BOTANIC GARDENS CONSERVATION INTERNATIONAL (BGCI)

is the world's largest plant conservation network, comprising more than 500 botanic gardens in over 100 countries, and provides the secretariat to the IUCN/SSC Global Tree Specialist Group. BGCI was established in 1987 and is a registered charity with offices in the UK, US, China and Kenya.

THE IUCN/SSC GLOBAL TREE SPECIALIST GROUP (GTSG)

forms part of the Species Survival Commission's network of over 7,000 volunteers working to stop the loss of plants, animals and their habitats. SSC is the largest of the six Commissions of IUCN – The International Union for Conservation of Nature. It serves as the main source of advice to the Union and its members on the technical aspects of species conservation. The aims of the IUCN/SSC Global Tree Specialist Group are to promote and implement global red listing for trees and to act in an advisory capacity to the Global Trees Campaign.

THE CRITICAL ECOSYSTEM PARTNERSHIP FUND is a joint initiative of l'Agence Francaise de Développement, Conservation International, the European Union, the Global Environment Facility, the Government of Japan and the World Bank. A fundamental goal is to ensure civil society is engaged in biodiversity conservation.

TANY MEVA is the CEPF regional implementation team for the Madagascar and Indian Ocean Islands biodiversity hotspot. Together, they enable civil society to protect ecosystems and species.

ACKNOWLEDGEMENTS

Madagascar littoral forest (Paul Smith)

We would like to thank all the assessors who contributed assessments for this analysis, as well as those taxonomic experts who reviewed the assessments. We are grateful to all members of the IUCN SSC Madagascar Plant Specialist Group for their work to review the Red List assessments for this project. We are grateful to those who contributed to the case studies in this report.

Thanks go to the Global Tree Assessment team at BGCI and the IUCN SSC Global Tree Specialist Group for their efforts in preparing the assessments for submission to IUCN as well as organising and facilitating the Red List workshops. Thank you to the IUCN Red List Unit for their support in the entry and publication of these assessments.

This work was funded by a Critical Ecosystem Partnership Fund (CEPF) project ("Assessing the Conservation Status of Madagascar's Trees for Effective Conservation of Key Biodiversity Areas and Protected Areas") and Fondation Franklinia.

We are indebted to Professor Bakolimalala Rakouth for the translation of the Executive Summary into Malagasy. Thanks to Fano Rajaonary for the spatial analysis.

All the gardens that shared their collection information and published data on BGCI's PlantSearch database are gratefully acknowledged.

FOREWORD

The place of trees in the life of humankind no longer needs to be proven. As an illustration of their importance, trees or **Hazo** in Malagasy are mentioned in many Malagasy proverbs and adages:

Hazo avo alan-drivotra: the wind first destroys the emergent trees: (jealousy);
ny Hazo no vanonko lakana , ny ala naniriany no tsara: if we make a pirogue from a tree, it is thanks to the forest that nourished it (all good things are the fruit of their environment); **Hazo tokana tsy mba ala:** a single tree is not a forest (union is strength). Nowadays, it is not unusual to find a single tree in a vast bare landscape, with the distant echoes of a forest that was

once there, a witness to the deforestation that Madagascar has experienced since the first arrival of humans to the island. Since 1950, or in the last 70 years, the island has lost almost half of its natural forests (a loss of 44% has been recorded, or 1.6% per year). This loss of forest cover is accentuated by the fragmentation of the remaining intact forest.

Many authors have repeatedly warned that deforestation and fragmentation constitutes a great danger to Madagascar's unique biodiversity, causing a loss of both quality (taxa) and quantity (individuals). This loss could also be thought of in terms of habitat decline as the vegetation shelters and feeds the fauna.

The causes of deforestation are multiple, but here we are highlighting the anarchic exploitation of our valued woods, which leads to imbalances in their known populations. Analyses to assess the conservation status of species are necessary to better guide decision-making for tree species management. It is no longer necessary to demonstrate the central ecological role of different tree species in regulating the functioning of the elements of our ecosystem.

This Red List of tree species mentions that of the 2,904 endemic species, 1,828 are assessed as threatened. This Red List is an indicator for monitoring the status of forest tree species. With this tool, it will be possible to identify priorities for action and to raise awareness among stakeholders in order to take action to limit extinction. The use of this document will contribute to improving governance and, by extension, to the development of legal and regulatory tools as well as forest resource management techniques.

I commend the fruitful collaboration of the botanical community of Madagascar with Botanic Gardens Conservation International, which has resulted in the production of this national report on the status of our trees. However, the reach of this report goes beyond Madagascar; this report will be useful at a global level, as Madagascar's rich, endemic biodiversity is a global asset.

Julien Noël Rakotoarisoa,
Director General of Environmental Governance

Adansonia suarezensis (KMCC SE Rakotoarisoa)

AVANT-PROPOS

La place des arbres n'est plus à démontrer dans la vie de l'humanité, à titre d'illustration, les arbres ou **Hazo** en Malagasy figurent dans bon nombre de proverbes et d'adages Malagasy :

Hazo avo alan-drivotra : le vent décime en premier les arbres émergents : (jalouse) ; **ny Hazo no vanonko lakana**, **ny ala naniriany no tsara** : si avec un arbre on arrive à fabriquer une pirogue, c'est grâce à la forêt qui l'a nourrie (toute bonne chose est le fruit de son milieu) ; **Hazo tokana tsy mba ala** : un seul arbre n'est pas une forêt (l'Union fait la force). Actuellement il n'est pas rare de rencontrer dans un vaste paysage dénudé un seul arbre, témoin l'existence lointaine d'une forêt, témoin de la déforestation qu'a connue Madagascar depuis la venue de ses premiers peuples. Depuis 1950, c'est-à-dire en 70 ans, l'île a perdu presque la moitié de ses forêts naturelles (une perte de 44% a été enregistrée soit 1,6% par an). Cette perte en surface est accentuée par la fragmentation des massifs forestiers restants.

Bien d'auteurs n'ont cessé d'alarmer que la déforestation et la fragmentation constituent un grand danger pour la biodiversité unique de Madagascar qui connaît une perte en qualité (taxons) et en quantité (individus). Cette perte pourrait être également traduite en termes de déclin de l'habitat comme la végétation (flore) abrite et nourrit la faune.

La cause de la déforestation est multiple mais ici signalons juste l'exploitation anarchique de nos bois précieux qui entraîne un déséquilibre des populations connues. Des analyses pour apprécier les risques d'extinction des espèces s'avèrent nécessaires pour une meilleure orientation de la prise de décision dans les activités de gestion des espèces d'arbres. Il n'est

Delonix floribunda (Malin Rivers)

plus à démontrer le rôle central écologique de différentes espèces arbres dans la régulation du fonctionnement des éléments de notre écosystème.

Ce livre sur la Liste Rouge des espèces d'arbres mentionne que sur les 2,904 espèces endémiques, 1,828 appartiennent aux catégories des menacées. Cette Liste Rouge est un indicateur pour suivre l'état des essences d'arbres forestières. Avec cet outil, l'identification des priorités d'action et la sensibilisation des parties prenantes pour agir en vue de limiter le taux d'extinction seront possibles. L'exploitation de ce document va dans le sens d'une amélioration de la gouvernance et par extension dans le développement d'outils juridiques, règlementaires et de techniques de gestion des ressources forestières.

Je loue la collaboration fructueuse de la communauté botanique de Madagascar avec le Botanic Gardens Conservation International qui s'est soldée par la production de cette référence nationale de l'état de Santé de nos arbres. Mais ce référencement va au-delà de la territorialité de Madagascar car ce livre trouvera son utilité au niveau planétaire étant donné que la Biodiversité de Madagascar riche en terme d'endémicité constitue une richesse mondiale.

