THE present Work on FERNS having been brought to a close, it only remains for the Authors to return their grateful acknowledgements to those Botanists who have, in the most liberal manner, assisted them with specimens and observations. The names of these are, indeed, invariably given under the respective species which they have had the kindness to furnish ; but it behoves the Authors, in an especial manner, to express their thanks to Dr. Wallich, of the Calcutta Botanic Garden ; to the Rev. Lansdowne Guilding, of St. Vincent ; to Dr. Bancroft, Mr. Wiles, and Mr. Lunan, of Jamaica ; to Professor William Jameson, of Quito ; to Charles Telfair, Esq. and Professor Bojer, of the Mauritius ; and to Mr. Charles Fraser, of New Holland. To the first of these Gentlemen, in particular, they have been indebted for continued supplies of the Ferns of the vast continent of India ; and these have now arrived to so great an extent,—and not from Dr. Wallich alone, but also from Dr. Wight, of Madras,—that it is in contemplation with the Authors, under the sanction and patronage of the Honourable the Board of Directors of the East India Company, to form from them a new and separate publication, under the title of “*FILICES ASIATICÆ RARIORES*,” to appear on the same size and plan as the “*PLANTÆ ASIATICÆ RARIORES*” of Dr. Wallich.

Radix e fibris ramosis, pubescens.

Caudex nullus, nisi reliquia stipitum vetustorum.

*Stipes* 6—8-pollicaris, crassitie pennæ anserinae, semiteres, densissime villosus, villis longis, purpureo-nigris, basi dilatatis, horizontalibus.

*Frondes steriles* non raro pedatae, ellipticas seu ovales, basi apiceque obtusissimæ, paululum undulatae, crassiæ, luteo-virides, costa prominentia percursæ, utrinque villis nigris margineque ciliatae. Hi villi insigniter fragiles sunt et sub lente basi dilatatae, reticulatae, marginibus involutis. *Frondes fertiles* plerumque duplo minores, supra margine villosæ, subtus fructiferae.

*Capsulae* totam inferiore partem, costa excepta, tegentes, intense fuscæ, annulo vix completo cinctæ, pedicellatae, pedicello capsula subæque longo.

*Semina* sphaerica, subreticulata.

Fig. 1. Capsula clausa. f. 2. Eadem dehiscens. f. 3. Pedicellus. f. 4. Semina:—*magn. auct.*

---

*Acrostichum crinitum* seems to be a plant of very rare occurrence; the only station, hitherto given, being the Island of Martinique, where indeed the fructification does not appear to have been discovered. Our friend Mr. Guilding has sent us truly magnificent specimens from the Island of St. Vincent, in various states; and from these our figures have been made.

*Storckia maxigolium.*

TAB. II.

---

*ACROSTICHUM succisæfolium*; fronde simplici oblonga coriacea obtusissima stipiteque ferrugineo-squamosis, squamis lanceolatis spinuloso-serratis.

*Acrostichum succisæfolium*. Pet. Th. Esq. de la Flore de Trist. d'Ac. p. 31. Carm. Descr. of the Isl. of Trist. d'Ac. in Linn. Trans. v. 12. p. 510. Kaulf. Enum. Fil. p. 60. Poir. in Encycl. Meth. Suppl. v. 1. p. 120.

HAB. In sylva insulae Tristan d'Acunha. Aubert du Petit Thouars. Carmichael. Insulæ Mauritiæ. Aubert du Petit Thouars.

*Caudex* repens, hic illuc fibrosus paleis squamosis, subulatis, intense fuscis ubique obsitus.

*Stipes* 6-pollicaris et ultra, erector, crassiusculus, undique ferrugineo-paleaceus.

*Frons* digitalis, coriacea, oblonga, costa medio instructa, basi apiceque valde obtusa, utrinque paleaceo-squamosa, squamis lanceolatis, acuminatis, spinuloso-ciliatis, membranaceis, reticulatis, non raro subpellatis:—*fertilis* magis angusta basi apiceque obtusissima.

*Capsulae* numerosissimæ, totam inferiorem partem frondis tegentes, costa excepta, intense fuscae, pedicellatæ; *annulo* fere completo.

*Semina* subsphaerica, reticulata, marginata.

Fig. 1. Squamae. f. 2. 2. 2. 2. Capsulæ. f. 3. Semina:—*magn. auct.*

---

This very distinct species of *Acrostichum* seems to have been found by M. du Petit Thouars in the Isle of France, as well as in Tristan d'Acunha. Our specimens are from the latter island, where they were gathered by Captain Carmichael.

Poiret has given this plant upon the authority of Jussieu's Herbarium as the *A. succisæfolium* of that author; but he probably only adopted the name of Du Petit Thouars.

*Acrostichum glandulosum.*

TAB. III.

ACROSTICHUM GLANDULOSUM.

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd.

GEN. CHAR. *ACROSTICHUM*, Linn. *Sori* amorphi, seu *Capsulae* per totam paginam inferiorem frondis (interdum diversæ) vel ad ejus partem sparsæ. *Indusium* nullum (nisi squamulæ v. setæ in quibusdam capsulis interstinctæ). *Br.*

---

*ACROSTICHUM glandulosum*; fronde simplici oblonga coriacea basi apiceque acutiuscula subnervosa nudiuscula glabra glanduloso-punctata, stipite subsquamoso, caudice dense paleaceo.

*Acrostichum glandulosum*. Carmichael MSS.

*Acrostichum oblongum?* Desv. Journ. de Bot. 1813. p. 271.

HAB. In promontorio Bonæ Spei. Carmichael.

*Caudex* repens, crassus, lignosus, squamis ferrugineis, membranaceis, ciliato-dentatis, densissime obsitus.

*Stipes* 2—5 uncias longus, hinc sulcatus, basi præcipue subsquamosus.

*Frondes* 3—5-pollicares, oblongae, coriaceæ, margine parum revolutæ, medio costatae, nervis obscuris parallelis, punctis glandulosis pellucidis adspersæ, cetero glabre, nitide, costa subtus paululum paleacea, basi apiceque acutiusculæ:—*fertiles* fronde minore angustiore, sed stipite longiore.

*Capsulae* totam frondem tegentes, fuscæ, numerosissimæ; longe pedicellatae, annulo magno.

*Semina* sphærica, marginata, margine tuberculata.

Fig. 1. Capsula. f. 2. Capsula magis aucta. f. 3. Semina:—*magn. auct.*

---

This is very nearly allied to *A. conforme* of Swartz: but our specimens of that plant are perfectly destitute of glandular dots. Still more closely does it approach the *A. oblongum* of Desvaux, which Kaulfuss unites with the *A. conforme*.

*Stachys sylvatica*

TAB. IV.

ACROSTICHUM · RADDIANUM.

FILICES.—GYRATÆ. *Br.* POLYPODIACEÆ. *Kaulf.* FILICES veræ. *Willd.*

GEN. CHAR. *ACROSTICHUM*, Linn. *Sori* amorphi, seu *Capsulae* per totam paginam inferiorem frondis (interdum diversæ) vel ad ejus partem sparsæ. *Indusium* nullum (nisi squamula v. seta in quibusdam capsulis interstinctæ). *Br.*

---

*ACROSTICHUM Raddianum*; frondibus stipiteque villosissimis, sterilibus linear-lanceolatis, fertilibus ellipticis integris.

*Acrostichum spathulinum*. *Raddi, Fl. Brasil. p. 3. t. 15. f. 2.*

HAB. In uidis rupibus torrentium super Montes Estreljenses, Brasiliæ. *Raddi.*

*Radix* dense caespitosa, fibris valde ramosis subpinnatis.

*Stipites* plurimi ex eadem radice, 2—3 uncias longi, erecti, densissime pilosi, pilis patentibus rufescensibus.

*Frondes steriles* 3—4 uncias longæ, linear-lanceolatae, obtuse, basi sensim in petiolam attenuatae, utrinque marginaque ferrugineo-pilosa. Hi pili sub lente serrulati sunt, basi dilatati, concavi, reticulati, membranacei:—*fertiles* sterilibus multo breviores, ellipticae, acutiusculæ, dorso marginaque solummodo pilosæ.

*Capsulae* totam frondem dorso tegentes, longe pedicellatae, sphaericæ, late annulatae, annulo incompleto.

*Semina* parva, sphaerica.

Fig. 1. Pilus vel squama. f. 2. Capsulae. f. 3. Semina:—*magn. auct.*

---

We have changed the name which Professor Raddi applied to this Fern, because of its similarity with that of *spathulatum*, given by Bory de St. Vincent to a species of the Isle of France, and which, as far as we can judge from the figure in the *Voyage aux Quatres Isles des Mers d'Afrique*, we agree with Raddi in considering very nearly indeed allied to the present; differing almost solely in the very obtuse and emarginate extremity of the fertile fronds.

*Ceterach pedunculata.*

TAB. V.

CETERACH PEDUNCULATA.

FILICES.—GYRATAE. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd.

GEN. CHAR. *CETERACH*. *Sori* lineares transversales. *Indusia* nulla. Willd.

---

*Ceterach pedunculata*; fronde simplici lato-lanceolata sinuato-crenata reticulata basi attenuata, fertili longe stipitata, soris e costa ad marginem frondis attingentibus.

HAB. Sylhet Ind. Orientalis, ubi legit D. Smith. Misit clariss. Wallich.

*Caudex* repens, lignosus, tortuosus, pennis passerinæ crassitie, subtus radiculosa, radiculis e fibris ramosis descendentibus, quorum majoribus hirsutis.

*Frondes* steriles et fertiles ex eadem caudice, utraque stipitata.

*Sterilis*: *Stipes* erectus, glaber, gracilis, nitidus, pallide fuscus hinc sulcatus, 3—4-pollicaris. *Frons* 4—6-pollicaris, lato-lanceolata, membranacea, fusco-viridis, apice acuminata, basi attenuata, decurrente, margine sinuato-crenata, costa instructa venisque horizontali-patentibus, venulis anastomosantibus.

*Fertilis*: *Stipes* ut in sterilis, sed triplo longior. *Frons* ut in sterilis, sed magis angusta, crenata, substantiaque firmiore. *Indusium* nullum. *Sori* lineares, intense fusi, in venis parallelis et cum iis alternantibus et totam latitudinem e costa ad marginem occupantes. *Capsulae* sphærica, sublonge pedicellatae, reticulatae, annulo fere completo. *Semina* minuta, oblonga, vix angulata, fusa.

Fig. 1. *Capsulae*. f. 2. *Semina*:—*magn. auct.*

---

How far the genus *Ceterach* merits to be distinguished from *Grammitis* must be left to be determined by future observation. Kaulfuss makes one of the characters to depend on the chaffy scales with which the fructification is covered, as in *Ceterach Officinaria*. These scales are totally wanting in our plant; but the *sori* are *transverse*, upon which appears to rest the main character of the genus as distinguishable from *Grammitis*.

*Grammitis* again, according to Mr. Brown, has the *sori* “venulâ unicâ insidentes.” In *Ceterach pedunculata* they occupy each a number of veinlets or reticulations exactly intermediate between the straight lateral veins.

Grammitis decurrens

TAB. VI.

GRAMMITIS DECURRENS.

FILICES.—GYRATE. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd.

GEN. CHAR. *GRAMMITIS*. *Sori* oblongi, lineares, recti, sparsi. *Indusia* nulla. Willd.

---

*GRAMMITIS decurrens*; fronde pinnatifida, segmentis remotis lanceolatis acuminatis integerrimis, stipite rachique glabris.

*Grammitis decurrens*. Wall. MSS.

HAB. In India Orientali (Nepal?). Wallich.

*Caudex* repens, crassus, valde fibrosus, fibris ramosis non raro hirsutis.

*Stipes* pedalii et ultra, pennæ corvinæ crassitie, erectus, glaber, nitidus, fuscus, teres, hinc sulcatus.

*Frons*, circumscriptione late ovata, profunde pinnatifida, segmentis 6—8-pollicaribus, patentibus, lanceolatis, acuminatis, coriaceo-membranaceis, apice acuminatis, marginibus integerrimis; rachi lœvi superne late, inferne anguste alata.

*Sori* in medio frondis ut et in segmentis, lineares, obliqui, venulis suppositi, prope costam, sed non ad marginem attingentes.

*Capsulae* sphaericae, longe pedicellatae, reticulatae, annulo incompleto.

*Semina* parva, oblongo-subreniformia.

Fig. 1. 1. Capsulae. f. 2. Semina:—*magn. auct.*

---

In the *Grammitis decurrens* of Dr. Wallich we have a species quite unlike any other described plant of the genus, and very similar in habit to many species of *Polyodium*.

We have received specimens from Dr. Wallich in 1820, and again in 1826 from the Honourable the East India Company; but the exact place where the plants were gathered is not mentioned.

TAB. VII.

TÆNITIS FURCATA.

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES verae. Willd.

GEN. CHAR. *TÆNITIS*. *Sorus* linearis, continuus, quandoque interruptus, longitudinalis, inter costam et marginem exteriorem frondis situs. *Indusium* nullum. Willd.

---

*Tænitis furcata*; frondibus dichotomo-partitis pinnatifidisve, laciniis linear-lanceolatis acutissimis, subtus squamuoso-punctatis.

*Tænitis furcata*. Willd. Sp. Pl. v. 5. p. 136. Smith in Rees Cycl.

*Pteris furcata*. Linn. Sp. Pl. p. 1531. Swartz. Syn. Fil. p. 95.

*Lingua cervina furcata*. Plum. Fil. p. 122 et 141.

HAB. In sylvis Hispaniolæ. Plumier. Insula Sancti Vincentii. Rev. L. Guilding. Insula Trinitatis. D. Lockhart.

*Caudex* repens, ramosus, densissime squamuoso-tomentosus, intense fuscus.

*Stipes* fere nullus.

*Frons* spithameæ ad pedalem, erecta, inferne indivisa, linearis, basi attenuata, superne vel dichotomo-partita vel pinnatifida; laciniis ultimis et nonnunquam lateraliibus furcatis; omnibus linear-lanceolatis vel linearibus, 3—6 vel ad 8 uncias longis, 6 lineas (in specimine Plumieri unciam) latis, coriaceo-membranaceis, integerimis, acutissimis, costatis et obscure venosis, facie superna viridibus, subnitidis fere nudis, subtus pallidioribus punctato-squamulosis, squamuulis minutis, ovatis, reticulatis, peltatis.

*Sori* in duas lineas longitudinales prope marginem frondis, et totam fere longitudinem laciniarum plerumque occupantes. *Indusium* omnino nullum.

