Fungicide resistance is an increasing risk to crop production and knowledge around the frequencies of relevant resistant genotypes is critical for informed management strategies. Using droplet digital PCR of leaf lesion DNA and the net blotch pathosystem in barley, we demonstrate the ability to quantify both *Pyrenophora teres* f. *teres* and *P. teres* f. *maculata*, and 23 genotypes associated with different levels of sensitivity to DMI (demethylation inhibitor) or SDHI (succinate dehydrogenase inhibitor) fungicides. Across 20 fields sampled in Western Australia in 2021, genotypes associated with reduced sensitivity or resistance to

DMIs were detected in every field (3 to 92% of the population). Genotypes associated with reduced sensitivity or resistance to SDHIs were detected in 15 fields (1 to 89% of the population). The most frequently detected pathogen was *P. teres* f. *maculata*, while the most frequently detected genotypes were the PtTi insert (*Cyp51A* promoter) and N75S (*SdhC* subunit). Across the combined field data, the frequency of reduced sensitivity or resistance genotypes was 31% for DMIs and 18% for SDHIs, likely reflecting the historical use of each fungicide. Fungicide applications varied between fields, however no strategy resulted in populations with less than 10% of both DMI and SDHI reduced sensitivity or resistant genotypes. This workflow will improve investigations into fungicide management impacts in the field for both researchers and growers.

FUNGICIDE RESISTANCE MECHANISMS AND MANAGEMENT IN FUSARIUM GRAMINEARUM SPECIES COMPLEX

MA Zhonghua . (1)

(1) Zhejiang Univ., Hangzhou, CHINA

Text

Fusarium head blight (FHB) caused by *F. graminearum* (Fg) and several other Fusarium spp. is a devastating disease of cereal crops worldwide. In addition to yield losses, mycotoxins deoxynivalenol (DON) and its derivatives produced by Fg complex in infested grains represent a serious threat to human and animal health. Currently, the application of fungicides during wheat anthesis is a primary method for management of FHB. In this presentation, we will review recent advances in 1) chemical control and fungicide resistance situations in FHB; 2) molecular mechanisms of Fg complex to various fungicides, including benzimidazoles, cyanoacrylates, sterol demethylation inhibitors, and succinic dehydrogenase inhibitors; 3) management strategy against fungicide resistance in FHB. In addition, DON has been the most frequently detected mycotoxin in cereal grains worldwide, we will also summary effects of fungicide applications on DON management.

Text

Emergence of fungicide resistance in plant pathogenic fungi impairs chemical control. *Erysiphe necator*, the pathogen causing grapevine powdery mildew has been effective in developing fungicide resistance. This includes resistance against demethylation inhibitors, and boscalid, a succinate dehydrogenase inhibitor. DNA markers of the resistance are nucleotide changes in the coding genes of the proteins targeted by those fungicides, *CYP51* and *sdhB*. In *E. necator*, these markers are known as A495T and A794G, respectively. By combining datasets on the prevalence of A495T (in 1415 samples) and A794G (in 505 samples) obtained by simple diagnostic methods, we aimed at investigating (i) if the prevalence of the markers is influenced by fungicide treatments, and/or the wine region of sample origin; and (ii) the co-occurrence of A495T and A794G in individual samples. The prevalence of A495T was not significantly different between treated and untreated fields. Presence of A794G was strongly correlated with fungicide treatments. The prevalence of both markers was dependent on the geographic origin of the samples, i. e., wine-region. Moreover, the presence of the two markers in the same sample was found not to be independent, that is, one marker occurred in the same sample more frequently if the other marker was also present. Our results, beside others, imply that fungicide use should be adjusted regionally, and should ideally be based on monitoring of fungicide resistance.

FROM MITOCHONDRIAL GENOME TO STROBILURIN RESISTANCE: IN SILICO ANALYSIS OF GROUP I INTRON EVOLUTION IN FUNGAL PLANT PATHOGENS

CINGET Benjamin. (1,2), DUPLAIN Rebecca. (1,2), BELANGER Richard. (1,2)

(1) Université Laval, Québec, CANADA; (2) Centre de recherche en innovation des végétaux, Québec, CANADA

Text

The QoIs, also known as strobilurins, represent a group of fungicides with arguably the greatest resistance risk. In 2023, the FRAC reported more than 50 species with a resistant status to QoIs. Resistance is mainly caused by the replacement of Glycine into Alanine (G143A) in the target cytochrome b protein. This substitution is conferred by a single nucleotide mutation in the cytochrome b gene. In fungi, a group I intron, situated directly after codon 143, prevents QoI resistance by blocking the G143A mutation. However, group I introns have the ability to move from a donor gene into an intronless acceptor gene. The mobility of group I introns has been speculated to be a compensation mechanism to restore the potential for QoI resistance mutation. On this basis, an extensive in silico analysis of whole mitochondrial fungal genomes was performed to characterize the distribution of the group I introns among CFR fungal species. Our results showed that one subtype of group I is associated with QoI resistance and that CFR fungi can be classified according to the presence/absence of this subtype in their genome, resulting in their capacity to acquire the G143A mutation, and thus become resistant. Accordingly, this classification allows to predict the potential of QoI resistance among fungi. At a time when the use of synthetic fungicides can lead to resistance and environmental problems, this predictive model could be a valuable tool in managing the use of QoIs for disease control.

Text

Azoles are commonly used control Wheat powdery mildew caused by Blumeria graminis f. sp. tritici (Bgt). Tebuconazole and epoxiconazole were used for more than 10 years, while prothioconazole was registered for the control of wheat powdery mildew in 2019 in China. To investigate the current status of azole resistance in Bgt. Totally 106 isolates collected in 9 provinces in China were determined by leaf segment method. The EC50 values of Bgt isolates in 2019 was significantly right shift in comparison with the isolates before 2000 to all three azoles. In addition, there was positive cross resistance among the three azoles. According to amino acid subsitutues of BgtCYP51, 7 types were classified. Type I (79S136Y175K442F496R), type II (79S136W175K442F496R), and type III (79T136F175N442F496R) were dominantly genotypes including 89.34% isolates, while type I as the wild type were only 10.66%. Currently, type II, and type III as the main resistance type were dominantly genotypes in China. The EC50 of Type II and type III isolates to three azoles were significantly higher than that of wild Type I. The expression levels of Bgtcyp51 gene were increased in the isolates reduced sensitivity to the three azoles. The findings in this study suggest that azole resistant is very common in Bgt in China. Molecular basis of azole resistance were caused by Y136F, Y136W, S79T/Y136F/K175N mutations, over-expression, and increased gene copy numbers of Bgtcyp51 gene, individually or synergetically.

MOLECULAR CHARACTERIZATION OF PROPICONAZOLE RESISTANT TILLETIA HORRIDA ISOLATES IN THE UNITED STATES

KHANAL Sabin. (1,2), ZHOU Xin-Gen. (2), ANTONY-BABU Sanjay. (1)

(1) Texas A&M University, College Station, UNITED STATES; (2) Texas AgriLife Research Center, Beaumont, UNITED STATES

Text

Rice kernel smut, caused by Tilletia horrida, is a new emerging disease threatening rice production in the US. Heavy use of propiconazole fungicides of the demethylation inhibitor (DMI) class for midseason preventive applications has resulted in reduced efficacy or even failures to control kernel smut in recent years. Propiconazole resistance might be involved in observed control efficacy reductions. In this study, 63 isolates of T. horrida were collected from across the US. Three of the isolates from organic rice, where no fungicides were applied ever, were used to establish the propiconazole baseline sensitivity of 0.2 ml/ml. While most isolates shown no inhibition at the concentration of 10 ml/ml, only 14 isolates tolerated at 25 ml/ml, with a single isolate that was not inhibited even at 50 ml/ml. Variations in CYP51 gene, the target gene for propiconazole resistance, in the resistant and sensitive isolates were further characterized, and mutations were confirmed to be present in CYP51 gene of the resistant isolates. The results show, for the first time, that propiconazole

resistance has developed in the US T. horrida populations. There is an urgent need for further research on searching for effective fungicides alternative to propiconazole for managing kernel smut in rice.

QOI FUNGICIDE RESISTANCE IN SUNFLOWER PHOMOPSIS

MOHAN Karthika. (1), MARKELL Samuel. (1), HARVESON Robert. (2), **MATHEW Febina. (1)**

(1) North Dakota State University, Fargo, UNITED STATES; (2) Panhandle Research and Extension Center, University of Nebraska-Lincoln, Scottsbluff, UNITED STATES

Text
Phomopsis stem canker of sunflower (*Helianthus annuus*), primarily caused by *Diaporthe helianthi* (syn. *Phomopsis helianthi*), can cause yield losses up to 40% worldwide. For managing Phomopsis stem canker, fungicides containing Quinone outside Inhibitor (QoI) are recommended, which have a high risk to select resistant fungal strains. The objective of this study was to assess sensitivity of *D. helianthi* to azoxystrobin (QoI) fungicide in the greenhouse. The experiment was established in a factorial completely randomized design [isolates (10) x fungicide concentration (3)] and repeated once. For each factorial combination, three seeds of a *Diaporthe*-susceptible hybrid were sown in two pots each containing potting mix. At four true leaves growth stage, fungicide was sprayed using a backpack sprayer. Plants with no fungicide served as control. After 24-h, all plants were inoculated using mycelial-contact inoculation method and maintained at 25°C. Disease severity was rated 10-d post-inoculation, and analyzed using relative treatment effects (RTE). A significant isolate-fungicide concentration interaction (P<0.0001) was observed. For isolates with QoI-reduced sensitivity, significant differences in RTE were not observed between control and fungicide-treated plants using 95% confidence intervals. The molecular basis of QoI resistance was identified as G143A mutation, and farmers must consider alternating fungicides with different modes of actions for Phomopsis stem canker management.

Text
Cercospora leaf spot (CLS) is the most damaging foliar disease of sugar beet globally. To combat CLS, multifaceted efforts are widely employed, including breeding for resistance,

cultural practices, and the application of fungicides. However, populations of Cercospora beticola have become resistant to most fungicides used for CLS management, including those in the sterol demethylation inhibitor (DMI) class of fungicides. In this study, we sampled nearly 600 isolates of Cercospora beticola from MN and ND during the 2021 sugar beet growing season. For each isolate, EC50 values were determined for DMIs tetraconazole (Eminent), prothioconazole (Proline), difenoconazole (Inspire), and mefentrifluconazole (Revysol). Using the CYP51 gene sequence for each isolate, we determined that the synonymous E170 mutation and the synonymous/nonsynonymous L144(F) can be used to predict resistance to these four DMIs. The prevalence and accuracy of the six mutation combinations were calculated and specific combinations can predict resistance with greater than 90% accuracy. Interestingly, one prevalent mutation combination resulted identified cross-resistance to difenoconazole and mefentrifluconazole, but sensitivity to tetraconazole and prothioconazole. This data reveals the importance of codon bias in fungicide resistance and is the first demonstration of the use of synonymous mutations to predict fungicide resistance.

LOCATION, LOCATION, LOCATION: THE FIRST RULE OF POSTHARVEST EPIDEMIOLOGY FOR LOCATING FUNGICIDE RESISTANT BLUE MOLD FUNGI IN COMMERCIAL PACKINGHOUSES

CASTRO Johanny. (1), JURICK II Wayne M.. (2), PETER Kari A.. (1)

(1) Penn State University, Biglerville, UNITED STATES; (2) USDA-ARS, Beltsville, UNITED STATES

Text

Apple blue mold (*Penicillium* spp.) impacts fruit quality and increases the chances of mycotoxin contamination in processed fruit products. Blue mold is the primary postharvest apple disease in the USA. Management relies on synthetic fungicides; consequently, fungicide resistance has been reported. Therefore, the role of inoculum sources (IS) was evaluated as reservoirs of *Penicillium* spp. having fungicide resistance phenotypes. Ten orchards and packinghouses were sampled in the Mid-Atlantic, USA, between 2020 and 2022. The surfaces of harvesting equipment, packinghouse facilities and cold room air, dump tank water, and apple fruit surfaces were sampled. *Penicillium* spp. were isolated from each IS using Petri dishes containing PDA amended with discriminatory doses of pyrimethanil, fludioxonil, and thiabendazole. The frequency of *Penicillium* spp. per IS was determined, and representative isolates were identified to species using DNA sequencing. *Penicillium* spp. from apples with blue mold were assessed on discriminatory doses as above. The packinghouse and cold room air, and dump tank water had the highest frequency of fungicide resistant isolates (10%-65%), while the frequency was 5%-34% on rotten apple fruit. *P. expansum* was the most frequently isolated species in both, IS and apples with blue mold. The differences in the IS indicate that targeted management practices are needed and can now be executed, based on these findings, to prevent fungicide failures on stored fruit.

THE IN VITRO AND IN VIVO PHOSPHITE SENSITIVITY OF PHYTOPHTHORA CINNAMOMI ISOLATES FROM AVOCADO ORCHARDS IN TAIWAN

LIANG Yu-Ping. (1), NI Hui-Fang. (1)

(1) Chiayi Agricultural Experiment Station, Taiwan Agricultural Research Institute, Chiayi City, TAIWAN

Text

Phytophthora root rot (PRR) caused by *Phytophthora cinnamomi* is one of the most important diseases of avocado in Taiwan. The application of phosphonate fungicides has been used to manage this disease for decades in many countries, and it had been observed that the prolonged use of phosphite had led to a reduced sensitivity to phosphite in *P. cinnamomi* isolates. In this study, the phosphite sensitivity of 50 *P. cinnamomi* isolates from 18 Taiwanese avocado orchards was tested with phosphite-amended Ribeiro's modified medium. The results showed that most isolates were sensitive or intermediate sensitive to phosphite, while only 8 isolates were tolerant to phosphite, found in only 4 orchards. Interestingly, there was no extensive phosphonate application history in these 4 orchards, and the genotypes of the tolerant isolates were all different among these orchards. Three isolates representing sensitive, intermediate sensitive and tolerant isolates were inoculated to avocado treated with different rates of phosphite. The detached root bioassay showed that the tolerant isolate had higher colonization rates than the other two isolates when the root phosphite concentrations were over 1000 µg/g-fresh weight. The information obtained in this study will be helpful for establishing the critical root phosphite concentration required for suppressing *P. cinnamomi* in avocado, and managing the development of phosphite resistance.

DETECTION AND CHARACTERIZATION OF FUNGICIDE RESISTANT NET BLOTCH PATHOGEN PYRENOPHORA TERES F. TERES ISOLATES FROM ESTONIA

KIIKER Riinu. (1), PÜTSEPP Regina. (1), MÄE Andres. (1), ANDRESEN Liis. (1), PÕLLUMAA Lee. (1)

(1) Centre of Estonian Rural Research and Knowledge, Jõgeva Alevik, ESTONIA

Text

Reliance on fungicides in disease control creates a selection pressure for the evolution of resistance in fungal pathogens. One of the major pathogens of barley in Northern Europe is *Pyrenophora teres f. teres* (*Ptt*). FRAC has classified *Ptt* as medium-risk pathogen for developing resistance to fungicides. We isolated a total of 206 *Ptt* single-spore isolates from nine different counties across Estonia in 2021 and 2022. The baseline sensitivity of Estonian population to demethylase inhibitor (DMI; Cyp51), succinate dehydrogenase inhibitor (SDHI; SdhC and SdhD) and strobilurin (QoI; CytB) fungicides was established. Generally, fungicide sensitivity in the Estonian *Ptt* population is high or moderately declined. Among the samples, we found single isolates showing resistance to tested fungicides. The prevalence and contribution of different resistance mechanisms involved in fungicide sensitivity were investigated in *Ptt* population. A high proportion of *Ptt* isolates carry a DMI resistance-

associated substitution F489L in Cyp51. Further investigation revealed a 134 bp insert in Cyp51 promoter in few isolates only from year 2022. Differences in sensitivity to the SDHI fungicides were observed among the isolates with mutations C-S135R and D-H134R in SDH subunits. The sensitivity to azoxystrobin decreased in CytB F129L mutated isolates. The data presented confirm the ongoing evolution of fungicide sensitivity in the *Ptt* population.

PROTEOMIC ANALYSIS REVEALED THAT THE OOMYCETICIDE PHOSPHITE MAY POSSESS A MULTI-MODAL FUNCTION IN AN OOMYCETE PATHOSYSTEM

TAN Kar-Chun. (1), ANDRONIS Christina. (1,2), JACQUES Silke. (1), LOPEZ-RUIZ Francisco. (1), LIPSCOMBE Richard. (2)

(1) Curtin University, Perth, AUSTRALIA; (2) Proteomics International, Perth, AUSTRALIA

Text
Phytophthora cinnamomi is a phytopathogenic oomycete that causes dieback disease in a wild variety of dicots of significant conservational and horticultural importance. The oomyceticide phosphite is widely used to minimise the impact of dieback however, the mode of action of the chemical has not been fully deciphered. It is unclear whether it only works directly on the pathogen or also through the host. Additionally, resistance to phosphite is emerging in *P. cinnamomi* isolates and other oomycete phytopathogens. In this study, we used a label-free quantitative proteomics approach to investigate possible modes of action of phosphite on the pathogen as well as a model host. Phosphite was applied to sensitive and resistant *P. cinnamomi* isolates. Significant changes in protein abundances associated with general metabolism, stress, signalling and regulation of gene expression were observed in the sensitive isolate only. When the model host *Lupinus angustifolius* was treated with phosphite, enrichment of proteins that are associated with photosynthesis, carbon fixation and lipid metabolism in the host was observed. An increase in the production of a range of defence-related proteins was also observed. Based on our findings, we proposed possible models of the multi-modal action of phosphite that directly targets the pathogen as well as alters plant metabolism and immune response. This will be discussed.

P5.4-011

MEFENOXAM SENSITIVITY TYPING OF SOUTH AFRICAN PHYTOPHTHORA ISOLATES

MÖLLER Heike. (1), ROSE Lindy Joy. (1)

(1) Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text
Citrus nursery plants infected with *Phytophthora citrophthora* and *Phytophthora nicotianae* are treated with mefenoxam, a systemic fungicide, effective for the control of oomycetes. Resistance to mefenoxam in oomycetes has recently been reported in several countries

including South Africa. However, the genetic mutations responsible for the resistance are unknown. Furthermore, the full genome for *P. citrophthora* has not yet been published which leads to further complications in reliable mutation detection. In this study, 11 *P. citrophthora* and *39 P. nicotianae* isolates with unknown sensitivity to mefenoxam were subjected to fungicide sensitivity evaluation. The isolates were exposed to eight mefenoxam concentrations ranging from 0 to 100 ppm to classify isolates as sensitive, intermediate, or resistant to mefenoxam. Six isolates were sensitive to mefenoxam (relative growth (RG) at 100 pm < 10%), 36 intermediate (RG 10 - 30%) and eight resistant (RG > 30%). Three isolates from each category were selected per species for whole genome sequencing. The full genome sequences from isolates with differing mefenoxam sensitivity levels can be compared to identify the genetic markers responsible for resistance development. Once the mutations are identified, a diagnostic quantitative PCR can be developed to detect these and predict an isolate's sensitivity level accurately. The monitoring of resistance to mefenoxam is vital to fungicide efficacy and its responsible use in citrus production.

P5.4-012

CROSS-RESISTANCE OF CLARIREEDIA JACKSONII TO DMI FUNGICIDES

RETHER Andrea. (1), YU Katherine. (1), HSIANG Tom. (1)

(1) University of Guelph, Guelph, CANADA

Text

Dollar spot is the most common turfgrass disease of the Great Lakes region in North America, and is controlled by repeat fungicide applications every season. There are reports of decreased sensitivity to propiconazole, a demethylation inhibiting (DMI) fungicide, in populations of *Clarireedia jacksonii*, the causal agent. Cross-resistance occurs when an organism shows resistance to more than one fungicide with the same mode of action, and had been reported for *C. jacksonii* and DMI fungicides in earlier studies, but not for more recently introduced DMI fungicides. The purpose of this study was to compare resistance values among 20 isolates of *C. jacksonii* with varying sensitivity to propiconazole (very sensitive to highly resistant to propiconazole) and compare them using correlation analysis. EC_{50} values (effective concentration for 50% inhibition) were generated for each isolate for each fungicide, and these values were subjected to pairwise correlation analysis. Among the 11 fungicides examined in amended agar tests, pairwise correlation values (R) ranged from 0.56 to 0.97 ($p<0.007$). The results suggest that there is significant cross-resistance among these DMI fungicides examined in *C. jacksonii*.

P5.4-013

FUNGICIDE RESISTANCE ACTION COMMITTEE (FRAC) MOA POSTER

TORRIANI Stefano. (1)

(1) Syngenta, Stein, SWITZERLAND

Text
Fungicides have become an integral part of efficient food production. The loss of a fungicide to agriculture through resistance is a problem that affects us all. FRAC works to prolong the effectiveness of fungicides liable to encounter resistance problems and to limit crop losses should resistance occur. Fungicide resistance management strategies must combine the long-term conservation of fungicide effectiveness with relevant use patterns that are sufficient to satisfy the needs of the farmer. Thus to have a chance of success, any strategy must be reached by agreement and depend upon a commitment to implementation from all supply companies involved. Also, it must be understandable and acceptable to the farmer. FRAC provides background information as well as annually updated Fungicide Resistance Management Recommendations for fungicides of the major modes of action. The FRAC Mode of Action (MoA) classification provides growers, advisors, extension staff, consultants and crop protection professionals with a guide to the selection of fungicides for use in an effective and sustainable fungicide resistance management strategy. Here we present usefull information about Fungicide Classification and Resistance Management.

P5.4-014

DEVELOPMENT OF A MICROPLATE ABSORBANCE ASSAY FOR ASSESSING FUNGICIDE SENSITIVITY OF FILAMENTOUS FUNGI AND COMPARISON TO AN AMENDED AGAR ASSAY

MCNAB Edward. (1), RETHER Andrea. (1), HSIANG Tom. (1)

(1) University of Guelph, Guelph, CANADA

Text
An absorbance assay using 96-well microplates to assess the sensitivity of *Clarireedia jacksonii*, a non-sporulating fungus, to the fungicide propiconazole was developed as an alternative to the labor intensive amended-agar assays. This microplate assay allowed for the assessment of multiple isolates at different fungicide concentrations with many technical replications in a single plate. Among methods tested for inoculating microplate wells, our “microplug” method was the simplest to perform, requiring only a micropipette with 1 ml tips to punch plugs from agar plates. The EC_{50} values for 30 isolates of *C. jacksonii* with varying sensitivities to propiconazole were calculated for the microplate absorbance assay and for a traditional amended-agar assay. A correlation of $\log_{10}$ transformed EC_{50} values of both assays revealed a significant relationship ($R = 0.75$, $p < 0.001$). Additionally, the microplate assay was more sensitive in detecting resistance ($EC_{50} > 0.1$ µg/ml) and revealed five isolates to be resistant to propiconazole that were not found as such with the amended agar assay. Only one of the assessed isolates was observed to have a significantly different EC_{50} value between the two assays that resulted in a different sensitivity classification. These results imply that the microplate absorbance assay as implemented in this study is not exactly equivalent to the traditional amended agar assay for estimating EC_{50} values, but further developments may bring the values closer.

P5.4-015

FUNGICIDE RESISTANCE OCCURRENCE IN THE CUCURBIT POWDERY MILDEW FUNGUS IN THE UNITED STATES

MCGRATH Margaret. (1)

(1) Cornell University, Riverhead, Ny, UNITED STATES

Text
Fungicides at risk for resistance are critical for effective cucurbit powdery mildew (CPM) control. Podosphaera xanthii isolates were collected from research and commercial plantings each year since 1990 mostly in New York. Their fungicide sensitivity was determined with a leaf disk bioassay. Resistance to FRAC code 11 fungicides, boscalid (FRAC 7), quinoxyfen (13) and cyflufenamid (U6) were detected 3, 6, 8 and 5 years, respectively, after products with these became commercially available for CPM in the USA. Cyflufenamid resistance developed quickly despite label restrictions compelling implementation of a good resistance management program (no consecutive applications allowed and maximum of two applications per crop) and availability of up to three other effective chemistries (FRAC 3, 13, 50) to use in rotation. Resistance to FRAC code 1 and 11 fungicides continues to be very common although these have not been recommended for years. Boscalid resistance is somewhat common. Sensitivity to FRAC 3 chemistry has exhibited little change since 1990s, thus while the pathogen is fully resistant to the first fungicide in this group (triadimefon), fungicides developed subsequently have provided good to excellent control in field efficacy trials. Isolates have been detected with resistance to FRAC 1, 7 (boscalid), 11, 13, and U6 chemistry and with reduced sensitivity to fluopyram (7) and metrafenone (50). Multi-fungicide resistance is a challenge to effectively managing CPM.

P5.4-016

DOES RESISTANCE OF WINTER WHEAT VARIETIES AFFECT THE INFECTION AND SPREAD OF FUNGICIDE-RESISTANT ZYMOSEPTORIA TRITICI MUTANTS?

BERGER Beatrice. (1), ZAMANI-NOOR Nazanin. (1), RODEMANN Bernd. (1)

(1) Julius Kuehn Institute, Institute for Plant Protection in Field Crops and Grassland, Braunschweig, GERMANY

Text
Septoria leaf blotch (SLB) caused by *Zymoseptoria tritici* is one of the most important diseases in wheat. Resistant varieties and application of DMI and SDHI fungicides are used to controll SLB. In order to avoid resistance and maintain the effectiveness of fungicides for as long as possible, different groups of active substances should be used alternately and attention should be paid to a diverse cultivation of resistant wheat varieties. However, the extent to which the resistance of wheat varieties influences the infection and spread of fungicide-resistant *Z. tritici* mutants in the pathogen population is still unclear. Here we tested different wheat varieties and estimated their susceptibilities to *Z. tritici* under field conditions. Furthermore, we isolated *Z. tritici* from field samples and re-inoculated isolates with different virulences to a range of wheat varieties growing under glasshouse conditions. Additionally, the effect of different fungicidal agents on *Z. tritici* infection depending on variety resistance was investigated. For this purpose, infestation development was visually recorded over a period of 35 dpi and microtiterassays with DMI (Mefentrifluconazole, Epoxiconazole) and SDHI (Bixafen, Fluopyram) fungicides were performed. Results indicated a high effectivness of Mefentrifluconazole against *Z. tritici*, while Epoxiconazole, Bixafen and Fluopyram showed high variances. Relations between wheat varities and the virulence of the pathogen were rather weak.

P5.4-017

FUNGICIDE SENSITIVITY AND FITNESS PROFILES OF VENTURIA INAEQUALIS: AN INTEGRATED APPROACH TO EFFECTIVE APPLE SCAB CONTROL

LECCHI Beatrice. (1), MADDALENA Giuliana. (1), MARCIANÒ Demetrio. (1), TOFFOLATTI Silvia Laura. (1)

(1) University of Milan, Milano, ITALY

Text

Nowadays chemical control, based on repeated fungicide application, represents the principal means to reduce the severe damages caused by *Venturia inaequalis*, the ascomycete responsible of apple scab. The onset of resistance is a consequence of pathogen adaptation under field conditions. Fungicide resistance is a widespread phenomenon that involves single site classes and should be monitored to predict the shift in pathogen populations sensitivity and prolong the active life of fungicides. The aim of this work was the phenotypic characterization of *V. inaequalis* strains collected at different altimetric areas in Northern Italy orchards for the sensitivity profile to five active substances (dodine, trifloxystrobin, cyprodinil, myclobutanil, boscalid). Fitness traits, like mycelial growth and conidial production (concentration and size), were assessed on each strain. The overall results shown an altitude-dependent spore production and an equal competitivity between resistant and sensitive strains. Some advantages in terms of mycelial growth and conidia production were found for cyprodinil and trifloxystrobin resistant strains, suggesting that the latter could spread and replace the sensitive ones in filed populations. Moreover, the occurrence of multidrug resistant strains along with the lack of fitness penalty underlines the relevance of antiresistance strategy application as a mean to achieve an effective disease control in an ever-changing resistance scenario.

Text

Net- and spot-type net blotches of barley, caused by the related fungal pathogens

Pyrenophora teres f. teres (Ptt) and P. teres f. maculata (Ptm), respectively, are major diseases of barley in many parts of the world. As host resistance to both diseases is moderate at best, fungicides such as demethylase inhibitors (DMI) and succinate dehydrogenase inhibitors (SDHI) are often used to control these diseases. In Australia, in recent years there have been increasing detections of cases of resistance (R) and reduced sensitivity (RS) to both DMI and SDHI fungicides in both pathogens. Practices that promote frequencies of the RS and/or R types in the pathogen populations reduce efficacies of fungicide products. However, frequencies of the R or RS strains at which products become ineffective in the field is unclear. In this presentation we will report on results from field and glasshouse studies on dose-responses of Ptm and Ptt to DMI and SDHI fungicides. Results such as these are key inputs in (economic) models for determination of threshold frequencies, of the R or RS or mixtures of both in the pathogens populations, at which it would be beneficial to adjust treatment programmes when resistance is increasing.

RESISTANCE OF PHYTOPHTHORA COLOCASIAE TO AZOXYSTROBIN IN FUJIAN, CHINA

CHEN Songyu. (1), WANG Jingmiao. (1), ZHENG Yulong. (1), **CHEN Fengping. (1)**

(1) Fujian Agriculture and Forestry University, Fuzhou, CHINA

Text

Taro leaf blight caused by Phytophthora colocasiae is the mainly disease in taro production. The quinone outside inhibitor (QoI) azoxystrobin has been uesd to manage this disease. Despite the application of azoxystrobin, the disease still occurs frequently in Fujian, China. In order to explore the reason, the sensitivity of 40 Phytophthora colocasiae strains collected from different cities in Fujian to azoxystrobin were evaluated by mycelial growth inhibition assay. The result showed that 92.5% strains possessed relative growth greater than 80% at discriminatory dose of 10 μg/mL supplemented with salicylhydroxamic acid at 50 μg/mL, while 7.5% strains grew less than 80%. The further analysis of mitochondrial cytochrome b gene showed that two types of strains had only one nucleotide variant, which leading to codon change at 425(GGT to GCT) in the cyt b gene and an amino acid substitution at position 142 (glycine to alanine). The above data indicated high resistance frequency of P. colocasiae to azoxystrobin in Fujian, China. The taro grower should stop use of QoIs in management of taro leaf blight in these fields.

Text

Erysiphe necator, the causal agent of grapevine powdery mildew (GPM) is controlled mostly by sterol demethylation inhibitor (DMI) fungicides, which act by inhibiting eburicol 14α-demethylase (CYP51), a key enzyme in the biosynthesis of ergosterol. The occurrence and spread of the fungicide resistance in GPM populations have been reported; a common marker of DMI resistance is an A to T nucleotide substitution at position 495 (A495T) in the *CYP51* gene. We analysed the effects of (i) wine region, cultivar and DMI fungicide treatment, (ii) season and (iii) year of collection on the probability of the presence of A495T in Hungarian vineyards. More than 2000 field samples were collected from GPM populations in six wine regions, and the presence of A495T was assayed with sequencing of a fragment of the *CYP51* gene or qPCR. Overall, A495T was present in approx. 17 percent of the samples. A495T was detected in all wine regions; its prevalence ranged between 3 and 35%. The occurrence of A495T differed significantly among wine regions and grape cultivars, and sampling years but did not show seasonality. The treatment with DMI-fungicides did not have a significant effect on the presence of the A495T marker. These results suggest that local differences are among the main factors influencing the prevalence of a DMI-resistance marker and this should be considered during fungicide treatments.

This research was supported by the Hungarian Scientific Research Fund (NKFIH OTKA FK142735).

Text

Cercospora leaf spot, caused by *Cercospora beticola*, is one of the most widespread foliar diseases of sugar beet. Over the last few decades there has been a decrease in the sensitivity of *C. beticola* to triazoles. Several mechanisms involved in this sensitivity diminution have been identified such as: i-mutations in the *Cyp51* gene leading to a change in the *α*-14-demethylase structure of the triazole target protein; ii- the overexpression of *Cyp51* gene; iii- the increase in membrane efflux through transporters. The present study has focused on the involvement of the overexpression of the *Cyp51* gene in the different haplotypes of *C. beticola* isolated in France. Quantitative PCR was optimised to study *Cyp51* gene expression across all haplotypes know as our knowledge. *Cyp51* expression was studied in 29 strains (10 haplotypes). Compared wild-type strains, this study showed that strains carrying one or more mutations in the *Cyp51* gene constitutively overexpressed this gene. However, no clear relationship was found between the level of *Cyp51* expression and the level of resistance to triazoles in strains carrying the same substitutions on the *α*-14-demethylase. *Cyp51* expression induced by triazole application was also studied in strains sensitive and resistant to triazoles fungicides. This study provides new insights into the relative importance of constitutive and induced overexpression of the *Cyp51* gene, which

encodes the *α*-14-demethylase, in different haplotypes of *C. beticola*.

NATURALLY OCCURRING PROPICONAZOLE-TOLERANT FUNGAL ISOLATES IN THE PHYLLOSPHERE OF AGROSTIS STOLONIFERA

MCNAB Edward. (1), **HSIANG Tom. (1)**

(1) University of Guelph, Guelph, CANADA

Text
Agrostis stolonifera is commonly used amenity turfgrass and can experience frequent fungicide applications because of intensive management. The frequent use of fungicides has given rise to problems with fungicide resistance in several major turfgrass pathogens. However, there are other organisms in this environment, which may be naturally tolerant of particular fungicides and of which little is known. The purpose of this work was to examine the identity and diversity of these organisms during two growing seasons by sampling asymptomatic leaf blades of *A. stolonifera* from research plots which were only established one or two years before the sampling and had no or very little exposure to fungicides. Leaf samples were obtained from March through October in two years, and were plated on media amended with 1 ug/ml of propiconazole and antibiotics. From among the 21 morphotypes, we were able to identify 19 different species, three of which were yeasts. The five species that showed the greatest representation among the ~2200 isolates were as follows: *Microdochium bolleyii* (23%), *Rhizoctonia solani* (11%), *Papiliotrema flavescens* (9%), *Cryptococcus aspenensis* (9%), and *Mucor nidicola* (8%). Why these species are naturally tolerant of propiconazole remains to be explored, as well as whether the types of genes and mutations that confer this tolerance are the same as the ones that produce acquired resistance in other species.

P5.4-023

DIFFERENTIAL SENSITIVITY TO SINGLE-SITE FUNGICIDES MAY EXPLAIN WHY RAMULARIOPSIS PSEUDOGLYCINES IS THE PREVALENT RAMULARIOPSIS SPECIES ASSOCIATED WITH RAMULARIA LEAF SPOT (RLS) IN COMMERCIAL UPLAND COTTON FIELDS IN BRAZIL

MILANESI Diogo. (1), SILVA Mariana Aparecida Da. (1), SACON Deivid. (1), LOURENÇO Joao Mauricio Coelho. (1), HOLTMAN Valéria Cristina. (1), **BROMMONSCHENKEL Sergio. (1)**

(1) Universidade Federal de Viçosa, Viçosa, BRAZIL

Text
Ramulariopsis gossypii (Rg) and *R. pseudoglycines* (Rpg) are the etiological agents of Ramularia Leaf Spot (RLS) in Brazil, with Rpg being the prevalent species in commercial

fields. Resistant varieties and chemical control are the most important strategies used to manage RLS. However, the unsatisfactory response to some single-site fungicides suggested adaptation to fungicides currently used. Differential fungicide resistance could also explain the prevalence of Rpg. To address these hypotheses, we used a combination of classical and cutting-edge genomic tools. ITS and RPB2 sequence analysis from 110 *Ramulariopsis* sp. isolates revealed the occurrence of Rpg in 104 samples, and Rg in six samples. Rg was only found in samples from unsprayed breeding plots. Whole genome resequencing (WGS) of 71 isolates indicated that a combination of SNPs and expansion of the number of copies of the *Cyp51* gene (CNV) are associated with increased resistance to triazoles only in Rpg. *β-tubulin* mutations associated with benzimidazole resistance were observed for both Rpg and Rg. The G143A substitution of CytB associated with strobilurin resistance was also only observed in Rpg. The resistance genes currently been used in breeding programs aiming develop RLS resistant cultivars are not effective against Rg. The findings reported here highlight the importance of the integrated used of chemical control and resistant varieties to maintain the durability of the main sources of RLS resistance.

One health: impact of resistance to antibiotics and fungicides in plant pathogens

C7.4-1

MEDICAL IMPLICATIONS OF AZOLE FUNGICIDE USE ON ASPERGILLUS FUMIGATUS: A ONE HEALTH CHALLENGE REQUIRING A MULTIDISCIPLINARY APPROACH

VERWEIJ Paul. (1)

(1) Radboud University Medical Centre, Nijmegen, NETHERLANDS

Text

Aspergillus fumigatus is a saprobic fungus that causes a range of diseases in humans, including invasive aspergillosis. Triazoles represent that main treatment option for *Aspergillus* diseases, with very limited alternative treatment options. Resistance to azoles has emerged globally, which was shown to be mainly driven by environmental exposure of *A. fumigatus* to azole fungicides. Azole resistance causes important challenges in the management of invasive aspergillosis, including resistance diagnosis and treatment. Clinical studies have shown a 25% higher mortality rate in patients with azole-resistant invasive aspergillosis compared to azole-susceptible infection. Studies in the (agricultural) environment have shown that stockpiling of plant waste material and the presence of azole fungicide residues drives azole resistance selection in *A. fumigatus*. Such hotspots have been identified in flower bulb waste, green waste and wood chippings. Current studies are directed towards monitoring interventions aimed at reducing the acculumlation of (resistant) spores in the environment and tracking transmission routes from the environment to the patient. Dual use of antifungal drugs represents a risk to human health and may require

authorization procedures to include activity against non-target human fungal pathogens as part of the risk assessment. This is relevant given the development of new fungicides and antifungals drugs with the same mode of action, such as the DHODH-inhibitors.

C7.4-2

SENSITIVITY TO AZOLE FUNGICIDES IN NORDIC POPULATIONS OF PARASTAGONOSPORA NODORUM CAUSING STAGONOSPORA NODORUM BLOTCH OF WHEAT AND ASPERGILLUS FUMIGATUS CAUSING INVASIVE ASPERGILLOSIS IN HUMANS

FICKE Andrea. (1), AUBER Clara. (2), MORAIS Mateus. (3), MERLIN Morgane. (1)

(1) Norwegian Institute of Bioeconomy Research (NIBIO), Aas, NORWAY; (2) UniLaSalle, Rouen, FRANCE; (3) University of São Paulo , São Paulo , BRAZIL

Text

Fungicide resistance is an increasing challenge to global food production and human health. *Zymoseptoria tritici*, a major leaf pathogen on wheat, has developed resistance to azoles through mutations in the cyp51 gene and is increasingly difficult to manage. Development of resistance to antifungal azoles in *Aspergillus fumigatus* leaves health professionals with few alternatives for effective treatment. In the national funded project 'Navazol- navigating the threats of azole resistance development in human, plant and animal pathogens in Norway', we isolated *Parastagonospora nodorum*, the dominating leaf pathogen in Norwegian wheat and *Aspergillus fumigatus* from agricultural and landscape samples. The fungal isolates were tested on 6-8 different concentrations of Proline, a prothioconazole containing fungicide, to determine the concentration that reduced fungal growth by 50% (EC_{50}). An R script was developed to facilitate computation of the EC_{50} value based on the log-logistic function. Testing 50 *P. nodorum* and *A. fumigatus* isolates showed low prevalence of fungicide resistance (EC_{50} >10ppm) under Norwegian conditions. These results suggested that disease management in Norwegian field crops have not increased the risk of fungicide resistance in either plant, nor human pathogens. However, as crop production adapts to global changes, monitoring of azole resistance and optimizing demand-guided fungicide input are essential to maintain effective plant and human health management.

THE HUNT FOR KILLER ASPERGILLUS FUMIGATUS IN THE ENVIRONMENT - SURVEILLANCE OF TOMATO AND CORN FIELDS IN OHIO

IVEY Melanie. (1), PAUL Pierce. (1), PAUL Raees. (1), MILLER Sally. (1)

(1) The Ohio State University, Wooster, UNITED STATES

Text

Azole resistance in clinical isolates of *Aspergillus fumigatus* has been linked to the intensive use of azole fungicides in the environment. Although *A. fumigatus* is not a phytopathogen,

agricultural azole fungicides have activity against it and resistance can develop through off-target contact with A. fumigatus. Soil and leaves from 16 tomato fields and residue from 15 corn fields in Ohio were collected across four 6 m transects. Most (68%) of the fields received at least one application of a triazole fungicide during the growing season. *Aspergillus* spp. were isolated and screened for resistance to three medical triazoles–itraconazole, posaconazole, and voriconazole in accordance with European Commission on Antimicrobial Susceptibility Testing (EUCAST) guidelines. A total of 49, 46, and 58 putative *A. fumigatus* isolates were recovered from soil, tomato leaves and corn residue, respectively. No resistant isolates were recovered from the tomato fields. Two isolates from corn, one from a field that was not treated with a triazole fungicide (MLI996-21) and one from a field treated with a triazole fungicide (MLI1004-21), exhibited growth on RPMI-agar amended with clinical breakpoint concentrations of itraconazole. On broth microdilution MIC testing, MLI1004-21 revealed reduced sensitivity to itraconazole. These results suggest that corn and tomato crops as produced in Ohio are not hotspots for medical triazole-resistant A. fumigatus, although further investigation is warranted.

C7.4-4

ELUCIDATING THE IMPACTS OF ANTHROPOGENIC ACTIVITIES ON BENEFICIAL AND PATHOGENIC PLANT MICROBE INTERACTIONS

WICAKSONO Wisnu Adi. (1), BERG Gabriele . (1)

(1) Graz University of Technology, Graz, AUSTRIA

Text

Plant microbiomes are increasingly exposed to anthropogenic activities. The growth of multi-resistant bacteria and emerging plant and human pathogens are acknowledged as a global concern. We suggest that different human activities are commonly linked to decrease of plant microbial diversity that likely disturb the plant microbe interaction and lead to the disease outbreak. By combining a multi-omics approach, we extensively investigated the impact of anthropogenic activities i.e., management practices and use of antibiotics on plant associated bacterial communities. We also used a lichen, a model of native microbiota, to obtain mechanistic insights into the effects of antimicrobial exposure on natural microbiota. We observed that putative beneficial bacteria are among the most sensitive responders to the anthropogenic activities. The overall bacterial community structures were altered by the anthropogenic activities including the use of antimicrobial compounds, which resulted in a relative increase of low abundant taxa with r-strategy and potential traits as emerging pathogen. Moreover, using shotgun metagenome and RNA sequencing, we revealed different strategies of these bacterial groups to overcome antimicrobial exposure i.e., regulating influx and efflux systems to limit uptake of antimicrobial substances. Our study provides indications that beneficial and pathogenic plant microbial interaction are compromised when the plant host is exposed to anthropogenic activities.

Text

Plant pathogenic bacteria (PPB) cause devastating losses of crops, e.g. in the wine industry (*Xylella fastidiosa*) or pear orchards (*Erwinia amylovora*). On a worldwide scale, farmers resort to antibiotics to control these diseases, despite the threatening impact of antibiotic resistance genes (ARGs) on human and animal health. There is an urgent need to evaluate the current use of antibiotics in plant agriculture as ARGs have already emerged in PPB. There is a need to investigate the contribution of mobile genetic elements to the spread of antibiotic resistance among PPB and other bacteria.
Streptomycin is the most widely used antibiotic on plants. Tn*5393* and its variants are the main streptomycin resistance vectors in PPB. They are also found in *Salmonella enterica* and *Klebsiella pneumoniae*, two major human pathogens. Comparing the genetic organization of the Tn*5393* variants shows that the insertion of IS elements and other transposons have resulted in more complex entities, potentially carrying other ARGs. In PPB, Tn*5393* structures are relatively simple, but in human or animal pathogens, variants of the transposon show the potential complexity that could be attained in PPB within a few years, with the formation of expanded transposons carrying several ARGs.
Our study highlights that, besides understanding the potential transfers between bacteria, there is a crucial need for more detailed information on the type and quantities of antibiotics used as plant protection products.