Julien Noël Rakotoarisoa,
Directeur Général de la Gouvernance
Environnementale

EXECUTIVE SUMMARY

English

The Red List of Trees of Madagascar provides the first comprehensive assessment of the conservation status of the trees of Madagascar. Madagascar is home to 3,118 tree species, making it the twelfth most species rich country in the world with respect to tree diversity. Moreover, 93% (2,904) of these trees are endemic to Madagascar. Until now, there was very limited data on the conservation status of Madagascar's trees.

Overall, 1,828 (63%) of Madagascar's endemic tree species are threatened with extinction (assessed as Critically Endangered, Endangered or Vulnerable). The majority of these trees are threatened by small ranges, few locations and declines. The primary threats to Malagasy tree species are logging and wood harvesting, agricultural expansion and increased fires.

Currently, only 285 (16%) of threatened trees endemic to Madagascar are found in ex situ collections. This falls far short of Target 8 of the Global Strategy for Plant Conservation which states that at least 75% of threatened species should be held in ex situ collections.

This publication establishes the first baseline for the conservation status of the trees of Madagascar and highlights the opportunities to increase and create protections for the island's unique tree diversity.

Didierea madagascariensis (Malin Rivers)

Ny lisitra mena ny Hazon'i Madagasikara dia manome ny fanadihadina vohalohany mikasika ny sata fiarovana ny hazon'ny Madagasikara. Madagasikara dia manana karazan-kazo 3118, izay mametraka azy ho anisan'ireo firenena 12 manankarena indrindra maneran-tany raha ny maha marolafy ny hazo no jerena. Mihoatra ny 93% (2,904) n'ireo hazo ireo dia zana-tany na tsy misy afa tsy eto Madagasikara. Hatramin'izao , dia vitsy dia vitsy ireo antontan-kevita momban'ny sata fiarovana ny hazon'i Madagasikara. Raha antotaly dia 1828 (63%) an'ireo karazan-kazo zanatanin'i Madagasikara no tandidomindoza ho lany tamingana (kilasiana :Ahiana tena ho lany tamingana, ahiana ho lany tamingana, ary marefo). Ny ankamaroan'ireo hazo ireo dia noho izy tsy mielipatranana, na hita amin'na toerana vitsy, na izy miha vitsy isa. Ny loza fototra ho an'ireo karazan-kazo malagasy dia ny fanapahana ny ala, fanangonana hazo, fanitarana tanim-boly ary ny fitombon'ny afo. Ankehitriny diany 285 (16%) fotsiny amin'ireo hazo zanatany tandidomindoza eto Madagasikara no hita any amin'toerana ivelan'ny ala tahiry. Izany dia tena manalavitra ny tarigetra faha 8 ny Tetikady maneran-tany momban'ny fiharovana ny zava-maniry izay manambara fa fara faha keliny dia ny75% ny karazany tandidomindoza no tokony ho tehirizina amin'ny toerana ivelan'ny ala voajanahary nisy azy. Ity lahatsoratra navoaka ity dia mametraka ny fototra ho an'ny sata fiarovana ny hazon'ny Madagasikara sady manazava ireo toe-javatra hahazoana mampitombo sy mamorona fomba hiharovana ireo hazo marolafy tsy manampaharoan'ny Nosy.

Southern plateau (Paul Smith)

BACKGROUND

Madagascar is well known for its iconic fauna and flora. The island has a wealth of habitat types and climatic conditions, explaining its status as a biodiversity hotspot. Madagascar is home to 3,118 tree species, making it the twelfth most species rich country in the world with respect to tree diversity (BGCI 2020a). Moreover, 93% of these trees are endemic to Madagascar. Plant species in Madagascar have become increasingly threatened, with some estimates suggesting Madagascar has lost at least 44% of its forest cover since the 1950s (Vieilledent *et al.* 2018). Despite Madagascar being home to over 2,900 unique tree species and an increasing awareness of the threats facing plants, until relatively recently there has been limited data available about the conservation status of the country's trees.

In 2017, there were only 379 assessments for trees of Madagascar on the IUCN Red List. Over the past three years, more than 2,400 assessments have been compiled by researchers from Missouri Botanical Garden Madagascar Program, Kew Madagascar Conservation Centre, University of Antananarivo, Madagascar Plant Specialist Group, and other institutions across the world, in order to provide a full picture of the status of the trees of Madagascar. Over 94% of these assessments represented the first IUCN Red List assessment for the species. This work was funded by the Critical Ecosystem Partnership Fund in a project called “Assessing the Conservation Status of Madagascar’s Trees for Effective Conservation of Key Biodiversity Areas and Protected Areas” and Fondation Franklinia. This is the first comprehensive assessment of the status of the trees of Madagascar.

This work has contributed to the Global Tree Assessment, an initiative to assess the world's tree species by 2020 (see Box 1).

Dry thicket Southern Madagascar (Paul Smith)

Box 1: Global Tree Assessment (GTA)

The Global Tree Assessment (GTA) is assessing the conservation status of every known tree species.

Despite the importance of trees, many are threatened by over-exploitation and habitat destruction, as well as by pests, diseases, drought and their interaction with global climate change. In order to estimate the impact of such threats to trees there is an urgent need to conduct a complete assessment of the conservation status of the world's 60,000 tree species – the Global Tree Assessment.

The Global Tree Assessment, led by BGCI and the IUCN SSC Global Tree Specialist Group, prioritises the tree species at greatest risk of extinction. The Global Tree Assessment provides information to ensure that conservation efforts are directed at the right species so that no tree species becomes extinct. www.globaltreeassessment.org.

METHODS

Lowland moist evergreen forest, Masoala, Eastern Madagascar

(Above and right: Laurent Gautier, Conservatoire et Jardin botaniques de la Ville de Genève)

All species that met the IUCN SSC Global Tree Specialist Group tree definition were included in this study: a woody plant with usually a single stem growing to a height of at least two metres, or if multi-stemmed, then at least one vertical stem five centimetres in diameter at breast height.

All accepted tree names were considered for this project. The list of trees of Madagascar was created using the Catalogue of Plants of Madagascar (Madagascar Catalogue 2020) and BGCI's GlobalTreeSearch database (BGCI 2020a). The validity of names was determined using the Catalogue as well as Plants of The World Online database (POWO 2020). Of the list of Malagasy tree species, those without an IUCN Red List assessment or those with an old assessment (pre-2010), were assessed by Missouri Botanical Garden Madagascar Program and Kew Madagascar Conservation Centre.

Data were gathered on the distribution, habitat and ecology, population, use and trade, threats and conservation actions. Distribution maps (using georeferenced herbarium records) were also produced following the IUCN Red List Mapping guidelines (IUCN RLTWG, 2019). Assessors then evaluated this information against the IUCN Categories and Criteria. If the data met certain thresholds, the species was assigned one of three threatened categories - Critically Endangered (CR), Endangered (EN), Vulnerable (VU) - or if the thresholds are almost met the species was assessed as Near Threatened (NT). Any species not meeting the thresholds were classified as Least Concern (LC) and those species with insufficient information to complete an assessment were assigned Data Deficient (DD).

For full IUCN Red List methodology please see the IUCN guidelines (IUCN Standards and Petitions Subcommittee, 2019).

Tsebona macrantha: a valuable giant tree in the family Sapotaceae. Masoala, Eastern Madagascar

To finalise the assessments, they were reviewed during five workshops hosted in Antananarivo, Madagascar by the Madagascar Plant Specialist Group. The purpose of the assessment review was to ensure the data used in the assessments were correct and that the IUCN Categories and Criteria had been applied accurately, giving a true reflection of extinction risk of the species. Following the review process, the assessments and maps were submitted to the IUCN Red List Unit for processing and publishing online. These assessments are now all available online, with supporting information and maps, at the IUCN Red List Website (www.iucnredlist.org).

