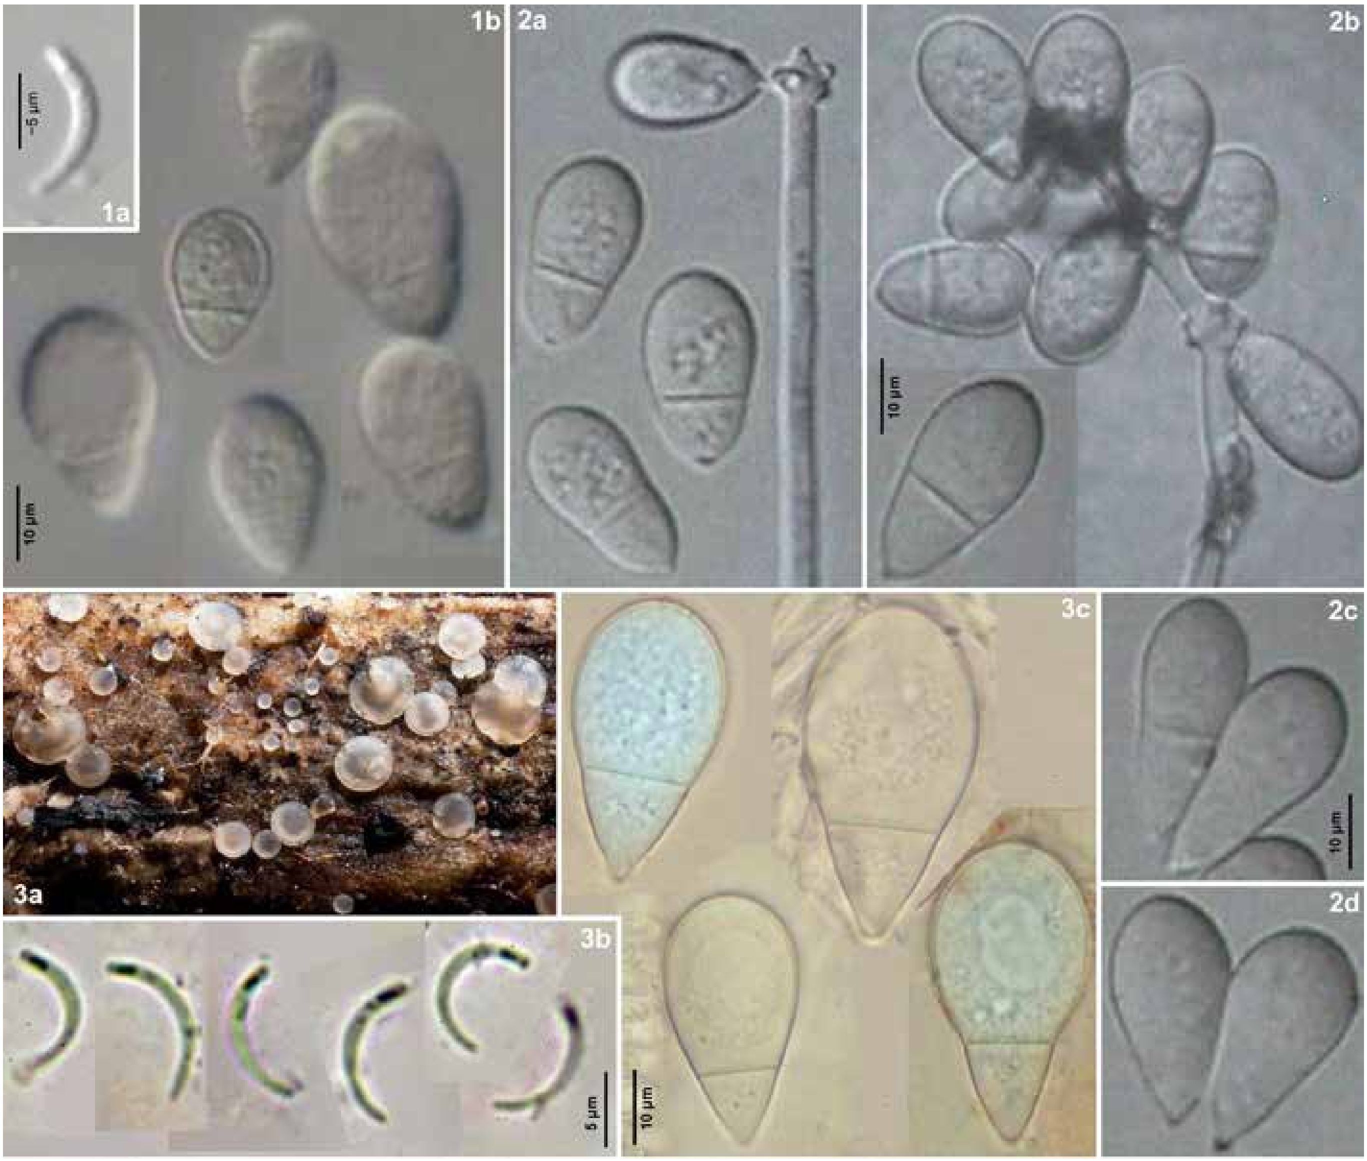

Plate 957. **2**: *Orbilia oligospora*; **1**, **3**: *O.* aff./cf. *oligospora*. – **3a**. fresh apothecia of assumed teleomorph; **1a**, **3b**. ascospores; **1b**, **2a–d**, **3c**. conidia and conidiophores (**1b**, **2a–d** from culture, **3c** from natural substrate). – Living state. – **1**: from Liu (2006), **2**: from Swe et al. (2008a), **3**: phot. E. Rubio. **— 1a–b**. B.L. 6225: China, Yunnan, on indet. tree (Liu 1006); **2a–d**. unspecified: China, Hong Kong; **3a–c**. E.R.D. 5918: Spain, Asturias, on *Brassica*.

Brassicaceae, which he assigned to *A. oligosporus* only with hesitation because of much smaller (9–14 × 5–7 µm) conidia with mostly ± median septum formed on branched or unbranched instead of proliferating conidiophores that lack nodules and inflated nodes. The conidiogenesis resembles that of *A. flagrans*, but the small conidia arranged in clusters of ca. 12 at each node of the branched conidiophores point to *A. cladodes*. Liu's (2006) ascospore isolate (B.L. 6225) was identified as *A. oligosporus* because of obpyriform conidia (17.5–35 × 10–17.5 µm) with a strongly eccentrical septum (Pl. 957: 1b), but its sequences cluster distantly from the *O. oligospora* clade. Likewise, an unillustrated strain under the name *A. oligosporus* (CBS 289.82), which was comprehensively studied for nematode-trapping by den Belder (1994) and characterized by attaching to nematodes through hyphae without prior formation of complex networks, is phylogenetically distant from *A. oligosporus*.

Not included collections. For the not included *A. globosporus* var. *microsporus* and var. *sarmaticus*, and *A. oviformis* see under Nomenclature and type studies. In a Spanish collection on *Brassica*, conidia with an even larger size and a similar shape as in *A. globosporus* var. *sarmaticus* occurred (*30–45 × 17–24 µm, E. Rubio pers. comm., Pl. 957: 3a–c), which resemble those of typical *O. oligospora* except for their large size. Regrettably, no conidiophores were seen. Apothecia occurred in close vicinity, which did not differ in any respect from those of *O. auricolor* or *O. oligospora*. However, their connection to the conidia is uncertain. For the not included sample from China (B.L. 6225) see under Misinterpretation.

Phylogeny. In the maximum parsimony analysis of the ITS region by Zhang et al. (2010), *A. oligosporus* formed a strongly supported clade of its own by forming with rather high support a sister group to the remaining taxa of *Arthrobotrys*. A similar position was obtained in the NJ analysis of ITS by Qiao et al. (2012), in which *A. oligosporus*, formed with *A. flagrans*, *A. amerosporus*, and *A. musiformis*, species not included by Zhang et al., as an unresolved paraphyletic sister group to the remaining species. This is in contrast to Yang et al.'s (2007: fig. 2A/B) ML analyses of ITS or *TUBB*+*RPB2*+*TEF1*, in which *A. oligosporus* (strain 920) clustered with *A. conoides*, *A. pseudoclavatus* (= *A. janus*), *A. musiformis*, and *A. vermicola* in a terminal clade which received strong support in the combined analysis.

Table 84. Diagnostic positions in the ITS region which separate three clades and two subclades within the *Orbilia oligospora* aggregate. * = strain FM01 (Mexico) has ‘`CTGT`’, # = two strains from Mexico have ‘`---TAACCGGGGGAA`’. Position numbers starting after ATCATTA by including all inserts.

In our combined analysis of SSU+ITS+LSU (Phyl. S33) *O. oligospora* clustered medium supported with *A. amerosporus*, *A. conoides*, *A. flagrans*, *A. musiformis*, and *O. javanica* (here called *oligospora-musiformis* clade). This clade is likewise obtained with medium support when analysing SSU (Phyl. S29). Also when analysing ITS (Phyl. 28) and LSU (S32) the clade is formed but received no support, and *A. musiformis* (in the LSU tree also *O. javanica*) clustered outside the clade. In the combined ML analysis in Baral et al. (2017b), *A. oligosporus* formed with *A. flagrans* a strongly supported clade, but this analysis comprised only six members of series *Arthrobotrys*. With our results concurs a combined analysis of ITS+LSU by X.Z. Liu & X.Z. Jiang (pers. comm., presented in Amsterdam in 2012), where *A. oligosporus* clustered in a medium supported clade with *A. amerosporus*, *A. javanicus*, and *A. musiformis* (*A. flagrans* was not included). A close association between *A. oligosporus* and *A. flagrans* was also noted by Ahrén et al. 2004).

About 30 more or less complete **ITS** sequences correctly identified as *Arthrobotrys oligosporus* were available in GenBank (accessed Oct. 2018) and three in NBRC. Although *O. oligospora* formed in our analysis a strongly supported clade (Phyl. 28), the available sequences exhibit considerable variation by forming three different subclades (A–C) that differ by 1.3–3 % (Phyl. 29, Tab. 84). The sharp separation of *O. oligospora* from other species of series *Arthrobotrys* confirms earlier, morphology-based species concepts. The clade includes the here designated epitype (CBS 115.81).

Despite this rather clear situation, strains exist that fit the morphology of *O. oligospora* but strongly deviate by molecular data: Liu’s (2006: fig. 15) ascospore isolate B.L. 6225 clustered distant from the *O. oligospora* clade, either unresolved near *O. multiformis* (ITS, Phyl. 28) or near two strains of unclear identity under the name *A. superbus* (LSU, S32) for which no ITS was available. Likewise, den Belder’s (1994, CBS 289.82) unillustrated strain differs from genuine *O. oligospora* by 3 nt in the V8 and 9 nt in the V9 loop of SSU (S29) but concurs in the V8–V9 region with *A. pravicovii* and *O. scaphoides* (*scaphoides-pravicovii* clade). Unofficial ITS data of den Belder’s strain in the CBS database confirm a close relationship particularly to *A. pravicovii* (2 % distance).

In their molecular study on three gene regions (ITS, *TUBB*, *RPB2*), Zhang et al. (2011b) investigated 97 *A. oligosporus* strains from various regions of China, which have been isolated mainly from agricultural and forest soils but also from water (Map. 155). In their combined tree but also in supplementary analyses of single regions, the authors detected the above-mentioned three lineages, which they classified as clades A–C and assumed to represent cryptic species. But they also observed significant variation within each clade. No morphological data were documented for any of these strains although conidia were available (Z.F. Yu pers. comm.). It is, therefore, impossible to hypothesize which of the morphology-based varieties of *A. oligosporus* might be represented by clades A–C. Also no efforts were undertaken to identify GenBank sequences regarding the three cryptic species.

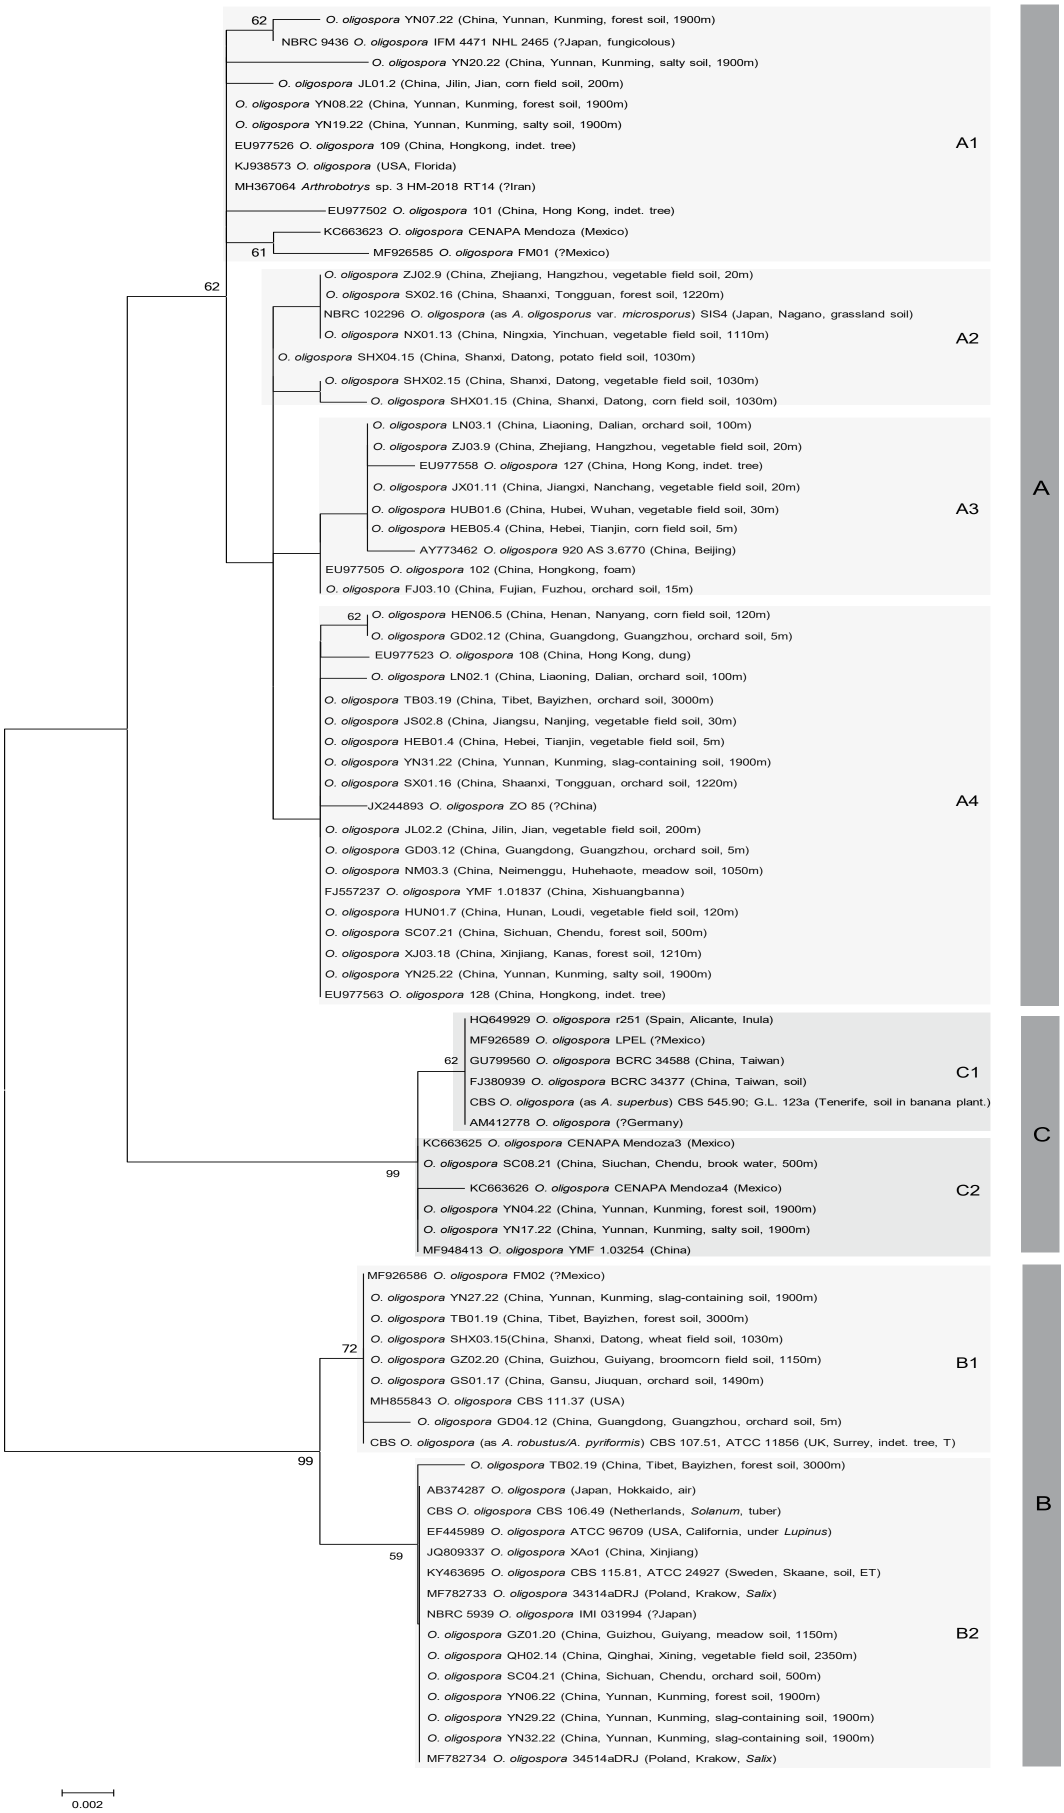
None of the sequences treated by Zhang et al. (2011b) were uploaded in an online database, but Z.F. Yu generously supplied us all ITS and *TUBB* data. An ITS tree is presented (Phyl. 29) which includes a selection of their 97 strains. We included also strains from official repositories and herewith identified their relationship with three lineages of Zhang et al. For instance, the Chinese strain 920 treated by Yang et al. (2007) clustered in clade A, whereas the Swedish epitype strain of *O. oligospora* (CBS 115.81) treated by Ahrén et al. (2004) clustered in clade B.

The distances between the three clades lie at 1.4–3 % (A–B), 1.3-2 % (A–C), and 2.3–2.9 % (B–C), and the observed variation within each clade at 0–1 % (A), 0–0.7 % (B), and 0–0.3 % (C). Each clade is characterized by a varying number of unequivocal nucleotides and indels Tab. 84: clade A by 1 nt, clade B by 7 nt and 2 inserts, and clade C by 6 nt, 5 inserts, and 2 deletions. Also within each clade a few nt correlate with the subclades obtained by ML analysis: 3 nt between A1–A4, 3 nt between B1 and B2, 1 nt between C1 and C2.

When analysing ***TUBB*** in GenBank (Phyl. S34), 20 strains, mostly identified as *A. oligosporus*, clustered in two associated clades, one clade comprising only strains from China (mainly Hong Kong) and the other only strains from Europe, India, and America. Because Zhang et al. (2011b) sequenced another region of *TUBB* (primer pair Bt1a-Bt1b) than Ahrén et al. (2004) and Yang et al. (2007) (‘tubA’, primer pair Bt2a-Bt2b), their isolates cannot be compared. However, strains which include also ITS permit to recognize in S34 the Chinese strains as clade A and the others as clade B (no sequences for Bt2a-Bt2b appear to exist for clade C). For Bt1a-Bt1b only the here designated epitype strain of *O. oligospora* exists in GenBank (ATCC 24927 = CBS 115.81, XM_011123192), and for this strain also Bt2a-Bt2b is available (AY444611).

Also Zhang et al. (2011b) found some geographical correlations in their analysis: clade A comprised almost all tested localities across China’s north, south, and west (0–3000 m a.s.l.), but clades B and C mainly sites in western China (500–3000 m a.s.l.). However, three exceptions question this correlation: their strain from Guangdong (5 m) clusters in clade B, and two GenBank strains from Taiwan in clade C. The fact that the large clade A comprises mainly Chinese strains, besides some from Japan, USA, and Mexico, might be simply due to the rich sequence data in Zhang et al.’s study.

Only **SSU** (V1–V9) was available for Pfister & Liftik’s strain from Massachusetts (D.H.P. 45/55, H.B. 5442). This shows over a length of 1687 nucleotides a distance of only 0.1–



Phylogenetic analysis 29. Phylogram of *Orbilia oligospora* s.l. inferred from ML analysis of ITS1-5.8S-ITS2 rDNA sequences from GenBank and NBRC (83 sequences, 627 positions, aligned with MUSCLE) using the K2+G model in MEGA6 (500 replicates), in comparison with a majority of Chinese strains (without repository number) treated in Zhang et al. (2011b), with indication of their geographical origin (province) and altitude. Clades A–C appear to represent 3 cryptic species, whereas subclades B1/B2 and C1/C2 merely differ by a few characteristic positions (Tab. 84). Note that all recognized subclades contain strains from different continents.

0.2 % to three further strains under the name *A. oligosporus* in GenBank. Hence, D.H.P. 45/55 obviously belongs in the scope of *O. oligospora* s.l. (see Phyl. S1). two of them (XAo1, from Xinjiang; CBS 115.81, from Sweden) comprise also ITS and belong in subclade B2 of *O. oligospora*. In the V8–V9 region of SSU they are identical with D.H.P. 45/55 (apart from 4 'N' in D.H.P. 45/55). No SSU sequence of other *O. oligospora* clades were available. Because SSU is highly conservative, it seems improbable that SSU permits to distinguish among the three clades of *O. oligospora*.

A third SSU sequence ('CBS 109.52', AJ001983, Ahrén et al. 1998) was named *A. conoides* and fully concurs in the V1–V9 with CBS 115.81 except for 3 gaps. It is in confusion, because three further sequences without SSU (U51949, Liou & Tzean 1997; KT215210; CBS ined.), taken from CBS 109.52, belong in the ITS or LSU to *A. superbus* (*O. auricolor* clade). This explains why in the phylogenetic analysis of SSU by Hagedorn & Scholler (1999: fig. 4) strain D.H.P. 45/55 clustered in a clade with '*A. superbus* CBS 109.52' (AJ001983) and *A. oligosporus* CBS 115.81 (KY463695).

The above-mentioned CBS 289.82, studied by den Belder (1994) and misidentified as *A. oligosporus*, differs in the entire SSU from the above four reliable strains of *O. oligospora* by 1.1–1.2 %, and *A. superbus* (CBS 107.81) differs from them by 2 %, therefore, these two strains clustered in Ahrén et al.'s (1998) analysis in a clade distant from genuine *A. oligosporus* [note that Ahrén et al.'s '*O. auricolor*' refers to D.H.P. 45/55, see Ahrén et al. 2004: 1210].

An unofficial ITS sequence at CBS (www.cbs-knaw/collections) of the type of ***A. robustus*** (CBS 107.51) and a GenBank sequence of *O. oligospora* (CBS 111.37, MH855843), apparently the one figured in Drechsler (1937a: fig. 3), are fully identical and cluster in clade B1 (Phyl. 29). They show a 0.6 % distance (3 nt) to the epitype strain from Sweden (CBS 115.81, clade B2). Another strain under the name *A. robustus* (CBS 602.80, unlocalized) was referred by Van Oorschot (1985) to *A. pyriformis* but its sequence belongs to *O. auricolor* (see p. 1535).

Since ITS is generally rather variable within *Orbilia*, we are reluctant in splitting *O. oligospora* into three species (clades A–C) based on distances of only 1.5–3 %, particularly since no morphological data were available to support the taxonomic value of the three genotypes.

A characteristic insert of ~55 (or sometimes only 19) nucleotides occurs at the 5'-end of ITS1 in almost every sequence of *O. oligospora*. This insert is absent in any other sequences of section *Arthrobotrys*, or rarely present but much shorter. The S1506 intron at the 3'-end of SSU is consistently absent in the six available sequences of *O. oligospora* that cover this region.

Ecology. *O. oligospora* seems to be among the most common predacious species by showing a worldwide distribution, judging from the many existing isolates. Drechsler (1937a) even wrote: 'Of all predacious fungi *Arthrobotrys oligospora* is undoubtedly by far the most widely known among mycologists'. Zhang et al. (2011b) found the species in 97 out of 400 soil or water samples from various regions of China. Among the taxa with adhesive nets it is by far the most often isolated species, therefore, it is used as a model organism to study the relationship between nematode-trapping fungi and their nematode host (Niu & Zhang 2011). Nevertheless, we did not come across an unequivocal collection of either the anamorph or teleomorph of *O. oligospora* for personal study, except for the sample from Massachusetts.

Map 155. Distribution of *O. oligospora* based on isolates investigated by Zhang et al. (2011b, China), Swe et al. (2008a, Hongkong), Kuo et al. (2008 ined., Taiwan), Tokumasu (ined., Japan); clades: cyan = A, yellow = B, red = C, green = A + B, magenta = A + B + C. Coordinates in Zhang et al. corrected according to their map, altitudes taken herefrom.

The few at present known records of both morphs on the natural substrate do not permit to circumscribe the ecological preferences of the fungus. The isolation sources of the reported cultures are very diverse and include, besides soil, gymno- and angiosperm wood and bark, decaying herbaceous plants, and dung. The climate includes cold-temperate to subtropical humid (partly winter-dry) and warm- to cold-continental semiarid regions.

Specimens included. **USA**: unlocalized, 1937, C. Drechsler (CBS 111.37, conid. isol., doc. vid.; sq.: MH855843, MH867347, AY444619 etc. [B1]). – **Massachusetts**, Middlesex, 28.5 km NW of Boston, 4.3 km N of Concord, Estabrook Woods, 65 m, on black crustose thallus of indet. *Lecanorales* covering a rock, IV.1994, D.H. Pfister (isolates D.H.P. 45 & 55, anam. cult., FH 304900, sq.: U72598; H.B. 5442 ø). – **Michigan & Missouri**, several collections from soil or rotten wood, K. & R. Haard (conid. isol., doc. vid., Haard 1968). — **SWEDEN**: **Skåne**, 7.5 km NE of Malmö, ~2 km SE of Lomma, Alnarp, ~10 m, from soil, undated, M. Paasuke, depos. I.1981 by B. Nordbring-Hertz (CBS 115.81 epitype, ATCC 24927, BBA 69390, conid. isol., doc. vid.; sq.: AJ001986, KU729032, KY463695, AY444611, XM_011123192 [B2]). — **GREAT BRITAIN**: **Yorkshire**, **North Yorkshire**, Scarborough, unlocalized, ?100 m, on indet. branches, undated, G. Orbilia multiformis (Dowsett, J. Reid & Kalkat) E. Weber & Baral, **comb. nov.**, MB 813986 — Pl. 958

Basionym: *Dactylella multiformis* Dowsett, J. Reid & Kalkat, Mycologia 76(3): 563 (1984)
≡ *Monacrosporium multiforme* (Dowsett, J. Reid & Kalkat) A. Rubner, Stud. Mycol. 39: 84 (1996)
≡ *Arthrobotrys multiformis* (Dowsett, J. Reid & Kalkat) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 103 (1999)
= *Trinacrium iridis* Ts. Watan., Mycologia 84: 794 (1992)
≡ *Dactylella iridis* (Ts. Watan.) K.Q. Zhang, Xing Z. Liu & L. Cao [as '*irida*'], Mycosystema 7: 112 (1995, '1994')
≡ *Monacrosporium iridis* (Ts. Watan.) A. Rubner & W. Gams, Stud. Mycol. 39: 77 (1996)
≡ *Arthrobotrys iridis* (Ts. Watan.) M. Scholler, Hagedorn & A. Rubner, Sydowia 51: 102 (1999)
= *Dactylella ramiformis* Xing Z. Liu & W.F. Qiu, Mycol. Res. 97: 359 (1993)
= *Arthrobotrys yunnanensis* M.H. Mo & K.Q. Zhang, in Mo et al., Fungal Diversity 1: 109 (2005)

Etymology: *iridis*: after the host; *multiformis*: referring to the different conidial types (unbranched macroconidia, 1-septate microconidia, non-septate secondary microconidia); *ramiformis*: referring to the partly branched macroconidia; *yunnanensis*: after the geographical origin.

Typification: Canada, Lake Manitoba, marsh soil, undated, J. Reid (ATCC, CBS 773.84, CMI, living ex-type culture, syntypes of ***Dactylella multiformis***; sq.: MH861834, AY261171). — Japan, Wakayama, *Iris ensata* var. *hortensis* roots, 27.IX.1982, T. Watanabe (FFPRI TW 82-567, holotype of ***Trinacrium iridis***; ex-type culture: CBS 686.94 = IFO 32554, sq.: EU107316, NBRC 32554). — China, Beijing, *Triticum aestivum* rhizosphere, IV.1989, X.Z. Liu (HMAS 62571, holotype of ***Dactylella ramiformis***; ex-type culture: CBS 166.95 = IFO 32587; sq.: AY773452). — China, Yunnan, Xiaobailong Mt., from wet soil, 15.VIII.2003, M.H. Mo et al. (HT 1.00593, holotype of ***Arthrobotrys yunnanensis***; ex-type culture: YMF 1.00593; sq.: AY509930).

Misapplied name: Mo et al. (2005a, teleomorph), as *O. auricolor*.

Description: — **TELEOMORPH** (after Mo et al. 2005a, values partly modified according to scale): **Apothecia** fresh 0.3–0.8 mm diam. (on CMA), white, finally pale yellowish-cream; disc flat, margin smooth; sessile. **Asci** *53 × 4.1 µm, †49–51 × 3.5–3.8 µm, 8-spored, spores *2–4-seriate, lower spores inverted, pars sporifera *21 µm long (†35 µm); **apex** (†) medium truncate (not indented, laterally not widened); **base** with short, thin stalk, h- to H-shaped. **Ascospores** *8–10 × 1.3–1.4 µm (~9–11 µm actual length), narrowly subcylindric-clavate, apex rounded, base slightly attenuated, medium to strongly curved (falcate); **SBs** *~1.5–2 × 0.6 µm, elongate tear-shaped, filum ?invisible. **Paraphyses** apically slightly clavate, also spathulate-lageniform, terminal cell *18–20 × 3–4(–4.5) µm, lower cells *5–7 × 2.5–3 µm, unbranched at upper septum. **Medullary excipulum** ~20 µm thick, small-celled, medium sharply delimited. **Ectal excipulum** of (†) thin-walled t. globulosa from base to margin, cells *10–20 × 8–18 µm; **glassy processes** not seen. **Anchoring hyphae** not examined. **SCBs** and **VBs** absent. **Exudate** over paraphyses absent. — **ANAMORPH** (after Dowsett et al. 1984, Watanabe 1992, Liu & Qiu 1993, Nakagiri & Ito 1996, Rubner 1996, and Mo et al. 2005a, values partly modified according to scale): arthrobotrys-like (from ascospore isolate {1} or isolated from culms, roots, or soil {4}). **Macroconidiophores** (10–)30–150(–210) µm long, 2.5–6 µm wide at base, ~2–3 µm at apex, conidia usually formed singly at apex; **macroconidia unbranched**, elongate fusoid to fusiform, */†(60–)80–150(–210) × (7.5–)10–16(–21) µm, (4–)5–10(–13)-septate {4}, or apically **branched** (Y-shaped, sometimes 3-armed), (75–)90–125 × 35–85 µm, stipe (45–)55–95 µm long, cylindrical or mostly fusoid, (2–)4–6(–8)-septate, arms (11–)20–75(–98) × (4–)5–8(–12) µm, ± gradually tapered, (0–)2–3(–5)-septate {3}. **Microconidiophores** emerging from hyphae or from macroconidia, (28–)50–150(–225) µm long, 3–6 µm wide at base, 1.5–2.5 µm at apex, 1–5(–12) conidia formed on denticles 2–6 × 1–1.2 µm near the tip, sometimes also further down; **microconidia** */†(15–)18–30(–36) × (3–)4–5(–6.2) µm {5}, cylindrical to ellipsoid-fusoid, sometimes lageniform, strongly tapered at the truncate base, non-septate or occasionally with 1(–2) septa. 3-dimensional **adhesive networks** formed when challenged by nematodes, loops with an inner diameter of †(11–)13–20(–25) µm and an outer diam. of (15–)20–40 µm, loop cells †(2–)3–5(–6) µm wide {3}; **chlamydospores** globose to ellipsoid, intercalary.

Habitat: on rotten stems or roots of *Iris ensata* var. *hortensis* {1}, *Oryza sativa* {1}, *Triticum aestivum* {1}, unspecified soil isolate {2}. **Associated**: none reported. **Desiccation tolerance**: probably intolerant. **Altitude**: ~10 m a.s.l. (Japan), 1900 m (southern China), 250 m (Canada). **Phenology**: unknown (teleomorph).

Taxonomic remarks (teleomorph). *Orbilia multiformis* is only known from a few isolates of the anamorph, except for the type of *A. yunnanensis* in which primarily the teleomorph was obtained in culture (Mo et al. 2005a), which was identified as *Orbilia auricolor* because of a very similar micromorphology. Mo et al. spread a wet soil sample from Yunnan (China) on agar (CMA), and on the soil granules and surrounding agar the apothecia developed within 20 days. In the rather short and wide ascospores which are medium to strongly curved and only slightly attenuated towards base, the teleomorph resembles also *O. desertorum* (series *Neodactylella*). That species differs in a marginal excipulum composed of rows of rectangular cells lying at an oblique angle, whereas Mo et al.'s fungus was described with a marginal excipulum of globose cells.

Anamorph. Ascospore isolates obtained by Mo et al. (2005a) formed an anamorph in pure culture, which the authors described as a new species, *Arthrobotrys yunnanensis*. It was characterized by small, narrowly cylindric-ellipsoid or somewhat lageniform, 0(–1)-septate conidia formed in small groups on conidiophores of the candelabrelloid type (Pl. 958: 1g–h). Since the isolate strongly deviated from the currently known anamorphs of *O. auricolor*, the authors described it as a new species. Based on a comparison of their rDNA data (see below), we here conclude that the conidia of *A. yunnanensis* are microconidia and the species is conspecific with *Dactylella multiformis*, *Trinacrium iridis*, and *D. ramiformis*.

The holotype strain of *T. iridis* from *Iris* roots in Wakayama, Japan (Watanabe 1992) formed three types of conidia: 0–1-septate microconidia similar to *A. yunnanensis*, and two types of macroconidia: unbranched, 4–10-septate (phragmosporous) and branched (Y-shaped, rarely 3-armed). The branched conidia fit the generic concept of *Trinacrium*, in which genus Watanabe placed the species. Almost

(2005a), **2a–f**: from Watanabe (1992). — **1a–i**. YMF 1.00593 (holotype of *A. yunnanensis*): China, Yunnan, from soil; **2a–f**. TW 82-567 (FFPRI, holotype of *T. iridis*): Japan, Wakayama, on *Iris*.

simultaneously, the same polymorphous anamorph was described under the name *Dactylella ramiformis* by Liu & Qiu (1993) from *Triticum* roots in Beijing (China), with non-septate microconidia and unbranched (4–12-septate) or partly branched macroconidia. About 8 years earlier, Dowsett et al. (1984) published *Dactylella multiformis* isolated from marsh soil in Manitoba (Canada) with 0–1-septate micro- and 4–12-septate, always unbranched macroconidia. One of its ex-type strains (CBS 773.84) was restudied and illustrated by Rubner (1996).

Nakagiri & Ito (1996) reexamined the types of *T. iridis* and *D. ramiformis* and studied also a personal isolate from Osaka (Japan), thereby accepting placement in *Dactylella* (as *D. iridis*). Zhang et al. (1995) believed that *D. ramiformis* and *D. iridis* were different species, mainly because of the absence of chlamydospores in the former and occasionally 3-armed conidia in the latter (see Pl. 958: 2f), whereas Nakagiri & Ito regarded the two taxa as synonymous. Except for their large width, the conidia of *A. yunnanensis* fit quite well the microconidia in the other three strains. Based on our molecular comparison, we assume that Mo et al.'s strain failed to produce macroconidia, though possibly being able to do so, and likewise Dowsett et al.'s strain might produce branched macroconidia on suitable media. In her key, Rubner (1996: 43, 86) argued with the much larger middle cells in the macroconidia of *Monacrosporium multiforme* (due to conspicuously inequidistant septation) compared to *M. iridis* (= *D. ramiformis*). However, large middle cells are also seen in the photos and drawings of *D. ramiformis* (Liu & Qiu 1993) and *T. iridis* (Pl. 958: 2d).

Adhesive networks were reported by Mo et al., Dowsett et al., and Liu & Qiu, while Watanabe merely assumed that his strain was nematophagous. Nakagiri & Ito tested Watanabe's, Liu & Qiu's and their own strain with nematodes and obtained adhesive networks in all of them. They also observed a filiform hyphal 'appendage' emerging from the subbasal cell of branched conidia in all three strains, but also at the tip of the arms or stipes (Nakagiri & Ito l.c., fig. 1, 9; see also Pl. 958: 2c). These 'appendages' finally produced microconidia at the apex and may thus be considered as microconidiophores. Such terminal 'appendages' at the macroconidia were also drawn and photographed by Liu & Qiu. According to Nakagiri & Ito, the macroconidia are hydrophobous and float on the water surface, the 'appendages' thereby extending into the air.

Nomenclature. Cultures gained from the single isolate of *Dactylella multiformis* were deposited by Dowsett et al. (1984) in three different culture collections (ATCC, CBS, CMI). *D. multiformis* should be considered as validly published, because of the retroactive acceptance of metabolically inactive cultures as types (Art. 8.4 ICN), and because before 1990 there was no requirement for specifying a single institution where the type is deposited (Art. 40.7 ICN) (P. Kirk pers. comm.). We here adopt *Arthrobotrys multiformis* as the correct name for this species but transfer it to *Orbilia* following our broad generic concept. Also Yu et al. (2014) adopted *A. multiformis* and suggested *D. iridis* and *D. ramiformis* as synonyms because they 'share most morphological characteristics'.

Variation and measurement errors: In Watanabe's (1992) strain of *T. iridis* the macroconidiophores are distinctly shorter than in Liu & Qiu's (1993) strain of *D. ramiformis*, and only Watanabe occasionally observed 3-armed macroconidia. Liu & Qiu found 16% of the macroconidia to be branched (grown on CMA), whereas Watanabe stated that macroconidia were rarely branched when growing on V-8 juice agar or PDA, but predominantly branched when growing on oatmeal agar (OA). Dowsett et al. used potato-carrot agar (PCA) as culture medium and Rubner (1996) CMA:2, CMA:10, and WA plus nematodes, and both did not observe branched macroconidia in *D. multiformis*.

Measurements are partly severely erroneous in these papers, and Nakagiri & Ito (1996) and Rubner (1996) presented corrections of conidial size, according to their reexaminations. Dowsett et al.'s measurement of macroconidia [35–90.5(–116) × 4–7.5 µm] is in conflict with the given magnification of the plates which yields values of 125–210 × 11–17 µm (macroconidiophore 210 × 4 µm), but their measurements of secondary microconidia (15–17 × 5 µm) better fit those evaluated from the photos (16–22 × 5 µm). Rubner found the macroconidia in the ex-type culture at CBS particularly wider: 38–80–116(–145) × 7.5–14 µm (95–115 × 10–14 µm when evaluated from her drawing).

Liu & Qiu (l.c.) gave a width of 0.9–3.6 µm for the macroconidial arms, although their illustrations yield a width of 4–7 µm which seems more trustworthy, since Nakagiri & Ito found in this strain a width of 6–8 µm. A very wide range (13.7–98 µm) is given for the arm length by Watanabe (l.c.) and Nakagiri & Ito (l.c.), which is probably due to emerging microconidiophores at the arm tips. Watanabe gave a very high range in microconidial length (20–47.5 × 3–5.3 µm) which was corrected to 19–25 × 4–5 µm by Nakagiri & Ito. Likewise, Mo et al. (l.c.) gave a rather high range in width (17.5–32.5 × 2.75–7.5 µm), while their figure yields values of only 21–25(–31) × (4.5–)5.7–6.2 µm.

Measurements given for the asci (30–45 × 3.5–5 µm) by Mo et al. (2005a) indicate that both living and dead asci were included, based on the wide range in width. Indeed, on their figs 13–14 the authors show a dead and a living, fully turgescent ascus, the latter also after spore ejection. According to the scale the size of 1 ascus is †49 × 3.5 (fig. 13) and the other *53 × 4.1 and †51 × 3.8 µm (fig.14). We conclude that the length values in the description are erroneous or exclude the ascus stalk. We further suspect that the scales in their figs 15–16 should be 10 µm, not 7 µm; this would result in wider paraphyses and excipular cells than indicated in their description, but the paraphyses then better concur in length with the asci (see our Pl. 958: 1c the scale is changed accordingly), and the excipular cells fit better those in their fig. 11. The scale bar in their fig. 7 is assumed to have a length of 20 µm instead of 10 µm, considering the given width of 2–4 µm for the mycelial hyphae and the fact that loops with an outer diameter of 10–13 µm are unknown in *Arthrobotrys*.

Phylogeny. Sequences of five strains exist in GenBank: the Canadian type of *A. multiformis* (ITS, LSU), the Japanese type of *T. iridis* (LSU), the northern Chinese type of *D. ramiformis* (ITS, *TUBB*, *RPB2*, *TEF1*), and the southern Chinese type of *A. yunnanensis* (ITS). Three further sequences in the NBRC database under the name *A. iridis* comprise ITS and LSU: two of them refer to the types of *T. iridis* and *D. ramiformis*, and one to the isolate of Nakagiri & Ito. The ITS sequences of the types of *A. yunnanensis* and *A. multiformis* include the S1506 intron, while the other sequences are unclear in this respect.

In the ITS region, the types of *T. iridis*, *D. ramiformis* and *A. yunnanensis* show a 100% similarity (without gaps, see also the analysis by Qiao et al. 2012), which permits to conclude that the three are conspecific. The type of *A. multiformis* differs from them in the ITS by 0.7% (3 nt), though also in the LSU (D1–D2) by 0.5–0.7% (3–4 nt, thereby pos. 330 concurring with the type of *T. iridis*). The S1506 intron in the type of *A. yunnanensis* differs by only 1% (4 nt) from the type of *A. multiformis*. We may therefore conclude that also *A. multiformis* is conspecific with *A. iridis*. An ITS sequence under the name *Penicillium chrysogenum* in GenBank (DQ093690), isolated from decayed *Picea* root in Lithuania by Menkis et al. (2006), matches the above *O. multiformis* strains with a 0.4–0.8% distance. Perhaps it got contaminated when it was sent to CBS for identification (A. Menkis pers. comm.).

In phylogenetic analyses of the ITS region by Yang & Liu (2006) and Yang et al. (2007), *A. iridis* is found with high support in a sister position to all remaining strains of series *Arthrobotrys*, whereas in a combined analysis of ITS, *TUBB*, *RPB2*, and *TEF1* it clustered in a well-supported clade with *A. anomalus* and *A. sinensis* which are, however, morphologically very different among another and show in the ITS region a distance of 7.5–10.5%. In our combined analysis (Phyl. 25) or that of ITS (Phyl. 28), LSU (S32), or S1506 intron (S30), *O. multiformis* clustered unresolved by showing a high distance to other strains.

Ecology. The Japanese strains of *O. multiformis* were from subtropical humid lowlands around Osaka, being isolated from stems and roots of rice or Japanese iris incubated under water. The Chinese isolates were from roots of a continental, temperate humid (winter-dry) wheat field near Beijing and from unspecified soil in the subtropical humid (winter-dry) highland near Kunming. The Canadian site was a boreal humid, continental marshland at a large lake, and the European isolate from conifer roots in a hemiboreal humid forest plantation.

Specimens included. **CANADA**: **Manitoba**, Lake Manitoba, Delta Marsh, University Field Station, 250 m, marsh soil, undated, J. Orbilia javanica (Rifai & R.C. Cooke) Bin Liu, Baral & E. Weber, **comb. nov.**, MB 813987 — Pl. 959

Basionym: *Candelabrella javanica* Rifai & R.C. Cooke, Trans. Br. Mycol. Soc. 49(1): 162 (1966)

≡ *Arthrobotrys javanicus* (Rifai & R.C. Cooke) Jarow. [as ‘*javanica*’], Acta Mycol. 6(2): 373 (1970)

Etymology: after the geographical origin, Java.

Typification: Indonesia, Java, Bogor Botanical Gardens, soil, XI.1963, N. Wariwan (IMI 108725, holotype, doc. vid.).

Misapplied name: Liu (2006: 51, teleomorph), as *O. auricolor*.

Description: — **TELEOMORPH**: **Apothecia** with ~10 µm protruding ?smooth margin. **Asci** †4 µm wide, apex strongly truncate (not indented, not inflated), thin-walled, lower spores inverted. **Ascospores** *~7–9 × 1.2–1.5 µm (in situ), medium attenuated towards base, slightly to medium curved; **SBs** subglobose/tear-shaped, ~1.5 × 0.8 µm. **Paraphyses** apically hardly inflated, covered by exudate. **Ectal excipulum** at base and flanks of textura angularis, ~20 µm thick at margin, forming a t. prismatica oriented at a 0° angle to the surface; **glassy processes** absent. **— ANAMORPH** (after Rifai & Cooke 1966 and Liu 2006): arthrobotrys-like (from ascospore {1} and soil isolate {1}). **Conidiophores** erect, 275–480 µm long, 8–12 µm wide at base, 2.5–3.5 µm at apex, branched only at the very apex, 3–15 conidia formed on distinct denticles (~3–9 × 2–3 µm) at apex (candelabrelloid). **Conidia** *(25–)28–34(–42.5) × (7.5–)10–12(–15.5) µm {2}, narrowly obpyriform (clavate), 1-septate, septum slightly eccentrical or almost at lower third of conidia, slightly constricted. Trapping nematodes by 3-dimensional **adhesive network** with loops with ~30–35 µm outer diameter, loop cells 3.5–4.5 µm wide.

Habitat: on twig of indet. woody plant on moist ground {1}. **Desiccation tolerance**: unknown (possibly intolerant). **Altitude**: 260–1000 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: XI (teleomorph).

Taxonomic remarks. Liu (2006: 51) identified a collection from subtropical southern China (Pl. 959: 1) as *Orbilia auricolor*, but with ascospores shorter than in typical collections. No description of the teleomorph was provided. The marginal ectal excipulum is composed of elongated, narrow cells oriented at a very low angle, which recalls the broader cell rows running under a low angle typical of some species of series *Neodactylella*, such as *O. oxyspora* or *O. desertorum*. Yet, these species are connected

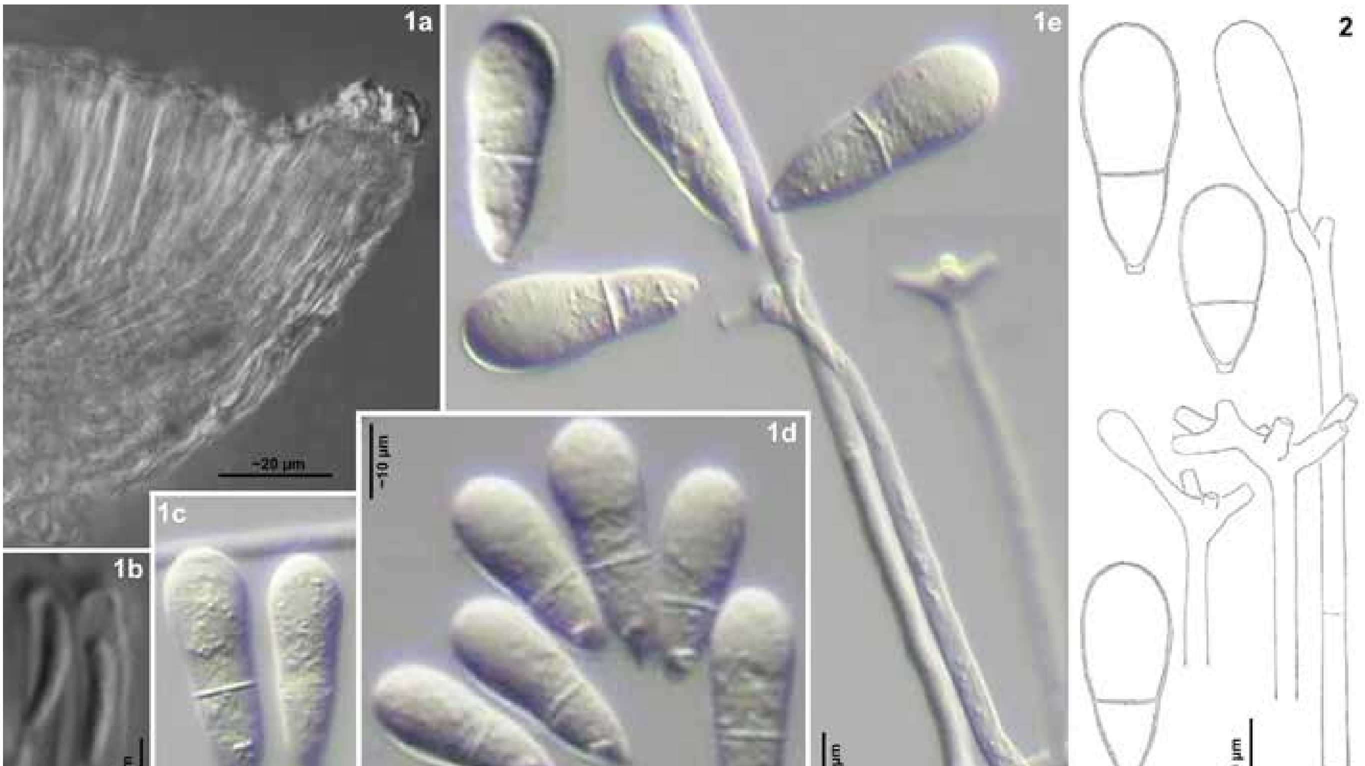

Plate 959. **1–2**: *Orbilia javanica*. – **1a**. marginal ectal excipulum in median section; **1b**. ascospores; **1c–e**, **2**. conidia and conidiophores (from culture). – Living state, except for **1a–b**, ?**2**. – **1a–e**: from Liu (2006); **2**: from Rifai & Cooke (1970). — **1a–e**. HMAS 139636: China, Yunnan, on indet. woody plant; **2**. IMI 108725 (holotype): Java, from soil.

to non-predacious dactylella-like anamorphs with multiseptate conidia, whereas Liu's collection formed adhesive networks in pure culture that refer the fungus to series *Arthrobotrys*. Z.F. Yu et al. (pers. comm., see IVV) obtained *Arthrobotrys musiformis*, an anamorph morphologically very similar to *O. javanica*, in pure culture from apothecia, which differed in longer and narrower spores and a marginal excipulum of broad, roundish cells.

Anamorph. Liu (2006) identified the anamorph of his collection as *Arthrobotrys javanicus*. The narrowly obpyriform conidia developed on candelabrelloid conidiophores (Pl. 959: 1e). The type of *A. javanicus* was isolated from soil in Java. It differs from Liu's strain in somewhat wider conidia produced on conidiophore tips with partly more branches forming a typical candelaber-like structure (Pl. 959: 2). *A. javanicus* is the type species of the genus *Candelabrella* Rifai & R.C. Cooke.

A. javanicus closely resembles *A. musiformis* in having the same type of conidiophores and similar-sized conidia, which differ merely in lacking a constriction at the septum and in being sometimes slightly curved (19–42.5 × 7–14 µm, Van Oorschot 1985). *A. conoides* has similarly shaped but longer conidia and an arthrobotryoid conidiogenesis. Elshafie et al. (2003, fig. 8) described a soil isolate from a *Citrus* plantation in Nizwa, Oman (CBS 109508) and noted a high variability of the species; however, this isolate belongs to *A. cladodes* (see below).

Phylogeny. Sequences exist for the type of *O. javanica* (ITS, LSU), Liu's ascospore isolate from Yunnan (ITS, LSU), two soil isolates (Hong Kong, Swe et al. ined., ITS; Taiwan, Kuo et al. 2008, ITS), and an isolate of unclear origin (YNUCC 6907, Li et al. ined., LSU). In the ex-type strain and that from Yunnan the S1506 intron is absent, while this is unclear for the other two ITS sequences.

In the phylogenetic analysis by Liu et al. (2006a), Liu's isolate from Yunnan clustered close to the ex-type strain by showing a much higher distance to *O. auricolor* s.l. In the ITS region, the four sequences show a distance of 1–2% among each other by forming a strongly supported clade (Phyl. 28). In our combined analysis (S33), *O. javanica* clustered in the medium supported *oligospora-musiformis* clade, which received no support in the ITS tree. *A. musiformis* shows a high distance of 8–9% to *O. javanica* and also differs by various characteristic gaps. In the LSU (D1–D2), however, *O. javanica* is very close to *A. musiformis* (0.7–1.5%), differing only at pos. 539 (C vs. T) and 546 (G vs. T), respectively. *O. javanica* forms a monophyletic clade also here by forming an unsupported clade with *A. musiformis* outside the *oligospora-musiformis* clade (S32).

According to molecular data (ITS, LSU) in the CBS database, Elshafie et al.'s soil isolate of *A. javanicus* (CBS 109508) was misidentified. In concordance with its more arthrobotryoid conidiophores it belongs to the *cladodes-botryosporus* clade (see LSU analysis S32), with *A. botryosporus* (C4) as closest taxon when comparing the low distance of ITS (2.7%) or LSU (0.6%) together with a characteristic position in the LSU D1 (pos. 201, Tab. 83), although its 1-septate conidia and pos. 541 in LSU D2 (Tab. 83) point to *A. cladodes*.

Ecology. *O. javanica* is mainly known from anamorphic soil isolates, and only once from the teleomorph collected on an unidentified twig. The type strain from Indonesia was from a tropical humid rainforest, an area with the highest precipitation recorded in Java. The other samples are from monsoon-dominated, winter-dry regions: a subtropical humid (winter-dry) montane forest in Yunnan and subtropical mountainous and tropical low-land areas in Taiwan.

Specimens included. **CHINA**, **Yunnan**, **Xishuangbanna**, Jinghong, 1000 m, twig of indet. tree, 9.XI.2002, B. Liu et al. (B.L. 6214, HMAS 139636, anam. cult., doc. vid.; sq.: DQ656611, DQ656666). – **Hong Kong**, unlocalized, soil isolate, Swe et al. (strain 105, conid. isol., doc. vid.; sq.: EU977514). – **Taiwan**, **Yilan**, Songluo, from humus, 16.VIII.2007, K.T. Chen (SL11; ?BRC 34375, conid. isol., [doc. vid.]; sq.: FJ380932). – **Kaohsiung**, Maolin, from humus, 8.II.2007, K.T. Chen (ML13, conid. isol., [doc. vid.]). — **INDONESIA**: **Java**, **West Java**, 43 km S of Jakarta, Bogor Botanical Gardens, 260 m, soil isolate, XI.1963, N. Wariwan (IMI 108725, **holotype** of *Arthrobotrys javanicus*, CBS 534.63, conid. isol., doc. vid.; sq.: U51947, AB161069, AY261136, MH858347). – **Unlocalized** (YNUCC 6907, non vid.; sq.: AY261150).

Arthrobotrys nonseptatus [as '*nonseptata*'] Z.F. Yu, S.F. Li & K.Q. Zhang, in Li et al., Mycotaxon 109: 249 (2009) — Pl. 960

Etymology: after the non-septate conidia.
Typification: China, Yunnan, Yuxi, bark of indet. angiosperm tree, 18.VIII.2006, Y. Zhang (YMF 1.01852, holotype, doc. vid.).

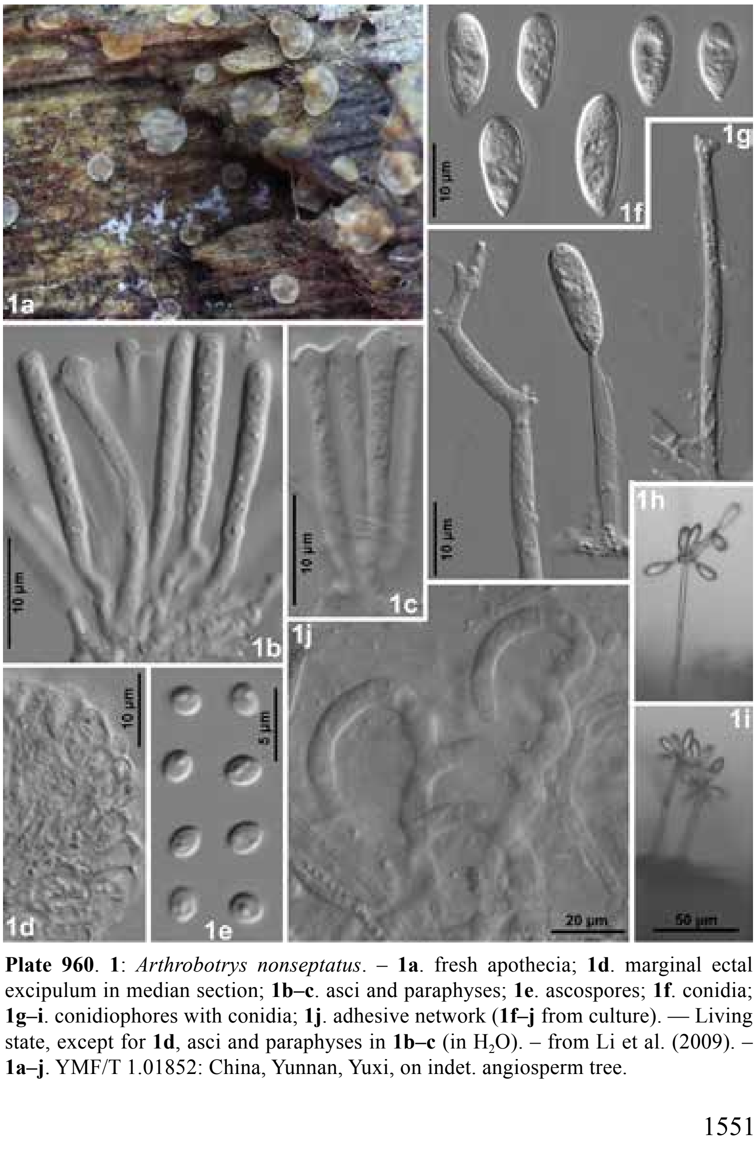

Plate 960. **1**: *Arthrobotrys nonseptatus*. – **1a**. fresh apothecia; **1d**. marginal ectal excipulum in median section; **1b–c**. asci and paraphyses; **1e**. ascospores; **1f**. conidia; **1g–i**. conidiophores with conidia; **1j**. adhesive network (**1f–j** from culture). — Living state, except for **1d**, asci and paraphyses in **1b–c** (in H_2O). – from Li et al. (2009). – **1a–j**. YMF/T 1.01852: China, Yunnan, Yuxi, on indet. angiosperm tree.

Description: — Anamorph (after Li et al. 2009): arthrobotrys-like (from ascospore-isolate {1}). **Conidiophores** erect, septate, unbranched, 40–120 µm high, 2–4 µm wide in the lower part, 1.5–2 µm at apex, producing 3–10 conidia from retrogressive conidiogenous loci on nodules or short denticles (1–1.3 × 1.2–1.3 µm) on indistinctly swollen nodes at the apex (arthrobotryoid), sometimes two in a row. **Conidia** *11–16.8 × 5–6.6 µm, (cylindric-)ellipsoid, narrowed at base to form a small truncate protuberance, non-septate. Trapping nematodes by means of 3-dimensional **adhesive networks**, loops with a *30–35 µm outer diam. and 18–25 µm inner diam., loop cells *5.5–7.5 µm wide.

Habitat: on rotten bark of indet. angiosperm tree. **Altitude**: 1750 m a.s.l. **Geology**: metamorphic rock. **Phenology**: VIII.

Taxonomic remarks. Li et al. (2009) described *A. nonseptatus* based on the anamorph. It was gained from an ascospore isolate, reportedly from a species with subglobose ascospores. In ascospore shape this teleomorph resembles taxa of series *Drechslerella* (*O. tonghaiensis*) or series *Orbilia* (e. g., *O. cejpii* and *O. fissilis*), but not a member of series *Arthrobotrys*. Particularly O. *tonghaiensis* (Pls 1027, 1028: 1) resembles *A. nonseptatus* in the teleomorph and even in the microconidial anamorph, but forms constricting rings.

Due to the unexpected anamorph, Li et al. (2009) hesitated in validly describing a new species for the teleomorph, but hoped for further isolates to clarify the observed connection to the anamorph. The authors did not provide a description of the teleomorph, only the spore length was said to be ~2.5–3 µm. According to the scale the figured spores measure *2.2–2.6 × 1.8–1.9 µm. Because of the unusual spore shape we here refrained from giving a description of the teleomorph.

Phylogeny. A sequence of the ex-type strain comprises S1506 intron and ITS. In our ITS analysis (Phyl. 28) and that by Li et al. (2009), *A. nonseptatus* clustered unresolved within series *Arthrobotrys*, with a high distance (~10%) to other species. It clustered in an unsupported clade with *A. reticulatus* and *A. polycephalus* when analysing the intron (S30). Possibly the authors had a culture containing a mixture of two different species, *O. tonghaiensis* and an unknown *Arthrobotrys*. The observed conidiophores and conidia would then belong to *O. tonghaiensis*, and only the figured adhesive network and the sequence would derive from the *Arthrobotrys* species. In this case, lectotypification would be necessary to fix the name *A. nonseptatus* on one of the two species included in the protologue.

Ecology. *A. nonseptatus* was collected on rotten bark of an unidentified angiosperm tree in a montane mixed forest with *Quercus schottkyana* and *Pinus armandii* in subtropical humid (winter-dry) southeastern Asia.

Specimens included. **CHINA**, **Yunnan**, **Yuxi**, Yimen, 54 km NW of Yuxi, 3 km NW of Fangtunxiang, Dalongkou, ~1750 m, on bark of indet. angiosperm tree, 18.VIII.2006, Y. Zhang (Y.Z. ym-28, YMF/T 1.01852, **holotype**, anam. cult., doc. vid.; sq.: FJ185261).

adhesive networks, forming loops with an inner diam. of (6–)10–20 µm and outer diam. 14–28 µm, loop cells *(3.5–)4–6(–6.5) µm wide (taken from drawings by Drechsler 1944a and Duddington 1951). **Chlamydospores** not observed.

Habitat: on previous year's leaves of *Scirpus maritimus* {1}, medium decayed, without algae; dung of *Oryctolagus cuniculus* {1}, *Ovis* {1}; isolated from soil {6}. **Associated**: *Orbilia scaphoides* {1}. **Desiccation tolerance**: unknown (probably intolerant). **Altitude**: 1–60 m a.s.l. (temperate Europe), 3010 m (Ecuador). **Phenology**: unknown (teleomorph).

Taxonomic remarks. *Orbilia elegans* is very similar to *O. auricolor* in the teleomorph, which explains Rubner's (1996) identification of this morph as *O. auricolor*, although the two species sharply differ in their anamorph (see below). Asci, ascospores, and terminal cells of paraphyses in *O. elegans* show virtually the same width as in *O. auricolor*, and also their length is only very slightly higher. The presence of short glassy processes could perhaps be diagnostic, though such are sometimes also present in *O. auricolor*. Despite the absence of distinctive characteristics of the teleomorph, *O. elegans* is recognized here as a species of its own based on the deviating anamorph and the deviating molecular data. Some of those specimens without a known anamorph, assigned to *O. auricolor* in the present study, could as well belong to *O. elegans*. Such confusion is not unlikely: e. g., the Chinese specimen on bark (Pl. 962: 2), here tentatively assigned to *O. elegans*, hardly differs in the teleomorph from the predominantly bark-inhabiting *O. auricolor*.

Anamorph. Rubner (1996) established for the first time the connection between anamorph (as *Monacrosporium psychrophilum*) and teleomorph (as *O. auricolor*) based on both being formed in pure culture of an Ecuadorian soil isolate (CBS 319.94). The anamorph sharply deviates from taxa previously reported for *O. auricolor* (*Arthrobotrys cladodes* and *A. oligosporus*) by its much larger, (2–)3(–4)-septate, fusiform to top-shaped conidia with a strongly enlarged, ventricose middle cell, formed singly or in groups of 2–3 at the conidiophore tip. Cylindric-clavate, 0(–1)-septate microconidia were occasionally observed in this strain together with the macroconidia.

Species concepts in this group are difficult, however (see Rubner 1996). Based on molecular data we here consider the two Ecuadorian strains identified by Rubner as *M. psychrophilum* (CBS 318.94, Rubner 1996: fig. 47b; CBS 319.94, Pl. 961: 1) as conspecific with *M. elegans* as circumscribed by Rubner. The two Ecuadorian strains differ from the type of *M. psychrophilum* (Pl. 961: 5) in slightly smaller, especially shorter conidia which are partly more distinctly top-shaped, with a strongly ventricose middle cell, but possibly these differences do not warrant separation between *M. psychrophilum* and *M. elegans*. The conidia of *Arthrobotrys thaumasius* (Drechsler) S. Schenck et al. are also similar to *M. elegans* in shape but are again slightly shorter and often formed in clusters of 2–4(–10). *A. reticulatus* is a further taxon to be confused with *M. elegans*, with (3–)4(–5)-septate conidia with a less swollen middle cell (see Rubner 1996). Also *A. eudermatus* and *A. megalosporus* are very similar to *M. elegans* (see Rubner 1996).

Variation in anamorph. In her concept of *Monacrosporium psychrophilum*, Rubner (1996) observed some variation in the morphology of conidia and conidiophores. She united under this name several European and Ecuadorian isolates, which varied somewhat in conidial size, shape, and number of septa, and in branching of conidiophores, though sometimes within a collection. In a German strain from wheat field soil (Rubner l.c., fig. 47a, CBS 548.63, epitype, Pl. 961: 6) she figured mainly fusiform conidia, whereas her drawings of the two Ecuadorian isolates (fig. 47b, CBS 318.94; Pl. 961: 1f$_1$) show a tendency to top-shaped conidia, and one from Sweden (fig. 47c, L.P. 9203) again more fusiform conidia. In all these strains occurred also smaller, strongly clavate conidia with only 1–2 septa. The large conidia are mainly figured with 3 septa, but Drechsler (1944a) observed also often 2- and 4-, rarely 5-septate conidia (Pl. 961: 5). In the three strains figured by Rubner under the name *M. elegans* from Sweden (CBS 397.93) and Germany (CBS 300.94; 301.94, epitype, Pl. 961: 4) the conidia were consistently top-shaped and generally 3-septate, but the conidiophores also varied between apically unbranched and branched.

In the two isolates examined by us (Pls 961: 1–2; 962: 1) we saw mainly 3-septate conidia, but also some with 2 septa, and exceptionally one with 4. Conidial shape and size was rather different between the two strains: top-shaped in the soil isolate from Ecuador but more fusiform in that on *Scirpus*. However, the conidia in Rubner's unpublished drawing of the Ecuadorian strain (Pl. 961: 1f$_1$) considerably deviate in size from those observed by us in the same culture. The conidia from the *Scirpus* strain and those drawn by Rubner better fit the holotype or epitype of *M. psychrophilum*, but those in 1f$_2$ better fit the epitype of *M. elegans* or *A. thaumasius*.

Based on the morphological similarity of these anamorphs and on molecular data (see below), we conclude that the two Ecuadorian strains are conspecific with Rubner's three figured *M. elegans* strains. The variable features within this group were also stressed by Rubner (1996: 63) regarding the identification of the two Ecuadorian strains which she left in *M. psychrophilum* although the conidia were morphologically closer to *M. elegans*. Conidial shape in this group appears to be subjected to a certain degree of variability between fusiform and top-shaped, even within a strain, rather than representing a valuable species marker.

The holotype material of *M. psychrophilum* from North America now appears to be empty (Rubner 1996), and no sequence was available for the German epitype. In conidial shape the epitype fits quite well the holotype of *M. psychrophilum*, but its conidia are distinctly smaller when evaluated from the scale in Rubner's drawing than those of Drechsler (see Pl. 961: 5–6).

Not included collections. Two not included Chinese samples comprising teleomorph and anamorph differ rather severely from each other in conidial size and shape, including their microconidia. They were studied by H.Y. Su who kindly provided her data. One of them (Pl. 962: 3) closely matches the original description of *M. cystosporum* R.C. Cooke & C.H. Dickinson (1965, = *A. thaumasius* fide Rubner 1996) though the conidia are shorter [*(28.5–)30–37(–42) × (15–)16.5–19.5(–22) µm, 2–3-septate; microconidia *17–22(–26.5) × 4.3–6.2 µm, 1-septate]. From this strain the other (Pl. 962: 2) differs in longer macro- and microconidia (*46.5–69 × 16–23 µm, 3–4-septate; *21–32 × 4.7–6 µm, 0–3-septate). It was compared by H.Y. Su with *A. longiphorus*, a species with rather narrow, fusiform conidia (Liu & Lu 1993), but we believe that it also fits quite well in the scope of *M. elegans*. Actually, its macroconidia hardly differ in size and shape from the epitype of *M. elegans*, except for being frequently 4-septate. Its microconidia are also distinctly longer than in Rubner's Ecuadorian isolate (Pl. 961: 1g) and differ in being partly 3-septate. Drechsler (1944a) observed in an aberrant culture of *Dactylaria psychrophila* rather large, 0–1-septate microconidia of 14–35 × 4.8–7.5 µm, and Rubner (1996) in *M. elegans* non-septate microconidia of 13–16.5 × 5–6 µm.

A more striking difference appears to lie in the trapping organs of the two Chinese collections. Their loops have a distinctly larger diameter compared to illustrations by Drechsler (1944a) and Duddington (1951), although their cells show a similar width, resulting in more gracile networks (but note that Duddington's measurements do not match his scale and appear to be too large). In Pl. 962: 3l the loops measure 40–55 µm outer diam. (28–45 µm inner diam.) according to the scale and their cells are 3.5–7 µm thick. Also *A. thaumasius* shows larger, more gracile networks when screening the literature. Therefore, and because of the mentioned deviations in the macroconidia, this strain might indeed belong to *A. thaumasius*. Regrettably, molecular data were not available for the two Chinese strains.

For the not included *A. psychrophilus* (*O.* cf. *elegans*) see under Anamorph.

Phylogeny. Sequences of *O. elegans* s.l. (in the following called *elegans-gampsosporus* clade) were available in GenBank and the CBS database for a total of 12 isolates: three from soil, moss, or sheep dung in Germany, three from soil in Ecuador, one from soil in Sweden, one from soil and one from apothecia on *Scirpus* in the Netherlands, two from nematodes or litter in California, and one from dung in Australia. Seven of them were identified as *M. elegans* (or *A. oudemansii*, a nomen novum, including the epitype), two as *M. psychrophilum*, two as *M. thaumasium*, and one as *M. eudermatum*. In addition to ITS some of these strains comprise also SSU and LSU. The S1506 intron is present in the *Scirpus* strain and perhaps in the one from Sweden, but absent in the other six strains that cover this region.

The two Ecuadorian soil isolates referred by Rubner (1996: 92) to *M. psychrophilum* (CBS 318.94, 319.94) show to the morphologically very similar *Scirpus* isolate (H.B. 6972a) a 4.1–4.6 % ITS distance (13 nt in ITS1 and 13 nt in ITS2, 12–14 gaps). Yet, also between the two Ecuadorian isolates 7 nt (1.3 %) and 4 gaps differ. When including all available ITS sequences, high distances are also observed between strains from the same continent, and very low distances also occur between strains from different continents.

Two main groups can be distinguished within *O. elegans* s.l., subclade E1 (*O. elegans* s.str.) and subclade E2, which differ by 4.1–5 % and a characteristic pattern of more than 10 gaps (Phyl. 30). Two subclades can be distinguished within clade E1 (a/b) which differ by 1.3–1.7 % (7 consistent and 2 variable nt, 4 gaps). Likewise, two subclades can be distinguished within clade E2 (a/b), which differ by 1.3 % (7 nt, 0 gaps). Variation in subclade E1a at 1 position in the ITS1 (C in E1a-1, G in E1a-2) is so far correlated with the geographical origin. Subclade E1a-1 includes three strains from central Europe: the epitype of *M. elegans* on dung and two isolates under the name *M. thaumasium*. Subclade E1a-2 includes two Ecuadorian soil isolates (as *M. elegans* and *M. psychrophilum*) and the Australian *M. elegans* from dung. Subclade E1b varies by 1 nt in the ITS2: C in E1b-1 (another Ecuadorian *M. psychrophilum*), T in E1b-2 (the Californian nematode isolate under the name *A. eudermatus*).

To clade E2 belongs our *Scirpus* strain from the Netherlands (E2a) and one of the German isolates referred by Rubner (1996: 60) to *M. elegans* (E2b). The Californian leaf litter isolate, which comprises only ITS2 (and LSU), fully matches subclade E2b in the available ITS2 region (except for 1 gap), where this subclade deviates by 3 nt from subclade E2a.

All differences in the ITS region in total include 26 nucleotides or gaps that separate between clades E1 and E2 (Tab. 85). Two aberrant deviations were neglected in the above discussion: a rare deviation in the 5.8S region in the *Scirpus* strain, and an unusual repeat (GAAGAA) in the ITS2 of the Californian strain ATCC 96679.

The observed ITS distance of 4.1–5 % between clade E1 and E2 suggests that two different species are involved, particularly when considering that *A. gampsosporus* shows a comparable distance of 4.5–5.5 % to *O. elegans* s.l. (see also p. 1582). However, in the LSU D1–D2 domain the two genotypes (E1/E2) cannot be differentiated because the 3 deviating nucleotides are not correlated with them, and the single sequence of the morphologically different *A. gampsosporus* deviates from all of them only at 1 position in the D2. Since morphological differences could not be found between clades E1 and E2, we refrain here from splitting *O. elegans* into two species. We did not include holo- and epitype of *A. psychrophila* in the description of *O. elegans* because of lacking molecular data.

Table 86. 14 nucleotide positions in the ITS1 region that separate *O. elegans* s.l. from *O. auricolor* and *O. cladodes*, in comparison with *A. gampsosporus*, *O. latispora* s.l., *A. botryosporus*, and the unidentified strain ATCC MYA-4125 (Houseknecht & Zhou ined.). No positions were found in the ITS2 region that separate *O. elegans* s.l. from *O. auricolor* and *O. cladodes*. – Alignment and position numbers are the same as in Tab. 82, Str. = number of strains.

Species	Str.	17	25	30	38	52	59	61	89	91	101	107	133	135	141

Phylogenetic analysis 30. NJ analysis of ITS1-5.8S-ITS2 rDNA dataset (15 sequences, 595 positions, aligned with MUSCLE, 500 replicates), showing relationship within the *elegans-gampsosporus* clade. U72610 deviates from AF106525 and the CBS database at pos. 34 of 5.8S (T vs. A) which is probably erroneous. The tree is rooted with *A. flagrans* and *A. thaumasius*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, * = without ITS1 and partial 5.8S.

Also in the phylogenetic analysis of the ITS region by Hagedorn & Scholler (1999: fig. 2), two German isolates of *O. elegans* (as *M. elegans*, CBS 300.94, 301.94) clustered with two from Ecuador (as *M. psychrophilum*, CBS 318.94, 319.94) in a clade that included also a sequence of *M. gampsosporum* (CBS 127.83). Three isolates of *A. thaumasius* (including an ex-syntype strain) formed in Hagedorn & Scholler's and our analyses (Phyls 28, S32) a separate clade very distant from the *elegans-gampsosporus* clade. Therefore, *A. thaumasius* (see p. 1582) can be excluded from synonymy with *O. elegans*. Also *A. eudermatus*, *A. mangrovisporus*, and *A. janus* clustered distantly (see there).

Between *O. elegans* and *O. auricolor* s.l. a distance of ~7–11 % in the ITS region is observed, which is slightly higher to the *cladodes-botryosporus* clade in comparison to the *O. auricolor* clade. 14 characteristic nucleotides in the ITS1 region but none in the ITS2 distinguish *O. elegans* from *O. auricolor* (Tab. 86, see also Tabs 82–83).

Ecology. The strains here included in *O. elegans* were isolated from a variety of substrates (soil, dung, moss, decaying herbaceous plants) in Europe, North and South America. Literature reports of *M. elegans* or *M. psychrophilum* include various European countries (Great Britain, Ireland, Sweden, Denmark, Netherlands, Germany), but also Macaronesia, Turkmenistan, Arabian Peninsula, eastern USA, and Antarctica (Drechsler 1944a, Duddington 1951a, Elshafie et al. 2003, Gray 1985, Oudemans 1885, Rubner 1994, 1996, Shepherd 1956, Soprunov 1958).

The apothecia of the collection on *Scirpus maritimus* (≡ *Bolboschoenus maritimus*) from northwestern Europe were obtained during storage of dead leaves for about 2 months in a moist chamber. They were collected in a nearly dominant stand of *Scirpus maritimus* in a subatlantic coastal brackish marsh influenced by the tides (G. Van Ryckegem pers. comm.). Rubner's (1996) soil isolates, in which partly apothecia developed on agar, were from ruderal places between path and a meadow in a subtropical humid highland climate of Ecuador (with a dry season during 3 months). The German and Swedish isolates from dung, moss, or soil are from subcontinental, cold-temperate humid areas, and the western North American isolate from a nematode originates from a mild-maritime humid (summer-dry) coastal region. Further samples, particularly of the teleomorph, are needed to explore the substrate preferences of *O. elegans*.

Not included collections were from a wheat field in cold-temperate humid, subcontinental-maritime northern Germany (epitype of *M. psychrophilum*) and from remnants of potato under a similar climate in northeastern North America (holotype of *M. psychrophilum*). Those from southern China were from lake water mud and from bark in montane evergreen forests in subtropical humid (winter-dry) eastern Asia (at the eastern end of Himalaya).

Specimens included (subclades: E1a-1 = includes epitype, E1a-2 = 1 nt deviation from epitype, E1a-3 = 2 nt deviation from epitype, E1b = 7–8 nt and 4 gaps deviation from epitype, E2 = 4.4–4.8 % and 12–13 gaps deviation from E1): **SWEDEN**: **Skåne**, Bjärröd (near Gyllsjö?), loamy soil under *Salix*, 9.V.1989 L. Orbilia menageshae Baral & U. Lindem., **sp. nov.**, MB 813989 — Pls 963–965

Etymology: named after the type locality, Menagesha Suba State Forest.

Typification: Ethiopia, Addis Ababa, Menagesha Suba, branch of indet. angiosperm, 26.III.2010, Dawit Abate & U. Lindemann (ex H.B. 9275a, M-0276510, holotype; sq.: KT222439).

Latin diagnosis: *Apothecia rehydratata 0.8–5.5 mm diam., dilute cremea vel intense ochracea, disco conspicue concavo vel plano, margine laevi. Asci 8-spori. Ascosporae *9.5–14 × 1.2–1.5 µm, subulatae, apice rotundati. basi attenuatae, interdum subcaudatae, modice ad valde arcuatae, corpusculum refringens subulatum vel cylindricum, ad apicem filo indistincto affixum continentes. Paraphyses ad apicem leniter vel modice inflatae, saepe ellipsoideae, exsudato calyptriforme tectae, cellulae vivae absque vacuolis refringentibus. Cellulae excipuli marginalis sub angulo alto orientatas formantes, processis vitreis brevibus vel carentibus. Habitat ad corticem putridum angiospermarum, in zona temperata humida afromontana Africae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.8–)1–2.5(–5.5) mm diam., 0.27–0.4 mm high (receptacle 0.19–0.28 → 0.11–0.15 mm), pale greyish-cream to light or bright ochraceous(-orange), slightly translucent, round, somewhat undulating when large, slightly gelatinous, scattered to gregarious in small groups; disc medium concave, finally flat, margin distinct, thin or thick, not protruding, smooth; sessile on a broad base, superficial; dry ± cupulate, pale to bright yellowish-cream to greyish-ochraceous. **Asci** *55–60 × 3.6–4.5 µm {2}, †45–53 × 3.2–3.8 µm {T}, 8-spored, spores indistinctly 4-seriate, 4–5 lower spores inverted {2} (sometimes mixed); **apex** (†) medium to strongly truncate (not indented, laterally sometimes slightly inflated); **base** with short to medium long, thin or thick, ± flexuous stalk, Y- or h-shaped. **Ascospores** *(9.5–)10–13(–14) × (1.2–)1.3–1.4(–1.5) µm {2} (~12–15 µm actual length), †12–14.5(–15.5) × 1–1.3 µm {T}, narrowly fusoid, apex rounded, base gradually attenuated or with a ± distinct tail, medium to (very) strongly curved (falcate), (†) slightly to medium curved; **SBs** *2–3 × 0.2–0.4 µm {2}, subulate or often divided into a narrowly cylindrical, 1.5–2 µm long lower part and a ± invisible filum. **Paraphyses** apically slightly to medium capitate-clavate or often ellipsoid, terminal cell *26–33 {1} or 35–40 {T} × (2.8–)3–4(–4.3) µm {2}, †25–33 × (2–)3–4.5 µm {T}, lower cells *6–9 × 2–2.5 µm {2}, †5–7 × 1.5–2 µm {T}, branched only near base, partly pale ochraceous below. **Medullary excipulum** hyaline, 80–170 µm thick in centre, of (†) not or slightly gelatinized textura angularis-globulosa (upper 30–40 µm small-celled), very indistinctly delimited from ectal excipulum, more clearly so at flanks by a 10–20 µm thick layer of t. porrecta. **Ectal excipulum** hyaline to pale ochraceous near surface, of vertically oriented textura angularis(-globulosa) from base to mid flanks, ~50–250 µm thick near base, cells */†(20–)27–55(–85) × (15–)20–30(–48) µm {3}, (†) (not or) slightly (to medium) gelatinized (outer wall of cortical cells up to 1.5–2.5 µm thick); 20–25 µm thick at margin, oriented at a 60–80° angle to the surface, marginal cortical cells */†11–15(–17) ×(3–)3.5–4.5 µm {2}; **glassy processes** 2–4 × 4–5(–5.5) µm {T}, refractive. **Anchoring hyphae** ± sparse, †(3.5–)4–5.5(–6) µm wide, walls 0.3–0.6(–1.2) µm thick {2}. **SCBs** globose, in paraphyses ~0.8–1.8 µm diam., in medullary excipulum at flanks 1.8–2.7 µm; **VBs** absent. **Exudate** over paraphyses 1–3(–4) µm thick {2}, cap-like, hyaline to pale yellowish, firmly attached, over margin and flanks hyaline to light golden(-ochraceous). — **ANAMORPH**: arthrobotrys-like (from ascospore isolate {T}). **Mycelial hyphae** *(2.5–)3–5(–8) µm wide, covered by a 0.8–2.5 µm thick gel sheath, with scattered LBs, cells ~4-nucleate. **Conidiophores** *(75–)140–270(–600) µm long, *(3.5–)5–7.5(–9) µm wide at base, 3.5–4.3 µm at apex, near base up to middle part (0–)2–3(–7)-septate, sometimes branched in lower or upper half, conidia formed terminally, singly. **Large conidia** *(32–)40–50(–63) × (12–)14.5–18.3(–20.7) µm, (1–)2(–3)-septate {T}, obpyriform or more often fusoid to fusoid-clavate, with a large central cell if 3-septate; containing some small LBs. **Small conidia** *21–26.5 × (9–)10.5–13.3(–15.5) µm, (0–)1-septate {T}, obpyriform, not sharply differentiated from large conidia. **Adhesive networks** not formed in the presence of a nematode and springtails (but a few loops formed in the not included strain on *Solanecio*). **Chlamydospores** not observed.

Habitat: close to the ground, corticated, 11–22(?–30) mm thick branches of indet. angiosperms {2}, on slightly to strongly decayed bark {2} (periderm and bast), often on small cracks in periderm, ± darkened, green algae absent or very sparse. **Associated**: *Cosmospora* sp. {1}, *Lanatonectria flocculenta* {1} (apothecia partly very close to or even on perithecia). **Desiccation tolerance**: many cells of ectal and medullary excipulum, some paraphyses and mature asci and many ascospores still viable after 2 months, conidia formed in culture did not survive 2 days. **Altitude**: 2500 m a.s.l. **Phenology**: III.

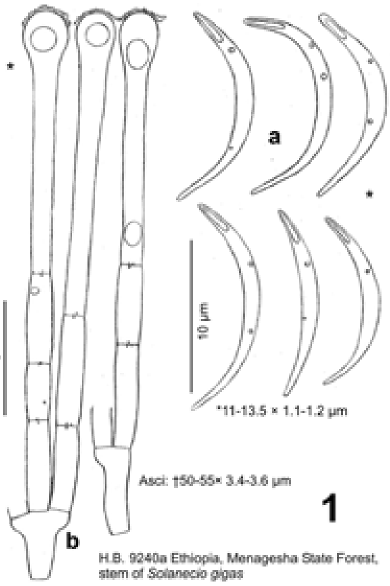

Plate 963. **1a–b**: *Orbilia* aff. *menageshae*. – **a**. ascospores; **b**. paraphyses.

Taxonomic remarks. *Orbilia menageshae* resembles *O. auricolor* or *O. elegans* in the ascospores. It differs in the paraphyses that tend to ellipsoid tips and to being covered by conspicuous, 1–3 µm thick, firmly attached caps of exudates (but not so on *Solanecio*), in the frequent presence of glassy processes, also in comparatively long spores and in rather large and thick apothecia. Yet, the main characteristic of *O. menageshae* is the deviating anamorph.

Variation. At the type locality, four samples were collected on bark of apparently two different angiosperms. The apothecia concurred very well in their microscopic features, but differed by colour: bright ochraceous in two (Pl. 964: 1a–d, holo- & isotype), pale greyish-cream in the other two (2a–c). Also the apothecial diameter varied between 0.8–1.7 (holo/isotype) and (1–)2.5–4.5(–5.5) mm (paratype).

Not included collections. In addition to these corticolous collections, two further samples were taken at the type locality which were on herbaceous stems of *Solanecio gigas* (Pls 963, 964: 3). These differ in some details from the corticolous ones: (1) the exudate over the paraphyses does not form caps but instead a thin (0.2–0.5 µm) continuous to granular layer, (2) the glassy processes are longer (2–15 µm up to 8–30 µm, 4–6 µm wide), therefore, the margin is finely crenulate, (3) the heads of the paraphyses are never ellipsoid, and (4) the spore apices are usually more subacute and the SBs more subulate and visibly attached (Pl. 963: 1a). In the dead state, however, the shape of the spores is very similar (Pl. 964: 1j, 2e, 3g), and their length [†(10–)12–15.5(–16)((–18)) × (0.9–)1–1.3(–1.4) µm] only slightly exceeds spore length of the corticolous specimens. One of the *Solanecio* specimens (H.B. 9309b) deviates in further points: the apothecia are up to 0.8 mm thick due to an apparently 600 µm thick basal ectal excipulum (however, the delimitation from the similarly large-celled medullary excipulum is quite obscure), and the marginal cortical cells are distinctly larger (†15–28 × 4–6 µm). These

Plate 964. **1–2**: *Orbilia menageshae*; **3**. *O.* aff. *menageshae*. – **3a**. *Solanecio gigas* in Menagesha Suba State Forest; **1a–d**, **2a–b**, **3b–d**. rehydrated apothecia; **1e**, **3e**. apothecia in median section; **1g–h**, **3h**. id., marginal ectal excipulum; **1f**. id., basal ectal excipulum; **1i**, **2f–g**, **3f**. paraphyses; **1j–k**, **2d–e**, **3g**. ascospores. – Living state (**1f**, **1k**, **2d**) or mainly dead state: **1g–h** (some cells alive), **1j**, **2e–g**, **3f–h** (in H_2O), **1i** (in KOH+CR). – **3a**: phot. U. Lindemann. — **1a–k**. H.B. 9275a (holotype, but **1b**, **e**, **h**, **1k** the rightmost spore from isotype in H.B.): Ethiopia, Menagesha, on indet. woody angiosperm; **2a–f**. H.B. 9310a: ibid., on indet. angiosperm; **3a–h**. H.B. 9240a: ibid., on *Solanecio*.

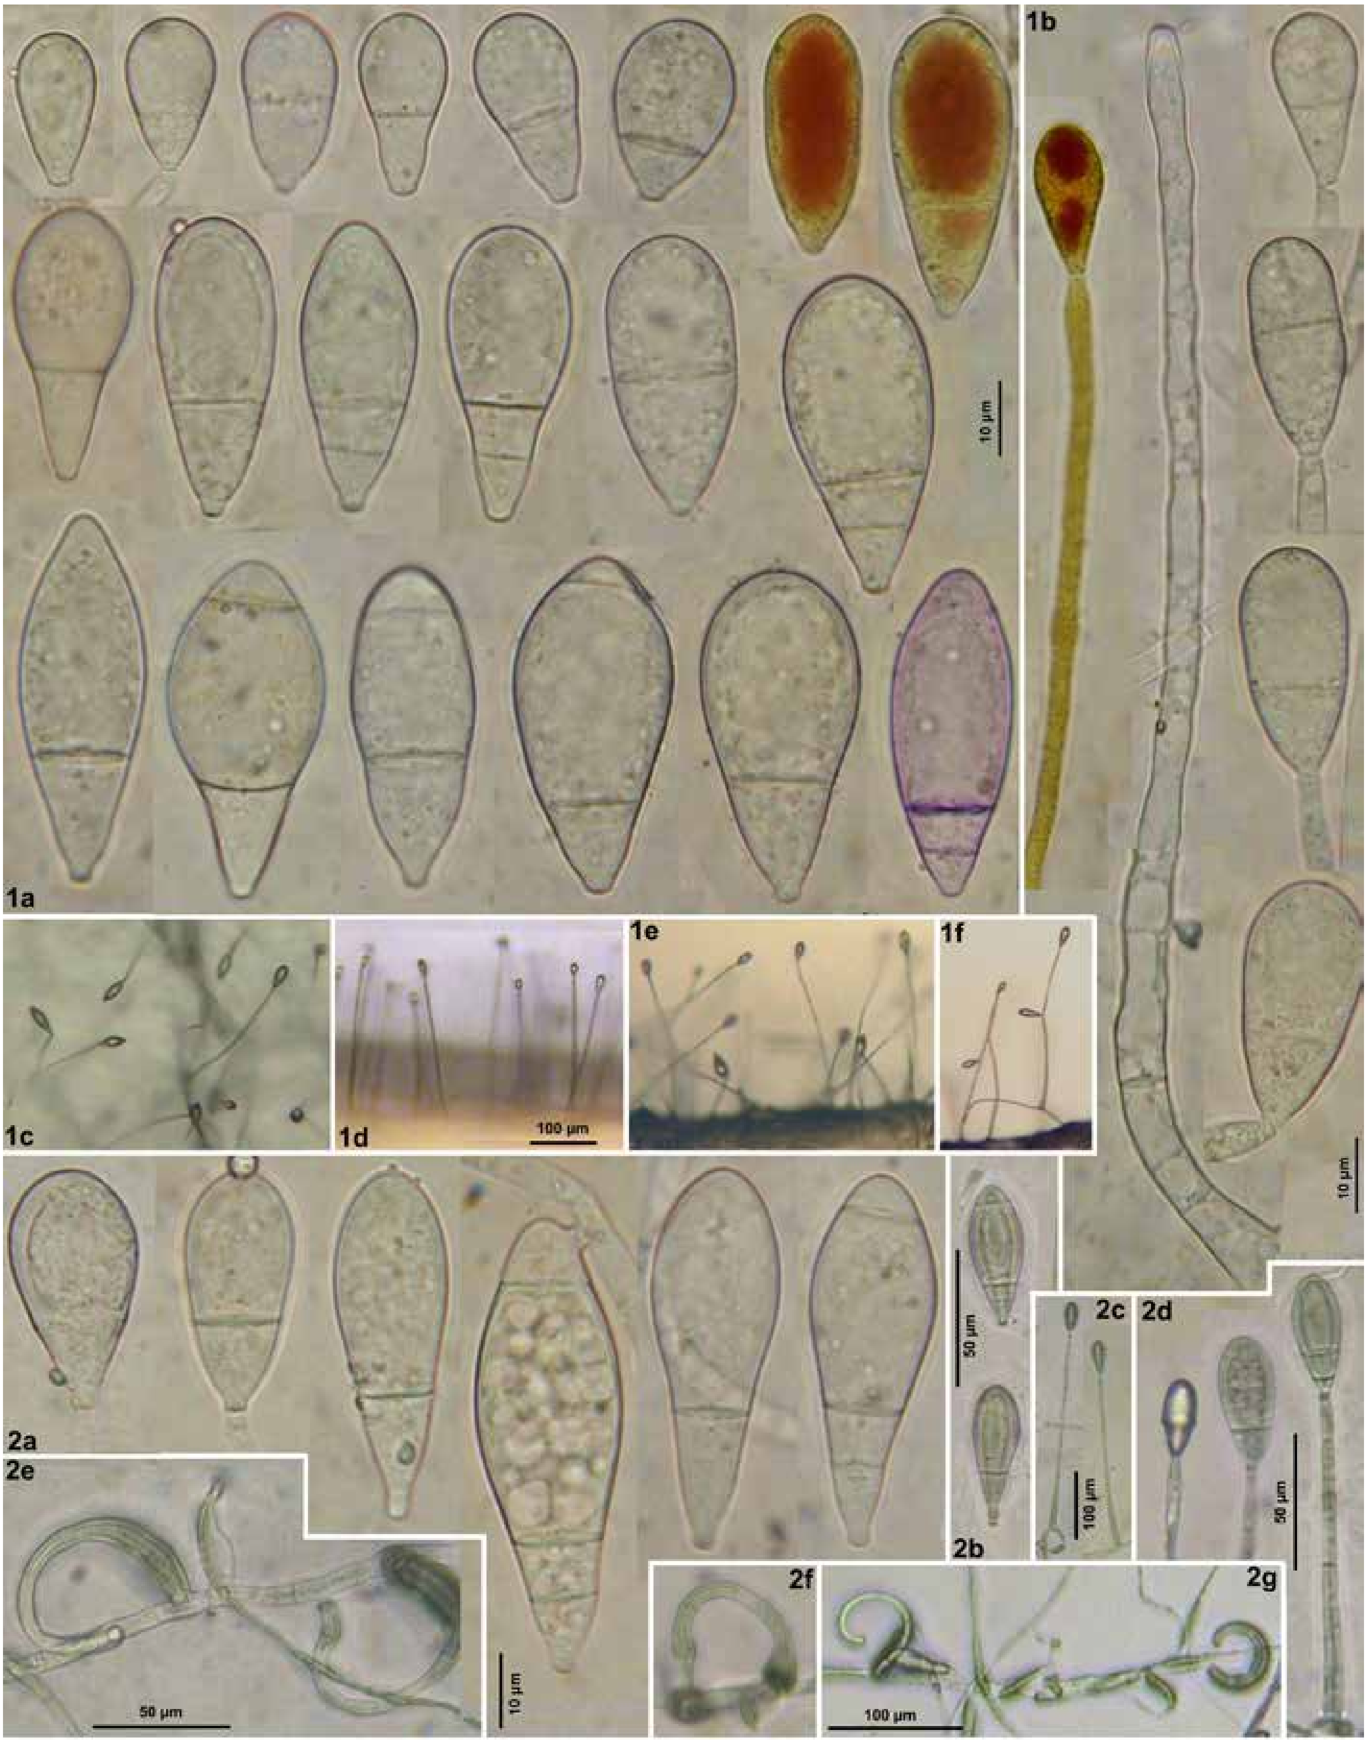

Plate 965. **1**: *Orbilia menageshae*; **2**: *O.* aff. *menageshae*. – **1a**, **2a–b**. conidia; **1b–f**, **2c–d**. conidiophores with conidia; **2e–g**. adhesive loops (all from culture). – Living state (partly stained by IKI or CRB). — **1a–f**. H.B. 9275a (holotype): Ethiopia, Menagesha, on indet. woody angiosperm; **2a–g**. H.B. 9309b: ibid., on *Solanecio*.

herbicolous specimens are not included in the description of *O. menageshae* because of deviating DNA data, although the anamorph obtained in pure culture closely concurs with that of the ex-type strain (see below).

Two samples from places other than the type locality are also not included. One on bamboo (*Yushania*, IVV: H.B. 9960) from southwestern Ethiopia has rather small and thin, flat, light cream-amber apothecia. It lacks caps on the paraphyses and has rather short and wide marginal cortical cells with thin glassy caps (1–2 µm) and comparatively long spores (†11–17 × 1.1–1.2 µm); also its DNA deviates from the type, therefore, it is referred to as *O.* cf. *menageshae* here. A collection on a herbaceous stem of *Euphorbia* from Kenya was studied by I. Olariaga (IVV; 29.XII.1968) when revising an associated *Hydropisphaera*. It concurs quite well with those on *Solanecio*, showing rather long and narrow spores (†11–17.5 × 0.8–1.2 µm), thin exudate over the paraphyses, and 25–60 µm long glassy processes at the margin.

Anamorph. Within the *O. auricolor* aggregate, the anamorph of *O. menageshae* is characterized by conidiophores being unbranched in the apex region where only 1 terminal conidium is formed, also in the conidia having often 2 septa. The species herein resembles *O. elegans*, which differs in wider, more regularly top-shaped, often 3-septate conidia and a tendency to apically branched conidiophores bearing 2–3 conidia. Unlike *O. elegans*, the conidia of *O. menageshae* show a rather high variability in size and shape. The predominant type is obpyriform, but fusoid (to fusiform) conidia are also frequent. There are usually (1–)2 septa near the base, but sometimes a further septum near the apex. Distinctly smaller, 0–1-septate obpyriform conidia are partly abundant but are not sharply separable from the large ones. Trapping organs could not be observed in the ex-type culture.

In the ascospore isolate from the not included sample on *Solanecio* (Pl. 965: 2) the large conidia were quite similar in size and shape to those in the holotype (965: 1): *(32–)42–59 × (13.5–)15.5–18.5 µm, 1–3-septate. Small obpyriform conidia were not seen in culture, but 1 such conidium was found on the natural substrate. The conidiophores had a similar length (120–350 µm) as in the ex-type strain and were never branched towards the apex. Only in this isolate a few adhesive networks were spontaneously formed (without presence of nematodes). They consisted of 1–2 loops with an outer diameter of 45–55 µm, their cells being *4.5–6 µm wide (near the attachment *7–9 µm).

The anamorph of *O. menageshae* somewhat resembles *A. fusiformis* R.C. Cooke & C.H. Dickinson (1965), isolated from soil in Shropshire in England, which differs in consistently fusiform conidia. The same applies to the type of *Arthrobotrys vermicola* (= *O. blumenaviensis*), but here the conidiophores are of the arthrobotryoid type. *A. mangrovisporus* Swe et al. (2008b) very closely matches the anamorph of *O. menageshae* in conidial characters, including the high variability in shape and septation. The species differs in mostly branched conidiophore tips bearing 1–6 conidia, also in the habitat (submerged wood in a mangrove swamp in southeastern Asia).

Phylogeny. Sequences were gained from an ascospore isolate of the holotype of *O. menageshae* (SSU with S1506 intron, ITS, LSU), also from apothecia of one of the *Solanecio* samples from the type locality (H.B. 9240a; S1506 intron, ITS, LSU) and of the *Yushania* sample (H.B. 9960; ITS). In the ITS region the three strains differ by 3.1–3.9% (3.9% between type and *Solanecio*, 3.3% between type and *Yushania*, 3.1% between *Solanecio* and *Yushania*). In comparison, *A. cystosporius* differs from them by 3–4.5%. In the LSU D1–D2 domain the distance is 0.9% between the *O. menageshae* type and the *Solanecio* sample, although both differ by only 0.3–0.6% from *A. paucisporus* and 0.5–0.7% from *A. superbus* (ATCC 96676).

In our ITS analysis (Phyl. 30), the type of *O. menageshae* clustered with the *Yushania* sample in a medium supported clade with unresolved position, whilst the *Solanecio* sample clustered unsupported with *A. cystosporius* in a similarly unresolved position. In phylogenetic analyses of SSU+ITS+LSU (Phyl. 25, S33), *O. menageshae* s.l. clustered unsupported with the *O. auricolor* clade and the *elegans-gampsosporus* clade. Also when analysing SSU (V8–V9), *O. menageshae* clustered with low distance (0.2–0.3%) with the *O. auricolor* clade and *elegans-gampsosporus* clade (S29).

In contrast, *A. mangrovisporus* differs from *O. menageshae* s.l. by 6.7–8.5% in the ITS and by 2.9–3.2% in the LSU. In the available SSU (V1–V5), *A. mangrovisporus* differs by 1.5–3.5% from other sequences. In our combined analyses (Phyls 25, S33), *A. mangrovisporus* clustered strongly supported with '*Dactylaria*' *sahelensis*. In the ITS analysis of Zhang et al. (2010), *A. mangrovisporus* is found near the base of *Arthrobotrys*, with only *A. oligosporus* situated more basally.

In the S1506 intron, the type of *O. menageshae* differs from the *Solanecio* sample by 7%. The intron occurs also in the *A. mangrovisporus* sequence and shows a high distance of 17% to *O. menageshae* s.l. When analysing this region, *A. mangrovisporus* clustered unresolved whereas *O. menageshae* s.l. is found in a strongly supported clade with *A. gampsosporus* and *A. cystosporius* (S30). The *Yushania* sample apparently lacks the intron, according to the used ITS1F primer.

Ecology. *O. menageshae* was collected on ± rotten bark of corticated mesic branches of apparently two different angiosperms in a subtropical humid (winterdry), evergreen, predominantly broad-leaved afromontane forest, with the large herbs *Lobelia giberroa* and *Solanecio gigas*, at the western slope of an old volcano in the central plateau of the Ethiopian highlands. The intimate growth with two species of *Hypocreales* might indicate a fungicolous habitat.

The not included collections do not seem to be closely associated with pyrenomycetes. The one at the type locality was on a mesic herbaceous stem of *Solanecio gigas*. The sample on bamboo (*Yushania alpina*) in southwestern Ethiopia was collected in an afromontane bamboo forest with a climate comparable to the type locality. Here populations of apothecia grew on fallen bamboo stems on the upper and lateral side. Also the collection on a herbaceous stem of *Euphorbia* in Kenya was from a similar subtropical highland climate.

Specimens included. **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, southern part of Menagesha Suba State Forest, 2500 m, branch of indet. angiosperm, on bark, 26.III.2010, Dawit Abate & U. Lindemann (M-0276510, **holotype**; anam. cult.; sq.: KT222439; **isotypes** in H.B. 9275a & U.L. 0310-6). – ibid., branch of indet. angiosperm, on bark, 26.III.2010, U. Lindemann (U.L. 0310-41, H.B. 9310a).

Not included. **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, southern part of Menagesha Suba State Forest, 2520 m, stem of *Solanecio gigas*, 22.XII.2009, U. Lindemann (U.L. 1209-7, H.B. 9240a; sq.: KY419174). – ibid., stem of *S. gigas*, 26.III.2010, U. Lindemann (U.L. 0310-40, H.B. 9309b, anam. cult.). – **Menjiwo**, 62 km SW of Jimma, 23 km E of Bonga, 4 km E of Boka, 2.5 km S of Kaka, Boka forest, bamboo forest, 2650 m, stem of *Yushania alpina*, 4.XII.2014, A. Gminder (A.G. eth-032, H.B. 9960; sq.: MK514442). — **KENYA**: **Kiambu**, 32 km NNW of Nairobi, ~2 km E of Uplands (railway station), Uplands Forest at southern end of Gatamaiyo Forest, 2360 m, on branch of *Euphorbia*, 29.XII.1968, O.E. Eriksson, vid. I. Olariaga (UPS F-639415, doc. vid.).

Orbilia blumenaviensis (Henn.) Baral & E. Weber, in Qiao et al., Mycol. Progr. 11: 257 (2012) — Pls 966–968, Map 156

Basionym: *Helotium blumenaviense* Henn., Hedwigia 41: 24 (1902)
= *Orbilia fici* E.K. Cash & Corner, Trans. Br. Mycol. Soc. 41: 280 (1958)
= *Arthrobotrys vermicola* (R.C. Cooke & Satchuth.) Rifai, Reinwardtia 7: 371 (1968)
≡ *Dactylaria vermicola* R.C. Cooke & Satchuth., Trans. Br. Mycol. Soc. 49(1): 27 (1966)
= *Arthrobotrys guizhouensis* K.Q. Zhang, in Zhang, Zhou, He & Huang, Acta Mycol. Sin. 13(2): 101 (1994), [non *A. guizhouensis* (K.Q. Zhang, Xing Z. Liu & L. Cao) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 102 (1999), nom. illegit., ICN Art. 53.1 (≡ *A. huaxiensis*)]

Etymology: *blumenaviensis*: referring to the type locality, Blumenau (Brazil); *fici*: according to the substrate of the type, *Ficus irregularis*; *guizhouensis*: named after the province Guizhou in China; *vermicola*: after the ability to prey on nematodes.

Typification: Brazil, Blumenau, (?)leaves of indet. *Arecales*, 17.I.1892, A. Möller (S, lectotype of ***Helotium blumenaviense***, designated here, MBT202394). — Singapore, branch of *Ficus irregularis*, IV.1935, E.J.H. Corner (BPI, holotype of ***Orbilia fici***). — Uganda, Mpanga forest, leaves of indet. plant, undated, R.C. Cooke (IMI 113071, holotype of ***Dactylaria vermicola***; ex-type culture: CBS 513.66; sq.: U51944, GU178821). — China, Guizhou, rotten debris, IX.1987, K.Q. Zhang (nr. 8736, type of ***Arthrobotrys guizhouensis***).

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated (0.7–)1–3.5(–4) mm diam., 0.3–0.4 mm up to 0.6–0.8 mm high (receptacle 0.11–0.19 up to 0.4–0.6 mm), at first greyish-white, then pale to light greyish- to chlorinaceous-yellowish-cream to (honey-)yellow-ochre or amber-brown to orange-reddish-brown, slightly to medium translucent, somewhat gelatinous, round, slightly undulating or with small lobes when large, scattered to gregarious in small groups; disc young strongly, later slightly concave to flat, margin distinct, 0–15 µm protruding, more or less inrolled, smooth, even; sessile on a narrowed base or sometimes with a very broad, obconical or abrupt stipe 0.15–0.25 × 0.9–1.2 mm, superficial, dry honey-brown, ± strongly deformed. **Asci** *36–42 × 3.7–4 µm {1}, †(26–)28–42(–53) × (2.8–)3–3.8(–4) µm {6}, 8-spored, spores 4-seriate, lower 3–4 spores inverted {3}; **apex** (†) slightly to strongly truncate (not indented, laterally not or scarcely widened); **base** with short to medium long, flexuous stalk, h- to H-shaped. **Ascospores** *(8.8–)10–12(–14) × (1–)1.1–1.2(–1.3) µm {3} (~11–17 µm actual length), †(9–)9.5–13(–14.5) × (0.8–)0.9–1.2 µm {7}, narrowly subcylindric-clavate (subulate) to often fusoid-clavate, apex rounded, base ± strongly attenuated, rarely with a distinct tail, slightly to strongly curved (falcate, a little less curved in dead state); **SBs** 1.5–2.2(–2.5) {3, incl. invisible part} × (0.3–)0.4–0.6(–0.7) {2} or 0.7–0.8 µm {1}, rod-shaped to elongate ellipsoid or subglobose, with a (very) short invisible filum. **Paraphyses** apically narrowly to broadly lanceolate {6}, apex obtuse to acuminate, terminal cell *(9–)12–27(–29.5) × (2.7–)3–4 µm {1}, †12.5–29 × (1.5–)2–3(–3.5) µm {6}, exceeding the dead asci by (2–)3–6(–8) µm {7}, lower cells *5–14 × 2.7–3.5(–4.5) µm {1}, †4–9(–11) × 1.5–2.5(–3) µm {5}; unbranched at upper septum. **Medullary excipulum** subhyaline to yellowish, 15–40 µm thick, of dense textura intricata-porrecta-angularis, not or often medium (to strongly) gelatinized, horizontally oriented, overall very sharply delimited from ectal excipulum. **Ectal excipulum** of (†) thin- to firm-walled, hyaline, indistinctly vertically oriented t. globulosa-angularis(-prismatica) from base to margin, 220–600 µm thick near base, cells */†(18–)25–50(–80) × (12–)15–35(–40) µm {5}, at base and near medullary excipulum smaller; cortical cells from lower to mid flanks externally with 1–2(–3) µm thick pale yellowish-chlorinaceous walls {5}, in external view forming strongly transversely oriented rows of cells with 1–4 thin longitudinal septa; 20–30 µm thick near margin, oriented at an 80–90° angle to the surface, marginal cortical cells */†6–11(–14) × (3–)5–7.5(–9.5) µm {6}, uppermost cells with slightly conical apex, firm-walled; **glassy processes** 0.4–1(–3) × 3–5 µm {7}, high-refractive, partly stratified. **Anchoring hyphae** either only present among but not above host cells, medium abundant, †3–7 µm wide, wall 0.2–1 µm thick {2}, or forming a 30–200 µm thick, compact t. prismatica-angularis with cells of †7–12(–18) × (3–)4–6(–8) µm with gelatinized walls (common walls 1–1.5 µm) {2}. **SCBs** in paraphyses globose, medium refractive, 1.5–2.2 µm diam., 1((–2)) per cell, sometimes also with elongate, strongly refractive **VBs**; in marginal excipulum no cell contents seen. **Exudate** absent {8}. — **ANAMORPH**: arthrobotrys-like (from ascospore isolate {2} or natural substrate {2}; isolated from soil, water, leaves, or unidentified litter {4}) (including data of Cooke & Satchuthananthavale 1966, Van Oorschot 1985, Zhang et al. 1994, Swe et al. 2008a, and Qiao et al. 2012). **Conidiophores** 113–500(–1500) µm long, 4–9 µm wide at base, 3.5–6.5 µm below nodes, unbranched or branched below or above, at nodes not or often recommencing growth to form up to 3–4(–7) clusters of conidia in a row, conidia formed on conical nodules on indistinctly swollen nodes (arthrobotryoid), 1–8 conidia per node. **Conidia** variously shaped, of 3 main types: (a) obpyriform to obovoid, 1-septate, the upper cell often or always distinctly larger than the lower, (b) elongate cylindric-clavate, 1–2(–4)-septate, (c) elongate ellipsoid-fusoid, 2–3-septate, *(16.5–)21–38(–48.5) × ((8.5–))(10–)12.5–19(–22.5) µm {9}. Forming **adhesive networks** after adding nematodes, loops *33–43 µm outer diam., *21–33 µm inner diam., loop cells *(3.8–)5–7(–8.5) µm wide {3}. **Chlamydospores** present {2}, yellowish; or absent {2}.

Habitat: lying on ground, decorticated or corticated, ~2–20 cm thick branches and trunks of *Albizia lebbeck* {1}, *Ficus irregularis* {1}, *Phoenix canariensis* {1}, *Tabebuia rigida* {1}, indet. angiosperm trees {6}, 0.1–0.3 mm deep medium to strongly decayed wood {6} or bark {6} (periderm, rarely bast), (?)petiole of indet. *Arecaceae* {1}, textile (tentage). **Associated**: *Diplodia* sp. {1}, *Hyalorbilia ?juliae* {1}, ?*Nectria* sp. {1}, *Nectriopsis* sp. {1/1}. **Desiccation tolerance**: intolerant, a few spores and many conidia still viable after 1 month. **Altitude**: 5–385 m a.s.l. (Middle & South America), 1200 m (central Africa), 1–1850 m (southeastern Asia), 8 m (southeastern Europe). **Geology**: Devonian-Carboniferous & Jurassic sedimentary rock; felsic plutonic & metamorphic rock. **Phenology**: VII–VIII, X (teleomorph, northern hemisphere), XI–I, VI (teleomorph, tropical belt and southern hemisphere).

Taxonomic remarks. *Orbilia blumenaviensis* is well characterized by lanceolate paraphyses with obtuse to ± acute tips which distinctly protrude beyond the asci, the absence of exudate on them, also by the thick-walled, pale yellowish cortical cells of the ectal excipulum which form transversely oriented cell rows (Pl. 968: 1d, h–i), and by rather large, fleshy, ± gelatinous apothecia that turn honey-yellow or amber-brown with age and lack a visible subiculum. In other features the teleomorph hardly differs from *O. auricolor*. A SEM micrograph of a collection from Puerto Rico (D.H.P. PR 116, as *Orbilia* sp.) showing obtusely lanceolate paraphyses is given by Pfister (1997: fig. 2, bottom row, hymenium in top view).

Variation. The species shows some variation in several features. Spore length varies from *9–12 µm up to sometimes *11–14 µm (in situ). A thick compact texture of gelatinized cells at the base of the apothecia, representing the anchoring hyphae, was only seen in the type of *O. blumenaviensis*, whereas a comparable layer in a sample from Guadeloupe (H.B. 8413a) was almost non-gelatinized. In contrast to the American specimens studied, a medium strong gelatinization of the medullary excipulum was noted in the southeastern Asian holotype of *O. fici* and in the specimen from the Comoros. The glassy caps on the marginal cortical cells are usually only present as moderate wall thickenings (Pl. 966: 1f, 2f), but attain a thickness of 1–3 µm in two of the samples from Puerto Rico (Pl. 966: 4f and D.H.P. PR 116). Finally, the apothecia may strongly vary in size, ranging usually around 1–3 mm in diam. but sometimes only 0.7–1.5 or rarely 1.5–6 mm (see Qiao et al. 2012). Apothecial thickness was often around 0.3–0.4 mm, but showed extraordinarily high values (0.6–0.8 mm) in the lectotype of *O. blumenaviensis* and in the specimen from the Comoros. A distinct stipe was only sometimes present (Pls

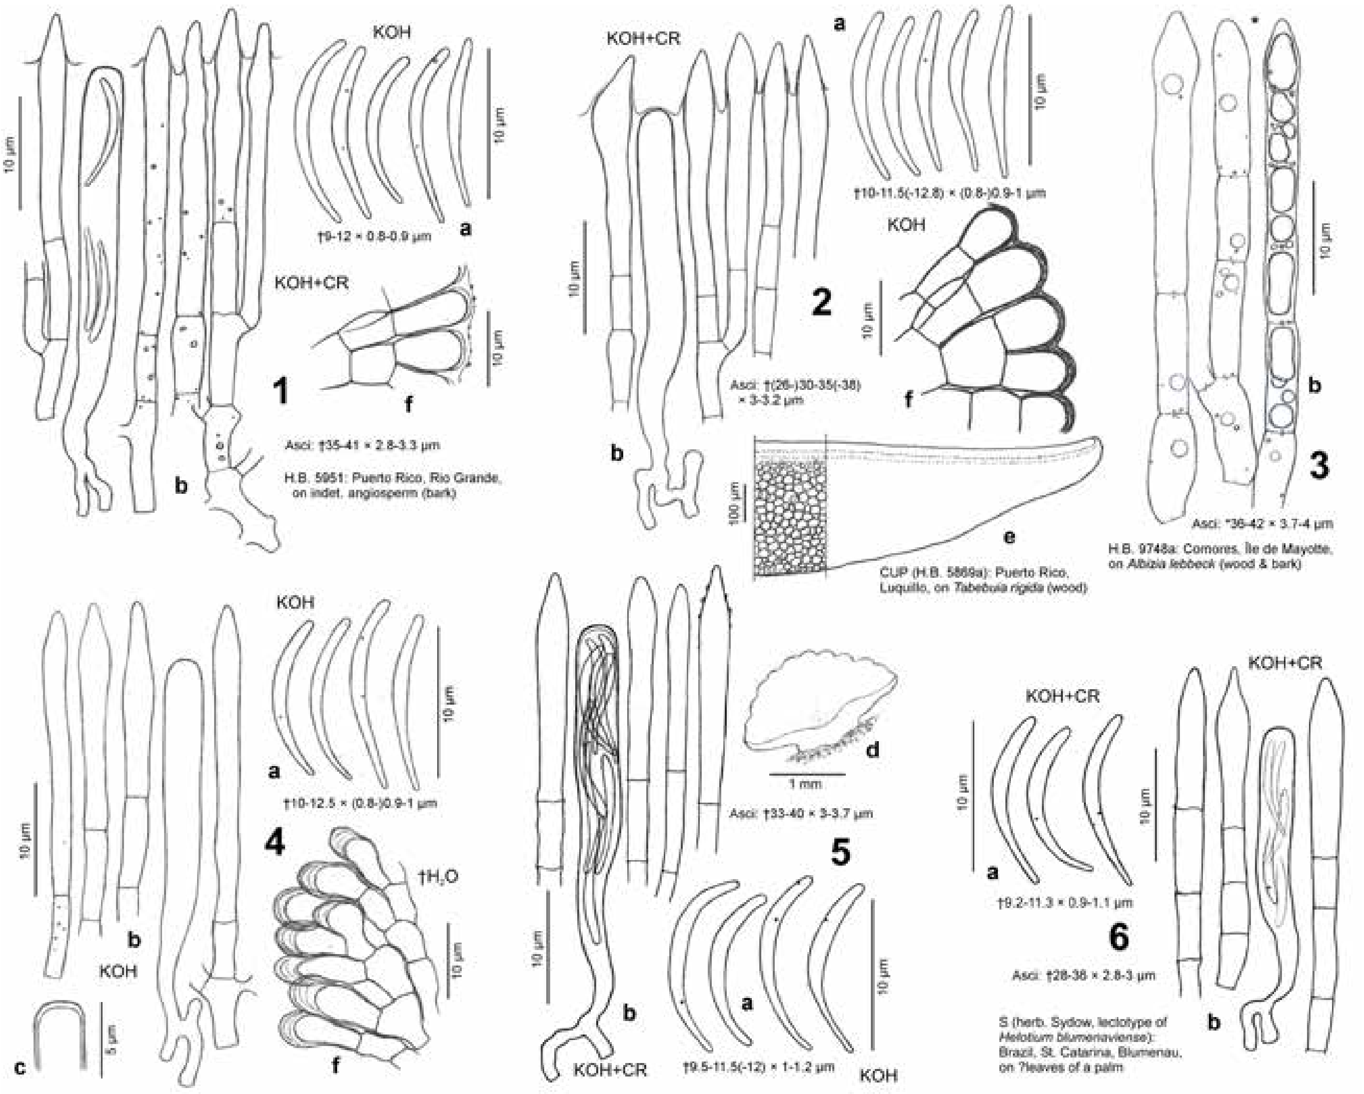

Plate 966. **1–9**: *Orbilia blumenaviensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. rehydrated apothecium; **e**. apothecium in median section; **f**. id., ectal excipulum at margin; **g**. conidia and conidiophores (**7** from substrate, **8–9** from culture). Scale in **9** adjusted to given conidial size (Van Oorschot's scale is ca. 2.5 × too long).

966: 5d; 967: 3c). Whitish apothecia were only seen in the two European samples (Pl. 967: 4), but this may be so because they are the only ones which were photographed in the fresh state.

Type studies. ***Helotium blumenaviense*** was examined from the 'holotype' in S by Dumont (1981: 323) who found it to represent an *Orbilia*. Dumont was unable to see the paraphyses and ascospores 'owing to the poor preservation', therefore, he did not compare the species with other taxa. The apparently same specimen, though labelled 'ISOTYPUS' by the museum, was reexamined here and found to contain 8 extraordinarily thick (0.7–0.8 mm), honey-yellow apothecia (cream-hazel in protologue) which are in quite good shape (Pl. 967: 1). The protruding lanceolate paraphyses are clearly visible, but free spores very rare (Pl. 966: 6). The anchoring hyphae form a compact stromatic texture, a character not observed in most of the other collections referred here. The protologue is rather inaccurate in describing the paraphyses as narrowly filiform (0.5–0.8 µm wide) and in neglecting the curvature of the spores which were described as acicular, acute at both ends, biguttulate, 9–11 × 1.5–2 µm. The specimen in S (herb. Sydow) examined in this study is designated here as **lectotype** of *Helotium blumenaviense* (ICN Art. 9.11, Turland et al. 2018); a duplicate in B was destroyed during the Second World War.

The holotype of ***Orbilia fici*** (Pl. 966: 5) contains abundant apothecia which were described as drab or greyish olive in the protologue, but now showed a dirty ochre-orange colour (rehydrated). Although the authors reported the paraphyses as 'apically sublanceolate', they stressed only the hymenial colour as diagnostic against *O. curvatispora* (= *O. auricolor*). The spores were described as straight or curved, filiform, 10–11 × 0.5 µm. A blue iodine reaction of the ascus pore is an error in the protologue.

Anamorph. Two Chinese ascospore isolates of *O. blumenaviensis* from Tonghai and Lianghe in Yunnan formed an anamorph (Pl. 967: 6–7; Qiao et al. 2012). At first glance, the two differ in shape of the predominant type of conidia (clavate vs. fusoid), which seem to point to a species aggregate. However, both isolates show a distinct conidial polymorphism. In fact, three types of conidia can be observed. In the isolate from Tonghai only heteropolar conidia occurred, being either obpyriform to obovoid, 1-septate, *(16.5–)20.5–28 × (10–)13.5–15.5(–19) µm (type a, Pl. 967: 7a upper row), but sometimes also more elongate cylindric-clavate, with often 2 septa and a size of *(21.5–)30–34.5(–39) × 12.7–14 µm (type b, 7a lower row). In the isolate from Lianghe predominantly homopolar (ellipsoid-fusoid), 2–3-septate, *33–35(–40) × (10.5–)13–16(–17) µm large conidia where found (type c, Pl. 967: 6a–b), but also a few of types a and b. No difference in the teleomorph was noted (see also Qiao et al. 2012). A soil isolate from Dehong without teleomorph formed mainly fusoid conidia (type c, see Qiao et al. l.c.: fig. 3).

Additionally, in two Caribbean apothecial samples a few conidia were found on the natural substrate, which all belonged to type a (1-septate, obpyriform to obovoid, Pls 966: 7g; 967: 2f, 5d), but differ from those of the Tonghai isolate in their larger size. However, also here the conidia differ somewhat in size (H.B. 8029: *32–36 × 17–21 µm, H.B. 8413a: *29–31 × 17–18 µm). In an unlocalized isolate from the Panama Canal Zone (CBS 119.54) the conidia measured only 22–25 × 13–15 µm (?dead state, G. Verkley pers. comm.) and were undoubtedly 1-septate, which explains the misidentification as *A. arthrobotryoides*.