DMI SENSITIVITY OF BASELINE AND FUNGICIDES EXPOSED ISOLATES OF ALTERNARIA ALTERNATA FROM TANGERINES

LOURENÇO Silvia. (1), AMIN Mateus. (1), REIS Ana Carolina . (1), MARTINS Marise. (3), SILVA Geraldo. (2), AMORIM Lilian. (1)

(1) UNIVERSITY OF SAO PAULO, Piracicaba, BRAZIL; (2) Fundecitrus, Araraquara, BRAZIL; (3) Apta, Piracicaba, BRAZIL

Text

Alternaria brown spot, caused by Alternaria alternata, is the main fungal disease that affects tangerines and their hybrids. In Brazil, the disease is mainly controlled by the use of fungicides from the group of Quinone outside inhibitor (QoI) in mixture with 14α-Demethylation inhibitor (DMI), in addition to copper fungicides. The inefficiency of QoI fungicides in controlling the disease in tangerine orchards at the State of São Paulo was reported in 2017 and in 2021, the resistance of A. alternata isolates to QoI has been proven. Given the scenario of loss of sensitivity to QoI fungicides this study aimed to evaluate the sensitivity of A. alternata to fungicides from DMI group. To achieve this goal, the evaluation of A. alternata sensitivity to DMI fungicides was performed by determining the effective concentration of tebuconazole and difenoconazole to inhibit 50% (EC_{50}) of mycelia development. The EC_{50} of tebuconazole and difenoconale were determined, respectively, for 170 and 103 isolates of A. alternata, by the Spiral Plater technique. A. alternata isolates were collected from tangerine commercial fields in 2003 (baseline), 2017, 2018 and 2021. All

baseline isolates were sensitive to both fungicides (EC_{50}<1.0 µg.ml^{-1}). From 2017 to 2021 only 17 % and 1% of A. alternata isolates showed reduced sensitivity to tebuconazole and difenoconazole, respectively. A shift in sensitivity of A. Alternaria collected from 2003 to 2021 was noticed only for tebuconazole.

P7.4-002

TEMPERATURE AND HOST-DEPENDENT FUNGICIDE EFFICACY

ZHAN Jiasui. (1), YAHUZA Lurwanu. (2), ANDERSSON Björn . (1), YANG Li-Na. (3)

(1) Swedish University of Agricultural Sciences, Uppsala, SWEDEN; (2) Bayero University , Kano, NIGERIA; (3) Minjiang University, Fuzhou, CHINA

Text

Fungicides are one of the most important strategies for the controlling plant diseases. Research on fungicides has focused on their biochemical properties and strategies to mitigate pathogen resistance. The influence of ecological factors on the efficacy has been largely ignored. We investigated the effects of temperature, host diversity, and host resistance on the efficacy of fungicides. Fungicide efficacy was measured in vitro by calculating the mycelial growth rate of the pathogen in the presence of fungicides relative to that without fungicides or by calculating EC50 in three independent experiments each with 150-300 *Phytophthora infestans* genotypes. In Experiment 1, the pathogen populations from nine locations were exposed to five temperatures (13 ?, 15 ?, 19 ?, 22 ? and 25 ?). In Experiment 2 and 3, pathogen populations from potato populations differing in genetic diversity or quantitative resistance were tested for their tolerance to two fungicides of different action modes. Fungicide efficacy was found to respond quadratically to experimental temperatures, with the lowest efficacy at the optimal growth temperature of the pathogen. Fungicide efficacy was also found to be positively correlated to host diversity but negatively correlated to quantitative host resistance and these association patterns were independent of fungicide property. These results suggest that fungicide doses should be adjusted according to air temperature and host genetics during field practice.

Text

Phoma stem canker is a damaging disease of oilseed rape (Brassica napus), caused by two related fungal pathogens Leptosphaeria maculans (Lm) and L. biglobosa (Lb). Control of severe UK phoma stem canker epidemics relies on use of fungicides. To investigate effects

of different fungicides on control of Lm and Lb, field experiments with different cultivars and in vitro experiments with different isolates were done. Results from field experiments with six cultivars over three cropping seasons showed that fungicides Proline (prothioconazole) and Refinzar (penthiopyrad+picoxystrobin) reduced phoma stem canker severity caused by Lm and Lb measured by amounts of Lm and Lb DNA in stem tissues but there were variations between different cultivars or different seasons. Ten Lm and ten Lb isolates were tested for sensitivity to three fungicides (prothioconazole-desthio, picoxystrobin and penthiopyrad) in-vitro. All fungicides were effective in control of Lm and Lb growth, with prothioconazole-desthio being the most effective. Lb isolates were less sensitive to prothioconazole-desthio than Lm isolates. To investigate differences between Lm and Lb in fungicide sensitivity mechanisms, five Lm and five Lb isolates with different levels of fungicide sensitivity were inoculated onto cultivar Topas and leaves were sampled at 7 and 12 days post inoculation for gene expression analysis. Results showed different levels of expression of LmCYP51 and LbCYP51 genes among the Lm and Lb isolates.

IN VITRO SENSITIVITY TO SOME FUNGICIDES OF MONILINIA LAXA

SENYURT Hamza. (3), **DEMIR Dudu. (1)**, EKEN Cafer. (2)

(1) Isparta University of Applied Sciences, Isparta, TURKEY; (2) Aydin Adnan Menderes University, Aydin, TURKEY; (3) Directorate of Plant Protection Central Research Institute, Ankara, TURKEY

Text

Brown rot caused by *Monilinia laxa*, *M. fructigena*, and *M. fructicola* causes severe losses in important commercial crops such as peach and nectarine, apricot, plum, sweet and sour cherry, almond, apple, and pear, with a significant economic impact. *Monilinia laxa* is the most common species in Türkiye. Fungicides are frequently used to control this pathogen. Resistance to fungicides, which provide effective and rapid pathogen control, is currently a major issue. In this study, the resistance of 35 isolates of *M. laxa* to captan, cyprodinil, and thiophanate methyl fungicides was evaluated under *in vitro* conditions. Significant differences were found in the EC_{50} values of fungicides among fungal isolates. According to the results of the petri dish assay, the isolates with the highest EC_{50} values were KOKI1 (32451,2 ppm) in captan, ISKA20 (1,980 ppm) in cyprodinil, and ISKA32 (4,142 ppm) in thiophanate methyl. It is required to develop integrated control programs that can be used for the pathogen's management.

The work was supported by the Ministry of Agriculture and Forestry, the General Directorate of Agricultural Research and Policies (TAGEM), Project No. TAGEM/BSAD/A/21/A2/P1/2716.

DETERMINATION OF IN VITRO ANTIFUNGAL EFFICIENCIES OF SOME FUNGICIDES AGAINST THE DIPLODIA BULGARICA AS A NEW PATHOGEN OF APPLE IN TÜRKIYE

EKEN Cafer. (2), DEMIR Dudu. (1), **CAGLAYAN Kardelen. (1)**

(1) Isparta University of Applied Sciences, Isparta, TURKEY; (2) Aydin Adnan Menderes University, Aydin, TURKEY

Text

The apple (*Malus domestica*) is one of the most important commercially grown fruit crops in the world. In Türkiye, apples are an economically important horticultural crop more than 4,300,000 t of apples are produced every year, making the country the third largest producer worldwide. Members of the family Botryosphaeriaceae can cause canker, dieback, gummosis, fruit rot, and twig blight diseases in numerous woody hosts. Recently, a botryosphaeriaceous species (*Diplodia bulgarica*) associated with canker and fruit rot symptoms in apples was reported in the Egirdir district of Isparta province, Türkiye. The aim of this study is to determine the sensitivity of *D. bulgarica* to some fungicides. Nine fungicides (captan, chlorothalonil, dodine, fluazinam, fosetyl-al, mancozeb, tebuconazole, thiophonate methyl, and trifloxystrobin) were tested in vitro for their antifungal effects against the pathogen at different concentrations. Probit analysis was used to determine the mean effective concentration (EC_{50}) values. The most effective fungicides were fluazinam, tebuconazole, and thiophonate methyl, for which EC_{50} values were <1.0 mg/L.

Text

A new concept called One Health, which unites the health of humans, animals and the environment, is being used to control the upcoming epidemic. Plant health is also important in terms of providing healthy food for humans. Although various agricultural antibiotics are used to control bacterial diseases in crops, antibiotic-resistant bacteria in agriculture have hardly been investigated. This study was conducted to provide basic data for antibiotic resistance research through the investigation of antibiotic resistant bacteria in agricultural products and agricultural environments in Korea. *Klebsiella* spp., including *Klebsiella pneumoniae*, were isolated from lettuce and pepper, agricultural water, soil and compost using selective media. A total of 56 *Klebsiella* spp. was isolated, especially these bacteria were isolated in high proportions from soil and agricultural water. As a result of the resistance test of the isolates against 16 antibiotics including ampicillin, 78% of the strains showed resistance to one or more antibiotics. Among the antibiotics, the ratio of resistant bacteria to cefoxitin and ampicillin was the highest at 52% and 27%, while showing sensitivity to all 9 antibiotics including gentamicin. Investigation of antibiotic resistance to various harmful microorganisms such as *Escherichia coli* is also in progress, and continuous data accumulation will provide the basis for various antibiotic resistance studies in the future.

(1) GYEONGGI-DO AGRICULTURAL RESEARCH & EXTENSION SERVICES, Hwaseong-City, Gyeonggi-Do, REPUBLIC OF KOREA

Text
The purpose of this study was to develop safe agricultural production technology by controlling agricultural environmental factors in relation to antibiotic-resistant bacteria in humans. In this study, prevalence and antibiotic resistance of *Pseudomonas* spp. were investigated in 137 different samples collected from lettuce (n = 12), garlic chives (n = 14), soil (n = 26), compost (n = 20), and irrigation water (n = 26) in 26 farms between 2021 and 2022 in the Republic of Korea. Species of Pseudomonas were prevalently isolated from samples as follows; *P. aeruginosa* 36.5% (n = 50), *P. putida* 14.6% (n = 20), *P. plecoglossicida* 11.7% (n = 16), *P. guariconensis* 9.5% (n = 13), *P. taiwanensis* 7.3% (n = 10), and Pseudomonas other species 20.4% (n = 28). The most isolates of *Pseudomonas* spp. showed high susceptibility to gentamicin (97.8%), amikacin (96.3%), and ceftazidime (89.7%), but some isolates showed resistance against to antibiotics such as imipenem (8.2%), ciprofloxacin (6.5%) and colistin (5.1%). Among them, 15 isolates of *P. aeruginosa* resistant to three antibiotics were from irrigation water 9, soil 2, garlic chives 2, and lettuce 2. In the future, more samples will be analyzed to track the source of antibiotic resistance in agricultural environments, and a systematic examination of how to acquire antibiotic resistance should be carried out.

Particle based delivery of biomolecules for crop protection

C6.4-1

BIOCLAY – DELIVERING RNA SPRAYS TO CROPS USING CLAY PARTICLES FOR SUSTAINABLE CROP PROTECTION

MITTER Neena. (1)

(1) The University of Queensland, St Lucia, AUSTRALIA

Text
Innovation driving sustainable crop protection resonating with health of the planet and the

future consumer is key to food and nutritional security. The ongoing usefulness of chemical pesticides suffers from issues such as residual toxicity, run-off, pest specificity and resistance. RNA based biopesticides or 'RNA sprays' for plants as a next generation crop protection platform without the need for genetic modification is gaining momentum globally. Series of papers have shown that exogenous application of doble stranded RNA (dsRNA) can induce RNAi-mediated protection against pests and pathogens. However, the instability of topically applied naked dsRNA on the leaf surface is a major limitation. The BioClayTM technology to deliver dsRNA as biological active using clay particles (Layered double hydroxide) as carriers presents a non-GM, residue free, specific, and environmentally sustainable alternative to chemical pesticides. RNAi effectors delivered as BioClay are stable, do not get washed off and provide protection to the sprayed and unsprayed leaves of a wide range of host plants against the targeted pest or pathogen. BioClay platform is being progressed to target viruses, insect pests such as white flies and fungi including Botrytis, Verticillium, Fusarium and Phytophthora. Real world application of RNA based biopesticides with sustainable credentials will be governed by factors such as cost-effective production of dsRNA, the regulatory landscape and public licensing.

C6.4-2

USING NANOCARRIERS FOR TARGETED RNAI THERAPY IN CONTROLLING PLANT PATHOGENS

DA SILVA Washington. (1), MUTHURAMALINGAM Raja. (1)

(1) The Connecticut Agricultural Experiment Station , New Haven, UNITED STATES

Text

Plant diseases cause significant economic losses in agriculture worldwide. Traditional methods of disease control, such as chemical pesticides, have been found, in many cases, to be ineffective and harmful to the environment. Therefore, strategies to sustainability control plant diseases are much needed and nanotechnology is gaining attention as a potential solution for such problems. Nanocarriers are small particles that can be engineered to target specific organelles in plants and deliver biocargos, such as RNA interference (RNAi) precursors (siRNAs and dsRNAs), to plant cells. These particles offer a more targeted and effective way to control plant pathogens compared to traditional methods. Our research focuses on designing and optimizing these nanocarriers for efficient delivery of RNAi precursors to plant cells. We have synthesized and characterized different nanocarriers and evaluated their ability to protect and deliver nucleic acid to plant cells. Our results show that the protein nanocarriers have high stability, are able to protect the genetic material from degradation, and efficiently deliver it to the target cells. Moving forward, our studies will focus on optimizing the design of these nanocarriers for practical applications.

Text

Nanotechnology could represent an innovative way to control plant pathogens, providing alternative solutions to the pesticides traditionally employed to manage plant diseases. In this work a novel nanoparticles-based formulation (NPF) made of cellulose nanocrystals as carriers, high-amylose starch as excipient, and chitosan and gallic acid as active principles, was evaluated to control the worldwide distributed pathogen *Pseudomonas syringae* pv. *tomato* (Pst), the causal agent of the tomato bacterial speck disease. We firstly described the antimicrobial properties of cellulose nanocrystals alone, which displayed the capability of reducing bacterial flagellar motility, inducing cell aggregation and delaying biofilm production by preventing surface adhesion. In combination with chitosan and gallic acid, NPF at 2% was able to inhibit *in vitro* cell multiplication up to 80%. The application of the NPF on host plants reduced the disease severity compared to copper hydroxide as much as reduced the spread of Pst, which was evaluated by Real-Time qPCR. This work provides valuable characterizations of the several mode of actions of a novel bio-based NPF, which could be potentially useful to control Pst even in organic agriculture regime.

Text

Fungal pathogens are a major threat to global food security, and current management strategies are limited to mainly chemical control, which is harmful to human health and the environment. Therefore, innovative, eco-friendly, strategies for combating fungal pathogens must be developed. Recent advances, in which our research group has been pioneer, have shown that Spray-Induced Gene Silencing (SIGS) via topical application of pathogen gene-

targeting RNAs can inhibit plant diseases caused by fungal pathogens that can effectively take up RNAs from the environment. These antifungal RNAs can be versatility designed to be species-specific and to target multiple genes simultaneously. Though promising, a major drawback to SIGS approaches is the instability of RNA in the environment, which can be rapidly degraded when exposed to rainfall, high humidity, and UV light. Previously, we discovered that plant hosts utilize extracellular vesicles to protect and deliver small RNAs into fungal cells to suppress fungal virulence, so inspired by this naturally occurring pathway, we examined three artificial nanovesicle formulations to shield pathogen gene targeting double-stranded RNAs from degradation for topical application to control the fungal pathogen, Botrytis cinerea. All three formulations are effective in both RNA delivery and protection, and greatly extend the length of RNA-mediated plant protection.

Text
Many plant diseases and particularly those caused by bacteria lack effective treatment to fend off pathogens and minimize yield losses. We have previously shown that membrane vesicles of Gram-negative bacteria prime the plant immune system and protect it from subsequent infection. This knowledge was exploited to develop synthetic lipid nanoparticles (LNPs) as a delivery vehicle of biomolecules to induce disease resistance in plants. Fluorescently labelled LNPs with different lipid composition were synthesized and applied to plant to determine uptake, distribution and persistence. Plant uptake was more effective when LNPs were applied through the root system compared with leaf applications. From the roots, LNPs were transported to the stem and leaves preferentially via the vascular system, and were detectable at least 25 days post-application. To examine whether LNPs can activate plant immunity, we rationally designed LNPs coated with the plant immune elicitor flg22 (LNP-flg) and used them to treat Arabidopsis plants. LNP-flg induced a robust upregulation of immune gene markers in seedlings and elicited a reactive oxygen species burst in disc leaves. Further, plants pretreated with LNP-flg promote a significant reduction in bacterial growth in infected as well as in distant leaves. This priming effect was evident up to a week after LNP application. In summary, our results indicate that rationally designed LNPs may represent a promising alternative to mitigate plant diseases.

Text

The last decades, increased food production demand along with climate change is expected to make crops more disease and stress vulnerable. In addition, pesticide use reduction in the frame of Green Deal necessitates the need for development of new generation plant protection products. In this challenging era, the role of nanotechnology in crop protection needs to be considered. In this study, chitosan nanoparticles (CNPs) and CNPs with enclosed Cu^{+2}, Gibberellic acid (GA3) or Salicylic acid (SA) were produced and tested for phytotoxicity and defense stimulating efficiency on *A. thaliana* Col-0 control plants and *npr1*, *hsp90.2* and *RNAiHsp90.1* mutant lines by examining ROS production through NBT and DAB staining. In the absence of disease and after artificial inoculation with *P. xanthii* conidia, it was shown that various SA-CNPs formulations induced *PR1* resistance marker gene at 5ppm and reduced disease severity on leaves of *PR1prom::GUS* transgenic plants. Additionally, CNPs were tested on a commercial courgette variety for efficacy against *P. xanthi*i in relation to their particle sizes and concentrations. However, confocal microscopy on leaves and protoplasts of *N. benthamiana* and *A. thaliana* after FITC-CNPs treatment, revealed a time- and size-dependent CNP movement in cell membranes. Therefore, CNP potential use should be balanced between effectiveness and safety.

P6.4-001

EFFECT OF DIFFERENT CONCENTRATION OF SIO2, TIO2 AND ZNO2 NANOPARTICLES ON GERMINATION PERCENTAGE, VIGOUR AND SEED HEALTH PARAMETERS OF CHICKPEA SEEDS

THAKUR Anubhav. (1)

(1) CHAUDHARY SARWAN KUMAR HIMACHAL PRADESH KRISHI VISHVIDYALA, Palampur, INDIA

Text

Explosive demand of higher agricultural productivity to feed the increasing population demands innovative technologies to improve the seed quality in order to harness the full potential of genetic resource and other agronomic inputs. The use of nano-based technology for seed treatment has a potential to upgrade the seed quality with minimalistic exposure to chemicals making it ecologically and economically sustainable. The present study is an attempt to assess the prospects of nanotechnology as an alternative approach to improve the seed quality. The seeds of chickpea variety Pusa-547 were treated using zinc, silicon, and titanium oxides in various combinations (viz., 50, 100, 250, 500 and 750 ppm). The observations for various seed quality parameters were recorded to find out the best treatment that could improve the physiological and biochemical attributes of seed. Amongst the various treatments given to the seeds of the chickpea variety Pusa-547, the treatment Dry Bulk ZnO@ 500 ppm recorded significantly the highest values for most of the quality parameters and thus it can be used to enhance the seed quality.

P6.4-002

THE EFFECT OF SODIUM CHLORIDE AQUEOUS SOLUTION ON THE GROWTH AND DEVELOPMENT OF SUNFLOWER PLANT (HELIANTHUS ANNUUS L.) AFTER THE SEED GERMINATION STAGE INSIDE THE GREENHOUSE.

BOUKABCHA Maamar. (1)

(1) University of Chlef, Abou El Hassen, ALGERIA

Text

The response of sunflower plant (Helianthus annuus L.) after early germination to sodium chloride was investigated at the stages that come after germination and early seedling growth. Sunflower plant were treated with a series of five different concentrations of sodium chloride aqueous solution 0, 50, 75, 100 and 200 mM and tap water for control and were allowed to grow under cultivation conditions in special pots at the rate of one plant per pot. The results showed that the highest concentration of salinity (200 mmol NaCl) led to a decrease in the growth rate and growth rate of sunflower plant. Fresh and dry masses of sunflower plant were significantly reduced at 0-200 mM NaCl aqueous solution. A decrease in stem growth and length, in addition to its diameter, was observed with increasing NaCl concentration. The results also show that up to 75 mM NaCl, all growth indicators and fresh and dry biomass were moderately salinity tolerant. Thus, the present study concluded that sunflower plant can be grown in brackish soil.

(1) Newcastle University , Newcastle Upon Tyne, UNITED KINGDOM; (2) Agriculture Genetic Engineering Research Institute, Agriculture Research Centre, Giza, EGYPT; (3) Fera , Newcastle Upon Tyne, UNITED KINGDOM

Text

RNA interference (RNAi) applications are one of the sustainable possibilities for crop health management that could be used to replace other chemically based alternatives. One of the most relevant to farming applications in the case of crop treatment is spray-induced gene silencing (SIGS). Potato Virus Y (PVY) is the most widespread and damaging virus in potato production across the world. We have produced dsRNA fragments of conserved regions that cover the whole viral genome to be sprayed in gene silencing experiments. The experiment was designed to generate the dsRNA under a newly designed bacterial expression system developed based on Golden Gate assembly. The dsRNA fragment was applied to Nicotiana tabacum plants to test its ability to inhibit viral infection by topical spraying application. By

using qPCR, frequent samples were taken and tested to calculate the silencing percentage. In addition, symptom development was recorded in three levels mild, moderate & severe.

A NOVEL PHYTO-FUMIGANT VOLATILE FORMULATION UNVEILS THE SUPPRESSIVE NATURE OF DAMPING OFF AND FUSARIAL WILT PATHOGENS IN TOMATO

THANGARAJ Praveen. (1)

(1) TAMIL NADU AGRICULTURAL UNIVERSITY, Coimbatore, INDIA

Text

Soil-borne fungal diseases are a major threat to vegetable crops that severely affects plant growth and development. The present study aimed to evaluate Plant/microbial volatile organic compounds (p/mVOCs) against *P. aphanidermatum (Pa)* and *F. oxysporum f. sp. lycopersici* (FOL).
Among them, the volatilomes of *M. spicata (Ms)* and *C. citratus* (Cc) showed the maximum inhibitory effect on mycelial growth of the target pathogens. The volatilomes of *T. asperellum* (Ta) showed the maximum inhibitory effect on Pa and FOL. To identify the nature of VOCs involved in the suppression of pathogens, the volatilomes of *Ms* and *Cc* leaves were subjected to HS GCMS, and the volatilomes of *Ta* were subjected to GC-MS-ATD. The results revealed the production of carvone by *Ms*; citronellol by *Cc*; isopentyl alcohol and limonene by *Ta* with increased peak area percentage. To develop a new phytofumigant formulation, the effective volatilomes were immobilized separately in a vermiculite bound with castor oil as the vermiculite ball formulation. Studies on defense gene expression revealed that PR1 and LOX were highly expressed after 48h of exposure to the *Ms* vermiculite balls against Pa in tomato plants. Similarly, tomato plants inoculated with FOL also revealed increased expressions of PR1 after 72h and WRKY after 48h on exposure to the *M. spicata* balls. The research concluded that p/mVOCs at low concentrations positively affect plant growth promotion and induce systemic resistance against plant pathogens.

DEVELOPMENT OF A REPRODUCIBLE SYSTEM FOR ASSESSMENT OF BOTRYTIS BUNCH ROT DISEASE IN GRAPEVINES AND THE IMPACT OF BIOCLAY™ RNAI TECHNOLOGY ON DISEASE INCIDENCE.

CLARKE Victoria. (1), TAIWO Akeem. (1), EVANS Katherine. (1)

(1) University of Tasmania, Hobart, AUSTRALIA

Text
The fungal pathogen *Botrytis cinerea* causes the grapevine diseases botrytis bunch rot (BBR) and grey mould. BBR outbreaks in vineyards can cause substantial economic loss from a reduction in yield and a downgrade in fruit quality. We have developed a consensus

flower *B. cinerea* inoculation protocol for inducing and assessing infection throughout berry development and veraison. Further, we have used this methodology to assess impact of the novel botryticide BioClay™ on BBR. BioClay™ utilises double-stranded RNA (dsRNA) to trigger RNAi silencing of targeted virulence-related pathogen genes, with the stability and durability of the dsRNA improved through combination with clay particles. We report on the effectiveness of BioClay™ against *B. cinerea* infection in Riesling grapevines and discuss adaptability of the system for testing other crop protectants in grapevine.

Text

The development of new ecofriendly methods to control Phytophthora cinnamomi (Pc) root rot disease that is threatening the survival of oak woodlands in the Mediterranean Basin is essential. An alternative to standard fungicides is chalcones (1,3-diphenyl1-2-proper-1-one), aromatic compounds naturally produced by plants and synthesizable. The main goal of this work was to determine the biocide activity against Pc of two chalcones, a dihydrochalcone (DC) and a thiolchalcone (TC). Their effect, individually and combined, were evaluated at three doses (10-6, 10-5 and 10-4 M), on the mycelial growth of the pathogen by in vitro experiments. DC and TC separately and in combination at the highest dose (10-4 M) reached a mycelial growth significantly lower than the untreated controls, reaching percentages of mycelial growth inhibition higher than 65% with both chalcones combined. Based on these results, the commercial product Nemanol (Telluris Biotech India) composed by DC and TC at 10-4 M was chosen to be tested against Pc survival and root disease development by in planta experiments. A significant reduction of the viable inoculum density was recorded in soil treated with Nemanol before and after soil infestation. In addition, Lupinus luteus seedlings growing in soil treated before soil infestation showed a severity of root symptoms significantly lower than the plants that grew in untreated and infested soil. Our results support the efficacy of chalcones to control Pc root disease.

Text

The strain, Bacillus velezensis BS07 has been reported to induce multiple spectrums of systemic resistance and growth promotion in various crops. the strain was compared with the representative strains of B. velezensis BS07M by comparing 16s rRNA sequence analysis and utilization of carbon sources such as L-arabinose, D-Xylose, Mannose, and Trehalose with B. amyloliquefaciens DSM7, B. siamensis KCTC13613, and B. velezensis LMG22478. Cyclic dipeptide, cyclo(L -Pro -L -Gly) was purified by various column chromatography from culture filtrates of BS07M. The compound was identified as cyclo(L -Pro-L -Gly) based on the analysis of NMR spectra. The compound induced systemic resistance in the cucumber plant against C. orbiculare. Infiltration or spray of the compound at a low concentration (0.1 ppm) induced systemic resistance against P. capsici, P. carotovorum, etc., and involved in defense gene activation. We investigated the BS07M combination with cyclic dipeptides on tobacco or red-pepper seedlings for priming; this caused a significant yield increase and soft rot disease suppression as well. The ISR mechanism was supported by enhanced expression of defense-related genes on chili-pepper after pathogen challenge by using the RT-PCR technique. These results suggest that a bacterial metabolite, cyclo dipeptides, and bacterial cell combination is a great potential for disease suppression and yield increase in various crops.

TOPICAL APPLICATION OF RNA INTERFERENCE TO IMPROVE GRAIN CROP HEALTH AGAINST THE FUNGAL PATHOGEN FUSARIUM GRAMINEARUM

RAVICHANDER Pratyush. (1), CZISLOWSKI Elizabeth. (1), GARDINER Donald. (1), AITKEN Elizabeth. (1), MITTER Neena. (1)

(1) The University of Queensland, Brisbane, AUSTRALIA

Text

Fusarium Head Blight (FHB) is a fungal disease affecting grain crops caused by Fusarium graminearum. It can lead to yield loss and produce mycotoxins during infection, which is harmful to humans and animals. Chemicals such as Demethylation Inhibitors are used to reduce the incidence of FHB. However, its overuse can cause potential harm to soil-beneficial microorganisms and lead to fungicide resistance. RNA interference (RNAi) is a gene-silencing mechanism that has emerged as a promising tool to overcome pests and diseases. We are investigating its potential as an exogenous application for treating FHB in wheat and barley. Confocal microscopy confirmed environmental uptake of exogenous dsRNA within the germ tubes, with variable uptake efficiency. With these results, an in vitro method for screening potential target genes using target-specific dsRNA was developed to investigate fungal inhibition. In planta seedling assays using the Fusarium graminearum – wheat/barley pathosystems were also tested by spray application of dsRNA. The in vitro assays also showed some inhibition of the fungi, indicating the potential to upscale. Whereas the in planta assays showed significant inhibition in barley but surprisingly poor inhibitory effects in wheat, possibly due to low uptake efficiency. The findings suggest high potential in using target-specific dsRNA as a biocontrol against F. graminearum, but more research is required to test

its potential against FHB in mature plants.

Text

Pseudomonas syringae pv. *actinidiae* (Psa) and *P. savastanoi* pv. *savastanoi* (Psav) are impacting bacterial pathogens and are managed by following good agornomical practices and by the preventive application of cupric salts. There is an urgent need to find efficient and bio-based solutions to mitigate bacterial diseases. We formulated a novel nanoparticle-based formulation (NPF) composed of cellulose nanocrystals and high-amylose starch as carriers and excipient, while chitosan and gallic acid were included as active antibacterial. The NPF was tested *in vitro* and *in vivo* at 2% against Psa and Psav. Antibacterial assays demonstrated that the NPF inhibited the cell multiplication from 50% to 80%. In-broth assays demonstrated that the NPF drastically reduced the ability of the *Pseudomonas* spp. to produce biofilms and its adhesion to plastic surfaces. The application of the NPF on host plants reduced the disease severity compared to standard cupric salts, as much as reduced the spread of Psa, which was evaluated by Real-Time qPCR. Interestingly, the application of NPF boosted innate immunity in Olive and Actinidia plants, by up-regulating several salicylic acid responsive genes. This work provides novel and valuable information regarding the several mode of actions of a novel bio-based NPF, which could be potentially useful to control Psa and Psav even in organic agriculture.

Text

Botrytis cinerea, the causal agent for Botrytis grey mould disease, is one of the devastating necrotrophic fungal pathogens responsible for significant yield losses in a wide range of crops including chickpea. Under favourable environmental conditions the pathogen infects all plant parts including the flowers and pods, making it difficult to manage this disease especially during the canopy closure stage. Breeding for host resistance has been elusive,

and repeated use of broad-spectrum fungicides may lead to loss of sensitivity through adaptation. Consequently, the use of double-stranded RNA (dsRNA) as RNAi-based bio-fungicides to target functional sequences triggering RNAi machinery are considered as an alternate management approach. In this study, we demonstrated that exogenous application of dsRNA targeting B. cinerea Dicer-like (DCL) genes protects against B. cinerea infection In Planta up to 14 days post inoculation (DPI) under controlled environment conditions. In vitro assessment on the direct impact of dsRNA, showed significant reduction in B. cinerea growth up to 120 hours post inoculation (HPI). Histopathology revealed significant reduction in spore germination, germ tube length and formation of appressoria, suggesting that topical application of dsRNA targeting B. cinerea specific genes may effectively control B. cinerea growth and disease development sustainably within natural agroecosystems.

FORGOTTEN NUTRIENT THAT ENHANCES THE PASSIVE DEFENCE PATHWAY, SO REDUCING DISEASE LEVELS?

ASIANA Ifeoma. (1), **HALL Avice. (1)**, JIN Xiaolei. (1), LIU Bo. (1), SIDIQUE Siti Nordahliawate Mohamed . (2)

(1) University of Hertfordshire, Hatfield, UNITED KINGDOM; (2) Faculty of Fisheries & Food Science, Universiti Malaysia Terengganu (UMT), Kuala Nerus, MALAYSIA

Text
A characteristic of the passive defence pathway is that the thickness and strength of the leaf surface inhibits penetration by pathogens. Silicon is one of the most widespread elements on the planet and is found in the trichomes of plant. However much of the silicon is unavailable to plants as plants can only take up silicon if it is in a bio- available form such as silicilic acid. The literature on the use of silicon nutrient demonstrates a wide range of potential benefits to plants. In particular disease levels on a range of crop species are reduced when silicon nutrient is applied regularly. The work presented here shows disease reduction in strawberries, courgettes, dragon fruit, wax apple, cocoa, rice and rubber. The work presented demonstrates the up take of silicon and how the silicon is deposited on the surface of strawberry leaves and deposited under the walls of the epidermis and palisade cells thus strengthening the leaf and inhibiting penetration by pathogens (and pests). Epidemic development is significantly reduced on the crops tested. The use of bio available silicilic acid enables disease reduction and reduction in environmental impact due to the reduced need for fungicides, thus contributing to sustainable production.

Pathovars of Pseudomonas and Xanthomonas spp.: do they really exist?

C7.5-1

THE PATHOVAR CONCEPT MISREPRESENTS THE REALITY OF DISEASE AS A MULTIFACTOR PROCESS; IT'S TIME TO MODERNIZE

MORRIS Cindy. (1), BERGE Odile. (1)

(1) INRAE, Montfavet, FRANCE

Text

The pathovar concept intends to define groups of closely related strains with like pathogenic potential - in terms of the susceptible plant species and the type of symptoms. In turn, pathovar identity is supposed to be useful for diagnostics and disease management. We argue that the pathovar concept cannot meet its intended goals for two fundamental reasons. Firstly, expression of symptoms is the outcome of a process that involves a multitude of factors as represented in the disease triangle. Some of these factors have stochastic or chaotic behaviors. Hence, the outcome of the interaction of a bacterial strain with a plant is conditional and not absolute. This leads to the second obstacle: defining standard criteria by which pathovar identify is attributed objectively. These criteria should specify if pathovar is defined according to natural disease outbreaks or host range tests under controlled conditions. The former ignores differences in opportunity for infection and impedes anticipation of new disease emergences, especially by strains from environmental sources. The latter is faced with unlimited options for host species, cultivars, plant age and physiology and environmental conditions. Furthermore, for numerous plant pathogens, extensive host range tests do not reveal distinct pathovars. We propose that disease potential be estimated by situating bacterial genotypes in a map of risk likelihoods that account for all relevant factors contributing to disease outbreaks.

Text

Plants from the *Brassicaceae* family can be attacked by different *Xanthomonas campestris* pathogens. *Xanthomonas campestris* pv. *campestris* (Xcc), the cause of black rot of brassicas, is one of the most important diseases of crops like cabbage and cauliflower worldwide. Ornamental *Brassicaceae* plants like wallflowers and garden stocks and some common weeds can also be infected by *X. campestris* pathogens including *X. campestris* pv. *incanae* (Xci). In contrast to Xcc and Xci, which cause vascular diseases, *X. campestris* pv. *raphani* (Xcr) causes leaf spots in a larger range of *Brassicaceae* and other hosts including

tomato. At least two pathovars, Xcc and Xcr, have race structures defined by the ability of causing disease in different brassica differential accessions. We are characterising the pathogenicity and sequencing a collection of *Xanthomonas* spp. isolates from different origins and spanning over 60 years, including different pathovars of *X. campestris*. The results of our work allowed us to reclassify some pathovars from *X. campestris* as other species, thus clarifying the taxonomy. We are designing diagnostic testing for important pathovars and races of *X. campestris*. Screening brassica collections has led to the identification of sources of resistance and we are developing chlorophyll imaging and whole plant imaging techniques to study *X. campestris* infections. We aim to characterise and map resistances and identify resistance-linked markers that can assist future breeding.

Text

Rapid whole genome and metagenomics sequencing is redefining how we track bacterial pathogen outbreaks in real time. Diagnostic clinics, centers and front-line pathologists are increasingly implementing these technologies to support producers in identification of emerging, unknown and unculturable agricultural threats. Current bacterial pathogen typing and naming with pathovar designations limits our ability to properly identify the causal agent of infection especially in the context of the complexity of the microbiome. Pathovar designation is phenotypic and does not always follow the genetics of a species, which is critical for tracking the evolution of an outbreak. Pathovars are also impractical and rely on host range or phenotypic assays, which are slow and varies at each laboratory. Genome based approaches instead allow for standardized identification and precisely track organism evolution especially new variants of emerging importance. Metagenomics also captures genetic content of the whole biome, and pathovar testing is not possible for an organism detected only by metagenome sequencing. Moreover in light of the metagenome, our definitions may even shift of defining a community of organisms for disease development rather than a single one pathogen, one symptom concept. This presentation will describe our current work using genomics and metagenomics for real-time pathogen tracking to push past pathovar typing for pathogen characterization.

Text

Bacterial spot of tomato and pepper is caused by multiple taxa of bacteria within *Xanthomonas*, including *X. euvesicatoria* and *X. perforans*. Recent studies have proposed consolidation of two species as pathovars of *X. euvesicatoria*, owing to >95% average nucleotide identity (ANI) between two species. However, *X. perforans* and *X. euvesicatoria* are both pathogenic on the same set of host plants, thus the use of pathovar as defined in the International Code of Nomenclature of Prokaryotes is not useful in discerning between the two. To infer the taxonomic position of the two species, we calculated whole genome ANI and inferred core genome phylogeny from whole-genome-sequenced pathovars of *X. euvesicatoria sensu lato*. We found that *X. euvesicatoria* (ANI > 99.7%) and *X. perforans* (ANI > 99.4%) are classified into separate (ANI < 99.1%) clusters, with monophyly supported by core genes, and thus are taxonomically distinct. We also identified a divergent group of *X. perforans* strains that form a distinct cluster only distantly related to typical *X. perforans* (< 99.2% ANI). Thus, we propose reclassification of *X. euvesicatoria sensu stricto* as *X. euvesicatoria* subsp. *euvesicatoria* and split *X. perforans* into subsp. *perforans* and a yet unnamed subsp. of *X. euvesicatoria*.

TIME TO REVISIT THE PATHOVAR CONCEPT, TOWARDS A POLYPHASIC APPROACH ?

FISCHER-LE SAUX Marion. (1)

(1) Univ Angers, Institut Agro, INRAE, IRHS, SFR QUASAV, F-49000 Angers, FRANCE

Text

The pathovar concept was proposed as a provisional solution to avoid losing names of plant pathogenic species, that were not retained on the Approved Lists of Bacterial Names. Pathogenicity tests, to determine host range and symptomatology, are the cornerstone of this special purpose definition. However, they suffer from many drawbacks. Their outcome largely depends on inoculation conditions. Extended overlapping host range or gradient of virulence can sometime hinder pathovar circumscription, and large-scale assays to determine the extent of host range are seldom conducted.
During the last decades, our understanding of pathogenicity mechanisms, host specificity and pathogen evolution has benefited from genetics and genomics. Host adaptation of *Pseudomonas* and *Xanthomonas* strains, was shown to be driven by the evolution of the repertoire of type three effectors (T3E). Within *Xanthomonas arboricola*, it was shown that the most aggressive pathovars form three distinct clonal complexes, while less aggressive ones and non-pathogenic strains formed a recombinant network of strains with fewer or no T3E and sometime no type three secretion system. These differences of genetic structure and gene content are consubstantial with the ecological success of the strains and their ability to cause epidemics. Should we give more weight to these biological traits in the pathovar definition ?

Such a polyphasic approach could help to reconcile the pathovar concept with a natural classification.

PELTIGERA LICHENS IN ICELAND: YET ANOTHER RESERVOIR OF THE PLANT PATHOGEN PSEUDOMONAS SYRINGAE?

RAMIREZ Natalia. (1), CAULLIREAU Emma . (2), MORRIS Cindy. (3), SIGURBJÖRNSDÓTTIR Margrét Auður . (1), VILHELMSSON Oddur. (1)

(1) University of Akureyri, Akureyri, ICELAND; (2) University of Verona, Verona, ITALY; (3) INRAE - National Research Institute for Agriculture, Food and the Environment , Avignon, FRANCE

Text

The study of Pseudomonas syringae has recently shifted from an agrocentric context to an ecological perspective. The discovery of new niches inhabited by P. syringae improves our knowledge of the adaptive skills of this bacterial group and helps us realize the extent of its dispersion. The objective of this doctoral research project is to determine if lichens, the major vegetation of Iceland – an island where only 1% of its land is used for agriculture – harbor P. syringae with pathogenic potential for crops. Of the 16 different types of lichen analyzed, species of only one genera were consistently found to harbor P. syringae: Peltigera spp. Those strains isolated from Peltigera were later compared in terms of fitness and pathogenic potential with strains with well-known epidemiological importance on ten different plant species. For this question, population dynamics and virulence of lichen strains and reference epidemic strains were compared by inoculating species of crop plants of which some are grown in Iceland (barley, cucumber, kale...). Surprisingly, P. syringae isolated from Peltigera lichen has fitness and pathogenic potential similar to P. syringae from epidemics on crops in the plant species tested. Overall, the results of this work offer a unique opportunity to mark the starting point of observations on potential disease emergence as temperature, prevailing weather, and land use change in Iceland as consequences of climate and global change.

Text

Recently, MLSA-based approaches are increasingly being applied for the re-evaluation of some plant pathogenic bacterial species including Xanthomonas species. Nucleotide primers, *dnaK*, *fyuA, gyr*B, and *rpoD*, have been used for PCR amplification and sequencing

from *Xanthomonas* species. But their specificity to extended species is not fully tested. This study was performed to evaluate their amplification ability with 32 *Xanthomona*s strains consisting of 28 species and 5 pathovars. All the four primers did not amplify the target genes from *X. campestri*s pv. *armoraciae*, *X. theicola*, and *X. hortorum* pv. *carotae*. The primers for dnaK amplified the target sequences from 26 *Xanthomonas* strains, but did not from *X. hyacinthi, X. translucens* pv. *translucens*, *X. sacchari*, and *X. theicola*. The primers for *fyu*A amplified the target sequences from 19 *Xanthomonas* strains, but did not from *X. hyacinthi, X. translucens* pv. *translucens, X. sacchari*, and *X. theicola, X. arboricola* pv. *corylina, X. codiaei, X. campestris* pv. *campestris, X. alfalfae* subsp. *alfalfa, X. gardneri, X. vasicola* pv. *vasculorum*, and *X. nasturtii*. The primers for *gyrB* amplified the target sequences from 28 *Xanthomonas* strains, but did not from *X. translucens* pv. *translucens*. The primers for *rpoD* amplified the target sequences from 28 *Xanthomonas* strains, but did not from *X. hyacinthi* and *X. sacchari.* Application of MLSA based analysis of the four gene sequences of 32 Xanthomonas strains was discussed.

A NEW BACTERIAL DISEASE OF OLEANDER

FODOR Attila. (1), PALKOVICS László. (2,3), VÉGH Anita. (1)

(1) Hungarian University of Agriculture and Life Sciences, Institute of Plant Protection, Budapest, HUNGARY; (2) Széchenyi István University, Department of Plant Sciences, Mosonmagyaróvár, HUNGARY; (3) ELKH-SZE PhatoPlant-Lab, Széchenyi István University, Mosonmagyaróvár, HUNGARY

Text

Nerium oleander L. of the family *Apocynaceae*, is an evergreen shrub or small tree of the Mediterranean region. The abundant and long-lasting flowering makes it a popular ornamental plant. Only a few bacteria can infect oleander such as *Pseudomonas savastanoi* pv. *nerii, Agrobacterium tumefaciens* and *Xylella fastidiosa*. We have been investigating oleander canker disease for years, and during sample collection we observed atypical symptoms on the leaves and stems of oleander. In our work, we aimed to identify the pathogen. The collected samples were decontaminated, homogenized and streaked on King B agar. The isolates formed yellow-coloured, smooth-edged and convex bacterial colonies on the medium. The isolates were Gram negative, oxidase negative and induced a hypersensitive reaction in tobacco leaves. The biochemical properties were determined by API20E tests. Pathogenicity was performed on young oleander plants with bacterial suspension. Two weeks after the artificial infestation, brown necrosis was observed on the leaves of the oleander. The pathogen was successfully reisolated Koch's postulates were fulfilled. For molecular identification of the pathogen, the 16S rDNA region were amplified using a universal bacterial primer pair. According to symptoms, colony morphology, biochemical features, pathogenicity and molecular methods, the pathogen was identified as *Xanthomonas campestris*.

The research was supported by the ELKH TKI (project number: 3200107).