RESULTS

There are 3,118 tree species found in Madagascar, with 2,904 (93%) considered endemic to Madagascar. To contrast with the entire flora of Madagascar, 11,262 species of vascular plants are reported as native, with 82% endemic to Madagascar (Madagascar Catalogue, 2020; Clubbe et al., 2020). The trees of Madagascar are found across 102 plant families. The most speciose families when considering trees are Rubiaceae (284), Malvaceae (247) and Fabaceae (235) (Table 1).

Plant family	Number of species
Rubiaceae	284
Malvaceae	247
Fabaceae	235
Euphorbiaceae	158
Lauraceae	124
Arecaceae	105
Salicaceae	102
Sapotaceae	90
Sapindaceae	89
Ebenaceae	83

Table 1: The ten most tree species rich plant families

Of the tree species endemic to Madagascar, 1,828 species (63%) are considered threatened globally (i.e. assessed as Vulnerable, Endangered and Critically Endangered) (Figure 1, Table 2). There are 155 species (5%) assessed as Near Threatened, almost meeting the criteria for a threatened category. Furthermore, 769 species were considered Least Concern (27%). A further 152 species (5%) are considered to be Data Deficient.

No tree species are categorised as Extinct or Extinct in the Wild. However, 59 species were considered Critically

Table 2: The number of Malagasy tree species in each IUCN Red List Category

Endangered with the tag “Possibly Extinct”. Many species listed as Data Deficient have not been seen for a long period of time and are so poorly known a conservation category could not be assigned.

CRITERIA USED IN THE RED LIST

Almost all the endemic threatened and Near Threatened species were assessed under criterion B, indicating that they

IUCN Red List Criteria	Number of species
Criterion A	35
Criterion B	1,873
Criterion C	24
Criterion D	96
Criterion E	0

Table 3: The number of CR, EN, VU and NT endemic Malagasy species assessed under each of the five Red List Criteria.

have restricted distributions (Table 3). There are very few species assessed using criterion A, population size reduction, indicating a lack of data on the decline of species over time. It also highlights the lack of knowledge of the generation length of these species, required for this criterion, as it is difficult to estimate for many tree species. Criteria C and D apply to species with small populations. Few species were assessed under these criteria indicating a lack of population level information.

HABITATS

The majority of Madagascar's endemic trees are found in forest habitats, ranging in temperature, humidity and altitude (Figure 2). To a lesser extent, trees are also found in shrublands, grasslands and wetlands as well as rocky areas. The majority of species are only found in a single habitat type. When considering only threatened species, the same patterns emerge, with lowland forest the habitat with the highest number of threatened species, followed by dry forest and montane forest.

Albizia arenicola flower (KMCC SE Rakotoarisoa)

Southwest Madagascar (Malin Rivers)

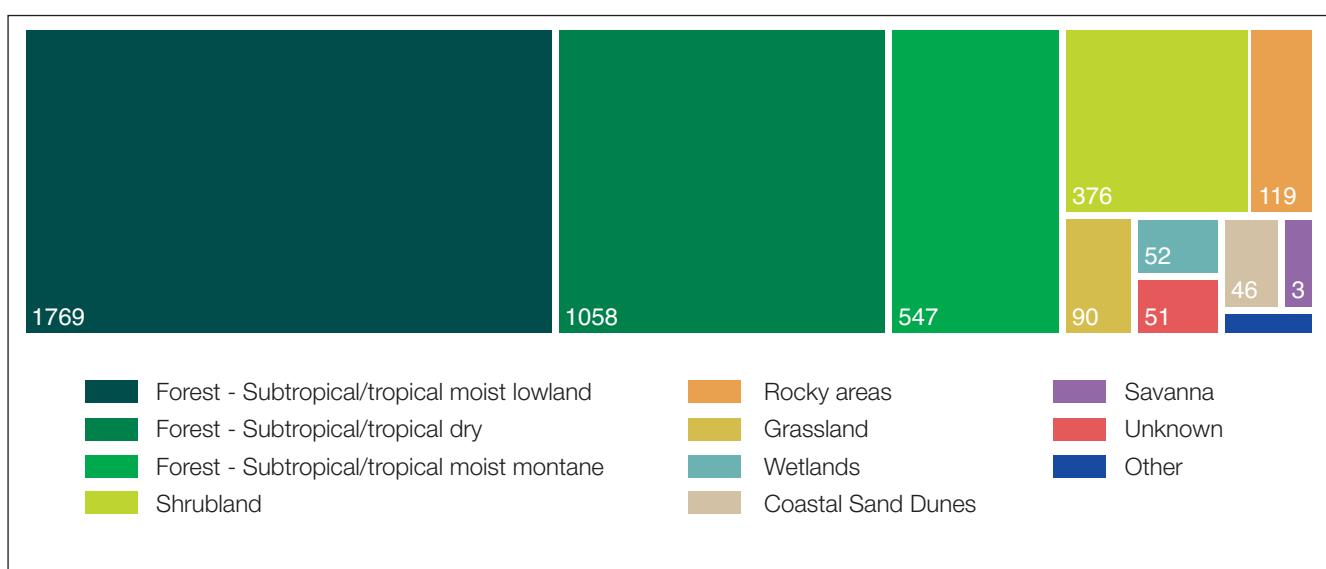

Figure 2: The habitats Malagasy endemic trees grow in

USES

The endemic trees of Madagascar have a range of uses, with more than half having at least one use (1,533 species or 53%, Figure 3). This represents the importance of trees to

the livelihoods and life of Malagasy people. The most common use is as timber for construction (513 species), followed by fuels (charcoal production and fuelwood) (202 species) and medicines (173 species).