*Capsulae* pedicellatae, annulo completo.

*Semina* oblonga vel subreniformia.

Fig. 1. Squamula. f. 2. Portio frondis cum soris. f. 3. Capsulae. f. 4. Semina:—magn. auct.

---

If we are right in referring this undoubted species of *Tænitis* to the *T. furcata* of Swartz and the *Lingua cervina furcata* of Plumier, it would seem to be a species of very rare occurrence, and only hitherto known to Plumier. The figure in our plate indeed differs from that of Plumier in its much narrower fronds, and in the divisions being rather such as to give the character of pinnatifid than regularly dichotomous: but since the annexed engraving was finished, we have received specimens from His Excellency Sir Ralph Woodford of Trinidad, gathered by Mr. Lockhart, which have the fronds considerably broader, still narrower than Plumier's plant, and with some of the individuals (evidently the younger ones) simply dichotomously divided. The more perfect state of the plant is perhaps constantly pinnatifid with few segments, and the breadth of the frond is liable to much variation.

*Pteris australis*

---

A beautiful and we believe very rare species of *Trichomanes*, remarkable for its numerous marginal fructifications, and, as Kaulfuss well observes, for the nature of its *venation*. The lateral parallel veins resemble those of many monocotyledonous plants; and from the extreme delicacy of the parenchyme between these veins, the pinnae are frequently torn in the direction of them, as we see to be the case in the different species of *Musa*.

The late Baron de Schach favoured us with the specimens here figured, from the shores of the Asphaltum lake in Trinidad.

---

Excellent, in almost every respect, as is the description that Dr. Swartz has given us of this plant, yet, probably in consequence of the indifferent figure referred to in Plumier, it has had the misfortune of being little understood; the *Trichomanes lucens* having generally been sent to us by the name of *alatum*,—a larger and much finer plant, as will be seen by our figure.

This must not be confounded with the *Trichomanes alatum*\* of *Hook. in Fl. Lond.* (the *Hymenophyllum alatum* of *Engl. Bot.*) On referring that species to its proper genus, the old specific name was retained, without recollecting that it was preoccupied. It should now be called, after Smith in Rees's Cyclopædia, *T. europeum*.

Our finest specimens of the true *T. alatum* are from the Rev. Lansdown Guilding.

\* The two species are nevertheless very nearly allied. The European plant is much more divided, so as to be 3—4 pinnatifid, the ultimate segments never serrated.

*Trichomanes crispum*

---

This is perhaps the species of this curious genus which is the most generally dispersed, being found in the West as well as the East Indies, in Japan, in the Society and Sandwich Isles, and in New Holland. All these countries, however, are intratropical, except Japan and Nepal. The plant is liable to considerable variation. The specimen figured in the *Flora Japonica*, and those which we have received from M. Bojer at the Mauritius, as well as our New Holland individuals, have the lowermost segments of the fronds pinnatifid, so as to appear like those of the original *Gleichenæ*, with which we think Mr. Brown has justly united the *Mertensia*.

From the Prince of Wales Island we have a species which scarcely differs from this but in having the segments of the frond much longer and equally linear, so that each frond has almost exactly the appearance of that of *Polyodium pectinatum*. Probably the *Mertensia emarginata* of Raddi, from Brazil, is not really distinct from our plant. It has the lower segments of the frond shorter, the whole frond somewhat narrower: the emarginate apices are common to both. To this Raddi refers the *M. glaucescens* of Humboldt and Willdenow.

*Pteris immissa.*

---

This seems to agree so well with the *Mertensia immersa* of Kaulfuss, that we can have little doubt of the two plants being the same. It is possible that it may be the *M. pubescens* of Humboldt and Willdenow; though that is said to be clothed beneath with white down. Again, the *M. bifida* of the same author has many points in common with this; but according to the figure in *Act. Holm.* the branch immediately below the ultimate one is pinnatifid on each side. May not this be the *M. decurrentis* of Raddi?

Mr. Brown, in his admirable *Prodromus Flora Novæ Hollandiæ*, mentions that this plant is liable to great variation both in regard to the number of pinnae, of which the fructifying appendage is composed, and to the roughness of the frond. Sir James Smith, too, mentions an Otaheitan variety, or, as he is inclined to think, a distinct species, which he would call *S. fastigiata*, having "the segments of its fertile fronds level-topped and exceedingly numerous, the appendages uniformly four pair, as nearly as possible, in each spike, all of them erect and parallel, not divaricated, nor are the spikes recurved." We have received what we consider to be the same plant, from the East India Company; named by Dr. Wallich *S. dichotoma*: but here the appendages are not one-fourth the size of those we have figured.

The specimens here represented were sent to us from the Mauritius by M. Bojer.

---

We are not aware that any attempt has yet been made to cultivate this handsome and curious species of Fern: but now that we have been so successful with many other individuals of this graceful tribe of plants, we do not yet despair of seeing it flourish in our stoves.

It is probably a native of several of the West India islands, having been found in Martinique by Plumier, in Jamaica by Swartz, and in the fertile island of St. Vincent by our friend the Rev. Lansdown Guilding, whose inestimable botanical communications from that country, particularly of Ferns, have been one of the principal inducements for us to undertake the present publication.

The genus *Danæa* is a very distinctly marked one, having the under side of the *pinnæ* almost wholly covered with closely placed, parallel, immersed sori, formed of a double row (the rows joined by the lateral nerve upon which the sorus is inserted) of closely united capsules, each opening by a pore at the extremity. Upon removing a sorus, a deep cell or cavity remains; as at fig. 2.

*Ophioglossum pendulum.*

TAB. XIX.

OPHIOGLOSSUM PENDULUM.

FILICES.—OPHIOGLOSSAE. Br., Kaulf. STACHYOPTERIDES. Willd.

GEN. CHAR. *OPHIOGLOSSUM*. Linn. *Capsula* nudæ, in spicam articulatam disticham connatae, uniloculares, transverse dehiscentes, bivalves. Willd.

---

*OPHIOGLOSSUM pendulum*; fronde pendula linearis dichotoma, spica pedunculata medio frondis inserta.

*Parasiticum*. Frondes 2—3 ex eadem parva tuberculata radice, pendentes, bi-tripedales, usque ad quinque pedes longæ, basi angustæ, deinde lineares, tenues, siccitate coriaceo-membranaceæ, 6 lineas ad pollicem latæ, simpliciter vel bis dichotomæ, virides, reticulatæ, areolis elongatis; segmentis apice obtusis, margine undique integerrimo.

Spica pedunculata, nunc basin versus, prope medium, vel infra apicem, frondis sita, digitum ad pedem longa, pendula, linearis, compressa, marginibus utrinque capsulifera. Hæ *capsulae* arcte connatae, sphaericæ, transversim dehiscentes.

Pedunculus duas uncias longus, teres.

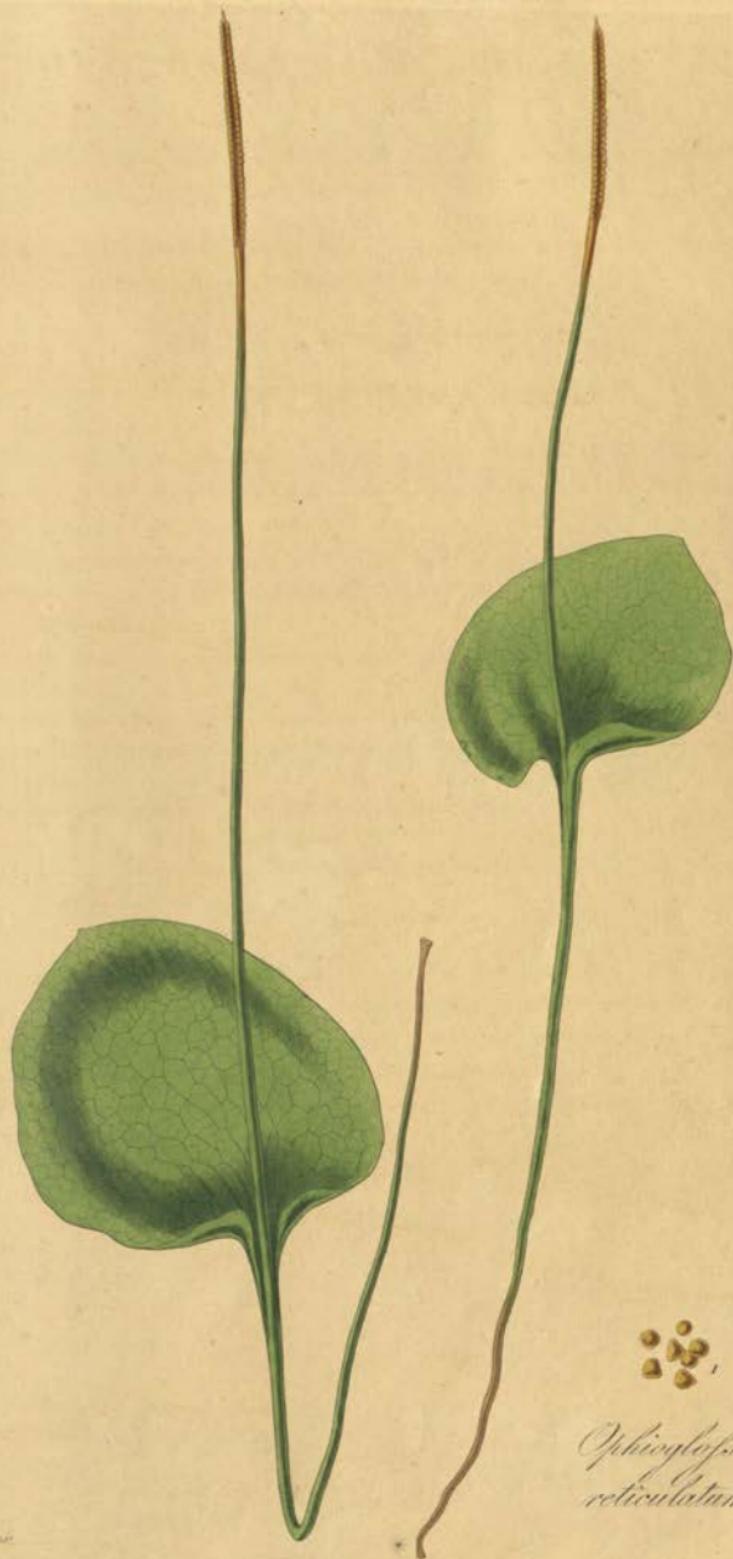

Semina parva sphaerica fusco-lutea.

Fig. 1. Capsula dehiscens. f. 2. Semina:—magn. auct.

---

This noble species of *Ophioglossum*, only perhaps exceeded in size by the South American *Ophioglossum palmatum*, has been sent to us from the Mauritius by Captain Carmichael (from whose specimens the accompanying figure has been drawn) and by Dr. Sieber. It is probably not uncommon there. In Amboyna, Rumphius says, it is exceedingly rare. In the Banksian Herbarium, Sir James Smith tells us, very fine specimens are preserved, gathered by Mr. David Nelson upon the high mountains of Owhyhee.

Leman, in the *Dictionnaire des Sciences Naturelles*, suggests that on more minute examination of the fructification, this species will be found distinct from the genus *Ophioglossum*: but we see no reason for entertaining such an opinion.

*Ophioglossum  
reticulatum.*

TAB. XX.

OPHIOGLOSSUM RETICULATUM.

FILICES.—OPHIOGLOSSEÆ. Br., Kaulf. STACHYOPTERIDES. Willd.

GEN. CHAR. *OPHIOGLOSSUM*, Linn. *Capsulae* nudæ, in spicam articulatam disticham connatae, uniloculares, transverse dehiscentes, bivalves. Willd.

---

*OPHIOGLOSSUM reticulatum*; spica caulina longissime pedunculata, fronde cordata apiculata reticulata "radice elongata."

Ophioglossum reticulatum. Linn. Sp. Pl. p. 1518. Swartz. Syn. Fil. p. 170. Willd. Sp. Pl. v. 5. p. 60. Smith in Rees Cycl.—Lam. Illustr. t. 864. f. 2. Sieber Herb. Fil. n. 19.

Ophioglossum cordatum et reticulatum. Plum. Fil. p. 141. t. 164.

HAB. In Insulis Mauritii et Borboniae, Indiae Orientalis. In Hispaniola, Jamaica, et Guiana, Indiae Occidentalis.

*Radix* (fide Plumieri) descendens, elongata, carnosa, 2—3-pollicaris, fibris plurimis albidis simplicibus instructa.

*Stipes* 4—6-pollicaris, erectus, teres, viridis.

*Frons* solitaria, ad apicem stipitis, lato-cordata, vel cordato-rotundata, carnosso-membranacea, reticulata, areolis angulato-rotundatis, margine integerrimo, apice apiculata, basi profunde emarginata, marginibus in stipite decurrentibus.

*Pedunculus* e sinu frondis, erectus, teres, gracilis, 6—7 uncias longus.

*Spica* terminalis, solitaria, biuncialis, linear-compressa, mucrone terminata.

*Capsulae* parvæ, arctissime connatae, seminibus angulato-sphaericis repletæ.

Fig. 1. Semina:—magn. auct.

---

It is the case with this, as with many other tropical Ferns, that it is found equally in the New as in the Old World. Our specimens are all from the Mauritius; but judging from the figures of Plumier above quoted, and the testimony of other writers, there appears to be no difference between them and those that are natives of the West Indies.

The drawing was made from specimens gathered by Captain Carnichael in the Mauritius.

*Soriostichum hybridum*

## TAB. XXI.

## ACROSTICHUM HYBRIDUM.

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd.

*Acrostichum ciliare*. *Pet. Th. Trist. d'Acugn.* p. 32? *Carmichael in Descr. of the Island of Tristan da Cunha, in Linn. Trans.* v. 12. p. 510. (fide specim. ejus.)

*Acrostichum villosum*. *Sieber, Syn. Fil.* n. 27. non *Swartzii*.

HAB. Insula Bourboniae. *Bory*. Mauritio. *Sieber, Bajer*. *Tristan da Cunha. Carmichael*. *Caudex repens*, brevis, squamis longis, numerosissimis, fuscis, lanceolato-subulatis dense obsitus, inferne fibris plurimis, ramosis, ferrugineo-tomentosis instructus.

*Stipes* 6—8-pollicularis, fusco-flavescens, squamis subulatis, fuscis, horizontalibus sparsim tectus.