P7.5-004

CHARACTERIZATION OF XANTHOMONAS ARBORICOLA PV. JUGLANDIS ISOLATES IN HUNGARY

VÉGH Anita. (1), **ATTILA Fodor. (1)**, BÉKÉSI Orsolya. (1), SZANI Zsolt. (2), BUJDOSÓ Géza. (3)

Text

*Xanthomonas arboricol*a pv. *juglandis* is the causal agent of walnut blight, the most important bacterial disease of *Juglans* species, which affects a high percentage of pistillate flowers and fruits, but does not kill bearing trees. Symptoms of the disease consist of dark brown to black spots on new leaves, stems and nuts. Many nuts fall prematurely; others reach full size, but their kernel become blackened, dried and wrinkled.
In Hungary, walnut blight disease occur and cause important damage in gardens and orchards. Since 2020, we have been constantly monitoring the symptoms. The collected leaf and fruits samples were decontaminated, homogenized and streaked on King B agar. After 24 hours of incubation at 26 °C the Gram property of isolates was determined by KOH test. We examined all isolates to induce a hypersensitive reaction on tobacco leaves. Biochemical API test was also used for identification. Finally, the pathogenicity of the isolates was checked. In the case of walnut blight, immature walnut fruits and leaves were artificial infected with a bacterial suspension. For molecular identification of the isolates, the 16S rDNA region were amplified using a universal primer pair (63F, 1389R). *Xanthomonas arboricola* pv. *juglandis* isolates that cause walnut blight disease have been identified by classical and molecular methods in Hungary.

This project was supported by the János Bolyai Research Scholarship (bo_671_20) of the Hungarian Academy of Sciences”.

FIRST REPORT OF PSEUDOMONAS SYRINGAE PV. SYRINGAE CAUSING A LEAF SPOT DISEASE ON WATERMELON PLANTS IN GREECE

GOUMAS Dimitrios. (1), MPALANTINAKI Evaggelia. (1), PAGOULATOU Marianthi. (1), MALLIARAKIS Dimitris. (1)

(1) Hellenic Mediterranean University, Heraklion , GREECE

Text

In May 2022, a bacterial infection was found during microscopic examination, in watermelon seedlings, with symptoms differing from known watermelon bacterial diseases. The disease destroyed more than 3.000 plants at the nursery. On the leaves lamina, small oily, watery round spots were observed which grow in concentric rings and may merge. The spots acquire a brown necrotic center with a watery margin and/or a weak chlorotic halo. Similar elongated spots/cankers were observed on the stems, which may damage part or all the leaf lamina. From the infected tissues, on King's B medium, bacterial colonies were constantly

growing in pure culture with diffuse blue fluorescent pigment. Isolates in LOPAT tests showed the phenotype [+ - - - +]. Based on the morphological and biochemical profile, the isolates were characterized as members of Pseudomonas syringae species complex, a fact that also confirmed by the analysis of 16S rRNA. In addition, phylogenetic analyses based on the sequencing of multiple loci (MLSA) utilizing four housekeeping genes (gapA, gltA, gyrB, rpoD), showed that isolates from watermelon seedlings were grouped with corresponding sequences of other strains of Pseudomonas syringae pv. syringae. Koch's postulates were fulfilled on watermelon plants. This is the first report of Pseudomonas syringae pv. syringae, causing a new watermelon disease in Greece.

Text
Xanthomonas vasicola is one of the 27 described *Xanthomonas* phytopathogens, and members of this genus form characteristic yellow colonies due to the production of xanthomonadins. These phytopathogens cause diseases in 124 monocotyledonous and 368 dicotyledonous plants. In the mid-2000s, an outbreak of bacterial blight and dieback caused by *X. vasicola* pv. *vasculorum* occurred in a newly established *E. grandis* plantation with a single clonal origin, and it was hypothesised that this phytopathogen jumped from the adjacent sugarcane fields onto *Eucalyptus*. A comparative genomics study was undertaken to understand the molecular changes that may have contributed to this host jump and the adaptation of this bacterial pathogen to *E. grandis*. The phylogenetic relationship of five *E. grandis* strains and eighteen *X. vasicola* strains of other hosts was determined. Genomic islands and insertion sequences were identified, and some insertion sequences predicted were present within these islands. In addition, orthologous clusters of *X. vasicola* strains from different hosts were predicted, and the phylogeny of clusters unique to the *E. grandis* strains was inferred. Together these analyses identified unique genes from the *E. grandis* strains involved in chemotaxis, plant cell wall degradation, the suppression of reactive oxygen species, and the T4SS. Therefore, it is possible that these genes may have contributed to the adaptation of *X. vasicola* pv. *vasculorum* to *E. grandis* from sugarcane.

Text

Common bacterial blight (CBB) is an endemic disease of common bean (Phaseolus vulgaris) caused by Xanthomonas phaseoli pv. phaseoli and X. citri pv. fuscans. In favourable conditions, it reduces yield of beans up to 40 %. Despite the numerous efforts to improve the genetic resistance of common bean to CBB, a complete resistance is lacking and the efficacy of known resistance varies depending on the strains tested. Methods for disease assessment and resistance scoring differ by their efficacy in differentiating the virulence of strains and the resistant genotypes. Effective disease phenotyping methods is essential for searching novel resistant genotypes, therefore we compared 4 different inoculation methods with two Xanthomonas spp. strains (USB 749, USB 771) on 2 bean varieties. The methods were ranked according to the time required to complete the procedure and according to their ability to discriminate the virulence of the two strains. This comparative study allows to select the appropriate method of infection depending on the research objective considered and will be essential for our future breeding activity.

Plant pathogens interactions in multi stress conditions (abiotic and biotic stresses): viruses and other pathogens?

C5.7-1

PLANT-VIRUS-VECTOR INTERACTIONS UNDER ABIOTIC STRESSES

TREBICKI Piotr. (1,2), **VAN MUNSTER Manuella. (3)**

(1) Applied BioSciences, Macquarie University, Sydney, AUSTRALIA; (2) School of Agriculture and Food, University of Melbourne, Parkville, AUSTRALIA; (3) UMR PHIM Plant Health Institute, Montpellier, FRANCE

Text

Biotic and abiotic stresses shape plants communities and distribution in ecosystems. Among biotic stresses, plant viruses can cause significant losses in agriculture. Moreover, the majority of plant viruses rely on a third-party for host-host spread, insects being by far the most important vectors of these plant pathogens. Therefore, environmental conditions that influence the vector biology will as a result influence virus transmission efficiency, spread

and persistence in ecosystems. In this context, climate change disturbs multiple processes that may impact the epidemiology of plant viruses interactions under multi stress conditions, adding another layer of uncertainty in crop protection, as well as current and future food security. The impact of different abiotic stresses, especially related to climate change (temperature, water availability, CO2 etc..), on plant-virus-vector interactions will be presented and discussed.

SEARCHING FOR SUSTAINABLE AND EFFICIENT SOURCES OF DISEASE RESISTANCE UPON FLUCTUATING CLIMATE: CHARACTERIZATION OF THE WHEAT-SPECIFIC RESPONSES TO FUSARIUM HEAD BLIGHT UNDER CONTRASTING IRRIGATION

ADAMIK Larissa. (1), DOU Samir. (1), LANGIN Thierry. (2), BONHOMME Ludovic. (1)

(1) Université Clermont Auvergne, Clermont-Ferrand, FRANCE; (2) CNRS, Clermont-Ferrand, FRANCE

Text

Fusarium head blight (FHB), primarily caused by *Fusarium graminearum*, is a prominent disease of small grain cereals impacting yield and grain quality. In wheat, many efforts are still produced to find alternative sources of resistances, especially focusing on susceptibility factors. Despite the important role of the abiotic environment in the establishment of the disease, only few studies have included the impact of future climate scenarios on the expression of the plant susceptibility or resistance. Focusing on fluctuating water regimes, this work aims to initiate the phenotypic and molecular characterization of the FHB-induced responses in wheat facing soil water deficit preceding infection. A setup of mild drought of different durations during spike development demonstrated a specific and non-additive response to the constraint combination. A strong decrease of symptoms in plants subjected to previous drought during at least 6 days have been observed compared to well-watered. A relationship between symptom reduction and water stress duration was observed. Metabolite profiling and dual-transcriptomics of spike samples is used to identify molecular mechanisms specifically set up upon combined stress as compared to well-watered plants and plants subjected to respective individual stresses. These results will provide new candidates for the selection of sustainable and efficient sources of FHB resistance with promising potential in the context of climate change.

Grains Innovation Park, Horsham, Vic, AUSTRALIA; (4) School of Agriculture and Food, The University of Melbourne, Parkville, Vic, AUSTRALIA

Text

Canola (Brassica napus L.) is one of the most important crops worldwide. It is affected by several pathogens which can cause significant losses and increase production costs. Aphid-borne, turnip yellows virus (TuYV, Polerovirus, Family: Luteroviridae) is one of the most damaging and difficult to control. Under future climate, for many parts of the world, more intense and prolonged drought events are predicted, adding another factor that can significantly impact the epidemiology of plant diseases. In this study, we aimed to understand the impact of drought on canola plants previously infected with TuYV. We conducted glasshouse trials, where TuYV infected and noninfected canola plants were exposed to different watering regimes as well as terminal drought. Canola plants were inoculated with TuYV at three leaf stage then at four leaf stage, water treatments were initiated. Several parameters including: height, number of leaves, growth stage and leaf area were recorded as well as chlorophyll content, water use efficiency, symptom expression and biomass, to assess the impact of virus infection and drought on canola growth. TuYV exacerbated the effects of water stress and terminal drought on biomass and other plant growth parameters when compared to non-infected plants. These results suggest that drought could aggravate the negative impact of TuYV on canola crops as a consequence of climate change.

C5.7-4

THE BOTRYTIS CINEREA PECTIN LYASE BCPNL1 IS INVOLVED IN PATHOGENICITY AND ITS PECTINOLYTIC ACTIVITY CONTRIBUTES TO THE IMPACT OF HOST NITROGEN NUTRITION ON DISEASE SEVERITY

DAVIERE Antoine. (1,3), VOXEUR Aline. (1), JOLIVET Sylvie. (1), VERNHETTES Samantha. (1), SOULIE Marie-Christine. (2), FAGARD Mathilde. (1)

(1) Université Paris-Saclay, INRAE, AgroParisTech, Institut Jean-Pierre Bourgin (IJPB), Versailles, FRANCE; (2) Sorbonne Universités, Pierre et Marie Curie Université Paris 06, UFR 927, Paris, FRANCE; (3) Ecole Doctorale 567 Sciences du Végétal, Univ Paris-Sud, Univ Paris-Saclay, bat 360, Orsay, FRANCE

Text

Host nitrogen nutrition is known to impact the expression of plant defense genes but also pathogen virulence factors. In this study we found that pectinolytic enzymes of *Botrytis cinerea* are strongly affected by plant nitrate nutrition during infection of *Arabidopsis thaliana* at the transcriptional level leading to changes in the final oligogalacturonide (OG) production. We report here the importance of *BcPNL1*, the first pectin lyases (PNLs) of *B. cinerea* described as involved in pathogenesis and OG production during the infectious process. Indeed, CRISPR-Cas9 *ΔBcpnl1* deletion mutants were hypovirulent on several hosts plants and the absence of PNL products found by LC-MS/MS analysis of OGs produced during the interaction confirmed that BcPNL1 is the major PNL of *B. cinerea*. Furthermore, during infection with the *ΔBcpnl1* mutants, negative regulators of the jasmonate (JA) defence pathway such as *AtJOX3* and *AtJAZs* were down regulated whereas the JA marker gene *AtPDF1.2* was strongly induced. These results confirmed a previously mentioned role of OGs produced by PNL in repression of the JA pathway. We also revealed that varying nitrogen nutrition status of the

plant have a different impact on defense gene expression during infection with the *ΔBcpnl1* mutant. Altogether, we provide evidences that plant cell wall degradation and particularly BcPNL1 activity are important factors contributing to the complex interaction between host nitrogen nutrition and pathogenesis.

CAN TEMPERATURE ADAPTATION DRIVE RALSTONIA SOLANACEARUM RANGE EXPANSION IN THE FUTURE?

CARDENAS GOMEZ Karla. (1), FRIMAN Ville. (1,2), HARPER Andrea. (1)

(1) UNIVERSITY OF YORK, York, UNITED KINGDOM; (2) UNIVERSITY OF HELSINKI, Helsinki, FINLAND

Text

The *Ralstonia solanacearum* species complex (RSSC) consists of a group of phytopathogenic β-proteobacteria with extensive genetic diversity responsible for lethal wilts or rots in a variety of plants worldwide. RSSC strains have adapted to survive across different environments and to infect a wide range of plant hosts. While human agricultural activity has played an important role in the distribution of the pathogen, it is less clear how RSSC strains will adapt and spread in light of global warming. In this work, I will use experimental evolution to expose the cold-adapted strain UW551 to increasing environment temperatures in the laboratory and quantify the effect on its virulence and fitness. Secondly, I will evaluate how the warm-adapted strain GMI1000 evolves in response to exposure to a cold environment. These experiments will help to assess whether RSSC strains currently inhabiting cold regions will become a more severe threat due to global warming, and if strains inhabiting warmer regions can potentially adapt to colder climates, leading to pathogen migration and range expansion in the future. These studies will also provide insights into the genes and mechanisms used by RSSC strains to adapt and survive under changing environmental temperatures.

Text

Little is known about the interplay of biotic and abiotic stress responses in crop plants. Spring barley is susceptible to Fusarium Head Blight (FHB), which is highly affected by weather conditions. We combined barley ear infection with Fusarium culmorum with or without

previously applied drought stress in the greenhouse and studied the influence of drought on FHB severity in three differently susceptible spring barley varieties. We found strongly reduced FHB severity in susceptible varieties under drought stress. We conducted a global transcriptome analysis of barley spikes and correlated physiological stress markers such as abscisic acid with co-expressed gene networks using weighted gene correlation network analysis. These networks may help to explain common or genotype-specific responses to complex stress situations. An infection-related module contained co-expressed genes for defence, programmed cell death and mycotoxin-detoxification indicating that diverse genotypes use a similar defence strategy towards FHB albeit with different success. Further networks are highly associated with drought or genotypes, but no network is correlated with the combination of drought with infection, indicating a modular composition of single stress responses. Our analysis further (re-)discovered both established and new players in response to stress and fungal toxins and provides a route for diverse analyses of combined physiological and global gene expression data.

Text

High temperatures are known to exacerbate rice panicle blight caused by Burkholderia glumae. Our long term goal is to develop rice with increased tolerance to combined heat and disease stresses. Our first steps have been to develop a robust experimental system to test how heat stress tolerance interacts with B. glumae infection. A set of rice genotypes with contrasting tolerance to heat was inoculated with B. glumae at anthesis stage. Genotype response to bacterial infection was measured by quantifying the proportion of empty spikelets as well as the total number of grains obtained from inoculated panicles. Preliminary results identified promising rice genotypes that can tolerate heat stress and the infection by B. glumae separately. These rice genotypes will be valuable for studying the molecular mechanisms responsible for tolerance and enable development of new rice varieties that withstand combined stresses under field conditions.

(1) University of Canterbury, Christchurch, NEW ZEALAND; (2) AgResearch Ltd, Christchurch, NEW ZEALAND; (3) John Innes Centre, Norwich, UNITED KINGDOM

Text

Signal transduction enables plants to detect and respond to environmental stress. Calcium (Ca^{2+}), considered a key signalling molecule in plants, regulates gene expression, hormone release and cell death. However, it remains unclear how specificity of Ca^{2+} signalling responses is achieved. Firstly, we established a bi-directional dual-flow-RootChip microfluidic device to expose G-CaMP3 *A. thaliana* primary roots to asymmetric solute gradients. Fluorescent live-cell imaging detected and quantified cytosolic Ca^{2+} and root growth. We observed the Ca^{2+} signal induced by different osmolytes (NaCl, PEG and Mannitol) and pathogen associated molecular patterns (flg22, PEP-13, chitin). The signal dispersed differently depending on treatment condition and orientation (shoot-to-root, root-to-shoot, transverse), exhibiting a directional response. Secondly, a label-free quantitative proteomic approach was used to link early signalling with changes in protein profiles and phosphorylation events. For this, we compared roots treated for 5 minutes with 20% PEG, 500 µM flg22 and ½ MS medium (control). Up to 300 phosphoproteins and 6000 proteins were detected in each sample, showing distinctive treatment groups with supervised clustering methods. Proteins of interest with functions in osmotic stress adaptation and immunity were identified and further analysed. We will discuss their potential role in signalling to distinguish between different stressors to fine tune root adaptation processes.

SUFFICIENT COUMARIN ACCUMULATION IMPROVES APPLE RESISTANCE TO CYTOSPORA MALI UNDER HIGH POTASSIUM STATUS

SUN Guangyu. (1), DU Youwei. (1), JIA Hongchen. (1), YANG Zi. (1), WANG Shuanghong. (1), LIU Yuanyuan. (1), LIANG Xiaofei. (1), GLEASON Mark. (2), HSIANG Tom. (3), ZHANG Rong. (1), MA Huiya. (1)

(1) Northwest A&F Univerisity, Yangling, CHINA; (2) Iowa State University, Ames, UNITED STATES; (3) University of Guelph, Ontario, CANADA

Text

Cytospora canker, caused by *Cytospora mali*, is the most destructive disease in production of apples (*Malus domestica*). Adding potassium (K) to apple trees can effectively control this disease. Here, we found that series of resistance events were active in high K (HK, 9.30 g/kg) apple tissue, especially upregulation of resistance genes, callose deposition and formation of ligno-suberized tissues. Further multi-omics revealed that the phenylpropanoid pathway was reprogrammed by HK status, leading to increases of 18 antifungal chemicals. Among them, the physiological concentration of coumarin became sufficient to inhibit *C. mali* growth, and its exogenous application could improve the apple resistance. The transgenic apple calli with overexpression of *MdBGLU40* that encoded beta-glucosidase for coumarin synthesis contained higher levels of coumarin and exhibited high resistance to *C. mali* even under low K conditions. Meanwhile, suppression of *MdBGLU40* through RNAi reduced coumarin content and resistance in HK apple calli, supporting the importance of coumarin in apple resistance. Moreover, we found that the upregulation of transcription factor *MdMYB1r1* directly activated

MdBGLU40, and the binding affinity of MdMYB1r1 to the *MdBGLU40* promoter increased in HK apple tissue, leading to high levels of coumarin and resistance in HK apple. Overall, our results highlight the optimization of K content in fertilization practices as a novel disease management strategy.

HOW WILL ATMOSPHERIC CO2 CONCENTRATION IMPACT THE VIRAL SUSCEPTIBILITY/RESISTANCE? : PHASEOLUS VULGARIS AS A MODEL PLANT

SCANDOLERA Tiffanie. (1), TEANO Gianluca. (1), ALVAREZ-DIAZ Juan Camilo. (1), GRATIAS-WEILL Ariane. (1), PREJEAN Maria Victoria. (1), GEFFROY Valérie. (1), PFLIEGER Stéphanie. (1)

(1) Institut des Sciences des Plantes Paris-Saclay, Gif-Sur-Yvette, FRANCE

Text

One major concern of this century is the impact of climate change, notably on crop cultures. Experts of climate change have forecast an increase in atmospheric CO_2 level from 400 µL.L-1 in 2014 to ~1000 µL.L-1 in 2100 in the worst predictive scenario, as well as a raise of 3.3-5.7°C in temperature. Plants are directly impacted by these changes as well as pathogen populations including viruses.
In that context, an important question is to what extent the increase in CO_2 will affect plant-virus interactions, whether susceptibility or resistance?
The objective of our work is to study the impact of elevated CO_2 (eCO_2) level on viral susceptibility/resistance using common bean (*Phaseolus vulgaris* L.) as a model plant. We used the *P. vulgaris*/*Bean pod mottle virus* (BPMV, *Comovirus*) pathosystem to investigate the impact of eCO_2 on the level of susceptibility/resistance to BPMV using two natural genotypes BAT93 (resistant to BPMV) and Black Valentine (susceptible to BPMV).
In that aim, we analyzed viral titers in plants grown under eCO_2. We also monitored the accumulation of salicylic acid (SA). Moreover, we studied the expression of genes encoding enzymes of the SA pathways, as well as genes encoding PR proteins and components of the RNA silencing pathway.
Our preliminary results show that both genotypes are more resistant/less susceptible under eCO_2 and this seems correlated with a higher accumulation of SA and with an increased expression of defense genes.

Text

Closure of stomata on plant epidermal cells can prevent the invasion of pathogenic bacteria and plays an important role in plant innate immunity. Abscisic acid (ABA) can induce plants

to close stomata, while bacterial infection can antagonize ABA by secreting coronatine (COR), reopening the stomata to promote infection, but the internal molecular mechanism is not clear. Our previous experiments found that COR treatment could upregulate the content of ABI1, a negative regulator of ABA signaling pathway, to reduce plant sensitivity to ABA signaling. We also identified a nucleoplasmic transporter that may mediate the nucleoplasmic shuttling of ABI1 to regulate its function. Therefore, this project can reveal the molecular mechanism of COR antagonizing ABA function and opening stomata, and finally provide new ideas and theoretical basis for the improvement design of drought-resistant and water-saving crops.

Text

Rice is the staple food of more than half of the world's population. With economic development and population growth, global warming has become a problem that cannot be ignored. The high-temperature stress caused by climate warming will seriously affect rice growth and development and reduce rice yield. Previous studies have shown that high temperatures may increase the risk of the destructive rice blast caused by *Pyricularia oryzae* in subtropical regions and tropical winters. However, little is known about the interactions between *P. oryzae* and rice under higher temperatures. We first tested the effects of different temperatures on the mycelial growth and sporulation of 25 representative *P. oryzae* isolates from different years and regions in Taiwan. A heat-tolerant isolate was selected to evaluate the effectiveness of three blast resistance genes, i.e., *Pi2*, *Pi9*, and *Ptr*, in the genetic backgrounds of ‘Lijiangxintuanheigu (LTH)’ and a heat-tolerant cultivar ‘Kaohsiung 145 (KH145)’. Plants with *Pi2* and *Pi9* showed resistance no matter at normal (28°C), higher (32°C), or the highest temperature (35°C); however, KH145 with *Ptr* showed unstable resistance at 35°C. How high temperatures affect gene expressions in *P. oryzae* and the resistance regulatory networks of different *R* genes in rice are worth further investigation.

Text

Crops are facing increasing biotic and abiotic stress pressures due to global changes. However, trade-off mechanisms between these stresses and the underlying physiological processes are still poorly understood, especially in perennial crop species. To better understand these trade-offs, we studied the effect of drought on grapevine (*Vitis vinifera*) physiology and esca-related wood fungal communities. Esca is a vascular disease caused by a community of wood-infecting pathogenic fungi, and characterized by trunk necroses, leaf scorch symptoms, yield losses, and mortality. This grapevine disease leads to leaf symptoms associated with xylem hydraulic failure, and leaf symptoms are inhibited by severe drought. To characterize the molecular processes underlying the interactions between drought and esca, we conducted two greenhouse experiments on 30-years-old Sauvignon blanc vines. Esca leaf symptoms expression was monitored and vines were subjected to drought stress or not under controlled conditions. Sapwood samples from the trunks were used to perform a community-level transcriptomics (i.e. metatranscriptomics) analysis. Results will be also related to metabolomic and ecophysiological data acquired on wood and leaf samples. This integrative approach will provide new insights into the understanding of the grapevine/esca pathosystem under drought, in terms of physiological and functional responses in both host and pathogens.

STRATEGIES FOR BIOTIC STRESS MANAGEMENT IN PULSES UNDER CHANGING CLIMATE

SHARMA Mamta. (1)

(1) International Crops Research Institute for the Semi-Arid Tropics, Hyderabad, INDIA

Text

An increasing agricultural productivity is a critical first step in meeting the Sustainable Development Goals of ending hunger and poverty by 2030. Majority of poor farmers survives in Sub-Saharan Africa and South Asia where an overall loss of attainable yield from pest & disease (P&D) is much greater. In particular, significant damage has been caused globally by transboundary pests against the background of climate change and globalized movement of people and goods. Climate change, disruption of pest & diseases biological synchrony, promotion of minor pest into major, soil moisture deficit and lack or apparent failure of resistance cultivars seems to be major reasons for the production loss in pulses like chickpea and pigeonpea. Tailored research information on transboundary and emerging P&D, climate vulnerabilities for epidemics, crop resistant and new management technologies could be essential to bring the transformation in poor farming families. Accelerated pest's damages prejudice the obligation of pest prioritization and risk assessment for optimization of the preemptive breeding in demarcated target population environments, determination of socio-economic condition of farmers and rapid action on climate smart crop management and

adaptation. New tools and technologies linked to the advisory will help in providing rapid response to the farmers for managing their crops in a real time manner.

Text
Crop plant adaptation to stresses, including heat and disease, affects chromatin accessibility and expression of numerous genes by exposing short sequences in promoter areas, specifically cis-regulatory elements (CRE) or combinations of CRE that are organized as modules (cis-regulatory modules or CRM). Increasing evidence demonstrates that conserved CRE/CRM are found in promoters of genes that are co-activated by a single stress and/or are common to genes co-activated in plants with enhanced tolerance to different stresses. Moreover, genetic polymorphisms modifying CRE/CRM can significantly impact gene activity and plant responses to stresses. We have shown that many genes involved in broad-spectrum disease resistance (BSDR) share a set of CRMs in rice. Also, accumulating genes with the most ‘active’ form of CRMs in several BSDR genes leads to enhanced disease resistance in the field. Presently, we are testing modifications of specific CRE/CRM via genome editing and transient assays to analyze their relevance. Based on these results, we propose a strategy to simultaneously breed for crop resilience to heat and disease through the identification of shared CRE/CRMs. The identified elements, and detected polymorphisms affecting them, can be used to develop conserved molecular markers for breeding. Our goal is to enable genome-wide selection of complex traits governed by multiple genes with a reduced number of markers rather than the traditional one marker-one gene approach.

P5.7-009

UNDERSTANDING THE IMPACTS OF HEAT STRESS ON BACTERIAL BLIGHT RESISTANCE GENES IN RICE

SHIPP Jennifer. (1), LEACH Jan. (1)

(1) Colorado State University, Fort Collins, UNITED STATES

Text
By the year 2100, average air temperatures are predicted to increase by 2°C to 6°C around the world. This impacts the day-to-day conditions in which plants grow and is a threat to production of many cereal crops, including rice. When rice plants are exposed to combined stresses, such as high temperatures and disease, there is often a reduction in the effectiveness of bacterial disease resistance mechanisms within the plant. These

mechanisms include the protective actions provided by resistance genes (*R* genes), which have previously been effective at controlling the spread of bacterial blight, a yield-reducing disease caused by *Xanthomonas oryzae* pv. *Oryzae*, in rice. Diminishing disease resistance in the face of increasing temperature trends will expose growers to additional acceleration of predicted yield losses in the coming decades. Interestingly, one rice *R* gene, *Xa7*, shows milder disease phenotypes under heat stress, indicating improved *R* gene efficacy under these conditions. Transcriptome analysis predicts that alternative stress response signaling involving hormonal crosstalk may be occurring in this phenotype, but the enhanced efficacy and molecular changes observed in *Xa7* interactions have not previously been compared in interactions with other *R* genes. The impacts of high temperatures on rice and bacterial blight disease for other *R* genes including *Xa3*, *xa5*, *Xa10*, and *Xa21* will be presented.

RASPBERRY PHYSIOLOGY AND LATE LEAF RUST SEVERITY IN PLANTS UNDER WATER STRESS AFTER THE PATHOGEN INFECTION

BARBOSA Lucas. (1), SPÓSITO Marcel. (1), APPEZZATO-DA-GLÓRIA Beatriz. (1)

(1) “Luiz de Queiroz” College of Agriculture, University of São Paulo, Piracicaba, BRAZIL

Text

Aculeastrum americanum is the causal agent of late leaf rust. The fungus penetrates raspberry leaves only through the stomata. In raspberries under water deficit, the penetration capacity of *A. americanum* is drastically affected, due to stomatal closure, leading to less disease severity. The study aimed to investigate what happens with the plant and the disease when water limitation occurs after pathogen penetration. For this, we compared epidemiological parameters of the disease and the gas exchange of inoculated plants ($5x10^4$ mL^{-1} urediniospores of *A. americanum*) submitted to two water conditions: 30% and 60% of soil water storage capacity (WSC) after inoculation. The plants grown without water limitation exhibited higher disease severity and lesion density than plants grown at 30% WSC. The production of urediniospores per lesion did not differ between treatments. Our results revealed that under water stress there was reduction in the leaf gas exchange since the beginning of the experiment. Consequently, the development of these plants was drastically affected, which could have interfered with the severity of the disease.

P5.7-011

APOPLASTIC METABOLIC AND PROTEOMIC CONTENTS ARE AFFECTED BY ABIOTIC STRESS AND CONTROL PATHOGEN VIRULENCE.

JERIDI Roua. (1), DAVIÈRE Antoine. (1), JOLIVET Sylvie. (1), BOUTET Stéphanie. (1), CLEMENT Gilles. (1), ROUFFET Justine. (1), SOULIÉ Marie-Christine. (1), **FAGARD Mathilde. (1)**

Text
Plant responses to pathogen invasion leads to the production of defence proteins, metabolites and hormones. Since the apoplastic space represents the first layer of defence, important changes take place in this compartment. These changes have not been described yet in the case of necrotrophic fungal pathogens that kill host cells rapidly and proliferate on dead tissues. However, the initial phase of the interaction is critical since these pathogens have to cope directly with plant defenses, in particular in the apoplastic space. In this study we describe for the first time the modifications that occur in the apoplast of Arabidopsis thaliana in this initial phase of infection by two necrotrophic pathogens, E. amylovora and B. cinerea. Our results showed that important changes are triggered in the first hours of infection at the proteomic and metabolomic level. In parallel, we analyzed the impact of nitrogen nutrition on apoplast content. N is an essential nutrient not only for plant development but also for defense against abiotic and biotic stress. Changes in the plant apoplast status in response to E. amylovora colonization are highly beneficial to the hrp-dependent bacterial cycle under low N. Taken together, this cartography of the early apoplastic molecular dialogue between plants and pathogens revealed putative defence, susceptibility and virulence factors that play a critical role in the outcome of interactions and on the impact of abiotic stress on these interactions.

Text
Plants are often challenged by stresses acting in combination and the response to combinatorial stress differs from that triggered by each factor individually. Pomegranate cultivation in Italy is currently limited by the emerging *Coniella granati* and *Phytophthora palmivora* pathogens. It is ignored if they benefit from previous stress caused in pomegranate by periods of heavy rainfall or intense drought. We hypothesized that drought and waterlogging experienced by plants will increase damage caused by subsequent infection. In June 2022, two-year-old plants were subjected to regular watering (C), drought (D) and waterlogging (W) conditions and stem-inoculated, individually or simultaneously, with *C. granati* and *P. palmivora* (n=10) or with a PDA plug as control (n=10). Lesion length in the stem was assessed and used as a proxy of plant susceptibility. W prior to *C. granati* infection significantly increased lesion length (140%), and D prior to *P. palmivora* infection significantly decreased lesion length (60%), in relation to C-infected plants. Lesion length caused by *C. granati* significantly increased if plants were co-infected by *P. palmivora* and this was dependent on conditions experienced by plants before infection (ca. 100, 50 and 30% for C, D and W plants, respectively). Lesion length caused by *P. palmivora* was not altered if plants were co-infected *C. granati* irrespective of the conditions experienced by plants before infection.

(1) Auburn University, Auburn, UNITED STATES

Text

Climate change accompanied by modern agricultural practices has presented a threat of emerging novel pathogen lineages capable of compromising host resistance or expanding host range. Here, we tested the influence of altered ozone levels on plant disease development and pathogen evolution under otherwise natural field conditions using *Xanthomonas perforans*, a causal agent of bacterial leaf spot disease, on resistant and susceptible pepper cultivars. We observed significantly higher disease severity, but with more variations, under concurrent stress conditions, which led us to hypothesize that pathogen populations adapt by accommodating higher plasticity. It would reflect in altered ecological interactions among pathogen genotypes and overall pathogen diversity at the genomic levels. Our data revealed high strain turnover in the pathogen community under concurrent stress by the end season, accompanied by high and variable nucleotide diversity and mutation rates in contrast to the individual stresses. The signatures of parallel evolution with positive selection of different alleles at high frequency along with a high degree of flux in dispensable genes and reduction in certain high-cost effector genes to possibly limit the fitness constraints. Together, increased ecological and evolutionary plasticity was obsered for pathogen adaptation to resistant host and altered ozone, indicates to further examine the outcomes of this plasticity in evolution of virulence.

Plant protection potential of persistent (cryptic) viruses in fungi, plants and insect vectors of plant disease

Text
Mycoviruses can be found in almost all kinds of fungi, they are rich in diversity and have been assigned into 29 families by ICTV in 2022. A few of mycoviruses that infect plant pathogenic fungi could cause hypovirulence, and can be potentially used to control fungal diseases. One of the strategies to control diseases with mycoviruses is to target on fungal pathogen, using mycovirus to weaken fungal virulence. However, because the transmission of mycoviruses is limited by host vegetative incompatibility system, this fungi-target strategy has not been widely adopted in field. Previously, we isolated a hypovirulence-associated DNA mycovirus (SsHADV-1) from a hypovirulent strain of Sclerotinia sclerotiorum. We found that SsHADV-1 could convert its host from a necrotrophic pathogen to a mutualistic endophyte; when virus-infected-strain growing on plants, it could enhance plant resistance and promote plant growth. We then, developed virus-infected strain as plant vaccine and used it to inoculate rapeseed seeds, and found that the seed yield of rapeseed was significantly improved in the field. The vaccine strategy targets on both plant and pathogens and overcomes the biocontrol efficiency issue limited by mycovirus transmission. Importantly, the vaccine strategy can be used widely in the field since more and more hypovirulence associated mycoviruses have been found to have ability to convert its host to mutualistic endophyte on plants.

C7.2-2

EFFECTS ON THE SPOROGENESIS AND BIOCONTROL FUNCTIONS OF TRICHODERMA SPP. BY THE MYCOVIRUSES

BEILEI Wu. (1), CHENCHEN Liu. (1), RONGQUN Wang. (1), ZHAOYAN Tan. (1), XILIANG Jiang. (1)

Text
Trichoderma spp. are known to impact host plant growth and defense activities. With the findings of the mycoviruses from Trichoderma spp., more and more effects on the sporogenesis and biocontrol functions of host induced by mycoviruses were known. In our researches, Trichoderma harzianum partitivirus 2 (ThPV2) from *T. harzianum* strain (T673) showed higher conidiospore, and chlamydospore production than the virus-infected strain T673-F, and moderately but statistically significantly improved biocontrol activity when compared with the T673-F in the experiments with cucumber seeds inoculated with *Fusarium oxysporum* f. sp. *cucumerinum*. Trichoderma harzianum mycovirus 1 (ThMV1) from *T. harzianum* strain (T525) not only affected the phenotype of the host strain but also reduced its biocontrol function on *F. oxysporum* f. sp. *cucumerinum*. The yeast two hybrid nuclear system screened the hexokinase1 (HXK) also was the interacted protein with ThMV1-CP, Then the hexokinase gene knockout mutant (T525^{-hxk}) and reverse mutant (T525^{Rhxk}) of T525 were obtained. connecting the results of transcriptomic analysis, Real-time RT-PCR and the phenotype of cucumber, the interaction of ThMV1-CP/HXK in T525 was proved to negatively regulate the disease resistance pathway of T525 and positively regulate the growth promotion effect of T525 in the cucumber.

CONDITIONAL MUTUALISM BETWEEN GRAPEVINE RUPESTRIS STEM PITTING-ASSOCIATED VIRUS AND VITIS VINIFERA CONFERS TOLERANCE TO DROUGHT AND FUNGAL DISEASES

GAMBINO Giorgio. (1)

(1) National Research Council of Italy (CNR), Torino, ITALY

Text
Plants and phytobiome (composed by microbiome and macrobiome) interact with each other and with the environment, modulating plant responses to biotic and abiotic factors. In this framework, plant–virus interactions can be addressed not only from the point of view of a classical binary relationship (host–pathogen) but also as a single microecosystem adapting to the external environment. Viruses are not necessarily detrimental in all situations, indeed, in specific cases they could display a mutualistic relationship according to their host and the environment. An interesting example of this phenomenon is related to grapevine rupestris stem pitting-associated virus (GRSPaV), one of the most prevalent viruses that infect grapevines, usually found in Vitis vinifera cultivars in a latent state, without the development of macroscopic phenotypic alterations. Eco-physiological analyses proved that GRSPaV-infected grapevines exposed to drought stress had higher rates of photosynthesis and stomatal conductance, low hydraulic resistance to water transport, and increased ability to extract water from the soil. GRSPaV also alters the profiles of several genes and microRNAs that act as important players in the regulation of the interplay between GRSPaV and drought in grapevine. Furthermore, multiple interactions among grapevine, GRSPaV, powdery and downy mildews revealed an interesting cross-reaction among different pathogens that could be useful for implementing pest management strategies.

C7.2-4

INVESTIGATING PLANT PERSISTENT VIRUSES IN PEPPER

VISWANATHAN Satish Bharathwaj. (1), MURPHY Alex. (1), PATE Adrienne. (1), CARR John. (1)

(1) UNIVERSITY OF CAMBRIDGE, Cambridge, UNITED KINGDOM

Text
Plant viruses have been mostly studied for their role as pathogens. However, research on plant-viral interactions in populations of wild plants has shown that some viruses have non-pathogenic effects on their hosts. Plant persistent viruses (PVs) are vertically transmitted, i.e., inherited through pollen and seed, and are not infectious. PVs cause little or no disease symptoms in their hosts, and it has been hypothesised that these RNA viruses are mutualists rather than pathogens. Building on these ideas, PV-mediated effects on host phenotypes are being investigated in pepper (Capsicum annuum). Using RT-PCR, genomic RNAs of Partitiviridae and Endornaviridae were detected in eight accessions of pepper. PV RNAs were observed in all tissues of PV-harbouring lines. Virus-virus interactions between PVs and pathogenic viruses were investigated in pepper using tobacco mosaic virus (TMV) and cucumber mosaic virus (CMV). Preliminary experiments show that TMV and CMV RNA levels were lower in PV-harbouring pepper varieties compared to PV-free varieties, possibly due to interaction between PVs and pathogenic viruses. To improve future analyses, virus-induced gene silencing using tobacco rattle virus vectors has been used successfully to

generate isogenic PV-harbouring and PV-free pepper plant lines. The effects of PVs on a broad range of host traits, from seed yield, resistance to aphids and aphid-vectored pathogens, to drought tolerance are being examined using these isogenic lines

Text

The advent of Next-Generation Sequencing (NGS) technologies applied to viral metagenomic analyses of insect pest populations has significantly accelerated the rate of virus discovery and opened new avenues for the exploitation of virus-based tools to counteract plant diseases and insect pests. Among the vast number of newly identified viruses infecting insect vectors, members of Iflaviridae, a family of nonenveloped, single-stranded RNA viruses that infect arthropods, were frequently detected. Iflaviruses often cause mild or asymptomatic infections and are frequently found in mixed infections within the same host. Investigating the effects of covert infections on insect transmission capabilities and fitness, alone or in combination with other stress factors, is an important step to describe the interactions between insect viral communities, the host insects, and the plant pathogens they transmit. The case study of the Euscelidius variegatus Virus 1 (EVV1), an iflavirus causing covert infection in the leafhopper *Euscelidius variegatus*, vector of phytoplasmas, provides valuable insights into the role of latent infections in shaping insect ecological traits and possibly phytoplasma transmission ability. Finally, EVV1 may be used as a tool of Virus-Induced Gene Silencing (VIGS) to alter the expression of insect genes involved in plant pathogen transmission, thus paving the way to transmission suppression.

Text

Erysiphe necator is a biotrophic fungus causing powdery mildew in grapevine, affecting different parts of the plant. Grapes and leaves with powdery mildew were collected in the

major grapevine areas of Spain and Italy. A total of 220 samples were collected and 101 samples were selected. Total RNA extracted from the 101 samples were mixed in 17 pools for next generation sequencing. The results of each pool were analysed separately to identify the virome associated to each one, resulting in 17 distinct lists of viruses. The degree of contamination with plant and other organisms was determined, but all samples were mainly represented by E. necator. To avoid erroneous host assignment, all viruses were named as “Erysiphe necator associated” to maintain open the possibility that the real host could be grapevine or some other organisms present in the samples. A total of 514 viruses were identified in our samples, 429 with a genome of positive single strand RNA (ssRNA (+)), 41 with double-stranded RNA (dsRNA) and 44 with negative-sense RNA (ssRNA (-)). Most of the ssRNA (+) viruses belong to the phylum Lenarviricota while ssRNA (-) viruses were placed in the order Bunyavirales inside the phylum Negarnavircota. Grapevine viruses, such as Grapevine leafroll associated viruses, Grapevine rupestris stem pitting associated virus or Grapevine fanleaf virus, and other plant viruses were also associated to the analysed samples. The phylogenetic relationship of the viruses will be discussed.

Text

Frankliniella occidentalis (WFT) and *Thrips tabaci* (OT) are insect species that greatly impact horticultural crops through their transmission of tomato spotted wilt virus (TSWV) and iris yellow spot virus, members of the family *Tospoviridae* in the *Bunyavirales*. We have identified 64 viral segments in samples from 12 populations of OT and WFT from Italy, corresponding to 41 viruses. Fifteen were assigned to WFT, and 17 to OT, while 9 viruses could not be assigned to any species based on our stringent criteria for host association. All these viruses are putative representatives of new species, and some are the type members of new higher-ranking taxa. Repeated sampling in a subset of locations, and further virus characterization in a subset of four populations, reared in laboratory on a controlled diet for more generations, provided evidence of a locally persistent thrips core virome that characterizes each population.

Two WFT populations differentially infected by a virgavirus, a mononegavirus and a densovirus were tested for their efficiency in transmitting TSWV; some preliminary results indicate that densovirus infection inversely correlates with TSWV accumulation and transmission. Furthermore, the only virus that persisted over one year in an OT population is a member of the family *Mitoviridae*, among the first viruses of this family associated with insects: here we present different approaches to determine its host, tissue and subcellular localization unequivocally.

THE DIVERSITY OF VIRAL COMMUNITY IN APHIDS, VECTORS OF THE BARLEY YELLOW DWARF VIRUS, REVEALED BY METATRANSCRIPTOMICS

KIM Sung-Woong. (1), LEE Hyo-Jeong. (1), JEONG Rae-Dong. (1)

(1) Chonnam National University, Gwangju, REPUBLIC OF KOREA

Text

Plant viruses are closely linked to aphid virome and plant virome because plants and aphids regularly and efficiently exchange and transmitted viruses. However, few studies on aphid viromes have been reported. Therefore, high-throughput sequencing (HTS) was used to monitor viral community in three species (Rhopalosiphum maidis; RM, Rhopalosiphum padi; RP and Sitobion avenae; SA) of aphids known to transmit barley yellow dwarf virus (BYDV). The paired end sequencing of the library with Illumina HiSeq 4000 resulted in raw data of 7.68 Gb for RM, 7.65 Gb for RP and 7.65 Gb for SA, respectively. In this study, virus populations were identified from three aphid libraries, and barley virus G (BVG), BYDV-PAV and sugarcane yellow leaf virus in RM, BVG in RP and BYDV-PAS and BYDV-PAV in SA. Most viral genomes were successfully assembled de novo using metagenomic analysis. To confirm the presence of the plant viruses identified in the three aphids by HTS, specific primers for each virus were designed and RT-PCR was performed to confirm of the viruses. In addition to plant viruses, hubei wuhan insect virus, wuhan aphid virus, wuhan house centipede virus, wuhan insect virus were also identified in the aphid virome. These results show that the HTS-based metatranscriptomic analysis was a reliable and powerful tool for detection and identification of viruses in aphids.

P7.2-002

INVESTIGATING MYCOVIRUS-MEDIATED SYSTEMIC RESISTANCE IN OILSEED RAPE

LOCKE-GOTEL Jacob. (1), FITT Bruce . (1), HUANG Yongju. (1), KOTTA-LOIZOU Ioly. (1,2), COUTTS Robert. (1)

(1) University of Hertfordshire, Hatfield, UNITED KINGDOM; (2) Imperial College London, London, UNITED KINGDOM

Text

Oilseed rape, *Brassica napus*, is an important and popular food crop. Fungal diseases of oilseed rape, namely light leaf spot (caused by *Pyrenopeziza brassicae*) and phoma stem canker (caused by *Leptosphaeria maculans* and *L. biglobosa*), inflict >£100M annual yield losses in the UK alone.