The Lianghe isolate concurs quite well with the protologue of ***Arthrobotrys vermicola*** concerning conidial size, shape, and septation. *A. vermicola* was described by Cooke & Satchuthananthavale (1966, as *Dactylaria*) from Uganda, with ellipsoid-fusoid, (1–)2(–3–4)-septate conidia measuring 27.5–47.5 × 13.5–20 µm (Pl. 966: 8). However, when van 0orschot (1985) redescribed the type strain, she found besides ellipsoid-fusoid to cymbiform, (1–)2–3-septate conidia also some 1-septate ones with an obovoid shape (size of both types 28.5–48.5 × 17–22.5 µm, Pl. 966: 9). In her drawing the conidia partly emerge from distinct denticles suggestive of the candelabrelloid type, but in the protologue drawing the conidiogenesis is clearly arthrobotryoid. Swe et al. (2008a) reported *A. vermicola* isolates from three mangrove habitats in southeastern Asia, which well correspond to the type as redescribed by Van Oorschot 1985 (erroneously as CBS 513.60 in the legend). Also here some elongate obpyriform (0–)1(–2)-septate conidia occurred along with fusoid (1–)2–3-septate ones (size of both *24–40 × 13–20 µm).

The obpyriform 1-septate conidia of *A. vermicola* (type a) resemble those of *A. oligosporus* in shape and eccentrical septation, but those of *A. oligosporus* are distinctly smaller, and isolates of that species cluster in a separate clade (Qiao et al. 2012, fig. 2a). In conidial morphology *A. perpastus* and *A. cystosporius* resemble *A. vermicola* in size and shape, but sharply differ in geniculate conidiophores, also in the conidial septum being more eccentrical.

A. guizhouensis K.Q. Zhang was described in Zhang et al. (1994) from an isolate from rotten debris in Guiyang, Guizhou, Sept. 1987 (date fide Yu et al. 2014). Although Yu et al. considered this species as distinct from *A. vermicola* based on branched conidiophores and mainly 1-septate conidia, we see a close morphological resemblance to the type of *A. vermicola*, and molecular data of a strain referred by Yu et al. to *A. guizhouensis* (YMF 1.00014) confirms synonymy with *A. vermicola*. The type was deposited as a living culture ('cultura viva 8736') in Coll. Agr. Guizhou, Guiyang (China), which was later retroactively permitted by the Code (Art. 8.4 ICN) if preserved in a metabolically inactive state. The illegitimate homonym *A. guizhouensis* (K.Q. Zhang et al.) M. Scholler et al. is a different species of series *Arthrobotrys* having much larger, partly fusiform conidia formed acrogenously on the conidiophores.

According to Zhang et al. (1994), *A. guizhouensis* K.Q. Zhang differs from *A. vermicola* by 1-, rarely 2–3-septate conidia and by branched conidiophores. Yu et al. (2014) examined the type culture and included three soil isolates from Guizhou and Yunnan. One of them (YMF 1.00014) was gained by Z.W. Zhao in 2002 from field soil at Wenshan, Yunnan, and is shown on their fig. 3.19, but erroneously under the name '*A. huaxiensis*', while fig. 3.18, which is labelled '*A. guizhouensis*', represents *A. huaxiensis*. Note further, that the scale bars in fig. 3.19 yield much smaller conidia than given in Yu et al.'s description of *A. guizhouensis* K.Q. Zhang. In fact the bars should be reduced by ~72% to achieve a correct conidial size. According to Zhang et al. (1994), *A guizhouensis* has partly rather small conidia down to 19 × 8.4 µm, which Yu et al. named microconidia, but which are not sharply separated from the normal ones. The presence of yellowish chlamydospores in culture was reported by Zhang et al. (1994) for the type of *A guizhouensis* and its absence by Swe et al. (2008b) for *A. vermicola*.

Not included collection. Based on a recent collection from Puerto Rico, the new species ***Orbilia jesu-laurae*** Quijada, Beltrán-Tejera, Pfister & Baral was described (Quijada et al. 2020). It differs from *O. blumenaviensis* in paraphyses with lageniform-mammiform apices with one or often several terminal or lateral abrupt beaks that are covered by exudate, and in thinner apothecia (0.1–0.2 mm vs. 0.3–0.8 mm) though of a similar size (1–2 mm). In the anamorph obtained in pure culture the species differs in shorter and narrower conidiophores and consistently (0–)1-septate, never fusoid conidia of a smaller size (see key p. 1519), being reminiscent of those of *O. auricolor* (*A. superbus*) or *O. oligospora*. For its phylogenetic position see below.

Phylogeny. A sequence was taken from apothecia of a specimen from Mayotte (Comoros, H.B. 9748), comprising ITS and LSU (the S1506 intron is absent). Further sequences of *O. blumenaviensis* as circumscribed in Qiao et al. (2012) were available for the ITS region from six eastern Asian strains (deposited in GenBank as *O. fici*, *A. guizhouensis*, or mainly *A. vermicola*, two of them from ascospore isolates), and the ex-type strain of *A. vermicola* from Uganda. LSU sequences exist in GenBank for two eastern Asian strains (125, 126, Swe et al. 2008a), for which the ITS region comprised only ITS1, and two under the name *A. guizhouensis* (YMF 1.00014, YNUCC 0076) from an unpublished study by W.P. Li et al., one of them being from Guizhou (YNUCC 0076). Further sequences concern samples from Mexico (SA305, ITS) and Panama (CBS 199.54, as *A. arthrobotryoides*, ITS+LSU). The S1506 intron is present in five strains (YMF 1.03002, Tonghai; YMF 1.00014, Wenshan; strain 629, unlocalized; strains 125, 126, Hong Kong), but absent in the ex-type strain of *A. vermicola* and H.B. 9748, whereas the other sequences are unclear in this respect. For YMF 1.00014 also SSU V1–V3, mtLSU, *RPB2, TEF1,* and *TUBB* exist.

In analyses of the ITS region by Qiao et al. (2012) and in the present study (Phyl. 28), *O. blumenaviensis* including the ex-type strain of *A. vermicola* clustered with high support in a clade, though with a comparatively high variation which lies in the range of 0.2–3 %, whereas, e.g., the type of *A. menageshae* shows a distance of 6.5–7.5 % and *A. musiformis* 7–9 %. Qiao et al. concluded that all *O. blumenaviensis* and *A. vermicola* strains belong to a single variable species. Due to the variation, different clades can be recognized within the species, and the observed conidial types show a certain correlation with the clades: strains with ± fusoid conidia (from Dehong and type of *A. vermicola* from Uganda) clustered with a 0.8–1.1 % distance in a clade. The Wenshan isolate (as *A. guizhouensis*) with mainly obpyriform conidia clustered with 0.6 % distance in a clade with strain 629 (without data). The remaining two strains with anamorph data have mainly obpyriform conidia (YMF 1.03002) or partly also fusoid conidia (isolate 103, in Swe et al. 2008a). However, these authors did not specify to which isolate their illustration (fig. 8) belongs. For strain 103 they gave the conidia as 2–3-septate but did not indicate the shape. Because of the repeatedly observed mixture of different conidial types within a single strain, we agree that a separation of *O. blumenaviensis* into different taxa is impossible.

For *O. jesu-laurae* sequences of ITS and LSU D1–D4 exist in GenBank. In the ITS region the species differs from *O. blumenaviensis* by 7–8 %, but in the LSU D1–D2 by only 0.2–0.6 %. Higher ITS distances are observed to *O. elegans* and *O. musiformis* s.l. (ITS 9–11 %, LSU 0.4–0.6 %), whereas the closest ITS sequences were '*A. musiformis*' (EVLL02, EVLL-2) with 3.6 % distance, and '*O. auricolor*/*A. oligosporus*' (B.L. 6225) with 3.7 % distance (but in LSU 0.7–0.9 %). In Quijada's analysis of ITS+LSU, *O. jesu-laurae* clustered supported with '*A. musiformis*' (see also p. 1578).

The type strain of *A. vermicola* from Uganda was sequenced for the ITS by Liou & Tzean (1997, U51944) and resequenced by Qiao et al. (2012, GU178821 = NR_144911). The two sequences differ by 6 nt and 1 gap, but in comparison to other sequences of this and related species it seems that all deviations in U51944 are based on sequencing errors. This is confirmed by a sequence in the CBS database (with the wrong name *Arachniotus hebridensis* and the possibly wrong number CBS 360.66) which matches perfectly GU178821 in the ITS region and should instead derive from CBS 513.66. In Qiao et al. (2012) Liou & Tzean's sequence is erroneously said to originate from a strain from Taiwan, and also Yang et al.'s (2007) strain was assumed to originate from Beijing although in fact no information is available about it.

In Hagedorn & Scholler's (1999: fig. 2) neighbour joining analysis of ITS, Liou & Tzean's sequence of *A. vermicola* clustered in a medium supported clade with *A. musiformis*, a species with candelabrelloid conidiophores and cylindric-clavate, 1-septate conidia, positioned with medium support sister to a clade with *A. amerosporus*, *A. flagrans*, and *A. javanicus*. The entire clade corresponds to the *oligospora-musiformis* clade, in which, however, *O. blumenaviensis* did not cluster in our combined analyses (Phyls 25, S33), whereas an unsupported association with *A. musiformis* is also seen in our ITS analysis (Phyl. 28). In Qiao et al.'s (2012) neighbour joining analysis of ITS, the *O. blumenaviensis* clade clustered with medium support as a sister group to the major clade of *Arthrobotrys* species, but with *A. amerosporus*, *A. flagrans*, *A. musiformis*, and *A. oligosporus* more basally positioned. In the two parsimony analyses by Yang et al. (2007), *A. vermicola* clustered with *A. musiformis*, *A. oligosporus*, and *A. conoides*, either with ITS alone (unsupported) or in combination with *TUBB*, *RPB2* and *TEF1* (here with strong support and only here including *A. pseudoclavatus*).

In the LSU D1–D2 the five available sequences of *O. blumenaviensis* vary by a few nt in the D1 (pos. 99, 107, 126, 128) and by 1–2 nt in the D2 (pos. 523, 545). Yet, also *A. musiformis* and some other species deviate from *O. blumenaviensis* in the D1–D2 domain by only 1–2 nt, and *O. elegans* by only 0–1 nt. Therefore, it is impossible to differentiate among species with LSU alone (see Phyl. S32), and analyses of ITS+LSU lead to virtually the same result as with ITS. At 1 position in LSU D2 (516) *A. musiformis* and *O. javanica* differ by GGGA**T**AAA compared to GGGA**C**AAA in *O. blumenaviensis* and various other species. Based on this position, a strain under the name *A. vermicola* in GenBank (AY261143, YNUCC 2428) belongs to *A. musiformis* s.l.

When analysing the S1506 intron (~400 nt), three strains are very close (125, 126, 629, 0.3–0.5 % distance) but differ from the two YMF strains by 3.2–5.7 %, and the YMF strains even by 8.8 %. Nevertheless, the five sequences clustered in a strongly supported clade (S30, strains 125 and 126 not shown). This result and BLAST similarities of the ITS1 confirm that strains 125 and 126 clearly belong to *O. blumenaviensis*.

Ecology. Apothecia of *O. blumenaviensis* occur on rotten wood and bark of hygric branches and trunks of angiosperms including palms. The species shows a pantropical distribution, being so far mainly recorded from tropical humid maritime Middle America (Caribbean belt) and southeastern Africa (Comoros) and tropical humid central Africa (Uganda), as well as subtropical humid eastern South America (type of *O. blumenaviensis*), and subtropical humid (winter-dry) to tropical humid (type of *O. fici*) southeastern Asia. *O. blumenaviensis* was also once collected in thermotemperate humid atlantic southeastern Europe (Galicia). A further European record was made by M. Wilhelm (pers. comm.) in the Masoala tropic house at the Zoo in Zürich, which represents the tropical rainforest flora and fauna of the Masoala peninsula in northeastern Madagascar.

Specimens included. **MEXICO**: **Veracruz**, 170 km NW of Veracruz, 18 km SSE of Papantla de Olarte Ocampo, 166 m, *Vanilla planifolia*, on bark, 2013, M.C.A. González Chávez & R. Orbilia neglecta Penz. & Sacc., Malpighia 15(7–9): 219 (1902) — Pls 969–970

Etymology: meaning 'overlooked'.

Typification: Indonesia, Java, Cibodas, leaves of *Elettaria*, 6.II.1897, A.J.O. Penzig (PAD, nr. 442 ex parte, lectotype, designated here, MBT202392)

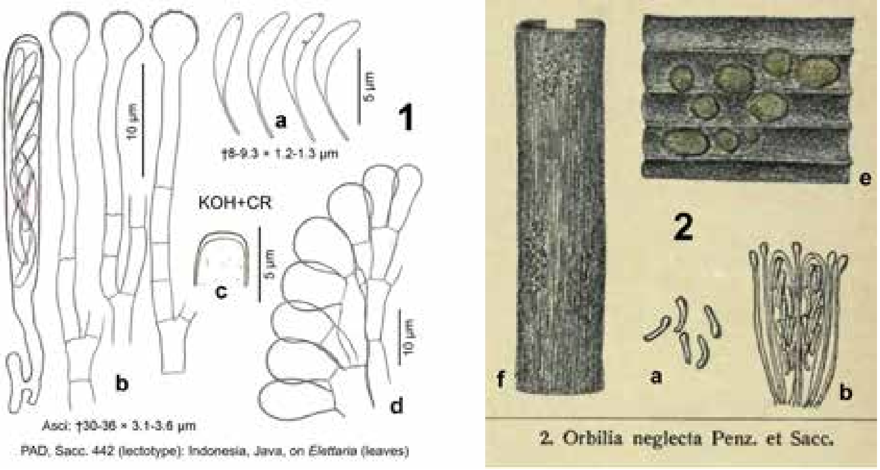

Plate 969. **1–2**: *Orbilia neglecta*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. median section of ectal excipulum at margin; **e**. apothecia; **f**. *Elettaria* leaf. – **2**: uncalibrated original drawing in Penzig & Saccardo (1904: pl. 57 fig. 2).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.7 mm diam., 0.14 mm high, now pale cream (light honey-yellow in the protologue), translucent, round, gregarious over large areas; disc flat, margin distinct, not protruding, smooth; broadly sessile, superficial; dry light amber, with white subiculum around each apothecium. **Asci** †30–36 × 3.1–3.6 µm, 8-spored, spores (†) obliquely 2-seriate, 3–5 lower spores inverted (not mixed); **apex** (†) medium to strongly truncate (not indented, laterally not widened); **base** with medium long, thin, flexuous stalk, h- to H-shaped. **Ascospores** †8–9.3 × 1.2–1.3 µm (~9–10 µm actual length), divided into a narrowly ellipsoid-fusoid upper part and an abrupt, very thin tail of 2.5–3 × 0.1–0.2 µm (about ⅓ of spore length), apex obtuse, medium

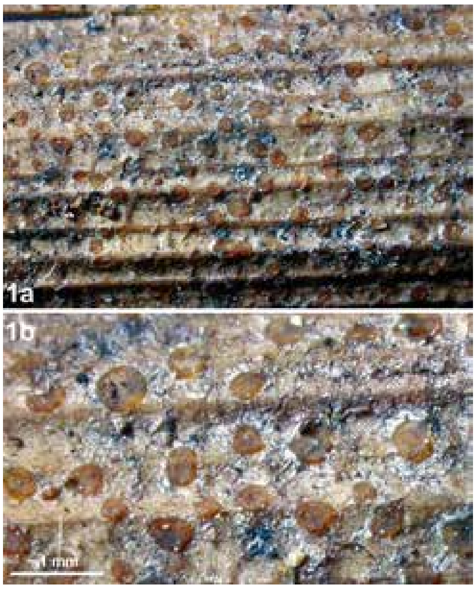

Plate 970. **1**: *Orbilia neglecta*. – Dry apothecia. — **1a–b**. PAD, nr. 442 (lectotype): Indonesia, Java, on *Elettaria*.

to strongly curved; **SBs** not seen. **Paraphyses** apically strongly (to very strongly) capitate, terminal cell †15.5–23 × 3–4.5 µm, lower cells †3–7.5 × 1.7–2.3 µm; unbranched at upper septum. **Medullary excipulum** 10–15 µm thick, of dense, horizontal textura prismatica-porrecta. **Ectal excipulum** of thin-walled to slightly gelatinized, indistinctly oriented t. angularis-globulosa from base to margin, 90–100 µm thick near base, cells †15–40 × 15–30 µm; 15 µm thick near margin, oriented at a high angle to the surface, marginal cortical cells †10–16 × 6–12 µm, thin-walled; **glassy processes** absent. **Anchoring hyphae** very abundant, †3–4.5 µm wide (near insertion up to 6.5 µm), walls (0.2–)0.3–0.8 µm thick. **SCBs** and **VBs** no data available. **Exudate** over paraphyses 0.2–0.4 µm thick, finely rough, firmly attached, over margin and flanks absent. **— ANAMORPH**: unknown.

Habitat: on upper side of dead leaves of *Elettaria* sp. **Associated**: hyphomycete with dark brown setae. **Desiccation tolerance**: unknown (possibly intolerant). **Altitude**: 1350 m a.s.l. **Phenology**: II (tropical belt).

Taxonomic remarks. *Orbilia neglecta* is easily recognized by its curved, narrowly ellipsoid-fusoid ascospores being abruptly attenuated in a very thin tail. *O. neglecta* and *O. latispora* s.l. (see below) are the only known members of section *Arthrobotrys* with a distinct basal spore tail, though similar tails were found in some spores of *O. clavispora*. *O. disseminata* somewhat resembles *O. neglecta* in the spores, but it deviates in a helicoid spore shape and is assumed here to belong to the vicinity of *O. comma* (section *Aurantiorubrae*).

Penzig & Saccardo (1902) compared *Orbilia neglecta* with *O. luteorubella*, from which they separated it by smaller asci and spores. One member of section *Helicoon*, *O. falciformis*, indeed resembles *O. neglecta* in the curved spores which are, however, attenuated at the base instead of tailed. *Orbilia carpathica* Velen. was figured with spores very similar to *O. neglecta*, but they were said to have the double length (20 µm, see p. 1664).

Because of a strong similarity with Chinese lignicolous collections here reported as *O. latispora* s.l. and belonging to series *Arthrobotrys*, *O. neglecta* is assumed to be also a member of that series.

Type studies. In the protologue the spores are described as ‘cylindrical, often clavate, mostly curved, 6–7 × 0.7 µm (mature?)’ and the asci as ‘27–30 × 4.5–5 µm, subsessile’ (see also Penzig & Saccardo 1904: 85, pl. 57 fig. 2, Pl. 969: 2). The paraphyses are figured with a distinctly inflated, clavate apex. A microscopic sketch matching the original description (including a spores size of ‘6–7 × 0.7’ and an ascus size of ‘27–30 × 5’) is found on the here examined authentic specimen. Although the rich material appears to be fully mature, according to the many asci that contain spores, only a few free spores could be observed (Pl. 969: 1a), and only after strong pressure. Based on observations on other species, their fine tail has probably been wider in the living state. Penzig & Saccardo’s rough microscopic sketch shows much thicker spore tails and herein fits well the spore shape in the Chinese collections of *O. latispora* s.l. on woody substrate. However, in the latter taxon (Pls 971: 1a; 972: 1f, 2f) little difference in tail width is seen between living and dead spores.

The present examination of *O. neglecta* (Pls 969: 1; 970) is based on ‘nr. 442 ex parte’ (herb. Saccardo, PAD). The specimen contains several fragments of leaves with abundant apothecia (the protologue gives both leaves and stems as substrate). Another specimen, labelled ‘*Orbilia neglecta*?, Java, t. 406’ (herb. Saccardo, PAD), contains a single leaf fragment which might also belong to *Elettaria*, but on which no apothecia could be found. Further specimens are mentioned in the protologue: nrs 41 & 449 (on *Zalacca*), nr. 33 (on bark). These were stated to be immature and were not received from PAD. Collection ‘442 e.p.’ (PAD) is designated here as **lectotype** of *O. neglecta*. A further number cited in the protologue and in Penzig & Saccardo (1904), nr. 38 (on *Elettaria*), appears to represent an isolectotype.

Ecology. *O. neglecta* was collected on dead herbaceous leaves and stems of *Elettaria* (Cardamom, *Zingiberales*) in a tropical humid rainforest area at the foothill of Mt. Gede volcano in western Java. In the examined lectotype the apothecia grew gregariously and exclusively on the upper side of the leaf blades.

Specimens included. **INDONESIA**: **Java**, **West Java**, 60 km SSE of Jakarta, 30 km SE of Bogor, Cibodas (‘Tjibodas’), ~1350 m, leaves of *Elettaria*, 6.II.1897, A.J.O. Penzig (PAD, nr. 442 ex parte, **lectotype** of *O. neglecta*, H.B. 7342 ø).

Orbilia latispora (H.Y. Su & X.Y. Yang) Baral, Ying Zhang & E. Weber, **comb. nov.**, MB 830234 — Pls 971–973

Basionym: *Arthrobotrys latisporus* H.Y. Su & X.Y. Yang [as ‘*latispora*’], Mycotaxon 117: 32 (2011)

Etymology: *latispora*: according to the broad conidia.

Typification: China, Yunnan, Jinguangsi, branch of *Castanopsis orthacantha*, VIII.2008, X.J. Su, Z.L. Luo & H.Y. Su (YMF 1.03168, holotype; sq.: HQ735415).

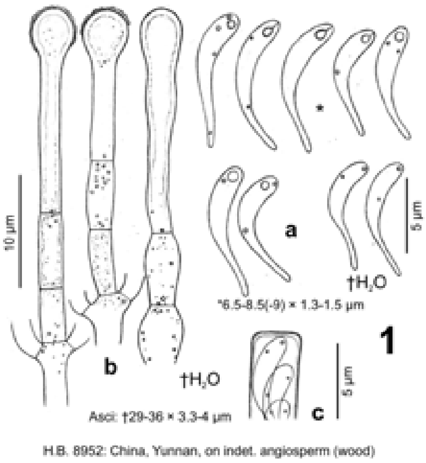

Plate 971. **1**: *Orbilia latispora*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

Description: — **TELEOMORPH**: **Apothecia** fresh (0.3–)0.5–1.8 mm diam., 0.2–0.28 mm high (receptacle 0.09–0.11 mm), whitish or yellowish to pale orange, rehydrated pale to bright cream-brown, somewhat translucent, round to irregular or slightly lobed, ± gregarious, partly in groups; disc flat to slightly convex, margin ± indistinct, not protruding, smooth; with a ± distinct stipe 0.08–0.12 × 0.45–1 mm, superficial. **Asci** ~*35–41 × 3.6–4.2 µm {2}, †29–36 × 3.3–4 µm {1}, 8-spored, spores *4(–8)-seriate, 3(–4) lower spores inverted {2} (rarely mixed), pars sporifera *(9–)11–17 µm long (†17–21.5 µm); **apex** (†) strongly truncate (not indented, laterally not or hardly inflated); **base** without or with short to medium long, ± thick, flexuous stalk, Y-, h- to H-shaped. **Ascospores** *6.5–8.5(–9) × (1.1–)1.3–1.5 µm {3} (~7–10 µm actual length), †6–8.5(–9.5) × (1.1–)1.3–1.5 µm {2}, strongly clavate, apex rounded to obtuse, strongly attenuated into a tail-like base or often distinct tail */†2–3 × 0.3–0.5 µm, medium to strongly curved in middle or upper part (falcate, not helicoid); **SBs** *1–1.2 × 0.5–0.8 µm {3}, (sub)globose, with a very short, fine filum, partly somewhat eccentrical. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cell *20–24 × 2.6–3.6 µm {2}, †13.5–32 × (2.5–)3–4 µm {1}, lower cells *3.5–5(–7.5) × 2.2–2.7 µm {2}, †5–7 × 2–2.5(–3.3) µm {1}; never branched at upper septum. **Medullary excipulum** pale cream-ochraceous, 40–50 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited from ectal excipulum. **Ectal excipulum** hyaline, of (†) thin-walled to slightly gelatinized, vertically oriented t. globulosa-angularis from base to margin, 100–170 µm thick near base, cells †25–50 × 20–35 µm {1}; 20–30 µm thick near margin, oriented at a 70–90° angle to the surface, marginal cortical cells †8–13 × 5–8 µm {1}; **glassy processes** absent. **Anchoring hyphae** abundant, †2.5–3.5(–5) µm wide, walls 0.2–0.3 µm thick {1}, forming a medium dense, hyaline t. intricata ~20–80 µm thick. **SCBs** not observed; **VBs** in terminal cells (sub)globose to very elongate, medium refractive. **Exudate** over paraphyses absent or usually 0.1–0.2 µm thick, finely rough, firmly attached, over margin and flanks 0.1–0.2 or 0.2–1(–1.5) µm thick, continuous, ± smooth. **— ANAMORPH** (from Su et al. 2011b and Y. Zhang pers. comm.): arthrobotrys-like (from ascospore isolate {2}). **Conidiophores** erect, septate, 60–210 µm long, 4.5–7.5 µm wide at base, slightly tapering to 2–6 µm near tip, with 4–8(–12) conidia in a loose capitate arrangement, formed on short denticles on ± swollen nodes (arthrobotryoid), unbranched, not proliferating. **Macroconidia** *16.5–18.5 × 7.7–11.7 µm {1} or *14.8–21.5 × 10–16.3 µm {type of *A. latisporus*}, obovoid-pyriform to subcylindrical, (0–)1-septate, septum median or eccentrical. **Microconidia** much more abundant than macroconidia, non-septate, ± cylindric-clavate, rounded at apex, tapered towards the ± beaked base, *11–17 × 4.5–6(–8.5) µm {1}. **Adhesive networks** formed when nematodes were added, outer diameter of loops ~35–40 µm, cells 4–7 µm wide, at insertion 7–8 µm {1}. **Chlamydospores** not observed.

Habitat: collected on moist ground, decorticated, ~4 cm thick branches of *Castanopsis orthacantha* {1}, *Salix* {1}, indet. angiosperm trees {3}, on 0.1 mm deep medium decayed wood {1} or bark {3} (?periderm), partly on thin black stroma of old pyrenomycete, no algae. **Associated**: ?*Bisporella* sp. {1}, *Nectria* sp. {1}, *Orbilia nemaspora* {1}. **Desiccation tolerance**: intolerant, many spores and a few cells of medullary excipulum still viable after 3 weeks. **Altitude**: 400 m a.s.l. (northern China), 2700–2730 m (southern China). **Geology**: Paleozoic, Jurassic & Tertiary sedimentary rock; mafic volcanic, felsic plutonic & metamorphic rock. **Phenology**: VIII–X (teleomorph).

Taxonomic remarks. *Orbilia latispora* differs from the type of *O. neglecta* in ascospores with wider tails or only tail-like or gradually attenuated bases, and in larger and thicker apothecia growing on wood and bark of angiosperms instead of monocot leaves. A similar spore shape as in *O. latispora* is also found in *O. clavispora* (series *Neodactylella*), but that species deviates in the marginal excipulum composed of distinct cell rows oriented at a rather low angle, and in lacking nematode-induced trapping organs. *O. latispora* is also similar to *O. terrestris*, a species which differs in distinctly larger asci and spores, the latter being only basally curved and without tails, possibly also in larger, tear-shaped SBs.

Because of the unclear relationship to the type of *O. neglecta*, for which molecular data were not available, and because of the molecular heterogeneity of *O. latispora* s.l., we here refrain from adopting the name *O. neglecta* for the here included collections.

Variation in teleomorph. The first two collections of *Orbilia latispora* s.l. have been made in 2004. One was reported by Zhang et al. (2009b: 152, fig. 8) under the name *O.* cf. *neglecta* (Pl. 972: 2), while Liu (2006) included a sample from Heilongjiang (northern China) in *O. auricolor* (IVV: HMAS 96799), although it shows the characteristic spores of *O. latispora*. Photos of three further records were forwarded to us by Z.F. Yu (pers. comm., Pl. 973: 2–4), and a duplicate of a sixth sample was sent to us by H.Y. Su (Pls 971: 1; 972: 1). All these specimens closely concur in their microscopic characteristics of the teleomorph, without any variation worth mentioning. An unillustrated report by Zhuang & Wang (1998: 28) on bark from Hainan under the name *O.* cf. *fimicola* might refer to the same species, but was not examined by us. The type of *O. latispora*, which is the dried agar plate of the anamorph, was gained from an ascospore isolate from an ‘unidentified *Orbilia* sp.’, but no illustration or description was provided by Su et al. (2011b).

Anamorph. In three of the six Chinese samples of *O. latispora* s.l. conidia were gained from ascospore isolates (Pl. 973: 2–4). In two of them (2, 4) smaller conidia resembling microconidia were also produced. The macroconidia showed a certain degree of variation, some resemble those of *Arthrobotrys oligosporus*, others *A. superbus* or *A. cladodes*. Chlamydospores were not formed. The type of *A. latisporus* (Pl. 973: 1) differs in slightly longer and distinctly wider conidia. Conidiophores are often branched. Moreover, chlamydospores were present, and conidial dimorphism was not observed. *A. latisporus* was described by Su et al. (2011b) from an ascospore isolate of an unidentified *Orbilia* (jgs-31) which we here refer to *O. hoana* of section *Helicoon*, according to an unpublished photo plate (IVV: YMF 1.03168). The authors hesitated to publish this teleomorph because we had expressed our doubts about *O. hoana* being connected to an arthrobotrys-like anamorph. In Yu et al. (2014: 78) *A. latisporus* was erroneously said to have been isolated from soil.

A strain described by Drechsler (1944a) under the name *A. arthrobotryoides* resembles *A. latisporus* but differs in longer conidia reaching a length of 28(–30) µm. The conidia of *A. botryosporus* show a size similar as *A. latisporus* but are consistently non-septate. Drechsler 1937a (p. 458, fig. 18 R) mentioned apothecia with tear-shaped ascospores of ~4.5–5.2 × 1–1.3 µm, growing in a non-sterile, nematode-infested culture of *A. superbus*. The hymenial characters recall *O. latispora*, but Drechsler (l.c.: fig. 1) did not mention or illustrate small non-septate conidia for his cultures of *A. superbus*, and the large 1-septate conidia are distinctly narrower than in *O. latispora*.

Phylogeny. Sequences from seven Chinese strains (mainly ascospore isolates) and one from North America, were available: S1506 intron and ITS in four strains from Yunnan and two without collection data (YMF 1.03242, 1.03243), and ITS in two strains from northern China (Jilin, Heilongjiang). Whether or not the latter two possess the intron is unclear, but it is absent in the anamorphic strain from Massachusetts under the name *A.*

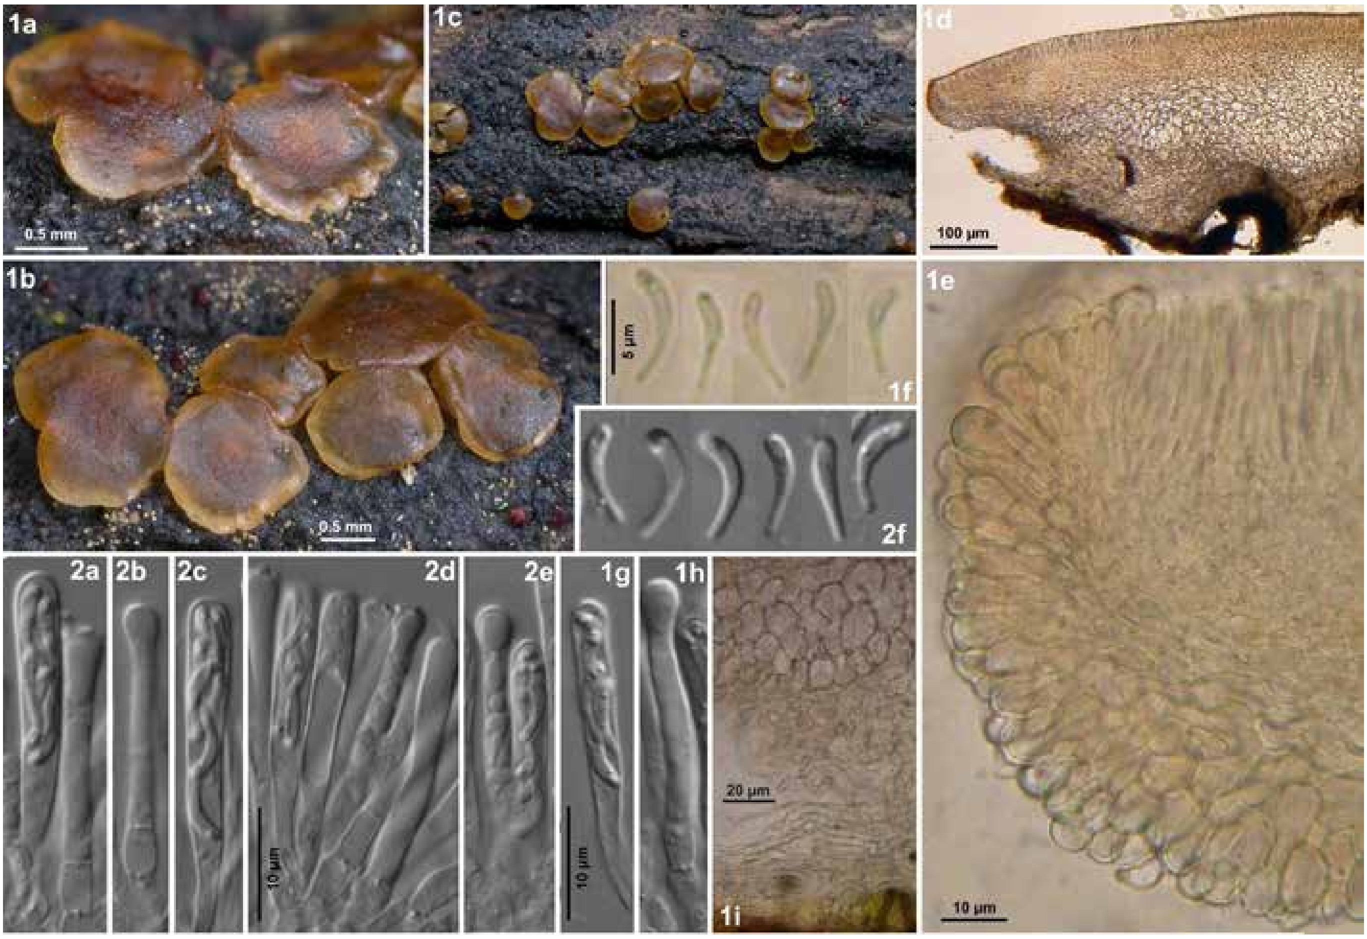

Plate 972. **1–2**: *Orbilia latispora*. – **1a–c**. rehydrated apothecia; **1d**. apothecium in median section; **1e**. id., at margin; **1i** id., ectal excipulum and anchoring hyphae at base; **1g–h**, **2a–e**. asci and paraphyses; **1f**, **2f**. ascospores. – Living state, except for 4 right spores in **1f**, 1 left and 3 right spores in **2f**, asci in **1g** & **2c** (all in H_2O); apothecial sections in **1d–e**, **i** (?in KOH). – **2a–f**: from Zhang et al. (2009b, DIC), **1g–h**: phot. H.Y. Su (DIC). — **1a–i**. H.B. 8952: China, Yunnan, Dali, Jizushan, on indet. angiosperm; **2a–f**. Y.Z. jz-30: ibid., on indet. angiosperm.

superbus (CBS 116.61, on textile), for which an unofficial ITS sequences exists in the CBS database.

When analysing the ITS region, *O. latispora* surprisingly formed with a 5 % distance two separate subclades (C2 & C3), which clustered with *O. cladodes* (subclade C1) and *A. botryosporus* (C4) in the strongly supported *cladodes-botryosporus* clade (see Phyl. 28). The 5 % distance suggests that two different species are involved. Subclade C2 includes four very similar sequences from Yunnan, including the type of *A. latisporus* (YMF 1.03168). Two of them (YMF 1.03213, YMF 1.03242) deviate by 1 nt from another and from the other two (YMF 1.03168, H.B. 8952) which are identical in the ITS. With strong support and a 1.2–1.3 % distance clustered the strain from Heilongjiang (HMAS 96799) in this subclade. Subclade C3 comprises the strains from Jilin (YMF 1.03506), Yuxi (YMF 1.03507), and YMF 1.03243, which are identical in the ITS though coming from very remote provinces of China, and the strain from Massachusetts (CBS 116.61) which shows a 1.2 % distance to them. Strains YMF 1.03242 and YMF 1.03243 are not shown in Phyls 28, S30 as we obtained them very late.

This result is surprising, because the morphology of the teleomorph is the same in the two subclades and the observed differences in the anamorph do not correlate with them. Because of the 5 % distance, we refer to subclade C3 as *O.* cf. *latispora*. The ex-type strain of *A. botryosporus* (subclade C4) also nests in the *cladodes-botryosporus* clade by showing a 4.5–5.5 % distance to the two subclades of *O. latispora* s.l. and 4.5–5 % to Pfister's two American *O. auricolor* strains (D.H.P. 60 and 90, subclade C1, *O. cladodes*), the latter two strains differing by 3.3–5.5 % to *O. latispora* l.s.

Analysing the S1506 intron (Phyl. S30) confirms the above result: within subclade C2 strains YMF 1.03213, YMF 1.03242, and H.B. 8952 (the 2 latter not shown) are identical in the overlapping 359 nt (except for 1 gap in YMF 1.03213), and YMF 1.03168 differs by 1 nt. Subclade C3 includes YMF 1.03507 and YMF 1.03243 (the latter not shown), which differ by 1 nt in the overlapping 391 nt. Subclade C3 differs from subclade C2 by 10–10.5 %, and *A. botryosporus* by 13–16 % from both. Also *A. pravicovii* (SBUG M12) and *A. obovatus* clustered strongly supported with *O. latispora* s.l., whereas *A. botryosporus* clustered in another clade. In contrast to this, in the ITS analysis *A. pravicovii* and *A. obovatus* did not cluster in the *cladodes-botryosporus* clade, but the former in the *scaphoides-pravicovii* clade and the latter unresolved.

LSU was only available for *O.* cf. *latispora* (CBS 116.61, subclade C3), which clustered in the analyses of LSU (Phyl. S32) or SSU+ITS+LSU (S33) with subclades C1 and C4.

Ecology. *O. latispora* s.l. grew on ± decayed wood and bark of hygric branches of angiosperms in oro- to cold-temperate humid (winter-dry) continental colline to montane deciduous forests of northern China and subtropical humid (winter-dry) montane evergreen forests in southern China. The CBS isolate is from cold-temperate humid northeastern North America.

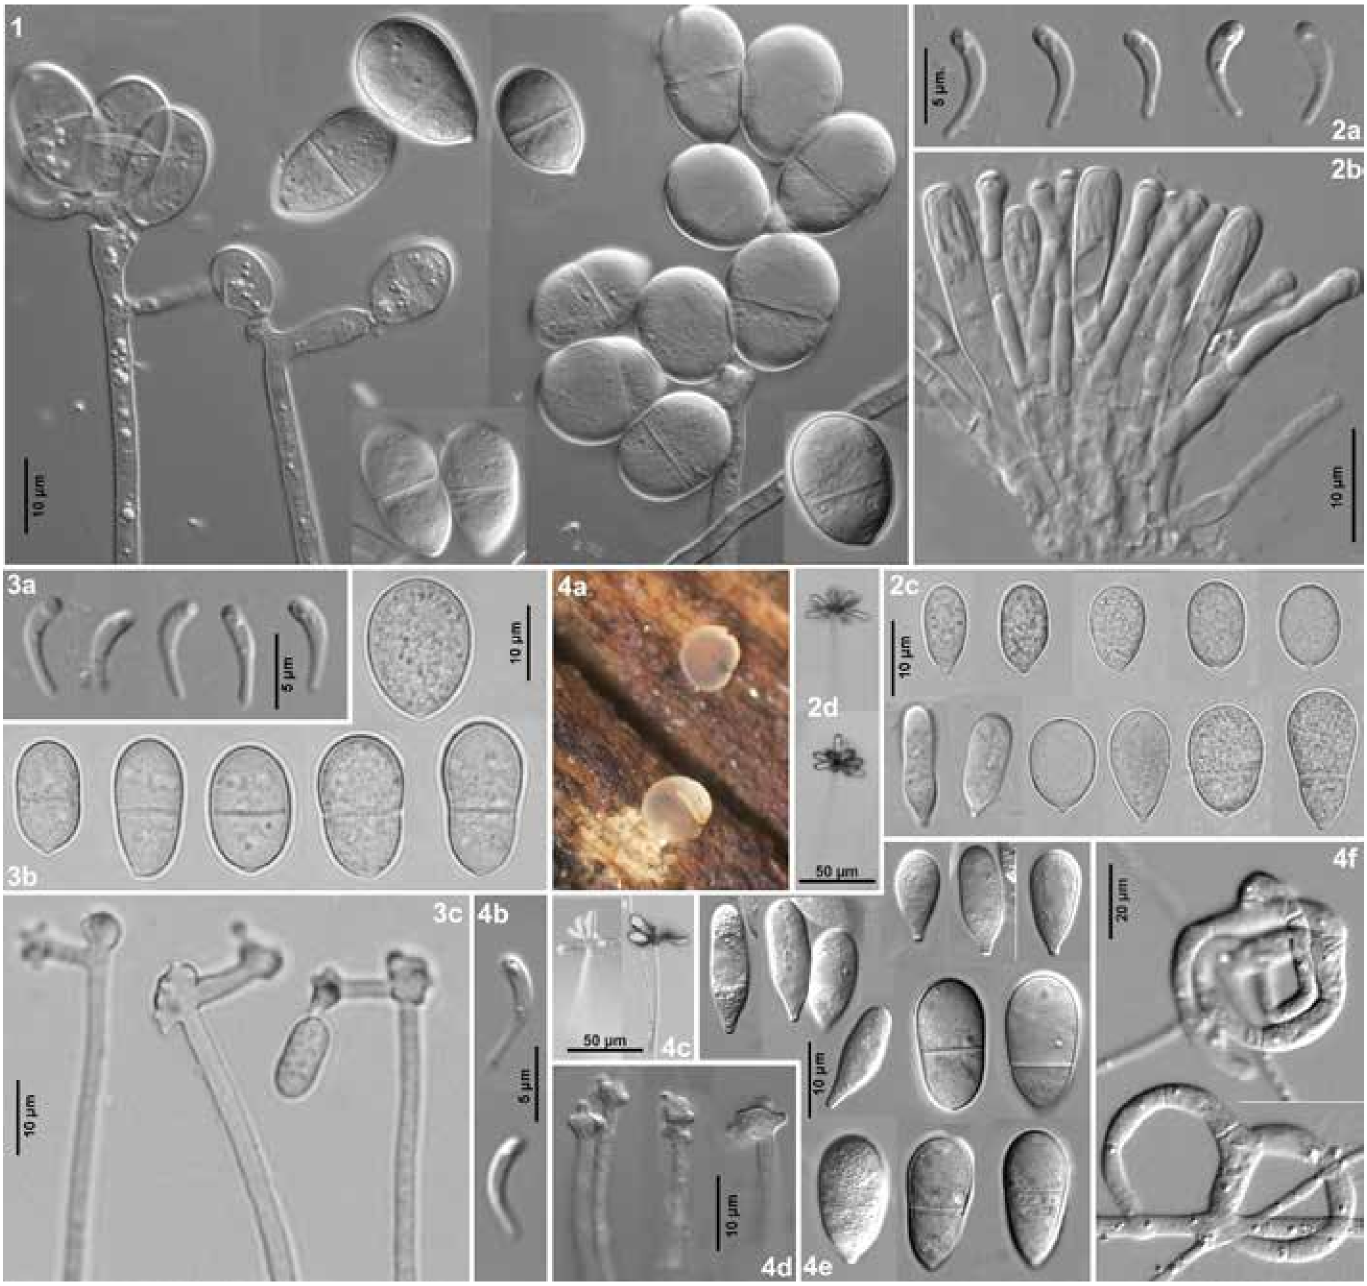

Plate 973. **1–2**: *Orbilia latispora* (subclade A2); **3–4**: *O.* cf. *latispora* (subclade A3). – **4a**. fresh apothecia; **2b**. asci and paraphyses; **2a**, **3a**, **4b**. ascospores; **1**, **2c**, **3b**, **4e**. conidia (**4e**. micro- and macroconidia); **1**, **2d**, **3c**, **4c–d**. conidiophores; **4f**. adhesive networks (**2–4** from ascospore isolate). – Living state. – **1**: from Su et al. (2011b), **2–4**: phot. Z.F. Yu. – **1**. YMF 1.03168 (holotype of *Arthrobotrys latisporus*): China, Yunnan, Dali, Yongping, on *Castanopsis*; **2a–d**. Etymology: according to the boat-like shape of the conidia.

Typification: Great Britain, London, leaves and rhizomes of *Typha latifolia*, IX.1950, isolated by M.P. Peach (K(M), type; CBS 226.52, ex-type culture of ***Dactylaria scaphoides***; sq.: GU171370). – Azerbaijan, Baku, from plant remnants, IX.1977 (BAK, holotype of ***Dactylaria nematopaga***).

Description: — **TELEOMORPH**: unknown (but see below). — **ANAMORPH**: arthrobotrys-like (conidial or soil isolates {3}), including data of Peach (1952) and Zhang et al. (2010). **Conidiophores** arthrobotryoid, unbranched, with 1 node or by proliferation 2–4 nodes, very sparsely septate, 80–200 µm up to 365–430(–690) µm long, 4.5–5.5 µm wide below, 3–5 µm wide above, conidia formed singly or usually in clusters of 4–8(–12) at each node. **Macroconidia** fusiform, sometimes ± curved, *((26–))(37–)50–80(–86) × (11–)13–15(–17.5) µm {3}, ((1–))2(–3–4)((–6))- {2} or (1–)2(–3)-septate {T}. **Microconidiophores** 50–160 µm long, conidia formed on nodes in groups of ~6 {T}. **Microconidia** 14–22 × 5–8.5 µm {T}, ellipsoid, non-septate. **Adhesive networks** formed in the presence of nematodes, loops with ~35–50 µm outer diameter {1}, (15–)25–30(–45) µm {T} (inner diam. 14–18 µm), cells 4–7 µm wide {2}. **Chlamydospores** not observed.

Habitat: previous year's leaves & rhizomes of *Scirpus maritimus* {1}, *Typha latifolia* {1}. **Associated**: *Orbilia elegans* {1}. **Desiccation tolerance**: not tested (probably intolerant). **Altitude**: 3–20 m a.s.l. (northwestern Europe), 1450 m (northern China).

Taxonomic remarks. *Orbilia scaphoides* was reported by Zhang et al. (2010) based on a Chinese soil isolate and a European strain, the latter grew in an ascospore isolate of the morphologically very different *O. elegans* (H.B. 6972a) as a mixture. From the same collection G. Van Ryckegem (pers. comm.) obtained in his ascospore isolate solely the *A.*

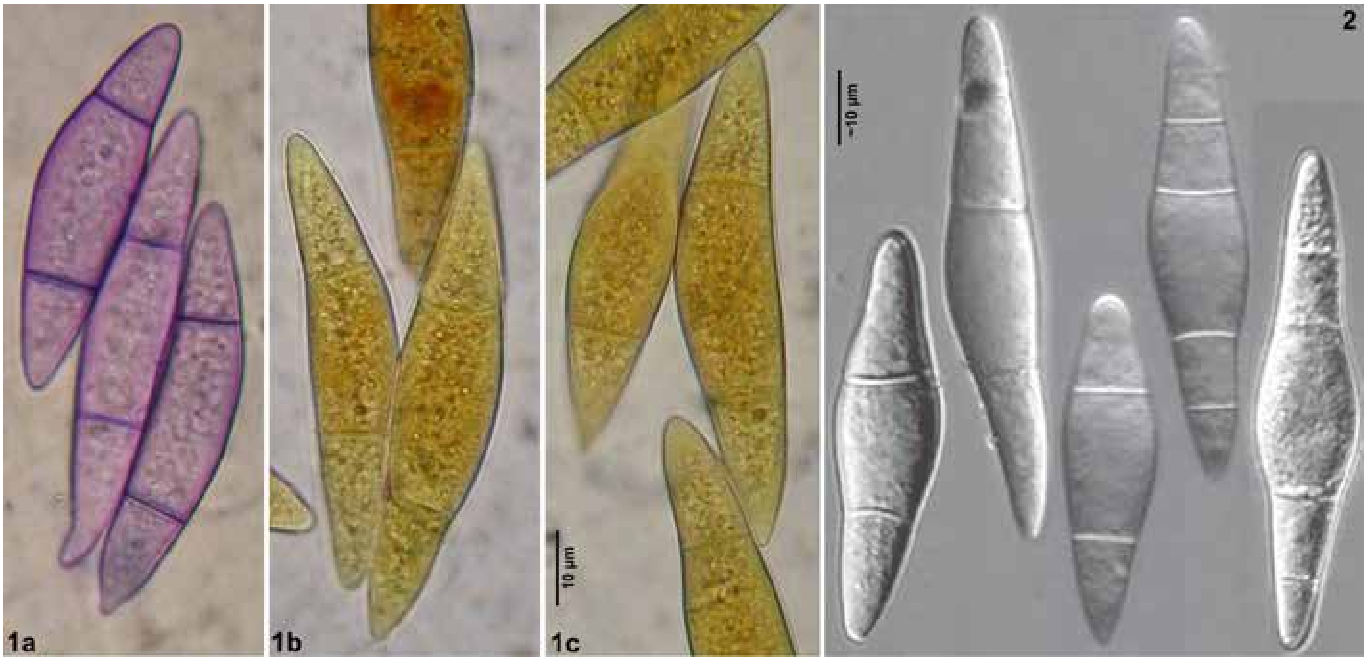

Plate 975. **1–2**: *Orbilia scaphoides*. – **1a–c**, **2**. macroconidia from culture. – Living state (**1a** in CRB, **1b–c** in IKI). – **2**: from Zhang et al. (2010) **— 1a–c**. H.B. 6972b: Netherlands, on *Scirpus*; **2**. YMF 1.01895: China, Gansu, from soil (here scale adjusted to description in Zhang et al. 2010).

oudemansii anamorph, hence we conclude that *A. scaphoides* was a contamination in our culture.

Peach (1952) obtained the anamorph in a culture taken from remnants of *Typha latifolia* in the mud of a lake in England (Pl. 974: 2). Its macroconidia match well the Dutch and Chinese ones in size, but were only up to 3-septate. Peach also observed microconidia formed on germinated macroconidia (2c), which were not observed in the other two strains.

Arthrobotrys nematopagus closely resembles *O. scaphoides* in its conidia (35–90 × 10.7–14.8 µm), conidiophores, and trapping organs, and might be a synonym. It merely differs in mainly 4-septate conidia, with only 1–4 conidia at the conidiophore tip (but a conidiophore is figured with min. 6 nodules). The similar *A. gampsosporus* differs in having mostly 4-septate, slightly narrower, partly more distinctly curved conidia and in forming chlamydospores (Drechsler 1962, Rubner 1996). Likewise, *A. polycephalus* has smaller, mostly 4-septate conidia. *A. microscaphoides* differs in shorter, top-shaped conidia, and also *A. mangrovisporus* has somewhat shorter and wider, partly top-shaped conidia; in both taxa chlamydospores were formed. Also *Dactylellina copepodii* (Barron) Scholler et al. has conidia very similar to *A. scaphoides*, though mainly 4-septate, but here only 1 conidium is formed at the conidiophore apex and the prey (copepods) is captured by adhesive knobs (Barron 1990).

In a presentation held in Amsterdam in 2012, X.Z. Liu reported an ascospore isolate (BJ08-20) under the name '*Orbilia auricolor*' being conspecific with *O. scaphoides*, but we did not see a documentation of this collection.

Phylogeny. Sequences of *O. scaphoides* were taken from three strains: two comprise SSU, ITS, and LSU (England: CBS 226.52, Netherlands: H.B. 6972b) and one only ITS (China: YMF 1.01895). The distance between them is 0–0.8 % in the ITS region, thereby the ex-type strain differs by 4 nt and 1–2 gaps from the other two, which differ only by 1 gap. Distances to morphologically similar species lie in the range of 5–7.5 % to *A. thaumasius*, and 9.5–10 % to *A. gampsosporus* (CBS 127.83), whereas *A. pravicovii* (SBUG M12) and *A. macroides* (SBUG 160), characterized by 1-septate conidia, show only 1.2 % and 2.1–2.3 % distance, respectively. Zhang et al. (2010) gave much higher distances which are obviously due to inclusion of false nucleotides in the adjacent SSU and LSU in strain YMF 1.01895.

In the LSU (D1–D2), H.B. 6972b differs from the type of *O. scaphoides* by 1 nt, whereas the deviation to sequences of other species is min. 5–8 nt in this region. In the SSU (V8–V9) the two *O. scaphoides* sequences are identical, but also *A. pravicovii* (SBUG M12) fully concurs here.

In the ITS analysis by Zhang et al. (2010) *O. scaphoides* clustered with *A. pravicovii* (as *A. conoides*) in a weakly supported clade that formed with the *cladodes-botryosporus* clade a strongly supported clade of species with arthrobotryoid conidiophores. In our analyses of SSU+ITS+LSU or ITS (Phyls 25, 28, S33) it formed a medium supported clade with *A. pravicovii* and *A. macroides*, here called *scaphoides-pravicovii* clade, which formed in the combined trees with strong support a sister clade to the *cladodes-botryosporus* clade whereas in the analysis of ITS this association remained unsupported. According to their ITS sequences, *A. microscaphoides* is a synonym of *A. thaumasius*, and also *A. gampsosporus*, *A. mangrovisporus*, and *A. polycephalus* clustered very distant from *O. scaphoides*.

Ecology. Both the type and the specimen from the Netherlands grew on decayed remnants of monocots in aquatic habitats at planar altitude in subatlantic to atlantic, temperate humid northwestern Europe. The Asian record was a soil isolate under probably irrigated *Malus asiatica* in a suburban plantation, located in a cold-continental arid high plateau in northern China between Qilian Shan mountain range and Gobi Desert, and the type of *A. nematopagus* was from a temperate semiarid lowland in Azerbaijan.

Specimens included. **GREAT BRITAIN**, **South East England**, **Surrey**, 33 km SW of London, Wisley Pool, 20 m, leaves & rhizomes of *Typha latifolia*, IX.1950, isolated by M.P. Peach (K(M), **type**, CBS 226.52, MUCL 9430, IMI 050675, conid. isol., doc. vid.; sq.: GU171370). — **NETHERLANDS**: **Zeeland**, 18 km NW of Antwerpen, old harbour facing the Hertogin Hedwighe Polder, easternmost part of Verdronken Land van Saeftinghe, 3 m, leaves of *Scirpus maritimus*, 23.III.2001, G. Van Ryckegem (H.B. 6972b dried culture, CBS 140808, conid. isol.; sq.: GU171371). — **CHINA**: **Gansu**, **Jiuquan**, 1450 m (2450 m in Zhang et al. 2010 is incorrect), from soil under *Malus asiatica*, VIII.2006, Y. Zhang et al. (Y.Z. zn-1, YMF 1.01895, conid. isol., doc. vid.; sq.: FJ609176).

Not included. **AZERBAIJAN**: **Baku**, ~50 m, isolated from plant remnants, IX.1977 (**holotype** of *Dactylaria nematopaga*, conid. isol., doc. vid.).

Comments on the nomenclature and molecular identity of selected species without known teleomorph

Conidiophores arthrobotryoid

Arthrobotrys amerosporus S. Schenck, W.B. Kendr. & Pramer [as '*amerospora*'], Can. J. Bot. 55(8): 979 (1977) [1976]

= *Arthrobotrys elegans* (Subram. & Chandrash.) Seifert & W.B. Kendrick, in Seifert, Kendrick & Murase, Univ. Waterloo Biol. Ser. 27: 21 (1983)
  ≡ *Candelabrella elegans* Subram. & Chandrash., Kavaka 6: 47 (1979) [1978]

Five strains in GenBank (CBS 268.83 USA, type; SBUG M1257, Germany; AA1, ?England; S41, Sweden; BCRC 34371, Taiwan) and four in CBS (331.94, Germany; 267.83, 435.83, Canada; 110396, Australia) are fully identical in the ITS region, except that CBS 435.83 deviates by 2 adjacent nt in the ITS2, and both Canadian strains include some inserts (?sequencing errors) (Phyl. 28). All strains carry the name *A. amerosporus*, except for that from Sweden which is an environmental isolate. In the LSU D1–D2 (4 strains), CBS 435.83 differs from SBUG M1257, CBS 331.94, and CBS 267.83 by 3 nt in the D1 domain. *A. amerosporus* clustered in our combined analyses with medium support in the *oligospora-musiformis* clade (Phyl. S33) where it formed a strongly supported subclade with *A. flagrans*. The S1506 intron is absent (SBUG M1257).

Another species with consistently non-septate conidia, *A. botryosporus*, differs in often strongly branched conidiophores and shorter conidia arising in denser clusters, and nested in the *cladodes-botryosporus* clade.

Arthrobotrys conoides Drechsler, Mycologia 29(4): 476 (1937)

?= *Arthrobotrys tortor* Jarow., Acta Mycologica, Warszawa 4: 241 (1968)
?= *Arthrobotrys doliiformis* Soprunov [as '*dolioformis*'], Khishchnye Nematofagovye Griby - Gifomitsety (Baku): 138 (1958)
  ≡ *Didymozoophaga dolioformis* Soprunov & Galiulina, Microbiol., Reading 20: 497 (1951), nom. inval., ICN Art. 39.1 (Latin diagnosis missing)

Arthrobotrys conoides was originally described from two sites in North America (Arlington in Virginia, Beltsville in Maryland, Drechsler 1937a). Sequences of the partly incomplete ITS region of five strains under the name *A. conoides* in GenBank (including YMF 1.00009 and strain 670) clustered with a 0–1.5 % distance in a strongly supported clade (Phyl. 28), in which also three unofficial ITS sequences under this name in the CBS database (CBS 265.83, 575.91, 361.94) belong, as they differ by only 0–3.3 % from those. In this clade clusters also Drechsler's ex-syntype strain (CBS 108.37, not shown), a recently released sequence (MH855840) which differs by 2–3 % from *A. conoides* in GenBank and up to 5 % in CBS (CBS 265.83). In our combined analyses (Phyls 25, S33) *A. conoides* clustered in the *oligospora-musiformis* clade, and also in our ITS tree it nested in that clade.

However, there are sequences of three further strains under the name *A. conoides* (SBUG-M12 in GenBank, CBS 253.82 and CBS 606.84 in CBS) which show a 0–0.2 % ITS distance among another but differ from the true *A. conoides* by ~ 10.5 %. This aberrant *A. conoides*, which clustered in the *scaphoides-pravicovii* clade, is reidentified here as *A. pravicovii* (see below), a species with conidia resembling *A. superbus* rather than *A. conoides*.

LSU (D1–D2) exists in GenBank for three strains of the true *A. conoides* (1 as *A. oviformis*, YNUCC 2628) and in CBS for six unofficial sequences (two as *A. oviformis*). They all formed with low support a distinct clade (see S32) with a variation of 1 nt in the D1 and 3 adjacent nt at the 3'-end of D2, whereas *A. pravicovii* clustered with *O. scaphoides*. No illustrations were available for these '*A. oviformis*' strains, and it is assumed that they resemble in their conidia *A. conoides* more than *A. oviformis*. Also *A. pyriformis* was confused with *A. conoides*, according to an Ecuadorian strain under this name (CBS 339.94) which shows a min. 2 % distance to the true *A. conoides*.

Zhang et al. (2014) reported different isolates under the name *A. oviformis*, but apparently without providing sequences for them. In conidial size and shape *A. oviformis* resembles *O. oligospora* but deviates in a tendency to branched conidiophores and sometimes 2-septate conidia, judging from theses isolates and the protologue (Soprunov 1958). It must be noted here that Soprunov & Galiulina (1951) erroneously interchanged their figs II (*oviformis*, as *dolioformis*) and VI (*dolioformis*, as *oviformis*) on pl. 5 when invalidly describing *A. oviformis* under the name *Didymozoophaga oviformis*. A strain which belongs from its ITS data to *O. oligospora* was at first misidentified as *A. oviformis* (CBS 251.82, see CBS database), which illustrates the difficulty to distinguish these two species.

When analysing *RPB2*, *A. conoides* (YMF 1.00009) fully concurs with *A. conoides* (strain 670) and clustered with *O. oligospora* (YMF 1.03254) and *A. pseudoclavatus* (type strain 1130) in a medium supported clade (not shown), although the latter is a member of the *A. janus* clade.

Arthrobotrys doliiformis and *A. tortor* are currently treated as synonyms of *A. conoides*, based on their very similar morphology (Van Oorschot 1985, Scholler et al. 1999), but no sequences were available. Interestingly, Jarowaja (1970) observed in the ex-type strain of *A. tortor* three types of conidiophores (candelabrelloid, geniculate, and arthrobotryoid), although *A. conoides* is typically of the arthrobotryoid type.

An anamorph referable to *A. conoides* with narrowly obpyriform-clavate conidia of *30–36 × (11–)12–13.5(–15) µm, very similar to *A. javanicus* but with arthrobotryoid conidiogenesis, was observed on the natural substrate in a collection from Luxembourg (on inner surface of *Fagus* bark, IVV: H.B. 8428c). It grew in association with apothecia of *O. auricolor* (H.B. 8428a) and *O. oxyspora* (H.B. 8428b), but for these two populations very different anamorphs were noted: *A.* cf. *superbus* in pure culture for the former (Pl. 954: 4) and *D. oxyspora* from the natural substrate for the latter species (Pl. 933: 1f).

Specimens included. **LUXEMBOURG**: **Gutland**, 10 km WNW of Echternach, 1.2 km SW of Beaufort, Längt, 340 m, trunk of *Fagus sylvatica*, on bark, 3.II.2007, G. Marson (H.B. 8428c, anam. only).

Arthrobotrys ellipsosporus Tubaki & K. Yamanaka [as '*ellipsospora*'], Trans. Mycol. Soc. Japan 25(4): 350 (1984)

= *Arthrobotrys dendroides* Kuthub., Muid & J. Webster, Trans. Br. mycol. Soc. 84(3): 564 (1985)
?= *Arthrobotrys straminicola* Pidopl., Mikrobiol. Zh. 9(2-3): 55 (1948)
?= *Arthrobotrys stilbaceus* J.A. Mey. [as '*stilbacea*'], Bull. trimest. Soc. mycol. Fr. 74(3): 246 (1958)

?= *Arthrobotrys anomalus* G.L. Barron & J.G.N. Davidson [as '*anomala*'], Can. J. Bot. 50(8): 1773 (1972)

?= *Roigiella lignicola* R.F. Castañeda, Revta Jardín bot. Nac., Univ. Habana 5(1): 64 (1984)

Based on similarities of conidiophores and conidia, the inconsistent formation of synnemata, and available sequence data (ITS/LSU D1–D2) of the type strains, we conclude that *A. dendroides* with synnemata is a later synonym of *A. ellipsosporus* with solitary conidiophores (distance 1.2/0.2%). Also the synnemata forming *Roigiella lignicola* is possibly conspecific (distance 3.4/0.9% to *A. dendroides*, 3.2/0.7% to *A. ellipsosporus*). No sequences were available for the type strains of *A. anomalus* and *A. straminicola* (solitary), and *A. stilbaceus* (synnematous), therefore, their exact identity remained unclear. The oldest name, *A. straminicola*, was considered by Van Oorschot (1985) as a probable earlier synonym of *A. ellipsosporus*. Because of the high molecular variance within this complex, we adopt here for the time being the name *A. ellipsosporus* as the oldest name for which DNA data were available.

The ex-type strain of *A. ellipsosporus* from Japan (Ibaraki, Tsukuba, Sakura-mura, from sap of *Pinus densiflora*, IV.1979, NBRC 31826, TKB-F-5089, TKB-C-1053; Tubaki & Yamanaka 1984), for which ITS and LSU exist, fully concurs with a Chinese strain under the name *A. anomalus* in Yang et al. (2007, YNWS02-5-1, as *Arthrobotrys* sp. in GenBank), for which only ITS was available. The type of *A. anomalus* was isolated as a contaminant from soil in Canada (unlocalized, OAC 100761, dried culture; Barron & Davidson 1972). In fact, the protologues of the two species and a report of *A. ellipsosporus* by Matsushima (1995: nr. 0785) appear to represent a single species. In their survey on nematophagous taxa, Scholler et al. (1999) and Yu et al. (2014) treated *A. anomalus* but did not mention *A. ellipsosporus*.

A. anomalus, *A. ellipsosporus*, and *A. straminicola* were described with solitary conidiophores, but otherwise closely resemble three taxa with synnematous conidiomata in having ± cylindrical, basally acute, 1-septate, microconidia-like conidia formed on arthrobotryoid conidiophores: *A. stilbaceus* (Kongo, Yangambi, on rachis of palm leaves), *A. dendroides* (CBS 431.85, Malaysia, Kuala Lumpur, living leaves of fruit trees), and *R. lignicola* (CBS 222.85, Cuba, Havana, *Cecropia peltata* dead branch). Morphologically, all these taxa are similar, except for slight differences in conidial size, *R. lignicola* and *A. stilbaceus* having the smallest conidia and *A. anomalus* and *A. dendroides* the largest. In addition, the synnemata of *R. lignicola* are with 0.25–0.57 mm much shorter than those of *A. dendroides* (1.2–1.75 mm) and *A. stilbaceus* (2–3 mm) (Castañeda Ruíz 1984, Kuthubutheen et al. 1985, Meyer 1984). However, the synnemata figured by Kuthubutheen and Meyer appear to measure also only ca. 0.5 mm in height.

A collection on palm petioles from Peru was referred by Matsushima (1995: nr. 0787) to *A. stilbaceus* but would fit as well *A. dendroides* in conidial size and synnemata height (0.3–1 mm). A Chinese strain referred to *A. dendroides* (YMF 1.00010) fully matches in the ITS region the Chinese *A. anomalus* (YNWS02-5-1). This strain formed besides synnemata ('1 cm tall', probably an error for 1 mm) sometimes also solitary conidiophores (Yu et al. 2014: fig. 3.12). Also in the protologue of *A. dendroides* conidiophores were solitary or synnematous, though mainly synnematous on natural substrata (Kuthubutheen et al. 1985).

The type of *A. anomalus* combines both adhesive networks and adhesive columns ('hyphal branches'), but the columns were not considered as homologous to those of *Gamsylella* (Scholler et al. 1999: 94). Adhesive networks were also reported in *A. dendroides*, but not in the other two synnemata-forming taxa *A. stilbaceus* and *R. lignicola*, probably because no nematodes were added to the cultures.

The S1506 intron is absent in the type strains of *A. ellipsosporus* and *A. dendroides*, while in the other sequences this region is not covered. For strain YMF 1.00010 sequences of six different gene regions exist in GenBank. *A. ellipsosporus* (= *A. dendroides*) clustered medium or weakly supported with *A. polycephalus* in our analyses of SSU+ITS+LSU or ITS (Phyls 25, 28, S33), while in the LSU it clustered unresolved (S32). *R. lignicola* clustered likewise with medium support with the *ellipsosporus-polycephalus* clade (not shown), whereas in our analysis of LSU (S32) it clustered instead unsupported with *A. pyriformis* (EU586333) or (NJ, not shown) unsupported with *A. polycephalus* and *A. ellipsosporus*.

Arthrobotrys macroides (Drechsler) Mekht., Khishchnye Nematofagovye Griby – Gifomitsety: 89 (1979)

≡ *Arthrobotrys cladodes* var. *macroides* Drechsler, Mycologia 36(2): 144, fig. 1 (1944)

Arthrobotrys macroides was erected as a variety of *A. cladodes* by Drechsler (1944a: fig. 1), based on a strain isolated from roots of *Viola tricolor* and leaf mould in Beltsville, Maryland, USA, X.1936, C. Drechsler. The name *macroides* appears to refer to the more elongated conidia which are in both species cylindric-ellipsoid with a ± median septum.

No sequence of the type strain was available, but two strains under this name (SBUG 160: Germany, Stralsund, forest soil; NHL 2442: ?Japan, on decaying higher fungi) and two further strains (CBS 693.86: ?France, as *A. robustus*, later changed to *A. pyriformis*; 'YMF 1.01884/1.01888': China, as *Arthrobotrys* sp.) have identical sequences of ITS and LSU (see Phyl. 28, S33), except for a few inserts in both regions in CBS 693.86. We here tentatively consider these sequences to represent *A. macroides*. However, illustrations of any of them were not available to us. Moreover, the morphological distinction between *A. cladodes* and *A. macroides* is problematic (see under *O. auricolor*, p. 1531).

Arthrobotrys mangrovisporus Swe, Jeewon, Pointing & K.D. Hyde [as '*mangrovispora*'], Bot. Mar. 51(4): 332 (2008)

The ex-type strain (culture accession no. IFED2016) was isolated in 2005 from decaying submerged wood from Mai Po mangrove in Hong Kong (Swe et al. 2008b). The two available sequences (ITS, LSU) were uploaded in III.2008 under the title of the original publication and the strain number MGDW17 (decaying mangrove wood). Therefore, it can be assumed that they refer to a topotype, if not the holotype. *A. mangrovisporus* shows in the ITS a distance of 3% to the unofficial sequence of the ex-epitype strain of *A. eudermatus* from La Palma (CBS 305.94) and 3.7% to '*Dactylaria*' *sahelensis*, which formed with *A. mangrovisporus* a strongly supported clade (Phyls 25, S33), but a much higher distance to any other strain in GenBank or CBS.

Arthrobotrys pravicovii (Soprunov) Mekht. [as '*pravicovi*'], Dokl. Akad. Nauk Azerb. SSR 20(6): 71 (1964)

≡ *Didymozoophaga pravicovii* Soprunov & Galiulina [as '*pravicovia*'], Microbiol. 20: 496 (1951), nom. inval., ICN Art. 39.1 (Latin diagnosis missing)

≡ *Trichothecium pravicovii* Soprunov [as '*Pravicovi*'], Khishchnye Nematofagovye Griby - Gifomitsety: 117 (1958)
≡ *Arthrobotrys pravicovii* (Soprunov) Sidorova, Gorlenko & Nalepina [as '*pravicovi*'], Bot. Zh. SSSR 49: 1598 (1964), nom. inval., ICN Art. 41.1

A. pravicovii was isolated from soil near Mary (Merv), Turkmenistan (Soprunov 1958). Based on a 'possibly authentic' strain from (?)Turkmenistan in BAKU (VKM-F 2242) and CBS 606.84, the species (as '*A. pravicovia*') has been considered as a synonym of *A. conoides* by Van Oorschot (1985: 74) and Hoog & Van Oorschot (1985: 117). Regrettably, the authors did not describe or illustrate this strain by neglecting the quite different conidial shape and size in the protologues of the two species: ellipsoid in *A. pravicovii* similar as in *A. superbus*, much longer and conical in *A. conoides*.

The unofficial ITS sequence of this strain shows a 10.5 % distance to Drechsler's North American type strain of *A. conoides* (CBS 108.37, see above), but it clustered with a 0–0.2 % distance in a clade with two further strains that were misidentified as *A. conoides* (SBUG-M12 from Germany, in GenBank; CBS 253.82 from France, in CBS database). Also LSU (D1–D2) exists for CBS 606.84, in which *A. pravicovii* deviates from *A. scaphoides* by only 1–2 nt, although the conidia strongly differ in size and shape. In our analyses of ITS and SSU+ITS+LSU (Phyls 28, S33), *A. pravicovii* clustered in the medium supported *scaphoides-pravicovii* clade (see also Hagedorn & Scholler 1999: fig. 3, SBUG-M12).

A strain under the name *D. parvicollis* (CBS 426.91, Berlin-Dahlem, from dead *Poa nemoralis*, A.R. 8915, in Rubner 1996 erroneously as CBS 429.91) differs in the ITS region from SBUG-M12 by only 0.4 % and thus represents *A. pravicovii*. A strain under the name *A. pyriformis* (CBS 577.91, Québec, from soil) clustered near *A. pravicovii* when drawing an ITS tree in the CBS database, but with a 4 % distance.

Arthrobotrys pyriformis (Juniper) Schenk, W.B. Kendr. & Pramer, Can. J. Bot. 55(8): 984 (1977)

≡ *Dactylaria pyriformis* Juniper, Trans. Br. mycol. Soc. 37(4): 437 (1954)
≡ *Dactylariopsis pyriformis* (Juniper) Mekht., Khishchnye Nematofagovye Griby - Gifomitsety (Baku): 119 (1979)

A. pyriformis was described by Juniper (1954) from England (Lincolnshire, Nocton Fen, dung, V.1953, K and CMI), with elongated-obovoidal, (1–)2–3-septate conidia of 26–41 × 9–14 µm. Van Oorschot (1985) studied the 'type culture' (CBS 221.54, IMI 56803, UK, Essex, Langdon Hills, cow dung, undated, A.J. Juniper) and two further strains accepted by her as belonging to this species (CBS 602.80 = IMI 101310, ?UK, C.L. Duddington; CBS 221.82, Netherlands, W. Gams).

In her discussion of *A. pyriformis* Van Oorschot did not mention the strong mismatch in the geographical data of the ex-type collection (CBS 221.54), nor did she explain why she used another number (CBS 204.83) when stating that the ex-type strain has changed in comparison to the protologue, e. g., by having now smaller (15–25 × 5–8 µm), 1-septate conidia. In fact, CBS 221.54 and CBS 204.83 are listed in the CABRI HyperCatalogue (http://frc.cabri.org/HyperCat/fun/cabi403238.htm) as representing the same strain, to which also IMI 56803 and MUCL 9431 belong.

Also Rubner (1996: tab. 1) examined CBS 221.54 regarding the formation of trapping organs and conidia, but without providing morphological data. However, the numbers 221.54 and 204.83 cannot now be found in the CBS database. According to G. Verkley (pers. comm.), the number 204.83 was removed and only that of the first deposit was kept. But also CBS 221.54 was withdrawn following communication by A. Rubner in 1992, as it did not match the original description 'by the production of adhesive hyphal branches instead of a network and by the length and the number of septa of the conidia'. The original entry of CBS 221.54 was 'England, Lincolnshire, Nocton Fen, dung of cow, A.J. Juniper, No. 37, May 1953; other strain numbers: CBS 204.83; IMI 056803; MUCL 9431' (G. Verkley pers. comm.).

An LSU sequence of CBS 221.54 was recently uploaded in GenBank (MH868833) as 'authentic' and is annotated with these latter data. This sequence fully concurs with CBS 221.82 and obviously belongs to *A. musiformis* (Phyl. S32), a species with consistently 1-septate conidia. Unofficial ITS of CBS 221.54 does not exist in the CBS database, but exists for CBS 221.82. This shows a rather high similarity with clade B strains of *A. pyriformis* (Tab. 87), but not with *A. musiformis*, suggesting some confusion.

Table 87. Strains in the CBS database and GenBank to which the name *A. pyriformis* has been applied, but which belong according to their DNA data to at least eight species in five different clades. The two available SSU sequences include the V1–V4 region (in 340.94 V1–V9), and those of nuclear LSU the D1–D2 or sometimes D3 domain. CBS 107.51^{T}: ex-type strain of *A. robustus*, later synonymised with *A. pyriformis* but here with *O. oligospora*; CBS 221.54^{T}: authentic strain of *A. pyriformis* but apparently confused; CBS 221.82§: ?chimere (LSU apparently not conspecific with ITS); YMF 1.01884*: LSU erroneously as YMF 1.01888 (EU586333) but uncertain whether it belongs to 1.01884.

CBS 221.82§	Netherlands	ITS		*A. pyriformis* (B)		CBS

Since the available LSU sequence of CBS 221.54 belongs to *A. musiformis*, and this authentic strain differs morphologically from the protologue, the correct identity of *A. pyriformis* cannot now be clarified with certainty, because the name *A. pyriformis* was very differently used. Based on a similar conidial morphology, we consider two subclades of an unsupported clade as presumed candidates for the true *A. pyriformis* (Tab. 87, Phyl. 28). The reason why the name *A. pyriformis* was applied in very different ways is possibly due to divergences in conidial shape and septation between the protologue and strain CBS 204.83 as observed by Van Oorschot (1985).

Six strains under the name *A. pyriformis* exist at present in GenBank, and two further ones (YNWS02-3-1, YMF 1.01884, erroneously as 1.01888) were uploaded as *Arthrobotrys* sp. but fit strains under that name (the former has been renamed to *A. pyriformis* by Yang et al. 2007). At least eight strains exist in CBS under the name *A. pyriformis*, all with unofficial sequences, and only three of them exist in GenBank (see Tab. 87). 12 of these 14 strains include ITS and 9 LSU. They derive from different regions in Europe, North and South America, and eastern Asia. According to their molecular data these 14 strains fall in five different main clades (Tab. 87) and belong to eight different species.

Two strains are members of the ***scaphoides-pravicovii* clade**: CBS 577.91 (Québec) clustered in vicinity of *A. pravicovii*, and CBS 693.86 (?France) belongs to *A. macroides* (SBUG 160). Three strains clustered in the ***O. auricolor* clade**: CBS 340.94 (Berlin) closely concurs with members of genotype A1, CBS 602.80 (?UK, as *A. robustus*, reidentified by Van Oorschot 1985 as *A. pyriformis*) is distantly related to members of genotype A2, and the LSU of CBS 578.91 (Berlin) concurs with *A. superbus* (CBS 115.61), a member of genotype A2 (Phyl. 28). Two strains are members of the ***oligospora-musiformis* clade**: CBS 339.94 (Ecuador) clustered close to *A. conoides* with which it seems to be conspecific; CBS 107.51 (UK), the ex-type strain of *A. robustus* was reidentified as *A. pyriformis* in CBS, but belongs to *O. oligospora* (for details see also p. 1542). Three Chinese strains form the ***A. pyriformis* subclade A** and vary by only 0–0.2% in the ITS. Two further Chinese strains vary by 3% in the ITS and form the strongly supported ***A. pyriformis* subclade B** (Phyl. 28).

The two subclades of *A. pyriformis* (A and B) clustered in our analysis of ITS in an unsupported clade (Phyl. 28), with a distance of 8–8.5% (the Hubei strain is incomplete in the ITS1). In this clade clustered also a European strain under the name *A. psychrophilus*/*O. auricolor* (Staffordshire, UK, CBS 547.63), which fully concurs in the ITS with an unpublished Chinese strain under the name *A. microscaphoides* (YMF 1.01453, Y. Zhang pers. comm.). These two unclarified strains with apparently top-shaped conidia shows an ITS distance of 2.7–2.8% to subclade A and 7–7.2% to subclade B. An unofficial sequence of the *A. pyriformis* strain from the Netherlands (CBS 221.82) clustered in the CBS database with YNWS02-3-1 (subclade B) with a 3.3% ITS distance, but not with IFRD_M1.123, to which it surprisingly differs by ~9%, perhaps because of various gaps.

In the LSU D1–D2, CBS 221.82 fully concurs with CBS 221.54 = CBS 204.83 (MH868833), and in our analysis (Phyl. S32) this genotype clustered with the low distance of 0.2–0.4% with 14 strains of *A. musiformis* s.l. However, in the ITS no close relationship between CBS 221.82 and *A. musiformis* can be seen in the CBS database, while no ITS appears to exist for CBS 221.54 or 204.83. It seems, therefore, impossible at present to clarify the identity of the authentic strain.

There is some confusion with the YMF numbers and sequences. Four sequences with two strain numbers were uploaded under the name *Arthrobotrys* sp.: YMF 1.01884 (EU586330 ITS, EU586331 LSU) and YMF 1.01888 (EU586332 ITS, EU586333, LSU). According to Y. Zhang (pers. comm.) the two ITS sequence were confused. In fact, EU586331 and EU586332 are conspecific with *A. macroides* (SBUG 160, NBRC 9382, CBS 693.86), whereas EU586330 concurs with *A. pyriformis* (YMF 1.00018, KT932056) and EU586333 clustered unsupported with *Roigiella lignicola* (Phyl. 28, S32). Since there was no other strain of *A. pyriformis* with both ITS and LSU, we could not clarify whether EU586330 and EU586333 belong to the same species. The unpublished plate of YMF 1.01884 (IVV) shows elongated cylindric-pyriform, mainly 2–3-septate conidia typical of *A. pyriformis*, therefore, we conclude that this confusion rather concerns LSU than ITS. However, the unpublished plate of YMF 1.01888 (IVV) shows elongated ellipsoid-fusoid, 3-septate conidia and represents *A. polycephalus*, which is confirmed by another ITS sequence with the number YMF 1.01888 in GenBank (MH179760). Therefore, the ITS and LSU sequences of *A. macroides* cannot be linked to either YMF 1.01884 or YMF 1.01888.

Further microphotographs which fit *A. pyriformis* were available for YMF 1.00018 (Yu et al. 2014) and IFRD_M1.123 (Swe et al. 2008a). Swe et al. stated that their strain differs from the type in longer and slightly wider conidia (*38–52 × 10–16 µm) compared to 26–41 × 9–14 µm in the protologue and 15–25 × 5–8 µm in the 1-septate conidia observed by Van Oorschot (1985) in the ex-type strain. In contrast to this, strain YMF 1.01884 (*27–37.5 × 10–13.5 µm) is pretty close to the protologue and also YMF 1.00018 concurs rather well (*24–38 × 8–11 µm).

CBS 693.86 was later renamed to *A. pyriformis*, but its original name was *A. robustus* (= *A. oligosporus*), which would explain confusion with *A. macroides*. Actually, Van Oorschot (1985) considered the protologue of *A. robustus* in Duddington (1952) as strongly reminiscent of *A. cladodes* var. *macroides*. On the other hand, she believed that CBS 602.80, a strain which Duddington referred to *A. robustus*, belonged to *A. pyriformis*, while DNA data suggest this to belong to *O. auricolor* genotype A2. Hagedorn & Scholler (1999: tab. 1) synonymised *A. robustus* with *A. pyriformis* regarding strain CBS 340.94 (= *O. auricolor* genotype A1 in present study), while Scholler et al. (1999) listed both *Arthrobotrys* species as distinct.

Conidiophores candelabrelloid or of *Duddingtonia* type

Arthrobotrys musiformis Drechsler, Mycologia 29(4): 481 (1937)

≡ *Candelabrella musiformis* (Drechsler) Rifai & R.C. Cooke, Trans. Br. mycol. Soc. 49(1): 163 (1966)

≡ *Dactylella musiformis* (Drechsler) Matsush., Microfungi of the Solomon Islands and Papua-New Guinea (Osaka): 22 (1971)

Numerous sequences exist under the name *A. musiformis* in GenBank and the CBS database. Judging from the ITS region they appear to belong to three distinct and rather homogeneous, closely related taxa (Phyl. 28): the largest clade (A) includes the type (CBS 110.37), while no names are available for the other two clades (B & C), both of which we here call *A.* aff.

musiformis. When comparing complete ITS sequences (in YMF 1.00575 almost 100 nt are missing), the distance between *A. musiformis* (10 strains) and *A.* aff. *musiformis* (B & C, 8 strains) lies in the range of 4.8–6.5 %, and between B and C at 3.6–4.2 %. In relation to this, the variation within each clade was in *A. musiformis* 0–1.5 % and in *A.* aff. *musiformis* 0–1.3 %. *A. musiformis* s.l. differs from *O. blumenaviensis* by 7–9 % and from *O. javanica* by 7.5–9 %. A fourth very distant group under the name *A. musiformis* is represented by two sequences (EVLL02, MF926582; EVLL-2, MF926583, not shown in phylotrees) which clustered in the ITS+LSU analysis of Quijada et al. (2020) supported with *O. jesu-laurae*.

In the LSU D1–D2 domain the available sequences (8 strains in clade A, 3 strains in clade C, none in clade B) are fully identical, except for a few singular deviations in some of them (0–0.2 % distance). In this region *A. musiformis* s.l. differs from *O. blumenaviensis* by 0.2–0.6 % and from *O. javanica* by 0.7–1.5 %, but also, e. g., *O. elegans* differs from *A. musiformis* s.l. by only 0.2–0.9 %. In the D3 domain, however, a single position (728) distinguishes seven strains of clade A (AGTC**T**TCGG) from three strains of clade C (AGTC**C**TCGG). The identity of the two groups could be ascertained for five strains, because they include both ITS and LSU D1–D3: 3 of *A. musiformis* (CBS 117.81, 465.88, 743.95) and two of *A.* aff. *musiformis* (CBS 437.83, ATCC 96675). Two uncultured clones of *A. musiformis* s.l. from Australia could not be identified because they lack both ITS and D3 domain. Based upon pos. 728, a strain under the name *A. vermicola* in GenBank (AY261143, YNUCC 2428) belongs to *A.* aff. *musiformis*.

Because several ITS sequences from CBS were not or only incompletely available, they could not be included in the analysis. Also not included are nine unpublished Chinese isolates received from Y. Zhang (pers. comm.). Eight fall in clade A, one in clade C (YMF 1.00122), and three formed a further clade situated close to clade A (YMF 1.01891, 1.01892, 1.01893). Two sequences in GenBank which fall in clade C appear to be confused (YMF 1.00022, 1.00024, see under *A. shizishananus* and *A. cookedickinsonianus*).

Z.F. Yu (pers. comm.) obtained morphologically typical *A. musiformis* anamorphs in ascospore isolates from apothecia of various Chinese collections. A photo plate of one of their teleomorphs shows features reminiscent of *O. auricolor*, except that the ascospores (*7.7–10 × 1.1–1.2 µm in situ) are less curved (see IVV). Sequences gained from these ascospore isolates and also from Chinese conidial isolates clustered in the two here observed clades of *A. musiformis* s.l. (Z.F. Yu pers. comm.). Also D.H. Pfister obtained an *A. musiformis* anamorph in an ascospore isolate from Puerto Rico (Quijada et al. 2020, PR 98-20).

Arthrobotrys shizishananus (X.F. Liu & K.Q. Zhang) J. Chen, L.L. Xu, B. Liu & Xing Z. Liu [as '*shizishanna*'], Fungal Diversity 26(1): 124 (2007)

≡ *Dactylella shizishanana* X.F. Liu & K.Q. Zhang [as '*shizishanna*'], Fungal Diversity 14: 104 (2003)

Dactylella shizishanana was described by Liu & Zhang (2003) from a soil sample taken on 8.XI.2001 in Shizishan, Wuhan, Hubei, China (YMF W7244021). Sequences of ITS, mtLSU, *TEF1*, *RPB2*, *MAD1*, *TUBB*, and cuticle-degrading serine protease gene exist in GenBank for an authentic strain (YMF 1.00022) under this name which is possibly taken from the original culture, judging from Yu et al.'s (2014) statement 'isolated from field soil in Shizishan, Hubei in February 2001 by Xuefeng Liu'.

A. shizishananus was originally placed in *Dactylella* because of its cylindric-clavate phragmoconidia formed singly at the conidiophore tip, but its adhesive networks refer it to series *Arthrobotrys* and also its molecular data place it there. However, this authentic strain must be confused, because it shows a strong similarity in many of the mentioned gene regions to the morphologically very different *A. musiformis* s.l., which has 1-septate, ellipsoid-clavate conidia, whereas *A. shizishananus* has 2–9-septate, cylindric-fusoid conidia (see Yu et al. 2014).

In the ITS region *A. shizishananus* belongs to clade C of *A. musiformis* s.l., showing an ITS distance of 0–1.3 % to YMF 1.00024 (*A. cookedickinsonianus*) and two strains under the name *A. musiformis* (YMF 1.00575, SQ77-1). Perhaps the *A. shizishananus* strain YMF 1.00022 is confused with SQ77-1. Clade C clustered with genuine *A. musiformis* with an ITS distance of 5–6.5 % in a supported clade which contains some other sequences uploaded under this name (Phyl. 28, see also under *A. musiformis*, p. 1578).

A. shizishananus matches *A. musiformis* s.l. also regarding the *MAD1* gene uploaded by Li et al. (2016) without specification of the culture number. In the *TEF1* gene the two species clustered in a clade though with a moderate distance, whereas *RPB2* places it in clade C of *A. musiformis*.

Arthrobotrys flagrans (Dudd.) Mekht., Dokl. Akad. Nauk Azerb. SSR 20(6): 70 (1964)

≡ *Trichothecium flagrans* Dudd., Trans. Br. mycol. Soc. 32(3-4): 287 (1950)
≡ *Arthrobotrys flagrans* (Dudd.) Sidorova, Gorlenko & Nalepina, Bot. Zh. SSSR: 1598 (1964), nom. inval., ICN Art. 41.1
≡ *Duddingtonia flagrans* (Dudd.) R.C. Cooke, Trans. Br. mycol. Soc. 53(2): 316 (1969)

Arthrobotrys flagrans forms a rather homogeneous and distant clade in analyses of ITS (Phyl. 28). In our combined analysis (Phyl. S33) it formed with *A. amerosporus* a strongly supported subclade as a part of the medium supported *oligospora-musiformis* clade. Numerous sequences of different protein-coding regions and also D6, D7, and D9 of LSU exist in GenBank under the name *Duddingtonia flagrans*. An authentic strain (CBS 565.50, ITS, *TUBB*) confirms the identity of the clade. A *TUBB* sequence of *Arthrobotrys pseudoclavatus* (1130, AY773359) appears to be confused since it fully matches several strains of *A. flagrans*, whereas the ITS of it belongs to the *A. janus* clade.

Conidiophores acrogenous

Arthrobotrys cookedickinsonianus Z.F. Yu [as '*cookedickinson*'], in Yu et al., Fungal Diversity Res. Ser. 23: 61 (2014), non *A. cystosporius* (Dudd.) Sidorova et al.

≡ *Monacrosporium cystosporum* R.C. Cooke & C.H. Dickinson, Trans. Br. mycol. Soc. 48(4): 623 (1965)
≡ *Golovinia cystospora* (R.C. Cooke & C.H. Dickinson) Mekht., Khishchnye Nematofagovye Griby - Gifomitsety (Baku): 146 (1979)

Monacrosporium cystosporum was isolated from soil in Bogor, Java (Indonesia, Cooke & Dickinson 1965) and has obovoid to turbinate, 2–3-septate, acrogenously formed conidia with one very strongly inflated cell. Rubner (1996) synonymised it with *Arthrobotrys thaumasius*, but Yu et al. (2014) considered it to be different and renamed it to *A. cookedickinsonianus* in order to avoid confusion with *A. cystosporius* with broadly obovoid, 1-septate conidia. The authors compared *A. cookedickinsonianus* with *A. eudermatus* and *A. sphaeroides* and referred strains from different provinces of China to it.

Sequences exist for two of these strains: YMF 1.00024 (ITS, as *A. cookedickinsonianus*) and YNUCC 2128 (LSU D1–D3, as *M. cystosporum*). An illustration was available for YMF 1.00024 (Yu et al. 2014: fig. 3.11) which matches well the protologue of *M. cystosporum*. This strain fully concurs with *A. thaumasius* CBS 322.94 in the ITS, supporting Rubner's synonymisation, but only when using the unpublished sequence from the chromatogram of YMF 1.00024 (Y. Zhang pers. comm.), not the uploaded sequence (MF948393) which belongs to *A.* aff. *musiformis* (clade C).

M. cystosporum (YNUCC 2128) fully concurs with *A. salinus* (YNUCC 2328) and *A. eudermatus* (YNUCC 2228) in the LSU. They formed with the close *A.* cf. *thaumasius* (CBS 591.91) a strongly supported clade which nested near the *A. thaumasius* clade (Phyl. S32). Since no ITS was available for any of these four strains, their identity remains unsettled; perhaps they represent *A. janus* for which no LSU was available. Also the identity of the unsequenced type of *A. cookedickinsonianus* (≡ *M. cystosporum*) is uncertain. Rubner (1996) synonymised *M. cystosporum* with *A. thaumasius*, apparently based on the protologue, but she did not discuss her opinion. Placement of *A. cookedickinsonianus* near *A. thaumasius* is supported by the fact that other gene regions of YMF 1.00024 (RPB2, TEF1, TUB) cluster in the clade of *A. thaumasius*.

Arthrobotrys salinus (R.C. Cooke & C.H. Dickinson) M. Scholler, Hagedorn & A. Rubner [as '*salina*'], Sydowia 51(1): 104 (1999)

≡ *Monacrosporium salinum* R.C. Cooke & C.H. Dickinson, Trans. Br. mycol. Soc. 48(4): 626 (1965)
≡ *Golovinia salina* (R.C. Cooke & C.H. Dickinson) Mekht., Khishchnye Nematofagovye Griby - Gifomitsety (Baku): 145 (1979)

Under the name *M. salinum* a sequence of LSU (D1–D3) of a strain from Yunnan, China (YNUCC 2328) exists in GenBank. It fully concurs with two other strains from Yunnan under the names *M. cystosporum* and *A. eudermatus* (see under *A. cookedickinsonianus*, p. 1579).

Arthrobotrys cystosporius (Dudd.) Mekht. [as '*cystosporium*'], Dokl. Akad. Nauk Azerb. SSR 20(6): 70 (1964)

≡ *Trichothecium cystosporium* Dudd., Trans. Br. mycol. Soc. 34(4): 600 (1952) [1951]
≡ *Arthrobotrys cystosporius* (Dudd.) Sidorova, Gorlenko & Nalepina [as '*cystosporia*'], Bot. Zh. SSSR 49: 1598 (1964), nom. inval., ICN Art. 41.5
≡ *Genicularia cystosporia* (Dudd.) Rifai & R.C. Cooke, Trans. Br. mycol. Soc. 49(1): 154 (1966)
≡ *Geniculifera cystosporia* (Dudd.) Rifai, Mycotaxon 2(2): 215 (1975)
?= *Arthrobotrys paucisporus* (R.C. Cooke) Jarow. [as '*paucispora*'], Acta Mycologica, Warszawa 6(2): 381 (1970)
≡ *Genicularia paucispora* R.C. Cooke, in Rifai & Cooke, Trans. Br. mycol. Soc. 49(1): 157 (1966)
≡ *Geniculifera paucispora* (R.C. Cooke) Rifai, Mycotaxon 2(2): 215 (1975)

The types of *A. cystosporius* (UK, Surrey, Mickleham, rotten wood) and *A. paucisporus* (UK, Derbyshire, Cressbrook Dale, *Briza* roots) are morphologically similar in their obovoid to obpyriform conidia with eccentrical septum. *A. paucisporus* differs in narrower conidia, and different authors, including Van Oorschot (1985), segregated the two taxa even in different genera (*Arthrobotrys* and *Geniculifera*) based on a deviating conidiogenesis: proliferation at the conidiophore apex (candelabrelloid) in *A. cystosporius*, subapical proliferation (geniculate) in *A. paucisporus*.

Two Californian strains under the names *A. paucisporus* (ATCC 96704) or *Geniculifera paucispora* (CBS 495.92) fully concur in the LSU D1–D3. The ATCC strain comprises also S1506 intron and ITS and shows a high similarity with two strains under the name *A. cystosporius* (CBS 439.54, UK; CBS 591.92, Netherlands), with distances in the intron/ITS/LSU D1–D2 of 1.8/0.4/0.3 % (UK) and ~3/~0.4/0.3 % (NL). This result suggests that the four strains are conspecific.

CBS 439.54 is the ex-type strain of *A. cystosporius* fide Van Oorschot (1985: 92), with ATCC 13418 and IMI 101313 (Van Oorschot l.c.), CCRC 32918 (Hagedorn et al. 1999), and CBS 130.83 (CBS database) representing the same strain. In the CBS database originally only Duddington's number C.L.D. 143 and ATCC 13418 was mentioned under CBS 439.54, and only IMI 101313 under CBS 130.83. According to the Latin diagnosis in Duddington (1952) the type locality is Mickleham, with the collection date X.1948 (no herbarium number indicated), but Duddington mentions in the discussion two further collections. Whether illustrations of the other three strains exist is unknown to us. *O. blumenaviensis* (H.B. 9748a) and *A. gampsosporus* (CBS 127.83) are very close to *A. cystosporius* in the LSU (Phyl. S32) but cluster very distantly in the ITS (Phyl. 28).

Arthrobotrys eudermatus (Drechsler) M. Scholler, Hagedorn & A. Rubner [as '*eudermata*'], Sydowia 51(1): 102 (1999)

≡ *Dactylaria eudermata* Drechsler, Mycologia 42(1): 40 (1950)
≡ *Monacrosporium eudermatum* (Drechsler) Subram., J. Indian bot. Soc. 42: 293 (1964) [1963]
≡ *Genicularia eudermata* (Drechsler) Rifai, Reinwardtia 7(4): 367 (1968)
≡ *Golovinia eudermata* (Drechsler) Mekht., Dokl. Akad. Nauk Azerb. SSR 27(2): 73 (1971)
≡ *Geniculifera eudermata* (Drechsler) Rifai, Mycotaxon 2(2): 216 (1975)
≡ *Dactylella eudermata* (Drechsler) Seifert & W.B. Kendr., in Seifert, Kendrick & Murase, Univ. Waterloo Biol. Ser. 27: 30 (1983)

Arthrobotrys eudermatus is a frequently confused species. Based on rDNA data, strains identified so turned out to belong to very different clades (*A. janus*, *O. elegans*, *mangrovisporus-sahelensis* clade, *A. thaumasius*). No type culture appears to exist. Rubner (1996) designated a strain from La Palma, Macaronesia (CBS 305.94) as epitype of this North American species. The strain represents a further distinct taxon based on its unofficial ITS sequence in CBS which shows a 6.5–10 % distance to the above taxa and also min. 7 % to *O. elegans* s.l., but only 3 % to the type strains of *A. mangrovisporus* and '*Dactylaria*' *sahelensis*.

Also Rubner's concept of *A. eudermatus* was too wide, which is obvious from the three existing ITS sequences of isolates referred by her to this species, which show a high distance among each other. Only one of them is in GenBank (CBS 769.85, unlocalized, as *A. rutgeriensis*) and falls in the *A. janus* clade (Phyl. 28). The other two sequences appear to have no further matches: CBS 305.94 (epitype) is close to *A. mangrovisporus* (3 %), and CBS 584.91 (Germany, Berlin) is distant from all tested sequences (minimum 6 % to *O. blumenaviensis* H.B. 9748a). Whether Rubner's epitype choice was justified remains to be clarified by rDNA data from North America. In the LSU no comparison of CBS 305.94, recently available in GenBank

(MH874116), to *A. janus* is possible because the whole clade lacks this gene region.

Two isolates from Burkina Faso (CBS 377.97, as *A. eudermatus*; CBS 247.93, type of '*Dactylaria*' *sahelensis*) are identical in the ITS and differ by 1 nt in the LSU. In our combined analyses, they clustered with a 3.7 % ITS and 3 % LSU distance with the type of *A. mangrovisporus* in the strongly supported *mangrovisporus-sahelensis* clade (Phyls 25, S33), which nested unresolved in series *Arthrobotrys* and show, e. g., a 6–7.5 % ITS distance to the *A. janus* clade. The epitype of *A. eudermatus* shows a 3 % ITS distance to *A. mangrovisporus* (0.7 % in LSU), but 9.8 % to '*Dactylaria*' *sahelensis* (3 % in LSU).

Arthrobotrys huaxiensis Z.F. Yu, in Zhang & Hyde (eds), Nematode-trapping Fungi: 72 (2014)

≡ *Arthrobotrys guizhouensis* (K.Q. Zhang, Xing Z. Liu & L. Cao) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 102 (1999), nom. illegit., ICN Art. 53.1, non *Arthrobotrys guizhouensis* K.Q. Zhang (1994) (?= *O. blumenaviensis*)

≡ *Monacrosporium guizhouense* K.Q. Zhang, Xing Z. Liu & L. Cao, Mycol. Res. 100(3): 275 (1996)

Arthrobotrys huaxiensis was described as *M. guizhouense* by Zhang et al. (1966). It sharply differs from the earlier described *A. guizhouensis* (Zhang 1994, = *O. blumenaviensis*), in acrogenous conidiophores and much larger, 1–4-septate conidia that vary between obpyriform and fusiform (see also Yu et al. 2014: fig. 3.18, redrawn and modified, legend with the wrong name *A. guizhouensis* [K.Q. Zhang]). No sequence was available, since the type culture of *A. huaxiensis* (CBS 616.95, under the illegitimate name *A. guizhouensis* as combined by Scholler et al. 1999, KT215198) seems to be confused: when querying the CBS database, CBS 616.95 fully concurs in the ITS region with the ex-type strain of *Dactylellina yunnanensis* (CBS 615.95), a species closely related to *D. haptotyla* (see p. 1607). A possible confusion in the trapping organs of *A. huaxiensis* seems to be excluded by the much narrower conidia of *D. haptotyla* s.l., although conidial shape and septation is similar in these two species.

Arthrobotrys janus (S.D. Li & Xing Z. Liu) Z.F. Yu, in Yu et al., Fungal Diversity Res. Ser. 23: 75 (2014) (erroneously MB number of *A. cookedickinsonianus* cited)

≡ *Monacrosporium janus* S.D. Li & X.Z. Liu, in Li, Miao, Zhang & Liu, Mycol. Res. 107(7): 890 (2003)

= *Arthrobotrys rutgeriensis* (R.C. Cooke & Pramer) Z.F. Yu [as '*rutgeriense*'], in Zhang & Hyde (eds), Nematode-trapping Fungi: 108 (2014)

≡ *Monacrosporium rutgeriense* R.C. Cooke & Pramer [as '*rutgeriensis*'], Phytopathology 58: 544 (1968), nom. inval., ICN Art. 40 (type material not indicated)

= *Arthrobotrys pseudoclavatus* (Z.Q. Miao & Xing Z. Liu) J. Chen, L.L. Xu, B. Liu & Xing Z. Liu [as '*pseudoclavata*'], Fungal Diversity 26(1): 123 (2007)

≡ *Dactylella pseudoclavata* Z.Q. Miao & X.Z. Liu, in Miao, Liu, Li & He, Can. J. Bot. 81(5): 453 (2003)

Three strains under the name *Arthrobotrys eudermatus* (from Mexico and China) form in our ITS analysis with six Chinese strains under the names *A. janus* (3 strains including ex-type), *A. pseudoclavatus* (type), *A. sphaeroides*, and *A. thaumasius*, and one from North America (*A. rutgeriensis*, ?topotype), a strongly supported clade (Phyl. 28). The comparatively low distance (0–2.3 %) among the strains of this clade suggests that all belong to a single species. This clade is referred to as *A. janus* here, because the unofficial sequence of the epitype of *A. eudermatus* (CBS 305.94) differs by 7–8 % from members of this clade. LSU was not available for members of *A. janus*, but perhaps the clade of the four LSU sequences without ITS (including *A. cookedickinsonianus* YNUCC 2128) represents *A. janus*.

The type of *A*. ***rutgeriensis*** was isolated from soil at the Rutgers University in New Brunswick, New Jersey, USA (undated, Cooke & Pramer 1968). The taxon is invalid because no type specimen was cited (Rubner 1996). An isolate by W.D. Rosenzweig of unknown date and origin (CBS 769.85) possibly represents a topotype, since Rosenzweig worked at this university during the 1980s. *A. rutgeriensis* was synonymised with *M. eudermatum* by Rubner (1996), but was considered as distinct from both, *A. eudermatus* and *A. janus*, by Yu et al. (2014). The sequence in GenBank comprises SSU and ITS. Rubner's concept of *A. eudermatus* includes this strain, but it differs by 8 % from the La Palma epitype and by 13 % from *A. eudermatus* CBS 584.91. Actually, it clustered in the *A. janus* clade with a distance of 1.3 % to the types of *A. janus* and *A. pseudoclavatus*.

The type of *A*. ***janus*** was isolated in IX.2000 from soybean field soil in Gaomi, Shandong, China (85-1, HMAS 77942, ex-type culture CGMCC (AS) 3.6626). It comprises ITS, *TUBB*, *RPB2*, and *TEF1*, and shows a 1.3 % ITS distance to *A. rutgeriensis* and 7 % to the epitype of *A. eudermatus*. Two further strains under the name *A. janus* (YMF 1.01312, from Mixian, Shandong, Yu et al. 2014; unlocalized, YMF 1.01889, Li et al. 2016) differ in the ITS by 0 % and 1.4 %, respectively.

The type strain of *A*. ***pseudoclavatus*** was isolated in II.1998 from field soil in Haiding, Beijing, China (HMAS 84442). Sequences (ITS, *TEF1*, *RPB2*, *TUBB* etc.) exist in GenBank for 'strain 1130', which represents the ex-type strain (X.Z. Liu, pers. comm.). In the ITS this strain is fully identical with a strain of *A. sphaeroides* (SDT24) and the type of *A. janus*, except for one doubtful insert in the motif AAAAAAA in ITS1. When analysing *RPB2* or *TEF1* (not shown), however, it clustered distantly with *A. conoides* and *O. oligospora* in a supported clade, whereas the identical sequences of *A. sphaeroides* and *A. janus* clustered in another clade. The *TUBB* sequence of *A. pseudoclavatus* fully matches *A. flagrans* (strain R4). All these results suggest some confusion of sequences.

A. pseudoclavatus was solely described from its microconidial state, which was also reported in *A. eudermatus* by Drechsler (1950a), but not in *A. rutgeriensis*, *A. janus*, and *A. sphaeroides*. Because of its small conidia *A. pseudoclavatus* was thought to represent a distinct species.

No type culture of *A*. ***sphaeroides*** is available (Rubner, 1996). A Chinese strain under this name in GenBank (SDT24) comprises ITS (AY773465), *RPB2*, and *TEF1* and might be misidentified (X.Z. Liu, pers. comm.). Another *A. sphaeroides* strain (YNUCC 0077, unlocalized) has only LSU (AY268930) and *TUBB*. Strain SDT24 is identical in the ITS and *RPB2* with the type of *A. janus*, hence must be conspecific. YNUCC 0077 (LSU) appears to be conspecific with four YNUCC strains under the names *M. globosporum*, *M. rutgeriense*, *A. superbus*, and *A. sinensis*: in the D1–D2 domain, three of them are identical, from which *A. sphaeroides* differs by 2 nt (1 in D1, 1 in D2) and 6 inserts, and *A. sinensis* by 3 nt in the D2 (no inserts). Between *A. sinensis* and *A. sphaeroides* 5 nt differ (1 in D1, 4 in D2). Also two CBS strains which belong from their ITS to *A. thaumasius* fall in this clade. Possibly the associated clade with *A. cookedickinsonianus* (Phyl. S32) represents *A. janus*, but no sequence with both ITS and LSU was available for that species.

Arthrobotrys gampsosporus (Drechsler) S. Schenck, W.B. Kendr. & Pramer [as '*gampsospora*'], Can. J. Bot. 55(8): 982 (1977)

≡ *Dactylaria gampsospora* Drechsler, Sydowia 15(1-6): 9 (1962) [1961]
≡ *Woroninula gampsospora* (Drechsler) Mekht., Khishchnye Nematofagovye Griby - Gifomitsety (Baku): 112 (1979)
≡ *Dactylella gampsospora* (Drechsler) de Hoog & Oorschot, Stud. Mycol. 26: 110 (1985)
≡ *Monacrosporium gampsosporum* (Drechsler) Xing Z. Liu & K.Q. Zhang, Mycol. Res. 98(8): 865 (1994)

A strain isolated by G. Barron from soil in Florida (from where also the holotype derives) and identified as *Arthrobotrys gampsosporus* (CBS 127.83) comprises S1506 intron, ITS, and LSU D1–D3. In our analyses of ITS or SSU+ITS+LSU (Phyls 28, S33), this strain clustered in the strongly supported *elegans-gampsosporus* clade, with an ITS distance of 4.5–5.5% to *O. elegans* s.l. We did not see a photo of Barron's isolate, but Drechsler's (1962) original illustration and the drawing of the type by Rubner (1996: fig. 30) shows conidia reminiscent of *A. scaphoides*, very different from *O. elegans*. A strain under the name *Arthrobotrys* sp. from southern Africa (SBUG-M 1264) comprises SSU and ITS. It clustered with Barron's isolate with a 1.2% ITS distance and thus seems to be conspecific with it, but it differs in lacking the S1506 intron.

In the LSU the differences to other species are too sparse to enable identification. Barron's strain clustered here in an unsupported clade with some of the strains of *A. cystoporius*, *O. blumenaviensis*, and *O. menageshae* s.l. (Phyl. S32) When analysing the S1506 intron, *O. elegans* clustered with *O. auricolor* (as *A. superbus*, CBS 109.52, clade A2 of *O. auricolor*, see p. 1534), whereas *A. gampsosporus* is found in a strongly supported clade with *O. menageshae* s.l. and *A. cystosporius* (S30). This is similarly astonishing because *A. cystosporius* has 1-septate conidia and only *O. menageshae* tends to fusiform conidia with 2–3 septa.

ITS Sequences of CBS 703.74 (Netherlands, as *Drechslerella bembicodes*, GenBank), CBS 586.92 (Netherlands, as *Arthrobotrys megalosporus*, CBS), and *A.* cf. *psychrophilus* (dm3w d4, California) clustered in a strongly supported clade with the ex-type strains of *A. reticulatus* (CBS 201.50, England) and *A. xiangyunensis* (B04, C04, China) (Phyl. 28). The five taxa have similar conidia which are acrogenously formed on unbranched conidiophores. The six sequences differ from each other by only 0–1.2% (0% between the two ex-type strains), therefore, they can be considered as conspecific, and *A. xiangyunensis* becomes a synonym of *A. reticulatus.* Also in the LSU D1–D2 the ex-type strains of *A. reticulatus* and *A. xiangyunensis* and the strain from California are fully identical, while a Chinese strain (YNUCC 3228) differs by 5 nt in the D2.

When Liu et al. (2014) described *A. xiangyunensis*, they provided a morphological comparison with other *Arthrobotrys* species, but not with *A. reticulatus* or the also similar *A. megalosporus*. An ITS sequence under the name *M. megalosporum* (SOM-5, Japan, AB114475) fits the syntype of *A. thaumasius* by a 0.2% distance. However, since the size of the predominantly 4-septate conidia in the unsequenced type of *A. megalosporus* fits more *A. reticulatus*, we placed it as a doubtful synonym here. In case of synonymy, *A. megalosporus* would provide an earlier name for *A. reticulatus*.

'Dactylaria' sahelensis Sawadogo & Cayrol, Riviéra Scientifique: 27 (1990), nom. inval., ICN Art. 39.1 (without Latin diagnosis)

One of the many isolates under the name *Arthrobotrys eudermatus* derives from marshy soil in Oubritenga in the centre of Burkina Faso (CBS 377.97, J.L. Devineau, AF106528, KT215215). This strain fully concurs in the ITS and with 0.2% distance in the LSU (D1–D2) with the ex-type strain of the invalidly described '*Dactylaria*' *sahelensis* (CBS 247.93, MH862395, MH874055), which was isolated by A. Sawadogo & J.C. Cayrol from agricultural soil near Djibo in the north of Burkina Faso. The species was described with very large conidia with a long flagellum-like apical appendage (Sawadogo & Cayrol 1990), but otherwise resembles species such as *A. eudermatus* or *A. thaumasius*. Thus, strain CBS 377.97 is better identified as '*Dactylaria*' *sahelensis*, since it shows a 9.8% distance to the epitype of *A. eudermatus* and 6% to the syntype of *A. thaumasius*. The species formed with *A. mangrovisporus* the strongly supported *mangrovisporus-sahelensis* clade in our combined analyses (Phyls 25, S33), with an ITS distance of 3.7%, but also the ex-epitype of *A. eudermatus* (see p. 1580) appears to belong in this clade, showing a 3% distance to those.

≡ *Monacrosporium sinense* Xing Z. Liu & K.Q. Zhang, Mycol. Res. 98(8): 863 (1994)
= *Arthrobotrys microscaphoides* var. *multisecundarius* (W.F. Hu & K.Q. Zhang) Juan Li, J.K. Yang, L.M. Liang & K.Q. Zhang [as '*multisecundaria*'], Journal of Microbiology 46(5): 517 (2008)
≡ *Arthrobotrys multisecundarius* W.F. Hu & K.Q. Zhang [as '*multisecundaria*'], in Hu, Li, Mo & Zhang, Mycotaxon 95: 182 (2006)

The *Arthrobotrys thaumasius* clade includes numerous strains that show an ITS distance of 0–1.7% to each other (Phyl. 28), which suggests conspecificity of all these strains. Based on an ITS sequence of the ex-syntype strain from Virginia (CBS 176.37), the name ***A. thaumasius*** was correctly applied to four strains from Hong Kong, one from Taiwan, one from Guizhou, and one from Germany. The remaining strains of this large clade carry various other, partly wrong names: *M. megalosporum* (from Japan), *Drechslerella bembicodes* (from Burkina Faso), *A. indicus* (from China), and *M. eudermatum* (unlocalized). Also Chinese strains of *A. microscaphoides*, *A. multisecundarius* (ex-type), and *A. sinensis* (ex-type) clustered in this clade, the latter two consequently representing synonyms of *A. thaumasius*. Only for two of the above strains also LSU was available (CBS 322.94, Germany; CBS 376.97, Burkina Faso). When analysing the D1–D2 domain, further strains appear to belong to *A. thaumasius*: *A. rutgeriensis* (YNUCC 1828), *M. globosporum* (YNUCC 1928), and *A. sphaeroides* (YNUCC 0077) (Phyl. S32). However, since ITS was not available for them, their closeness to *A. thaumasius* remains uncertain.

The type of ***A. indicus*** was isolated from horse dung used for mushroom cultivation in New Dehli, India (ITCC 3081, HCIO 33760, Chowdhry & Bahl 1982), and no sequence appears to exist. A Chinese sequence under the name *A. indicus* (YMF 1.01845) exists in GenBank which might correspond to the first of two isolates reported by Yu et al. (2014) under this name (Sjz3.11.1). The other isolate (XZM-7) was provided with an illustration which fits the type of *A. indicus* and indeed resembles taxa here included in *A. thaumasius*, but also taxa here referred to *A. janus*.

The type of ***A. sinensis*** was isolated in IV.1990 in Nanchang, JiangXi, China, apparently from plant remnants in soil. The holotype was deposited in HMAS 62568 and the ex-type culture as AS 3.6755, from which sequences of ITS, *RPB2*, *TEF1*, *TUBB*, and *MAD1* under the number 105-1 in GenBank derive (X.Z. Liu pers. comm.). In the ITS the strain differs from *A. microscaphoides* and the syntype of *A. thaumasius* by 0.6% and from the two YNUCC strains of *A. microscaphoides* by only 0.2%. Rubner (1996) already treated *M. sinense* as a possible synonym of *M. thaumasium*.

The type of ***A. microscaphoides*** was isolated in 22.III.1992 from the rhizosphere of *Cocos nucifera* near Sanya, Hainan, China. The holotype was deposited as HMAS 66381, but no culture and sequence appear to exist. Sequences of ITS, *TUBB*, and *MAD1* exist in GenBank for two Chinese isolates treated by Yu et al. (2014: 85): a field soil sample from Lincang, Yunnan, isolated in 1999 (YMF 1.00028) and uploaded by Li et al. (2008), and a forest soil isolate from Changbaishan, Jilin, isolated in X.2002 (YMF 1.00546) and uploaded by Li et al. (2016).

The type of ***A. multisecundarius*** was isolated in 2005 from soil in Tengchong, Yunnan (Hu et al. 2006). Li et al. (2008) observed a 0.2% ITS distance and 0.5% in *TUBB* between the type culture (YMF 1.01821) and *M. microscaphoides* (YMF 1.00028), therefore, they reduced *A. multisecundarius* to a variety of *A. microscaphoides* by considering it as a spontaneous mutant.

Two unsequenced Chinese ascospore isolates are mentioned under *O. elegans* (Pl. 962: 2–3) but could as well belong to *A. thaumasius* and would then represent the first report of the teleomorph state of *A. thaumasius*.

Incertae sedis (?series *Arthrobotrys*)

Orbilia terrestris Raitv. & Faizova, Nov. Sist. Niz. Rast. 20: 106 (1983) — Pl. 976

Etymology: referring to the soil habitat.

Typification: Tajikistan, Dushanbe, Varzob river, soil, 15.VI.1978, A. Raitviir (TAAM 64761, holotype).

Description: — **TELEOMORPH**: **Apothecia** fresh 1–2 mm diam. (dry 0.45–1.1 mm), 0.22–0.25 mm high, pale ochraceous (fresh orange-red), ± round, ?scattered, sometimes two apothecia clustered; disc flat to slightly convex, margin smooth, not protruding; sessile but with a very broad stalk-like base; dry apothecia yellow-ochraceous. **Asci** †40–53 × (4.2–)4.8–5.4(–5.8) µm, 8-spored, ~4–6 lower spores inverted, pars sporifera †18–24 µm long; **apex** (†) strongly truncate, hemispherical in profile view (not or very slightly indented), thin-walled; **base** with medium long, slightly flexuous stalk, h-shaped. **Ascospores** †9–11 × 1.4–1.7 µm (~9.5–12 µm actual length), clavate to fusoid-clavate, apex rounded to obtuse, rarely subacute, base strongly attenuated (often tail-like), medium to strongly curved below; **SBs** visible as a transparent, tear-shaped region of 1.5–1.7(–2) × 0.7–1.2 µm. **Paraphyses** apically medium to strongly clavate-capitate, terminal cell †17–22 × 2.8–4.2(–4.8) µm, lower cells †6–13 × 1.5–2.5 µm, unbranched at upper septum. **Medullary excipulum** hyaline, 50–70 µm thick, of dense, horizontal textura prismatica-angularis, cells †10–22 × 9–16 µm, distinctly delimited from ectal excipulum only towards margin by a parallel, 10–15 µm thick layer of t. porrecta. **Ectal excipulum** of thin-walled, vertically oriented t. angularis(-prismatica) from base to margin, 80 µm thick near base, cells †20–40 × 15–25 µm; 30 µm thick at lower flanks, 25 µm thick at mid flanks and margin, oriented at a 90° angle, marginal cortical cells †10–19 × 5–8 µm; **glassy processes** absent. **Anchoring hyphae** very sparse, †2.5–4 µm wide, walls 0.2 µm thick. **SCBs** in apices of dead terminal cells of paraphyses (SCBs or VBs?) globose, medium-refractive, KOH-soluble, 1–3 per cell, 1.2–2.3 µm diam; **LBs** in paraphysis cells at level of ascus base, very pale yellowish. **Exudate** over paraphyses, margin and flanks granular, partially detaching. **— ANAMORPH**: unknown.

Habitat: on fine sandy to clayey ground of light grey-brown colour, with a few organic particles (?bark), a few green algae among anchoring hyphae. **Desiccation tolerance**: unknown (possibly intolerant). **Altitude**: 1450–1750 m a.s.l. **Geology**: granite. **Phenology**: VI.

Taxonomic remarks. *Orbilia terrestris* was characterized in the protologue (Raitviir & Faizova 1983) mainly by the terrestrial habitat and the orange-red apothecia of 1–2 mm diam. which superficially resemble the operculate discomycete *Pulvinula constellatio*, also by fusoid-clavate spores with a strongly tapered, medium curved base. *O. terrestris* might be closely related to *O. auricolor*, from which it differs in distinctly wider ascospores and asci and a more clavate spore shape. *O. neglecta* differs from *O. terrestris* in smaller asci and spores, the latter with distinct narrow tails. Particularly *O. latispora* s.l. quite closely resembles *O. terrestris*. Due to this similarity in the teleomorph, *O. terrestris* might belong to series *Arthrobotrys*, although the anamorph and the type of trapping organ are unknown.

Type studies. The protologue of *O. terrestris* concurs rather well with the here reexamined holotype which contains ~10 apothecia. The present spore measurements well correspond to those evaluated from the protologue illustration (9–10 × 1.4–1.6 µm), whereas the protologue gives longer spores (10–12 µm), perhaps because referring to the actual length, and an inaccurate width of 1–2 µm. No spore contents were reported in the protologue, although the present study revealed a faintly visible, medium-sized, apparently closely attached, tear-shaped spore body without a filiform upper part.

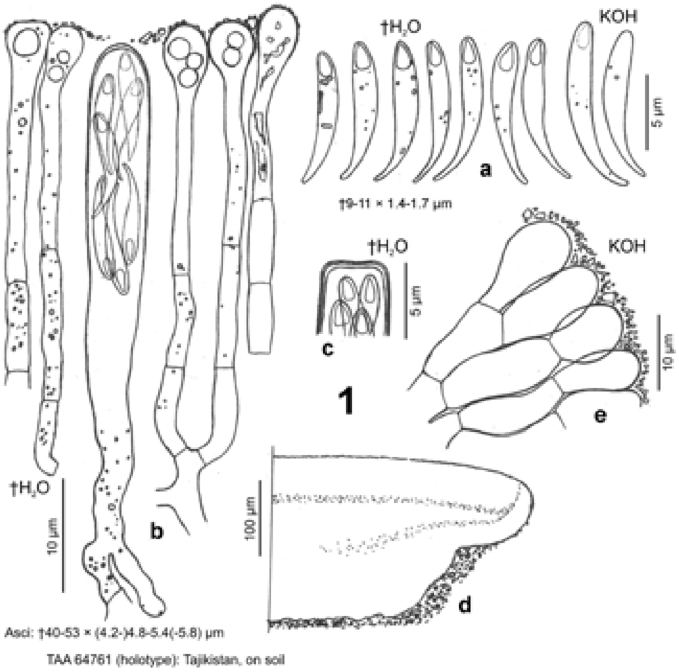

Plate 976. **1**: *Orbilia terrestris*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. ectal excipulum (margin, median section).

Ecology. The type of *O. terrestris* grew on acidic clayey-sandy (granitic) soil with a few organic particles, which might be remnants of bark, in a streambed of a gorge and valley in the warm-continental semihumid (mediterranean) Hissar Range in the western part of the Pamir-Alay mountain range at the northwestern end of Himalaya (central Asia).

Specimens included. **TAJIKISTAN**: Pamir-Alay Mts., Hissar Range, 35 km NNE of Dushanbe, ~5 km E of Varzob river, base of Tagob (Takob) gorge, near Tagob, ~1450 m, on clayey-sandy ground, 15.VI.1978, A. Raitviir (TAAM 64761, **holotype** of *O. terrestris*, H.B. 5206 ø). – ibid., southern slope of Hissar Range, side gorge of Tagob gorge, 1730–1800 m, 5.VI.1980, K. Kalamees & S. Faizova (TAAM, paratype, non vid.).