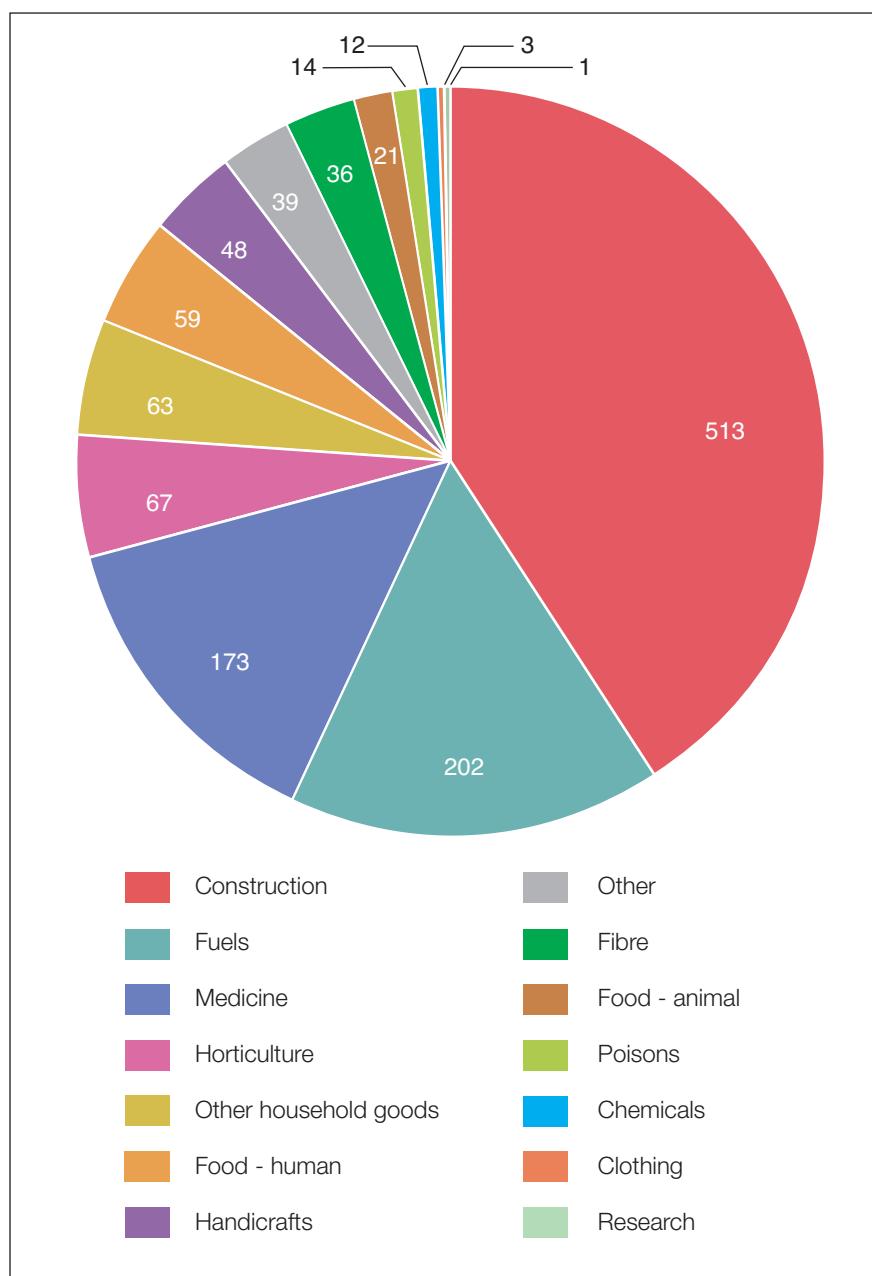

Figure 3: The recorded uses of Malagasy endemic trees

Andriantantely (Eastern Madagascar)
(Katharine Davies)

Avenue of the Baobabs (Malin Rivers)

Diospyros humbertiana (Fidy Ratovoson)

THREATS

The major threat to tree species in Madagascar is logging and wood harvesting with over 2,400 (83%) of the country's endemic trees impacted (Figure 4). This links directly to how the

Charcoal production (KMCC SE Rakotoarisoa)

species are used (Figure 3). Over 600 threatened endemic tree species are exploited intentionally for their timber. The next most prevalent threats are annual or perennial crops, fire and mining. Many of these threats represent a complete destruction of tree ecosystems, with conversion to a less biodiverse landscape. It is also clear that the uses and threats to tree species in Madagascar are intertwined and the protection of tree species for their continued local use represents an important economic and social driver for conservation action. Given that the majority of tree species in Madagascar are found in forest habitats, deforestation is a clear driver of species extinction risk.

Slash & burn (KMCC SE Rakotoarisoa)

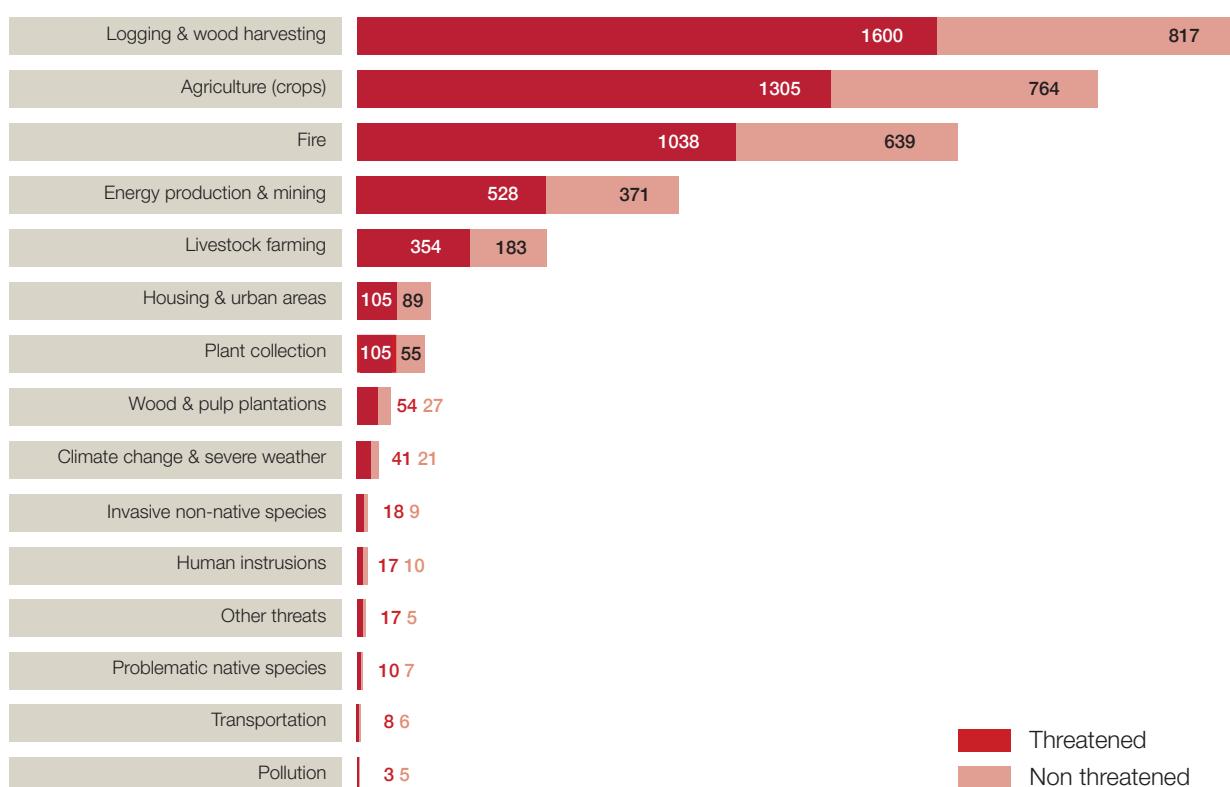

Figure 4: Threats to Malagasy endemic tree species

Ankarana forest (KMCC SE Rakotoarisoa)

REGIONAL DISTRIBUTION OF THREAT

The threatened tree species of Madagascar are not uniformly distributed across Madagascar. The majority of the endemic threatened species are found in the north western region of Madagascar, with over 860 (47%) threatened tree species found in SAVA, DIANA and Analanjirofo (Figure 5). Anosy, a region in the south east of Madagascar, also has a large number of threatened trees, likely due to the presence of dry, sub-humid and humid forests within this region.

IN SITU PROTECTION

There are 2,438 endemic tree species in Madagascar recorded in protected areas, representing 84% of endemic tree species. Considering threatened endemic tree species, 83% are recorded in at least one protected area. This is not surprising as protected areas represent where much of the remaining natural vegetation is. More research could be done to understand the protection levels for these species.

Overlaying the species distribution for the endemic threatened tree species over the protected area network reveals that eleven protected areas are home to over 75 threatened endemic tree species (Table 4). The majority of these protected areas are in the north west of Madagascar (Figure 5).

There are 307 threatened species endemic to Madagascar that occur entirely outside of the protected area network. Work should be done to investigate how these species could be effectively protected in their natural environment.

EX SITU SURVEY

Ex situ surveys identify the number of *ex situ* collections of a specific species found in botanic gardens, arboreta and seed banks worldwide. *Ex situ* collections represent an important conservation method to prevent the extinction of threatened species. BGCI's PlantSearch database (BGCI 2020b) holds records of plant collections held in botanic gardens, arboreta and seedbanks around the world. Of the 2,904 endemic Malagasy tree species, only 658 (22%) are recorded in *ex situ* collections, including 286 threatened species (Figure 6). This means that 84% of Madagascar's threatened tree species are not found in *ex situ* collections, falling short of Target 8 of the Global Strategy for Plant Conservation which calls for 75% of threatened plants to be held in *ex situ* collections (CBD, 2012). Eighty-three percent of the threatened species reported in collections are found in fewer than five collections. Small *ex situ* collection numbers are unlikely to capture sufficient genetic diversity to be used in restoration or reintroduction programmes. The diversity of the collections is not taken into account in this study, but genetic diversity is key if these collections are to have use in the future.