This project involves screening and characterising mycoviruses in the three fungal pathogens and quantifying how the plant host recognises and responds to each fungus. Virus-infected and virus-free isogenic lines of a Chinese *L. biglobosa* isolate (W10) have been resuscitated to inoculate plants of the oilseed rape cultivar Charger. Samples were collected from distinct parts of the plants and will be compared in terms of gene regulation using RNA-seq and quantitative PCR.

Field isolates across Europe and Canada were collected and, to date, 48 *L. maculans*, 63 *P. brassicae* and 19 *L. biglobosa* isolates have been screened. Six UK *L. biglobosa* isolates have been confirmed to contain LbQV-1, and one Canadian isolate contained a novel

polymycovirus, as shown by Sanger sequencing. Nine UK *L. maculans* isolates showed the first incidence of a large dsRNA species. None of the *P. brassicae* isolates from six countries across northern Europe appeared to be virus-infected.
Further work involving genome walking will be done to fully characterise the novel viruses identified. Virus-infected and virus-free isogenic lines are also being produced using cycloheximide treatment to investigate their pathogenicity.

Text
Fusarium poae virus 1 (FpV1), is one of mycoviruses that is discovered earlier. Due to the vegetative incompatibility barrier that often exists between different species or strains of filamentous fungi, FpV1 is thought to be limited to its host, F. poae, as a non-hypovirulence mycovirus in the past 20 years. Here, a novel strain of FpV1 (FpV1-Fa) with two dsRNA segments (2157- and 2080-nt), was consistently identi?ed in *F. asiaticum* isolates in the field. FpV1-Fa induced abnormal morphology and hypovirulence of *F. asiaticum*, along with a high viral load. FpV1-Fa was detected only from the *F. asiaticum* and *F. tricinctum* strains at FpV1-Fa sampling site (119.014289, 33.8261), while the other strains from other sites were not identified FpV1-Fa. Horizontal transmission experiment showed FpV1-Fa can be transformed from *F. asiaticum* to *F. poae* and *F. tricinctum* but not *F. graminearum*. The selection analysis of FpV1-Fa revealed RdRP and CP were under strong purifying selection, and the C-terminal side of RdRP was under positive selection. In these regions, 9 amino acid mutations in RdRp and 21 mutations in CP appeared to cause the variation of host range and virulence in FpV1-Fa.

Text
Botrytis cinerea is one of the most important plant-pathogenic fungi, causing the gray mold disease in more than 200 crops worldwide. In recent years, mycoviruses gained interest as potential biocontrol agents, since they can induce hypovirulence in its fungal hosts. In a previous study, a total of 248 B. cinerea field isolates were collected from vineyards in

different main regions of Italy and Spain. These field isolates were mixed in 29 pools and their mycovirome was analyzed by next generation sequencing (NGS). Mycoviruses, putative related to hypovirulence in B. cinerea or other different fungal hosts, were identified in these analyses. Several mycoviruses were selected for further studies based on biological, molecular and evolutionary aspects. The presence of these mycoviruses was confirmed by PCR detection in field isolates. Subsequently, the mycoviral content of these independent field isolates, and the new obtained single-spore and single-protoplast isolates was analyzed by NGS. These isolates showed differences in growth and virulence, then, further analyses are in progress to determine if the observed differences can be associated to the presence or absence of specific mycoviruses.

Text
Mycoviruses infect filamentous fungi, yeast and oomycetes and some of them have been shown to affect the phenotype and virulence of the infected hosts. The induction of hypovirulence in their host makes them a very attractive target to be used in biocontrol strategies. Then, most research efforts have been focused on understanding the phenotypic effects they cause in the fungus and not on their molecular biology. Although much has been studied regarding the function of capsid proteins in plant viruses, not much is known about the specific function in mycoviruses, particularly regarding the transmission and maintenance of mycoviral infection. In plants, viral capsid proteins have been shown to be essential for extracellular infection, but cell-to-cell movement relies on movement proteins, exemplified by the ability of a capsidless tobacco mosaic virus to infect and spread through a plant. Botrytis virus F (BVF) is a positive-sense, single-stranded RNA virus within the Gammaflexiviridae family of the plant-pathogenic fungus Botrytis cinerea. BVF genome contains two open reading frames encoding an RNA dependent RNA polymerase (RdRp) and a coat protein (CP). We addressed the effect of several mutations on the CP gene to determine whether these modifications affect or not the ability of BVF to replicate or move inside the fungal host.

(1) Henan Agricultural University, Zhengzhou, CHINA; (2) Henan Academy of Agricultural Sciences, Zhengzhou, CHINA

Text

The root rot of *Salvia miltiorrhiza* is a common root disease caused by *Fusarium* spp., which has become one of the main diseases affecting the production of *S. miltiorrhiza*. Currently, several hypovirulence-related mycoviruses have been identified in many phytopathogenic fungi including *Fusarium* spp., which showing potential as biological control. In this study, we report a new mycovirus, Fusarium oxysporum partitivirus 1 (FoPV1), isolated from *F. oxysporum* strain FCR51, a causal agent of *S. miltiorrhiza* dry rot. The FoPV1 genome contains two double-stranded RNA segments (dsRNA1 and dsRNA2). The size of dsRNA1 is 1773bp, and it encodes a putative RNA-dependent RNA polymerase (RdRp), The dsRNA2 is 1570bp in length, encoding a putative capsid protein (CP). Multiple sequence alignments and phylogenetic analyses based on the amino acid sequences of RdRp and HP indicated that FoPV1 appears to be a new member of the family *Partitiviridae* that is related to members of the genus *Gammapartitivirus*. Assay of pathogenicity showed that FoPV1 confers hypervirulence to its host, *F. oxysporum*. This is the first report of a partitivirus infecting *F. oxysporum* and the first hypovirulence-related mycovirus from causal agent of *S. miltiorrhiza* dry rot.

Text

Cannabis cryptic virus (CanCV) belongs to the Betapartitivirus genus within the *Partitiviridae* family. Its genome consists of two double strand (ds) RNA molecules, each of which is encapsidated in independent non-enveloped icosahedral particles. Each single positive sense strands RNA (ssRNA (+)) is monocistronic: the longer one (2397 nts) codes for the RNA dependent RNA polymerase (RdRp) while the shorter one (2266 nts) codes for the coat protein (CP). CanCV life cycle is restricted to the cytoplasm and the virus propagates in the plant exclusively during cell division of meristematic cells. Furthermore, CanCV is transmitted only vertically, it is persistent and asymptomatic. Such biological characteristics make this virus a good candidate viral vector for plant genetic engineering and functional genomics in *Cannabis* spp. through the virus mediated expression of heterologous sequences. For this purpose we cloned the cDNA copy of each CanCV ssRNA(+) into an *Agrobacterium tumefaciens* binary expression vector. Agroclone infectivity was tested in *Nicotiana benthamiana* by their co-infiltration in mature leaves with or without the transient expression of Tomato bushy stunt virus p19, used to suppress the sense transgene-induced post-transcriptional gene

silencing. CanCV particles were then purified and observed by transmission electron microscopy. RNA extraction, DNase I and RNase T1 digestion were performed to quantify viral dsRNA in the purified particles.

Text

Pear ring rot disease induced by Botryosphaeria dothidea is one of the important diseases, which has seriously hindered the development of pear industry. Mycovirus-mediated hypovirulent strain is a novel idea and an effective measure used for the biological control of pear ring rot disease. Increasing evidences showed that vsRNAs play important regulatory roles in disease-resistant defensive response. Therefore, it is helpful to explore the possibility of mycovirus to prevent and control the disease by manipulation vsRNA genes. In this study, obtaining the hypovirulent LW-C with BdCV1?and the candidate vsR5636 involved in the interaction between mycovirus and B. dothidea. It is verified that the existence of vsRNA5636 was dependent on BdCV1 in B. dothidea strains, whose expression level was affected by BdAgo3. The predicted targets of BdCDKc (Cyclin-dependent protein kinase complex) mediated by vsRNA5636 in B. dothidea was verified by 5' RLM-RACE. It showed that gene expression levels of BdCDKTc mRNA and BdCV1 RdRp were decreased, meanwhile LW-1 mycelia vegetative growth rate became fast, the pathogenicity was enhanced. It was more sensitive to cell wall and cell membrane stress in LW-1/OE-vsRNA5636. It indicated that vsRNA5636 mediated BdCDKc and BdCV1 involved in antiviral response and host biological regulation. It provided valuable genetic resources with the mycovirus-mediated biological control of fungal diseases in practice by manipulation vsRNA genes.

Text

Mycoviral infections alter the metabolism of their hosts. This can have direct effects on the aggressiveness of phytopathogenic fungi. When the infection results in a reduced aggressiveness, this is referred to as hypovirulence.
In this study, we report the occurrence of four RNA viruses of the genera *Ambivirus*, *Mitovirus*, *Sclerotimonavirus*, and *Partitivirus* in a single isolate of *Fusarium graminearum*. Coinfection of the wild type suppressed the production of the type B trichothecenes deoxynivalenol, 3- and 15-acetyl-deoxynivalenol *in vitro*. This effect was confirmed by transfection of a virus-free strain via hyphal anastomosis. After transfection, a reduction in the production of aurofusarin, a bis-naphthopyron pigment that protects *Fusarium* fungi from a variety of animal predators, was also observed. In addition, infection of the wild type suppressed the production of an unknown volatile sesquiterpene and increased the release of 1-butanol compounds. Increased concentrations of 3-octanone and sylvestrene were also measured after transfection. Food preference experiments with springtails (*Folsomia candida*) revealed a preference for the infected wild type of *F. graminearum.*
Combining the studies on the relationship between virus infection, secondary metabolism, and food preference provides valuable information on the modulation of secondary metabolism by viruses, hypovirulence in mycotoxin-producing fungi, and changes in feeding behavior of fungivorous arthropods.

INVESTIGATING THE ADAPTATION MECHANSIMS OF MITOVIRUS-INFECTED CHENOPODIUM QUINOA PLANTS TO BIOTIC AND ABIOTIC STRESS

CIUFFO Marina. (1), VIGANI Gianpiero. (2), **TURINA Massimo. (1)**

(1) National Research Council of Italy, Torino, ITALY; (2) Plant Physiology Unit, Dept Life Science and Systems Biology, University of Turin, Turin, ITALY

Text

The promotion of quinoa is part of a broader FAO strategy to encourage the cultivation of traditional, resilient crops. Other than for its high nutritional properties, quinoa is an interesting plant since it is adapted to a wide range of marginal agricultural soils, including those with high salinity and those tending to drought. We recently provided evidence of a mitovirus named Chenopodium quinoa mitovirus 1 (CqMV1) accumulation in symptomless *Chenopodium quinoa* lines. We compared two mitovirus-infected lines (Regalona and IPSP1) and two mitovirus-free lines (BO78 and BO25). The virus is apparently cryptic (no obvious symptoms) in normal growth conditions. We therefore looked at the effect of some physiological parameters in abiotic stress condition (water stress and mechanical damage) and some biotic stress (virus infections, herbivore damage, aphid colonization). We looked and characterized the volatilome and leaf ionomic profile. Furthermore, since the mitovirus limits its replication inside the mitochondria, we looked at the differential mitochondrially-enriched proteome of mitovirus-infected and mitovirus-free leaf extracts, showing some specific virus-caused down-regulation or up-regulation of a number of interesting proteins.

Finally, we began the process of obtaining mitovirus-infected and mitovirus-free quasi-isogenic lines developing markers to monitor reciprocal crosses of virus-infected and virus free lines.

Text

Diplodia shoot blight is an emerging disease caused by *Diplodia sapinea* which becomes pathogenic under stressful conditions. Gaining knowledge about the mycovirome of D. sapinea could help identify biological control agents. Double-stranded RNA were extracted from 110 isolates obtained from *Pinus* spp. in Europe, South Africa and America. Electrophoresis profiles of the dsRNA elements indicated the presence of mixed infections and/or potential segmented viral genomes. Twelve isolates from distinct locations in France were characterized by high throughput sequencing of purified ds RNA. Over 20 mono-and multi segmented new mycoviruses with dsRNA, ssRNA+ and ssRNA- genomes were identified. All the isolates had mixed infections except one that was single infected. On the other hand, one isolate was found to be infected with up to 14 viruses, some of which were present as several variants. The two dsRNA viruses already described in D. sapinea were found in coinfection in two isolates and individually detected in one and two isolates respectively. Three new viruses belonging to the families Polymycoviridae, Partitiviridae and Botourmiaviridae showed the highest prevalence. Specific primers were designed to assess the presence of some of the identified mycoviruses by RT-PCR. They will enable us to screen the *D. sapinea* isolates collection and study the prevalence and diversity of *D. sapinea* mycoviruses. Our results provide new hopes for potential biological control candidates.

Text

Xanthomonas bacteria are widespread plant pathogens that cause disease on a variety of plants. We have identified opportunistic Xanthomonas in the leaf-associated microbiota of Arabidopsis thaliana, that cause disease in immunocompromised rbohD knockout plants resulting in an altered microbiota composition. However, the virulence factors of such opportunistic Xanthomonas and how they affect the overall microbial community are currently not known. Here, we found that these Xanthomonas secrete a cocktail of cell wall degrading enzymes via the type-2 secretion system (T2SS) that disintegrate leaf tissue and promote Xanthomonas growth during plant infection. Both disease and leaf degradation activity were stronger in rbohD compared to Col-0 plants, substantiating the opportunistic behaviour of these Xanthomonas strains. Gnotobiotic plant experiments using a synthetic bacterial community and drop-in of Xanthomonas wildtype and non-virulent mutants showed that the T2SS is required for plant disease and for the shift in microbiota composition. Overall, our data suggest that opportunistic Xanthomonas cause tissue damage in leaves thereby creating an environment for specific commensal bacteria to thrive.

INFLUENCE OF ELEVATED TEMPERATURES ON RESISTANCE AGAINST PHOMA STEM CANKER

NOEL Katherine. (1), WOLF Ivan. (2), VALENTE Gui. (3), FITT Bruce. (1), **STOTZ Henrik. (1)**

(1) University of Hertfordshire, Hatfield, UNITED KINGDOM; (2) University of North Carolina, Charlotte, UNITED STATES; (3) São Paulo State University (Unesp), Botocatu, BRAZIL

Text

Cultivar resistance is an important tool for controlling pathogen-related diseases in crops. As temperatures increase due to global warming, temperature-resilient disease resistance will be important for crop protection. However, mechanisms behind temperature-sensitivity of disease resistance responses remain poorly understood in crop species, and little is known about the effect of elevated temperatures on quantitative disease resistance (QDR). The influence of elevated temperatures on both QDR and R gene-mediated disease resistance was analysed using field experiments and controlled environment (CE) inoculation assays. The impact of increased temperatures in spring or summer on the severity of phoma stem canker was of special interest, and high maximum June temperature was associated with increased phoma stem canker severity. Although higher June temperatures did decrease resistance of *Brassica napus* lines with *R* genes (*Rlm7*, *LepR3*, *Rlm4*) and with or without QDR in field experiments, resistance of cv. ES Astrid with only QDR was not affected by temperature. In contrast, resistance of cv. ES Astrid decreased when temperature increased to 25oC under CE conditions, suggesting that sustained periods of higher temperatures can weaken QDR. In the absence of QDR or R gene-mediated resistance, increased temperature decreased susceptibility to *Leptosphaeria maculans* in the field and CE conditions. Transcriptomics was used to study temperature responses of different *WAKL10* genes.

C1.3-3

IMPACT OF GLOBAL WARMING ON SUSCEPTIBILITY OF EUROPEAN MAIZE CULTIVARS TO CORN SMUT INFECTIONS

SCHWARZ Christian. (1), **VAN DER LINDE Karina. (1)**

(1) University of Regensburg, Regensburg, GERMANY

Text

Maize is the most grown staple crop worldwide. Yet, severe yield losses are forecasted for the next decades due to man-made global warming. Rising temperatures can negatively impact yield directly and also are predicted to increase infections with plant pathogens. However, experimental data regarding the influence of climate change on plant-pathogen interactions are still missing. Therefore, we addressed this issue by infecting 17 European dent or flint maize cultivars with the corn smut fungus *Ustilago maydis* at different temperature conditions: i) Bavaria in 1985, ii) modelled conditions for Bavaria in 2050, iii) a short heat wave of three days. Besides scoring for symptoms, we measured leaf length as a proxy for biomass production, determined time of spore formation, and performed RNAseq experiments to identify differences in the transcriptional response of maize.
Our data showcase the serious consequences a small temperature increase of ~1.5 °C, as it is predicated within the next 30 years resulting from climate change, will have on plant-pathogen interactions and subsequently yields

ARABIDOPSIS NAD KINASE C (NADKC): A MISSING LINK BETWEEN CA2+ SIGNALING, METABOLISM, AND PLANT STRESS RESPONSE

DELL'AGLIO Elisa. (1), GIUSTINI Cécile. (2), GRENZI Matteo. (1), NASTASI Sara Paola. (1), TOCCI Claudia. (2), CURIEN Gilles. (2), COSTA Alex. (1,2)

(1) University of Milan, Milan, ITALY; (2) Univ. Grenoble Alpes, CNRS, CEA, INRA, BIG-LPCV, Grenoble, FRANCE

Text

Plant perception and propagation of stress signals depend on calcium ions (Ca2+) and reactive oxygen species (ROS). The current model establishes that, in stressed cells, Ca2+ binds to NADPH oxidases localized on the plasma membrane, generating apoplastic ROS that can move to the neighboring cells. In turn, ROS trigger the activation of Ca2+ permeable channels, allowing the influx of Ca2+ that again stimulates ROS production. Thus, a long-distance signal is established thanks to a ROS/Ca2+ positive feedback loop, leading to signal propagation.
By a combination of proteomics, enzymology, and physiological observations, we have shown that the pathogen-triggered ROS burst in Arabidopsis seedlings is dependent on a new NAD kinase (NADKc) whose enzymatic activity is dependent on Ca2+-Calmodulin (CaM). In vivo analyses showed that the ROS burst induced by the pathogen elicitor flagellin 22 is absent in nadkc seedlings. In parallel, in concomitance with the ROS burst, wild type but not nadkc seedlings, show an increase in NADP(H)/NAD(H) ratio. The NADKc-dependent NADP/H increase is therefore required for the apoplastic ROS production in response to bacterial elicitors.

Analysis of NADKc homologues from a variety of plant species showed that this tight Ca2+-CaM control over the NADP pool is a recent evolutionary acquisition. Furthermore, a combination of plant sensor lines for Ca2+, ROS and the NADP pool are being used to unravel the long distance signaling orchestrated by NADKc1.

Text

Septoria tritici blotch (STB), caused by *Zymoseptoria tritici* represents a threat for European wheat production as the very high natural genetic diversity of *Z. tritici* and its plasticity make this fungus capable of rapidly bypassing most disease management strategies such as fungicides and resistant cultivars. Therefore, there is an urgent need to deepen our understanding on wheat resistances to STB to develop sustainable knowledge-driven wheat resistant cultivars. We previously showed that the major *Stb16q* gene mainly stops an avirulent isolate during its penetration attempts through the stomata. Here, we investigated the resistance mechanisms of cultivars showing qualitative to quantitative resistance to *Z. tritici*. Following inoculations that either mimic natural infection or bypass the penetration stage with virulent and avirulent *Z. tritici* isolates, we studied the temporal dynamics of symptoms on quasi near-isogenic lines for five major *Stb* genes, on cultivars carrying quantitative resistances and on non-host species. The use of avirulent and virulent *Z. tritici* isolates constitutively expressing GFP allowed the quantification of the different steps of the infection cycle from spores germination to pycnidia formation. Finally, we investigated if stomatal closure plays a prominent role in these resistances. We will present how stomata, one of the most important structures for wheat growth, are most likely key determinants of the wheat/*Z. tritici* interaction.

C1.3-6

SNTOX5 MODULATES THE HOST IMMUNE SYSTEM TO INDUCE PROGRAMMED CELL DEATH AND FACILITATE MESOPHYLL COLONIZATION

KARIYAWASAM Gayan. (1), WYATT Nathan. (2), LIU Zhaohui. (1), FARIS Justin. (2), FRIESEN Timothy. (1,2)

(1) Department of Plant Pathology, North Dakota State University, Fargo, Nd , UNITED STATES; (2) Edward T. Schafer Agricultural Research Center, USDA-ARS, Fargo, Nd, UNITED STATES

Text
Parastagonospora nodorum, that causes Septoria nodorum blotch of wheat, is known to secrete multiple necrotrophic effectors that interact with corresponding wheat susceptibility genes to induce programmed cell death (PCD). To date, necrotrophic effectors SnToxA, SnTox1, SnTox267, SnTox3 and SnTox5 have been cloned and functionally characterized. SnTox5 is the latest to be characterized and showed that in addition to induction of PCD, SnTox5 facilitates the colonization of the mesophyll tissue even in the absence of the susceptibility gene Snn5. To further investigate the role of SnTox5, we generated RNA-Seq data sets for Snn5 differential line LP29 inoculated with the P. nodorum strain Sn2000, that harbors SnTox5, and its SnTox5 disruption mutant. Samples were collected at 0,4,12,24,48,72, and 96 hours post inoculation (hpi) and differentially expressed genes of LP29 between the two treatments were evaluated. Differentially expression of 0,0,1,17,1666,11380, and 6000 genes were observed between the two treatments at each time point respectively. Gene ontology enrichment analysis showed that host defense related genes including WRKY transcription factors, WAKs and PR genes were up regulated, whereas other defense related transcription factors and negative regulators of PCD were downregulated in LP29 inoculated with Sn2000 compared to the mutant. The data suggest that SnTox5 facilitates PCD as well as mesophyll colonization by modulating components of the host immune system.

Text
The ubiquitin-proteasome system is a selective protein degradation pathway, which plays a vital role in the regulation of disease resistance in plants, such as the homeostasis of NLR proteins. However, most E3 ligases, the key subunits of ubiquitination enzymatic cascade, have not been functional characterized in rice, whose genome encodes large number E3 ligases. Here, we identified an E3 ligase OsFBX388, whose downregulation resulted in cell death, enhanced resistance against fungal and bacterial pathogens, and retardation of growth. OsFBX388 interacts with an Skp1 homolog OSK25 through its N-terminal F-box. Further, we showed that OsFBX388 targets an HMA domain-containing protein OsHIPP56 for ubiquitination and degradation via 26S proteasome. Disruption of OsFBX388 resulted in the overaccumulation of OsHIPP56. Overexpression of OsHIPP56 also resulted in enhanced disease resistance without yield penalty. In addition, both OsFBX388 and OsHIPP56 are required for pattern-triggered immunity. Furthermore, OsHIPP56 interacts with another HMA-domain containing protein RGA5, the sensor NLR protein of the NLR pair RGA4/RGA5. Co-expression of OsHIPP56 with RGA4/RGA5 induces cell death in both tobacco cells and rice protoplasts, suggesting OsHIPP56 functions as an innate mimic AVR protein. Together, our results provide a new mechanism in which the E3 ligase OsFBX388 balances the growth and immunity of rice by at least partially mediating the homeostasis of the AVR mimic OsHIPP56.

F1.3-2

IDENTIFICATION AND FUNCTIONAL VALIDATION OF SOFT-ROT SUSCEPTIBILITY GENES IN THE SPICE CROP GINGER - A STEPPING STONE TOWARDS GENOME EDITING FOR SOFT ROT RESISTANCE.

VARGHESE Lini. (1), THOMAS George. (1)

(1) RAJIV GANDHI CENTRE FOR BIOTECHNOLOGY, Thiruvananthapuram, INDIA

Text

Little is known about host susceptibility genes that facilitate the infection process of soil-borne, necrotrophic oomycete pathogen Pythium myriotylum Drechsler, which cause soft rot disease in spice crop ginger (Zingiber officinale Roscoe). From the differential accumulation of jasmonic acid (JA) and salicylic acid (SA) between the pathogen inoculated ginger and the highly resistant wild congener Z. zerumbet (L.) Smith, we presumed a susceptibility function for JA in Zingiber-Pythium pathosystems. This presumption was vindicated when the exogenous application of Z. zerumbet with JA produced high susceptibility to P. myriotylum. Consistent with this, the application of SA prior to JA application in Z. zerumbet reverted the susceptibility. The susceptibility function of JA was confirmed following the real time expression analysis, phytohormone quantification and histopathological methods. With this background, in ginger, we silenced four key genes involved in the JA signalling pathway using virus induced gene silencing. The silenced plants showed tolerance to P. myriotylum. Histopathology of the silenced plant showed no pathogen ingress as compared to unsilenced inoculated and mock inoculated plants. The study depicted a key role for the relative concentration of SA/JA in deciding the host response to P. myriotylum and helped to identify four putative susceptibility genes for the CRISPR based genome editing in ginger for soft rot tolerance.

ZAP1 AND STE12: ANTAGONISTIC ROLES IN THE VIRULENCE OF THE DUTCH ELM DISEASE FUNGUS OPHIOSTOMA NOVO-ULMI.

CAMPOS DE OLIVEIRA Thais. (1), TANGUAY Philippe. (2), BERNIER Louis. (1)

(1) Université Laval, Québec, CANADA; (2) Laurentian Forestry Centre, Québec, CANADA

Text

Dutch elm disease, caused by the highly virulent ascomycete fungus *Ophiostoma novo-ulmi*, has devastated the American elm (*Ulmus americana*) and caused catastrophic losses throughout the range of this species. In order to better understand the molecular bases of the interaction between *O. novo-ulmi* and *U. americana*, we performed an in planta analysis of the transcriptome during the host-pathogen interaction. The results obtained for *O. novo-ulmi* enabled us to undertake the functional study of over 20 candidate genes, including the gene which encodes the transcriptional regulator Zap1 controlling the expression of genes sensitive to zinc, as well as the gene encoding the Ste12 transcription factor found exclusively in the fungal kingdom. Null mutants were generated by CRISPR-Cas9 genome editing and

inoculated into young elm saplings in a greenhouse. The delta-Zap1 mutant became more virulent than the wild-type *O. novo-ulmi* H327 strain from which it was derived, whereas the delta-Ste12 mutant was avirulent. Moreover, elm saplings first inoculated with the delta-Ste12 mutant showed increased resistance when challenged with the wild-type strain two weeks later. Ongoing work aims to identify, in these mutants, the other genes whose expression has been altered by the inactivation of the zap1 and ste12 genes.

RESISTANCE OF ABACA HYBRID BC2-7 (BANDALA) TO BUNCHY TOP VIRUSES IN EASTERN VISAYAS REGION OF PHILIPPINES

MATI-OM Jofil. (1,2), GAPASIN Ruben. (2), PIAMONTE Robelyn. (2)

(1) BILIRAN PROVINCE STATE UNIVERSITY-BILIRAN CAMPUS, Biliran, PHILIPPINES;
(2) VISAYAS STATE UNIVERSITY, Baybay, PHILIPPINES

Text
Abaca (*Musa textiles* Nee) is an important fiber crop in the Philippines. Infection of bunchy top viruses (BTVs) causes significant economic losses on the abaca plantations in Eastern Visayas region. The Institute of Plant Breeding-University of the Philippines Los Baños (IPB-UPLB) developed the abaca hybrid to tolerate the BTVs that is prevalent throughout the Philippines archipelago. In Eastern Visayas, this abaca hybrid needs to be tested with the different isolates of BTVs in the region to assess their resistance thus, the resistance and reaction of abaca hybrid to BTVs was evaluated and compared to Inosa and Pacol in this study. Based on disease incidence, all BTVs isolates infected 100% of Inosa plants but none of the abaca hybrid and Pacol. BTVs symptoms appeared in Inosa 26 days after inoculation (DAI) in Leyte isolate, Southern Leyte (30 DAI), Biliran (32 DAI), and Samar (38 DAI), while no symptoms were observed in abaca hybrid and Pacol. In terms of disease reaction, abaca hybrid and Pacol showed high resistance to BTVs, whereas Inosa is highly susceptible. BTVs were detected using Polymerase Chain Reaction (PCR) with primers BBT-1 and BBT-2 in Inosa from Leyte and Southern Leyte isolates at 5 DAI, Samar (6 DAI), and Biliran (7 DAI). The use of *Musa* tagged microsatellites primes AGMI025 and AGMI026 confirmed the accuracy of BTVs detection by PCR. The study confirms that abaca hybrid and Pacol are highly resistant to all BTVs isolates in Eastern Visayas.

Text
Ganoderma boninense, identified as a major threat to the palm oil industry in Southeast Asia. TTo date, the only practical and sustainable approach to controlling *G. boninense* is by breeding disease resistant or tolerant palm lines as one of the approaches in Intergrated

Ganoderma Management programme. However, the success of this strategy depends on the variability of *G. boninense* isolates as the pathogen is ideally suited to cope with this selection pressure through outcrossing and prolific spore production to adapt for aggressiveness traits. Therefore, the effect of the most aggressive *G. boninense* isolate was studied. One hundred and twenty-eight oil palm progenies have been tested for their resistance / tolerance or susceptible and based on the data obtained, two progenies namely TUP 1319 and TUP 1269 have been identified as potential tolerant to Ganoderma disease with infection recorded at 11.1% (TUP 1319) and 20% (TUP 1269) respectively. Two potential susceptible were also identified namely TUP 1309 and (86.67%) and TUP 1364 (83.33%). It was noted that for the potential tolerant progenies were derived from Chemara Dura background. TUP 1319 was from parental background of Chemara Dura X Ekona pisifera and TUP 1269 was derived from parental background Chemara Dura X Nigerian Pisifera. For potential susceptible progenies, TUP 1309 was derived from parental background Ulu Remis Dura X Ekona pisifera and TUP 1364 was derived from Ulu Remis Dura X Nigerian Pisifera.

RESEARCH HIGHLIGHTS ON THE EVALUATION OF SOYBEAN GENOTYPES FOR RESPONSES TO PATHOGENS IN THE SOUTHERN STATES OF THE USA

LI Shuxian. (1)

(1) United States Department of Agriculture, Agricultural Research Service (USDA, ARS), Stoneville, UNITED STATES

Text

Soybean is one of the most important crops in the world. However, various soybean diseases cause substantial losses annually. Analysis of plant responses to pathogens is an important step towards breeding disease resistant soybeans. Phenotyping soybean genotypes for their responses to Phakopsora pachyrhizi, the causal agent of soybean rust, was carried out using both seedling and detached leaf assays. PI 200492 (Rpp1) had near immune reaction when tested with a Mississippi isolate MS06-1b, but resistant RB lesions to four Florida isolates and one Louisiana isolate. PI 230970 (Rpp2), PI 462312 (Rpp3), PI 459025B (Rpp4), PI 567102B (Rpp6) and PI 605823 (Rpp7) had RB lesions to isolate MS06-1b, whereas Williams 82 (Susceptible) and PI 200526 (Rpp5) had susceptible TAN reactions with high disease severity and sporulation ratings to isolate MS06-1b. Screening hundreds of soybean lines for their responses to Diaporthe longicolla, a causal agent of Phomopsis seed decay (PSD), identified new sources of resistance. Although PSD is a seed disease, a cut-seedling inoculation technique was developed to rapidly evaluate soybeans for reaction to D. longicolla and identify PSD resistant genotypes without waiting a whole growing season. Nine accessions having resistant reactions to Cercospora spp., causing purple seed stain of soybean, were also resistant to PSD. These accessions could be useful in breeding programs to develop soybean cultivars with improved resistance to both seed diseases.

TERATOSPHAERIA DESTRUCTANS-RESISTANT EUCALYPTUS GENOTYPE PRODUCE A WAX COMPOUND THAT INHIBITS PATHOGEN GERMINATION IN-VITRO AND IN-VIVO

SOLÍS Myriam. (1), NAIDOO Sanushka. (1), **WINGFIELD Michael. (1)**, HAMMERBACHER Almuth. (1)

(1) university of pretoria, Pretoria, SOUTH AFRICA

Text

Waxes on leaf surfaces are amongst the first anatomical barriers that foliar pathogens must overcome in order to initiate infection. We analysed the wax composition of *Eucalyptus* genotypes leaves having contrastanting levels of resistance to Teratosphaeria leaf blight disease (TLB) caused by *Teratosphaeria destructans*, an important disease of *Eucalyptus* in tropical and sub-tropical environments. Analysis of cuticular waxes of four *Eucalyptus* genotypes using gas chromatography-mass spectrometry revealed significant differences in the wax composition. A triterpenoid, resembling cycloartanol (CAS) was identified only in the most resistant genotype and not in the other host genotypes. The effect of five concentrations of CAS on *T. destructans* spore germination was evaluated *in-vitro* and *in-vivo* using light and scanning electron microscopy. Spore germination was significantly inhibited with increasing CAS concentrations ($P < 0.01$) in Petri dishes as well as on healthy *Eucalyptus* leaves. These results show that waxes are an important component of resistance to infection of *Eucalyptus* by *T. destructans* and that CAS inhibits spore germination and subsequent foliar infection by the pathogen via stomata.

Text

Due to climate change, the expansion of tree pests and pathogens are expected. The novel studies are focused on anticipatory strategies that could help to strengthen tree itself resistance. Concentrations of secondary metabolites and antioxidant activity have an impact on tree resistance. In our study we used seed treatment with low-temperature plasma (CP), which induced physical stress for plant.Eleven different half-sib families of Pinus sylvestris L. were selected. The seeds were treated with CP 1 min (CP1) and 2 min (CP2). We found that seed treatment with CP had an impact on concentrations of biological activity compounds and antioxidant enzymes in 2-year-old P. sylvestris needles. We evaluated that CP1 increased (from 0.29 to 1.28 mg/g) total phenolics (TPC) in needles in five and (from 0.57 mg/g to 2.15 mg/g) total flavonoids content (TFC) in four ($p < 0.05$) half-sib families. However, in one family CP1 reduced TPC and TFC. The seed treatment with CP2 increased TPC and TFC in lower number of half-sib families than CP1. Estimation of antioxidant enzymes (CAT, APX, and POX) also showed changes between treated (CP) and control seeds in 2-year-old needles which depended on half-sib family. Our results confirmed that

short-term stressor (CP) might increase secondary metabolites (TPC and TFC), as well as concentrations of antioxidant enzymes. The results are relevant as guides for forestry industries to increase the quality of P. sylvestris seeds in danger of climate change.

DISEASE RESISTANCE SCREENING IN A SUGARCANE PLANT BREEDING PROGRAMME: CAN WE DO THINGS DIFFERENTLY?

RUTHERFORD Richard S. (1), SPELMAN Zizipho. (1)

(1) SA Sugarcane Research Institute, Durban, SOUTH AFRICA

Text

Smut caused by Sporisorium scitamineum is an important fungal disease of sugarcane. Screening for resistance in the plant breeding programme is limited by cost, difficulty, time, labour, number of genotypes and field requirements. Due to these factors, screening is delayed to later selection stages, closer to new cultivar release. Consequently, susceptible genotypes are “carried” before they can be screened and discarded. Application of new screening tools at earlier stages will result in cost savings, productivity benefits and increased numbers of resistant clones progressing to later selection stages. Near Infra-red Spectroscopy (NIRS) is a potential means of examining the interaction between sugarcane and its’ attackers. Resistance to smut comprises two separate mechanisms, external (constitutive, lateral bud based) and internal (responsive, physiological). Previous NIRS models have predicted external resistance using spectra gathered from intact dormant lateral buds. Here we describe novel methodology for screening internal resistance using leaf discs inoculated with smut teliospores, despite S. scitamineum not normally being considered a leaf pathogen. Predictive chemometric models were derived using samples with known resistance ratings from field trials and spectral data. These models are superior to those developed for external resistance. One technician can make predictions for 100 genotypes per week whereas only 300 genotypes can be screened per year in the field.

(1) Institute of Plant Protection, Gansu Academy of Agriculture Sciences, Lanzhou, CHINA

Text

Identification of leaf rust resistance genes in wheat cultivars from Gansu Province in China

Wheat leaf rust is one of the most important wheat diseases worldwide, which is a fungal disease caused by Puccinia triticina. It can reduce production by up to 40% in susceptible cultivars. Over the past decade, leaf rust has periodically caused severe yield losses in China. Five Chinese provinces, including Gansu, recorded high yield losses in 2012. Resistant wheat cultivars are the most economical, effective and environmentally friendly

way to control leaf rust. So, 37 main wheat cultivars from Gansu province of China and a set of 35 near isogenic lines with Thatcher background and 7 lines with known Lr genes were inoculated in a greenhouse with 22 Pt pathotypes to identify seedlings effective Lr genes. By comparing the infection types (ITs) produced on the 37 cultivars by the 22 Pt races with the ITs on the differential sets, the Lr genes were postulated. The results show that the six leaf rust-resistant genes Lr2B, Lr13, Lr16, Lr22A, Lr30 and Lr14B have been postulated in seven cultivars, either singly or in combination. No Lr gene was detected in fifteen cultivars. Fourteen cultivars were deduced containing other genes different from the 42 known Lr genes used in this study. Identification of leaf rust resistance at the adult stage indicates that 11 cultivars are highly adult–plant resistant, with potential applications in wheat production and wheat resistant cultivar breeding.

Text

In order to find alternative solutions to the suppression of neonicotinoids in the fight against viruliferous aphids, the National Plan for Research and Innovation (PNRI) must find alternative solutions to chemical control, which are both effective and environmentally friendly.

The PNRI Yellows Resisbeet project (2021-2024), led by GEVES, in partnership with ITB, aims to develop a protocol for assessing varietal resistance/tolerance to 4 virus species responsible for virus yellow in EU: Beet Yellows Virus (BYV), Beet Chlorosis Virus (BChV), Beet Mild Yellowing Virus (BMYV) and Beet Mosaic Virus (BtMV). The ambition is to rapidly promote the inclusion of tolerant/resistant varieties in the French Catalogue and their availability to farmers.

This project has made it possible:

- to develop a method to produce inoculum, from viruliferous aphids (Myzus persicae),
- to define the parameters of inoculation in the field and under controlled conditions ensuring a homogeneous infestation of viruses and a significant discrimination of symptoms and yield between inoculated and non-inoculated modalities,
- to develop a multiplex RT-qPCR method to detect and identify these 4 viruses,
- to study the most relevant criteria for assessing varietal tolerance based on productivity data, visual or RGB ratings of symptoms, and viral load.

This genetic lever will be proposed to the Experimental Pilot Farms to develop an integrated control method in an agro-ecological context

DEVELOPING A DISEASE SCREENING PIPELINE FOR RESISTANCE TO FUSARIUM HEAD BLIGHT OF WHEAT

ROSE Lindy. (1), BADENHORST Anja. (1), VAN COLLER Gert. (2), VILJOEN Altus. (1)

(1) Stellenbosch University, Cape Town, SOUTH AFRICA; (2) Western Cape Department of Agriculture, Cape Town, SOUTH AFRICA

Text

Host resistance is the most sustainable and affordable means to manage Fusarium head blight (FHB) of wheat and other small grains. This study aimed to establish a disease-screening pipeline to effectively evaluate local wheat germplasm for resistance to FHB in South Africa. A greenhouse screening technique was developed by evaluating the pathogenicity, virulence and mycotoxigenic potential of several isolates of F. graminearum, F. pseudograminearum and F. equiseti. Three wheat cultivars were selected for greenhouse evaluation namely SST 806 (susceptible), Sumai 3 (resistant) and SST 0166 (resistance unknown). Disease parameters were determined following artificial inoculations (either a centre- or top-floret point-inoculation). Breeding line Sumai 3 demonstrated the greatest tolerance with SST0166 being moderately tolerant and SST 806 being most susceptible. Fusarium graminearum was the most virulent on all cultivars, except for Sumai 3, where F. equiseti was more virulent. Additionally, thirteen published primer pairs were selected for the screening of seven QTL positions on three chromosomes using DNA from Sumai 3, SST 0117, SST 0127 and SST 8154 (tolerant to FHB); SST 806 and SST 0166. Ten of the 13 primer pairs positively detected the target regions present in the plant material. An optimised disease assessment protocol with molecular markers provides an efficient and effective tool for the identification of plant resistance to FHB pathogens.

Text

Plum leaf scald (PLS) is the main obstacle to plum expansion in Brazil. This disease is caused by *Xylella fastidiosa*, which colonizes the foregut of xylem-sap feeding insects and the xylem of the plants. Breeding programs identified new plum genotypes that showed no leaf scald symptoms in the field. However, the mechanisms that confer this resistance are not fully elucidated. We hypothesized that the performance of these genotypes may be related to the

vector feeding behavior influenced by the emission of volatile organic compounds (VOCs) by the host. To verify this hypothesis, we investigated the feeding behavior of sharpshooters on the PLS-resistant plum genotypes (SC7 and Zafira) and on the naturally infected cultivar (Laetitia), using the EPG technique. Also, we investigated the volatile compound profile from six plum genotypes with different resistance levels to PLS. Probing and feeding activities differed between individuals held on Zafira and Laetitia. Specifically, duration of xylem sap ingestion events differed for *B. xanthophis* held on Zafira and Laetitia. We observed that the VOCs emitted from resistant genotypes are different from susceptible cultivars. An example, cedrol was not detected in susceptible genotypes, but was found in the resistant ones. We will test these substances in the olfactory assays. If these compounds prove to be efficient, foliar applications can be carried out in order to repel the vectors, preventing the *X. fastidiosa* transmission.

P1.3-013

UNDERSTANDING PYRENOPEZIZA BRASSICAE POPULATIONS FOR EFFECTIVE CONTROL OF LIGHT LEAF SPOT IN WINTER OILSEED RAPE

SAPELLI Laura. (1), KARANDENI DEWAGE Chinthani. (1), RITCHIE Faye. (2), FITT Bruce. (1), HUANG Yongju. (1)

(1) University of Hertfordshire, Hatfield, UNITED KINGDOM; (2) ADAS Boxworth, Cambridge, UNITED KINGDOM

Text

Light leaf spot, caused by the fungal pathogen *Pyrenopeziza brassicae*, is the most economically damaging disease of oilseed rape (*Brassica napus*) in the UK. Fungicide insensitivity development highlights the need for non-chemical controls like host resistance. Currently, there is limited information on virulence of UK *P. brassicae* populations, which is crucial for effective use of host resistance. To study pathogen populations, isolates from different regions and different hosts were tested in glasshouse experiments. *P. brassicae* isolates were obtained from oilseed rape and kale cultivars across England, and other European isolates were acquired through Rothamsted Research. A total of 24 *P. brassicae* isolates were tested on a differential set of nine oilseed rape cultivars/lines. In addition, field experiments were done in England for the 2021/2022 cropping season at Hereford and Huntingdon with cultivars Aquila and Flamingo. Disease severity was assessed by measuring disease score (scale 1-8, with 1 being resistant), percentage area with sporulation on leaves and presence of necrotic flecking (collapsed epidermal cells). Results from glasshouse experiments showed differences in disease severity between both cultivars and isolates. Results from field experiments differed between locations and cultivars, suggesting variations in pathogen populations between locations. Genotypic differences between *P. brassicae* isolates will be studied using molecular techniques.

P1.3-014

A NOVEL RESISTANCE PATHWAY IN N-GENE TOBACCO AGAINST TMV IDENTIFIES AN OLD INHIBITOR AND AN EARLIER FUNCTION

BAEK Eseul. (1), PALUKAITIS Peter. (1), YOON Ju-Yeon. (1)

(1) Jeonbuk National University, Jeonju, REPUBLIC OF KOREA

Text
The transcription factor (TF) SHE1 is induced by TMV infection of *N* gene tobacco. SHE1 is involved in a novel resistance pathway and interacts with the inhibitor of virus replication (IVR), in vivo and in vitro. SHE1-overexpression (OEx-SHE1) in tobacco reduced susceptibility to TMV infection, whereas SHE1-silencing (si-SHE1) in tobacco had no local effect on TMV infection but resulted in a slow systemic infection. OEx-SHE1 tobacco plants constitutively expressed IVR, whereas si-SHE1 tobacco plants inhibited the expression of IVR. SHE1 expression occurs earlier than IVR expression. IVR was shown to comprise the C-terminal 34% of anaphase-promoting complex 7 (APC7), part of the cellular cyclosome, a 13-subunit E3-ubiquitin ligase controlling the progression of mitotic division. APC7 contains six tetratricopeptide repeats (TPRs, each containing a helix-turn-helix structure). The 199-amino acid IVR contains 10 helices (3.5 TPRs and three additional single helices), as well as an unstructured 28-amino acid C-terminus. The C-terminal half of IVR contains the SHE1 interaction site. The sequences of the tobacco *APC7* gene, upstream of the IVR coding region, contain several putative promoter sites for various TFs including four GCC binding elements for SHE1, upstream of putative transcription start sites. We propose that IVR binding to SHE1 acts to prevent further SHE1 expression, a classic example of end-product inhibition.