Series *Dactylellina*

Orbilia subgenus ***Orbilia*** section ***Arthrobotrys*** series ***Dactylellina*** (M. Morelet) Baral & E. Weber, **comb. et stat. nov.**, MB 814994 – Type species: *Dactylella leptospora* Drechsler [≡ *Dactylellina leptospora* (Drechsler) M. Morelet]

Basionym: *Dactylellina* M. Morelet, Bull. Soc. Sci. Nat. Archéol. Toulon et du Var 178: 6 (1968)

?= *Dactylium* Nees, Syst. Pilze: 58 (1816) [1816–1817]; – Fr., Syst. Mycol. 3: 382, 412 (1832), nom. utique rej., ICN Art. 56.1 – Type species: *D. candidum* Nees [?non *Dactylaria candida* (Nees) Sacc. s. Drechsler (1937a: 523), = *D. haptotyla* (Drechsler) M. Scholler et al.]

= *Anulosporium* Sherb., Mycologia 25: 262 (1933) – Type species: *A. nematogenum* Sherb. (nom. dub., identity unclear at the species level)

≡ *Dactylosporium* Mekht. (1967), Mikol. Fitopatol. 1: 278 (1967), nom. illegit., ICN Art. 53.1 [non *Dactylosporium* Harz 1871] – Type species: *Dactylella leptospora* Drechsler

= *Laridospora* Nawawi, Trans. Br. Mycol. Soc. 66: 344 (1976) – Type species: *Dactylella appendiculata* Anastasiou [≡ *D. appendiculata* (Anastasiou) M. Scholler et al.]

= *Kafiaddinia* Mekht. Mikol. Fitopatol. 12: 8 (1978) – Type species: *K. fusariispora* Mekht. (= *D. leptospora* fide Rubner 1996)

Etymology: *Anulosporium*: referring to the non-constricting rings (misinterpreted by Sherbakoff as ring-like conidia); *Dactylellina*, *Dactylium* and *Dactylosporium*: modifications of *Dactylella*; *Kafiaddinia*: named after the Azerbaijanian poet Kafiaddin Omar; *Laridospora*: referring to the characteristic conidial shape and semiaquatic habitat reminiscent of seagulls (*Laridae*).

Emended diagnosis: **Teleomorph**: Apothecia with smooth or finely crenulate margin, desiccation-sensitive. Ascospores subcylindrical to subulate, straight to strongly curved; spore bodies rod- to tear-shaped, rarely (sub)globose, central or sometimes eccentrical. — **Anamorph**: Conidiogenous loci singly or on prominent denticles. Conidia fusiform to cylindrical or clavate, 0–15-septate, straight, microconidia rare. Forming adhesive knobs, partly also non-constricting rings.

Description: — **TELEOMORPH**: **Apothecia** hydrated (0.2–)0.3–1.5(–6) mm diam., whitish or pale to bright yellowish-orange or rose- to blood-red, margin smooth or finely crenulate, sessile or with ill-defined stipe. **Asci** *(24–)27–47(–51) × 3–5.5 µm, 8-spored, (1–)3–4(–5) lower or sometimes upper spores inverted; **apex** (†) medium to strongly truncate, not or rarely ± indented, not or slightly laterally inflated; **base** generally partly H-shaped. **Ascospores** *4.5–13 × 0.8–1.4 µm, narrowly subcylindrical to fusoid-clavate (subulate), apex rounded to obtuse, sometimes with a more or less distinct tail, straight to strongly curved (falcate); **SBs** central or sometimes eccentrical, (0.8–)1–1.8(–2.2) × 0.2–0.7 µm, rod- to tear-shaped, rarely (sub) globose, apically narrowed to a minute to wide point, or attachment invisible. **Paraphyses** uninflated or mostly slightly to medium (rarely strongly) capitate(clavate) at apex, also spathulate to lanceolate-lageniform, terminal cells (1.2–)2–4(–6)× longer than lower cells. **Ectal excipulum** of (†) thin-walled to slightly, rarely medium gelatinized (common walls 0.3–0.5 µm or rarely up to 1–2 µm thick), vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, cells near base *(7–)10–30(–39) × (5–)8–25(–30) µm, margin of t. (globulosa-)prismatica oriented at (10–)30–90°; **glassy processes** near margin absent or up to 5–10(–20) µm long. **SCBs** globose or absent; **VBs** low-refractive, hyaline to yellowish or reddish, also absent. **Exudate** (0.1–)0.2–1.5 µm thick, continuous to granular-cloddy, loosely or often firmly attached, hyaline or yellowish to reddish, also absent. — **ANAMORPH**: dactylellina-like. **Conidiophores** 32–220 µm long, apically ± unbranched, with single terminal conidium, or geniculate to candelabrelloid. **Conidia** (13–)17–70(–132) × (4–)6–16(–18) µm, fusiform to elongate top-shaped, or cylindric-ellipsoid to -clavate, 1–7(–9–15)-septate, with or without oversized cell; **conidial dimorphism**: microconidia only observed in *D. leptospora* and *O. biforma*, sharply differentiated or not. **Trapping organs**: short- to long-stalked adhesive knobs with globose, ± detachable heads, some species additionally with detachable non-constricting rings, traps spontaneously formed in culture.

Habitat: on hygric wood and bark (rarely leaves) of both gymno- and angiosperms, also herbaceous stems and leaves of monocots, isolated also from rhizosphere of trees, capturing nematodes, rarely copepods, temperate to tropical, humid, ± desiccation-sensitive.

Recognized species: 16 (9 of them without teleomorph), plus 4 unnamed species (‘affinis’); for further 7 species see Tabs 46 and S9.

Taxonomic remarks. The morphology of the teleomorph hardly permits recognition of series *Dactylellina*. Somewhat diagnostic are the rod-shaped SBs in the ascospores of *Orbilia rubrovacuolata* and *O. mammillata*, being centrally attached in the spore apex and often lacking a filiform upper part. Yet, also *O. blumenaviensis*, *O. menageshae* and sometimes *O. auricolor* (series *Arthrobotrys*) possess, besides series *Gamsylella* and *Drechslerella*, rod-shaped SBs, though often with a short, usually invisible filum. In *O. mammillata* p.p. and the Chinese *O. quercus* the SBs are instead ± globose.

Anamorph (see also p. 224–228 and Tab. S9). Members of series *Dactylellina* are characterized by forming stalked adhesive knobs with globose heads more or less spontaneously in pure culture. In addition to adhesive knobs, several species form non-constricting rings. All anamorphs with these characteristics are referred to as dactylellina-like here. However, delimitation against series *Gamsylella* is problematic, and the original concept of that genus had to be revised based on available molecular data (see p. 235). For instance, *Dactylellina phymatopaga* forms both stalked and sessile adhesive knobs together with adhesive columns that may grow out to form rings (see Pl. 8: i). This species and its synonym *D. parvicollis* were transferred to *Gamsylella* when that genus was erected, but the available molecular data better fit *Dactylellina* (see below).

The conidia of dactylellina-like anamorphs are usually fusiform, comparatively long, and often with inflated central cell, (2–)3–4(–6)-septate. In '*Arthrobotrys*' *paucus* and *Dactylellina hertziana*, however, they are small to medium-sized, cylindric-ellipsoid, 1–3-septate, and in *D. asthenopaga* clavate. Long and narrow, fusoid, multiseptate conidia occur in *D. leptospora*. Clear cases of microconidia have rarely been reported in species of *Dactylellina*, but smaller, not sharply delimited conidia with fewer septa are often seen. The conidiophores are usually very long, and the conidia are often formed singly at the tip (acrogenous) or on a few apical branches (geniculate). In some species a tendency to candelabrelloid is observed (e. g., *D. haptotyla*).

Species delimitation. In our analyses of the ITS region (Phyl 36), various well-defined clades were obtained within series *Dactylellina*. However, applying names to these clades proved difficult, since a large number of strains were misidentified. For instance, the four available sequences of *O. lysipaga* clustered at four different positions. Confusion appears to have happened even regarding the correct affiliation to a series. The ex-type strains of *D. multiseptata* and *D. varietas*, two species being described in *Dactylellina* because of their adhesive knobs, surprisingly clustered in series *Neodactylella* (Phyl 26, see also phylogram in Li et al. 2005), the former with *D. intermedia* and the latter with *D. qiluensis*.

Yu et al. (2014) listed a total of 28 accepted species treated by us in series *Dactylellina* and *Gamsylella*, and for many of them the connection to a teleomorph is as yet unknown. Many species of series *Dactylellina* are difficult to distinguish by morphological characteristics of both their teleomorph and anamorph (for the latter see Pls 7–9), also the morphological variability of the two morphs is little explored. During our study only *O. rubrovacuolata* was examined from a large number of collections of the teleomorph, and also the conidia of its anamorph were seen in five of them. This species appears to be easily recognizable by its bright red apothecia caused by pigmented vacuolar bodies. However, a few collections completely lack the pigment, although fully concurring in their rDNA. Likewise, species delimitation in anamorph-typified taxa is often rather complicated (see under the species). *O. quercus* and *O. lysipaga* are morphologically hardly separable if no trapping organs of the anamorph are observed.

Phylogeny. In the neighbour joining analysis of LSU by Liu et al. (2006a), series *Dactylellina* (represented by *O. quercus*, *O. quercus* var. *hainanensis* and var. *hunanensis*, and *D. leptospora*) formed a paraphyletic sister group to the monophyletic series *Arthrobotrys*, whereas in Liu et al.'s parsimonious ITS analysis it formed together with two species from GenBank with medium support a monophyletic sister group to *Arthrobotrys*. Also in the analysis of ITS by Hagedorn & Scholler (1999: fig. 1) and in combined analyses of ITS, *TUBB*, *RPB2* and *TEF1* by Yang & Liu (2006: fig. 1B) and of SSU+ITS+LSU in Baral et al. (2017b), *Dactylellina* formed with *Gamsylella* a moderate (Yang & Liu) or unsupported monophyletic sister clade to *Arthrobotrys*. In the present analyses of SSU+ITS+LSU (Phyls 7, 25) no such monophyly was obtained but the three series clustered unresolved in a supported clade that represents all taxa with adhesive traps. In Li et al.'s (2005) combined analysis of 5.8S+LSU+*TUBB*, *Dactylellina* clustered as a distant sister group of *Drechslerella* and *Dactylella*, with *Gamsylella* and *Arthrobotrys* diverging earlier, but all main branches did not receive support.

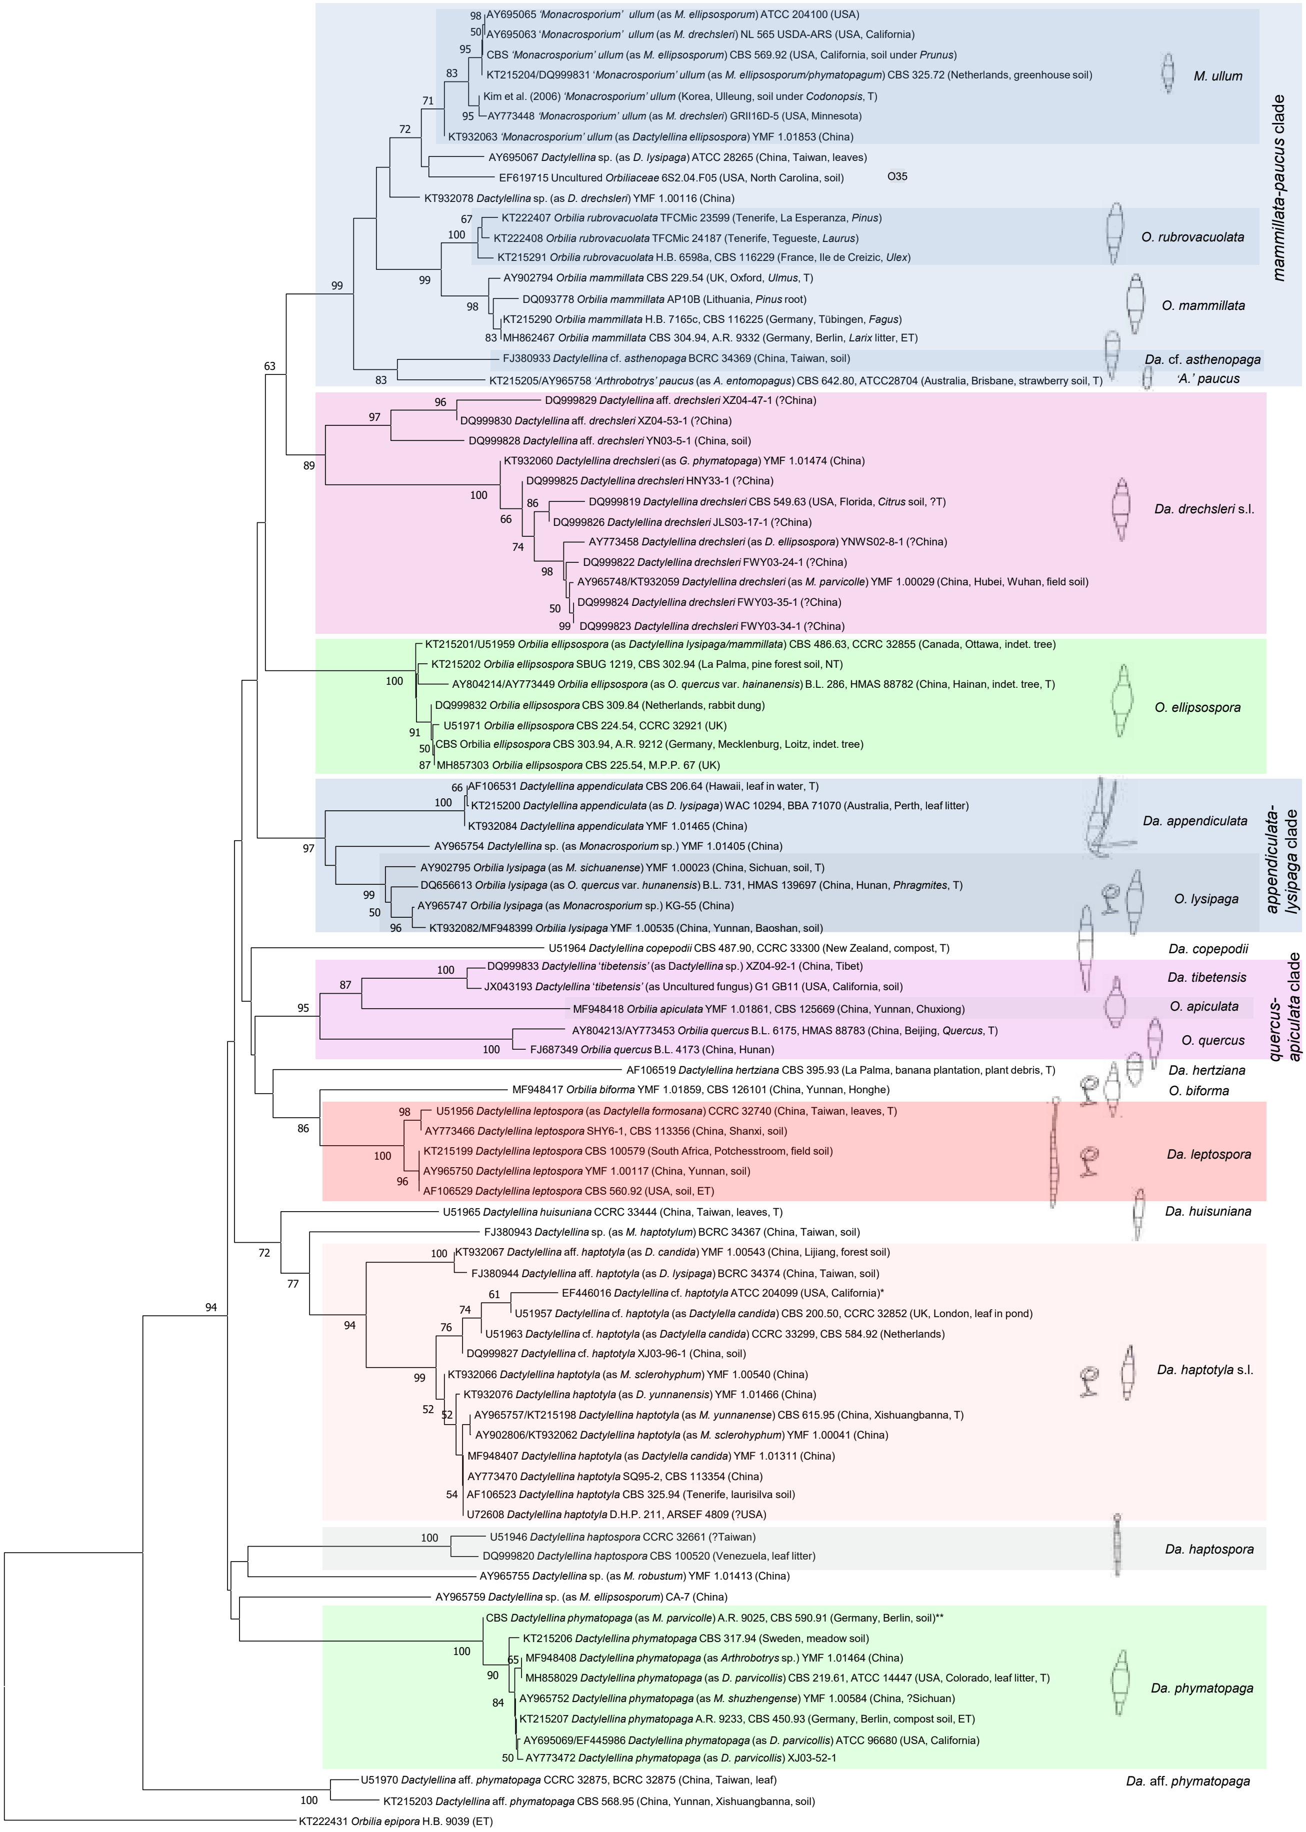
The phylogenetic relationship within series *Dactylellina* was mostly unresolved when analysing the ITS region, and only some species showed supported associations with other taxa (Phyl. 31, NJ), but also in the combined analyses many taxa clustered unresolved (Phyl. 25, S35, ML). One such clade is that around *O. mammillata* and *O. rubrovacuolata*, to which also '*Monacrosporium*' *ullum* and '*Arthrobotrys*' *paucus* belong (here called *mammillata-paucus* clade), and which received strong support in Phyls 31, S35. Another clade concerns *D. appendiculata* and *O. lysipaga* (type of *D. sichuanensis*) which clustered with medium (S35) or strong support (Phyls 32, 33) in the *appendiculata-lysipaga* clade. All the other species clustered in a more or less unresolved position, but for some only ITS was available. The identity of almost all these taxa are affirmed by type sequences in GenBank or CBS. Some of the clades remained unnamed as they included only incorrectly identified strains.

In analyses of Yang & Liu (2006, ITS+LSU) and Yang et al. (2007, ITS and ITS+LSU), *D. leptospora* clustered with *D. haptotyla*, whereas in the ITS phylogram of Yang & Liu (2006) it clustered with *D. appendiculata* (= *M. tentaculatum*). However, in Hagedorn & Scholler's (1999) and our ITS and LSU analyses (Phyl. 31, 32) but also in the combined trees (Phyls 25, S35), *D. leptospora*, *D. haptotyla*, and *D. appendiculata* clustered quite distantly and unresolved, although the strains in any of these analyses do not appear to be misidentified.

A certain correlation was noted in our analyses with regard to the two types of trapping organs: non-constricting rings occur in four species (*O. biforma*, *D. haptotyla*, *D. leptospora*, *O. lysipaga*, see Phyl. 31), whereas the entire *mammillata-paucus* clade, but also *O. ellipsospora*, *D. copepodii*, *D. hertziana*, and some other, unresolved clades are devoid of them. Only in the *appendiculata-lysipaga* clade taxa with and without non-constricting rings occur. Yang et al.'s (2007) analysis, however, suggests occurrence of non-constricting rings in a single clade which contains *D. leptospora* and *D. haptotyla*.

Specific nucleotide positions. Series *Dactylellina* as circumscribed here shows at pos. 13–15 of the ITS2 region a characteristic motif (TC**GGT**), by which it consistently differs from series *Gamsylella* and *Drechslerella* that have TC**GAC**, and from series *Arthrobotrys* and *Neodactylella* that have TC**AGC** (Tab. 76). Two strains under the name *M. phymatopagum* in GenBank (CCRC 32875, CBS 568.95), here called *D.* aff. *phymatopaga*, clustered outside the *Dactylellina* clade but also without clear association to other series. Their intermediate position is supported by the deviating motif TC**GGC**, which otherwise occurs only in Chinese *O.* cf. *orientalis* (series *Drechslerella*), but when studying other diagnostic motifs in Tab. 76 series *Drechslerella* can be excluded.

In the 5.8S region, species here accepted in series *Dactylellina* are identical, except for *D. haptotyla*, *D.* aff. *haptotyla*, *D. haptospora*, and *D.* aff. *phymatopaga*, which



Phylogenetic analysis 31. NJ analysis of series *Dactylellina* based on ITS1-5.8S-ITS2 rDNA dataset (90 sequences, 621 positions, aligned with MUSCLE) using MEGA7 (500 replicates). The tree is rooted with *O. epipora*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, NT = neotype, * = without ITS1 and partial 5.8S, ** = without ITS2. NJ was chosen because ML gave a similar tree topology with much less bootstrap support.

Phylogenetic analysis 32. Phylogram of series *Dactylellina* inferred from ML analysis of LSU (D1–D2) rDNA dataset (55 sequences, 575 positions, aligned with MUSCLE) using the K2+G+I model in MEGA7 (500 replicates). The tree is rooted *with Lilapila oculispora* and *O. patellarioides*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, NT = neotype.

deviate in stem-loop B8 at 4 symmetric positions (pos. 122–123 & 132–133), *D. haptotyla* also at pos. 119 & 136 and at pos. 147 (Tab. 77). The character C at position 147 is otherwise found within *Orbiliomycetes* at present only in *Orbilia multicurvula*, *Amphosoma resinicola*, and the four species of *Lecophagus*.

Ecology. Members of series *Dactylellina* have more or less desiccation-sensitive apothecia that grow on a wide variety of woody and herbaceous substrates. They occur worldwide in temperate to tropical humid to subhumid regions.

Orbilia rubrovacuolata Baral, Priou & E. Weber, **sp. nov.**, MB 814376 — Pls 977–980, Map 157

Etymology: referring to the paraphyses and excipular cells containing large rose-red vacuoles.

Typification: France, La Gacilly, branch of *Ulex europaeus*, 25.II.2000, J.P. Priou (ex H.B. 6588, M-0276580, holotype).

Misapplied name: H. & P. Crouan (in sched., as *Helotium coccinellum* and *Peziza infixa*).

Latin diagnosis: *Similis* Orbiliae auricolori *sed apothecia dilute ad intense salmoneo-roseo-rubra, raro pallide chlorinacea, margine saepe minutissime crenulato, ascosporae vivae corpusculum refringens bacilliformem, ad apicem late vel anguste affixum continentes, paraphyses in statu vivo vacuolas dilute purpureo-roseo-rubras continentes, cellulae excipuli marginalis processis vitreis brevibus praeditae. Habitat ad corticem vel lignum putridum ramorum uvidorum fruticum vel arborum angiospermarum, raro coniferarum, ad caules Rubi, in zona atlantica temperata ad mesomediterranea (semi)humida Europae occidentalis et Macaronesiae.*

Description: — **TELEOMORPH**: **Apothecia** fresh (0.2–)0.3–1.3(–2) mm diam., 0.15–0.25 mm high (receptacle 0.12–0.16 mm), pale to mostly light to bright (pinkish- or lilac-)salmon-rose-red (or carmine-rose), also orange- or blood-red, rarely whitish-greyish-yellowish(-chlorinaceous), slightly to strongly translucent, round, slightly lobate when large, subscattered to subgregarious; disc saucer-shaped to flat, finally slightly convex, margin distinct, thin, scarcely protruding, smooth to often (very) finely crenulate, rarely toothed; broadly sessile, sometimes with a small stipe-like base 30 × 90 µm, superficial; dry bright to deep carmine-lilac to orange-red or carmine, with a more thick and raised margin. **Asci** *(32–)35–47(–51) × (3.3–)3.5–4.5(–5.2) µm {8}, †30–43 × 3.3–4 µm {3}, 8-spored, spores 4-seriate, (2–)3–4 lower spores inverted (not mixed) {12}, pars sporifera *18–24 → 14 µm long; **apex** (†) (slightly to) medium (to strongly) truncate (not indented, laterally sometimes slightly inflated); **base** with a short to medium long, flexuous stalk, T-, h- or H-shaped. **Ascospores** *(8.5–)9–12(–13) × (0.8–)0.9–1.2(–1.3) µm {11} (~9.5–14 µm actual length), †9–13(–14) × (0.9–)1(–1.2) µm {3}, narrowly subcylindric- to fusoid-clavate, apex rounded, base slightly or often medium to strongly attenuated, often with a more or less distinct tail; medium to strongly

Key to species of series *Dactylellina* with known teleomorph

1. Spores slightly to strongly curved, length/width ratio ~8–12 based on actual length (i.e., < 1.3 µm wide if actual length = 10 µm 2
1. Spores straight to medium curved, length/width ratio < 7(–8).. 4

2. Spores *(8.5–)9–12(–13) × (0.8–)0.9–1.2(–1.3) µm (in situ); SBs consistently rod-shaped, 0.2–0.4(–0.5) µm wide, apical attachment broad or only slightly narrowed; apothecia pale to bright red (pigmented VBs in paraphyses), rarely whitish; conidia fusiform, (2–)3–4(–6)-septate; bark & wood of angio- & gymnosperms, *Rubus* stems, polypores, cold- or warm-temperate humid to mesomediterranean semihumid, (sub)atlantic western Europe, Macaronesia .... ***O*. *rubrovacuolata***, p. 1587
2. Spores *8–10(–11.5) µm long, slightly to medium curved; SBs globose to rod-shaped, 0.3–0.6 µm wide; apothecia whitish, sometimes pale rosaceous or light yellow-orange, without reddish vacuoles 3

3. Spores *(6.5–)8–10(–11.5) × 1–1.3(–1.4) µm; marginal excipulum oriented at a 50–80° angle, cortical cells *8–16 × 4–6 µm; conidia fusiform, (2–)3–4-septate; wood & bark of angio- & gymnosperms, hemiboreal to cold-temperate humid Europe ***O*. *mammillata***, p. 1594
3. Spores *8–10 × 1–1.1 µm; marginal excipulum oriented at 10–40°, cortical cells †6–11 × 3–3.5 µm; anamorph unknown; leaf of *Quercus*, cold-temperate humid atlantic Europe .... ***O*. cf. *mammillata***, p. 1596

4. Spores slightly to medium curved (allantoid), *4–6 × 1–1.2 µm; indet. bark, subtropical humid eastern Asia ....***O*. *biforma***, p. 1605
4. Spores ± straight 5

5. Paraphyses at least partly distinctly spathulate or lanceolate-lageniform; anchoring hyphae 3–6 µm wide; heads of adhesive knobs ellipsoid to lageniform, covered by strongly swellable gel; SBs often distinctly eccentrical, subglobose to rod-shaped; marginal cortical cells without glassy processes ....**series *Gamsylella***, p. 1610
5. Paraphyses uninflated or slightly to medium capitate, never apically attenuated; anchoring hyphae 1.5–4 µm wide; heads of adhesive knobs ± globose, without conspicuous gel 6

6. Marginal cortical cells without glassy processes; spores *3.5–6.8 × 1–1.4 µm........................7
If spores longer and/or wider, SBs 1.5–2.5 × 0.3–0.6 µm, with a short filum, compare *O. yuanensis* (section *Helicoon*).
6. Marginal cortical cells with very short to long glassy processes........................11

7. Asci †20–32 µm long; apothecia 0.2–0.55 mm diam., whitish to pale yellowish........................8
7. Asci †(30–)33–40(–43) µm long; apothecia 0.3–1.2 mm diam........................10

surface of bark), sometimes among and on *Thelonectria discophora* or indet. old pyrenomycetes, also on old dark brown *Corticiaceae*; with very few green algae and brown hyphae. **Associated**: *Brachysporiella gayana* {1}, *Brachysporium bloxamii* {1}, *Calycina* sp. {1}, *Chaetosphaerella phaeostroma* {1}, *Chalara* sp. {1}, ?*Cosmospora* sp. {1}, *Endophragmiella boothii* {3}, *Hamatocanthoscypha laricionis* {1/1}, *Herpotrichia macrotricha* {1}, *Hyaloscypha ?vitreola* {1}, *Lachnum ?subvirgineum* {1}, *Mollisia* sp. {3}, *M. fusca* {1}, *M. ulicis* {1}, *Nemania serpens* {1}, *Orbilia auricolor* {2}, *O. eucalypti* {1}, *O. fabacearum* {1}, *O. leucostigma* {1}, *O. luteorubella* {1}, *O. rosea* {1}, *O. sarraziniana* {1}, *Pezicula rubi* {1}, *Pleurothecium recurvatum* {1}, *Pseudorbilia bipolaris* {1}, *Thelonectria discophora* {2}, *Trichoderma aureoviride* {1}, sometimes with bryophytes (*Lophocolea bidentata*, pleurocarpous mosses). **Desiccation tolerance**: Asci, terminal cells of paraphyses, and marginal excipular cells dead already after half a day in the herbarium; lower cells of paraphyses viable up to 3 weeks, some basal excipular cells and ascospores after 5 weeks, and some medullary excipular cells after 8 weeks. **Altitude**: 2–268 m a.s.l. (western Europe), 7–512 m (Spain), 825–1203 m (Tenerife). **Geology**: Cambrian siltstone & quartzitic wacke, Ordovician, Silurian & Carboniferous mud-, silt- & sandstone and coal, quartzite, Keuper (marl- & sandstone), Upper Jurassic limestone, Cretaceous & Tertiary marl-, sand- & mudstone, Quaternary sand, gravel & clay, marsh over Middle Jurassic limestone; granite, granodiorite, andesite, quartz diorite & biotite-amphibole, gabbro, mica schist, gneiss; Tenerife: basaltic flows and pyroclasts. **Phenology**: throughout the year.

Phenology of *O. rubrovacuolata*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
4	7	13	5	10	3	4	3	5	4	3	0

Taxonomic remarks. *Orbilia rubrovacuolata* is easily recognized in the field by its conspicuously red (mostly carmine-rose) colour due to a vacuolar pigment in the living cells of both paraphyses and marginal ectal excipulum. Further characteristics separating the species from the microscopically similar *O. auricolor* are consistently rod-shaped spore bodies being attached at the ascospore apex without a filum, narrower anchoring hyphae, and usually present glassy processes at the margin which vary in length between 2–4 and 8–20(–40) µm, whereas in *O. auricolor* they were only sometimes present and then max. 6 µm long. The main difference to *O. auricolor* is the dactylellina-like anamorph with large, fusiform, mostly 4–5 septate conidia and stalked adhesive knobs. The other here reported *Orbilia* spp. with a dactylellina-like anamorph differ in whitish apothecia and in shorter and less curved ascospores.

The taxonomic value of the red vacuolar pigment of *O. rubrovacuolata*, which has never been seen in *O. auricolor*, is affirmed by the deviating anamorph and molecular data. Although the dried apothecia show an intensified bright red colour, there is no red pigment or only some remnants visible inside the rehydrated dead cells so that the tissue appears ± hyaline under the microscope. Adding alkali or acids instantly removes the pigment in fresh specimens, without extruding in the medium. The apothecia get discoloured in the herbarium by becoming very pale cream-rosaceous, sometimes already after 1–2 years, or only after a much longer period of time. As a consequence of this colour loss, the species can hardly be separated from *O. auricolor* on the basis of herbarium material, if notes on the fresh colour were not made and if the characteristic anamorph is not found on the substrate.

Variation. A certain variation was noted in the length of the glassy processes and in the width and attachment of the SBs. Also the red pigment, which was present in 59 out of 62 collections, varied somewhat in the intensity and shade. The pigment was entirely absent in the not included sample from Luxembourg (H.B. 5274, on *Quercus*, see Pls 979, 980: 3), and in two from Macaronesia (Tenerife, on *Laurus* and *Pinus*), according to photos made by L. Quijada (Pl. 980: 1–2). From both Luxembourg and Macaronesia no records of *O. rubrovacuolata* with red apothecia are so far known (see Map 157). In the Macaronesian specimens the paraphyses were narrower and often individually tipped by exudate caps, and the apothecia distinctly toothed at the margin.

We have included the Macaronesian specimens in the description because their sequence data unexpectedly indicated conspecificity with *O. rubrovacuolata* (no data were available for that from Luxembourg). From *O. auricolor* they differ by narrow marginal cortical cells tipped by rather long glassy processes (Luxembourg: 6–30 µm, Tenerife: 12–40 µm). The lack of pigment in Macaronesian *O. rubrovacuolata* does not seem to originate from a hidden growth protected from light, because also strongly pigmented populations frequently occurred on the underside of branches or were covered by litter.

Type studies. According to a reexamination by J.P. Priou (pers. comm.), three specimens in H. & P. Crouan's herbarium (CO) under the names *Peziza infixa* Wallr. (on bark of *Salix* branches, 26.IX.1863, on stems of *Rubus fruticosus* agg., VIII.1865) and '*Helotium coccinellum* (Sommerf.) Crouan' in sched. (on stems of *R. fruticosus* agg., 12.VIII.1867), which represent the first known records of *O. rubrovacuolata*. For both substrates the collectors noted the apothecia to be 'carmine-red in the living state'. In this material, even today the red colour is still present to a certain degree. Despite the characteristic falcate ascospores, this fungus was obviously included in the concept of *Peziza infixa* by Crouan & Crouan (1867: 49), a name which the authors mainly used in the sense of *O. eucalypti* (see p. 1675).

Not included collections. Because of lacking DNA data, the sample with whitish apothecia from Luxembourg (H.B. 5274, on *Quercus*, see Pls 979, 980: 3) in not included in the description. Also a specimen from Czechia (on *Populus*, IVV: H.B. 6422) with 5–12 µm long glassy processes is unclear. It might either belong to *O. rubrovacuolata* or to *O. mammillata*. The apothecia are now bright ochraceous with orange centre. On his manuscript plate, Velenovský described them as pale amber, but this plate shows a species with ellipsoid spores, suggesting a mixture or confusion. The specimen was believed by Svrček (1954) to represent *O. auricolor* (as *O. curvatispora*) and was designated by him as lectotype of *Orbilia tremulae* Velen., but this lectotypification is against the Code (see p. 1375).

Anamorph. Among the known anamorph-typified taxa with adhesive knobs, four resemble the anamorph of *O. rubrovacuolata* regarding conidial morphology: (1) *Dactylellina haptotyla* is excluded by having clusters of 3–10 conidia at the candelabrelloid conidiophore tip, stalks of adhesive knobs < 2 µm thick, and forming of non-constricting rings; (2) *D. ellipsospora* differs in wider conidia (40–50 × 12–16 µm) formed always singly at the unbranched conidiophore tip; (3) *D. drechsleri* and (4) *D. mammillata* are morphologically hardly separable from *O. rubrovacuolata*. Available molecular data of isolates under these names, including the types of *D. mammillata* and *D. drechsleri* and the neo- and epitypes designated by Rubner (1996), suggest that all of them are not conspecific with *O. rubrovacuolata*. The most closely related species is *O. mammillata*, which is shown here to be connected to a different teleomorph (see p. 1596). Since no molecular data exist in GenBank and CBS that fit

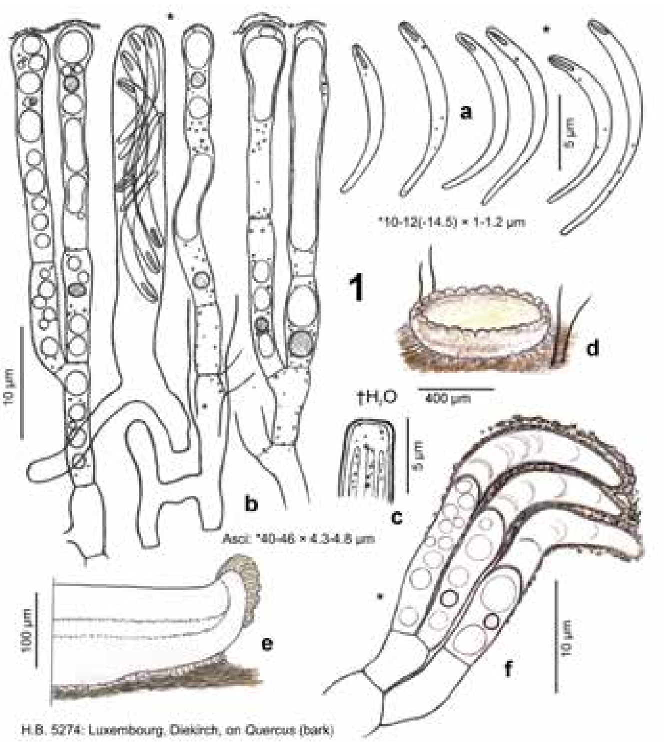

Plate 979. **1**: *Orbilia* cf. *rubrovacuolata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. fresh apothecium; **e**. apothecium in median section; **f**. marginal cortical cells with glassy processes, in median section.

O. rubrovacuolata, we assume that its anamorph has not been isolated previously.

Phylogeny. A sequence from our ascospore isolate (Morbihan, H.B. 6598a) comprises SSU, ITS, and LSU. Sequences were also gained from the two Macaronesian samples with whitish apothecia, comprising ITS and LSU. In all of them the S1506 intron is absent. A distance of only 0.6–1 % is observed in the ITS region between the French and the two Macaronesian samples which differ by 0.6 %. 1 of the 3 deviating nt between the Macaronesian strains lies in the 5.8S at pos. 84 (C vs. T), the T representing a very rare exception (verified from chromatogram, see Tab. 18). In the LSU (D1–D2), the two samples from Macaronesia are identical and differ from the French ones by 2 nt (0.3 %).

When analysing the ITS region (Phyl. 31), *O. rubrovacuolata* clustered with *O. mammillata* in a strongly supported clade which, however, received only medium support in our combined analysis (Phyl. S35) and included '*M.*' *ullum* when analysing LSU (Phyl. 32). Together with *D.* cf. *asthenopaga* and '*A.*' *paucus* these taxa form the strongly supported *mammillata-paucus* clade (Phyl. 31, S35). The distance between *O. rubrovacuolata* and *O. mammillata* is 2.5–3.8 % in the ITS (2.5–3 % regarding the ex-type strain of *O. mammillata*, for the characteristic nucleotides see Tab. 88), and 0.7–0.9 % in the LSU. *O. rubrovacuolata* shows a 4.5–5 % ITS distance to '*M.*' *ullum* and 5.7–6 % to '*A.*' *paucus*.

Much more distant are the other three species with similar conidia, which clustered in separate clades: the neotype of *D. ellipsospora* (CBS 302.94) shows a 10 % ITS distance to *O. rubrovacuolata*, *D. haptotyla* (CBS 325.94) 10.5 %, and the presumed ex-type strain of *D. drechsleri* (CBS 549.63) 12.5 %.

Ecology. Populations of *O. rubrovacuolata* with red apothecia have so far only been observed in the atlantic to subatlantic, supra- to thermotemperate humid and mesosubmediterranean semihumid western Europe, partly only a few kilometres from the sea shore. The species occurs on ± rotten bark and wood of hygric branches of various angiosperm but also gymnosperm trees and shrubs, rarely large fruitbodies of polypores. Preferred hosts were *Rubus* {15}, *Salix* {14}, *Ulex* {10}, and gymnosperms {7}. The vegetation includes atlantic woodlands with *Ulex* and *Pteridium aquilinum*, also floodplain forests with *Salix*, *Fraxinus*, *Corylus*, *Tilia*, *Oenanthe crocata*, *Arum maculatum*, *Hedera helix* etc.

O. rubrovacuolata is obviously a common species in the atlantic belt. For instance, in Asturias it is said to be very frequent, especially on stems of *Rubus fruticosus* agg., therefore, collection data have often not been noted and specimens not preserved (E. Rubio pers. comm.). The first German record was presented by Lindemann & Wieschollek (2010). The apparent rareness or absence of the species in the regions of Poitou-Charentes, Aquitaine, and Cantabria is difficult to explain and might be due to a preference of *O. rubrovacuolata* for acidic soil, although occurrence on calcareous soil is ascertained.

Populations with whitish-chlorinaceous apothecia are known from subcontinental cold-temperate humid Luxembourg on bark of *Quercus* in a dense deciduous forest over Middle Keuper, and from lower mesomediterranean (semi)humid Macaronesia (Tenerife) on bark of *Laurus* in the laurel evergreen cloud forest (*Lauro novocanariensis-Perseetum indicae*) and on wood of *Pinus* in the Canarian pine forest (*Sideritido solutae-Pinetum canariensis ericetosum arboreae*) on volcanic soil (L. Quijada pers. comm.).

Orbilia mammillata (S.M. Dixon) Baral & E. Weber, **comb. nov.**, MB 813997 — Pls 981–982

Basionym: *Dactylella mammillata* S.M. Dixon, Trans. Br. Mycol. Soc. 35: 144 (1952)

≡ *Monacrosporium mammillatum* (S.M. Dixon) R.C. Cooke & C.H. Dickinson, Trans. Br. Mycol. Soc. 48: 622 (1965)

≡ *Golovinia mammillata* (S.M. Dixon) Mekht., Khishchnye Nematofagovye Griby – Gifomitsety (Baku): 159 (1979)

≡ *Dactylellina mammillata* (S.M. Dixon) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 111 (1999)

Etymology: named according to the blunt (obtuse) upper end of the conidium. **Typification**: Great Britain, Oxford, wood of *Ulmus*, IX.1950, S.M. Dixon (K, holotype; ex-type culture: CBS 229.54, not sporulating fide Rubner 1996; sq.: AY902794, AY902802, MH868837); Germany, Berlin, leaf litter of *Larix decidua*, 22.VIII.1993, A. Rubner (A.R. 9332, CBS H-5694, epitype, designated by Rubner 1996; ex-epitype culture: CBS 304.94, sq.: MH862467, MH874115). **Misinterpretation**: Rubner (1996: 83, CBS 486.63), = *O. ellipsospora*.

Description: — **TELEOMORPH**: **Apothecia** fresh (0.3–)0.5–1.1 mm diam., 0.1–0.22 mm high, pale to light (whitish-)cream-greyish(-yellowish), turning bright dirty amber with age, translucent, round to very slightly undulating, ± gregarious; disc flat to slightly convex, margin 0–15 µm protruding, smooth to very finely rough; broadly sessile, superficial, dry pale cream(-ochraceous). **Asci** *(24–)27–35(–40) × 4.3–5.5 µm {2}, †25–36 × 3.4–4.3 µm {2}, 8-spored, spores *4–8-seriate, 3–4(–5) lower spores inverted {1} (sometimes mixed), pars sporifera *10–14.5(–18.5) µm long; **apex** (†) medium to strongly truncate (rarely very slightly indented, laterally often slightly inflated); **base** with short to medium long, thin or thick, flexuous stalk, Y- to h- or H-shaped. **Ascospores** *(6.5–)8–10(–11.5) × 1–1.3(–1.4) µm {2} (~8–12 µm actual length), †(6–)7–10(–11.3) × 1–1.1 µm {2}, narrowly subcylindrical to mostly cylindric- to fusoid-clavate, apex rounded, sometimes obtuse, base slightly to medium (to strongly) attenuated, slightly (to medium) curved (falcate), rarely straight; **SBs** *(0.8–)1–1.5(–2) × 0.3–0.5(–0.6) µm {3}, rod-shaped (to subulate), apically narrowed to a minute or wide point, also tear-shaped to subglobose with often invisible attachment (?overmature). **Paraphyses** apically (not or) slightly to medium capitate(-clavate), terminal cell *(12–)15–22(–25) × (2.2–)3–4(–4.5) µm {2}, lower cells *4–8(–9) × 2.2–3(–4.5) µm {2}; rarely branched at upper septum, hymenium hyaline to pale yellowish. **Medullary excipulum** hyaline, 40–50(–70) µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum, especially at flanks. **Ectal excipulum** hyaline, of thin-walled, vertically oriented t. globulosa(-angularis) from base to mid flanks, 40–60(–110) µm thick near base, cells *10–30 × 9–24 µm {1}; 25–30 µm thick near margin, of t. prismatica oriented at a 50–80° angle to the surface, marginal cortical cells *(6–)8–16 × 4–6 µm {2}; **glassy processes** (0–)2–9 × 4–5.5(–6.5) µm {3}, low-refractive, stratified. **Anchoring hyphae** abundant, */†(2–)2.5–3.5(–5) µm wide, walls 0.2 µm thick {2}. **SCBs** not seen; **VBs** in paraphyses very low- to low-refractive, (very) pale chlorinaceous-yellow, globose to strongly elongate {T}. **Exudate** over paraphyses and marginal excipulum

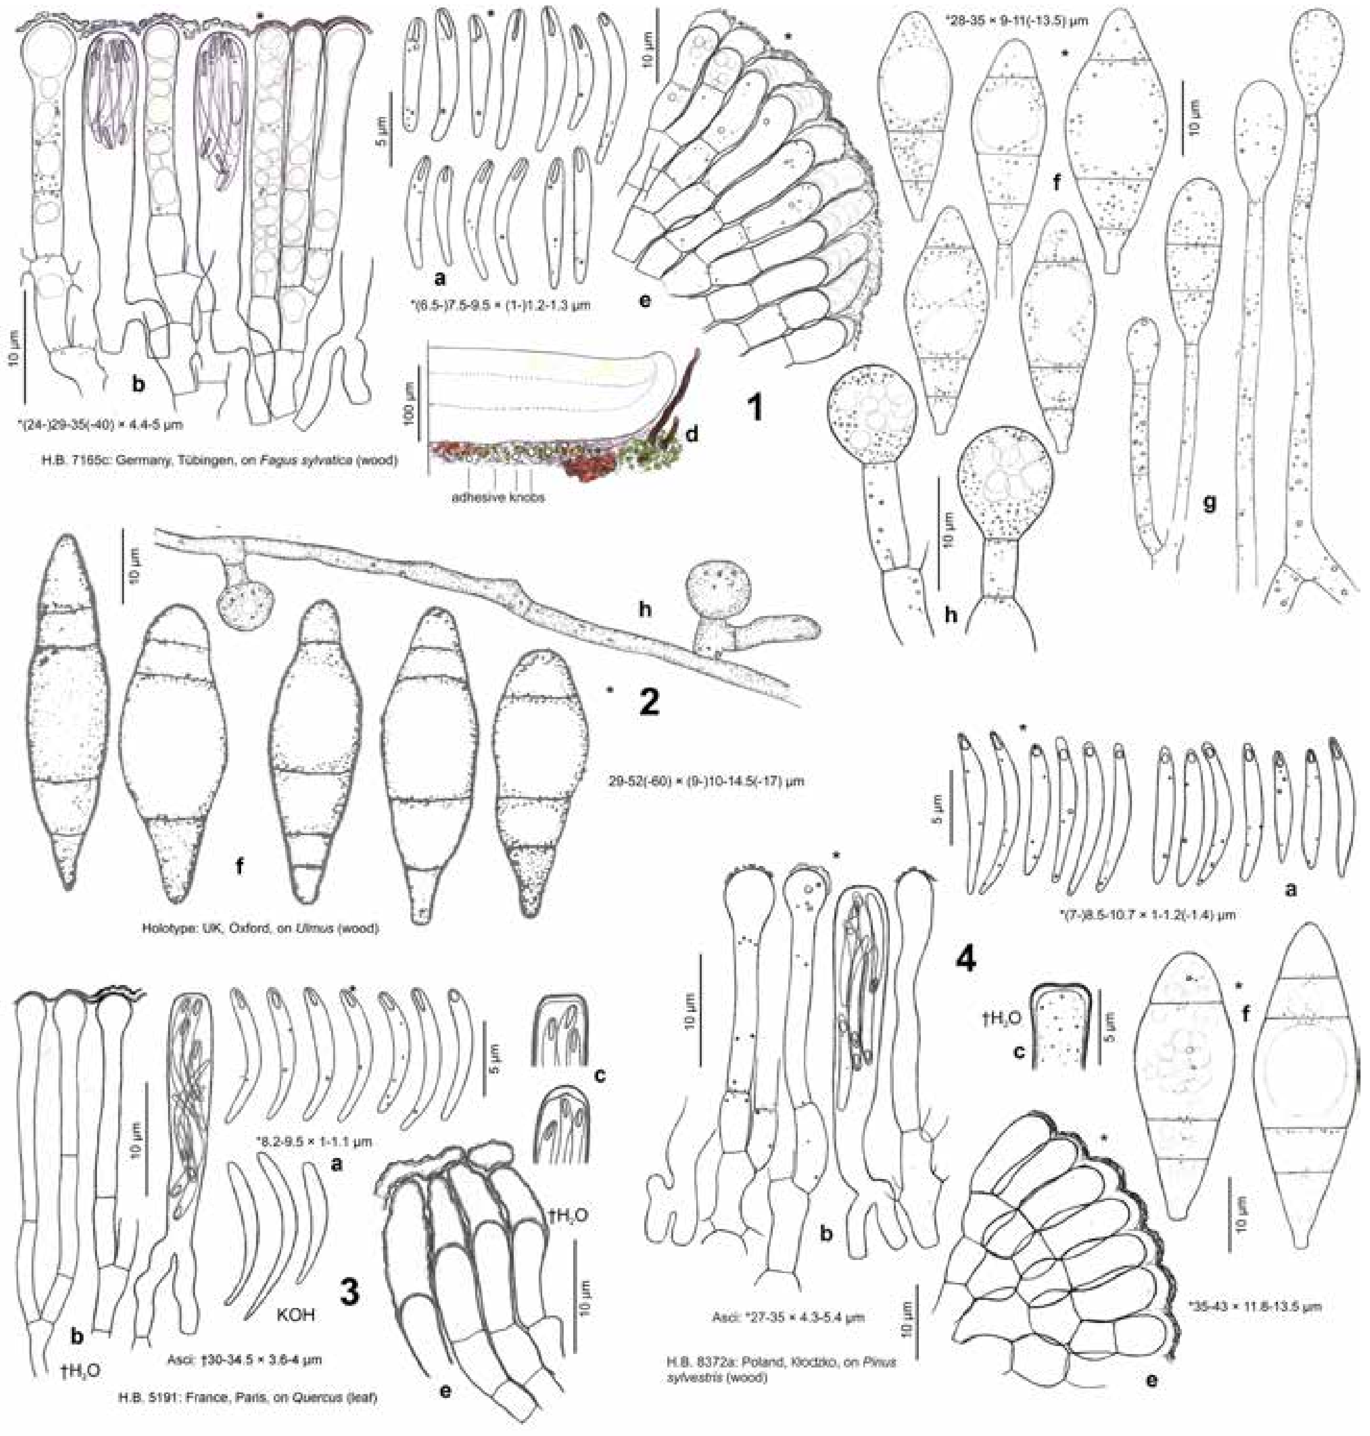

Plate 981. **1–2**, **4**: *Orbilia mammillata*; **3**. *O.* cf. *mammillata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section (with adhesive knobs below); **e**. marginal ectal excipulum in median section, cortical cells with or without glassy processes; **f**. conidia; **g**. conidiophores; **h**. adhesive knobs (**1f–g**, **2f**, **h**, **4f** from culture, **1h** from substrate). – **2**: from Dixon (1952).

0.2–0.5(–1) µm thick, granular-cloddy, loosely attached, hyaline to pale chlorinaceous-yellow or sometimes pale (olivaceous-)brown. — **ANAMORPH**: dactylellina-like (from ascospore isolate {2} and natural substrate {3}). **Conidiophores** 32–60 µm long, ~3–3.5 µm wide at base, 1.8–2.2 µm wide at apex, unbranched {1}, 0–1-septate, with a single conidium at apex. **Conidia** fusiform (to fusiform-clavate), with obtuse apex, *(27.5–)30–43(–47.3) × (9–)10–13.5(–14.5) µm {4}, 29–52(–60) × (9–)10–14.5(–17) µm {T}, (2–)3–4-septate, middle cell always distinctly larger than other cells {3}. **Chlamydospores** not observed. **Adhesive knobs** short-stalked, heads *7.5–10.2 × 7–8.2 µm, stalks 5–9 × 2–3 µm, arising either from excipular cells and anchoring hyphae, or from mycelium in pure culture. **Non-constricting rings** absent.

Habitat: 0–50 cm above the ground, partially to entirely decorticated, 45–70 mm thick branches or ~30–40 cm thick cut stumps of *Fagus sylvatica* {2}, *Picea abies* {1}, *Pinus sylvestris* {2}, ?*Populus* sp. {1}, *Ulmus* sp. {1}, on underside or laterally, or on cut surface, on 2–3 mm or deeper strongly decayed wood {5}, sometimes on old pyrenomycete, no algae. **Associated**: *Brachysporium nigrum* {1}, *Cacumisporium capitulatum* {1}, *Chaetosphaeria* sp. {1/1}, *C. myriocarpa* {1}, *Claussenomyces prasinulus* {1}, *Dematioscypha delicata* {1}, *Lentomitella cirrhosa* {1}, *Leptodontidium trabinellum* {1}, *Metatrichia vesparium* {1}, *Mollisia* sp. {1}, *M.* ?*oblonga* {1}, *Orbilia bembicodes* {1}, *O. dryadum* {1}, *O. xanthostigma* {1}, *Rhizodiscina lignyota* {1}, *Tubeufia cerea* {1}. **Desiccation tolerance**: apparently intolerant, but a few inflated cells of the medullary excipulum still viable after 2 months. **Altitude**: 62–430 m a.s.l. **Geology**: Keuper (Stubensandstein), Pleistocene sand & gravel, mica schist & gneiss. **Phenology**: VII, X–XI (teleomorph).

Taxonomic remarks. *Orbilia mammillata* is characterized by slightly curved (falcate), only partly distinctly heteropolar ascospores, with ± rod-shaped but also subglobose spore bodies, short-stalked, rather thick asci, and short glassy processes at the margin. The closest relative *O. rubrovacuolata* has longer and narrower, more curved spores, and *O. quercus* has shorter, almost straight spores with tear- to broadly rod-shaped SBs. The more distant *O. rectispora* and *O. cardui* (series *Neodactylella*) differ in less curved, partly shorter spores with globose to tear-shaped SBs, and longer and narrower asci, and also the type of *O. vestimenti* (= *O.* cf. *clavispora*) resembles *O. mammillata* but differs in a tendency to tailed spore bases and in slightly narrower asci with rather long and thin stalks (Pl. 938: 3).

Variation. The specimens from Poland (on *Pinus* and ?*Populus*) differ from the collection from southern Germany (on *Fagus*) in often subglobose SBs and very short glassy caps, the *Pinus* specimen also in more fusoid spores and the absence of VBs in the paraphyses (these features are possibly due to a slight senescence of the apothecia).

Misapplication. According to available molecular data, some of the strains assigned by Rubner (1996) to *M. mammillatum* belong instead to *O. ellipsospora*.

Not included collection. A sparse sample on a fallen leaf of *Quercus* (Pl. 981: 3) is very similar to *O. mammillata*. It differs in more curved spores and a marginal excipulum of distinctly smaller cortical cells (†6–11 × 3–3.5 µm) oriented at a lower angle (10–40°). Conidia could not be observed here, but placement in series *Neodactylella* seems less probable, as members of that series with similar spores differ in globose SBs and distinct marginal cell rows.

Anamorph. The anamorph of the present species fits well *Dactylellina mammillata* as described by Dixon (1952, Pl. 981: 2) and Rubner (1996, fig. 39a). Yet, in the closely related *O. rubrovacuolata* we also obtained an anamorph very similar to that of *O. mammillata*, and delimitation from *D. ellipsospora* and *D. drechsleri* is also problematic (see p. 1591). The conidia of *O. mammillata* are slightly shorter and wider than those of *O. rubrovacuolata*, and the conidiophores always formed only a single conidium. However, conidial dimensions strongly overlap. Moreover, some variation was noted within the strains here included in *O. mammillata*: in that from *Pinus* the conidia were partly 4-septate and larger (Pls 981: 4f; 982: 1j) compared to that from *Fagus* in which 4-septate conidia were not seen (Pl. 981: 1f). However, in another sample on a *Fagus* branch, collected not far from the locality of the latter one, the conidia were larger and 3–4-septate (Pl. 982: 4).

Dactylellina quercus, described by Liu et al. (2005a) as anamorph of *O. quercus*, is morphologically also very similar to *O. mammillata*. It has conidia of the same size and shape, but the middle cell is not so much enlarged, also the stalks of the adhesive knobs are shorter or even absent (0–5.5 µm).

When adding nematodes to our cultures, many of them adhered to the adhesive knobs. Where nematodes were captured, the mycelium produced many adhesive knobs in direct vicinity. A lot of adhesive knobs were also found on the natural substrate in two collections (Pls 981: 1d, h; 982: 3c). They occurred at the apothecial base and lower flanks, where they clearly emerged from the excipular cells, or from anchoring hyphae attached to excipular cells.

Typification of anamorph. Rubner could not redescribe Dixon's living ex-type culture of *D. mammillata* because it did no longer sporulate. In the dried specimen she found much smaller conidia of another shape (15–23 × 6–9 µm, ellipsoid-clavate, 3-septate) than given in the protologue (30–60 × 9–17 µm, fusiform, mostly 4-septate, also 2–3-septate). Because of this divergence, Rubner designated an epitype. She selected a collection with mostly 3-septate, apically rounded conidia (CBS 304.94, Berlin-Dahlem), because in her studied strains this type of conidia strongly prevailed, and also Dixon emphasized conidia with more rounded apices as typical. Yet, our strains of *O. mammillata* and *O. rubrovacuolata* had predominantly conidia with attenuated apices, in the latter species sometimes with up to 5–6-septa.

Phylogeny. A sequence from our ascospore isolate of *O. mammillata* (Tübingen, H.B. 7165c) comprises SSU (without S1506 intron), ITS, and LSU. In the ITS region it shows a distance of 0.4% (2 nt, 0 gaps) to the ex-type culture of *D. mammillata* (Oxford, CBS 229.54, ITS+LSU) and no difference at all to the sequence of the ex-epitype culture (Berlin, CBS 304.94, ITS+LSU) (see Phyl. 31). An environmental sequence uploaded as *D. mammillata* (Lithuania, AP10B, ITS) differs by 3 nt from H.B. 7165c and by 5 nt from the holotype. In the LSU (D1–D2) H.B. 7165c fully concurs with the ex-type and epitype of *D. mammillata* (Phyl. 31, epitype not shown). A molecular extract (ITS2) from a *Picea* log in northwestern Russia (Karelia) matches the holotype except for a few gaps (denovo110, Kazartsev et al. 2018).

O. rubrovacuolata differs from *O. mammillata* in the ITS region by ~12–20 nucleotides and some gaps (2.5–3.8%), and in the LSU D1–D2 by 4–5 nt (0.7–0.9%), but no difference was noted in the D3. We conclude that the ex-type strain of *D. mammillata* is conspecific with our ascospore isolate, consequently we name the here described holomorph *O. mammillata*. A strain from Ontario under the name *D. mammillata* (CBS 486.63) shows a 7% distance in the ITS to the type strain and belongs to *O. ellipsospora*. The distance between *O. mammillata* and *O. quercus* ranges at 14–15.5%.

Ecology. *O. mammillata* was found on rotten wood of hygric or mesic branches and stumps of *Fagus*, *Pinus*, ?*Populus* and *Ulmus* in atlantic to subcontinental, hemiboreal to cold-temperate humid Europe. The type grew on rotten elm wood in a ditch in southern England, and the epitype was isolated from *Larix* litter in northeastern Germany. The vegetation at the two sites in southern Germany was a *Fagetum* on Stubensandstein at a south-exposed slope and a periodically flooded place along a rivulet in a shady valley nearby. In Poland it was a rich mixed forest on calcareous soil, in Lower Silesia Ordovician marble and in Lublin upper Cretaceous limestone.

Specimens included. **GREAT BRITAIN**: **South East England**, **Oxfordshire**, 9 km WNW of Oxford, near Eynsham, 65 m, on wood of *Ulmus*, IX.1950, S.M. Orbilia quercus Bin Liu, Xing Z. Liu & W.Y. Zhuang [as '*querci*'], FEMS Microbiol. Lett. 245: [99] (2005) — Pls 983–984

= *Dactylellina quercus* Bin Liu, Xing Z. Liu & W.Y. Zhuang [as '*querci*'], FEMS Microbiol. Lett. 245: [99] (2005)

Etymology: referring to the substrate, wood of *Quercus*.

Typification: China, Beijing, Huairou, trunk of *Quercus*, 10.VII.2002, B. Liu (HMAS 88781, holotype of teleomorph; HMAS 88783, permanent slide culture, holotype of anamorph; sq.: AY804213, AY773453).

Misapplied names: *O. cunninghamii* with anamorph *M. parvicolle* (Liu et al. 2002).

Description: — **TELEOMORPH**: **Apothecia** fresh 0.2–0.35 mm diam., 0.09 mm high (receptacle 0.07 → 0.045 mm), whitish to pale yellowish when fresh, translucent, round, subgregarious; disc slightly concave to flat, margin distinct, thin, not protruding, smooth; broadly sessile, superficial; dry brownish-yellowish. **Asci** †20–30 × 3.2–3.7 µm, 8-spored, spores †2–3-seriate, ~2–4 lower spores inverted (probably often mixed); **apex** (†) medium to strongly truncate (indistinctly indented, laterally not inflated); **base** unstalked or with short, ± thin stalk, Y- to h- or often H-shaped. **Ascospores** *5–6 × (0.8–)1–1.2 µm, †(4.5–)5–6.5 × 0.9–1.1 µm {T}, subcylindrical to narrowly fusoid-clavate, apex obtuse, base not or only slightly attenuated (slightly to medium attenuated in dead state), straight to ± inequilateral; **SBs** ~1–1.5 × 0.6–0.7 µm {1}, tear- to broadly rod-shaped, attached to the less attenuated spore end, ± centrally oriented. **Paraphyses** apically slightly to medium (clavate-)capitate, terminal cell †(11–)15–18 × (2–)2.5–3 µm {1}, lower cells †2.7–5.5 × 1.5–2 µm {1}; sometimes branched at upper septum. **Medullary excipulum** 20–30 µm thick, of dense textura intricata with some inflated cells, sharply delimited from ectal excipulum. **Ectal excipulum** of (†) slightly gelatinized, vertically oriented t. angularis from base to mid flanks, 30 µm thick near base, cells †9–13 × 4–9 µm {1}; 10 µm thick at margin, of t. globulosa to t. prismatica oriented at a 30–70° angle to the surface, marginal cortical cells †6–8 × 3.5–5 µm {1}; **glassy processes** absent. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2 µm thick {1}. **SCBs** and **VBs** no data available. **Exudate** over paraphyses 0.2–0.5(–1.3) µm thick, continuous, finely rough, firmly attached, over margin and flanks 0.3–1 µm thick, granular. **— ANAMORPH**: dactylellina-like (from ascospore isolate {1}, Liu et al. 2005a). **Conidiophores** mostly 130–180 µm high, 5–6.5 µm wide at base, 1.5–2.5 µm at apex, sometime branched near the apex, tips with a single conidium. **Conidia** mostly fusiform, apically rounded to obtuse, truncate at base, *25–40(–50) × 8–12 µm, with 3(–5) septa, middle cell not much larger than the others. **Chlamydospores** not observed. Trapping nematodes by means of ± stalked **adhesive knobs**, stalk ~1–5.5 × 2.8–3.2 µm wide, heads spherical to subspherical, 8–12 × 7.5–10 µm, produced frequently on the nutritional agar plates even without presence of nematodes; **non-constricting rings** absent.

Habitat: on trunk of *Quercus* ?*mongolica* {1} lying on the moist ground, on medium decayed wood {1}, on dark layer of *Tomentella* sp., no algae. Further **associated**: none observed. **Desiccation tolerance**: unknown (probably intolerant). **Altitude**: 850–~3500 m a.s.l. Felsic **Geology**: Beijing: felsic plutonic rock. **Phenology**: VII, X.

Taxonomic remarks. *Orbilia quercus* is characterized by rather small, ± straight, subcylindrical (in the dead state narrowly fusoid-clavate) ascospores containing ± tear-shaped spore bodies, in combination with a dactylellina-like anamorph with fusoid to fusiform conidia. *O. bambusina* (incertae sedis, without known anamorph, Pls 1025–1026) appears to be very closely related, differing mainly in the presence of short glassy caps on the margin and (in the holotype collection) also on the paraphysis tips, spores with partly subacute apices, and in growing on monocots. The European *O. mammillata* differs from *O. quercus* in longer and more curved spores and in the presence of glassy processes, but in the anamorph it is very similar.

Two Chinese collections, from Hunan (on *Phragmites*) and Hainan (on indet. wood), were separated from *O. quercus* at the variety level by Liu (2006: 96, 99), based mainly on a deviating anamorph which was identified as *Dactylellina lysipaga* and *D. ellipsospora*, respectively, but also for molecular reasons. In the teleomorph the two varieties appear to be hardly distinguishable from the type of *O. quercus*. The differences lie in the conidia and the stalk length of the adhesive knobs. In the present work they are recognized at the species level as *O. lysipaga* and *O. ellipsospora*. For the questionable *O.* aff. *quercus* without anamorph see below.

O. rectispora deviates in longer spores with globose SBs with a ± invisible filum, and a dactylella-like anamorph with cylindric-fusoid conidia. Also *O. polybrocha* resembles *O. quercus* in the spores, but differs in ± eccentrical SBs, long glassy processes, an often pigmented exudate, and a drechslerella-like anamorph.

Variation. The collection from Tibet on wood of *Pinus* (without description) was said to deviate from the type merely by larger apothecia (Liu et al. 2006b: 115).

Nomenclature and type studies. Apothecial size was given in the protologue as 0.2–0.5 mm, and in the present reexamination of an isotype it was rehydrated 0.2–0.35 mm. Liu et al. (2005a) described the asci distinctly narrower (18–30 × 2.5–3 µm) than here found, but from his photograph a size of 26–31 × 3.2–3.7 µm can be evaluated. The height of the ectal excipulum in the protologue (78–96 µm) is in conflict with Liu's plate (fig. 1B), where a height of 30 µm can be measured, which is in concordance with the examined isotype. The spores are distinctly tapered at the base in the dead state, whereas on Liu's photos the living spores are cylindrical or hardly narrowed below. The SBs are given as 1.1–1.8 × 0.7–1 µm in the protologue, but they are somewhat smaller, especially narrower when evaluated from the scale.

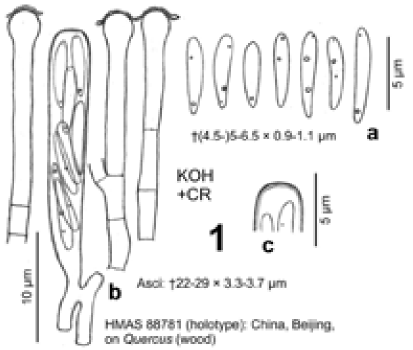

Plate 983. **1**: *Orbilia quercus*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

The orignal specific epithet '*querci*' is improper because both nominative and genitive are '*Quercus*' (Latin 4th declension).

Anamorph. According to Liu et al. (2005a), *Dactylellina quercus* resembles *D. haptotyla*, *D. ellipsospora*, and *D. drechsleri*. Especially the latter two differ in their conidia having a distinctly larger middle cell. The same is true for the also similar *O. mammillata*. Apart from *D. haptotyla*, the conidia of these species are wider than in *D. quercus*. *D. haptotyla* differs in adhesive knobs with much longer stalks and in 3–10 conidia at the candelabrelloid conidiophore tip. Yang et al. (2012a) classified the partly very short-stalked adhesive knobs of *O. quercus* as sessile and suggested, also based on their multigene analysis, a transfer to the genus *Gamsylella*. The phylogenetically close *D. leptospora* differs in much longer and narrower conidia with more septa.

Phylogeny. Besides the type sequence gained by Liu et al. (2005a) from the ascospore isolate (S1506 intron, ITS, LSU), two further ITS sequences were available in GenBank: AY773453 was used by Yang et al. (2007) but is exactly a copy of AY804213, whereas FJ687349 refers to a collection from Hunan (B.L. 4173) used by Yang et al. (2012a), being incomplete in the ITS1 and showing 0.4 % distance (2 nt) to the type sequence.

In Liu et al.'s (2005a) analysis of the ITS region, *O. quercus* clustered with weak support in a clade with two strains of *D. leptospora* (CBS 560.92, epitype; SHY6-1). In our analysis we could not confirm this association, instead, *O. quercus* formed a strongly supported clade with *O. apiculata* and *D. tibetensis* nom. nud. in our NJ analysis of the ITS region (Phyl. 31, medium supported under ML), here called *quercus-apiculata* clade, with a distance of 7.7–8 % to *D. tibetensis* and 11–13 % to *D. apiculata*, *D. leptospora*, and *D. phymatopaga*. When analysing the intron, which is absent in *O. apiculata* and *D. tibetensis*, *O. quercus* clustered in a weakly supported clade with *D. leptospora*, but with a very high distance (S30). In the LSU D1–D2, *O. quercus* differs from *D. tibetensis* by 1.7 % (no LSU available for *D. apiculata*), and both clustered with *D. phymatopaga* (2.2–2.3 % distance) in a weakly supported clade Phyl. 31). This clade received medium support in our combined analysis of SSU+ITS+LSU (S35, *D. tibetensis* not shown).

Also Liu et al. (2005a) observed a high molecular distance between *O. quercus* and the previously mentioned,

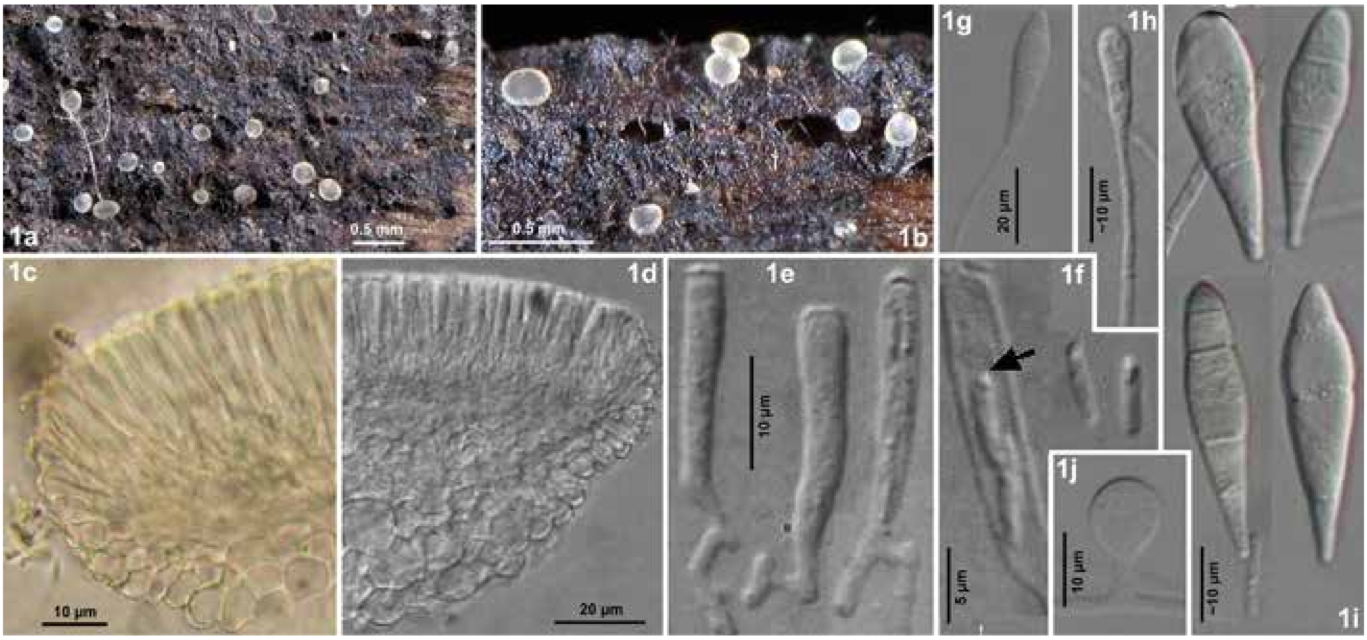

Plate 984. **1**. *Orbilia quercus*. – **1a–b**. rehydrated apothecia (after 3 years); **1c–d**. median section of ectal excipulum at flanks and margin; **1e**. asci; **1f**. ascospores; **1g–h**. conidiophores; **1i**. conidia; **1j**. adhesive knob (**1g–j** from culture). – Living state, except for **1c** (in KOH), **1e**, **h**, ascus in **1f**. – **1d–j**: from Liu et al. (2005a). — **1a–f**. HMAS 88781 (holotype of *O. quercus*); **1g–f**. HMAS 88783 (holotype of *D. quercus*): China, Beijing, on *Quercus*.

morphologically similar species *D. haptotyla*, *D. ellipsospora*, and *D. drechsleri* (11–16.5% in our evaluation). In Yang et al.'s (2012a) multigene analysis, *D. quercus* clustered strongly supported with *Gamsylella cionopaga* in a clade, and with *G. robusta* and *G. parvicollis* (= *D. phymatopaga*) forming a paraphyletic sister clade to them within the strongly supported *Gamsylella* clade. Therefore, the authors used the name '*Gamsylella querci*', but did not propose a valid combination for it. In any case, *O. quercus*, *O. apiculata*, and *D. tibetensis* concur at 2 positions of the ITS2 region (pos. 14–15) with all other sequences of series *Dactylellina* (TCG**GT**), whereas all members of series *Gamsylella* have the motif TCG**AC** (Tab. 76).

Ecology. Apothecia of *O. quercus* s.str. were so far only found in central and eastern Asia, on rotten wood of hygric logs of both gymno- and angiosperms. The type was in an orotemperate humid (winter-dry) deciduous *Quercus* ?*mongolica* forest with *Betula platyphylla* and other species in the mountain range north of Beijing (northeastern China). Another sequenced strain was reported by Liu (in GenBank) from a probably subtropical humid (winter-dry) area in Hunan (southeastern China). The collection on wood of *Pinus* was from a continental humid, subalpine site in Tibet (eastern Himalaya).

Specimens included. **CHINA**: **Beijing**, **Huairou**, 115 km N of Beijing, ~11 km WNW of Labagoumenxiang, Sunzhazi, 850 m, log of *Quercus* ?*mongolica*, on wood, 10.VII.2002, B. Liu (B.L. 6175, HMAS 88781, **holotype** of *O. quercus*, **isotype** in H.B. 7810; HMAS 88783, permanent slide from culture, **holotype** of *D. quercus*, CGMCC (AS) 3.6762 culture, anam. cult., doc. vid.; sq.: AY804213=AY773453, DQ656669). – **Hunan**, unlocalized, X.2002, B. Liu (B.L. 4173, non vid.; sq.: FJ687349). – **Tibet**, **Nyingchi**, Gongbujiangda, ?3500 m, on wood of *Pinus*, 21.VII.2004, B. Liu (HMAS 138526, non vid.).

Orbilia aff. *quercus* 8986 Pls 985–986

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–0.6 mm diam., 0.28 mm thick (receptacle 0.11 → 0.08 mm), pale cream, non-translucent, ± round, scattered; disc flat to medium convex, margin finely crenulate; with abrupt stalk 0.1 × 0.3 mm. **Asci** †28–32(–40) × 3.3–3.7 µm, 8-spored, orientation unknown; **apex** (†) medium truncate; **base** with short to long, thin, slightly flexuous stalk, H-shaped. **Ascospores** *4.6–5.2 × 1.3–1.5 µm, †(3.5–)4–5(–5.5) × (1–)1.2–1.3(–1.4) µm, narrowly ellipsoid to slightly fusoid, apex obtuse (to subacute), base obtuse to sometimes medium attenuated, straight, rarely slightly curved; **SBs** 1.5–1.7 × 0.25–0.3 µm, rod-shaped to subulate, narrowed to a wide or small point, ± centrally oriented. **Paraphyses** apically slightly to medium clavate-capitate, terminal cell †12–15.5 × 2.5–3.5 µm, lower cells †4–6 × 1.7–2.5 µm; unbranched at upper septum. **Medullary excipulum** 20 µm thick, of dense textura angularis(-intricata), indistinctly delimited from ectal excipulum. **Ectal excipulum** of (†) not or slight to medium gelatinized, of t. globulosa-angularis from base to margin, 230 µm thick near base, cells †(12–)15–30 × 10–20 µm, common walls up to 1–2 µm thick; 25 µm thick at margin, of t. prismatica oriented at an 80° angle to the surface, marginal cortical cells †(6–)8–11(–14) × 4–6 µm; **glassy processes** 10–20 × 3–4 µm, outwards curved, refractive, slightly stratified. **Anchoring hyphae** medium abundant, †3–4.5 µm wide, walls (0.2–)0.3–0.5(–0.8) µm thick. **SCBs** and **VBs** no data available. **Exudate** over paraphyses 0.2–0.3 µm thick, finely rough, firmly attached. **— ANAMORPH**: unknown.

Habitat: on decorticated, ?5 cm thick branch of indet. angiosperm lying on moist ground, on medium decayed wood. **Associated**: *Brachysporium* sp. **Desiccation tolerance**: unknown (probably intolerant), very few spores alive when studied after 6 weeks. **Altitude**: 1845 m a.s.l. **Phenology**: VIII.

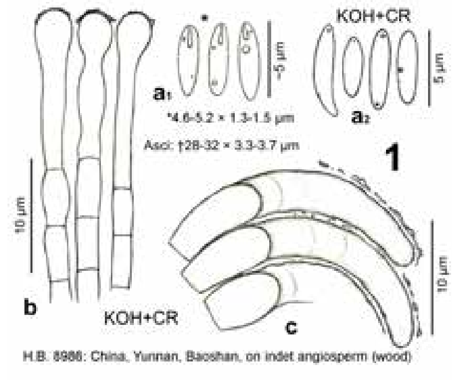

Plate 985. **1**: *Orbilia* aff. *quercus*. – **a**. ascospores; **b**. paraphyses; **c**. marginal cortical cells with glassy processes.

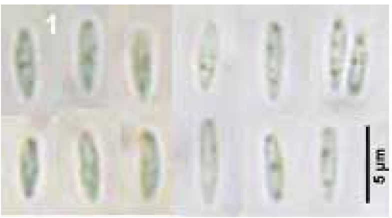

Plate 986. **1**: *Orbilia* aff. *quercus*. – Ascospores (dead state, left **6** spores in H_2O, right in KOH). – H.B. 8986: Yunnan, Baoshan, on indet. angiosperm.

Taxonomic remarks. The present sample resembles *Orbilia quercus* in the spores, which are slightly shorter and especially wider, and more fusoid. The spores contain narrowly rod-shaped to subulate SBs which are not distinctly eccentrical, an unusual feature in series *Gamsylella* and *Drechslerella* to which the species might instead belong. A certain gelatinization of the ectal excipulum and particularly the presence of short glassy processes further separate this taxon from *O. quercus*.

Ecology. The very sparse apothecia were found on rotten hygric wood of an unidentified angiosperm in a subtropical humid (winter-dry) montane evergreen broad-leaved forest in southern China.

Specimens included. **CHINA**: **Yunnan**, **Baoshan**, Tengchong, 52 km SW of Baoshan, 31 km SE of Tengchong, Gaoligongshan, 1845 m, branch of indet. angiosperm, on wood, 4.VIII.2008, X.J. Su, H.Y. Su & X.N. Zhao (H.B. 8986).

Orbilia lysipaga (Drechsler) Bin Liu, Baral & E. Weber, **comb. nov.**, MB 831501 — Pls 987–988

?= *Dactylellina illaqueata* D.S. Yang & M.H. Mo, in Yang et al., Mycotaxon 94: 215 (2006, '2005')

Etymology: *lysipaga*: named after the non-constricting rings that get broken from their attachment by the trapped nematode; *sichuanensis* & *hunanensis*: named after the Chinese provinces Sichuan and Hunan; *illaqueata*: referring to the capturing of nematodes by trapping devices.

Typification: USA, Maryland & Virginia, leaf mould, undated, C. Drechsler (holotype of ***Dactylella lysipaga***, illustration in Drechsler 1937a: fig. 10); Azores, Faial, *Sphagnum*, V.1988, A.R. Bernitzky (CBS 581.91, RefSpec, designated here; sq.: AY261165). — China, Sichuan, Emei Shan, soil, 7.VIII.2002, L. Cao (YMF 1.000234, holotype of ***Dactylellina sichuanensis***). — China, Yunnan, Simao, soil, X.2005, D.S. Yang (YMF 1.01846, holotype of ***D. illaqueata***).

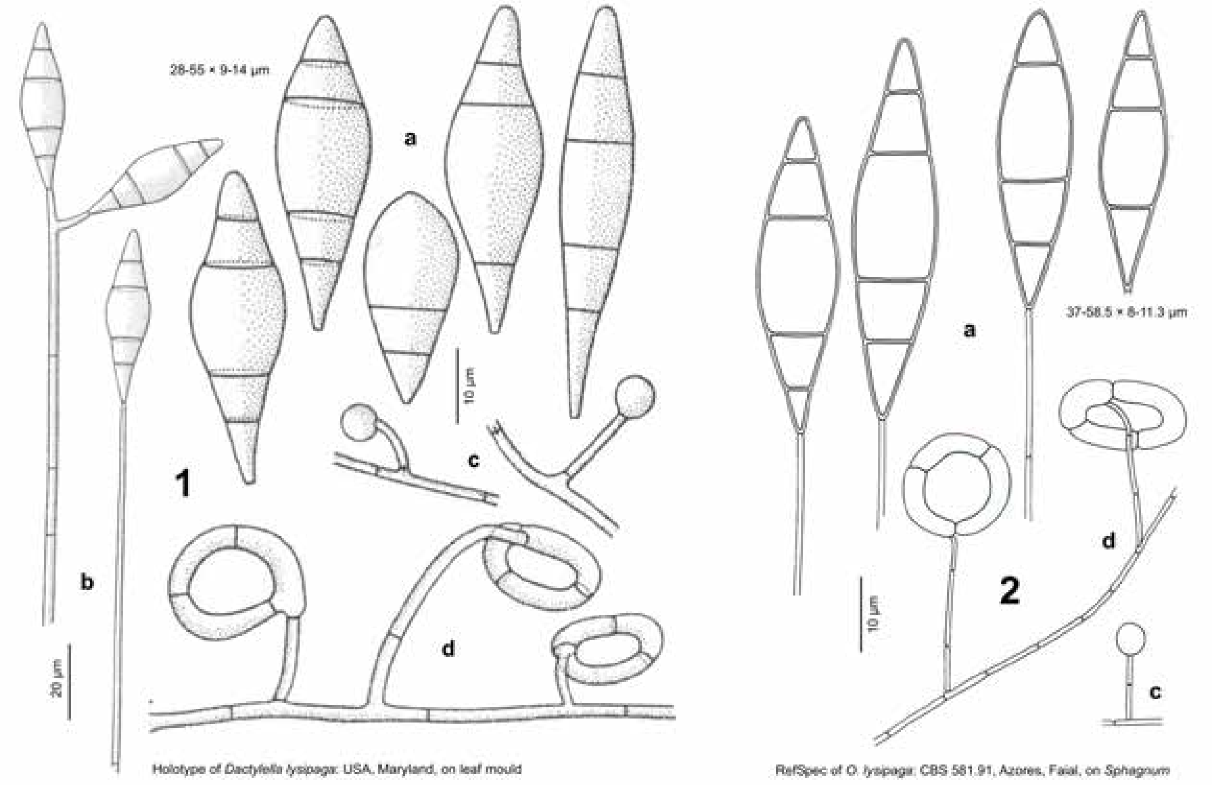
Description: — **TELEOMORPH**: **Apothecia** fresh 0.26–0.8 mm diam., white, translucent, round, scattered; disc flat, margin smooth, not protruding; sessile. **Asci** †23–32 × 3–3.4(–3.8) µm, 8-spored, 4 lower spores inversely oriented; **apex** truncate or hemispherical, thin-walled; **base** without or with medium long stalk, L-, h- or H-shaped. **Ascospores** *5–6 × 1–1.2 µm, †4.5–6 × 1.1–1.3 µm, cylindric-clavate, apex rounded to obtuse, base medium attenuated, ± acute, straight, rarely slightly curved; **SBs** ovoid to short cylindrical, ~1.4–1.6 × 0.5–0.7 µm, ± central, attachment not clearly seen. **Paraphyses** apically not or slightly, rarely medium capitate. **Medullary excipulum** not examined. **Ectal excipulum** 30 µm thick near base, of (†) thin-walled t. prismatica-angularis, cells 6.2–11 × 4–6 µm, 15 µm thick at margin, of t. prismatica oriented at 40–70°, marginal cortical cells †9–10.5 × 3–3.5 µm; terminated by short, refractive **glassy processes** 2–3 × 3.5–4 µm. **Anchoring hyphae** not examined. **VBs** no data available. **Exudate** over paraphyses and margin 0.3–1.5 µm thick, granular-cloddy, firmly attached. **— ANAMORPH** (from Drechsler 1937a, Fritsch & Lysek 1992, Liu 2006, Li et al. 2006): dactylellina-like (from ascospore isolate {1}): **Conidiophores** 85–250 µm long, unbranched, 3–5 µm wide at base, 1.1–2.2 µm at apex, conidia formed singly, exceptionally on a short apical side branch. **Conidia** *(28–)35–70(–80)((–117)) × (7.5–)9–14(–17.5) µm {4}, fusiform (partly resembling a distaff), rarely clavate, (2–)4(–6)-septate, with a large middle cell, straight, rarely curved below; exceptionally forming conidiophores with secondary conidia. **Adhesive knobs** with subglobose to obovoid heads of *(5–)6–8(–9) × (4.5–)5–7(–7.5) µm, stalks *(5–)10–60(–146) × 1.2–1.7 µm {3}. **Non-constricting rings** *(13–)15–20(–24) µm outer diam., (8.5–)10–13(–16) µm inner diam., composed of (2–)3(–4) ring cells *2.5–4 µm wide, stalks *9–20(–35) × 1.5–2 µm {3}.

Habitat: on culms of *Phragmites australis* {1}. **Desiccation tolerance**: probably intolerant. **Altitude**: ?100 m a.s.l. (USA), 575 m (Azores), 600–?2000 m a.s.l. (China). **Phenology**: IX (teleomorph).

Taxonomic remarks. Apothecia of *Orbilia lysipaga* are only known from a Chinese record on *Phragmites* (Liu 2006), which are described above as a compilation of Liu's data and the present reexamination. The teleomorph coincides to a certain degree with *O. bambusina* (incertae sedis), especially with the paratype collection on *Cocos*, though the spores of *O. lysipaga* are apically more rounded. Regrettably, the shape of the SBs is not clearly recognizable on the spore photos of Liu's collection (Pl. 988: 1f), who called it '*O. querci* var. *hunanensis*'. The present reexamination (Pl. 988: 1a–e) seems to indicate that differences to *O. quercus* merely exist in slightly wider spores, larger apothecia, and a caulicolous habitat. A similar collection on leaves of *Bambusa* is treated as *Orbilia* sp. 8963 (incertae sedis, Pls 1021–1022), and the lignicolous *O. quercus* var. *hainanensis* under *O. ellipsospora*.

Anamorph. In an ascospore isolate of the *Phragmites* collection, Liu (2006) obtained an anamorph which he identified as *Dactylellina lysipaga*. It formed adhesive knobs with partly very long stalks, also non-constricting rings (Pl. 988: 1g–i). Similar as in *O. ellipsospora*, the middle cell of the fusiform conidia is much larger than the adjacent cells. Drechsler's drawing and description of the type of *D. lysipaga* (Pl. 987: 1) fits very well this isolate, though here the conidiophores sometimes produced an additional conidium on a short branch below the tip. Fritsch & Lysek (1992) described a collection from Azores under the name *Monacrosporium lysipagum*, which is said to have rather long and narrow conidia (47–58.5 × 8–11.3 µm, Pl. 987: 2). When evaluating their size from the scale bar, however, they are of the typical size of that species (37–51 × 9–11.3 µm). In all these strains the conidia have never more than 4 septa.

D. sichuanensis as described by Li et al. (2006) differs from the above strains in larger, especially longer conidia of 35–82.5 × 7.5–17.5 µm [mean value 53.5 × 13 µm, *(47–)50–70(–74) × 12.5–15.5 µm when evaluated from the scale], with sometimes up to 5(–6) septa. Phylogenetically, however, this taxon is conspecific with Liu's *D. lysipaga* (see below). The higher number of septa considered by Li et al. as diagnostic ('usually characterized by more than 4 septa') might correspond to the larger conidia, but the authors noted that, in fact, only 9% of the conidia had 5 septa, and only 1% 6 septa. Despite their molecular conformity, the difference in size between the illustrated conidia of *D. sichuanensis* (Li et al. 2006) and *D. lysipaga* (Liu 2006) is very striking (Pl. 988: 1a vs. 2a). Although Li et al. gave a mean value of 53.5 × 13 µm, they figured mainly conidia at the upper size range. Another possibility is that their scale bar is incorrect.



Holotype of *Dactylella lysipaga*: USA, Maryland, on leaf mould

RefSpec of *O. lysipaga*: CBS 581.91, Azores, Faial, on *Sphagnum*

Plate 987. **1–2**: *Orbilia lysipaga*. – **a**. conidia; **b**. conidiophores with conidia; **c**. adhesive knobs; **d**. non-constricting rings (from culture). – **1**: from Drechsler (1937a: fig. 10); **2**: from Fritsch & Lysek (1992).

D. illaqueata as described by Yang & Mo (2006) closely resembles *D. sichuanensis* and might be conspecific, but molecular data are wanting. Here the number of septa is predominantly 5 and sometimes up to 8. The conidia are given as 25.5–117.5 × 5.5–15.2 µm, therefore, the scale bar of 10 µm appears to be erroneous as it would lead to 18–22 µm wide conidia. With an assumed 5 µm bar, the figured mature conidia would have a size of 37–50 × 9–11 µm.

In all these strains the conidia are usually straight, except that in *D. sichuanensis* they sometimes show a strongly curved base. Conidia curved in this way occurred also in *D. appendiculata* (≡ *Monacrosporium tentaculatum*), a species isolated from leaves in a stream in Hawaii and deviating by its molecular data from the above strains (see below). *D. appendiculata* deviates also in lacking non-constricting rings and in very long and thin, arm-like hyphae arising always from the second cell of the main axis (see Rubner 1996: 98). However, such arm-like hyphae formed at the second cell were also drawn by Drechsler (1937a: fig. 10 W) in *D. lysipaga*, though here they appear to be conidiophores on which further conidia are formed (fig. 10 X).

The adhesive knobs in the protologue of *D. lysipaga* are slightly smaller (5–8 × 4.5–6 µm) compared to those of *D. sichuanensis* (7.5 × 7 µm) or Liu's strain (~6.5–9 × 5.5–7.5 µm). On the drawing of the strain from Azores the scale bar for the trapping organs seems to be incorrect, because the knobs would show a width of only 3.3–3.7 µm and the stalks 0.6–0.7 µm, also the relation in cell width between ring and stalk appears to be erroneous.

In order to settle the confusion about the name *D. lysipaga*, we here designate a **reference specimen**: PAO4728s, the strain from Azores described by Fritsch & Lysek (1992). It concurs morphologically rather well with Drechsler's protologue (Tab. 89) and its sequence fits Liu's (2006) concept of *D. lysipaga*. There is, however, confusion about its CBS number. GenBank has this strain as CBS 581.91 (PAO4728s, AY261165), but under the same CBS number also *Arthrobotrys polycephalus* (PAO5428s, AY261172). The CBS database lists under CBS 581.91 *D. lysipaga* from Azores, with reference to both LSU sequences which cluster in different series of section *Arthrobotrys*. An LSU sequence alignment with *A. polycephalus* (EU107317) in CBS shows under 581.91 *A. polycephalus*, but when inserting the type strain of *D. sichuanensis* (AY902795) no dactylellina-like strain with the number 581.91 appears, indicating that a culture of the *D. lysipaga* strain from Azores might not exist at CBS.

O. lysipaga (Pl. 8: c) matches *D. haptotyla* in conidial morphology but its conidiophores bear 1(–2) conidia at the tip in contrast to 1–5 conidia in *D. haptotyla*. In the trapping organs *O. lysipaga* matches *D. candida* s. Drechsler, the latter differing in 3–10 narrower conidia at the conidiophore tip. *O. lysipaga* differs from *O. quercus* and *O. ellipsospora* in conidial characters, but especially in the adhesive knobs having distinctly thinner and partly much longer stalks, and in the presence of non-constricting rings.

Phylogeny. Sequences (ITS+LSU) of strains here referred to *O. lysipaga* were available for the types of *O. quercus* var. *hunanensis* and *D. sichuanensis* (here also SSU V1–V5) and for an unlocalized strain under the name *Monacrosporium* sp. (KG-55). Only LSU exists for the here designated reference specimen of *D. lysipaga* and an unlocalized strain under that name (YNUCC 3251), and only ITS for a Chinese strain under the name *D. lysipaga* (YMF 1.00535). The *D. sichuanensis* type includes the S1506 intron, which is absent in *O. quercus* var. *hunanensis*. Regrettably, no sequence of *D. illaqueata* and no ITS of the reference specimen were available.

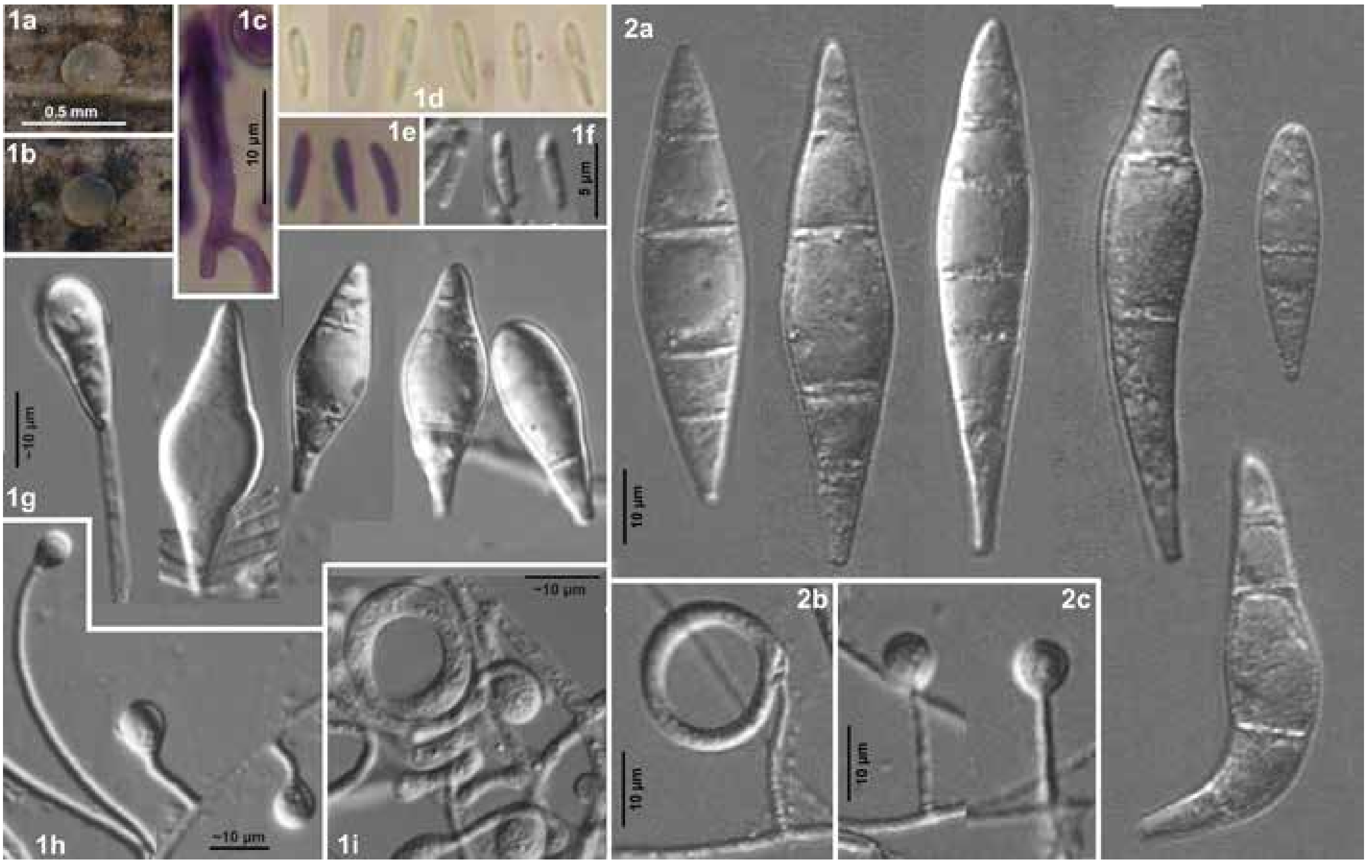


Plate 988. **1–2**: *Orbilia lysipaga*. – **1a–b**. rehydrated apothecia; **1c**. ascus; **1d–f**. ascospores; **1g**, **2a**. conidia; **1h**, **2c**. adhesive knobs; **1i**, **2b**. non-constricting rings (**1g–i**, **2a–c**. from culture). – Living state, except for **1d** (in H_2O), **1c**, **e** (in KOH+CB). – **1f–i**: from Liu (2006, figs 36–37), **2**: from Li et al. (2006). – **1a–i**. HMAS 1399697, H.B. 9202: China, Hunan, on *Phragmites*; **2a–c**. YMFT 1.000234 (holotype of *D. sichuanensis*): China, Sichuan, from soil.

The four strains with ITS vary by 0.5–1.8 %, the highest distance occurring between the types of *O. quercus* var. *hunanensis* and *D. sichuanensis*. The five strains with LSU are fully identical in the D1–D3 domain, except that KG-55 deviates by 1 nt in the D3 (pos. 919, GA**T**CC vs. **A**) and the reference specimen by 1 nt in the D2 (pos. 511, GG**T**GG vs. **C**) and 1 nt in the D3 (pos. 701, CG**G**AA vs. **A**). The deviating T in the D2 occurs in about 1/3 of the strains of series *Dactylellina*, therefore, it appears to be a trustable deviation, also G at pos. 701 is not unusual. T at pos. 919 is a rare exception in *Orbiliomycetes*, therefore, it could be erroneous. All these results permit to conclude that the four strains with ITS are conspecific, despite the absence/presence of the S1506 intron. Also the reference specimen might be conspecific, but it would be desirable to affirm this by an ITS sequence which does not exist in the CBS database. For the time being, we consider all these strains as belonging to *O. lysipaga*. The S1506 intron, which was only available for the type of *D. sichuanensis* (Tab. 89), shows a very high distance to any other strain which has this intron.

The similar *D. appendiculata* clustered strongly supported with *O. lysipaga*, but with a 6–6.5/1.7–1.9 % distance in the ITS/LSU (D1–D2) (Phyls 31, 32). An unlocalized strain under the name *Monacrosporium* sp. (YMF 1.01405, ITS+LSU) is somewhat intermediate, differing from *O. lysipaga* by 4–5/1.5 % and from *D. appendiculata* by 5.7/0.7 %.

The epithet *lysipaga* has very inconsistently been applied according to available molecular data. Besides YMF 1.00535 (China, *O. lysipaga* s.str.), ITS sequences of four further strains under the name *D. lysipaga* exist in GenBank. They appear very scattered in our phylogenetic analysis (Phyl. 31) and show distances of 10–13 % among each other, which permits to conclude that they belong to five different species: one from Australia (WAC 10294, ITS+LSU) fully concurs with the type of *D. appendiculata* (see p. 1606), one from Ottawa (CBS 486.63, Liou & Tzean 1997, SSU+ITS+LSU) fits the epitype of *D. ellipsospora*, one from Taiwan (ATCC 28265, Meyer et al. 2005, ITS) clustered in the *mammillata-paucus* clade near '*Monacrosporium*' *ullum,* and one from ?Taiwan (BCRC 34374, C.C. Kuo et al. ined., ITS) clustered near *D. haptotyla*. Regrettably, no morphological data from all these strains were available to us.

In Liu et al.'s (2006a) phylogenetic analysis of the ITS region, *O. quercus* var. *hunanensis* (= *O. lysipaga*) clustered in a clade with *O. quercus* var. *hainanensis* (= *O. ellipsospora*) and *M. ullum* (as *D. drechsleri* (GRII16D-5), but they show a rather high distance of 9–10.5 % to each other. *O. quercus* s.str. is situated with even higher distance (13–15 %) sister to this clade, which supports its separation at the species level. Also in the LSU the three varieties of *O. quercus* distinctly deviate from each other (3.5–5.3 %, see also Liu et al. l.c.).

In the *TUBB* gene region a Chinese strain under the name *D. lysipaga* (YMF 1.00535) fully matches one under the name *M. phymatopagum* (CBS 325.72), and both differ from KG-55 and the ex-type strain of *D. sichuanensis* by only ~1–2 %, while other species of *Dactylellina* differ by ~5–10 %. According to ITS analyses, however, CBS 325.72 belongs to *M. ullum*.

Ecology. *O. lysipaga* was originally isolated from leaf mould at two sites around Washington D.C. (Beltsville and Arlington) in warm-temperate humid eastern North America. The reference specimen of *O. lysipaga* is from a *Sphagnum* peat bog in a subtropical humid (somewhat summer-dry, mediterranean)

Table 89. Comparison of conidial and trapping features of the *O. lysipaga* type and reference strains and synonymous taxa (upper block). *D. appendiculata* (lower block) deviates phylogenetically from the here listed sequenced strains and probably represents a species of its own. Conidial size given according to the author's description, Curvat. = basal curvature of conidia, Tent. = basally inserted tentacles, Rings = non-constricting, S1506 = intron at 3'-end of SSU.

Species/strain	Conidia (µm)	Septa	Curvat.	Tent.	Rings	S1506	ITS	LSU
quercus var. *hunanensis* (type)	*30.4–40.2 × 10.6–13.2	2–**4**	–	–	+	–	DQ656613	DQ656704

volcano caldera in the Azores archipelago. The Asian records were from subtropical humid (winter-dry) forests, on *Phragmites* culms in the Suoxi Valley in the montane rocky (calcarean) Zhangjiajie Forest Park in southern China and from soil of the Emei Shan Permian volcano in southeastern China.

Specimens included. **USA**: **Maryland**, Beltsville, ?50–100 m, and **Virginia**, Arlington, ?0–100 m, leaf mould, undated, C. Drechsler (**type** of *O. lysipaga* [illustration], conid. isol., doc. vid.). — **MACARONESIA**: **Azores**, **Faial**, caldera of central volcano, 575 m, *Sphagnum* peat, V.1988, A.R. Bernitzky (**RefSpec** of *O. lysipaga*, strain PAO4728s [CBS 581.91], conid. isol., doc. vid.; sq.: AY261165). — **CHINA**: **Hunan**, **Zhangjiajie**, ~27 km N of Zhangjiajie, Suoxiyu river, 600 m, culms of *Phragmites australis*, 14.IX.2005, B. Liu & X.Z. Liu (B.L. 731, HMAS 139697, H.B. 9202, type of *O. quercus* var. *hunanensis*, anam. cult.; sq.: DQ656613, DQ656704, as *O.* cf. *quercus*). – **Sichuan**, Emei Shan, ?2000 m, from soil, 7.VIII.2002, L. Cao (YMFT 1.000234 **holotype** of *D. sichuanensis*; YMF 1.00023 ex-type culture, conid. isol., doc. vid.; sq.: AY902795, AY902803). — **UNLOCALIZED**: KG-55 (Li et al. 2006, as *Monacrosporium* sp., sq.: AY965747, AY965760). – YMF 1.01405 (Li et al. 2006, as *Monacrosporium* sp., AY965754, AY965768). – PAO4628s (YNUCC 3251, Li et al. ined., as *D. lysipaga*, sq.: AY261164).

Not included. **CHINA**: **Yunnan**, **Pu'er**, Simao, ?1300 m, soil, X.2005, D.S. Yang (YMF 1.01846, **holotype** of *D. illaqueata*).

Orbilia ellipsospora (Preuss) Bin Liu, E. Weber & Baral, **comb. nov.**, MB 813999 — Pls 989–990

Basionym: *Menispora ellipsospora* Preuss, in J.W. Sturm, Deutschl. Fl. Abt. 3, 6(29/30): 93, pl. 47 (1851)
≡ *Dactylella ellipsospora* (Preuss) Grove, J. Bot. (London) 24: 200 (1886)
≡ *Monacrosporium ellipsosporum* (Preuss) R.C. Cooke & C.H. Dickinson, Trans. Br. Mycol. Soc. 48: 622 (1965)
≡ *Dactylellina ellipsospora* (Preuss) M. Scholler, Hagedorn & A. Rubner, Sydowia 51: 110 (1999)
= *O. quercus* var. *hainanensis* Bin Liu, Xing Z. Liu & W.Y. Zhuang [as '*querci*'], in Liu (2006: 99, nom. inval., ICN Art. 29

Etymology: *ellipsospora*: after the ellipsoid conidia (though having a limoniform shape, with pointed ends); *hainanensis*: after the Chinese province Hainan.
Typification: Germany, Hoyerswerda, needles of *Pinus sylvestris*, undated, C.G.T. Preuss (holotype, illustration in Preuss 1851b: pl. 47); La Palma, Virgen del Pino, soil under *Pinus canariensis*, X.1992, G. Lysek (CBS H-5682, dried culture of CBS 302.94, neotype, designated by Rubner 1996; sq.: KT215202).
Misapplied name: Rubner (1996: 83, p.p.), as *Monacrosporium mammillatum*.

Description: — **TELEOMORPH** (after Liu 2006: 99): **Apothecia** fresh 0.3–0.8 mm diam., white, translucent, round, subgregarious; disc flat, margin smooth, not protruding; sessile. **Asci** †25–30 × 2.5–3 µm, 8-spored, spores †2–3-seriate, inversion unknown; **apex** medium truncate or hemispherical, thin-walled; **base** partly bifurcate. **Ascospores** *4.5–7 × 1–1.2 µm, subcylindrical to subfusoid, homopolar, apex obtuse, base only slightly attenuated, straight, rarely slightly inequilateral; **SB** 1 × 0.5 µm, ovoid, central, apically attached. **Paraphyses** apically hardly inflated. **Medullary excipulum** not examined. **Ectal excipulum** 25 µm thick near base, of textura angularis, cells 6–8 µm diam., 15 µm thick at margin, of t. prismatica oriented at 60–70°, marginal cortical cells without **glassy processes**. **Anchoring hyphae** not examined. **VBs** no data available. **Exudate** over paraphyses ?0.5–1 µm thick, cloddy, ± firmly attached. — **ANAMORPH** (after Drechsler 1937a, Rubner 1996 and Liu 2006): dactylellina-like (from ascospore isolate {1}): **Conidiophores** 50–300 µm long, unbranched, 3–4 µm wide at base, 1.5–2.5 µm at apex, conidia formed singly. **Conidia** *40–53(–57) × (8.5–)10–16.5(–18.5) µm, fusiform with both ends strongly attenuated, occasionally clavate with obtuse apex, (2–)4-septate, with a large swollen middle cell. **Adhesive knobs** with globose, 6–10 µm wide heads, stalks 5–23 × 2.2–4 µm. **Non-constricting rings** not formed.

Habitat: on rotten wood of unidentified trees {2}, *Picea abies* {1}, dung of *Oryctolagus cuniculus* (rabbit) {1}, or soil isolate {1}. **Desiccation tolerance**: probably intolerant. **Altitude**: 10–120 m a.s.l. (Europe), 1050 m (Macaronesia), 900 m (southern China). **Geology**: Tenerife: tephritic and phonolitic mafic flow. **Phenology**: XII (teleomorph, tropical belt).

Taxonomic remarks. No specimen of *Orbilia ellipsospora* was examined in the present study. The above description is taken from Liu (2006), who examined a sample from Hainan which he named '*O. querci* var. *hainanensis*'. According to his observations, the teleomorph hardly differs from that of *O. quercus* var. *hunanensis* (= *O. lysipaga*) and *O. quercus* s.str.

Anamorph. In the ascospore isolate of the collection from Hainan a dactylellina-like anamorph was obtained, which Liu (2006) identified as *Dactylellina ellipsospora* (Pl. 990). It is characterized by fusiform conidia with a strongly inflated middle cell, very similar in shape to the anamorph of *O. lysipaga* but very different from that of *O. quercus*. In conidial size *O. ellipsospora* distinctly overtops the other two species. Differences to *O. lysipaga* exist also in the trapping organs (see there).

Type studies. The original diagnosis by Preuss (1851a, 1851b, on *Pinus* needles) features ellipsoid conidia with pointed ends (limoniform), and ignores the septa. Grove (1886: 200, tab. 266 fig. 9) gave an emended description based on a personal sample, with fusiform conidia with 2 septa near each end very similar to those reported by Liu (2006). The 'central guttule' in the middle cell as reported by Grove and also mentioned by Preuss refers to glycogen, not to a lipid body. Also the description by Drechsler (1937a: fig. 8, Pl. 989: 2), who named the species '*Dactylella ellipsospora* Grove', fits well Liu's isolate.

According to Rubner (1996: 64), 'authentic material of *Menispora ellipsospora* is not preserved in B and could not be found in Klotzsch Herbarium vivum mycol. (in B)'. In the absence of type material and because the original description is insufficient, Rubner designated a neotype (from Tenerife, as *Monacrosporium ellipsosporum*, Pl. 989: 1, the here given conidial size was evaluated from the scale). This specimen could alternatively be considered as epitype because Preuss' illustration represents the holotype (Arts 9.9, 40.5 ICN).

Misapplication. According to available molecular data, some of the strains assigned by Rubner (1996) to *M. mammillatum* belong instead to *O. ellipsospora*.

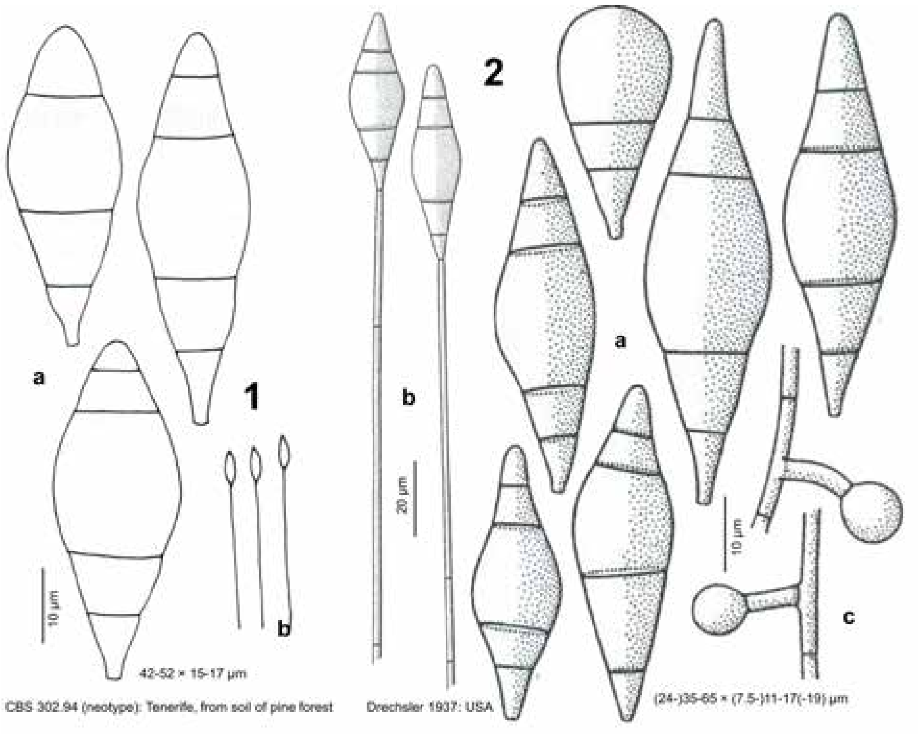

Plate 989. **1–2**: *Orbilia ellipsospora*. – **a**. conidia; **b**. conidiophores; **c**. adhesive knobs (from culture). – **1**: from Rubner (1996: 64), **2**: from Drechsler (1937a: 493).

Phylogeny. Sequences of seven strains that cluster in the *O. ellipsospora* clade were available, six in GenBank and one only in the CBS database. They comprise mainly ITS, also LSU (La Palma, Ottawa, Hainan, UK), and SSU (La Palma, Ottawa). The S1506 intron is absent, according to three strains that cover this region. In the ITS region *O. ellipsospora* shows a variation of 0–1.5 %. The strain from Ottawa was deposited as *D. lysipaga* in GenBank and reidentified as *D. mammillata* by Rubner (1996), but the other strains bear the name *M. ellipsosporum* or *D. ellipsospora*. With the here provided rDNA data of the ex-neotype strain (CBS 302.94) the molecular identity of *D. ellipsospora* could be settled. A molecular extract (ITS2) from a *Picea* log in northwestern Russia (Karelia) matches *O. ellipsospora* except for min. 2 nt and 1 gap (denovo140, Kazartsev et al. 2018).

Some other strains under the name *D. ellipsospora* exist in GenBank (e. g., Netherlands, CBS 325.72; USA, ATCC 204100), but they clustered in a different clade which includes also *D. 'drechsleri'* (GRII16D-5). Because also the ex-type strain of '*Monacrosporium*' *ullum* falls with high similarity in this clade, we here refer to this species as *M. ullum*. The presence of *D. ellipsospora* in two distant clades illustrates the confusing situation around this taxon, which was also stressed by Meyer et al. (2005). Another '*D. ellipsospora*' strain (YNWS02-8-1) belongs to *D. drechsleri*.

The type of *O. mammillata* clustered with *O. rubrovacuolata* and *M. ullum* in the strongly supported *mammillata-paucus* clade, which is phylogenetically distant from *O. ellipsospora* (Phyl. 31). The high molecular distance in the ITS (11–13 %) between *O. quercus* and *O. ellipsospora* supports separation of *O. quercus* var. *hainanensis* (= *O. ellipsospora*) at the species level. *O. lysipaga* and *D. leptospora* showed the lowest observed distance to *O. ellipsospora* (8–11.5 %). In the LSU *O. ellipsospora* varies by 1–2 nt.

When analysing LSU (Phyl. 32), *O. ellipsospora* formed with *D. drechsleri* a medium supported clade, but in the other analyses *D. drechsleri* clustered unresolved.

Ecology. The strains here included in *O. ellipsospora* have been collected on or isolated from hygric wood, leaf litter, dung, or soil. They derive from a tropical humid (winter-dry) rainforest in Hainan at the very south of China, a mesomediterranean semihumid Canary pine forest (*Sideritido solutae-Pinetum canariensis*) in Macaronesia, subcontinental cold-temperate humid areas in northwestern and central Europe, a boreal humid forest in eastern Canada, and a warm-temperate humid climate in eastern USA. The British Fungal Database lists four records from Yorkshire and Surrey between 1885 and 1948.

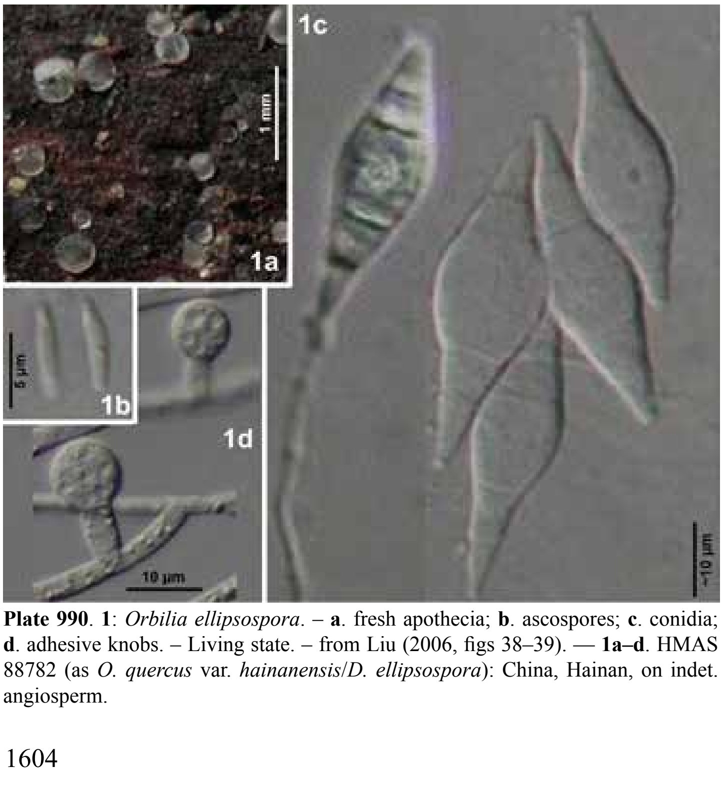

Plate 990. **1**: *Orbilia ellipsospora*. – **a**. fresh apothecia; **b**. ascospores; **c**. conidia; **d**. adhesive knobs. – Living state. – from Liu (2006, figs 38–39). — **1a–d**. HMAS 88782 (as *O. quercus* var. *hainanensis*/*D. ellipsospora*): China, Hainan, on indet. angiosperm.

Orbilia apiculata Z.F. Yu & M. Qiao, in Zhang et al. (in prep.) — Pl. 991

Etymology: referring to the tail-like upper end of conidia.

Typification: China, Yunnan, Chuxiong, on indet. wood, 10.X.2006, Z.F. Yu & M. Qiao (YMF1.01861, holotype; ex-type culture: CBS 125669; CGMCC 3.18830).

Description (from Zhang et al. in prep.): — **TELEOMORPH**: **Apothecia** gregarious, 0.2–0.5 mm diam., pale yellow with white centre when fresh, margin indistinctly finely crenulate; sessile, superficial. **Asci** *30–33 × 3.5–3.6 µm wide, †26.5–32 × 3.2–3.6 µm, 8-spored, lower ~3 spores inverted, pars sporifera *13.5–16.5 µm long; **apex** truncate; **base** with short to medium long stalk, h-shaped. **Ascospores** *4–6 × 1–1.2 µm, subcylindrical to slightly fusoid, straight, apex rounded to obtuse, slightly attenuated towards base. **SBs** ~1–1.5 × 0.3–0.5 µm, rod- (to tear-)shaped, slightly eccentrical, apically attached, with 2–3 LBs ~0.2–0.4 µm diam. **Paraphyses** slightly capitate, terminal cell †20 × 2.3–2.6 µm, lower cells 4.5 × 1.8 µm. **Ectal excipulum** of textura globulosa-angularis, upper margin of hyphoid cells oriented at a ~40–50° angle to the surface, cortical cells inflated, balloon-like, †6–8 × 3.5–5 µm. **SCBs** and **VBs** no data available. **Exudate** 0.2–0.5 µm thick, granular, firmly attached. **ANAMORPH**: dactylellina-like (from ascospore isolate). **Conidiophores** 50–160 µm high, unbranched, 2–2.5 µm wide at base, gradually tapering to a width of 1.5 µm at the apex, bearing a single conidium. **Conidia** *(34–)40–48.5(–51) × (9.3–)12–17(–18.5) µm, (3–)4(–5)-septate, fusiform (top-shaped), strongly tapered towards both ends, upper part tail-like, always longer than basal part, apex subacute, base subtruncate, middle cell much larger than other cells. **Adhesive knobs** subsessile, head subglobose to broadly ellipsoid, *3.2–4.2 × 2.9–3.3 µm, stipe-like base very short and broad, 0.3–0.5 × 1.5–2 µm. **Chlamydospores** not observed in culture.

Habitat: on indet. rotten wood lying on moist ground. **Desiccation tolerance**: probably intolerant. **Altitude**: ~1870 m a.s.l. **Geology**: Proterozoic metamorphic rock. **Phenology**: X.

Taxonomic remarks. *O. apiculata* resembles *O. quercus* which appears to differ merely in slightly longer ascospores (*5–6.5 µm).

Anamorph. In contrast to *O. quercus*, *O. apiculata* has larger, fusiform conidia with strongly attenuated ends, the upper end being elongated like a tail, and with predominantly 4 septa, also in almost sessile and much smaller adhesive knobs (*3.5–4.2 × 3.2–3.6 vs. *8–12 × 7.5–10 µm). Among species without known teleomorph, *D. phymatopga* (= *D. parvicollis*) has comparable though larger subsessile to sessile adhesive knobs.

Phylogeny. In our NJ analysis of the ITS region (Phyl. 31), *O. apiculata* clustered with an 8.5–13% distance with *D. tibetensis* nom. nud. and *O. quercus* in a strongly supported clade (*quercus-apiculata* clade).

Ecology. *O. apiculata* derives from a subtropical humid (winter-dry) highland evergreen forest in southern China.

Specimens included. **CHINA**: **Yunnan**, **Chuxiong**, Lufeng, 53 km NW of Kunming, ~2 km S of Bichengzhen, Yulong Temple, N of Shengli, ~1870 m, on indet. wood, 10.X.2006, Z.F. Yu & M. Qiao (YMF 1.01861, **holotype**, CBS 125669, CGMCC 3.18830; sq.: MF948418).

Orbilia biforma Z.F. Yu & M. Qiao, in Zhang et al. (in prep.) — Pl. 992

Etymology: referring to the formation of 2 types of conidia.

Typification: China, Yunnan, Honghe, Pingbian, on indet. bark, 16.VIII.2006, Z.F. Yu, M. Qiao & Y. Zhang (YMF/T 1.01859, holotype; further ex-type cultures: CBS 126101, CGMCC3.18829).