Some Malagasy species are highly sought after in horticulture and are, therefore, represented in a large number of botanic garden collections across the world (Table 5). The majority of these species are

classified as Least Concern but two species of palms, *Dypsis lutescens* (NT) and *Dypsis decaryi* (VU), are in a large number of *ex situ* collections.

Facing biodiversity loss due to deforestation, climate change and natural disaster, Royal Botanic Gardens Kew launched one of the biggest *ex situ* conservation programmes through seed banking around the world in 1996. The aim was to collect and to bank 25% of the world flora by 2020. The programme

started in Madagascar at the end of 2000. Since the programme started, three big projects have operated in Madagascar: the Millennium Seed Bank Partnership, the People's Postcode Lottery and Garfield Weston. Since these programmes started, about 3,700 collection of trees have been made, 1,488 of which have yet to be identified. The identified collections represent 884 (28%) tree species. The majority of these collections have been made outside of the protected area system.

Table 5: Ten endemic Malagasy tree species with the largest numbers of *ex situ* collections

RECOMMENDATIONS AND CONCLUSIONS

Aloe heleneae (KMCC SE Rakotoarisoa)

It is clear from the data gathered that Madagascar's tree flora is under threat, with 63% of endemic trees assessed as threatened. The following recommendations are made for the protection of Madagascar's tree species and ecosystems in the future.

Research:

- Increased survey effort to establish population data and indications of decline rate over time.
- Monitoring of populations to ascertain population size and generation length which are required for assessing species under criteria A and C.

Ex situ protections:

- Threatened species not held in ex situ collections should be bought into collections as a priority.
- Species should be found in more than one ex situ institution and locality if possible.
- Genetic diversity should be considered when curating ex situ collections.
- Ex situ collections in country should be expanded.

In situ protections:

- Key Biodiversity Areas (KBAs) should receive increased protection.
- Monitoring of effectiveness of protected areas should be carried out.
- Further integrated conservation action plans should be created for the most threatened species.

Restoration

- Further efforts should be made to include threatened tree species in restoration activities.
- Local nurseries should be expanded to incorporate threatened tree species and produce material for restoration.

Raise awareness, build local capacity and mobilise action:

- Local communities should be informed about the importance of threatened tree species in their vicinity.
- Capacity should be built in conservation, propagation and horticulture techniques to empower local partners and communities.

Madagascar is one of the most tree species rich countries, however Malagasy tree species are highly threatened and require immediate action to prevent their extinction. The *Red List of Trees of Madagascar* aims to both provide information to prioritise conservation efforts and inspire action to improve the conservation status of those most at risk of extinction, to maintain this diversity for years to come.

CASE STUDIES

CASE STUDY 1: CONSERVATION OF A THREATENED DALBERGIA IN SOUTHWEST MADAGASCAR

By Tabita Randrianarivony

Analavelona forest, with an area of 4,487 ha (representing 80% of the remaining subhumid forests), is one of the 80 Important Plant Areas identified for Madagascar in 2004. A sacred forest, it has been the site of community based-conservation for 11 years under Missouri Botanical Garden Madagascar Program.

The Analavelona forest, is unique in Madagascar because not only is it a key biodiversity area, but it is the only subhumid forest in a dry bioclimate and in addition it is a sacred forest with high social and cultural value for the surrounding communities.

The species, *Dalbergia hirticalyx* was assessed as Endangered in 1998. Since then, the distribution area of the species has expanded as populations have been

Dalbergia hirticalyx fruit (Fortunat Rakotoarivony)

found in the south-western part of the island, including the Analavelona forest. The current known populations of this species have been found in areas where fires from grazing, illegal logging and logging for cultural uses or camping reasons occur, and as a consequence, it has experienced a decline in both its habitat and area of occupancy.

This species *Dalbergia hirticalyx* is among the ca. 30 large *Dalbergia* tree species. This plant is very popular to local people, as a precious wood of Madagascar, and it is very sought after for cultural uses as wood for coffins. This use poses a direct threat to the species.

This species has not been assessed during the Critical Ecosystem Partnership Fund project as the genus is currently under revision. The previous assessment of this species classified it as Endangered. With the currently available data, it will still qualify as threatened.

The Analavelona community based conservation project aims to improve the conservation status of these species for their sustainability by integrating local

Dalbergia hirticalyx (Roger Bernard)

community members in the *in situ* and *ex situ* conservation actions for these species.

The main activities that will guarantee the conservation of the species are:

- 1) Use a participatory approach to identify existing tree populations through research and monitoring activities.
- 2) Use available eco-biogeographic and demographic knowledge to define priority actions for better protection of tree populations.
- 3) Intensify patrol activities to reduce threats in sensitive zones of the protected area and raise awareness among local population about the main threats to the species.
- 4) Engage local communities in threatened tree species conservation, so that they will be aware of the intrinsic, conservation and economic values of these species.

Local conservation action on this species is closing the IUCN SCC Species Conservation Cycle (TO ACT).

CASE STUDY 2: WOOD REFERENCE LIBRARY OF MADAGASCAR CITES-LISTED DALBERGIA AND DIOSPYROS FOR TAXONOMY, IDENTIFICATION AND TRACEABILITY.

By Harisoa Ravaomanalina

Madagascar is home to 36% of the world's *Dalbergia* species including rosewood and palissander (Mabberley, 2008; Missouri Botanical Garden, 2021) and 34% of *Diospyros* including ebonies in the world (Govaerts, 2018; Missouri Botanical Garden, 2021). Malagasy precious wood is some of the most sought after in the world, and also some of the most difficult to identify, due to the lack of reference material available for scientific study. After their listing in Appendix II of CITES, Madagascar is expected to effectively limit the illegal trade and promote the development of sustainable legal timber industries within Madagascar. Thanks to Malagasy Precious Wood consortium effort, the first wood library collection was established at the University of Antananarivo in December 2020 including 4,295 specimens of branch and stemwood, mainly representing *Dalbergia*

The wood library collection (Ravaomanalina, H.)

and *Diospyros* species and their look-alike species. To overcome the problem of reliable species identification, the consortium emphasized the importance of the collection of samples from flowering and fruiting trees and have developed, tested and improved a standardized sampling protocol to collect samples from standing trees. This reference collection, accompanied by herbarium vouchers allows for comparison of specimens and provides reference samples for several complementary identification methods available in Madagascar. These methods include DNA analysis of dried leaf material, and heartwood samples for wood

anatomy and near infrared spectroscopy (NIRS). Identification tools have specifically been developed to support species identification to enforce CITES regulations. By better understanding, cataloging, collecting and curating the wealth of natural timber resources in Madagascar, the Malagasy government can: (i) enforce its illegal logging laws, (ii) help its international partners enforce CITES and (iii) promote new in-country industries to utilize their unique natural heritage in a sustainable way. Moreover, this progress contributes to the expectations of the CITES action plan for *Diospyros* and *Dalbergia*, in the establishment of a reference collection and identification system for CITES-listed species.

CASE STUDY 3: CONSERVATION ASSESSMENTS IN MALAGASY SAPOTACEAE

By Laurent Gautier, Aina Randriarisoa, Carlos G. Boluda, Camille Christe,
Kathryn Cornelisse and Yamama Naciri
Conservatoire et Jardin botaniques de la Ville de Genève and University of Geneva

An outcome of the project *Understanding Madagascar Sapotaceae: a critical step towards conservation of a threatened group of prime importance trees* of the Conservatoire et Jardin botaniques de la Ville de Genève, with funding from the Swiss National Fund for Scientific Research and the Franklinia Foundation. In collaboration with the Antananarivo University and the Missouri Botanical Garden (G3D project).