P1.3-015

TOBACCO MYB TRANSCRIPTION FACTOR NTMYB92 IS INVOLVED IN THE NEGATIVE REGULATION OF N GENE-INDEPENDENT VIRUS RESISTANCE

YOSHIKAWA Munehisa. (1), SHIRAI Rikako. (2), MATUSHITA Yasuhiko. (1,2,3), SASAKI Nobumitu. (1,2,3)

(1) United Graduate School of Agricultural Science, Tokyo University of Agriculture and Technology, Tokyo, JAPAN; (2) Institute of Agriculture, Tokyo University of Agriculture and Technology, Tokyo, JAPAN; (3) Gene Research Center, Tokyo University of Agriculture and Technology, Tokyo, JAPAN

Text
MYB transcription factors regulate gene expression by binding upstream cis-element in biotic and abiotic stress responses. However, the virus resistance-related MYB transcription factors in tobacco are poorly understood. In the present study, we isolated cDNA of an MYB transcription factor gene (Nt*MDP92*) whose transcript level decreased during *N*-gene-mediated resistance induction in tobacco mosaic virus-infected *Nicotiana tabacum*. Next, we examined the intracellular localization of NtMDP92 fused to YFP in *N. benthamiana* and showed that MDP92 localized in the nucleus. To further investigate the biological function of *NtMDP92*, we performed transient co-expression of *NtMDP92* cDNA and an *N* genomic sequence, together with a GFP-encoding infectious clone of tomato mosaic virus (*ToMV-GFP*) or potato virus X (*PVX-GFP*) in *N. benthamiana*. As a result, transient expression of *NtMDP92* increased the fluorescent area of GFP and the transcript level of *GFP*, with or without co-expression of the *N* genomic sequence. Based on these results, we suggest that

NtMYB92 is the transcription factor involved in the negative regulation of *N*-independent virus resistance.

ASSESSMENT OF QUANTITATIVE RESISTANCE AGAINST PYRENOPEZIZA BRASSICAE IN BRASSICA NAPUS TILLING MUTANTS

GIMENEZ MOLINA Laura. (1), MUTHAYIL-ALI Ajisa. (1), FELL Heather. (1), CHINOY Catherine. (2), WELLS Rachel. (2), STOTZ Henrik. (1)

(1) University of Hertfordshire, Hatfield, UNITED KINGDOM; (2) John Innes Centre, Norwich, UNITED KINGDOM

Text

Pyrenopeziza brassicae is a pathogenic fungus responsible for light leaf spot disease, one of the most important diseases affecting winter oilseed rape (*Brassica napus*) crops across the UK and Europe, currently considered the most economically damaging disease affecting the UK crop. Current cultural and chemical control practices are insufficient to manage epidemics of the disease, therefore genetic host resistance against *P. brassicae* has become of increasing importance as an effective control strategy. In a previous study, screening of 195 lines of *B. napus* against *P. brassicae* revealed eight gene expression markers (GEMs) significantly associated with infection. One of them, an HXXXD-type acyl transferase gene, was negatively correlated with quantitative disease resistance, suggesting its function as a potential susceptibility gene. The expression of this gene was induced during infection in susceptible, but not in resistant lines, of *B. napus*. Screening of a TILLING mutant with a D167N substitution in the HXXXD-motif was performed in a controlled environment via spray inoculation with *P. brassicae* and the resistance phenotype evaluated using visual assessment and the counting of spores released from acervuli. The D167N mutant was significantly more resistant than background cv Cabriolet when using visual assessment (P=0.0283) or spore counting (P=0.0190), supporting our hypothesis that the HXXXD-type acyl transferase acts as a susceptibility factor against *P. brassicae.*

P1.3-017

IS THERE A POTENTIAL FOR A GENETIC CONTROL OF THE BARLEY DISEASE, RAMULARIA LEAF SPOT?

ROEHRIG Laura. (1,2), DUSSART Francois. (2), RUSSEL Joanne. (3), HOUSTON Kelly. (3), BROSNAN James. (4), JACK Frances. (4), SPOEL Steven. (1), HAVIS Neil. (2)

Text

Since the 1980's, barley production across many regions in the world, has been facing challenges posed by the fungus *Ramularia collo-cygni* (*Rcc*), which causes Ramularia leaf spot (RLS). The appearance of fungicide resistance in *Rcc* populations, together with the lack of known genetic resistance in widely grown barley varieties, indicates limited options to control this disease in the medium to long-term. This highlights the importance of investigating the potential control of RLS via host genetics and an improved understanding of the host/pathogen interaction. We identified one major QTL involved in RLS resistance at the end of the barley chromosome 4H, by using a genome-wide association study on 238 spring barley varieties. Based on this study, a subset of the identified spring barley cultivars was tested in field trials in both Scotland and Germany between 2021 to 2022. The results on disease development support the conclusion that resistant QTL carrying barley lines exhibit an increased tolerance to RLS. Moreover, results from controlled environment experiments further support this link. We further found that *Rcc*-DNA levels in planta did not correlate with symptom expression, under both controlled and field conditions, suggesting that endophytic colonisation by the fungus may not always lead to the appearance of symptoms. Future research will investigate what triggers symptom expression in barley and elucidate associated factors in both host and pathogen.

Text

Cultivars with B genome component are reportedly less susceptible to infection by banana bunchy top virus (BBTV). In the Philippines, the 'Lakatan' (AAA) is very susceptible to BBTV while the 'Saba' (BBB/ABB) may escape field infection for years. Wild progenitors of bananas, two M. acuminata ssp. errans (AA) accessions and 34 M. balbisiana (BB) from the germplasm collections of the Institute of Plant Breeding, UP Los Banos were evaluated for disease response against BBTV through artificial inoculation. Symptoms were monitored and plants were indexed by PCR three and six months after inoculation. All M. acuminata ssp. errans and all Lakatan controls were infected with BBTV, whereas all plants of M. balbisiana accessions remained uninfected. M. balbisiana plants were transferred to a field under high BBTV inoculum pressure and remained uninfected for up to five years, while all Lakatan control plants were infected after two months. To our knowledge, this is the first report of apparent immunity to BBTV and these M. balbisiana accessions are further studied to uncover novel sources of BBTV resistance genes for functional genomics research, genome-wide association studies, and marker-assisted plant breeding applications.

P1.3-019

A MODERATE RESISTANCE IN OAT VARIETIES TO DON PRODUCERS DOES NOT GUARANTEE A MODERATE RESISTANCE TO HT2+T2 PRODUCERS

HOFGAARD Ingerd Skow. (1), BRODAL Guro. (1), ALMVIK Marit. (1), LILLEMO Morten. (2), RUSSENES Aina Lundon. (1), EDWARDS Simon. (3), AAMOT Heidi Udnes. (1)

(1) Norwegian Institute of Bioeconomy Research, Ås, NORWAY; (2) Norwegian University of Life Sciences, Ås, NORWAY; (3) Harper Adams University, Newport, UNITED KINGDOM

Text

Oat harvested from plants infested with plant pathogenic fungi within the Fusarium head blight (FHB) complex may sometimes contain high levels of mycotoxins, which makes the grain unsuitable for food and feed. Fusarium graminearum, a deoxynivalenol (DON) producer, and Fusarium langsethiae, a T-2 toxin (T2) and HT-2 toxin (HT2) producer, are commonly occurring in Norwegian oats. We have analysed grains of Nordic oat varieties and breeding lines for the content of mycotoxins and DNA of Fusarium species belonging to the FHB disease complex (Hofgaard et al. 2022). The grains were harvested from field trials located in South-East Norway in the years 2011-2020. The ranking of oat varieties according to HT2+T2 levels corresponded with the ranking according to the DNA levels of F. langsethiae. However, this ranking did not resemble the ranking for DON and F. graminearum DNA. Our results implies that a moderate resistance to DON producers does not guarantee a moderate resistance to HT2+T2 producers. Separate tests are therefore necessary to determine the resistance towards DON and HT2+T2 producers in oats. This creates practical challenges for the screening of FHB resistance in oats as todays' screening focuses on resistance to F. graminearum and DON. We identified oat varieties with generally low levels of both mycotoxins and FHB pathogens which should be promoted to mitigate mycotoxin risk in Norwegian oats.

(1) University of São Paulo (USP), Piracicaba, BRAZIL; (2) University of Campinas (UNICAMP), Campinas, BRAZIL

Text

Several studies have shown that rust fungi negatively interfere with the host gas exchange. The objective of this study was to analyze the effect of *Austropuccinia psidii* infection, the causal agent of myrtle rust, on the stomatal control of guava leaf. Guava potted plants were inoculated with urediniospores suspension of *A. psidii* and kept under favorable environmental conditions to infection. As a control, guava plants were sprayed with distilled water and kept under the same conditions. The stomatal conductance (g_s) in healthy and diseased leaves was measured 15-20 days post-inoculation using a portable infrared gas analyzer. The measurements begun under photosynthetically active radiation of 800 µmol m^{-}

^{2} s^{-1} (30 min), which was reduced to 80 µmol m^{-2} s^{-1} (50 min) and then increased to 800 µmol m^{-2} s^{-1} (50 min), with data logging every 1 min. The analysis of the pathogen colonization was performed on leaf tissues prepared with histological techniques. Diseased leaves (mean rust severity of 20.4%) showed a reduction of 40% in g_s compared with healthy leaves. The maximum g_s values in healthy and diseased leaves were, respectively, 0.21 and 0.13 mol H_2O m^{-2} s^{-1}. Furthermore, diseased leaves closed and opened their stomata more slowly when exposed to low and high light, respectively. This stomatal impairment probably resulted from the obstruction of the substomatal chamber by pathogen hyphae, evidenced by histopathological analyzes.

SCREENING RESISTANCE LOCI TO PLASMOPARA VITICOLA, THE CAUSAL AGENT OF GRAPEVINE DOWNY MILDEW, IN VITIS AMURENSIS WITH FOLIAR SPECTROSCOPY

SIMANGUNSONG Robetauli Mastiur. (1), SAPKOTA Surya D.. (2), UNDERHILL Anna. (3), PAUL Angela. (2), HOSSEINZADEH Saeed. (2), REISCH Bruce. (2), GOLD Kaitlin M.. (4), CADLE-DAVIDSON Lance. (3)

Text

European grapevine (*Vitis vinifera*) is highly susceptible to grapevine downy mildew (GDM, *Plasmopara viticola*) in humid regions, necessitating frequent fungicide applications for effective management at great financial and environmental expense. Breeding disease-resistant varieties can broadly improve sustainability and profitability, but progress has historically been slow due to a lack of phenotyping precision and throughput. The wild species *V. amurensis,* native to East Asia, has been identified as a source of disease resistance due to its numerous resistance quantitative trait loci (QTLs) for both GDM and other diseases, including powdery mildew, anthracnose, and white rot. We crossed *V. amurensis* '588634' with the interspecific hybrid 'NY84-0101-03' to produce 229 grape seedlings segregating for moderate and stable QTLs for GDM resistance. The goal of this project was to quickly and non-invasively screen these offspring with GDM resistance QTLs using handheld foliar spectroscopy in the visible to shortwave infrared range (SWIR, 400-2400nm) and compare speed and accuracy to traditional phenotyping methods. Our preliminary results found that wavelengths spanning the near to SWIR are associated with GDM resistance QTLs. These spectral regions are known to be associated with plant chemistry and secondary metabolite concentration. Thus, hyperspectral sensing could potentially accelerate development of disease-resistant grape varieties through rapid GDM-resistance screening.

P1.3-022

CHARACTERIZATION OF HT-RESISTANCE GENES AGAINST EXSEROHILUM TURCICUM

LUDWIG NAVARRO Barbara. (1,2), HANEKAMP Hendrik. (1), NOGUEIRA JUNIOR Antonio Fernandes. (3), STREIT Sebastian. (1), VON TIEDEMANN Andreas. (1)

(1) Georg August Universität Göttingen, Göttingen, GERMANY; (2) KWS SAAT SE & Co. KGaA, Einbeck , GERMANY; (3) Escola Superior de Agricultura Luiz de Queiroz - Universidade de Sao Paulo, Piracicaba , GERMANY

Text

Northern corn leaf blight (NCLB) is one of the important maize diseases worldwide. Disease control is mainly based on the use of fungicides and resistant varieties. Curiously, the resistance reaction expressed against Exserohilum turcicum infection may differ between the major genes. Histological, epidemiological, physiological, and biochemical studies have been conducted on maize plants of the line B37 carrying the genes *Ht1*, *Ht2*, *Ht3* and *Htn1*. The histological characterization using the Chlorazol Black E staining indicates that main differences are in xylem and mesophyll colonization and strong necrosis was observed in plants carrying *Ht1*. According to the epidemiological parameters, sporulation has higher for plant carrying *Ht2* gene. Physiological measurements demonstrate that CO_2 assimilation, transpiration, and stomatal conductance were not decreased in plants carrying *Ht3*. The biochemical parameters indicate an increase in the peroxidase activity for *Htn1*, whereas H_2O_2 was localized in penetration sites in all resistant lines. Cluster analysis using histological and epidemiological parameters indicates that *Ht1* and *Ht2* are in the same group, whereas *Ht3* and *Htn1* form a second group. For the biochemical and physiological parameters, a cluster was formed within *Ht2* and *Ht3* whereas the second cluster was formed within *Ht1* and *Htn1*. In conclusion, the resistance conferred by the *Ht* genes is distinct and influences photosynthesis and sporulation.

P1.3-023

THE ROLE OF EAR DOMAIN IN PLANT IMMUNITY

ABDELSAYED Sara. (1), GRANT Murray. (1)

(1) University of Warwick, Coventry, UNITED KINGDOM

Text

Plants have evolved well-orchestrated defence strategies against pathogen attacks.Consequently, pathogens have evolved strategies to overcome these defences.A key early outcome is transcriptional reprogramming mediated pathogen effectors. this can be achieved by activation or repression.The latter involves the rapid and targeted removal of negative regulators, enabling induction of key response pathways.We previously undertook a 13-time point infection series designed to capture transcriptome changes associated with disease and defence following challenge of Arabidopsis thaliana with the virulent pathogen,P.syringae pv.tomato strain DC3000 or its non-pathogenic hrpA type III secret deficient mutant.Only1%of the transcriptome was differentially expressed between DC3000 challenged and mock treatment 3hpi, which rapidly increased to20%by7hpi and37% across the 13-time points.These represented~30%ofall the annotated Arabidopsis transcription factors in Arabidopsis. To understand the role of ABA in enhancing the susceptibility of plant to DC3000. we modelled theseTFs against genes encoding proteins involved inABA perception and signalling.The model identified as a core hub a MybTF hub encoding a transcriptional repressor domain with unusual expression dynamics, predicted to influence knownABA signalling. The key objectives are characterise this novel Myb transcription factor

and elucidate its role in DC3000's virulence strategy using a variety of genetic and physiological methods.

P1.3-024

ARE PHYTOHORMONES THE MESSENGERS IN SYSTEMIC INDUCED RESISTANCE IN AUSTRIAN PINE?

BONELLO Pierluigi. (1), **BONELLO Pierluigi. (1)**

(1) The Ohio State University, Columbus, Oh, UNITED STATES

Text

Microbe-induced whole plant-level immunity, known as systemic induced resistance (SIR), and its underlying mechanisms, remain largely underexplored in trees. We conducted a study in which we elicited a systemic defense response by inducing lower stems of 4-6-year-old Austrian pine by either wounding or inoculating with Diplodia pinea. Then, we sampled stem phloem 15 cm upstream of induction at 12 h, 24 h, 36 h, 48 h, 72 h, or 7 h days post induction to quantify systemic accumulation of phytohormones using LC-MS/MS. The acquisition and quantification methods were optimized for (±)-jasmonic acid, methyl jasmonate, jasmonoyl-isoleucine, 12-oxo phytodieonic acid, dihydrojasmonic acid, salicylic acid, methyl salicylic acid, abscisic acid, gibberellic acid (GA3), gibberellin (GA4), 3-indole acetic acid, and indole-3-carboxylic acid. We found higher concentrations of several stress hormones and intermediates, such as jasmonic acid and abscisic acid, alongside elevated levels of auxin intermediates, in response to pathogenic induction. We are now conducting gene expression analyses to further validate these findings. These results will be discussed in relation to the potential role of phytohormones in SIR as mobile signaling molecules.

P1.3-025

PHENOLIC CONTENT AND ANTIOXIDANT CAPACITY OF SWEET PEPPER FRUITS INFECTED WITH ALTERNARIA ALTERNATA

PRVULOVIC Dejan. (1), PEIC TUKULJAC Marijana. (1), DANOJEVIC Dario. (2), MEDIC-PAP Sladjana. (2)

(1) University of Novi Sad, Novi Sad, SERBIA; (2) Institute of Field and Vegetable Crops, Novi Sad, SERBIA

Text

Sweet pepper (*Capsicum annuum* L.) is vegetable susceptible to many pathogen infections, including postharvest decay caused by fungus *Alternaria alternata*. Pathogen inoculation and mechanical damages could provoke the accumulation of defensive phenolic compounds and increase antioxidant activity in plants.The aim of this study was to evaluate total phenolics and total flavonoid content and antioxidant capacity in the fruits of two sweet pepper genotypes: line 112/16 and line 134/16 infected with *A. alternata*. The fruits were grown in the experimental field of the Institute of Field and Vegetable Crops, Novi Sad, Serbia, and harvested at the

technological maturity. Fruits of each genotype were divided into three experimental groups: the intact fruits (control group), the fruits injected with sterile water and fruits inoculated with a fungal spore suspension. For the inoculation monohyphal isolate (K-93) of *A. alternata* was used. The fruit assessment was performed 10 days after inoculation. Content of phenolics, flavonoids and antioxidant capacity measured by three different assays (2,2-Dyphenyl-1-picrylhydrazyl (DPPH) assay, 2,2′-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) assay and Ferric Reducing Antioxidant Power (FRAP) assay) were determined in 70% methanol extracts of fruits. Both genotypes manifested low tolerance to *A. alternata* infection. Content of phenolic compounds and antioxidant capacity decreased in infected sweet pepper fruits.

P1.3-026

PLANT EPIGENETICS FOR FOREST RESILIENCE AGAINST INVASIVE PATHOGENS

Text

Plant diseases, both endemic and recently emerging, are spreading and exacerbated by climate change. For example, in the last years, Acute oak Decline (AOD) and Ash Dieback Disease (ADD) are emerging diseases endangering oak and ash landscapes. Plant epigenetics has recently acquired extraordinary interest as it has been shown to contribute to both short-term phenotypic plasticity and the longer-term adaptive capacity of plant responses to abiotic and biotic stresses, including the capacity to transmit these marks to progenies. Our work aims to study how disease pressures alters DNA-methylation imprinting in oak and ash. For this, trees were scored, classified in disease severity levels and sampled. Leaf-DNA was extracted and subjected to Whole Genome Bisulfite Sequencing (WGBS). Bismark software and R scripts (DSS., DMRcaller) were employed to analyse methylomes. Differentially Methylated Regions (DMR's) were observed in different C-context. Correlation analysis identified global and targeted changes in DNA methylation with AOD and ADD disease severity. The identification of epigenetic mechanisms marking oak and ash disease resilience could be used to reforestation and conservation of future forests in a hostile environment.

PROFILING MOLECULAR RESPONSES OF NICOTIANA GLUTINOSA TO INFECTION WITH LETTUCE NECROTIC YELLOWS VIRUS SUBGROUPS TO UNDERSTAND VIRUS DISPERSAL

HIGGINS Colleen. (1), VALMONTE-CORTES Gardette. (1), SHINDE Shweta. (1)

(1) Auckland University of Technology, Auckland , NEW ZEALAND

Text
We have analysed the molecular responses of the model dicot species *Nicotiana glutinosa* to the type cytorhabdovirus, lettuce necrotic yellow virus (LNYV). LNYV infects a broad range of monocot and dicot hosts, yet the impacts of cytorhabdoviruses are understudied. In addition, the responses of *N. glutinosa* have not been well explored. The LNYV population exists as two subgroups, SI and SII; SII appears to be dispersing more rapidly than SI, particularly in Australia where SI appears to have become extinct. Interactions with the host may influence the rate of dispersal, and there are concerns that SII may overtake SI in NZ to cause more devastating disease. We have compared the molecular responses of *N. glutinosa* to infection with LNYV SI and II at 28 dpi to identify candidate genes and metabolites that may cause differences in subgroup dispersal. Metabolomic analyses have identified subgroup specific sugar, amino acid, organic acid, and fatty acid profiles. RNA seq, and RT-qPCR analyses have identified differentially expressed genes associated with responses to biotic stimulus, defense, photosynthesis, and metabolic processes affecting primary and secondary metabolism. Findings of this study will significantly contribute to our understanding of the complicated mechanisms of plant responses to cytorhabdoviruses in general, but also provide clues as to the mechanisms this virus uses to improve its spread.

P1.3-028

THE ROLE OF DORMANCY-ASSOCIATED (DRM) DISORDERED PROTEINS IN PLANT – PATHOGEN INTERACTIONS.

WOOD Marion. (1)

(1) Plant and Food Research, Auckland, NEW ZEALAND

Text
Intrinsically disordered proteins (IDPs) are surprisingly common in biological systems and comprise approximately 25% to 30% of eukaryotic proteomes, with additional data suggesting that over 50% of eukaryotic proteins and 70% of signalling associated proteins have regions of long disorder. Due to their inherent plasticity and lack of ordered structure, IDPs rapidly undergo conformational changes when bound to their biological partners. Indeed, it is this plasticity that lends itself to the characteristic promiscuous nature of an IDP, often occupying salient roles as hub proteins in signalling cascades. Amino acid composition analyses of the highly conserved plant-specific Dormancy-associated (DRM) protein family clearly demonstrates that members of this family are enriched in major disorder-promoting residues and depleted in major order-promoting residues; in a manner typical for structurally characterized IDPs. Using the DRM protein family as an exemplar, we present data that this protein family plays a pertinent role in a plant's response to both biotic and abiotic stresses, with individual members displaying potential antagonistic functions to each other, including the regulation of reactive oxygen species (ROS) following pathogen infection. We will also discuss further the importance of protein disorder in biological signalling cascades within plant-pathogen interactions.

EVALUATION OF GREEK OLIVE CULTIVARS FOR SUSCEPTIBILITY TO FOMITIPORIA MEDITERRANEA

MARKAKIS Emmanouil. (1), LIGOXIGAKIS Eleftherios . (1), ROUSSOS Peter . (2), SERGENTANI Chrysi . (1), KAVROULAKIS Nektarios . (1), RODITAKIS Emmanouil . (3), KOUBOURIS Georgios . (1)

(1) Institute of Olive Tree, Subtropical Crops and Viticulture, Hellenic Agricultural Organization “Demeter”, Heraklion, GREECE; (2) Agricultural University of Athens, Athens, GREECE; (3) Hellenic Mediterranean University, Heraklion, GREECE

Text

In the present study, five of the most significant Greek olive cultivars (Amfissis, Chalkidikis, Kalamon, Koroneiki and Mastoidis) were evaluated for their susceptibility to *Fomitiporia mediterranea*. Artificial inoculations were carried out by drilling a hole into the trunk and inserting mycelial plugs of the fungus into the wood. Tissue reactions were evaluated by carrying out longitudinal and transverse sections of the trunks and measuring the length of bark and wood lesions, 33 months post inoculation. Trunk scanning and image pixel analysis were employed to estimate the total discoloration and decay area of infected wood. Moreover, *F. mediterranea* re-isolation ratio from wood chips taken from different sites above and below the inoculation point was also estimated. Data indicated that the susceptibility of olive cultivars to *F. mediterranea* varied significantly. ‘Amfissis’ and ‘Chalkidikis’ were the most susceptible, whereas ‘Kalamon’ and ‘Koroneiki’ were comparatively resistant; ‘Mastoidis’ showed an intermediate level of susceptibility. Measurements of lignin content showed that the resistance of olive cultivars to *F. mediterranea* could be associated with the level of lignin in their trunk wood. This is the first experimental evidence of differential susceptibility responses of olive cultivars against *F. mediterranea*, and reveals the potential exploitation of host resistance as a promising approach in the effort to control wood decay disease of olive in practice.

HERE COMES THE SUN! AN INNER NUCLEAR ENVELOPE PROTEIN THAT REGULATES PLANT NUCLEAR DYNAMICS AND TRANSCRIPTIONAL STRESS RESPONSES AGAINST PATHOGENS

SHARMA Akriti. (1), KV Abhilash. (1), VERMA Ankita. (1), **CHANDRAN Divya. (1)**

(1) Regional Centre for Biotechnology, Faridabad, INDIA

Text

Nuclear repositioning and cytoskeletal rearrangements constitute the earliest plant cellular responses to pathogen invasion. Yet, their molecular aspects and biological significance remain underexplored, particularly in legumes, which are hosts to symbiotic and pathogenic fungi. We investigated the host nuclear dynamics during compatible *Pisum sativum* (pea)-powdery mildew (PM) interactions and observed that the host nucleus moves towards the fungal appressorium before penetration and subsequently positions itself adjacent to the newly formed primary haustorium. Actin depolymerization inhibits nuclear movement and haustorium formation suggesting that actin-mediated host nuclear repositioning is crucial for PM establishment. For further insights, we investigated the role of the pea inner nuclear envelope

(NE) SUN protein, an integral component of LINC (Linkers of Nucleoskeleton and Cytoskeleton) complexes known to regulate nuclear dynamics. *PsSUN* knockdown alters the nuclear shape and hinders PM-induced host nuclear movement and fungal growth in pea. *PsSUN* stable expression in Arabidopsis causes NE deformation and up-regulation of defense-related genes involved in the salicylic acid (SA), pipecolate, and camalexin pathways. Notably, *PsSUN* overexpression lines accumulate elevated levels of SA and exhibit reduced susceptibility to a bacterial pathogen. Overall, our results suggest that PsSUN may regulate plant immunity through its impact on nuclear movement and gene expression.

CHARACTERIZATION OF OLIVE FRUIT RESISTANCE TO COLLETOTRICHUM GODETIAE

MIHO Hristofor. (1), **EXPOSITO DIAZ Anabel. (1)**, MARQUEZ Maria Isabel. (1), LEDESMA ESCOBAR Carlos. (1), MUÑOZ DIEZ Concepcion . (1), PRUSKY Dov. (2), PRIEGO CAPOTE Feliciano. (1), MORAL MORAL Juan. (1)

(1) University of Cordoba, Spain, Cordoba, SPAIN; (2) Agricultural Research Organization, Rishon Letzion, Israel, ISRAEL

Text

Anthracnose, caused by *Colletotrichum spp.*, is the olive's most severe fruit disease. The pathogen causes fruit rot that negatively impacts the oil quality. Marked differences in resistance to the pathogen are observed between cultivars during the ripening in the field, but little is known about the defense mechanisms involved. Here, we used microbiological and chemical approaches to fill part of this gap. Inoculations showed that developing fruits were immune to the pathogen independently of the cultivar and the presence or absence of wounds on the peel. Conversely, fruit resistance was depended on the peel wounds once the fruit reached its maximum size at the beginning of the ripening process. Peel and mesocarp EtOH extracts of developing fruit caused a high inhibition of spore germination (> 80%) independently of the olive cultivars. On the contrary, in mature fruits, peel and mesocarp extracts, and to a lesser extent fruit wax, of resistant cultivars significantly affect the viability of the pathogen spores and their capacity to form appressoria compared with susceptible fruit cultivars. The current experiments point that the speed of transformation of the phenolic compounds in the ripe fruit, from primary compounds (ligstroside and oleuropein) to aglycones and, then, sercoroids, together with the concentration of terpenes in its peel, may contribute to cultivar resistance.

P1.3-033

A DEAD-BOX RNA HELICASE REGULATES IRON HOMEOSTASIS AND IMMUNE RESPONSE IN ARABIDOPSIS

XING Yingying. (1), LIU Jun. (1)

(1) China Agriculture University, Beijing, CHINA

Text

Abstract
Acquisition of nutrients from plants is essential for pathogen colonization. As a key mineral nutrient for nearly all organisms, iron plays an important role in plant growth and disease resistance. However, how plant regulates iron homeostasis to enhance plant immunity remains unclear. Our previous studies showed that iron sensor protein BTS (BRUTUS), a key regulator of iron homeostasis, positively regulated plant disease resistance and is an important disease-resistance factor in plant immunity. Therefore, we proposed that there is an important relationship between iron homeostasis and plant immunity. To identify the immune elements regulated by BTS, we performed EMS (ethyl methane sulfonate) mutagenesis screening on *bts-2* seeds. A key gene that regulates BTS-mediated iron metabolism was identified by map-based cloning, which encodes a DEAD-box RNA helicase (RHa). Our data showed that RHa is an ATP-dependent RNA helicase that negatively regulated the resistance of plants to pathogens and the susceptibility to iron deficiency. RHa interacts with BTS in the nucleus and regulates the activities of the downstream iron deficiency regulatory proteins, leading to the accumulation of iron in plants, thereby facilitating pathogen proliferation. Our findings suggest that RHa regulates iron homeostasis through BTS and thus affects plant immune response.
Key word: *Arabidopsis thaliana*, plant innate immunity, BRUTUS, DEAD-box RNA helicase, iron homeostasis

DIFFERENTIAL RESPONSE OF SUGAR BEET GENOTYPES TO THE LOCAL AND SYSTEMIC BEET CURLY TOP IRAN VIRUS INFECTION: VIRUS ACCUMULATION AND TRANSCRIPTOME ASSAY IN RESISTANT AND SUSCEPTIBLE GENOTYPES

EINI Omid. (1), VARRELMANN Mark. (1)

(1) IFZ (Institute of Sugar Beet Research), Göttingen, GERMANY

Text

Curly top disease caused by geminiviruses including Beet curly top Iran virus (BCTIV) is a limiting factor for sugar beet production. The most economical control of curly top disease in sugar beet would be through resistant cultivars though, most commercial cultivars possess only low to moderate resistance. A doubled haploid Line KDH13 showed resistance to Beet curly top virus (BCTV) and produced mild symptoms. However, the response of Line KDH13 to BCTIV which is genetically different from BCTV was not studied before. Here we tested the response of the resistant line and two susceptible genotypes (KDH19 and 9B) to the BCTIV local and systemic infection. Real-time PCR showed that BCTIV replicated in the locally agroinfiltrated cotyledons in all tested genotypes. However, in systemic assay, the virus was detected only in susceptible genotypes. Transcriptome analysis for the BCTIV infected plants showed a higher number of genes were deregulated in the locally infected tissues compared to the systemic infection. Among them, DNA recombination and defense response genes were the most upregulated candidates. However, in the systemic infection, genes related to the gibberellin and salicylic metabolic were the most upregulated groups. This work demonstrates the response of sugar beet plants to BCTIV infection at both local and systemic infection and highlights the metabolic pathways and defense-related genes for their contribution towards BCTIV resistance.

P1.3-035

THE RICE HVA22 PROTEINS IN RICE IMMUNITY

YINGBO Liang. (1), **LIU Jun. (1)**

(1) China Agricultural University, Beijing, CHINA

Text

The endoplasmic reticulum (ER) is the largest intracelluar endomembrane system. ER-phagy removes excessive ER and the associated cargo proteins, thereby remodeling ER morphology and functions. ER-phagy receptors selectively target ER subdomains and induce autophagic sequestration. Despite multiple ER-phagy receptors have been reported, their functional counterparts in plants remain largely unexplored. Here, we report a HAV22 family protein OsHLP1 that is a novel ER-phagy receptor in plants. OsHLP1 interacts with ATG8b and recruits ER subdomains and the cargo protein OsNTL6, a negative immune regulator, to autophagosomes upon the fungal pathogen Magnaporthe oryzae infection, which substantially actives the disease resistance in rice. OsHLP1 orthologous induced similar ER-phagy in Arabidopsis thaliana. We therefore discovered a conservative protein family that act as ER-phagy receptors and highlight their roles in plant immune response.

Text

Fusarium circinatum is a fungal pathogen causing Pine Pitch Canker (PPC). In Europe, it is an invasive pathogen established in northern Spain and Portugal where the disease affects forest stands of *Pinus radiata* and *P. pinaster*. Of these, *P. radiata* is considered one of the most susceptible pine species to PPC disease while *P. pinaster* has shown a moderate disease resistance. *P. pinaster* is also the Iberian species from which resin is collected. Defence mechanisms employed by conifers include the production of terpenoid oleoresin, which act as physical and chemical barriers against insect and pathogen attack. The aim of this work is to identify the most relevant terpenes produced in response to *Fusarium circinatum*, which may explain the differences in PPC disease susceptibility, and to determine the effect of these terpenes on the in vitro growth of the pathogen. For this, a controlled experiment was carried out by inoculating with *F. circinatum* or wounding seedlings of both species. The terpene profile (170 metabolites) was analysed by GC-MS

after 11 and 18 dpi. To determine terpenes produced in the presence of *F. circinatum* colonizing seedlings, a comparison of inoculated vs. mock-inoculated seedlings in an OPLS-DA model was performed for each dpi (all models were significant at p-value < 0.05 for *P. pinaster* and *P. radiata*). The inhibitory or enhanced effect of these terpenes on mycelial growth of *F. circinatum* was studied using turbidimetric measurements with Bioscreen C.

Text

Pine pitch canker (PPC) disease, caused by the fungus Fusarium circinatum Nirenberg and O'Donnel, poses a serious threat to several Pinus species affecting plantations and nurseries worldwide, with important economic losses. In plant pathogen interactions, phytohormones play a crucial role in determining the progression of diseases. In the present work, we explore the phytohormone profile in two Pinus species with different degrees of susceptibility to F. circinatum, Pinus radiata (highly susceptible) and P. pinaster (moderately resistant), at different stages of infection. Dual-RNA sequencing assay showed that the moderate resistance of P. pinaster can be explained by the early activation of defence-related genes and a complex phytohormone signalling at 3, 5 and 10 days post-inoculation, which includes mainly salicilyc acid, jasmonic acid, ethylene and to a lesser extent auxins. We also hypothesise the key steps in which the pathogen could be manipulating host defence. Given that metabolism is driven by specific enzymatic products of gene expression, the phytohormone metabolome of both pine species by GC-MS at 5 and 10 dpi was explored. Abscisic acid (ABA), jasmonic acid (JA), salicylic acid (SA), indole acetic acid (IAA), gibberellic acid (GA1 and GA4) and cytokinins (DHZ, iP, tZ) were quantified. Integration of "omic" data and the validation of key genes by qPCR will allow the core pathways that explain differences between Pinus species to be identified.

P1.3-038

INTRASPECIFIC DIVERSIFICATION OF PATHOGEN DEFENCE SIGNALLING IN THE WILD TOMATO SPECIES SOLANUM CHILENSE

KAHLON Parvinderdeep Singh. (2), DUTTA Anik. (1), MUNOZ Lina. (2), TOMINELLO RAMIREZ Christopher. (2), DAWID Corinna. (2), **STAM Remco. (1)**

(1) Christian Albrechts University of Kiel, Kiel, GERMANY; (2) Technical University of Munich, Freising, GERMANY

Text
Natural plant populations need to adapt to their environment. What the implications are of such adaptations for the functioning of the pathogen defence signalling network is not known.

We study the species-wide diversity in pathogen defence mechanisms in the wild tomato species Solanum chilense. It grows in Chile and Peru and its specific demography, allows us to learn how evolution of resistance properties happens in new diverse habitats.

We performed large-scale phenotyping and measured defence responses in plants representing 9 different wild populations. Variations in defence properties are not limited to responses triggered by major resistance genes like NLRs or RLPs and also affect the often assumed assumed conserved mechanisms involved in quantitative defence responses (QDR).

We established that QDR components, such as ROS or phytohormone regulation, are highly variable within the species. Quantitative resistance can only be explained by effects of multiple components. The effect of each component differed dependent on the population's origin. We also find that genes in diverse defence pathways are under differential selection, dependent on the location of origin of the population and are now further studying the transciptomic and metabolimic response triggered in the plant.

This work thus shows that QDR is more variable in nature than previously assumed. It also highlighs the importance of looking beyond model plants and single accessions to understand defence signalling.

P1.3-039

HLB TOLERANCE IS ASSOCIATED WITH ENHANCED CARBOHYDRATE DYNAMICS IN THE LEAVES, UPREGULATION OF DEFENSE ACTIVATORS, AND PRESERVATION OF XYLEM CONNECTIVITY

ROBLEDO Jacobo. (1), WELKER Stacy. (1), VASHISTH Tripti. (1), VINCENT Christopher. (1), LEVY Amit. (1)

(1) University of Florida - Lake Alfred, FL, Lake Alfred, UNITED STATES

Text
While HLB is still one of the most severe citrus diseases worldwide, improved tolerant cultivars, such as the Sugar Belle® [SB] mandarin, have been developed in Florida-USA. To understand the responses that this tolerant material is undergoing upon infection, we compared leaf carbohydrate dynamics, callose accumulation in the phloem, relative gene expression of plant defense activators, and anatomical sections of vascular elements between healthy and infected SB trees and susceptible sweet orange (SO). Physiologically, SB showed a 250% increase in 14CO2 fixation and a 13% decrease in 14C-carbohydrate export whereas SO presented a decrease of 33% and 50%, respectively. Localized callose accumulation was differentially encountered in infected SB. Pathologically, expression of papain-like cysteine proteases (PLCPs) known for interacting with the SDE1 effector of Candidatus Liberibacter asiaticus was upregulated in SB but downregulated in SO. Anatomically, SB showed minor alterations in the total area of the midribs pith and xylem, but 29% fewer and 19% smaller cells in the phloem. Contrastingly, SO showed a 200% and

181% increase in cell number and 156% and 136% growth of cell lumen area in the xylem and phloem, respectively. Three mechanisms of tolerance in SB are hypothesized: i) increase carbohydrate availability induced by differential carbohydrate dynamics in the leaves, ii) increase in the defense response activated by PLCPs, and iii) maintenance of xylem connectivity.

AVOCADO SUNBLOTCH VIROID: THE SMALLEST AVOCADO PATHOGEN CAUSING BIG CHANGES IN HOST GENE EXPRESSION

JOUBERT Melissa. (1,2), VAN DEN BERG Noelani. (1,2), THERON Jacques. (1), SWART Velushka. (1,2)

(1) Department of Biochemistry, Genetics and Microbiology, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, SOUTH AFRICA; (2) Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, SOUTH AFRICA

Text
Avocado sunblotch disease is caused by avocado sunblotch viroid (ASBVd) - a small, single-stranded molecule of RNA. This economically important disease is associated with symptoms such as the formation of coloured, sunken lesions on avocado fruit, yellow streaks on stems and chlorosis of leaves. Under field conditions, infection by ASBVd may remain asymptomatic for long periods of time, though avocado trees without chlorotic symptoms have been known to display altered growth habits and decreased fruit yield. Despite the global prevalence of the viroid and its impact on the avocado industry, molecular mechanisms underlying ASBVd infection remain unknown. In this study, we used RNA-seq to determine transcriptomic changes in avocado triggered by ASBVd infection. RNA was extracted from leaves of asymptomatic Hass grafted seedlings, and infection status of individual nursery trees was determined. The mRNA of ASBVd-infected and uninfected replicates was sequenced using Illumina NovaSeq 6000. RNA-seq data indicated that ASBVd infection induced significant changes to avocado gene expression, despite asymptomatic infection. Pathway analyses revealed that host processes such as plant defense response and phytohormone signalling pathways were significantly affected by ASBVd infection. These findings represent the first global transcriptomic study in ASBVd-infected avocado; an important advancement in improving our understanding of the interactions between this viroid and its host.

EPIDEMIOLOGY AND MOLECULAR CHARACTERIZATION OF A NEWLY EMERGING MONOPARTITE BEGOMOVIRUS IN SOUTH AFRICA, CAPABLE OF INDUCING SEVERE SYMPTOMS IN COMMERCIAL TOMATO CULTIVARS WITH MULTIPLE TY RESISTANCE GENES.

ESTERHUIZEN Lindy. (1), VAN ZYL Esna. (2)

(1) Agricultural research council South Africa, Pretoria, SOUTH AFRICA; (2) Sakata Vegenetics RSA (Pty) Ltd., Lanseria, South Africa., Johannesburg, SOUTH AFRICA

Text

Tomato curly stunt virus (ToCSV) is a tomato yellow leaf curl disease present in southern Africa. Since its introduction in South Africa (1998), ToCSV has become one of the most destructive tomato viral diseases in the country. Over the last three years, commercial tomato cultivars known to be ToCSV-resistant, have been found to show particularly severe symptoms characteristic of begomovirus infection. The increasing occurrence in tomato growing areas in the northern parts of the Limpopo province, prompted further investigation. Tomato plants with TY-resistance, showing severe symptoms of leaf curling and stunting were collected (field isolate) and used as source material in a whitefly-mediated inoculation greenhouse trial. The disease symptom severity of susceptible and resistant cultivars were compared to a severe variant of ToCSV, maintained via agroinoculation. The symptoms induced by the field isolate was much more severe in both susceptible and resistant cultivars, in contrast to the ToCSV isolate. Rolling circle amplification (RCA) and PacBio, single molecule, long read sequencing was used to characterize the begomovirus isolates present in the field isolate. Sequence comparison and phylogenetic analyses revealed the presence of multiple begomovirus isolates, with 85 – 99% sequence identity with known begomovirus species. Ongoing epidemiological and further molecular characterization of these viral isolates will be discussed.

BREEDING FOR RESISTANCE AGAINST PHOMOPSIS HUSK ROT DISEASE IN THE AUSTRALIAN MACADAMIA ORCHARDS

RINCON FLOREZ Vivian. (1), AKINSANMI Olufemi. (1), ALAM Mobashwer. (1), TOPP Bruce. (1)

(1) Centre for Horticultural Science, The University of Queensland, Brisbane, AUSTRALIA

Text

Macadamia is an evergreen tree nut that produces high-value kernels used in the food and cosmetic industries. Major production areas are found in the tropical and subtropical regions worldwide. Australia is one of the top producers of macadamia with a farm gate value of USD$204 million. Annually, macadamia orchards undergo major yield losses due to pests and diseases, prompting the development of new resistant cultivars with marketable characteristics. One of the major fungal diseases in macadamia orchards is Phomopsis husk rot (PHR) caused by Diaporthe species, which provokes the premature drop of the immature nut reducing orchards profitability. Here, we investigated the diversity of PHR resistance in 14 macadamia cultivars, 7 open-pollinated (OP) progeny and their parents. In vivo wound inoculation assays of the fruit pericarp were used to evaluate host resistance to D. australiana over two years. Significant differences among cultivars were observed, but not in the OP and parent populations. This suggests breeding for resistance for PHR is a viable option for disease control. Studies on heritability of resistance to PHR in macadamia are currently underway.

Text

Fusarium head blight (FHB) is a severe disease of cereals, including bread (*Triticum aestivum*) and durum wheat (*Triticum turgidum* subsp. *durum*) caused by *Fusarium* spp. The main effect of FHB is a drastic reduction of yield and mycotoxins contamination in the raw materials (flours). Pigmented wheat genotypes have flavonoid-rich kernels, especially in the external layers (pericarp and/or aleurone) and polyphenols are known to be antioxidant and antimicrobial agents in plants. Main aims of present work were: to verify if genotypes rich in anthocyanins are more resistant to FHB; to elucidate if *Fusarium* spp. infection affects the phenylpropanoid pathways in wheat. Six pigmented wheat genotypes were artificially inoculated, taking into account type II and type IV resistance, AUDPC and fungal biomass quantification. The results showed that some pigmented genotypes are very susceptible (Purple durum, Skorpion and Rosso), other are quite resistant (Purendo and Indigo) or resistant (Vanilnoir), but pigmentation and resistance seems to be not correlated, even if total phenolic content in mature spike is the parameter more related to the infection. The relative expression of 10 genes related to phenylpropanoid pathways were screened in the pigmented genotypes. In addition, for the bread wheat genotypes an RNA-seq experiment was carried out comparing infected and control plants.