*Frons* oblongo-lanceolata, 6—8 uncias longa, duas uncias et ultra lata, submembranacea, indistincte marginata, medio costata, nervis subhorizontalibus versus eorum basin bis terve dichotomis, costa, superficie raro, marginibusque dense squamoso-hirsutis. *Squamæ* subulatae, purpureo-fuscae, duas vel tres lineas longæ, sub lente minute serrulatae atque pulcherrima reticulatae, areolis oblongis. *Frons* *fertilis* sterilis triplo minor, squamis nullis.

*Capsula* totam inferiorem partem, costa excepta, tegentes, fuscae vel flavo-fuscae, pedicellatae, annulo crasso incompleto cinctæ.

*Semina* oblonga, subreniformia.

Fig. 1. *Capsula*. f. 2. *Semina*. f. 3. *Squama*, e margine frondis:—*magn. auct.*

This seems in every essential particular to accord with the *A. hybridum* of Bory, who found the plant in the Isle of Bourbon, and whose name we have here adopted. We have received the same plant from Dr. Sieber, under the name of *A. villosum* of Swartz, which, besides being a native of Jamaica, is described as having the sterile fronds on both sides, and the fertile one on the upper surface, clothed with hairs; and so Plumier figures them. It is also the *A. ciliare* of Capt. Carmichael, and probably of Du Petit Thouars.

---

In those *Grammitides* of Swartz and Willdenow, which have much divided fronds, the nerves are more decidedly furcate than in those with simpler fronds, and the sori have this forked character likewise. These species are removed by Desvaux, and we think with propriety, to the genus *Gymnogramma*. The present is one of the most rare and the most beautiful of the genus. Our specimens were received from Captain Carmichael, who gathered them at a considerable elevation on the face of the Table-land, and on a detached hill in the middle of the plain, in Tristan da Cunha.

---

In the character we have here given of *Aspidium*, we have in view the adopting Michaux's and Mr. Brown's idea of separating the old *Aspidium* of Swartz into three genera, *Aspidium*, *Nephrodium*, and *Athyrium*. We have not yet ourselves had sufficient experience to determine how far their characters are well defined; but feeling the necessity of grouping into something more than divisional characters the overgrown genus *Aspidium*, we willingly follow such able botanists as those now quoted.

Of the original *Aspidia*, three only are described by Willdenow with "undivided fronds;" and they have all an articulated or jointed stipes. There is a fourth species with a stipes destitute of joint given in the Exotic Flora, *Asp. Wallichii*, Hook.: but that would be a *Nephrodium* of Brown, and has the soris confined to a line on each side the midrib; whereas here the fructifications are very numerous, arising, as in some *Polyodia*, from the ultimate divisions of the veins: and indeed the whole plant has much the appearance of a *Polyodium*.

We are indebted for our specimens to our liberal friend Dr. Wallich.

*Semina* sphærica, subangulata.

Fig. 1. Frondis portio cum soris. f. 2. 2. Capsule. f. 3. Semina.

---

To the specimens with which we have been favoured by the Honourable the East India Company in 1825, the name *Asplenium rigidum* of Wallich is attached: and we should have adopted this, had it not been applied by Swartz to a very different species. Again, the name of *Aspidium erosum*, Wall., which accompanied Dr. Wallich's original specimens in 1820, is given by Linnæus to a West Indian species.

It is intermediate between *Asplenium* and *Diplazium*; the main central nerve of a fascicle of nerves, as it appears to us, bearing the involucra of a *Diplazium*, while the lateral nerves on branches have those of *Asplenium*.

Frondes pedales, nunc, fide Raddi, bipedales, circumscriptione ovatae, vel deltoidea, pinnatæ. Pinnae plerumque exacte opposita, lanceolatae, acuminatae, costatae, reticulatae; superiores decurrentes, reliquæ magis minusve petiolatae; intermediae ad basin divise, infime margine exteriore (nunc interiore) pinnatifidae, lacinia rarissime divisa. Pinnae omnes, planta sterili, margine dentatae, dentibus setosis, fertili, ad apicem, solummodo, dentato-spinulosi. Rachis petiolique alati, superiore parte præcipue.

Sori continuo, omnem marginem, præter apices, occupantes.

Capsulae in sinus involuci numerose, sphæricæ, annulatae, longissime pedicellatae, pedicello gracili, articulato, celuloso.

Semina triangularia, granulis minutissimis immixta.

Fig. 1. Frons fertilis. f. 2. Frons sterilis. f. 3. Pinnae portio cum soro. f. 4. Sorus, intus visus. f. 5. Capsula. f. 6. Semina cum granulis:—magn. auct.

---

If we are not deceived, this is a plant liable to considerable variation. We know, from specimens received from the author, as well as from the description and figure, that it is Raddi's *Pt. Brasiliensis*: but then we equally believe it to be the *Pt. denticulata* of Swartz and Willdenow. And we have in our own possession such a series of specimens, as almost make us believe that the *Pt. tristicula* of Raddi, and even his *Pt. spinulosa*, are states of the same plant.

The Messrs. Shepherds of the Liverpool Botanic Garden cultivate this plant in the stove: and it is well worthy a place in every collection.

---

To so admirable a description of this plant as that here copied verbatim from Mr. Brown, we can add nothing. We believe the plant has never been found except in the stations above given. Mr. Brown has drawn up the character of the genus so as to include our *Pteris crispa*; which he, nevertheless, considers a doubtful species of *Cryptogramma*. To us, however, there appears no generic difference; and the fertile fronds have the closest similarity, in almost every particular, except in the rather shorter *sori* or *capsules*. In the sterile fronds the pinnules are much broader and never wedge-shaped, in the plant now before us.

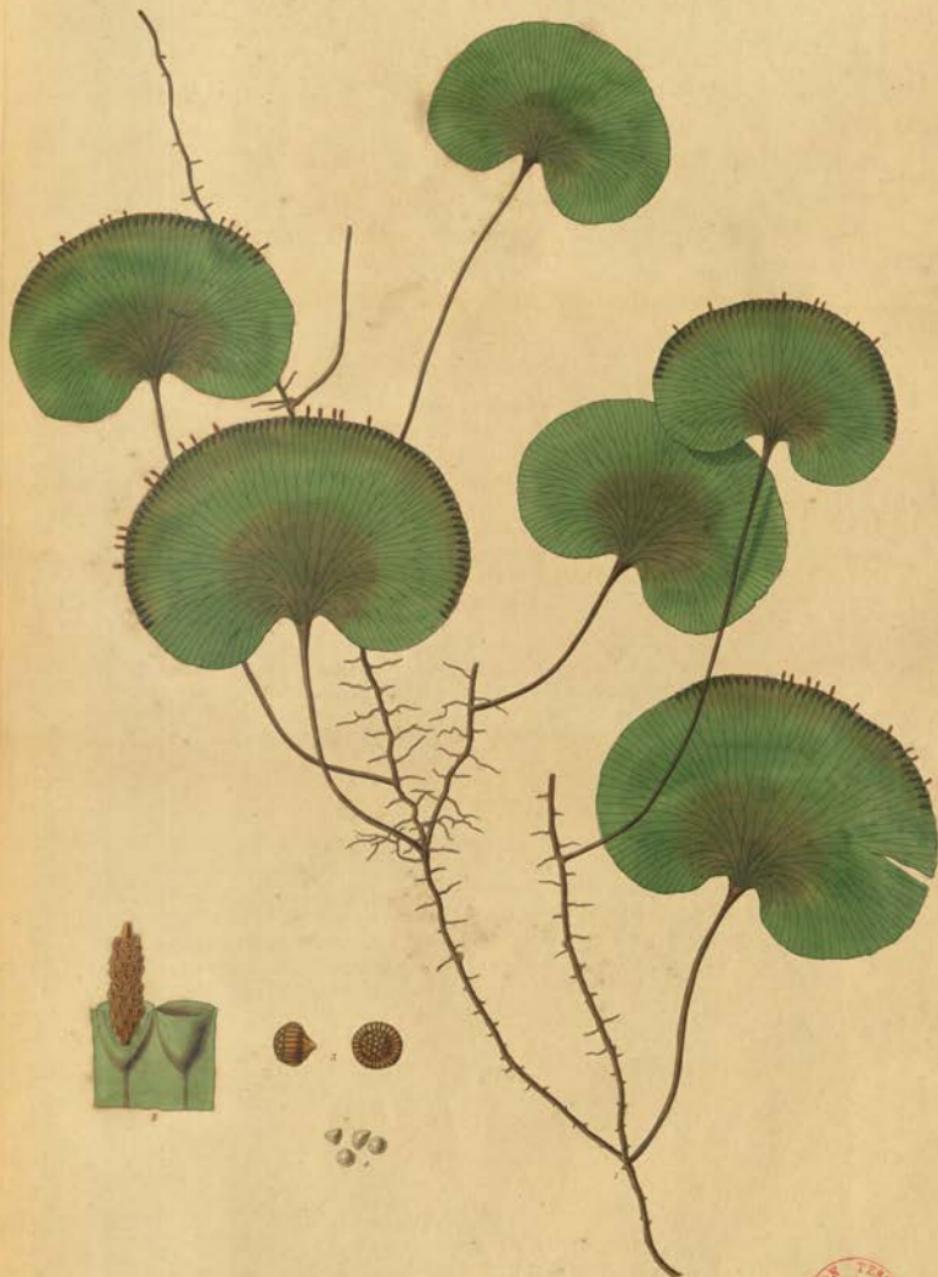

Fig. 1. Planta juvenis. f. 2. Planta adulta fructifera:—*magn. nat.* f. 3. Pinnula. f. 4. Involucrum, intus visum.

f. 5. Capsula. f. 6. Semina:—*magn. auct.*

There appears to us to be great difficulty in determining the species of the genus *Adiantum* without the aid of figures; especially of that division which includes our European *A. Capillus Veneris*, and which division or group is characterized by having petiolated pinnules of a thin membranaceous texture, and more or less regularly cuneate in form.

The present plant is allied in general appearance to the species just mentioned, *A. Capillus Veneris*, but may be distinguished by its more compound frond, smaller pinnules, and, essentially, by the sori being placed in the bottom of the sinus of the notches. Still nearer does it approach to the *A. assimile* of New Holland (the *A. trigonum* of Billardiére, *Nov. Holl. t. 248.*) ; and I scarcely know how they may be recognized, but by the more decided lobes of the pinnae of our plant, and the much deeper notches, within which the fructification is inserted: add, too, that the segments of these lobes are so incurved and meet together in such a manner as to render the notch itself almost obsolete; so that at first sight the involucra seem to be intramarginal, or upon the disk of the pinnulae.

In Brazil, the *A. cuneatum* appears to be not uncommon; and we have received an *Adiantum*, which we can in no way distinguish from it, from St. Vincent, sent by the Rev. L. Guiding. The Messrs. Shepards received the plant from M. Otto of Berlin, under the name of *A. pendulinum*.

---

This singular and very beautiful Fern is, we believe, entirely confined to New Zealand, where it climbs over the trunks of trees. We have received it from Mr. Menzies; but our finest specimens were recently sent to us by Mr. Fraser, the colonial botanist in New South Wales.

The substance of the frond is rather thick, and it is pellucid, and of that nature which would lead to the suspicion of its having, in a fresh state, been succulent. In drying, therefore, the specimens may have shrunk considerably, especially at the margins; and to this circumstance, perhaps, may be attributed the exserted state of the capsules.

---

Numerous beautiful specimens, received from our friend the Rev. Lansdown Guilding, of this minute Fern, enable us to give what we trust will be found to be satisfactory figures of this little known, though we believe not uncommon, species. The only ones that exist, that we are aware of, are, that of the younger Hedwig, which is acknowledged by Willdenow and Smith to be bad; and that of Sloane, which, though usually (and even by Swartz) quoted under *Tr. muscoides*, we think is better referred to this.

We have reason, indeed, to believe that the *Tr. muscoides* and *reptans* have been confounded by botanists; but the former differs from the latter (as we propose on another occasion to show more clearly by a plate) by its narrower, more beautifully reticulated and less veined frond, in the substance of which the involucres are inserted. We have another nearly allied species from Guiana, gathered by Mr. Parker, in which there is a strong nerve, having only as many divisions as there are lobes to the frond.

Fig. 1. Plantæ:—*magn. nat.* f. 2. Frons, cum pôrtione caudicis. f. 3. Frondis apex cum soro. f. 4. Capsula:—*magn. auct.*

---

At first sight, and with the eye unaided by a microscope, this plant has very much the appearance of *Trichomanes lanceum*; but a more careful examination will show it to be very distinct, even as to its genus: the involucrum here being completely that of a *Hymenophyllum*, and the margin wants the ciliae of that plant,—being furnished instead with a thickened margin.

We have only received specimens from Mr. Fraser, gathered in New Holland, and, we believe, in the neighbourhood of Port Jackson.

---

The *Angiopteris indica* of Desvaux we have quoted as a synonym to the present species with a mark of doubt. All the character given is “*frondibus pinnatis, pinnis lanceolatis:*” and the observation is added, that it is easily distinguished from the already known species—“*n'etant point cordiforme-lancolée.*” Our specimens are never cordiform at the base of the pinnules, but are generally obtuse, sometimes acute.

From Dr. Wallich again we have a plant marked “*Angiopteris, vix ab A. crassipeda, Wall. diversa.*” We are unacquainted with the *crassipeda* of Wallich; but of the plant just mentioned, except in its pinnules being narrower and considerably more attenuated than the figure here given, we do not see how it differs from *A. erecta*. Our Sylhet specimen exactly accords with Mr. Menzies' from Otaheite.

HAB. In monte Hatouna, Nepaliæ, arboribus (?). *Wallich.*

*Radix* valde fibrosa, fibris ramosis tomentosis intertextis fuscis.

*Caules* plurimi ex eadem radice, ut videtur, pendentes, 8—10-pollicares, dichotome divisi, ubique foliosi.

*Folia* sparsa, subremota, semiuncialia, erecto-patula, exacte linearia, glabra, integerrima, medio obscure costata, apice acutiuscula, *inferiora* plerumque fuscescentia, *superiora* viridia; omnia siccitate flexuosa atque etiam subtortuosa.

*Capsulae* axillares, solitariae, ad basin foliorum versus apicem ramorum, reniformes, flave, bivalves, granulis minutissimis pallide flavis replete.

Fig. 1. Folium. f. 2. Folium cum ejus capsula. f. 3. Capsula aperta cum granulis:—*magn. auct.*

---

Sent by Dr. Wallich from Nepal in 1820, marked as “*Cosca*” of the natives: and again we received it from the Honourable the East India Company with the MS. name of Dr. Wallich, which we have here adopted. It has the habit of our *Lyc. subulifolium*; but that has the leaves decidedly awl-shaped, and erect, and imbricated.