Description (from Zhang et al. in prep.): — **TELEOMORPH**: **Apothecia** fresh 0.2–0.5 mm diam., gregarious, sessile, superficial; disc pale yellow, margin ?smooth. **Asci** †24.5–27 × 2.8–3.2 µm, 8-spored, spores †1–2-seriate, orientation unknown, pars sporifera

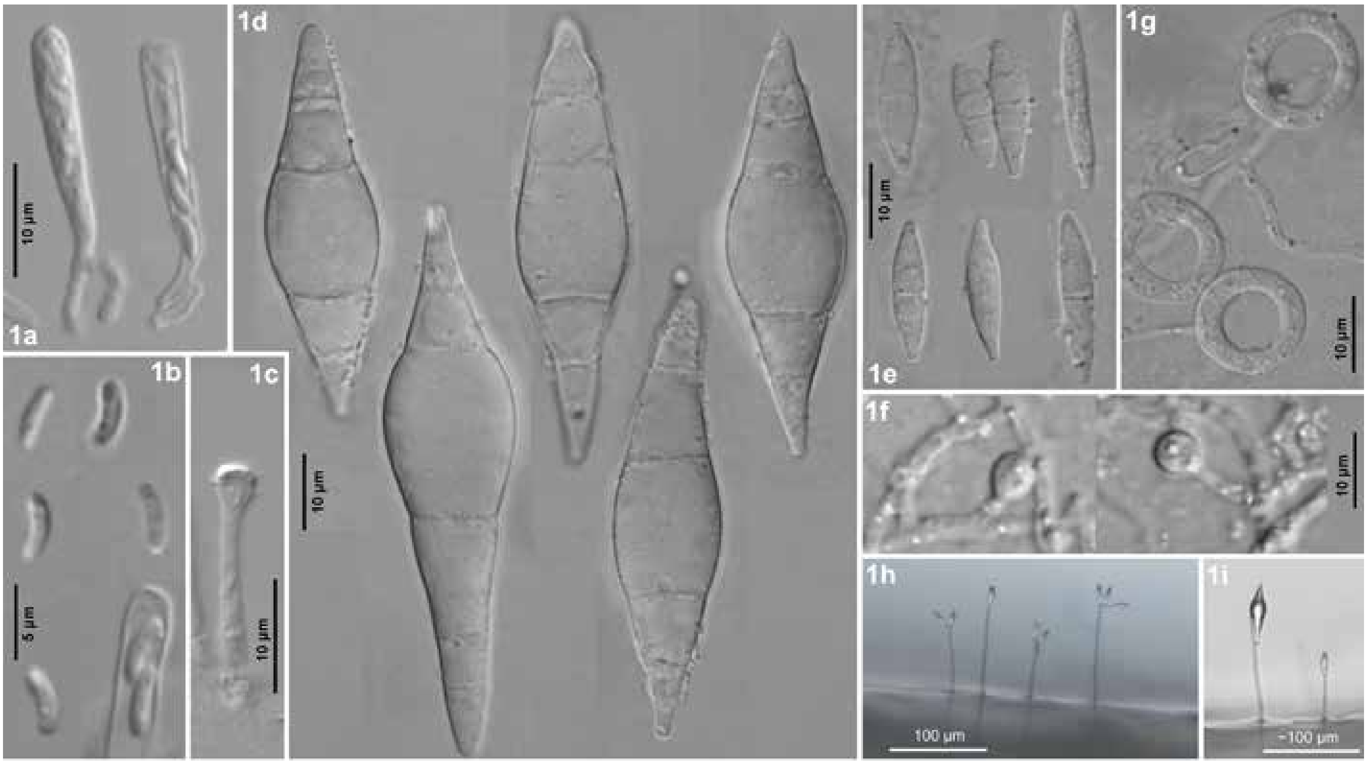

Plate 992. **1**: *Orbilia biforma* (holotype). – **1a**. asci; **1b**. ascospores; **1c**. paraphysis; **1d**. macroconidia; **1e**. microconidia; **1f**. adhesive stalked knobs; **1g**. non-constricting rings; **1h**. microconidiophores with microconidia; **1i**. macro- (left) and microconidiophore (right). – Living state, except for asci, paraphyses, and spores inside asci (in H_2O), **1d–i** from culture. – from Zhang et al. (in prep.). – **1a–i**. YMF1.01859 (holotype): China, Yunnan, on indet. woody plant.

†~16–19 µm long; **apex** truncate, hemispherical in profile view, thin-walled; **base** usually with short stalk, h- to L/H-shaped. **Ascospores** *4.2–4.7 × 1–1.2 µm, cylindrical, with rounded ends, slightly to mostly medium curved (allantoid). **SBs** 1–1.2 × 0.5 µm, rod- to tear-shaped, apically attached, partly eccentrical, with 1–2 small LBs. **Paraphyses** slightly to medium capitate, terminal cells †13–14 × 2.5–3.5 µm, lower cells †3.5–4.5 × 2.3–2.5 µm. **Ectal excipulum** not studied. **SCBs** and **VBs** no data available. **Exudate** 0.2–0.5 µm thick, ± granular, firmly attached. — **ANAMORPH**: dactylellina-like (from ascospore isolate). **Macroconidiophores** 96–182 µm high, unbranched, 2–2.5 µm wide at base, gradually tapering upwards to a width of 0.5–1 µm, bearing 1 single conidium. **Macroconidia** *42–72.5 × 12–17 µm, ((3–))4(–5)-septate, fusiform, strongly narrowed towards both ends, truncate at base, rounded at apex, middle cell much larger than other cells. **Microconidiophores** 47–90 µm high, unbranched or with short apically branches, bearing 1–3 conidia. **Microconidia** *14–24 × 3.7–5 µm, 1(–3)-septate, narrowly subcylindrical to fusoid to fusiform, with or without basal protrusion. **Adhesive knobs** stalked, with subglobose head of *6–7 × 4.5–5.5 µm and long stalk of *5.5–11 × 2 µm. **Non-constricting rings** with an outer diameter of *13–17 µm and an inner diameter of 7–10 µm, 3-celled, ring cells *3–3.5 µm wide, slightly constricted at septa, stalk ~12–15 × 1.5 µm. **Chlamydospores** not observed in culture.

Habitat: on indet. rotten bark lying on moist ground. **Desiccation tolerance**: probably intolerant. **Altitude**: 1320–1400 m a.s.l. **Geology**: Proterozoic metamorphic rock. **Phenology**: VIII.

Taxonomic remarks. In the ascospores *O. biforma* and *O. umbilicata* (treated under series *Orbilia*) are very similar, but *O. umbilicata* sharply differs in having globose SBs, lanceolate paraphyses, and larger apothecia.

Anamorph. *Orbilia biforma* differs from most other species of series *Dactylellina* in forming both macro- and microconidia. Microconidia were otherwise only described in *D. leptospora* (Tab. 15) which has much narrower macroconidia without a larger middle cell. In its fusiform macroconidia *O. biforma* resembles the anamorphs of *O. ellipsospora* and *O. lysipaga*, but differs in smaller non-constricting rings with equally broad ring cells, consequently a distinctly narrower inner diameter.

Phylogeny. In our NJ analysis of the ITS region (Phyl. 31), *O. biforma* clustered with medium support and a 5.8–6.5% distance sister to *D. leptospora*, suggesting taxonomic relevance for the presence of microconidia.

Ecology. *O. biforma* was collected in a subtropical humid (winter-dry) montane evergreen forest in southern China.

Specimens included. **CHINA**: **Yunnan**, **Honghe**, Pingbian, 1.5 km SW of Yuping, Aoga, 1320–1400 m, on bark of indet. tree, 16.VIII.2006, Z.F. Yu, M. Qiao & Y. Zhang (YMF/T1.01859, **holotype**, further ex-type cultures in CBS 126101, CGMCC 3.18829; sq.: MF948417, MF948531, MF948457, MF948601).

Species without known teleomorph

Dactylellina appendiculata (Anastasiou) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 110 (1999) — Pl. 9: c

≡ *Dactylella appendiculata* Anastasiou, Pacific Sci. 18: 202 (1964)
≡ *Laridospora appendiculata* (Anastasiou) Nawawi, Trans. Br. mycol. Soc. 66(2): 344 (1976)
≡ *Monacrosporium tentaculatum* A. Rubner & W. Gams, Stud. Mycol. 39: 97 (1996) [non *Monacrosporium appendiculatum* (Mekht.) Xing Z. Liu & K.Q. Zhang]

The ex-type strain of *D. appendiculata* from Hawaii (CBS 206.64) and a strain under the name *D. lysipaga* from Australia (WAC 10294) are fully identical in the overlapping SSU (V8–V9), ITS, and LSU (D1–D2), except for a possibly erroneous deviation at the 3'-end of the D2 domain. In both strains the S1506 intron is absent. *D. appendiculata* differs from *O. lysipaga* in lacking non-constricting rings (Tab. 89), but it forms a medium to strongly supported clade with this species in the here proposed sense, with a 6–6.5/1.7–1.9 % distance in the ITS/LSU (D1–D2) (Phyls 31–32, S35).

Dactylellina asthenopaga (Drechsler) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 110 (1999) — Pl. 7: d

≡ *Dactylariopsis asthenopaga* (Drechsler) Mekht., Mikol. Fitopatol. 1: 279 (1967)
≡ *Dactylella asthenopaga* Drechsler, Mycologia 29(4): 498 (1937)
≡ *Monacrosporium asthenopagum* (Drechsler) A. Rubner, Stud. Mycol. 39: 50 (1996)

Although *D. asthenopaga* was described with stalked adhesive knobs, two strains identified so belong to series *Neodactylella*. One from the Netherlands (**CBS 917.85**, U51962, on decaying wood) clustered in Li et al.'s (2006) phylogenetic analyses of ITS, LSU, or *TUBB*, and in Hagedorn et al.'s (1999: 34) ITS analysis in a clade which corresponds to series *Neodactylella*. This strain did not form trapping organs when studied by Rubner (1996: 52), hence it seems to be misidentified. In conidial morphology it resembles *Dactylella clavispora*, and actually it fully concurs in the ITS with the type (CBS 844.70), except for 2 gaps, and in the LSU D1–D2 it differs by 2 nt from H.B. 8371a (see Phyls 26–27, S31). Another strain (**CBS 262.83**, Australia, Queensland, from soil), for which only LSU exists in GenBank (AY965770), fully concurs in the D1–D2 domain (and almost so in D3) with one under the name *D. implexa* (AY261175, unlocalized) when comparing the unofficial LSU sequence in CBS, hence appears to be conspecific (see S31). Also an ITS sequence exists in the CBS database for CBS 262.83, which shows a ~15–17 % distance to *D. clavata*, *D. ramosa*, and *D. xinjiangensis* (no ITS of *D. implexa* exists in GenBank).

Three further strains under the name *Dactylellina asthenopaga* or *Monacrosporium asthenopagum* belong in series *Dactylellina*: a British strain (**CBS 222.54**, S.M.D. 47, unlocalized) shows a 5.5–6.5 % ITS distance in the CBS database to three Chinese strains of *D.* aff. *drechsleri* (DQ999828, DQ999829, DQ999830) as closest taxon, which form a distinct subclade within the *O. drechsleri* s.l. clade and differ by 1–4 % from each other. In the LSU D2–D3 (MH868834) it clustered with *D.* aff. *drechsleri* YMF 1.00573 (not shown, 5 nt difference, all in D2). Another British strain (**CBS 227.52**, S.M.D. 33, Wimbledon Common, wood of *Quercus petraea*) fully matches in the LSU (D1–D3) *D. phymatopaga* (CBS 325.72), which in turn belongs to *M. ullum* according to its ITS sequence. Thus, CBS 227.52, for which no ITS sequence appears to exist, is *M. ullum*. A strain from Taiwan (FJ380933, **BCRC 34369**) reported by Kuo et al. (2008) shows a 4.7 % ITS distance to *A. paucus*, 5.5–6 % to *M. ullum*, and 9 % to CBS 222.54.

No authentic sequence or ex-type culture appears to exist for *D. asthenopaga*, which was described by Drechsler (1937a) from humus and especially seeds of *Quercus prinus* in Maryland and Virginia (USA). Its stalked adhesive knobs prompted Scholler et al. (1999) to transfer it to *Dactylellina*. Rubner (1996) examined the four CBS strains and could not observe trapping organs in any of them, including those belonging to series *Dactylellina*, although Duddington (1951) reported them in strain CBS 227.52. For the Taiwan strain, Kuo et al. (2008) illustrated stalked adhesive knobs and fusoid-clavate conidia on unbranched conidiophores which closely resemble Drechsler's *D. asthenopaga* except for slightly wider, more fusoid conidia with longer terminal cells when 2-septate.

Dactylellina haptotyla (Drechsler) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 110 (1999) — Pl. 8: b (**non-constricting rings absent**, **adhesive knobs large**)

≡ *Dactylaria haptotyla* Drechsler, Mycologia 42(1): 48 (1950)

≡ *Monacrosporium sclerohyphum* (Drechsler) Xing Z. Liu & K.Q. Zhang, Mycol. Res. 98(8): 865 (1994)

Dactylellina yunnanensis (K.Q. Zhang, Xing Z. Liu & L. Cao) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 111 (1999) (**non-constricting rings present**, **adhesive knobs small**)

≡ *Monacrosporium yunnanense* K.Q. Zhang, Xing Z. Liu & L. Cao, Mycol. Res. 100(3): 275 (1996)
= *Dactylaria candida* s. Drechsler (1937a), Peach (1950) and others

Dactylaria candida s. Drechsler (1937a, see Pl. 8: h) was synonymised with *Monacrosporium haptotylum* (Pl. 8: b) by Rubner (1996: 72), although Drechsler (1950a) distinguished the former by producing non-constricting rings and much smaller adhesive knobs (*4–7 × 3.8–6 vs. *7–10 × 6–8.5 µm diam.). Rubner (1996: 120) further assumed that *Monacrosporium yunnanense* (erroneously cited as *Dactylella yunnanensis*), a taxon which likewise formed non-constricting rings and small knobs of 5–7.5 × 4.5–6 µm (Zhang et al. 1996, see Pl. 8: f), is conspecific with *M. haptotylum*, based on personal study of the type culture (CBS 615.95) but without seeing the protologue which presents distinctly longer conidia than described by Drechsler. Also *Dactylaria sclerohypha* (Drechsler 1950a) was included in synonymy by Rubner, because it differs from the protologue of *M. haptotylum* merely in producing chain-like chlamydospores, a feature found to be variable and therefore unreliable (see Cooke & Satchuthananthavale 1966). Yu et al. (2014) accepted Rubner's concept but adopted instead the name *Dactylellina candida* instead of *D. haptotyla*.

Available molecular data suggest that three different, though closely related species are involved in the current concept of *D. haptotyla*/*D. candida*, which form three distinct clades (A–C) when analysing ITS (Phyl. 33): clade A comprises nine strains, including the Chinese isotype of *D. yunnanensis* (CBS 615.95), clade B comprises five strains, including the German epitype of *D. haptotyla* (CBS 326.94, Berlin, with non-constricting rings, knobs not figured), and clade C includes two strains with unavailable morphology (one identified as *D. candida*). To clade B belongs also the Californian strain ATCC 204099 (EF446016) for which only ITS2 was available (not shown).

Each clade is genetically highly homogeneous: 1 nt varies in the ITS1 of clade A (4 strains have C, 5 strains T), and 1–2 gaps occur in the ITS2 of two strains of clade B. Rare deviations in the 5.8S in clades A (pos. 51, YMF 1.01466) and B (pos. 32, CBS 200.50) are accidental mutants or sequencing errors (the deviation at pos. 32 is absent in the sequence of the CBS database). Clades A and B differ by 1.4–1.5 %, whereas clade C deviates by 3.7–5 % from clade B and 4.5–5.7 % from clade A.

Three other names were previously in use for strains of *D. haptotyla* s.l.: (1) *M. sclerohyphum* for two strains of clade A, (2) *D./D. candida/M. candidum* for two strains of clade A, 4 of clade B, and one of clade C, and (3) *D. lysipaga* for one species of clade C. For two strains of clade B the presence of non-constricting rings was documented (CBS 200.50, Peach 1950: fig. 8; CBS 326.94, Rubner 1996: fig. 32a), and for one of clade A the absence of non-constricting rings and broader conidia (CBS 325.94, Rubner 1996: fig. 32b). This suggests that clade A represents *D. haptotyla* and clade B *D. yunnanensis*. However, the type of *D. yunnanensis* (CBS 615.95), which forms non-constricting rings, clustered in clade A, which supports Rubner's opinion that non-constricting rings are of doubtful value and dimensions of conidia and adhesive knobs variable.

Irrespective of this problem, we suspect a confusion regarding CBS 616.95, the type culture of the adhesive net forming *Arthrobotrys guizhouensis* nom. inval. (≡ *A. huaxiensis*, see p. 1581), described in the same paper as *M. yunnanense* (CBS 615.95), because ITS and LSU sequences in the CBS database fully concur with those of CBS 615.95. Also G. Hagedorn's SSU+ITS+LSU sequence of CBS 616.95 (KT215198) fully concurs herewith and with GenBank ITS sequences of CBS 615.95 (AY965757, MH862541), therefore, when uploading Hagedorn's data we changed the CBS number to 615.95. Resequencing of CBS 616.95 or reexamination of the culture for conidial and trap organ morphology could clarify this confusing case.

When analysing LSU D1–D2 (Phyl. 32), 2 nt (pos. 133/561) differ among the available strains of *D. haptotyla* s.l. and sharply separate clade A (2 strains, A/A) from clade B (5 strains, G/G) (no LSU sequence was available for clade C). In our analysis of SSU+ITS+LSU, only one species of *D. haptotyla* s.l. (CBS 615.95, clade A) was included in Phyls 25, S35 where it clustered unresolved in series *Dactylellina*.

Based on the available data we may conclude that Drechsler was right in separating different species. However, whether one of them (his *Dactylaria candida*) can be distinguished based on smaller adhesive knobs, narrower conidia, and non-constricting rings remains unclear. Because of the possible taxonomic value of non-constricting rings, Rubner's epitypification of *D. haptotyla* on CBS 326.94 (from Berlin, clade B) seems unacceptable. Better would have been to propose CBS 325.94 (from Tenerife, clade A) as epitype, which seems to be in closer concordance with Drechsler's protologue of *D. haptotyla*.

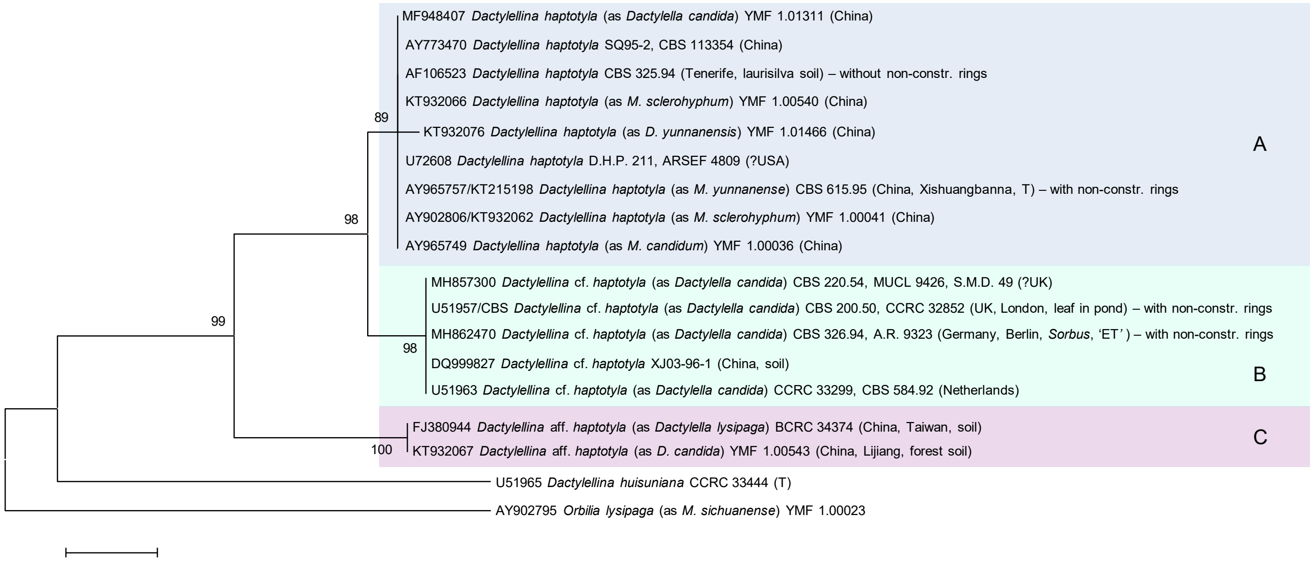
The original identity of *Dactylium candidum* Nees, the type species of *Dactylium* Nees, is dubious. Both genus and species are treated as nomina utique rejicienda (ICN appendix V) following a proposal by Gams & Rubner (1997), who argued that *Dactylium* would replace the widely used *Monacrosporium* if *Dactylium candidum* would be neotypified in the sense of *M. haptotylum*. In the new classification (Scholler et al. 1999) *Dactylium* would likewise replace the established generic name *Dactylellina*.

Monacrosporium chiuanum Xing Z. Liu & K.Q. Zhang was tentatively synonymised with *M. haptotylum* by Rubner (1996) and Yu et al. (2014). Since the taxon was described by Liu & Zhang (1994) without trapping organs and no sequence was available, its relationship remains obscure.

Dactylellina leptospora (Drechsler) M. Morelet, Bull. Soc. Sci. nat. Arch. Toulon et du Var 178: 6 (1968) — Pl. 7: k

≡ *Dactylella leptospora* Drechsler, Mycologia 29(4): 507 (1937)
≡ *Dactylosporium leptosporum* (Drechsler) Mekht., Mikol. Fitopatol. 1: 277 (1967)
≡ *Monacrosporium leptosporum* (Drechsler) A. Rubner, Stud. Mycol. 39: 79 (1996)
= *Dactylaria dasguptae* S.K. Shome & U. Shome [as '*dasguptaii*'], Mycopath. Mycol. appl. 30: 216 (1966), nom. inval., ICN Art. 40 (type material not indicated)
≡ *Arthrobotrys dasguptae* (S.K. Shome & U. Shome) S. Schenck, W.B. Kendr. & Pramer, Can. J. Bot. 55(8): 982 (1977)
≡ *Dactylella dasguptae* (S.K. Shome & U. Shome) de Hoog & Oorschot [as '*dasguptaii*'], Stud. Mycol. 26: 105 (1985)
= *Dactylellina formosana* (J.Y. Liou, G.Y. Liou & Tzean) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 110 (1999)

Rubner (1996) incorrectly stated a North American strain (ATCC 36915 = CBS 560.92), which was deposited under the name *Dactylaria dasguptae*, to be the type of *D. dasguptae*, which was actually collected in West Bengalen, India (Shome & Shome 1966). Simultaneously, Rubner proposed this North American strain as epitype of *Dactylellina leptospora*. *Dactylaria dasguptae* she considered as a synonym of *D. leptospora*, because differences in apical branching of conidiophores



Phylogenetic analysis 33. Phylogram of *Dactylellina haptotyla* s.l. complex inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (18 sequences, 544 positions, aligned with MUSCLE) using the JC+I model in MEGA6 (500 replicates). The tree is rooted with *O. lysipaga* and *D. huisuniana*. T = type, ET = epitype.

seemed not convincing, and the absence of adhesive knobs on hyphae (but not on conidia) in Drechsler's material remained the only distinguishing character.

This epitype strain clustered in a clade with the type strain of *D. formosana* (Taiwan, CCRC 32740) and three further strains from China and South Africa identified as *D. leptospora* (Phyl. 31). The species formed with *O. biforma*, for which only ITS was available, a medium supported clade with a distance of 5.8–6.5%. The high ITS similarity among the strains (0–1% distance, 1% between the two types) suggests conspecificity. Also in the LSU (D1–D2) only 0.2% differ among the three available sequences of *D. leptospora* (Phyl. 32). *D. leptospora* clustered unresolved in series *Dactylellina* in our combined analyses (Phyls 25, S35).

Hagedorn & Scholler (1999: 36), however, doubted Rubner's concept and assumed that the ex-epitype strain might not belong to *D. leptospora* in a narrow sense, because it formed solely adhesive knobs on conidia and hyphae but no non-constricting rings. Also *D. formosana* was described with adhesive knobs only, and for the three further strains no information was available in respect to trapping organs. Since *D. leptospora* and also *D. dasguptae* were originally described with both adhesive knobs and non-constricting rings, it appears possible that the true *D. leptospora* is still without a sequence.

The description of *D. dasguptae* is invalid because two collection sites were mentioned in the Latin protologue (gardens of two different towns, Kalyani and Haringhata) and no holotype was designated, although description and plates solely derive from the Haringhata sample.

Dactylellina multiseptata (H.Y. Su & K.Q. Zhang) Z.F. Yu, in Zhang & Hyde (eds), Nematode-trapping Fungi: 155 (2014) — Pl. 9: f

≡ *Monacrosporium multiseptatum* Hong Y. Su & K.Q. Zhang, Mycotaxon 92: 194 (2005)

See under series *Neodactylella* (p. 1513).

'Arthrobotrys' paucus J.S. McCulloch [as '*pauca*'], Trans. Br. mycol. Soc. 68(2): 176 (1977)

The ex-holotype strain of *Arthrobotrys paucus* (Australia, Queensland, Woodridge, soil around strawberry, I.1969, A. Shewchenko, isolated by J. McCulloch, Pl. 7: a) is found in different culture collections (CBS 642.80, ATCC28704, IMI 143686, BRIP 11223) and in GenBank under the name *A. entomopagus* (AY965758, ITS), because it was synonymised herewith by Roxon & Jong (1975) followed by Van Oorschot (1985: 78), based on similar adhesive knobs and 1-septate conidia. Roxon & Jong studied the ex-type strain before it was given the name *A. paucus* by McCulloch (1977), and declared it as neotype of *A. entomopagus*.

Roxon & Jong described the adhesive knobs of the later *A. paucus* type strain with globose upper cells, but they did not provide an illustration. According to the protologues in Drechsler (1944b) and McCulloch (1977), and a LM/TEM study of *A. entomopagus* by Saikawa et al. (2010), *A. entomopagus* differs from *A. paucus* by adhesive knobs with ellipsoid head with a very thick mucilage that capture springtails, also by conidiophores with longer denticles and slightly longer and narrower conidia (Pl. 14: b). *A. paucus* is sufficiently different in having adhesive knobs with (sub)globose head covered by very thin mucilage.

No sequence of the ex-type strain of *A. entomopagus* was available. Because of the special trapping organs adapted to arthropods we suppose that *A. entomopagus* belongs in close relationship of *Orbilia alba*, a member of series *Gamsylella*, in contrast to the opinion of Scholler et al. (1999) who placed *A. entomopagus* in *Dactylellina* because of having adhesive knobs. Our sequence of the ex-type strain of *A. paucus* (KT215205, SSU, ITS, LSU) concurs with AY965758 in the ITS and clustered in series *Dactylellina* in the strongly supported *mammillata-paucus* clade (Phyl. S35). Also *RPB2*, *TEF1, MAD1,* and *TUBB* of *A. paucus* exist in GenBank under the wrong name *Arthrobotrys entomopagus*.

Dactylellina phymatopaga (Drechsler) Yan Li, in Li, Hyde, Jeewon, Cai, Vijaykrishna & Zhang, Mycologia 97(5): 1042 (2006) [2005] — Pl. 8: d, i

≡ *Dactylella phymatopaga* Drechsler, Mycologia 46(6): 775 (1954)
≡ *Monacrosporium phymatopagum* (Drechsler) Subram. [as '*phymatophagum*'], J. Indian bot. Soc. 42: 293 (1964) [1963]

= *Dactylellina parvicollis* (Drechsler) Yan Li, in Li, Hyde, Jeewon, Cai, Vijaykrishna & Zhang, Mycologia 97(5): 1042 (2005) [2006]
≡ *Dactylella parvicollis* Drechsler, Sydowia 15(1-6): 13 (1962) [1961]
≡ *Monacrosporium parvicolle* (Drechsler) R.C. Cooke & C.H. Dickinson, Trans. Br. mycol. Soc. 48(4): 622 (1965)
≡ *Golovinia parvicollis* (Drechsler) Mekht., Khishchnye Nematofagovye Griby - Gifomitsety (Baku): 162 (1979)
≡ *Gamsylella parvicollis* (Drechsler) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 109 (1999)
= *Monacrosporium shuzhengense* X.F. Liu & K.Q. Zhang nom. nud. (in Li et al. 2005)

Dactylellina parvicollis was thought by Rubner (1996) and Scholler et al. (1999) to be a species distinct from *D. phymatopaga* because of slightly smaller conidia and the frequent presence of superimposed knobs that form rings on their tip. Yet, molecular data show that the ex-syntype strain of *D. parvicollis* from Colorado (CBS 219.61) is conspecific with the German ex-epitype strain of *D. phymatopaga* (CBS 450.93, KT215207), showing an ITS distance of only 0.2% (1 nt). Liu et al.'s (2002) report of *M. parvicolle* as anamorph of *O. cunninghamii* refers to *O. quercus*/*D. quercus* (see p. 1597).

Various European and Asian strains belong to this species based on available ITS and LSU data (Phyls 31–32), including *Monacrosporium shuzhengense* (discussed in Li et al. 2005 but not validly published). They differ by 0–0.6% in the ITS, though sequences in the CBS database differ up to 1.2% (CBS 590.91), and show full identity in the LSU (D1–D2). Two misidentified strains are referred to as *D.* aff. *phymatopaga* here, as they clustered outside of series *Dactylellina* (see under Specific nucleotide positions in series *Dactylellina*, p. 1585).

Dactylellina tibetensis nom. nud. (mentioned in Yang et al. 2007: 8380, 8382)

This undescribed Chinese taxon clustered with an ITS distance of 0.6% (3 nt) with an obviously conspecific environmental strain from grassland soil in California. Both formed a strongly supported clade with *O. apiculata* and *O. quercus*, with a distance of 7.7–10% to them (Phyl. 31). Also LSU D1–D2 exists for the Californian strain, differing from *O. quercus* by 1.7%. In our combined analysis (S35), *O. quercus* and *D. tibetensis* (not shown) formed with *D. phymatopaga* a medium supported clade, with an ITS/LSU distance of 9.5–10.5/2.2–2.3 % between *D. tibetensis* and *D. phymatopaga*.

CHINA: **Tibet**, collection data unavailable (XZ04-92-1, sq.: DQ999833). — **USA**: **California**, 70 km WNW of Los Angeles, 5 km SW of Newbury Park, Rancho Sierra Vista, grassland soil, 275 m, 30.V.2008 (G1_GB11, mol. extr., JX043462, JX043463).

'Monacrosporium' ullum D.G. Kim, Ryu & H.G. Hwang, Pl. Path. J. 22(2): 174 (2006), nom. inval., ICN Art. 40 (type material not indicated)

= *Dactylellina drechsleri* s. Meyer et al. (2005)

When describing *M. ullum*, Kim et al. (2006) provided an ITS sequence of the ex-type strain isolated from soil around *Codonopsis lanceolata* in Ulleung island (east of South Korea). The authors published this sequence in their article but did not upload it in an official database repository. Except for one insert in the ITS1 (GGCG**C**CTTAA), it fully coincides with one of the three sequences of *D. drechsleri* s. Meyer et al. (2005: AY773448, from Minnesota, USA), whereas Meyer et al.'s other two sequences (AY695063, AY695065), which are identical (a repeat of TAACATT in the ITS1 might be an error), deviate by 3 nt (always C instead of T). Some further strains from China, USA, and the Netherlands under the names *M. ellipsosporum*, *M. phymatopagum*, and *D. asthenopaga* (erron. as *asterospermum*) are undoubtedly conspecific according to molecular data of either ITS or LSU (see Phyls 31–32), including an uncultured North American clone for which only ITS1 is available (FJ778149). In the ITS a variation of 0–1 % is observed, and in the LSU 0–0.2 %. Accordingly, *M. ullum* was isolated from rotten plant material or soil in Europe, North America, and Asia.

Morphologically, Kim et al. (2006) characterized *M. ullum* by the absence of non-constricting rings in contrast to *M. candidum*. They also stressed the smaller, mainly 2-septate conidia in comparison to *M. ellipsosporum*, *M. drechsleri* and others. In Kim et al.'s phylogenetic analysis, '*M. ellipsosporum*' and '*M. drechsleri*' (s. Meyer et al.) belong with *M. ullum* to a single species, while their '*M. lysipagum*' (s. Meyer et al., ATCC 28265) represents a close, possibly distinct taxon showing a 2.5 % distance to them.

In our combined analysis (Phyl. S35), the only *M. ullum* strain with both ITS and LSU (CBS 325.72) clustered within series *Dactylellina* in the strongly supported *mammillata-paucus* clade.

Dactylellina varietas Yan Li, K.D. Hyde & K.Q. Zhang, in Li, Jeewon, Hyde, Mo & Zhang, Mycol. Res. 110(7): 792 (2006) — Pl. 9: a

Series *Gamsylella*

Orbilia subgenus ***Orbilia*** section ***Arthrobotrys*** series ***Gamsylella*** (M. Scholler, Hagedorn & A. Rubner) Baral & E. Weber, **comb. & stat. nov.**, MB 814995 – Type species: *Dactylella arcuata* Scheuer & J. Webster

Basionym: *Gamsylella* M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 108 (1999)

Etymology: in honour of the Austrian mycologist Walter Gams and in reference to the genus *Dactylella*, to which most of the included anamorphic species formerly belonged.

Emended diagnosis: **TELEOMORPH**: Apothecia with smooth margin, desiccation-sensitive or -tolerant. Ascospores subulate, straight to slightly curved; spore bodies subglobose to rod-shaped, ± eccentrical. — **ANAMORPH**: Conidiogenous loci singly or on prominent denticles. Conidia mainly 1–4-septate, straight, cylindrical to fusiform, microconidia present or absent. Forming sessile or stalked adhesive knobs, columns, arches and bridges.

Description: — **TELEOMORPH**: **Apothecia** hydrated (0.4–)1–5(–7.5) mm diam., white or pale isabelline to bright yellowish-orange, margin smooth, sessile. **Asci** *26–40 × 3–4 µm, 8-spored, (1–)3–5 lower or upper spores inverted; **apex** (†) slightly to strongly truncate, not or somewhat indented and slightly laterally inflated; **base** partly H-shaped. **Ascospores** *(3.6–)4–7.5(–8.5) × 0.8–1.3 µm, subcylindric- to fusoid-clavate (subulate), apex rounded to obtuse, base ± tapered, straight to slightly curved; **SBs** mostly distinctly eccentrical, 0.8–1.6 × 0.2–0.4(–0.6) µm (total length), subglobose to often rod-shaped, attachment invisible. **Paraphyses** uninflated or usually lanceolate (to lageniform), rarely capitate-clavate, terminal cells 2–4 × longer than lower cells. **Ectal excipulum** (†) thin-walled to slightly gelatinized, vertically or irregularly oriented textura (globulosa-)angularis(-prismatica), cells near base *(8–)12–40(–55) × (6–)10–25(–44) µm, margin or t. (angularis-)prismatica oriented at 10–80°; **glassy processes** absent. **SCBs** globose or absent; **VBs** absent. **Exudate** absent or 0.1–3 µm thick, continuous, finely rough, firmly attached, hyaline. — **ANAMORPH**: gamsylella-like. **Conidiophores** 50–500 µm long, conidiogenesis acrogenous (unbranched) or geniculate to candelabrelloid. **Conidia** (15–)18–68(–85) × 4.5–21(–30) µm, cylindric(-clavate) to fusoid or fusiform, 1–4(–6)-septate, with or without much larger central cell; **conidial dimorphism** only reported for *G. gephyropaga*, microconidia sharply separated. **Trapping organs**: sessile adhesive knobs, adhesive columns, arches and bridges, also long-stalked, large adhesive knobs with ellipsoid to lageniform, non-detachable heads covered by thick mucilage; traps spontaneously formed in culture.

Habitat: on hygric (also xeric) bark and wood of angiosperms, also herbaceous stems and leaves of monocots, capturing nematodes, rotifers, rhizopods, and arthropods, temperate to tropical, humid to semihumid, desiccation-sensitive or sometimes -tolerant.

Recognized species: 5 (3 of them without known teleomorph), plus 1 unnamed species ('affinis'); for further 2 species see Tabs 50 and S11.

Taxonomic remarks. Two species with a known teleomorph are assigned here to series *Gamsylella*, *Orbilia alba* and *O. anigozanthi*. Both have exceptionally large apothecia which are desiccation-sensitive in the former and highly desiccation-tolerant in the latter species. Without their anamorph or DNA data they can hardly be distinguished from other groups, particularly from series *Dactylellina* and *Drechslerella*. The ascospores contain subglobose to ± rod-shaped, distinctly eccentrical SBs without a visible attachment, a feature characteristic also of series *Drechslerella*. The two species are somewhat exceptional within section *Arthrobotrys* by their (sub)lanceolate paraphyses and wide anchoring hyphae, *O. anigozanthi* also by inversely oriented upper spores.

Anamorph (see also p. 235–236 and Tab. S11). The genus *Gamsylella* was erected for its more or less unique type of trapping organs, comprising sessile adhesive knobs and/or adhesive columns, arches and bridges. However, delimitation from *Dactylellina* is problematic. We here maintain *Gamsylella* at the series level in a modified sense, with *D. phymatopaga* (= *D. parvicollis*) remaining in *Dactylellina*, and with *D. alba* (= *O. alba*), *D. entomopaga*, and *D. ferox* tentatively transferred to *Gamsylella*. This concept is predominantly based on molecular data, with the exception of *D. entomopaga* and *D. ferox*, for which such data were not available (a sequence under the name *D. entomopaga* in GenBank refers to the type of *Arthrobotrys paucus*, a member of series *Dactylellina*, see p. 1609). Our emended concept extends the morphological diversity of *Gamsylella* by including robust stalked adhesive knobs covered by thick mucilage. *D. ferox* is not included in the above description because it is the only species of this group with arthrobotryoid conidiophores.

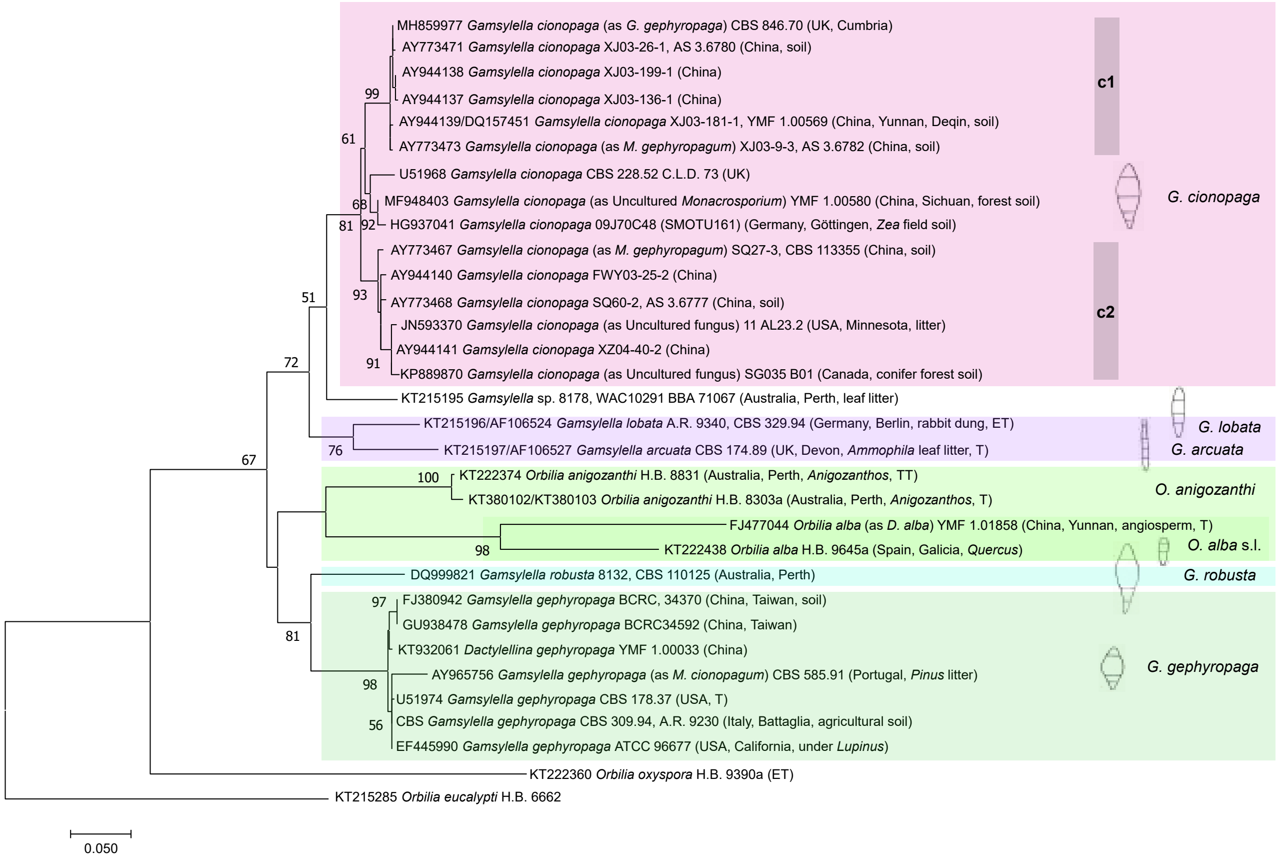
We consider *D. ferox* and *D. entomopaga* as possibly related to *Gamsylella* because the two available sequences of *O. alba* fall in the *Gamsylella* clade (no anamorph is known in *O. anigozanthi*) and the three species are quite similar in their trapping organs, having large, distinctly stalked adhesive knobs with either globose, ellipsoid, or lageniform heads (respectively) covered by thick mucilage. Due to the size of the knobs and the thick mucilage, all three species are able to capture arthropods (springtails, flies, mites etc.).

The conidiophore diversity observed in series *Gamsylella* includes most of the different types of conidiogenesis known from other series of section *Arthrobotrys* (acrogenous, candelabrelloid, arthrobotryoid). The conidia vary from short, cylindric-clavate, 1-septate (*O. alba*, *D. entomopaga* and *D. ferox*) to long, narrowly to broadly fusoid or fusiform, 3–4-septate (*G. arcuata*, *G. lobata*, *G. robusta*, *G. cionopaga*, *G. gephyropaga*).

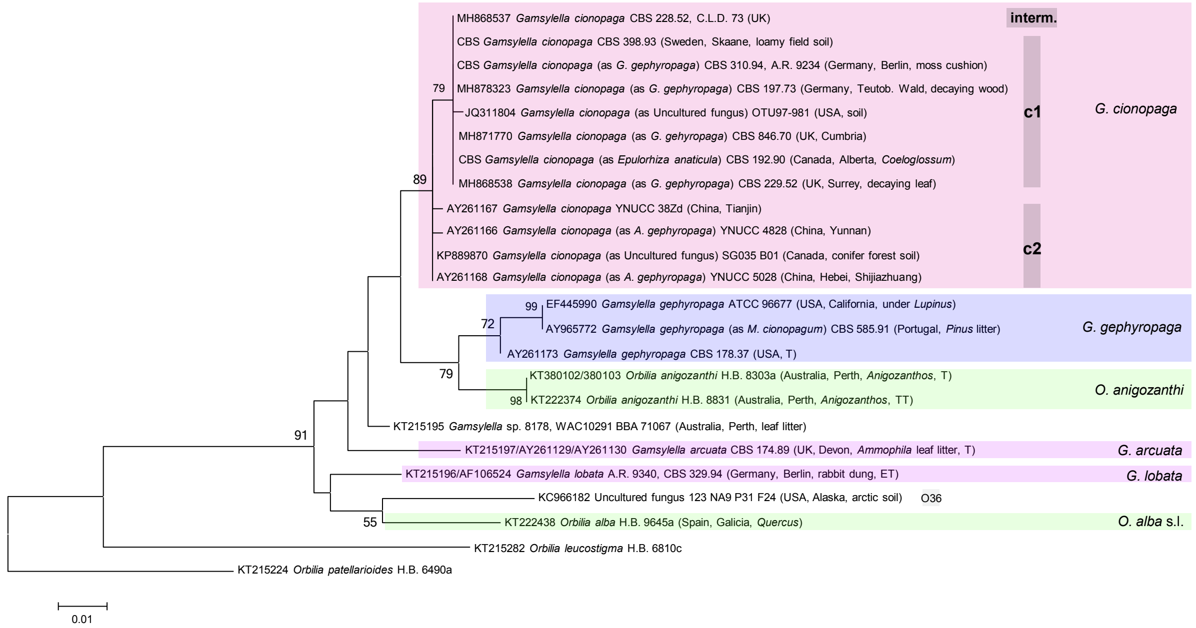
Species delimitation. *O. alba* might be a collective species, with different taxa occurring on different continents. This can be concluded from slight morphological and strong molecular differences. *G. cionopaga* was synonymised with *G. gephyropaga* by Rubner (1996) and Scholler et al. (1999), but deserves recognition at the species level based on strong molecular differences.

Previous phylogenetic concepts. Hagedorn & Scholler's (1999: fig. 1) and Scholler et al.'s (1999: fig. 2) phylogenetic analysis of the ITS region included four species: *G. arcuata*, *G. lobata*, *G. gephyropaga* (s.l.), and *G. phymatopaga*. The former three formed with high bootstrap support a sister clade to *Dactylellina*, while *G. phymatopaga* was situated unresolved between both. In another molecular phylogenetic study based on 5.8S+LSU and *TUBB*, Li et al. (2005) could not find support to accept *Gamsylella* as a separate genus, because the included species are found in different clades in their phylogenetic trees of rDNA as well as *TUBB*: the three species *G. arcuata*, *G. gephyropaga*, and '*M. cionopagum*' (*G. gephyropaga* according to ITS sequence) clustered in their analysis of 5.8S+LSU with *Arthrobotrys thaumasius* as sister taxon, the only included typical species of *Arthrobotrys*, whereas *G. parvicollis*, *G. phymatopaga*, and *G. robusta* clustered with species of *Dactylellina*. As a consequence, they provided the necessary new combinations, although their ß-tubulin and combined analyses gave partly quite different results.

In their multigene analysis (ITS, *RPB2*, *TEF1*, *TUBB*), Yang & Liu (2006) likewise found that *G. parvicollis* clustered together with species of *Dactylellina* (particularly in their ITS tree), whereas *D. cionopaga* formed a clade of its own, though situated closer to *Dactylellina* than *Arthrobotrys* when using a combined dataset (no further species of *Gamsylella* was included in this study). Therefore, Yang & Liu combined *D. cionopaga*, but also the not analysed *G. arcuata* and *G. gephyropaga*, into *Dactylellina*, and *Gamsylella* was consequently synonymised with *Dactylellina*. In a similar analysis by Yang et al. (2007)



Phylogenetic analysis 34. Phylogram of series *Gamsylella* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (32 sequences, 605 positions, aligned with MUSCLE) using the K2+G model in MEGA7 (500 replicates). The tree is rooted with *O. eucalypti* and *O. oxyspora*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype.



Phylogenetic analysis 35. Phylogram of series *Gamsylella* inferred from ML analysis of LSU (D1–D2) rDNA dataset (24 sequences, 506 positions, aligned with MUSCLE) using the K2+G model in MEGA6 (500 replicates). Three environmental strains from GenBank are included, one of them representing an unidentified species (O36). The tree is rooted with *O. patellarioides* and *O. leucostigma*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype.

based on more species of *Gamsylella*, *G. parvicollis* and *G. phymatopaga* clustered with typical species of *Dactylellina* in a monophyletic group, whereas *G. robusta*, *G. arcuata*, *D. cionopaga* and *G. gephyropaga* formed a monophyletic sister group. The latter three species are very similar in having adhesive columns, arches or bridges, while *G. robusta* has sessile, peg-like adhesive knobs. Both groups together formed a monophyletic sister group to *Arthrobotrys*.

The four Chinese strains of *D. cionopaga* analysed by Yang et al. (2007) show a remarkable distance to the strains of *G. gephyropaga*, indicating that two distinct species are involved. Further Chinese sequences in GenBank support this distinction, though being partly labelled with the opposite name. When applying a narrow species concept, Abiko et al.'s (2005) apparently unsequenced four strains of '*D. gephyropaga*' are more likely *G. cionopaga* because of their high conidial length (40–64 µm) with up to 5 septa. On the other hand, adhesive branches with scalariform bridges were frequent in these strains, but are more rare in *G. cionopaga*, according to Drechsler (1950).

Yang et al. (2012a) conducted phylogenetic analyses of 5 protein-coding genes and found the genus *Gamsylella* to be well founded. However, among the accepted species only *G. cionopaga* is morphologically typical of that genus, showing adhesive columns and scalariform bridges, while *G. robusta* forms only peg-like adhesive knobs, and *G. parvicollis* and the also included *Orbilia quercus* (as '*G. querci*') mainly form globose adhesive knobs. Li et al. (2016) analysed the *MAD1* gene of nematode-trapping fungi and retrieved *Gamsylella* (*Ga. gephyropaga*, *G. cionopaga*, *G. robusta*) as a paraphyletic sister group of *Arthrobotrys*.

Present phylogenetic concept. When analysing SSU+ITS+LSU, five species of series *Gamsylella* for which sequences were available formed a weakly supported monophyletic clade positioned without support sister to series *Dactylellina* (Baral et al. 2017b) or unresolved (Phyls 7, 25). Within series *Gamsylella*, analyses of ITS and LSU, or SSU+ITS+LSU produced different phylogenies (Phyls 34–35, S35), particularly regarding *O. anigozanthi* which clustered in the LSU and the combined tree medium supported with *G. gephyropaga*, but in the ITS tree without support in a clade with *G. gephyropaga*, *G. robusta*, and *O. alba*. In the ITS or combined analyses, *G. arcuata* and *G. lobata* clustered in a medium (Phyl. 34) or strongly (S35) supported clade which formed with medium support a sister clade to *G. cionopaga*. A rather high distance is observed between all seven species for which DNA data were available. Even the currently synonymised *G. gephyropaga* and *G. cionopaga* are very different and clustered with other species in separate clades.

Specific nucleotide positions. Position 98 of the 5.8S region is informative in regard to subgroups within series *Gamsylella*. It is consistently CATCGA**A** in *G. cionopaga*, *G. arcuata*, *G. lobata*, and *Gamsylella* sp. (WAC10291), but CATCGA**G** in *G. gephyropaga*, *G. robusta*, *O. alba*, and *O. anigozanthi*. The former motif occurs also in members of *Mycoceros*, *Lilapila*, *Amphosoma*, *Microdochiella*, *Vermispora*, *Lecophagus*, *Hyalorbilia erythrostigma*, *H. orbiliicola*, *H. latispora*, and in a few taxa of *Orbilia* (*O. patellarioides*, *O. ovalis*, *O. comma*, and series *Piliferae*), and it is widespread in other groups of *Ascomycota*. All remaining members of *Orbilia* and *Hyalorbilia* possess the latter motif. Also the 3'-end of ITS1 (left of AAAACTTT) is informative, being C in *G. gephyropaga* and *G. robusta* but T in all other *Gamsylella* species.

A motif in the ITS2 region (pos. 14–15) permits to distinguish between series *Gamsylella* (TCG**AC**) and *Dactylellina* (TCG**GT**, Tab. 76). This motif supports placement of *D. robusta* (type), *O. alba*, and *O. anigozanthi* in series *Gamsylella*, and *M. robustum* (YMF 1.01413) and *O. quercus* in series *Dactylellina*. Also in stem-loop B8 of 5.8S (pos. 119–126) series *Gamsylella* differs from series *Dactylellina* in the combination of 4 symmetric nucleotides, except for *Gamsylella* sp. 8178 which concurs with series *Dactylellina* p.p.maj. (Tab. 77).

At pos. 243–245 of the LSU D1 domain, *G. gephyropaga* and *O. anigozanthi* differ by C**GAT**CATG from any other

Key to species of series *Gamsylella* with known teleomorph

1. Apothecia whitish, 0.4–7.5 mm diam.; spores *(3.6–)4–6.5(–7) × 0.8–1.2 µm, lower spores predominantly inverted within asci; conidia 1(–2) septate; hygric to mesic bark & wood of *Aroideae*, *Eucalyptus*, *Quercus*, thermotemperate to tropical humid southern Europe, eastern Asia, South America .... ***O. alba***, p. 1613

1. Apothecia pale to bright isabelline-orange, 0.7–2.2 mm diam.; spores *(5.3–)6–7.5(–8.5) × (1–)1.1–1.3 µm, upper spores predominantly inverted within asci; anamorph unknown; xeric stems, leaves & fruits of *Anigozanthos*, subtropical semihumid Australia ....***O. anigozanthi***, p. 1619

If spore bodies eccentrical and trapping organs unknown, see also series *Drechslerella* (p. 1623).

Orbiliomycetes which usually have C**TTC**CA or C**TTC**TA, supporting their close relationship. At pos. 399 of the D2 domain, *G. cionopaga* and the syntype of *G. gephyropaga* (CBS 178.37) deviate by CAG**C**ACG from any other *Orbiliomycetes* which have CAG**T**ACG, except for *Amphosoma resinicola* and *Dactylellina* aff. *phymatopaga* CBS 568.95 which also have CAG**C**ACG.

Ecology. Members of series *Gamsylella* have desiccation-sensitive apothecia, except for *O. anigozanthi* which shows a high tolerance to drought. Apothecia, which are only known in the two marginal members *O. alba* and *O. anigozanthi,* were found on woody angiosperms and herbaceous monocots. Records are known from boreal to tropical, humid to semihumid regions of Europe, Asia, Australia, and America.

Orbilia alba Dennis; Kew Bull. 9: 295 (1954) — Pls 993–996

= *Dactylella alba* Z.F. Yu & K.Q. Zhang, in Yu et al., J. Microbiol. 47: 266 (2009), nom. illegit., ICN Art. 53.1 [non *Dactylella alba* (Preuss) Sacc., Syll. fung. 4: 194 (1886)]

Etymology: teleomorph: referring to the colourless apothecia; anamorph: in reference to the associated teleomorph.

Typification: Trinidad, Arima, twigs of *Aroideae*, 23.X.1949, R.W.G. Dennis (K(M) 36045, holotype of ***Orbilia alba***). — China, Yunnan, Wenshan, branch of indet. angiosperm, 30.VI.2006, Z.F. Yu (YMF 1.01858, holotype of ***Dactylella alba***; sq.: FJ477044, MH179758).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.4–)1–1.8(–2.3) {Spain} or 2.5–7.5 mm diam. {China}, rehydrated 3.5–5 mm diam. {T}, 0.08–0.12 {China} or 0.13–0.2 mm high {Spain} (receptacle 0.08–0.14 → 0.045–0.08 mm), (greyish–)white, pale cream to chlorinaceous when rehydrated, round to slightly undulating, slightly to strongly translucent, non- or slightly gelatinous, gregarious in smaller or larger groups; disc young strongly concave, soon flat or remaining medium concave, margin 0–10 µm protruding, externally smooth or sometimes finely pubescent ± up to margin; sessile on a narrow or very broad base, superficial; dry with slightly inrolled margin, whitish to cream. **Asci** *(26–)28–35(–39) × 3.2–3.8(–4) µm {2, Spain}; †(22–)24–30(–33) × (2.5–)2.7–3.3 µm {4}, 8-spored, spores */†2–4-seriate, (2–)3–5 of lower spores inverted (slightly to strongly mixed) {4}, pars sporifera */†(11–)14–16(–20) µm long; **apex** (†) slightly (to medium) truncate (never indented nor inflated); **base** with short to long, ± thin, flexuous stalk, Y- to T- or h- to H-shaped. **Ascospores** *(3.6–)4–5(–6.5) × 0.8–1.1 µm {China} or *(5–)5.5–7 × (1–)1.1–1.2(–1.3) µm {2, Spain}, †(4–)4.5–6(–6.5) × (0.7–)0.8–1.1 µm {3}, narrowly cylindrical to often subcylindric-clavate-fusoid, apex rounded to obtuse (sometimes subacute), base slightly to strongly attenuated, straight or slightly curved; **SBs** subglobose to rod-shaped, often distinctly eccentrical, 0.5–0.8 × (0.2–)0.3–0.4(–0.6) µm {2, Spain}, 0.3–0.6 µm away from apex (total length 1–1.4 µm), attachment invisible. **Paraphyses** apically uninflated to slightly (rarely medium to strongly) inflated, very slightly or sometimes distinctly obtusely lanceolate (to spathulate), rarely capitate-clavate {2}, terminal cell *(10–)12–19(–21) × 2.5–3(–4) µm {2, Spain}, †(7–)12–21 × 1.5–3(–6) µm {China & T}, exceeding the dead asci by 1–3.5 µm, lower cells *(4–)5–8(–9) × 2–3(–3.8) µm {2}, †3.5–7(–8) × 1.4–2.7 µm {1}. **Medullary excipulum** 20–70 µm thick, of loose, non-gelatinized textura intricata {3} with or without inflated cells, or of dense, strongly gelatinized horizontal t. prismatica {China}, mostly (very) sharply delimited from ectal excipulum. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, irregularly to distinctly vertically oriented t. (globulosa-)angularis(-prismatica) from base to margin, 30–70 µm thick near base, cells *(12–)20–40(–45) × (8–)15–27(–32) µm {2, Spain}, †(7–)10–24(–30) × (5–)8–19 µm {China & T} (Dennis: up to 40 × 20 µm); 20–30 µm thick at lower flanks, 15–20 µm at margin, of t. globulosa-angularis-prismatica oriented at a 10–50° angle, marginal cortical cells */†(5–)6–13(–15) × (3.5–)5–7(–9) µm {3}; **glassy processes** absent. **SCBs** low-refractive, globose to elongate, present in some paraphyses {2}; **VBs** absent; **LBs** in paraphyses absent or sparse and minute, but in excipular cells of senescent apothecia with some peripheral LBs 1–2(–2.5) µm diam. **Exudate** absent or as very sparse minute granules, tips of paraphyses and asci and also marginal cortical cells somewhat immersed in gel. **Anchoring hyphae** medium to very abundant, */†(3–)4–6(–8) µm wide, walls 0.2–0.7(–1.2) µm thick {4}, singly projecting or forming a very loose t. intricata up to 40 µm thick. — **ANAMORPH**: gamsylella-like (from ascospore isolate {2} and natural substrate [trapping organs only] {2}). **Conidiophores** erect, *50–80 µm {China} or *(30–)90–175 µm long {Galicia}, 3–3.5 µm wide at base {China}, ~2–2.5 {China} or 2.7–3.2 µm {Galicia} at apex, here ± strongly branched (candelabrelloid), ~3–11 denticles of *3.5–10 × 1.5–2.5 µm {China}, or 1–9 denticles of 2–6.5 × 1.5–3.5 µm {Galicia}. **Conidia** *(18–)19–26(–32) × (5–)5.5–7.5(–8) µm {China, modified according to scale} or *18–26(–34) × 5–6 µm {Galicia}, cylindric-ellipsoid to cylindric-clavate, with {China} or without {Galicia} prominent basal protrusion, 1(–2)((–3))-septate, containing a few small LBs at septa or lateral wall. **Adhesive knobs** abundant, gregarious, erect, (35–)65–130 µm long {2}; **stalks** 0–1-septate, *35–90 × 4.5–5.5 µm [†~28–35 × 2–2.5 µm {China}], at base *5.5–7(–8) µm wide, apically *3–4.7 µm, emerging from basal hyphae or often by repeated branching of the stalks (stalks then also only 8–35 µm long); **heads** on natural substrate {Spain}: *26–36 × 8.5–11(–12) {2}, †26–34 × 7–10.5 µm {1}, spathulate to lageniform, apically narrowed to a width of *5.5–6 µm; in pure culture: *14–20(–27) × 8.7–10 µm {China}, *22–29 × (9–)10–12.5 µm {Galicia}, ellipsoid to narrowly obovoid; cytoplasm mainly vacuolated, with some small LBs, apical wall delicate, lateral wall often more firm, entire heads embedded in a globose adhesive mucilage of (25–)30–40(–45) µm total diam. when soaked with water, under normal condition strongly dehydrated and mucilage then only 10–20 µm total diam. and with strongly wrinkled, rough surface, mucilage staining bright lilac in CRB; **overmature heads** *30–40(–48) × 9.5–12(–13) µm {2}, renewed formation of trapping organs by proliferation at base, tip, or lateral part of heads; **infection bulb** *7 µm diam., globose, **assimilative hyphae** *4–6(–7) µm wide, entirely colonizing the interior of the animal; very distinct globose **WBs** on both sides of septa in assimilative hyphae, aerial mycelium, and anchoring hyphae *0.3–0.4 µm diam., in stalks of adhesive knobs *(0.3–)0.4–0.5(–0.7) µm diam. (†0.4–0.8 µm diam); otherwise without visible cell contents. **Non-constricting rings** absent.

Habitat: lying on ground; 0.7 mm thick, living corticated stem of *Aroideae* {T}; corticated, 2 cm thick branches of *Quercus robur* {1}, indet. angiosperm tree {1}; detached bark of trunk of *Eucalyptus globulus* {1}; on slightly to strongly rotten bark {3} (periderm and bast), also on 0.5–1.5 mm deeply very rotten wood {1}, on upper- and underside. **Associated**: *Acrodictys* sp. {1}, *Gamsylella cionopaga* {1}, *Heteroconium tetracoilum* {1}, *Orbilia* ?*bembicodes* {1}, *O.* ?*cotoneastri*

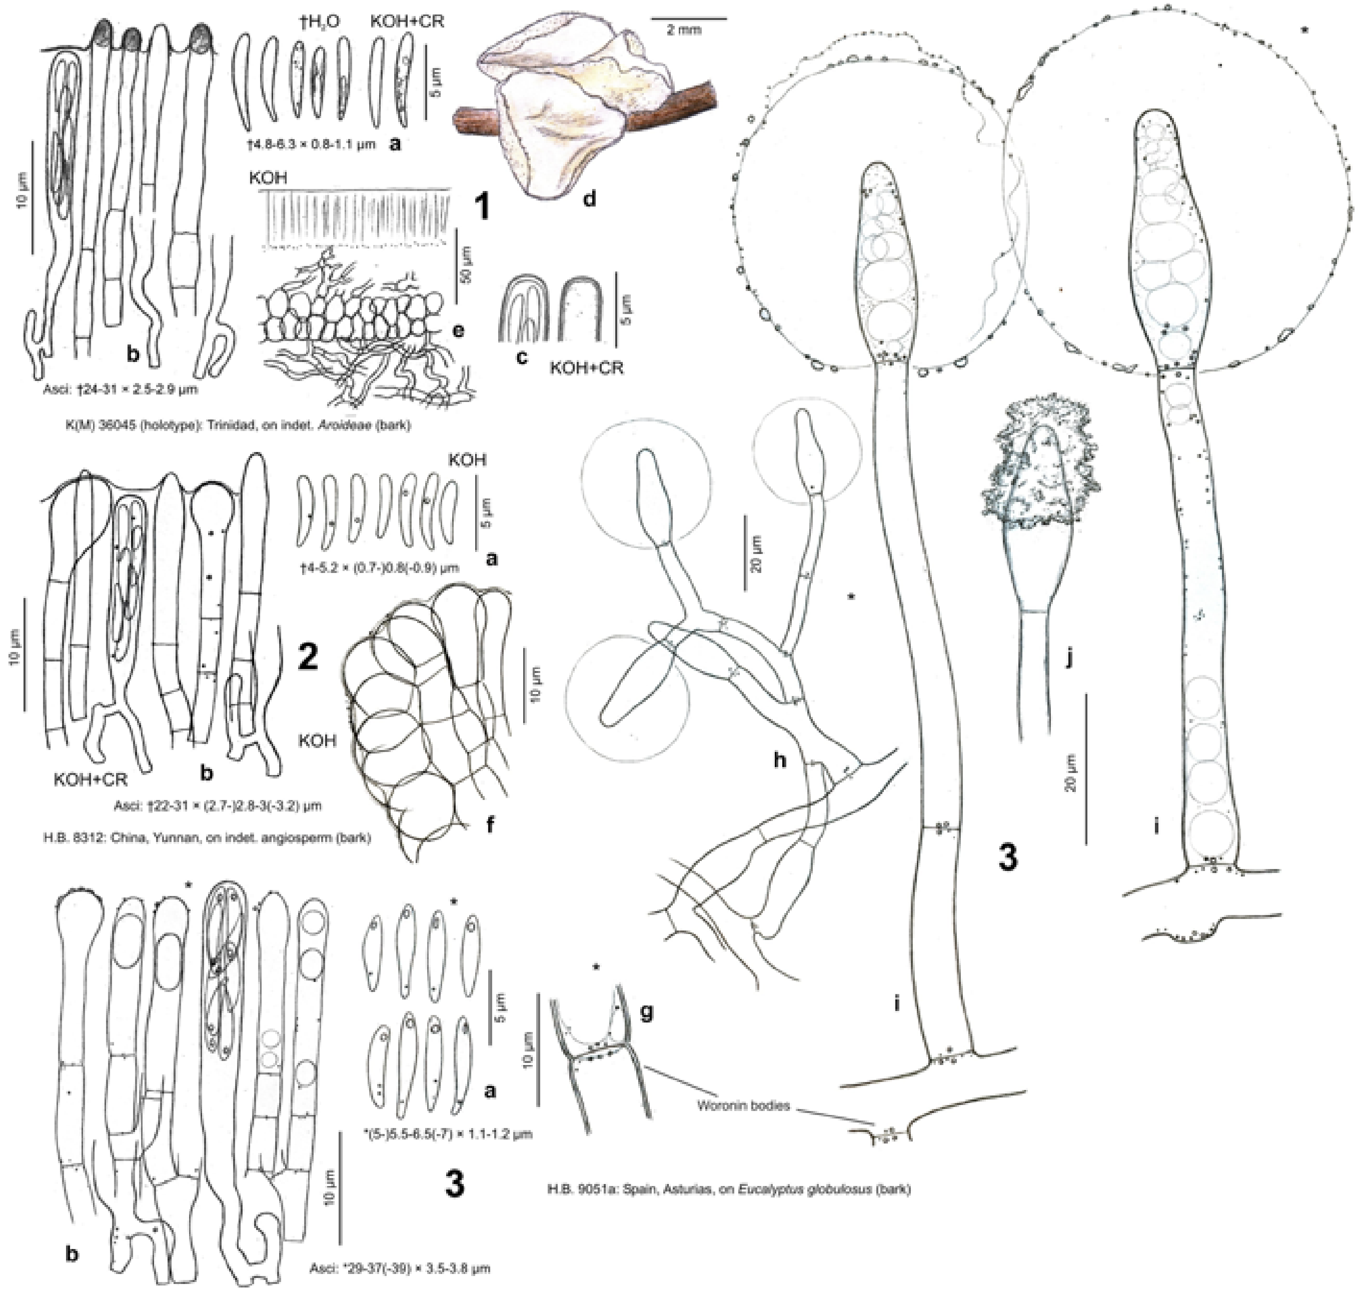


Plate 993. **1–3**: *Orbilia alba*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. median section of apothecial receptacle at lower flanks, showing hymenium, medulla, ectal excipulum, and anchoring hyphae; **f**. id., marginal ectal excipulum; **g**. detail of anchoring hypha; **h–j**. adhesive knobs (from substrate; **h–i**: hydrated, **j**: dehydrated in ethanol).

{2}, *Pleurothecium recurvatum* {1}. **Desiccation tolerance**: mature asci still viable after 12 hours, but dead in all parts after a few days, except for the ascospores which were dead when reexamined 3 months later (H.B. 9051a). **Altitude**: 40–80 m a.s.l. (southwestern Europe), 850 m (tropical America), 1272 m (southern China). **Geology**: China: Devonian sedimentary rock; Spain: Silurian-Devonian red sandstone, shale, dolomite; granite, amphibolite, serpentinite. **Phenology**: IV, VI, XII (northern hemisphere, extra-tropical), X (tropical belt).

Taxonomic remarks. *Orbilia alba* is characterized by comparatively large and thin, whitish, sessile apothecia, a thin, sharply delimited ectal excipulum of large excipular cells, extraordinarily wide anchoring hyphae, predominantly non-capitate to obtusely sublanceolate paraphyses, and by small and narrow, basally ± attenuated, straight or slightly curved ascospores. *O. alba* resembles *O. anigozanthi* in the teleomorph (for the differences see p. 1620), and our molecular data confirm a close relationship. *O. quercus* differs, e. g., in much smaller apothecia and consistently slightly capitate paraphyses, in addition to a very different anamorph.

Variation. The Chinese specimen reported by Yu et al. (2009a) differs in several details from the Southern American holotype and the collections from Spain. The ascospores are a bit smaller and their ends almost untapered. However, this difference in shape is only obvious when comparing spores in the living state (Spain: Pls 993: 3a; 994: 1l; 995: 1e; China: Pl. 996: 1h). In the dead state the spores of the Chinese specimen are also distinctly tapered and their shape hardly differs from the holotype (Pl. 993: 1a, 2a). The paraphyses are more distinctly lanceolate in the Chinese specimen, but capitate-clavate paraphyses with distinctly shorter and wider terminal cells frequently likewise occurred (Pl. 993: 2b), at least in some of the apothecia examined. Yet, such inflated paraphyses were also seen in one of the specimens from Spain (3b, left paraphysis). The medullary excipulum is rather strongly gelatinized in the Chinese specimen by a refractive intercellular gel (faintly visible in Pl. 996: 1d–e), whereas no such gel could be observed in the other three specimens.

The rehydrated apothecia of the Chinese specimen have a diameter of 2.5–7.5 mm (Pl. 996: 1a–b), and those of the holotype 3.5–5 mm. In contrast, the fresh ones in the Spanish specimens measured only 0.4–2.3 mm. Despite their large size, the apothecia in the Chinese specimen were thinner than in the Spanish ones. In the holotype they are affixed to the thin twig by a rather narrow base and have a deeply concave disc. The apothecia in the other samples grew on much larger pieces of substrate; apparently therefore, they are attached to the substrate by a ± broad base and soon have a more or less flat disc. In the holotype the paraphysis apices contained a large, slightly refractive inclusion (in H_2O as well as KOH, Pl. 993: 1b) which might correspond to the faint SCBs seen in some paraphyses of the two Spanish collections (3b). No such structure was seen in the Chinese specimen in either the living or dead state.

Anamorph (see also p. 235). In their ascospore isolate of a southern Chinese collection, Yu et al. (2009a) obtained an anamorph which they named *Dactylella alba* (Pl. 996: 1i–k). It is characterized by long, candelabrelloid conidiophores with loose terminal clusters of small-sized, mainly 1-septate conidia (the statement 'mainly 2-septate' in the English description is an error, correct is: '30 % 2-septate, 70 % 1-septate', Z.F. Yu pers. comm.). As an exception, a 3-septate conidium occurred (1i upper right). It must be mentioned that the stated conidial size does not well correspond to the scale bar: either the bar is ~ 8 % too long or the measurements ~ 8 % too large. A photo of further, unpublished conidia kindly sent by Z.F. Yu shows distinctly longer and narrower conidia, which led us to believe more in the published scale bar; therefore, we slightly diminished the conidial measurements in the protologue. In pure culture of the specimen from Galicia (Spain) a very similar anamorph developed (Pl. 995: t–w), with slightly narrower conidia with indistinct instead of prominent basal protrusion. Also here 70–80 % of the conidia were 1-septate, the remaining 2-septate.

Dactylellina entomopaga has very similar conidiophores and conidia, except that the conidia are often formed in whorls at intervals (Pl. 14: b). Also the trapping organs are distinctly smaller. Molecular data were not available since the only sequence in GenBank under this name refers to '*Arthrobotrys*' *paucus*, a member of series *Dactylellina* (see p. 228 and Pl. 7: a). *Dactylella vermiformis*, the anamorph of *Orbilia vermiformis*, resembles *D. alba* in conidial morphology. It differs in conidiophores with single conidia at the tip (sometimes subapically branched but not candelabrelloid), and in lacking trapping organs. With its candelabrelloid conidiophores, *Dactylella alba* was compared by Yu et al. with *D. pulchra*, which has much larger multiseptate conidia and also lacks trapping organs.

Adhesive knobs. *O. alba* captures small invertebrates by means of comparatively large, long-stalked adhesive knobs with elongate, flask-like (lageniform) heads surrounded by thick mucilage (Pl. 993: 3h–j). In the hydrated state the mucilage attains the shape of small balls whereas under normal atmospheric conditions it is strongly dehydrated and shows a wrinkled surface. This rather unusual type of trapping organ, which is already macroscopically visible (Pl. 994–995), strongly recalls the short-stalked and distinctly smaller adhesive knobs of *Dactylellina entomopaga* with ellipsoid heads or *D. ferox* with globose heads, which are similarly surrounded by thick mucilage (Pl. 14: b, c).

Particularly *D. entomopaga* appears to be very closely related to *O. alba*, including its ability to trap collembola. It differs in the smaller size of the trapping organ (data after Drechsler 1944b and Saikawa et al. 2010): the ellipsoid heads measure *8–13 × (4.5–)6–7.5(–8) µm [in *O. alba* *(14–)20–30(–36) × 8.5–11(–12) µm] and the total width of the swollen mucilage 15–21 µm [in *O. alba* (25–)30–40(–45) µm]; also the mostly non-septate stalks are with *7–18 × (2–)3–4.5(–5) µm much shorter than the often 1-septate, 28–90 × 2–5.5 µm large stalks of *O. alba*. This indicates that *O. alba* is able to trap also larger invertebrates in comparison to *D. entomopaga*. A further difference might be in the mucilage which attains in *D. entomopaga* a lobed surface when dehydrated (Drechsler 1944b: fig. 5, see Fig. 106: d, e; Saikawa et al. 2010, fig. 3), whereas that in *O. alba* becomes strongly wrinkled but not clearly lobed (Pls 993: 3j; 1002: 1w).

Yu et al. observed in their *D. alba* 'a new type of spores similar to chlamydospores' (Pl. 996: 1j), being formed 'terminal to intercalary, solitary' from aerial mycelium. The authors believed that trapping organs were not formed and, therefore, placed this anamorph in *Dactylella*, despite the fact that it clustered in their phylogenetic analysis near *Dactylellina quercus*. That these 'chlamydospores' are, in fact, adhesive knobs is supported by the observation of some slime around them (Z.F. Yu pers. comm.).

In the two Spanish specimens the trapping organs occurred in high frequence around the apothecia, while in that from China no such organs could be found. The adhesive knobs possess rather thick stalks with conspicuous Woronin bodies (WBs) at the septa (Pls 993: 3i; 994: 1s; 995: 1n–o). WBs are also found in the wide hyphae from which the stalks emerge. These hyphae and their WBs closely correspond in size to the anchoring hyphae of the associated apothecia of *O. alba* (Pl. 993: 3g). Moreover, in the specimen from Galicia a direct connection between the hyphal system of the trapping organs to that of an apothecium could unequivocally be demonstrated on the natural substrate. In an ascospore isolate from this specimen the same type of trapping organs were formed without the presence of prey (Pl. 995: 1k–m, o–s).

The trapping organs of *O. alba* grow gregariously in great number by covering several square millimetres of substrate. They are able to capture arthropods at their legs or antennae. Several dead individuals of mites (*Acari*), flies (*Diptera*), and springtails (*Collembola*) occurred on the bark in close proximity to the apothecia when the two Spanish specimens were collected and studied. These were infected and overgrown by mycelium and surrounded by many adhesive knobs.

The adhesive mucilage is virtually invisible in water mounts (even under phase contrast), because it is instantly soaked to maximum hydration when placed in water. It becomes more visible when adding a drop of 96 % alcohol which dehydrates the mucilage (Pl. 994: 1v, x), or by adding CRB which stains the mucilage bright lilac (Pl. 995: 1p–q, see also Fig. 107 on p. 118). Under natural condition, even under a high air humidity, the mucilage is rather strongly dehydrated (Pls 994: 1m–n; 995: 1h–i) and has a very rough, wrinkled surface. Direct placement in 96 % alcohol allows to study this situation under the microscope (Pls 993: 3j; 994: 1w). In this state the mucilage covers mainly the narrower upper part of the head. When spraying water over

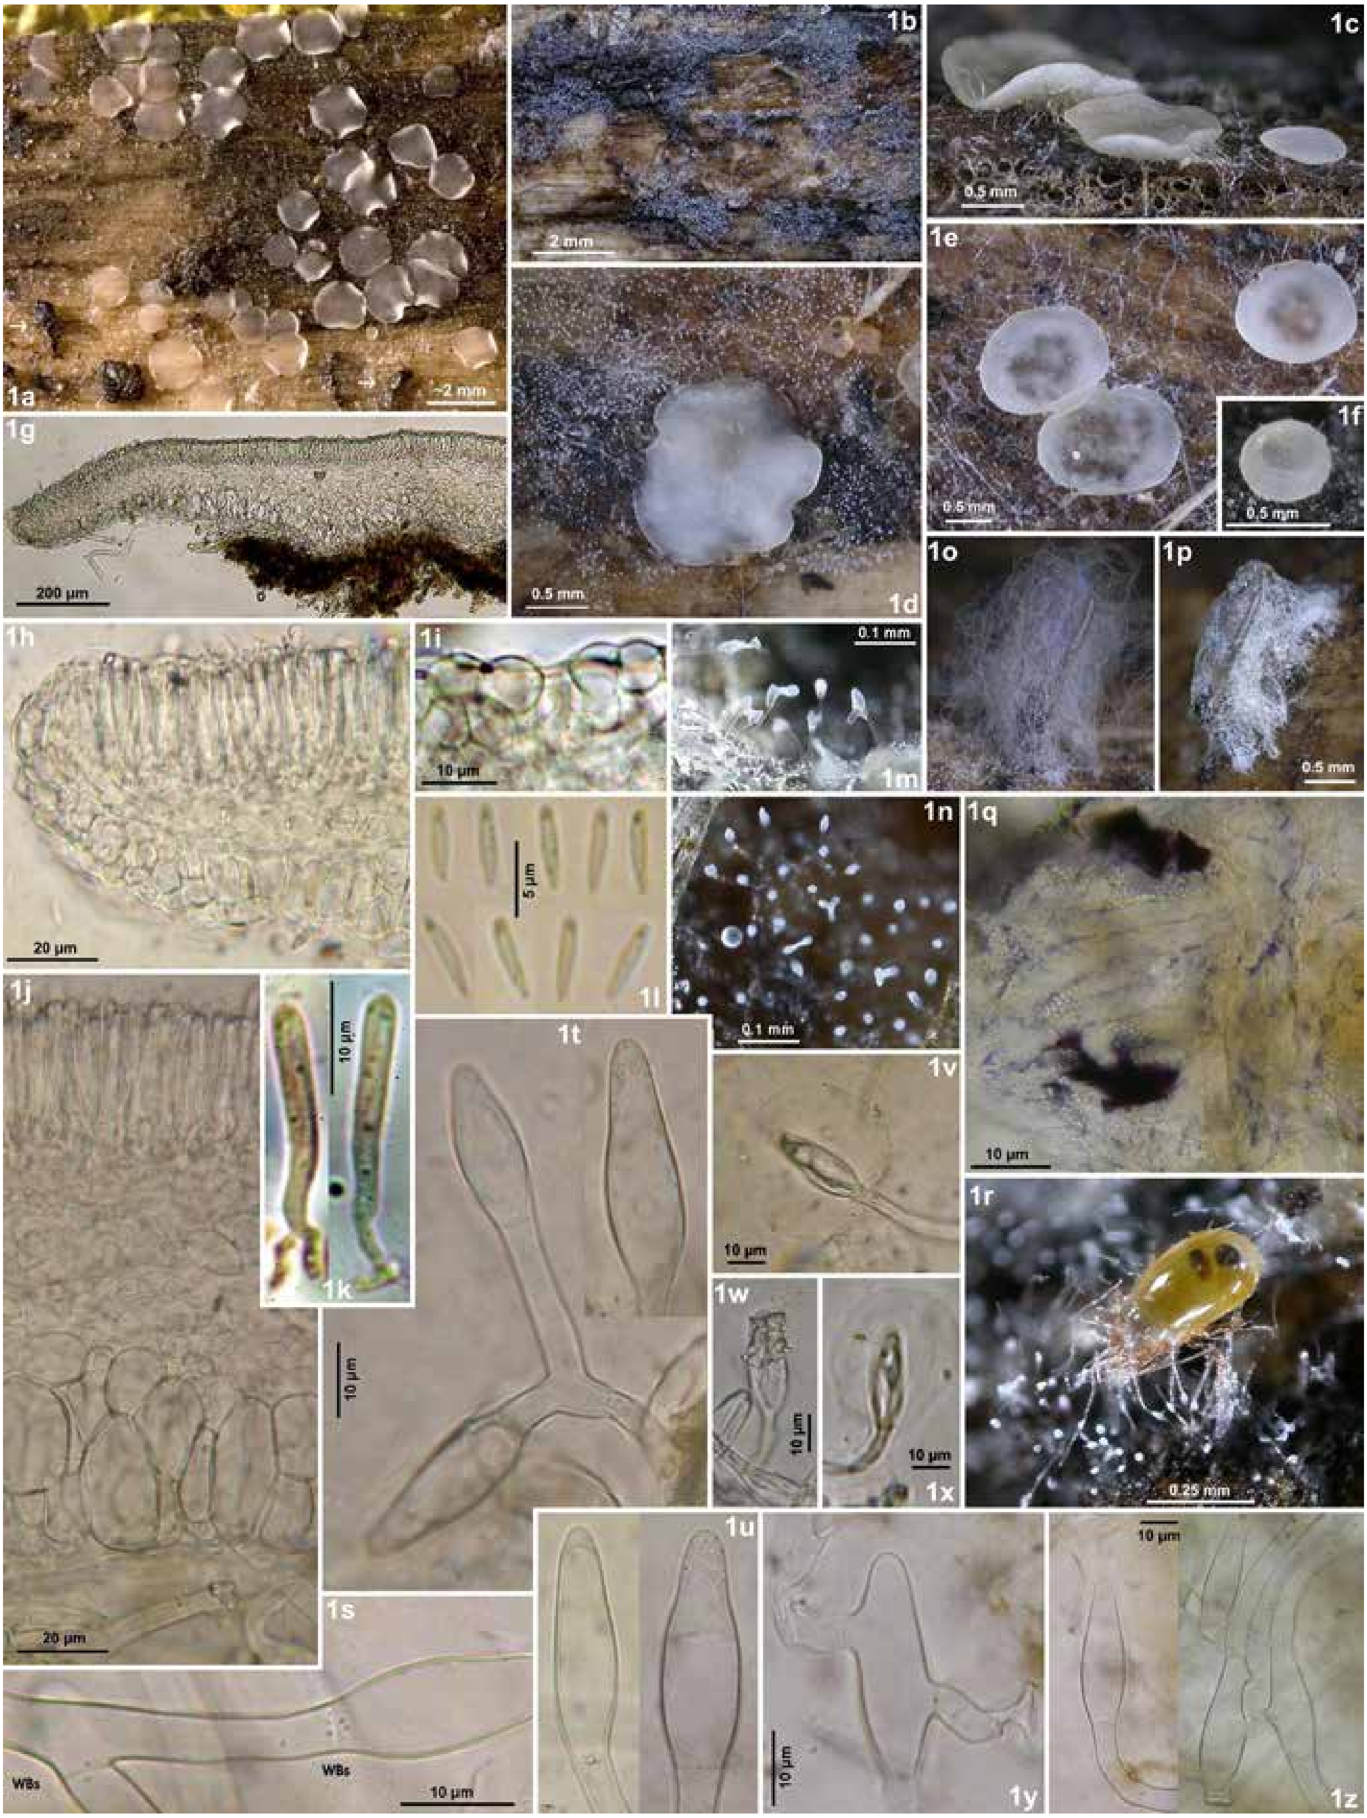

Plate 994. **1**: *Orbilia alba*. – **1a–f**. fresh apothecia (**1a**. arrows: 2 trapped dipterans, **1b**, **d**. with numerous adhesive knobs); **1g**. apothecium in median section; **1h**. id., ectal excipulum at flanks and margin; **1j**. id., near base; **1i**. marginal cortical cells in top view; **1k**. asci; **1l**. ascospores; **1m–n**. adhesive knobs; **1o–p**. trapped fly overgrown by mycelium (**1p** after spraying with water); **1q**. head of trapped springtail (with 2 dark eyes), colonized by assimilative hyphae; **1r**. trapped juvenile mite, hyphae starting to overgrow the prey; **1s–z**. adhesive knobs [**1y–z**: proliferating terminally or laterally; mucilage only visible in **1v**, **x** (soaked) and **1w** (dehydrated)] (**1m–z** on natural substrate). – Living state (in water, but **1v** & **x** in water to which ethanol was added, **1w** directly in ethanol 96 %), except for asci in **1k** (in CR). – **1a**, **k**: phot. E. Rubio. — **1a–z**. H.B. 9051a: Spain, Asturias, on *Eucalyptus*.

the substrate, or under natural conditions during rainfalls, the mucilage swells to a spherical shape in the same way as in a water mount. The mucilage then entirely encompasses the flask-shaped terminal cell. A few knobs in Pl. 994: 1n and Pl. 995: 1i show the hydrated state.

Adhesive knobs grown in pure culture differed somewhat from those on the natural substrate in their heads being distinctly shorter and more ellipsoid to obpyriform instead of lageniform, by lacking the neck-like apex, also in having distinctly thickened lateral walls (Pl. 995: 1o–s; 996: 1j). In the specimen from Galicia the heads are slightly larger than in that from China. The mucilage showed a fibrous microstructure when stained in CRB (Pl. 995: 1p–q), but in those heads with pronounced wall thickenings (1o, r–s) no mucilage could be demonstrated. In the dead state the lateral wall is considerably more thick-walled (1s right), but abruptly thin at the apex. Whether outer parts of the thick wall get disintegrated to produce the mucilage is unclear.

In the Galician specimen, apothecia developed in some agar plates which partly contained wood fragments, but these remained rather small and immature. Although the apothecia in the collection from Asturias got senescent on the natural substrate during some weeks in the moist chamber, the trapping organs strongly increased in number. Repeated photographic documentation showed that these traps are rather quickly formed: a large group of fully-developed traps was detected at a spot where almost no traps were present about 2 days before. Tests with small invertebrates (spiders, mites, springtails) proved that these animals immediately get stuck with their legs or antennae to the mucilage of the large adhesive knobs of *O. alba* (see also Fig. 107: k–m). Attraction oft the animal by the knobs could not be observed, instead, the trapping occurred accidentally. Larger invertebrates (spider, adult mite) which were tested escaped from the knobs within some minutes, but none of the springtails and young mites succeeded to get free.

The process of adhesion of the animal to the adhesive knob does not require strong hydration of the mucilage. Instead, the knobs are highly sticky also when the mucilage is comparatively dehydrated. Often several adjacent knobs get attached to 1 leg and also among one another. Then the animal needs two- to three-fold force to escape.

The trapped animals try to escape the traps over a period of about 5–10 minutes. When an hour or more has passed and they are still affixed to the knobs, movements get slower or are hardly visible anymore. But even after about 10–12 hours, when the mycelium starts to overgrow the animal body, legs or antennae still show distinct occasional movement. The aerial mycelium soon completely covers and masks the animal, perhaps in order to avoid capture by other predators (Pl. 994: 1o–p). Death and collapsing of the animal was noted 2 days after capture. Probably rather quickly after capture a globose infection bulb is formed inside the animal, and from this emerge assimilative hyphae which finally colonize the entire interior (Pl. 994: 1q).

Variation is also noted in the anamorph. The conidia in the two strains closely correspond in shape and septation, also in length, but in that from Galicia they tend to be narrower (*5–6 μm, China: *5–8 μm). The heads of the adhesive knobs were slightly larger in the Spanish collections when compared in pure culture to that from China, and particularly their stalks were distinctly larger (*35–90 × 4.5–5.5 μm, China: †~28–35 × 2–2.5 μm).

Type studies. The present reexamination of the holotype well corresponds to the protologue, except for the paraphyses which Dennis (1954) illustrated as capitate and not protruding. The pubescent exterior of the apothecia is due to the anchoring hyphae forming a loose texture that extends over the flanks. This appears to be what Dennis described as a 10 μm thick gelatinous covering layer containing a few slender hyphae, although no gel matrix between the hyphae could be observed in the present study.

Other conidial states observed in association. Three orbiliaceous anamorphs grew in association on the natural substrate in the collection from Asturias: *Dactylella* sp., *Gamsylella cionopaga*, and *Drechslerella* cf. *bembicodes*, the latter two also with their trapping organs. All of them are obviously not connected to *O. alba*. In fact, apothecia of *O.* cf. *cotoneastri*, to which the dactylella-like anamorph obviously belongs, appeared during incubation of the substrate in a moist box (Pl. 909: 2), partly very close to the trap areas of *O. alba*. A similar dactylella-like anamorph was abundantly present in the specimen from Galicia, where it occurred in close connection to the apothecia and adhesive knobs of *O. alba*. Also here, a single apothecium reminiscent of *O. cotoneastri* appeared during incubation in a moist box. This undoubtedly represents the teleomorph of the dactylella-like anamorph which, unlike the above, resembles *Dactylella rhopalota* (Pl. 909: 4). Conidiophores and conidia of *O. alba* have so far not been observed on the natural substrate.

Phylogeny. Molecular data of *O. alba* were available from the ascospore isolate from China (ITS) and from apothecia of the specimen from Galicia (SSU+ITS+LSU). In both the S1506 intron is absent. In the ITS region the two sequences show a high distance of 13% to each other, compared to their distance to *O. anigozanthi* which lies around 16.5% for both strains. In combination with slight morphological differences between European and Chinese specimens this indicates that two different species are involved. Since no molecular data were available for the holotype, the identity of the three recent records remains unsettled.

Our combined analyses of SSU+ITS+LSU (Baral et al. 2017b, Phyl. S35) placed *O. alba* and *O. anigozanthi* with strong or medium support in a clade with *G. gephyropaga*, though with a high distance. This placement suggests that the two species belong to series *Gamsylella* inspite of the different trapping organs in *O. alba* and *G. gephyropaga*. Further research is necessary to settle the taxonomy in this interesting group, including its relationship to *Dactylellina entomopaga* and *D. ferox*.

Ecology. The holotype of *O. alba* grew on the epidermis of very thin, living stems of a terrestrial aroid (*Aroideae*, *Araceae*) in a tropical humid rainforest in the Northern Range of Trinidad (southeastern Caribbean Sea). The Chinese collection was on rotten bark of a mesic branch of an unidentified angiosperm tree lying on calcareous soil in a subtropical humid (winter-dry) montane evergreen forest. The specimens from northern Spain grew in a cantabroatlantic, thermotemperate humid (somewhat summer-dry) climate: that from Asturias was in a *Eucalyptus* plantation on the underside of detached rotten bark of *Eucalyptus* fallen to the ground, and that from Galicia in a forest with *Laurus nobilis* and *Castanea sativa* on a fallen, partially corticated branch of *Quercus robur*.

Specimens included. **Trinidad**, 30 km ENE of Port-of-Spain, ~10 km NNE of Arima, El Cerro del Aripo Mt., ~850 m, near cave, stems of *Aroideae*, on bark, 23.X.1949, R.W.G. Dennis (Dennis 483, K(M) 36045, **holotype** of *O.*

Orbilia anigozanthi Baral & G. Marson, **sp. nov.**, MB 813993 — Pls 997–998

Etymology: named after the host plant, *Anigozanthos*.

Typification: Western Australia, Perth, stems and leaves of *Anigozanthos manglesii*, 7.IX.2006, G. Marson (ex H.B. 8303a, MEL 2389239, holotype; sq.: KT380102).

Latin diagnosis: *Apothecia rehydratata 0.7–2.2 mm diam., pallide isabellino-cremea vel intense luteo-aurantiaca, sessilia, margine prominuli, laevi. Ascosporae *5.3–8.5 × 1–1.3 µm, (clavato-)fusoideae, apice rotundatae vel obtusae, subrectae, corpusculum refringens minutum, plerumque bacilliformem, iuxta apicem plus minusve excentricum continentes, saepe superiores inverse orientates. Paraphyses ad apicem saepe obtuse lanceolatae ad lageniformes, exsudato tenuissimo tectae. Excipulum basale cellulis magnis, tenuitunicatis, marginale absque processis vitreis, exsudato valido tectum. Hyphae basales abundantes, latae. Cellulae vivae excipuli et paraphysium corpuscula globosa continentes. Habitat ad culmos putridos siccos, etiam ad folia et capsulas* Anigozanthi *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.7–)1–1.5(–2.2) mm diam., 0.11–0.28(–0.35) mm high (receptacle 0.09–0.2 → 0.06–0.09 mm), very pale to light isabelline-cream or light to bright yellow-orange-apricot, slightly to strongly translucent, round to very slightly undulating, slightly gelatinous, subgregarious; disc flat, margin slightly to strongly inrolled, 0–35 µm protruding, smooth; broadly sessile, superficial; dry pale to deep cream or yellow-orange-apricot. **Asci** *34–40 × 3–3.3 µm {1}, †28–39 × 2.5–2.8 µm {1}, 8-spored, spores *2–3-seriate, (1–)3–4 upper spores inverted {2} (often mixed, sometimes lower spores inverted), pars sporifera *23–25 µm long; **apex** (†) strongly truncate (very slightly to distinctly indented, laterally sometimes inflated); **base** without or with short, thick stalk, h- or sometimes H-shaped. **Ascospores** *(5.3–)6–7.5(–8.5) × (1–)1.1–1.3 µm {2}, †5.3–7 × 1–1.1 µm {1}, subcylindrical to mostly fusoid, sometimes slightly clavate to fusoid-clavate, apex rounded to obtuse, base slightly to medium tapered, straight to slightly inequilateral; **SBs** *0.5–1 × 0.2–0.3 µm {1, visible part, total length 0.8–1.6 µm}, consistently ± eccentrical (close to lateral wall) near spore apex, subglobose to mostly rod-shaped, attachment invisible. **Paraphyses** apically uninflated to often obtusely lanceolate to lageniform, terminal cell *(14–)17–24 × 2.5–3.5(–4)((–4.5)) µm {2}, exceeding the dead asci by 3–5 µm (the living asci by 2–3 µm),

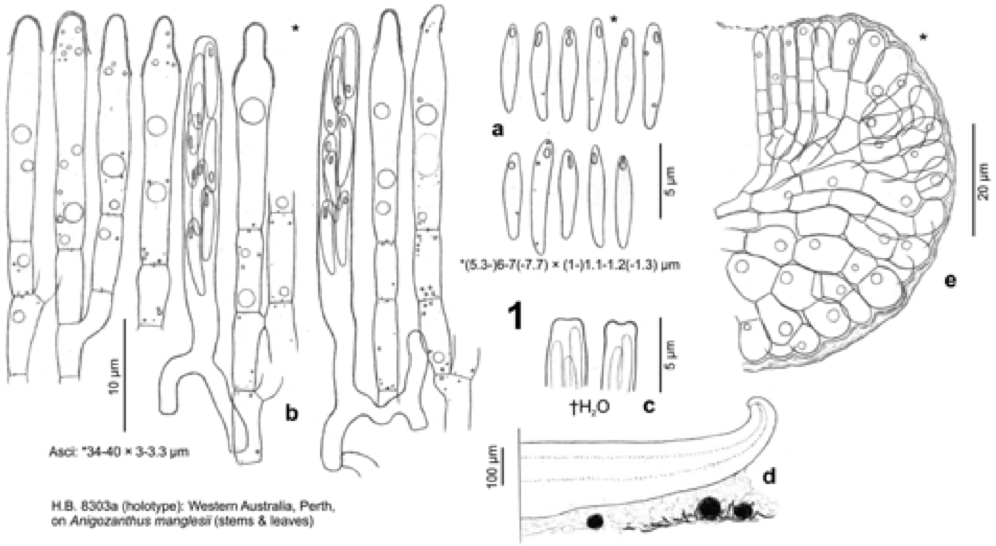

Plate 997. **1**: *Orbilia anigozanthi*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., ectal excipulum at margin.

lower cells *4.5–8 × 2–3.2 µm {1}; never branched at upper septum, hymenium pale rose-orange. **Medullary excipulum** hyaline to very pale rose-orange, 40–120 µm thick, of loose to ± dense, non-gelatinous textura intricata-prismatica, mainly composed of rather large cells (*5–15 µm wide), somewhat horizontally oriented, sharply delimited from ectal excipulum. **Ectal excipulum** hyaline to very pale rose-orange, of thin-walled, vertically oriented t. globulosa-angularis-prismatica from base to mid flanks or margin, (30–)70–120(–200) µm thick near base, cells *(12–)20–48(–55) × (10–)16–23(–44) µm {2}; 40–80 µm thick at flanks, 15–25 µm at margin, of short-celled t. prismatica oriented at a 50–80° angle to the surface, marginal cortical cells *5–9 × 4–7.5 µm {2}, at upper margin often oriented at 10–20°, partly of t. prismatica(-porrecta) with cortical cells †/*9–15(–20) × 4–6 µm; **glassy processes** absent. **Anchoring hyphae** very abundant, *2.7–6(–8) µm wide, walls 0.15–0.3(–0.6) µm thick {2}, with 1–2 µm thick indistinct gel sheath, forming a medium to very loose hyaline, t. intricata ~40–100 µm thick. **SCBs** globose, in paraphyses (1–)1.5–2.5(–3) µm diam., in ectal excipulum 1.5–3.7(–4.5) µm; **VBs** absent. **Exudate** over paraphyses 0.1–0.2 µm thick, finely rough, mostly reaching down to the widest part of terminal cell, firmly attached; over margin and flanks 1–3 µm thick, continuous, hyaline. **— ANAMORPH**: unknown.

Habitat: lying ± close to dry sandy soil or sticking in soil by 1 end, 2.5–8 mm thick, previous year's stems (partly on leaf sheaths), also leaves and empty capsules of *Anigozanthos manglesii* {2}, medium to strongly decayed and greyed, partly on blackened areas, algae very sparse. **Associated**: *Orbilia kingsiana* {1} (on separate stems), *O.* cf. *nothoaprilis* {1}, dematiaceous hyphomycete. **Desiccation tolerance**: a few mature asci still viable after 6 months, many paraphyses after 13.5 months, many excipular cells and ascospores even after 2.5 years. **Altitude**: 48–58 m a.s.l. **Geology**: Cenozoic regolith (whitish sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia anigozanthi* is easily recognized in the field by its large, dry pale to mostly bright yellow-orange apothecia. The straight, fusoid ascospores with eccentrical, rod-shaped SBs strongly resemble those of *O. polybrocha*. *O. anigozanthi* is extraordinary within series *Gamsylella* and also *Dactylellina* because of its desiccation-tolerant apothecia. *O. pilosa* resembles *O. anigozanthi* in paraphysis shape but differs, e.g., in white, ± desiccation-sensitive apothecia with thick-walled hairs at the margin, and much shorter spores with globose SBs. *O. alba* resembles *O. anigozanthi* in the large apothecia, large excipular cells, wide anchoring hyphae, sublanceolate paraphyses, and ± eccentrical SBs, but differs in smaller spores and white apothecia growing on hygric woody substrate.

Phylogeny. Sequences were gained from apothecia, two from the holo- and one from the paratype, comprising ITS and LSU. Those from the holotype include a small part of SSU, in which the S1506 intron is absent. Among these three sequences interesting variation occurs at 3 positions of the ITS region, which is clearly not the result of a sequencing error, according to the consensus analysis of two different runs for pos. 85 and 3 for pos. 359 and 461 (Tab. 90). These positions are otherwise consistent among members of series *Gamsylella* and *Dactylellina*, except for a few deviations: *D.* aff. *phymatopaga* CBS 568.95 deviates at pos. 85 by A and *D. haptotyla* in this region by 13 gaps from other *Dactylellina* and *Gamsylella* species which have G, and *D. haptospora* differs at pos. 461 by a gap from the typical situation (T).

The three sequences of *O. anigozanthi* were gained from a few small fragments of detached apothecia found in the envelope. Therefore, each sequence could derive from one or several apothecia, and it remains unclear whether the observed variation is due to multinucleate cells, or the genome deviates among apothecia of a population.

The morphological similarity between *O. alba* and *O. anigozanthi* in the teleomorph is supported by our combined phylogenetic analyses (Baral et al. 2017b, Phyl. 25) in which they form with *G. gephyropaga* a strongly or medium supported clade. However, a distance of 16.5% in the ITS region and 4% in the LSU D1–D2 is found between the two species. When analysing LSU or SSU+ITS+LSU (Phyls 35, S35), *O. anigozanthi* clustered with medium support with *G. gephyropaga*, whereas in the ITS alone this association remained unsupported (Phyl. 34). Actually, the distance between *O. anigozanthi* and *G. gephyropaga* is only 11–13.5/1.9–2.1%, compared to 14–19.5/3.8–4.3% between *O. alba* and *G. gephyropaga*.

Ecology. *O. anigozanthi* was found on decayed, xeric herbaceous stems, leaves, and fruits of *Anigozanthos* (*Commelinales*), an attractive Australian plant genus known as Kangaroo Paw. The substrate was lying on the dry ground in a subtropical semihumid banksia-eucalypt woodland in southwestern Australia. The paratype collection was gathered only 430 m away from the holotype locality. Apothecia have been collected during the dry season, though the first record was made shortly after the humid wintertime. Despite its conspicuous apothecia the species was only observed in the Kings Park in Perth.

Specimens included. **AUSTRALIA**: **Western Australia**, **Swan Coastal Plain**, 3 km SW of Perth, Kings Park, NE of Matilda Bay, non-cultivated part, 48 m, stems & leaves of *Anigozanthos manglesii*, 7.IX.2006, G. Marson (MEL 2389239, holotype; isotype in H.B. 8303a; sq.: KT380102, KT380103). – ibid., 430 m NE of type locality, 58 m, stems, leaves & fruits of *A. manglesii*, 14.XI.2007, G. Marson (H.B. 8831; sq.: KT222374).

Gamsylella cionopaga was synonymised with *G. gephyropaga* by Rubner (1996) and Scholler et al. (1999). Drechsler (1950a) distinguished it because of adhesive branches that seldom fuse to a scalariform network, noticeably longer conidia with a more variable pattern of septation. Yet, Rubner could not draw a line between the many studied strains which included both species according to two unpublished sequences in CBS.

In fact, strong molecular differences are observed among strains under these two names. These resulted in two very distant main clades (Phyls 34–35, S35) which show an ITS distance of 11–14.5 % and an LSU (D1–D2) distance of 2.5–3.7 %. However, the two names occur mixed within both clades, but also a rather high infraspecific variation in the ITS/LSU (D1–D2) is obvious within the two clades: 0–3.6/0–0.7 % in *G. gephyropaga* and 0.2–4.2/0–0.7 % in *G. cionopaga* in the here applied sense. Syntype sequences (ITS and LSU) were only available for *G. gephyropaga* (CBS 178.37), whereas *G. cionopaga* requires epitypification. Due to their very similar morphology, the correct nomenclature of the two main clades is not fully assured, particularly since morphological documentations were not available regarding sequences in GenBank.

We assume that the larger clade of the ITS tree, in which 10 of 15 strains originally carried the name *G. cionopaga* and two *G. gephyropaga*, represents *G. cionopaga*. If this is true, five strains bear the wrong, opposite name in GenBank: CBS 585.91 (ITS) is in fact *G. gephyropaga*, whereas SQ27-3 & XJ03-9-3 (both ITS) and YNUCC 4828 & 5028 (both LSU) belong to *G. cionopaga*. Three uncultured strains turned out to belong to *G. cionopaga*. One of them (from Canada) represents the only strain of this species in GenBank that includes both ITS and LSU, and it was this strain which enabled us, together with some unofficial sequences in CBS, to identify the *G. cionopaga* clade for the LSU (Phyl. 35). The *G. gephyropaga* clade in the LSU tree was identified by two sequences (including the syntype) which comprise both ITS and LSU.

Some mostly unofficial ITS and LSU sequences in the CBS database under the names *G. gephyropaga* can herewith be assigned to the two species: *G. gephyropaga*: CBS 309.94 (ITS), CBS 109507 (ITS+LSU); *G. cionopaga*: CBS 229.52 (LSU), CBS 310.94 (ITS+LSU), CBS 311.94 (ITS+LSU), CBS 398.93 (LSU), CBS 846.70 (ITS+LSU). The predominant use of the name *G. gephyropaga* is mainly a result of a broad species concept: some of the strains previously carried the name *G. cionopaga* but were later renamed to *G. gephyropaga* at CBS (228.52, 398.93, 846.70). Two further sequences under the name *G. gephyropaga* (308.94, 587.91; unofficial) could not be clarified because of a ca. 7–9 % ITS distance to *G. gephyropaga* and ca. 14–24 % to *G. cionopaga*. The drawings supplied by Rubner (1996) refer to *G. cionopaga* as here defined regarding figs 31b (CBS 310.94, trapping organs,) and 31d–e (CBS 311.94, 398.93, conidiophores and conidia), while for the other two illustrated strains no sequence data could be detected. CBS 109507 from Oman (Elshafie et al. 2003: fig. 3) belongs in the relationship of *G. gephyropaga* but differs from it by 4.5 % in the ITS and 0.7 % in the LSU.

G. cionopaga appears to include two different cryptic taxa (c1/c2), because most of the available sequences cluster unequivocally in two distinct clades, with 19 consistently deviating positions: 10 nt and 5 gaps in the ITS1, 5 nt in the ITS2, and 2 nt at the 3'-end of the D2 domain of LSU (Tab. 91). However, four strains clustered in an intermediate position by sharing the character of either c1 or c2 (the unofficial CBS 310.94 was not available).

According to the available collection data, *G. cionopaga* and *G. gephyropaga* prefer different climatic zones. *G. cionopaga* is so far known from temperate to boreal regions of Asia, Europe, and North America, whereas *G. gephyropaga* occurs more in subtropical regions of the same continents.

An ITS sequence of the Australian ex-type strain of *G. robusta* (CBS 110125, DQ999821) clustered unequivocally in series *Gamsylella* (in a medium supported clade with *G. gephyropaga*, Phyl. 34), in which relationship it was placed by Scholler et al. (1999) based on morphological reasons, when the sequence was not yet available. In the ITS2 the characteristic motif TCGAC confirms this placement (see Tab. 76). A misidentified Chinese strain under the name *M. robustum* (YMF 1.01413, ITS+LSU) clustered in series *Dactylellina* (Phyls 25, S35) and has the characteristic motif of that series (TCGGT).

Series *Drechslerella*

Orbilia subgenus ***Orbilia*** section ***Arthrobotrys*** series ***Drechslerella*** (Subram.) Baral & E. Weber, **comb. & stat. nov.**, MB 814996 – Type species: *Dactylella acrochaeta* Drechsler

Basionym: *Drechslerella* Subram., J. Indian Bot. Soc. 42: 299 (1964) [‘1963’]
= *Orbiliaster* Dennis, Kew Bull. 9: 294 (1954) — Type species: *Orbiliaster pilosus* Dennis [≡ *Orbilia pilosa* (Dennis) Baral]
= *Golovinia* Mekht., Mikol. Fitopatol. 1: 275 (1967) – Type species: *Dactylella bembicodes* Drechsler [≡ *Orbilia bembicodes* (Drechsler) E. Weber & Baral]
= *Dactylariopsis* Mekht., Mikol. Fitopatol. 1: 278 (1967) – Type species: *Dactylella brochopaga* Drechsler [≡ *Orbilia brochopaga* (Drechsler) E. Weber & Baral]

Etymology: *Dactylariopsis*: referring to the similarity with *Dactylaria*; *Drechslerella*: named after the North American mycologist C. Drechsler; *Golovinia*: named after the Russian mycologist P.N. Golovin; *Orbiliaster*: an *Orbilia* with long hairs at the apothecial margin appearing star-like.

Emended diagnosis: **TELEOMORPH**: Apothecia with smooth or crenulate to hairy margin, desiccation-sensitive or slightly -tolerant. Ascospores rod-shaped to ellipsoid, straight; spore bodies subglobose to rod-shaped, ± eccentrical. — **ANAMORPH**: Conidiogenous loci singly or on prominent denticles. Conidia 1–4((–5))-septate, straight or curved, microconidia often present. Forming constricting rings.

Description: — **TELEOMORPH**: **Apothecia** hydrated 0.2–1.5(–3) mm diam., white, pale to light cream-chlorinaceous or sulphur-yellow, or bright vinaceous to greyish-brown, margin smooth to distinctly crenulate, sessile or often with a prominent obconical to cylindrical stipe. **Asci** *(20–)23–42(–47) × (3.2–)3.5–4.5(–5.2) µm, 8-spored, lower (2–)3–5(–6) spores inverted; **apex** (†) medium to strongly truncate, not to distinctly indented and laterally inflated; **base** always partly H-shaped. **Ascospores** *(2.7–)3.5–8(–9) × 1–1.4(–1.9) µm, subcylindrical or (narrowly) cylindric-ellipsoid to fusoid-clavate or ellipsoid-obovoid, apex rounded to obtuse (rarely subacute), base exceptionally tail-like, straight or rarely slightly curved below, **SBs** slightly to strongly eccentrical (close to lateral wall below spore apex), rarely central, 0.4–1.7(–2) × 0.15–0.5 µm, rod- to tear-shaped or subglobose (often mixed in an apothecium), with a fine, very short, often hardly visible (or invisible) filum. **Paraphyses** slightly to strongly capitate(-clavate) at apex, also spathulate to lanceolate, terminal cells (1.5–)2.5–5 × longer than lower cells. **Ectal excipulum** of (†) thin-walled to medium gelatinized textura globulosa-angularis(-prismatica) [common walls †0.3–1(–2) µm], cells near base *(7–)10–40(–58) × (5–)9–30(–42) µm, margin of t. globulosa-prismatica or t. prismatica-porrecta oriented at (30–)50–90°; **glassy processes** near margin absent or up to 10–60 µm long, sometimes with septate, 12–110 µm long **hairs**. **SCBs** absent, rarely globose; **VBs** absent or often low- to medium refractive, hyaline to light yellow. **Exudate** absent or usually or 0.2–1.5(–8) µm thick, granular to cloddy, loosely or firmly attached, hyaline to pale yellowish or olivaceous-brown. **— ANAMORPH**: drechslerella-like. **Conidiophores** (40–)90–500 µm long, 3–8 µm wide at base, 2–4.5 µm at apex, unbranched, with a single terminal conidium, rarely apically branched, also with a few to many denticles or nodules at or near tip. **Macroconidia** *25–65 × 5–9.5 or 10.5–26.5 µm, fusiform to top-shaped, fusoid, ellipsoid, obovoid, clavate, or cylindrical, 1–4((–5))-septate, with or without inflated cell, straight or curved; **conidial dimorphism** often present, sharply differentiated. **Trapping organs**: spontaneously forming constricting rings in culture, with 1-septate stalk of *7–19 × 3.5–6 µm; rings *18–40 µm outer diam. (9.5–27 µm inner diam.), 3-celled, inner wall with triangular wall thickenings at the 3 septa (in optical cross section), cells strongly expanding inwards when nematodes enter the ring, smaller rings of *(8–)15–22 µm outer diam. formed directly on macroconidia, giant rings of *80–130 µm outer diam. (60–110 µm inner diam.) formed together with normal ones in some species.

Habitat: hygric or mesic wood and bark of angiosperms, also isolated from rhizosphere of trees (including conifers) and mono- or dicot herbs, capturing nematodes (occasionally rotifers), altimontane to tropical, humid, desiccation-sensitive or slightly -tolerant.

Recognized species: 10 (1 of them without known teleomorph), plus 3 unnamed species (‘affinis’); for further 11 species see Tabs 48 and S10.

Taxonomic remarks. Like in most other series of section *Arthrobotrys*, species cannot with certainty be assigned to series *Drechslerella* based on the teleomorph alone, i.e., without cultivation of the anamorph or without molecular data. Species recognition is likewise quite problematic without such data.

Up to now, only straight or slightly curved ascospores are known within series *Drechslerella*. Similar as in series *Gamsylella*, the spores contain slightly to strongly eccentrical, often rod-shaped but also more or less globose SBs attached by a fine filum. However, some unidentified taxa with predominantly roundish SBs (as incertae sedis) also tend to an eccentrical orientation (Pls 1021–1024).

Apothecia of series *Drechslerella* tend to be stipitate and may resemble members of *Helotiales* by external appearance. *O. pilosa* is exceptional in having broad, septate, thick-walled marginal hairs and a gelatinized excipulum. Marginal glassy processes are typical of *O. orientalis*, *O. polybrocha* and some other taxa. Species of series *Drechslerella* have comparatively wide anchoring hyphae of usually (3–)4–6(–8) µm.

Anamorph (see also p. 231–232 and Tab. S10). Members of series *Drechslerella* are charaterized by constricting rings formed ± spontaneously in pure culture, i.e., without presence of nematodes (see p. 119–121). Anamorphs that form such trapping organs are named drechslerella-like here. The macroconidia are medium- to large-sized and very different in shape (see Pl. 12, Phyl. 36): (1) ± cylindrical, often slightly curved (musiform), 3-septate, the individual cells having ± equal width (e.g., *O. brochopaga*); (2) cylindric-clavate to broadly obovoid, with 1 median or strongly eccentrical septum (e.g., *Drechslerella dactyloides*, *O. polybrocha*); (3) (cylindric-)ellipsoid, with 2 terminal septa and an inflated middle cell (*D. stenobrocha*, *D. heterospora*); (4) fusiform to top-shaped, with 2–4 septa and strongly inflated middle cell (e.g., *O. bembicodes*). *D. dactyloides* and *D. effusa* are intermediate in forming typically 1-septate cylindric-clavate conidia but also 2-septate cylindric-clavate, ellipsoid to fusiform conidia.

Microconidia are frequently formed (see Tab. 15). They differ from macroconidia in being much smaller, usually 1-septate, and always cylindric(-clavate). In some isolates only microconidia were observed. For instance, *D. yunnanensis* was described with small, 1-septate conidia, but another strain with identical ITS sequence formed besides microconidia also 3-septate macroconidia.

Fusiform macroconidia as in *O. bembicodes* are formed singly at the tip of long unbranched conidiophores (acrogenous), rarely from conidiophores with 2 apical branches (*D. effusa*, geniculate). Cylindric-allantoid 3-septate macroconidia as in *O. brochopaga*, or cylindric-clavate 1-septate ones as in *D. dactyloides* and *D. anchonia* differ in conidiophore tips with aggregated denticles or nodules on which the conidia are formed in a loose, capitate arrangement (candelabrelloid to almost arthrobotryoid).

Trapping organs of series *Drechslerella* are quite uniform in shape (see p. 119), consisting of a 2-celled stalk and a 3-celled ring. They vary considerably in size among the species and may serve as species marker. Sharply separated giant ring traps of a much larger size may occur in association with the normal traps and were so far recorded in *O. brochopaga*, *O. dactyloides*, and *O.* cf. *tonghaiensis*. In all cases where constricting rings where studied under oil immersion, triangular to lens-shaped wall thickenings occurred at all 3 ring septa. Bulge-like projections of the three cells at the inner part of the unexpanded ring are typical of three species (*Drechslerella acrochaeta*, *D. doedycoides*, *D. heterospora*).

Species delimitation. Morphological variation in the teleomorph is observed in species with a known teleomorph treated here, which obscures the limits between closely related taxa. *O. naumburgensis* and *O. flavovacuolata* resemble *O. polybrocha* in the ascospores, but sharply differ in apothecial colour and conidial morphology (the latter unknown in *O. flavovacuolata*). However, these species have been collected only rarely, hence their variation is little explored.

Yu et al. (2014) listed a total of 14 accepted species, but a teleomorph is as yet unknown in most of them. A morphological group of species with very uniform, cylindrical, often ± curved conidia includes *O. brochopaga*, *O. naumburgensis*, *O. orientalis*, *O. tonghaiensis*, and *O. yunnanensis*. Their members are also similar in the teleomorph, therefore, they can safely be distinguished only by molecular data.

Drechslerella anchonia and *D. dactyloides* are treated at present as synonyms in Species Fungorum and MycoBank, although Van Oorschot 1985 and Scholler et al. (1999) accepted them as two distinct species. In fact, their cylindric-clavate, 1-septate conidia are quite different in size, those of *D. anchonia* being much wider. However, *D. dactyloides* may also form much wider conidia which are usually more fusiform and 2-septate and sometimes just like in *D. anchonia* (Drechsler 1937a: 484, fig. 18K; Pl. 12: c right conidium), which obscures the difference.

Molecular species concept. High molecular distances are observed within the morphologically defined *O. brochopaga* group, despite a rather uniform conidial morphology. This indicates that several more or less cryptic species exist which at least do not markedly differ in their anamorph, and prompted us to consider *O. brochopaga* and *O. orientalis* as distinct species.

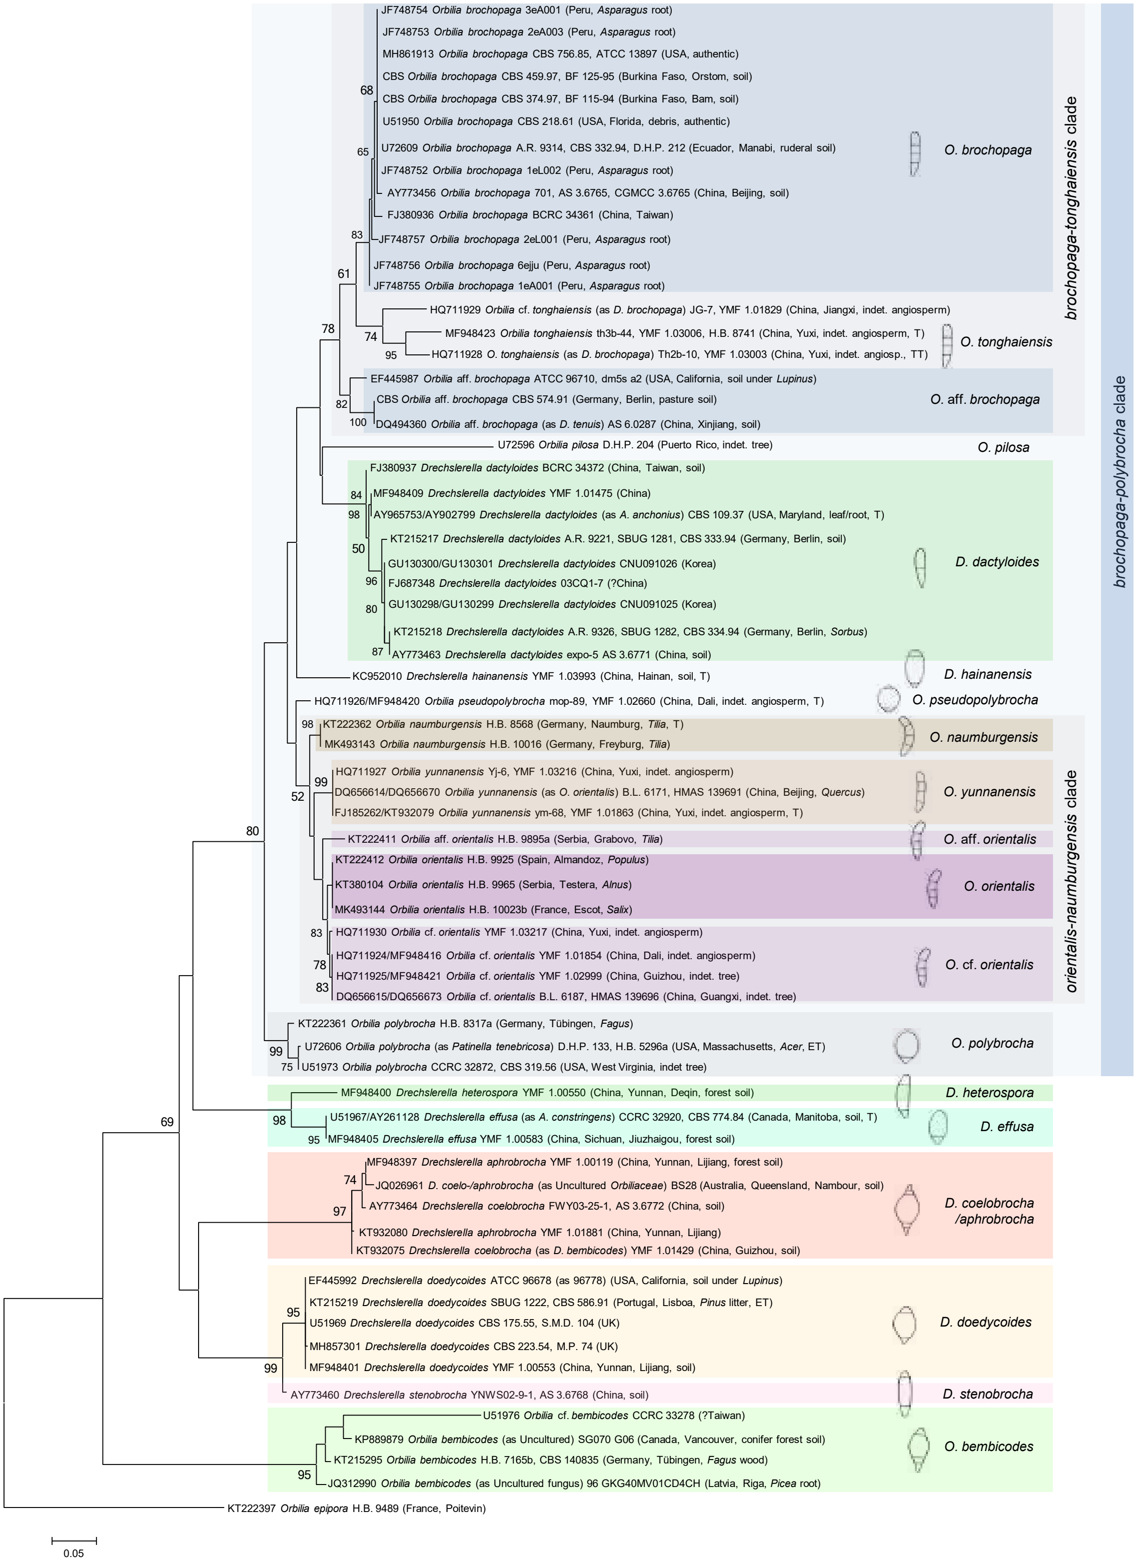
Molecular data under the name *Arthrobotrys anchonius* (CBS 109.37) in GenBank misleadingly support synonymisation of *D. anchonia* and *D. dactyloides*, based on ITS which fits various strains under the name *D. dactyloides*: However, CBS 109.37 in fact represents the ex-syntype strain of *D. dactyloides*, whereas no type culture of *D. anchonia* appears to exist (Van Oorschot 1985). Why Li et al. (2005) named this strain *A. anchonius* is unclear, particularly since the name is younger than the basionym of *D. dactyloides*.

Phylogeny. In our phylogenetic analysis of the ITS region, *Drechslerella bembicodes*, *D. coelobrocha*, *D. doedycoides*, *D. effusa*, *D. heterospora*, and *D. stenobrocha*, formed a paraphyletic basal group, whereas the remaining taxa clustered with medium support in a monophyletic group (Phyl. 36), which received strong support in our combined analysis (S37) and is called *brochopaga-polybrocha* clade here. Within the paraphyletic basal group, *D. doedycoides* and *D. stenobrocha* clustered in a clade, which received strong support in all three analyses (including LSU, S36), and also *D. effusa* and *D. heterospora* clustered in a strongly supported clade (Phyl. 36).

Our analysis suggests that fusiform (top-shaped) macroconidia characteristic of *D. bembicodes* represent the plesiomorphic character within series *Drechslerella*. Although cylindrical conidia can be considered as more primitive in shape, they seem to have evolved within this series by retrogression from conidia with a swollen middle cell. In *D. dactyloides*, in which both conidial types occur, this retrogression appears to be incomplete.