EVALUATION OF SOYBEAN GENOTYPES FOR RESPONSE TO CONIOTHYRIUM GLYCINES, THE CAUSE OF RED LEAF BLOTCH

MISIANI Sprine. (1), MUTHURI Harun. (1), COYNE Danny. (1)

(1) INTERNATIONAL INSTITUTE OF TROPICAL AGRICULTURE,, Nairobi, KENYA

Text

Red leaf blotch (RLB) is a significant fungal disease of soybean caused by the fungus Coniothyrium glycines. Currently, up to 50% loss in yield can be attributed to RLB infection in sub-Saharan Africa. Until now, there are no known varieties with resistance to RLB. 230 soybean lines were screened under screen-house conditions to identify sources of resistance. RLB ZS20B isolate and line SB25 were used as the fungi isolate and susceptible check, respectively. Seeds from each line were germinated in trays filled with a sterile potting mixture of red soil, sand, and manure (2:2:1). Seedlings were maintained in the screen-house (25°C) for two weeks before infection. Infection with RLB was achieved by spraying a spore suspension (2.08×109 spores/ ml) on plant leaves using a spray bottle until runoff. Plants were then transferred into a humid chamber at 25°C. Disease severity was assessed three weeks post-infection based on a 1–5 scale, with 1 representing no disease and 5 representing 66-100% severity. 54 lines had a disease severity ranging between 1-1.9, 103 in the range of 2-2.9, 54 in the range of 3-3.9, and 19 had a severity of 4-5. Lines with a severity of 1-2.5 were re-screened under similar conditions. 38 of these had a severity

ranging from 1-2. Four lines had a severity of 3, while two lines had a severity of 4. The 38 lines are regarded as potential sources of resistance and will be further evaluated to ascertain the presence of resistant genes.

Text

Cassava leaf spot is a complex disease caused by many fungi. The objective of this study was to detect the biochemical change in epidermis and mesophyll tissues leaf spot disease by using Synchrotron Fourier-transform infrared spectroscopy (SR-FTIR). After inoculation of *Curvularia lunata* HC-04, the cassava leaf containing spot symptoms was collected and frozen in optimal cutting temperature. Then the samples were cut-cryosectioned with a thick 12 microns, which were placed on BaF_2 windows and measured by SR-FTIR. In epidermis tissues, the PC1 and PC2 loadings were explained by 33 and 12%, respectively. Similarly, in mesophyll tissues, the PC1 and PC2 loadings were 56 and 12%, respectively. In the second derivative analysis, the lipid (2919, 2850 cm^{-1}), pectin (1733 cm^{-1}), amide I (1652, 1606 cm^{-1}), amide II (1540, 1513 cm^{-1}) and lignin (1442, 1374, 1311 cm^{-1}) were significantly decreased in epidermis tissue when *C. lunata* HC-04 infected. Furthermore, the amide I (1654, 1608 cm^{-1}), amide II (1542, 1513 cm^{-1}), lignin (1446, 1342 cm^{-1}), were significantly decreased in mesophyll tissue when *C. lunata* HC-04 infected while the pectin (1735 cm^{-1}), polysaccharide (1278, 1203, 1145, 1114, 1060, 1037, 993, 962 cm^{-1}) were significantly increased. Mean the polysaccharide and lipid were not significant in the epidermis and mesophyll tissue between control and *C. lunata* HC-04, respectively. In conclusion, the SR-FTIR was an effective tool for detecting biochemical changes in plant tissue.

Text

The aim of this study to investigate the influence of salicylic acid formulation (SA) on total chlorophyll content, reactive oxygen species (ROS) accumulation, phenylalanine ammonia-lyase (PAL) enzyme activity, and endogenous salicylic acid accumulation in cassava. The results found that cassava after enhanced with SA three times has the highest total chlorophyll content in cassava leaves treated with SA 0.155±0.011 µg/mm2. In addition, the production of ROS has a higher accumulation of O2- and H2O2 in leaves tissue reached a maximum at 12 and 24 hours after inoculation (HAI) and then reduce to a low level in 48 HAI. Moreover, PAL activity of cassava leaves showed the increased response of PAL activity level at 24 HAI at 6.93 µmol trans-cinnamic acid min-1 mg-1 protein and decreased to low-level in 48 HAI. Furthermore, endogenous salicylic acid showed that the SA formulation can enhance the higher level of endogenous SA content at 24 HAI to approximately 16.77% and decrease in 48 HAI. These data could be con?rm the enhanced ROS response before SA biosynthesis can trigger systemic acquired resistance (SAR) in cassava to control anthracnose pathogen. The interaction of amino acids ARG31, LEU32, ALA93, and GLN97 resulted in a strong hydrogen bond with SA. According to this theory, salicylic acid was bound to the active site and formed a complex with the active portions of PAL. According to this mode of binding, salicylic acid was bound to the active site of PAL.

Text

Xanthomonas oryzae pv. *Oryzae*, the causal agent of rice bacterial blight disease is now a threat to rice production in Africa. Resistance break-down has accelerated because *Xoo* evolves rapidly. The continuous evolving *Xoo* and breakdown of resistance in cultivated rice varieties needs discovery of new loci to enable breeding broad-spectrum resistant elite rice . East African germplasm holds useful genetic variation for bacterial blight (BB) resistance. This study was conducted to identify loci associated to BB resistance and new genetic donors for breeding program.
To identify candidate sources of resistance for advancing breeding, we used highly four virulent strains of *Xoo* (*PXO99*, *MAI1*, *BAI3* and *Xoo3-1*) to screen 78 East African accessions by GWAS. The core genetic base of the diverse accessions exhibited high degree of resistance

to the Xoo strains. 50.63% of the accessions were highly resistant to the Philippines strain PX099, while 20.25% were highly susceptible to the virulent West African strain MAI1. Two novel resistant loci significantly associated hotspots were identified using 1901 SNPs. The two hits were located on Chr12 (*Xa25*) and Chr6 (*Xa7*, *Xa27*, *Xa33*).
Our finding have identified novel loci that gives a useful basis for more investigation and a wide core genetic pool of high resistance for broad-spectrum resistance genetic improvement.
Keywords: genome-wide association, Oryza sativa, bacterial blight (BB), Xanthomonas oryzae, disease resistance

Text
Plant volatile organic compounds (VOCs) play a crucial role in plant responses against plant pathogens. Previous studies revealed that the abundance of terpenes was higher in resistant than in susceptible grapevine genotypes upon Plasmopara viticola inoculation, indicating their possible involvement in defense mechanisms. This work aims at identifying the metabolic response of terpene-treated grapevine leaves and the potential activation of VOC-mediated defense mechanisms against P. viticola. Functional analyses showed that terpene treatments reduced downy mildew severity on leaf disks. An untargeted metabolomics approach was performed on VOC-treated leaf disks at one and six days post inoculation with P. viticola. A principal component analysis was carried out on the detected features and it discriminated samples according to treatment and time point, indicating global metabolite changes after VOC application. Features with significant increases in abundance were selected, annotated by searching mass spectra in different chemical databases, and validated with analytical standards. Results showed that terpene treatment increased the abundance of phenylpropanoids, terpenoids, and lipids, suggesting that VOC treatments can activate a metabolic response in grapevine leaves that include defense-related compounds.

CLONING AND MECHANISM ANALYSIS OF ADULT PLANT RESISTANCE GENES TO RUST IN WHEAT

LAN Caixia. (1), LI Zhikang. (1), ZHANG Yichen. (1)

(1) Huazhong Agricultural University, Wuhan, CHINA

Text
Growing resistant cultivars remain the most economical, environmentally friendly and

effective method to manage wheat leaf rust and stripe rust. In the present study, a QTL on chromosome 6BL form durum wheat explained 13.1-30.7% of leaf rust severity variation and was designated as Lr84. We confirmed TRITD6Bv1G225630 as the gene that underly Lr84 and it encodes a classic nucleotide binding leucine rich repeat (NLR) protein that is typical of classic disease resistance immune receptors through transgenic and VIGS. Interestingly, Atred#2+Lr84 and overexpressed T2 plants showed susceptibility up to the three-leaf stage but the necrosis associated with a resistance reaction occurred at the four-leaf stage and near immunity was expressed after the five-leaf stage. Furthermore, we found thicker, more rigid leaf cell walls and greater penetration resistance against fungal invasion, in wheat lines harboring the Lr34/Yr18/Sr57/Pm38 gene than in lines lacking it, indicating the involvement of a cell wall-associated defense mechanism. Yeast accumulation assay confirmed the role of Lr34/Yr18/Sr57/Pm38 in the transportation of sinapyl alcohol in vitro. Both genetic and virus-induced gene silencing (VIGS) approaches revealed that the disease resistance conferred to wheat by Lr34/Yr18/Sr57/Pm38 could be enhanced by the presence of the TaCOMT-3B gene. The above studies played an important role in improvment rust resistance for both durum wheat and bread wheat.

Text

Nitrogen (N) fertilizers not only maximize the crop yield but also modify the plant's ability to resist pathogen infections. The interaction between *Magnaporthe oryzae* (*M. oryzae*) and rice is one such example where excess N fertilization results in nitrogen-induced susceptibility (NIS). We hypothesized that N supply would dictate the rhizosphere microbiota of rice, which may in turn modulate susceptibility to the rice blast fungus. To test our hypothesis, we established a system in which 2N compared to 0N increased susceptibility to *M. oryzae* without causing apparent physiological aberration. Community structure was assessed by 16S rRNA (V3-V4) and ITS2 region using Illumina MiSeq. Our results showed that community structures are significantly affected by both N supply and pathogen inoculation. The defense related genes of 2NI were weakly induced. SA levels significantly reduced in leaves of 2N plants at 24- and 48—hpi compared to 0N plants, resulting in increased susceptibility. To recapitulate NIS, MF separated from 2NI regime was treated to 0N plants in MF-treated experiment. This showed increased susceptibility of 2N-MF treated plants. We conclude that both N and *M. oryzae* inoculation impacted microbiome assembly as well as plant defense. Our work would provide not only novel glimpse into what pathobiome of the rice blast disease looks like but also the empirical basis to build a model for predicting and intervening the outcome of interaction between plants and microbes.

EVALUATING THE EFFECT OF PLASMODIOPHORA BRASSICAE VIRULENCE ON GLUCOSINOLATE PROFILES IN CLUBROOT-RESISTANT AND SUSCEPTIBLE OILSEED RAPE CULTIVARS

ZAMANI-NOOR Nazanin. (1), HORNBACHER Johann . (2), JOY COMEL Christel . (2), PAPENBROCK Jutta . (2)

(1) Julius-Kuehn-Institute, Braunschweig, GERMANY; (2) Leibniz University Hannover, Hannover, GERMANY

Text

Clubroot is a disease caused by the soil-borne pathogen Plasmodiophora brassicae, which affects cruciferous plants. Previous studies have shown that clubroot infection can change the glucosinolate profiles of affected plants. Depending on the case, specific glucosinolate levels may either increase or decrease. This study evaluated changes in glucosinolates in the roots and leaves of different clubroot-resistant and susceptible oilseed rape cultivars following artificial inoculation with P. brassicae isolates of varying virulence. The results showed significant differences in clubroot incidence and severity, as well as the amount of total and individual glucosinolates between oilseed rape cultivars in response to the pathogen's virulence. Both single and total aliphatic and indolic glucosinolate contents were significantly lower in the leaves and roots of susceptible cultivars compared to resistant ones. The different isolates of P. brassicae analyzed differ in their ability to reduce gluconasturtiin contents in the host. The more aggressive isolate, P1 (+), may suppress gluconasturtiin synthesis of the host more significantly than isolate P1. Furthermore, a potential interplay between aliphatic and indolic glucosinolates, which may be involved in water homeostasis in resistant cultivars, is discussed.

Text

Common cypress (*Cupressus sempervirens* L.) represents one of the major features of the Mediterranean landscape. Unfortunately, since the first half of the last century, cypress trees came under heavy attack by *Seiridium cardinale* (Wagener) Sutton & Gibson, the main causal agent of the Cypress Canker Disease. Nowadays, among the management strategies to limit the spread of this lethal disease, the use of resistant cypress selections for new plantations seems the most promising. This pioneer study aims to elucidate hormonal responses, at bark and twig level, in resistant and susceptible clones of *C. sempervirens* inoculated with *S. cardinale*. In inoculated susceptible cypress, a high production of ethylene (Et) and jasmonic acid occurred (more than 2-fold higher than uninoculated ones) at 3- and 4-days post inoculation (dpi) in the bark, suggesting a not efficient attempt to counteract

fungal infection and its detrimental effect. In inoculated resistant cypress, Et biosynthesis raised at 3 and 13 dpi in the bark (more than 2-fold higher). Conversely, an increase of salicylic acid levels (more than 2-fold) occurred at 1 dpi in the foliage, concomitantly to an accumulation of abscisic acid, that reached the maximum values at 9 dpi. The early activation of phytohormones and signaling molecules may counteract oxidative burst and prevent lipid peroxidation by offering protection to bark tissues and foliage in resistant cypress.

Text

Infestation by the soil-borne fungus Verticillium dahliae involves a multitude of key crops worldwide, including almond. In this context, four commercial almond cultivars (Ferragnes, Vairo, Marinada, Texas), all budded on GF-677 rootstocks were evaluated for their sensitivity against V. dahliae infection. Potted plants were inoculated with V. dahliae conidia and disease symptoms were recorded in time. Moreover, the distribution of the fungus in different parts of the plant was determined by molecular detection methods. The amount of disease (expressed as relative AUDPC) presented a positive correlation with nested PCR results indicating that the most susceptible cultivars are Ferragnes and Texas, while the most tolerant cultivars are Vairo and Marinada. In addition, the concentration of specific secondary metabolites (total phenols, flavonoids, flavanols, o-diphenols) as well as the total antioxidant capacity (TAC) was determined in wood samples corresponding to different sections of the plants. After statistical processing of the results, it was possible to make the appropriate comparisons and determine the way in which the disease affects the characteristics of the plant. Significantly higher concentration of phenols was detected in the stem of the rootstock on which the tolerant Marinada cultivar, was grafted. In the same treatment, the concentration of phenolic components was positively correlated with detection of the pathogen in the different parts of the plant.

IDENTIFICATION OF NEW SOURCES OF RESISTANCE TO BACTERIAL SPOT AND BACTERIAL CANKER IN WILD TOMATO VARIETIES

RAY Shatrupa. (1), TEPER Doron. (1)

(1) Institute of Plant Protection, Rishon Letsiyon, ISRAEL

Text
Bacterial diseases pose a major threat to tomato production around the world. The introduction of resistance loci into commercial varieties is an effective and environmentally friendly way to counter the damage caused by bacterial pathogens. To identify new sources for disease resistance and/or tolerance to bacterial canker and bacterial spot, we screened a library of more than 100 accessions of Solanum pimpinellifolium and Solanum lycopersicum var. cerasiform. Plants were independently inoculated with the bacterial canker pathogen Clavibacter michiganensis and bacterial spot pathogens Xanthomonas euvesicatoria pv. euvesicatoria, Xanthomonas euvesicatoria pv. perforans (Xeup) and Xanthomonas vesicatoria, and visually monitored for disease symptoms. Our screen identified multiple accessions that harbored high tolerance or partial resistance to the four pathogens. In particular, Solanum pimpinellifolium line P3031 exhibited little to no symptoms upon infection with each of the four pathogens. Additionally, syringe infiltration of Xeup into P3031 leaves, but none of the other pathogens, elicited a hypersensitive response (HR)-like cell death. Our screen identified Solanum pimpinellifolium P3031 as a potential source of tolerance and/or resistance loci against bacterial diseases in tomato.

THE PLANT IMMUNE SYSTEM OF FERNS AND LIVERWORTS

CASTEL Baptiste. (1), BAKER Madeleine. (1), DELAUX Pierre-Marc. (1), JACQUET Christophe. (1)

(1) UMR 5546 CNRS-UPS, Auzeville-Tolosane, FRANCE

Text
Land plants evolved five major lineages: angiosperms, gymnosperms, ferns, lycophytes and bryophytes. All can interact with microbes. Angiosperm is by far the most diverse. Hence the angiosperm immune system has been deeply studied. It relies on cell surface and intracellular receptors. The genetic diversity and the signalling pathways of these receptors are well known, with remarkable breakthroughs in the recent years.
We hypothesised that other plant lineages also rely on different mechanisms to resist pests. To test this hypothesis, we explore the natural intraspecific diversity of Marchantia polymorpha (a bryophyte). We inoculated a collection of sequenced accessions with the oomycete Aphanomyces euteiches, the cause of root rot in legumes. We seek to map the genes associated with resistance using GWAS, further characterise them and assess their potential in root rot resistance.
In ferns, the genetic resources are limited due to large size genomes. We aim at developing pathosystems with several fern species. We found polymorphic responses to several microbes, including many ascomycetes. Upon further phenotypic description of the pathosystems, we will investigate the genetic base of immunity using comparative transcriptomic.
By characterising the immune system of liverwort and ferns, our goal is to propose novel solutions for crop protection and understand the evolution and diversification of the plant immune system for the last 450 million years.

Text

The cultivation of pea (Pisum sativum) is highly constrained by various soil-borne pathogens. Together these pathogens form a pea root rot complex (PRRC) and trigger soil fatigue. Microbiome-mediated disease resistance poses a possible mechanism to mitigate yield loss through PRRC. It is however largely unknown how the PRRC interacts with other members of the root microbiome and how this affects plant resistance. Here, we compared the root microbiome of 252 pea lines in a controlled soil-based phenotyping assay that was previously shown to predict field-relevant resistance against PRRC. Root bacteria and fungi were characterized by 16S rRNA and ITS amplicon sequencing. We analyzed alpha diversity and microbial community composition, and identified heritable hub OTUs. Based on differential abundance analysis we further identified heritable bacterial and fungal hub taxa that are associated with root rot resistance. Subsequent genome-wide association studies revealed plant genomic regions that are significantly correlated with beneficial hub taxa and overall microbial community composition. In a next step, the identified genetic markers will be used to select pea breeding material for field validation of microbiome-mediated resistance against PRRC. This work demonstrates the potential of microbiome-assisted breeding to promote sustainable farming practices.

CANDIDATUS LIBERIBACTER ASIATICUS ATTENUATES PHLOEM DEFENSE RESPONSES TO ALLOW ITS PROPAGATION AND MOVEMENT IN CITRUS

LEVY Amit. (1), BERNARDINI Chiara. (1), WELKER Stacy. (1), ACHOR Diann. (1), VINCENT Christopher. (1), WANG Chunxia. (1)

(1) University of Florida, Lake Alfred, UNITED STATES

Text

Huanglongbing (HLB), caused by the Gram-negative bacteria Candidatus Liberibacter asiaticus (CLas), poses an existential threat to the industry worldwide. Developing more

tolerant or resistant HLB cultivars is needed, but our understanding of the basic biology of the disease is difficult due to the low levels and irregular distribution of the bacteria in the plant, and their restriction to the phloem sieve elements. We show that in HLB infected trees, callose accumulates and plugs the phloem, and that the accumulation of CLas and callose inhibits the translocation of sugars. These results explained some of the symptoms observed in the HLB trees but raised the question of how the bacteria can move in the occluded phloem. To explain this, we compared CLas-phloem interactions in the leaves and the seed coats. In the leaves, we saw that both phloem occlusion and ROS levels increased in the infected phloem, but in the bacterial titer was very low, and the cells examined were for the most part bacteria-free. We found that in the seed coats the bacteria accumulate to very high levels, and we demonstrate that when bacteria are present, either in the leaves or fruit phloem, they reduce both callose and ROS levels. Our results demonstrate a constant arms race between CLas and the phloem, and that during pathogen colonization, the bacteria inhibit the plant defence response, aimed to block bacteria movement, which allows the pathogen to move through the sieve pores and the plant.

ATNPR1 BOOSTS THE BASAL IMMUNE RESPONSES AND ENHANCES TOLERANCE TO LIBERIBACTER INFECTION IN CITRUS

SARKAR Poulami. (1), TURNER Donielle. (1), ORBOVIC Vladimir. (1), MOU Zhonglin. (2), LEVY Amit. (1,2)

(1) Citrus Research and Education Center, University of Florida, Lake Alfred, UNITED STATES; (2) University of Florida, Gainesville, UNITED STATES

Text

Citrus Greening, caused by Candidatus liberibacter asiaticus (CLas) is a devastating disease of citrus imposing a huge economic downfall in Florida. Most commercial citrus cultivars are susceptible to HLB, and there needs to be an effective disease management strategy to combat this pathogen. In susceptible varieties, strong activation of phloem defense responses leads to phloem collapse and reduction of phloem transport. Transgenic citrus expressing the Arabidopsis thaliana NPR1 (AtNPR1) protein exhibits enhanced tolerance against HLB. However, the mechanism underlying this tolerance is unknown. In this study, we analyzed the phloem defense responses in transgenic ‘Duncan’ grapefruit, ‘Hamlin’ sweet orange, and Arabidopsis thaliana lines expressing AtNPR1 protein. We discovered that AtNPR1 lines had elevated levels of callose in the phloem but did not over-accumulate callose or ROS like the wild-type plants upon CLas infection. Expression analysis of callose synthase genes (CalS), RESPIRATORY BURST OXIDASE HOMOLOG D (RBOHD), and systemic acquired resistance-related genes validated these phenotypes. Furthermore, microscopy analysis revealed thicker phloem fibers and reduced phloem collapse in the transgenic lines upon CLas infection. Our results suggest that AtNPR1 plants have elevated basal immune responses and may suppress CLas-triggered robust immune responses seen otherwise in the wild-type plants, resulting in reduced symptom development and high tolerance to CLas.

Text

A total transcriptome provides knowledge of early plant-microbe interaction between sugarcane and three pathogens (2 bacteria and 1 fungus). Susceptible and tolerant sugarcane plants are inoculated with *Xanthomonas albilineans*, *Leifsonia xylii*, and *Sporisorium scitamineum* and 48 hours post-infection total RNA was prepared for comparative purposes. A NovaSeq run yielded 19 billion PE reads from depleted ribosomal genes of total RNA samples prepared from 16 experimental conditions in three biological replicates. After QC filters, reads were mapped to 398,353 sugarcane gene spaces from SP80-3280, a Brazilian cultivar, using Kallisto. Over a third of the genes are expressed in all conditions tested. Statistical analysis based on gene co-expression networks and functional GO categories discloses 63 connections shared by all tolerant inoculated cultivars and 56 connections shared by all susceptible cultivars, irrespective of the pathogen. A collection of previously selected 580 genes reveal that some genes are pathogen specific, others are bacteria specific and some are cultivar or condition specific. As few as 19 genes were not expressed at any conditions. In addition, non-mapped reads disclosed expression from the resident microbiome and yet to describe genes from sugarcane. The approach opens new avenues for breeding programs and a broader understanding of the commonalities and uniqueness of these plant-microbe interactions.

PERFORMANCE OF COMMERCIAL VARIETIES AGAINST PHYTOPHTHORA SOJAE

GRIJALBA Pablo. (1), PUCHETA Juan. (1), PALMUCCI Hemilse. (1)

(1) Universidad de Buenos Aires, Caba, ARGENTINA

Text

Phytophthora stem and root rot of soybean, caused by Phytophthora sojae, is mainly managed with single or stacked qualitative disease resistance genes. As pathotype complexity of the population increases, management through the tolerance of the commercial varieties would be advisable. The goal of this study was to evaluate the response of commercial genotypes against the pathogen. We used the hypocotyl inoculation and infected rice techniques. Six commercial genotypes were used together with “Sloan” variety as susceptible control, and 3 pathotypes of P. sojae (which differed in virulence on 1 to 6 Rps genes and are the most representative on the pampeana region). In the first technique, the response of the genotypes was identified as susceptible (70 % or more seedlings killed) or resistant (30% or less seedlings killed). The infected rice technique was

carried out in a Randomized Design with 3 repetitions per treatment. The total length of the roots of the surviving plants in the pots was evaluated 21 days after sowing. The data obtained were subjected to ANAVA and Fisher's LSD test ($p<0.05$). The variety identified as commercial 4 is the only one that presented significant differences compared to the control and the rest of the varieties. It was classified as resistant and reached 316% more growth in length. We conclude that it could be possible to use this variety as a tolerant control for future field resistance trials against Phytophthora sojae in Argentina.

Text

Understanding of plant defense mechanisms is essential for developing alternative solutions to fight against cryptogamic diseases. Among these mechanisms, increasing evidence indicate that sugar transporters and invertases play important roles in plant resistance to pathogens. We previously reported that the overexpression of PM-localized H+/ hexose symporters STP13 enhanced Arabidopsis basal resistance to the necrotrophic fungus *Botrytis cinerea*, whereas STP13-deficiency resulted in an enhanced susceptibility indicating that STP13 may improve resistance by depriving the pathogen from resources and fueling the plant defense responses. By contrast, STPs could also play a negative role in defense by promoting the proliferation of biotrophic fungi during infection, as previously demonstrated in wheat and barley. Based on these studies, we now expand our research to plant of agricultural interest such as grapevine. To explore the functional role of sugar transporter genes upon *Botrytis cinerea* infection, we used a gain-of-function approach. Here, we present the phenotypic analysis of the ectopic expression of a candidate gene. Our results indicate that the control of apoplastic sugars by the activity of PM-localized hexose transporters may constitute a host-defense strategy that limits fungal proliferation.

Plant virus and host interactions - from molecular mechanisms to crop protection

C1.2-1

UNDERSTANDING THE PLANT MANIPULATION BY GEMINIVIRUSES

LOZANO-DURÁN Rosa. (1)

(1) Center for Molecular Plant Biology (ZMBP), University of Tübingen, Tübingen, GERMANY

Text
Viruses, as intracellular parasites, need to subvert the host cell in order to enable viral replication and spread. Due to strict coding limitations, viruses commonly produce a reduced number of proteins; this is the case of geminiviruses, plant DNA viruses believed to contain only 4-8 translated ORFs in their circular single-stranded genome. Strikingly, geminiviruses, like other plant viruses, are still able to successfully infect host plants, dramatically altering plant development and physiology, and ultimately causing devastating diseases to crops worldwide. In our group, we are interested in understanding how geminiviruses manipulate the plant cell and lead to disease, for which we use a combination of approaches, including molecular biology, cell biology, and genetics. By studying individual viral proteins, our results have shed light onto the molecular mechanisms underlying the replication of viral DNA, plant anti-viral defence and geminiviral counter-defence, and symptom development; in addition, we are interested in the identification of novel virulence strategies potentially employed by geminiviruses to maximize their coding capacity and impact on the host cell. These strategies include a prevalence of intra-viral protein-protein interactions, which shape the localization of viral proteins and their effect on the infected cell. The next challenge to be tackled is the study of the potentially expanded viral protein functional repertoire in a context-dependent manner

C1.2-2

A NOVEL ILARVIRUS PROTEIN IS EXPRESSED VIA STOP CODON READTHROUGH AND SUPPRESSES RDR6-DEPENDENT RNAI

LUKHOVITSKAYA Nina. (1), BROWN Katy. (1), HUA Lei. (1), CARR John. (1), FIRTH Andrew. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text
Due to the limited size of their genomes, RNA viruses often use non-canonical translation mechanisms to optimize their coding capacity. One of such mechanisms is stop codon readthrough. By applying coding potential prediction algorithms to the genome sequences of ilarviruses, we discovered that ribosomal read-through of the coat protein (CP) stop codon can lead to the production of a C-terminal extended version of CP named CP-RT. We found that CP-RT of Asparagus virus 2 (AV2) is expressed upon infection. AV2 CP-RT deficient mutants unlike the wild type virus could not establish persistent infection. Heterologous RT domain of TSV, an ilarvirus belonging to a different subgroup, complemented the lack of AV2 RT domain which suggests evolutionary conserved function of CP-RT within the ilarvirus genus. We found that CP-RT acts as a viral silencing suppressor (VSR). RDR6-deficiency compensated for the lack of CP-RT we anticipate that CP-RT allows persistent AV2 infection by suppressing RDR6-dependent RNAi. RDR6 is a key factor limiting virus entry to the meristems. AV2 is vertically transmitted and infects shoot apical meristem (SAM)persistently. Mutations of RT domain changed the infection pattern of SAM from persistent into transient in the wild type plants but not in RDR6 knockdown plants. Further investigation is needed to find out whether attenuation of AV2 CP-RT mutants is a consequence of transient invasion of

SAM or both are manifestation of the same process.

Text

Luteoviruses and poleroviruses cause many severe diseases in plants. A deep understanding of the molecular pathogenesis of these viruses will facilitate the development of novel measures for controlling their damages to global crop productions. The two types of viruses carry similar but not identical genomes, with the 17K protein conserved between them. Studies conducted using barley yellow dwarf luteoviruses (e.g., BYDV-PAV and BYDV-GAV) suggest that 17K play multiple roles to promote viral infection by acting as a movement protein, a suppressor of gene silencing, and an inhibitor of host mitosis. However, host plants have evolved an ability to limit the function of 17K by phosphorylating it, with the phosphorylated 17K subverted to enhance antiviral defense by elevating vsiRNA abundance. Clearly, the functions of 17K in luteovirus pathogenesis are regulated in a complex manner, although the proteins interacting with 17K in host cells remain fully characterized. Therefore, we have taken three complementary approaches (i.e., co-immunoprecipitation coupled mass spectrometry analysis, yeast two hybrid experiment, and phospho-proteomics) to identify the proteins interacting with BYDV 17K. A large number of host factors interacting with BYDV 17K have been identified and several of them have been characterized in depth, which has provided new insights into the molecular pathogenesis of BYDVs, as well as innovative strategies for enhancing host resistance to BYDV infection.

Text

Autophagy has emerged as an integral part of antiviral immunity in metazoans and plants,

including the selective elimination of viruses or their individual components. Adapted viruses have evolved multiple strategies to antagonize xenophagic degradation. The mechanistic understanding of the complex interplay between viruses and host autophagy is still limited in plants. We have previously shown that the autophagy cargo receptor NEIGHBOR OF BRCA1 (NBR1) mediates the degradation of virus particles of cauliflower mosaic virus (CaMV). Intriguingly, CaMV-induced viral inclusion structures formed by the viral P6 protein protect against autophagic destruction by sequestering capsid proteins. To further dissect the molecular processes underlying NBR1-mediated xenophagy and its counteraction by CaMV, we have applied a proteomics approach to isolate proteins associated with ATG8 and NBR1. We found that the actin-binding kinesin-like protein KAC1 is enriched in both interactomes during CaMV infection. We show that KAC1 and its close homolog KAC2 suppress the xenophagy pathway and promote viral accumulation and insect transmission. We further demonstrate that KAC1 associates with P6 inclusions in an actin filament-dependent manner and interacts with viral capsid proteins and particles. Our findings indicate that CaMV recruits host kinesin motor proteins to evade NBR1 targeting and to sequester virus material in autophagy-resistant inclusions.

(1) Gregor Mendel Institute (GMI), Vienna, AUSTRIA; (2) Max Planck Institute for Molecular Plant Physiology (MPIMP), Potsdam, GERMANY

Text

Stem cells are essential for the development and organ regeneration of multicellular organisms, so their infection by pathogenic viruses must be prevented. Accordingly, mammalian stem cells are highly resistant to viral infection due to dedicated antiviral pathways including RNA interference (RNAi). In plants, a small group of stem cells harbored within the shoot apical meristem (SAM) generates all postembryonic above-ground tissues, including the germline cells. Many viruses do not proliferate in these cells, yet the molecular bases of this exclusion remain only partially understood. We show that a plant-encoded RNA-dependent RNA polymerase, after activation by the plant hormone salicylic acid, amplifies antiviral RNAi in infected tissues. This provides stem cells with RNA-based virus sequence information, which prevents virus proliferation. Furthermore, we find RNAi to be necessary for stem cell exclusion of several unrelated RNA viruses, despite their ability to efficiently suppress RNAi in the rest of the plant. In parallel to this work we developed cutting edge live microscopy techniques to track virus movement in plant reproductive organs, which will allow unparalleled analysis of infection dynamics. Finally, we have developed biological tools to investigate the antiviral mechanisms preventing virus vertical transmission through the germline, which ensure most infections are not transmitted by seed.

C1.2-6

TWO VIRAL PROTEINS TRANSLATED FROM ONE OPEN READING FRAME TARGET DIFFERENT LAYERS OF PLANT DEFENCE

ZHOU Xueping. (1)

(1) Institute of Plant Protection, China Academy of Agricultural Sciences, Beijing, CHINA

Text
Multi-layered defence responses are activated upon pathogen attack. Viruses utilize a number of strategies to maximize the coding capacity of their small-sized genomes and produce viral proteins for infection, including suppression of host defence. Here, we uncover translation leakage as one of these strategies: two viral effectors, cC4 and mC4, encoded by tomato golden mosaic virus (TGMV) are translated from two in-frame start codons and function cooperatively to suppress defence. cC4 localizes in chloroplasts, to which it recruits NbPUB4 to induce ubiquitination of the outer membrane; as a result, this organelle gets degraded, and chloroplast-mediated defences are abrogated. However, chloroplast-localized cC4 induces the production of singlet oxygen (1O2), which in turn promotes the translocation of the 1O2 sensor NbMBS1 from the cytosol to the nucleus, where it activates the expression of the CERK1 gene. Importantly, an anti-viral effect exerted by CERK1 is countered by mC4, localized at the plasma membrane. mC4, similarly to cC4, recruits NbPUB4 and promotes the ubiquitination and subsequent degradation of CERK1, suppressing membrane-based receptor-like kinase-dependent defences. Importantly, this translation leakage strategy seems to be conserved in multiple viral species and is related with host range, underscoring its adaptive value.

IDENTIFICATION OF A. THALIANA ALY PROTEINS AS NOVEL HOST INTERACTING PARTNERS OF THE TURNIP YELLOWS VIRUS (TUYV) CP AND CP-RT PROTEINS

KIERVEL Déborah. (1), BOISSINOT Sylvaine. (2), PICCINI Céline. (1), SCHEIDECKER Danièle. (1), RODRIGUEZ-MEDINA Caren. (1), VILLEROY Claire. (2), BRAULT Véronique. (2), ZIEGLER-GRAFF Véronique. (1)

(1) Institut de biologie moléculaire des plantes (IBMP), Strasbourg, FRANCE; (2) Institut National de Recherche pour l'Agriculture, l'Alimentation et l'Environnement (INRAE), Colmar, FRANCE

Text
As for all viral pathogens, the establishment of turnip yellows virus (TuYV) cycle, belonging to the Polerovirus genus and newly to the Solemoviridae family, requires the expression of viral proteins whose function depends on their dynamic interactions with host factors. The investigation of these protein-protein interactions by yeast two-hybrid screen identified ALY proteins as potential interactants of two TuYV proteins. In Arabidopsis thaliana, four ALY family proteins (AtALY1 to 4) have been described. They participate redundantly in the nuclear export of cellular mRNAs mediated by the THO-TREX multiprotein complex.
Using co-immunoprecipitation experiments, we confirmed the interaction of all four AtALY proteins with the major capsid protein (CP) and also with the CP-RT fusion protein, which is notably involved in virus movement and in the plant aphid transmission.
Confocal microscopy analysis of agro-infiltrated Nicotiana benthamiana leaves confirmed the

nuclear colocalization of the four AtALY:eGFP with the CP:RFP protein in viral context, while the CP-RT:tRFP protein expressed by the virus localized in perinuclear vesicles associated with viral infection.
Importantly, we have shown that the inhibition of expression of the four AtALY genes in a quadruple mutant of A. thaliana induced a significant increase in TuYV accumulation, proposing the AtALY as a potential target to elaborate a novel strategy to fight against TuYV infection.

F1.2-2

P13 PROTEIN OF CITRUS TRISTEZA VIRUS IS A KEY REGULATOR OF STEM-PITTING SYMPTOM DEVELOPMENT IN CITRUS MACROPHYLLA

KHALILZADEH Maryam. (1,2), ORBOVIC Vladimir. (1), WEBER Kyle Clark . (1), DUTT Manjul . (1), EL-MOHTAR Choaa Amine . (1), LEVY Amit. (1,2)

(1) University of Florida, Citrus Research and Education Center, Lake Alfred, Fl, UNITED STATES; (2) University of Florida, Department of Plant Pathology , Gainesville, Fl, UNITED STATES

Text
Stem-pitting (SP), an important malady of many fruit trees, is caused by *Citrus tristeza virus* (CTV) in citrus. CTV mutant with deletion of p13 displays very mild SP symptoms in *Citrus macrophylla* (Cmac). To reveal the role of this protein in SP development, we performed a combined study of transcriptome and microscopy analysis and characterization of phloem cell occlusions in Cmac infected with infectious clone of CTVΔp13 and CTV wild type (WT). CTVΔp13 induced non-visible SP symptoms and few defense response and development related genes, while the transcriptome responses of CTV WT infected trees, that caused moderate SP, was significantly affected. Transcriptomic and microscopic analyses of the stem-pitted area revealed that phloem regeneration is a characteristic manifestation of CTV-SP disease, while phloem regeneration was not observed in CTVΔp13 infected trees. CTVΔp13 induced less callose accumulation and lower *PP2* gene expression comparing to CTV WT. To further define the role of p13 protein in SP, p13 transgenic Carrizo and Cmac were generated. In Cmac transgenic tree, we observed longitudinal stem-pit like symptoms and ropey-like appearance of the stem that mimics CTV-SP symptoms. Microscopic analysis of vasculature tissue of symptomatic stem indicated collapse of phloem cells. Collectively, p13 activates plant responses and induces phloem occlusion factors which disrupt phloem cells, resulting in regeneration of new cells that contribute to SP symptom development.

P1.2-001

PATHOSYSTEM DRIVERS OF CHANGE INFLUENCING FIRST REPORT OF PHASEY BEAN MILD YELLOWS VIRUS INFECTING GROUNDNUT IN KENYA

MABELE Anthony. (1), WERE Hassan. (1), MUYEKHO Francis. (1)

(1) Masinde Muliro University of Science and Technology, Kakamega, KENYA

Text
Pathosystem drivers of change parameters have impacted directly and indirectly on the declining economic and nutritive value of groundnut (Peanut, Arachis hypogaea) in Kenya. PBMYV naturally infects Phasey bean (Macroptilium lathyroides) and has not been reported in Kenya. Transmission of PBMYV is by the groundnut-cowpea aphid (Aphis craccivora), whitefly (Bemisia tabaci) and grafting with infected scions. A survey in Bungoma, Busia, Kakamega and Siaya Counties during the short and long rains of 2020-2021, collected symptomatic leaves with mild yellowing, chlorotic streaking, chlorotic spots, mottling, bunching, puckering, curling downwards, stunting and those with evidence of aphid colonies. They were subjected to RT-PCR diagnostics and the positive samples were pooled then sequenced on the Illumina MiSeq platform for complete genome studies. Phylogenetic analysis was done using MEGA X software and Cucurbit aphid-borne yellows virus polerovirus (MZ508305.1) was used as a rooting outgroup. The PBMYV full genome sequences from Kenya (PBMYV_6, PBMYV_7) clustered together with other PBMYV and had closest sequence identity (91-95%) with PBMYV (KT963000.2, MT966033.1 and MT966038.1) from the GenBank. The PBMYV Kenyan strain is similarly diverse to the genetically distinct PBMYV Australian variants by descent. Further studies are needed to understand the contribution of climate change on the new disease distribution and molecular diversity of PBMYV in groundnut pathosystems.

P1.2-002

PSAC AND ATPSYN-A GENES INDUCE THE RNA SILENCING PATHWAY AND CAUSE RESISTANCE AGAINST THE SOYBEAN MOSAIC VIRUS

BWALYA John. (1), ALAZEM Mazen. (1), **KIM Kook-Hyung. (1)**

(1) Seoul National University, Seoul, REPUBLIC OF KOREA

Text
Increasing lines of evidence indicate that chloroplast-related genes are involved in plant–virus interactions. However, the involvement of photosynthesis-related genes in plant immunity is largely unexplored. RNA-Seq analysis showed that several chloroplast-related genes were strongly induced in response to infection with the avirulent strain of soybean mosaic virus (SMV), G5H, but were weakly induced in response to the virulent strain, G7H. For further analysis, we selected the *PSaC* gene from the photosystem I (PSI) and the ATP-synthase α-subunit (*ATPsyn-α*) gene whose encoded protein is part of the ATP-synthase complex. Overexpression of either gene within the G7H genome reduced virus levels in the susceptible cultivar Lee74 (*rsv3*-null). Both proteins are localized in the chloroplast envelope and the nucleus and cytoplasm. Because the chloroplast is the initial biosynthesis site of defense-related hormones, we determined whether hormone-related genes are involved in the *ATPsyn-α*- and *PSaC*-mediated defense. Interestingly, genes involved in the biosynthesis of several hormones were upregulated in plants infected with SMV-G7H expressing ATPsyn-α and PSaC. Both chimeras induced the expression of several antiviral RNA silencing genes, which indicates that such resistance may be partially achieved through the RNA silencing

pathway. These findings highlight the role of photosynthesis-related genes in regulating resistance to viruses.

P1.2-003

A PLANT-SPECIFIC HOMOLOG OF DP1/YOP1 FAMILY PROTEINS PLAYS A PROVIRAL ROLE IN POTYVIRUS INFECTION

XUE Mingshuo. (1), SOFER Luc. (1), SIMON Vincent. (1), ARVY Nathalie. (1), BORDAT Amandine. (1), LION Roxane. (1), DIOP Mamoudou. (2), GALLOIS Jean-Luc. (2), TILSNER Jens. (3,4), GERMAN-RETANA Sylvie. (1)

Text

The *Potyvirus* genus is one of the largest genera of plant RNA viruses responsible for serious diseases in crops worldwide. As potyviruses hijack the host secretory pathway and plasmodesmata (PD) for their transport, the goal of this study was to identify membrane and/or PD-proteins that interact with the 6K2 protein, a potyviral protein involved in replication and cell-to-cell movement of turnip mosaic virus (TuMV). Using Split-ubiquitin membrane Y2H assays we screened an Arabidopsis cDNA library for interactors of TuMV-6K2. We isolated AtHVA22a (*Hordeum vulgare* abscisic acid responsive gene 22) that belongs to a multigenic family of proteins homologous to DP1/Yop1 family proteins in yeast and interactors of reticulons. The role of HVA22 proteins in plants are not well-known, except the role in blast disease resistance in rice. Interestingly, proteomics analysis of PD fractions showed that AtHVA22a is highly enriched in Arabidopsis plasmodesmata proteome. We confirmed the interaction between 6K2 and AtHVA22a in yeast, as well as *in planta* by using bimolecular fluorescence complementation (BiFC) and showed that the interaction occurs at the level of the viral replication complexes (VRC) during TuMV infection. Finally, we showed that the propagation of TuMV in plants is increased when AtHVA22a is overexpressed but slowed down upon mutation of *AtHVA22a* by CRISPR-Cas9. Altogether, our results indicate that AtHVA22a plays an agonistic effect on TuMV propagation.

TRANSCRIPTOMIC RESPONSES TO THE BANANA BUNCHY TOP VIRUS IN BANANA

MAHLANZA Tendekai. (1), PIERNEEF Rian. (1), JOOSTE Anna. (1)

(1) Agricultural Research Council , Pretoria, SOUTH AFRICA

Text

The banana bunchy top virus is the most important virus disease of banana and there is no natural resistance in any Musa spp. Towards identifying potential susceptibility factors that facilitate BBTV infection, the current study profiled transcriptomic responses to BBTV in banana using RNASeq. Using a time course approach, 563, 1052, and 818 genes were differentially expressed between infected and uninfected plants at 7, 30, and 45 days post-inoculation, respectively. Enrichment analysis revealed that genes involved in the regulation of the cell cycle, DNA replication, far-red light signaling, stomatal movement, and chromatin-associated regulation of transcription, were associated with BBTV infection. Upregulated differentially expressed genes (DEGs) included the proliferating cell nuclear antigen (a key factor in the cell cycle), DNA replication licensing factors mcm2-6 that are central to the initiation of replication, histone subunits involved in epigenetic regulation of transcription, and HY5 and MYB transcription factors. DEGs involved in defence, including a thaumatin-like protein, ethylene-responsive transcription factor ERF024, a germin-like protein, and chalcone synthase, were downregulated in BBTV-infected plants. CRISPR/Cas9-mediated knock-out of candidate susceptibility factors identified among DEGs in this study is currently being pursued towards determining their potential utility in engineering resistance to BBTV in banana.