With ca. 1,300 species worldwide, Sapotaceae are an important family of slow-growing, large, valuable tropical trees, highly praised for their mechanical properties and resistance to parasites (Figure 1). Several species have achieved fame on the international market for their wood (e.g. Moabi, Makoré), but also for their oil-rich seeds (Argan, Shea-butter) and their latex (Gutta-Percha, Balata).

On Madagascar, Sapotaceae are represented by ca. 100-120 species, all but three island-endemics. They are distributed mostly in the Eastern humid evergreen forests but with a few genera extending to Western dry deciduous forests. A few species are even found in the Southwestern dry spiny thicket. Their timber is highly praised locally and, like Ebonies, attract international traders as Palisanders and Rosewoods become rarer. Their biological traits are perfectly adapted to mature forest. As a consequence, only a few species are found in secondary forests, and they totally disappear if disturbances further increase. As such, they are particularly sensitive to the massive deforestation that has been occurring throughout the island in the last 100 years. Forest clearing for shifting agriculture appears to be the major threat, but they are also prone to be selectively logged, even within protected areas. Therefore they are

at a particularly high risk of extinction. These issues are intensified by the high fragmentation of their habitats like the littoral forest, the low altitude evergreen rainforest or the western dry deciduous forests, where very restricted subpopulations certainly experience severe intraspecific genetic erosion.

A further problem arises from their difficult taxonomy, which stems from the relative scarcity of specimens due to the tall stature of the trees and their delayed flowering maturity. Until recently, the only identification tool was the 50-years old, outdated *Flore de Madagascar et des Comores* treatment.

The authors have embarked on a complete taxonomic revision of the Malagasy members of the family, in parallel with conservation assessments. Phylogenetic studies have confirmed their uniqueness: the discovery of an endemic tribe of three genera, has further shed light on their exceptional endemism, even at high taxonomic ranks. However, it is at specific rank that most work is still ongoing, implementing gene capture on ca. 1,000 loci and Next Generation Sequencing. Such an in-depth study on *Capurodendron* has revealed a twofold increase in number of species which ranks it as the most species-rich Malagasy endemic plant genus. Many of these new species had

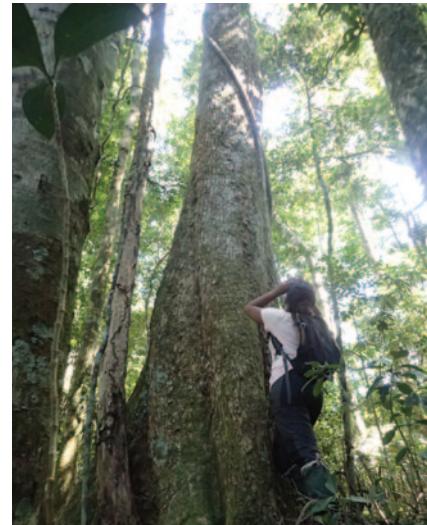

Figure 1: *Labourdonnaisia* sp. observed by Aina Randriarisoa in Beampingaratsy forest, SE Madagascar

already been collected, and were simply confounded with described species because of lack of fertile material or hasty identification. Their vegetative characters had often converged with those of unrelated described species.

This of course has a tremendous impact on species conservation assessments: as an example, *Capurodendron ludiifolium*, described from the Eastern sublittoral humid evergreen forests, had been previously assessed as VU due to its relatively large range, extending to the dry forest of the extreme North. It turned out that the northern specimens used in the assessment actually belong to four different unrelated, range-restricted, new species, two of them assessed as CR and two as EN. As for *C. ludiifolium*, it had to be reassessed and is now EN (Figure 2).

Another issue that we face is species complexes. One of them, in the southwestern subarid zone, involves *C. androyense* and *C. mandrarensis*, two morphologically distinct widespread species and several rare outliers, including a putative hybrid between *C. mandrarensis* and *C. greveanum*, a widespread western dry forest species, sympatric in the southernmost part of its range.

Two outliers were confirmed as new CR species, whereas the putative hybrid showed to have genetically very little in common with the western species and to be a new species that still has to be described and assessed.

In a distantly related western dry deciduous forest group, disentangling another species complex around *C. perillei*, revealed that an ancient described variety that was later subsumed in the Flora turned out to be a plain species. A couple of morphologically intermediate specimens between the three species collected at the convergence of their respective distribution ranges were demonstrated to be hybrids, that are probably sterile and need neither description, nor assessment (Figure 3).

Much work remains to be conducted, and although the genus *Capurodendron* can now be considered as revised, we expect many similar cases in the difficult genera *Mimusops*, *Labramia* and *Labourdonnaisia* (incl. *Faucherea*).

As a whole, the family Sapotaceae in Madagascar can be considered as under major threat, with 73.3% of its described species threatened (CR: 14, EN: 20, VU: 10), and only nine species LC and seven NT. However, only the species that were considered as taxonomically sound have been assessed and 31 species in the three aforementioned genera have been listed as DD, pending the results of ongoing phylogenetical studies. As they have not yet been effectively published, most of the recently discovered new species have not been taken into account in these figures, but their assessments meet criteria for the most threatened categories. This trend is expected in the species still to be discovered, so the portion of threatened species will significantly increase as the taxonomy is resolved.

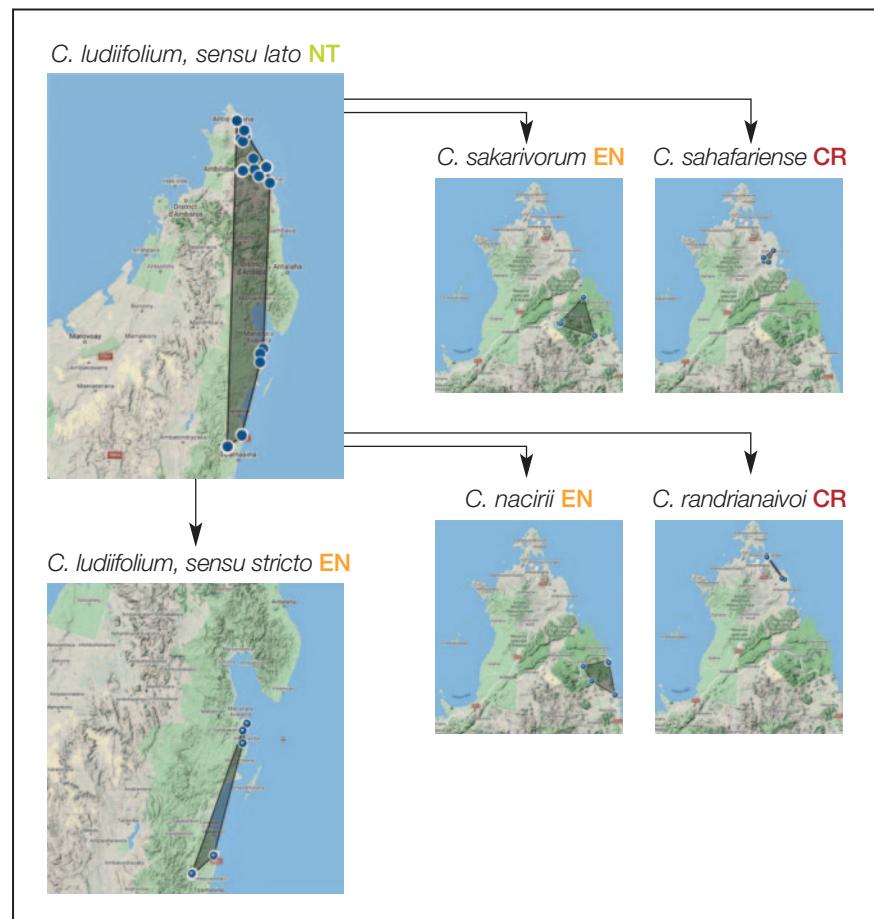

Figure 2: Bad taxonomy leads to bad conservation, the case of *Capurodendron ludiifolium* (see text).