*Lycopodium atro-viride*

TAB. XXXIX.

LYCOPODIUM ATRO-VIRIDE.

LYCOPODINEÆ. *Swartz.*, *Br.*, *Kaulf.* STACHYOPTERIDES. *Willd.*

GEN. CHAR. *LYCOPODIUM*, Linn. *Capsule* uniloculares axillares, sessiles; *aliae* bivalves, farina repleta; *aliae* 2—3-valves, corpusculis 1—6, globosis. *Br.*

*LYCOPODIUM atro-viride*; foliis bifariis horizontalibus acinaciformibus integerrimis vel serrulatis subcostatis striatis, stipulis ovatis costatis serrulatis longe mucronatis, spicis tetragonis sessilibus, squamis ovatis acutissimis carinatis serrulatis.

*Lycopodium atro-viride*. *Wallich MSS.*

*Lycopodium cuspidatum*. *Hook. MSS. apud Hort. Soc. Lond.*

HAB. In Insula "Prince of Wales Island" dicta, Indiae Orientalis. *Wallich.*

*Caulis*, ut videtur, repens, pedalis et ultra, bi-tripinnatum ramosus, pallide fuscus, flexuosus sultatus, hic illic radicans.

*Folia* bifaria, horizontalia, facie inferiore caulis inserta, rigida, nitida, arcte disposita, acinaciformia, obtusa, lineis tribus longitudinalibus notata, linea centrali e costa obscura, integerrima vel serrulata, intense viridia, subtus pallidiiora.

*Stipulae* foliis quintuplo minores, facie superiore caulis insertae, appressæ, liberae, foliis alternantes, ovatae, acute, tenuissime marginatae, serrulatae, costatae, costa longe producta, cuspidatae.

*Spicae* ad apices ramorum, solitariae vel binæ, vix unciam longæ, tetraquadræ, e squamis viridibus, rigidis, ovatis, acute carinatis, imbricatis, patentibus, acutissimis, serrulatis, costa ad apicem attingente, dorso serrulata.

*Capsulae* ovato-rotundatae, flavae, squamis breviores, axillares, solitariae.

*Semina* minutissima, quaterna, flavae.

Fig. 1. Portio caulis, facie superiore visa. f. 2. Eadem, a dorso visa. f. 3. Stipula. f. 4. Spica. f. 5. Squama. f. 6. Squama cum capsula. f. 7. Capsula. f. 8. Semina:—*magn. auct.*

---

This very handsome species of *Lycopodium* we were first acquainted with by means of a valuable collection of dried specimens which the Horticultural Society of London had received from Prince of Wales Island; and in that collection we named the species *L. cuspidatum*: but having since received the same plant from the Honourable the East India Company under the name of *L. atro-viride* of Wallich (in all probability gathered in the same island by that gentleman), we hasten to adopt this appellation of our liberal friend.

A. *Ophioglossum ellipticum*

D'Uvresville del.

B. *Ophi. opacum.*

J. Swan Sculpt.

## OPHIOGLOSSUM ELLIPTICUM.

FILICES.—*OPHIOGLOSSEAE. Br., Kaulf.* STACHYOPTERIDES. *Willd.*

GEN. CHAR. *OPHIOGLOSSUM*, Linn. *Capsulae* nudæ in spicam articulatam disticham connatae, uniloculares, transverse dehiscentes, bivalves. *Willd.*

---

*OPHIOGLOSSUM ellipticum*; spica caulinæ longe pedunculata, fronde elliptica obtusa reticulata medio costata, radice fibrosa.

HAB. In Demerara, Americae meridionalis; legit et communicavit *amiciss. C. S. Parker.*

*Radix* e fibris numerosis, longiusculis, simplicibus, fuscescentibus.

*Stipes* unciam ad tres uncias longus, erectus, gracilis, fronde terminatus.

*Frons* bi-triangularis, elliptica, membranacea, integerrima, apice obtusiuscula, inferne in stipitem sensim decurrente, reticulata, media evidenter costata, costa versus apicem obsoletiore.

*Pedunculus* e basi frondis et ex apice stipitis, fronde duplo longior, erectus, teres.

*Spica* sub-biuncialis, lineari-compressa.

*Capsulae* numerosæ, arcte connatae.

Fig. 1. Capsula. f. 2. Semina:—*auct.*

---

This was discovered by our excellent friend C. S. Parker, Esq. of Liverpool, in one of the many herborizing excursions he made during his visit to Demerara. In the shape of the frond it comes nearest to the Cape *Ophioglossum nudicaule*; but that is much smaller in size, and has no appearance of midrib, which is very observable in our plant. It is probably allied to the New Holland *Oph. costatum* of Mr. Brown.

## OPHIOGLOSSUM OPACUM.

*OPHIOGLOSSUM opacum*; spica caulinæ, fronde cordata opaca spica longiore, venis inconspicuis, radice bulbosa.

*Ophioglossum opacum. Carmichael in Descr. of the Island of Tristan da Cunha, in Linn.*

*Trans. v. 12. p. 509.*

HAB. In locis elevatis montis Insulae Tristan da Cunha. *Carmichael.*

*Ophioglosso reticulato* valde affine: differt radice bulboso, fronde opaca, spica fronde breviore, et magnitudine quadruplo minore.

---

This may be called an alpine plant. Tristan da Cunha is situated in 37° 6' South latitude; and the plant is said to grow "high up on the dome" of that island. This dome, Captain Carmichael tells us, in his very interesting account of that island, above quoted, is in itself 5000 feet high, and placed upon the top of a cone itself 3000 feet high. It is certainly very nearly allied to the *O. reticulatum*; and may perhaps prove a variety depending upon place of growth and other circumstances.

*Polypodium muticum*

TAB. XLI.

POLYPODIUM OVATUM.

FILICES.—GYRATE. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd., Spreng.

GEN. CHAR. *POLYPODIUM*, Swartz. *Sori* subrotundi (seriati, sparsi v. conferti). *Involucrum* nullum. Br.

---

*POLYPODIUM ovatum*; frondibus indivisis stipitatis membranaceis e basi decurrente ovatis acuminatis integerrimis costatis nervis parallelis, soris inter nervos simplici serie.

*Polypodium ovatum*. Wall. MSS.

HAB. In India Orientali. Wallich.

*Radix* e fibris numerosis, fuscis, ramosis, hic et illic ferrugineo-tomentosis.

*Caudex* teres, repens, nigro-fuscus, squamis membranaceis tectus.

*Stipes* digitalis ad palmarem, subflexuosus, rigidus, fusco-viridis, glaberrimus, inferne hispido-paleaceus.

*Frons* stipite subbrevior, e basi decurrente vel in stipitem attenuata, ovata, acuminata, omnino integerrima, membranacea, glabra, costata, venis lateralibus oblique patentibus parallelis, venulisque transversis has connectentibus instructa.

*Sori* simplici (rarissime duplo) serie dispositi, rotundati, nudi.

*Capsulae* longe pedicellatae, sphaericæ, annulo lato incompleto cinctæ.

*Semina* ovalia, subangulata, reticulata.

Fig. 1. Capsulae. f. 2. Semina:—*magn. auct.*

---

We have no means of ascertaining in what part of India this curious and rare Fern was discovered. It approaches the character of *P. scolopendrium* of Hamilton in Don's *Flora Nepalensis*; and this may perhaps be a native of the same country.

*Polypodium* *solanderianum*

TAB. XLII.

POLYPODIUM SCOLOPENDRIOIDES.

HAB. In Insula Martinicæ. Plumier. Jamaica. Plukenet. Swartz. D. Wiles.

*Radix* e fibris nigris, ramosis, hic et illic tomentosis.

*Caudex* repens, squamis lanceolatis membranaceis fuscis dense obsitis.

*Stipes* digitalis et ultra, nigro-fusca, nitidissimus, basi subpilosus.

*Frons* palmaris ad spithameam sesquiunciam lata, lanceolata, costata, venisque obliquis ramosis, sinuato-pinnatifida, sinubus acutis, laciniis triangulari-ovatis, obtusiusculis, sub lente remote ciliatis, basi attenuata, spica acuminate, integerrima.

*Sori* parvi, subrotundi, venulis inserti, in duas lineas, venis primariis paralleli, dispositi.

*Capsulae* longe pedicellatae, fuscæ, globosæ, annulo elastico lato fere completo.

*Semina* minutissima, sphaerica.

Fig. 1. Portio frondis hinc epidermide sublata, ut vene interne in conspectum veniunt. f. 2. Frondis segmentum contra lucem sub lente visum. f. 3. Capsulae. f. 4. Semina:—*magn. auct.*

---

The *Polyodium incisum* of Swartz, appears, as far as we can judge from the description, to be a species very nearly allied to this; and Linnæus is himself said to have confounded the two; the *P. scolopendrioides* of the first edition of *Sp. Pl.* being now considered as the *P. incisum*, and that of the last edition our true plant. Swartz tells us that the *P. scolopendrioides* has the smaller, but broader, fronds, and that the lower segments or divisions are remote from each other, so as to be there pinnate, as in Plukenet's figure. But the same author equally refers to Plumier's plant, which exactly, in this respect, resembles our own, having those segments coadunate.

In this Fern the cuticle or epidermis is easily removed by the aid of a dissecting knife; and then the nerves are rendered distinctly visible, with the dots or scars whence the sori have proceeded; as shown at fig. 1. of our plate.

We are indebted to A. B. Lambert, Esq. for our specimens, who received them from Mr. Wiles of Jamaica.

*Radix* fibrosa, nigra, ramosa, dense ferrugineo-tomentosa.

*Caudex* longe repens, crassitie pennæ corvinæ, squamis nigrescentibus, ovatis longe acuminatis, reticulatis, serratis obsoitus.

*Stipes* subnullus.

*Frond* spithameæ, ubique glabra, submembranacea, indistincte reticulata areolis oblongis, plana, margine integerrima, basi in stipitem per breve attenuata, apice acuta, vix acuminata, medio costata, costa vix prominula.

*Sori* in partem superiorem frondis plerumque dispositi, costæ contigui et ei paralleli aut rarius subobliqui, fere simplici serie, lineares, nunc duas ad tres lineas longi, nunc unciales, lineam lati, prominuli, basi apiceque obtusi, venulis inserti: supremis non raro confluentibus.

*Capsulae* numerosæ, arctissime dispositæ, pallide fuscae, annulo incompleto cinetæ.

*Semina* angulata, lœvissime punctulata, opaca, albo-virescentia.

Fig. 1. Portio frondis, cum soro. f. 2. Capsulae. f. 3. Semina:—*magn. auct.*

---

We are indebted for our beautiful specimens of this little-known Fern to M. Bojer of the Mauritius, who took it for a *Tenitis*, and marked it *Tenitis simplicifolia* of his MSS. We think, however, that there is no doubt of its being the *Grammitis lanceolata* of Swartz: but it must be allowed that the fructification, especially in the upper part of the frond, has a good deal the appearance of that of a *Tenitis*.

Schkuhr (t. 7.) mistook a West Indian Fern (the *Grammitis elongata* of Sw. and Willd.) for this of the Mauritius; but that differs from our plant in its much smaller size, more rigid texture, in the presence of numerous stellated scales, and in the sori of fructification being short, uniform, and forming a regular series or single line between the margin and the midrib.

*Niphobolus bicolor*

*Caudex* repens, flexuosus, pennae corvinæ crassitie, squamis numerosis arce appressis tectus, inferne hic et illic radiulosus.

*Stipes* duas ad tres uncias longus, pilis minutis radiatis obsitus.

*Frons* digitalis ad palmarem, coriacea, lineari-lanceolata, basi attenuata, apice obtusa, margine omnino integerrima, costata, costa subtus prominente, facie superna viridi pilis radiatis sparsa, subtus dense stellato- vel radiatim pilosa, albo-tomentosa. Haæ stellulae e pilis pellucidis 6—10.

*Sori* in parte superiori frondis numerosi valde convexi fere hemisphaerici, fusci, approximati, vel discreti.

*Capsula* longe pedicellata, ovato-sphaerica, lato annulata, pilis radiatis longe stipitatis peltatis immixta.

*Semina* reniformia, subangulata, flavo-virescentia.

Fig. 1. Pili stellati e dorso frondis. f. 2. Pili stellati stipitati e soris. f. 3. Capsulæ. f. 4. Semina:—magn. auct.

---

Whether or not the genus *Niphobolus*, (so called from the snow-like covering of down which invests several of the species,) be founded in nature, we do not at present pretend to determine. Perhaps it may be better to incorporate its species, as well as those of *Pleopeltis*, as had previously been done, with *Polyodium*. Indeed, with *Pleopeltis* our genus has much affinity; the stellated or radiated hairs in *Niphobolus* being exactly analogous to the little peltate *scales* of that genus.

*Radix* cæspitosa, fibrosa, fibris nigris ramosa.

*Stipites* plurimi, ex cadem radice, digitales ad palmares, graciles, nitidi, subtetragoni, flavo-virescentes, basi nigro-fusi.

*Frons*, circumscriptione, ovata, vel deltoidea, tenera, acuminata, tri-quadripinnata, ubique glabra, nuda. *Pinnæ* primarie remote, ovato-lanceolatae, vel in partem superiore anguste lanceolatae, bipinnatae, inferioribus tri-pinnatis, pinnulis pinnatifidis, inciso-lobatis, segmentis linearibus, acutis, rachibus ubique alatis. *Pinnule* steriles multoties latiores, fere flabelliformes. *Color* pallide viridis.

*Sori* oblongi, furcati, in omnibus pinnulis dispositi.

*Capsula* laxe dispositæ, sphæricaæ, sessiles, pulcherrime reticulatae: annulo incompleto.

*Semina* triangularia, pallide viridi-flava.

Fig. 1. Pinna cum soris. f. 2. Capsulæ. f. 3. Semina:—magn. auct.

---

This delicate and very beautiful Fern has, in a great degree, the habit and general appearance of *Cryptogramma leptophylla*; but it is much larger, more divided, and the pinnules are of a different figure.

The specimens here figured were communicated in 1826 by the Messrs. Shepherds, from the Liverpool Botanic Garden, whence it was received from M. Otto of Berlin. Our friend Mr. Menzies has given us a specimen which he gathered in Jamaica, and which he has marked as the *Hemionitis cicutaria* of the Banksian Herbarium; a name certainly equally applicable with that already published by Poiret and Desvaux.

Professor Raddi has not included this in his *Filices Brasilienses*.