P1.2-005

NMD-MEDIATED VIRUS RESTRICTION IS COMPROMISED BY VIRUS-INDUCED AUTOPHAGIC DEGRADATION OF SMG7 IN PLANTS

LI Fangfang. (1), CHEN Yalin. (1), GE Linhao. (1), GONG Pan. (1), LI Zhaolei. (1)

(1) Institute of Plant Protection, China Academy of Agricultural Sciences, Beijing, CHINA

Text

Increasing evidence has suggested that NMD acts as a general virus restriction mechanism in eukaryotes. However, whether NMD factors, including SMG7 and UPF3, regulate virus infection is largely obscure. Here we show that overexpression of NbSMG7 and NbUPF3 attenuates cucumber green mottle mosaic virus (CGMMV) infection by targeting viral internal termination codon (iTC) and knock-down of NbSMG7 and NbUPF3 cooperatively facilitates virus infection. CGMMV infection upregulates the NbSMG7 transcription level but decreases its protein accumulation. Furthermore, NbSMG7, rather than NbUPF3, is subjected to autophagic degradation, which is executed by interacting with one of the autophagy-related proteins, NbATG8i. Mutation of the ATG8 interacting motif (AIM) in NbSMG7 (SMG7AIM1) abolishes its interaction with NbATG8i and comprises its autophagic degradation. Silencing of NbSMG7 and NbATG8i, or NbUPF3 and NbATG8i, compared to silencing of an individual one, leads to more virus accumulations, but overexpression of NbSMG7 and NbATG8i fails to achieve more potent virus inhibition compared to overexpressing one of them. However, overexpressing NbSMG7AIM1 and NbATG8i, or NbUPF3 and NbATG8i with CGMMV, exhibits more aggravated virus symptoms and more virus titers compared to their expression. These data show that both NMD and autophagy restrict virus infection, while NMD-mediated virus inhibition could be impaired by virus-induced autophagic degradation of NbSMG7.

TRANSCRIPTOMIC AND FUNCTIONAL ANALYSES REVEAL THE ROLES OF EXOGENOUS BORON IN ALLEVIATING CUCUMBER GREEN MOTTLE MOSAIC VIRUS INFECTION

BI Xinyue. (1), GUO Huiyan. (1), LI Xiaodong. (1,2), JIANG Dong . (3), CAI Ming. (3), MENG Wei. (3), AN Mengnan. (1), WANG Zhiping. (1), XIA Zihao. (1), WU Yuanhua. (1)

(1) Shenyang Agricultural University, Shenyang, CHINA; (2) National Forestry and Grassland Administration, Shenyang, CHINA; (3) Liaoning Province Green Agriculture Technology Center, Shenyang, CHINA

Text

Cucumber green mottle mosaic virus (CGMMV)-induced watermelon blood flesh disease (WBFD) severely reduces the yield and edibleness of watermelon. We have found that application of exogenous boron can suppress CGMMV infection in watermelon fruit and alleviate WBFD symptoms. Here, the combined analysis results of proteomic and metabolomic showed that the main metabolic pathways of watermelon resistance to CGMMV infection by boron were concentrated in pyrimidine metabolism, sulfur metabolism, steroid biosynthesis, pyruvate metabolism, propanoate metabolism and photosynthesis. The most up-regulated differentially expressed genes (DEGs) were related to polyamine and auxin biosynthesis, abscisic acid catabolism, defense-related pathways, cell wall modification, and energy and secondary metabolism, while the down-regulated DEGs were mostly involved in ethylene biosynthesis, cell wall catabolism, and plasma membrane functions in transcriptome analysis. Additionally, in virus-induced gene silencing assays, silencing of *SPDS*, *BG12*, *SBT*, and *TUBB1* expression in watermelon caused an inhibited CGMMV infection correlating with no WBFD symptoms. In contrast, silencing *XTH23*, *PE/PEI7*, *GST*, and *ATPS1* expression promoted CGMMV accumulation, and *UGDH*, *AST*, *4CL4*, *RAP2-3*, *MYB6*, *WRKY12*, *H2A*, and *DnaJ11* are likely to participate in host antiviral resistance. Our results provide a novel molecular mechanism on the roles of boron in watermelon resistance to CGMMV-induced WBFD.

P1.2-007

UNDERSTANDING THE ROLE OF WRKY1 TRANSCRIPTION FACTOR IN PLANT RESISTANCE TO GEMINIVIRUS INFECTION

SUN Shaoshuang. (1), LI Shupeng. (1), ZHOU Xueping. (1), **YANG Xiuling. (1)**

(1) Institute of Plant Protection, Chinese Academy of Agricultural Sciences, Beijing, CHINA

Text

Geminiviruses constitute the largest group of known plant viruses and cause devastating diseases and economic losses in many crops worldwide. Understanding plant antiviral defense against geminiviruses is critical for development of strategies for geminivirus control especially in the case of limited naturally occurring resistance genes. Here we identified NbWRKY1 as a positive regulator of plant defense against geminivirus infection. We found that NbWRKY1 was upregulated in response to tomato yellow leaf curl China virus/tomato yellow leaf curl China betasatellite (TYLCCNV/TYLCCNB) infection. Overexpression of NbWRKY1 attenuated TYLCCNV/TYLCCNB infection, whereas knockdown of NbWRKY1 enhanced plant susceptibility to TYLCCNV/TYLCCNB. We further revealed that NbWRKY1 bound to the promoter of the NbWHIRLY1 (NbWhy1) transcription factor and inhibited the

transcription of NbWhy1. Consistently, NbWhy1 negatively regulates plant resistance against TYLCCNV/TYLCCNB. Furthermore, we demonstrated that NbWhy1 interfered with the antiviral RNAi defense and disrupted the interaction between NbCaM3 and NbCAMTA3. Moreover, the NbWRKY1-NbWhy1 also confers plant resistance toward tomato yellow leaf curl virus infection. Taken together, our findings suggest that NbWRKY1 positively regulates plant resistance to geminivirus infection by repressing NbWhy1. We propose that the NbWRKY1-NbWhy1 cascade could be further employed to control geminiviruses.

OCCURRENCE OF YELLOWING VIRUSES INFECTING CUCURBITS IN KOREA AND DEVELOPMENT OF MULTIPLEX RT-PCR ASSAY FOR SIMULTANEOUS DETECTION OF THREE CUCURBIT VIRUSES

KWAK Hae-Ryun. (1), BYUN Hee-Seong. (1), CHOI Hong-Soo. (1), LEE Bong-Choon. (1)

(1) National Institute of Agricultural Sciences, RDA, Wanju, REPUBLIC OF KOREA

Text
Cucurbits are one of the highly cultivated and economically important crops worldwide but their production is often limited by plant viruses. In the recent years, yellowing diseases caused by viruses have been damaging to cucurbit crops in Korea. A survey of the incidence of yellowing viruses in melon, cucumber, and watermelon crops was conducted in Korea during 2022. Reverse-transcription polymerase chain reaction (RT-PCR) was performed with specific primers for cucurbit aphid-borne yellows virus (CABYV) and cucurbit chlorotic yellows virus (CCYV) in melon and cucumber and melon aphid-borne yellows virus (MABYV) in watermelon. The results showed that the infection rates of CABYV were 35.1% (n=259/738) for melon; 10.4% (n=78/747) for cucumber and the infection rates of CCYV were 9.2% (n=68/738) for melon; 11.2% (n=84/747) for cucumber. MABYV, which was first reported in 2021, was detected only in 6 greenhouses growing watermelon from 2 areas with an infection rate of 3.6% (n=20/562). Sequence analysis based on the complete genome sequences of CABYV, CCYV, and MABYV revealed 96~99% nucleotide identities, respectively, with previously reported sequences. Since the yellowing symptoms of the three viruses CABYV, CCYV, and MABYV are virtually identically and occur as mixed infections in cucurbits grown in Korea, we developed a multiplex RT-PCR method for rapid, sensitive, and simultaneous detection of the three viruses.

Text
Squash (*Cucurbita moschata*) is an important crop worldwide. However, cucurbit leaf curl

disease (CuLCD), causing by whitefly-transmitted begomoviruses results significant yield losses. In Southeast Asia, three major bipartite begomoviruses, Tomato leaf curl New Delhi virus (ToLCNDV), Squash leaf curl China virus (SLCCNV) and Squash leaf curl Philippines virus (SLCuPV) are associated with CuLCD. Resistance squash cultivars are important for the disease control, but limited for resistant resources. So far, few squash lines were resistant to CuLCD. In Taiwan, SLCuPV is the major squash begomovirus. Two SLCuPV resistant lines, TOT8101A and Bi were screened by whitefly inoculation. The Bi line was also confirmed with SLCCNV resistance by agroinoculation of infectious virus. Furthermore, the resistance of TOT8101A is single recessive gene, and Bi is one dominance. Based on the F2 population generated by crossing of susceptible squash with Bi line, five resistance marker candidates were screened by sequence-related amplified polymorphism (SRAP). Consequently, one SRAP marker was verified in a F3 population. Following the sequence analysis of the resistance SRAP marker, it has 99.63% nucleotide identity with putative disease resistance protein at 3806932-3807467 nt of chromosome 6 of the squash whole genomic sequences. The co-dominant marker of the dominant resistance is under developing for marker-assessed selection in the squash breeding.

Text

Physalis peruviana (Solanaceae), native to the South America Andean region, is an exotic plant whose cultivation is still emerging in Brazil. Five viruses have been reported naturally infecting physalis plants in the country. However, two have been drawing attention due to the severity of symptoms: the sobemovirus PhyRMV and the orthotospovirus GRSV. The present work aimed to evaluate the damage caused by single and double infections of PhyRMV and GRSV in the development, yield, and postharvest fruits parameters of *P. peruviana* plants. Both viruses caused severe systemic symptoms in infected plants, and double infection caused plant death. Plant height and aerial dry weight mass were significantly affected by infection with PhyRMV and GRSV. Double-infected plants were the most affected, with an average height and aerial dry weight mass reduction of 70.9% and 89.7%, respectively. PhyRMV- and GRSV-infected plants showed an average fruit yield reduction of 66.4% and 85.2%, respectively, compared to healthy plants. Double-infected plants did not produce fruits. Fruits produced by infected plants were smaller than those produced by healthy plants. Virus infection also affected postharvest parameters such as titratable acidity, total soluble solids (ºBRIX), the concentration of phenolic compounds, and antioxidant activity. The viruses did

not affect fruit color but affected pulp firmness and palatability. Therefore, strategies for disease management should be studied.

Text

The production of cassava, a staple crop for many people in Africa, Asia, and Latin America, is threatened by viral infections such as cassava brown streak disease (CBSD) and cassava torrado-like virus (CsTLV). These viruses encode atypical Ham1 proteins with a specific structural domain known as the Maf/HAM1, which has a highly conserved inosine triphosphate (ITP) pyrophosphohydrolase (ITPase). Maf/HAM1 domains in viral genomes are uncommon; only two other viral species that infect euphorbia hosts have been identified (EuRV) and (CBSD). This study investigated the role of HAM1 proteins and their ITPase activity in CsTLV, the cassava plant, Nicotiana benthamiana, and CBSV. Our results showed that all the Ham1 proteins studied had high ITPase activity against non-canonical nucleotides such as ITP. Interestingly, we found that the CsTLV-Ham1 and Cassava plant Ham1 proteins had higher pyrophosphohydrolase activity specifically for ITP but not for dITP. Furthermore, we observed that the CBSVD-Ham1 protein with a specific point mutation (SHA) significantly reduced ITPase activity against noncanonical and canonical nucleotides such as GTP. These findings suggest that the leucine residues in the GLR motif of CsTLV-HAM1 may be important for substrate selection and activity in HAM1 protein, and further research is required. This study provides a deeper understanding of the mechanism of ITPase activity in CsTLV and its potential role in reducing viral mutation rates during infection.

Text

Potato virus Y (PVY) is an economically important plant pathogen that reduces the productivity of a wide range of host plants. PVY causes symptoms such as stunted growth, severe chlorotic mosaic, and leaf curling affecting the lamina. To develop PVY-resistant cultivars, it would be essential to identify the plant-PVY interactome and decipher the biological significance of those molecular interactions. We performed a yeast two-hybrid (Y2H) screen of *Nicotiana benthamiana* cDNA library using PVY-encoded NIa-pro as the bait. The *N. benthamiana Indole-3-acetic acid-amido synthetase* (IAAS) was identified as an interactor of NIa-pro protein. The interaction was confirmed via targeted Y2H and bimolecular

fluorescence complementation (BiFC) assays. We have shown the subcellular localization of both NIa-pro and IAAS protein in the nucleus and cytosol. IAAS converts free (active) IAA to the inactive, conjugated form, which plays a crucial regulatory role in auxin signaling. Transient silencing of IAAS in *N. benthamiana* plants interfered with the PVY-mediated symptom induction and virus accumulation. Conversely, overexpression of IAAS enhanced the symptoms induction and virus accumulation in the infected plants. In addition, the expression of several auxin-responsive genes was found to be downregulated during PVY infection. Our findings demonstrate that PVY NIa-pro protein potentially promotes disease development via modulating auxin homeostasis.

Text

Potato virus Y (PVY) is an important viral pathogen of potato. So far, the molecular plant-virus interactions underlying this pathogenicity are not fully understood. Gas chromatography coupled with mass spectroscopy (GC–MS) was used to study the changes in leaf metabolomes of PVY-resistant cv. Premier Russet (PR), and a susceptible cv. Russet Burbank (RB), following inoculation with three PVY strains, PVY-NTN, PVY N-Wi, and PVYO. Analysis of the resulting GC–MS spectra showed several common and strain-specific metabolites that are induced by PVY inoculation. In PR, the major overlap in differential accumulation was found between PVY N-Wi and PVYO. However, the 14 significant pathways occurred solely due to PVY N-Wi. In contrast, the main overlap in differential metabolite profiles and pathways in RB was between PVY-NTN and PVYO. Overall, limited overlap was observed between PVY-NTN and PVY N-Wi. As a result, PVY N-Wi induced necrosis may be mechanistically distinguishable from that of PVY-NTN. Furthermore, 10 common and seven cultivar-specific metabolites as potential indicators of PVY infection and susceptibility/resistance were identified. In RB, glucose-6-phosphate and fructose-6-phosphate were particularly affected by strain–time interaction. This highlights the relevance of the regulation of carbohydrate metabolism for defense against PVY. Some strain- and cultivar dependent metabolite changes were also observed.

Text

Whether photosynthetic metabolites participate in host defenses against pathogens remains unclear. Here, we found the triose phosphate/phosphate translocator (TPT) located on the inner membrane of the chloroplast interacts with the movement protein (MP) of brassica yellows virus (BrYV) in vivo and in vitro, and its expression is significantly down-regulated by viral infection or transgenic expression of the MP. The loss-of-function mutants of tpt mutant shows increased accumulation of BrYV and conversely increased expression of TPT confers enhanced resistance. The antiviral activity of AtTPT requires its phosphate transport capacity, suggesting that it functions in fighting the virus via its transported substrate(s). To this end, we discovered that one of the TPT substrates, glyceraldehyde 3-phosphate (GAP), directly acts as an activator of the immune system to depress viral accumulation in leaves. At the mechanistic level, we revealed that exogenous application of GAP drastically triggers defense-related genes expression and prominently induces defense signaling pathways, such as MAPK. Both TPT and GAP demonstrate strong inhibitive activities against multiple types of plant pathogens. Collectively, we proposed that GAP exported by TPT to the cytosol triggers antimicrobial immunity and thus mediates broad-spectrum resistance to a variety of plant diseases by virtue of the chloroplast-to-nucleus/cytosol retrograde signaling.

Text

Plant viruses primarily consist of nucleic acids and proteins, and their degradation in host plants is considered as a defense mechanism against viruses. The RNA silencing mechanism, triggered by double-stranded RNAs derived from infected viruses, effectively degrade the viral genomic RNA. Meanwhile, growing evidences suggest that autophagy (AP), a major proteolytic system, plays a crucial role in antiviral defense in plants. Our earlier research demonstrated that RNA silencing and AP work in tandem against cucumber mosaic virus (CMV). To counteract antiviral RNA silencing, most plant viruses express RNA silencing suppressors; CMV has the 2b protein (2b). AP strengthens RNA silencing against CMV by targeting 2b through the calmodulin-like protein called rgs-CaM for degradation. In this study, we explored the interactions between CMV and AP by creating AP-defective *Nicotiana benthamiana* plants. Upon inoculating the CMV vectors that express foreign proteins by replacing 2b with the genes encoding these foreign proteins, we observed a great increase in CMV multiplication and accumulation of these foreign proteins. Our findings suggest that: 1) CMV-encoded protein levels may be affected by autophagy in addition to 2b, and 2) AP-defective *N. benthamiana* plants can serve as an excellent platform plant to produce useful proteins using the CMV vectors.

Text

The *Capsicum annuum* / potato virus Y (PVY) pathosystem is characterized by an intriguing type of resistance as isolates belonging to most PVY phylogenetic groups are able to infect pepper only locally with virus remaining restricted at the sites of entry after mechanical inoculation. Previous studies using synthetic chimeras between infectious cDNA clones derived from adapted (C1 group) and non-adapted (N and C2 groups) PVY isolates showed that the infectivity of PVY towards *C. annuum* is effectively linked to the P3-6K1-CI genetic region of the viral genome. The P3 region, and specifically a nonsynonymous substitution in the P3 and P3N-PIPO cistrons (clone N605Y) was shown to be essential for the adaptation of the virus to *C. annuum*, as a 50% infection at the systemic level was established. To elucidate the effect of 6K1 and CI on PVY infectivity in pepper, a series of additional chimeras were constructed exchanging the 6K1 and CI regions of the N605Y clone with those derived from a C1-group isolate, individually or in combination. Infectivity experiments with the obtained infectious chimeras unveil the role of the 6K1 and CI regions in PVY adaptation to pepper increasing our understanding on this uncharacterized type of resistance.

Text

Papaya is one of the important fruits in many countries, including Taiwan. The papaya ringspot virus (PRSV) is the major virus in the field. Although the use of PRSV-resistant transgenic papaya effectively controls PRSV, the papaya leaf distortion mosaic virus (PLDMV) is becoming a new threat to papaya production. In this study, we analyzed the symptoms, host range, and whole genome sequence of a new PLDMV isolate, PLDMV-CZ, from Taiwan. We found that PLDMV-CZ can cause more severe symptoms in PRSV-tolerant papaya cultivars. Since it is important to study the pathogenicity of PLDMV-CZ for the development of control strategies, the generation of the cDNA clone of the virus is essential. However, the large genome size of PLDMV-CZ (10,154 nucleotides) and instability in the bacterial cell make construction of the infectious clone difficult. Therefore, we developed a

fosmid-based system to generate stable infectious clones of PLDMV-CZ. We modified the nucleic extraction and reverse transcription approach for the generation of full-length viral cDNA. We further used a low-copy fosmid pCC1FOS as a vector for cloning viral cDNA. Our results showed that the cDNA clone of PLDMV-CZ was stable in Escherichia coli. The papaya seedlings inoculated with viral RNA transcripts derived from the PLDMV-CZ clone showed similar symptoms to the wild-type virus. The total time needed for construction is about one week, and this approach can be applied to other large and unstable plant viruses.

Text

Sugarcane mosaic virus (SCMV), as the main causal agent of maize dwarf mosaic disease in major maize production regions of many countries, is a representative of monocot-infecting members of the genus *Potyvirus* in the family *Potyviridae*. Intriguingly, though potyviral replication only takes place in the cytoplasm, a few potyvirus-encoded proteins, such as the nuclear inclusion protein a protease (NIa-Pro) can accumulate in nuclei of infected cells. The significance of NIa-Pro nuclear localization remains largely unknown. In this study, using SCMV-encoded NIa as a bait, we screened and identified 77 unique maize proteins that could potentially interact with NIa through a TurboID-based proximity labeling approach followed by LC-MS/MS. The KEGG pathway enrichment analysis showed that potential maize NIa-interactors were significantly annotated in the ribosome, spliceosome, photosynthesis, and metabolisms. Further functional annotations identified nine conserved pre-mRNA splicing-associated proteins that have the potential to interact with SCMV NIa. Since NIa is cleaved into NIa-Pro and VPg in potyvirus infected cells, we subsequently determined the role of SCMV NIa-Pro and VPg on pre-mRNA splicing through a splicing reporter system *in planta*. We found that NIa-Pro along can regulate pre-mRNA splicing in cells. Together, these data suggest that upon SCMV infection, NIa-Pro possesses the capacity to manipulate pre-mRNA splicing through associating with splicing factors.

P1.2-019

DEVELOPMENT OF BARLEY YELLOW DWARF VIRUS (BYDV) INFECTIOUS CLONES

SANDOVAL-CARVAJAL Izayana. (1,2), BRAMHAM Lawrence. (1), HAMMOND-KOSACK Kim . (1)

(1) Rothamsted Research, Harpenden, UNITED KINGDOM; (2) University of Bristol, Bristol, UNITED KINGDOM

Text

Barley yellow dwarf virus (BYDV) is widely distributed and can infect more than 150 Poaceae spp, causing yield losses in economically important cereals such as maize, wheat, barley, and rice. Studies exploring BYDV generally require already infected plants, and aphid colonies to maintain and transmit viral isolates. However, these can prove very costly due to space requirements and efforts to maintain them. Additionally, cross-contamination among aphid colonies can prove highly problematic. Virus transmission using aphids can also prove unreliable due to no guaranteed behavioural consistency, for instance, colonies can suddenly decrease, or viral transmission efficiency may vary. For these reasons, an effective method to maintain and transmit BYDV for relevant studies is of value. A practical alternative to maintaining the source(s) of BYDV and continual transmission of the virus is the development of infectious clones. These have many advantages; they allow the long-term storage of inocula in a cost-effective manner and eliminate the dependence on insect vectors for challenging target plants, as infectious clones can be reliably introduced into a plant via Agrobacterium-based methods. Infectious clones may prove key in different viral research where replication is fundamental, such as understanding the function and interactions of viral genes. The aim of work here is to develop BYDV infectious clones representing UK-wide viral diversity for future research applications.

Text

The ability of a virus to infect a host is attributed to complicated interactions among viral and host proteins. Previous studies using hybrid virus constructs between adapted (C1 group) and non-adapted (N and C2 groups) potato virus Y (PVY) isolates showed that the adaptation of PVY to pepper is associated with the *P3-6K1-CI* genetic region of the viral genome, with *P3* region being essential. To further comprehend the role of each the four encoded proteins (P3, P3NPIPO, 6K1 and CI), their subcellular localization and co-localization were studied. The analyzed proteins derived from three PVY isolates: a pepper-adapted one, a non-adapted one that remains restricted to the sites of inoculation, and a point-mutant of the latter in the *P3* coding region with the ability to infect pepper systemically. Results indicate that the P3 protein is localized differently depending on the isolate. More specifically, the P3 of the adapted isolate is localized in the actin/ER network, whereas the one derived from the non-adapted isolate is found in the cytoplasm. On the other hand, the P3 of the point-mutant shows an intermediate phenotype with the formation of aggregates in the actin/ER system. The CI proteins analyzed are found in both the nucleus and the actin/ER network, whereas the 6K1 proteins are mainly targeted to chloroplasts. The full set of data obtained from the localization studies enlightens the complex cellular processes that regulate the adaptation of PVY to pepper.

Text

The present study aims to unravel the basis of an uncharacterized form of resistance observed in the *Capsicum annuum* / potato virus Y (PVY) pathosystem. Evolutionarily distinct PVY isolates exhibit a contrasted ability to infect pepper which is linked to at least a single amino acid substitution in the viral P3 coding region. The role of the early plant response in this phenomenon was assessed through transcriptomic analysis of pepper plants challenged with three PVY isolates: an adapted one, a non-adapted one that remains restricted to the sites of inoculation, and a point-mutant of the latter with the ability to infect pepper systemically. Using standard in silico methods, differentially expressed genes (DEGs), gene ontology (GO) terms and pathways were identified and evaluated as putative resistance factors and markers of infection. The analysis depicts the important role of genes associated with the defence regulation, the cell wall metabolic processes and the hormonal response. Furthermore, an immunoprecipitation assay using the P3 proteins of the three isolates pinpoints plant interacting proteins associated to this differential response of pepper. The data that emerge from this study significantly contribute to unravelling the host key factors associated with this type of resistance.

IS THE GLYCOPROTEIN RESPONSIBLE FOR DIFFERENCES IN DISPERSAL RATES BETWEEN LETTUCE NECROTIC YELLOWS VIRUS SUBGROUPS?

HIGGINS Colleen. (1), VALMONTE-CORTES Gardette. (1), DARLING Toni. (1), BUCKLEY Elizabeth. (1), DUXBURY Mark. (1), SEALE Brent. (1), PRABOWO Eko Yakoso. (2)

(1) Auckland University of Technology, Auckland , NEW ZEALAND; (2) The National Agency of Drug and Food Control, Jakarta, INDONESIA

Text

The population of lettuce necrotic yellows virus (LNYV), a cytorhabdovirus, comprises two subgroups, SI and SII. The virus is vectored by aphids primarily by *Hyperomyzus lactucae*. It appears to be endemic to Australia and Aotearoa New Zealand (NZ) but shows different population structures in each country; S1 dominates in NZ, while it appears to have become extinct in Australia. It has been suggested that SII is outcompeting SI, possibly through greater vector transmission efficiency and/or higher replication rate in its host plant or insect

vector. Rhabdovirus glycoproteins are important for virus–insect interactions. Analysis of LNYV glycoprotein sequences from NZ shows the same subgroup structure as previous analysis of the nucleocapsid protein. Prediction of the 3D protein structures revealed domain architectures similar to Vesicular Stomatitis Virus (VSV). Importantly, amino acids at positions 244 and 247 of the post-fusion form of the LNYV SII glycoprotein influenced the predicted structure, glycosylation at N248 and the overall stability of the protein. These data support the glycoprotein as having a role in the population differences of LNYV observed between Australia and NZ.

P1.2-023

DETERMINATION OF PVY RESISTANCE AND EXPRESSION OF RESISTANCE ASSOCIATED GENES IN TOMATO PLANTS

GUNES Nihan. (1), GUMUS Mustafa. (1)

(1) Ege University, Faculty of Agriculture, ?zmir, TURKEY

Text
Tomato is a well-developed model system for molecular genetic studies and a natural host of potato virus Y (PVY). In recent years, it has been reported that the eukaryotic translation initiation factor 4E gene family is associated with resistance to the Potyvirus genus. In Türkiye, the agent has been detected in many tomato production areas including diverse regions. The resistance status of some wild Solanum species and some tomato cultivars were evaluated for reaction to a PVYN:O isolate obtained from the ?zmir province of our country. Few amino acid changes in the eIF4E protein explain resistance to PVY. For this reason, the polymorphism of eIF4E in the genotypes was determined. Pot-1 locus, which plays a role in PVY resistance in tomato, was shown to be associated with eIF4E. Genetic linkage of them was investigated by using the dCAPS marker (eIF4E-SpeI) in the tomato genotypes used. Viral genome-linked protein (VPg) protein plays a role in breaking resistance genes in some PVY-resistant genotypes. The virulence status of the virus isolate was determined by sequencing VPg. The expression of eIF4E-related genes suggests their role in the tomato-PVY interaction. The expression status of eIF4E1, eIF4E2 and eIF(iso)4E genes during PVYN:O infection in Solanum arcanum LA2157 was analyzed at different time points by Real-time Quantitative PCR. GAPDH, UBI, UK and ACT genes were used to determine the reference gene which shows the least variation during PVY infection.

Text
TSWV, belongs to the genus *Orthotospovirus*, is broadly distributed worldwide. It infects more than 1,350 species of monocotyledons and dicotyledons, and causes great economic loss. In order to identify early-expression genes related to TSWV resistance in *Arabidopsis*, *Arabidopsis* protoplasts transfected with TSWV were collected for differential gene expression analysis at 1, 2, and 4 hours post transfection. The results of transcriptome analysis showed that when compared with the buffer transfection control group, there were 16 genes showed an increase in expression level at 1 and 2 hours after TSWV transfection, while 37 genes showed a decrease in expression level. There were 3 genes showed an increase in expression level at 2 and 4 hours after TSWV transfection, while 18 genes showed a decrease in expression. The expression levels of 9 genes were confirmed by RT-qPCR and was consistent with the results of transcriptome analysis. TRV-based gene silencing system were conducted to characterize their functions. Results showed that silencing of plant viral-response family protein gene caused an increase of the TSWV N gene expression. Silencing of calcium-dependent phosphotriesterase gene, tasiR480/255 regulating target gene, G-box binding factor 4 gene, and Pam16 transporter protein gene caused a decrease of the N gene expression. The analyses of the resistance of transgenic *Arabidopsis* against TSWV are ongoing.

P1.2-025

THE ROLE OF CI HELICASE ACTIVITY IN POTYVIRAL MOVEMENT

ASPELIN William. (1)

(1) University of Helsinki, Helsinki, FINLAND

Text
Potyviruses are some of the most common and widely distributed plant pathogens which infect a wide range of both cultivated and wild plants. One of their distinctive features is the formation of cytoplasmic inclusions by their helicase, cylindrical inclusion protein (CI). CI is involved in many potyviral infection processes, most importantly, replication, and the spread of infection from one cell and tissue to another, also known as “movement”.
My poster will present the preliminary results of my doctoral thesis project which aims to better understand the role of CI helicase domain in potyviral infection. Six CI helicase domain mutations were selected from previous studies and introduced into Potato virus A (PVA) CI. One of these was deficient in replication and the other five in movement. The effect of these mutations on CI’s ATPase and helicase activity were measured in vitro. Additionally, their effects on PVA replication, translation, and movement in Nicotiana benthamiana were monitored. Levels of replication were measured by RT-qPCR, and translation by dual luciferase assays. Effects on movement were measured by fluorescent confocal microscopy using a dual fluorophore assay. The project will also map the CI interactome using proximity labelling and yeast two-hybrid.

SNEAKY SUO: PLANT PROTEIN PROMOTING POTYVIRAL TRANSLATION

DUTTA Pinky. (1), XHELILAJ Kaltra. (1), POLLARI Maija. (1), MÄKINEN Kristiina. (1)

(1) University of Helsinki, Helsinki, FINLAND

Text
SUO is required for miRNA mediated translation repression, independent of miRNA biogenesis and stability. *suo* is a loss of function mutant which reduces the activity of miR156/miR157 and AGO1 causing early vegetative maturity in *Arabidopsis thaliana (A.t.)*. To study if *suo* has an effect on potyvirus infections, we infected *suo- A.t.* and *suo* knock-down *Nicotiana benthamiana (N.b.)* with turnip mosaic virus (TuMV:GFP) and potato virus A (PVA:Rluc), respectively. Col0 plants and empty hairpin-infiltrated *N.b.* were used as controls, respectively. Viral gene expression was quantified by GFP-ELISA for TuMV, while Dual luciferase assay was performed to quantify Rluc levels from PVA:Rluc. Viral RNA transcript levels were measured by relative quantification RT-qPCR. We observed a two-fold and three-fold reduction in viral protein levels when SUO was downregulated in TuMV-*A.t*. and PVA-*N.b*. pathosystems, respectively. Viral transcript levels in both pathosystems did not change compared to the controls. In the absence of SUO, viral translation was inhibited. This result suggests that the virus hijacks SUO to assist the infection by promoting viral translation. Interestingly, we did not observe any significant change in the transcript levels of the three SUO homologs and AGO1 during PVA infection in *N.b*. Based on our results, we put forward a conjecture that SUO likely contributes to translation-associated control of potyviral infection in a transcription independent manner.

EVOLUTION OF PAPAYA LEAF CURL VIRUS IN INDIA: INTERPLAY BETWEEN MUTATION, RECOMBINATION AND SELECTION FORCE

SRIVASTAVA Aarshi. (1), PANDEY Vineeta. (1), GAUR Rajarshi Kumar. (1)

(1) Deen Dayal Upadhyaya Gorakhpur University, Gorakhpur, Gorakhpur, INDIA

Text
Genome variability and virus evolution are fundamentally based on the rapid accumulation of mutations, which expedite the spread and survival of begomoviruses and its vector, allowing preferential replication of genes and the pattern of more complex infections by crossing geographical origin and host range. In this study, we studied the mutational and selection parameters of the complete genome of Papaya leaf curl virus (PaLCV) and associated betasatellite isolates from Gorakhpur, India, to comprehend how the virus is evolving in this geographical region. Consequently, phylogenetic and recombination analyses suggest the exchange of genetic material among and between the various begomovirus isolates infecting different crop varieties, implying the occurrence of natural inter- and intraspecies recombinations. 45% of the polymorphic sites show substitutions in the third nucleotide codon position, indicating that non-synonymous substitutions are more frequent. Although isolates indicate strong evidence of purifying selection at most polymorphic sites, considerable positive selection was also identified in some proteins of isolates, pointing to the adaptive evolution of PaLCV and its betasatellites. Therefore, these findings on evolutionary rates due to selection pressure and mutation of begomovirus isolates from Indian populations are imperative for the critical perception that will elucidate the dynamics of rapidly evolving begomoviruses.

Text

Pepper mild mottle virus (PMMoV) causes severe damage on pepper production worldwide. As a member in the genus *Tabmovirus*, PMMoV is highly transmitted and is stable in environment. It is urgent to develop new strategies and measures for PMMoV control. Since virus relies on host factors for infection and proliferation via direct or indirect interaction, and the virus-encoded replicase, coat protein (CP) and movement protein (MP) play essential roles in infection, it is of great significance to identify host proteins and their functions for virus infection cycle. In this study, we screened pepper proteins that might interact with PMMoV replicase, CP or MP by using TurboID-based proximity labeling approach followed by LC-MS/MS. The biologically function important proteins that might interact with replicase, CP or MP were evaluated through yeast two-hybrid and firefly luciferase complementation imaging assays. For PMMoV replicase, CP, and MP, interaction networks were separately constructed with screened pepper proteins. Functional studies are going on with focusing on interacting proteins involved in immunity and splicing regulation in pepper.
Junmin Zhang and Tao Zhou are corresponding authors.

Text

Rhizomania is one of the most economically devastating disease of sugar beet and is caused by Beet necrotic yellow vein virus (BNYVV). The sugar beet taproot undergoes massive reprogramming of auxin-responsive genes upon BNYVV infection governed by P25, the virulence factor of the virus. P25 on its own localize to nucleus and in the cytoplasm, may associate with host chromatin and, thus, act as transcriptional activator/ repressor. To address this hypothesis, a genome-wide ChIP-seq was performed to identify P25-interacting promoter region of Beta vulgaris. ChIP-seq data highlighted genes of several pathways involved in cell cycle, osmoregulation, chloroplast function, auxin signaling, lateral root development etc.,

probably activated/repressed by P25 for the virus benefit. We assessed the transactivation activity of P25 on the promoters of those genes by dual-luciferase assay and P25 was found to repress the activity of selected ten candidate promoters. Interestingly, P25 repressed a promoter of a gene encoding UDP-glucuronosyltransferase (UGT). UGT negatively regulates auxin signaling by glycosylating and thereby sequestering IAA and inhibiting auxin-mediated responses such as lateral root development. BNYVV, on the other hand, seems to repress negative regulators of auxin signaling and auxin response. Thus, our work provided new insights on P25 action as a virulence factor. The mode of action of P25 and the effect of P25 target genes on virus replication will be discussed.

Text

Tomato spotted wilt orthotospovirus (TSWV, Orthotospovirus) is one of the most economically important emerging plant viruses. TSWV has an extremely broad host range, including more than 1000 species. The most efficient control strategy against TSWV so far is the use of available resistant varieties. In tomato, resistance is determined by the Sw-5b gene. However, the use of resistant varieties led to the emergence of TSWV isolates capable of overcoming the resistance genes (RB strains). Most of the tomato TSWV RB strains had one of the two amino acid changes (C118Y or T120N) in the non-structural protein (NSm gene). Recently, another mutation (D122G) was found to be associated with RB isolates. Symptomatic tomatoes in Croatia and Slovenia were screened for potential TSWV RB isolates. During the three-year period (2020-22), we collected a total of 93 tomato samples. For 13 representative samples, total RNA was isolated, depleted of rRNA and prepared for high-throughput sequencing using Illumina or Oxford Nanopore platforms. No specific amino acid changes characteristic of RB isolates were detected in any of these tomato samples. Our future work will focus on a more detailed molecular characterisation of TSWV isolates from Croatia and Slovenia.

THE INTERPLAY BETWEEN VIRAL PROLINE/SERINE-RICH PROTEINS AND THE PLANT POSTTRANSLATIONAL MODIFICATIONS DYNAMICS

XU Qiuyu. (1), SAYURI Iwasaki. (1), **MATSUMURA Emilyn. (1)**

(1) Wageningen University and Research, Wageningen, NETHERLANDS

Text
While plants activate a vast array of defense responses against virus pathogens, viruses utilize versatile strategies to manipulate cellular regulatory systems of a plant host for successful infection. Posttranslational protein modifications (PTMs) are crucial for rapid reprogramming of cellular signaling in response to virus infections; but viruses appear to hijack a variety of PTM dynamics to suppress host defense and promote infection. We have been investigating viral proteins that potentially undergo PTMs to increase their functional diversity during plant-virus interactions. Inspired by preliminary data, we focus on a protein of 16 kDa (p16), unknown function, and that has been predicted to be encoded by a small ORF located at the genomic 3' end of some members of the family *Tymoviridae*. From a systemic genome analysis across 197 virus accessions, 464 predicted ORFs (including multiple strains of the same virus and multiple ORFs of single strain) were selected for *in silico* analysis. The proteins predicted from the selected ORFs showed to have a very high proline/serine content as well as several conserved sites predicted as potential sites for kinases-mediated phosphorylation. Using a virus infectious clone and its predicted p16 protein as model of study, we showed that p16 targets chloroplast, interact with many chloroplastic proteins, potentially including chloroplastic kinases, and interfere with the plant hypersensitive response during virus infection.

P1.2-033

SPITFIRE – SCREENING OF PISUM SATIVUM ACCESSIONS FOR PNYDV RESISTANCE

TAN Shin-Yee. (1), GRAUSGRUBER-GRÖGER Sabine. (2), LOHWASSER Ulrike. (3), ZIEBELL Heiko. (1)

(1) Julius Kühn-Institut, Institute for Epidemiology and Pathogen Diagnostics, Braunschweig, GERMANY; (2) Austrian Agency for Health and Food Safety (AGES), Institute for Sustainable Plant Production, Vienna, AUSTRIA; (3) Leibniz Institute of Plant Genetics and Crop Plant Research (IPK), Gatersleben, GERMANY

Text
Pea (*Pisum sativum*) is a high-value leguminous crop that is generally used for livestock feed and human consumption. Pea production in Germany and Austria suffers from the infection of a nanovirus, pea necrotic yellow dwarf virus (PNYDV). PNYDV is a multipartite, single-stranded, circular DNA virus that infects leguminous crops and is transmitted by aphids in a circulative, persistent manner. The first identification of PNYDV in peas was in 2009 in Germany; then subsequently detected in Austria, the Netherlands, and Denmark. Infected peas show symptoms of leaf rolling, chlorosis, stunted growth, poorly developed pods; sometimes complete plant death, thus leading to severe yield losses. Currently, the control of virus vectors using pesticides is often expensive and not efficient, especially with the concerns for sustainability and environmental issues. Moreover, some insect vectors developed resistance to pesticides. Therefore, virus-resistant plant varieties are needed for the sustainable production of pea crops. As to date, no commercial PNYDV-resistant pea lines are known, the SPITFIRE project aims to identify genetic resources of peas that may confer resistance or at least tolerance to PNYDV infection. In a collaboration between the German Genebank (IPK), Julius Kuehn Institute, the Austrian Agency for Health and Food Safety, and pea breeders, screening for potential PNYDV resistance pea varieties, landraces, heritage cultivars, and wild Pisum spp. are being performed.

P1.2-034

OAT STERILE DWARF

LINNELL Anna. (1)

(1) HS Konsult AB, Nyköping, SWEDEN

Text

Oat sterile dwarf is a disease that can cause sever yield losses in oats. It is most found in the middle parts of Sweden where oat is an important crop. Oat sterile dwarf disease is caused by the Oat sterile dwarf virus (OSDV) and transmitted by a planthopper vector Delphacidea, Javesella pellucida. If disease outbreak tends to increase, then ability to make accurate predictions will be appreciated. This study aimed to develop a method that would - in a relatively simple way - test a large number of individual planthoppers for virus content. This method would be a tool in trying to predict disease outbreak in next year's crop.
OSDV is a Fiji virus, genus Reoviridae, which are double-stranded RNA viruses. It replicates in its vector and in the plant host and is transmitted in a persistent way by planthoppers. The virus stays in the insect when it moults but is not passed on to eggs. The planthopper acquires and transmits the virus by feeding on cereals and grass.
The methods used for virus detection were reverse transcription polymerase chain reaction (RT-PCR) and dot-blot hybridisation. Primers for RT-PCR were developed, the fragments cloned and sequenced. The sequenced fragments were used to synthesise a probe for hybridization.
Virus was detected in extracts of individual planthopper nymphs with RT-PCR and dot-blot hybridization and in oat plants with RT-PCR. Percentage of planthoppers containing virus range from 0-30 percent in the populations studied.

Text

RNA uridylation, the addition of one to several uridines at the 3' end of RNAs, is a post-transcriptional modification found on both mRNAs or non-coding RNAs in eukaryotes. Recently, uridylation was revealed as an antiviral defense mechanism in *Caenorhabditis elegans* and in human. In this study, we evaluated the diversity of uridylation patterns for representatives of positive-sense single-stranded RNA phytoviruses. Using 3' RACE-seq, a technique combining rapid amplification of cDNAs 3' ends with high-throughput Illumina sequencing, uridylation patterns were analyzed on viral RNAs of 21 phytoviruses from 11 families. Our results uncover important variations in uridylation profiles across plant viral RNAs.

Interestingly, viral RNAs of grapevine fanleaf virus (GFLV, *Nepovirus*, *Secoviridae*) are uridylated to very high levels (>81%) with a mono-uridylation pattern. To evaluate the evolutionary conservation of GFLV 3' terminal features among *Secoviridae*, we investigated RNA uridylation patterns from nine other viruses from this family. Interestingly, only RNAs from GFLV and its closed relative, arabis mosaic virus, had in common this remarkable high percentage of mono-uridylation.
The immediate perspectives of this work are to identify which plant or viral factor catalyzes the mono-uridylation in GFLV RNAs and to determine the importance of GFLV RNA 3' terminal uridylation for viral infection using uridylated or non-uridylated GFLV viral infectious transcripts.

Text
Pea (*Pisum sativum* L.) is a widely grown grain legume in temperate regions and contributes largely to protein rich food and feed and biological nitrogen fixation in the crop rotation. However, many biotic stresses, such as fungal and viral pathogens and insect pests are crucial constraints of successful pea production. Pea necrotic yellow dwarf virus (PNYDV), an obligate aphid transmitted nanovirus, emerged in Central Europe only recently during the last 10-15 years. In contrast to other viral diseases of pea, PNYDV leads to substantial yield reduction or even complete loss in highly epidemic years. Control of this virus is challenging particularly in organic agriculture, where insecticidal treatment against the aphid vector is very limited or not allowed. The selection and breeding of resistant pea varieties is therefore the most promising approach. We have established a screening system for the selection of resistant lines by employing a newly developed qPCR assay for the differential assessment of the virus load between pea accessions upon inoculation with aphids carrying PNYDV. This quantitative assessment will allow the identification of breeding lines able to limit or suppress the virus multiplication. Breeding lines will be selected based on qPCR assay and validated in the field. This novel screening approach can be translated to other obligate aphid transmitted virus in different crops and become an important selection tool for breeding and genomic analysis.