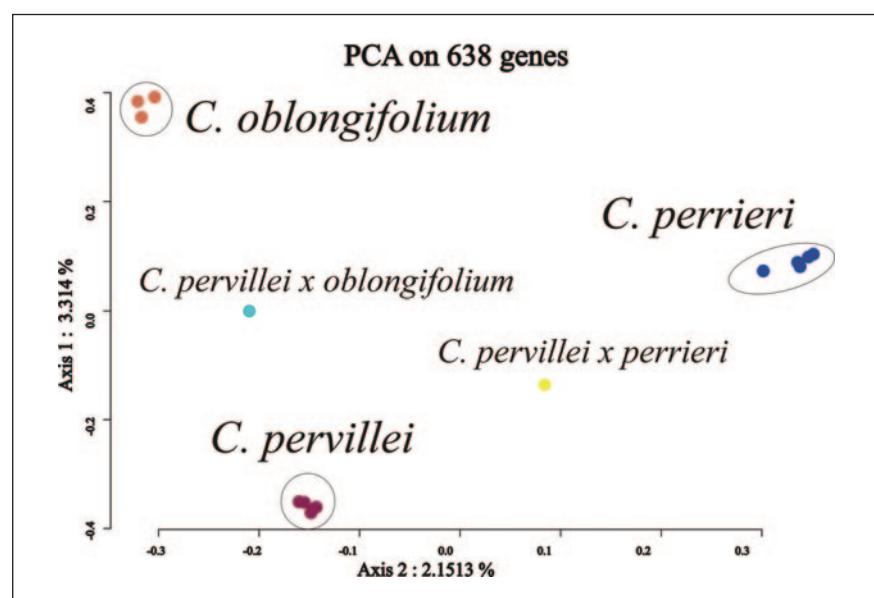

Figure 3: A taxonomic complex around *Capurodendron perillei* resolves in three clear species and two hybrids using Principal Component Analysis on genetical data.

J. Beal Botanical Garden; Waimea Valley Arboretum and Botanical Garden; Wuhan Botanic Garden; Xiamen Botanical Garden; Xishuangbanna Tropical Botanical Garden, CAS;

Adansonia rubrostipa (KMCC SE Rakotoarisoa)

APPENDIX 3

IUCN Red List Categories and Criteria

EXTINCT (EX)

A taxon is Extinct when there is no reasonable doubt that the last individual has died. A taxon is presumed Extinct when exhaustive surveys in known and/or expected habitat, at appropriate times (diurnal, seasonal, annual), throughout its historic range have failed to record an individual. Surveys should be over a time-frame appropriate to the taxon's life cycle and life form.

EXTINCT IN THE WILD (EW)

A taxon is Extinct in the Wild when it is known only to survive in cultivation, in captivity or as a naturalized population (or populations) well outside the past range. A taxon is presumed Extinct in the Wild when exhaustive surveys in known and/or expected habitat, at appropriate times (diurnal, seasonal, annual), throughout its historic range have failed to record an individual. Surveys should be over a time-frame appropriate to the taxon's life cycle and life form.

CRITICALLY ENDANGERED (CR)

A taxon is Critically Endangered when the best available evidence indicates that it meets any of the criteria A to E for Critically Endangered (see Section V), and it is therefore considered to be facing an extremely high risk of extinction in the wild.

ENDANGERED (EN)

A taxon is Endangered when the best available evidence indicates that it meets any of the criteria A to E for Endangered (see Section V), and it is therefore considered to be facing a very high risk of extinction in the wild.

VULNERABLE (VU)

A taxon is Vulnerable when the best available evidence indicates that it meets any of the criteria A to E for Vulnerable (see Section V), and it is therefore considered to be facing a high risk of extinction in the wild.

NEAR THREATENED (NT)

A taxon is Near Threatened when it has been evaluated against the criteria but does not qualify for Critically Endangered, Endangered or Vulnerable now, but is close to qualifying for or is likely to qualify for a threatened category in the near future.

LEAST CONCERN (LC)

A taxon is Least Concern when it has been evaluated against the criteria and does not qualify for Critically Endangered, Endangered, Vulnerable or Near Threatened. Widespread and abundant taxa are included in this category.

DATA DEFICIENT (DD)

A taxon is Data Deficient when there is inadequate information to make a direct, or indirect, assessment of its risk of extinction based on its distribution and/or population status. A taxon in this category may be well studied, and its biology well known, but appropriate data on abundance and/or distribution are lacking. Data Deficient is therefore not a category of threat. Listing of taxa in this category indicates that more information is required and acknowledges the possibility that future research will show that threatened classification is appropriate. It is important to make positive use of whatever data are available. In many cases great care should be exercised in choosing between DD and a threatened status. If the range of a taxon is suspected to be relatively circumscribed, and a considerable period of time has elapsed since the last record of the taxon, threatened status may well be justified.

NOT EVALUATED (NE)

A taxon is Not Evaluated when it has not yet been evaluated against the criteria.

THE CRITERIA FOR CRITICALLY ENDANGERED, ENDANGERED AND VULNERABLE

CRITICALLY ENDANGERED (CR)

A taxon is Critically Endangered when the best available evidence indicates that it meets any of the following criteria (A to E), and it is therefore considered to be facing an extremely high risk of extinction in the wild:

A. Reduction in population size based on any of the following:

1. An observed, estimated, inferred or suspected population size reduction of $\geq 90\%$ over the last 10 years or three generations, whichever is the longer, where the causes of the reduction are clearly reversible AND understood AND ceased, based on (and specifying) any of the following:
 - (a) direct observation
 - (b) an index of abundance appropriate to the taxon
 - (c) a decline in area of occupancy, extent of occurrence and/or quality of habitat
 - (d) actual or potential levels of exploitation
 - (e) the effects of introduced taxa, hybridization, pathogens, pollutants, competitors or parasites.
2. An observed, estimated, inferred or suspected population size reduction of $\geq 80\%$ over the last 10 years or three generations, whichever is the longer, where the reduction or its causes may

- not have ceased OR may not be understood OR may not be reversible, based on (and specifying) any of (a) to (e) under A1.
3. A population size reduction of $\geq 80\%$, projected or suspected to be met within the next 10 years or three generations, whichever is the longer (up to a maximum of 100 years), based on (and specifying) any of (b) to (e) under A1.
 4. An observed, estimated, inferred, projected or suspected population size reduction of $\geq 80\%$ over any 10 year or three generation period, whichever is longer (up to a maximum of 100 years in the future), where the time period must include both the past and the future, and where the reduction or its causes may not have ceased OR may not be understood OR may not be reversible, based on (and specifying) any of (a) to (e) under A1.
- B. Geographic range in the form of either B1 (extent of occurrence) OR B2 (area of occupancy) OR both:
1. Extent of occurrence estimated to be less than 100 km², and estimates indicating at least two of a-c:
 - a. Severely fragmented or known to exist at only a single location.
 - b. Continuing decline, observed, inferred or projected, in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) area, extent and/or quality of habitat
 - (iv) number of locations or subpopulations
 - (v) number of mature individuals.
 - c. Extreme fluctuations in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) number of locations or subpopulations
 - (iv) number of mature individuals.
 2. Area of occupancy estimated to be less than 10 km², and estimates indicating at least two of a-c:
 - a. Severely fragmented or known to exist at only a single location.
 - b. Continuing decline, observed, inferred or projected, in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) area, extent and/or quality of habitat
 - (iv) number of locations or subpopulations
 - (v) number of mature individuals.
- C. Population size estimated to number fewer than 250 mature individuals and either:
1. An estimated continuing decline of at least 25% within three years or one generation, whichever is longer, (up to a maximum of 100 years in the future) OR
 2. A continuing decline, observed, projected, or inferred, in numbers of mature individuals AND at least one of the following (a-b):
 - (a) Population structure in the form of one of the following:
 - (i) no subpopulation estimated to contain more than 50 mature individuals, OR
 - (ii) at least 90% of mature individuals in one subpopulation.
 - (b) Extreme fluctuations in number of mature individuals.
- D. Population size estimated to number fewer than 50 mature individuals.
- E. Quantitative analysis showing the probability of extinction in the wild is at least 50% within 10 years or three generations, whichever is the longer (up to a maximum of 100 years).