---

The genus *Antrophyum*, established by Kaulfuss in his valuable *Enumeratio Filicum*, is well distinguished from *Hemionitis* by the presence of an involucre, always, we believe, following the lines of the veins, although in some species the veins themselves are scarcely visible when not rendered so by the presence of the fructification.

The present plant, for specimens of which, from the Isle of France, we are indebted both to Captain Carmichael and to A. B. Lambert, Esq., is remarkable in having the lines of fructification immersed in the very substance of the frond.

Our specimens vary in size, but they are all larger than those described by Willdenow.

---

Mr. Pursh seems to consider that the minuteness of this plant may have caused it in many cases to be passed by unobserved: but hitherto we believe no one has detected it except in the spot where it was originally discovered, as we learn from Mr. Nuttall, by Dr. Eddy of New York.

Our specimens were gathered by Dr. Torrey, who informs us that the spot (Quaker-Bridge, in Burlington County, New Jersey) is thirty-one miles N.W. from Philadelphia:—so that it grows further from the tropics than any species of the genus we are yet acquainted with.

---

It is difficult to say whether this *Lycopodium* should be arranged among those species which have a spicate fructification, or those whose capsules are simply placed in the axils of the leaves. The uppermost leaves, which mostly contain the capsules, are shorter and broader than the rest, and collectively form a terminal sessile *spike*; but by no means so distinct as in many species of the genus. Some authors have considered the fructification to be spicate, and others axillary; and hence botanists have differed about the species, which in reality is, in other respects, a very distinctly marked one, and very aptly named, from its resemblance to some individuals of the genus *Gnidia* or to *Daphne gnidioides*.

Our specimens were communicated from the Cape of Good Hope by M. Villet, who has sent us many excellent plants from that rich botanical country.

---

Our friend Mr. Guilding, who seems to live surrounded by the noblest of the tropical Ferns, marked this fine species of *Danæa* as distinct both from *D. alata* and *D. nodosa*. With the latter, indeed, there is no danger of its being confounded; and Sir James Smith, who certainly appears to have had the same plant in view, in describing his *D. elliptica*, well observes, that the greater breadth of the pinnæ and their being acute, not cordate, at the base, will afford the distinguishing characters. This greater proportionate breadth exists in the fertile as well as the barren pinnæ, and even in the fronds, so as to give a character to the plant at first view. Sloane's figure is very characteristic for the barren frond.

---

Willdenow was only acquainted with the fructified state of the frond: but it is in the sterile fronds that the most striking differences are found to exist between this species and *D. alata* and *D. elliptica*. Some of the fronds which Mr. Guilding has sent us, including the stipes, measure not less than six feet in height, and almost a foot and a half in diameter in the widest part. The pinnae are remarkable for their pale colour, their shining surface, and rigid texture. In drying, the knots at the insertion of the leaves, probably, in a certain degree, disappear, for they are by no means so visible in our specimens as in Plumier's figure.

---

We cannot say whether in a living state the margin of this Fern is involute: to us it appears to be the effect of drying, as we know to be equally the case in the *Polypodium pertusum*. There is too, on the surface of the present plant, as seen in the herbarium, a rugose or wrinkled appearance, the consequence of the drying and shrinking of the parenchymatous substance beneath the epidermis.

Our plants were gathered by Dr. Wallich in Nepal, and were sent to us with the name of *Grammitis?* *plantaginea*; whilst Dr. Hamilton seems previously to have given the MSS. specific name of *involutum*, which is adopted by Mr. Don. Again, we have received specimens from the Honourable the East India Company, bearing the name “*Grammitis flavescens. Wall.*”

---

We are indebted for the superb specimens of this truly elegant Fern to our excellent friend C. S. Parker, Esq. of Liverpool, who gathered them in Demerara in 1824. The same plant had been previously found in the neighbouring district of the Esscquebo in Dutch Guiana, and we believe no where else.

It certainly bears a very close affinity with the *Schizæa digitata* of the East Indies (the *Schizæa marginata* of Wall. MSS.): but that has broader, more compressed, almost winged fronds, and the capsules are not intermixed with the curious chaffy hairs which are so conspicuous in this species.

We regret that our not being able to have access to *Cavanilles's Icones* prevents us from determining, by his figure, what we can now only conjecture from his descriptive character; namely, that this is the *Ugena dichotoma* of that author. It is said by Willdenow to be similar to the *Ugena macrostachya* of the same writer (*Lygodium longifolium* of Swartz); and our plant, we must confess, also comes very near to the *L. circinatum* of Authors, figured in *Rumph. Amb. t. 33*. Indeed, were the pairs of barren leaflets in our figure united by the membranaceous portion at their base (which is almost the case in some of our specimens), we should then have a plant perfectly corresponding with the figure of Rumphius, in which the fertile leaflets are actually compound. May not the three species therefore which we have just mentioned, be considered as mere varieties of each other? They are all inhabitants of the islands of the Indian Ocean; and, on account of their beauty, are employed by the natives of Amboyna for adorning the entrances of their houses on marriage festivals, whilst the larger stems are made into cordage for the purpose of binding different utensils.

*Polypodium Scouleri*

---

Among the interesting collection of plants which Dr. Scouler has recently brought from the North-West coast of America is the present very distinct species of Fern. It may perhaps rank next to *Polyodium vulgare*, but is distinguished from that, as from every other of the same division, by the small number of lobes, their relative breadth and length, their bluntness, and the large terminal one with its distinct and prominent spots of fructification.

---

We have no authentic specimen of Willdenow's *L. lavigatum*; but that author's description so well accords with this plant, that we have no hesitation in considering it to be that species. Lamarck had, however, previously given the name of *lavigatum* to a very different *Lycopodium*; and hence Desvaux has changed the name to *L. Willdenovii*. In habit it is nearly allied to the *Stachygnandrum scandens*, figured by Palisot de Beauvois in his *Fl. d' Oware et de Benin*; but that plant has serrated leaves, whereas here both the leaves and stipules are quite entire.

---

The dichotomous ramification of this plant is scarcely observable, except in the young shoots; for it is remarkably proliferous; and, the young shoots originating from the centre of the dichotomies, the old branches then become pinnated in an opposite manner. In a young state too, we may observe, the whole plant is covered with a dense tomentum as well as with brown scales; but in age both disappear, except on the under side of the rachis of the ultimate pinnae. So closely are the lobes of the pinnae placed, and so remarkably convex on the upper side, that each pinna seems to be formed by two beaded lines. The deep concavity of the under surface is scarcely less remarkable, and can only be accurately seen when the scales of the rachis are removed; and if a transverse section be made through the rachis and lobes, the appearance is as if the lobes were jointed upon that rachis: indeed the whole structure of the plant is highly curious, and quite different from that of any Fern we are acquainted with. The substance of the fronds is remarkably thick, rigid, and coriaceous; and these are said by Mr. Fraser (to whom we are indebted for our specimens) to form large masses or beds on the summit of Mount Wellington.

---

We have scarcely less pleasure in figuring a species of Fern which has been involved in obscurity, than in making known one which is altogether new. In the present instance we have, from the Island of St. Vincent, given what we believe to be the true *Acrostichum viscosum* of Swartz and Willdenow, of which no representation has hitherto been published. We think, however, that too much stress must not be laid upon the viscid nature of the plant, nor upon the scales of the frond; both of which are liable to vary: and the latter in particular, we know almost entirely disappear with age, remaining on the midrib, and at the margin, and on the underside of the frond, the longest. The scales, too, vary in size and in the relative length of the ciliæ, which sometimes give the appearance of mere stellated hairs to the scales. This kind abounds more on the upper surface of the frond of our specimens from the Mauritius, which can by no fixed character be distinguished from the species of the West Indies.

*Grammitis furcata*

*Sori* longitudinales, interrupti, prope marginem frondis inserti, involucro nullo.

*Capsulae* sphaericæ, annulo lato fere completo cinctæ, pedicellatae. *Capsulae* plurimæ abortivæ (f. 3.).

Fig. 1. Portio frondis, cum soro. f. 2. Capsulae. f. 3. Pedicelli cum capsulis abortivis:—*magn. auct.*

---

Received from the Honourable the Directors of the East India Company; but from what part of India is not mentioned. Its affinity is evidently with *T. blechnoides* Sw. (*T. pteridoides* of Schkuhr); but that is a vastly larger plant, with the pinnae remarkably attenuated. Of that species Swartz observes that the capsules are mixed with articulated setæ, terminated by a torulose rounded club. These are doubtless analogous to what we here consider pedicels with abortive capsules—capsules indeed reduced to a portion of the annulus, which is all that is formed of them.

---

Desvaux first separated from the *Hemionitides* of Swartz and Willdenow the genus *Gymnogramma* (Tab. xxv.), and Kaulfuss, more recently, that of *Antrophyum* (see Tab. xlvi.); thus reducing *Hemionitis* to the single species *H. palmata*, which certainly had little or no natural affinity with its former associates. With that, however, our present plant entirely agrees, both in general habit and in essential characters. It was discovered many years ago by Dr. Roxburgh; and, in his unpublished Catalogue, is marked generally as an inhabitant of Bengal: and upon the ticket written by Dr. Wallich, which accompanied the specimens kindly communicated by the Honourable the Directors of the East India Company, it is described as flourishing in the rainy season in the neighbourhood of Calcutta. We find beautiful specimens of the same plant in a valuable botanical collection presented to us by the late excellent Dr. Shuter. These specimens, however, have the fronds more acute at the angles than is the case in our plant.

*Polypodium longissimum*

*Rachis* etiam fusco-setaceus, versus apicem pubescens.

*Frons* pedalis, circumscriptione ovato-subpyramidalis, pinnata, pinnae plerumque oppositis, subhorizontalibus quadri- ad sex-pollicaribus, lanceolatis, breviter acuminatis, profunde pinnatifidis, fere omnino glabris, costa (setosa) nervisque pubescentibus, lacinia semiunciam longis, paululum falcatis, obtusis, oblongis v. linearioribus oblongis, inaequilateralibus, basi subaequalibus versus apicem sensim minoribus, penninervibus.

*Sori* biserialis, nervis ultimis seu venulis prope medium utrinque inserti, parvi.

*Capsule* sphaerico-subcompressæ, annulo crasso cinctæ, pedicellata.

*Semina* subreniformia, flavescens, pellucida.

Fig. 1. Pinne lacinia, a dorso visa, cum soris. f. 2. Capsulæ. f. 3. Semina:—magn. auct.

---

The difficulty of distinguishing many of the species of Fern by mere descriptions is, it must be acknowledged, very great. In looking simply at the short character of *P. thelypteroides* given by Desvaux above quoted, it is quite indicative of our present plant; but then he describes it afterwards as having “very few leaves (pinnae), of two inches and a half in length, the frond only five inches long, and the stipe eight or nine inches in length:” in which respects, he tells us, it differs from the *P. crinitum* of Poiret. Poiret’s description, again, perfectly agrees with our plant in every thing except in not having the soris inserted upon the extremities of the veins: they are evidently inserted near the middle.

Sieber’s *P. thelypteroides* must not be confounded with our plant, similar as it is in the structure of its pinnae; for it is pubescent on both sides, and the stipes, rachis, costa and nerves, are simply pubescent, quite destitute of setæ.

*Pleopeltis percussa.*

---

We had the good fortune to receive from our valuable correspondent Dr. Torrey, of New York, an authentic specimen of the *Alsophila perriniana* of Sprengel, gathered in the island of St. Thomas, and specimens of a Fern gathered near New York, which upon comparison prove to belong to the same species. Afterwards Dr. Barratt sent it to us also from the United States.

Sprengel has in some degree altered the generic character of Mr. Brown's *Alsophila*, so as to include the present plant: but as the original species of *Alsophila* embrace a tribe of Ferns arborescent and quite different from our plant, as well in aspect as in generic character, we have considered it best to remove *A. perriniana* from that genus altogether.

It would be easy for us, seeing that it does not precisely accord with any described genus of the *Filices*, to have invented a new one. But as our design is rather by a series of well executed figures and descriptions to give a correct idea of the structure of the fructification of Ferns, which may be employed in future for the formation of genera, than too hastily to constitute new ones, we have preferred placing the present plant in the genus *Woodsia*. Its habit, we think, is sufficiently similar; and, except that the involucrum is larger in proportion to the sorus, and that, in a young state, it covers more fully the capsules, and is not marginated with hairs, there is not a difference even in the character of the fructification. And we are not without an idea, that had the learned Brown himself been acquainted with the present Fern, he might have framed the character so as to have included it also.

*Lyptium corytidium*

TAB. LXIX.

**ASPIDIUM CARYOTIDEUM.**

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES verae. Willd., Spreng.

*Semina* minuta, sphærica, marginata, margine tuberculata, flavo-viridia.

Fig. 1. *Aspidium caryotideum*,  $\frac{1}{2}$  diminutum. f. 2. *Pinna*:—*magn. nat.* f. 3. Portio frondis ut venae reticulatae videantur. f. 4. *Sorus* immaturus involucro tectus. f. 5. *Sorus* maturus, verticaliter sectus. f. 6. *Capsulae*. f. 7. *Semina*.

---

This is a very distinctly marked species of *Aspidium*, for which we are indebted to the Honourable the East India Company. The fronds, when seen through a good magnifying lens, present a very beautiful appearance, from the nature of the reticulation. Each areola has a branch of a vein, sometimes simple, sometimes forked, passing upwards, through the centre, but not reaching to the top. These veinlets, probably, though it is difficult to ascertain the fact, are what terminate in the sori.

---

Of this elegant and rare Northern species of Fern no figure has yet been published. The name is given from the fragrant scent of the species yielding an odour, even in the dried state, not unlike that of the common Primrose.

It is peculiarly an arctic plant; and our finest specimens, from which the accompanying figure is taken, are from the island of Igloolik, where they were gathered by Captain Parry.

---

We have received specimens of this very distinct *Asplenium* both from Dr. Wallich and the Honourable the Directors of the East India Company. It is probably Mr. Don's *A. Phyllitidis*; but we think ourselves bound to preserve the name given to the plant by its estimable discoverer, Dr. Wallich. There are but few species of the genus with entirely simple fronds; and those have all, except the present species, the sori arranged in a much more horizontal direction from the costa. Here they are in the lower part of the frond, at least, almost parallel with the midrib; and the rest form a very acute angle with it. Another remarkable character is, that the involucrum (besides being denticulate), as soon as it opens, is reflected upon the frond, so as to expose the whole cluster of capsules; and it remains there even after the capsules are dispersed.

*Stipes* digitalis ad palmarem, compressus, basi paleaceo-setosus.