The *brochopaga-polybrocha* clade comprises two monophyletic subclades which both contain species with cylindrical, mainly 3-septate conidia: (1) the medium (ITS, LSU) supported *brochopaga-tonghaiensis* clade, and (2) the weakly (ITS) or strongly (LSU) supported *orientalis-naumburgensis* clade (Phyls 36, S36). The *brochopaga-polybrocha* clade includes also *D. dactyloides*, *D. hainanensis*, *O. pilosa*, *O. polybrocha*, and *D. pseudopolybrocha* which clustered unresolved within this clade. Four of them possess top-shaped conidia, and *D. dactyloides* cylindrical 1-septate or rarely top-shaped conidia. The very similar conidial morphology in the *brochopaga-tonghaiensis* clade and the *orientalis-naumburgensis* clade suggests a common ancestor with cylindrical 3-septate conidia, although this is not supported by phylogenetic analysis. More probable seems that *O. polybrocha*, *O. pseudopolybrocha*, and *D. hainanensis* retained the plesiomorphy of the strongly inflated conidial cells, but these taxa are missing in the combined analysis (S37) because they lack LSU.

Specific nucleotide positions. In the SSU V8–V9 region, series *Drechslerella* is unique at pos. 70 (AGG**C**TTG, rarely AGG**C**CTG), whereas other members of section *Arthrobotrys* have mostly AGG**T**TTG but never **C** which is generally rare in the *Orbiliomycetes*. Pos. 109 and 126 differ from other



Phylogenetic analysis 36. Phylogram of series *Drechslerella* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (66 sequences, 551 positions, aligned with MUSCLE) using the K2+G model in MEGA6 (500 replicates). The tree is rooted with *O. epipora*. Asci 8-spored in all teleomorph taxa; T = type, ET = epitype, NT = neotype, TT = topotype.

predacious members of section *Arthrobotrys* by concurring with series *Neodactylella* (Tab. 76) and all other members of *Orbilia* outside that section. However, SSU was only available for four taxa of series *Drechslerella* (Phyl. S29). In the LSU D1–D2 domain, series *Drechslerella* has at pos. 502 AG**C**TGG unlike any other member of *Orbiliomycetes* which have AG**T**TGG, GG**T**TGG, GG**T**TGA etc. but only very rarely **C**. Three further positions (182: CC**C**AA, 511: GG**T**GG, 574: CC**A**CC) are consistent within series *Drechslerella* but the remaining series of section *Arthrobotrys* differ only partly herein.

The *brochopaga-polybrocha* clade, but also *D. effusa* and *O. pilosa* which clustered near to it, show full identity in the 5.8S region (a deviation at pos. 102 in U51973, G vs. T, is erroneous according to a sequence at CBS). A single nucleotide position in the 5.8S (pos. 111, GCA**T**ATT) distinguishes this clade (including *D. effusa* and *O. pilosa*) from the five more

Key to species of series *Drechslerella* with known teleomorph

(for a key based on anamorphs see Zhang et al. 2020)

1. Paraphyses predominantly obtusely lanceolate to spathulate or lageniform; apothecia smooth or with thick-walled septate hairs with a wide central lumen 2
1. Paraphyses predominantly capitate-clavate; apothecia smooth or with solid glassy processes 3

2. Apothecial margin with 12–45 µm up to 70–100 µm long, 5–9 µm wide, septate, thick-walled hairs; spores *3.5–5 × 1–1.4 µm, cylindrical, straight to very slightly curved; SBs globose; conidia broadly fusoid, with large middle cell; wood of angiosperms, warm-temperate to tropical humid oceanic Europe & Middle America .... ***O. pilosa***, p. 1629
2. Apothecial margin hairless; SBs subglobose to rod-shaped, often eccentrical; conidia ± cylindrical, with 1 median septum .... see **series *Gamsylella***, p. 1610

3. Apothecia 0.2–0.25 mm diam., pale yellow, margin smooth; paraphyses and marginal cells containing yellow VBs; spores *4.8–8(–9) × (1–)1.2–1.3(–1.4) µm; SBs predominantly roundish; wood of *Fagus*, cold-temperate humid central Europe .... ***O. flavovacuolata***, p. 1639
3. Apothecia whitish to vinaceous-brown, if yellowish then spores shorter and margin crenulate; VBs hyaline or absent 4

4. Macroconidia ellipsoid to obovoid or subglobose, *26–39 × 16–26 µm, with 1 strongly inflated cell and 1–3 much smaller terminal cells, formed singly at the conidiophore tip; apothecia whitish to vinaceous-brown 5
4. Macroconidia cylindrical, straight to ± allantoid, *28–45 × 5.3–9 µm, with (1–)3 equidistant or centrally aggregated septa, formed in clusters on denticles at the conidiophore tip; apothecia whitish or cream 7

5. Macroconidia broadly obovoid, with 1 subbasal septum; conidiophore tips not swollen; apothecia typically dull vinaceous-brown, 0.3–1.8 mm diam., with a denticulate margin due to glassy processes; spores *(4.2–)5–6.5(–7.5) × (1–)1.1–1.3(–1.4) µm; SBs usually rod-shaped; wood of angiosperms, orotemperate to subtropical humid Europe & North America .... ***O. polybrocha***, p. 1631
5. Macroconidia broadly ellipsoid to fusiform, with mainly 2–3 terminal septa and a strongly swollen middle cell 6

6. Spores *5–6.8 × 1.2–1.4 µm; SBs subglobose to tear-shaped, 0.5–0.8 µm wide; macroconidia (presumed) 3-septate, fusiform, *38–42.5 × 16–22 µm, conidiophores and trapping organs not observed; apothecia whitish, with smooth margin; dung, orotemperate humid central Europe .... ***Orbilia* sp. H.B. 8749**, p. 1655
Compare also *O. lysipaga* (Pls 987–988) and *Orbilia* sp. H.B. 8963 (Pls 1021–1022).
6. Spores 2.8–5.5 × 1.2–1.5 µm; SBs rod-shaped, 0.3–0.4 µm wide; macroconidia 2-septate, broadly ellipsoid to fusoid, *26–32.5(–39) × (15.5–)17–21(–24) µm, formed on ± swollen conidiophore tips; apothecia yellowish-cream, margin finely denticulate; angiosperm bark, subtropical humid eastern Asia .... ***O. pseudopolybrocha***, p. 1637
7. Spores *3.5–5(–5.7) × 1.3–1.7 µm, ellipsoid-fusoid, slightly to strongly attenuated below; wood of *Tilia*, cold-temperate humid (almost subhumid) central Europe .... ***O. naumburgensis***, p. 1640
7. Spores *(2.7–)3–4.3 µm long, cylindric-ellipsoid to ellipsoid, not or slightly attenuated below; wood & bark of various angiosperms, rarely gymnosperms 8

8. Spores *2.1–2.8(–3.5) × (1.4–)1.6–2(–2.2) µm; SBs tear-shaped, slightly eccentrical; glassy processes absent; apothecia substipitate; wood of indet. angiosperms, subtropical humid eastern Asia .... ***O. tonghaiensis***, p. 1653
8. Spores *(2.6–)3–4.5 µm long; glassy processes present or absent 9

9. SBs globose, central; apothecia smooth, ± sessile; woody ?& herbaceous plants, cold-temperate to tropical, humid to semiarid, worldwide .... ***O. brochopaga* s.l.**, p. 1649
9. SBs rod-shaped or sometimes almost globose, ± strongly eccentrical; apothecia smooth or often with crenulate margin, stipitate 10

10. Outer diameter of constricting rings *35–39 µm; glassy processes mostly present, 20–60 µm long, forming a crenulate margin; spores *(1.2–)1.3–1.7(–1.9) µm wide, SBs tear- to rod-shaped, eccentrical; apothecia (0.3–)0.5–1.5(–3) mm diam., with a distinct stalk up to 0.5 × 0.6 mm; angiosperm (& gymnosperm) wood, cold- to warm-temperate humid Europe .... ***O. orientalis***, p. 1644
10. Outer diameter of constricting rings *19–27 µm (rarely giant rings in addition); glassy processes absent or present; humid eastern Asia 11

11. Spores *1.2–1.5 µm wide; apothecia 0.4–0.6 mm diam.; subtropical .... ***O.* cf. *orientalis***, p. 1645
11. Spores *1.6–2 µm wide; apothecia 0.3–2 mm diam.; cold-temperate to subtropical .... ***O. yunnanensis***, p. 1642

basal *Drechslerella* species and all other members of section *Arthrobotrys*, which have instead the motif GCA**C**ATT.

In stem-loop B8 of the 5.8S region (Tab. 77), series *Drechslerella* concurs with a majority of series *Dactylellina* and some species of series *Neodactylella* (*rhamni-fraxini* clade) in having **TT**GGTATTCC**AT** at the 2 symmetric positions 122–123/132–133, except for *D. bembicodes* which has **TC**GGTATTCC**GA** (CCRC 33278) or **TT**GGTATTCC**GA** (H.B. 7165b). The latter motif occurs also in *D.* aff. *phymatopaga*, *Arthrobotrys nonseptatus*, and *A. polycephalus*, and many non-predacious *Orbilia* spp.

Ecology. Members of series *Drechslerella* form apothecia on wood and bark of angiosperms. Species were recorded on most continents from boreal (altimontane) to tropical, but always humid regions (records from arid areas concern irrigated agricultural fields).

Orbilia bembicodes (Drechsler) E. Weber & Baral, **comb. nov.**, MB 814000 — Pls 999–1000

Basionym: *Dactylella bembicodes* Drechsler, Mycologia 29(4): 491, fig. 7 (1937)
≡ *Monacrosporium bembicodes* (Drechsler) Subram., J. Indian Bot. Soc. 42: 293 (1964, '1963')
≡ *Golovinia bembicodes* (Drechsler) Mekht., Mikol. Fitopatol. 1: 275 (1967)
≡ *Drechslerella bembicodes* (Drechsler) M. Scholler, Hagedorn & A. Rubner, Sydowia 51(1): 99 (1999)

Etymology: named according to the top-shaped (turbinate) conidia.

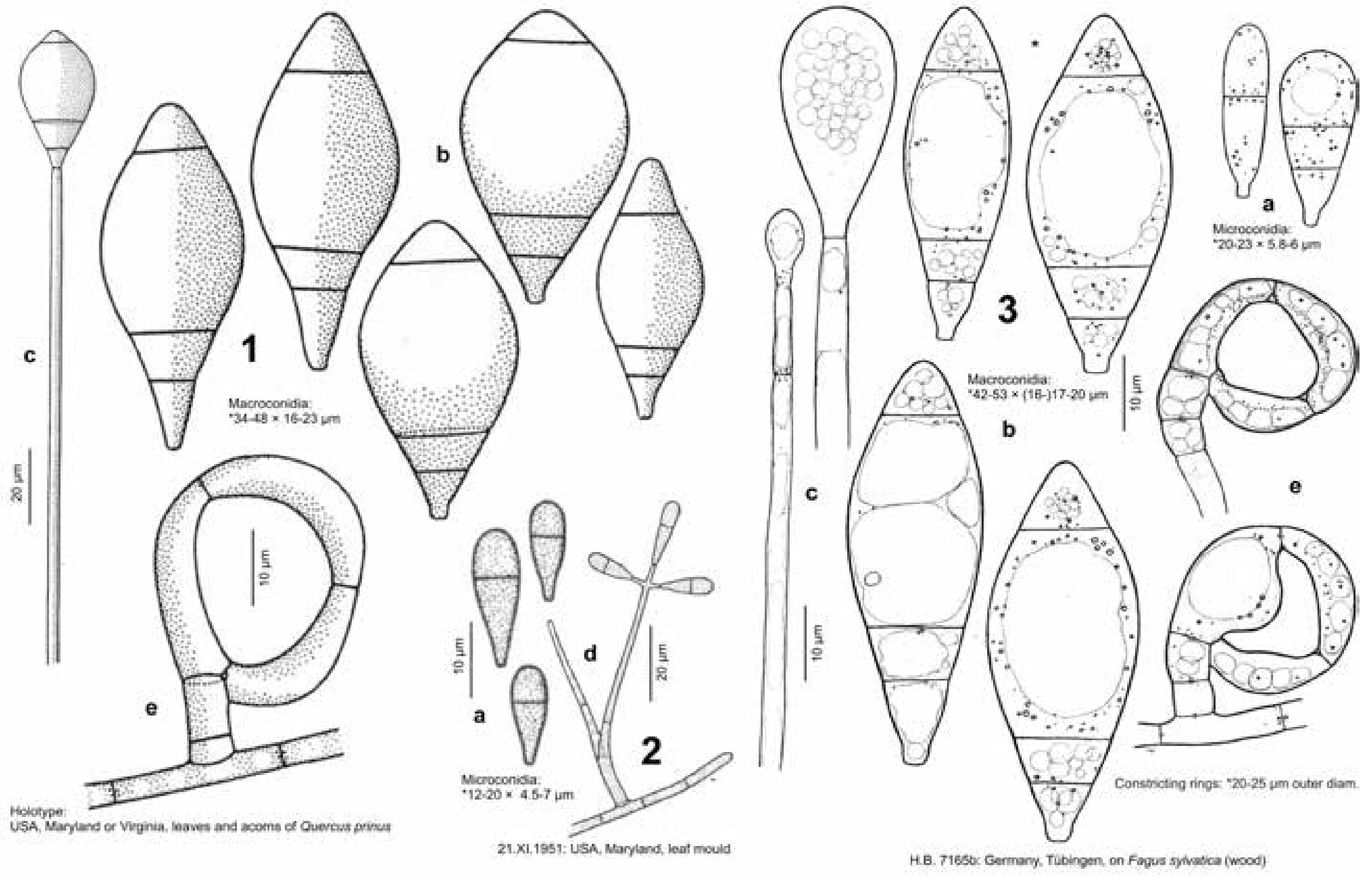


Plate 999. **1–3**: *Orbilia bembicodes*. – **a**. microconidia; **b**. macroconidia; **c**. macroconidiophores; **d**. microconidiophore; **e**. constricting rings, 1 ring cell in **2d** expanded (from soil or conidial isolate); **1**: from Drechsler 1937a, **2**: from Drechsler 1962.

Typification: USA, Maryland & Virginia, leaves and acorns of *Quercus prinus*, undated, C. Drechsler (holotype, illustration in Drechsler 1937a: 491 [ex-type culture in CBS 177.37 is a contaminant]).

Description: — **TELEOMORPH**: unknown. **— ANAMORPH**: drechslerella-like (isolated from mould {T & Drechsler 1962} or from conidia on wood {1}). **Macroconidiophores** *250 {1} or (250–)300–450(–500) {T} µm long, *3–4 µm {1} or 5–7.5 {T} µm wide at base, *2–3.2 µm at apex, very sparsely septate, with a single conidium at apex. **Macroconidia** fusiform, *34–48 × 16–23 µm {T}, *42–53 × (13.7–)16–20 µm {1}, 3-septate, consistently with 2 septa near base and 1 near apex, middle cell very large, containing a large vacuole. **Microconidiophores** *55 µm long, 3.5 µm wide at base, 1.2 µm at tip, forming 4–8 conidia on 2.5–4 µm long denticles {1962}. **Microconidia** *12–20 × 4.5–7 µm {1962}, *20–23 × 5.8–6 µm {1}, clavate to cylindric-ellipsoid, 1-septate, septum slightly above middle; also intermediate conidia of *23 × 10 µm, clavate, 2-septate {1}. **Chlamydospores** not observed. **Constricting rings** with 1-septate stalk of *7–14 × 4.5–6 {T} or *11 × 6–6.5 µm {1}; ring unexpanded *22–37 µm {T} or *20–23 × 22–25 µm {1}, 3-celled, ring cells *4.5–7 µm wide {2} (up to *12.5 µm when expanded), with small triangular wall thickenings at the 2 distal septa {1}, capturing nematodes (but also rotifers, Drechsler 1937a: fig. 18).

Habitat of German collection: lying on ground, decorticated, 45 mm thick branch of *Fagus sylvatica* {1}, on lateral upperside, on 2–3 mm deep strongly decayed wood {1}, no algae. **Associated**: *Cacumisporium capitulatum* {1}, *Chaetosphaeria myriocarpa* {1}, *Claussenomyces prasinulus* {1}, *Dematioscypha delicata* {1}, *Mollisia* ?*oblonga* {1}, *Orbilia mammillata* {1}, *O. xanthostigma* {1}, *Rhizodiscina lignyota* {1}, *Tubeufia cerea* {1}. **Desiccation tolerance**: apparently intolerant. **Altitude**: 15–350 m a.s.l. (Europe), ~10–100 m (USA). **Geology**: Tübingen: Keuper (Stubensandstein).

Taxonomic remarks. *Orbilia bembicodes* is characterized by broadly fusiform (top-shaped), consistently 3-septate conidia, with 2 septa always in the basal part and a very large middle cell, in combination with constricting rings. Because of differences in molecular data (see below), the taxon seems to comprise a species aggregate, but no morphological data were available for the isolate of Liou & Tzean. *Drechslerella doedycoides* and *O. pseudopolybrocha* deviate in conidia with only 1 basal septum and in apically swollen conidiophore tips (Pls 12: l; 1009).

The teleomorph of *O. bembicodes* is unknown. In the two records here identified as *D. bembicodes* s.l. (Pls 999: 2; 1000), two different teleomorphs grew in association (*O. mammillata*, *O. alba*). It could be shown, however, that these are not connected to *D. bembicodes* but to two very different anamorphs. Conidia comparable to *O. bembicodes* occurred associated with apothecia on dung in Austria (Pls 1023–1024), but here no trapping organs were found. Another possible teleomorph is *O. flavovacuolata* (see p. 1639).

In the collection on *Fagus* (Pl. 999: 2), the associated apothecia of *O. mammillata* and its anamorph occurred at a distance of ~10 cm. Problematic was the fact that the conidia of both species are very similar, those of *O. mammillata* being only slightly smaller. Yet, adhesive knobs were associated on the natural substrate with both the conidiophores and apothecia of *O. mammillata*, and constricting rings with the conidiophores of *O. bembicodes*. Conidiophores and trapping devices of these two anamorphs developed also in pure culture of the two conidial isolates from this mixed collection when nematodes were added.

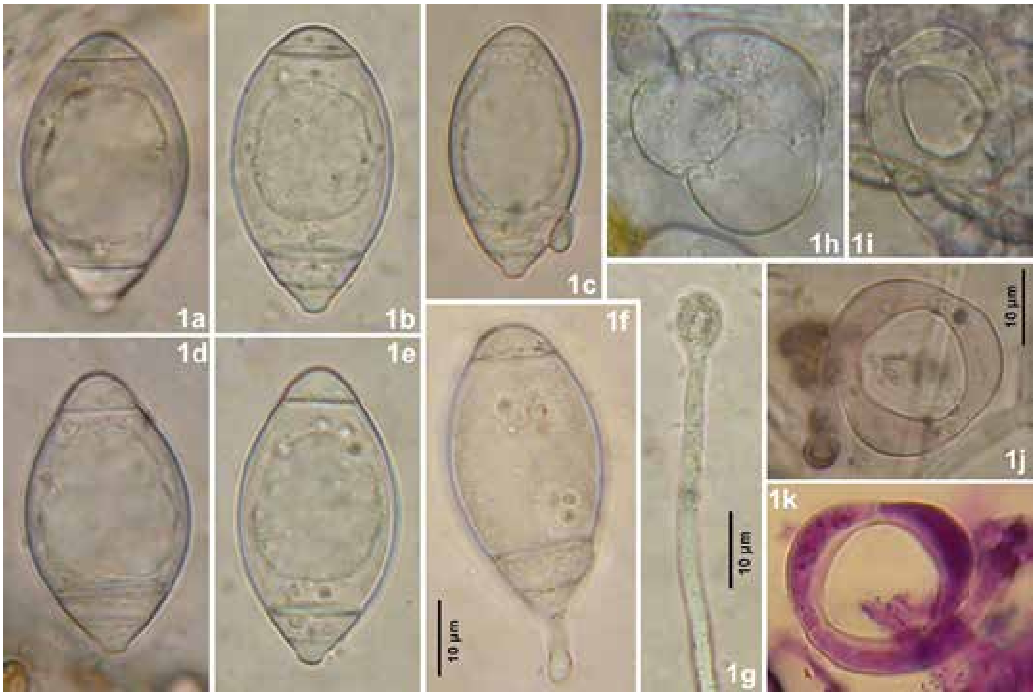

Plate 1000. **1**: *Orbilia* cf. *bembicodes* (on natural substrate). – **1a–f**. macroconidia; **1g**. macroconidiophore, **1h–k**. constricting rings (**1h** expanded) (all from substrate). – Living state, except for **1g** (in H_2O), **1j** (in KOH), **1k** (in KOH+CRB). — **1a–k**. H.B. 9051g: Spain, Asturias, on *Eucalyptus*.

Drechsler's (1937a) type illustration of *Dactylella bembicodes* (from leaves and acorns of *Quercus prinus*, Pl. 999: 1) shows top-shaped, slightly shorter and wider conidia and somewhat larger constricting rings compared to the strain on *Fagus*, but in conidial shape the two fit quite well. Couch (1937) described a North-American collection on pine wood, probably from North Carolina, with 400–1500 µm long conidiophores, conidia of ca. 47.5–49.5 × 21–23 µm, and constricting rings of 24–31 µm outer diam. Conidial size was not indicated in the text, however, and a wrong magnification of ×110 was given for figs 2–4 that show the conidia. The above size was evaluated with an assumed magnification of ×525, which is indicated for figs 6–11 that show constricting rings.

Not included collection. In association with *O. alba* (on *Eucalyptus* bark) we observed several anamorphs which are obviously not connected to each other. One (Pl. 1000) resembles *D. bembicodes* but differs in more ellipsoid-fusoid macroconidia with rather short terminal cells and a size comparable to the type [*(33–)36–39 × (17.5–)19.5–22 µm, †34–37(–39) × 18.5–21.3 µm], with conidiophores of †340 × 6 µm. The unexpanded constricting rings measured *20–26 µm outer diam. The large vacuole in the central conidial cell is surrounded by a few refractive, KOH-soluble guttules of 0.4–0.7 µm diam. (?SCBs). In conidial size and shape this specimen matches very well '*Dactylella*' *megalobrocha* Glockling (in Glockling & Dick 1994), described on rabbit dung from Great Britain with conidia of 36–40 × 20–22 µm. This taxon was perhaps incorrectly treated as a synonym of *D. bembicodes* by Rubner (1996), as its constricting rings are reported with an outer diameter of 40–48(–56) µm, which is twice as large as in the specimens on *Fagus* and *Eucalyptus*.

Phylogeny. A sequence was gained from our isolate from *Fagus*, comprising SSU (with S1506 intron), ITS, and LSU. It differs from a sequence of unknown origin in GenBank (?Taiwan) uploaded under the name *M. bembicodes* by Liou & Tzean (1997; S1506 intron, ITS) by 11% in the ITS region and 12.5% in the intron, which suggests heterogeneity of *O. bembicodes*. Two unidentified uncultured soil isolates from conifer forests in GenBank are obviously conspecific with *O. bembicodes* from *Fagus*. One is from northern Europe (Latvia) and comprises parts of 5.8S and ITS2, differing from our strain by only 1.9% in the ITS2. Another isolate is from Canada (SG070_G06) and comprises ITS and LSU (S1506 intron absent in the partial SSU), differing from the *Fagus* strain by 2.7% in the ITS (1.1% in LSU D1–D2) and from Liou & Tzean's strain by 11.5% in the ITS. We here refer to the three similar strains as *O. bembicodes* s.str. Regrettably, molecular data of the ex-type (CBS 177.37) was not available, since this culture turned out to be a contaminant: a sequence gained by G. Hagedorn belongs to *Peniophora pini*, and the same result was obtained at CBS (see CBS database).

Especially the ITS2 of *O. bembicodes* s.l. is very different from other strains of *Orbiliomycetes* and does not align in a GenBank BLAST. Even within *O. bembicodes* s.l. the ITS2 varies in the range of 1.9–21.5% among the four strains: 1.9% within *O. bembicodes* from Europe, 3.2% to the Canadian strain, 21.5% for the Taiwanese strain. A misidentified Chinese strain (YMF 1.01429) appears to belong to *D. coelobrocha*, together with another identified as *D. aphrobrocha* (YMF 1.01881), see Phyl. 36

In our phylogenetic analysis of the ITS region, *O. bembicodes* s.l. formed a strongly supported clade situated at the very base of series *Drechslerella*, with a high distance to all other species of this series (Phyl. 36). Also when analysing LSU, *O. bembicodes* s.str. formed a basal sister clade to the rest of the series (Phyl. S36). In the intron analysis, *O. bembicodes* surprisingly clustered in a weakly supported clade with *O. tonghaiensis* s.l. from Jiangxi and Tonghai which is associated unsupported with taxa with adhesive traps, whereas the remaining members of series *Drechslerella* (including *O. brochopaga* and *O. orientalis*) clustered with 100% bootstrap support in a distant clade (S30).

Two CBS cultures under the name *D. bembicodes* were sequenced by G. Hagedorn (SSU, ITS, LSU), but turned out to belong to series *Arthrobotrys*. One (CBS 703.74, Netherlands) coincides with the ex-type strains of *A. xiangyunensis* and *A. reticulatus*, and the other (CBS 376.97, Burkina Faso) belongs to *A. thaumasius*.

Ecology. Drechsler's isolates were from two sites around Washington D.C. (Beltsville and Arlington) in warm-temperate humid eastern North America. Our collection from southern Germany was made on the lateral upperside of a decorticated *Fagus* log in a *Fagetum* at a south-exposed slope in subcontinental, cold-temperate humid central Europe. The strain from northeastern Europe (Latvia) was isolated from soil of the *Picea* rhizosphere of a hemiboreal humid spruce forest (Menkis et al. 2012), and that from Canada was a soil isolate in a boreal conifer forest (unpublished). The not included Spanish collection was on the hygric underside of detached rotten bark of *Eucalyptus* in an atlantic, thermotemperate humid (somewhat summer-dry) eucalypt plantation. Two Scottish collections under the name *Monacrosporium bembicodes* are listed in the British database (FRDBI): from Arran (on *Ilex perneyi* leaf, IX.1980, P.M. Kirk) and Perthshire (from soil, 1985, G.C. Ainsworth).

Specimens included. **GERMANY**: **Baden-Württemberg**, 5 km ENE of Tübingen, 1 km S of Pfrondorf, Bitzle, 350 m, branch of *Fagus sylvatica*, on wood, 12.VII.2002, E. Weber (H.B. 7165b, conid. isol., CBS 140835; sq.: KT215295). — **LATVIA**: 30 km SW of Riga, 16.5 km N of Jelgava, 5.5 km E of Kalnciems, 15 m, *Picea abies* forest soil, VI.2009, Menkis et al. (2012, 96_GKG40MV01CD4CH, mol. extr.; sq.: JQ312990). — **CANADA**: **?British Columbia**, unlocalized, conifer forest soil, undated (S.H.A. Guichon & S.W. Simard, SG070_G06, mol. extr.; sq.: KP889879). — **USA**: **Maryland**, Beltsville, ~50–100 m, and **Virginia**, Arlington, ~0–100 m, leaf mould and acorns of *Quercus michauxii* (as *Q. prinus*), undated, C. Drechsler (**type** of *O. bembicodes* [illustration], conid. isol., doc. vid.). – **Maryland**, near Salisbury, ~10 m, leaf mould, 21.XI.1951, C. Drechsler (1962, conid. isol., doc. vid.).

Not included. **SPAIN**: **Asturias**, 5 km WSW of Avilés, 2 km SSW of Piedras Blancas, Las Bárzanas, 80 m, detached bark of trunk of *Eucalyptus globulus*, 25.IV.2009, E. Rubio & A. Suárez (H.B. 9051g ø, anam. only). — ?**CHINA**: **Taiwan**, unlocalized (CCRC 33278, Liou & Tzean 1997, sq.: U51976).

Orbilia pilosa (Dennis) Baral, Syst. Ascom. 13: 120 (1994) — Pls 1001–1002.

≡ *Orbiliaster pilosus* Dennis, Kew Bull. 9: 294 (1954) [as '*pilosa*', ICN Art. 62.1]

Etymology: named after the long hairs on the apothecial margin.
Typification: Trinidad, Diego Martin, trunk of indet. angiosperm, 22.IX.1949, R.W.G. Dennis (K(M) 36046, holotype).

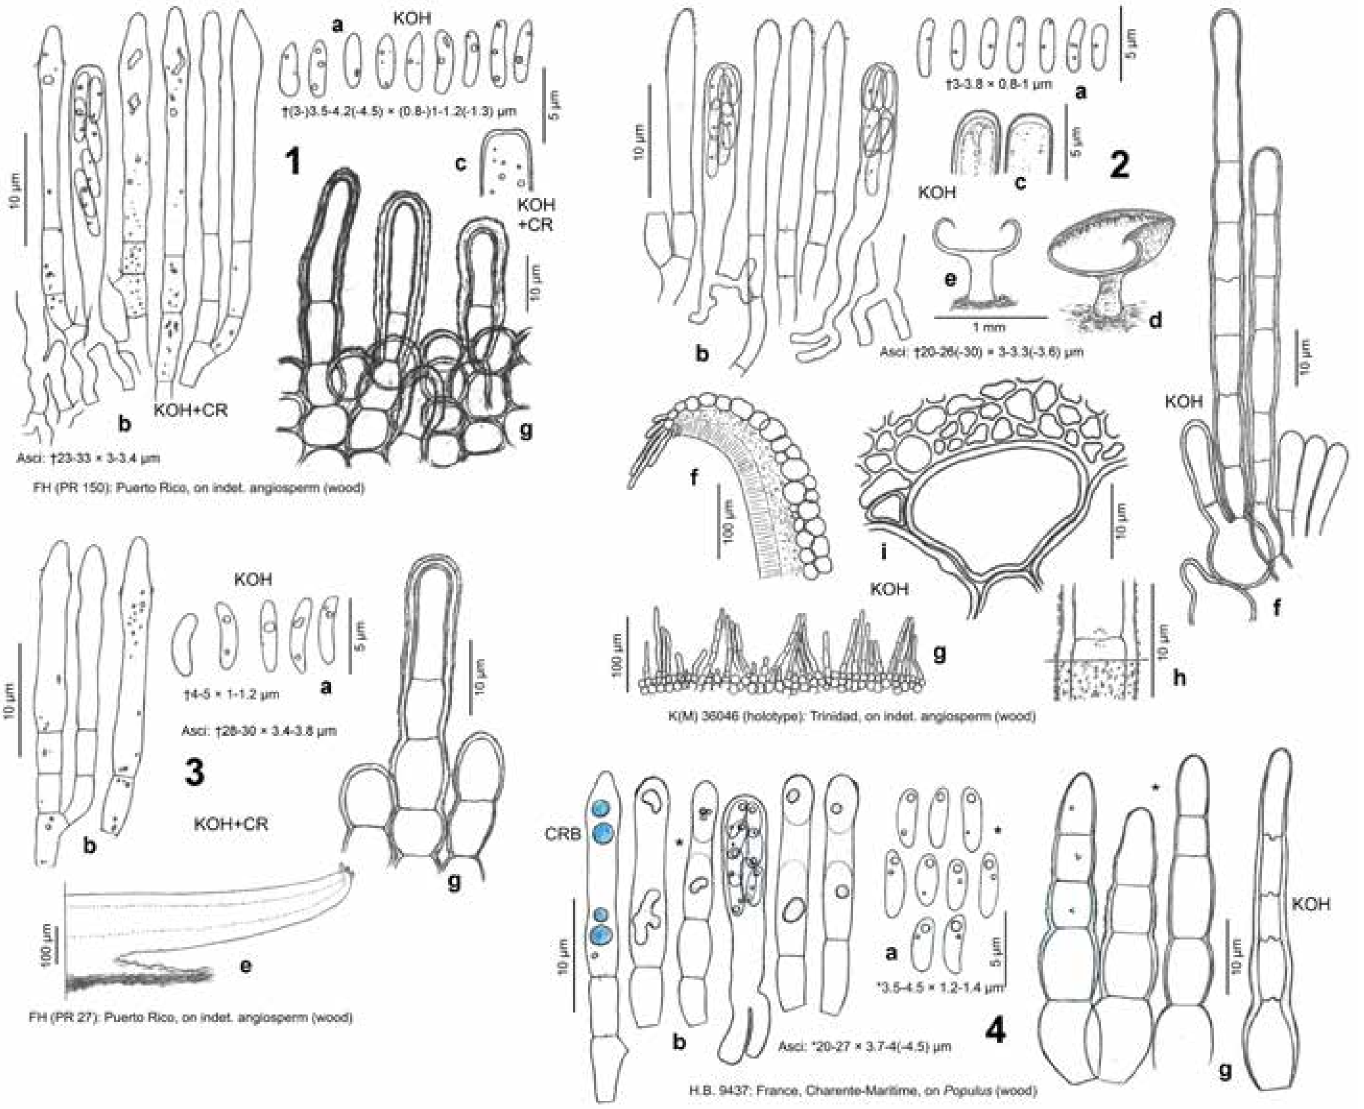
Description: — **TELEOMORPH** (values in [...] from 2 Puerto-Rican collections): **Apothecia** rehydrated 0.5–1.5(–1.8) mm diam., 0.5–0.7 {T} or 0.2–0.45 mm tall (receptacle 0.08–0.17 → 0.06–0.08 mm), white {1} or light fawn {T} [cream-yellowish-ochre], round, ± gelatinous, scattered to medium gregarious; disc deeply cupulate, sometimes with inrolled margin {T} [slightly cupulate to flat], with prominent hairs exclusively at the margin, these either free {3} or loosely agglutinated to form distinct teeth {T}; exterior glabrous, white to cream, subsessile or mostly with an obconical to cylindrical, white to cream stipe 0.05–0.3 × 0.15–0.25 {3} or 0.2–0.4 × 0.2–0.3 mm {T}, superficial; dry with strongly inrolled margin with the teeth directed downwards to the hymenium {T}. **Asci** *20–27 × 3.7–4(–4.5) µm {1}, †20–25(–30) × 3–3.4(–3.7) {2}, [†23–33 × 3–3.8 {2}], 8-spored, spores 2–3-seriate, basal ~4 spores inverted {1}, pars sporifera *10.5 µm long, †8–11.5 µm; **apex** (†) hemispherical to slightly [medium to strongly] truncate (not or rarely slightly indented, laterally not inflated), thin-walled; **base** without or with short to medium long, flexuous stalk, h- to H-shaped. **Ascospores** *3.5–4.5 × 1.2–1.4 µm, †(3–)3.2–3.8 {2} × 0.8–1 {T} or 1.1–1.2 {1} µm, [†3–5 × (0.8–)1–1.2(–1.3) µm {2}], (sub)cylindrical with rounded ends, also narrowly ellipsoid, straight to (very) slightly curved [sometimes 1 end subacute]; **SBs** 0.5–0.7 µm diam., globose, central or eccentrical, filum invisible (total length 0.8–1.3 µm) {1}. **Paraphyses** apically uninflated or often slightly to medium spathulate or lanceolate, with ± obtuse tips, terminal cell *10.5–18 × (2.2–)2.5–3.3 µm {1}, †15–20 × 1.5–2.3(–2.5) µm {T}, [†15–23 × 1.8–2.8(–3) µm {2}], exceeding the asci by *2–3 or †3–5 [2–5] µm, lower cells *(3–)4–6(–7) × 2.2–3 µm {1}, †3.5–6.5 × 1.3–2(–2.5) µm {T}, [†3–7 × 1.5–2.3 µm {2}]; unbranched at upper septum, not immersed in gel. **Medullary excipulum** 20–100 µm thick, of horizontal textura prismatica-porrecta, t. globulosa-intricata, or t. intricata, cells †9–13 × 2–6 µm, slightly to strongly gelatinized, common walls 0.5–1(–1.5) µm thick {T}, very sharply delimited from ectal excipulum {T} or only at flanks. **Ectal excipulum** of (†) thick-walled t. globulosa-angularis from base to margin, 40–70 µm thick at lower flanks, cells *(10–)20–50 × (10–)20–35 µm {1}, †(10–)20–37 µm diam. {T}, [†15–30(–45) µm diam. {2}], single walls †0.8–1.5 µm thick {T} [common walls †0.8–2 µm]; 15–20 µm thick near margin, marginal cortical cells *8–14 × 6–9.5 µm {1}, oriented at 80–90°; **hairs** †(20–)70–100(–110) × (5–)6–7.5(–9.5) µm {T}, †23–38(–45) × 6.5–8 µm {1}, [†12–35 × 5–9 µm {2}], hyaline {3} or pale yellowish-ochraceous {T}, thick-walled (walls near base 1–1.5 µm, in long hairs at middle part 0.7–1.2 µm, near apex 0.3–1 µm), 3–6- {T} or (0–)1–3(–4)-septate {3}, septa very delicate, smooth or very finely warted {4}, **glassy processes** absent. **Anchoring hyphae** forming a 30–50 µm thick, dense layer at base of stipe, *(2.7–)3–5 µm wide, wall 0.2 µm thick {1}, towards excipulum forming globose cells *8–15 µm diam.; [abundant, strongly gelatinized, forming an up to 60 µm thick layer of narrow hyphae]. **SCBs** absent; **VBs** in paraphyses strongly refractive, globose to irregularly shaped, inside large non-refractive vacuole {1}, in hairs forming a few minute droplets. **Exudate** over paraphyses absent or very thin, rough to minutely granular; also over ectal excipulum and hairs often finely warted. — **ANAMORPH**: [drechslerella-like (from ascospore isolate {1})]. **Conidiophores** and **conidia** not documented, identified by Pfister (1997) as *Monacrosporium* ?*doedycoides*.

Habitat: lying on ground, decorticated, 30–50 cm thick logs of *Populus* sp. {1}, indet. angiosperm trees {3}, on 0.5 mm or very deeply medium to strongly decayed wood {4}. **Associated**: *Orbilia* ?*eucalypti*, ?*Rhizodiscina lignyota*, remotely with indet. pyrenomycetes {2}. **Desiccation tolerance**: probably intolerant. **Altitude**: 20–250 m a.s.l. (tropical America), 26 m (western Europe). **Geology**: France: Upper Cretaceous lime- & sandstone. **Phenology**: IX, I (tropical belt), IX (Europe).

Taxonomic remarks. The stipitate, ± cupulate, pubescent to hairy, whitish, rather large apothecia of *Orbilia pilosa* resemble under a hand lens a helotialean discomycete (*Lachnum* or *Cistella*). The species is characterized by short to long, septate, thick-walled hairs restricted to the margin, obtusely lanceolate paraphyses, small, cylindrical, straight to slightly curved ascospores, and an ectal excipulum of large, globose, thick-walled cells which is often very sharply delimited from the gelatinized medullary excipulum.

Without vital characters and without information about its anamorph, *O. pilosa* could be taken for a member of section *Orbilia*. For instance, *O. umbilicata* resembles *O. pilosa* in some points. It differs in strongly curved ascospores, smaller, thin-walled excipular cells, and in lacking hairs. *O. alba* (series *Gamsylella*) resembles *O. pilosa* in its apothecia with a finely pubescent exterior and large excipular cells, but differs in sessile apothecia, a non-gelatinized medullary and a thin-walled ectal excipulum, the absence of thick-walled hairs, and spores with distinctly tapered bases.

Variation. In the holotype the rehydrated apothecia have a concave disc, with the margin ± inrolled, the hairs being agglutinated as teeth pointing inwards (Pl. 1001: 2). When dry the margin is even more inrolled, whereas upon rehydration the apothecia open within some seconds, obviously due to the thin receptacle composed of two very differently constructed layers. In the fresh state the long marginal hairs have probably been oriented more upwards. The two samples from Puerto Rico (Pl. 1001: 1, 3) concur quite well with the specimen from France (Pls 1001: 4; 1002) in having much shorter hairs with fewer septa, less cupulate apothecia with shorter stipes, slightly longer and wider spores, and a less sharply differentiated border between ectal and medullary excipulum. Whether these differences are the result of variation or due to different taxa should be investigated by molecular methods.



FH (PR 150): Puerto Rico, on indet. angiosperm (wood)

K(M) 36046 (holotype): Trinidad, on indet. angiosperm (wood)

FH (PR 27): Puerto Rico, on indet. angiosperm (wood)

H.B. 9437: France, Charente-Maritime, on *Populus* (wood)

Plate 1001. **1–4**: *Orbilia pilosa*. – **a**. ascospores; **b**. asci and paraphyses (in **4b** containing VBs); **c**. ascus apices; **d**. apothecium (sectioned); **e**. apothecia in median section; **f–g**. marginal hairs emerging from ectal excipulum (**f**: median section, **g**: external view); **h**. detail of a hair; **i**. border between small-celled medullary and large-celled ectal excipulum.

Type studies. Because of the presence of septate hairs, Dennis (1954) and Huhtinen (1992) separated *Orbiliaster pilosus* from *Orbilia* at the generic level. In their examination of the holotype, the authors described the paraphyses as filiform and the apothecia as sessile (Dennis) or sessile to clearly stipitate (Huhtinen). Dennis reported the spores as bacilliform, straight, 5 × 0.5 µm, whereas from Huhtinen's drawing a spore size of 3–4 × (0.9–)1.1(–1.3) µm can be evaluated in accordance with the present result (Pl. 1001: 2a).

Anamorph. In one of the two collections from Puerto Rico here included in *O. pilosa* (D.H.P. 204, Pl. 1001: 1), Pfister (1997: 16, tab. 1, fig. 12) obtained a drechslerella-like anamorph which he named '*Monacrosporium* ?*doedycoides*' (teleomorph as *Orbilia* sp.). Regrettably, he did not describe and illustrate this isolate but he reported to have seen both macro- and microconidia.

Phylogeny. From one of the two collections from Puerto Rico (D.H.P. 204) an ITS sequence was available (the presence of the S1506 intron is unclear because the ITS1 primer was used). This clustered with high distance and unresolved inside the medium supported *brochopaga-polybrocha* clade (Phyl. 36). To *D. doedycoides* it shows a 20 % distance, which provides evidence that two distinct species are involved. *D. doedycoides* exists in GenBank and CBS with four strains which comprise ITS and LSU, one also SSU (ATCC 96778, CBS 175.55, 223.54, 586.91), the latter being the epitype. They coincide in the ITS region by a 0–1 nt difference. Also other species of *Drechslerella* show a rather high distance of min. 15 % (*O. brochopaga*) to D.H.P. 204.

Ecology. *O. pilosa* was collected on ± rotten wood of hygric logs of angiosperm trees in tropical humid rainforests of Lesser Antilles in the eastern part of the Caribbean region, and in a cavity of an entirely very rotten, decorticated *Populus* log in a mesosubmediterranean humid riverbank forest with *Ruscus aculeatus* in atlantic western France.

Specimens included. **Trinidad**, 3 km NNW of Diego Martin, River Estate, 45 m, trunk of indet. angiosperm, on wood, 22.IX.1949, R.W.G. ≡ *Patinella tenebricosa* Svrček, Česká Mykol. 31: 135 (1977)

Etymology: *polybrocha*: with many lassos (bróchos = noose, meaning the constricting rings); *tenebricosa*: referring to the dark pigmentation of the apothecia.

Typification: USA, Virginia, Norfolk, decaying rootlets of *Spinacia oleracea* undated, C. Drechsler (holotype of ***Trichothecium polybrochum***, illustration in Drechsler 1937a: fig. 18A–E); USA, Massachusetts, Concord, trunk of *Acer*, 20.VI.1995, D.H. Pfister (ex H.B. 5296a, M-0276567, epitype, designated here, MBT202637; ex D.H.P. 133, FH 00458180, FH 00458181, isoepitypes; sq.: U72606). — Czechia, Písek, Otava valley, trunk of *Tilia cordata*, 3.IX.1972, M. Svrček (PRM 804304, holotype of ***Patinella tenebricosa***).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.3–)0.5–1.3(–1.8) mm diam., 0.22–0.35(–0.4) mm high, receptacle (0.1–)0.12–0.18(–0.2) → 0.07–0.1(–0.14) mm, typically light (greyish-) or (reddish- or purplish-)umbra-brown, also pale cream-rosaceous(-amber), translucent if pale-coloured, round, slightly undulating when large, ± scattered or in small groups; disc flat, sometimes slightly (to medium) convex, margin subhyaline or bright greyish- to blackish-brown, finely to distinctly crenulate, teeth protruding for 10–30 µm; (sub)stipitate, stipe 0.05–0.2 × 0.2–0.55 mm (partly composed of anchoring tissue), superficial; dry dark olivaceous- to black-brown **Asci** *(28–)32–42(–47) × (3.5–)4–4.5(–5) µm {3}, †(28–)32–40(–42) × 3.2–4 µm {3}, 8-spored, spores 3–4-seriate, 2–5 lower spores inverted {3} (often mixed), pars sporifera *12–17 → 10–13 µm long; **apex** (†) strongly truncate (not or sometimes very slightly indented, laterally usually not inflated); **base** with short to long, thin or thick, flexuous stalk, Y- to h- or mostly H-shaped. **Ascospores** *(4.2–)5–6.5(–7.5) × (1–)1.1–1.3(–1.4)((–1.6)) µm {4}, †5–6.8 × (0.9–)1–1.1 µm {3}, subcylindrical to narrowly cylindric-ellipsoid or fusoid(-clavate), apex rounded to obtuse, base slightly to medium attenuated (rarely not or strongly so), straight, rarely slightly curved below; **SBs** *0.8–1.5 × 0.2–0.5 µm {3}, slightly to strongly eccentrical, usually rod- but also tear-shaped to subglobose, attachment mostly invisible, rarely narrowed to a small point; with small or sometimes rather large LBs up to 0.5–0.7 µm. **Paraphyses** apically (uninflated to) slightly to medium, rarely strongly capitate(-clavate), terminal cell *(14–)16–24(–26) × (2–)2.5–4(–4.7) µm {3}, †15–21 × 2.5–3.7(–5.5) µm {2}, lower cells *(4–)5–7.5(–9) × 1.8–2.8(–3.3) µm {3}, †4–8.5 × 1.3–2.3 µm {2}; never branched at upper septum. **Medullary excipulum** hyaline, 60–100(–170) µm thick, of ± dense textura globulosa-intricata with large globose cells in lower part, distinctly delimited from ectal excipulum only towards margin by a parallel, 10–20 µm thick layer of t. prismatica, here sometimes pale to bright brown. **Ectal excipulum** hyaline, of thin-walled († very slightly gelatinized), vertically oriented t. globulosa-angularis-prismatica from base to mid flanks, 100–180 µm thick at base, cells *(15–)20–40 × (12–)18–25 µm {3}, †20–35 × 13–20 µm {1}; 30–60 µm thick at lower flanks, 25–35 µm at mid flanks, cells *10–17 × 6–12 µm; 20–35 µm thick near margin, of t. prismatica-porrecta oriented at a (45–)70–90° angle to the surface, marginal cortical cells *(10–)12–17(–20) × (2.5–)3–4(–6) µm {3}, submarginal cells partly shorter and thicker; **glassy processes** abundant at mid flanks and margin, (5–)10–40(–50) × (2.5–)3–5(–7) µm {5}, medium to strongly curved outwards {6}, low- to mostly highly-refractive, stratified or not, coherent to form ± distinct small teeth. **SCBs** absent in both paraphyses and excipulum {3}, but ring-shaped SCBs seen in cells of medullary excipulum after rehydrating a section {1}; **VBs** ± globose, low to medium refractive, hyaline, present in a few or most paraphyses, nearly completely filling the terminal cell. **Exudate** over paraphyses 0.5–1.5 µm thick, granular-cloddy, hyaline or typically very pale to light chlorinaceous-olivaceous to brass-brown, firmly attached but absent on some apices, unchanged in KOH; glassy processes covered by a thin or 1–3(–8) µm thick layer of granular-cloddy or homogeneous, hyaline to often pale brass-olivaceous-brown exudate, in perihymenial part of medulla sometimes with pale to bright grey-brown-olivaceous, granular intercellular exudate. **Anchoring hyphae** abundant at base of stipe, *(3–)4–6(–7) µm up to *5–10 µm wide, walls 0.2 µm thick {2}, forming a loose or dense, hyaline, 50–150 µm thick t. globulosa-angularis-intricata. — **ANAMORPH**: drechslerella-like (from ascospore isolate {2}). **Macroconidiophores** 275–400 µm long, unbranched, 7–8 µm wide at base, 3–4.5 µm above, with a single conidium at apex {T}. **Macroconidia** broadly obovoid, *33.5–36 × 23.5–25 µm {T}, *27–29.5 × 16–18 µm {ET}, *32–37 × 23.5–26.5 µm {Germany}, 37–41 × 20–21 µm {West Virginia}, 1-septate, septum very close to base, covered by a 2–3 µm thick surrounding gel sheath {T, Germany} or an 8–12 µm thick lateral gel cap {ET, West Virginia}. **Microconidiophores** ~30–60 µm long, forming 1–4 conidia on denticles near the conidiophore tip {ET}. **Microconidia** *16–23 × 3.7–5.5 µm {ET}, *19 × 5.5 µm {Germany}, cylindric-ellipsoid-clavate, 1–2-septate. **Constricting rings** with 1-septate stalk of *10–12.5 × 4–4.8 µm {T} or *11–19 × 4.5–5.5 µm {Germany}; ring unexpanded *22–30 µm outer diam. {T}, *31.5–36.5 × 32.5–34.5 µm {Germany}, *12.5–15 µm inner diam. {T}, *16–22 {Germany}, 3-celled, with triangular wall thickenings especially at the 2 distal septa.

Habitat: on partly water-soaked old, decorticated branches or logs lying on the ground, also on the bank close to a stream or rivulet, on lower, sometimes upper side, 50–300 mm thick, of *Acer* sp. {1}, *Corylus avellana* {2}, *Fagus sylvatica* {2}, *Fraxinus excelsior* {1}, *Tilia cordata* {1}, on partly eroded, deeply medium to strongly decayed wood {7} (brown- or white-rot), sometimes in old beetle galleries, without or with minute green algae. **Associated**: *Ascocoryne ?cylichnium* {1}, *A. inflata* {1}, *Brachysporium ?nigrum* {1}, *Hyalorbilia tortuosa* {1}, *Hypnum cupressiforme* {1}, *Lasiosphaeria hirsuta* {1}, *Leptodontidium trabinellum* {1}, *Mollisia ?oblonga* {1}, *Orbilia ?cejpii* {1}, *O. dryadum* {1}, *O. leucostigma* {2}. **Desiccation tolerance**: mature asci survive for a few hours on the dry slide, only spores viable after 2 days. **Altitude**: 335–485 m a.s.l. (central Europe), ~1200 m (eastern Europe), 5–280 m (eastern USA). **Geology**: Germany: Keuper (Knollenmergel), Lower Jurassic limestone (Arietenkalk), Tertiary molasse, syenogranite, amphibole-biotite; USA: Carboniferous (Pennsylvanian) sedimentary rock, Quaternary sediment, granite. **Phenology**: VI, VIII–X (teleomorph).

Taxonomic remarks. *Orbilia polybrocha* is characterized by usually light umbra-brown, comparatively large apothecia when fresh, with a crenulate margin of glassy processes, cylindric-fusoid ascospores with ± eccentrical, rod-shaped to subglobose SBs, and by a drechslerella-like anamorph with obovoid, balloon-shaped macroconidia with a single subbasal septum and a gel sheath. *O. orientalis* s.l. differs in usually distinctly shorter and wider, ellipsoid spores, whitish to cream apothecia, and in very different cylindrical, 3-septate macroconidia. However, in *O. naumburgensis* (Pls 1012–1013) the spores hardly differ from those of *O. polybrocha*, but the macroconidia closely resemble those of *O. orientalis* or *O. brochopaga*.

O. flavovacuolata, but also *O. anigozanthi* and *O. alba* of series *Gamsylella*, have ascospores very similar to *O. polybrocha*, but they differ, e. g., in the absence of glassy processes, the latter two species also in lanceolate-lageniform paraphyses, the former in minute apothecia with yellow vacuoles.

O. aff. *polybrocha* from Taiwan (Pls 1007–1008) differs from *O. polybrocha* in whitish apothecia with a smooth margin (see p. 1636). Some members of series *Dactylellina* (*O. mammillata*, *O. quercus*) and series *Neodactylella* (*O. cardui*, *O. zhongdianensis*) have also ascospores with a similar shape, but deviate in more centrally positioned, usually globose SBs.

Variation. The colour of mature apothecia varies in *O. polybrocha* to a high extent. In a majority of collections, including the type of *P. tenebricosa*, a light (reddish-)umbra-brown exudate, which turns bright olive in KOH, occurs on the tips of paraphyses, on the cortical excipular cells and glassy processes, and to a varying extent also among the marginal cells between medullary and ectal excipulum (Pls 1003: 1e–f; 1006: 1). Pfister's North American collection fits herein very well the European samples. In typical collections the fresh apothecia were light umbra-brown (Pls 1003: 1d; 1005: 1b–g; 1006: 3a–b), whereas the rehydrated herbarium specimens showed a darker brown pigmentation, with the margin almost blackish (Pls 1003:

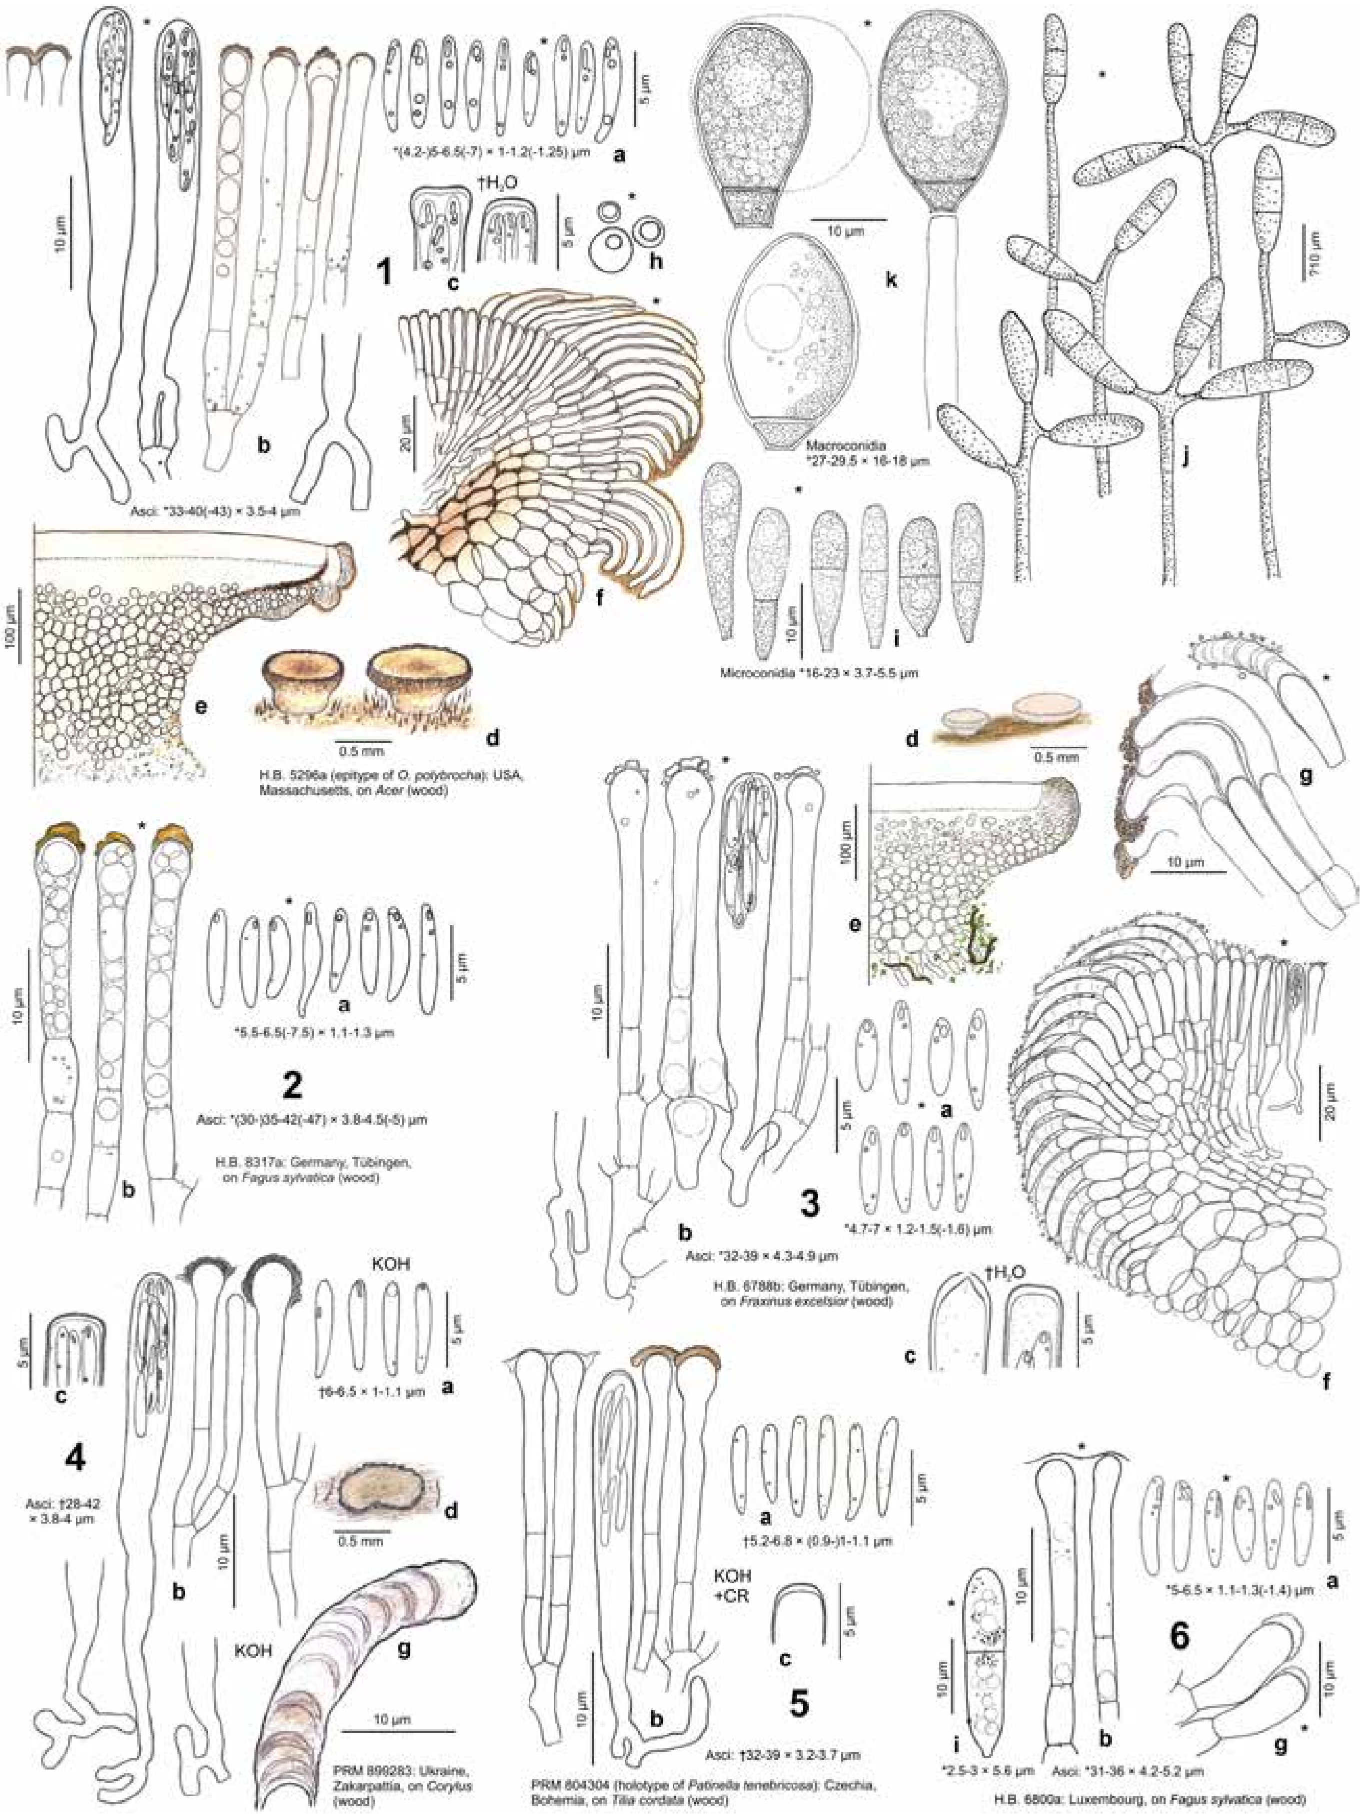

Plate 1003. **1–5**: *Orbilia polybrocha*; **6**: *O.* cf. *polybrocha*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. fresh or rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum; **g**. id., marginal cortical cells tipped by curved glassy processes; **h**. SCBs in medullary excipulum (after rehydration); **i–j**. microconidia and microconidiophores; **k**. macroconidia (**1i–k**. from culture, **6i**. from substrate). – **1i–k**: from Pfister (1997).

4d; 1006: 2b–e). Yet, in one collection the fresh apothecia were pale cream-rosaceous with a pale chlorinaceous-olivaceous exudate over the margin (Pl. 1003: 3).

Type studies. Drechsler (1937a, Pl. 1004) described *Trichothecium polybrochum* from decaying rootlets of *Spinacia oleracea* from Norfolk (Virginia, USA). Neither a type culture nor a dried specimen appear to exist (see Rubner 1996: 91). We here designate Pfister's North American isolate (Massachusetts, Concord, on *Acer*, ex H.B. 5296a, M-0276567), from which a sequence was gained by Pfister (1997), as **epitype** of *T. polybrochum*.

Svrček (1977b) described the apothecia of the holotype of *Patinella tenebricosa* as 1–3 mm diam., deep violaceous, dry blackish-brown, with a brown, denticulate margin, and the marginal teeth composed of 40–60 × 4–5 µm large clavate hyphae. With the latter statement he obviously neglected the solid nature of the processes. In the present reexamination of the holotype the apothecia were rehydrated 0.6–1 mm diam. and dark (purplish-)brown. The somewhat stratified, solid downwards curved processes of the marginal teeth measured 30–40 × 3.5–5 µm. Although the spore size in the protologue (5–6.5 × 0.8–1 µm, with partly 1 small guttule at each end) quite well corresponds to the present reexamination (Pl. 1003: 5), Svrček's drawing shows too narrow and too cylindrical spores. A clear reference to the spore body is not found in Svrček's description which apparently shows all elements in the dead state.

A completely hyaline, marginally associated single apothecium occurs in the holotype which is microscopically very similar, including the marginal teeth, but differs in cylindric-ellipsoid ascospores †4–4.5 × 1.2–1.4 µm. Whether this is an albinotic form of *P. tenebricosa* or more probably belongs to *O. orientalis* could not be clarified.

Because of the light brown excipular cells, Svrček placed his collection in *Patinella*, a genus which was considered to be orbiliaceous by Nannfeldt (1932). Due to Svrček's misleading description of the marginal hairs, Spooner (1987: 158) and Huhtinen (1992) discussed a possible placement in *Orbiliaster*, a genus which has been characterized by septate hairs without glassy processes.

Not included collections. A specimen from Luxembourg (Pl. 1003: 6) is not included because of whitish apothecia with a smooth margin with only 1–2 µm thick glassy caps. Here a single microconidium was found on the substrate.

Two Chinese samples of unclear identity were reported under the name *O. tenebricosa* although having yellowish apothecia. No anamorph was observed, and the asci are with †22–30 µm a bit too short to be included in *O. polybrocha*. Liu's (2006: 110, pl. 44) sample from Guangxi has 15–50 × 4–5 µm large glassy processes, whereas Guo et al.'s (2014b) sample from Yunnan is without them and herein resembles *O.* aff. *polybrocha* illustrated in Pl. 1007. *O. pseudopolybrocha* deviates from both in shorter and wider spores.

Anamorph. Pfister (1997) obtained *Drechslerella polybrocha* (as *Monacrosporium polybrochum*) in pure culture of a North American collection identified as *Patinella tenebricosa*, which formed macro- and microconidia (Pl. 1003: 1i–k) and constricting rings. In a German sample we obtained distinctly larger conidia (Pl. 1005: 1o), which fit well in size Drechsler's (1937a) holotype ('ca. 35 × 24 µm' in protologue, Pl. 1004). In a strain of *D. polybrocha* from West Virginia examined by Rubner (1999, fig. 46, CBS 319.56) the macroconidia were longer though narrower than in the holotype.

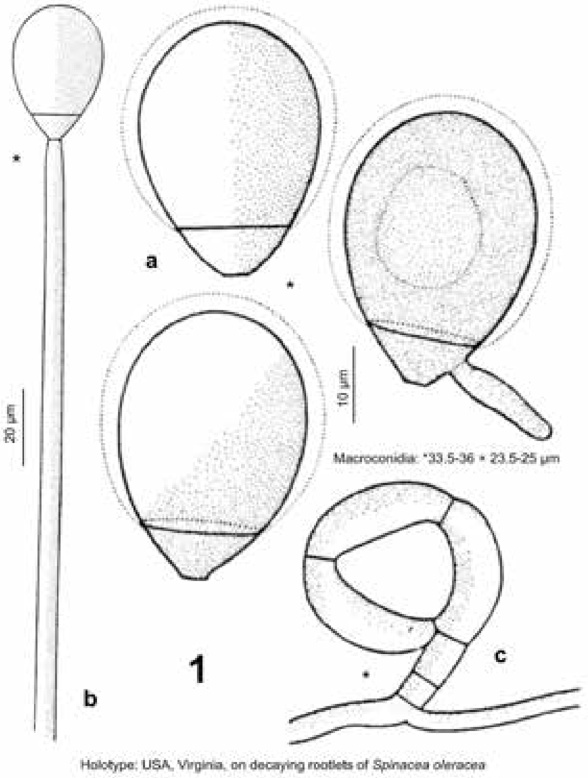

Plate 1004. **1**: *Orbilia polybrocha*. – **a**. conidia; **b**. conidiophore; **c**. constricting ring (from culture). – from Drechsler (1937a).

Much smaller, cylindric-ellipsoid, 2-septate microconidia were reported by Pfister (1999) in pure culture, formed in abundance on apically branched microconidiophores (Pl. 1003: 1i–j). Those drawn by him on the conidiophores (Pfister 1999, fig. 11 F–H) appear to have an erroneous scale (Pfister pers. comm.) which is tentatively reduced here by 75 % of the original length (1j). Similar but only single microconidia were observed on the natural substrate near apothecia in the German collection (Pl. 1005: 1p) and that from Luxembourg (Pl. 1003: 6i).

The constricting rings are distinctly smaller in the holotype (Pl. 1004: 1c) compared to the sample from Germany (Pl. 1005: 1q). No measurements of trapping organs were available for the epitype.

Phylogeny. Sequences of three strains of *O. polybrocha* were available, one (?) conidial and two ascospore isolates. They comprise the ITS region, one also the S1506 intron: Pfister's strain (D.H.P. 133, from Massachusetts) lacks any parts of SSU; the other two (CBS 319.56, from West Virginia; H.B. 8317a, from Tübingen) encompass a small part of the SSU, and here the S1506 intron occurs only in the strain from West Virginia.

Pfister's strain differs in the ITS region only by 2 nt (0.4 %) from the strain from West Virginia (1 nt lies in the 5.8S and is possibly a sequencing error, the other is in the ITS2), whereas the European sample shows a 3 % distance to those (15 nt). In our ITS analysis (Phyl. 36), *O. polybrocha* nested unresolved in the medium supported *brochopaga-polybrocha* clade by showing a high distance of 7–8 % to *O. pseudopolybrocha*, 9–9.5 % to *O. naumburgensis*, and 9.5–11 % to *O. orientalis* and *O. yunnanensis*. When analysing the intron, *O. polybrocha* clustered with medium support with these species (S30, *O. orientalis* is without intron).

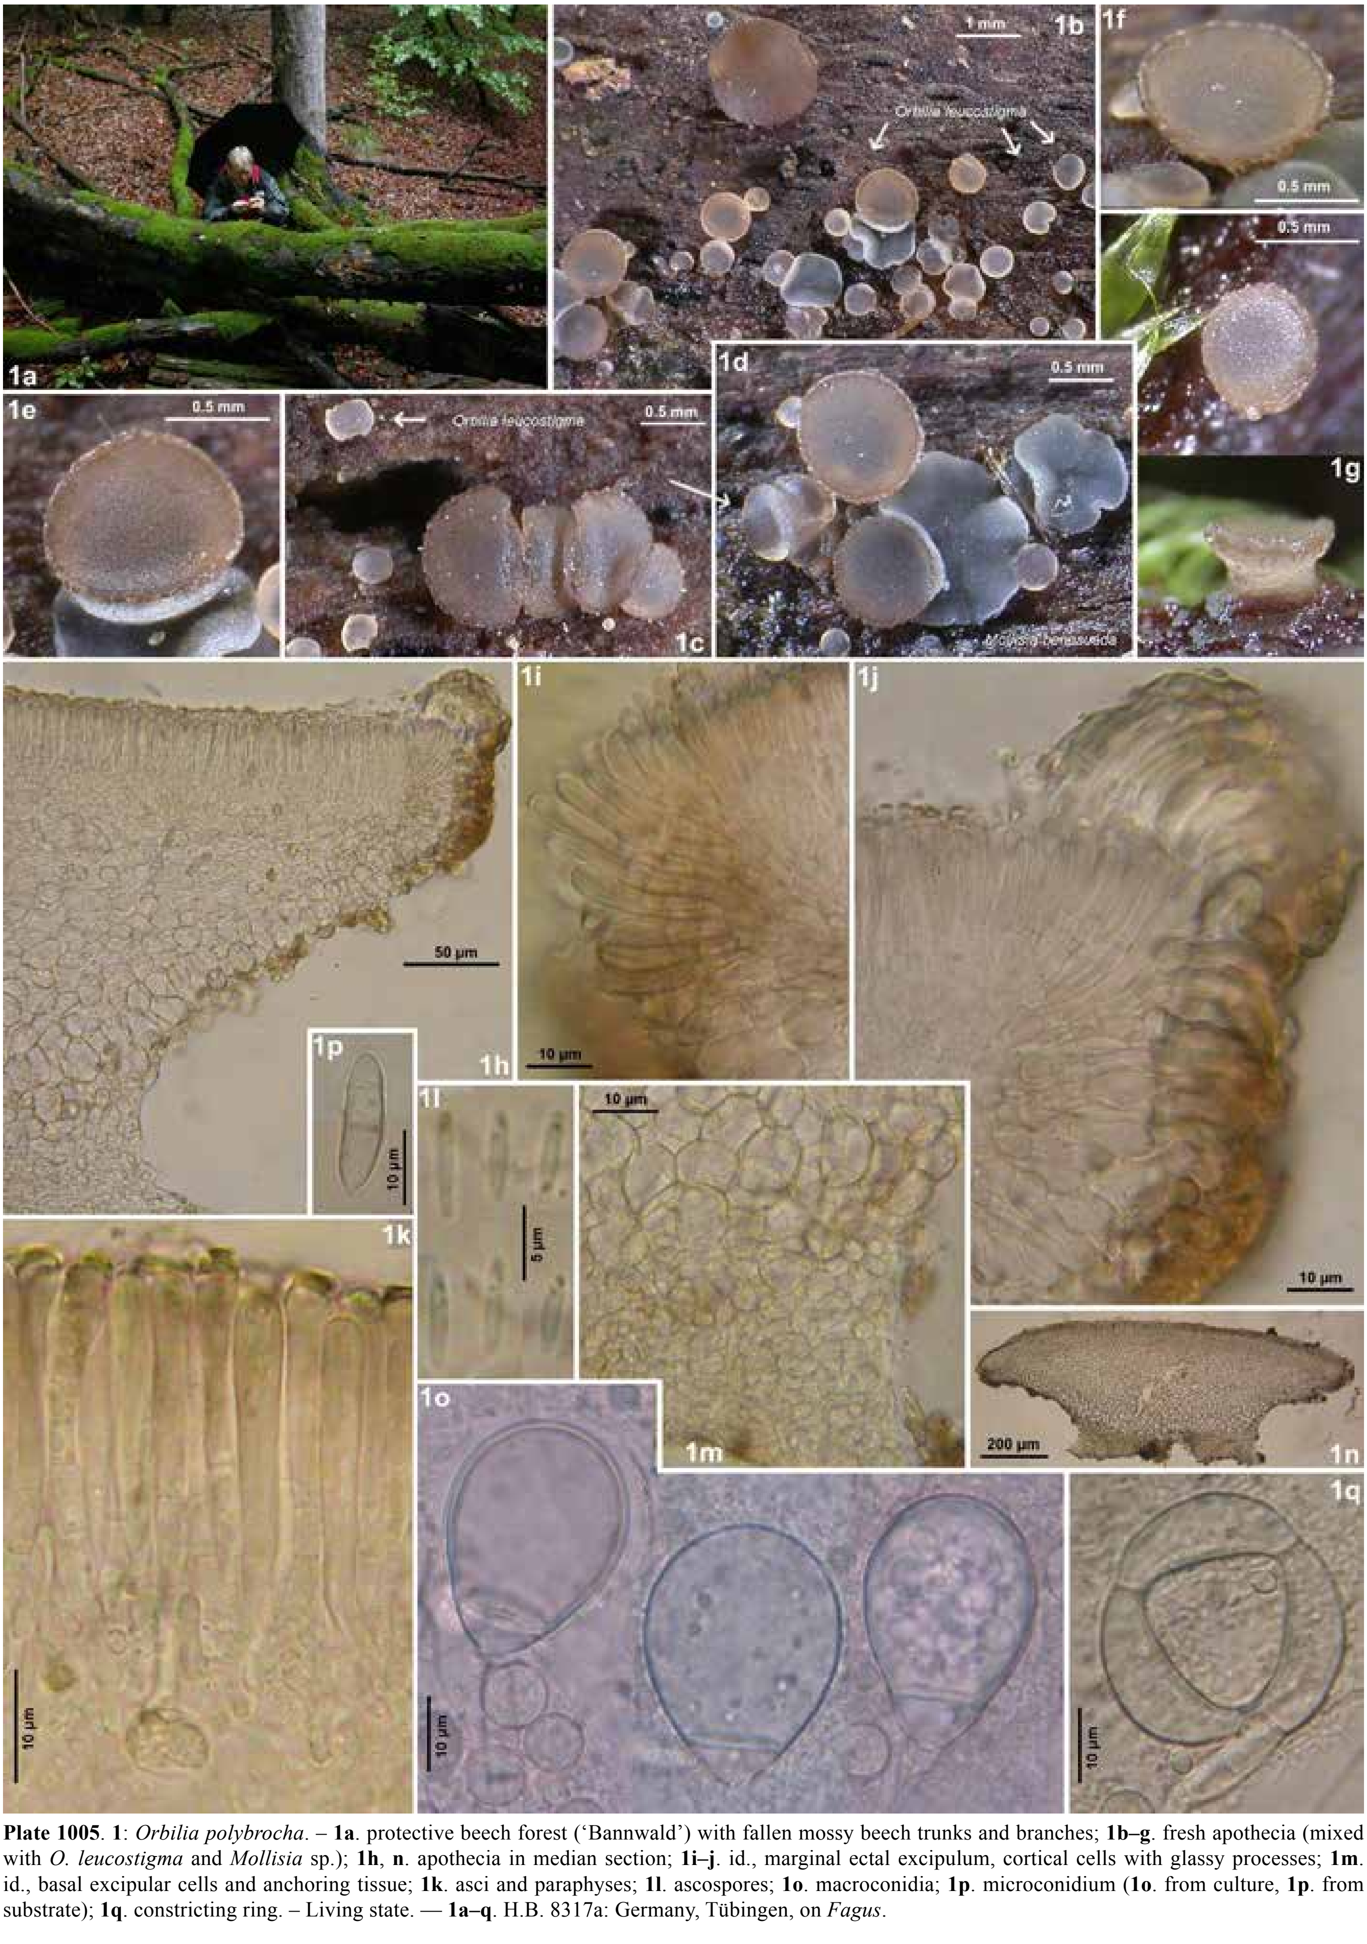

Plate 1005. **1**: *Orbilia polybrocha*. – **1a**. protective beech forest ('Bannwald') with fallen mossy beech trunks and branches; **1b–g**. fresh apothecia (mixed with *O. leucostigma* and *Mollisia* sp.); **1h**, **n**. apothecia in median section; **1i–j**. id., marginal ectal excipulum, cortical cells with glassy processes; **1m**. id., basal excipular cells and anchoring tissue; **1k**. asci and paraphyses; **1l**. ascospores; **1o**. macroconidia; **1p**. microconidium (**1o**. from culture, **1p**. from substrate); **1q**. constricting ring. – Living state. — **1a–q**. Ecology. *O. polybrocha* was found on ± rotten wood of hygric branches and logs of various angiosperm trees, in subcontinental to continental cold- to orotemperate humid central and eastern Europe, but also in cold- to warm-temperate or warm-continental humid northeastern and eastern North America. Our collections were on a log of *Fagus* in a shady protective forest (*Fagetum*), and on a log of *Fraxinus* lying on the bank of a rivulet in a shady and moist ravine (*Aceri-Fraxinetum*). The type strain was isolated from *Spinacia* in a warm-temperate coastal region of Virginia. The two deviating collections were made on a *Fagus* log in a somewhat thermophilous mixed *Querco-Fagetum* with *Pinus* in cold-temperate humid Luxembourg, and on bark and wood in a subtropical humid rainforest in the Shiwan Dashan mountain range in the southernmost part of mainland China.

Specimens included. **CZECHIA**: **South Bohemia**, ~8 km N of Písek, ~1 km E of Vráž, Otava valley, Žlíbky, ?400 m, trunk of *Tilia cordata*, on wood, 3.IX.1972, M. Orbilia aff. *polybrocha* — Pls 1007–1008

Description: — **TELEOMORPH**: **Apothecia** fresh 0.15–0.6 mm diam., 0.1 mm high (receptacle 0.07 mm), translucent white, round, subgregarious; disc flat, margin distinct, thin, not protruding, smooth; broadly sessile, superficial. **Asci** †25–32 × 3.3–3.7 µm, 8-spored, spores †2–3-seriate, ~3–5 lower spores inverted (± mixed); **apex** (†) medium (to strongly) truncate (not indented, laterally not or very slightly inflated); **base** with short stalk, h- to H-shaped. **Ascospores** *4.2–5.7(–6) × 1–1.3(–1.4) µm, †4.4–6(–7.3) × 0.8–1(–1.2) µm, cylindrical, sometimes fusoid(-clavate), apex rounded to obtuse, rarely subacute, base not or only slightly, rarely medium attenuated, straight to slightly inequilateral; **SBs** 1–1.7 × (0.2–)0.3–0.4(–0.5) µm, rod-shaped, sometimes ellipsoid or tear-shaped, with a very short, mostly invisible filum, ± centrally or often very eccentrically oriented. **Paraphyses** apically uninflated or slightly (to medium) (clavate-)capitate, terminal cell †14–20 × 1.6–3.2 µm, lower cells †4.5–6 × 1.4–2.2(–3) µm; unbranched or branched at upper septum. **Medullary excipulum** 20–35 µm thick, of dense textura intricata-angularis, medium sharply delimited. **Ectal excipulum** of (†) ± thin-walled t. globulosa-angularis from base to margin, 30–40 µm thick near base, cells †~6–10 × 5–7 µm; 15 µm thick at margin, of t. globulosa-prismatica oriented at an 80° angle to the surface, marginal cortical cells †6–8 × 3–4(–5) µm; **glassy processes** absent. **Anchoring hyphae** abundant, †1.5–4.5 µm wide, walls 0.2–0.25 µm thick. **SCBs**

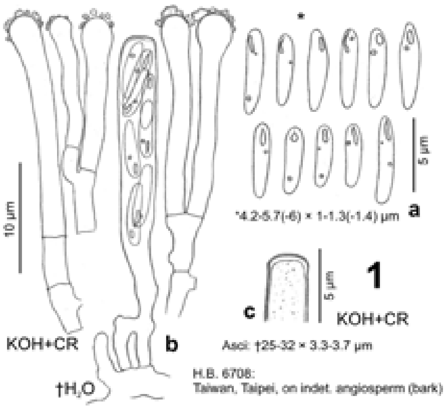

Plate 1007. **1**: *Orbilia* aff. *polybrocha*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

and **VBs** no data available. **Exudate** over paraphyses 0.3–1 µm thick, granular-cloddy, firmly attached, over margin and flanks sparse, 0.2–0.3 µm thick, rough. **— ANAMORPH**: unknown.

Habitat: on ~4 cm thick branch of indet. angiosperm lying on the ground, on very decayed bark (periderm and bast), on blackened areas, no algae. **Associated**: none observed. **Desiccation tolerance**: intolerant, but many spores still alive after 5 weeks. **Altitude**: 1000 m a.s.l. **Phenology**: V.

Taxonomic remarks. This specimen from Taiwan resembles *Orbilia polybrocha* in ascospore size and shape and in the SBs being predominantly narrowly rod-shaped, strongly eccentrical, and always very narrowly attached. However, it has a textura globulosa-angularis up to the margin, with short marginal cortical cells, whereas in *O. polybrocha* the marginal cells consistently showed a length of *12–18 µm. *O. naumburgensis* has slightly wider, more fusoid ascospores, and apothecia with a crenulate margin. Since neither an anamorph nor molecular data are known, a relationship to other series of section *Arthrobotrys*, especially to *Gamsylella* (*O. alba*, *O. anigozanthi*), is possible.

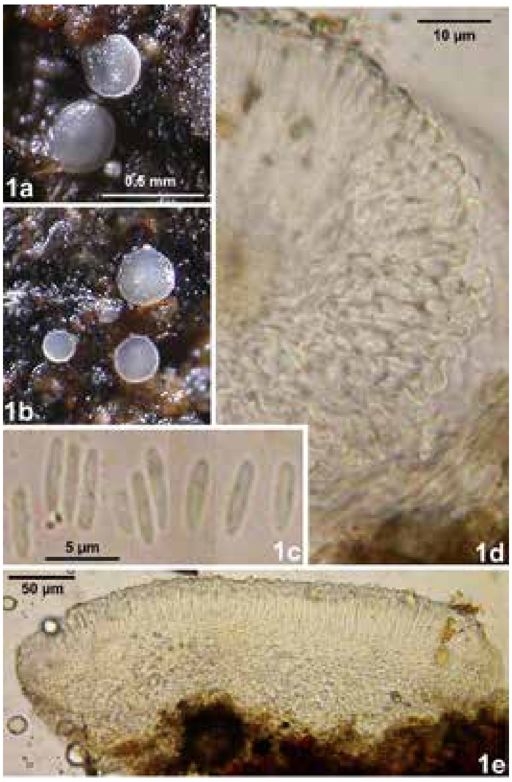

Plate 1008. **1**: *Orbilia* aff. *polybrocha*. – **1a–b**. rehydrated apothecia; **1e**. apothecium in median section; **1d**. id., marginal ectal excipulum; **1c**. ascospores. – Dead state (in KOH). — **1a–e**. H.B. 6708: Taiwan, Taipei, on indet. angiosperm bark.

Ecology. *O.* aff. *polybrocha* was found on rotten hygric bark of an unidentified angiosperm in a montane subtropical humid (winter-dry) evergreen broad-leaved forest at the northern end of Taiwan in southeastern Asia.

Specimens included. **CHINA**: **Taiwan**, **Taipei**, 14.5 km N of Taipei, Yangmingshan, Tatun Shan, ~1000 m, branch of indet. angiosperm, on bark, 17.V.2000, R. Kirschner (H.B. 6708).

Orbilia pseudopolybrocha Z.F. Yu & M. Qiao, in Zhang et al., Int. J. Syst. Evol. Microbiol. 70: 2666 (2020) — Pl. 1009

Etymology: referring to the morphological similarity with *O. polybrocha*.
Typification: China, Yunnan, Yuxi, Xinping, Mopanshan, indet. angiosperm bark, 8.IX.2008, S.F. Li (YMFT 1.02660 holotype, CGMCC 3.18832).

Description: — **TELEOMORPH**: **Apothecia** fresh 0.3–0.6 mm diam., up to 0.26 mm high (receptacle 0.11 mm thick), whitish to pale cream-chlorinaceous, slightly translucent, round, scattered to gregarious; disc flat, margin thin, not protruding, smooth to finely crenulate by minute blunt teeth; with a hidden stipe 0.12 mm tall, superficial, dry light yellow-chlorinaceous or pale pink. **Asci** *23–33 × 3.2–3.8 µm {2}, 8-spored, spores *2–3-seriate, lower spores inverted, pars sporifera *11–15.5 µm long; **apex** (†) slightly truncate (not indented, laterally not inflated); **base** without or with short stalk, h-shaped. **Ascospores** *2.8–4 or 4.5–5.5 × 1.2–1.5 µm {2}, cylindrical to slightly fusoid-clavate, both ends obtuse, slightly tapered towards base, straight; **SBs** *~0.8–1.2 × 0.3–0.4 µm, rod-shaped, eccentrical. **Paraphyses** apically slightly to medium capitate, terminal cell *13.5–17 × 2.2–3.7 µm {2}, lower cells *3–5.5 × 1.8–2.5 µm {2}; unbranched at upper septum. **Medullary excipulum** ~15 µm thick, indistinctly delimited from ectal excipulum. **Ectal excipulum** hyaline, of thin-walled, indistinctly oriented textura globulosa at base and flanks, 180 µm thick at base, 60 µm at lower flanks, cells †10–16(–26)((–32)) × 8–13(–20)((–28)) µm {2}; margin of t. globulosa (orientation not noted); **glassy processes** possibly sometimes present (not examined). **Anchoring hyphae** not examined. **SCBs** absent; **VBs** in paraphyses hyaline, elongate-cylindrical, low to medium refractive. **Exudate** over paraphyses scattered, granular, 0.2–0.5 µm thick. **— ANAMORPH**: drechslerella-like (from ascospore isolate {3}, data from Zhang et al. 2020a and H.Y. Su pers. comm.). **Mycelium** on CMA scanty, hyaline, hyphae 2.5–4 µm wide. **Macroconidiophores** erect, unbranched, 3–5-septate, 80–250 µm high, 4–7 µm wide at base, 2.5–3.5 µm at apex, here abruptly swollen to 3.5–4.5 µm {2}, with 1 terminal conidium. **Macroconidia** *26–33(–39) × (15.5–)17–21(–24) µm {2}, broadly ellipsoid to subglobose or fusoid, with short and broad basal protrusion, 2-septate, with 1 septum at each end and a very large middle cell, less often (0–)1-septate, often with 2–4.5 µm thick lateral mucus. **Microconidiophores** short, simple or branched, with 3–4 apical denticles. **Microconidia** *(15–)16.5–24 × (3.3–)4–6 µm {2}, 1-septate, with distinct basal protrusion. **Chlamydospores** present. **Constricting rings** abundantly obtained in the presence of nematodes, with 1-septate stalk of *12–20 × 5–5.5 µm; ring *23–24 {T} or 29–33 µm {1} outer diam., *15 {T} or 19–22 µm {1} inner diam., with triangular wall thickenings at the septa.
Habitat: lying on moist ground, on thick, corticated branch of unidentified angiosperms {3}, on medium rotten bark (periderm) {3}, no algae seen. **Associated**: black setae of hyphomycete. **Desiccation tolerance**: unknown, possibly intolerant. **Altitude**: 1800–2730 m a.s.l. **Geology**: Proterozoic metamorphic & Jurassic sedimentary rock. **Phenology**: VIII–IX.

Taxonomic remarks. *Orbilia pseudopolybrocha* was investigated by H.Y. Su (pers. comm.) and two years later by Z.F. Yu (pers. comm.), based on totally three collections of the teleomorph from which the anamorph was obtained in pure culture. In the teleomorph the species differs from

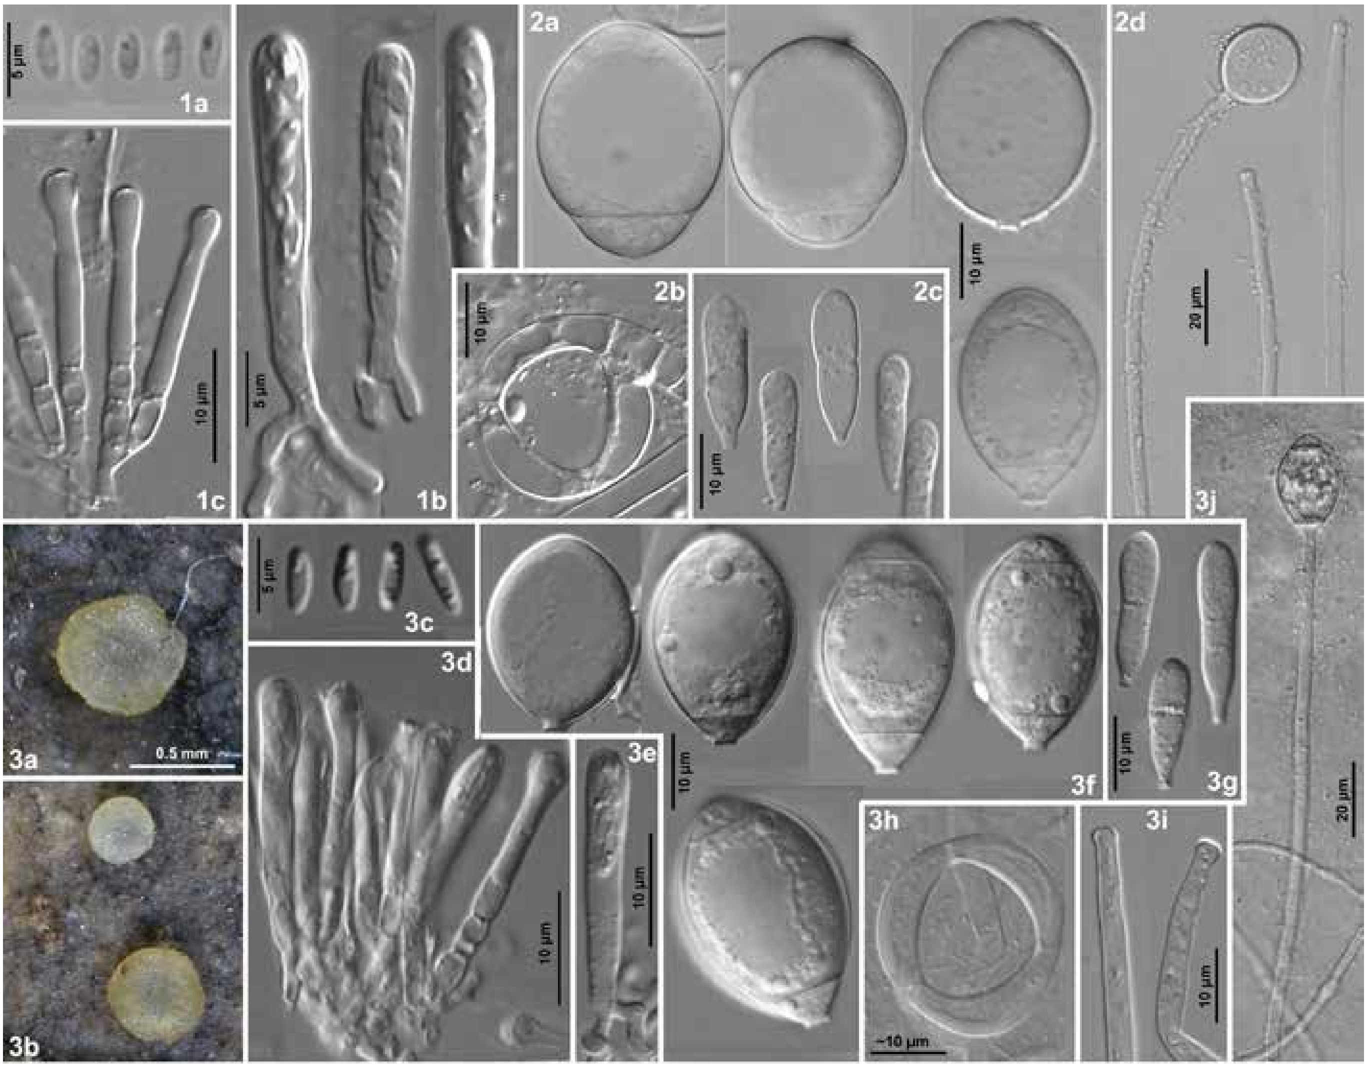

Plate 1009. **1–3**: *Orbilia pseudopolybrocha*. – **3a–b**. rehydrated apothecia; **1b–c**, **3d–e**. asci and paraphyses; **1a–b**, **3c**. ascospores; **2d**, **3i–j**. conidiophores with macroconidia; **2c**, **3g**. microconidia; **2a**, **3f**. macroconidia; **2b**, **3h**. unexpanded constricting rings (**2a–d**, **3f–j**. from culture). – Living state, except for **3i**. – **1a–c**, **2a–d**: from Zhang et al. (2020), **3a–j**: phot. H.Y. Su. — **1a–c**. Z.F.Y. jgs-63: China, Yunnan, Dali; **2a–d**. YMF 1.02660 (holotype): Yunnan, Yuxi, on indet. angiosperm; **3a–j**. H.B. 8929: Yunnan, Baoshan, on indet. angiosperm bark.

O. polybrocha in apothecial colour and shorter, more blunt marginal teeth, also in shorter asci and slightly shorter ascospores. Based on the teleomorph alone the species can hardly be segregated from *O. orientalis* s.l.

Variation. The sample from Gaoligongshan has longer ascospores (*4.5–5.5 × 1.3 µm) than that from Jinguangsi (spores *2.8–4 × 1.2–1.4 µm), also it has partly longer conidia which are more frequently 2-septate than in the other two strains. Regrettably, features of the teleomorph have not been documented in the holotype, and the apothecial margin was not studied in detail in the other two samples. The margin in the Gaoligongshan sample is finely crenulate whereas that from Jinguangsi was said to have an even margin.

Anamorph. *O. pseudopolybrocha* differs from *O. polybrocha* in macroconidia with mostly 2 septa, one close to each end, also in apically swollen conidiophores. These characteristics are reminiscent of *Drechslerella doedycoides* as described by Drechsler (1940). *O. pseudopolybrocha* differs in macroconidia with smaller terminal cells, microconidia with distinct apiculi, and in lacking inner bulge-like projections of the unexpanded constricting rings. In the sample from Jinguangsi the conidia were similar to those from Yuxi (Z.F. Yu pers. comm.), but photographs were not available to us.

Phylogeny. A sequence was obtained by Z.F. Yu (pers. comm.) from the ascospore isolate from the ex-type culture from Yuxi, comprising S1506 intron and ITS. *O. pseudopolybrocha* clustered unresolved in the *brochopaga-polybrocha* clade when analysing either ITS (Phyl. 36) or the intron (S30). The distance in the ITS region is 4.5 % to *O. naumburgensis*, 7–8 % to *O. polybrocha* (11 % in the intron), and 17 % to the epitype of *D. doedycoides*.

Ecology. *O. pseudopolybrocha* is known from three collections on bark of hygric branches of unidentified angiosperms in subtropical humid (winter-dry) evergreen broad-leaved mountain forests at the southeastern extension of Himalaya in southern China.

Specimens included. **CHINA**: **Yunnan**, **Baoshan**, Tengchong, 52 km SW of Baoshan, 31 km SE of Tengchong, Gaoligongshan, 1845 m, branch of indet. angiosperm, on bark, 4.VIII.2008, X.J. Su, H.Y. Su & X.N. Zhao (H.Y.S. glgs-3, CBCD, anam. cult., H.B. 8929 ø). – **Yuxi**, Xinping, 75 km SW of Yuxi, ~18 km S of Xinping, Mopanshan, ~1850 m, branch of indet. angiosperm, on bark, 8.IX.2008, S.F. Li (Z.F.Y. mop-89, YMF/T 1.02660, **holotype**, CGMCC 3.18832, anam. cult., doc. vid., sq.: HQ711926, MF948420). – **Dali**, Yongping, ~35 km ENE of Baoshan, Jinguangsi, ~2550 m, on bark of indet. angiosperm, 18.VII.2010, Z.F. Yu (Z.F.Y. jgs-63, YMFT 1.03549, anam. cult., doc. vid.).

Orbilia flavovacuolata Baral & E. Weber, **sp. nov.**, MB 814002 — Pls 1010–1011

Etymology: named after the pale yellow vacuoles in the exposed peripheral parts of the apothecia.

Typification: Germany, Tübingen, branch of *Fagus sylvatica*, 22.X.2005, E. Weber (ex H.B. 7943a, M-0276481, holotype).

Latin diagnosis*: Similis* Orbiliae tenebricosae *sed apothecia minora, dilute sulphureo-lutea, margine laevi, ascosporae paulo longiores, apice partim subacutae, paraphyses vivae vacuolas dilute luteo-chlorinas continentes, absque exsudato, excipulum cellulis marginalibus latioribus, absque processis vitreis. Habitat ad lignum putridum trunci uvidi* Fagi sylvaticae *in zona temperata humida subcontinentali Europae centralis.*

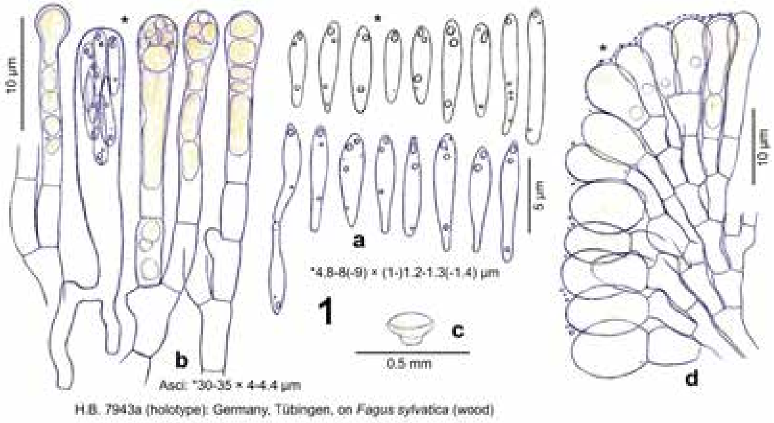

Plate 1010. **1**: *Orbilia flavovacuolata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. fresh apothecium; **d**. ectal excipulum (margin, median section).

Description: — **TELEOMORPH**: **Apothecia** fresh 0.2–0.25 mm diam., 0.13 mm high (receptacle 0.09 mm), pale to light sulphur-yellow, medium translucent, round, very scattered; disc flat, margin thin, not protruding, smooth; with a distinct stipe 0.04 × 0.09–0.1 mm, superficial. **Asci** *30–35 × 4–4.4 µm, †25–30 × 3.4–3.7 µm, 8-spored, spores *3–4-seriate, ~4 lower spores inverted (not always all 8 spores developed), pars sporifera *10.5–12 µm long; **apex** (†) strongly truncate (not indented, laterally not inflated); **base** with short stalk, h- to H-shaped. **Ascospores** *4.8–8(–9) × (1–)1.2–1.3(–1.4)((–1.6)) µm, narrowly cylindric-ellipsoid to fusoid-clavate, exceptionally cylindrical, apex obtuse to subacute, base not or often medium to strongly attenuated, sometimes with a tail-like end, straight, rarely slightly curved below; **SBs** *0.4–0.8 × 0.3–0.5 µm, often eccentrical, close to spore apex, subglobose to tear- or short rod-shaped, attachment invisible. **Paraphyses** apically slightly (to medium) clavate-capitate, terminal cell *15–18 × 2.8–3.5(–4) µm, lower cells *5.5–7.5 × 1.8–2.5(–2.8) µm; unbranched at upper septum. **Medullary excipulum** hyaline, 30 µm thick, of ± dense textura angularis-prismatica-intricata, quite sharply delimited from ectal excipulum. **Ectal excipulum** hyaline, of thin-walled, vertically oriented t. globulosa(-prismatica) from base to margin, 60 µm thick near base, cells *10–17(–30) × (5–)9–13(–15) µm; 15 µm thick near margin, oriented at a (50–)70–90° angle to the surface, marginal cortical cells *(6–)8–13 × 4–8 µm; **glassy processes** absent. **Anchoring hyphae** fairly abundant, *3–4 µm wide, walls 0.2–0.4 µm thick. **SCBs** in paraphyses and ectal excipulum (at margin) globose, 1–1.5 µm diam., hyaline; **VBs** in paraphyses and marginal cortical cells light yellowish-chlorinaceous, globose to elongate-cylindrical, medium refractive. **Exudate** over paraphyses absent; over margin and flanks absent or as 0.2–1 µm thick sparse granules. — **Macroconidia** unknown. **Microconidia** cylindric-clavate, *26 × 5.5 µm, 1-septate. **Trapping organs** unknown. **— ANAMORPH**: unkonwn (but see below).

Habitat: lying on moist ground, decorticated, ~10 cm thick log of *Fagus sylvatica*, on entirely strongly decayed wood, blackened, green algae sparse. **Associated**: *Ascocoryne inflata*, *Brachysporium* sp., *Hyalorbilia polypori*, *Mollisia ?oblonga*, *Orbilia dryadum*, *O. ?xanthostigma*, *Psilocistella quercina.* **Desiccation tolerance**:

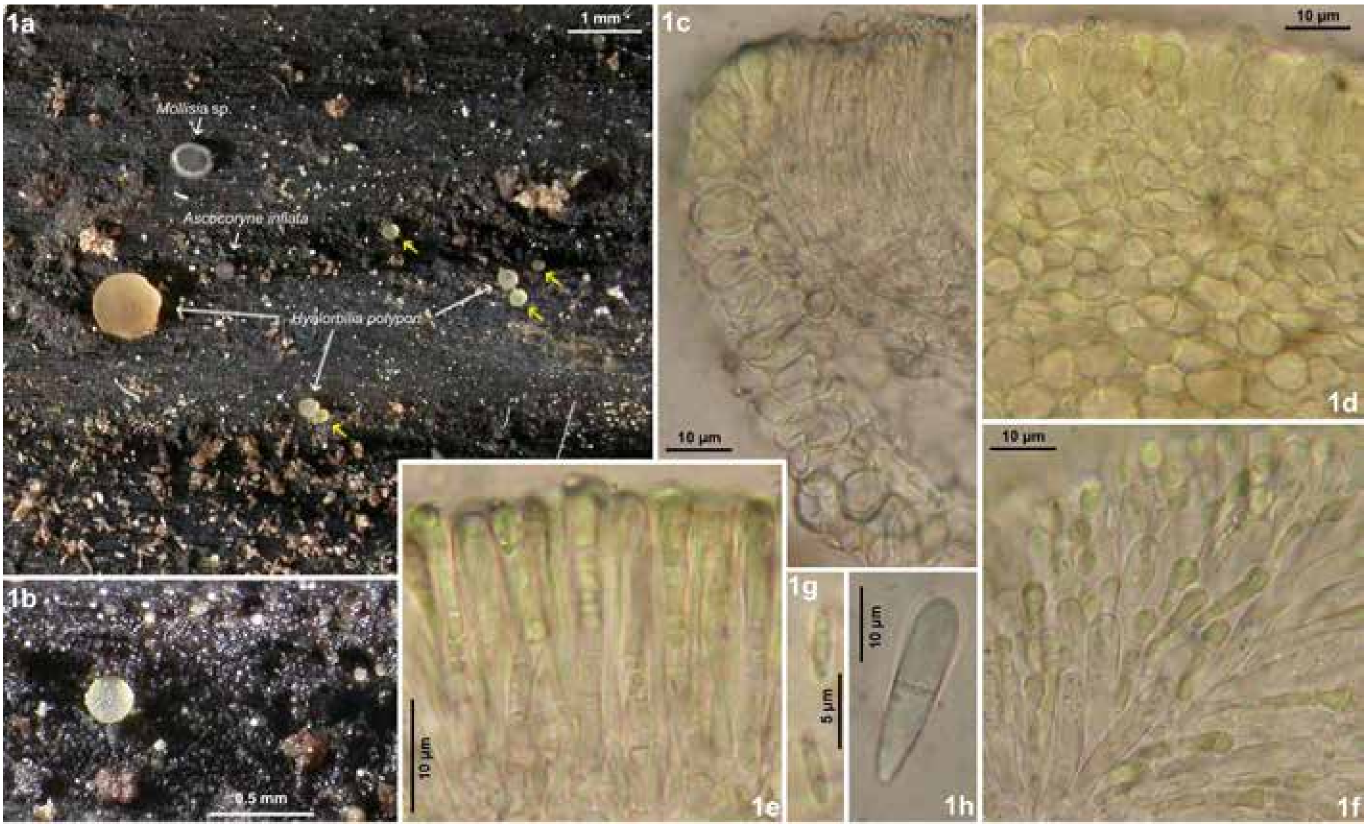

Plate 1011. **1**: *Orbilia flavovacuolata*. – **1a–b**. fresh apothecia (pale yellow in contrast to associated whitish to ochraceous *Hyalorbilia polypori*); **1c**. median section of ectal excipulum at flanks and margin; **1d**. id., external view; **1e–f**. asci and paraphyses (containing pale yellow VBs); **1g**. ascospores; **1h**. microconidium from substrate. – Living state, except for some cells in **1c**. — **1a–h**. H.B. 7943a (holotype): Germany, Tübingen, on *Fagus*.

many mature asci still viable after 12 h dry on slide. **Altitude**: 410 m a.s.l. **Geology**: Keuper (Rhätsandstein over Knollenmergel). **Phenology**: X.

Taxonomic remarks. *Orbilia flavovacuolata* resembles *O. polybrocha* in its hymenial characters, especially in the ascospores and their SBs and LBs. It differs in smaller apothecia with a smooth margin and a light yellow colour due to yellowish-chlorinaceous vacuoles (VBs) in paraphyses and marginal cortical cells, also in lacking exudate over the paraphyses, furthermore in the inflated marginal cortical cells lacking glassy processes, and in slightly longer spores. *O. flavovacuolata* resembles *O. mammillata* (series *Dactylellina*) in the rather short and wide asci, but differs from that species in shorter, straight spores with often eccentrical SBs, also in the marginal excipulum. From *O. atlantis* (series *Neodactylella*) it differs in a tendency to distinctly larger spores with a tail-like base and smaller, much more eccentrical SBs.

Anamorph. Only two microconidia could be found on the substrate. A possibility would be that the anamorph of *O. flavovacuolata* is *D. bembicodes*, a species which we have collected on the same substrate under similar conditions about 1 km away from the type locality. Judging from the SBs in the ascospores, *O. flavovacuolata* might be connected either to a drechslerella- or a gamsylella-like anamorph. Because microconidia rarely occur in series *Dactylellina* (*D. leptospora*, *O. biforma*) and *Gamsylella* (*G. gephyropaga*) but frequently in series *Drechslerella*, *O. flavovacuolata* is tentatively placed here in series *Drechslerella*. Another possibility would be that *O. flavovacuolata* lacks conidial dimorphism comparable to *O. alba* and '*Dactylellina*' *entomopaga*, the conidia of which resemble microconidia.

Ecology. *O. flavovacuolata* was found on rotten wood of a decorticated hygric log of *Fagus* lying on wet soil very close to a small pond in a rather shady *Fagetum* on upper Keuper (Rhätsandstein) in the southern part of Schönbuch in subcontinental cold-temperate humid southern Germany (central Europe).

Specimens included. **GERMANY**: **Baden-Württemberg**, 6 km ENE of Tübingen, 1 km ESE of Pfrondorf, Hinterpfand, 410 m, branch of *Fagus sylvatica*, on wood, 22.X.2005, E. Weber (ex H.B. 7943a, M-0276481, **holotype**).

Orbilia naumburgensis Baral & E. Weber, **sp. nov.**, MB 814003 — Pl. 1012–1013

Etymology: from the geographical origin, Naumburg in Sachsen-Anhalt (Germany).

Typification: Germany, Naumburg, log of *Tilia cordata*, 30.VI.2007, W. Huth (ex H.B. 8568, M-0276536, holotype; sq.: KT222362).

Latin diagnosis: *Similis* Orbiliae orientali *sed ascosporae longiores, subtus partim valde attenuatae, conidia magis curvatae. Habitat ad lignum rami et trunci uvidi* Tiliae *in zona temperata humida subcontinentali Europae centralis.*

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated (0.6–)1–2 mm diam., 0.25–0.5 mm high (receptacle 0.16–0.2 → 0.08–0.1 mm), whitish-cream-greyish, slightly translucent, round or slightly undulating when large, subgregarious; disc slightly to strongly concave, finally flat with a central depression, margin finely rough to crenulate {1} or with distinct minute teeth {T}, teeth 20–35 µm protruding and ~50–120 µm wide; exterior rough, whitish; with a cylindrical stipe 0.13–0.3 × 0.35–0.8 mm, superficial or ± immersed in small clefts. **Asci** *(29–)32–37(–40) × 3.4–4.2 µm {2}, †31–39 × 3–3.5 µm {1}, 8-spored, spores *~3-seriate, lower spores inverted (± strongly mixed), pars sporifera *13–15 → 9 µm long; **apex** (†) medium truncate (not indented, laterally not widened); **base** with short, thick stalk, h- (to H-)shaped. **Ascospores** *3.5–5(–5.7) × (1.3–)1.4–1.5(–1.7) µm {2}, narrowly cylindric-ellipsoid or mainly fusoid to fusoid(-clavate), apex obtuse (to subacute), base slightly to strongly attenuated, rarely tail-like, straight to distinctly inequilateral, also slightly to medium curved; **SBs** visible part *0.8–1.8 × 0.1–0.3 µm {2}, consistently eccentrical, filiform, filum hardly visible [total length (1–)1.2–1.8 µm]. **Paraphyses** apically slightly to medium capitate, terminal cell *18–28 × (2–)2.5–3.8 µm {3}, lower cells *4–7(–8) × 2–2.5 µm {2}; unbranched at upper septum. **Medullary excipulum** hyaline, at flanks of dense textura intricata-porrecta, sharply delimited. **Ectal excipulum** hyaline, near base of (†) slightly gelatinized t. globulosa-angularis, cells *13–30(–42) × 8–28(–40) µm {1}, †14–28 × 10–12 µm {T}; 25 µm thick at margin, of t. porrecta oriented at a 30–80° angle, marginal cortical cells hyphoid, †~2–2.5 µm wide {T}; **glassy processes** 20–30 {T} or 50–80{1} × 2.8–4 µm {2}, only outer layer refractive, internally not stratified, strongly downwards curved, ± granular by exudate, coherent to form or a crenulate or toothed margin. **Anchoring hyphae** sparse, †2.5–5 µm wide, wall 0.2–0.4 µm thick {1}. **SCBs** absent, **VBs** absent, vacuoles in paraphyses non-refractive {2}. **Exudate** hyaline to pale yellowish, over paraphyses 0.2–0.7 µm thick, granular(-cloddy), firmly attached, hyaline; over marginal processes abundant, granular. — **ANAMORPH**: drechslerella-like (from apothecium at lid of Petri dish {1}). **Conidiophores** not observed. **Macroconidia** cylindrical, rounded above, shortly tapered-truncate below, medium to strongly curved (entirely or especially towards upper end), *33–38 × 7–8 µm, 3-septate {T}, terminal cells not or distinctly longer (up to 2×) than middle cells, with small LBs at the septa but also forming roundish aggregations, lipid content low to medium. **Microconidia** not observed. **Constricting rings** not observed.

Habitat: lying on moist ground, partially to entirely decorticated, 5–10 cm thick branches and logs of *Tilia* sp. {1}, *T. cordata* {4}, on underside on 0.1–1 mm deep slightly to strongly decayed wood {5}, sometimes on insect excrements or old *Lasiosphaeria hirsuta*, ungreyed but sometimes blackened, without algae. **Associated** (on same or different *Tilia* branches and logs, W. Huth, T. Richter & M. Reul pers. comm.): *Basidiopycnides* sp. {1}, *Ceratostomella cirrhosa* {2}, *Chaetosphaerella fusca* {1}, *Hyalorbilia inflatula* {4}, *Lasiosphaeria ovina* {1}, *Mollisia cinerea* {2}, *Orbilia crenatomarginata* {1}, *O. leucostigma* {2}, *O. tremulae* {1}, *O. xanthostigma* {1}, *Protounguicularia transiens* {1}, *Rhizodiscina lignyota* {1}, *Tulasnella cystidiophora* {1}, brown hyphomycetes. **Desiccation tolerance**: only ascospores and some inflated cells of medullary excipulum alive after 8 days. **Altitude**: 85–215 m a.s.l. **Geology**: Muschelkalk, Pleistocene sand & loess over Upper Buntsandstein. **Phenology**: VI–XI.

Taxonomic remarks. *Orbilia naumburgensis* is morphologically very close to *O. orientalis*, *O. yunnanensis*, and *O. tonghaiensis*, especially in the conidia. It differs in longer ascospores that are sometimes apically subacute and basally strongly attenuated. *O. polybrocha* resembles *O. naumburgensis* in spore size and shape, but has very different conidia and usually light reddish-brown apothecia.

Variation. One of the paratypes differs in more cupulate apothecia with only finely crenulate margin, although much longer glassy processes were observed (Pl. 1013:

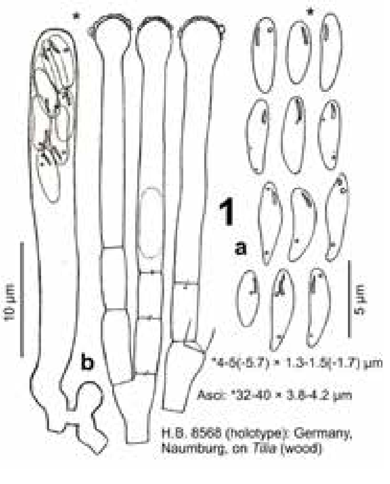

Plate 1012. **1**: *Orbilia naumburgensis*. – **a**. ascospores; **b**. ascus and paraphyses.

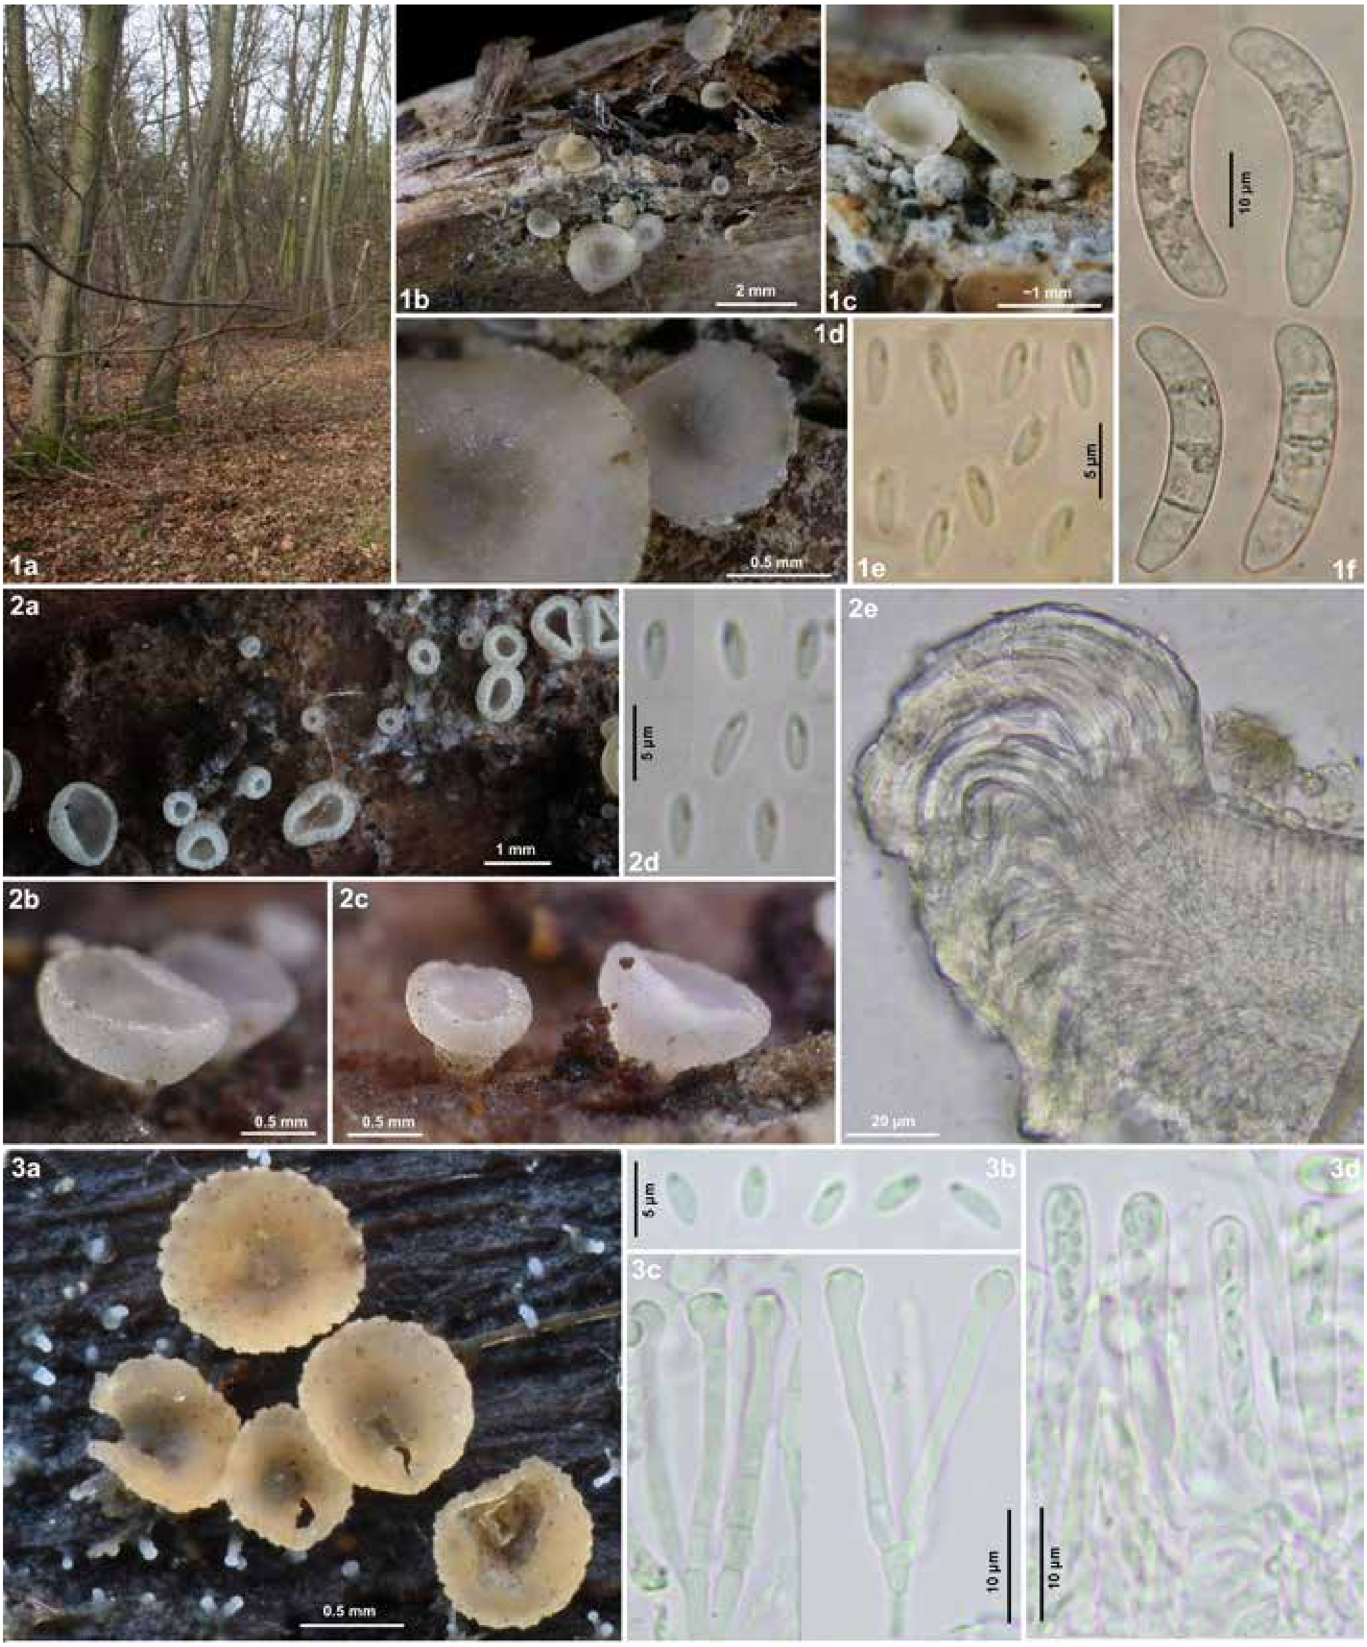

Plate 1013. **1–3**: *Orbilia naumburgensis*. – **1a**. thermophilous *Tilia cordata* forest in wine-growing region; **1b–d**, **2a–c**, **3a**. fresh apothecia (**3a** with *Basidiopycnides* sp.); **2e**. marginal part of apothecium in median section; **3c**. paraphyses; **3d**. asci; **1e**, **2d**, **3b**. ascospores; **1f**. conidia (from culture). – Living state, except for 1 ascus in **3d**. – **1a–b**, **2a**: phot. M.R. 6432: Colbitz, on *Tilia*.

2). The spores were here slightly shorter and never strongly tapered below (Pl. 1013: 2d).

Anamorph. Conidia similar to *O. orientalis* and allied taxa, but more strongly curved, were formed from mycelium growing out of an apothecium in a Petri dish. A pure culture was not obtained.

Phylogeny. Sequences were gained from apothecia of the holotype from Keilholz and a paratype from Alte Göhle, which both comprise S1506 intron and ITS, the latter also LSU D1–D2. In the overlapping parts the two sequences are completely identical.

O. naumburgensis clustered in our LSU (Phyl. S36) or combined analysis (S37) with *O. orientalis* and *O. yunnanensis* in a strongly supported clade, here called *orientalis-naumburgensis* clade. When analysing the ITS region it clustered weakly supported in this clade (Phyl. 36). The distance in the ITS is 4.5% to *O. pseudopolybrocha*, 4.6–4.8% to *O. orientalis*, 7% to *O. yunnanensis*, and 9–9.5% to *O. polybrocha*, in the LSU 0.5–0.8% to *O. yunnanensis* and 1.3–1.6% to *O. orientalis* s.l., but 3.8–4.2% to *O. brochopaga*. When analysing the intron (S30), *O. naumburgensis* clustered medium supported with *O. yunnanensis* (6% distance), and more distant from *O. pseudopolybrocha* (8%), *O. polybrocha* (12%), and *O. brochopaga* (14%).