ENDANGERED (EN)

A taxon is Endangered when the best available evidence indicates that it meets any of the following criteria (A to E), and it is therefore considered to be facing a very high risk of extinction in the wild:

- A. Reduction in population size based on any of the following:
1. An observed, estimated, inferred or suspected population size reduction of $\geq 70\%$ over the last 10 years or three generations, whichever is the longer, where the causes of the reduction are clearly reversible AND understood AND ceased, based on (and specifying) any of the following:
 - (a) direct observation
 - (b) an index of abundance appropriate to the taxon
 - (c) a decline in area of occupancy, extent of occurrence and/or quality of habitat
 - (d) actual or potential levels of exploitation
 - (e) the effects of introduced taxa, hybridization, pathogens, pollutants, competitors or parasites.

2. An observed, estimated, inferred or suspected population size reduction of $\geq 50\%$ over the last 10 years or three generations, whichever is the longer, where the reduction or its causes may not have ceased OR may not be understood OR may not be reversible, based on (and specifying) any of (a) to (e) under A1.
 - (ii) area of occupancy
 - (iii) area, extent and/or quality of habitat
 - (iv) number of locations or subpopulations
 - (v) number of mature individuals.
 3. A population size reduction of $\geq 50\%$, projected or suspected to be met within the next 10 years or three generations, whichever is the longer (up to a maximum of 100 years), based on (and specifying) any of (b) to (e) under A1.
 4. An observed, estimated, inferred, projected or suspected population size reduction of $\geq 50\%$ over any 10 year or three generation period, whichever is longer (up to a maximum of 100 years in the future), where the time period must include both the past and the future, AND where the reduction or its causes may not have ceased OR may not be understood OR may not be reversible, based on (and specifying) any of (a) to (e) under A1.
- B. Geographic range in the form of either B1 (extent of occurrence) OR B2 (area of occupancy) OR both:
1. Extent of occurrence estimated to be less than 5000 km², and estimates indicating at least two of a-c:
 - a. Severely fragmented or known to exist at no more than five locations.
 - b. Continuing decline, observed, inferred or projected, in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) area, extent and/or quality of habitat
 - (iv) number of locations or subpopulations
 - (v) number of mature individuals.
 - c. Extreme fluctuations in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) number of locations or subpopulations
 - (iv) number of mature individuals.
 2. Area of occupancy estimated to be less than 500 km², and estimates indicating at least two of a-c:
 - a. Severely fragmented or known to exist at no more than five locations.
 - b. Continuing decline, observed, inferred or projected, in any of the following:
 - (i) extent of occurrence
- C. Population size estimated to number fewer than 2500 mature individuals and either:
1. An estimated continuing decline of at least 20% within five years or two generations, whichever is longer, (up to a maximum of 100 years in the future) OR
 2. A continuing decline, observed, projected, or inferred, in numbers of mature individuals AND at least one of the following (a-b):
 - (a) Population structure in the form of one of the following:
 - (i) no subpopulation estimated to contain more than 250 mature individuals, OR
 - (ii) at least 95% of mature individuals in one subpopulation.
 - (b) Extreme fluctuations in number of mature individuals.
- D. Population size estimated to number fewer than 250 mature individuals.
- E. Quantitative analysis showing the probability of extinction in the wild is at least 20% within 20 years or five generations, whichever is the longer (up to a maximum of 100 years).
- ### VULNERABLE (VU)
- A taxon is Vulnerable when the best available evidence indicates that it meets any of the following criteria (A to E), and it is therefore considered to be facing a high risk of extinction in the wild:
- A. Reduction in population size based on any of the following:
1. An observed, estimated, inferred or suspected population size reduction of $\geq 50\%$ over the last 10 years or three generations, whichever is the longer, where the causes of the reduction are: clearly reversible AND understood AND ceased, based on (and specifying) any of the following:
 - (a) direct observation
 - (b) an index of abundance appropriate to the taxon
 - (c) a decline in area of occupancy, extent of occurrence and/or quality of habitat

- (d) actual or potential levels of exploitation
 - (e) the effects of introduced taxa, hybridization, pathogens, pollutants, competitors or parasites.
2. An observed, estimated, inferred or suspected population size reduction of $\geq 30\%$ over the last 10 years or three generations, whichever is the longer, where the reduction or its causes may not have ceased OR may not be understood OR may not be reversible, based on (and specifying) any of (a) to (e) under A1.
3. A population size reduction of $\geq 30\%$, projected or suspected to be met within the next 10 years or three generations, whichever is the longer (up to a maximum of 100 years), based on (and specifying) any of (b) to (e) under A1.
4. An observed, estimated, inferred, projected or suspected population size reduction of $\geq 30\%$ over any 10 year or three generation period, whichever is longer (up to a maximum of 100 years in the future), where the time period must include both the past and the future, AND where the reduction or its causes may not have ceased OR may not be understood OR may not be reversible, based on (and specifying) any of (a) to (e) under A1.
- B. Geographic range in the form of either B1 (extent of occurrence) OR B2 (area of occupancy) OR both:
1. Extent of occurrence estimated to be less than 20,000 km², and estimates indicating at least two of a-c:
 - a. Severely fragmented or known to exist at no more than 10 locations.
 - b. Continuing decline, observed, inferred or projected, in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) area, extent and/or quality of habitat
 - (iv) number of locations or subpopulations
 - (v) number of mature individuals.
 - c. Extreme fluctuations in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) number of locations or subpopulations
 - (iv) number of mature individuals.
 2. Area of occupancy estimated to be less than 2000 km², and estimates indicating at least two of a-c:
 - a. Severely fragmented or known to exist at no more than 10 locations.
- b. Continuing decline, observed, inferred or projected, in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) area, extent and/or quality of habitat
 - (iv) number of locations or subpopulations
 - (v) number of mature individuals.
 - c. Extreme fluctuations in any of the following:
 - (i) extent of occurrence
 - (ii) area of occupancy
 - (iii) number of locations or subpopulations
 - (iv) number of mature individuals.
- C. Population size estimated to number fewer than 10,000 mature individuals and either:
1. An estimated continuing decline of at least 10% within 10 years or three generations, whichever is longer, (up to a maximum of 100 years in the future) OR
 2. A continuing decline, observed, projected, or inferred, in numbers of mature individuals AND at least one of the following (a-b):
 - (a) Population structure in the form of one of the following:
 - (i) no subpopulation estimated to contain more than 1000 mature individuals, OR
 - (ii) all mature individuals are in one subpopulation.
 - (b) Extreme fluctuations in number of mature individuals.
- D. Population very small or restricted in the form of either of the following:
1. Population size estimated to number fewer than 1000 mature individuals.
 2. Population with a very restricted area of occupancy (typically less than 20 km²) or number of locations (typically five or fewer) such that it is prone to the effects of human activities or stochastic events within a very short time period in an uncertain future, and is thus capable of becoming Critically Endangered or even Extinct in a very short time period.
- E. Quantitative analysis showing the probability of extinction in the wild is at least 10% within 100 years.