*Frons palmaris* ad pedalem, coriaceo-membranacea, oblongo-elliptica, non raro superne latior, margine ubique integerrimo, apice acuto, basi in stipitem attenuata, ecostata, pulcherrime venis elevatis reticulata, areolis oblongis angulatis 4—5 lineas longis.

“Vene fructificantes prominentes.” Willd.

---

We possess specimens of this noble Fern, of which we have only represented here some of the smaller states, from the late Captain Carmichael, from M. Bojer, and Dr. Sieber, all of them destitute of the fructification. In some parts of the frond, indeed, the veins are darker than in others; but on the most careful dissection, they contain no sori. Willdenow describes the fructification as elevated, not immersed, as it is in *Antr. pumilum* and *A. reticulatum*.

All the species seem to possess very thickly downy roots.

So sportive are the forms of the pinnae in many of the species of this genus, that it is difficult to characterize them in words. We have given the present plant under the name by which we received it from the Honourable the East India Company: at the same time we must observe that it comes very near to the *Lindsæa flabellata* of Dryander, in the third volume of the *Transactions of the Linnean Society*, p. 41. t. 8. f. 2. That species, however, differs from ours, in being more decidedly bipinnate, in having most of the pinnae larger, regularly flabelliform, and in the apices of the fronds and compound pinnae being obtuse.

---

The name of *lanuginosum* appears to have been given to this species by Dr. Wallich in consequence of a woolly substance which is attached to the upper part of the bulb; but this does not appear very distinctly on our specimens, which have been communicated by the Honourable the East India Company. In general aspect, the plant has much affinity with the North American *B. dissectum*; but there the frond is placed much lower down upon the stem or scape, and the foliage is much more compound or divided.

---

The genus *Polybotrya* was founded by Humboldt and Kunth upon the species *P. osmundacea*: and the character was made to depend upon the capsules occupying the whole circumference of the fertile pinnules. We possess, from Jamaica, a Fern that we can in no point distinguish from this of Humboldt; but in which the young fertile pinnæ have the capsules only on one side, while in their more advanced state the capsules appear on all sides of them. This difference in appearance, in all probability, arises from the revolution or reflexion of the margin of these pinnæ: and it perfectly accords with what Dr. Swartz says of the present plant, which he has seen in a growing state, and of which he observes, that "in an old state the fructification appears to be on both sides, in consequence of the revolution of the margin of the pinnæ." If such be really the case, and if it exists in all the species of *Polybotrya*, then the genus is scarcely distinguishable from *Acrostichum*.

No author, as far as we know, has noticed the young, quite simple, fronds of this species. The Rev. Mr. Guilding has sent them to us in that state.

---

*Botrychium simplex* seems to be a plant liable to much variation in regard to size. The smaller specimen here figured, which we received from our zealous friend Dr. *Torrey*, seems to be the state which gave rise to the specific name and character in *Silliman's Journal* :—but we have received a plant through the kindness of Mr. *Lambert*, gathered by *Pursh* in Canada, which we can by no means distinguish from that just mentioned, except that it is twice the size, has the frond decidedly pinnatifid, and the segments much cut. This is the larger specimen here represented. Both varieties are abundantly distinguished from any species with which we are acquainted.

*Gymnomphylloides semicirratus.*

---

We are indebted to Mr. Menzies for specimens of this New Zealand *Hymenophyllum*. The name of "*Hym. asplenoides*" was upon the label which accompanied them, written probably by mistake, since that is a West Indian species, and described amongst those which have *simple* fronds.

The present individual is remarkable for the structure of its involucre, which may be reckoned almost intermediate between that of *Trichomanes* and *Hymenophyllum*; the lower half, or even more, being sunk into the extremity of the frond, and the upper portion forming two short almost semi-circular lips or valves.

---

Much as this plant is liable to vary in the length of the stipes and shape of the frond, we can still scarcely satisfy ourselves that the reference of authors to Plumier is correct. His plant is thrice the size of ours, every where deeply bipinnatifid, and having a distinctly winged stipes. Yet that is probably the original authority of Linnaeus. Raddi is disposed to refer it to his *Hymenophyllum Boryanum*.

In our specimens the fronds might rather be called pinnatifid than pinnate; and the segments are never more than bifid, more frequently quite entire.

---

Hedwig and Willdenow describe the margin of this rare species of *Trichomanes* as serrated or serrulata. We find no such appearance in our specimens, gathered by Mr. Menzies in Otaheite; nor does its original discoverer Forster, nor Swartz (who seems to have described it from authentic specimens), notice such a peculiarity. The margined appearance of the frond arises not from a thickening of the very edge, but from a nerve running along, parallel with, but at a little distance from, the margin, and which is connected with the margin by means of transverse veins or bars.

Communicated, with several other rarities of this family, from South America by William Jameson, Esq., resident at Guayaquil. The species is unquestionably very nearly allied to *Acrostichum obtusatum*, figured at Tab. 22. of this work: but that, besides its widely different geographical situation (the Island of Tristan da Cunha), has fewer and narrower scales upon the frond and stipes, a longer pedicel to the capsules, and a much less distinct costa or midrib; and it wants the pellucid margin to the fertile fronds, which is so distinct in this.

Mr. Jameson has remarked a curious property in the fertile fronds. "When the plant," he says, "is in a young and tender state, their fronds are invariably *expanded*; but as soon as the seeds begin to ripen, they *collapse*, as in the specimens sent;" and as the generality of those here figured.

The *Acrostichum piloselloides* of Presl. (*Reliq. Henk.*), *A. Pilosella*, Spreng., a Peruvian plant, differs from this in its almost sessile and spathulate sterile fronds; and the *Acrostichum spathulatum* of Bory (from the Isle de Bourbon), by its much larger size and differently-shaped fronds. They should, however, all together, with our *Acrost. Raddianum*, rank next to each other in a natural system.

Fig. 1. Portio pinnae, cum soris. f. 2. Pili e margine laciniarum. f. 3. Capsulae. f. 4. Semina:—magn. auct.

In the autumn of last year (1827), together with many other excellent plants we were favoured with specimens of this Fern by the Rev. Mr. Lowe, gathered in the Island of Madeira, “near P<sup>to</sup> Pargo, in a narrow ravine, and in other places in the interior, growing at an elevation upon the mountains of more than 2000 feet\*, upon rocks, and steep and moist banks, where there is but a thin stratum of vegetable mould:—the root or caudex creeping extensively just beneath the surface.” The plant is assuredly not described in any work to which I have had access: but Mr. Lowe suggests, that it may probably be the *Acrostichum pilosum* of Von Buch’s List of Plants of the Canary Isles; and that the same name (but equally without description or character) likewise exists in a manuscript catalogue of Madeira Plants, which he has seen in the island, purporting to be taken from the Banksian Library, and probably left there by Masson: but the identity of the two plants we have no means of determining. An *Acrostichum* the plant assuredly is not; and though we have placed it in the genus *Gymnogramma*, it seems to form a connecting link between it and *Grammitis*, having the habit of the former, and the constantly simple sori of the latter.

The species we have named in compliment to the gentleman who sent us such fine specimens, and who has accompanied them by some valuable observations: and we feel that he is justly entitled to this honour, not merely because he has brought so interesting a plant under our notice, but because, still resident in Madeira, he is furthering the cause of science by collecting materials, which he will soon be enabled to give to the world, for a *Flora* and *Fauna* of the island. Already he possesses many novelties in the different departments of natural history; and perhaps no spot could be pointed out, whether its geographical situation or its geological features and structure be considered, which better deserves to have its productions described, than that island.

We have only very recently received Schlechtendal’s *Adumbrationes Plantarum*, in which we find a species of *Cryptogramma* from the Cape of Good Hope, represented and described, which has a very near affinity with this, *Gymnogramma totta*, Schlecht. That, however, has very much longer and narrower pinnae, and the lower laciniae erose; whereas they are quite entire in our plant.

\* Since the above was written, we have received more specimens of the same plant, gathered in the Ribeiro d’Ametade, at an elevation of 3000 feet above the level of the sea. It scarcely descends below 2000 feet.

---

As *Grammitis* now stands in the recently published *Systema Vegetabilium* of Professor Sprengel, it contains none but species with simple fronds. At Tab. 6. of our *Icones Filicum* we have, however, given a species which has the fronds pinnatifid; and at Tab. 89. one with the fronds bipinnatifid. In those species which have compound fronds, we find the nerves to be more ramified; and by the union of two sori at the forking of a nerve, the sori themselves appear to be divided. This at least is the character of M. Desvaux's *Gymnogramma*; and hence it may be considered as intermediate between *Grammitis* and *Hemionitis*, where the nerves are much branched and reticulated, and the sori form a continued series. If the genus should prove permanently distinct from *Grammitis*, we think that this and the following species *Gymn. subglandulosa* will be rightly placed in it.

*Gymnogramma subglandulosa.*

---

In what part of New South Wales this curious species of *Gymnogramma* was found we are not informed. We at first took the specimens for very luxuriant states of *Gymn. rutefolia*: but a more careful examination soon convinced us of our error. The plant is more than twice the size of that species, the pinnae are distinctly pinnatifid, of a more membranaceous texture, and (what will afford a still better character,) the nature of the pubescence, although it may appear to the naked eye the same in both, is here not composed of short setiform hairs, but of obtuse linear ones, having what appears an abortive gland at the extremity; that is, irregular in its shape, and not filled with any secreting fluid. Below the apex, too, are not unfrequently a contraction and a brown mark.

---

Sent to us by our valued correspondent Mr. Jameson, who gathered the specimen on the western declivity of the mountain Pichincha, where Humboldt and Bonpland discovered some of their most valuable plants. We find it to agree entirely with the *Aspl. feniculaceum* of Humboldt and Kunth; and we scarcely know whether to consider the *Aspl. delicatulum* of Presl. in *Reliquæ Hænkeanae*, to be otherwise than a starved variety of it. It is also nearly allied to *Asplenium fragrans* of Swartz (a Jamaica plant), and to the East Indian *Asplenium concinnum* of Wallich, but has narrower and more distantly placed pinnæ. The sori are almost exactly as in the *Darea* of Smith, (*Cenopteris* of Swartz).

*Asplenium rupestre.*

---

Mr. Brown has already observed, that this plant is allied to *Polyodium stellatum* (*N. bicolor* of this work) and to *P. adnascens*; and all are downy with the same curiously stellated pubescence.

We are indebted to Mr. Lindley for some of our specimens of this plant, and which are marked as coming from New Zealand; but we know not by whom gathered.

Alpinia galanga (Ginger).

## NIPHOBOLUS SPHÆROCEPHALUS.

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd., Spreng.

GEN. CHAR. *NIPHOBOLUS*, Kaulf. *Sori* subrotundi, congesti, terminales, pilis stellatis obtecti. *Spreng.*

---

*NIPHOBOLUS sphærocephalus*; frondibus simplicibus coriaceis, sterilibus oblongo-lanceolatis acutis, basi subrotundatis petiolatis glabris, fertilibus linearibus acuminatis basi in petiolum attenuatis subtus stellarum tomentosis, soris ovalibus distinctis.

*Polypodium sphærocephalum*. *Wallich MSS.*

HAB. Ex India Orientali (e Nepalia?) misit *D. Wallich*. In arboribus, ut videtur, crescit. *Caudex* longus, flexuosus, ramosus, crassitie pennae corvinæ, squamis ovatis, acutis, imbricatis, scariosis tectus, hic illuc radieulosus.

*Frondes* steriles fertilibus dissimiles, coriaceæ.

*Steriles* breviter stipitatae, 4—5 uncias longæ, lato- vel oblongo-lanceolatae, integerrimæ, utrinque glabrae, siccitate margine revolute, costatae, penninerviae, nervis obscuris, apice acutæ, basi rotundatae.

*Fertiles* pedales, lineares vel lineari-lanceolatae, integerrimæ, margine subrevolute, superne glabrae, subtus (costa prominente excepta) lana compacta alba e pilis pulcherrime stellatis, ubique tecta, apice acuminate, basi in petiolum bi-triunciale sensim attenuatae.

*Sori* numerosi, magni, convexi, oblongi, lineatim dispositi, primum pilis stellatis pedicellatis albis omnino tecti.

*Capsulae* longe pedicellatae.

*Semina* oblonga, subreniformia, non raro, ad utramque extremitatem, appendiculo aucta, flava.

Fig. 1. Portio frondis cum soro statu juniore, atque pilis stellatis tecta. f. 2. Eadem cum soro, capsulis maturis. f. 3. Pili stellati e soro. f. 4. Pili stellati e frondis pagina inferiore. f. 5. Capsulae. f. 6. Semina:—*magn.* *auct.*

---

Whether or not the sterile fronds of this plant are in a young state clothed on the underside, like the fertile frond, with pubescence, I am not able to say. In our specimens they are quite glabrous. The species is, in any case, abundantly distinct from all of the genus with which we are acquainted, and the texture is remarkably thick and coriaceous.

*Acorus villosum*

## ACROSTICHUM VILLOSUM.

*Stipites* aggregati, 4—6 uncias longi, ferrugineo-villosi, pilis longis horizontalibus.

*Frondes* oblongo-lanceolatae, membranaceæ, acuminatae, utrinque margineque pilis numerosis longis patentibus rufo-ferrugineis vestitæ, costatae, penninerviae, nervis ad marginem attингentibus, in nostris exemplaribus omnino integerrimæ (marginæ subcrenulatae & fere integræ, leviter undulatae. Sw.). *Pili*, sub lente visi, subulati, membranacei, concavi, reticulati, apice serrulati. *Color* fusco-viridis. *Frondes* fertiles sterilibus duplo minores, utrinque, superne præcipue, pilis numerosis ferrugineis villosissimæ.

*Capsula* fusca, pedicellata.

*Semina* parva, ovalia, reticulata.

Fig. 1. Portio frondis sterilis. f. 2. Capsulae. f. 3. Semina. f. 4. Pilus:—*magn. auct.*

We are the more anxious to figure this species of Fern, because it has, by Dr. Sieber, been confounded with an East Indian species of the same genus, namely *Acrostichum hybridum* (*Ic. Fil.* t. 21.); but from that it is distinguished by its much smaller size, more acuminate apex; and especially by the numerous reddish hairs, which spring not only from the margin, midrib, nerves, and stipes, but also from the whole superficies of the frond, both above and below, giving the entire plant a very singular appearance.

The Plumierian figure, which Dr. Swartz mentions with approbation, is by no means good as to the margin of the fronds and in the glabrous upper sides; nor is the representation given by Lamarck at all more satisfactory.