Ecology. *O. naumburgensis* was found on the underside of fallen, ± decayed branches and logs of *Tilia*. The thermophilous, almost pure *Tilia cordata* forest at the type locality is situated close to a vineyard, on a very slightly inclined southeastern-exposed slope. The site near Almrich is a *Fagus* forest with *Acer pseudoplatanus* and a few *Tilia cordata*, that near Freyburg (5 km from the type locality) a *Querco-Carpinetum* with *Tilia cordata* and *T. platyphyllos*, and that from Colbitz (130 km N of Naumburg) a *Tilia* forest. Naumburg belongs to an area with a relatively warm climate and low annual precipitation (W. Huth pers. comm.) in the otherwise subcontinental cold-temperate humid central Europe. Also Magdeburg receives a low annual precipitation (below 500 mm), but is in the temperature in the nationwide average of Germany.

Specimens included. **GERMANY**: **Sachsen-Anhalt**, 24 km NNW of Magdeburg, 3.5 km WNW of Colbitz, Colbitzer Heide, 85 m, log of *Tilia*, on wood, 1.XI.2018, T. Richter, vid. M. Reul (M.R. 6432, doc. vid.). – 8 km N of Naumburg, 2.3 km ENE of Freyburg, Alte Göhle, 215 m, branch of *Tilia cordata*, on wood, 1.VIII.2016, W. Huth (W.H., H.B. 10016; sq.: MK493143). – ibid., 27.IX. & 2.X.2016 (W.H., doc. vid.). – 3 km NNE of Naumburg, NW of Hotel Henne, Keilholz, 160 m, log of *T. cordata*, on wood, 30.VI.2007, W. Huth (ex H.B. 8568, M-0276536, **holotype**, anam. apoth.; sq.: KT222362). – 2.7 km WSW of Naumburg, S of Almrich, Sperlingsholz, 195 m, branches of *Tilia cordata*, on wood, 12. & 13.VIII.2019, W. Huth (W.H., doc. vid.).

Orbilia yunnanensis (Z.F. Yu & K.Q. Zhang) Bin Liu, E. Weber & Baral, **comb. nov.**, MB 814004 — Pl. 1014

Basionym: *Drechslerella yunnanensis* Z.F. Yu & K.Q. Zhang, in Yu et al., Mycotaxon 110: 254 (2009)

Etymology: named after Yunnan province in China.
Typification: China, Yunnan, Fangtunxiang, branch of indet. angiosperm, VIII.2008, Z.F. Yu (YMF 1.01863, holotype; sq.: FJ185262, MH179759).
Misapplied name: Liu (2006: 88 p.p.), as *O. orientalis*.

Description: — **TELEOMORPH**: **Apothecia** fresh 0.3–2 mm diam., white to yellow, round, translucent, scattered or in groups; disc flat or slightly concave, margin almost smooth or distinctly dentate (teeth 25–40 × 35–70 µm), stipe 0.2–0.8 × 0.8–0.9 mm, dry pale yellow to light brown. **Asci** *31–41 × 3.8 µm {1}, †25–40 × (3–)3.2–3.5(–3.7) µm {3}, 8-spored, spores *~2-seriate, 3–5(–7) lower or upper spores inverted (sometimes strongly mixed), pars sporifera *12 µm long; **apex** (†) truncate, thin-walled; **base** unstalked or with short to medium long stalk, L-, Y-, h- or H-shaped. **Ascospores** *3–4.3 × 1.6–2 µm {2}, †2.6–3.5 × 1.2–1.8 µm {2}, (cylindric-)ellipsoid, straight to slightly inequilateral; **SBs** *~1.2–1.5 × 0.3–0.4(–0.8) µm (visible part 0.9–1.1 µm long) {2}, rod-shaped, rarely almost globose, very eccentrical. **Paraphyses** apically slightly to medium capitate(-clavate) {3}, terminal cell *19–24 × 2.2–3 µm {1}, †12–19 {1} × 2–3 µm {2}, lower cells */†4–7.5 × 1.5–2.3 µm {2}; unbranched at upper septum. **Medullary excipulum** not examined. **Ectal excipulum** of thin- or somewhat thick-walled t. globulosa-angularis, 20–40 µm thick, cells 7–16 × 6.5–11 µm, margin not examined; **glassy processes** almost absent {1} or 14–22 × 3.5–4.5 µm {1}, refractive. **Anchoring hyphae** not examined. **SCBs** and **VBs** absent. **Exudate** over paraphyses 0.2–0.5 µm thick, granular, firmly attached.
— **ANAMORPH**: drechslerella-like (from ascospore isolate {3}, according to Yu et al. 2009b, Z.F. Yu pers. comm., Liu 2006). **Macro- & microconidiophores** usually unbranched, erect, *(40–)60–100(–200) µm high, 2.5–4.2 µm wide at base, 1.5–2 µm at apex, with 2–7(–10) denticles of 2.3–5 × 1.5–1.8 µm at not or indistinctly swollen nodes, sometimes proliferating to form nodes in a row. **Macroconidia** cylindrical to subclavate, straight to slightly curved, *(16–)20–32 × 5.0–6.5 µm {1}, (1–)3-septate, ± equidistantly septate. **Microconidia** cylindric-ellipsoid-clavate, below with a short truncate protuberance, straight, *(8–)10–14(–17.5) × 3.3–4.5(–5.5) µm, (0–)1-septate {2} (values of Yu et al. modified according to scale). **Constricting rings** with short and thick stalk (not clearly seen on photos); ring unexpanded *18–25(–28) µm outer diam., 12–15(–17.5) µm inner diam. {2}, 3-celled, with triangular wall thickenings at the septa.

Habitat: lying on moist ground, on branches of *Quercus* {2}, indet. angiosperm {2}, indet. tree {1}, on rotten wood {3} or bark {1}. **Desiccation tolerance**: unknown, possibly intolerant. **Altitude**: 850 m a.s.l. (northern China)), 500–1750 m (southern China). **Geology**: felsic plutonic and metamorphic rock. **Phenology**: VII–VIII.

Taxonomic remarks. Yu et al. (2009b) described *Drechslerella yunnanensis* for an anamorph obtained in an ascospore isolate from Yimen county (Yunnan, Pl. 1014: 1e–h). In the teleomorph the species fits *Orbilia orientalis* in most respects, apart from the absence of distinct glassy processes at the minutely crenulate margin. A collection from Yuanjiang county (Yunnan) was not mentioned by Yu et al. and was not documented for the margin, but phylogenetically concurs with the type. However, three collections which apparently possessed medium long glassy processes, all from a single locality near Beijing (HMAS 139691–139693) and included by Liu (2006) in his concept of *O. orientalis*, are transferred here to *O. yunnanensis* because of their molecular data.

A specimen from southern China (Guangxi, on wood, HMAS 139696), identified as *O. orientalis* by Liu (2006), deviates from those from Beijing (see below) in much longer glassy processes and concurs with other Chinese strains of *O. orientalis*.

Yu et al. (2009b) named the teleomorph of *Drechslerella yunnanensis* '*O.* cf. *orientalis*' because of differences in anamorph and DNA data to a strain from Jiangxi province, which Yu et al. (2006) named *D. brochopaga* and believed to be the anamorph of *O. orientalis*, but which is shown here to be closely related to *O. tonghaiensis*.

Not included collections. Among the seven collections reported by Liu (2006) under the name *O. orientalis*, three from Beijing and Guangxi were without sequence data. Since Liu described *O. orientalis* with distinct marginal teeth composed of glassy processes, it can be assumed that the three also possessed them. Liu's concept of *O. orientalis* includes both *O.* cf. *orientalis* (1 ×) and *O. yunnanensis* (3 ×) based on available DNA data, whereas the three unsequenced samples remain of unclear identity.

Anamorph. Yu et al. (2009b) characterized *Drechslerella yunnanensis* by small, (0–)1-septate conidia (see Pl. 1014: 1e) very different from the much larger 3-septate conidia of *D. brochopaga*. Since the latter and its possible synonym *Dactylaria gracilis* were described by Drechsler (1937a) and Duddington (1951) without microconidia, Yu et al. took the small conidia as homologous to the large conidia of *D. brochopaga*, but did not consider that *D. yunnanensis* might

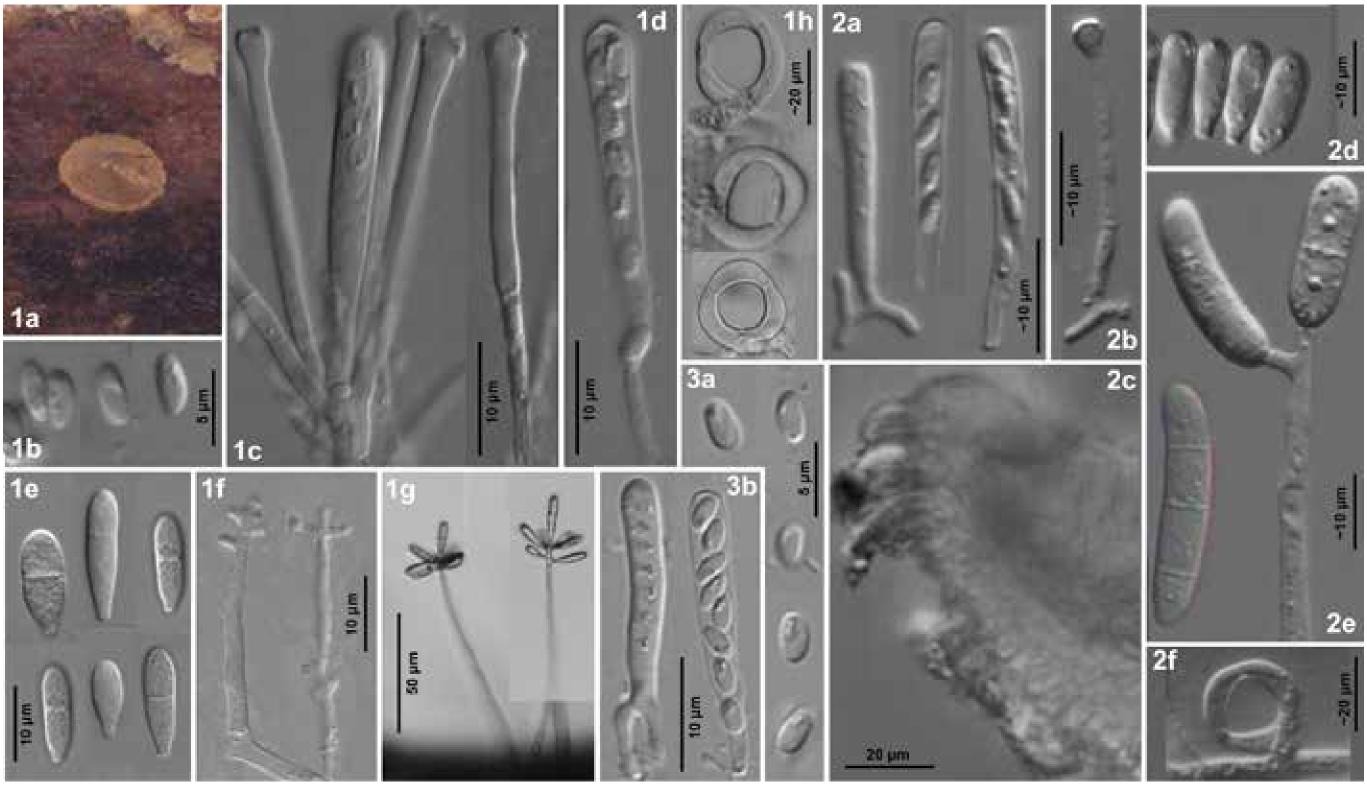

Plate 1014. **1–3**: *Orbilia yunnanensis*. – **1a**. fresh apothecium; **2c**. marginal ectal excipulum in median section; **1c–d**, **2a–b**, **3b**. asci and paraphyses; **1b**, **3a**. ascospores; **1f–g**, **2e**. conidiophores; **1e**, **2d**. microconidia; **2e**. macroconidia; **1h**, **2f**. constricting rings (anamorph from culture). – Living state, except for **1d**, **2a**, **3b** (asci) and **2b**. – **1**: from Yu et al. (2009b), **2**: from Liu (2006, figs 32–33). — **1a–h**. YMF 1.01863 (holotype): China, Yunnan, Yimen, on indet. angiosperm (Yu et al. 2009b); **2a–f**. HMAS 139691: Beijing, on *Quercus* (Liu 2006); **3a–b**. Z.F.Y. yj-6: Yunnan, Yuanjiang, on indet. angiosperm.

also form macroconidia. Not only the ex-type strain (YMF 1.01863) but also the isolate from Yuanjiang (YMF 1.03216) produced only small conidia (Z.F. Yu pers. comm.). However, two unpublished macrophotos made under the microscope show an apothecium of the holotype growing on agar and surrounded by mycelium with conidiophores and conidia, the latter being distinctly curved and rather long for their width, suggesting that they were macroconidia. The photos are uncalibrated, therefore it is impossible to tell the size of these conidia.

At least 1 of Liu's (2006) three ascospore isolates from Beijing (HMAS 139691), which belong phylogenetically to *O. yunnanensis*, formed both micro- and macroconidia (Pl. 1014: 2). From the anamorph of *O. orientalis* these macroconidia differ only gradually in being less curved. From all this we conclude that *D. yunnanensis* was misleadingly characterized by small, 1-septate conidia. Yu et al. (2009b) compared *D. yunnanensis* with *D. dactyloides*, which represents the only hitherto known species of series *Drechslerella* with similar 1-septate though distinctly larger conidia.

Phylogeny. Sequences were gained by Yu et al. (2009b) from two Chinese strains from Yimen (type) and Yuanjiang, comprising S1506 intron and ITS. The two strains fully concur in the ITS except for 1 gap, and in the intron except for 1 nt and 1 gap in the overlapping 350 nt. Liu et al. (2006a) gained LSU D1–D2 sequences from three strains from Beijing under the name *O. orientalis* (HMAS 139691–139693), and ITS from one of them (139691). The ITS sequence fully concurs with the type of *O. yunnanensis*, but it is too short to see whether it possesses the intron. Also the three LSU sequences from Beijing differ by only 0–1 nt. Another identical ITS sequence from China was given by Li et al. (2016) the provisional name *D. longkoensis*.

O. yunnanensis shows an ITS distance of 7–9% to *O. orientalis* and *O. naumburgensis*, and ~7–13% to *O. brochopaga* and *O. tonghaiensis*. The LSU D1–D2 distance is 1–1.5% to *O. orientalis*/*O. naumburgensis* and 3.5% to *O. brochopaga*. In a NJ analysis of the ITS region by Yu et al. (2009b), *D. yunnanensis* clustered in an unsupported clade with *D. polybrocha* distant from *D. brochopaga*. In our analyses, *O. yunnanensis* clustered with weak (ITS, Phyl. 36) or strong support (LSU and SSU+ITS+LSU, S36–37) in the *orientalis-naumburgensis* clade.

Ecology. The type of *O. yunnanensis* was found on decayed bark of an unidentified angiosperm tree in a subtropical humid (winter-dry) mixed evergreen mountain forest dominated by *Quercus schottkyana* and *Pinus armandii* in southern China. Records from northern China (near Beijing) were on wood of *Quercus*, *Betula* etc. in continental cold-temperate humid (winter-dry) forests.

Specimens included. **CHINA**: **Beijing**, **Huairou**, 115 km N of Beijing, ~11 km WNW of Labagoumenxiang, Sunzhazi, 850 m, wood of *Quercus*, 10.VII.2002, B. Liu (B.L. 6171, HMAS 139691, anam. cult., doc. vid.; sq.: DQ656614, DQ656670). – ibid., wood of *Quercus* (B.L. 6174, HMAS 139692, doc. vid.; sq.: DQ656671). – ibid., wood of indet. tree (B.L. 6180, HMAS 139693, non vid.; sq.: DQ656672). – **Yunnan**, **Yuxi**, Yimen, 54 km NW of Yuxi, 3 km NW of Fangtunxiang, Dalongkou, ~1750 m (Yu et al. 2009b as 1580 m, with erroneous coordinates), branch of indet. angiosperm, on bark, VIII.2006, Z.F. Yu (Z.F.Y. ym-68, YMF 1.01863, **holotype** of *D. yunnanensis*, anam. cult., doc. vid.; sq.: FJ185262, MH179759). – Yuanjiang, ~500 m, branch of indet. angiosperm, VIII.2008, S.F. Li (Z.F.Y. yj-6, YMF 1.03216, anam. cult., doc. vid.; sq.: HQ711927). – ?**Shandong**, Longkou (KQZ-2016a, YMF 1.01863, as *D. longkoensis* or *D.* sp.; sq.: KT932079).

Not included (without sequence data). **CHINA**: **Beijing**, **Yanqing**, Matsuyama, 750 m, *Betula*, on wood, 31.VIII.2003, B. Liu (HMAS 139694). – **Mentougou** East Mountain, 800 m, on indet. wood, 15.IX.2003, B. Liu & X.Z. Liu (HMAS 139695, non vid.). – **Guangxi**, **Fangchenggang**, Shangsi, Great Mountain, 800 m, on indet. bark, 20.VI.2003, B. Liu (HMAS 138522, non vid.).

Orbilia orientalis (Raitv.) Baral, in Krieglsteiner, Regensb. Mykol. Schriften 9: 271 (1999) — Pls 1015–1017, Map 158

≡ *Hyalinia orientalis* Raitv., in Azbukina, Plantae non vasculares, Fungi et Bryopsida Orientis extremis Sovietici, Fungi, Tom. 2, Ascomycetes: 362, fig. 252 (1991)

Etymology: from the geographical origin, the Far East of Russia (*orientalis* = eastern).

Typification: Russian Far East, Petrova island, branch of *Tilia amurensis*, 2.IX.1961, A. Raitviir (TAAM 42475, holotype).

Misinterpretation of *O. orientalis*: Liu (2006: 88 p.p.), = *O. yunnanensis*; Yu et al. (2006), ?= *O. tonghaiensis*.

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated (0.3–)0.5–1.5(–3) mm diam., 0.21–1 mm high (receptacle 0.1–0.23 mm), fresh whitish to pale flesh-cream-chlorinaceous or ochraceous, slightly to medium translucent, round, sometimes ± undulating when large, scattered or subgregarious; disc medium to strongly concave (cup-shaped), flat to slightly convex with age, margin slightly curved upwards or not, distinctly crenulate to denticulate by minute teeth of 20–35 × 50–100 or up to 60 × 150–180 µm; externally ± rough or nearly smooth, concolorous; (sub)sessile or mostly with prominent cylindrical stipe 0.15–0.5 × 0.2–0.6 mm, superficial (or erumpent below periderm); dry light honey-yellow-ochraceous-amber, margin strongly inrolled. **Asci** *29.5–41(–44) × (3.2–)3.5–4.3(–4.7) µm {4}, †26–40 × 3–4 µm {5}, 8-spored, spores *2–4-seriate, (2–)3–5(–6) lower spores inverted {4} (sometimes strongly mixed), pars sporifera *10–13(–15) → 8–11 µm long, †12–15 µm; **apex** (†) medium to strongly truncate (rarely very slightly indented, laterally not widened); **base** with short to medium long, flexuous stalk, L- or mainly Y-, h- to H-shaped. **Ascospores** *(2.6–)3–4 × (1.2–)1.3–1.7(–1.9) µm {12}, †2.7–3.8 × (1.1–)1.2–1.5(–1.8) µm {3}, cylindrical to cylindric-ellipsoid, also ellipsoid(-clavate), sometimes ovoid, rarely slightly tapered at base, ends rounded to obtuse, straight, sometimes slightly inequilateral or curved; **SBs** *0.8–1.7 × 0.15–0.4 µm {3}, consistently eccentric, divided into a small tear- to rod-shaped lower part and a fine, somewhat shorter, often invisible, apically attached filum. **Paraphyses** apically mostly slightly to rather strongly capitate(-clavate), terminal cell *15–22.5 × (2–)3–4(–5) µm {4}, †20–25 {1} × 1.8–4 µm {2}, lower cells *3–7(–9) × 1.7–3 µm {4}, †5–7.5 × 1–1.8 µm {1}; unbranched at upper septum. **Medullary excipulum** hyaline, 50–200 µm thick in centre, 2-layered: lower part up to 100–120 µm thick, of ± loose to dense textura intricata-globulosa with inflated moniliform cells of */†13–30 × 6–17 µm, upper part 60 µm thick, of dense t. intricata with scattered inflated cells of smaller size, towards margin of irregular t. prismatica-porrecta with inflated cells of *20–35 × 8–14 µm, only here sharply delimited. **Ectal excipulum** hyaline, of thin-walled, indistinctly vertically oriented t. globulosa-angularis(-prismatica) from base to flanks, 170–300 µm thick near base, cells *18–58 × 12–42 µm {3}, †20–40 × 15–32 µm {2}; 30–40 µm thick at lower flanks, cells */†10–30 × 8–23 µm {3}, 20–30 µm thick at mid flanks, of vertical t. globulosa or t. prismatica, cells */†6–16 × 4–8 µm; 15–20 µm at margin, of t. prismatica-porrecta oriented at a 70–90° angle, marginal cortical cells *(6–)9–16(–19) {3} or 16–22 {1} × (2.7–)3–5(–6) µm {5}, †7–10 {T} or 12–15 {1} × 3–5 µm {2}; **glassy processes** (10–)20–50(–60) × (2.5–)3–4(–5) µm {12}, rarely only 3–7 µm long {1}, low- (to high-)refractive, partly stratified, strongly curved downwards {7}, covered by finely granular exudate, coherent to form teeth. **Anchoring hyphae** sparse to very abundant, */†(2.5–)3–5(–6) µm wide, walls †0.2–0.3(–0.5) µm thick {4}, forming a dense, thick, hyaline t. intricata. **VBs** in paraphyses long-cylindrical or large-guttulate, low-refractive {2}, 12–16 µm from tip, or vacuoles nearly non-refractive {3}; in ectal excipulum absent; **SCBs** absent. **Exudate** hyaline to pale yellowish, over paraphyses 0.3–1(–1.4) µm thick, granular-cloddy, ± loosely or firmly attached, hyaline; over margin and flanks sparse or abundant, granular. **— ANAMORPH**: drechslerella-like (from ascospore isolate {1} or from apothecia on lid of Petri dish {1}). **Conidiophores** unbranched below, erect, *90–150 µm high {1}, *4.2–5 µm wide at base {1}, *2.5–3.5 µm at apex {2}, here with 2–10 denticles. **Macroconidia** cylindrical (to cylindric-ellipsoidal), rounded above, shortly tapered-truncate below, slightly to medium curved (especially towards upper end), *(27.5–)30–39(–45) × 6.5–7.5(–9) µm, (1–)3-septate {2}, terminal cells often slightly longer (up to 1.7×) than middle cells, strongly varying in lipid content among strains. **Microconidia** not observed. **Constricting rings** with 1-septate stalk of *11–19 × 5.2–5.5 µm {1}; ring unexpanded *35–39 µm outer diam. (expanded 30–37 µm), *22–26 µm inner diam. {1}, 3-celled, with triangular wall thickenings at the septa.

Habitat: collected usually on the moist or wet ground (sometimes half submerged) but also in 1–2.5 m above the ground, corticated to decorticated, 15–150 mm thick branches and logs of *Alnus glutinosa* {1}, *Carpinus betulus* {1}, *Corylus avellana* {1}, *Fagus sylvatica* {3}, *Pinus nigra* {1}, *Populus nigra* {1}, *P. tremula* {1}, *Prunus avium* {1}, *Quercus* sp. {1}, *Q. ilex* {1}, *Salix* sp. {2}, *Rosaceae* sp. {1}, *Tilia amurensis* {1}, *T. cordata* {1}, *T. platyphyllos* {1}, on usually deeply strongly decayed wood {15}, sometimes splitted, also on decayed bark (periderm and bast) {3}, in cracks or holes of periderm, on underside if lying on ground, medium to strongly greyed or blackened, with a few or many green algae. **Associated**: *Annulusmagnus* sp. {1}, *Calycina claroflava* {1}, *Chaetosphaeria* sp. {1}, *Corticiaceae* {1}, *Cryptodiscus foveolaris* {1}, *Dematioscypha olivacea* {2}, *Flagelloscypha* sp. {1}, *Hyalorbilia juliae* {1}, *H. tortuosa* {1}, *Hypoxylon fuscum* {1}, *Melanomma* sp. {1}, *Mollisia* sp. {3}, *Orbilia cejpii* {4}, *O. clavispora* {1}, *O. crenatomarginata* {1}, *O. eucalypti* {2}, *O. xanthostigma* {1}, *Parmelia* sp. {1}, *Pleurothecium recurvatum* {1}, *Rhizodiscina lignyota* {1}, *Stilbella* sp. {1}. **Desiccation tolerance**: a few mature asci still viable after 3 days. **Altitude**: 13–650 m a.s.l. (Europe), 50–400 m (Far East of Russia, Japan). **Geology**: Buntsandstein, Muschelkalk, Keuper (Lettenkohle), Middle & Upper Jurassic limestone, Upper Cretaceous calcareous clay- & marlstone, flysch, Tertiary limestone & molasse; andesite, ophite. **Phenology**: III–IV, VI–X.

Taxonomic remarks. *Orbilia orientalis* is characterized by small, (cylindric-)ellipsoid ascospores with a small, rod-shaped, eccentrical spore body, and rather prominent glassy processes that are agglutinated to form a crenulate margin. The cupulate, usually stipitate, whitish apothecia resemble somewhat a helotialean discomycete, e.g., a *Hymenoscyphus*, *Cyathicula*, or *Calycina*. Since cultural or molecular data are unavailable in the type of *O. orientalis*, conspecificity with the here included European specimens is only assumed, because very similar Chinese collections (Pl. 1017) might as well fall in the narrow scope of this taxon. Even *O. brochopaga* and *O. yunnanensis* cannot be excluded with certainty from being conspecific with the type of *O. orientalis*.

The Chinese *O. yunnanensis* (Pl. 1014) differs from *O. orientalis* as interpreted here in a tendency to shorter glassy processes, shorter, less curved macroconidia, and in the formation of microconidia. It is separated at the species level mainly for molecular reasons. *O. naumburgensis* (Pls 1012–1013) and *O. polybrocha* differ from *O. orientalis* particularly in distinctly longer and partly narrower ascospores with a more tapered base, *O. naumburgensis* also in the marginal excipulum oriented at a rather low angle (30–40°), *O. polybrocha* also in usually having a (purplish-)brown pigment and, above all, in very differently shaped macroconidia. Both species differ also strongly in their molecular data. Difficult to distinguish are also *O. tonghaiensis* (Pl. 1019–1020, p. 1653) and *O. brochopaga* (Pl. 1018: 1), at least based on their anamorph. *O. dryadum* (section *Orbilia*) might be confused with *O. orientalis* and related species due to similar hymenial characters; it differs in usually narrower spores which contain in the living state a globose, central spore body, and in a non-predacious dactylella-like anamorph.

Variation. Within Europe the teleomorph exhibits some variation between the collections. The ascospores vary

H.B. 8146a: France, Charente-Maritime, on *Carpinus betulus* (wood)

Plate 1015. **1–4**: *Orbilia orientalis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. fresh or rehydrated apothecia; **e**. apothecia in median section; **f**. id., marginal ectal excipulum; **g**. marginal cortical cells with glassy processes; **h**. anchoring hypha; **i**. conidia; **j**. conidiophore (both from culture). – The long, filiform, refractive, serpentinoid inclusions in the dead spores of **2a** & **c** are artifacts caused by coagulation of cytoplasm.

somewhat in size and shape. The SBs are usually thin (rod-shaped) and strongly eccentrical (Pls 1015: 3a, 4a; 1016: 2g, 3e), but in one collection they were predominantly central and more tear-shaped (Pl. 1015: 1a). In the dead spores, long, filiform, refractive, serpentinoid inclusions were frequently seen in water mounts, especially when still within the asci (Pl.1015: 2a). These are artifacts which are caused by the coagulation of cytoplasm, but can easily be mistaken for spore bodies.

Type studies of teleomorph. Some differences between the protologue of ***Hyalinia orientalis*** and the present reexamination of the holotype need to be mentioned (see Pl. 12: b and Pl. 1015: 2). Raitviir (1991) described the paraphyses with only slightly inflated ('apically subclavate', here ± strongly clavate-capitate) tips, and the spores as broadly ellipsoid-fusoid with pointed ends (here ellipsoid to slightly ovoid). The given spore size (3–4 × 1.5–2 µm) is confirmed here. The apothecia were described as sessile, but are found here to be partly stipitate (the stipe is hidden in holes of the periderm). Raitviir placed the species in *Hyalinia* because of 40–60 µm long 'solid glassy hairs' at the margin (present study: 15–40 µm).

Not included collections. A sample from Serbia (Pl. 1016: 7) fits morphologically *O. orientalis* quite well [spores *(3–)3.2–

Plate 1016. **1–6**: *Orbilia orientalis*; **7**: *O.* aff. *orientalis*. – **2a**. branches of *Tilia* on a heap in small *Quercus robur* forest; **1a–f**, **2b–c**, **3a–b**, **4a–b**, **5a**, **7a**. fresh apothecia; **1g**. apothecium in median section; **1h–i**. id., ectal excipulum at flanks and margin; **3f**. id., medullary excipulum; **1j**. id., ectal excipular cells with MCs; **3c**. apothecium in external view (squash mount); **1k**, **2d–e**, **3d**. asci and paraphyses; **2f**. ascus apex; **2g**, **3e**, **5b**, **6**, **7b**. ascospores; **1l**, **7c**. conidiophore tips; **1m**, **7d**. macroconidia (from culture). – Living state (**1j–k** in Neutral Red, **2d**. YMF 1.01854: China, Yunnan, Dali, Yongping, on indet. angiosperm.

3.5(–4) × (1.3–)1.4–1.6 µm, conidia *(20–)22–39 × (5.7–)6–6.6(–7) µm]. It is not included in the description because it deviates for > 3 % in the ITS region (see below).

Three Chinese records from Guizhou and Yunnan (Yongping and Yuxi) studied by Z.F. Yu et al. (pers. comm., Pl. 1017: 1–2) and one from Guangxi reported by Liu (2006) fit *O. orientalis* in most respects (3 further strains of B. Liu under the name *O. orientalis* from Beijing belong phylogenetically to *O. yunnanensis*). They cluster very close to European *O. orientalis*, but are tentatively kept apart here mainly due to their geographical origin and because they form a clade of their own (see below). For one of them (Guizhou) no anamorph was obtained in culture. Rather long glassy processes of 20–40 × 2.5–3.5 µm reminiscent of *O. orientalis* were observed here (1b, Z.F. Yu pers. comm.) and in the strain from Guangxi (HMAS 139696, B. Liu pers. comm.). Glassy processes were possibly absent in the strain from Yongping (IVV: YMF 1.01854). Ascospore size was with *3.3–4.2(–4.5) × 1.2–1.6(–2.2) µm in the range of European *O. orientalis*. For the isolate from Yuxi no documentation was available. A description is given in Zhang et al. (2020a).

Anamorph. The macroconidia of *O. orientalis* as figured in Pls 1015–1016 (2 strains from France) tend to be apically curved. This is also the case in the not included strains from Serbia (Pl. 1016: 7) and China (Pl. 1017: 2), but also in *O. naumburgensis* (Pl. 1013: 1e). Microconidia were not observed in either of these strains.

Measurements of Chinese strains were available for the two isolates from Yunnan, which closely resemble those of European *O. orientalis* (data from Z.F. Yu pers. comm., partly modified): conidiophores erect, 58–166 µm high, 3.2–5 µm wide at the base, 3 µm at apex, bearing 3–9 denticles 2–3 × 2 µm in a capitate arrangement. Macroconidia cylindrical to very slightly clavate, shortly attenuated below, with a truncate hilum, slightly to medium curved near distal end, *28–39 × 6–8 µm, 3-septate but often also 1–2-septate. Constricting rings unexpanded *21–22 diam., inner diameter 12–13.5 µm, 3-celled, with triangular wall thickenings at the septa.

O. brochopaga and *O. yunnanensis* differ from *O. orientalis* in their macroconidia which tend to be more straight, *O. brochopaga* also in having the septa distinctly centrally aggregated, *O. yunnanensis* in a smaller conidial size and the presence of microconidia (Tab. 95).

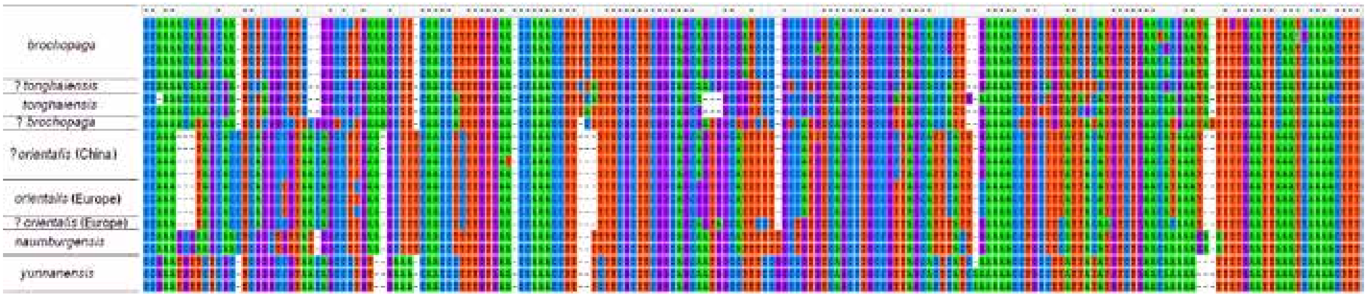
Phylogeny. Sequences of *O. orientalis* s.l. were gained from apothecia of three European samples (Pyrénées Atlantiques, Navarra, Serbia H.B. 9965; ITS+LSU) and from four Chinese ascospore isolates (*O.* cf. *orientalis*), three from Yunnan (ITS) by Zhang et al. (2020a), and one from Guangxi (HMAS 139696, ITS+LSU) by Liu et al. (2006a, as *O. orientalis*/*D.* cf. *brochopaga*). A further sequence of *O. orientalis* s.l. was gained from an ascospore isolate of the not included *O.* aff. *orientalis* from Serbia (H.B. 9895a, ITS+LSU). The S1506 intron is absent in the four European samples, and also the three Chinese strains which cover this region do not have it. All these sequences clustered in a medium (ITS, Phyl. 37) or strongly (LSU, SSU+ITS+LSU, S36–S37) supported clade.

In the phylogenetic analyses of the ITS and LSU region by Liu et al. (2006a), the Guangxi strain clustered distant from their '*O. orientalis*' strains which are reidentified here as *O. yunnanensis*, and also distant from authentic *D. brochopaga*. Also in the analyses of Zhang et al. (2020a), *O. yunnanensis* formed a clade distinct from the four Chinese and three European strains.

Two subclades are recognized within *O. orientalis* s.l. (see Phyl. 36, 37). Three of the four European strains differ by only 0–1 nt in the ITS region and fully concur in the LSU. The four Chinese strains vary in the ITS by 0–0.4 %, thereby the strains from Guangxi (Guilin), Guizhou (Suiyang), and Yunnan (Dali, Yongping) fully concur. Between both subclades a distance of 1.2–2.5 % is observed. Based on the 7 positions at which the two subclades consistently differ, the Chinese and European specimens are possibly not conspecific (Tab. 94).

One of the two strains from Serbia (H.B. 9895a) deviates from the three European *O. orientalis* strains by 3.3–3.5 % in the ITS and 0.5 % in the LSU D1–D3 (4 nt in D1). Also from the four Chinese strains this sample deviates by 3–4 % in the ITS

Table 92. Alignment of ITS1 region for all known members of the *O. brochopaga* aggregate (with very similar ana- and teleomorph). Three blocks can be recognized: (1) *brochopaga-tonghaiensis*, (2) *orientalis-naumburgensis*, and (3) *yunnanensis*. Incomplete sequences are omitted.



region. This strain shares many nucleotides with the other seven strains of *O. orientalis* s.l., at which *O. naumburgensis* deviates (Tab. 93), or only those of Chinese *O.* cf. *orientalis* (Tab. 94), but also 3 positions that are characteristic of *O. naumburgensis* (Tab. 94). Therefore, we did not include it in our description of European *O. orientalis*. To *O. naumburgensis* this aberrant strain shows an ITS distance of 4.8 %.

When viewing the alignment of the ITS1 region (Tab. 92), the eight available sequences of *O. orientalis* s.l. form a rather distinctive block with characteristic gaps, whereas *O. naumburgensis* clearly deviates. A higher distance is observed between these taxa and the morphologically very similar *O. yunnanensis*, *O. brochopaga*, and *O. tonghaiensis* (~6–13 %), which are also more clearly set apart in the appearance of the ITS1 alignment.

More sequences are needed in order to clarify how many different species are involved. Extraction of DNA from the holotype of *O. orientalis* is recommended to clarify the identity of this name.

Ecology. *O. orientalis* was found on ± rotten wood or more rarely bark of hygric to mesic branches and logs of various angio-, rarely gymnosperms. In two collections the apothecia grew at a height of 1–2.5 m above the ground. Yet, even after some dry days the deeply rotten wood of the rather thick branches still retard some moisture. A slight desiccation tolerance was noted in one of these collections. This may also be true for the holotype for which the protologue says 'on dry bark'.

O. orientalis was infrequently collected in western and central Europe in atlantic to subcontinental, cold- to warm-temperate, usually shady deciduous forests. The vegetation includes rich *Quercus*-mixed forests, thermophilous *Quercetea pubescentis*, also acidic forests. The type was collected in a mixed deciduous forest with *Tilia amurensis* and *Pinus* on a small island in the region of Wladiwostok in the Far East of Russia. Despite the coastal situation the climate is continental, cold-temperate humid (winter-dry), with average temperatures of -8 to -15 °C in January. The collection from Japan is from a similar but warm-temperate climate.

The not included Serbian sample on *Tilia* wood was on serpentinite at the northern foothill of western Fruška Gora mountains, whereas typical *O. orientalis* in the same mountain range grew on *Alnus* bark over Cretaceous & Tertiary sediments. Collections from southeastern Asia were on hygric rotten bark and wood of unidentified angiosperm trees in subtropical humid (winter-dry) evergreen forests mountain forest of southern China (1420–2400 m a.s.l.).

O. yunnanensis	4	C	A	C	T	C	G	T	A	T	AAA

Etymology: *brochopaga*: trapping nematodes by lassos (bróchos = noose, pagída = snare, trap); *gracilis*: 'on account of the long, slender conidia'.

Typification: USA, Maryland & Virginia, from leaf mould in deciduous woods, undated, C. Drechsler (holotype of ***Dactylella brochopaga***, illustration in Drechsler 1937a: fig. 13). — Great Britain, Devon, Marlborough, in various bryophytes, IX.1948, C.L. Duddington (K, holotype of ***Dactylaria gracilis***).

Misapplied name: Ren et al. (2014a), as *O. orientalis*.
Misinterpretation of *O. brochopaga*: Yu et al. (2006), ?= *O. tonghaiensis*, Liu (2006: 88), = *O. yunnanensis*.

Description: — **TELEOMORPH** (from Ren et al. 2014a, data partly obtained from scale): **Apothecia** 0.3–1.1 mm diam., pale yellow, translucent, ± round, ± sessile, dry orange. **Asci** ?*36 × 4.4 µm, †~30 × 2.8–3.2 µm, cylindrical, 8-spored, spores biseriate above, obliquely uniseriate below; **apex** slightly truncate, thin-walled; **stipe** medium to very long, flexuous, sometimes L-shaped. **Ascospores** *3.1–4.3 × (1.2–)1.4–1.5 µm, subcylindrical, rounded to obtuse at both ends, straight to very slightly inequilateral; **SBs** ~1–1.2 × 0.8–1.1 µm, ± globose, centrally situated a short distance below apex, attachment not seen. **Paraphyses** slightly to medium capitate-clavate, terminal cells *11.5–13 × 2.1–2.8 µm, lower cells *3–4 × 1.5–1.8 µm, branched below. **SCBs** in terminal cells of paraphyses globose, 1–1.2 µm diam. **Medullary and ectal excipulum** without data. **Exudate** absent. **— ANAMORPH**: drechslerella-like (from ascospore isolate {1}), description from Drechsler 1937a {T} and Turnbull & Zachariah 1978): drechslerella-like (from leaf mould isolates) – **Conidiophores** unbranched, erect, (40–)200–325(–400) µm, 4–7 µm wide near base, 2.4–3.5 µm at apex, with (2–)3–8(–12) ((–15)) short denticles {T}. **Macroconidia** straight or slightly curved, cylindrical (to cylindric-ellipsoid), rounded above, shortly tapered-truncate below, *26–46 × (5–)6–7(–9) µm, ((1–))(2–)3((–4))-septate, terminal cells often slightly longer (up to 1.7×) than middle cells {T}. **Microconidiophores** absent {T} or present, 80–140(–220) × 2–2.8 or 4–5 µm {2}, 2 µm wide above, apically slightly swollen, with 2–5 denticles of 2.8–4.5 × 1.6–1.9 µm. **Microconidia** (13–)14–17(–21) × (4–)4.5–5(–6.2) µm {2}, cylindrical to elongate-ellipsoid, with basal protrusion, 1-septate or rarely 2–3-septate. **Constricting rings** formed on mycelium, with 1-septate stalk of *7–13 × 3.5–5(–6) µm {T}; ring unexpanded *20–35 {T} or 25–40 µm {ATCC 13897} outer diam., *16–22 {T} or 20–27 µm inner diam. {ATCC 13897}, 3-celled, with triangular wall thickenings at the septa; smaller rings formed directly on conidia, *19–22 µm outer diam., *12–14 µm inner diam. {T}; giant traps of 105–130 µm outer diam., 70–110 µm inner diam., sometimes formed together with normal rings {ATCC 13897}.

Habitat: fallen branch of indet tree, on wood {1, apothecia}, isolated from leaf mould in deciduous forests {T}, ruderal and agricultural soil. **Altitude**: ~50–200 m a.s.l. (eastern North America), ~30–100 m (Peru), ~350 m (subtropical Africa). **Drought tolerance**: unknown (probably intolerant). **Phenology**: VIII (teleomorph).

Taxonomic remarks. The *Orbilia brochopaga* aggregate comprises a group of species with very similar conidia, though being phylogenetically rather diverse, including *O. orientalis*, *O. naumburgensis*, *O. orientalis*, *O. tonghaiensis*, and some unnamed clades, all being characterized by cylindrical, 3-septate, ± allantoid macroconidia (see Phyl. 38). *O. brochopaga* s.str. is almost exclusively known from its anamorph, which was originally isolated by Drechsler (1937a) from leaf mould in deciduous woods in Maryland and Virginia. The present species concept is based on molecular data gained from two authentic strains from USA isolated by Drechsler, and from strains from Ecuador, Peru, Beijing, Guangxi, and Taiwan. For all of them no illustrations or descriptions were available, except for the ascospore isolate from Guangxi which provides data from both morphs (Ren et al. 2014a).

Anamorph. Morphological differences in the anamorph within the *O. brochopaga* aggregate are shown in Tab. 95. They include curvature of conidia, arrangement of septa, and presence vs. absence of microconidia, but also conidial and constricting ring size (see also under *O. orientalis*, p. 1647). For instance, the closely related Chinese *O. tonghaiensis* differs from *O. brochopaga* in smaller traps.

The outer diameter of the unexpanded rings seems to be correlated with macroconidial size (Tab. 95): *O. yunnanensis* and *O. tonghaiensis* with rather small macroconidia have comparatively small rings of 18–25 µm diam. (Pl. 1014: 1h, 2f), whereas *O. brochopaga* and *O. orientalis* with distinctly larger macroconidia have rings of 20–39 µm diam. (including the type of *Dactylaria gracilis*). Also *O.* cf. *tonghaiensis* (from Jiangxi) with conidia more of the smaller size have rather small rings. Yet, in *O.* cf. *orientalis* the conidia are more of the larger size though the rings are small (Pl. 1017: 2b, 2f). The given ring diameters refer to rings formed from mycelium, not directly from conidia, from which considerably smaller rings emerge.

Together with the normal ring traps, much larger 'giant ring traps' were formed in some strains. *O.* cf. *tonghaiensis* was associated with giant traps of 80–85 µm diam. (Z.F. Yu pers. comm.). Giant ring traps among the normal ones have also been reported by Turnbull & Zachariah (1978) for a mutant of the unlocalized authentic strain of *Drechslerella brochopaga* (ATCC 13897) which was unexplainably renamed to *D. bembicodes* in Zachariah & Insell (1979). Also in *D. dactyloides* a mutant with such giant traps was observed (Fig. 110: t–u).

Microconidia are known from the similar *O. yunnanensis* (Pl. 1014: 1–2) and *O. tonghaiensis* (Pl. 1020: 1–2). Because *D. brochopaga* was described without microconidia and with larger macroconidia, also with more abundant denticles at the conidiophore tip, Liu (2006) hesitated to assign the anamorph of his strain to *D. brochopaga*. However, Barron (1979a) observed microconidia in a strain of *D. brochopaga* from Ontario (Canada). The only figured, equidistantly 3-septate macroconidium in his fig. 11 has a rather small in size of ~30 × 6.5 µm (estimated from the given size of microconidia).

Ren et al. (2014a) reported an anamorph (as *D.* cf. *brochopaga*) which developed in an ascospore isolate of a collection from Guangxi (China, as *O. orientalis*), with 1–3-septate straight conidia of 14.3–21 × 4.5–6.2 µm. Only 1(–2)-septate conidia of about that size were illustrated, however, which must be microconidia, judging from their small size. Perhaps macroconidiophores did not develop because it seems that no nematodes were added to the culture.

Based on the reported molecular analysis (see below), we conclude that Ren et al.'s sample represents *O. brochopaga* and the first report of a teleomorph of this species. Ren et al. doubted identity with *D. brochopaga* because of smaller conidia with basal nodule and often fewer septa, also because of a certain distance in the ITS rDNA, which however seems to lie, in our opinion, in the range of infraspecific variation.

Type studies. In the protologue of ***Dactylella brochopaga*** (Drechsler 1937a, Pl. 1018: 1) the depicted conidia are mainly 6–7 µm wide). Duddington (1951a, Pl. 1018: 3) reported in the protologue of ***Dactylaria gracilis*** 3(–4)-septate macroconidia of *46–66 × 8–11 µm, i.e., distinctly larger than Drechsler's. This larger conidial size might suggest that *Dactylaria gracilis* is a species distinct from *D. brochopaga*. The conidia were obtained in a non-sterile culture from bryophyte material with soil and nematodes. However, in pure culture (maize-meal agar) the conidia measured only 36–53 × 6–11 µm. Duddington emphasized that the distal and partly also the proximal cell of the conidia was often about twice as long as the middle cells, but also Drechsler stressed shorter middle cells in his description. Also in *O. tonghaiensis* (Pl. 1020: 1g, 2c) the terminal cells tend to be much longer than the middle cells, whereas this is much

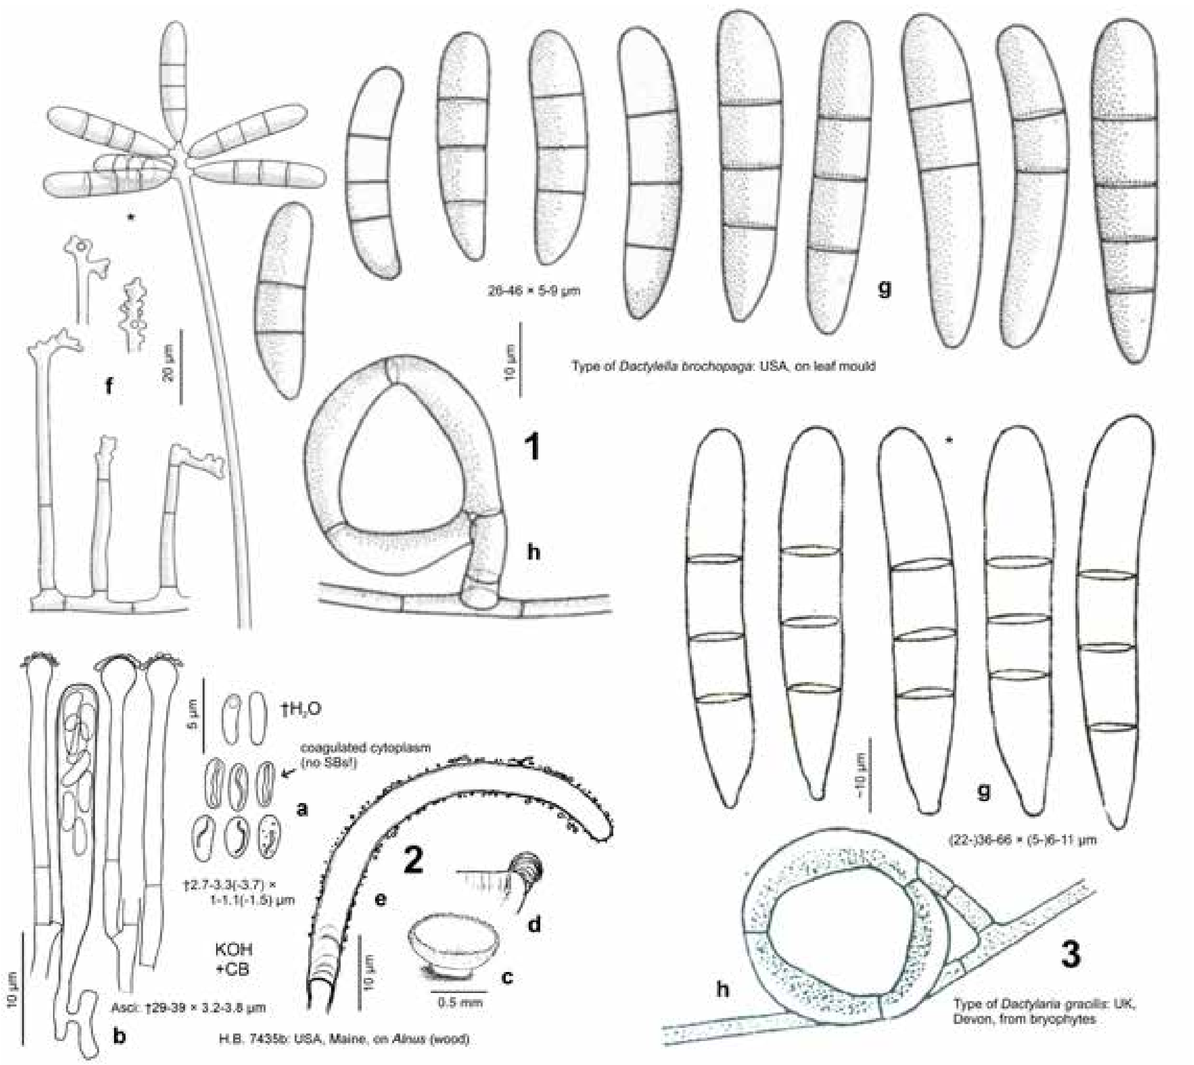

Plate 1018. **1**: *Orbilia brochopaga*; **2–3**: *O.* cf. *brochopaga*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. rehydrated apothecium; **d**. marginal region in median section with agglutinated glassy processes; **e**. closeup of glassy process; **f**. conidiophores; **g**. conidia; **h**. constricting ring (anamorph from soil isolates). – **1**: from Drechsler (1937a), **3**: from Duddington (1951, scale adjusted). – The long filiform, refractive, serpentinoid inclusion in dead spores of **2a** is an artifact caused by coagulation of cytoplasm.

less the case in European (Pls 1015: 3i, 4i; 1016: 1m, 7d) or Chinese strains (Pl. 1017: 2f) of *O. orientalis* s.l. In correlation with this almost equidistant septation, the macroconidia of *O. orientalis* s.l. tend to be apically curved, unlike those of *D. brochopaga* or *Dactylaria gracilis*.

Neither Drechsler nor Duddington observed microconidia in their cultures. A few conidia with shorter terminal cells, which Duddington considered as apparently imperfectly developed, he reported with only 22–31 × 5–9 µm. On Duddington's drawing the conidia measure 39–43 × 6.2–7 µm when evaluated from the scale. Since also the outer diameter of the constricting ring, for which he gave a size of 24–33 µm, measures only 22 µm on his drawing, we assume that his scale was wrong, and we adjusted it in the present reproduction according to his measurements.

Misinterpretations. The following reports do not represent genuine *D. brochopaga* but phylogenetically distinct though morphologically very similar species. Yu et al. (2006) reported *Drechslerella brochopaga* as anamorph of *O. orientalis*, gained from ascospore isolates of two collections, one from China (Jiangxi, treated here as *O.* cf. *tonghaiensis*, Pl. 1020: 3) and one from Europe (here referred to *O. orientalis*, Pls 1015: 4; 1016: 1). Simultaneously, Liu (2006: 88, as *D.* cf. *brochopaga*/*O. orientalis*) reported a similar anamorph-teleomorph connection based on an ascospore isolate of a Chinese collection (here referred to *O. yunnanensis*, Pl. 1014: 2). In a further European specimen (W-France, Pl. 1015: 3i–j) the anamorph was formed on mycelium growing out of the fruitbody at the lid of a Petri dish.

Not included collections. A single apothecium growing in a collection of *O. dryadum* from Maine (Pl. 1018: 2) fits quite well the type of *O. orientalis* but is named here *O.* cf. *brochopaga* because of its northeastern North American origin. Two similar samples from tropical Middle America (Puerto Rico, IVV: H.B. 5952; Martinique, Pl. 450: 1a–b) entirely lack glassy processes and their paraphyses are apically not inflated; whether they belong in series *Drechslerella* or instead in series *Orbilia* is uncertain. For the not included anamorph-typified *Dactylaria gracilis* see under Anamorph, and for other anamorphic isolates see under Phylogeny.

Phylogeny. ITS sequences of 13 strains in GenBank and/or CBS, all under the name *Drechslerella* (or *Arthrobotrys*) *brochopaga*, form a rather homogeneous, medium supported clade (Phyl. 36). This clade includes two authentic strains of Drechsler (from Florida and unlocalized) sequenced by Liou & Tzean (1997) and CBS, a strain from Ecuador isolated by A. Rubner and sequenced by Pfister (1997), strains from Beijing (Yang et al. 2007), Taiwan (Kuo et al. 2008), and Burkina

Faso (CBS, isolated by J.L. Devineau), and seven strains from Peru (Murga-Gutierrez et al. 2012). The Peru sequences are incomplete in the ITS1, once in the ITS2 (JF748757), and once entirely lacking ITS2 (JF748758).

The distance among these sequences lies in the range of 0–1.6 % in the ITS region. This variation occurs especially among the strains from Peru. On the other hand, one species from Africa shows full identity with some from North and South America. A distance of 0.4 % (2 nt) is observed between the two authentic North American strains, but one of these nucleotides (pos. 157 in ITS1) seems to be incorrect in GenBank (CBS 218.61, ‘G’), as it is T in the CBS sequence in agreement with other strains. An incomplete sequence of a Peruvian isolate (JF748758, lacking ITS2) shows various sequencing errors in the 5.8S but matches others in the ITS1. Because this clade includes Drechsler’s authentic strains, it is considered here to represent the genuine *O. brochopaga*.

A sequence obtained by Ren et al. (2014a) remained unpublished and was not available to us. It clustered in their neighbour joining tree of ITS with a low distance (~ 1–2 %) with strains of *O. brochopaga* from Peru (JF748752, JF748753) and Taiwan (FJ380936), whereas its distance to *O. yunnanensis* and *O. orientalis* is expected to lie above 10 %.

In our analysis of the ITS region, two further taxa need to be separated from genuine *O. brochopaga*. *O. tonghaiensis* comprises three somewhat heterogeneous ascospore isolates from Yunnan, and *O.* aff. *brochopaga* contains an obviously misidentified soil isolate from Xinjiang (Chen et al. 2007b, as *Dactylella tenuis*, AS 6.0287) and a nematode isolate from California (Smith & Jaffee 2009, as *D. brochopaga*, dm5s_a2), with a distance of 4.5 % to each other. Two further ITS sequences under the name *A. brochopagus* in the CBS database (CBS 574.91, Germany; CBS 597.92, Netherlands, not shown) are associated with this clade, the former differing from *D. tenuis* only by 3 indels, and the latter from both by 4 %. The distance between this and *O. tonghaiensis* lies at 8–10 %, and the distance of both to *O. brochopaga* at 6.5–9.5 %. The morphologically similar *O. yunnanensis*, *O. naumburgensis*, and *O. orientalis* cluster in distant clades and differ from the above by ~ 9–12 %.

For the strain from Ecuador and one from Oman also LSU (D1–D3) was available. The two strains are identical in this region, although a 13 % distance in the ITS between them is observed in the CBS database. Here *O. brochopaga* differs from European *O. orientalis* by 3 %, and from *D.* aff. *brochopaga* from California (dm5s_a2) by 1.2–1.3 % (3–3.5 % between *O. orientalis* and *D.* aff. *brochopaga*).

Two of the *O. brochopaga* s.str. strains include a short part of SSU (Florida and Taiwan), and both possess the S1506 intron in which they differ by 1.5 % (in accordance with a 1.4 % distance in the ITS), whereas the distance to other taxa with similar conidia lies at ~ 10–18 %. When analysing this gene region, *O. brochopaga* clustered with strong support sister to the rest of the *brochopaga-polybrocha* clade, except that *O. tonghaiensis* clustered with *O. bembicodes* distant from those (S30).

Ecology. *O. brochopaga* is mainly known from its anamorph which was isolated from soil or plant material (herbaceous roots, leaf mould). The species is verified from eastern North America with a warm-continental (Maryland) to warm-temperate (Virginia) humid, or a subtropical subhumid climate (Florida). The South American isolates were from ruderal soil in a tropical subhumid coastal forest of Ecuador (A. Rubner 1994) and from irrigated *Asparagus* cultivations on sandy alluvial soil in coastal tropical hyperarid northern Peru (Murga-Gutierrez et al. 2012). The African isolate is from the subtropical semiarid savannah in the Sahel belt of the southern Sahara, and the Chinese ones from continental temperate to subtropical humid, monsoon-influenced climates.

Records under the name *Drechslerella brochopaga* actually show a worldwide distribution, which is exemplified here by two reports without molecular data, originating from nematode-infested soil of *Citrus* plants in the hyperarid subtropical eastern part of the Arabian peninsula (Nizwa, Oman, Elshafie et al. 2003) and from nematode-infested roots of *Oryza* in subtropical humid (winter-dry) rice fields in southern Asia (Benares, northern India, Singh et al. 2007).

Among the not included collections, the four strains with sequence data include temperate humid Europe, mild-maritime humid coastal California, and cool-continental ?semiarid northwestern China, and the two without molecular data are from cold-temperate humid coastal northeastern North America and from atlantic mesotemperate humid coastal southwestern England (holotype of *Dactylaria gracilis*).

Specimens included. **CANADA**: **Ontario**, unlocalized (Barron 1979a). — **USA**: **Maryland**, near Cumberland, and **Virginia**, Arlington, leaf mould in deciduous forest, ?100–300 m, undated, C. Orbilia tonghaiensis Z.F. Yu, Baral & E. Weber, in Zhang et al., Int. J. Syst. Evol. Microbiol. 70: 2669 (2020) — Pls 1019–1020

Etymology: from the geographical origin, Tonghai, a county in Yunnan province. **Typification**: China, Yunnan, Tonghai, Xiushan, branch of indet. angiosperm, IX.2007, J.W. Guo & S.F. Li (Z.F.Y. th3b-44, YMFT 1.03006, holotype; sq.: MF948423).

Latin diagnosis: *Similis* Orbiliae orientali *sed ascosporae breviores et latiores, conidia leniter curvatae, cellulae terminales conidiarum longiores, laquei constringentes minores. Habitat ad lignum ramuli uvidi angiospermarum in zona subtropica humida Asiae meridio-orientalis.*

Description: — **TELEOMORPH** (from type): **Apothecia** rehydrated 0.5 mm diam., 0.18–0.2 mm high (receptacle 0.11→ 0.06 mm), whitish to light orange; disc flat, margin smooth; substipitate, stipe 0.09 × 0.3 mm; dry pale yellowish-cream. **Asci** *30–33 × 4.3–4.8 µm {YMF 1.03006}, †23–30 × 3–3.3 µm {H.B. 8741}, 8-spored, spores *biseriate, †uniseriate, ~2–4 lower spores inverted (sometimes strongly mixed), pars sporifera *12.5–15 µm long, †11–16(–19) µm; **apex** (†) medium to strongly truncate (not indented, laterally not widened); **base** with short to long, thick or thin, flexuous stalk, T-, Y-, h- or H-shaped. **Ascospores** *2.1–2.5 × 1.4–1.7 µm {H.B. 8741} or *2.5–2.8(–3.5) × 1.8–2(–2.2) µm {YMF 1.03006}, subcylindric-ellipsoid to ovoid, ends rounded, sometimes slightly inequilateral; **SBs** *0.8–1.2 × 0.3–0.4 µm, not or slightly eccentrical, divided into a small tear-shaped to ovoid lower part and a fine, short, apically attached filum. **Paraphyses** apically slightly to (very) strongly capitate-clavate(-spathulate), terminal cell *12–16 × 3–4 µm, †(7.5–)11–15 × 2–3.5(–4) µm, lower cells *3–6 × 1.7–2.3 µm, †4–7 × 1.3–1.7 µm; unbranched at upper septum. **Medullary excipulum** 20–50 µm thick, of dense textura globulosa-intricata, sharply delimited. **Ectal excipulum** of (†) slightly gelatinized, t. globulosa-angularis at base and flanks, 100–150 µm thick near base, cells †16–38 × 10–30 µm, common walls 0.5–1(–1.5) µm thick; 15 µm at margin, of t. globulosa(-prismatica) oriented at a 60–80° angle, marginal cortical cells †6–10(–13) × 4–8 µm; **glassy processes** absent. **Anchoring hyphae** not examined. **SCBs** and **VBs** apparently absent. **Exudate** over paraphyses 0.2–0.3 µm thick, ± continuous. — **ANAMORPH**: drechslerella-like (from ascospore isolate {2}). **Macroconidiophores** unbranched below, erect, *150–190 µm high, ~2–2.5 µm wide at base, *1.7–2 µm at apex, here with 5–10 denticles, sometimes proliferating. **Macroconidia** cylindrical, rounded above, shortly tapered-truncate below, straight to very slightly curved, *(27–)29–37(–39) × 5–6.5(–7.5) µm {2}, (1–)3-septate, terminal cells partly much longer (up to 3.5×) than middle cells, lipid content low. **Microconidiophores** similar to macroconidiophores but more tiny. **Microconidia** *10–14(–16.5) × 3.5–4(–4.5) µm {2}, cylindrical with tapered base, 1-septate. **Constricting rings** with 1-septate stalk of *12–14 × 4–4.6 µm; ring unexpanded *26–28.5 µm outer diam., *18.5–20 µm inner diam., 3-celled, ring cells *5.5–6 µm wide, at septa apparently with internal triangular wall thickenings.

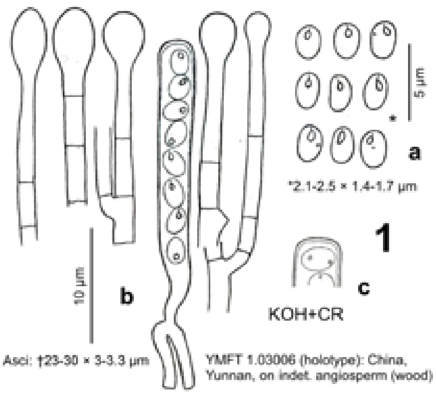

Plate 1019. **1**: *Orbilia tonghaiensis*. – **1a**. ascospores; **1b**. ascus and paraphyses; **1c**. ascus apex.

Habitat: collected on the moist ground on decorticated, thin branch of indet. angiosperm trees {2}, on strongly decayed wood {1}. **Associated**: none observed. **Desiccation tolerance**: intolerant, except for the ascospores which abundantly survived after 6 months in the herbarium. **Altitude**: ~1850 m a.s.l. **Geology**: Devonian to Carboniferous sedimentary rock. **Phenology**: VII, IX.

Taxonomic remarks. *Orbilia tonghaiensis* differs from *O. orientalis* and *O. yunnanensis* in shorter ascospores, shorter terminal cells of paraphyses, and in lacking glassy processes, perhaps also in the SBs being tear-shaped and only slightly eccentrical. In the anamorph it differs from *O. orientalis* in forming microconidia, less curved macroconidia with the septa more accumulated in the middle, and smaller constricting rings. Also from *O. brochopaga* it seems to differ in smaller constricting rings.

The drawing of the teleomorph of *O. tonghaiensis* (Pl. 1019) originates from a single apothecium of the holotype which was received in the dry state. The original photo plate (Pl. 1020: 1) was based on another apothecium and yields distinctly larger measurements of asci, spores, and paraphyses when evaluated from the scale in Zhang et al. (2020a), given that this scale is correct. The topotype collection (Pl. 1020: 2) is without data of the teleomorph which was not retained in a herbarium (Z.F. Yu pers. comm.).

Not included collections. A sample from Dali (IVV: H.B. 8932) without molecular or cultural data has smooth apothecia and an ascospore size (*2.7–3 × 1.7–1.8 µm) very similar to *O. tonghaiensis*, but the SBs are partly rod-shaped and very eccentrical, therefore, this could instead be a short-spored form of *O. orientalis*. Also not included is the collection from Ji'an, Jiangxi, which was reported by Yu et al. (2006, YMFT 1.01829, partly erroneously as 1.01892) under the names *O. orientalis*/*D. brochopaga* (Pl. 1020: 3), with longer ascospores of *3.1–3.9 × 1.6–1.8 µm which contain hardly eccentrical tear-shaped SBs as in *O. tonghaiensis* (for differences in the anamorph see below). The apothecial margin was reported with very short or perhaps even absent glassy processes (Yu et al. 2006).

Anamorph. Ascospore isolates were gained from the holo- and topotype of *O. tonghaiensis*. In both the formation of macro- and microconidia was observed, and in the holotype also constricting rings occurred. The conidia match typical *O. orientalis* in size except that they are less curved. The not included collection from Jiangxi (Tab. 95, IVV: YMFT

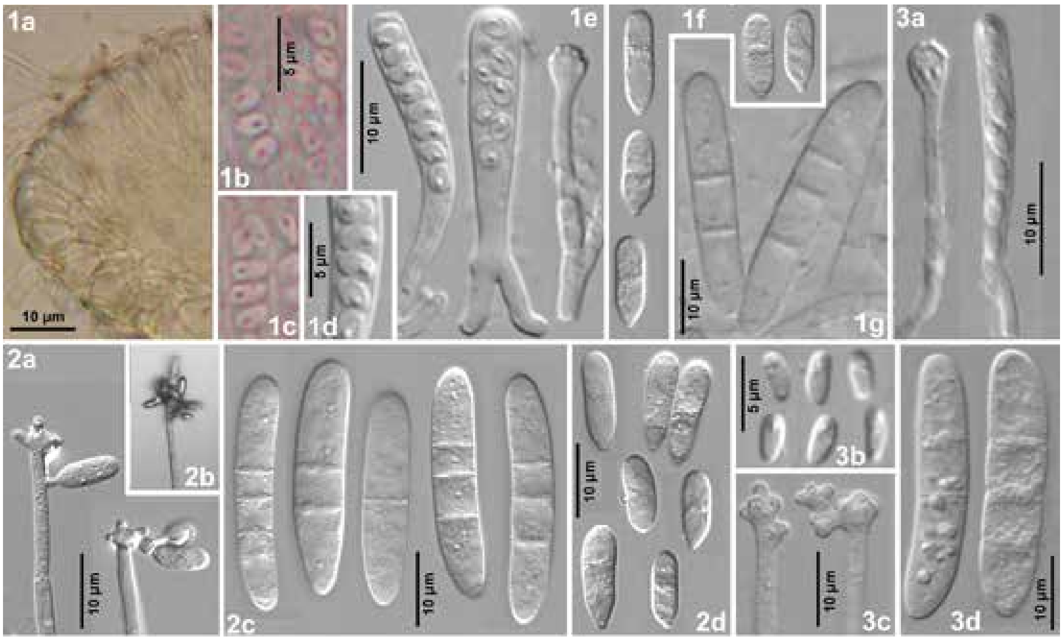

Plate 1020. **1–2**: *Orbilia tonghaiensis*; **3**: *O.* cf. *tonghaiensis*. – **1a**. marginal ectal excipulum in median section, lacking glassy processes; **1e**, **3a**. asci and paraphyses; **1b–d**, **3b**. ascospores; **3c**. macroconidiophores; **1g**, **2c**, **3d**. macroconidia; **2a–b**, microconidiophores; **1f**, **2d**. microconidia (anamorph from pure culture). – Living state, except for **1a** (in KOH), left ascus in **1e**, ascus and paraphysis in **3a**. – **1d–g** & **2a–d**: phot. Z.F. Yu, **3a–d**: from Yu et al. (2006). — **1a–g**. YMFT 1.03006 (holotype): China, Yunnan, Yuxi, Tonghai, on indet. angiosperm; **2a–d**. YMFT 1.03003: ibid.; **3a–d**. YMF 1.01829: China, Jiangxi, Ji'an, on indet. angiosperm.

1.01829) appears to differ from *O. tonghaiensis* in not forming microconidia. Both the constricting rings and macroconidia have a comparable size. Yet, a discrepancy in measurements occurs in Yu et al. (2006) who gave macroconidia of *20–36 × 5–7.5 µm, in correspondence to their fig. 2 G–J (without oil immersion) with *24–29 × 5–6 µm according to scale, whereas their Fig. K–L (with oil immersion) yields a possibly wrong size of 35–36 × 6.5–8 µm. The constricting rings occurred in two very different sizes: besides the normal ones of 25–27 µm diam. were also giant ring traps with an outer diameter of 80–85 µm (60–65 µm inner diam.) frequently present 1–2 days after the normal ones were formed (Z.F. Yu pers. comm.). The statement of 30–40 µm large rings in Yu et al. (2006) refers to *O. orientalis* from France (H.B. 7379).

Phylogeny. Sequences of the ITS region were available for the holo- and topotype from Tonghai and for *O.* cf. *tonghaiensis* from Jiangxi. The holotype and the Jiangxi strain cover also the 3'-end region of SSU and include the S1506 intron. Holo- and topotype clustered in a strongly supported clade (Phyl. 36), though with a 5 % distance in the ITS region. The Jiangxi strain (YMF 1.01829) clustered with medium support and a 7.3–7.7 % distance sister to *O. tonghaiensis* s.str. In fact, the Jiangxi strain shares some nucleotides with the holo- and some with the topotype, therefore, the three strains might well be conspecific. The three strains require exclusion from *O. brochopaga*, to which they clustered weakly supported as a sister clade, with a distance of 7.5–9.5 % (8.5–10 % to *O.* aff. *brochopaga*).

In the S1506 intron the holotype of *O. tonghaiensis* differs by 11 % from the Jiangxi strain. When analysing this gene region, the two strains clustered unexpectedly in a weakly supported clade with *O. bembicodes*, very distant from the rest of the *brochopaga-polybrocha* clade (S30).

Ecology. *O. tonghaiensis* s.l. was collected on rotten wood (type) and bark (not included samples) of hygric branches of unidentified angiosperms in the subtropical humid (winter-dry) evergreen broad-leaved montain forests in southern (Yunnan) and southeastern China (Jiangxi).

Specimens included. **CHINA**: **Yunnan**, **Yuxi**, Tonghai, ~35 km SE of Yuxi, ~3.5 km S of Tonghai, eastern part of Xiushan, ~1850 m, branch of indet. angiosperm, on wood, IX.2007, J.W. Guo & S.F. Li (Z.F.Y. th3b-44, YMFT 1.03006, **holotype**; ex-type culture CGMCC 3.18835, anam. cult.; sq.: MF948423, MF948496, H.B. 8741 ø). – ibid., branch of indet. angiosperm, on wood, VII.2007, J.W. Guo & S.F. Li (Z.F.Y. th2b-10, YMF/T 1.03003, CGMCC 3.18836, anam. cult., doc. vid.; sq.: HQ711928/ MF948422, MF948495).

Not included. **CHINA**: **Jiangxi**, **Ji'an**, ~13 km SW of Ji'an, Jinggangshan, 848 m, bark of indet. angiosperm, 1.X.2005, Y. Zhang (Y.Z. jg-7, YMFT 1.01829, anam. cult., doc. vid.; sq.: HQ711929, as *D. brochopaga*). – **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, virgin forest around Golden Light temple (Jinguangsi), 2730 m, branch of indet. angiosperm, on bark, 25.X.2008, H.Y. Su et al. (H.Y.S. jgs-24, H.B. 8932).

Incertae sedis

Five species without known anamorph are treated as 'incertae sedis' within section *Arthrobotrys*. They show similarities to species in series *Neodactylella*, *Dactylellina*, *Gamsylella*, and *Drechslerella*. *O. cyparissias* and *O. acuum* are only known from the old holotype specimens, therefore no information about SBs and VBs were available and a relation to members of series *Orbilia* (section *Orbilia*) cannot be excluded.

Orbilia sp. H.B. 8963 — Pls 1021–1022

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1.2 mm diam., 0.12–0.13 mm high (receptacle 0.09–0.11 mm), light cream-rose, translucent, ± round, subgregarious; disc flat, margin ± thick, not protruding, smooth; broadly sessile, superficial; dry light to bright cream-orange, with sunken disc and protruding margin. **Asci** †34–40 × 3–3.8 µm, 8-spored, spores †1–2-seriate, 3–5 lower spores inverted (± mixed); **apex** (†) medium truncate (not indented, laterally not inflated); **base** without or with short to medium long, ± thin, flexuous stalk, h-shaped. **Ascospores** *5.3–6.8 × 1–1.2 µm, †5–6.3 × 1–1.2 µm, cylindrical to fusoid, homopolar, apex rounded to obtuse, base not or slightly attenuated, straight to slightly inequilateral; **SBs** 1–1.5 × 0.4–0.6 µm, subglobose to ellipsoid, rarely tear-shaped, ± eccentrical, filum not seen, attachment mostly invisible. **Paraphyses** apically slightly to strongly (clavate-)capitate, terminal cell †17–20 × 2.5–3.8 µm, lower cells †6–7 × 1.5–1.8 µm; unbranched at upper septum. **Medullary excipulum** 15–20 µm thick, of dense textura porrecta(-intricata), horizontally oriented, slightly gelatinized, with many small inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled, vertically oriented t. prismatica-angularis from base to margin, 50–80 µm thick near base, cells */†12–28 × 10–18 µm; 20 µm thick at

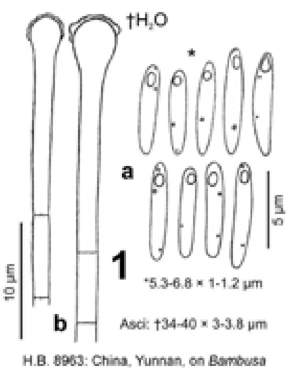

Plate 1021. **1**. *Orbilia* sp. H.B. 8963. – **a**. ascospores; **b**. paraphyses.

margin, oriented at a 80–90° angle to the surface, marginal cortical cells †6–11 × 2.5–5 µm; **glassy processes** absent. **Anchoring hyphae** medium abundant, †2–3 µm wide, walls 0.2 µm thick. **VBs** present at least in lower cells, elongate, medium refractive. **Exudate** over paraphyses 0.2–0.5 µm thick, firmly attached, ± rough, over margin 0.5–1.5 µm thick, cloddy to cap-like, very pale yellowish. — **ANAMORPH**: unknown.

Habitat: at tip of dead rotten stems of *Bambusa* sp. {1}, on leaf sheaths, ± blackened, no algae. **Associated**: black setae of hyphomycete. **Desiccation tolerance**: many basal excipular cells and ascospores viable after ~6 weeks. **Altitude**: 2700 m a.s.l. **Phenology**: X.

Taxonomic remarks. The present taxon differs from *Orbilia quercus*, *O. lysipaga* (series *Dactylellina*), and *O. bambusina* in longer asci and larger basal excipular cells, from the latter two also in the complete absence of glassy processes at the margin which are, however, very short in the above two taxa. A further difference is seen in the morphology of the spore bodies, which are ± eccentrical and apically apparently not visibly connected. In ascospore and SB morphology the specimen strongly resembles also a coprophilous Austrian sample (Pls 1023–1024, see below).

Ecology. *Orbilia* sp. H.B. 8963 grew on rotten leaf sheaths of bamboo stems in an altimontane subtropical humid (winter-dry) broad-leaved evergreen forest at the eastern end of Himalaya in southern China.

Specimens included. **CHINA**: **Yunnan**, **Dali**, 42 km NNE of Dali, Jizushan, 2700 m, on leaf sheaths of stems of *Bambusa*, 20.X.2008, X.M. Gao et al. (H.B. 8963).

Orbilia sp. H.B. 8749 — Pls 1023–1024

Description: — **TELEOMORPH**: **Apothecia** fresh 0.5–1 mm diam., 0.2–0.23 mm high, whitish(-cream), slightly translucent, ± round; disc slightly to strongly convex, margin indistinct, not protruding, smooth; broadly sessile, superficial. **Asci** *(30–)33–36(–43) × 3.9–4.2 µm, †28–33 × 3.4–4.2 µm, 8-spored, spores *4-seriate, 4–5 lower spores inverted (often mixed), pars sporifera *12–14 → 10 µm long; **apex** (†) strongly truncate (not or slightly indented and laterally inflated); **base** with short to medium long, ± thin, flexuous stalk, Y-, h- or H-shaped. **Ascospores** *5–6.8 × 1.2–1.4 µm, cylindric(-ellipsoid) to very slightly fusoid-clavate, apex rounded to obtuse, base not or slightly attenuated, straight to slightly curved below; **SBs** *1.4–1.7 × 0.5–0.8 µm, ± eccentrical, subglobose to tear-shaped, narrowed to a fine, very short, mostly invisible filum. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cell *15–25 × (3–)4–5.5 µm, lower cells *4–10 × 2.3–3.3 µm; unbranched at upper septum. **Medullary excipulum** ~60 µm thick, of dense textura globulosa(-intricata), very indistinctly delimited from ectal excipulum. **Ectal excipulum** of thin-walled t. globulosa from base to margin, 70–100 µm thick near base, cells *9–25 × 7–20 µm; 30 µm thick near margin, oriented at an 80–90° angle to the surface, marginal cortical cells *10–20 × 8–12 µm, firm-walled; **glassy processes** absent. **Anchoring hyphae** sparse, *3–5 µm wide, walls 0.1–0.2 µm thick. **SCBs** and **VBs** absent. **Exudate** over paraphyses and ectal excipulum 0.1–0.3 µm, firmly attached, smooth to finely rough. — **ANAMORPH**: (presumed, from natural substrate). **Conidiophores** ~120–180 µm long, conidia formed singly at apex. **Conidia** *38–42.5 × 16–22 µm, fusiform, with 2 septa near the base and 1 near the apex. **Trapping organs** unknown.

Habitat: on dung of *Ovis*. **Associated**: none observed. **Desiccation tolerance**: unknown, possibly intolerant. **Altitude**: 1500 m a.s.l. **Phenology**: unknown.

Taxonomic remarks. This collection resembles *Orbilia polybrocha* (series *Drechslerella*) in ascospore characters, but differs in hyaline apothecia, absence of glassy processes, much wider marginal cortical cells, wider SBs, and in the presumed

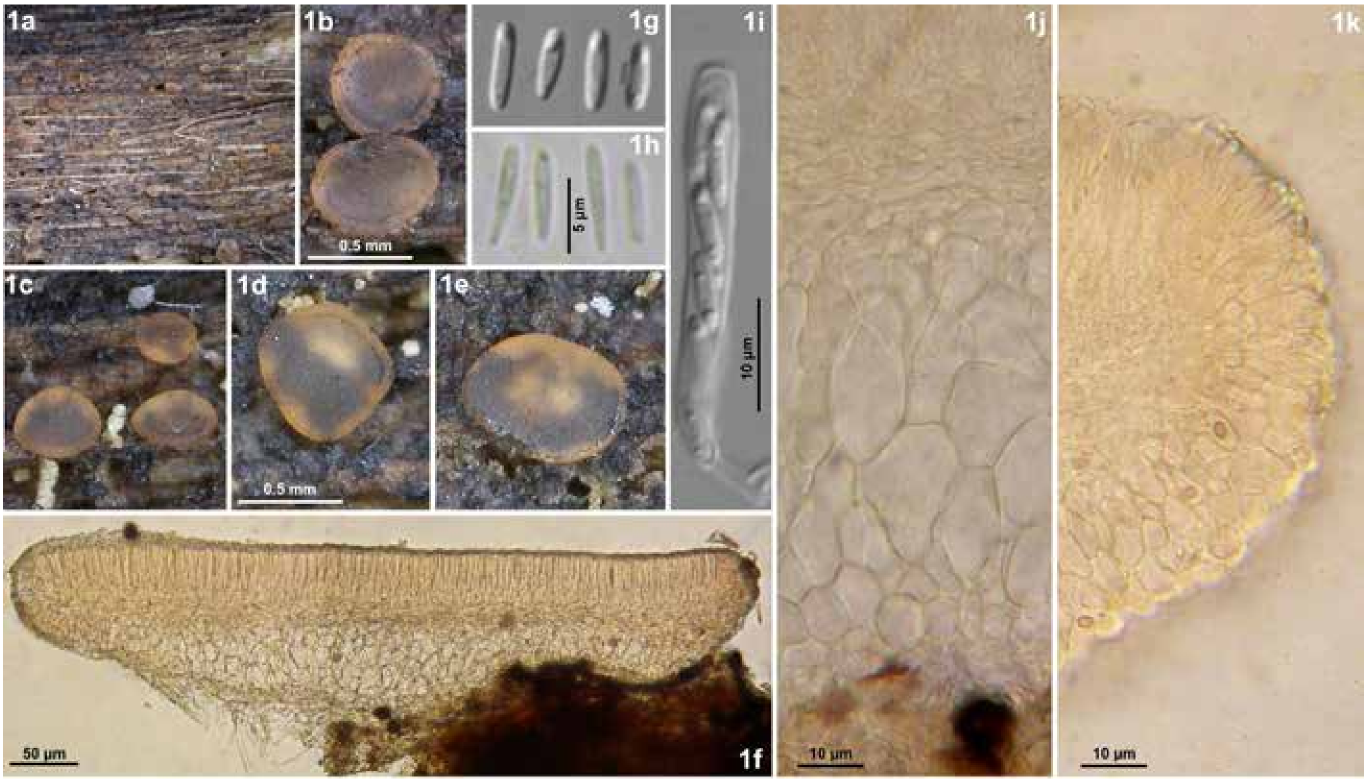

Plate 1022. **1**: *Orbilia* sp. H.B. 8963. – **1a–e**. rehydrated apothecia; **1f**. apothecium in median section; **1j**. id., central part; **1k**. id., marginal region; **1i**. ascus; **1g–h**. ascospores. – Living state (spores in **1g** & **1i**), except for **1f** (in H_2O), **1h**, **k** (in KOH), ascus in **1i**. – **1g**, **i**: phot. H.Y. Su. – **1a–k**. H.B. 8963: China, Yunnan, Dali, on *Bambusa*.

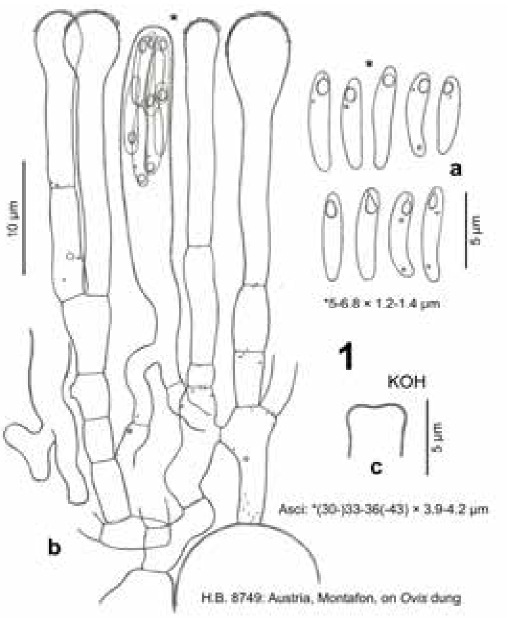

Plate 1023. **1**: *Orbilia* sp. H.B. 8749. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

anamorph (fusiform conidia with 3 septa). In the ascospores and SBs this specimen resembles the Chinese collection of *O. alba* (series *Gamsylella*), but it lacks sublanceolate paraphyses, also the conidia are different. A subtropical Chinese collection on leaves (husks) of *Bambusa* (Pl. 1021–1022) strongly resembles the Austrian collection in spore and SB morphology, with the SBs also somewhat eccentrical and not visibly connected to the spore apex. Also a specimen mentioned under *O. cardui* (series *Neodactylella*, Pls 906: 7; 907: 4) is similar but deviates in wider ascospores with consistently globose SBs.

Anamorph. The conidia of *Drechslerella bembicodes* (≡ *O. bembicodes*) strongly resemble the present anamorph, especially when comparing the Drechsler's (1937a) type description. Since no trapping organs could be observed, its relationship remains uncertain.

Ecology. *Orbilia* sp. H.B. 8749 was collected on droppings of sheep in a pasture near a subalpine *Picea* forest in the orotemperate humid central northern part of the calcarean Alps.

Specimens included. **AUSTRIA**: **Vorarlberg**, Montafon, 12 km S of Schruns, W of Gargellen, ~1500 m, dung of *Ovis*, 12.VIII.07 W. & H. Friese, 26.I.2008 grown in moist box, P. Welt pers. comm. (H.B. 8749, anam. substr.).

Orbilia bambusina Baral, **sp. nov**., MB 813998 — Pls 1025–1026

Etymology: named after the substrate of the type, *Bambusa*.

Typification: Australia, Queensland, Cape Tribulation, stem of *Bambusa*, 30.VIII.2006, G. Marson (ex H.B. 8497b, BRI AQ799193, holotype).

Latin diagnosis: *Similis* Orbiliae quercus *sed ascosporae apice partim subacutae, corpuscula refringentes angustiora, excipulum marginale processis vitreis brevissimis praeditum. Habitat ad culmos vel folia putrida sicca* Bambusae *et* Cocois *in zona tropica humida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.28–0.34 {1} or 0.4–0.8 mm diam. {T}, 0.08–0.12 mm high (receptacle 0.07–0.09 → 0.5–0.7 mm), pale greyish-cream, somewhat translucent, round, scattered to subgregarious; disc flat, margin distinct, 5–10 µm protruding, very finely crenulate; broadly sessile, superficial. **Asci** †22–33 × 3–3.5 µm {2}, 8-spored, spores †2–3-seriate, 4 lower spores inverted {1} (often mixed), pars sporifera †13–20 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not or very slightly inflated); **base** without or with short to medium long, ± thin, flexuous stalk, Y- or h-, rarely H-shaped. **Ascospores** *(4.5–)5–6.8(–7.5) × (1–)1.1–1.2(–1.3) µm {2}, †5–6 × 1–1.1 µm {1}, fusoid to often fusoid-clavate, apex obtuse to subacute, base medium to strongly attenuated, straight to inequilateral or slightly curved; **SBs** 0.9–1.7 × 0.3–0.6 µm {2}, tear- to rod-shaped or slightly ampulliform, narrowed to a wide or small point. **Paraphyses** apically slightly to strongly (clavate-)capitate, terminal cell †(11–)13–18(–22) × 2.5–4(–5) µm {2}, lower cells †(3–)5–7 × 1.2–2.5 µm {2}; unbranched at upper septum. **Medullary excipulum** 15–20 µm thick, of dense textura intricata, horizontally oriented, with many inflated cells, indistinctly to ± sharply delimited from ectal excipulum. **Ectal excipulum** of (†) thin-walled, indistinctly vertically oriented t. angularis-globulosa from base to mid flanks or margin, 20–60 µm thick near base, cells †8–16 × 6–11 µm {2}; 15–20 µm thick near margin, of t. prismatica-angularis oriented at a 70–80° angle to the surface, partly forming distinct cell rows, marginal cortical cells †4.5–13 × 3–5.5 µm {2}; **glassy processes** (0–)1–4 × 3–5 µm {2}, low-refractive, not or indistinctly stratified. **Anchoring hyphae** medium abundant, †1.5–3 µm wide, walls 0.1–0.2 µm thick {2}. **SCBs** and **VBs** no data available. **Exudate** over paraphyses forming 0.1–0.5 {1} or 1–2(–3) µm {T} thick, firmly attached glassy caps, over margin and flanks 0.3–2 µm thick, (rough-)cloddy to granular. **— ANAMORPH**: unknown.

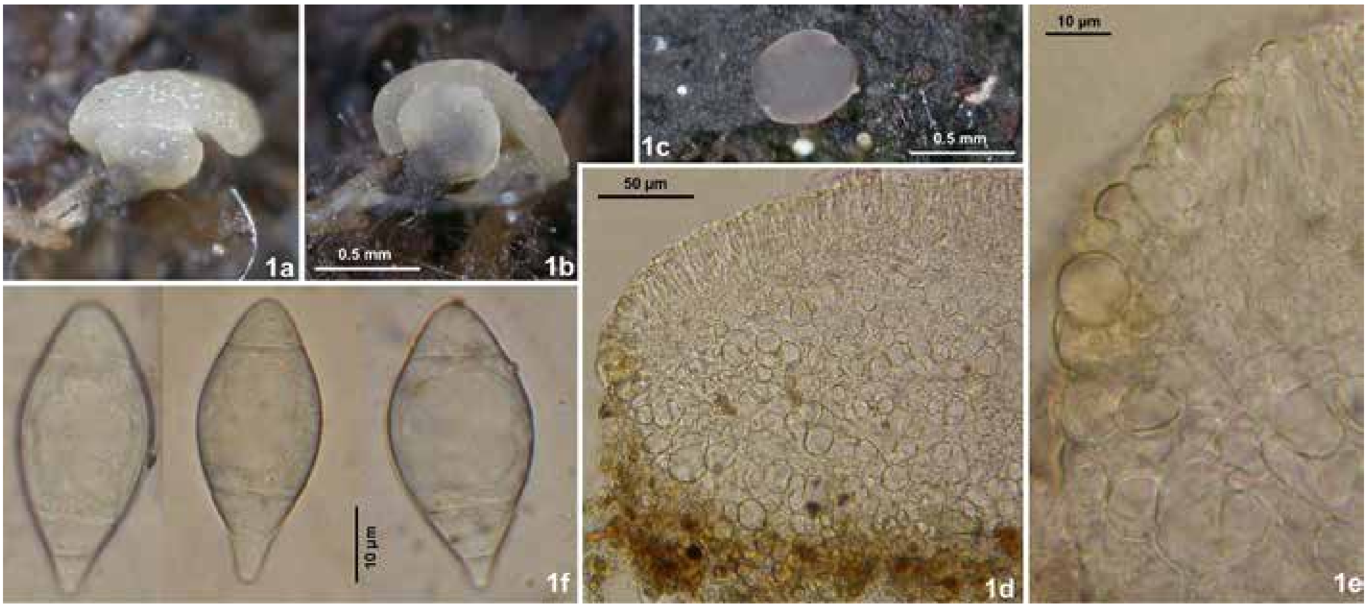

Plate 1024. **1**: *Orbilia* sp. H.B. 8749. – **1a–c**. fresh apothecia (surrounded by conidiophores); **1d**. apothecium in median section; **1e**. id., marginal ectal excipulum; **1f**. conidia from substrate. – All in living state. — **1a–e**. H.B. 8749: Austria, Montafon, on *Ovis* dung.

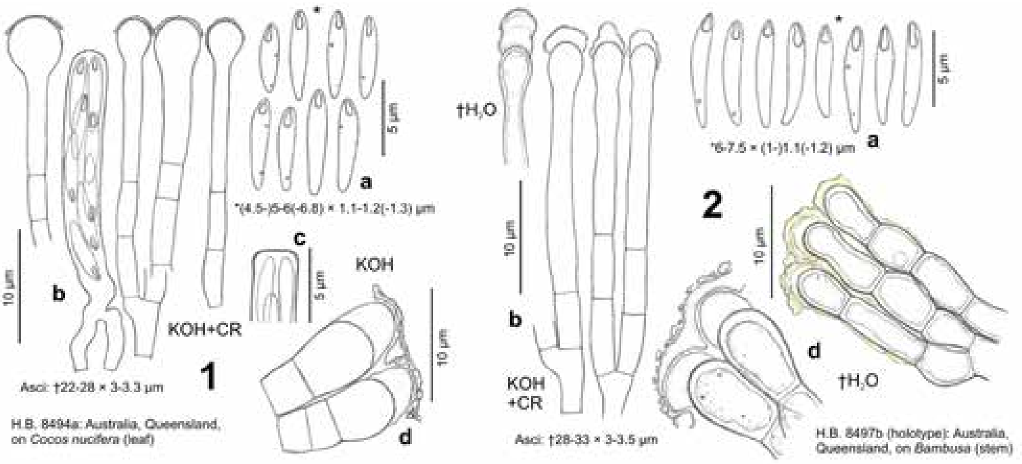

Plate 1025. **1–2**: *Orbilia bambusina*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal cortical cells with glassy caps.

Habitat: collected 0.5–3 m above the ground, on 14 mm thick standing dead rotten stem of *Bambusa* sp. {1}, rotten leaf of *Cocos nucifera* {1}, strongly greyed, no algae. **Associated**: *Hyalorbilia citrina* {1}, *Orbilia cejpii* {1}, *O.* ?*tremulae* {1}. **Desiccation tolerance**: probably slightly tolerant, but only the ascospores viable when examined after 8.5 months. **Altitude**: 14 m a.s.l. **Geology**: Devonian sedimentary rock. **Phenology**: VIII (southern hemisphere).

Taxonomic remarks. *Orbilia bambusina* is characterized by rather small, fusoid ascospores containing tear- to rod-shaped SBs, and by a marginal ectal excipulum of textura prismatica terminated by short glassy caps.

O. bambusina is similar to the teleomorphs of *O. quercus* and *O. lysipaga* (series *Dactylellina*, for the differences see under these species). It might instead be close to *O. cardui* and *O. cocois* (series *Neodactylella*) which differ in more globose SBs, longer asci, and distinctly thicker apothecia. The partial distinctness of marginal cell rows in *O. bambusina*, though running under a high angle, actually suggest a connection with

Plate 1026. **1–2**: *Orbilia bambusina*. – **1a–b**. tropical rainforest with *Bambusa* stand (holotype locality); **1c–i**, **2a–c**. rehydrated apothecia; **1j**, **2d**. marginal ectal excipulum in median section. – Dead state (in KOH). — **1a–j**. H.B. 8497b (holotype): Australia, Queensland, Cape Tribulation, on *Bambusa*; **2a–d**. H.B. 8494a: ibid., on *Cocos*.

a dactylella-like anamorph. Species of series *Regales* (section *Aurantiorubrae*) with non-spathulate paraphyses (*O. aradi*, *O. puyae*) differ from *O. bambusina* in thicker, yellow to orange apothecia, longer and/or wider, more curved spores, and in wider SBs with a more globose lower part. Other species with similar spores (e. g., *O. cylindrospora* of section *Orbilia* or *O. atlantis* of series *Neodactylella*) differ from *O. bambusina* mainly in globose SBs and the absence of caps of exudate on the paraphyses.

Variation. The very sparse collection on *Cocos* (Pl. 1025: 1) differs from the holotype in smaller apothecia, slightly shorter and wider ascospores, smaller SBs, shorter asci, and paraphyses with distinctly more inflated apices lacking glassy caps. Until the variability of the species is further explored, the two specimens are considered as conspecific. In the type collection (Pl. 1025: 2) the exudate caps over paraphyses and glassy caps stained bright reddish-brown in IKI.

Ecology. *O. bambusina* was found on xeric stems and leaves of large monocotyledons (*Bambusa*, *Cocos*) in a tropical humid (dry in the less warm winter) rainforest area in northeastern Australia.

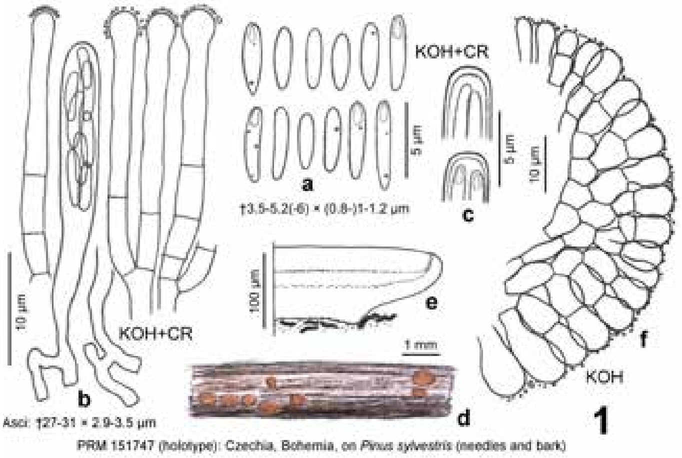
Specimens included. **AUSTRALIA**: **Queensland**, Wet Tropics, border of Daintree forest, 43 km N of Port Douglas, Cape Tribulation, 14 m, leaf of *Cocos nucifera*, 30.VIII.2006, G. Marson (H.B. 8494a). – ibid., stem of *Bambusa*, 30.VIII.2006, G. Marson (ex H.B. 8497b, BRI AQ799193, **holotype**).

Orbilia acuum Velen., Monogr. Discom. Bohem.: 94, pl. 11 fig. 22 (1934) — Pl. 1027

Etymology: according to the substrate in the type, needles of *Pinus*.
Typification: Czechia, Lysá nad Labem, needles and branch of *Pinus sylvestris*, VI.1927, J. Velenovský (PRM 151747, holotype).
Misinterpretation of *O. acuum*: Spooner (in Kirk & Spooner 1984: 573, fig. 9B, erroneously as 'A' on the plate), = *O. dryadum*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.55 mm diam., 0.11 mm high (receptacle 0.08 mm), pale cream-orange (fresh whitish, glassy-translucent), round, gregarious in small groups; disc flat, margin distinct, not protruding, smooth; broadly sessile, superficial; dry bright brick-red-orange. **Asci** †27–31 × 2.9–3.5 µm, 8-spored, spores †2–3-seriate, basal spores inverted, pars sporifera 14.5 µm long; **apex** (†) slightly, rarely medium to strongly truncate (not indented, laterally not inflated); **base** with medium long, thin, slightly flexuous stalk, h- to H-shaped. **Ascospores** †3.5–5.2(–6) × (0.8–)1–1.2 µm, subcylindrical (rarely narrowly ellipsoid-fusoid), apex rounded to obtuse, base not or slightly attenuated, rarely acute, straight to slightly inequilateral; **SBs** †1.2–1.4 × 0.5 µm, partly visible as a transparent, narrowly tear-shaped region. **Paraphyses** apically uninflated or slightly, rarely medium capitate, terminal cells †12–18 × 1.8–3 µm (× 3–4 µm fide Svrček), lower cells †(2–)4–5(–7) × 1.8–2.6 µm; unbranched at upper septum. **Medullary excipulum** 20 µm thick. **Ectal excipulum** of thin-walled, vertically oriented textura globulosa-angularis from base to margin, 40 µm thick near base, cells †14–18 (–23 fide Svrček) × 10–12 µm; 20 µm thick near margin, oriented at a 90° angle to the surface, marginal cortical cells almost globose, †6–10 × 5–8 µm; **glassy processes** absent. **Anchoring hyphae** †2.5–4 µm wide, thin-walled (fide Svrček). **SCBs** no data available. **Exudate** over paraphyses, margin and flanks 0.2–0.4 µm thick, granular, ± firmly attached. **— ANAMORPH**: unknown.

Habitat: on a corticated, ~15 mm thick branch of *Pinus sylvestris*, on medium decayed bark (periderm) and needles, strongly greyed or blackened, no algae seen. **Associated**: none observed. **Desiccation tolerance**: unknown (possibly slightly desiccation-tolerant). **Altitude**: 200 m a.s.l. **Geology**: Upper Cretaceous calcareous clay- & marlstone. **Phenology**: VI.



PRM 151747 (holotype): Czechia, Bohemia, on *Pinus sylvestris* (needles and bark)

Plate 1027. **1**: *Orbilia acuum*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. pine needle with rehydrated apothecia; **e**. apothecium in median section; **f**. id., ectal excipulum at margin. – Most elements originate from an apothecium on a needle, but those in which a spore body was seen derive from bark.

Taxonomic remarks. In concordance with Svrček (1954: 8), *Orbilia acuum* is tentatively accepted here as a distinct species which is only known from the features of the dead type specimen (Velenovský's illustration does not show cell contents). Its characteristics are the small, subcylindrical, ± straight ascospores with apparently narrowly tear-shaped SBs, paraphyses which are only slightly capitate, and large, globose marginal cortical cells being externally covered by a thin granular exudate.

The species might be close to *O. epipora* (series *Neodactylella*) with which it was compared by Spooner (in Kirk & Spooner 1984: 573). However, the spores in *O. acuum* are longer, not shorter than in *O. epipora* as was thought by Spooner who did not examine type material of the two species. Actually, the collection which he identified as *O.* cf. *acuum* (on decorticated wood, Scotland) seems to be *O. dryadum* (section *Orbilia*). *O. acuum* appears to differ from *O. epipora*, *O. dryadum*, and also *O. atlantis* (series *Neodactylella*) in the shape of the spore body which could be discerned as an elongate tear-shaped transparent region in the more blunt end of the spore, whereas the mentioned species have globose SBs. The affinities of *O. acuum* might also be with *O. cyparissias*, a species with a much thicker, cloddy exudate (see p. 1659), or with species around *O. rectispora* (series *Neodactylella*) which have longer spores. It is also similar to members of series *Dactylellina*, e. g. *O. quercus*, *O. acuum*.

Type studies. The holotype of *O. acuum* contains ~15 apothecia on rotten needles (covered by thin blackish mycelium), and a further ~50 on bark. Bark was not mentioned by Velenovský in the protologue, but the apothecia on it were found to be conspecific by Svrček (1954) and in the present study, and showed more free spores. Only in the examined apothecium from bark the spore body could be seen in the present study (Pl. 1027: 1a, c).

Velenovský reported the apothecia as '0.5–1 mm, sessile, glassy translucent, whitish', but they were here found to be rehydrated distinctly smaller (0.25–0.55 mm) and are now pale cream-orange. Also Svrček reported them as 'dry pale yellowish-amber or straw-coloured yellow, 0.1–0.3 mm diam.'. He found the spores slightly smaller than evaluated here (3–4 × 0.8–1 µm, Velenovský: 2–3 µm), but the paraphyses apically clavate, 3–4 µm wide. Although the protologue says 'without epithecium', Velenovský's manuscript plate shows granular exudate over 1 paraphysis. This granular exudate was also observed by Svrček (especially in apothecia on bark) and in the present study. The asci are reported by both (Svrček as 20–24 × 3–3.5 µm, including stipe, Velenovský 20–24 × 3 µm), but on bark Svrček observed them often to be up to 30 µm long. The dark brown basal hyphae mentioned by Velenovský as 'hypothallus' belong to a different fungus.

Not included collection. Also an Australian sample on unidentified monocot (IVV: H.B. 8995b) was only studied in the dead state. It differs in smaller asci (†23–26 × 2.7–3 µm) and spores (†3.3–4 × 0.8–0.9 µm), a thicker exudate (0.5–1 µm) over the paraphyses, a marginal excipulum of elongated cells oriented at an oblique angle, and smaller apothecia (0.15–0.22 mm).

Ecology. *O. acuum* is only known from the holotype, which grew on rotten bark of a branch and on needles of *Pinus sylvestris* in subcontinental, cold-temperate humid central Europe. The monocot sample is from subtropical semihumid banksia-eucalypt woodland in southwestern Australia.

Specimens included. **CZECHIA**: **Central Bohemia**, ~30 km ENE of Praha, Lysá nad Labem, ~200 m, branch of *Pinus sylvestris*, on bark, also on needles, 11.VI.1927, J. Velenovský (PRM 151747, **holotype**, H.B. 6063 ø).

Not included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, Perth, Kings Park, 48 m, culms of (?)*Liliidae*, 14.XI.2007, G. Marson (H.B. 8995b).

Orbilia cyparissias Velen., Monogr. Discom. Bohem.: 101 (1934) — Pl. 1028

Etymology: referring to the host plant, *Euphorbia cyparissias*.

Typification: Czechia, Mnichovice, stem of *Euphorbia cyparissias*, IX.1933, J. Velenovský (PRM 721481, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.7 mm diam., 0.12 mm high, light yellowish-cream, fresh pale vinaceous fide Velenovský, round, scattered or in small groups; disc flat to slightly convex, margin indistinct, not protruding, smooth; sessile, superficial. **Asci** †30–40 × 2.8–3.5 µm, 8-spored, spores biseriate, 5 lower spores inverted (strongly mixed); **apex** (†) slightly to medium truncate (not indented, laterally not widened), hemispherical in profile view, ± thin-walled; **base** with short to medium long, thin, flexuous stalk, L- or H-shaped. **Ascospores** †(3–)3.5–4.5(–5.2) × 0.8–1.2 µm, subcylindric-clavate to clavate, apex rounded (to obtuse), base mostly slightly to medium attenuated, mostly slightly curved (comma-shaped); **SBs** visible as a transparent region †1.3–1.8 µm long, possibly tear-shaped. **Paraphyses** apically uninflated to slightly capitate-clavate, terminal cell †14–18 × 2–3 µm, lower cells †(3–)5–6 × 1.5–2.5 µm. **Medullary excipulum** 45 µm thick, of ± loose textura intricata, medium sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled, vertically oriented t. angularis from base to mid flanks, 50 µm thick near base, cells †7–12 × 6–8 µm; 20 µm thick near margin, marginal cortical cells vertically oriented, †6.5–11 × 2.5–3.5 µm, cylindric-clavate, thin-walled, without **glassy processes**. **Anchoring hyphae** medium abundant, †1.7–2.2 µm wide, walls 0.2 µm thick. **SCBs** and **VBs** no data available. **Exudate** over paraphyses 0.5–2 µm thick, cloddy, hyaline, ± firmly attached; at margin and flanks thin, ± granular. **— ANAMORPH**: unknown.

Habitat: 3.5 mm thick stem of *Euphorbia cyparissias*, slightly decayed. **Associated**: black, small, hysterioid, very senescent fungus (apothecia partly growing on it). **Desiccation tolerance**: unknown, probably slightly tolerant. **Altitude**: 400 m a.s.l. **Geology**: biotite-amphibolite & quartz diorite. **Phenology**: IX.

Taxonomic remarks. *Orbilia cyparissias* is characterized by small, slightly curved ascospores being mostly ± tapered at the base, with a probably tear-shaped SB in the apex, also by hardly inflated paraphysis apices covered by thick exudate. The species might be related to *O. cardui* (series *Neodactylella*), from which it differs in distinctly shorter, more curved spores and the absence of glassy processes. *O. acuum* has similar spores and apparently also similar SBs, but the spores are more straight and less attenuated at the base, the exudate over the paraphyses much thinner, and the marginal cortical cells much wider. *O. epipora* (series *Neodactylella*) differs in lacking exudate over the paraphyses and in straight spores with globose SBs. *O. alba* (series *Gamsylella*) and *O. quercus* (series *Dactylellina*) resemble *O. cyparissias*, but differ in a thinner exudate over the paraphyses, wider marginal cortical cells, and smaller SBs, the latter also in more straight, slightly longer spores, the former in larger apothecia and longer and narrower spores. Another possible relation might be with *O. caulicola* (section *Aurantiorubrae*), which differs in larger spores with globose SBs. However, in section *Aurantiorubrae* H-shaped ascus bases were generally not observed.

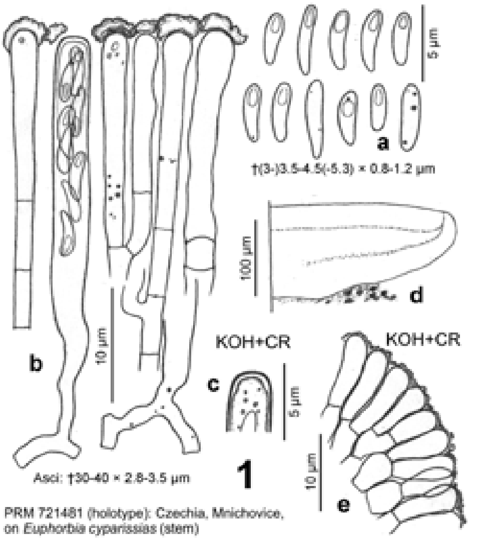


Plate 1028. **1**: *Orbilia cyparissias*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., ectal excipulum at margin.

Type studies. Velenovský (1934) described the apothecia as 0.5–1 mm diam., pale vinaceous, the spores as 2–3 µm long, arcuate, and the paraphyses covered by a strong 'epithecium'. The unpublished manuscript plate shows strongly allantoid, narrow, homopolar spores without contents. When considering a calibration error of ~50 %, these spores might have an actual size of ~5–6 × 0.8–1 µm in situ. Svrček (1954) found the spores 4–5 × 0.8 µm, slightly curved, rarely almost straight, the exudate over the paraphyses 3–4 µm thick, and compared the species with *O. minutispora* (section *Orbilia*, see p. 1385).

Ecology. *O. cyparissias* was collected on blackened, dead, possibly xeric stems of *Euphorbia cyparissias* in subcontinental, cold-temperate humid central Europe. The altitude is colline and the site a hill with probably thermophilous vegetation.

Specimens included. **CZECHIA**: **Central Bohemia**, ~27 km SE of Praha, Mnichovice, hill above, ~400 m, stem of *Euphorbia cyparissias*, IX.1933, J. Velenovský (PRM 721481, **holotype** of *O. cyparissias*, H.B. 6129 ø).

List of excluded, doubtful, or little-known taxa

Included in this list are all those taxa which have ever been combined in the orbiliaceous genera *Cheilodonta*, *Habrostictis*, *Hyalinia*, *Orbilia*, *Orbiliaster*, and *Orbiliella*. Only a small number of the many taxa ever combined in the genus *Patinella* have been examined in the present study and are mentioned below, since *Patinella* comprises only a few truly orbiliaceous members. Some taxa combined in genera other than those mentioned above have erroneously been assumed by previous workers to belong to *Orbilia*. They are also treated here, as well as two with the epithet '*orbilioides*' which have never been combined in orbiliaceous genera. The taxa are arranged according to their specific or infraspecific epithet.

Patinella abietina (Cooke) Sacc., Syll. Fung. 8: 771 (1889)

≡ *Patellaria abietina* Cooke, Grevillea 7: 4 (1878)
= *Patinella atroviridis* Rehm, Rabenh. Krypt.-Fl., 1.3: 312 (1889)

In the holotype material (USA, California, on '*Abies douglasii*' [= *Pseudotsuga menziesii*], undated, W.H. Harkness 763, K(M) 36005, IVV: H.B. 5529) the wall surface of the entire asci and the ascogenous hyphae stains distinctly blue in IKI (with or without KOH-pretreatment). The dark olivaceous-brown pigment in the excipulum dissolves in KOH and gives a strong honey-yellow stain to the medium (ionomidotic). The asci are thin-walled including the apex, arise from croziers, and contain 8 slightly heteropolar spores (6–8.2 × 1.8–2 µm) which include some minute LBs. *Patinella atroviridis* Rehm is a later synonym (see p. 1662).

Also two recent collections of this species (USA, Arizona, Flagstaff, Grand Canyon, on wood of *Pinus ponderosa*, G. Marson, IVV: H.B. 5776a; ibid., on wood of *Pinus edulis*, IVV: H.B. 5227d) were studied. A pure culture of H.B. 5776a produced a striking yellow-olivaceous mycelium and small conidia formed in phialides. The living ascospores did not contain refractive, KOH-sensitive contents.

The peculiar amyloid iodine reaction that gives a blue stain to the entire hymenium suggests a relationship with lichenized discomycetes, but any association with algae could not be observed. A very similar, unidentified species on decorticated xeric *Olea* branches in Spain with a similar yellow-orange KOH reaction of the excipulum deviates by larger ascospores (S. Tello, IVV: 26.VI.2015). Its ITS+LSU rDNA (KY462809) suggests a relationship with *Lecanoromycetes* (Phyl. 1).

Orbilia agyrioides (Desm.) Quél., Enchir. Fung.: 298 (1886)

≡ *Peziza agyrioides* Desm., Ann. Sci. Nat., Bot., sér. 2, 8: 9, pl. 2 fig. 5 (1837)
≡ *Hyalinia agyrioides* (Desm.) Boud., Hist. Class. Discom. Eur.: 104 (1907)
(?)= ***Iodophanus carneus*** (Pers.) Korf, in Kimbrough & Korf, Am. J. Bot. 54: 19 (1967)

The holotype (France, Haute-Vienne, date and collector not indicated, on dry plant stems, Desmazières Pl. Crypt. N. France no. 1803; PC 1054) was studied and found to be a species of *Iodophanus* Korf, probably *Iodophanus carneus* (Pers.) Korf. The asci measure 220 × 25 µm and react diffusely pale blue in KOH+IKI (not restricted to apex), and the spores are ellipsoid, smooth, 16–22 × 10–13 µm, without LBs.

For the very different *Helotium agyrioides* P. & H. Crouan see under *Hyalinia crouanorum*, p. 1668.

Hyalinia albella – see *H. albida*

Hyalinia albida (With.) Boud. [as '*H. albella*'], Hist. Class. Discom. Eur.: 103 (1907)

≡ *Peziza albida* With., Bot. Arr. Brit. Pl., ed. 2, 3: 440 (1792) [non *P. albida* (All.) Lam. 1804; nec *P. albida* Sowerby 1799; nec *P. albida* Roberge in Desm. 1850, ≡ *Hymenoscyphus albidus* (Gillet) W. Phillips]
≡ *Helotium albidum* (With.) P. Karst. [as '*H. albellum*'], Bidr. Känn. Finl. Nat. Folk 19: 116 (1871), nom. illegit., ICN Art. 53.1 [non *Helotium albidum* P. & H. Crouan 1867, ≡ *Mniaecia albida*, see below; nec *Helotium albidum* (Gillet) Pat. 1885, nom. illegit, ICN Art. 53.1, ≡ *Hymenoscyphus albidus*]
≡ *Pezizella albida* (With.) Sacc. [as '*P. albella*'], Syll. Fung. 8: 280 (1889)
≡ *Pseudopeziza albida* (With.) Massee [as '*P. albella*'], Brit. Fung.-Fl. 4: 202 (1895)

Peziza albida With. was first published by Withering in 1792 (see Ramsbottom & Balfour-Browne 1951, B. Spooner pers. comm.), but authors (e. g., Fries 1822: 146) have more frequently cited Withering (1796: ed. 3, vol. 4: 350) as basionym, which provides the same description. According to Nannfeldt (1939: 244), Withering's original description refers to a fungus which 'seems to be identical with, or closely allied to *Peziza adae* Sadl.' (= *P. domiciliana* Cooke, *Pezizales*). *Peziza albida* was described as growing on a cellar floor in joints of the bricks, with pinky white apothecia 1/4–3/4 of an inch (~7–20 mm) diam. If type material would be found, *P. albida* might provide an older name for *P. domiciliana*. However, nothing of Withering's taxa seems to have been preserved (B. Spooner pers. comm.).

Fries (l.c.) reduced *Peziza albida* (as '*albella*') to synonymy or infraspecific level of his new species *P. vulgaris* Fr. [≡ *Calycina vulgaris* (Fr.) Baral], a helotialean fungus described from bark of *Corylus*, with much smaller (max. ~2 mm), whitish apothecia. Phillips (1890, see also Rehm 1892: 710) pointed out the strange discrepancy in ecology and macroscopy of these two very distant taxa. Fries actually identified a collection on *Rubus*, with incarnate, later pale rose apothecia, as '*P. albella* With. arr. IV, p. 350'. Saccardo (1889: 281) interpreted this as the erection of a new variety, *Pezizella vulgaris* var. *incarnata* Fr. Fries (1822: 146) changed Withering's epithet *albida* to *albella*, a procedure considered as incorrect by Phillips (l.c.), Rehm (l.c.), and Nannfeldt (l.c.). Nevertheless, many authors have followed Fries's name change. Perhaps Fries did this in order to avoid confusion with homonyms. In any case, he wrote in the index to his volume the correct name '*Peziza albida*' (Fries 1832: 126), as already mentioned by Nannfeldt.

When interpreting *P. albida* With., later authors obviously relied on Fries's misinterpretation of Withering's taxon. For example, Saccardo (1889: 278, 280), followed by Boudier (1907), stated '*P. albella*' to be a synonym of *Peziza vulgaris*. Nevertheless, both authors published a new combination for the taxon (in *Pezizella* and *Hyalinia*, respectively), obviously because of priority of *P. albida* over *P. vulgaris*. Nannfeldt apparently reexamined Karsten's and Massee's specimens of *Helotium albellum* and *Pseudopeziza albella*, respectively, and stated that both belonged to *Allophylaria vulgaris* (Fr.) Nannf. (≡ *Calycina vulgaris*).

Orbilia albida (P. & H. Crouan) Quél., Enchir. Fung.: 299 (1886)

≡ ***Mniaecia albida*** (P. & H. Crouan) Priou & Baral, **comb. nov.** — MB 814586

Basionym: *Helotium albidum* P. & H. Crouan, Florule Finistère: 47 (1867) [non *Helotium albidum* (With.) P. Karst. 1871, see under *Hyalinia albida*]

≡ *Calycina albida* (P. & H. Crouan) Kuntze, Revis. Gen. Pl. 3: 448 (1898)
≡ *Ombrophila albida* (P. & H. Crouan) Boud., Hist. Class. Discom. Eur.: 93 (1907)
= *Epiglia gloeocapsae* Boud., Bull. Soc. Mycol. Fr. 1: 113 (1885)
≡ *Mniaecia gloeocapsae* (Boud.) Van Vooren, Bull. Mens. Soc. Linn. Lyon 74 (spéc.): 19 (2005)

The protologue of *Helotium albidum* (Crouan & Crouan 1867) and an unpublished original illustration preserved at CO refer to a terricolous fungus with sessile, whitish, smooth, hemispherical apothecia, clavate asci with ellipsoid-oblong, multiguttulate spores, and apically hooked paraphyses. Le Gal (1953: 108) redescribed the type material ('sur la terre, 22.X.1866') and referred the fungus to the *Hyaloscyphaceae*, close to *Cistella*, mainly because of small, smooth, unicellular hairs near the margin.

However, judging from Crouan's illustration which was not at Le Gal's disposition, the species is more reminiscent of a white member of *Mniaecia* Boud. Actually, reexamination of the type material by J.P. Priou (IVV: 22.X.1866) revealed it to be an earlier synonym of *Mniaecia gloeocapsae* (Boud.) Van Vooren as described and figured by Boudier (1904–10: 262, pl. 454). Le Gal found the rehydrated apothecia to measure 0.5–0.6 mm diam., not 2–3 mm as stated by Crouan & Crouan (1867), and to grow in groups in connection with small mosses. The dead spores are now filled with large and small oil drops as a result of fusion of the originally numerous small LBs (OCI 5). Typical of the genus *Mniaecia* are the inamyloid asci (in IKI, KOH-pretreated), a feature not tested by Le Gal and Boudier.

J.P. Priou found the spores in the type non-septate, 6–9 × 3–4 µm, whereas Le Gal reported them (8–)10–12 × (3–)4 µm, finally 1–3-septate, apparently because she examined a more senescent apothecium. In the protologue of *Epiglia gloeocapsae* the spores are *13–16 × 5–6 µm, but evaluating Boudier's spore drawing leads to a size of *10–13(–15) × 4–5.2(–5.7) µm. A few recent collections from Bretagne on loamy or sandy ground among *Jungermanniales* very well match this species (IVV: e. g. H.B. 7324, 21.III.2015). Here a spore size of *(8–)9.5–12 × 4.5–5(–6) µm was noted.

As a curiosity, the very same words ('parmi les Jungermannes/ jongermannes et les petites mousses') were used when authors reported the ecology of *Helotium albidum* and *Epiglia gloeocapsae* (*albidum*: Le Gal 1953 regarding Crouan's label of a non-type collection made in 15.III.1868; *gloeocapsae*: Grelet 1948b: 114). Since Crouan's taxon has priority over Boudier's, we here propose a new combination.

Orbilia albomarginata Rehm, Österr. Bot. Z. 56: 344 (1906), nom. nud.
?= ***Calycina discreta*** (P. Karst.) Kuntze, Revis. gen. pl. (Leipzig) 3(3): 448 (1898)

Reexamination of the material on which this taxon was based (Austria, Tirol, Schrofenpass above Warth, ?1650 m, stems of *Aconitum*, IX.1905, H. Rehm, S-F9994, IVV: H.B. 6427) revealed short stipitate, whitish-ochraceous apothecia 1.5–2.5(–4) mm diam. when dry, asci with croziers, with an IKI deep blue apical ring (BB, *Calycina*-type), and ascospores of 8–10.5 × 2–2.3 µm, with a few minute LBs. The collection clearly belongs to *Calycina* Nees ex Gray and is obviously closely related to *C. discreta*. It represents the more rare form with asci arising from croziers, slightly larger spores, and apothecia that tend to be larger. Rehm provided a handwritten Latin diagnosis attached to the specimen. Specimen and diagnosis do not seem to have any duplicates in other public herbaria, therefore, the taxon has no valid status. Saccardo & Trotter (1913: 725) listed the taxon as a 'nomen nudum' with only substrate and geographical data.

Hyalinia alboviridis (Saut.) Boud., Hist. Class. Discom. Eur.: 104 (1907)
≡ *Peziza alboviridis* Saut., Flora (Regensburg) 20: 314 (1841) [non *Peziza alboviridis* Cooke 1878, ≡ *Proliferodiscus alboviridis* (Sacc.) Spooner]
≡ *Pezizella alboviridis* (Saut.) Sacc., Syll. Fung. 8: 278 (1889)
≡ *Hymenoscyphus alboviridis* (Saut.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
?= ***Calycellina chlorinella*** (Ces.) Dennis, Kew Bull. 30: 350 (1975)

The type material (Austria, Salzburg, Pinzgau, Mittersill, rotten stems of *Rubus idaeus*, 31.X.1838, A. Sauter) was found to be immature by Keißler (1917: 86). The taxon was believed to be close to *Orbilia xanthostigma* (Saccardo 1889, as *Peziza xanthostigma*). Yet, Winter (1881: 132) considered synonymy with *Peziza dilutella* Fr. which is possibly a member of *Pyrenopeziza* Fuckel (see p. 1670). Saccardo treated the species shortly before *Pezizella chlorinella* (= *Calycellina chlorinella*, see under *Hyalinia chlorinella*, p. 1665), probably because of the greenish disc. *P. alboviridis* might, in fact, be a synonym of that species. Despite Keißler's report no material could be found in BREG, LI, SZB, and W. Saccardo gave the apothecial size as ½ cm by error (Sauter wrote '½ Linie'; in Austria this corresponds to ~1 mm).

Orbilia algiseda Velen., Novit. Mycol.: 177 (1940)

No type material exists of this taxon (Svrček 1954), which was said to grow on a layer of *Gloeocapsa* on a trunk of *Alnus*. The small, yellow to orange apothecia and the small, ellipsoid, biguttulate spores suggest identity with *O. eucalypti* or more probably *O. xanthostigma*.

Hyalinia alnicola (Feltgen) Boud., Hist. Class. Discom. Eur.: 104 (1907)
≡ *Cenangella alnicola* Feltgen, Rec. Mém. Trav. Soc. Bot. G.-D. Luxemb. 16: 89 (1903) [non *Cenangella alnicola* Rehm 1905]
= ***Phaeohelotium imberbe*** (Bull.) Svrček, Sb. nár. Mus. Praze 40B(3-4): 152 (1985) [1984]

The study of the holotype (Luxembourg, Grünew[ald]-Helms[ingen], corticated twig of *Alnus glutinosa*, J. Feltgen, LUX 43451, IVV: H.B. 6300) suggests that it is a synonym of *Phaeohelotium imberbe* (see also under *O. flexuosa*, p. 1672). The asci arise from croziers and the euamyloid apical ring is of the *Hymenoscyphus*-type.

Habrostictis diaphana var. **alpigena** (Rehm) Rehm, Ber. naturhist. Ver. Augsburg 26: 32 (1881)
≡ *Calloria fusarioides* var. *alpigena* Rehm, Ascomyc. 118 (1872)
≡ *Unguicularia alpigena* (Rehm) Höhn., Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. I, 127: 378 (1918)
= ***Laetinaevia diaphana*** (Rehm) Baral (see below)

This variety was placed in synonymy with *Naevia diaphana* (Rehm) Rehm already by Rehm (1888: 140), which is confirmed here: in two authentic specimens (both Austria, Tirol, on *Cirsium spinosissimum*: Stubai, Alpeiner Gletscher, ~2100 m, VIII.1872, H. Rehm Ascomyc. 118, M (syntype); Pitztal, ~1850 m, VIII.1875, H. Rehm, Thümen Mycoth. univ. 719, M) no differences to '*Naevia*' *diaphana* could be found (see under *Habrostictis diaphana*, p. 1669).

Pteromyces ambiguus – see p. 209

Patinella antarctica Speg., Bol. Acad. Nac. Cienc. 11 (1): 57 (1887)

≡ *Ascophanus antarcticus* (Speg.) Speg., in Saccardo, Syll. Fung. 8: 532 (1889)

Only a single, strongly overmature apothecium (rehydrated redb-rown, 0.4 mm diam.) was found in the holotype (Argentina, Santa Cruz, on dung of *Rhea darwinii* [≡ *R. pennata*], VIII.1882, C.L. Spegazzini, Fungi Patagonici 162, LPS 4861). No hymenial or excipular elements could be observed, except for abundant ellipsoid, firm-walled, smooth, eguttulate, hyaline ascospores measuring 14–18 × 10–11 µm in H_2O and 15–19.5 × 12–14.5 µm in KOH. A large, globose, non-refractive, subeccentric region (?nucleus) is very clear in H_2O but has only weak contrast in KOH. Spores and spore content closely fit Spegazzini's drawing on the convolute, except for their size (Spegazzini: 10–11 × 5–6½ µm). The observed spores appear to belong to a member of the ***Pezizales***.

Orbilia antenorea (Sacc.) Sacc., Syll. Fung. 8: 627 (1889)

≡ *Calloria antenorea* Sacc., Michelia 1(1): 64 (1877)
≡ *Hyalinia antenorea* (Sacc.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

No specimens could be found in PAD, PAL, TO, and W. The taxon (Italy, Padova, on wood or bark of *Prunus laurocerasus*, III.1877, G. Bizzozero) was compared with *Calloria chrysostigma* (Fr.) W. Phillips [≡ *Psilachnum chrysostigma* (Fr.) Raitv.] and *Peziza xanthostigma* by Saccardo. From the diagnosis its generic position remains obscure. The asci (50–60 × 8 µm) were said to have a rounded apex, and the cylindrical spores (10–11 × 2–3 µm) to be somewhat curved.

Orbilia arctica Allesch., in Allescher & Hennings, Biblioth. Bot. 42: 44 (1897)

≡ ***Naeviopsis arctica*** (Allesch.) B. Hein, Willdenowia, Beih. 9: 69 (1976)

According to Hein (1976) this species grows on stems and leaves of arctic-alpine *Rosaceae* (*Alchemilla*, *Geum*, *Potentilla*). It has inamyloid asci and ascospores of 11–18 × 5–6 µm. *N. arctica* is said to be very close to the type species of *Naeviopsis* B. Hein (*Calloriaceae*, *Helotiales*), *N. epilobii* (P. Karst.) B. Hein, which has an amyloid apical ring of the *Pezicula*-type ('T-shaped').

Orbilia assimilis (Cooke & Peck) Sacc., Syll. Fung. 8: 629 (1889)

≡ *Peziza assimilis* Cooke & Peck, in Cooke, Grevillea 1: 6, pl. 1 fig. 6 (1872)
≡ ***Calloria assimilis*** (Cooke & Peck) B. Hein, Willdenowia, Beih. 9: 59 (1976)

According to Hein (1976) this is a good taxon very close to the type species of *Calloria* Fr., *C. neglecta* (Lib.) B. Hein (*Calloriaceae*). In the lectotype (USA, [New York,] West Albany, V. [no year], stems of *Aster puniceus*, M.C. Cooke & C. Peck 278, K, IVV: H.B. 5350) the asci arise from croziers and their conical apices have a slight, inamyloid apical thickening. Only 5–6 spores were seen within them, which contain a few minute LBs and measure (9–)10–11 × (3–)3.5–4 µm [Hein: 9–11(–13) × 3–4 µm]. With their medium (capitate-)clavate apices the paraphyses resemble indeed those of *Orbilia*. Another specimen under the name *O. assimilis* (USA, Virginia, Shenandoah Nat. Park, below Horver Camp, Rapidan River, VI.1935, stems of *Impatiens*, C.L. Shear, herb. Petrak, M) deviates merely in narrower spores (7–11 × 2.4–2.7 µm).

C. assimilis resembles *Duebenia compta* in its elongate, erumpent apothecia and a reduced number of spores within the asci. *D. compta* deviates in an excipulum with a yellowish-ochraceous granular exudate and in more or less lanceolate paraphyses. Whether these differences justify separation at the generic level seems questionable.

Orbilia atropurpurea Clem., Bot. Surv. Nebraska 4: 16 (1896)

Seaver (1951: 236) considered this taxon as a possible synonym of *Ascocoryne sarcoides* (Jacq.) J.W. Groves & D.E. Wilson. Upon type material request, no response was received from NY. The original description (USA, Nebraska, Brown County, Hazel Creek Canyon, on dead wood) could also fit *Coryne inflata* Wilson (nom. inval.) because of the rather small apothecia (2–5 mm) and long spores (20–25 × 5–6 µm). The paraphyses are described as 'above broadened into a minute clavula', which is perhaps not as pronounced as in *C. inflata* but might have been the reason for Clements to place the fungus in *Orbilia*.

Patinella atroviridis Rehm, Rabenh. Krypt.-Fl., 1.3: 312 (1889)

= ***Patinella abietina*** (Cooke) Sacc., Syll. Fung. 8: 771 (1889)

This species was described from Italy (Tirol, Ortler above Sulden) on decorticated trunk of *Pinus cembra*. Two North American collections on *Pinus* were referred by Sydow & Petrak (1922: 198) to this species. One of them (USA, Idaho, St. Joe National Forest, Ward's Peak, 1220 m, on decorticated branches of *Pinus albicaulis*, VI.1920 [8.VII.1920 in Sydow & Petrak], A.S. Rhoads, herb. Petrak, M) was examined and fits the protologue: the 8-spored asci arise from croziers, the wall surface of the entire asci stains pale blue (euamyloid) in IKI, the spores are cylindric-clavate, 7–9.5 × 2–2.2 µm, eguttulate, some of the lower spores are often inversely oriented inside the asci, the whole excipulum contains a blackish-brown exudate which completely dissolves in KOH and gives an ochraceous-olive stain to the medium (ionomidotic). The iodine reaction of the entire ascus wall is also mentioned by Rehm (1889) and Sydow & Petrak (l.c.). Rehm's observation is confirmed that no trace of a thallus or algae could be found. *Patinella abietina* (see p. 1660) is obviously an earlier synonym, as already suggested by Sydow & Petrak.

Habrostictis aurantiaca Rehm, Ber. naturhist. Ver. Augsburg 26: 67 (1881)

≡ *Ocellaria aurantiaca* (Rehm) Rehm, Rabenh. Krypt.-Fl., 1.3: 135 (1888)
≡ ***Pezicula aurantiaca*** (Rehm) Rehm, Ber. Bayer. Bot. Ges. 13: 198 (1912)

In a syntype (Austria, Tirol, Oetz, Kühtai, Längenthal, dry corticated branch of *Alnus alnobetula* (as *A. viridis*), VIII.1874, H. Rehm, Ascomyc. 226, M) the now orange-brown apothecia are seated on a common stroma. The asci arise from croziers and vary in the ascus apex: the apical thickening is often nearly absent and entirely inamyloid (IKI), or an apical ring of the *Pezicula*-type is present which is, however, partly reactive only in the lower part of the dome (now euamyloid). Large druses of octahedral crystals are found in the (in KOH) deep yellow stroma. Verkley (1999: 49) accepted the taxon as a distinct species of *Pezicula* Tul. & C. Tul., but neither did he report the partly iodine-positive ascus apex, nor the presence of crystals, also he found the apothecia mostly solitary without a stroma.

Orbilia betulina (Alb. & Schwein.) Höhn., Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. I, 127: 336 (1918)

≡ *Peziza betulina* Alb. & Schwein., Conspect. Fung. Lusat.: 339 (1805)
≡ *Sclerotium betulinum* (Alb. & Schwein.) Fr., Syst. Mycol. 2(1): 262 (1822)
≡ *Mollisia betulina* (Alb. & Schwein.) Rehm, Ber. Bayer. Bot. Ges. 14: 96 (1914) [non *Mollisia betulina* Velen. 1934]
≡ ***Pyrenopeziza betulina*** (Alb. & Schwein.) Rauschert, Haussknechtia 4: 54 (1988)
= *Calloria winteri* J. Kunze, Fungi Sel. Exs. no. 283 (1880), nom. nud.
= *Pyrenopeziza betulicola* Fuckel, Jahrb. Nassau. Ver. Naturkd. 23 & 24: 294 (1870)
≡ *Mollisia betulicola* (Fuckel) Rehm, Rabenh. Krypt.-Fl., 1.3: 538 (1891)
≡ *Merostictis betulicola* (Fuckel) Svrček, Česká Mykol. 39(4): 207 (1985)

Hein (1976: 108) listed *Orbilia betulina* and *Calloria winteri* as synonyms of *Pyrenopeziza betulicola*, following Rehm (1891: 538, 1914: 96) and Höhnel (1918: 336), a *Dermateaceae* with uncertain generic affiliation, possibly related to *Orbilia mollisioides* Höhn. (Nannfeldt 1932: 188). Syntypes of *Calloria winteri* (Germany, Sachsen, Eisleben, Wolferode, Holzmarken, on rotten leaves of *Betula alba*, VI.1879, J. Kunze Fungi Sel. 283) were examined in the present study (Rabenh. Fungi Eur. Exs. 3570, M) and by Hein (1976, UPS). The reddish apothecia (rehydrated, ~0.25 mm diam.) grow on the underside of the leaves. The 8-spored asci (38–44 × 7 µm) arise from croziers and have a strongly conical apex reacting deep blue (euamyloid) in IKI, the cylindrical ascospores measured around 10 × 2 µm and contained a few small LBs. The hyaline ectal excipulum is a gelatinized textura globulosa with scattered light brown patches of cloddy exudate on its surface. According to Rehm (1914: 96), *Pyrenopeziza betulina* represents an earlier synonym of *P. betulicola*. See also under *Hyalinia tumidula*, p. 1688.

Some recent collections which include vital characters appear to belong here (IVV: e.g. H.B. 9308b, 20.V.2009, 13.IV.2017) and confirm a relationship with *Pyrenopeziza* and particularly *P. fuckelii* Nannf. (= *Microscypha monticola* Svrček) on *Salix* leaves.

Orbilia boydii A.L. Sm. & Ramsb., Trans. Br. Mycol. Soc. 4: 168 (1913)

= ***Pezicula myrtillina*** (P. Karst.) P. Karst., Bidr. Känn. Finl. Nat. Folk 19: 165 (1871)

Authentic specimens on twigs of *Vaccinium myrtillus* were reexamined by Nannfeldt (1936: 199) and found to be conspecific with *Pezicula myrtillina* (see also Verkley 1999: 100), a species which possesses hemiamyloid apical rings of the *Pezicula*-type, according to personal studies of recent collections.

Orbilia caesia Rick, Brotéria, sér. Cienc. Nat. 1: 44 (1932)

The description of this taxon (Brazil, Rio Grande, on bark) is too brief to recognize its identity (apothecia 0.5 mm diam., violet-hyaline, spores ovate to cylindrical, 5–12 × 3–4 µm, paraphyses apically globose). The 'sessile' asci appear to exclude an *Orbilia*. No material under this name could be found in GH, IACM, and W.

Orbilia calamaria (Ces.) Sacc., Syll. Fung. 8: 632 (1889)

≡ *Peziza calamaria* Ces., in Rabenh., Klotzschii Herb. Viv. Mycol., Cent. 20: no. 1926, 1855 [and Bot. Zeitung 13: 283 (1855), Flora 38: 267 (1855)]
= *Hydropisphaera arenula* (Berk. & Broome 1852) Rossman & Samuels, Stud. Mycol. 42: 30 (1999)

Syntype material of *Peziza calamaria* (Italy, Piemonte, Biella, on dry leaves and culms of *Festuca* or *Calamagrostis*, aut[umn]o [1]850, V. de Cesati, Rabenh. Klotzschii Herb. Viv. Mycol. Ed. 2, no. 18 [1855]) was seen from M and HBG. In one of the two convolutes from HBG that contained fragments of a *Poaceae*, several ascocarps could be found that fit the protologue ('carneous to saturn-red, cupulate, with obtuse margin'). These are collapsed perithecia of a *Bionectriaceae*, 0.25–0.35 mm diam., bright orange-brown, asci ~50–60 × 8–11 µm, ascospores 17–19 × 4.2–4.8 µm, 1-septate, hyaline, apparently smooth. Even after rehydration the perithecia retained their collapsed shape. The species was referred to synonymy with *Hydropisphaera arenula* by Lechat & Baral (2008), a taxon which is said to have usually longitudinally striate spores.

In the syntype in M no fruitbodies could be found. The convolute contains six fragments of substrate, four of which belong to a *Poaceae* but the remaining two are stems of a dicotyledonous plant. A duplicate in RO is devoid of any plant remains (A. Millozza pers. comm.). The short protologue printed on the label and in Saccardo (1889: 632) does not give any information on the microscopic features of the taxon. The herbarium label was reproduced by Braun (2018) who considered it as validly published.

Habrostictis callorioides Sacc. & Briard, in Briard, Rev. Mycol. (Toulouse) 7: 210 (1885)

≡ *Naevia callorioides* (Sacc. & Briard) Sacc. & Briard., in Saccardo, Syll. Fung. 8: 658 (1889)

The lectotype (France, *Chaerophyllum temulum*) was restudied by Hein (1976: 113), who found the asci to have an apical ring reacting blue in IKI and saw a similarity to *Merostictis* Clem. (= *Diplonaevia* Sacc.), except that the characteristic margin was missing in *N. callorioides*.

Orbilia calochroa Syd. & P. Syd., Bot. Jahrb. Syst. Pflanzengesch. Pflanzengeogr. 54: 258 (1917)

≡ ***Dicephalospora calochroa*** (Syd. & P. Syd.) Spooner, Bibl. Mycol. 116: 269 (1987)

Spooner (1987) erected a new genus *Dicephalospora* Spooner, with *Orbilia calochroa* as the type species (holotype: Papua New Guinea, on rotten bark), and *D. rufocornea* (Berk. & Broome) Spooner. His redescription of the holotype (Spooner 1987: fig. 43) shows apical rings of the *Hymenoscyphus*-type and ascospores with polar mucilaginous caps in both species. The genus was assigned to the *Sclerotiniaceae* on account of a slight blackening of the substrate. The microscopic characters, however, indicate relationship to *Hymenoscyphus* Gray (Baral, in Eriksson et al. 2001: note 3258), and molecular data confirm its placement near *Hymenotorrendiella* P.R. Johnst. et al. (Johnston et al. 2014a).

Naevia canadica Rehm, Ann. Myc. 11: 154 (1913)

Hein (1976: 33) considered the type material of *Naevia canadica* to be an *Orbilia*. However, he did not mention in which herbarium the examined specimen is deposited. No specimen under this name could be located in B, PAD, and S. The species was collected on dead stems of *Impatiens fulva* in Ontario (Canada). The minute apothecia are described as erumpent, yellowish-white, the inamyloid asci up to 45 × 4–5 µm, 8-spored, the spores 5 × 1.5–2 µm, and the paraphyses as filiform. Except for the uninflated paraphyses, a relationship to *Orbilia cookei* Baral (≡ *Peziza exigua* Cooke) would be possible.

Orbilia curvatispora var. ***caprina*** Velen., Monogr. Discom. Bohem.: 101 (1934)

No material is found in PRM (Svrček 1954). The extremely brief diagnosis gives as difference to *O. curvatispora* wine-rose ('vinoso-rosea') apothecia 0.5–1 mm diam. and only 5–8 µm long spores (for *O. curvatispora* Velenovský gave 8–15 µm). The collection was on *Salix caprea* from Mnichovice (Bohemia). In his manuscript notes the apothecia were described as yellow-rose ('luteo-rosella') and the spores illustrated as semicircular. This taxon appears to be a synonym of *O. auricolor* or a related taxon, assuming the possibility that the spore measurements are erroneous.

Habrostictis carneopallida P. Karst., Hedwigia 23: 40 (1884)

= *Ocellaria carneopallida* (P. Karst.) Sacc., Syll. Fung. 8: 658 (1889)

According to Verkley (1999: 142) no type specimen can be found. Karsten described this species (on bark of *Alnus incana*, Finland) with ascospores 27–34 × 14–15 µm, inequilateral, ellipsoid, eguttulate, with thick epispore, and compared it with *Habrostictis aurantiaca* Rehm (≡ *Pezicula aurantiaca* (Rehm) Rehm). The description could well refer to a *Pezicula*. However, Verkley (l.c.) stated that it might represent a lichenized discomycete. *Naeviopsis carneopallida* (Roberge ex Desm.) B. Hein is a different foliicolous fungus.

Calycina carneorosea (Cooke & Harkn.) Baral, **comb. nov.** — MB 814587

Basionym: *Peziza carneorosea* Cooke & Harkn., Grevillea 9: 130 (1881)
≡ *Pezizella carneorosea* (Cooke & Harkn.) Sacc., Syll. Fung. 8: 284 (1889)
≡ *Hymenoscyphus carneoroseus* (Cooke & Harkn.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)

This species appears to be only known from the type material which was redescribed by Dennis (1964: 38). It was assumed to be an *Orbilia* by Seaver (1951: 161). According to the holotype material in K (USA, California, on periderm of 3 mm thick, corticated twig of *Eucalyptus*, undated, Harkness 2164, K(M) 36002, IVV: H.B. 5526), the apothecia are dry 0.3–0.4 mm diam., yellowish-ochraceous, pubescent, without a brown basal ring, the asci measure 40–55 × 5.6–6(–6.5) µm, arise from croziers, and have a conical apex and an apical ring reacting strongly blue (BB) in IKI (*Calycina*-type). The ascospores (5–6.8 × 2.4–3 µm) are broadly ellipsoid-fusiform and contain a few minute LBs at each end. The ectal excipulum is composed of a thin-walled textura angularis-prismatica, the exterior of which is pubescent by thin-walled, smooth, ± cylindrical to moniliform, 1-septate hairs (15–25 × 3–3.5 µm). Dennis considered a relationship to *Cistella trabinella* (P. Karst.) Nannf. [≡ *Leptodontidium trabinellum* (P. Karst.) Baral, Platas & R. Galán]. However, species of *Leptodontidium* have much larger LBs in the spores, basally more densely septate paraphyses, and a marginal excipulum without hairs (see under *Orbilia diaphanula*, p. 1669). *Calycina carneorosea* should be studied from a fresh sample in order to clarify the presence of VBs in the paraphyses.

Orbilia carpathica Velen., Monogr. Discom. Bohem.: 103, pl. 11 fig. 6 (1934)

O. carpathica was based on a single specimen from the Carpathian Mountains (Ukraine), on wood of *Quercus*, VIII.1930, A. Pilát (PRM 151703). The protologue points to a desiccation-tolerant species of subgenus *Hemiorbilia*, according to the reported apothecial colour ('igneo-sanguinea') and the figured exudate over the paraphyses. The rather accurately described and illustrated spores with elongate heads and long and thin tails suggest identity with *O. flagellispora*, apart from the lack of a basal inflation of the tails. Velenovský based his new species on a peculiarity of the spore tails which he figured strongly geniculate in their upper part, a feature only rarely observed by us in a few spores of a few collections of *O. flagellispora*. The paraphyses are figured as apically medium clavate. Another possibility would be to compare *O. carpathica* with members of section *Arthrobotrys*. For example, the spores of *O. clavispora* (H.B. 8371a) have a thicker upper and a tail-like lower part. Especially the spores in the holotype of the Indonesian *O. neglecta* strongly resemble Velenovský's drawing of *O. carpathica*, but all these members of section *Arthrobotrys* have much smaller spores.

Svrček expressed doubts about the size (20 µm) and shape of the spores as indicated by Velenovský, which does not concur with the stated ascus size (25 × 4 µm, excluding stipe). Yet, when assuming an inverse orientation of some of the spores, the tails scarcely need any space within the asci and the spore heads of ~10 µm length could well have been arranged in a 4-seriate bundle within the asci.

The holotype of *O. carpathica* contains a microscopically entirely different fungus (IVV: H.B. 6054). The apothecia are ± gregarious, abundant (roughly 200), macroscopically uniform, with smooth margins. Some features in the protologue (gregarious growth, apothecial size, clavate apices of paraphyses) actually appear to fit this probably desiccation-sensitive species. Spore orientation was clearly seen in various asci, with the upper spores pointing with their acute end always downwards, and the lower spores always upwards. This fungus undoubtedly belongs to ***O. sarraziniana***, a semiaquatic species with ascospores without a tail. Svrček (1954: 12) identified this material as *O. luteorubella* f. *pellucida*, a taxon which is, however, treated as a synonym of *O. cardui* in the present study. He found the spores 6–9 × 0.8–1 µm, which is in discordance with the present measurement (7.3–8.7 × 1.4–1.7 µm in KOH). Unexplainably, Svrček stated that the type contains only a few apothecia.

The ring-pored woody fragments taken from a decorticated log clearly belong to *Quercus*, not *Fagus* as stated in the protologue. This discrepancy in substrate, together with the severe inconsistency in micromorphology might be due to some confusion of the material.

Orbilia caulophylli Ellis & Everh., Proc. Acad. Nat. Sci. Philadelphia 45: 145 (1893)

≡ *Laetinaevia caulophylli* (Ellis & Everh.) Korf, Phytologia 21: 204 (1971)
≡ ***Diplonaevia caulophylli*** (Ellis & Everh.) B. Hein, Sydowia 36: 99 (1983)

According to Hein (1983) the species is confined to herbaceous stems of *Caulophyllum thalictroides* in North America and has asci with an amyloid apical ring.

Orbilia chlorina Rick, Brotéria, sér. Cienc. Nat. 1(1): 46 (1932)

No material could be found in GH, IACM, and W. The description of this taxon (Brazil, Rio Grande, on wood) is too brief to recognize its identity (apothecia 1–2 mm diam., sessile, greenish-chlorinaceous, asci 25–40 × 3–4 µm, sessile, polysporous, spores small, not further described, paraphyses yellowish, apically globose).

Hyalinia chlorinella (Ces.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza chlorinella* Ces., Bot. Ztg. 12: 186 (1854) [also in Flora (Regensburg) 37: 203 (1854)]
≡ *Pezizella chlorinella* (Ces.) Sacc., Syll. Fung. 8: 278 (1889)
≡ *Hymenoscyphus chlorinellus* (Ces.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ ***Calycellina chlorinella*** (Ces.) Dennis, Kew Bull. 30: 350 (1975)
≡ *Mollisiella chlorinella* (Ces.) Svrček, Česká Mykol. 31: 13 (1977)

The type material was reexamined by Lowen & Dumont (1984) who accepted Dennis's placement in the genus *Calycellina* Höhn. The species is very common in central Europe on blackened areas of herbaceous stems. The asci have an amyloid apical ring and arise from croziers, the latter character being not examined by Lowen & Dumont.

Orbilia chrysocoma (Bull.) Sacc., Syll. Fung. 8: 624 (1889)

≡ *Peziza chrysocoma* Bull., Herb. France 8: tab. 376, fig. 2 (1788); – Fr., Syst. Mycol. 2(1): 140 (1822), nom. sanct.
≡ *Hymenoscyphus chrysocomus* (Bull.) Gray, Nat. Arr. Brit. Pl. 1: 674 (1821)
≡ *Bulgaria chrysocoma* (Bull.) Sommerf., Suppl. Fl. Lapp.: 299 (1826)
≡ *Calloria chrysocoma* (Bull.) Fr., Summa Veg. Scand.: 359 (1849)
≡ ***Dacrymyces chrysocomus*** (Bull.) Tul., Ann. Sci. Nat., Bot., sér. 3, 19: 211 (1853)
≡ *Mollisia chrysocoma* (Bull.) Gillet [as '*Mollicia*'], Champ. Fr., Discomyc.: 212 (1887)
≡ *Guepiniopsis chrysocoma* (Bull.) Brasf., Am. Midl. Nat. 20: 226 (1938)

No authentic material of *Peziza chrysocoma* could be traced in E and PC (see also McNabb 1973: 501). The taxon was interpreted by later authors in very different ways, applied for fungi belonging to basidiomycetes (*Dacrymycetales*) as well as ascomycetes (*Orbiliomycetes*), e. g., by Saccardo (1878: 429), see also Donk (1964: 97). Today the taxon is accepted in the *Dacrymycetales*.

Bulliard's (1788) protologue, published also in Bulliard (1791: 254), describes the fungus as ~ 2–3 mm diam., more or less dark golden yellow, young like a small hollow bell, more or less flattened with age, on rotten wood. Donk (l.c.) believed that 'these characters would tend to exclude some of the minute discomycetes of which one is reminded when glancing superficially at Bulliard's plate'. In the absence of authentic material, Donk followed Fries's (1822: 140) interpretation of *P. chrysocoma*, material of which has been preserved (e. g., Scleromyc. Suec. 331, UPS). Donk referred to this material as *Dacrymyces chrysocomus*, and considered it to be a basidiomycete not uncommon in Europe, whereas Dennis (1954: 297) identified it as *D. stillatus* Fr. Donk also identified a specimen in Persoon's herbarium under the name '*Peziza chrysocoma* Fries / *P. aurea* ? Pers.' as *D. chrysocomus* (L 910.261–259). Similar as Donk, McNabb (1973: 501) argued that 'there are no major discrepancies between the two descriptions' of Bulliard and Fries, and that 'it seems reasonable to assume that Bulliard's name was not misapplied by Fries'. Nevertheless, neither Donk nor McNabb selected a neotype for *Peziza chrysocoma*.

Fuckel (1870: 283) considered a possible synonymy between *Calloria chrysocoma* and *C. deliquescens* (Bull.) Fr. [≡ *Dacrymyces deliquescens* (Bull.) Duby], and his concept of *Calloria* comprised, like that of Fries (1849), both ascomycetes and basidiomycetes today assigned to *Dacrymyces* Nees, as he believed that those without asci were anamorphs of discomycetes. Reexamination of Fuckel's *C. chrysocoma* (Fungi Rhen. Exs. 1130) in the present study revealed identity with *Orbilia xanthostigma*. Several later authors interpreted *P. chrysocoma* as a basidiomycete. Under the name *Dacryomyces chrysocomus*, Saccardo (1888: 798) described the basidiospores as 20–28 × 9–11 µm, multiseptate. Under the same name Brefeld (1888: 156, pl. 10 fig. 12–17) treated a fungus which McNabb (1973: 501) believed to be probably *Dacrymyces estonicus* Raitv. When Brasfield (1938, see Donk 1964) transferred the taxon to *Guepiniopsis* Pat., he applied it for a North American basidiomycete 'very different from Fries's' and, according to McNabb (l.c.), most probably belonging to *Heterotextus* Lloyd. McNabb accepted *P. chrysocomus* as a species of *Dacrymyces*, based on the study of specimens collected on coniferous wood by E.M. Fries, whereas Jülich (1984: 442) accepted placement in *Guepiniopsis*. Today the species is generally accepted as belonging to *Dacrymyces*.

In our opinion, Bulliard's brief diagnosis does not for sure exclude a discomycete. The consistency of the fruitbodies is not mentioned, and a bell-like shape occurs, e. g., also in young *Hyalorbilia inflatula*. Likewise, Dennis (1954: 297) stated that 'Bulliard's figure does indeed resemble an *Orbilia* but it is impossible to say which species he had'. However, since Fries's interpretation concerns a *Dacrymyces*, Dennis concluded that 'It is, therefore, unwise to attempt to attach the epithet *chrysocoma* Bull. ex Fr. to a species of *Orbilia*'.

In fact, many authors applied the name to a discomycete. In Persoon's herbarium at least two specimens under the name *P. chrysocoma* are ascomycetous (Sowerby, L 910.261–250, identified by Donk as *Orbilia* sp., not examined in present study; Junghuhn, L 910.261-249, identified in present study as *O. xanthostigma*, IVV: H.B. 7709). Moreover, Persoon (1801, 1822) hesitated regarding distinction between *P. chrysocoma* and his *P. aurea*, which was listed as a synonym of *P. chrysocoma* by Fries (1822: 140, 1874: 699) and also by some later authors. Specimens under the name *P. aurea* (without question mark) in Persoon's herbarium are found in the present study to comprise *Orbilia comma* and *O. xanthostigma*.

Saccardo (1878: 429, 1889: 624) appears to be the first to describe asci in *Calloria* or *Orbilia chrysocoma*; yet, he (1888: 798) also referred to Tulasne's and Fries's interpretation as a basidiomycete under the name *Dacryomyces chrysocomus*. Saccardo (1889) cited various hosts and countries for *O. chrysocoma* and compared it with *O. luteorubella*, whereas his diagnosis (1878, 1889) refers to a collection from Italy ([Venice, Treviso,] Conegliano, corticated branches of *Morus alba*, autumn 1877, C.L. Spegazzini), with subgelatinous, golden yellow apothecia scarcely 0.5 mm diam., asci subsessile, 40–45 × 5 µm, apex obtuse, spores 14–15 × 0.75–1 µm, bacilliform, slightly curved, paraphyses apically clavate. This diagnosis could represent *Hyalorbilia berberidis* if the asci are correctly described, or to *O. auricolor* if the spore data refer to the actual spore length. Rehm's (1891: 457), Grelet's (1948a: 50) and Seaver's (1951: 153) diagnoses of *O. chrysocoma* are merely copies of Saccardo's (1889). Also the description to an illustration in Cooke's (1892: 220, pl. 20 fig. 161) Handbook of Australian Fungi under the name *O. chrysocoma* exactly repeats Saccardo's measurements, although the collection data read 'on wood, Victoria'. Perhaps this refers to a specimen in K (*Mollisia chrysocoma*, near Melbourne, 12.VII.1886) which was found by B. Spooner (pers. comm.) to be a *Bisporella*.

Saccardo (1889, as *O. chrysocoma*) and Donk (1964: 98, as *D. chrysocomus*) mentioned Patouillard (1886: 130, fig. 293, as *C. chrysocoma*) who illustrated a fungus completely different from Saccardo's interpretation, with ellipsoid-fusoid, straight spores with a large central oil drop. This could be *Agyrium rufum*, except for the longer spores (18–20 × 7.2–8.6 µm, evaluated from Patouillard's scale). Gillet (1887) described as *M. chrysocoma* a yellowish-orange discomycete 2–3 mm diam. on conifer wood, with short clavate asci and globose ascospores with a strong 'sporule' (lipid or spore body?). Schröter (1893: 121) referred to *O. chrysocoma* a number of collections with golden yellow apothecia on various woody substrates. These could belong to *O. xanthostigma*, if the spores had not been described as cylindrical, mostly slightly curved, 4.5–5 × 1 µm. Feltgen (1899: 55, 1901: 36) referred to *O. chrysocoma* several collections on ligneous substrate. Two of them were found in his herbarium: one (Grünewald-Walferdingen, *Quercus*, LUX 42533) is identified here as *O. vinosa*, another (Ettelbruck, *Fagus*, LUX 42534) as *O. sarraziniana*. He further described *O. chrysocoma* var. *brassicicola* Feltgen on *Brassica oleracea* with spores of 10–15 × 1 µm, which is treated here as a synonym of *O. auricolor*. Benny et al. (1978) applied the name *O. chrysocoma* to a briefly mentioned specimen of *Orbilia* sp. in which a spore body was seen with the TEM.

Orbilia circinella (Pat.) Sacc. 1889, Syll. Fung. 8: 628 (1889)

≡ *Calloria circinella* Pat., Rev. Mycol. (Toulouse) 8: 179, pl. 59 fig. 1 (1886)

The holotype (China, Yunnan Province, stem of *Cypripedium*, undated, Abbé Delavay, herb. Patouillard, IVV: H.B. 5454) is not lost as suspected by Hein (1976), but exists at FH and contains numerous apothecia in good shape. The gelatinized hyaline ectal excipulum of textura angularis and the erumpent ochraceous apothecia seem to indicate a relationship to the genus *Naeviopsis* as circumscribed by Hein (1976). However, the asci sharply differ in having an apical ring of the *Calycina*-type which reacts deep blue (euamyloid) in IKI, whereas in *Naeviopsis* they are much broader and of the *Allophylaria*- or *Pezicula*-type and react red (hemiamyloid) or sometimes euamyloid. The whole ectal excipulum stains distinctly pale blue in IKI, a character not known in the genus *Naeviopsis*. In addition, typical members of *Naeviopsis* are characterized by an ectal excipulum that initially covers the hymenium and lacerates at maturity into star-like lobes (Hein 1976: 61, fig. 17), a feature not observed in *C. circinella*. A further characteristic of *C. circinella* are the apically enlarged, strongly hooked to circinate paraphyses. The short ascus stalks probably arise from croziers although they mostly appeared simple-septate.

A very similar species in which the excipulum likewise reacts euamyloid is *Pezizella orbilioides* Feltgen (see p. 1681). The two taxa might belong in the genus *Loricella* Velen., which was established by Velenovský (1934) for two species, *L. juncina* Velen. and *L. loricata* Velen. Later, he added four further species (Velenovský 1939, 1947). Based on the description, *Loricella* is probably heterogeneous: *L. juncina* has the characteristic hooked paraphyses, whereas *L. loricata* is a later synonym of '*Mollisia*' *spectabilis* Kirschst., a species that appears to belong in *Helotiaceae* based on the *Hymenoscyphus*-type of apical ring. Reexamination of the types of *L. juncina* und *L. loricata* is required and a lectotypification of *Loricella* necessary before this name can be used.

Hyalinia cisti Maire, Treb. Mus. Ci. Nat. Barcelona, Ser. Bot. 15(2): 15 (1933)

Material could neither be found in BC and MPU (R. Galán pers. comm.), nor in NCY and PC. The drawing and description of the protologue (on rotten leaves of *Cistus laurifolius*, in the mountains over Prades, Catalonia, Spain) refers to a species of *Helotiales* rather than *Orbiliomycetes*. The species appears to resemble *Orbilia rubicunda* (see below) in both macro- and microscopy, but is said to have a gelatinized excipulum without hairs, and inamyloid asci (in MLZ without KOH). Maire compared it with *Helotium microspis* (P. Karst.) Boud. [≡ *Calycellina microspis* (P. Karst.) Dennis].

Peziza citrinella Schwein., Trans. Am. Philos. Soc. II, 4: 177 (1832)

≡ *Pezizella citrinella* (Schwein.) Sacc., Syll. Fung. 8: 287 (1889)
≡ *Hymenoscyphus citrinellus* (Schwein.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)

No apothecia could be found in the holotype specimen in PH (USA, Pennsylvania, Bethlehem, very rotten wood of *Salix*). Schweinitz compared *P. citrinella* with *P. chrysocoma*. Therefore, Saccardo who treated the latter as *Calloria chrysocoma*, noted that *P. citrinella* could be a *Calloria*. Seaver (1951: 161) stated that *P. citrinella* is 'probably an *Orbilia*'. The brief protologue of *P. citrinella* includes: apothecia sessile, with an always distinct, obtusely thick margin, ± flexuous, uniformly lemon-yellow, 1 line (~2 mm) diam. The identity of *P. citrinella* remains obscure.

Stictis coccinea Fr., Elenchus Fung. 2: 24 (1828)

≡ *Ocellaria coccinea* (Fr.) Rehm, Rabenh. Krypt.-Fl., 1.3: 136 (1888)
≡ *Propolis coccinea* (Fr.) Sacc., Syll. Fung. 15: 306 (1900)

Without seeing type material, Höhnel (1917: 333) assumed that this taxon (VI. [no year], on dead branches of *Morus alba*, [J.F. de] Chaillet) is very probably closely related to *Habrostictis rubra*. Sherwood (1977: 167, see also Verkley 1999: 144) found the holotype to be 'immature Hypocrealean stroma' and stated that Nannfeldt (1929) suggested this to be ***Nectria verrucosa*** (Schwein.) Sacc.

Helotium coccinellum (Fr.) Boud., Hist. Class. Discom. Eur.: 112 (1907)

≡ *Peziza coccinella* Fr., Syst. Mycol. 2(1): 125 (1822), nom. sanct. [non *P. coccinella* Sommerf. 1828, ≡ *Orbilia coccinella* Fr.]
≡ *Phialea coccinella* (Fr.) Gillet, Champ. Fr., Discomyc.: 211 (1887)

Fries (1822) described *Peziza coccinella* based on Micheli (1729: 205, pl. 86 fig. 12, as '11. Fungoides ...'). Judging from Micheli's and Fries's brief diagnoses (see also Saccardo 1892: 10) and Micheli's illustration, the taxon obviously refers to a cyphelloid basidiomycete. The minute fungus is described with thin and rather long stipes, and deeply urceolate cups. The fruitbodies are strongly geniculate at the connection between stipe and receptacle, with the cups pointing downwards. It appears that the existence of *Peziza coccinella* Fr. and its competition with the homonym *P. coccinella* Sommerf. has been neglected in the literature since Boudier (1907). Fries (l.c.) cited *P. nutans* Batsch and *P. cernua* Pers. as synonyms, which likewise seem to represent cyphelloid fungi (both names mean nodding). It remains mysterious why Fries introduced the epithet *coccinella* despite the existence of *P. nutans* and *P. cernua*.

The collections which Gillet (1887) reported under the name *Phialea coccinella* concern 'sessile or stipitate' fruitbodies. The microscopic features appear to refer to an *Orbilia*, perhaps *O. eucalypti* (asci cylindric-subclavate, spores ovoid, paraphyses with globose apical inflation).

Orbilia coccostigma (Wallr.) Sacc., Syll. Fung. 8: 631 (1889)

≡ *Peziza coccostigma* Wallr., Fl. Crypt. Germ.: 466 (1833)

No type material of this species (Germany, Harz mountains, on decorticated wood of *Abies*) could be found in PRM and STR. The fruitbodies were described as scarlet-red ('rubrococcinea') but their size was not stated and no information on the hymenial elements was given, therefore, *P. coccostigma* is considered as a nomen dubium. An old collection under that name in PRM (727318, without collection data except for 'Neuhof') was examined which contains abundant perithecia of an orange *Nectria* (?*peziza*) fruiting on decorticated wood of a ?*Rosaceae*.

Orbilia coleosporioides Sacc. & D. Sacc., Syll. Fung. 18: 139 (1906)

≡ *Orbiliopsis coleosporioides* (Sacc.) Syd., Ann. Mycol. 22: 308 (1924)

This is the type species of *Orbiliopsis* (Sacc.) Syd., a small group of fungi parasitic on living leaves. Following Nannfeldt (1932) the group could be of the ascolocular type (see also p. 207). No material of this species could be found in PAD.

Peziza conchella Schwein., Trans. Am. Philos. Soc. II, 4: 177 (1832)

≡ *Pezizella conchella* (Schwein.) Sacc., Syll. Fung. 8: 284 (1889)
≡ *Hymenoscyphus conchellus* (Schwein.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)

Without type study, Massee (1894b: 99) mentioned this species as a possible synonym of *Peziza cruenta* Schwein. The holotype specimen in PH (USA, Pennsylvania, Bethlehem, Syn. #942) was examined. It merely contains sporodochia of a hyphomycete growing erumpent through the periderm of a 6 mm thick woody branch of an unidentified angiosperm, with very sparsely occurring cylindric(-ellipsoid) conidia of 5.8–6.5 × 1.7–2.7 µm (conidiophores not seen). The tissue is composed of a light orange, medium gelatinized textura angularis. W.-R. Arendholz (in sched.) referred to this specimen as 'sporodochia of a *Tuberculariaceae*'.

Calloria coccinella f. **condensata** W. Phillips, Man. Brit. Discomyc.: 329 (1887)

No material has been studied of this taxon, which was considered to be a form of *Calloria coccinella* (Sommerf.) W. Phillips (≡ *Orbilia coccinella* Fr.). It was characterized by the words 'Forming condensed fasciculate heaps, Forres, N.B. [Scotland], in Herb. Currey'.

Orbilia corticalis Velen., Monogr. Discom. Bohem.: 101, pl. 11 fig. 25 (1934).

No material exists of this taxon (on *Picea* bark) following Svrček (1954), who concluded from the protologue that it is a synonym of *Orbilia berberidis* Velen. (≡ *Hyalorbilia berberidis*). The ascus bases, however, are figured with flexuous stalks which suggest identity with *O. auricolor*, if there were not the minute apothecia of '< 0.1 mm' diam. No manuscript notes were found for this taxon.

Patinella crandallii Sacc., Syll. Fung. 11: 434 (1895)

≡ *Patinella macrospora* Ellis & Everh., Proc. Acad. Nat. Sci. Philadelphia 46: 354 (1894) [non *P. macrospora* Massee 1893]

Ellis & Everhart described this taxon on dead stems of *Geum rossii* from Southern Rocky Mountains (USA, Colorado, above Cameron Pass, 3660 m, VII.1894, C.S. Crandall), with olive-black apothecia 3/4 mm diam., capitate olivaceous paraphyses, and hyaline ellipsoid spores 20 × 10 µm. A specimen under the name *P. crandallii* (USA, Colorado, Bottomless Pitt, 3600 m, on stems of *Sieversia turbinata* ≡ *Geum rossii* var. *turbinata*, VII.1906, F.E. & E.g. Clements, herb. Petrak, M) fits well the protologue. It has ellipsoid smooth spores 18.5–22 × 9.5–10.5 µm with 2 large LBs 5–7 µm diam. The ascus apex is broadly conical and has a strongly reactive (IKI blue, type BB), 1.5–2.2 µm high and 5–6 µm wide apical ring similar as in *Drepanopeziza* (Kleb.) Höhn. The asci arise from croziers and measure 105–120 × 18–22 µm. The brownish paraphyses have a ± globose apical cell 7–9 µm wide and are covered by dark brown exudate. The ectal excipulum is a blackish-brown textura angularis, and the black apothecia (dry 0.3–0.6 mm diam.) are subepidermally erumpent. The species shows some similarity with the genus *Drepanopeziza*, especially regarding its apical apparatus. Ellis & Everhart compared it with *P. hyalophaea*, the type species of *Patinella*.

Orbilia crocina (Mont. & Fr.) Sacc., Syll. Fung. 8: 632 (1889)

≡ *Peziza crocina* Mont. & Fr., in Montagne, Ann. Sci. Nat., Bot., sér. 2, 5: 289 (1836) [non *Peziza crocina* Berk. & Curt. 1868, ≡ *Calycella crocina* (Berk. & Curt.) Dennis]
= ***Dendrodochium citrinum*** Grove, J. Bot. 24: 206, pl. 287 fig. 8 (1886)
(?)= *Lemalis aurea* (Lév.) Sacc., Syll. fung. (Abellini) 3: 672 (1884)
≡ *Catinula aurea* Lév., Annls Sci. Nat., Bot., sér. 3, 9: 248 (1848)

Peziza crocina was described from decorticated unidentified branches (France, Ardennes, Sedan, Bois de Marfée, undated, J.P.F.C. Montagne) for sessile, gelatinous, saffron-yellow apothecioid fructifications up to 1 mm diam., which form at first purplish dots and stain the wood yellow around them (Montagne 1836). The hymenium was said to be composed of 'hyaline linear asci' from which 'numerous spheric sporidia' easily detach. The authors were, however, unsure whether the spores are formed inside these linear elements or only at their tips, and compared the fungus with the genus *Dacrymyces*, but also with *Peziza chrysocoma* Bull. and *P. coccinella* Fr. When Saccardo (1889) combined *P. crocina* in *Orbilia*, he referred to it another collection (on wood chips, Singapore, Malacca, [O.] Beccari).

A syntype in herb. Desmazières (IVV: Pl. Crypt. N. France, Ed. 1 1863 N° 8) was received from PC. The label bears handwritten notes which closely correspond to the protologue. The fungus is mitosporic and has a gelatinized excipulum, narrow phialides in a palisade, and subglobose conidia measuring †1.8–2.2 × 1.5–1.9 µm. Possibly it is the anamorph of a helotialean genus (*Calycina*?). When the specimen was studied, the wood anatomy was possibly examined but no notes were now found.

Conspecific or closely related recent collections were studied by us and by P. Perz (pers. comm.), forming white or yellow cupulate to disc-shaped conidiomata on coniferous substrate. The phialides and conidia of *P. crocina* closely resemble those of *Sarea resinae* (Fr.) Kuntze [= *Pycnidiella resinae* (Ehrenb.) Höhn.] (*Lecanorales*) as described in Hawksworth & Sherwood (1981) and frequently found by us on resinous wounds of conifers. Yet, the anamorph of *S. resinae* differs in having pycnidia with a defined ostiolum.

Grove (1886) described *Dendrodochium citrinum* on rotten wood of *Pinus sylvestris* from Barnt Green, Worcestershire, UK, including yellow sporodochia of 0.5 mm diam., verticillate, filiform 'basidia', and globose, smooth, yellowish, guttulate conidia of 1.75 µm diam. formed acrogenously. Based on the brief description and illustration, it is regarded here to be a synonym of *Peziza crocina*. No molecular data of this taxon appear to exist. In a strict sense, *Dendrodochium* Bonord. is probably a synonym of *Clonostachys* Corda (*Bionectriaceae*) (see Seifert et al. 2011).

Lemalis aurea, on rotten trunks of conifers in France, is a probable further synonym of *P. crocina*, being described with yellow sporodochia of pinhead size, conidiophores in parallel palisades, and globose, minute, smooth, concolorous conidia (no size given). The genus *Lemalis* Fr. is based on another species of unclear relationship.

Hyalinia crouanorum Boud., Hist. Class. Discom. Eur.: 104 (1907) [non *Hyalinia agyrioides* (Desm.) Boud.]

≡ *Helotium agyrioides* P. & H. Crouan, Florule Finistère: 47 (1867)
≡ *Calycina agyrioides* (P. H. Crouan) Kuntze [as '*agyriodes*'], Revis. Gen. Pl. 3: 448 (1898)
?= ***Agyrium rufum*** (Pers.) Fr., Syst. mycol. (Lundae) 2(1): 232 (1822)

An authentic specimen (on rotten wood of *Quercus*) was redescribed by Le Gal (1953: 122), who considered it to represent a pale form of *Agyrium rufum*. Le Gal found the lecanoralean-like asci to stain 'blue in iodine'.

Orbilia cruenta (Schwein.) Morgan, J. Mycol. 8: 182 (1902)

≡ *Peziza cruenta* Schwein., Trans. Am. Philos. Soc. ser. II, 4: 177 (1832) [non *P. cruenta* Wallr. 1833, see Saccardo (1889: 428, as *Trichopeziza cruenta*); nec *P. cruenta* Bong. 1836, see Saccardo (1889: 339, as *Mollisia cruenta*)]
≡ *Pezizella cruenta* (Schwein.) Sacc., Syll. Fung. 8: 284 (1889)
≡ *Hymenoscyphus cruentus* (Schwein.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ *Tubercularia cruenta* (Schwein.) Höhnel, Mitt. bot. Inst. tech. Hochsch. Wien 3: 69 (1926)

The type specimen (USA, Pennsylvania, Bethlehem, on bark of unidentified branches) could not be located in BPI, K, and PH. The translated protologue reads about as follows: 'small, sparse, sessile, flattened, blood-red ('cruenta'), subtranslucent, with a raised margin being whitish crenulate or sprinkled by pruina, disc concave, circular, hardly exceeding ½ line [~1 mm]'. Nannfeldt (1932: 252) tentatively placed *Orbilia cruenta* in synonymy with *O. rubella* (as *Hyalinia rubella*), yet without studying the type. As long as no type material can be located and the microscopic features determined, *O. cruenta* must be treated as a nomen dubium.

Massee (1894b: 99) redescribed *O. cruenta* under the name *Peziza cruenta* and considered *P. fibriseda* Berk. & Curt., *P. regalis* Cooke & Ellis, *P. rufula* Schwein., and *P. saccharifera* Berk. as synonyms. He mentioned to have examined 'specimens from Schweinitz, also Berkeley's type specimens', as well as Ellis & Everhart (N. Amer. Fungi II 2326) and Ellis (N. Amer. Fungi 438), probably all from K. Collection data are given for two specimens, according to which it can be seen that M.J. Berkeley 3311 was the type of *P. fibriseda* and M.J. Berkeley 5208 that of *P. saccharifera*. Although existing at K, Massee did not mention the type of *P. regalis* [M.C. Cooke 2778, U.S.A., New Jersey, Newfield, on bark of *Malus*, undated, J.B. Ellis, K(M) 35323], but only N. Amer. Fungi 438 (publ. 1880, Newfield, on bark of *Malus*, undated, J.B. Ellis, K(M) 180561), which possibly represents a duplicate exsiccata hereof. Since Massee wrote that he saw specimens from Schweinitz, it can be assumed that he examined the types of both *O. cruenta* and *P. rufula*. However, it is not clear then why the type of *O. cruenta* cannot now be found at K.

Massee (l.c.) described *Peziza cruenta* with paraphyses having clavate to lanceolate apices, small asci [size not given] with long, slender, crooked stalk, spores 4–5 × 1.5 µm, cylindric-oblong, ends obtuse, and apothecial margins with tufts of hairs 25–35 × 5–6 µm, agglutinated by honey-coloured amorphous lumps. It is not clear from which of the specimens this description was gained, also the identity of the described fungus cannot be stated in the absence of any illustration. Massee's synonymisation was followed by Morgan (1902: 182) and Seaver (1951: 158), and Seaver included also *O. occulta* in this synonymy.

In the present monograph, all these taxa (except for *P. cruenta*) were studied from the type material and found to belong to five different species of *Orbilia*. Apart from *P. rufula* (Pl. 875: 1), which has a smooth margin and belongs in the scope of *O. xanthostigma* (section *Orbilia*), they fit in their macroscopy the original description of *P. cruenta* in having a raised, whitish crenulate or pruinose margin. *Peziza fibriseda* (Pl. 572: 2) has rather large asci and spores and is considered here to be conspecific with *O. carpoboloides* (section *Habrostictis*). *O. occulta* (N. Amer. Fungi 438, Pl. 353: 3) has spores with a thin tail and asci with a rounded, thick-walled apex and is closely related to *O. aristata* (section *Hemiorbilia*); an immature population associated with the type of *O. regalis* in M.C. Cooke 2778 appears to belong to this species. The types of *P. saccharifera* (Pl. 426) and *P. regalis* (Pl. 389) correspond to Massee's description in their small asci and spores, but have differently shaped spores and belong in the vicinity of *Orbilia rubella* and *O. aradi*, respectively (section *Aurantiorubrae*).

N. Amer. Fungi II 2326 is a rich specimen issued under the name *Peziza cruenta* [USA, Delaware, Wilmington, bark of *Morus*, IX.1889, A. Commons, K(M) 48760]. It was also examined in the present study and found to belong to *O. carpoboloides*, particularly to the here synonymised *O. piloboloides* because of its short spores (Pl. 571: 2). A photocopy of an undated specimen (USA, Ohio, Preston, bark of *Gleditsia*, A.P. Morgan, herb. G. Massee) under the name *Pezizella cruenta* in K shows a sketch by Massee with much smaller spores of 5–7 × 1.5 µm, asci of 60 × 5 µm, and apically clavate paraphyses, which better corresponds to Massee's (1894b) description, but it might have been collected later as he did not mention *Gleditsia* there.

Höhnel (1926a: 69) found a specimen of *P. cruenta* (Ellis & Everhart, Fungi Columb. 1553) to be a mitosporic fungus, *Dendrodochium hymenuloides* Sacc. [= *Tubercularia hymenuloides* (Sacc.) Höhnel]. He concluded that *P. cruenta* must be combined as *Tubercularia cruenta* in the case this material is conspecific with Schweinitz's fungus.

Orbilia crystallina Rodway [as '*crystalina*'], Pap. Proc. Roy. Soc. Tasm.: 114 (1920) [non *Orbilia crystallina* (Quél.) Baral 1994, nom. illegit., ICN Art. 53.1, = *O. crenatomarginata* (Höhn.) Sacc. & Trotter]

The type (Tasmania, on soil) was not ordered. The habitat, the large ascospores (18 × 7 µm, ellipsoid with acute ends) and the large excipular cells suggest a member of *Pezizales*. The apothecia are described as 1–2 mm diam., orange, the hymenium at first covered by a crystalline membrane that bursts to form a toothed margin (see also Saccardo et al. 1928: 1239).

Orbilia cucurbitae (W.R. Gerard) Seaver, North American Cup-fungi (Inoperculates): 155 (1951)

≡ *Peziza cucurbitae* W.R. Gerard, Bull. Torrey Bot. Club 5: 26 (1874)
≡ *Pezizella cucurbitae* (W.R. Gerard) Sacc., Syll. Fung. 8: 285 (1889)
≡ *Hymenoscyphus cucurbitae* (W.R. Gerard) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
?= *Pseudombrophila deerrata* (P. Karst.) Seaver, North American Cup-fungi, (Operculates) (New York): 141 (1928)

Authentic material, on dried rinds of squash (*Cucurbita*) was restudied by Dennis (1964: 40) who found this to be a synonym of *Pseudombrophila deerrata* or a closely allied fungus.

≡ *Pezizella diaphanula* (Cooke) Sacc., Syll. Fung. 8: 279 (1889)
≡ *Hymenoscyphus diaphanulus* (Cooke) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ *Hyalinia diaphanula* (Cooke) Boud., Hist. Class. Discom. Eur.: 104 (1907)

Type material of *Habrostictis diaphana* (Romania, Siebenbürgen, Hunyad, at Zenoga lake below Retyezát, stems of *Angelica* ?*sylvestris*, VIII.1873, H. Lojka, Rehm, Ascomyc. 210, M, IVV: H.B. 4673) and several fresh collections referred to this species have been studied (IVV: e.g. H.B. 3798a, 9177b). The apothecia have sparse to abundant, broad, gradually tapering glassy hairs with an inflated base to which the lumen is restricted. A fine channel extends to the very tip but is nearly invisible in the middle part of the hair. The glassy matrix is inamyloid and loses refractiveness in 5 % KOH, at least when heated. The asci arise from croziers and have a rather strongly hemiamyloid (type RR) apical ring of the *Pezicula*-type, except that the upper part of the ring is less reactive. The species appears to be not uncommon on various large perennial herbs in subalpine to alpine but also colline regions of Europe.

Very similar is *Hyalopeziza raripila*, which occurs on a wide range of herbaceous stems in colline to altimontane habitats. It differs mainly in faintly hemiamyloid or often inamyloid ascus apices, a glassy hair matrix not dissolving in 5–10 % KOH (even when heated) and usually staining pale bluish-violet in IKI towards the hair base, and a tendency to form longer or narrower ascospores. In both species the hairs may be abundant or sparse, the abundance varying even within a population. In one collection of *H. raripila* (Luxembourg, Wiltz, Doncols, *Althaea rosea*, M.T. Tholl, H.B. 6936) the hairs were completely absent in most apothecia, with a single hair detected only on one of them.

Both taxa have apically flexuous to bent paraphyses and possibly belong to the *Calloriaceae* rather than the *Hyaloscyphaceae*. This view is supported by the presence of a mucilaginous sheath around the spores, being characteristic of both species as well as, e.g., *Laetinaevia adonis* (Fuckel) Hein. They appear to differ from typical members of *Laetinaevia* Nannf. merely in the presence of glassy hairs. Because of the inconsistent presence of these hairs they might well represent good members of *Laetinaevia*. Macroscopically both species can easily be mistaken in the field for an *Orbilia*, a fact also stated by Höhnel (1917: 330) for *Hyalopeziza raripila* (as *Unguicularia raripila*). Hein (1976: 59) tentatively placed *Naevia diaphana* close to *Chaetonaevia nannfeldtii* Arx, the type species of the monotypic genus *Chaetonaevia* Arx. The hairs of *C. nannfeldtii* as figured by Arx (1951) are actually very similar in shape, but with a broad lumen extending to the very apex, the walls being ~1 µm thick from base to tip. A further synonym of *Laetinaevia* appears to be the genus *Iridinea* Velen. (see also under *Calloria gentianae*, p. 1672).

Hyalopeziza latispora Raitv. and its synonyms *H. schachdarica* Raitv. and *H. archangelica* Olsen & Sivertsen appear to be synonymous with *Naevia diaphana*, judging from the description in Raitviir & Huhtinen (1997: 454), although the hair walls were stated not losing refractiveness in KOH. That the asci are described as inamyloid could be due to the use of MLZ without KOH-pretreatment. Yet, according to Huhtinen (pers. comm.) the paratype of *H. archangelica* from Greenland is inamyloid also after treatment with KOH, whereas a specimen from France (Val d'Isere, on *Cirsium spinosissimum*, 31.VIII.1992, TUR 105053), assigned to *H. latispora* by Raitviir & Huhtinen (l.c.), reacts deep blue in both MLZ and IKI (type BB) without KOH. This particular specimen, with the narrowest spores amongst the treated material, is a misidentification and represents another, unnamed species (Huhtinen pers. comm.). Though believed to be a synonym of *H. latispora*, *H. schachdarica* differs in the hair lumen extending to the very apex (Raitviir & Huhtinen l.c., fig. 7b) similar as in *C. nannfeldtii*.

Conclusions about the possible existence of different species in this group must await reexamination of the types concerning ascus amyloidity, and also need vital study of fresh collections. Molecular studies would be appreciated in order to clarify the relationship of this group within the *Helotiales*. An unpublished ITS sequence of *Hyalopeziza raripila* (S. Helleman pers. comm.) shows a high similarity (0.2–0.4 %) with various species of the anamorph genus *Tetracladium* de Wild. and 3 % with *Laetinaevia carneoflavida* (Rehm) Nannf. ex B. Hein. This result confirms a close relationship of *H. raripila* with *Laetinaevia* in the current circumscription of this genus and indicates an interesting, previously unknown connection to a genus of anamorphs.

Although no sequence was available of the type species *L. lapponica* (Nannf.) Nannf. [= *L. adonis* fide Hein 1976], its morphological similarity with *L. carneoflavida* suggests congenericity, according to recent studies of these two species in the living state (IVV: e. g. H.B. 2889, 6371, 9055b). Because the number of species accepted in *Laetinaevia* distinctly exceeds that in *Tetracladium*, we here propose to **protect** the younger name *Laetinaevia* over *Tetracladium*. As a consequence of this, new combinations in *Laetinaevia* are here proposed for the three involved teleomorph-typified species.

Laetinaevia raripila (Höhn.) Baral & Helleman, **comb. nov.** — MB 826712

Basionym: *Unguicularia raripila* Höhn., Ber. dt. bot. Ges. 35(3): 248 (1917)
≡ *Hyalopeziza raripila* (Höhn.) Huhtinen, Karstenia 27(1): 12 (1988) [1987]
(?)= *Iridinea anserina* Velen., Monogr. Discom. Bohemiae: 299, fig.a 61 (1934)

The type in K ([New Jersey,] VII.1874, on rotten, stromatized wood of a 30 mm thick decorticated branch of apparently *Magnolia*, according to wood anatomy, herb. Cooke, Ellis & Everh. N. Amer. Fungi 2161, K(M) 48782, IVV: H.B. 5755) consists of about a hundred subsessile apothecia (rehydrated 0.13–0.25 mm) in good shape. The species fits *Calycellina* in having an ectal excipulum of horizontal, gelatinized textura porrecta, and a grey-brown basal ring. The ascospores measure 10–12.8 × 3–4 µm and have a high lipid content (OCI 4, ?multiguttulate). A few obviously overmature spores are 1-septate and without lipid. The apical ring of the asci resembles the *Ploettnera*-type in having a small, strongly euamyloid lower part and a faintly reactive and slightly laterally extending middle part, whereas the upper part is inamyloid.

Peziza diaphanula appears to be closely related to *Leptodontidium trabinellum*, particularly because of the basally densely septate paraphyses. *L. trabinellum* markedly differs in a thin-walled textura globulosa(-prismatica) oriented under a high angle, and an apical ring of the *Calycina*-(or *Allophylaria*-)type. The protologue of *P. diaphanula* gives smaller apothecia (0.1 mm) and much larger spores (17–20 × 8 µm). Since the population in the type looks uniform, there seems to be no doubt that Cooke was dealing with this fungus. Probably Cooke's measurements are erroneous. Surprisingly, a note on the label indicates that R.W.G. Dennis could not find any apothecia.

Another specimen in K (USA, Newfield [New Jersey], VI.1887, branch of *Magnolia* lying on the ground in swampy woods, Ellis & Everh. N. Amer. Fungi II 2046, K(M) 36001, erroneously as 'type', IVV: H.B. 5528) differs from the type merely in growing on bark, and appears to be conspecific (ascospores 10–10.5 × 3–3.5 µm, multiguttulate). Unlike the type, a distinct blue IKI-reaction of the ectal excipulum was here observed, especially near the base, a feature also often seen in *L. trabinellum*. According to Seaver (1951: 153), the species was only known from the type locality, on bark and wood of decaying *Magnolia*.

For *Leptodontidium* de Hoog [type species *L. elatius* (F. Mangenot) de Hoog, anamorph of *L. trabinellum*], a new family *Leptodontidiaceae* was proposed (Hernández-Restrepo et al. 2017).

Hyalinia dilutella (Fr.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza dilutella* Fr., Syst. Mycol. 2(1): 147 (1822)
≡ *Pezizella dilutella* (Fr.) Fuckel, Jahrb. Nassau. Ver. Naturkd. 23–24: 300 (1870)
≡ *Mollisia dilutella* (Fr.) Gillet, Champ. Fr., Discomyc.: 131 (1882)
≡ *Niptera dilutella* (Fr.) Rehm, Rabenh. Krypt.-Fl., 1.3: 556 (1896)
≡ *Hymenoscyphus dilutellus* (Fr.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ *Pyrenopeziza dilutella* (Fr.) Gminder, Index Fungorum 302: 1 (2016)

The taxon was described by Fries (1822) on dry stems of *Epilobium angustifolium*, with sessile, glabrous, whitish-grey apothecia with a white margin. No type material could be found in UPS. A specimen in the herbarium E. Fries (UPS), collected by M.R. Roberge in Caen and identified by him as *Peziza dilutella* Fr., contains a black fungus growing on stems of *Cerastium*. It resembles a *Spilopodia* but was not examined with the microscope during a short stay at UPS and remained therefore unclarified (for macrophotos see IVV). Recent collections on *Rubus* stems tentatively identified as *Niptera dilutella* by Baral (in Weber 1992: 34) are shown here to be conspecific with the type of *Orbilia rubicola* (Cooke & Phill.) Sacc. (see p. 1684). In the absence of a type specimen, *P. dilutella* could be considered as a nomen dubium, if not Roberge's specimen as accepted by Fries is designated as epitype.

Orbilia divisa Velen., Monogr. Discom. Bohem.: 96, pl. 11 fig. 36 (1934)

No material under this name exists following Svrček (1954). The diagnosis (on bark of *Populus*) and the manuscript plate suggest a possible identity with *O. cardui* or *O. cotoneastri* (hardly inflated paraphyses, narrowly ellipsoid, 5–6 µm long spores).

Patinella dryadea Velen., Monogr. Discomyc. Bohem.: 75 (1934)

During a revision of the Slovakian type material (Tatra Mts, on stems of *Dryas octopetala*) and a French collection (Pyrenees) identified so by Chlebicki (1995: 396), the author found this taxon to be a species of *Lecanorales* and possibly a representative of the lichen genus *Lecidella* Körb. The spores, which were described as 10–12 µm long, ovoid-ellipsoid, hyaline, could not be found in the type. Ascus apical structure and iodine reaction were not reported by Velenovský and Chlebicki. Reexamination of the French collection revealed a deep blue IKI-reaction of the entire ascus (A. Chlebicki pers. comm.).

Hyalinia elaeina (Pass. & Beltr.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Niptera elaeina* Pass. & Beltr., *Atti R. Acad. Lincei*, Trans., sér. 3 **7**: 37 (1882) [also in Hedwigia 22: 121 (1883)]
≡ *Pezizella elaeina* (Pass. & Beltr.) Sacc., Syll. Fung. 8: 283 (1889)

When requesting type material, no response was received from PI and PARMA. The species was described from decorticated wood of *Olea europaea*, Monostalla, Sicilia (Italy). The apothecia were described as pale saturn-red ('miniata', no size stated), with in dry state undulating smooth margin, the asci as short-cylindrical, 27–30 µm long, 8-spored, inamyloid, the spores as narrow, rod-shaped, 12 × 4 µm. The indicated spore width could be erroneous, considering the given spore shape and ascus length. Until type material becomes available, the species is considered as a nomen dubium.

Habrostictis elegans Rabenh., Hedwigia 13: 184 (1874)

The brief, unillustrated diagnosis of this species (on wet wood near Salem, southern Germany, Rabenhorst Fungi Eur. Exs. XIX) is only microscopical and does not give any measurements: asci linear-sublanceolate, 8-spored, inamyloid, soon evanescent, ascospores uniseriate (straight or oblique), ovate-ellipsoid or subpyriform, hyaline, pseudoseptate (with divided cytoplasm), paraphyses filiform. Placement in *Habrostictis* Fuckel and comparison with *Stictis ocellat*a (= *Pezicula ocellata*) suggests that the apothecia resembled a *Pezicula* with a fringed margin. However, the habitat and the inamyloid, evanescent asci are in conflict with that genus. No reexamination of this exsiccata came to our notice.

Orbilia epiblastematica (Wallr.) Fr., Summa Veg. Scand.: 357 (1849)

≡ *Peziza epiblastematica* Wallr., Fl. cryptog. Germ. 2: 464, no. 2480 (1833)
≡ *Patellaria epiblastematica* (Wallr.) Sacc., Syll. Fung. 8: 788 (1889)
≡ ***Scutula epiblastematica*** (Wallr.) Rehm, Rabenh. Krypt.-Fl., 1.3: 294 (1890)
≡ *Biatorina epiblastematica* (Wallr.) A.L. Smith, Monogr. Brit. Lich. 2: 132 (1911)
≡ *Spilodium epiblastematicum* (Wallr.) Nieuwl., Am. Midl. Nat. 4: 385 (1916)
≡ *Catillaria epiblastematica* (Wallr.) Vain., Lichenogr. Fenn. 4: 448 (1934)

Scutula epiblastematica is a lichenicolous species that exclusively grows on thalli of *Peltigera* (Triebel et al. 1997). *Scutula* Tul. is a member of *Lecanorales*, but placement in a family seems not yet settled (P. Diederich pers. comm.). Lumbsch & Huhndorf (2010) placed it in *Pilocarpaceae*, but in Jaklitsch et al. (2016) it is in *Ramalinaceae*. See also under *Orbilia peltigerae*, p. 1681.

Orbilia erythrostigma (Mont.) Quél., Enchir. Fung.: 298 (1886) [non *Orbilia erythrostigma* (W. Phillips) Matočec et al. 2005, as '(Berk. & Broome) Boud.', nom.inval., Art. 41.5 ICN, ≡ *Hyalorbilia erythrostigma*]

≡ *Peziza erythrostigma* Mont., Ann. Sci. Nat., Bot., sér. 2, 18: 246, no 47 (1842) [non *Peziza erythrostigma* Berk. & Broome 1866, nom. illegit., ICN Art. 53.1, ≡ *Hyalorbilia erythrostigma*]
≡ *Nectria erythrostigma* (Mont.) Tul. & C. Tul., Select. fung. carpol. 3: 196 (1865)
≡ *Nectriella erythrostigma* (Mont.) Sacc., Syll. Fung. 9: 942 (1891)
≡ ***Octosporella erythrostigma*** (Mont.) Döbbeler, Feddes Repert. 115: 6 (2004)

This bryophilous species was recently (Döbbeler 2004) found to be an earlier synonym of *Octosporella urosperma* Döbbeler (*Pezizales*). The very small, perithecioid ascocarps appear to be confined to *Frullania dilatata*. Montagne (1842) placed the species in vicinity of *Peziza xanthostigma* and *P. leucostigma* and, perhaps therefore, Quélet made the combination in *Orbilia*, followed by Saccardo (1889: 632).

Hyalinia excavata (Saut.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza excavata* Saut., Flora (Regensburg) 24: 314 (1841)
≡ *Pezizella excavata* (Saut.) Sacc., Syll. Fung. 8: 287 (1889)
≡ *Hymenoscyphus excavatus* (Saut.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)

No material was found in BREG, LI, SZB, and W. Also Winter (1881: 132) and Keißler (1917: 109) were unable to locate a specimen. The taxon (Austria, Salzburg, Pinzgau, Mittersill, on rotten wood, 24.XI.1838, A. Sauter) was compared with *Mollisia leucostigma* [(Fr.) Gillet, ≡ *Orbilia leucostigma*] (see Saccardo 1889). The description (yellow, submembranaceous, smooth, concave, with undulating margin, ½ Linie [~1 mm] diam.) might refer to *Hyalorbilia inflatula* or *Orbilia xanthostigma*.

Orbilia fairmanii (Rehm) Seaver [as '*fairmani*'], North American Cup-fungi (Inoperculates): 154 (1951)

≡ *Pezizella fairmanii* Rehm [as '*fairmani*'], Ann. Mycol. 5: 519 (1907)

The asci of the holotype (USA, New York, Lyndonville, decorticated branch of *Tsuga canadensis*, IV.1906, C.E. Fairman, S-F9713, IVV: H.B. 6425) arise from croziers and have strongly euamyloid apical rings (*Calycina*-type), although Rehm (1907) stated 'I-'. The ascospores measure 4.5–7 × 2–2.4(–2.7) µm and contain some small LBs. The species strongly resembles *Orbilia hyalinula* (see p. 1674), which differs in distinctly smaller amyloid rings and in occurring on bark of ?*Acer*. Both taxa might belong in the genus ***Calycina***, but the excipular structure could not clearly be seen in *O. fairmanii*.

Orbilia flavoviridis (P. & H. Crouan) Quél., Enchir. Fung.: 298 (1886)

≡ *Helotium flavoviride* P. & H. Crouan [as '*flavoviridis*'], Florule Finistère: 47 (1867)
≡ *Calycina flavoviridis* (P. & H. Crouan) Kuntze, Revis. Gen. Pl. 3: 448 (1898)
≡ *Corynella flavoviridis* (P. & H. Crouan) Boud., Hist. Class. Discom. Eur.: 99 (1907)

According to a reexamination by J.P. Priou (pers. comm.), 2 packets bearing the name '*Helotium flavoviridis*' can be found at CO. One (Kergontès [part of Gouesnou, north of Brest], on rotten wood of a *Pinus* trunk, IVV: III.1866) represents ***Claussenomyces atrovirens*** (Pers.) Korf & Abawi or a very closely related species. The ~7-septate ascospores measure 21–22 × 3 µm and produce small cylindric-ellipsoid ascoconidia that fill the complete ascus. On the contrary, Crouan described the spores in the protologue as 'thick, ovoid, granular'. Broadly ellipsoid-ovoid spores with a granular content are actually figured on their herbarium label and also on a watercolour sketch which was undoubtedly made from this material. This conflict is easily explained by the fact that, in living asci, the conidia form 8 broadly ellipsoid 'balls' around the ascospores. Hence, the Crouan brothers misinterpreted balls of conidial masses as ascospores, a frequent mistake when studying living specimens of *Claussenomyces*. As a further error, Crouan gave the apothecia as 1–2 mm diam., whereas they are found here to measure rehydrated 0.3 mm at most.

The second packet (Penfeld [part of Brest], on rotten ?wood of a *Pinus* trunk, II.1866) contains a fungus showing a strongly blue IKI reaction of the outer ascus wall. The few apothecia are dark brown and measure 0.15 mm diam., with an ectal excipulum of brown textura globulosa. The spores have a size of 10–11 × 4–5 µm and contained, according to Crouan's sketch, several differently sized oil drops in the living state. This is a member of *Placynthiella* Elenkin, possibly *P. uliginosa* (Schrader) Coppins & P. James, a lichenized species of *Agyriales*.

Since the former collection fits much better the protologue, the collection from Kergontès is designated here as **lectotype** of *Helotium flavoviride* (MBT382123).

Orbilia flexuosa Crossl. in Massee, Grevillea 22: 44 (1894, '1893')

≡ *Phaeohelotium flexuosum* (Crossl.) Dennis, Kew Bull. 25: 354 (1971)

This species was transferred by Dennis to *Phaeohelotium* Kanouse. Reexamination of the holotype (Great Britain, Yorkshire, Lightcliffe, Halifax, 'on bark' [decorticated branch of *Alnus*], 6.VI.1893, C. Crossland, K(M) 32262, IVV: H.B. 5445) revealed that it is obviously a synonym of ***Phaeohelotium imberbe*** in the sense as reported in Baral & Krieglsteiner (1985), a species very common in central Europe on rotten wood and bark of both gymno- and angiosperms lying in wet habitats. In this species the asci arise from croziers and have a euamyloid apical ring of the *Hymenoscyphus*-type. The base of the ectal excipulum often shows an external faintly blue stain in IKI also in the holotype of *O. flexuosa*.

Orbilia fugax Sacc., E. Bommer & M. Rousseau, in Bommer & Rousseau, Bull. Soc. R. Bot. Belg. 29: 228 (1890)

≡ *Hyalinia fugax* (Sacc., E. Bommer & M. Rousseau) Boud., Hist. Class. Discom. Eur.: 104 (1907)

No material of this taxon was found in BR. The description (in Bommer & Rousseau 1890: 228, on leaves of *Calamagrostis sylvatica*, V.1890, Poix[-St.-Hubert, dépt. Luxembourg], Belgium) does not allow us to conclude whether it is orbiliaceous or not. The apothecia are described as very small ('36–45 mill.' diam.; 36–45 µm fide Saccardo 1892: 40), semitranslucent, white, the asci as 18–21 × 5–6 µm, sessile, the paraphyses as filiform, and the spores as 4–5 × 0.7–1 µm, oblong. Saccardo cited the authors differently as 'Bomm. Rouss. Sacc.'.

Orbilia fuscopallida Henn., Hedwigia 42, Beibl.: (85) (1903)

Reexamination of a syntype in S (herb. Sydow, Australia, southern Queensland, Eumundi, on petiole of *Lauraceae*, V.1902, Pritzel. no. 27, IVV: H.B. 7687) revealed that this taxon is a later synonym of *Orbilia myristicae* (see p. 1679).

Orbilia gelatinosa Sacc., Syll. Fung. 8: 624 (1889)

≡ *Peziza gelatinosa* Ellis & G. Martin, Amer. Nat. 17(12): 1283 (1883), nom. illegit., ICN Art. 53.1 [non *Peziza gelatinosa* Haller 1768, nom. inval., ICN Art. 32.1(c); nec *Peziza gelatinosa* Bull. 1790, = *Exidia recisa* (Ditmar) Fr.]
≡ *Coryne gelatinosa* (Sacc.) Rehm, Ann. Mycol. 5: 518 (1907)
≡ *Calloriopsis gelatinosa* (Sacc.) Syd. & P. Syd., Ann. Mycol. 15: 254 (1917)
= *Calloriopsis herpotricha* (Berk.) R. Sant., Svensk bot. Tidskr. 45(1): 300 (1951)
≡ *Peziza herpotricha* Berk., Hooker's J. Bot. Kew Gard. Misc. 3: 16 (1851)
≡ *Tapesia herpotricha* (Berk.) Sacc., Syll. fung. (Abellini) 8: 381 (1889)
≡ *Helotiella herpotricha* (Berk.) Sacc., Syll. fung. (Abellini) 8: 477 (1889)
= *Calloria meliolicola* Henn., Bot. Jb. 25: 509 (1898)
≡ *Coryne meliolicola* (Henn.) Höhn., Sber. Akad. Wiss. Wien, Math.-Naturw. Kl., Abt. 1 118: 106 (1909)
= *Diplothrix mirabilis* Vain., Ann. Acad. Sci. fenn., Ser. A 15(6): 154 (1921)

The above synonymy was established by Santesson (1951) and Pfister (1976), although Santesson did not mention *C. meliolicola* and Pfister overlooked that *P. herpotricha* has priority. *P. gelatinosa* is the type species of *Calloriopsis* Syd. & P. Syd. and *D. mirabilis* that of *Diplothrix* Vain., and further specific epithets have apparently not been combined in these two genera. Pfister erected for *Calloriopsis* the tribe *Calloriopsideae* which he referred to the *Leotiaceae* (see also Nannfeldt 1932: 254), whereas Baral (in Jaklitsch et al. 2016) considered it to belong to the new family *Helicogoniaceae*. For a description see Pfister (l.c.) and Baral & Marson (2001).

Calloria gentianae Grelet & Crozals, Bull. Trimest. Soc. Mycol. Fr. 44: 336, pl. 21 figs 1–4 (1928)

(?)= *Iridinea iridina* Velen., Monogr. Discom. Bohemiae: 299, figs 59–60 (1934)
(?)= *Unguicularia iridis* Svrček, Ceská Mykol. 42(3): 146 (1988)

Hein (1976: 34) stated that *Calloria gentianae* belongs to *Hyalinia*. However, in the type envelope (France, Haute-Savoie, La Clusaz, on stems of *Gentiana lutea*, VII.1927, A. de Crozals, PC), he noted that the species belongs in the relationship of *Unguicularia*. Two specimens bearing the same collection data were received from PC. One of them was examined (PC 0001045, IVV: H.B. 7759) and found to be a probable earlier synonym *Iridinea iridina* and *Unguicularia iridis*. The species possesses glassy hairs similar as in *Habrostictis diaphana* treated above, though without a lumen in their upper part, and also resembles this species in its hymenial characteristics. Documentations of several fresh collection of this species were available (IVV: H.B. 2897, E.R.D. 4495 etc.). A paper on this species, the relationship of which appears to be within the *Calloriaceae*, is in preparation. In this paper the genera *Chaetonaevia* (see under *Naevia diaphana*, p. 1669), *Hyalacrotes* (Korf & L.M. Kohn) Raitv., and *Iridinea* (see under *Habrostictis diaphana*, p. 1669) are discussed regarding their possible synonymy with *Laetinaevia*.

Orbilia geralensis (Henn.) Rick, Brotéria, sér. Cienc. Nat. 1(1): 46 (1932)

≡ *Ombrophila geralensis* Henn., Hedwigia 38, Beibl.: (65) (1899)
≡ ***Coenogonium geralense*** (Henn.) Lücking, Fl. Neotrop. Monogr. 103: 579 (2008)

A syntype specimen in S (Brazil, Santa Catarina, Serra Geral, on unidentified tree bark, E. Ule, herb. Sydow, IVV: IV.1891) was examined and found to be a representative of the genus *Dimerella* Trevis, a genus which is now considered as a synonym of *Coenogonium* Ehrenb. (*Coenogoniaceae*, *Gyalectales*, see Jaklitsch et al. 2016). In the protologue Hennings reported the bark to be covered by lichens, but obviously he overlooked the inconspicuous thallus of this lichenized discomycete. The apothecia are rehydrated 0.6–1 mm diam., bright yellow. The whole ascus wall reacts hemiamyloid (first blue then dirty olive-brown in IKI), the ascospores are 1-septate, 6.5–10 × 2.4–2.7 µm (Hennings: 9–11 × 3 µm, 'non-septate'), guttulate, the paraphyses densely septate, with inflated apical cell of 4–5 × 2.5–3.5 µm (Hennings: apically clavate, 3.5 µm wide). Based on the present reexamination, Lücking (2008: 579) made the combination in *Coenogonium* as *C. geralense* (Henn.) Lücking, which he considered to provide an earlier synonym of *C. flavicans* (Vězda & Farkas) Kalb & Lücking (but also of *Belonidium collemoides* Rehm and *Gyalecta marginalis* Vaino), for which he gave a spore size of 6–9 × 1.8–2.5 µm. In the substrate the type of *C. geralense* differs from the various pantropical collections reported by Lücking (l.c.) which were on living leaves. Yet, some species of *Coenogonium* are found to be both lignicolous and foliicolous (Lücking pers. comm.).

Orbilia glabrovirens (Boud.) Boud., Bull. Soc. Mycol. Fr. 1: 114 (1885)

≡ *Helotium glabrovirens* Boud., Bull. Soc. Bot. Fr. 28: 95, pl. III fig. VIII (1881)
≡ *Belonidium glabrovirens* (Boud.) Sacc., Syll. Fung. 8: 498 (1889)
≡ *Corynella glabrovirens* (Boud.) Boud., Icon. Mycol., liste prélim.: 4 (1904)

= ***Claussenomyces prasinulus*** (P. Karst.) Korf & Abawi, Can. J. Bot. 49: 1882 (1971)

When Boudier (1885: 114) assigned two species to his new genus *Corynella* Boud., *Coryne atrovirens* Pers. and *Helotium glabrovirens* Boud., he erroneously wrote for the latter basionym '*Orb. glabrovirens* Boud.'. According to ICN Art. 35.2 (Turland et al. 2018), the two intended combinations in *Corynella* were not realized because genus and species epithet were not definitely associated. They became valid only in 1907 and 1904, respectively. Van Vooren (2011) drew attention to the fact that most of the names newly included in genera by Boudier (1885) cannot be considered as valid combinations. However, the obviously unintended combination '*Orb. glabrovirens* Boud.' is valid. The Code allows abbreviations when they clearly refer to a name; the generic name *Orbilia* appears also unabbreviated on the same page, and the phrase '*glabrovirens* Boud.' can be interpreted as cryptic reference to *Helotium glabrovirens* (ICN Art. 41.3). It can hardly be argued that '*Orb.*' is a typographical error for '*Cor.*' (Art. 60.1 ICN), but it cannot be excluded that the error was made by the printer. *Helotium glabrovirens* is currently placed in synonymy with *Claussenomyces prasinulus*.

Orbilia glacialis Rehm, Rabenh. Krypt.-Fl., 1.3: 461 (1891)

No type material (Austria, Tirol, Pitztal, Taschach-Gletscher, on dry stems of inflorescence of *Petrocallis pyrenaica*) was found in M, PAD, S (see also Hein 1976: 34). Rehm described the apothecia as pale yellowish, 0.2–0.3 mm diam., asci sessile, with a hemispherical, strongly thickened apical wall (no iodine reaction stated), 30–36 × 12–14 µm, 8-spored, spores 5–7 × 3 µm. An authentic later collection studied by Hein (1976: 59, on *Apiaceae*, IX.09, Rehm as '*Orbilia ?glacialis*', S) showed hairs similar as in *Chaetonaevia* (*Calloriaceae*).

Patinella gnaphaliana (Cooke & Ellis) Sacc., Syll. Fung. 8: 771 (1889)

≡ *Patellaria gnaphaliana* Cooke & Ellis, Grevillea 6: 91 (1878)
≡ *Pyrenopeziza gnaphaliana* (Cooke & Ellis) Rehm, Ann. Mycol. 2: 354 (1904)

The type material (stems of *Gnaphalium decurrens*, New Jersey, USA, no. 2665) was not ordered, but a collection under the name *Patellaria gnaphaliana* was examined (unlocalized, herbaceous stems of *Gnaphalium polycephalum*, V.1879, Ellis N. Amer. Fungi 398, M). It has longer spores (12.5–14 × 5–5.4 µm) and smaller apothecia (0.2–0.35 mm when dry) compared to the protologue (spores ovoid, 8 × 5 µm, apothecia 0.5–1 mm). The collection studied has ascus apical rings of the *Ploettnera*-type (only the lower part of the apical thickening turns blue in IKI). Its position might be close to *Ploettnera* Henn. (*Calloriaceae*).

Orbilia griseocarnea Henn., Hedwigia 41: 19 (1902)

Type material (Brazil, Santa Catarina, Caetébach, on rotten trunks, 24.VII.1891, A. Möller no. 135) could not be located in B, GH, HBG, K, IAC, and S. The apothecia are described as 3–6 mm diam., the spores as broadly ellipsoid-ovoid, 4–5 × 3.5 µm. Whether or not this is an orbiliaceous fungus remains unclear.

Orbilia sericea f. ***grisea*** Girz., Bull. Jard. Bot. Kieff 10: 59 (1929)

The type specimen (dry branches of *Ribes nigrum*, 2.X.1927, in a garden in Kyiv, Ukraine) was not ordered, and no microscopic features are mentioned in the protologue. The 'small fungus' is said to differ from *O. sericea* merely in its light grey colour (no further macroscopic features are described). The occurrence on a dry substrate together with the given colour is quite unexpected within the *Orbiliomycetes* and seems to fit better a member of the *Helotiales*. Actually, a topotype specimen in LE turned out to represent a member of *Mollisia* (Fr.) P. Karst. when examined by E.S. Popov (pers. comm.).

Hyalinia gyalectoides (Saut.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza gyalectoides* Saut., Hedwigia 15: 151 (1876) [also in Mitt. Ges. Salzb. Landesk. 18: 112 (1878)]
≡ *Helotium gyalectoides* (Saut.) Sacc., Syll. Fung. 8: 240 (1889)
≡ *Calycina gyalectoides* (Saut.) Kuntze [as '*gyalectodes*'], Revis. Gen. Pl. 3: 448 (1898)

Type material could not be located in BREG, LI, SZB, and W. However, Keißler (1917: 94) was able to examine Sauter's type specimen (Austria, Salzburg, on rotten leaves of *Salix*, X.1869). He found a prosenchymatic ectal excipulum and thus confirmed Saccardo's placement in *Helotium*. Without describing further features, he believed the taxon to be identical with *Helotium epiphyllum* (Pers.) Fr. [≡ *Phaeohelotium epiphyllum* (Pers.) Hengstm]. According to Winter's (1881: 133) revision of Sauter's type, the asci measured 50–60 × 7 µm and the spores 8–10 × 2 µm, which clearly excludes *P. epiphyllum*. Keißler's reference to the protologue ('Flora, Bd. 24 (1841), p. 151') is erroneous, correct is Hedwigia 15: 151 (1876). Also Saccardo's reference ('Pilz. Salzb., p. 14') is a mystery.

Orbilia haematites (Wallr.) Sacc., Syll. Fung. 8: 632 (1889)

≡ *Peziza haematites* Wallr., Fl. Crypt. Germ.: 472 (1833)

No type specimen was found in PR and STR. The protologue (Germany, Thüringen, on dry stems of *Rubus idaeus*) is without microscopic features. Wallroth described the apothecia as obconical, smooth, deep blood-red, resembling *Sphaeria episphaeria* (≡ *Cosmospora episphaeria*) at first glance.

Rodwayella haematoidea (Cooke & W. Phillips) Baral & Quijada, **comb. nov.** — MB 826713

Basionym: *Peziza haematoidea* Cooke & W. Phillips, in Cooke, Grevillea 8: 62 (1879)
≡ *Pezizella haematoidea* (Cooke & W. Phillips) Sacc., Syll. Fung. 8: 284 (1889)
≡ *Hymenoscyphus haematoideus* (Cooke & W. Phillips) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ *Pseudohelotium haematoideum* (Cooke & W. Phillips) Dennis, Kew Bull. 15(2): 315 (1961)
?= *Remleria piceicola* Raitv., Scripta Mycol., Tartu 20: 110 (2004)

The species was compared with *Peziza rubella* Pers. (≡ *Orbilia rubella*) by Cooke & Phillips (in Cooke 1879). Therefore, the holotype material (New Zealand, Waitaki, [on wood and bark of unidentified angiosperm], undated, M.C. Cooke 1885, K(M) 36003, IVV: H.B. 5527) was examined. It contains a few dirty red-brown apothecia 0.4–1 mm diam. (in dry state) in a rather decayed stage (originally described as blood-red, 1–1.5 mm diam.). The asci (90–105 × 7–9 µm) have a slightly conical apex with an apical ring of the *Calycina*-type (deep blue in IKI after KOH-treatment). The ascus base was not clearly seen. The ascospores (13–21 × 2.5–3.7 µm) are at first non-septate but all 8 spores inside the asci later become 3-septate. The non-septate spores contain many small LBs in each half, the 3-septate ones fewer in each cell. The ectal excipulum is a thin-walled, yellow-orange, horizontal textura prismatica (more t. angularis towards the base).

The species belongs in the *Pezizellaceae*, judging from very similar, possibly conspecific recent European collections on *Rubus* (UK, IVV: H.B. 9851) and *Picea* (Spain, IVV: TFC Mic. 140830). Their 3-septate spores are found inside the living asci and are surrounded by an inconspicuous sheath that does not stain in CRB. The white, subsessile apothecia, which partly turn red-brown with age, are reminiscent of *Calycina* spp. with 2-septate spores but also resemble species of *Rodwayella* Spooner. Based on the protologue, *Remleria piceicola* could be conspecific.

ITS and LSU rDNA sequences gained by L. Quijada (pers. comm.) from the Spanish sample placed the species in a medium supported clade with *Rodwayella sessilis* (Rodway) Spooner (TFC Mic. 24329), the type of *Rodwayella*, but more distant from *Calycellina* and particularly *Calycina*.

Hyalinia helleboricola Ade, Hedwigia 64: 318 (1923)

(?)= ***Psilachnum rubicundum*** (Sacc. & Speg.) Baral

No type material (Germany, Untere Schrainbachalpe S of Königssee, on leaves of *Helleborus niger*, 19.VI.1921, A. Ade) could be located in B, M, and S. The species was described with asci stained blue in iodine and ascospores of 4–5 × 2–2.5 µm. *Hyalinia helleboricola* is probably a later synonym of *Psilachnum rubicundum* (see below).

Hyalinia hungarica (Rehm) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Pezizella hungarica* Rehm, in Winter, Flora N.S. 30: 526 (1872)
≡ *Hymenoscyphus hungaricus* (Rehm) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ *Hyaloscypha hungarica* (Rehm) Velen., Monogr. Discom. Bohem.: 274 (1934)
≡ *Clavidisculum hungaricum* (Rehm) Raitv., Scripta Mycol. 1: 77 (1970)
≡ *Cistella hungarica* (Rehm) Raitv., Scripta Mycol. 8: 151 (1978)

According to Dennis (1964: 47) and Raschle (1978), *Pezizella hungarica* is a synonym of *Dasyscyphus grevillei* (Berk.) Massee (≡ ***Cistella grevillei*** (Berk.) Raschle), but Raitviir (1970, 1978, 2004) considered it to be specifically distinct on account of shorter ascospores.

Orbilia hyalinula (Nyl.) P. Karst., Bidr. Känn. Finl. Nat. Folk 19: 99 (1871)

≡ *Peziza hyalinula* Nyl., Not. Sällsk. Fauna Fl. Fenn. Förh. 10: 57 (1869)
≡ *Hyalinia hyalinula* (Nyl.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

The holotype (Finland, Nylandia, Helsinki, in horto botanico, inner surface of bark of ?*Acer*, 6.II.1863, W. Nylander, H, IVV: H.B. 5250) belongs in the *Hyaloscyphaceae*. The most characteristic feature is the reduced apical dome (only subapically thickened) with an IKI pale blue apical ring (after KOH-treatment) visible as 2 minute apical dots. The ascospores measure 5–7.6(–8.2) × (1.8–)2–2.4 µm and contain several small LBs. The generic position of this species is unclear because vital characters, particularly the paraphysis contents, are unknown. *P. hyalinula* could belong to ***Calycina***, from which it differs in a reduced *Calycina*-type of apical ring. The clavate, smooth, hair-like cortical cells might instead indicate a relationship to *Cistella* Quél. Closely related is *Orbilia fairmanii* (p. 1671), which differs in a strongly euamyloid apical ring of the *Calycina*-type.

Patinella hyalophaea Sacc. – see p. 208, under *Patinella*.

Naevia rosella f. ***impatientis*** Höhn., in Strasser, Verh. Zool.-Bot. Ges. Wien 69: 366 (1919)

No type material of this taxon (Austria, [Niederösterreich, Amstetten,] Sonntagberg, rotten stems of *Impatiens noli-tangere*, VI.1917) could be located in PAD and S. Hein (1976: 34) apparently studied the type when stating that it is an *Orbilia*. The protologue gives asci of 40–48 × 8–12 µm (including the long and thick stipe), spores ovoid-oblong, 8–10 × 3 µm, paraphyses apically slightly enlarged. Hein further believed that a collection on *Impatiens* from Michigan (USA), identified by Kanouse (1936: 100) as *Laetinaevia rosella* (Rehm) Nannf. (≡ *Orbilia rosella*), was probably the same *Orbilia*. However, this assumption appears to be based only on the substrate, since Kanouse gives no microscopic characters. *Naevia rosella* (Rehm) Rehm (≡ *Pseudopeziza rosella* Rehm, non *Orbilia rosella*) was compared with *Naevia diaphana* by Rehm (1888: 146) and is probably a member of *Calloriaceae*.

Hyalinia incarnata (Cooke) Boud., Hist. Class. Discom. Eur.: 103 (1907)

≡ *Peziza incarnata* Cooke, Grevillea 1: 131 (1873)
≡ *Mollisia incarnata* (Cooke) W. Phillips, Man. Brit. Discomyc.: 191 (1887)
≡ *Pezizella incarnata* (Cooke) Sacc., Syll. Fung. 8: 285 (1889)
≡ *Hymenoscyphus incarnatus* (Cooke) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
= ***Pseudohelotium pineti*** (Batsch) Fuckel, Jb. Nassau. Ver. Naturk. 23-24: 298 (1870) [1869-70]

According to Nannfeldt (1936: 195) and Dennis (1964: 47), the type material (on needles of *Pinus sylvestris*) is a synonym of *Pseudohelotium pineti*.

Orbilia inconspicua Nograsek & Matzer, Nova Hedwigia 53: 460 (1991), nom. inval. (Art. 36.1(a), 39.1 ICN)

Orbilia inconspicua, proposed by Nograsek & Matzer (1991) as a nomen provisorium (with only German diagnosis) for samples on leaves and stems of *Dryas octopetala* from alpine eastern Austria and arctic Lapland (Sweden), resembles *O. vitalbae* and *O. caulicola* based on the authors' description and a reexamination of two authentic collections, GZU 60-92 (Austria) and GZU 64-92 (Sweden), judging from spore size and shape, and the partly capitate-clavate paraphyses. Spore bodies were not described and could also not be discerned in the dead spores. Two other specimens from Austria cited by the authors contained a very different *Orbilia* with thick-walled ascus apices and spores with short basal tails (see under *O. angustoaristata*, p. 700). A type was not designated by the authors.

Mollisia incrustata (Ellis) Seaver, North American Cup-fungi (Inoperculates): 215 (1951)

≡ *Peziza incrustata* Ellis, Amer. Nat. 17: 192 (1883)
≡ *Pseudohelotium incrustatum* (Ellis) Sacc., Syll. Fung. 8: 301 (1889)
≡ *Cistella incrustata* (Ellis) Dennis, Res. Norweg. Sci. Exped. Tristan da Cunha 36: 2 (1955)
≡ ***Hyphodiscus incrustatus*** (Ellis) Raitv., Scripta Mycol. 20: 74 (2004)
= *Mollisia trametis* Ellis & Everh., Proc. Acad. Nat. Sci. Philadelphia 45: 147 (1893)

Peziza incrustata was described growing on the pores of perennial basidiomycetes in North America. Seaver (1951: 215), who placed it in *Mollisia* and cited *M. trametis* as synonym, saw a similarity in apothecial colour with *Helotium* and *Orbilia*. Dennis (1955) transferred the taxon to *Cistella* and compared it with *C. stereicola* (Cooke) Dennis and *Peziza hymeniophila* P. Karst. (≡ *Hyphodiscus hymeniophilus* (P. Karst.) Baral). Type material of *Mollisia trametis* (USA, New Jersey, Newfield, on *Trametes stevensii*, Dec. 1888, J.B. Ellis, FH) was reexamined and found to be very close to European *H. hymeniophilus*. However, the *Phialophora* anamorph found in the type of *M. trametis* differs from that of *H. hymeniophilus*, *Phialophora rhodogena* (Mangenot) W. Gams, in lacking a red colour, as already stated by Raitviir (2004). The phialoconidia in the two taxa are about the same size [*M. trametis*: 3.3–4.5 × 1.3–1.6 µm; *H. hymeniophilus*: two personal collections *2.8–4.5(–7) × 1.3–1.8 µm, wood of *Fagus*, 21.II.1990, 4.X.1994 (H.B. 5161); Helfer 1991: 3–5 × 1.5–2.5 µm]. Further investigations are necessary to clarify whether *H. incrustatus* is distinct from *H. hymeniophilus* at the species level.

Orbilia infixa (Wallr.) Quél., Enchir. Fung.: 299 (1886)

≡ *Peziza infixa* Wallr., Fl. Crypt. Germ.: no. 2504 (1833)
≡ *Pezizella infixa* (Wallr.) Sacc., Syll. Fung. 8: 287 (1889)
≡ *Hymenoscyphus infixus* (Wallr.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ *Mollisiella infixa* (Wallr.) Boud., Hist. Class. Discom. Eur.: 142 (1907)

Type material of this taxon (Germany, Thüringen, on rotten wood of *Salix*) has not been ordered but is unlikely to exist. The apothecia are described as pale wax-coloured, dry orange-yellow (no size stated), scattered, first urceolate, later with a raised smooth margin. No information on the hymenial elements is given. In the case that no type material has survived, *Peziza infixa* must be considered as a nomen dubium.

Crouan & Crouan (1867: 49) reported under the name *P. infixa* collections from NW-France on various woody and herbaceous substrates, with ovoid spores and the apothecial colour varying from white over amber-yellow to red. The authors cited '*Peziza tenacella* Wallr. in sched.' and *P. coccinella* Sommerf. as synonyms. Eight specimens labelled *Peziza infixa* exist in Crouan's herbarium (CO) and were revised by J.P. Priou (pers. comm.). Three or four of them represent *O. eucalypti* (on *Carpinus*, *Pinus*, *Quercus* and *Ulex*), two *O. auricolor* (on *Fraxinus* and *Ulmus*), one perhaps *O. cardui* (on *Angelica*), and one *O. rubrovacuolata* (on *Salix*). Two further collections with red apothecia (on *Rubus*) labelled '*Helotium coccinellum* (Sommerf.) Crouan' (in sched., with *Peziza infixa* as a possible synonym) also represent *O. rubrovacuolata* (J.P. Priou pers. comm.).

Belonopsis ingae Seaver, in Chardon & Toro, J. Dept. Agric. Porto Rico 14, 4: 226 (1930)

Seaver described this taxon (Colombia, Cordillera Occidental, El Valle, Hacienda Bitaco, on dead pod of *Inga*, 11.VI.1929, no. 506) very briefly, with gregarious, pale yellow, semitranslucent apothecia up to 0.5 mm diam., asci clavate, short, 18–20 × 4–5 µm (as '48–20'), spores straight or slightly curved, 8–10 µm long, paraphyses very slender with globose, 3 µm wide apices. Dennis (1970: 352, 354) noted that the description sounds like an *Orbilia*. No material could be located in NY.

Patinella inquinans Sacc., Syll. Fung. 8: 770 (1889)

≡ *Peziza inquinans* Cooke, Hedwigia 14: 84 (1875), nom. illegit., ICN Art. 53.1 [non *Peziza inquinans* Pers. ≡ *Bulgaria inquinans* (Pers.) Fr.]
?= ***Durella macrospora*** Fuckel, Jb. Nassau. Ver. Naturk. 23-24: 281 (1870) [1869-70]

No type material has been studied. A collection under this name (USA, Alabama, Lee County, Auburn, decorticated twig of unidentified angiosperm, V.1896, F.S. Earle & L.M. Underwood, herb. Petrak, M) fits the protologue. This specimen has 3-septate, multiguttulate ascospores 20–25 × 4 µm, asci 60–67 × 9–10 µm, with hemispherical, thin-walled, inamyloid apex (IKI), arising from croziers, paraphyses apically covered by dark brown granular exudate, ectal excipulum of horizontal textura porrecta, with a KOH-inert dark pigment. This is a *Durella* and probably not different from *Durella macrospora*.

Orbilia lacustris (Fr.) Quél., Enchir. Fung.: 299 (1886)

≡ *Peziza lacustris* Fr., Syst. Mycol. 2(1): 143 (1822)
≡ ***Niptera lacustris*** (Fr.) Fr., Summa Veg. Scand.: 359 (1849)
≡ *Belonidium lacustre* (Fr.) W. Phillips, Man. Brit. Discomyc.: 149 (1887)
≡ *Belonopsis lacustris* (Fr.) Höhn., Mitt. bot. Inst. tech. Hochsch. Wien 4(2): 40 (1923)
≡ *Mollisia lacustris* (Fr.) Gillet, Champ. Fr., Discomyc.: 130 (1882)

When Fries (1849) erected the genus *Niptera* Fr., he designated *P. lacustris* as type species. The confusing interpretation of this species as pointed out by Höhnel (1927) was settled by Dennis (1972) who reexamined the type material. *Niptera* is accepted as a genus close to *Mollisia* (*Mollisiaceae*, *Helotiales*, see Dennis l.c., Baral 1994: 116).

Orbilia leightonii (W. Phillips) Sacc. [as '*Leightoni*'], Syll. Fung. 8: 631 (1889)

≡ *Calloria leightonii* W. Phillips [as '*Leightoni*'], Man. Brit. Discomyc.: 329 (1887)
≡ *Hyalinia leightonii* (W. Phillips) Boud. [as '*Leightoni*'], Hist. Class. Discom. Eur.: 104 (1907)
?= ***Hyaloscypha quercicola*** (Velen.) Huhtinen, Karstenia 29(2): 163 (1990) [1989]

The presumed holotype ([Great Britain, Shropshire, near Shrewsbury], on the pores of a brownish resupinate *Polyporaceae*, undated, W.A. Leighton, K(M) 36054, IVV: H.B. 5449) appears to be a species of *Hyaloscypha* Boud., although hairs could not be found. The asci arise from simple septa, the apex is distinctly conical and IKI-, and the nearly eguttulate ascospores measure 6–8.5(–9.5) × 2.3–2.5(–3) µm. These characters would fit *H. quercicola*, but in the absence of hairs this synonymy remains questionable. The genus *Parorbiliopsis* Spooner & Dennis was established to accomodate two such hairless species. Based on personal studies of type material in K and H (IVV: H.B. 5753), the type species *P. minuta* Spooner & Dennis [≡ *Hyaloscypha minuta* (Spooner & Dennis) Baral] is doubtfully distinct from *Hyaloscypha intacta* Svrček, although pointed hairs are almost absent in *P. minuta*. In fact, *Parorbiliopsis* is hardly separable from *Hyaloscypha* at the generic level (see also Phyl. 1). The other species originally included in *Parorbiliopsis*, *P. extumescens* (P. Karst.) Spooner & Dennis, is probably a synonym of *H. albohyalina* (P. Karst.) Boud. In its holotype (P. Karsten 3593, H, IVV: H.B. 5249) some of the apothecia possess hairs typical of *Hyaloscypha*, but the hymenial elements were too overmature in order to study the ascus base.

Orbilia lenticularis (Bull.) Riel, nom. inval. (P. Riel, unpublished colour drawing no. 2228)

≡ *Peziza lenticularis* Bull., Herb. France pl. 300 (1787) [also in Hist. Champ. France 1: 248 (1791)]
≡ *Peziza citrina* subsp. *lenticularis* (Bull.) Pers., Mycol. Eur. 1: 293 (1822)
≡ *Helotium lenticulare* (Bull.) Fr., Summa Veg. Scand.: 356 (1849)
≡ *Calycina lenticularis* (Bull.) Kuntze, Revis. Gen. Pl. 3: 448 (1898)
≡ *Calycella lenticularis* (Bull.) Boud., Hist. Class. Discom. Eur.: 95 (1907)

No type material was ordered. According to Bulliard's (1787) original plate, which shows two cut trunks of an unidentified tree with two populations that inhabit the wood surface, the fungus is obviously a mixture of two species, a sessile ?*Orbilia* (pl. 300 A, '*Peziza lenticularis sessilis*') and a stipitate ?*Bisporella* (pl. 300 B, '*P. lenticularis pediculata*', perhaps *B. subpallida* (Rehm) Dennis or *B. pallescens* (Pers.) S.E. Carp. & Korf). Besides this heterogeneity of *P. lenticularis*, Bulliard (1791) reported also the colour to vary from whitish to yellow-orange or brownish.

N. Van Vooren (pers. comm.) drew our attention to the unpublished colour drawings of Philibert Riel, a contemporary of Émile Boudier, preserved in the Herbarium of the Société linnéenne de Lyon. According to a handwritten note, Riel was in contact with Boudier concerning *P. lenticularis*, and Boudier appears to have used Bulliard's taxon at that time for a fungus 'frequent on rotten trunks of various trees, especially *Quercus*' (Boudier in litt. to Riel, 22.VIII.1897). Riel's plate 2228 (Rhône, Poule, 18.VIII.1897, Bracq & Renard) bears the name *Orbilia lenticularis*, an unpublished combination that was apparently suggested by Boudier who seems to have determined several dozens of Riel's plates (Van Vooren pers. comm.). This plate clearly represents *Orbilia eucalypti*. Riel also stated that Boudier (1907: 95) followed a different interpretation of *P. lenticularis* when proposing the combination in *Calycella* by referring more to the stipitate form of *Peziza lenticularis*.

Hyalinia leucostigma (Fuckel) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ ***Hyaloscypha leucostigma*** (Fuckel) Baral, **comb. nov.** — MB 814681

Basionym: *Niptera leucostigma* Fuckel [as '(Fr.?) Fuckel'], Jahrb. Nassau. Ver. Naturkd. 27–28: 59 (1874 [1873–74])

≡ *Pezizella leucostigma* (Fuckel) Sacc., Syll. Fung. 8: 279 (1889)

≡ *Mollisia leucostigma* (Fuckel) Rehm, Rabenh. Krypt.-Fl., 1.3: 516 (1891), nom. illegit., ICN Art. 53.1 [non *Mollisia leucostigma* (Fr.) Gillet 1882, ≡ *Orbilia leucostigma* (Fr.) Fr.]

≡ *Hymenoscyphus leucostigma* (Fuckel) Kuntze, Revis. Gen. Pl. 3: 485 (1898)

= *Hyaloscypha spiralis* (Velen.) J.G. Han, Hosoya & H.D. Shin, Fungal Biol. 118: 161 (2014)

≡ *Chrysothallus spiralis* Velen., Monogr. Discom. Bohem. (Prague): 269 (1934)

≡ *Hyaloscypha albohyalina* var. *spiralis* (Velen.) Huhtinen, Karstenia 29(2): 99 (1990)

= *Truncicola parasitica* Velen., Monogr. Discom. Bohem. (Prague): 289 (1934)

= *Hyaloscypha lignicola* Abdullah & J. Webster, Trans. Br. mycol. Soc. 80(2): 253 (1983)

When Fuckel (1874) described a collection 'on rotten stumps of *Fagus* (or *Betula*)' (Germany, Rheingau, [Mainz,] Hallgarten, Fuckel Fungi Rhen. Exs. 2572), he referred it to '*Peziza leucostigma* Fr.' or '*Orbilia leucostigma* Fr.', though with hesitation under the new name '*Niptera leucostigma* (Fr.?) Fckl. F. rh. ed. I. 2572 & ed. II.'. His major doubts he expressed by adding 2 question marks after the two mentioned names, According to Art. 52 Note 1 (ICN), the citation of a name with a question mark does not make the name of a new taxon nomenclaturally superfluous.

Although the new name *Niptera leucostigma* appears to have been intended merely as a new combination, it was taken up by later authors as the erection of a new species. Saccardo (1889: 279) and Rehm (1891: 516) shared Fuckel's doubts about the identity of his fungus with that of Fries, and proposed the combinations *Pezizella leucostigma* and *Mollisia leucostigma*. They gave as basionym '*Niptera leucostigma* Fuckel', thus explicitly excluding Fries's fungus, which they treated elsewhere (Saccardo 1889: 629, Rehm 1891: 454). Also Kuntze's (1898: 485) and Boudier's (1907: 104) combinations give Fuckel as the author of the species. As a consequence, all these combinations may not be connected to *Peziza leucostigma* Fr. (≡ *Orbilia leucostigma* (Fr.) Fr.), but refer to Fuckel's *Niptera leucostigma*, which represents a valid description of a new taxon (S.R. Pennycook pers. comm.).

Rehm did not find any apothecia when studying a syntype of Fuckel Fungi Rhen. Exs. 2572 (on wood of *Fagus*), neither did Arendholz in a syntype from G. When the latter specimen was examined in the present study (IVV: H.B. 7798), a small group of apothecia was discovered. These well correspond to Fuckel's diagnosis and belong to a member of *Hyaloscypha*. The microscopic features (asci with amyloid ring, without croziers, spores 7–10.5 × 2.5–3.2 µm, with some small oil drops in each half, OCI 1–2) refer this taxon to *Hyaloscypha albohyalina* var. *spiralis* as circumscribed by Huhtinen (1990a), who considered *H. lignicola* and *Truncicola parasitica* as synonymous. Fuckel's specimen deviates from typical populations of this taxon only in very short hairs which are, however, similarly depicted in one of the collections included by Huhtinen (l.c.: fig. 50).

H. albohyalina differs from *H. leucostigma* not only in the presence of croziers as stated by Huhtinen (l.c.), who separated the two taxa merely at the variety level, but also in having refractive SCBs in the living paraphyses (Baral 1992: 368). Obviously, the two taxa merit distinction at the species level. This was supported by a multigene analysis of two eastern Asian specimens by Han et al. (2014), which revealed a rather high molecular distance between the two taxa.

An exsiccata distributed by E.C. Bommer & M.H. Rousseau under the name *Mollisia leucostigma* (Fuckel) Rehm (Belgium, Champlon, on inner surface of undecayed bark of *Carpinus*, X.1909, M.H. Rousseau, BR 073559,33, IVV: H.B. 7645) contains a small *Mollisia*, which could not be identified at the species level. The paraphyses show a strong yellow KOH-reaction and the ascospores measure 10–13 × 2.8–3.5 µm and have a medium high lipid content (OCI 3, multiguttulate).

Hyalinia leucostigmoides (Sacc.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Calloria leucostigmoides* Sacc., Michelia 1(1): 63 (1877) [also in Michelia 2(6): 77 (1880)]

≡ *Mollisia leucostigmoides* (Sacc.) Gillet, Champ. Fr., Discomyc.: 131 (1882)

≡ *Pezizella leucostigmoides* (Sacc.) Sacc., Syll. Fung. 8: 277 (1889)

= ***Calycellina chlorinella*** (Ces.) Dennis, Kew Bull. 30: 350 (1975)

Two specimens in PAD labelled *Pezizella leucostigmoides* were examined (Italy, [Piemonte,] Valsesia, Riva Valdobbia, *Rumex scutatus*, 9.III.1891, A. Carestia; Czechia, Mährisch-Weißkirchen, *Galium sylvaticum*, VIII.1913, F. Petrak). Both showed euamyloid apical rings of the *Calycina*-type and refractive contents of paraphyses and clavate hairs, and clearly represent *Calycellina chlorinella* (see also under *Hyalinia chlorinella*, p. 1665). As a typical character of this species, the apothecia grew on black stromatic stripes that are acervuli of a coelomycete which might be the anamorph of this *Calycellina.*

Rehm (1891: 524) placed *P. leucostigmoides* in synonymy with *Mollisia teucrii* (Fuckel) Rehm, which in turn was suggested as a synonym of *C. chlorinella* by Svrček (1977a: 13). Höhnel (1926a: 67) studied *M. teucrii* (as *Pezizella teucrii* (Fuckel) Rehm) from the type and concluded that it is intermediate between *Helotium* and *Orbilia*. This taxon is included as *Mollisia teucrii* (Fuckel) Rehm in the British checklist. According to W.D. Graddon (in litt., Cannon et al. 1985: 150), its type belongs to *Calycellina* and a specimen under this name collected by M.C. Clark is *C. chlorinella*.

Orbilia limpida Kobayasi, Bot. Mag., Tokyo 53: 159 (1939)

?= ***Ombrophila violacea*** Fr., Summa veg. Scand., Sectio Post. (Stockholm): 357 (1849)

According to Korf (1958: 31) the type specimen cannot be located. Korf considered *O. limpida* as a possible pallid sessile form of *Ombrophila violacea*.

Hyalinia leightonii var. ***lignicola*** Bayl. Ell. [as '*Leightoni*'], Trans. Br. Mycol. Soc. 6: 266, pl. VI figs 1–2 (1920)

No material could be located in K. The parenchymatous, fuscous excipulum was emphasized by Bayliss Elliott (1920) as distinctive in contrast to the type variety of *Hyalinia leightonii* (see p. 1675) with a hyaline excipulum. Judging from the description, *H. leightonii* var. *lignicola* seems to be a *Mollisia*.

Orbilia loci-simiarum Henn., Hedwigia 41: 19 (1902)

?= ***Ombrophila violacea*** Fr., Summa veg. Scand., Sectio Post. (Stockholm): 357 (1849)

A syntype in S (Brazil, Santa Catarina, Blumenau, 'Affenwinkel', on rotten bark of a palm, 26.VII.1892, A. Möller no. 347, herb. Sydow, S, IVV: H.B. 7680) contains 3 overmature apothecia measuring (rehydrated) 2.5–8 mm diam. The asci are rather disintegrated, some showing a minute amyloid apical ring at the inner part of the dome. The 8 ellipsoid(-fusoid) ascospores (4.7–6.5 × 2.8–3.5 µm) contain two transparent areas (vacuoles?) but no LBs. The ectal excipulum is of a horizontal hyaline textura prismatica of large, thin-walled cells (25–50 × 17–27 µm), and the medullary excipulum of very thin hyphae immersed in abundant gel. This taxon appears to be close to or even conspecific with *Ombrophila violacea*. Typical of *O. violacea* are 2 medium-sized LBs in the spores which were also mentioned in the protologue of *Orbilia loci-simiarum*. Their absence in the present material is obviously due to senescence of the spores.

Under the name *O. loci-simiarum* Chardon & Toro (1930) reported a collection from Colombia on leaf sheaths of *Guadua latifolia*.

Orbilia luteola (Roum.) McPartl., in McPartland & Cubeta, Mycol. Res. 101(7): 854 (1997)

≡ *Calloria luteola* Roum., Rev. Mycol. (Toulouse) 3(12): 7 (1881)
(?)= ***Calycellina chlorinella*** (Ces.) Dennis, Kew Bull. 30: 350 (1975)

McPartland & Cubeta (1997) reexamined an authentic specimen which they named 'holotype' (France, Haute Garonne, Villermusi, undated, stems of *Cannabis sativa,* Roumeguère, Fungi Sel. Gall. Exs. 27, no.1671, BR), and 2 'isotypes' (BPI no. 802622A, CUP), but their brief description lacks important characters, such as ascus iodine reaction and type of ascus base ('Asci small, cylindrical, 8-spored, 26 × 4.5 µm, ... Ascospores hyaline, single-celled, fusiform, indistinctly guttulate, 6.5 × 1.5 µm'). No microscopic features are illustrated but only a macrophoto is provided. The species does not appear to have been restudied before, and McPartland & Cubeta's statement must be taken as a lectotypification.

The present reexamination of the lectotype in BR revealed a discomycete which fully matches *Calycellina chlorinella*, except for a single character: in contrast to all previously studied collections in which the iodine reaction was tested, the asci did not show a positive IKI reaction (with or without KOH-pretreatment). In deviation from McPartland & Cubeta's description, the cells of the ectal excipulum are distinctly thick-walled, and the spores cylindrical instead of fusiform, often slightly allantoid, 6.3–8.5(–9.5) × 1.3–1.5 µm, with 1–3 minute LBs near each end. The asci measured 32–44 × 3.5–4.2 µm, with the inamyloid apical wall only 0.2–0.5 µm thick, and arise from croziers. The paraphyses are densely filled with large, rectangular refractive bodies (VBs) when mounted in water, an important character of *Calycellina* which is sometimes still visible in herbarium material (in KOH the VBs disappear). The apothecia often grew on a black, stripe-like coelomycete with rod-shaped conidia 4–4.5 × 0.8 µm. Typical *C. chlorinella* with euamyloid asci is likewise regularly associated with this coelomycete, which might be the anamorph of the discomycete (see also under *Hyalinia leucostigmoides*, p. 1676).

The question remains open whether the observed difference in iodine reaction supports separation of two taxa. See also under the similar *Orbilia veratri* (p. 1689).

Orbilia macrospora Penz. & Sacc., Malpighia 15: 220 (1902)

Type material [Java, Cibodas ('Tjibodas'), on rotten wood] could not be located in PAD, PAL, and W. The species is described with fusoid, nearly unstalked asci (112–130 × 8–8.5 µm) with a conical apex, thin uninflated paraphyses, and fusoid, often very slightly curved, eguttulate spores of 28–30 × 4 µm (see also Penzig & Saccardo 1904: 86, pl. 57 fig. 4). The red semitranslucent apothecia (0.5–0.7 mm) appear to refer to an *Orbilia*, but the large asci and spores were mentioned by the authors as strange for that genus.

Patinella macrospora Ell. & Everh. – see under *Patinella crandallii* (p. 1667).

Orbilia marina Boyd, in Smith, Trans. Br. Mycol. Soc. 3: 113 (1909)

≡ *Laetinaevia marina* (Boyd) Spooner, in Kirk & Spooner, Kew Bull. 38: 568 (1984)
≡ ***Calycina marina*** (Boyd) Rämä & Baral, in Baral & Rämä, Bot. Mar. 58: 527 (2015)

Spooner (in Kirk & Spooner 1984) redescribed this algicolous species, which he tentatively transferred to *Laetinaevia* and for which he proposed a lectotype. Baral & Rämä (2015) provided a redescription based on fresh specimens and a molecular analysis of rDNA. *O. marina* nested with high support in the genus *Calycina* (*Pezizellaceae*), although its macro- and microscopic features only partly support such placement.

The apothecia are pulvinate and erumpent, the asci arise from simple septa (not bifurcate) and have a conical apex with a hemiamyloid (type RB) apical ring similar as in *Calycina*. The ring much resembles that of *Cyathicula cyathoidea* (*Conchatium*-type, Triebel & Baral 1996, fig. 5), whereas typical *Laetinaevia* species have a 'T-shaped' ring of the *Pezicula*-type. The living ascospores contain a few small LBs. The paraphyses are medium clavate at the apex and covered by a thick hyaline gel. The apical cell of each paraphysis contains a few large, globose, faintly refractive VBs which stain pale turquoise in

CRB but strongly blackish red-brown in IKI, a feature so far not seen in personal studies of typical *Laetinaevia* species. Both the gel and the total ascus wall stain lilac in CRB. Apart from the CRB-positive ascus wall, nothing points to a relationship to the *Orbiliomycetes*.

Orbilia medicaginis (Fautrey & Roum.) Sacc., Syll. Fung. 11: 426 (1895)

≡ *Calloria medicaginis* Fautrey & Roum., in Roumeguère, Rev. Mycol. (Toulouse) 14: 3 (1892)
= ***Duebenia compta*** (Sacc.) Nannf. ex B. Hein, Beih. Willdenowia 9: 105 (1976)

According to Nannfeldt (1929: 319, as *Duebenia purpurascens* (Rehm) Nannf.) and Hein (1976: 105), this is a synonym of *Duebenia compta*, a species currently placed in *Calloriaceae* (*Helotiales*). This species is confined to herbaceous stems of *Fabaceae* and has orange, elongate apothecia with a darker margin. The ascus iodine reaction is variable in Hein's concept of the species, being either amyloid or inamyloid.