---

We regret that we are not able to say what is the native country of this plant. It was given to us some time ago by our friend Mr. Lindley, with several West India Ferns, which had formed part of the Herbarium of the late Mr. Donn, of Cambridge. The Fern to which it is most nearly allied in the mode of growth and prolific habit, and in the structure of the sori and seeds, is the *Aspidium rhizophyllum*, figured at Tab. 59. of this work: but that has, except in the very youngest state of the plant, decidedly pinnated fronds; whereas here, both in the sterile and fertile fronds, there is not the slightest approach to a compound, or even to a divided appearance. The whole plant, too, is quite glabrous.

## PARKERIA PTERIDOIDES.

FILICES.—Div. PARKERIACEÆ. (*Capsulae* sparsæ, omnino sessiles, annulo lato brevissimo fere obsoleto, nonnunquam distincto subcompleto, notatae. *Semina magna*, trigona, striata.) GLEICHENÆ. Bory, Spreng.

---

The kindness of our friend C. S. Parker, Esq. (after whom this singular and beautiful genus had previously been named in the *Exotic Flora*), by putting into our possession numerous specimens in all stages of growth, and the opportunity we have enjoyed of seeing the noble individual here figured flourishing in the stove of the Liverpool Botanic Garden under the skilful management of the Messrs. Shepherds,—have enabled us to correct some very important errors which appear in the work just mentioned, and to lay before the public, we trust, a complete analysis of the plant.

The Figure above referred to at Tab. 231. of the *Exotic Flora*, represents the sterile fronds of the plant, of the very existence of which we were not aware, when the first Figure in that work (t. 147.)

appeared. But the point that needs most correction is, where it is said that the capsule is altogether destitute of a ring. It is so minute, however, as to have wholly escaped the notice not only of the author of *Exotic Flora*, but also of that of other and very acute botanists, who examined the specimens. An *annulus* indeed does exist; but so small, and so unlike that part in other Ferns, that we may well be pardoned for having overlooked it: nor should we now probably have detected it, were we not led to suspect its presence by knowing that some other Ferns now in our possession, most closely allied to this, are furnished in their capsules with a *remarkably* large, very broad, and almost complete ring. The Ferns we allude to are the *Ceratopteris thalictroides* of Brongniart (*Elleborus oleraceus* of Kaulf.), from the East Indies;—what we take for *Ceratopteris Gaudichaudii* of Brongn., said to be from St. Vincent;—and one, if not two, nearly allied plants, from New Holland. There could not be a question of all these belonging to the same natural group; and upon examining with the high power of the microscope the capsules of our *Parkeria*, we find on one side, near the point of insertion, a small oblong transversely striated spot or disk, which may indeed be compared with a very reduced annulus of *Ceratopteris*, but which can on no account be assimilated to that of the *Filices Gyrate* of Mr. Brown.

Since we have now ascertained an annulus to be present, or something analogous to it, we can no longer allow the genus to be separated from the *Filices*: but it becomes a question, to which of the Divisions it should belong. Brongniart (see *Dict. Classique*, v. 3, p. 350.) and Bory de St. Vincent have ranked the *Ceratopteris* with the *Gleichenæa*; the former indeed, doubtfully,—and he expressly points out a difference in the nature of the annulus; broad and flat and incomplete\* in *Ceratopteris*, narrow and projecting and complete in the *Gleichenæa*. Indeed the whole nature of the capsules is different in the two, though that difference is not easily expressed in words. They are large in *Ceratopteris* and *Parkeria*, quite sessile, of so thin and membranous and pellucid a texture, that the seeds are visible through the coat; and, even in *Ceratopteris*, the ring does not appear to have any elastic property, nor are these capsules arranged in *sori*, but scattered upon longitudinal veins beneath the *involute*. The seeds (incorrectly given in the *Exotic Flora*, but well defined by Mr. Brown) are large, and when seen under the high power of a microscope exhibit a most beautifully striated appearance. Their integument is comparatively thick and tough, and, when broken, it is found to contain a transparent oily substance, which floats upon the table of the microscope. In short, the whole habit of the plant, its place of growth, the situation of the capsules, their structure and that of the seeds,—all point out a group or tribe which cannot well be associated with any hitherto established. On this account we have formed a new one.

The *PARKERIACEÆ* are exclusively tropical plants, inhabiting Asia, Africa and America; and we are at present acquainted with but two genera,—*Ceratopteris*, distinguished by its very large and distinct annulus; and our *Parkeria*. Of the latter we possess two species, *Parkeria pteridoides* and *P. Lockharti*.†.

M. Brongniart attributes a double covering to the capsule of *Ceratopteris*; but such a structure we have never found to exist in any of our specimens.

\* We are aware that Mr. Brown attributes to his *Telezoma* (Brongniart's *Ceratopteris*) a *complete annulus*: but we have not found it to be so in any of our specimens.

† *P. Lockharti*: frondibus fertilibus pinnatis, pinnis pinnatifidis incisis, stipite æquali cylindraceo.

---

Our friend Mr. Burchell, as well as Mrs. Graham, have been so obliging as to communicate this very handsome species of Fern to us. Willdenow, correctly enough, compares it with the *Ad. trapeziforme*: but that has shorter, less acuminate *pinnules*, never deeply inciso-lobate at the margin as in our plant, which appears to be truly distinct from that and every other of the genus, and confined to the neighbourhood of Rio, in Brazil.

Fig. 1. Pinna, e medio frondis, fertilis. f. 2. Capsula. f. 3. Semina.

---

Communicated by our good friend Archibald Menzies, Esq., who found it in the Island of Owhyhee. It was marked by that gentleman, "*Asplenium, nova species*"; and we entirely agree with him in its being so. Its near ally is, unquestionably, *Asplenium monanthemum* of Linnaeus, and of Smith *Icones*, Tab. 73, an inhabitant of the Cape of Good Hope; and as we know, from specimens we have received from the Rev. R. T. Lowe, of Madeira also. That plant is always much broader in its circumscription near the middle, more attenuated at the base and at the extremity, having the pinnae of a more delicate texture, much longer and narrower, more disposed to be caniculated in the upper margin at the base, and with fewer sori, and those (mostly indeed solitary) confined to the lower side of the pinna.

Sprengel describes the *Aspl. monanthemum* as an inhabitant of New Spain, Martinique, Peru, &c.; and he makes the *Asplenium nanum* of Willdenow to be synonymous with it. Now this latter plant is indeed an inhabitant of Martinique, and is figured in Plumier; but, as that figure shows, it is quite a different species from *A. monanthemum*.

*Todea Brasiliensis*

Fig. 1. Pinnula cum capsulis. f. 2. Portio pinnulae. f. 3. 4. 4. Capsulae. f. 5. Semina:—magn. auct.

We have here followed Swartz, Willdenow, Kaulfuss, and Sprengel, in retaining the genus *Todea*, as distinguished from *Osmunda*, with which Brown, as Thunberg has done, unites it.

There is a difference of habit in the two genera, mainly however arising, we must confess, from the circumstance of the fructifications being placed on the back of the *unchanged* frond in *Todea*; whilst in *Osmunda* they are situated on the altered and contracted pinnules. In *Osmunda regalis*, however, we find the ring or gibbose portion distinctly striated; in *Todea* it is reticulated.

The very interesting species here represented,—the second only of the genus now described,—was communicated to us by Mr. Fraser, who observes, that he found it but in one spot, below moist rocks, at Bougainville's Cataract, in the Blue Mountains of New Holland. It differs remarkably from *T. africana*, which is equally a native of New Holland, by the delicate and subpellucid texture of its frond. A third species of *Todea*, but not probably an Australasian plant, is known to Mr. Brown, having a frond of a similar habit with that of *T. Fraseri*, as may be inferred from his observations, under the genus *Osmunda*, Prodr. p. 163: "Quoniam in *Todea* Willd. capsule vere pedicellatae, et cum porro alia species existit, iisdem pariter dorsalibus, at fronde pellucidâ *Trichomanis instar donata*, consultius duxi ambas ad *Osmundam* amandare."

---

That this species must have been known to the writers on American Botany, I cannot for a moment doubt: but if it be included in any of their Floras, it is confounded with some other species, perhaps with *Nephrodium cristatum* by Michaux, or with *N. Felix Mas* by Pursh, judging from a specimen sent me by Professor Torrey from New York; and it is very certain that both these authors consider their respective plants to be different from those of the same name in Europe.

The present is indeed a very handsome and a very decidedly marked species, coming, perhaps, nearest to the North American *Nephrodium marginale*, in which, as the name implies, the fructifications are altogether marginal.

---

Communicated by the Honourable the East India Company as a native of the East Indies; but of which particular district of the Indian possessions is not stated:—probably Nepaul. It differs from every species hitherto described, in many points; yet in the decidedly cuneate form of the foliola, it approaches the tribe with the membranaceous leaflets, to which *A. Capillaris Veneris* belongs. Here, however, the foliage is remarkably rigid and coriaceous; and on looking at the upper side of a frond, the stipes, rachis, and pedicels will be found to be rough with short close-set harsh brown hairs, whilst the rest of the plant is quite glabrous.

---

This very curious species of *Davallia* is evidently allied to the *D. pectinata* of Smith, and the *D. contigua* of Hedwig, as far as can be judged from the very imperfect account we have of the latter; both being natives of the islands of the Pacific Ocean, and both differing from ours in the shape and structure of the laciniae of the frond.

The only specimens we have were gathered by Dr. Emerson in Ceylon; an island which, were it properly investigated, would perhaps yield as abundant a harvest of interesting Ferns as any spot of the like extent on the surface of the globe.

---

The old genus *Cyathea* of Sir J. E. Smith has been divided by Mr. Brown; and the true *Cyathea* are by him considered to be *C. arborca*, *dealbata*, *medullaris*, *affinis*, &c., in all of which, as well as in four other undescribed species, there is a spherical involucrum, bursting transversely and equally, in a lacerated manner, inserted upon the forking of a vein;—but, observes Mr. Brown, in a fifth species from the Molucca Isles, the involucrum arises from the *middle of a vein*, “at quoniam hæc a congeneribus differt pennis integerrimis subensiformibus sorisque sparsis, legem insertionis haud multum infirmat.” To this *Cyathea* from the Molucca Isles, alluded to by Mr. Brown, our *C. sinuata* is, in all probability, closely allied, if it be not the same species. It is quite unlike any hitherto described one; and we regret not to have seen more perfect specimens than those here figured, which give no idea of the height of the caudex, or the thickness to which it may be supposed to arrive.

*magn. auct.*

---

Although in many particulars this agrees with the *Lomaria decomposita* of Don, yet I am inclined to think that, were it the same, so close an observer could not have failed to have remarked and described the singular and very beautiful colour of the whole underside of the frond; on which account Dr. Wallich, so long ago as 1816, when he gathered the plant in its native soil, named it *Lomaria aurea*. It is an extremely beautiful species, and no less remarkable in the striking contrast of colour which it exhibits, than in the much divided pinnae. The first aspect of the fructification might have indeed well led Dr. Wallich to consider it as belonging to the genus *Lomaria*: but if the capsules be carefully traced to their insertion, they will be found to be placed in the sinus itself of the involucrum, where a longitudinal vein passes, which may be looked upon as the receptacle.

There is a *Pteris aurea* of Poiret from Chili; so that, however unwillingly, we are obliged to change the specific as well as the generic name which Dr. Wallich had given to this plant.

*Polypodium heteromorphum!*

---

This is a very singular and interesting species of *Polyodium*, like none of the genus with which we are acquainted, or which we can find described in books. Indeed, so variable are the specimens from the same tuft, as gathered by Professor W. Jameson "upon the top of the mountain Pichincha, growing in large patches, straggling or hanging over the face of the dripping rocks," that if several of them were seen separately, they might well be supposed to constitute distinct species. The simple-fronded specimens have some affinity in their mode of growth with *Asplenium Trichomanes* and *viridis*, but those with the divided fronds have the ramifications as regularly dichotomous as in the *Gleichenie*: were this not the case, we might have supposed that the ramification depended upon innovations, or proliferous shoots.

---

The learned author of the *Prodromus Flora Nova Hollandie* has cited two varieties of this plant; the one, “ $\alpha$  umbrosum, caulis debilis, folia patentia, spicæ filiformes, simplices vel divisæ, flaccidæ, laxiusculæ; squamæ oblongo-lineares, capsulis multoties longiores;” and the other, “ $\beta$  alpinum, caulis erectus: folia arcta imbricata, opaca, ecostata; spicæ dichotomæ, tetragonæ, squamæ ovatae, capsulas vix superantes.” We find the plant, indeed, to be very variable in its fructification: some of our specimens, received since the plate was engraved, have the extremity of the spike running out into a shoot, with sterile scales or leaves, exactly resembling those of the stem and branches; in others, the part bearing the fructification scarcely forms a spike at all: but the fructification appears axillary; and then the species comes very near the *Lycopod. gnidioides*, Ic. Fil. t. 30.

*Folia* quadrifariam inserta, patentia, incurva, subulata, plana, obscure costata, omnino integerrima, apice concolora.

*Spica* subterna, longe pedunculata, cylindracea, erecta, subrobusta, insigniter squamosa.

*Pedunculus* terminalis, foliosus, foliis quadrifariis, caulinis similibus, sed magis distantibus, marginibus spinuloso-denticulatis in pilum longum diaphanum flexuosum attenuatis.

*Squama* ovata, acuminate, pilifera, margine spinuloso-denticulata.

*Capsula* reniformes, bivalves.

*Semina* pallido-flava, minutissima, subreticulata.

Fig. 1. Folium caulinum. f. 2. Portio pedunculi cum ejus foliis. f. 3. Squama cum capsula. f. 4. Semina:—*magn. auct.*

---

Discovered by A. Menzies, Esq. at Owyhee, during his voyage with Captain Vancouver. It is remarkable for the two kinds of leaves which it bears; those of the stem being perfectly destitute of a diaphanous hair point; while those of the peduncle, which in fact is but a prolongation of a branch, are singularly toothed, somewhat spinous at the margins, and terminated with a waved hair-like point. It will rank near *L. aristatum* of Humboldt.

*Asplenium raectum?*

HAB. In insula Bourbonie. *Commerson.* Inter saxos ad marginem rivulorum, in sylvis montosis insulae Mauritii. *Bojer.*

*Caudex* repens, squamosus, radiculos plures, fibrosas, fuscas, ramosas emittens.

*Stipes* digitalis, erectus, gracilis, atro-purpureus, nitidus, hinc sulcatus, basi subsquamatus.

*Frons palmaris* fere ad pedalem, circumscriptione lato-lanceolata, basi truncata, apice argute acuminata, pinnata, pinnis approximatis, plerumque alternis, subhorizontalibus, patentibus, tenuibus, membranaceis, oblongo-lanceolatis, obtuse acuminatis, unciam ad duas uncias longis, inaequaliter dentato-serratis, costatis, furcato-venosis, inaequilateribus, basi superiore truncatis, inferiore abscisso-cuneatis, integerrimis.

*Sori* in venis lateralibus siti, oblongo-lineares.

*Involucrum* membranaceum, fuscum, costam versus dehiscens.

*Capsula*, annulo lato fere completo, cinctæ, pedicellatæ.

*Semina* intense flavo-fusca, subrotunda, tuberculata.

Fig. 1. Pinna fructifera. f. 2. Capsula. f. 3. Semina:—*magn. auct.*

---

This, we believe, is certainly the *Aspl. resectum* of Smith in the *Icones* above quoted; but it must be confessed that it belongs to a group of the simply pinnated *Asplenia*, which are liable to much variation, and consequently to be determined with difficulty; on which account we are the more anxious to represent the present plant from perfect specimens, sent us by the excellent Bojer, through the kindness of Charles Telfair, Esq., from the Mauritius. It is indeed very nearly allied to the West Indian *Aspl. abscissum*, the pinnae being almost exactly the same in shape, but that has the rachis winged.

*Trichomanes quercifolium?*

## PTERIS AURICULATA.

FILICES.—GYRATE. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd., Spreng.

GEN. CHAR. *PTERIS*, Linn. *Sori* lineares, marginales, continui; capsulis sinu involuci insertis. *Involucrum* marginale, continuum, scariosum, intus liberum.

---

*PTERIS auriculata*; frondibus pinnatis, pinnis brevissime petiolatis triangulari-ovatis subtrilobis, vel basi sursum auriculatis inferioribus subrotundis, stipite rachique laevissimis nitidis.

*Pteris auriculata*. Thunb. Fl. Cap. ed. Schultes. v. 2. p. 733. Willd. Sp. Pl. v. 5. p. 365.

Swartz. Syn. Fl. p. 103. Spreng. Syst. Veget. v. 4. p. 71. Sieber Syn. Fil. no. 8.

Schlentend. Adumb. Pl. t. 22.

*Adiantum auriculatum*. Thunb. Prodr. Fl. Cap. p. 173.

HAB. Ad Promontorium Bonæ Speci. Thunberg; Villette; Thom; Mund; Carmichael.

*Radix* cespitosa, e fibris numerosis ramosis subpilosus.

*Stipes* brevis, vix duas uncias longus, erectus, flexuosus, atro-purpureus, longissimus, nitidus.

*Frons* palmaris usque ad spithameam, circumscriptione lanceolata, pinnata. *Pinnæ* alternae, plerumque subremote, forma mire variantes; *inferiores* subrotundæ, integerrimæ, obtusissimæ, reliqua magis minusve ovatae vel triangulares, basi utrinque vel sursum solummodo auriculatae, nunc obtusæ, nunc acutæ; *superiores* magis angustæ; *omnes* brevissime petiolatae, subcoriaceæ, glabre, supra intense virides, inferne pallidæ, costatae, vix, nisi oculo bene armato, venosæ. *Rachis* glaberrima, atro-purpurea.

*Sori* marginales, continui.

*Involucrum* e margine membranaceo formatum, pallide fuscum, apice inaequaliter crenulatum, subundulatum.

*Capsulae* numerosæ, pedicellatae, annulo lato donatae.

*Semina* parva, globosa.

Fig. 1. Portio pinnæ cum soro. f. 2. Capsulae. f. 3. Semina:—magn. auct.

---

At the time that our drawing was made, no figure existed of this species of *Pteris*; but since the engraving was executed, we find it represented in the last number of Schlentenda's excellent *Adumbrationes Plantarum*; of which, however, the descriptions have not yet reached us. The four numbers that we have seen are admirably illustrative of the Ferns of the Cape of Good Hope.

*Trichomanes speculum?*

## TAB. CXVII.

## TRICHOMANES APODUM.

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES vere. Willd., Spreng.

GEN. CHAR. *TRICHOMANES*, Sm., Sw. *Sori marginales. Capsulae sessiles, receptaculo communi cylindracco insertæ, intra Involucrum monophyllum, suburceolatum, ore hiante, textura frondis.* Br.

---

*TRICHOMANES apodum*; frondibus minutis (plerumque) sessilibus cordato-rotundatis profunde lobatis minutissime reticulatis patenti-nervosis, lobis obtusis sinuatis, involucris exsertis submarginatis bilabiatis, caudice longe repente tomentoso.

HAB. In insula, Barbadoes dicta. C. S. Parker.

*Caudex* repens, longus, ramosus, tomentoso-radiculosus.

*Stipes* vix ullus, plerumque sessilis.

*Frondes* plurimæ, parvæ, semiunciam longe, imbricatim decumbentes, cordatæ, rotundatae, obtuse, profunde lobatae, sinibus obtusis, lobisque obtusis, sinuntis, submembranaceis, pellucide virentes, minutissime sub lente reticulatae, nervose, nervis divaricatis in medio singuli lobi (nunquam radiatim vel parallelo-venosæ), ad marginem hic illuc pilosæ, pilis stellatim ramosis.

*Involucrum* (an semper?) solitarium, in singula fronde, liberum, oblongum, basi attenuatum, utrinque marginatum, apice bilabiatum, labiis margine rubris.

*Receptaculum* longissime exsertum, filiforme, basi ubi *capsulae*, paululum incrassatum.

*Capsulae* peltatae, annulo completo, ut in omnibus speciebus hujusc generis.

*Semina* subglobosa, limbo pellucido, circumscripta.

Fig. 1. Frons fertilis. f. 2. Pars inferior receptaculi, cum capsulis. f. 3. Semina:—*magn. auct.*

---

Closely as this species may appear at first sight to be allied to *Trich. reptans* (Ic. Fil. t. 32.) and *T. muscoides*, yet a more careful examination will prove it to be abundantly distinct. It is much smaller, has the fronds almost entirely sessile, more rounded and approaching to cordate, deeply and constantly lobed at the margin. The texture of the frond, too, is very different; here it approaches nearer to that of many frondose *Jungermanniae*; the reticulation is small, and the nerves much less frequent, the main branches from the midrib or central nerve always following the direction of one of the lobes.

We are not aware that it has been found by any botanist but our friend C. S. Parker, Esq., in the island of Barbadoes.

*Azorastichum tripartitum.*

Dr. Gmelini Dic.

J. J. Smith. Jr.

## ACROSTICHUM TRIPARTITUM.

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd., Spreng.

GEN. CHAR. *ACROSTICHUM*, Linn. *Sori* amorphi, seu *Capsulae* per totam paginam inferiorem frondis (interdum diversæ) vel ad ejus partem sparsæ. *Involucrum* nullum (nisi squamulæ, vel setæ in quibusdam capsulis interstinctæ). *Br.*

---

*ACROSTICHUM tripartitum*; frondibus longe petiolatis, sterilibus reniformibus tripartitis, lacinia cuneatis trilobis, fertili trilobo valde squamoso.

HAB. In sylvis provinciæ Esmeraldas, Am. Merid. arborum truncis, legit *D. Prof. Gul. Jameson*, ad alt. 5000 ped.

*Caudex* repens, hic illie radiculosus, undique ferrugineo-squamulosus.

*Stipites* erecti, frondium sterilium vix unciam, fertilium duas ad tres uncias longi, flavo-fusci, squamosi, squamis fuscis lanceolato-acuminatis membranaceis sparsis.

*Frondes* simplices, steriles, reniformes, subcoriaceæ, squamosæ, squamis demum deciduis, tripartitæ, lacinia cuneatis basi attenuatis, trilobis, lobis obtusis plerumque integris: *fertiles* circumscriptione cordatae, primum valde fuso-squamosæ, deinde nudiuscule, trilobæ, lobis rotundatis, integris vel subsinuatæ.

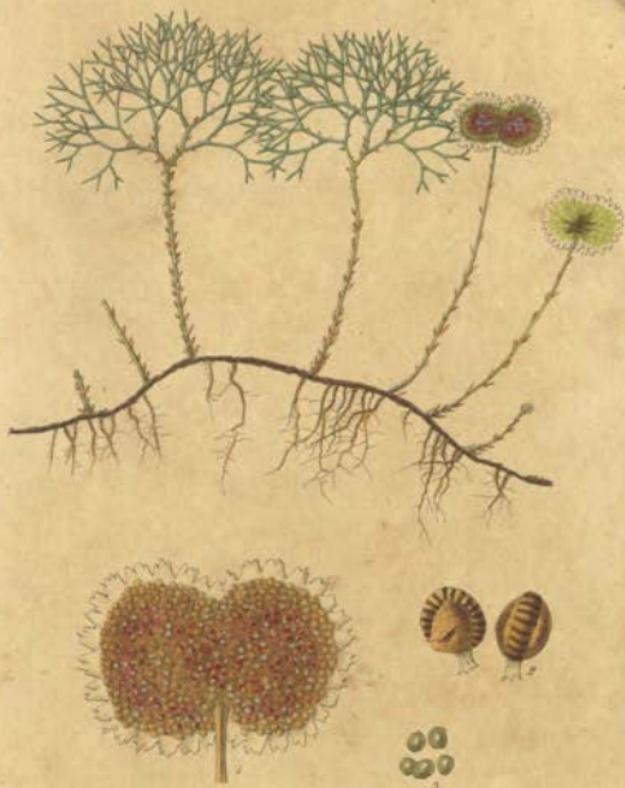

*Capsulae* totam inferiorem partem frondis tegentes, squamis interspersæ, sphericæ, intense fuscae, annulo lato fere completo cinctæ.

*Semina* ovalia, vel subrotunda, laevia.

Fig. 1. Capsulae. f. 2. Semina:—*magn. auct.*

---

The nearest affinity with this plant is unquestionably the *A. flabellatum* of Humboldt, a native of rocky places in Venezuela; but that is much larger, has the sterile fronds in the first instance bipartite, the segments multifid; whilst the fertile ones are orbicular and peltate, (according to the figure, but reniform in the description,) quite glabrous, or free from scales, and surrounded by a diaphanous and crenated margin. That species appears, as it were, intermediate between our plant and *A. peltatum* of Swartz.

*Saccostylum feniculaceum?*

J. Smith. 1802.

J. Smith. 1802.

TAB. CXIX.

ACROSTICHUM FENICULACEUM.

FILICES.—GYRATÆ. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd., Spreng.

GEN. CHAR. *ACROSTICHUM*, Linn. *Sori* amorphi, seu *Capsulae* per totam paginam inferiorem frondis (interdum diversæ) vel ad ejus partem sparsæ. *Involucrum* nullum (nisi squamula, vel setæ in quibusdam capsulis interstinetæ). *Br.*

---

*ACROSTICHUM feniculaceum*; frondibus sterilibus reniformi-multifidis, laciniis repetitim dichotomis lineariformibus fertilibus bilobis supra nudis, margine diaphano duplicato-crenato.

HAB. Supra truncos putridos arborum, in sylvis apud Esmeraldas, Amer. Sept. altit. 3000 ped.

D. Prof. Gul. Jameson.

*Caudex* longe repens, gracilis, squamosus, subtus radices plures, tenues, fliformes ramosas emittens.

*Stipites* 3—4 uncias longi, frondium steriliū et fertiliū subeque longi, errecti, graciles, squamosi.

*Frondes steriles*, circumscriptione reniformes, duas ad tres uncias latæ, repetitim dichotome ramosæ, laciniis divaricatis, tenuissime linearibus, planis, obscure costatis, glabris, apicibus furcatis, acutis: *fertiles* vix unciam latæ, bilobæ, lobis rotundatis, facie superiore nudo, margine diaphano duplicato-crenato, subtus vix squamułosæ.

*Capsulae* numerosæ, brevi-pedicellatae, globosæ.

*Semina* subglobosa.

Fig. 1. Frons fertilis, subtus visa. f. 2. Capsulae. f. 3. Semina:—*magn. auct.*

---

Received, along with our *A. tripartitum*, from W. Jameson, Esq., whose love of science has justly entitled him to the honour which has lately been conferred upon him, of the appointment to the Professorship of Natural History and Chemistry in the University of Quito. We trust that this situation will give him still greater opportunities for exploring the botanical riches of the magnificent country in which his residence is now fixed. The success which has already recompensed his exertions in pursuit of plants, is a sufficient proof of how much yet remains undiscovered.

*Cheilanthes triphyllum*

TAB. CXX.

MENISCIUM TRIPHYLLUM.

FILICES.—GYRATE. Br. POLYPODIACEÆ. Kaulf. FILICES veræ. Willd., Spreng.

GEN. CHAR. *MENISCIUM*, Schreb. *Capsulae* venulis transversalibus sublunulatis parallelis insidentes. *Involucrum* nullum.

*MENISCIUM triphyllum*; fronde ternata, foliolis oblongo-lanceolatis repando-subdentatis.

HAB. In India Orientali, China. Swartz. In Zeylona, in rupibus prope flumen Cultura. — Emerson, M.D.

*Caudex* crassitie pennæ corvinae, repens, radicosus, squamosus, demum denudatus.

*Stipes* palmaris ad spithameam, erectus, glaber, teres, hinc sulcatus, basi solummodo squamosus.

*Frondes* subspithameæ, e foliolis ternis, duobus lateralibus minoribus, digitalibus, alternis, basi inferiore nuda vel auriculata, breve petiolatis, intermedio terminali, petiolato, palmari ad spithameam, basi subhastata; omnibus oblongo-lanceolatis, acuminatis, basi obtuse vel oblique truncatis, supra glabris, subtus costa nervisque reticulatis, pubescenti-scabris. *Frondes steriles* plerumque latiores.

*Sori* intra nervos primarios, venis transversalibus insidentes, linearis-oblongi, curvati.

*Capsulae* subbrevis-pedicellatæ, annulo lato incompleto cinctæ.

*Semina* oblongo-subreniformia, flavo-fusci, sub summo lente reticulata.

Fig. 1. Portio frondis fructificantis. f. 2. Nervus in quo capsulae insertæ. f. 3. Capsulae. f. 4. Semina:— magn. auct.

This is probably by no means an uncommon plant in the East Indies, although the only specimens that have come under our observation are from Sylhet, gathered by Dr. Wallich in 1815; and from Dr. Emerson, collected in Ceylon. From the latter our drawings have been made.