Hyalinia microspis (P. Karst.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza microspis* P. Karst., Not. Sällsk. Fauna Fl. Fenn. Förh. 10: 178 (1869)
≡ *Helotium microspis* (P. Karst.) P. Karst., Bidr. Känn. Finl. Nat. Folk 19: 152 (1871)
≡ *Pezizella microspis* (P. Karst.) Sacc., Syll. Fung. 8: 281 (1889)
≡ *Hymenoscyphus microspis* (P. Karst.) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ *Hyaloscypha microspis* (P. Karst.) Velen., Monogr. Discom. Bohemiae: 280 (1934)
≡ *Calycellina microspis* (P. Karst.) Dennis, Trans. Bot. Soc. Edinb., 150th anniv. suppl. 45(3): 213 (1989) [also in Kew Bull. 45(2): 293 (1990)]

No type material could be located in H, although Dennis (1956: 181) has examined the type (Finland, Runsala, rotting leaves of *Phragmites*, 1.IX.1868). Dennis wrote that *Helotium microspis* can scarcely be separated from the genus *Mollisina* (*Helotiales*). However, he could not find the typical processes on the cortical cells of the ectal excipulum. The minute amyloid apical ring excludes *H. microspis* from the *Orbiliomycetes*. Recent collections assignable to *H. microspis* show globose refractive vacuoles (VBs) in the paraphyses and marginal cells reminiscent of the genus *Calycellina* (IVV: H.B. 9551b, 9957 etc.). However, similar collections without VBs likewise resemble Dennis' type description (IVV: H.B. 8471b etc.). *Hyalinia turgidella* (p. 1688) and *Orbilia succinella* (p. 1687) might be synonymous.

Orbilia oculifuga var. ***microspora*** Sacc., Syll. Fung. 8: 627 (1889)

≡ *Hyalinia oculifuga* var. *microspora* (Sacc.) Boud., Hist Class. Discomyc.: 104 (1907)
?= ***Calycina cruentata*** (P. Karst.) Kuntze, Revis. gen. pl. (Leipzig) 3(3): 448 (1898)

Le Breton & Malbranche (1884: 129) described from Forêt de Roumare, Mare de l'Epinay, 8.V.1884 (France, Haute-Normandie, Seine-Maritime, W of Rouen) a collection on culms of *Juncus communis* and leaves of *Eriophorum angustifolium*, which they referred with some doubts to *Orbilia oculifuga* Quél. By referring to this description, Saccardo (1889) erected the new variety *microspora*, and also Grelet (1948b: 108) only repeated Le Breton & Malbranche's brief description by accepting Boudier's (1907) placement in *Hyalinia*. Saccardo, Boudier, and Grelet refer to 'p. 15' in Le Breton & Malbranche (1884), probably by using a reprint with different page numbers.

There exist two sketches at the herbarium of Rouen labelled '*O. oculifuga* Quel.?' (I. Gaspérini pers. comm.). One of them shows a fungus on *Juncus* from Mare de l'Epinay (IVV: Le Breton, undated) with apparently sessile, short-haired apothecia, but the microscopic data are not the same as in the protologue, and a date is not indicated. The other shows short-stipitate and short-haired apothecia, but no collection data and no substrate are given. Since the herbarium does not send specimens on loan, this material could not be studied.

When asking for the type of *O. oculifuga* at PC, another specimen was received, identified by Le Breton & Malbranche as '*Orbilia oculifuga*?', collected in Forêt de Pont-de-l'Arche [Haute-Normandie, Eure, SSE of Rouen] on *Carex riparia*, undated, E. Niel & A. Le Breton (PC 0088500, IVV: H.B. 7749). This is identified here as *Calycina cruentata*, a taxon that fits quite well the characteristics reported by Le Breton & Malbranche (1884), e. g., faintly amyloid ascus tips and slightly allantoid spores.

Le Breton & Malbranche did not describe the apothecia of their *O. oculifuga* var. *microspora*, therefore, it remains unclear whether the protologue originates from sessile or short-stipitate apothecia, or perhaps from both. In PC 0088500 the apothecia had a very short stalk.

Orbilia miniata (Batsch) Sacc., Syll. Fung. 8: 632 (1889)

≡ *Peziza miniata* Batsch, Elenchus fung. II: 207, pl. 27 fig. 144 (1786)
≡ *Calloria miniata* (Batsch) Sacc., Michelia 1: 63 (1877)

No type material ([Germany, Weimar,] Webicht, on wood and rotten leaves, beginning of Sept. 1785) was found in JE, LE, PAD, PAL, and W. The description refers to a saturn-red (= miniate), short stipitate discomycete. Saccardo (1877, 1889) transferred the taxon with hesitation to *Calloria* and later to *Orbilia*, and considered a possible relationship to *Peziza haematites* (see p. 1673). Without studying the type he referred two Italian collections (on wood of *Fagus*) to this taxon. Based on the lignicolous vs. foliicolous habitat, it can be assumed that the original description includes two different fungi.

Orbilia minutissima (Rostr.) Sacc., Syll. Fung. 8: 629 (1889)

≡ *Calloria minutissima* Rostr., Medd. Grønl. 3: 537 (1888)
≡ ***Laetinaevia minutissima*** (Rostr.) Nannf. ex B. Hein, Willdenowia, Beih. 9: 50 (1976)

Hein (1976: 50) examined the holotype in C (Greenland, Kobbefjord, on *Angelica archangelica*, 28.VI.1884). The many included specimens from various parts of Europe inhabit herbaceous stems of a wide range of dicotyledonous plants and appear to show an arctic-alpine distribution. The species is said to differ from the very similar *L. adonis* (Fuckel) Nannf. ex B. Hein mainly in the absence of an amyloid apical ring.

A specimen under the name *O. minutissima* which is not listed by Hein in his examined specimens (Sweden, Torne Lappmark, Jukkarjärvi, Murlja, on stems of *Angelica archangelica*, VIII.1928, J.A. Nannfeldt, herb. Petrak, M) was studied and found to have long, acute, glassy hairs at the margin (30–40 × 3.3–3.8 µm), with an acute-conical lumen near the base. The asci arise from croziers and have hemiamyloid (type RR) apical rings, and the spores measured 12–14 × 4.2–4.7 µm. This appears to be conspecific with the type material of *Naevia diaphana* Rehm [≡ *Unguicularia diaphana* (Rehm) Nannf.], although the glassy substance did not dissolve in 5% KOH. These glassy-haired taxa perhaps belong to the genus *Iridinea* Velen. (see under *Habrostictis diaphana*, p. 1669).

Orbilia mitracea Velen., Monogr. Discom. Bohem.: 98, pl. 11 fig. 42 (1934)

No type material exists of this taxon (Svrček 1954) which was collected in June 1925 near Mnichovice (Bohemia). The stated ecology (humid trunk of *Picea*, shady forest) and the colourless apothecia of 0.5–1 mm diam. suggest a desiccation-sensitive taxon, but the small excipular cells of 12–15 µm diam. and the uninflated paraphyses covered by thick exudate might point to a desiccation-tolerant species, perhaps *O. vinosa*. The acicular, 10–12 µm long spores are also reminiscent of *Hyalorbilia juliae* or a member of section *Helicoon*. The mitra-like glassy processes on the marginal cortical cells, from which the name of the taxon is derived, and particularly the thin flexuous stalk of the rather short asci (25 × 3–4 µm incl. stalk), depicted on his manuscript plate, exclude the genus *Hyalorbilia.*

Laricina mollis Velen., Monogr. Discom. Bohem.: 104 (1934)

= ***Ascocorticium anomalum*** (Ellis & Harkn.) J. Schröt., in Engler & Prantl, Nat. Pflanzenfam., Teil. I (Leipzig) 1(1): 161 (1897)

The monotypic genus *Laricina* Velen. was compared by Velenovský (1934) with *Orbilia*. A recent unpublished revision of the type species *L. mollis* (on brachyblasts of twigs of *Larix*) by M. Svrček (I.2004, in sched., PRM 149442) revealed this to be a synonym of *Ascocorticium anomalum* (M. Šandová pers. comm.).

Orbilia mollisioides Höhn., Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. I, 118: 1521 (1909)

≡ ***Micropeziza mollisioides*** (Höhn.) Baral, Helleman & U. Lindemann, in Helleman et al., Ascomycete.org 5(4): 134 (2013)
= *Crustomollisia roburnea* (Velen.) Svrček, Sydowia 39: 219 (1987) [1986]
≡ *Pezizella roburnea* Velen., Monogr. Discom. Bohem. (Prague): 161 (1934)

Höhnel placed this foliicolous species in *Orbilia* on account of its clavate-capitate apices of paraphyses embedded in gel, and the yellowish clods of exudate on the marginal excipulum. According to a study of the holotype (Germany, Sachsen, Schandau, Kurpark, leaves of *Quercus rubra*, X.1900, W. Krieger [FH], IVV: H.B. 6293), this is an earlier synonym of *Crustomollisia roburnea*, the type of the genus *Crustomollisia* Svrček, and a very close relative of the North American *Micropeziza castanea* (Sacc. & Ellis) Baral & Guy Garcia (≡ *Calycellina castanea* (Sacc. & Ell.) Dennis, see Helleman et al. 2013). The species was also studied from fresh collections and seems confined to leaves of *Quercus*. The asci have a conical ascus apex with an amyloid ring of the *Calycina*-type. The genus *Micropeziza* Fuckel as redefined by Helleman et al. is considered to be closely related to *Calycellina*, differing in abundant brown clods of exudate on the excipulum, a gelatinized, slightly protruding margin, and swollen paraphysis apices containing in the living state a strongly refractive, hyaline to yellow-green vacuolar body (VB). See also under *Orbilia myristicae*.

Orbilia myriospora (W. Phillips & Harkn.) Sacc., Syll. Fung. 8: 631 (1889)

≡ *Calloria myriospora* W. Phillips & Harkn., Bull. Calif. Acad. Sci. 1: 23 (1884)
≡ *Myridium myriosporum* (W. Phillips & Harkn.) Clem., Gen. Fungi: 174 (1909)
≡ ***Laetinaevia myriospora*** (W. Phillips & Harkn.) Nannf. ex B. Hein, Willdenowia, Beih. 9: 51 (1976)

The type material (USA, California, herbaceous stems of *Psoralea macrostachya*, undated [1882 according to Hein 1976], W.H. Harkness 2779, K(M) 36056, IVV: H.B. 5544) contains numerous apothecia which are, however, immature as already stated by Hein (1976), who found the asci up to 10 µm wide and the 'apex (still?) without a wall thickening or iodine reaction'. A single, 14 µm wide ascus was found in the present study, which showed a distinct amyloid apical ring (blue in KOH+IKI), with the lower part most reactive (*Ploettnera*-type). The species was described in the protologue as having multispored asci ('sporidia excessively minute, innumerable'), but the authors noted on the label that 'The contents of the asci resemble granular plasma such as is often seen in *Peziza* in an immature shape of growth'. Both Hein's and the present examination confirm that these minute 'sporidia' are lipid bodies which fill the cytoplasm of immature asci. Presumably, the species is not more than 8-spored at maturity, since polyspored taxa are so far unknown in the *Naevioideae*. The asci appear to arise from croziers, and the species seems well-placed in *Laetinaevia* in concordance with Hein (l.c.). *Calloria myriospora* is the type species of *Myridium* Clem., hence this genus is a tentative synonym of *Laetinaevia*. *Myridium* was declared as a nomen rejiciendum in order to conserve *Laetinaevia* over *Myridium* (Korf 1988). The present material bears the original handwritten diagnosis. Hein (l.c.), who studied a duplicate deposited in PAD, named that specimen 'lectotype'.

Orbilia myristicae Henn., Hedwigia 41: 144 (1902)

The species and *Orbilia coleosporioides* Sacc. were placed by Saccardo & Saccardo (1906: 139) in an unranked subgroup of *Orbilia*, *Orbiliopsis* Sacc., to comprise fungi parasitic on living leaves. Sydow (1924) designated the latter as type species, raised the group to generic level, and added a further species, but did not mention *O. myristicae* at all (see also p. 207). In fact, *O. myristicae* shows little resemblance to the two species included by Sydow.

Reexamination of a syntype of *O. myristicae* [Java, Bogor ('Buitenzorg'), on living leaves of *Myristica fragrans*, undated, A.W.P. Zimmermann, herb. Sydow, S-F9972, IVV: H.B. 7686] revealed asci with conical apex and a slightly refractive apical ring that does not stain in IKI, with or without KOH-pretreatment). The ectal excipulum is of a rather pale brown textura angularis. The fungus is found here to be conspecific with *Orbilia fuscopallida* (p. 1672), and shows similarities to the genus *Micropeziza* (see also under *Orbilia mollisioides*, p. 1679), but differs in lacking both gel and brown clods, and in having short hair-like protrusions.

Orbilia nivea (P. & H. Crouan) Quél., Enchir. Fung.: 299 (1886)

≡ *Helotium niveum* P. & H. Crouan, Florule Finistère: 47 (1867) [non *Helotium niveum* Kirschst. 1907; nec. *Helotium niveum* Velen. 1947 = *Hymenoscyphus vernus* (Boud.) Dennis]
≡ *Calycina nivea* (P. & H. Crouan) Kuntze, Revis. Gen. Pl. 3: 448 (1898)
≡ ***Mniaecia nivea*** (P. & H. Crouan) Boud., Hist. Class. Discom. Eur. (Paris): 99 (1907)

Helotium niveum was described by Crouan & Crouan (1886) for white, sessile apothecia of 1/5 mm diam. growing on the stem base of living *Diplophyllum albicans* (as *Jungermannia albicans*), probably near Brest (Bretagne, Finistère). The unpublished watercolour sketch preserved at CO (J.P. Priou pers. comm.) shows distinctly larger apothecia in relation to the leaves of the host. The large asci are 8-spored, the ellipsoid spores multiguttulate (no size given), and the filiform, straight paraphyses eguttulate.

Le Gal (1953: 122) redescribed the original collection (30.I.1864), with asci of 160–240 × 22–30 µm and spores of 18–28 × 10–17 µm, but did not mention the apothecial size. J.P. Priou (pers. comm.) wanted to examine the holotype but found the cardboard inside the envelope empty. A recent collection on *Jungermannia gracillima* (E. Rubio, IVV: E.R.D. 6643) showed similarly large spores of *22–27 × 12.7–14.5 µm and apothecia of 0.17–0.35 mm diam., but curved paraphyses. Boudier (1904–10, 1909: 263, pl. 456) described under the name *Mniaecia nivea* a collection on an unidentified member of *Jungermanniales* from Jura, with slightly smaller spores [*17–25 × 10–12 µm, but 16–19.5(–25) × 8.2–10.3(–11) µm when evaluated from scale] and apothecia of 0.5–1 mm diam. (0.53–0.6 mm from scale). See also under *Orbilia albida* (p. 1660).

Hyalinia nostra Rehm, Ann. Myc. 6: 117 (1908)

≡ *Orbilia nostra* (Rehm) Sacc. & Trotter, Syll. Fung. 22: 724 (1913)
= ***Sarcotrochila alpina*** (Fuckel) Höhn., Sber. Akad. Wiss. Wien, Math.-Naturw. Kl., Abt. 1 126(4-5): 310 (1917)

This taxon is a later synonym of *Sarcotrochila alpina*, following reexamination of two syntype specimens (Germany, München, Park Neufriedenheim, leaves of *Larix japonica*, IV.1908, H. Rehm, Ascomyc. 1754, M, MPU, IVV: H.B. 5050). The apothecia open by a lateral ellipsoid lid of host epidermis, the short-stalked asci arise from croziers and have a strongly papillate apex with a small, IKI deep blue (euamyloid) apical ring. The multiguttulate ascospores (10.5–13 × 3.5–4 µm) have a median constriction and large, polar gelatinous caps. A yellowish refractive substance (remnants of VBs) is observed in the long, cylindrical terminal cells of the paraphyses. Various recent collections showed large, elongated, hyaline to chlorinaceous VBs (IVV: H.B. 6109, 9544 etc.). *Orbilia retrusa* is a further synonym (see p. 1683). The genus *Sarcotrochila* Höhn. is related to *Trochila* Fr. which has the same type of paraphyses that contain VBs. These refractive vacuolar contents were shown to be characteristic of the family *Cenangiaceae* (= *Hemiphacidiaceae*), to which the two genera belong (see Pärtel et al. 2016).

Orbilia obscura T. Ghosh, N. Mukherji & Basak, Jute Bull. 27: 135 (1964)

≡ ***Peziza multiguttulata*** A. K. Kar & K. P. Pal, Mycologia 60: 964 (1968) [non *Peziza obscura* Cooke (1878)]

Based on the examination of the type and further specimens from India, Kar & Pal (1968) reported this species to have operculate amyloid asci, and recognized it as a member of the genus *Peziza*.

Habrostictis ocellata (Pers.) Fuckel, Jahrb. Nassau. Ver. Naturkd. 25–26: 326 (1871)

≡ *Peziza ocellata* Pers., Syn. Meth. Fung. 2: 667 (1801)
≡ *Stictis ocellata* (Pers.) Fr., Syst. Mycol. 2(1): 193 (1822), nom. sanct.
≡ *Propolis ocellata* (Pers.) Sacc., Michelia 2: 333 (1881)
≡ *Ocellaria ocellata* (Pers.) J. Schröt., in Cohn, Krypt.-Fl. Schlesien 3.2: 150 (1893)
≡ ***Pezicula ocellata*** (Pers.) Seaver, North American Cup-fungi (Inoperculates): 345 (1951)

Pezicula ocellata has some macroscopic resemblance to *Orbilia carpoboloides* (P. & H. Crouan) Baral (= *Habrostictis rubra* Fuckel). Both species have therefore been treated by Fuckel in the same genus. The asci of *P. ocellata* have a large hemiamyloid (type RR) apical ring of the *Pezicula*-type, and the ascospores a very high lipid content (OCI 5, multiguttulate). Both features are typical of the genus *Pezicula* to which Verkley (1999) assigned the species that was earlier known under the name *Ocellaria ocellata*.

Orbilia oculifuga Quél., Compt. Rend. Associated Franç. Avancem. Sci. 9: 674, pl. IX fig. 16 (1881)

≡ *Hyalinia oculifuga* (Quél.) Boud., Hist. Class. Discom. Eur.: 104 (1907)
?= ***Calycina cruentata*** (P. Karst.) Kuntze, Revis. gen. pl. (Leipzig) 3(3): 448 (1898)

Type material (Normandie, on culms of *Glyceria*, spring, A. Le Breton) could not be located at PC, but a specimen exists at the herbarium of Rouen (I. Gaspérini pers. comm.) which seems to be part of the type. Because this herbarium does not send any material on loan, J.P. Priou (pers. comm.) visited it and examined that specimen but found only immature apothecia, therefore, he could not resolve the identity of this obviously helotialean discomycete. The label bears the data '1876, on *Glyceria*, Béch, Rouen' (France, Normandie, Seine-Maritime, IVV: 1876), and a diagnosis and sketch which exactly agree with Quélet's (1881) protologue. Obviously this is the handwriting of Le Breton, who was given as the finder of *O. oculifuga* by Quélet and who later added Quélet's diagnosis by referring to Quélet's publication. J.P. Priou reviewed another specimen at the herbarium of Rouen under the name *Orbilia oculifuga* (on leaves of *Cyperaceae*, Ferrières, A. Malbranche, IVV: VIII.1885), which had sessile, hairy apothecia, and identified it as *Calycina cruentata*.

In April 1879 Le Breton collected a similar fungus, on culms of *Glyceria aquatica*, prairies du Grand-Quevilly in Rouen (Le Breton & Malbranche 1884). Despite the same host genus, he doubted identity with *O. oculifuga* but considered this specimen to be conspecific with another sample collected in 1884, which became the type of Saccardo's *O. oculifuga* var. *microspora* (see above). Also a third specimen was doubted by Le Breton to be genuine *Orbilia oculifuga*, which was reexamined in the present study and found to belong as well to *Calycina cruentata* (see under *O. oculifuga* var. *microspora*, p. 1678). It has a very short stipe, whereas Quélet (1881) described the apothecia of *O. oculifuga* as sessile.

Belonium orbilioides Rehm, Rabenh. Krypt.-Fl., 1.3: 1232 (1896)

= ***Micropeziza umbrinella*** (Desm.) Baral, Helleman & U. Lindem., in Helleman, Lindemann, Baral & Yeates, Ascomycete.org 5(4): 134 (2013)

The holotype (Switzerland, Berner Oberland, Wengern-Alpe behind Jungfrau, on stems of *Apiaceae*, IX.1893, H. Rehm, S-F12076, IVV: H.B. 6429) was examined and found to be a later synonym of *Micropeziza umbrinella*. The species was also studied from Desmazière's type of *Peziza umbrinella* (IVV: H.B. 4674), which is the type of the genus *Calloriella* Höhn., as well as from fresh specimens. According to the original description, *Allophylaria soederholmii* Svrček is a further synonym. The species is characterized by its inamyloid, conical ascus apices, large fusoid ascospores containing two large and many small LBs, and paraphyses with strongly capitate-clavate apices (possibly, therefore, the name '*orbilioides*') containing VBs in the living state. The subsessile, yellowish-brownish apothecia have a distinctly gelatinized ectal excipulum, especially at the slightly protruding margin, which is covered by brown exudate. See also under *Orbilia mollisioides*, p. 1679.

Hyalinia orbilioides (Feltgen) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Pezizella orbilioides* Feltgen, Rec. Mém. Trav. Soc. Bot. G.-D. Luxemb. 16: 53 (1903)
≡ *Ombrophila orbilioides* (Feltgen) Höhn., Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. I 115: 1282 (1906)

Höhnel (1906) examined two authentic specimens of *Pezizella orbilioides* and found them to belong to two different taxa. Without specifying the envelopes, he referred one of them (with abundant apothecia) to Feltgen's taxon and combined it in *Ombrophila*. He did not supply a diagnosis of that fungus, which he found to be mostly immature. In the other envelope, Höhnel observed apothecia with a dentate margin, which he considered to belong to *Cistella ciliata* (Crouan) Höhn. However, he reported its spores as 6–12 × 1.4–1.8 µm, with obtuse ends, which would match those in the protologue of *P. orbilioides* (8–9.5 × 1.25–2 µm), whereas *Helotium ciliatum* P. & H. Crouan was described with certainly much longer, fusiform to falcate spores with acute ends (Crouan & Crouan 1867 and unpublished watercolour sketch, spore size not indicated).

Three authentic specimens exist at LUX. Though bearing slightly deviating data, they all appear to be part of the single collection mentioned in the protologue (Luxembourg, Kockelscheier, on petioles of *Petasites hybridus*, 8.IV.1902, J. Feltgen). In one (LUX 42513, undated) no apothecia could be found. Apothecia were abundantly seen in the other two: LUX 42512 (8.IV.1902) contains the original diagnosis together with a sketch of the apothecia and microscopy, but the examined apothecium was apparently not mature; in LUX 42532 (IV.1902, IVV: H.B. 9570) mature asci were found, and this specimen was thoroughly investigated. LUX 42512 and LUX 42532 undoubtedly contain the same species which fits well Feltgen's description and original sketch, particularly in the characteristic, apically mostly hooked paraphyses. We here designate LUX 42532 as **lectotype** of *Pezizella orbilioides* (MBT382125).

A specimen from France (Pay-de-Dôme, Mont. Dore, on stem of *Heracleum sphondylium*, 7.V.1993, R. Péan 9338A, IVV: H.B. 5183) was also examined only in the dead state. It appears to be conspecific with the lectotype and suggests a wider host spectrum. An unusual feature of this species is the slightly gelatinized ectal excipulum of textura angularis which stains distinctly blue in IKI in this as well as the two type specimens. There is also a yellow pigment in the paraphyses when mounted in KOH, which Feltgen mentions as 'reddish-yellow mass'. *P. orbilioides* appears to be congeneric with *Orbilia circinella* (see p. 1666). The two taxa might belong in the *Calloriaceae*, but their generic affiliation is unknown at present.

Tapesia orbilioides (Rehm) Sacc., Syll. Fung. 11: 410 (1895)

≡ *Eriopezia orbilioides* Rehm, Rabenh. Krypt.-Fl., 1.3: 695 (1889)
= ***Ascobolus foliicola*** Berk. & Broome, J. Linn. Soc., Bot. 14(no. 74): 109 (1873) [1875]

This species is listed in Aebi (1972: 69) as a synonym of *Ascobolus crouanii* Boud. (≡ *A. foliicola*).

Habrostictis pallida (Fuckel) Clem., Gen. Fungi: 174 (1901)

≡ *Pseudopeziza pallida* Fuckel, Jahrb. Nassau. Ver. Naturkd. 23–24: 291 (1870)
≡ *Naevia pallida* (Fuckel) Rehm, Rabenh. Krypt.-Fl., 1.3: 138 (1888)

The original description of *Pseudopeziza pallida* in Fuckel (1870, copied by Rehm 1888) refers to a discomycete with asci of 56 × 6 µm and ascospores of 10 × 2 µm, growing on the underside of leaves of *Buxus sempervirens*. Rehm placed the species in *Naevia* Fr., but he stated that its relationship was dubious because of the insufficient description and the lacking data on the iodine reaction. Hein (1976: 34) listed *P. pallida* as a mitosporic fungus. Yet, this opinion can hardly be accepted, as it does not match the original description of a fungus with a teleomorph. *P. pallida* is the type species of *Habrostictis* Clem. (non Fuckel, see p. 206).

Orbilia pannorum J. Schröt., in Cohn, Krypt.-Fl. Schlesien 3.2: 121 (1893)

No type material (Poland, Wrocław, botanical garden, on rotten [stems of] *Arctium*, July) could be located in M, W, WRSL, and Z. Apothecia were described as 0.5–1.5 mm diam., light carneous to almost rosaceous, at the base with white, delicate hyphae, and the spores as 'filiform, 9–11 × 0.5–1 µm', without any further details. The original description suggests identity with *O. auricolor*, but it remains unclear why Schröter did not mention curvature of the spores.

A specimen identified by Jaap (1922: 15) as *O. pannorum* (Germany, Prignitz, Triglitz, on rotten cloth in pine forest, 25.VIII.1905, O. Jaap, IVV: H.B. 7912) was reexamined from HBG. It contains abundant, often large and strongly undulating apothecia (Fig. 116e, Pl. 953: 10) referable to *O. auricolor*, with comparatively long spores (10–14 × 1 µm).

Orbilia parietina (Schrad.) S. Hughes

This is a misspelling for ***Orbicula parietina*** (Schrad.) S. Hughes (*Pyronemataceae*, *Pezizales*).

Orbilia peltigerae (Fuckel) Sacc., Syll. Fung. 8: 631 (1889)

≡ *Calloria peltigerae* Fuckel, Jahrb. Nassau. Ver. Naturkd. 23–24: 283 (1870)
≡ *Hyalinia peltigerae* (Fuckel) Boud., Hist. Class. Discom. Eur.: 104 (1907)
= ***Scutula epiblastematica*** (Wallr.) Rehm, Rabenh. Krypt.-Fl., 1.3: 294 (1890)

According to Keißler (1930: 151) and Nannfeldt (1932: 254) this is a synonym of *Scutula epiblastematica* (*Lecanorales*), see under *O. epiblastematica* (p. 1671).

Hyalinia perexigua (J. Schröt.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Hymenoscyphus perexiguus* J. Schröt. [as '*Hymenoscypha perexigua*'], in Cohn, Krypt.-Fl. Schlesien 3.2: 71 (1893)
≡ *Pezizella perexigua* (J. Schröt.) Sacc., Syll. Fung. 11: 405 (1895)

Type material ([Poland,] Breslau [Wrocław], Bischofswalde, on rotten leaves of *Carex* in swamps, October) could not be located in M, W, and WRSL. From ZT a specimen under the name *Pezizella perexigua* (Schröter) Sacc. was received (Austria, Sonntagberg, on leaves of *Carex glauca*, X.1905, P. Strasser, Rehm, Ascomyc. 1652). This is *Mollisia caricina* Fautrey 1891, with asci of 20–25 × 3.5–4 µm, with euamyloid apical ring, allantoid ascospores of 4.5–6 × 0.8–1 µm, and an only basally pigmented ectal excipulum of light olive-brown textura angularis. Also Höhnel (1926a: 71) identified Rehm Ascomyc. 1652 as *Mollisia caricina*. The protologue of *H. perexigua* differs in much wider asci (22–25 × 7–9 µm) and spores (5–6 × 2.5–3 µm). Since the apothecia were described as 'white, translucent', *H. perexigua* might represent a *Calycina* rather than a *Mollisia*.

Habrostictis persoonii (Moug.) Rehm in Hedwigia 21: 70 (1882)

≡ *Peziza persoonii* Moug., in Persoon, Mycol. Eur. 1: 288 (1822, tab. 12 figs 1–3); –Fr., Syst. Mycol. 2(1): 121 (1822), nom. sanct.
≡ ***Stamnaria persoonii*** (Moug.) Fuckel, Jahrb. Nassau. Ver. Naturkd. 23–24: 309 (1870)
≡ *Phialea persoonii* (Moug.) Gillet, Champ. Fr., Discomyc.: 106 (1881)
≡ *Calycella persoonii* (Moug.) Quél., Enchir. Fung.: 305 (1886)

Dennis (1956: 64) described British material of this species and mentioned Mougeot's 'excellent original figure'. The genus was previously placed in the *Helotiaceae* (see Künkele et al. 2005) but might belong to a family of its own (as *Stamnaria* lineage in Jaklitsch et al. 2016).

Orbilia phymatodes (W. Phillips) Seaver, North American Cup-fungi (Inoperculates): 156 (1951)

≡ *Peziza phymatodes* W. Phillips, Grevillea 5: 117 (1877)
≡ *Pezizella phymatodes* (W. Phillips) Sacc., Syll. Fung. 8: 285 (1889)
≡ *Hymenoscyphus phymatodes* (W. Phillips) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ ***Psilachnum phymatodes*** (W. Phillips) Declercq, Sterbeeckia 25: 24 (2005)

Dennis (1964: 60) redescribed the type of this badly known species (California, Sierra Nevada, Blue Canyon, on some soft swamp grass). He reported asci with small amyloid apical rings and cylindrical paraphyses, and tentatively kept the species in *Pezizella* Fuckel (= *Calycina*). Recent European collections (IVV: H.B. 3809, 8835, E.R.D. 7062 etc.) appear to match Dennis' description quite well. The species is probably better placed in *Psilachnum* instead of *Calycina*, e. g., because of the striking large guttule below the spores inside the living ascus. Originally restricted to taxa with lanceolate paraphyses, the concept of *Psilachnum* was widened to include also those with narrowly lanceolate to cylindrical paraphyses (Baral, in Baral & Krieglsteiner 1985: 86).

Orbilia picea Velen., Monogr. Discom. Bohem.: 98 (1934)

No material exists of this taxon (Svrček 1954), which was said to grow on a xeric branch of *Picea* near Mnichovice (Bohemia). The large, carneous apothecia of 1 mm diam., the stalked, bifurcate asci, the scarcely inflated paraphyses covered by exudate, and the very narrow, straight spores suggest *Orbilia cardui* or *O. atlantis*, except that the 8–10 µm long spores.

Orbilia primulae (Rehm) Sacc., Syll. Fung. 8: 630 (1889)

≡ *Calloria primulae* Rehm, Ber. naturhist. Ver. Augsburg 26: 66 (1881)
≡ *Naevia primulae* (Rehm) Rehm, Ber. Bayer. Bot. Ges. 13: 142 (1912)
≡ ***Naeviopsis primulae*** (Rehm) B. Hein, Willdenowia, Beih. 9: 74 (1976)

Hein (1976) studied the type material (Austria, Tirol, on *Primula glutinosa*) of this alpine species, and found inamyloid asci with very large (25–32 × 5–6 µm), finally asymmetrically 1-septate ascospores. The species is said to be close to another alpine species, *Naeviopsis salicis* B. Hein, that has asci with apical rings reacting faintly blue in IKI.

Patinella punctiformis Rehm, Rabenh. Krypt.-Fl., 1.3: 311 (1889)

The type (Germany, Bayern, Neustadt a. d. Aisch, Sugenheim, on bark of *Picea*, H. Rehm, S, IVV, H.B. 7716) was examined. It has large, ellipsoid-oblong, multiguttulate spores of 12.5–19.5 × 6.5–7.6 µm, inamyloid asci with obtuse, thin-walled apex, and a blackish-olivaceous-brown ectal excipulum of isodiametric cells running under a high angle to the surface, the pigment of which not dissolving in KOH. *P. punctiformis* was also recorded from a sun-exposed root of *Pinus* (Velenovský 1934: 75), whereas Saccardo (1892: 52) erroneously translated 'Auf Fichtenrinde' to 'ad corticem *Pinus*'. The relationship of this fungus is unclear.

Orbilia pulviscula (Cooke) Seaver, North American Cup-fungi (Inoperculates): 160 (1951)

≡ *Peziza pulviscula* Cooke, Bull. Buffalo. Soc. Nat. Sci. 2: 297 (1875) [also in Hedwigia 14: 84 (1875)]
≡ *Pezizella pulviscula* (Cooke) Sacc., Syll. Fung. 8: 278 (1889)
≡ *Hymenoscyphus pulvisculus* (Cooke) Kuntze, Revis. Gen. Pl. 3: 485 (1898)
≡ ***Calycellina pulviscula*** (Cooke) Dennis, Persoonia 3: 61 (1964)

Dennis (1964) redescribed the type (USA, New York, Poughkeepsie, on stems of *Phytolacca*) as having asci with a conical apex with a 'very small pore probably blued by Melzer's reagent'. The conical ascus tips, cylindrical paraphyses, and excipulum anatomy (with a basal brown-walled layer) led Dennis to place the taxon in '*Calycellina* rather than *Hyalinia*'.

Orbilia pusilla (Speg.) Sacc., Syll. Fung. 8: 630 (1889)

≡ *Calloria pusilla* Speg., Michelia 1(5): 473 (1879)
≡ *Hyalinia pusilla* (Speg.) Boud., Hist. Class. Discom. Eur.: 104 (1907)
≡ ***Naeviopsis pusilla*** (Speg.) B. Hein, Willdenowia, Beih. 9: 81 (1976)

The holotype (Italy, [Venice, Treviso,] Conegliano, leaves of *Cornus sanguinea*, 8.IV.1879, C.L. Spegazzini, LPS 28072, IVV: H.B. 6952) was examined. The taxon is characterized by asci arising from croziers, with a conical apex reacting deep blue (euamyloid) in IKI (*Pezicula*-type), ascospores ellipsoid-oblong, 9–13.5 × 4.3–4.5 µm, with a few minute LBs, and apically uncinate paraphyses. The minute apothecia grow on the under side of fallen leaves below the epidermis, which they split in 4 hyaline lobes.

Hyalinia querceti (Sacc.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Helotium querceti* Sacc., Michelia 1(1): 68 (1877)
≡ *Calycina querceti* (Sacc.) Kuntze, Revis. Gen. Pl. 3 (2): 449 (1898)
= ***Calycellina punctata*** (Fr.) Lowen & Dumont, Mycologia 76(6): 1006 (1984)

This is a synonym of *Calycellina punctata* according to a type study by Dennis (1956: 174, fig. 152 A), a species with euamyloid apical rings and yellow, elongate VBs in the living paraphyses and hairs.

Habrostictis quercicola Hazsl., Verh. K. K. Zool.-Bot. Ges. Wien 37: 151 (1887)

≡ *Ocellaria quercicola* (Hazsl.) Sacc., Syll. Fung. 8: 657 (1889)

The original description (Hungary, Eperies, on branches of *Quercus*) suggests a *Pezicula* (asci 4–8-spored, spores 20–26 × 8–12 µm, eventually 1–3-septate). However, Verkley (1999: 150), who did not study the type, doubted such a relation, because Hazslinsky reported numerous conidia within the asci ('filled with spermatia'), which are not known to occur in such high number in asci of *Pezicula*.

Algincola quercina Velen., Novit. Mycol.: 177 (1940)

No specimen under this name could be found in PRM. *A. quercina* was found in a layer of *Pleurococcus* on a rotten trunk of *Quercus* near Mnichovice (Bohemia). The honey-yellowish apothecia of 1 mm diam. contain small inamyloid asci with broadly ellipsoid, biguttulate, 2.5–3.5 µm long spores. The monotypic genus *Algincola* Velen. was thought by Velenovský (1940) to be related to *Agyrium* Fr. and *Orbilia*.

Orbilia racheophila (Sacc. & Speg.) Sacc., Syll. Fung. 8: 626 (1889)

= *Calloria succinella* subsp. *racheophila* Sacc. & Speg., Michelia 1(4): 430 (1878)

No material was received from PAD, PAL, and W. The authors compared the taxon (Italy, [Venice, Treviso,] Conegliano, main axis of rotten spike of *Zea mays*, spring 1878) with *Calloria succinella* Sacc. and *Orbilia luteorubella*. The description is too incomplete to recognize a genus or family: apothecia rose-red, scarcely 0.5 mm diam., flat, smooth, ectal excipulum rose, of a thin, parenchymatous texture, asci 45–50 × 5–5.5 µm, short-stalked, with rounded apex, paraphyses slightly clavate, spores 10–12 × 1.75–2 µm, cylindrical, straight to slightly curved.

Orbilia retrusa (W. Phillips & Plowr.) Sacc., Syll. Fung. 8: 630 (1889)

≡ *Peziza retrusa* W. Phillips & Plowr., in Phillips, Grevillea 4: 122 (1876)
≡ *Calloria retrusa* (W. Phillips & Plowr.) W. Phillips, Man. Brit. Discomyc.: 407 (1887)
≡ *Pseudopeziza retrusa* (W. Phillips & Plowr.) Massee, Brit. Fung.-Fl. 4: 294 (1895)
= ***Sarcotrochila alpina*** (Fuckel) Höhn., Sber. Akad. Wiss. Wien, Math.-Naturw. Kl., Abt. 1 126(4-5): 310 (1917)

The studied specimen (Great Britain, North Wales, leaves of *Larix*, date and collector not indicated, W. Phillips 126, M, IVV: H.B. 5052) appears to be part of the type material. *Orbilia retrusa* is conspecific with *Sarcotrochila alpina*. The apothecia open by a lateral lid of host epidermis, the ascus apex is strongly papillate, with a small, IKI deep blue (euamyloid) apical ring, the multiguttulate spores are slightly constricted, have polar sheaths, and measure 9–12 × 3–3.2 µm, the long terminal cells of paraphyses have deep yellowish-ochraceous contents. *Hyalinia nostra* is a further synonym (see p. 1680).

Habrostictis roseoflavida (Rehm) Höhn., Mitt. bot. Inst. tech. Hochsch. Wien 3: 95 (1926)

≡ *Pezizella roseoflavida* Rehm, Ann. Mycol. 11: 167 (1913)

The reddish colour of the apothecia seems to have prompted Höhnel (1926b) to believe that this taxon is 'very probably' conspecific with *Orbilia lasia* s. Schröter (1893) and very close to but different from the type of *Habrostictis lasia* (Berk. & Broome) Boud.

A syntype specimen was examined (Germany, Bayern, Burgkunstadt, on wood of *Tilia*, A. Ade, Rehm Ascomyc. 2029, PAD, IVV: H.B. 7320). *H. roseoflavida* hereafter clearly represents a member of the genus *Cistella*, with short uninflated hairs with distinct, partly rod-shaped warts restricted to the apex. It is further characterized by asci with croziers and hemiamyloid apical rings, spores of †5–7.3(–8) × 2–2.5 µm with several small LBs in each half, and an inamyloid medullary excipulum. *Cistella granulosella* (P. Karst.) Nannf., *C. xylita* (P. Karst.) Nannf., and *C. geelmuydenii* Nannf. are possible synonyms. Type material of these taxa should carefully be compared in order to clarify their identity (see also Raitviir 2004: 32). The substrate is *Tilia* as indicated in the protologue, not *Salix* as printed on the label.

Hyalinia roseola (Fr.) Boud. [as '*rosella* Quél.'], Icon. Mycol., liste prélim.: 4 (1904) [non *Orbilia rosella* (Rehm) Sacc.]

≡ *Peziza roseola* Fr., Syst. Mycol. 2(1): 101 (1822)
≡ *Lachnea roseola* (Fr.) Gillet, Champ. Fr., Discomyc.: 86 (1881)
≡ *Mollisia roseola* (Fr.) Quél., Compt. Rend. Associated Franç. Avancem. Sci. 11: 412 (1883) [1882]
≡ *Trichopeziza roseola* (Fr.) Sacc., Syll. Fung. 8: 429 (1889)

No authentic material of this taxon (Sweden, on bark of fallen branches of *Juglans* etc., autumn) could be located in UPS. Fries characterized it by a flexuous, non-dentate, whitish-puberulent margin and a concave, carneous-rose disc. Saccardo (1889) merely repeated Fries's description, whereas Quélet (1873: 403; 1883: pl. XII fig. 9) and Gillet (1881) added personal collections from France (Quélet: on fallen branches of *Juglans*, Gillet: on wood, coniferous branches, herbaceous stems). Quélet's (1883) combination *Mollisia roseola* in the legend (p. 412) to his pl. XII is nothing but the binomen without author citation, but with a reference to his previous treatment (Quélet 1873) by erroneously citing p. 398 instead of 403.

Boudier (1909: 269, pl. 465, as '*Hyalinia rosella*') interpreted Fries's taxon as a fungus with a 'regularly dentate' margin. This is in conflict with Fries's statement of a non-dentate but puberulent margin. Boudier's fungus grew on bark of *Tilia* and is referred here to *Orbilia crenatomarginata*.

Although very brief, the descriptions of Fries and Quélet appear to fit *O. phragmotricha* or *O. rubella* rather than *O. crenatomarginata*. The spores were figured as narrow and medium allantoid by Quélet (1883), but Gillet described them as 'ovoid, difficult to observe'. In the absence of microscopic characters in the protologue, Fries's taxon remains a nomen dubium.

Orbilia roseorubra (P. & H. Crouan) Quél., Enchir. Fung.: 298 (1886)

≡ *Helotium roseorubrum* P. & H. Crouan, Florule Finistère: 48 (1867)

Crouan & Crouan (1867) described this taxon from Bretagne (France), on a heap of muddy soil, with sessile, hemispherical or turbinate, rose-red apothecia 1–3 mm diam., 8-spored, subcylindrical asci, ovoid spores with a single large drop ('sporidiole'), and apically a little inflated, curved paraphyses. Together with the habitat this might refer to an *Octospora* (*Pezizales*), but no microscopic measurements are given. According to J.P. Priou (pers. comm.), material of *H. roseorubrum* exists at CO.

Orbilia rozei (Quél.) Quél., Compt. Rend. Associated Franç. Avancem. Sci. 9: 674, pl. IX fig. 15 (1881)

≡ *Peziza rozei* Quél., Grevillea 8: 38 (1879)
≡ *Pezizella rozei* (Quél.) Sacc., Syll. Fung. 8: 283 (1889) [also on p. 623, as *Orbilia*]
≡ *Hymenoscyphus rozei* (Quél.) Kuntze, Revis. Gen. Pl. 3: 486 (1898)
(?)= ***Psilachnum rubicundum*** (Sacc. & Speg.) Baral

Nannfeldt (1932: 253) excluded this species from *Orbiliaceae*. Two non-authentic collections (France, Presles, Forêt de Carnelle, on underside of dead leaves of *Helleborus foetidus*, 22.X.1924, R. Maire, as *Orbilia rozei*, MPU, IVV: H.B. 5460; Luxembourg, Kockelscheier, on petioles of *Helleborus viridis*, 10.III.1903, J. Feltgen, as *Orbilia*, LUX 42458, IVV: H.B. 7134) were studied and found to be conspecific with *Psilachnum rubicundum* (see below). Probably, the type of *O. rozei* (France, Jura, on dead stems of *Helleborus foetidus*) is the same species and hence a later synonym of *O. rubicunda*, and also *Hyalinia helleboricola* is probably a synonym (see under these epithets).

Orbilia rubens (Sacc. & Roum.) Boud., Hist. Class. Discom. Eur.: 193 (1907)

≡ *Helotium rubens* Sacc. & Roum., Rev. Mycol. (Toulouse) 6: 28 (1884)
≡ *Calycina rubens* (Sacc. & Roum.) Kuntze, Revis. Gen. Pl. 3: 449 (1898)
≡ *Pezicula rubens* (Sacc. & Roum.) Rehm, Ber. Bayer. Bot. Ges. 13: 200 (1912)
= *Mollisia ramealis* (P. Karst.) P. Karst., Bidr. Känn. Finl. Nat. Folk 19: 187 (1871)

The microscopic sketch on the label of the holotype (Reliquiae Libert. IV, no. 224, PAD) shows fusiform ascospores ranging from 18–20 × 2 up to 25–28 × 3.5 µm, and asci 80–100 × 8 µm. The protologue gives the spore size as 18–22 × 2–3 µm and the ascus size as 85–100 × 8 µm, with the following data: [Belgium,] Ardennes, on bark of *Rhamnus* (Saccardo 1889: 239, as 'Reliq. Libert. IV, no. 40'; Grelet 1948a: 55, as 'Reliq. Libert. IV, no. 10'). A hymenial fragment of no. 224 was examined. It showed IKI deep blue apical rings of the *Calycina*-type, but no spores. This is clearly *Mollisia ramealis*. as was also assumed by Verkley (1999: 151), a species which already Saccardo considered to be related ('subaffinis') to *Helotium rubens*.

Mollisia ramealis is misplaced in *Mollisia* (*Mollisiaceae*) but belongs in *Cenangiaceae* with unclear generic affiliation, according to unpublished molecular data by A. Gminder and K. Pärtel (pers. comm.). Dennis (1964: 62) found in the specimen under the name *Helotium rubens* at K a *Mollisia* (as *Tapesia*) with much shorter spores of 8–12 × 2 µm.

Orbilia rubicola (Cooke & W. Phillips) Sacc., Syll. Fung. 8: 622 (1889)

≡ ***Pyrenopeziza cookei*** Baral, **nom. nov.** — MB 831503
[non *Pyrenopeziza rubicola* Losa, An. Jard. bot. Madr. 8: 330 (1947, '1948']
Replaced synonym: *Calloria rubicola* Cooke & W. Phillips, in Phillips, Man. Brit. Discomyc.: 331 (1887)
≡ *Hyalinia rubicola* (Cooke & W. Phillips) Boud., Hist. Class. Discom. Eur.: 104 (1907)

Cooke & Phillips considered *Calloria rubicola* to be very similar to *C. vinosa* in their interpretation, which seems to concern a taxon around *Orbilia auricolor*. Originally the authors planned to describe it as a variety of *C. vinosa*, as can be seen from the handwriting on the label ('*Peziza vinosa* var. *rubicola*'). In the protologue the apothecia are described as 0.5–1.5 mm diam., reddish flesh-coloured, with smooth margin, and the spores as 9–11 × 1 µm in size.

The type material of *C. rubicola* (Great Britain, [Northamptonshire], King's Cliffe, on stems of *Rubus caesius*, undated, [M.J. Berkeley], herb. M.C. Cooke, K, IVV: H.B. 5351) contains a pale ochraceous, sessile discomycete 0.6–1.2 mm diam. when rehydrated, with a hairy margin. The asci arise from croziers and have a conical apex with an IKI deep blue (euamyloid) apical ring of *Calycina*-type, and the spores are multiguttulate (in KOH, OCI 3) and measure 10–12 × 2–2.4 µm. The ectal excipulum is a hyaline textura angularis with a thin, yellow-ochre intercellular gel, externally bearing 50–60 × 3–5 µm large, cylindric-moniliform, 4–5-septate, thin-walled, hyaline, smooth hairs.

C. rubicola fits a number of studied fresh collections from stems of *Rubus* spp. (e.g., H.B. 6367) in which the paraphyses and hairs are filled with many globose, medium refractive SCBs, and the spores measure *(7.5–)9–14(–16) × (2–)2.2–2.5(–2.8) µm and contain a varying number of small LBs at each end (OCI 1–3). It was referred with some hesitation to *Niptera dilutella* by Baral (in Weber 1992), which is considered here as a nomen dubium (see under *Hyalinia dilutella*, p. 1670). Although devoid of a brown excipulum, the remaining characters of *C. rubicola* strongly recall the genus *Pyrenopeziza* (*Ploettnerulaceae*) and suggest a close vicinity to *P. rubi* (Fr.) Rehm and *P. escharodes* (Berk. & Broome) Rehm. In fact, the combination *Pyrenopeziza dilutella* (Fr.) Gminder relates to these considerations.

Because of the dubious identity of *N. dilutella* it seems appropriate to adopt Cooke & W. Phillips's epithet. However, because of *Pyrenopeziza rubicola* Losa which was described on stems of *Rubus* sp. with spores of 5–6 × 2–3 µm, a new name, *P. cookei*, had to be chosen for Cooke & W. Phillips's fungus. The similar *P. rubi* (especially on *Rubus* spp.) and *P. escharodes* (especially on *Rubus fruticosus*, *R. saxatilis*) differ from *P. cookei* by shorter, ± clavate spores of ~6–9.5 × 1.5–3 µm (e.g., Rehm 1892, Gremmen 1954, Hütter 1958).

Orbilia rubicunda (Sacc. & Speg.) Sacc., Syll. Fung. 8: 622 (1889)
= ***Psilachnum rubicundum*** (Sacc. & Speg.) Baral, **comb. nov.** — MB 814590
Basionym: *Calloria rubicunda* Sacc. & Speg., Michelia 1(4): 429 (1878)

Nannfeldt (1932: 253) excluded this species from the *Orbiliaceae*, and Hein (1976: 34) suggested that it is similar to *Orbilia rozei* Quél. A topotype in RO (Italy, [Venice, Treviso,] Conegliano, on underside of dead leaves of *Helleborus viridis*, IV.1879, C.L. Spegazzini, IVV: H.B 7794) was studied. It bears abundant subsessile, light yellowish-amber apothecia (rehydrated 0.15–0.3 mm diam.). The asci arise from croziers and have a characteristic apical ring, of which only the inner part, which slightly protrudes in the ascoplasm, is reactive and stains distinctly blue in IKI. Very short, cylindrical, smooth hairs occur near the margin. An illustration is found in Saccardo (1883: fig. 1292).

A recent, undoubtedly conspecific Spanish collection on leaves of *Helleborus foetidus* studied in the living state (IVV: H.B. 7268) showed a distinct hair vesture at the apothecial margin and refractive globose to elongate VBs in both paraphyses and hairs. The species appears to fit the genus *Psilachnum* in many respects. See also under *O. rozei* and *O. helleboricola*.

Orbilia cardui var. ***rutae*** Velen., Monogr. Discom. Bohem.: 401 (1934)

According to Svrček (1954), only a bad microscopic preparation has been preserved of this taxon which grew on stems of *Ruta graveolens*. The inflated paraphyses and short (3–5 µm), narrowly subcylindrical spores appear to exclude synonymy with *O. cardui*. However, Velenovský's spore measurements are not trustworthy, as he described the spores of, e.g., *O. pellucida* (= *O. cardui*) with the same length of 3–5 µm, although in the lectotype a length of 5–7 × 1–1.2 µm was found in the present study (see Tab. 38).

Peziza vulgaris var. ***sanguinella*** Berk. & Curtis, in Berkeley, Grevillea 3: 159 (1875)

This taxon was based on three collections (USA, South Carolina, on *Liquidambar*, no. 2180; New England, C.J. Sprague, nos 5372, 5380). Dennis (1964: 70, fig. 54 right) reexamined no. 2180 (probably in K) and found it to belong to *Orbilia*. No specimen was examined in the present study. Dennis's figure shows asci with truncate apices and thin stalks with a furcate base, hence the taxon clearly belongs to *Orbilia*. The spores 'were not well seen but appear to be fasciculate and about 8 × 0.5 µm'. The name refers to the pale orange disc.

Patinella sanguineoatra (Rehm) Sacc., Syll. Fung. 8: 773 (1889)
≡ *Patellaria sanguineoatra* Rehm, in Britzelmayr & Rehm, Ber. Naturhist. Ver. Augsburg 24: 63 (1877)

An authentic specimen (Czechia, Böhmisches Erzgebirge, V.1912, on decorticated branch of *Fagus sylvatica*, vid. Rehm, herb. Kupka, M) was studied. This appears to agree with Rehm's

(1889: 311) description of the type (Germany, Augsburg, dry branch of *Fagus*). It is conspecific with some recent collections from Germany and Luxembourg (IVV: H.B. 3349, 3727, 6589). The size of the non-septate ascospores is in the protologue 15 × 5 µm, in Rehm (1889: 311) 15–17 × 5–6 µm, in Kupka's specimen 12–19 × 3.5–4.3 µm, and in our specimens *11–21.3 × 3.5–5.5 µm. They have 2 large ellipsoid glycogen regions that stain red-brown in IKI, each being densely surrounded by small LBs. The asci have a thin-walled, subconical, inamyloid apex (IKI), and arise from croziers. The ectal excipulum of a vertically oriented textura prismatica-globulosa is rich in red-brown exudate, which is partly dissolved in KOH by staining the medium deep red-brown. Based on its strong ionomidotic reaction, a relationship with the lichenicolous genus *Skyttea* Sherwood, D. Hawksw. & Coppins (*Cordieritidaceae*) seems possible.

Calloria scolicospora Rehm, Ascomyceten, fasc. 10: no. 461 (1878), nom. inval., Art. 38.1(a) ICN

The name was published by Rehm (1878 in sched.) on the printed label of Ascomyceten no. 461, as *Calloria scolicospora* Rehm f. *minor* (≡ *Orbilia rehmii*, see p. 904). No diagnosis was supplied, and also no later publication of this name could be detected, so it appears that it has never been validly published and must be regarded as a nomen nudum.

Hyalinia dilutella var. ***smyrnii*** (W. Phillips & Plowr.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Mollisia dilutella* var. *smyrnii* W. Phillips & Plowr., in Phillips, Man. Brit. Discomyc.: 192 (1887)
≡ *Pezizella dilutella* var. *smyrnii* (W. Phillips & Plowr.) Sacc., Syll. Fung. 8: 277 (1889)
≡ *Mollisia digitalina* var. *smyrnii* (W. Phillips & Plowr.) Massee, Brit. Fung.-Fl. 4: 212 (1895)

No type material of this taxon was ordered. Described on stems of *Smyrnium*, it is said by the original authors to 'differ only very little' from *Mollisia dilutella*, a species which was interpreted by Baral (in Weber 1992) as belonging to *Pyrenopeziza* (see under *Hyalinia dilutella*, p. 1670). *Mollisia digitalina* W. Phillips is likewise today treated as a *Pyrenopeziza*, *P. digitalina* (W. Phillips) Sacc.

Patinella stenotheca (P. Karst.) Sacc., Syll. Fung. 11: 434 (1895)

≡ *Patinellaria stenotheca* P. Karst., Hedwigia 31: 132 (1892)
≡ *Durella stenotheca* (P. Karst.) Nannf., Acta Soc. Sci. Upsal., ser. 4, 8: 293 (1932)
= ***Durella commutata*** Fuckel, Jb. Nassau. Ver. Naturk. 23-24: 281 (1870) [1869-70]

Two syntype specimens in Karsten's herbarium were studied. One (Fennia, Tammela, Mustiala, 2.X.1869, wood of *Betula*, herb. P. Karsten 3426, IVV: H.B. 7621) fits *Durella commutata* Fuckel in the non-septate ascospores (6–8.2 × 1.7–2.1 µm), inamyloid asci, and paraphyses which contain a single yellow vacuolar body (VB) in the apex. The other (ibid., 31.III.1870, wood of *Betula*, herb. P. Karsten 3427) contained both *D. commutata* (IVV: H.B. 7622a, asci inamyloid, spores 6–8 × 2.2–2.4 µm) and *D. macrospora* Fuckel (IVV: H.B. 7622b, asci with amyloid apical rings, spores 17–22 × 3.2–4.3 µm). The large, 3-septate ascospores of *D. macrospora* exclude this species from the protologue of *Patinellaria stenotheca*, which reads 'Sporae ... continuae, ... 6–10 × 2 µm'. *P. stenotheca* is, therefore, a later synonym of *Durella commutata*. Since the original diagnosis was clearly based on the specimen from 1869, judging from the microscopic measurements noted by Karsten on the label, Karsten 3426 (H) is designated here as **lectotype** of *P. stenotheca* (MBT382128).

Orbilia stipitata Ekanayaka & K.D. Hyde, in Ekanayaka et al., Mycosphere 9(1): 160 (2018)

Ekanayaka et al. (2018: 160, fig. 2) described *Orbilia stipitata* based on a collection on unidentified wood at the Kun Korn waterfall in Chiang Rai (Northern Thailand). The entire presentation is full of errors and it is impossible to clarify the taxon without a thorough restudy of the holotype. Undoubtedly, the description and illustration includes a mixture of two species. For instance, the capitate paraphyses are described as 'swollen at the apices, terminal cell 1–1.5 µm width'. This width is very unlikely to be correct, and the given scale bar of '10 µm' should better be 20 µm in order to fit the 15 µm scale bars of the asci.

The strongly falcate spores of †8–11 × 0.8–1.3 µm, with obtuse apex and tapered base, are reminiscent of *O. auricolor* agg. However, it is not fully clear which is the upper spore end. Although the authors studied the holotype in the dead state and did not mention spore bodies, the spores in their fig. 2j–k could be alive as they appear to show a vermiform spore body in the narrowed end. If this is true, the upper spores point with their apex downwards. The authors compared *O. stipitata* with *O. arcospora* and *O. vermiformis* and distinguished it based on shorter asci, although the main difference seems to lie in the spore shape: tapered towards both ends in *O. arcospora* and helicoid in *O. vermiformis*.

Moreover, straight spores of ~7 × 1 µm were observed and considered as immature spores of *O. stipitata* (fig. 2i, l–o). Since young and immature spores generally do not markedly differ in curvature from mature spores, these elements very probably derive from another apothecium which belonged to a different species, perhaps *Hyalorbilia inflatula*.

The sequence gained from *Orbilia stipitata* (ITS+LSU, MG599272/MG599275, identical sequences are NR_156687/NG_059860) clustered with *O. nemaspora* (Ekanayaka et al. 2018: fig. 1), with a 4 nt deviation in the ITS and 3 nt in the LSU. This surprising result points to a confusion since *O. nemaspora* has narrower and distinctly helicoid spores. We assume that the sequence of *O. stipitata* could well belong within the natural variation of *O. nemaspora*. A lectotype should be chosen which coincides to a major extent with the protologue, and it seems that the provided sequence does not belong to this lectotype.

The apothecia are figured with a size of 0.4–0.55 mm diam. but described as 0.4–2 mm diam., which might be due to a mixture of different species. The specific epithet suggests stipitate apothecia, although these are reported as 'subsessile to shortly stipitate'. The given etymology ('refers to the ascospore shape') should be an error as it seems to refer to another previously applied epithet.

Hyalinia strobincola Rehm, in Ade, Hedwigia 64: 316 (1923)

No material of this taxon (Germany, Bayern, Weismain, Islingerberg, blackened scales of dry *Pinus* cones, V.1909) could be found in PAD and S. The description (apothecia reddish-yellow, 0.2–0.35 mm diam., asci 33–42 × 4.5–7.5 µm, with rounded inamyloid apex, spores 8.5–13 × 1.5 µm, narrowly fusiform, paraphyses scarcely enlarged above, excipulum parenchymatous) could fit *Orbilia vinosa*, but since no mention is made of the ascus base or the presence of exudate, the taxon could also belong to the *Helotiales*.

Hyalinia subaurantiaca (Feltgen) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Pezizella subaurantiaca* Feltgen, Rec. Mém. Trav. Soc. Bot. G.-D. Luxemb. 16: 48 (1903)

No material of this taxon (Luxembourg, Grünewald-Helmsingen, at border of a pond, on rotten *Quercus* board, IX.1902) could be located in LUX. Feltgen compared it with *Pezizella bresadolae* Rehm, a species that seems to fit *Phaeohelotium imberbe*, according to the illustration in Bresadola (1928: pl. 1236). Höhnel (1906: 1277) examined the type of *P. subaurantiaca* and found it to be very poorly developed and possibly belonging to *Helotium citrinum* [≡ *Calycina citrina* (Hedw.) Gray], perhaps also to *Helotium trabinellum* (= *Leptodontidium trabinellum*). Feltgen's description may indeed refer to a pale form of *C. citrina*. The 'prosenchymatic' excipulum excludes identity with *P. imberbe*.

Hyalinia subcarnea (Schumach.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza subcarnea* Schumach., Enum. pl. (Kjbenhavn) 2: 427 (1803) [also in Hornemann, Flora danica 12, pl. 2084 fig. 1 (1832)] [non *Peziza subcarnea* Cooke & Peck 1875, nom. illegit., ICN Art. 53.1, ≡ *Roseodiscus subcarneus* (Sacc.) Baral]
≡ *Helotium subcarneum* (Schumach.) Sacc., Michelia 2(7): 260 (1881) [non s. Sacc.]
≡ *Pezizella subcarnea* (Schumach.) Rehm, Rabenh. Krypt.-Fl., 1.3: 657 (1892)
≡ *Hymenoscyphus subcarneus* (Schumach.) J. Schröt. [as '*Hymenoscypha subcarnea*'], in Cohn, Krypt.-Fl. Schlesien 3.2: 69 (1893) [non *Hymenoscyphus subcarneus* (Sacc.) Kuntze 1898, nom. illegit., ICN Art. 53.1, ≡ *Roseodiscus subcarneus*]

≡ *Orbiliopsis subcarnea* (Schumach.) Höhn., Mitt. bot. Inst. tech. Hochsch. Wien 3(3): 102 (1926)
≡ *Belonium subcarneum* (Schumach.) Velen., Monogr. Discom. Bohem.: 177 (1934)
≡ *Phaeohelotium subcarneum* (Schumach.) Dennis [as '(Schum. ex Sacc.)'], Kew Bull. 25 (2): 355 (1971)
= *Phaeohelotium carneum* (Fr.) Hengstm., Mycotaxon 107: 272 (2009)
≡ *Peziza carnea* Fr., Syst. mycol. (Lundae) 2(1): 135 (1822), nom. sanct.

No authentic material of *Peziza subcarnea* Schumach. could be located in C, H, L, and PAD, and none appears to have ever been redescribed (see also Hengstmengel 2009). Höhnel (1926b: 97) studied Saccardo's specimen (Italy, Padova, on fallen fragments of wood and cones of *Pinus*, XII.1880, G. Bizzozero) and considered it distinct from the description of *Peziza carnea* Fr. by Fries (1822: 135), who assessed Schumacher's diagnosis of *P. subcarnea* as seemingly conspecific. Höhnel, therefore, erected for Saccardo's collection a new species, *Eubelonis albosanguinea* Höhn. (probably a *Calycina*, judging from the description).

Höhnel (l.c.: 99) also studied a collection of Jaap (Brandenburg, Prignitz, Triglitz, on wood of *Betula*) which he believed to be undoubtedly the genuine *Peziza subcarnea* Schumach. In his diagnosis of this collection, the ectal excipulum of isodiametrical cells, the rather large asci with an amyloid (blue) pore, and the non-septate spores containing 2–4 large plasma portions (oil drops?) are worth mentioning. Höhnel considered this material to be related to *Calloria austriaca* Höhn., which he both placed in his new genus *Orbiliopsis* Höhn. (see p. 207). *C. austriaca* (IVV: H.B. 6290) is a synonym of *Leptodontidium trabinellum* (IVV: H.B. 4847), according to a restudy of type material, and *Peziza subcarnea* in the sense of Höhnel's diagnosis of Jaap's material seems also conspecific with that species (for the genus *Leptodontidium* see also under *Orbilia diaphanula*, p. 1669).

The original identity of *Peziza subcarnea* Schumach. remains unclear, however. Hengstmengel (2009, pers. comm.) relied on the study of eight recent specimens identified by the collectors as *Phaeohelotium subcarneum* (from the Netherlands, Belgium and France, all on bark or wood of deciduous or unidentified trees). However, he hardly provided any diagnostic microscopical characters which allow recognition of this species. For a further collection, Verkley (1993: figs 59–61) illustrated an ascus apex of the *Hymenoscyphus* type (France, Côte d'Or, Forêt de St.-Léger, on unidentified wood, 10.X.1990, J. van Brummelen 7963). According to a microscopic analysis by J. Hengstmengel (pers. comm., J.H. 474 = L 979.198-854), his concept of *Phaeohelotium carneum* might correspond to the concept of *Phaeohelotium imberbe* in Baral & Krieglsteiner (1985, as *Hymenoscyphus imberbis*). However, Hengstmengel (2009) considered the two taxa as distinct because *P. imberbe* lacks the uniformly pink colour of *P. carneum*.

Hengstmengel considered *Peziza carnea* Fr. as a heterotypic synonym of *Peziza subcarnea* Schumach., following authors of the 19th century, and he pointed out that the former epithet has priority over the latter. However, he admitted that the opinion of synonymy is solely based on macroscopical and ecological similarities, because 'there is no type material preserved for microscopical comparison'. *P. carnea* was described by Fries (1822) on 'wood of *Fagus*, *Carpinus* etc.', and *P. subcarnea* by Schumacher (1803) on wood of *Betula*. Because of the starting point of 1821 which was valid until 1981, Dennis (1971) stated that *P. subcarnea* Schumach. was illegitimate and, therefore, considered Saccardo (1881) as the validating author of the taxon. However, Dennis overlooked that *P. subcarnea* became valid already in 1832 (Hengstmengel pers. comm.). Therefore, Baral (1986: 17, Baral & Krieglsteiner 2006) erroneously considered Saccardo's specimen on *Pinus* as type and referred to *Phaeohelotium subcarneum* a collection on rotten coniferous wood (IVV: H.B. 1104) with hemiamyloid apical rings of the *Calycina*-type, and greyish-white apothecia which turn rose-carneous when dried. Because of the apical ring type, this collection is certainly not congeneric with the specimen investigated by Verkley.

Hyalinia subdiaphana (Sowerby) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza subdiaphana* Sowerby, Col. Fig. Engl. Fung. Mushr., vol. 1: 654, pl. 389 fig. 7 (1789–1791)
≡ *Peziza vulgaris* var. *diaphana* Fr., Syst. Mycol. 2(1): 147 (1822)
≡ *Mollisia diaphana* (Fr.) Gillet [as '*M. diaphana* (Sow.)'], Champ. Fr., Discomyc.: 132 (1882)
≡ *Calloria diaphana* (Fr.) W. Phillips [as '*C. diaphana* (Sow.)'], Man. Brit. Discomyc.: 335 (1887) [non *Calloria diaphana* Rehm 1874, nom. inval., see *Habrostictis diaphana*]
≡ *Orbilia diaphana* (Fr.) Sacc. [as '*O. diaphana* (Sow.) Sacc.'], Syll. Fung. 8: 633 (1889) *Peziza diaphana* (Fr.) Mussat, in Saccardo, Syll. fung. (Abellini) 15: 252 (1901)

The original diagnosis of *Peziza subdiaphana* reads: 'Of a semitransparent waxy appearance; not uncommon on the under sides of rotting wood in somewhat close places, and may be a variety of *P. cinerea*, t. 64, dried before perfected.' The illustration shows cupulate to saucer-shaped, ochraceous apothecia which are reminiscent of *Hyalorbilia inflatula*. No authentic specimen could be found in BM, E, and K. According to B. Spooner (pers. comm.), most Sowerby types were destroyed or not preserved, whereas later collections under '*Orbilia diaphana* Sowerby' from W. Phillips's herbarium in K have been reexamined by Spooner and redisposed under *Cistella* sp. and *H. inflatula* (as *Orbilia inflatula*). What Gillet referred to this taxon, on rotten cardboard, remains unclear but could likewise concern *H. inflatula*. In the absence of a type specimen *P. subdiaphana* remains a nomen dubium.

Fries (1822) did not comment on why he changed the epithet to *diaphana*, and he did not even mention Sowerby's epithet *subdiaphana* at all, but he clearly referred to Sowerby's plate 389 fig. 7. His description reads: 'sparse, first urceolate then flattened, whitish hyaline'. He considered the species to be intermediate between *Calycina vulgaris* and *Mollisia cinerea* (Batsch) P. Karst. (both as *Peziza*), but much thinner and subdiaphanous. Like Fries, also Gillet, Phillips, and Saccardo referred to Sowerby's plate but adopted Fries's epithet *diaphana* without mentioning Sowerby's epithet *subdiaphana*, and Mussat's combination in *Peziza* was likewise merely an erroneous citation of Sowerby's basionym.

Orbilia succinea (Fr.) Quél., Enchir. Fung.: 298 (1886) [non *Orbilia succinea* Velen. 1947, = *O. eucalypti*]

≡ *Calloria succinea* Fr., Summa Veg. Scand.: 359 (1849)
≡ *Mollisia succinea* (Fr.) Gillet, Champ. Fr., Discomyc.: 132 (1882), nom. illegit., ICN Art. 53.1 [non *Mollisia succinea* (Quél.) Quél. 1881, (?)= *Hyalorbilia inflatula*]
≡ *Hyalinia succinea* (Fr.) Boud., Hist. Class. Discom. Eur.: 104 (1907)
≡ *Siroscyphella succinea* (Fr.) Höhn., Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. I 127: 374 (1918)
≡ *Dacrymyces succineus* (Fr.) Fr., Hymenomyc. eur. (Upsaliae): 699 (1874), nom. illegit., ICN Art. 53.1 [non *Dacrymyces succineus* Sprée]
?= *Pseudocenangium succineum* (Sprée) Dyko & Sutton, Can. J. Bot. 57: 372 (1979)
≡ *Dacrymyces succineus* Sprée, in Rabenhorst, Fungi Eur. Exs. no. 680 (1864) [also in Bot. Ztg. (Berlin) 22: 175 (1864)]

Calloria succinea was described by Fries for a minute sessile fungus with immarginate, amber-coloured disc on needles of *Pinus* (without collection data). Fuckel (1870: 282) reported under that name a mitosporic fungus associated with fruitbodies which he interpreted as immature apothecia of the teleomorph. Fuckel's collection (Germany, [Mainz,] Budenheim, needles of *Pinus sylvestris*, spring, L. Fuckel, Fungi Rhen. Exs. 1600, MPU, IVV: H.B. 5600) was reexamined. Mainly the conidial stage was found, with short-stalked, light yellow apothecioid fruitbodies ~0.4 mm diam. (rehydrated), with a receptacle of strongly gelatinized textura oblita. The conidia are 1-septate, cylindrical to dumbbell-shaped, 14–15 × 2.3–2.5 µm.

According to Höhnel (1918), Fuckel's specimen is very probably conspecific with that of Fries, judging from Fries's description. Based on the studies of the anamorphs by Cooke & Ellis (1878: 91, *Hymenula fumosa* Cooke & Ellis) and Starbäck (1895: 34, *H. fumosellina* Starbäck), Höhnel (1918) concluded that *Peziza fumosella* Cooke & Ellis (ascospores 10 µm long) is conspecific with *Phialea fumosellina* Starbäck (ascospores 16–20 × 2 µm), and represents the teleomorph of *Calloria succinea*. For the anamorph he erected the genus *Siroscyphella* Höhn. Höhnel did not accept Phillips's (1880) opinion who believed that *Peziza electrina* W. Phillips & Plowr. (ascospores 5 × 1 µm) was the teleomorph of *Calloria succinea*.

Dyko & Sutton (1979) were unable to locate type material of *Calloria succinea*. According to McNabb (1973: 510), Sprée (1864) cited Fries' taxon as a questionable synonym when proposing the combination '*Dacrymyces succineus* Sprée', therefore, Donk (1966, fide McNabb) attributed this binomial solely to Sprée. This view was accepted by Dyko & Sutton who transferred the taxon to *Pseudocenangium* P. Karst. and listed *Phialea fumosella* (Cooke & Ellis) Sacc. as teleomorph.

Peziza fumosella is treated in *Phialea* (Pers.) Gillet by Dennis (1956) and Dyko & Sutton (1979), whereas Carpenter (1981: 215) believed that its type material shared several features with members of *Chloroscypha* Seaver. Several fresh collections on needles of *Pinus* were studied which appear to belong to *P. fumosella* (IVV: H.B. 3927, 8321a, 9914 etc.). This fungus has rather long, 1–3-septate spores (*23.5–26.5 × 2.3–2.6 µm) and is not a *Cyathicula* (= *Phialea*) but more probably a representative of *Allophylaria*, *A. fumosella* (Cooke & Ellis) Nannf., or *Calycellina*, e.g., because of the *Calycina*-type of apical ring and the elongate vacuolar bodies (VBs). The apothecia in H.B. 8321a grew intermingled with *Xiambola mirabilis* Minter & Hol.-Jech., a mitosporic fungus with toothed sporodochia and with a very similar grey colour and excipular texture. This similarity suggests that *X. mirabilis* is the anamorph of *Allophylaria fumosella*. Apart from its teeth, however, *X. mirabilis* resembles *Pseudocenangium succineum* quite well; moreover, the teeth are not always present in this sample of *X. mirabilis* as well as in a collection on *Picea* cone from Poland (P. Perz pers. comm.). Hence, *X. mirabilis* and *P. succineum* could well be synonyms.

Peziza electrina was placed in synonymy with *Orbilia succinea* by Saccardo (1889: 625) and Rehm (1891: 460), who used Fries' taxon as a teleomorph name. Rehm reexamined Phillips's type material and completed the diagnosis of *P. electrina*. A syntype was examined in the present study (Great Britain, Scotland, Morayshire, Forres, needles of *Pinus*, undated, C. B. Plowright, herb. W. Phillips no. 187, M). Judging from external appearance, *P. electrina* is the same species which Svrček (1978: 87) named *Pezizella pulchella* Fuckel [= *Antinoa proximella* (P. Karst.) Velen. fide Svrček]. This species has stalked apothecia with a yellow-ochre exterior and a blackish base, and very small, non-septate spores, and is obviously very close to *Antinoa acuum* Velen., the type species of *Antinoa* Velen. (see Baral & Krieglsteiner 1985: 46, IVV: H.B. 1010, 3129 etc.).

Orbilia succinella (Sacc.) Sacc., Syll. Fung. 8: 625 (1889)

≡ *Hyalinia succinella* (Sacc.) Boud., Hist. Class. Discom. Eur.: 104 (1907)
≡ *Calloria succinella* Sacc., Michelia 1(1): 62 (1877)

No apothecia could be found in the holotype (Italy, [Veneto,] Pianzano, on rotten culm of *Zea mays*, [XII.1876, C.L. Spegazzini], PAD). The original sketch on the label (see also the colour drawing in Saccardo 1877: fig. 1293) shows cylindric-subclavate ascospores of 6 × 2 µm, with a rather small drop at each end, and two asci with subconical apices and unstalked, crozier-like inflated bases. The apothecia were described as 1/6–1/8 mm diam., hyaline, then faintly amber, flat, nearly immarginate. The taxon could perhaps be conspecific with *Calycellina microspis* (P. Karst.) Dennis as redescribed by Dennis (1956: 181, as *Helotium microspis*; see also under *Hyalinia microspis*, p. 1678).

Habrostictis tithymalina (J. Kunze) Rehm, Ber. naturhist. Ver. Augsburg 26: 78 (1881)

≡ *Calloria tithymalina* J. Kunze, Hedwigia 15: 105 (1876)
≡ *Naevia tithymalina* (J. Kunze) Rehm, Rabenh. Krypt.-Fl., 1.3: 139 (1888)
≡ *Laetinaevia tithymalina* (J. Kunze) Petr., Ann. Mycol. 38: 153 (1940)
≡ ***Naeviopsis tithymalina*** (J. Kunze) B. Hein, Willdenowia, Beih. 9: 64 (1976)

This species is mainly found on herbaceous stems of *Euphorbia* (Hein 1976). A fresh collection (Germany, Schwäbisch Gmünd, Hornberg, Furtlochereck, on *E. cyparissias*, 8.V.1999, L. Krieglsteiner, H.B. 6368) showed asci arising from croziers, with a hemiamyloid apical ring of the *Pezicula*-type. The living ascospores measured 12.5–16.3 × 6.8–7.7 µm and contained some small LBs. The pale ochraceous apothecia open by large, light-coloured lobes.

Orbilia tricellularia Matsush., Matsush. Mycol. Mem. 10: 198 (2003, '2001')

The species is named after the anamorph, *Tricellula inaequalis* Beverw., which was reported from freshwater (see, e. g., Nilsson 1964, Czeczuga & Orlowska 2001). Matsushima's strain was isolated from leaves of an unidentified broad-leaved tree on forest soil (Mt. Rokko, Kobe, Japan, III.1999). Both the anamorph and teleomorph developed in pure culture. The abundant apothecia are described as 0.06–0.2 mm diam., cushion-shaped, sessile, white, with smooth margins. The ectal excipulum is of textura angularis, and the hymenial elements are not covered by gel or exudate. The asci are described as thick-walled without further specification; yet, on the photos they are overall thin-walled, though at an immature stage apically slightly thick-walled (Matsushima 2003: figs 1744–1745). The conical apices of the cylindric-fusiform asci are without apical rings, and the thick stalks appear to arise from croziers. The iodine reaction seems not to have been tested. The 8 spores are hardly visible on the photos, and are described as oblong to bean-shaped, 7–9 × 2.5–3.5 µm (no contents mentioned). The filiform paraphyses are not or slightly inflated at the apex and 1–1.5 µm wide. All elements are figured in the dead state. For the anamorph see Baral et al. (2017b).

Matsushima (2003) placed the species in *Orbilia* subgenus *Hemiorbilia*, obviously because of the thickened ascus wall. However, the conical shape of ascus apex and the presence of croziers excludes *Orbilia*, also a relationship to *Hyalorbilia* does not seem very probable. Possibly *O. tricellularia* belongs in the *Helotiales* rather than the *Orbiliomycetes*. A more detailed morphological documentation and a molecular study on this species should be carried out to find out its phylogenetic place.

Hyalinia tumidula (Roberge in Desm.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Peziza tumidula* Roberge in Desm., Pl. Crypt. Nord France, Edn 1: no. 2100 (1850) [also in Ann. Sci Nat., Bot. 16: 325 (1851)]
≡ *Pezizella tumidula* (Roberge in Desm.) Sacc., Syll. Fung. 8: 276 (1889)
≡ *Hymenoscyphus tumidulus* (Roberge in Desm.) Kuntze, Revis. Gen. Pl. 3 (2): 486 (1898)
≡ *Helotium tumidulum* (Roberge in Desm.) Massee, Fungus Fl. Yorkshire: 285 (1905)
≡ *Mollisia tumidula* (Roberge in Desm.) Höhn., Sitzungsber. Akad. Wiss. Wien, Math.-Naturwiss. Kl. 1, 115: 1284 (1906)
≡ *Discorehmia tumidula* (Roberge in Desm.) Kirschst., Ann. Mycol. 34: 204 (1936)
≡ *Hyaloscypha tumidula* (Roberge in Desm.) Grelet, Rev. Mycol. 16: 95 (1951)

Based on a restudy of the type material (France, Caen, leaves of *Betula*, M. Roberge), Arendholz (1979: 97) considered the species to be closely related to *Pyrenopeziza betulicola* Fuckel (see under *Orbilia betulina*, p. 1663) if not identical. He further argued that the species would fit in *Pyrenopeziza* because of its ectal excipulum of textura globulosa-angularis, except for the hyaline, somewhat glassy cell walls. So he retained it as *Mollisia tumidula*. Also White (1943: 165) studied the type material of *Peziza tumidula* and presented a very precise figure of the hymenial elements, but he omitted the excipular characters. Both authors reported the ascus apex as amyloid. The available data do not allow us to conclude with certainty whether *P. tumidula* should be placed in *Pyrenopeziza* or *Mollisia*, or perhaps even in *Calycellina*, a genus for which, in our opinion, an ectal excipulum with or without gelatinized cell walls should be accepted. For *Calycellina* the raised apothecial margin that covers the hymenium in the dry state does not fit.

According to White (l.c.), *H. tumidulum* is only known with certainty from the type collection, whereas most if not all of the material referred to this taxon by later authors has been wrongly identified. For example, when describing a British collection as '*Phialea* sp. I', Dennis (1956: 35) noted that this seems to be *Pezizella tumidula* s. Rehm (1892: 666) but clearly not s. Roberge. Dennis referred the British specimen to *Phialea* based on the thick-walled prosenchymatic ectal excipulum. However, judging from Dennis's description, this fungus is referable to *Calycellina* rather than *Phialea* (= *Cyathicula*).

Hyalinia turgidella (P. Karst.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Pezizella turgidella* (P. Karst.) Sacc., Syll. Fung. 8: 281 (1889)
≡ *Hymenoscyphus turgidellus* (P. Karst.) Kuntze, Revis. Gen. Pl. 3: 486 (1898)
≡ *Calycina turgidella* (P. Karst.) Van Vooren, in Ayel & Van Vooren, Bull. Mens. Soc. Linn. Lyon 74, num. spec.: 8 (2005)

Dennis (1956: 180) redescribed the lectotype (Finland, Mustiala, on culm of *Poaceae*, 2.X.1868, herb. P. Karsten 2195, H) and found the ascus apex to stain deep blue in MLZ. The present reexamination of the lectotype (IVV: H.B. 7624) revealed a possible relationship to *Calycellina microspis*, a species with a difficult taxonomy (see under *Hyalinia microspis*, p. 1678).

Hyalinia tyrolensis (Rehm) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Pezizella tyrolensis* Rehm, Ber. naturh. Vereins Augsburg 26: 31 (1881)
≡ *Hymenoscyphus tyrolensis* (Rehm) Kuntze, Revis. Gen. Pl. 3: 486 (1898)

Three authentic specimens from PAD (Austria, Tirol, Pitztal, Taschach-Gletscher, on stems of *Cirsium spinosissimum*, summer 1875) were received. Two (Rehm Ascomyc. 116, Rabenhorst Fungi Eur. Exs. 2475) were found to be empty, but one (Thümen Mycoth. Univ. 516), which is the only number cited in the protologue, contained a fungus which appears to belong to *Calycina*, possibly close to *C. discreta* (P. Karst.) Kuntze, but differing from the majority of recent collections of that species in asci arising from croziers. The asci measured 45–51 × 4.5–5.2 µm (Rehm 1883: 40–60 × 6–8 µm) and the spores 6.5–9.3 × 2–2.4 µm (Rehm 1881, 1883: 6–9 × 2.5 µm). The apical rings react strongly euamyloid and is of the *Calycina*-type. Höhnel (1926a) concluded that *Pezizella tyrolensis* is a synonym of *Peziza micacea* Pers. (≡ *Psilachnum micaceum* (Pers.) Dennis). Dennis (1964: 69, fig. 52), who examined Rehm Ascomyc. 116 with the date Aug. 1872, also measured narrower asci of 40 × 5 µm, but saw the paraphyses varying from cylindrical to lanceolate, which would exclude the genus *Calycina*.

Orbilia ulcerata (W. Phillips & Plowr.) Sacc., Syll. Fung. 8: 630 (1889)

≡ *Peziza ulcerata* W. Phillips & Plowr., Grevillea 4: 122 (1876)
≡ *Calloria ulcerata* (W. Phillips & Plowr.) W. Phillips, Man. Brit. Discomyc.: 330 (1887)

≡ *Hyalinia ulcerata* (W. Phillips & Plowr.) Boud., Hist. Class. Discom. Eur.: 104 (1907)
≡ *Phacidium ulceratum* (W. Phillips & Plowr.) Höhn., Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. I, 126: 322 (1917)
= ***Ploettnera solidaginis*** (Ces.) B. Hein, Willdenowia, Beih. 9: 96 (1976)

According to Hein (1976: 96) this is a synonym of *Ploettnera solidaginis*, a species growing on herbaceous stems of mainly *Asteraceae*, characterized by 4-spored asci and apically flexuous paraphyses. The ascus apex is variable in Hein's concept of the species: in some of the material it is thick-walled and contains a strongly blue (euamyloid) apical ring of the *Ploettnera*-type, whereas other specimens are devoid of apical thickenings and amyloid rings. Inamyloid asci were also found in a recent collection (Germany, Merseburg-Querfurt, Bündorf, Buna-Halde, on *Aster tripolium*, 28.VIII.2000, U. Richter, IVV: H.B. 6751). Here the ascospores measured *13–19.5 × 7–9.3 µm and contained many small and a few larger LBs, and apparently 2 nuclei. The asci arise from croziers. The partly strongly elongate apothecia with dark lobes at the margin resemble those of *Duebenia compta*.

Hyalinia uvidula (P. Karst.) Boud., Hist. Class. Discom. Eur.: 104 (1907)

≡ *Helotium uvidulum* P. Karst., Bidr. Känn. Finl. Nat. Folk 19: 127 (1871)
≡ *Pezizella uvidula* (P. Karst.) Sacc., Syll. Fung. 8: 279 (1889)
≡ *Hymenoscyphus uvidulus* (P. Karst.) Kuntze, Revis. Gen. Pl. 3 (2): 486 (1898)

Based on a study of the lectotype (Fennia, Tammela, Mustiala, Haarankorpi, 4.IX.1870, on rotten wood of *Betula*, herb. P. Karsten 2805, H), Dennis (1956: 195) found the taxon to be lichenized and concluded that it is conspecific or very close to *Epiglia gloeocapsae* Boud. (= *Mniaecia albida*, see under *Hyalinia albida*, p. 1660), a species growing on *Gloeocapsa* on the thallus of *Jungermanniales*.

Reexamination of the lectotype by S. Huhtinen (pers. comm.) and in the present study (IVV: H.B. 7625) revealed conspecificity with various recent collections from both temperate and mediterranean Europe. Although the type was said to grow on wet wood ('in ligno udo', the Latin *uvidus* means moist or wet), the species is desiccation-tolerant and was found by us in 1–4 m above the ground on xeric, decorticated, rotten branches of a great variety of mainly angiosperm trees and shrubs. Possibly the branch of Karsten's specimen has fallen to the ground shortly before he collected it. This hypothesis is supported by some black apothecia of a lichen growing in association in the lectotype.

The very small, cushion-shaped apothecia of this discomycete attain a size of rehydrated 0.08–0.35(–0.5) mm diam. (0.2 mm in lectotype). Due to their pale cream to rose colour they are easily confounded with desiccation-tolerant species of *Orbilia* which often grew in association. Among the anchoring hyphae are often many algal cells, but there was never a clear connection between hyphae and algae, consequently we do not believe in a lichenization in this fungus but in an optional coexistence with algae similar as often observed in *Orbilia*. The hyaline excipulum is very thin and composed of a textura porrecta, which is immersed in some inconspicuous gel like the paraphyses. The ellipsoid spores [10–12.8 × (5.5–)6–7 µm in the lectotype] are indeed reminiscent of a *Mniaecia*.

Our guess was to place the species in *Laetinaevia* or perhaps in *Gelatinopsis*. A sequence of *H. uvidulum* from a recent collection (KY462819) clustered unresolved in the *Helotiales* (Phyl. 1) and did not confirm a relationship with *Laetinaevia*. However, sequence data were unavailable for most of the *Calloriaceae*.

Orbilia veratri Velen., Monogr. Discom. Bohem.: 99, pl. 11 fig. 34 (1934)

The holotype (Czechia, Bohemia, Bilichov, on stems of *Veratrum nigrum*, 23.VII.1925, PRM 148759: IVV: H.B. 6399), probably belongs to *Calycellina*, especially on account of its gelatinized (refractive) ectal excipulum of angular to prismatic cells. The taxon is similar to the common *Calycellina chlorinella*, but differs, e.g., in the shorter, IKI-negative asci (27–30 × 3.8–4 µm) with an apical dome (immature 1.5–2 µm thick), also in the very short, clavate hairs (9–13 × 3.5–9 µm) being covered by a light ochraceous cloddy exudate. The somewhat fusiform, straight ascospores measure 4.8–6(–8) × 1.1–1.3 µm and contain several minute LBs. *Orbilia luteola* (see p. 1677) represents a similar inamyloid variant of *C. chlorinella*, but differs from *O. veratri* in a much thinner apical ascus wall. *Calycellina chlorinella* differs from *O. veratri* also in cylindrical, allantoid spores.

Orbilia vinosula (Rehm) Quél., Enchir. Fung.: 298 (1886)

≡ *Calloria vinosula* Rehm, Ascomyc. Lojk. no. 50 (1883)
≡ *Phragmonaevia vinosula* (Rehm) Höhnel, Sitzungsber. Kaiserl. Akad. Wiss. Wien, Math.-Naturwiss. Kl., Abt. I, 127: 339 (1918)

Höhnel (1918) reexamined the type specimen and found the asci to have an amyloid apical ring which excludes the taxon from the *Orbiliomycetes*. The spores are described as over 10 × 2 µm, with large oil drops, finally 1–3-septate, and the minute, pale rose apothecia (0.2 mm) as possessing hardly any excipulum. Höhnel referred *Phragmonaevia ebulicola* Höhn. to synonymy with *P. vinosula*. According to Rehm (in Saccardo 1889: 639) the paraphyses are apically branched and ellipsoid-clavate. The apothecia grew on stems of *Sambucus ebulus* and *Datura stramonium* in Kaposvar (Hungary).

Hyalinia vulgaris (Fr.) Boud., Hist. Class. Discom. Eur.: 103 (1907)

≡ *Peziza vulgaris* Fr., Syst. Mycol. 2(1): 146 (1822)
≡ *Mollisia vulgaris* (Fr.) Gillet, Champ. Fr., Discomyc. 119 (1882)
≡ *Pezizella vulgaris* (Fr.) Sacc., Syll. Fung. 8: 278 (1889)
≡ *Phialea vulgaris* (Fr.) Rehm, Rabenh. Krypt.-Fl., 1.3: 709 (1892)
≡ *Allophylaria vulgaris* (Fr.) Nannf., Nova Acta Regiae Soc. Sci. Upsal., ser. 4, 8: 291 (1932)
≡ *Hymenoscyphus vulgaris* (Fr.) Raschle & E. Müll., in Müller, Beitr. Krypt.-flora Schweiz 15: 49 (1977)
≡ ***Calycina vulgaris*** (Fr.) Baral, in Baral & Krieglsteiner, Beitr. Kenntn. Pilze Mitteleuropas 5: 227 (1989)

No authentic material of Fries's taxon seems to have been preserved following Arendholz (1989). According to Dennis (1964: 70), the current interpretation of *Peziza vulgaris* follows Rehm (1892: 709) and Höhnel (1926a: 56), who interpreted Fries's species for a fungus with inamyloid asci and aseptate, cylindrical, slightly curved spores. The species was correctly assigned to *Pezizella* by Saccardo (1889), a genus which was later recognized as a later synonym of *Calycina* (Baral in Baral & Krieglsteiner 1985). According to Dennis (1954: 297, 1964: 70) and present study, Berkeley (1875) interpreted *Peziza vulgaris* as an orbiliaceous taxon when he described the two taxa *P. vulgaris* var. *myceticola* Berk. & Curtis (= *Hyalorbilia* ?*inflatula*, see p. 345) and *P. vulgaris* var. *sanguinella* Berk. & Curtis (= *Orbilia* sp., see p. 1684). Also Boudier transferred *P. vulgaris* to the orbiliaceous genus *Hyalinia*.

Appendix 1. List of hosts on which *Orbiliomycetes* were recorded

Only orbiliaceous species are included for which a description is given in the present monograph. Plant nomenclature mainly follows the systematics of Angiosperm Phylogeny Group IV[1], for gymnosperms see Chase & Reveal (2009)[2], and for fungi mainly Species Fungorum. The number of records is given in parenthesis, numbers after the slash stand for *Orbiliomycetes* with uncertain identity (uncertain hosts are counted as if certain). When growing on leaves or fruits of woody plants this is indicated. Under 'soil' only those are listed that formed apothecia on soil. Cultural or molecular isolates from soil around the rhizosphere of plants (indicated as 'roots') are only included when their association is explicitly mentioned. Substrates that were solely recorded from a molecular extract are marked by 'mol. extr.'. Reports from the literature for which no illustration was available are generally omitted.

Appendix 2. List of countries in which *Orbiliomycetes* were recorded

Numbers in parentheses indicate the number of collections of a species (uncertain records after the slash or with '?'), for countries and continents the number of recorded species and after the slash the total number of collections. Included are those species for which an apothecial state is known, but also a few so far purely anamorphic taxa which are treated with collection data in this monograph. An asterisk (*) means that many further collections are reported in the literature. Literature reports without a sufficient description are omitted.

Appendix 3. Index to fungal taxa

Families, genera, subgenera, sections, series, species, and infraspecific taxa of *Orbiliomycetes* treated in this monograph, including taxa referred to other classes.

Appendix 4. List of anamorph-teleomorph connections

Included are all *Orbiliomycetes* species with known teleomorph treated in this monograph, together with their assured or presumed anamorph if any was observed (sorted according to the order in the taxonomic part). Assured connections relate to strains in which the anamorph was obtained in an ascospore isolate or was confirmed by molecular methods; presumed connections relate to conidial states observed on the natural substrate near the apothecia; * = previously published connections (red: strain numbers from literature); numbers in square brackets refer to not included collections; [1] = confirmed by molecular methods only, based on DNA from apothecia and conidia or culture, [2] = id., based on type culture.

Teleomorph species	Anamorph (predominantly form genera)	Connection certain	Ascospore isolate in which no anamorph developed	Ascospore isolate in which conidia developed	Conidia from natural substrate near apothecia

Appendix 5. List of new taxa, combinations, epitypes, lectotypes, neotypes, and reference specimens

New genera (gen. nov.): (4)
Amphosoma Baral
Bryorbilia Baral & E. Rubio
Liladisca Baral
Lilapila Baral & G. Marson

New or rank-altered subgenera (1), sections (5) and series (23) of *Orbilia*:
subgenus *Habrostictis* (Fuckel) Baral & E. Weber

subgenus *Habrostictis* **section** *Aurantiorubrae* Baral & E. Weber
subgenus *Habrostictis* **section** *Helicoon* (Morgan) Baral & E. Weber
subgenus *Hemiorbilia* **section** *Lentiformes* Baral & E. Weber
subgenus *Orbilia* **section** *Arthrobotrys* (Corda) Baral, E. Weber & Hagedorn
subgenus *Orbilia* **section** *Ovoideae* Baral & E. Weber

section *Arthrobotrys* **series** *Dactylellina* (M. Morelet) Baral & E. Weber
section *Arthrobotrys* **series** *Drechslerella* (Subram.) Baral & E. Weber
section *Arthrobotrys* **series** *Gamsylella* (M. Scholler, Hagedorn & A. Rubner) Baral & E. Weber
section *Arthrobotrys* **series** *Neodactylella* Baral & E. Weber
section *Aurantiorubrae* **series** *Abutilones* Baral & E. Weber
section *Aurantiorubrae* **series** *Albovinosae* Baral
section *Aurantiorubrae* **series** *Commatoideae* Baral & E. Weber
section *Aurantiorubrae* **series** *Hyalinia* Baral & E. Weber
section *Aurantiorubrae* **series** *Piliferae* Baral
section *Aurantiorubrae* **series** *Poitevinicae* Baral
section *Aurantiorubrae* **series** *Regales* Baral & E. Weber
section *Aurantiorubrae* **series** *Rubellae* Baral & E. Weber
section *Aurantiorubrae* **series** *Xanthoguttulatae* Baral, Quijada & E. Weber
section *Habrostictis* **series** *Ellipsospermae* Baral & E. Weber
section *Habrostictis* **series** *Serpentinae* Baral & E. Weber
section *Helicoon* **series** *Pseudotripoconidium* (Z.F. Yu & K.Q. Zhang) Baral & E. Weber
section *Hemiorbilia* **series** *Hesperideae* Baral & E. Weber
section *Hemiorbilia* **series** *Vibrioides* Baral, E.Weber & G. Marson
section *Lentiformes* **series** *Cercidicola* Baral
section *Lentiformes* **series** *Microspermae* Baral & E. Weber
section *Lentiformes* **series** *Ovales* Baral & E. Weber
section *Lentiformes* **series** *Phanosomates* Baral & E. Weber
section *Orbilia* **series** *Microsomates* Baral & E. Weber

New species (sp. nov.): (331)

Amphosoma atroolivaceum Baral & G. Marson
Amphosoma macrosporum Baral & G. Marson
Amphosoma natalense Baral
Amphosoma resinicola Baral & G. Marson

Bryorbilia arenicola E. Rubio & Baral

Hyalorbilia caucasica Baral & E. Weber
Hyalorbilia fagi E. Weber, Baral & J.W. Guo
Hyalorbilia fomentarii Baral
Hyalorbilia helicospora Baral & G. Marson
Hyalorbilia herbicola Baral, Priou & Perz
Hyalorbilia hergiswiliana Baral, Polhorský & E. Weber
Hyalorbilia japonica Baral, M.L. Wu & Y.C. Su
Hyalorbilia latispora Baral, G. Marson & P. Perz
Hyalorbilia macrohelicospora Baral & Hong Y. Su
Hyalorbilia multiguttulata Baral & B. Declercq
Hyalorbilia orbiliicola Baral, G. Marson, Polhorský & E. Weber
Hyalorbilia pleioerythrostigma Baral
Hyalorbilia puertoricensis Baral
Hyalorbilia resinae Baral
Hyalorbilia rotifera Baral & E. Batten
Hyalorbilia sibirica E. Weber & Baral
Hyalorbilia subfusispora Baral, G. Marson & P. Perz
Hyalorbilia texensis Baral & G. Marson
Hyalorbilia tortuosa Baral, E. Weber, Y.C. Su & M.L. Wu
Hyalorbilia ulicicola Baral & Priou
Hyalorbilia ulmi Baral & E. Batten

Lecophagus ellipsoideus Baral & G. Marson
Lecophagus pini Baral
Lecophagus subglobosus Baral, B. Coué & M. Hairaud

Lilapila jurana Stöckli, G. Marson, Baral, U. Graf, Gilgen, Wergen & E. Weber
Lilapila oculispora Baral & G. Marson
Lilapila oculisporella G. Marson, Baral & E. Weber

Orbilia acaciae Baral & G. Marson
Orbilia acicularis Baral & Hong Y. Su
Orbilia aethiopica Baral & U. Lindem.
Orbilia albidorosea Baral & G. Marson
Orbilia albovinosa Baral
Orbilia allantoobliqua Baral & G. Marson
Orbilia alpigena Baral & E. Weber
Orbilia amberina Baral & G. Marson
Orbilia angiosubvinosa Baral, R. Tena & E. Weber
Orbilia anguliobliqua Baral & G. Marson
Orbilia angustoaristata Baral & G. Marson
Orbilia angustoobliqua Baral & G. Marson
Orbilia anigozanthi Baral & G. Marson
Orbilia arachnopus Baral & G. Marson
Orbilia arachnovinosa Baral & E. Weber
Orbilia aradi Baral & G. Marson
Orbilia arizonensis Baral & G. Marson
Orbilia astrovinosa Baral & G. Marson
Orbilia asturiensis Baral, E. Rubio & J. Linde
Orbilia atlantis Baral, Spooner & Hairaud
Orbilia atriplicis Baral
Orbilia atrolentiformis Baral & G. Marson
Orbilia aureocrenulata Baral
Orbilia australiensis Baral & G. Marson
Orbilia austrocylindrica Baral & E. Weber
Orbilia austroobtusispora Baral
Orbilia austroocculta Baral & G. Marson
Orbilia austropleiomicrosoma Baral & G. Marson
Orbilia austroregalis Baral
Orbilia aviaristata Baral & G. Marson
Orbilia aviceps Baral & G. Marson
Orbilia aviflagellata Baral & G. Marson
Orbilia bambusina Baral
Orbilia barrowensis Baral & G. Marson
Orbilia basiflexa Baral
Orbilia battenii Baral & E. Weber
Orbilia beatricis Baral
Orbilia bicknellensis Baral & G. Marson
Orbilia binchuanensis Baral & Hong Y. Su
Orbilia brachychitonis Baral & G. Marson
Orbilia brettii O. Ceska, Baral, G. Marson & E. Weber
Orbilia breviaristata Baral, Priou & G. Marson
Orbilia breviclava Baral
Orbilia cactacearum Baral & G. Marson
Orbilia calyptrata Baral & G. Marson
Orbilia canadensis Baral & G. Marson
Orbilia carminorosea Baral
Orbilia carnegieae Baral & G. Marson
Orbilia caudimaeandrina Baral & G. Marson
Orbilia caulicola Baral & G. Marson
Orbilia cercidicola Baral, G. Marson & E.S. Popov
Orbilia cercocarpi Baral & G. Marson
Orbilia cisti Baral & E. Weber
Orbilia clavipisca Baral & G. Marson
Orbilia clavuliaristata Baral & E. Weber
Orbilia clavuliformis Baral & G. Marson
Orbilia cocois Baral
Orbilia colombiana Baral & Priou
Orbilia commarosa Baral & G. Marson
Orbilia concoloris Baral & G. Marson
Orbilia coniferarum Baral & E. Weber
Orbilia coronohesperidea Baral
Orbilia crenatofalcata Baral & S. Tello
Orbilia crenatonemaspora Baral & Hong Y. Su
Orbilia crenatovinosa Baral & Friebes
Orbilia cryptogena Baral & G. Marson
Orbilia cucumispora Baral & G. Marson

Orbilia cupressi Baral & E. Weber
Orbilia cupularis Baral & G. Marson
Orbilia curvatimyriella Baral & G. Marson
Orbilia curvatinavajoana Baral & G. Marson
Orbilia curvatiobliqua Baral
Orbilia curvatitrapeziformis Baral, G. Marson & Quijada
Orbilia curvativitalbae Baral & G. Marson
Orbilia cylindrosoma Baral, E. Weber & G. Marson
Orbilia cylindrospora Baral, E. Weber & G. Marson
Orbilia dalmatica Baral
Orbilia delphinus Baral & G. Marson
Orbilia denticulata Baral, R. Galán & G. Marson
Orbilia desertorum Baral & Priou
Orbilia disseminata (Henn.) Baral & E. Weber
Orbilia dixiensis Baral & G. Marson
Orbilia edulis Baral & E. Weber
Orbilia epilobii Baral & E. Weber
Orbilia eremaeae Baral
Orbilia fabacearum Baral & G. Marson
Orbilia farnesianae Baral
Orbilia ficicola G. Marson, Baral & E. Weber
Orbilia filiformis Baral, E. Weber & P. Perz
Orbilia fimbriata Baral & G. Marson
Orbilia flavovacuolata Baral & E. Weber
Orbilia flexisoma Baral & G. Marson
Orbilia floridensis Baral
Orbilia foliicola Baral & E. Weber
Orbilia frangulae G. Marson, Baral & E. Weber
Orbilia fraxini Baral & P. Perz
Orbilia frullaniae Baral & Priou
Orbilia fusiformis Baral & Hong Y. Su
Orbilia geijerae Baral
Orbilia gemma Baral & G. Marson
Orbilia graminis Baral & G. Marson
Orbilia gregorii Baral
Orbilia guyanensis Baral
Orbilia halimi Baral & E. Weber
Orbilia helicoobliqua Baral & G. Marson
Orbilia helicovinosa Baral
Orbilia hoana Baral, Hong Y. Su & Y.C. Su
Orbilia idahoensis Baral & G. Marson
Orbilia jacaensis Baral, Priou & E. Weber
Orbilia jinguangsiensis Baral & H.Y. Su
Orbilia jurana Baral
Orbilia kingsiana Baral & G. Marson
Orbilia lacrimispora Baral & G. Marson
Orbilia lamarcheae Baral
Orbilia lanternae Baral & G. Marson
Orbilia lentiformis Baral & G. Marson
Orbilia lilacina Baral & G. Marson
Orbilia liliputiana Baral, Quijada & E. Weber
Orbilia livistonae Baral
Orbilia lobeliae Baral
Orbilia macroasca Baral & G. Marson
Orbilia macrocarpa Baral & G. Marson
Orbilia macrodelphinus Baral & G. Marson
Orbilia macrohesperidea Baral & G. Marson
Orbilia macroserpens Baral & G. Marson
Orbilia macrotrapeziformis Baral & E. Weber
Orbilia maeandrina Baral & G. Marson
Orbilia magnifica Baral & G. Marson
Orbilia mali Baral
Orbilia mammifera Baral
Orbilia martinicensis Baral, Priou & Lechat
Orbilia megahesperidea Baral & G. Marson
Orbilia megaocculta Baral
Orbilia menageshae Baral & U. Lindem.
Orbilia mesaverdiana Baral & G. Marson
Orbilia microlentiformis Baral
Orbilia microserpens Baral
Orbilia microsoma Baral, G. Marson & E. Weber
Orbilia mirabilis Baral, G. Marson & E. Weber
Orbilia mongolica Baral
Orbilia montigena Baral & E. Weber
Orbilia multiaustraliensis Baral & G. Marson
Orbilia multiaustrocylindrica Baral
Orbilia multicercocarpi Baral & G. Marson
Orbilia multicreosoteris Baral & G. Marson
Orbilia multicurvula Baral & G. Marson
Orbilia multidelphinus Baral
Orbilia multigambelii Baral & G. Marson
Orbilia multihamulata Baral & G. Marson
Orbilia multimaeandrina Baral & G. Marson
Orbilia multinanosoma Baral
Orbilia multiphanosoma Baral & G. Marson
Orbilia multiserpens Baral & G. Marson
Orbilia multitrapezoidea Baral & G. Marson
Orbilia multiurosperma Baral & G. Marson
Orbilia multivinosa Baral & G. Marson
Orbilia multivirgula Baral & G. Marson
Orbilia myriella Baral & G. Marson
Orbilia myrioauris Baral & G. Marson
Orbilia myrioaustraliensis Baral & E. Weber
Orbilia myrioeuonymi Baral & G. Marson
Orbilia myrioflexa Baral
Orbilia myriofusiclava Baral & G. Marson
Orbilia myriofusoidea Baral
Orbilia myriohesperidea Baral
Orbilia myriolentiformis Baral & G. Marson
Orbilia myriolilacina Baral & G. Marson
Orbilia myriomuscula Baral & G. Marson
Orbilia myrionamibica Baral
Orbilia myrionanosoma Baral & G. Marson
Orbilia myrioobliqua Baral & G. Marson
Orbilia myrioolneyae Baral & G. Marson
Orbilia myriophanosoma Baral & G. Marson
Orbilia myriopseudoregalis Baral & G. Marson
Orbilia myriosphaera Baral & E. Weber
Orbilia myriourosperma Baral & G. Marson
Orbilia namibica Baral & G. Marson
Orbilia nanosperma Baral & G. Marson
Orbilia naumburgensis Baral & E. Weber
Orbilia navajoana Baral & G. Marson
Orbilia navicularis S. Tello, Baral & E. Weber
Orbilia nemaspora Baral, Bin Liu, A.I. Romero, Healy & Pfister
Orbilia neocomma Baral, S.F. Li, J.W. Guo, Z.F. Yu & G. Marson
Orbilia nothoaprilis Baral
Orbilia nothovinosa Baral
Orbilia obtusispora Baral & E. Weber
Orbilia ocellata Baral, G. Marson & E. Weber
Orbilia octocercocarpi Baral & E. Weber
Orbilia octocorculispora R. Tena, Baral & E. Weber
Orbilia octoserpentina Baral & G. Marson
Orbilia octosporoides Baral & G. Marson
Orbilia olivacea Baral & G. Marson
Orbilia ophiosoma Baral & G. Marson
Orbilia osteospermae Baral & G. Marson
Orbilia ovalis Baral & G. Marson
Orbilia ovoidea Baral & G. Marson
Orbilia palmicola Baral
Orbilia paloverdensis Baral & G. Marson
Orbilia paracaudata Baral & G. Marson
Orbilia paracylindrospora Baral & E. Weber
Orbilia paradoxoides Baral
Orbilia paramontigena Baral, Bometón & E. Weber
Orbilia paraobliqua Baral & G. Marson
Orbilia paravitalbae Baral, E. Weber, Priou & R. Tena
Orbilia parviclava Baral
Orbilia patellarioides Baral & G. Marson
Orbilia phanosoma Baral & Marson
Orbilia phragmitis Baral
Orbilia pileosoma Baral & G. Marson
Orbilia pisciculus Baral & G. Marson
Orbilia pleioalbidorosea Baral
Orbilia pleioaustraliensis Baral & G. Marson
Orbilia pleioaustrocylindrica Baral, G. Marson & E. Weber
Orbilia pleiocoronohesperidea Baral & G. Marson
Orbilia pleiocrescens Baral & G. Marson
Orbilia pleioeuonymi Baral, G. Marson & Priou
Orbilia pleiogambelii Baral
Orbilia pleiohesperidea Baral
Orbilia pleiolentiformis Baral & G. Marson

Orbilia pleiomesaverdiana Baral & G. Marson
Orbilia pleiomicrosoma Baral & G. Marson
Orbilia pleionavajoana Baral & G. Marson
Orbilia pleioobtusispora Baral
Orbilia pleioquaestiformis Baral & G. Marson
Orbilia pleioserpens Baral & G. Marson
Orbilia pleiostomachia Baral
Orbilia pleioungulata Baral, Quijada & R. Tena
Orbilia pleiourosperma Baral & G. Marson
Orbilia pleiovinosa Baral & G. Marson
Orbilia pleiovitalbae Baral
Orbilia pleistoeuonymi Baral & P. Perz
Orbilia pleistolilacina Baral, G. Marson & E. Weber
Orbilia pleistoobliqua Baral & G. Marson
Orbilia pleistosphaera S. Tello & Baral
Orbilia pleistovitalbae Baral & G. Marson
Orbilia plurilentiformis Baral & G. Marson
Orbilia plurililacina Baral, G. Marson & E. Weber
Orbilia pluristomachia Baral & G. Marson
Orbilia plurivacuolata Baral, G. Marson & E. Weber
Orbilia poitevinica Baral
Orbilia ponderosae Baral & G. Marson
Orbilia pseudoaristata Baral & G. Marson
Orbilia pseudeuphorbiae Baral, Quijada & Beltrán-Tej.
Orbilia pseudocylindrospora Baral & G. Marson
Orbilia pseudoflagellispora Baral & G. Marson
Orbilia purshiae Baral & G. Marson
Orbilia puyae Baral & Priou
Orbilia quaestiformis Baral & G. Marson
Orbilia quercus-ilicis Baral & E. Weber
Orbilia pyrenaica Baral, Priou & E. Weber
Orbilia rhamni Baral & Priou
Orbilia rehmii Baral
Orbilia rubrovacuolata Baral, Priou & E. Weber
Orbilia saguarina Baral & G. Marson
Orbilia sarcobati Baral & G. Marson
Orbilia sarothamni Baral
Orbilia scandens Baral & G. Marson
Orbilia scaphoides (Peach) E. Weber & Baral
Orbilia sedonensis Baral & G. Marson
Orbilia siculispora Baral, E. Weber, Friebes & G. Marson
Orbilia solidaginis Baral
Orbilia somedana Baral & E. Weber
Orbilia sonorensis Baral & G. Marson
Orbilia spathulata Baral & G. Marson
Orbilia spermoides Baral & G. Marson
Orbilia sphaerospora Baral & G. Marson
Orbilia spirillospora Baral & G. Marson
Orbilia spirospora Baral & E. Weber
Orbilia stansburyanae Baral
Orbilia stilbospora Baral
Orbilia subalbovinosa Baral & G. Marson
Orbilia subaristata Baral, G. Marson & Matočec
Orbilia subclavuliformis Baral, E. Weber & Priou
Orbilia subcryptogena Baral & G. Marson
Orbilia subcylindrospora Baral & E. Weber
Orbilia subdelphinus Baral
Orbilia suberis Baral & R. Galán
Orbilia subfabacearum Baral & G. Marson
Orbilia subocellata Baral & E. Weber
Orbilia subovoidea Baral, Matočec & E. Weber
Orbilia subsiculispora G. Marson & Baral
Orbilia subsphaerospora Baral
Orbilia subtrapeziformis Baral, E. Weber & G. Marson
Orbilia subuliformis Baral
Orbilia subulivinosa G. Marson, H.O. Baral, E. Rubio & E. Weber
Orbilia subvinosa G. Marson, Baral & E. Weber
Orbilia subvitalbae Baral & E. Weber
Orbilia tremuloidis Baral & E. Weber
Orbilia tenuispora E. Weber, Baral, H.Y. Su, M.L. Wu, Y.C. Su & Bin Liu
Orbilia trapeziformis Baral & G. Marson
Orbilia triangulispora Baral
Orbilia ungulata Baral, G. Marson & Matočec
Orbilia urosperma Baral & G. Marson
Orbilia velutina Baral & G. Marson
Orbilia vermiculati Baral & G. Marson
Orbilia vibrioides Baral, Priou & G. Marson
Orbilia wannerooensis Baral & G. Marson
Orbilia xanthoflexa Baral, Pfister & Healy
Orbilia yuccae Baral & G. Marson

New names (nom. nov.): (2)

Orbilia cookei Baral

Pyrenopeziza cookei Baral

New provisional names (nom. prov.): (8)

Lilapila gallica G. Marson, Baral & E. Weber

Orbilia multimacroasca G. Marson & Baral
Orbilia myriostomachia Baral
Orbilia pleiocreosoteris G. Marson
Orbilia pleiovirgula Baral
Orbilia pubescens Baral & G. Marson
Orbilia rosicola Baral & E. Weber
Orbilia senegalensis Baral, G. Marson & E. Weber

New combinations (comb. nov.): (38)

Calycina carneorosea (Cooke & Harkn.) Baral

Hyalorbilia anonyma (Rehm) Baral
Hyalorbilia citrina (A.L. Smith) Baral
Hyalorbilia fusarina (Burghouts & W. Gams) E. Weber & Baral
Hyalorbilia fusarioides (D.C. Harris) E. Weber & Baral
Hyalorbilia leguminacea (Juan Chen, L.L. Xu, Bin Liu & Xing Z. Liu) E. Weber & Baral
Hyalorbilia lignatilis (M.H. Mo & K.Q. Zhang) E. Weber & Baral
Hyalorbilia spermatophaga (Drechsler) E. Weber & Baral

Hyaloscypha leucostigma (Fuckel) Baral

Laetinaevia diaphana (Rehm) Baral
Laetinaevia raripila (Höhn.) Baral & Helleman

Leptodontidium diaphanulum (Cooke) Baral

Liladisca acicola (Fuckel) Baral

Mniaecia albida (P. & H. Crouan) Priou & Baral

Orbilia bembicodes (Drechsler) E. Weber & Baral
Orbilia brochopaga (Drechsler) Baral, E. Weber, Bin Liu & Z.F. Yu
Orbilia cladodes (Drechsler) E. Weber & Baral
Orbilia clavispora (J. Chen, L.L. Xu, B. Liu & Xing Z. Liu) Baral, E. Weber, P. Perz & G. Marson
Orbilia elegans (Oudem.) Baral, A. Rubner, E. Weber & Van Ryck.
Orbilia ellipsospora (Preuss) Bin Liu, E. Weber & Baral
Orbilia flagellispora (Raitv. & R. Galán) Baral & G. Marson
Orbilia javanica (Rifai & R.C. Cooke) Bin Liu, Baral & E. Weber
Orbilia latispora (H.Y. Su & X.Y. Yang) Baral, Ying Zhang & E. Weber
Orbilia lysipaga (Drechsler) Bin Liu, Baral & E. Weber
Orbilia mammillata (S.M. Dixon) Baral & E. Weber
Orbilia multiformis (Dowsett, J. Reid & Kalkat) E. Weber & Baral
Orbilia oligospora (Fresen.) Baral & E. Weber
Orbilia oxyspora (Sacc. & Marchal) E. Weber & Baral
Orbilia polybrocha (Drechsler) Baral, E. Weber & Pfister
Orbilia regalis (Cooke & Ellis) Baral
Orbilia rhopalota (Drechsler) Baral & E. Weber
Orbilia rosea (J. Webster & Descals) Baral & E. Weber
Orbilia saccharifera (Berk.) Baral
Orbilia xinjiangensis (J. Chen, L.L. Xu, B. Liu & Xing Z. Liu) E. Weber, Baral & Helleman
Orbilia yunnanensis (Z.F. Yu & K.Q. Zhang) Bin Liu, E. Weber & Baral
Orbilia zhongdianensis (J. Zhang & K.Q. Zhang) Baral, E. Weber & M. Bemmann

Psilachnum rubicundum (Sacc. & Speg.) Baral

Rodwayella haematoidea (Cooke & W. Phillips) Baral & Quijada

New epitypes: **(33)**

Hyalorbilia berberidis: BR5020213021208V, epitype of *Orbilia berberidis*
Hyalorbilia citrina: M-0291768, epitype of *Calloria citrina*
Hyalorbilia erythrostigma: M-0291773, epitype of *Peziza erythrostigma*
Hyalorbilia fusispora: M-0291770, epitype of *Orbilia fusispora*

Orbilia aprilis: M-0291762, epitype
Orbilia aristata: M-0291760, epitype of *Orbilia occulta* var. *aristata*
Orbilia aurantiorubra: M-0291763, epitype
Orbilia cardui: M-0291778, epitype
Orbilia carpoboloides: H.B. 6639c (illustration on Pl. 568: 3), epitype of *Peziza carpoboloides*, ex-epitype culture: CBS 116276
Orbilia cejpii: M-0291774, epitype
Orbilia comma: M-0291759, epitype
Orbilia cotoneastri: M-0177060, epitype
Orbilia crenatomarginata: M-0291776, epitype of *Hyalinia crenatomarginata*
Orbilia dryadum: M-0291769, epitype of *Orbilia alnea* var. *dryadum*
Orbilia ebuli: M-0276476, epitype
Orbilia epipora: M-0291771, epitype of *Peziza epipora*
Orbilia euonymi: M-0291775, epitype
Orbilia flavida: M-0291761, epitype
Orbilia flavidorosella: G.M. 2012-09-18.1 (illustration on Pl. 584: 5), epitype, GenBank KT222391
Orbilia hesperidea: M-0291758, epitype
Orbilia luteorubella: M-0291777, epitype of *Peziza luteorubella*
Orbilia occulta: GXU 1467, epitype *Calloria occulta*
Orbilia oligospora: CBS 115.81, epitype of *Arthrobotrys oligosporus*
Orbilia oxyspora: M-0276548, epitype of *Dactylella oxyspora*
Orbilia phragmotricha: M-0291767, epitype of *Orbiliaster paradoxus*
Orbilia polybrocha: M-0276567, epitype of *Trichothecium polybrochum*
Orbilia polyspora: M-0291765, epitype
Orbilia rectispora: M-0276578, epitype of *Hyalinia rectispora*
Orbilia rubella: M-0291772, epitype of *Peziza rubella*
Orbilia rosea: CCM F-18983, epitype of *Anguillospora rosea*
Orbilia sarraziniana: M-0291764, epitype
Orbilia tremulae: M-0276602, epitype
Orbilia vitalbae: M-0276607, epitype

New lectotypes: **(39)**

Claussenomyces atrovirens: the collection from Kergontès, lectotype of *Helotium flavoviride*

Hyalorbilia andina: FH, lectotype of *Orbilia andina*
Hyalorbilia citrina: K(M) 31762, lectotype of *Calloria citrina*
Hyalorbilia inflatula: W 6467, lectotype of *Orbilia sinuosa*
Hyalorbilia inflatula: PRM 152443, lectotype of *Orbilia linata*
Hyalorbilia inflatula: herb. L.J. Grelet, PC, lectotype of *Hyalinia rectispora* var. *majuscula*

Liladisca acicola: Fungi Rhen. Exs. 1965, M-0206556, lectotype of *Tympanis acicola*

Orbilia arachnovinosa: herb. P.A. Karsten 3196, H-6003827, lectotype of *Orbilia rubinella*
Orbilia auricolor: K, lectotype of *Peziza auricolor*
Orbilia auricolor: herb. E. Mussat, PC, lectotype of *Helotium karstenii*
Orbilia blumenaviensis: S, lectotype of *Helotium blumenaviense*
Orbilia brasiliensis: herb. J. Puiggari 2781, LPS 28075, lectotype of *Calloria brasiliensis*
Orbilia cardui: PRM 149600, lectotype of *Orbilia cardui* var. *farfarae*
Orbilia carpoboloides: herb. L. Fuckel 1894, G, lectotype of *Habrostictis rubra*
Orbilia carpoboloides: M-0206370, lectotype of *Peziza lasia*
Orbilia carpoboloides: S-F9979, lectotype of *Calloria rubrococcinea*
Orbilia clavispora: PRM 151613, lectotype of *Orbilia vestimenti*
Orbilia coccinella: herb. E. Fries, UPS, lectotype of *Peziza coccinella*
Orbilia crenatomarginata: FH 00304814, lectotype of *Hyalinia crenatomarginata*
Orbilia disseminata: S-F9997, lectotype of *Helotium disseminatum*
Orbilia epipora: herb. P.A. Karsten 5278, H-6003825, as *Peziza leucostigma*, lectotype of *Peziza epipora*
Orbilia epipora: S, herb. Sydow, lectotype of *Orbilia sericea*
Orbilia euphorbiae: S-F41427, lectotype of *Humaria euphorbiae*
Orbilia juruensis: K(M) 52784, lectotype
Orbilia luteorubella: herb. P.A. Karsten 5282, H-6003831, lectotype of *Peziza luteorubella*
Orbilia microspora: PRM 151768, lectotype
Orbilia neglecta: PAD, nr. 442 ex parte, lectotype
Orbilia occulta: herb. H. Rehm 770, M-0206545, lectotype of *Calloria occulta*
Orbilia oxyspora: PRM 148826, lectotype of *Orbilia sambuci*
Orbilia regalis: herb. M.C. Cooke 2778, K(M) 35323, apothecia on inner surface of bark, lectotype of *Peziza regalis*
Orbilia rosea: PRM 151737, lectotype of *Orbilia verrucosa*
Orbilia rosea: PRM 151715, lectotype of *Orbilia pseudorubella*
Orbilia rosella: M-0206546, lectotype
Orbilia tremulae: PRM 152382, lectotype
Orbilia vinosa: PRM, illustration in Velenovský's manuscript, lectotype of *Orbilia prunorum*
Orbilia vitalbae: S-F9983, short-spored apothecia, lectotype
Orbilia xanthostigma: L 910.261-262, lectotype of *Peziza aurea*

Patinella stenotheca: herb. P.A. Karsten 3426 (H), lectotype

Pezizella orbilioides: LUX 42532, lectotype

New neotypes: **(3)**

Hyalorbilia inflatula: M-0276411, neotype of *Peziza inflatula*

Orbilia leucostigma: M-0276499, neotype of *Peziza leucostigma*
Orbilia xanthostigma: M-0177061, neotype of *Peziza xanthostigma*

New reference specimens (RefSpec): **(4)**

Orbilia auricolor: M-0276438, RefSpec of *Peziza auricolor*
Orbilia cladodes: CBS 297.84, CBS H-8895, RefSpec of *Arthrobotrys cladodes*
Orbilia lysipaga: CBS 581.91, RefSpec of *Dactylella lysipaga*
Orbilia vinosa: H.B. 6715b, RefSpec of *Peziza vinosa*