Text

Plants rely on a variety of mechanisms to counteract infections. R factors encoded by dominant resistance R genes generally correspond to nucleotide binding-leucine rich repeat (NLR) proteins and recognize pathogen-derived avirulence (Avr) factors. Interaction between Avr and R factors activates a hypersensitive response (HR) characterized by a programmed death that more or less efficiently restricts the pathogen at its entry point.
Grapevine fanleaf virus (GFLV), of the genus Nepovirus in the family Secoviridae, is the main agent causing grapevine fanleaf disease which greatly impacts the harvest in vineyards, worldwide. When inoculated to *Nicotiana occidentalis*, GFLV strain F13 induces HR whereas strain GHu multiplies without inducing HR. The use of chimeric clones allowed to identify the 2A homing protein ($2A^{HP}$) as the Avr factor and to delineate the 50 C?terminal aminoacids as the viral determinant of the HR.
To identify proteins encoded by *N. occidentalis* and involved in HR we overexpressed EGFP tagged $2A^{HP}$ proteins i.e. $2A_{F13}$ and $2A_{GHu}$ originating from F13 and GHu strains or the recombinant protein $2A_{F209G}$ in which the 50 last residues are from the GHu strain. We hypothesized that cellular proteins important for the Avr recognition and HR should preferentially interact with protein $2A_{F13}$. Candidate proteins purified by co?immunoprecipitation were identified using LC?MSMS. The most relevant candidates and the ongoing validation work will be presented and discussed.

CHANGES TO THE HOST TRANSCRIPTOME TRIGGERED BY BEGOMOVIRAL DNA-B: A CASE STUDY USING SRI LANKAN CASSAVA MOSAIC VIRUS.

JAGRAM Neelam. (1), **DASGUPTA Indranil. (1)**

(1) University of Delhi South Campus, New Delhi, INDIA

Text

Sri Lankan cassava mosaic virus (SLCMV), a whitefly-transmitted bipartite begomovirus infecting cassava (Manihot esculenta) in south Asian countries can exist as both monopartite and bipartite, with differing pathologies in the experimental host Nicotiana benthamiana, when the viral DNA is inoculated using agrobacterium. This presents a unique opportunity to study the transcriptomic changes due to DNA-B. Plants inoculated with SLCMV DNA-A only and DNA-A + DNA-B, when monitored at three time points showed a faster onset of symptoms and higher symptom severity when both the DNAs were used, compared to only DNA-A. The accumulation of the two DNAs in newly emerged leaves varied widely over time, the DNA-A showing a more rapid accumulation compared to DNA-B in plants inoculated with DNA-A + DNA-B. The differentially expressed genes due to DNA-B only were computed following a comparison between the two groups of plants at a stage when both groups showed a similar accumulation of DNA-A. The results suggested that the presence of DNA-B under the given experimental setup triggered expression changes in a limited but defined set of genes. The transcriptomic changes were confirmed by quantitative PCR studies. The study reveals new facets about the pathological roles of the two DNA components of bipartite begomoviruses.

Text

Hemp (*Cannabis* spp.) is a rich source of natural compounds and fiber for medicinal and industrial use. While fungal and bacterial pathogens of hemp are quite well characterized, virus infections have been reported and seen as an emerging threat for hemp cultivation only in recent years. In this work we used Illumina small RNA sequencing for virome reconstruction and characterization of the antiviral defense based on RNA interference (RNAi) in industrial hemp plants (monoecious) and dioecious plants cultivated for production of CBD/CBG cannabinoids. By de novo and reference-based assembly of small RNA reads we identified and reconstructed previously-reported viruses such as Cannabis cryptic virus (family *Partitiviridae*), Cannabis sativa mitovirus 1 (*Mitoviridae*) and Grapevine line pattern virus (*Bromoviridae*) as well as a putative new species of *Partitiviridae*. Members of both *Partitiviridae* and *Bromoviridae* families were targeted by antiviral RNAi generating predominantly 21 and 22 nt small interfering RNAs from both strands of the entire virus genome. In contrast, mitovirus-derived small RNAs belonged to a wider size range, with 16 and 21 nt size classes being the most abundant, and resembled *Cannabis* mitochondrion genome-derived small RNAs. Association of disease symptoms (if any) with identified viruses and/or relative abundance of viral sRNAs will be presented. To our knowledge, this is the first characterization of antiviral RNAi in hemp plants.

OXIDATIVE STRESS AND ACTIVATED METHYL CYCLE-RELATED RESPONSES IN POTY-POTEXVIRUS SYNERGISM IN NICOTIANA BENTHAMIANA

POLLARI Maija. (1), DE Swarnalok. (1), SIPARI Nina. (1), **MÄKINEN Kristiina. (1)**

(1) University of Helsinki, Helsinki, FINLAND

Text

Poty- and potexviruses are positive-sense RNA viruses that cause mixed infections leading to significant yield losses in important crop plants. We have studied molecular mechanisms underlying coinfection between potato virus A (PVA), a potyvirus, and potato virus X (PVX), a potexvirus, in Nicotiana benthamiana. Glutathione is a scavenger of radical oxygen species involved in relieving oxidative stress associated with virus infections. Glutathione biosynthesis pathway is tightly connected to the activated methionine cycle (AMC). PVA helper component proteinase (HCPro) interferes with the key enzymes of AMC, S-adenosyl-

L-methionine synthetase (SAMS) and S-adenosyl-L-homocysteine hydrolase (SAHH). A strong downregulation in the amount of the reduced form of glutathione (GSH) is observed upon HCPro expression in PVX infected cells. In our recent study, we analyzed the metabolites related to AMC and glutathione synthesis pathway in PVA-PVX infection. The analysis revealed that both S-adenosyl methionine / S-adenosyl-homocysteine (SAM/SAH) ratio and GSH/GSSG ratio were significantly reduced in PVA-PVX coinfected plants during systemic infection. Decreased SAM/SAH ratio compromises transmethylation reactions, which has many negative effects on host cell function and defense against viruses. Since AMC and glutathione pathways have an essential role in viral coinfection, further research in this area may help finding solutions to diseases caused by mixed infections.

ALLELE MINING FOR EIF4G-MEDIATED RESISTANCE IN 3K RICE GENOMES, DETECTION OF SIGNALS FOR POSITIVE SELECTION, AND DEVELOPMENT OF PACE MARKERS FOR IDENTIFIED EIF4G ALLELE TYPES.

AMBITA Israel Dave. (1), **ATIENZA-GRANDE Genelou. (1)**, JONSON Gilda. (1), CHOI Il-Ryong. (1)

(1) IRRI, Los Banos, PHILIPPINES

Text

Genetic databases of agronomically important crops are rich resources of natural alleles for valuable traits such as stress resistance. Lee et al. (2010) conducted an association mapping analysis for RTSV resistance which suggested that resistance in rice cultivar Utri merah was controlled by a single recessive gene located at a 200-kb region of chromosome 7. Within this region is a gene coding for translation initiation factor 4 gamma (EIF4G), a protein involved in virus multiplication. Rice accessions with potential RTSV-resistance were identified among the 3000 rice genomes based on non-synonymous SNPs within a 30-nucleotide region spanning EIF4G. Examination of the 3,000 rice genotypes have shown that 10% carry natural EIF4G alleles. Phenotype analysis for RTSV resistance of rice accessions with natural EIF4G alleles have shown association of RTSV resistance with the presence of non-synonymous SNPs within the 30-nt region of EIF4G. Allele-types were designated as ARC, AS, BON, HAT, KG, KK, KM, KM-UR, NH, TKM, and UR. About 90% of the rice genotypes with homozygous EIF4G alleles were RTSV-resistant and those that are heterozygous have shown a segregating phenotype. Analysis of distribution of EIF4G allele types in terms of subpopulation and geographical location have shown over-representation of certain allele types to certain rice subpopulation and continental regions. Lastly, we used the identified allele-types to design PACE markers for high throughput SNP genotyping.

P1.2-043

THE CHARACTERIZATION OF THE HELPER COMPONENT PROTEINASE (HC-PRO) OF THREE TULIP-INFECTING POTYVIRUSES

Text

Tulips are among of the most economically important ornamental plants. Due to their vegetative propagation and long juvenile phase, tulips are prone to viral infections. The most widespread viral disease among tulips is the color-breaking syndrome, which is primarily caused by three potyviruses: tulip-breaking virus (TBV), Rembrandt tulip-breaking virus (ReTBV), and lily mottle virus (LMoV). Since limited information is available on the HC-Pro protein of these viruses, we successfully isolated, cloned, and determined their nucleotide sequence. All three HC-Pro sequences are deposited in NCBI GenBank, ReTBV HC-Pro being the first available nucleotide sequence. In this study, phylogenetic analysis and amino acid sequence comparison of the three HC-Pros were carried out. Furthermore, the silencing suppressor activity was compared using Agrobacterium-mediated transient expression of TBV, ReTBV, and LMoV HC-Pro in Nicotiana benthamiana plants. According to the GFP visualization and real-time PCR quantification, TBV HC-Pro had strong, and ReTBV HC-Pro showed moderate silencing suppressor activity. Interestingly, LMoV HC-Pro failed to have suppressor activity in the N. benthamiana plants. Moreover, the in situ localization of the HC-Pro of these tulip-infecting viruses was also evaluated using GFP fusion proteins.

GENOMIC CHARACTERIZATION OF PAPAYA RINGSPOT VIRUS (PRSV) ON CARICA PAPAYA AND ITS MANAGEMENT THROUGH APHID VECTORS IN PUNJAB PAKISTAN

WAHAB Muhammad. (1), RAJPUT Nasir Ahmed. (1), ATIQ Muhammad. (1), KACHELO Ghalib Ayaz. (1), AHMED Hadeed. (1)

(1) UNIVERSITY OF AGRICULTURE FAISALABAD, Faisalabad, PAKISTAN

Text

Papaya (Carica papaya L.) belongs to the family Caricaceae widely known for its economic importance throughout tropical and subtropical areas. Papaya productivity is affected by different factors mainly viruses causing huge economic losses. Papaya ringspot virus (PRSV) is major devastating disease right now. In Pakistan, PRSV has not been well defined for its genomic reference. Therefore, this study aims to quantify the PRSV disease impact in Punjab, Pakistan based on molecular characterization of virus and its management through controlling vector. The samples were collected from the fifteen locations of five districts in Punjab, Pakistan. The highest disease severity 85% was found in district Bahawalnagar whereas the lowest 60% was found in Gujrat. Primers amplified the CP gene region. The generated

sequence was 10,088 bp. BLAST analysis showed 100% similarity to PRSV. Phylogenetic analysis was performed with already available PRSV accessions and found similarity with indian and american strain. This study was also aimed to investigate the efficacy of four insecticides against aphid infestation in orchards. Results showed that Acetamiprid was found highly effective in controlling aphid population. The results of this study indicated that insecticide can be an effective method of controlling aphid populations in orchards.

Text

Cucumber mosaic virus (CMV) is one of the most devastating plant viruses and has an extremely
wide, variable host range. Despite the similar taxonomy and genome structure with CMV, peanut stunt virus (PSV) has a much limited host range, which consists mainly legumes. Since no data is available on the background of the limited host range of PSV, we analyzed it on a common host (Nicotiana benthamiana) and on a selective host (Capsicum annum cv. Bródy). All of the five proteins of cucumoviruses have a role in pathological characteristics, the least information is available on the movement protein (MP). As a result of inoculation with RNA3 reassortant and recombinant viruses, MP was determined responsible for the differences in infections. Since the main function of the MP is to promote cell-to-cell movement of the virus, and plasmodesmata (PD) localization is essential to cell-to-cell movement, intracellular localization and colocalization with PD were compared between CMV MP-eGFP and PSV MP-eGFP. In the case of CMV MP-Egfp a clear colocalization with PD was detected, while the presence of PSV MP-eGFP was divided between the PD and plasma membrane (PM). After plasmolysis of infiltrated cells, CMV MP-eGFP was still colocalized to PD but PSV MP-eGFP was weakly associated with PD. In the present study, we demonstrated that differences in PD localization of CMV and PSV could have consequences on the symptom phenotype (N. benthamiana) and on the host range determination (C. annuum).

P1.2-046

THE EFFECT OF TOMATO SPOTTED WILT VIRUS NSS PROTEIN SELF-INTERACTION ON SILENCING SUPPRESSION AND AVIRULENCE IN PEPPER PLANTS

Text

Tomato spotted wilt virus (TSWV) is an important plant pathogen causing heavy economic losses worldwide. The NSs protein encoded by the S RNA of the TSWV genome functions as a viral suppressor of RNA silencing (RSS) and also as avirulence determinant in pepper plants. We confirmed in vivo self-interaction of NSs proteins by bimolecular-fluorescence-complementation (BiFC) and yeast-two-hybrid (Y2H) assays. To determine if self-interaction is essential for these functions, three NSs mutants were constructed (NSs/R337A, NSs/H340A, NSs/E344A) in a highly charged alpha-helix structure of the NSs protein that plays a putative role in protein-protein interaction. BiFC, hypersensitive reaction (HR) induction, and RSS assay were carried out with agroinfiltration on Nicotiana benthamiana, and both TSWV-resistant and -susceptible pepper cultivars. BiFC assay demonstrated that the point mutations of the NSs resulted in the loss of self-interaction, thus the alpha-helix structure of the NSs protein plays an important role in oligomer formation. The HR was detected in all the TSWV-resistant pepper cultivars, including the mutant NSs variants. Although the RSS activity was not ceased completely, it was significantly reduced compared to the wild-type NSs. Our results indicated that the monomeric form of NSs is able to induce HR reaction, but RSS is more effective if self-interaction is present.

GENETIC DIVERSITY ANALYSIS OF BADNAVIRUSES INFECTING BANANA IN BURKINA FASO

OUATTARA Bakary. (1), SEREME Drissa. (1)

(1) Burkinabè, Ouagadougou, BURKINA FASO

Text

Badnaviruses are serious plant pararetroviruses affecting banana and causes serious economic losses to banana production worldwide. This study aims to examine the variability of BSV and SCBV nature infecting banana in Burkina Faso. Polymerase Chain Reaction (PCR) used the Badna FP/RP specific primers for the RT/RNase H regions present in badnaviruses. The PCR yielded about 579 bp amplicons from banana infected by BSV and SCBV. The 38 BSV isolates recorded low nucleotide identity ranging from 58.9% - 98.1%. Based on percentage nucleotide sequence identity and phylogenetic analyse, BSV isolates were categorized into four groups: 1, 2, 3 and 4. Group 4 shared 76.9% - 100% identity with BSOL species. However, Groups 1 and 3 recorded a low identity ranging, from 76.8% - 79.2%, 68.8% - 79.7% with BSCV, and 72.8% - 79.0% between Group 2 and BSOLV. Groups 1, 2 and 3 were assigned to a potentially new BSV species. The two SCBV isolates recorded a low nucleotide identity of 68% among themselves indicating high diversity. In addition, SCBV_Cd and SCBV_CE showed high nucleotide identity 91.3% and 58.7% with SCBV_C and SCBV, when they were compared to all published SCBV genotypes. In addition, phylogenetic analysis revealed the segregation of SCBV isolates into two

genotypes, SCBV_Cd in C and SCBV_CE segregated in a new genotype namely Z. Recombination analyses showed weak signatures of recombination among some of the BSV and SCBV sequences. Keywords: Banana streak virus, Sugarcan baciliform virus, RT/RNase H, Polymerase chain reaction, diversity

A THOUSAND-GENOME PANEL RETRACES THE GLOBAL SPREAD AND ADAPTATION OF A MAJOR FUNGAL CROP PATHOGEN

FEURTEY Alice. (1,2), CROLL Daniel . (2)

(1) ETHZ, Zürich, SWITZERLAND; (2) University of Neuchâtel, Neuchâtel, SWITZERLAND

Text
Human activity impacts the evolutionary trajectories of many species worldwide. Global trade of agricultural goods contributes to the dispersal of pathogens reshaping their genetic makeup and providing opportunities for virulence gains. Understanding how pathogens surmount control strategies and cope with new climates is crucial to predicting the future impact of crop pathogens. In this project, we address this by assembling a global thousand-genome panel of Zymoseptoria tritici, a major fungal pathogen of wheat reported in all production areas worldwide. We identify the global invasion routes and ongoing genetic exchange of the pathogen among wheat-growing regions. We find that the global expansion was accompanied by increased activity of transposable elements and weakened genomic defenses. Finally, we find significant standing variation for adaptation to new climates encountered during the global spread. Our work shows how large population genomic panels enable deep insights into the evolutionary trajectory of a major crop pathogen.

Text
Plants and their pathogens are locked in a perpetual coevolutionary battle for survival. We present a transcontinental investigation of coevolution in the *Hyaloperonospora arabidopsidis* – *Arabidopsis thaliana* pathosystem. We generate whole genome sequences of over 400 host-pathogen pairs from natural infections collected throughout both the native eurasian range and the human-commensal colonisation of North America, as well as new near-complete long-read genome assemblies with evidence-based annotation. We investigate the demographic history of both host and pathogen, examine coevolution both generally and of individual gene pairs, and describe variation in the genetic networks of interacting host and pathogen genes. Our results show that the negative-frequency dependent selection on both the pathogen and host genomes leads to the presence of balanced polymorphisms in the wild pathosystem, in contrast to the directional selection generally experienced by pathogens of crop pathosystems.

Text
The spatiotemporal origins of plant diseases and the molecular underpinnings of their dissemination remain elusive for many epidemics. Here we discuss our ongoing efforts to study the diversity and spread of the causal agents of Fusarium wilt of banana (FWB) that affect bananas worldwide. We genotyped a global collection of 650 *Fusarium* isolates and traced the origins of FWB to Southeast Asia, the center of origin of banana and a biodiversity hotspot for banana pathogens such as *Fusarium*. While the first FWB epidemic in Gros Michel bananas was caused by a suite of genetically diverse *Fusarium* lineages, we show that the ongoing epidemic that devastates Cavendish banana production is caused by a single clone known as *Fusarium odoratissimum* (TR4). We studied the pangenome of ~70 banana-infecting *Fusarium* isolates and discovered variable genomic regions that range from sub-telomeres to multiple complete chromosomes. These regions are enriched for in planta-expressed effector genes, giving rise to diverse, lineage-specific effector repertoires. Interestingly, ~70% of the genes located in variable regions evolved via gene duplications, and genes associated with segmental duplications occur almost exclusively in these regions, suggesting that these processes drive *Fusarium* evolution. Our study provides novel insights into the origin and genome evolution of banana-infecting *Fusarium* lineages, which provides an evolutionary framework for the molecular underpinnings of pathogenicity.

Text

Ascochyta blight of chickpea is a foliar disease that is caused by the necrotrophic ascomycete fungus *Ascochyta rabiei*, causing lesions on leaves, stem and pods and subsequently leading to significant yield and profit losses. In recent years, genomic resources were developed for *A. rabiei*, including the assembly of a near chromosome-level reference genome and transcriptome assemblies. Recent studies by our group revealed that despite a limited genetic diversity of the clonally propagated Australian population (in the absence of a second mating type), *A. rabiei* isolates rapidly adapt and overcome the resistant chickpea cultivars developed and used by the industry. To better understand what features in the *A. rabiei* genome drive this adaptation and pathogenicity potential, we performed an in-depth comparative genomics investigation using whole-genome resequencing data of 230 Australian *A. rabiei* isolates, which were phenotyped and assessed for their aggressiveness against a differential chickpea host set. We identified single nucleotide polymorphism (SNP) variants and loci with variable copy-number (CNV) that are associated with highly-aggressive isolates and annotated them and the genes they impact. These results shed new light on the molecular interactions between *A. rabiei* and chickpea and the underlying genes that govern pathogenicity and will allow us to develop targeted genomic and molecular assays to rapidly identify high-risk isolates.

C2.3-5

GENOME MINING OF PSEUDOMONAS POPULATIONS REVEALS A MECHANISM FOR STRAIN-SPECIFIC KILLING OF PSEUDOMONAS

KARASOV Talia. (1)

(1) University of Utah, Salt Lake City, UNITED STATES

Text

The spread of a bacterial pathogen in a host population depends on its ability to overcome host immunity and to defend against surrounding microbes and bacteriophages. Owing to their differential killing activity and capacity to integrate into their host genomes, phages are predicted to influence disease dynamics in plants. To test the influence of phages on a plant bacterial pathogen, we identified phages circulating in a metapopulation of diverse wild Pseudomonas plant pathogens abundant across Europe. We identified viral sequences in over 1500 Pseudomonas genomes and identified a viral sequence conserved across pathogenic isolates of Pseudomonas. Interestingly, through comparative genomics, proteomics and electron microscopy we discovered that this viral sequence was not a phage but was instead a phage-derived element termed a tailocin, a repurposed phage used by the Pseudomonas strains for interbacterial warfare. Different co-occurring Pseudomonas strains

encode different tailocin variants and these variants kill different suites of co-occurring pathogenic Pseudomonas. These results suggest that tailocin variants suppress the dominance of pathogenic lineages. In total, the genome mining of Pseudomonas phage diversity that we perform in this study revealed a different tailocin variants capable of suppressing specific Pseudomonas lineages. Tailocins present a novel and tunable mechanism for suppressing specific Pseudomonas lineages.

C2.3-6

UNDERSTANDING THE DRIVERS OF THE PATHOGEN POPULATION DYNAMICS USING STRAIN-RESOLVED METAGENOMICS

KAUR Amanpreet. (1), RUSSELL Ivory. (1), BHANDARI Rishi. (1), **POTNIS Neha. (1)**

(1) Auburn University, Auburn, UNITED STATES

Text

The agro-ecosystems continue to be threatened by a number of endemic plant diseases. Integrated solutions are suggested to the growers to mitigate the impacts of these diseases, although sporadic severe outbreaks are frequently yield-limiting. Genome sequencing technologies have enabled real-time monitoring of the pathogen population dynamics. However, the real challenge has been to understand how new pathogen variants continue to emerge. Using endemic pathogen, *Xanthomonas*, infecting tomato and pepper as a model pathosystem, we have investigated how intraspecific diversity is structured by environmental parameters, host genotypes and growth dynamics of different pathogen genotypes by conducting metagenome survey and parallel greenhouse experiments. Our strain-resolved metagenomics approach has allowed us to obtain fine-scale resolution into pathogen variation within a single growing season. We documented presence of multiple, often times, more than two pathogen genotypes in a single field, although patterns of seasonal succession vary across different states of the southeastern U.S. Our findings show that strain-level diversity can turnover in response to environmental changes modulating functional traits of communities. Together, increased ecological and evolutionary plasticity can be observed in the endemic pathogen population in the southeastern US in tomato fields despite the absence of obvious host selection pressure in the cultivated tomato varieties.

MINING HISTORIC HERBARIA TO TRACK PHYTOPHTHORA INFESTANS EFFECTOR AND SOLANUM R GENE DIVERSITY AND EVOLUTION OVER TIME

COOMBER Allison. (1), SAVILLE Jean. (1), **RISTAINO Jean. (1)**

(1) NC State University, Raleigh, UNITED STATES

Text

Phytophthora infestans caused the Irish Potato Famine of 1845-1852. We performed targeted enrichment sequencing of dried, infected leaf samples from 29 herbarium specimens collected from 1845-1954. Our bait library was designed to enrich both pathogen

effector genes and Solanum host R genes. We leveraged the targeted sequencing approach to generate high coverage of genes responsible for pathogen virulence and host resistance. Many modern well-characterized effector genes have historically been present in *P. infestans*. Both R genes and effectors showed signatures of selection. However, variant calling analysis revealed alternative alleles including avirulent forms compared to the reference genome for many effectors that likely impacted function. The effector *Avr3b* was the only well-described effector not present in Famine era samples but did appear in the mid-1900s. Interestingly, the resistance breaking allele of *Avr1* was present during the famine before the *Solanum R1* gene was deployed by plant breeders. Detailed ploidy analysis of 19 high coverage genomes showed that US-1 lineages appearing in the early 1940s were triploid, in contrast to the FAM-1 lineages from 1845 and thereafter that were diploid. This exploration of historic plant and pathogen genomes will shed light on the past host-pathogen evolutionary relationships of a globally important plant pathogen and could provide insight for future deployment of Solanum R genes.

Text

The field of ancient genomics has triggered considerable progress in the study of pathogens, including those affecting crops. Herbarium collections have been an important source of dated, identified and preserved DNA, whose use in comparative genomics and phylogeography may shed light into the emergence and evolutionary history of plant pathogens. I will present the reconstruction of 13 historical genomes of the bacterial crop pathogen *Xanthomonas citri* pv. *citri* (Xci) from infected citrus herbarium specimens using a shotgun-based deep sequencing strategy. After authentication of the historical genomes based on DNA damage patterns, we compared them to modern genomes to reconstruct their phylogenetic relationships, pathogeny-associated genes content and estimate several evolutionary parameters, using Bayesian tip-dating calibration and phylogeography inferences. Despite a challenging analysis of data, requiring adapted treatment before being compared to modern samples, our results reveal that Xci originated in Southern Asia ~11,500 years ago and diversified during the beginning of the 13th century, after Citrus diversification and before spreading to the rest of the world. This updated scenario links Xci specialization to Neolithic climatic change and the development of agriculture, and its diversification to the human-driven expansion of citriculture through the early East-West trade and later colonization.

P2.3-001

ADVANCES IN GENOMICS OF TILLETIA INDICA CAUSING KARNAL BUNT OF WHEAT

GURJAR Malkhan Singh. (1), SAHARAN Mahender Singh. (1), RASHMI Aggarwal. (1), TEJPRATAP Jitender Kumar. (1)

(1) ICAR-Indian Agricultural Research Institute, New Delhi, INDIA

Text
Karnal bunt of wheat is an internationally quarantined disease affecting trade, quality, and quantity of wheat. The T. indica genome was sequenced using Illumina and Pac Bio platforms with 33.7 Mb and a GC content of 55.0%. The whole genome sequence has been deposited at DDBJ/ENA/GenBank under the accession numbers MBSW00000000. A total of 1737 scaffolds were obtained with an N50 of 58,667 bp. The comparative genome analysis suggested 3751 proteins of T. indica had orthologs in five fungi, whereas 126 proteins were unique to T. indica. Putative pathogenicity-related genes were identified in the genome. Fourteen homologous sequences of putative pathogenicity-related genes were identified in T. indica by in silico analysis. Apart from that, quick diagnostic assays were developed. Genome-wide association mapping was performed using 41,473 SNPs, infection phenotyping data, and population structure, to find single nucleotide polymorphisms (SNPs) linked to virulence genes. Population structure analysis divided the T. indica population in India into three subpopulations with genetic mixing in each subpopulation. The association mapping revealed the presence of 13 SNPs associated with virulence. Using sequence analysis tools, one gene (g4132) near a significant SNP was predicted. Multilocus sequence typing (MLST) revealed that the population of T. indica was highly diverse.

P2.3-002

EXAMINATION OF LARGE CHROMOSOMAL INVERSIONS IN THE GENOME OF ERWINIA AMYLOVORA STRAINS REVEALS WORLDWIDE DISTRIBUTION AND NORTH AMERICA-SPECIFIC TYPES

YANG Ho-Wen. (1), THAPA Rinjita. (1), KHAN Awais. (1), **ZHAO Frank. (1)**

(1) Washington State University, Prosser, UNITED STATES

Text
Erwinia amylovora is a relatively homogeneous species with low genetic diversity at the nucleotide level. However, phenotypic differences and genomic structural variations among E. amylovora strains have been documented. In this study, we identified 10 large chromosomal inversion (LCI) types in the Spiraeoideae-infecting (SI) E. amylovora strains by combining whole genome sequencing and PCR-based molecular markers. It was found that LCIs were mainly caused by homologous recombination events among seven rRNA operons (rrns) in SI E. amylovora strains and tend to occur between rrns transcribed in the opposite directions and with the same tRNA content (tRNA-Glu or tRNA-Ile/Ala). Based on the LCI types, physical/estimated replichore imbalance (PRI/ERI) was examined and calculated. Among the 117 SI strains evaluated, the LCI types of Ea1189, CFBP1430, and Ea273 were the most common with ERI values at 1.31°, 7.87°, and 4.47°, respectively. These three LCI types had world-wide distribution, whereas the remaining seven LCI types were restricted to North America. Our results indicated on-going chromosomal recombination events in the SI E. amylovora population and showed that LCI events are mostly symmetrical, keeping the

ERI less than 15°. These findings provide first evidence about the prevalence of certain LCI types in E. amylovora strains, how LCI occurs, and its potential evolutionary advantage and history, which might help track the movement of the pathogen.

P2.3-003

POPULATION GENETIC DIVERSITY AND MIGRATION PATTERNS OF EXSEROHILUM TURCICUM FROM MAIZE-BASED CROPPING SYSTEMS IN SOUTH AFRICA

NSIBO David Livingstone. (1), SLIPPERS Bernard . (1), VISAGIE Cobus. (1)

(1) University of Pretoria, Pretoria, SOUTH AFRICA

Text

Exserohilum turcicum causes northern leaf blight of maize and is a major threat to South Africa's maize production. Previous population genetics studies in South Africa revealed a high genetic diversity of the pathogen, being driven in part by cryptic sexual recombination. The population genetic structure of *E. turcicum* in smallholder and emerging commercial farms from the Eastern Cape is, however, unknown, and we address that question in this study. We hypothesized that *E. turcicum* would be highly diverse and with no population differentiation across the province. To test this hypothesis, 203 isolates from three districts, namely Alfred Nzo, Chris Hani and OR Tambo, were genotyped using 12 microsatellite markers and two mating type markers. The results show that *E. turcicum* was highly diverse (Nei's gene diversity = 0.58; Shannon index = 1.29), but that no population differentiation was detected. Both mating types were recovered from all populations, with strains in OR Tambo segregating in accordance with the null hypothesis of random mating, while Alfred Nzo and Chris Hani populations were significantly skewed from the ratio of 1:1 in favor of an abundance of MAT1-2 alleles. Our study confirms the high levels of genetic diversity at local and regional scales in in South Africa, underpinned by high gene flow and sexual recombination. These results are important to consider in future studies on resistance breeding in maize for northern leaf blight.

P2.3-004

GENETIC DIVERSITY AND POPULATION STRUCTURE OF WHEAT STRIPE RUST PATHOGEN (PUCCINIA STRIIFORMIS F. SP. TRITICI) IN TÜRKIYE BASED ON GENOME-WIDE SINGLE NUCLEOTIDE POLYMORPHISMS

Text

Stripe rust caused by *Puccinia striiformis* f. sp. *tritici* (*Pst*) is the most devastating disease of wheat both in Türkiye and worldwide. The stripe rust pathogen is highly variable due to its high reproductivity and capability of long-distance dissemination. In this study, we aimed to determine the genetic diversity and population genomic structure of a *Pst* collection collected from six different regions of Türkiye using genome-wide single nucleotide polymorphisms (SNPs) developed by double digest RAD-Seq (ddRADSeq). The gene diversities were higher in isolates from Mediterranean (ME) region and Southeastern Anatolia (SA) region than from other regions. Analysis of molecular variance (AMOVA) revealed that a high gene flow was detected among regions because 62% and 39% of explained variance were from within isolates and among isolates within regions, respectively. A bayesian model-based hierarchical clustering (STRUCTURE) showed the presence of three subpopulations among the *Pst* isolates. The result of principal coordinate analysis (PCoA) also supported these results. The large number of SNPs clearly indicated that a small set of *Pst* is highly diverse. All of these findings may provide a critical information to develop management strategies to wheat stripe rust. The high-quality SNP data generated here can also be used in the development SNP markers for studying the pathogen biology, genetics, and evolution.

FUSARIUM AND THE EMERGENCE OF BAKANAE DISEASE IN BANGLADESH

HUSNA Asmaul. (1,2), MIAH Md Asaduzzaman. (2), ZAKARIA Latiffah . (1), MOHAMED NOR Nik Mohd Izham . (1)

(1) Universiti Sains Malaysia, Malaysia, Penang, MALAYSIA; (2) Patuakhali Science and Technology University, Bangladesh, Patuakhali, BANGLADESH

Text

Bakanae is widely distributed in all rice-growing areas in the world, especially in Asian countries. A series of samplings were conducted in 15 districts of Bangladesh for 4 consecutive years from 2019 to 2022. Diseased rice plants from different rice cultivars with typical bakanae symptoms such as root rot, abnormal elongation of stems, wilting, stunting and adventitious roots were collected. Disease Incidence and disease severity were recorded high in the northeast part of Bangladesh. A total of 121 isolates were determined using morphological characteristics, DNA sequences, and phylogenetic analyses of two genes, namely, TEF1-α, and RPB2. The phylogenetic analysis of TEF1-α and RPB2 gene sequences coupled with morphological characterization revealed that the collected isolates belonged to six Fusarium species, viz., Fusarium fujikuroi, F. incarnatum, F. commune, F. verticillioides, F. equiseti and F. proliferatum. Among the isolates, all were found to be pathogenic except F. equiseti under virulence assays. The knowledge on the occurrence of bakanae disease, the association of Fusarium species with bakanae, and their pathogenic nature is still lacking in Bangladesh. Therefore, this study aimed to identify, and characterize the Fusarium species association with bakanae disease, to assess the emergence of the disease and the virulence of the pathogens which will help in formulating effective strategies and policies for better control of bakanae disease in Bangladesh.

P2.3-006

EVOLUTIONARY IMPACT OF CHICKPEA (CICER ARIETNUM) HOST RESISTANCE ON A CLONAL ASCOCHYTA RABIEI POPULATION IN AUSTRALIA

WILSON Hayley. (1,2), BAR Ido. (1), FORD Rebecca. (1), HOBSON Kristy. (2)

(1) Griffith University, Brisbane, AUSTRALIA; (2) New South Wales - Department of Primary Industries - Tamworth Agricultural Institute, Calala, AUSTRALIA

Text

Ascochyta rabiei is a necrotrophic fungus of chickpea (*Cicer arietnum*), which can lead to complete yield loss under favourable conditions. The Australian population is clonally propagating with low genetic diversity, however, it is still capable of evolving and adapting to overcome host resistance. Evolutionary drivers of the *A. rabiei* population and its adaptation to integrated disease management practices are largely unstudied. This study aims to trace the selection and adaption potential of aggressive *A. rabiei* isolates on varying host genotypes and resistance levels. Six *A. rabiei* genotypes from the Northern NSW chickpea growing region were selected based on their unique allele combination (haplotype) at fifteen SNP loci as determined from whole genome sequencing. These isolates were used to evenly inoculate six chickpea hosts with ranging *A. rabiei* susceptibility under field conditions. *Ascochyta rabiei* was re-isolated from lesions sourced from each chickpea host and genotyped using genetic fingerprinting of the 15 unique SNP loci. This was used to trace changes in isolate distribution between each chickpea genotype indicating host-dependant selection that favours specific isolates. This demonstrates intricate host-isolate interactions and adaptation which will form the basis of a decision-making tool for growers on varietal choice based on the presence of specific *A. rabiei* isolates and provide useful information for informed disease management strategies.

Text

Papaya sticky disease (PSD), characterized by the oxidation of spontaneously oozed latex, is a major virus disorder of papaya (Carica papaya) in Brazil. The disease is caused by the co-infection of two viruses, papaya meleira virus (PMeV, a dsRNA toti-like virus) and papaya meleira virus-2 (PMeV-2, an umbra-like virus). Recently, a virus related to but distinct from PMeV was identified in a two-year-old papaya orchard (cv. Passion Red) exhibiting PSD-like

symptoms in Santa Elena province, Ecuador. The virus, referred to as papaya sticky fruit-associated virus (PSFaV), has an 8.8 kbp-long genome sharing 56% nucleotide identity with its counterpart from Brazil. Phylogenetic analyses showed that PMeV, PSFaV, and babaco meleira-like virus (BabMelV) –another toti-like virus identified in Vasconcellea x heilbornii in Ecuador– sharing a most recent ancestor, are the only plant-infecting viruses within the newly proposed 'Fusagraviridae' clade. However, the conserved 'Phytoreo S7' domain is not present in either PMeV, PSFaV or BabMelV. We discuss the genomic and biological features of newly discovered toti-like viruses which delineate distinct evolutionary pathways for those infecting fungi and plants, respectively.

Text

Orobanche foetida Poiret is a holoparasitic plant that lacks chlorophyll and totally depends on its host for its growth. It parasitizes host plant roots and extracts nutrients and water via a haustorium. The fetid broomrape is distributed in the Mediterranean region as a wild plant parasite. However, since 1992, it has become a real threat to faba bean in Tunisia causing serious damages which may reach 90% yield losses. Analysis of the genetic diversity of this parasite is important to better understand its evolution and spread, remaining largely unknown. In this work, we present the first study on genetic diversity and population structure using the robust technique Restriction-site-Associated DNA sequencing (RADseq) for *Orobanche* spp. We collected 244 samples of *O. foetida* from 18 faba bean fields in Tunisia. To overcome the difficulty of SNP discovery in the *O. foetida* genome as a non-model and tetraploid plant, we used three different informatics pipelines, namely UNEAK, pyRAD, and Stacks. This study showed that genetic differentiation occurred in the Tunisian *O. foetida* emphasizing the isolation by distance effect. However, no strong population clustering was detected in this work based on the three data sets and clustering methods used. The present study traces the current real situation of the distribution of *O. foetida* populations in Tunisia and could be a valuable reference for the upcoming research projects focusing on this parasitic plant.

(1) Montana State University, Bozeman, UNITED STATES; (2) Northwest Missouri State University, Maryville, UNITED STATES; (3) North Carolina State University, Raleigh, UNITED STATES

Text

Root rot caused by Fusarium spp. is a significant problem in chickpea growing regions of Montana. However, it is unclear which species of Fusarium cause the disease and which species are more prevalent. An extensive survey was conducted to identify the Fusarium species associated with chickpea in Montana. Three hundred fifty-seven Fusarium isolates were recovered from symptomatic roots of chickpea plants from 10 counties in 2020 and 2021. Isolates were identified by comparing the sequences of the translation elongation factor 1-α in the Fusarium-ID database. Alignments of the obtained sequences indicated that Fusarium oxysporum was the most abundant species (33%), followed by F. acuminatum (21%), F. avenaceum (15%), F. pseudograminearum (8%) F. culmorum (6%), F. equiseti (2%), F. redolens (14%), F. sporotrichioides (6%), F. solani (6%), F. proliferatum (0.2%), F. torulosum (0.9%), F. tricinctum (0.8%) and F. brachygibbosum (0.1%). The aggressiveness of a subset of 51 isolates representing various Fusarium spp. were tested on the chickpea cv. ‘CDC Frontier’. Non-parametric analysis of variance conducted on ranks of disease severity indicated that F. avenaceum had the most aggressive isolates compared to the other species. This knowledge is helpful for making crop rotation decisions, disease management options, and breeding resistant chickpea varieties against economically important pathogens.

Text

Monokaryon genome of G. boninense with haploid genome size estimated at 53.6Mbp (unpublished) were annotated and candidate genes for homeodomain-related genes (HD) and pheromone receptor (PR) were subsequently identified. The in-silico gene-mining results revealed a total of 16 candidate HD genes and 18 candidate PR genes. Validations of in-silico results by amplification of targeted genes were performed on banked G. boninense cultures. Concurrently, a population of G. boninense (basidiocarps and corresponding spores) was sampled from a single oil palm plantation for whole genome resequencing. Alignment of candidate genes, both individually and concatenated sequences, allowed the selection of genes that were capable of distinguishing isolates based on mating type. The cluster consists of four PR genes accurately segregated isolates based on mating type (arbitrarily assigned by mon-mon crossing). HD2 gene could not segregate isolates as intended; hence efforts to investigate the mip gene and other HR candidate genes are still underway. In addition to the testing population sampled from the Southern region of Peninsular Malaysia, three additional populations from Southern, Central and Northern regions will be collected and sequenced by targeted sequencing approach. Surveying of the mating-type diversity at a population level will enable the estimation of mating alleles

available in Peninsular Malaysia and intersections between mating alleles in different localities.

P2.3-011

ADAPTIVE EVOLUTION OF AN EXOTIC FOREST PATHOGEN IS MEDIATED BY INTERSPECIFIC GENIC INTROGRESSION

Text

Hybridization between the invasive North American fungal plant pathogen *Heterobasidion irregulare* and its Eurasian sister species *H. annosum* is ongoing in Italy. Genome admixing was evaluated in a total of 267 sympatric isolates of the two species using AFLPs. Based on the level of admixing, whole genomes of nine natural hybrids were chosen, sequenced, assembled and compared with those of three "pure" genotypes each of the two parental species. A multi-approach pipeline was used to assign introgressed genomic blocks to each of the two species. Alleles that introgressed from *H. irregulare* to *H. annosum* were associated with pathways related to saprobic processes, while alleles that introgressed from the native to the invasive species were mainly linked to gene regulation. There was no overlap of allele categories introgressed in the two directions. Experiments documented a fitness increase in *H. annosum* genotypes characterized by introgression of alleles from the invasive species, supporting the hypothesis that hybridization results in putatively adaptive introgression. Conversely, introgression from the native into the exotic species appeared to be driven by selection on genes favoring genome stability. Since the introgression of specific alleles from the exotic *H. irregulare* into the native *H. annosum* increased its invasiveness, we propose that two invasions may be co-occurring: the first one by exotic genotypes and the second one by alleles of the exotic species.

P2.3-012

WHO NEEDS A MATE? ADAPTATION IN DEFIANCE OF EXTREMELY LOW GENETIC DIVERSITY IN THE CLONALLY PROPAGATED ASCOCHYTA RABIEI POPULATION IN AUSTRALIA

VAGHEFI Niloofar. (1,2), BAR Ido. (3), CHRISTIE Melody. (3), FORD Rebecca. (3)

(1) Faculty of Science, University of Melbourne, Melbourne, AUSTRALIA; (2) Centre for Crop Health, University of Southern Queensland, Toowoomba, AUSTRALIA; (3) Centre for Planetary Health and Food Security, School of Environment and Science, Griffith University, Brisbane, AUSTRALIA

Text
Ascochyta rabiei is an economically important pathogen of chickpea, which was introduced to Australia in the 1970s from an unknown source population. Within only a few decades, it successfully established in all chickpea growing regions in Australia, causing substantial losses to the chickpea industry. Previous studies using a small number of microsatellite markers and single nucleotide polymorphisms highlighted the clonality of *A. rabiei* population in Australia, which is in line with presence of only one mating-type (MAT1-2) in Australia. We conducted whole genome sequencing of 230 isolates collected from different agroecological zones between 2013 and 2020 to obtain a higher marker density for accurate marker-phenotype association and to investigate spatial and temporal changes in pathogen population. Low levels of allelic polymorphism further corroborated the highly clonal structure of *A. rabiei* in Australia, with mutations being the only source of variation in the absence of sexual reproduction. Significant population structuring into distinct clonal lineages was detected, which likely resulted from genetic bottlenecks and anthropogenic-driven founder effects in ”new” growing regions. Variation in isolate aggressiveness within the same clonal lineages indicates that evolution of aggressiveness in Australian *A. rabiei* isolates is most likely driven by minor genomic changes at a sequence level or epigenetic factors that require further investigation.

POPULATION GENOMIC ANALYSES REVEAL EXTENSIVE GENOMIC REGIONS WITHIN SELECTIVE SWEEPS ASSOCIATED WITH ADAPTATION AND DEMOGRAPHIC HISTORY OF A WHEAT FUNGAL PATHOGEN

LIU Taiguo. (1), XING Yun. (1), XIA Chongjing. (1), CHEN Wanquan. (1)

(1) Chinese Academy of Agricultural Sciences, Beijing, CHINA

Text
Plant pathogens are notorious for their ability to quickly evolve in response to the changing host and environment, resulting in destructive epidemics, particularly in agriculture. The fungus *Puccinia striiformis* f. sp. *tritici* (*Pst*), causing wheat stripe rust disease worldwide, is one such pathogen. In the arms race between pathogens and hosts, changes in host populations exerted continuous selective forces on the dynamics of pathogens. However, the footprints of these selection forces and the demography of *Pst* remain poorly explored. In this study, we revealed unprecedented features of worldwide *Pst* populations through population genomic analyses. We detected widespread selective sweep regions across the *Pst* genome. Genes within the selective sweeps were enriched in secreted proteins and effectors and showed functions related to pathogenicity or virulence, temperature tolerance, and fungicide resistance implying that Chinese *Pst* populations suffered positive selection pressures from host and abiotic factors. Moreover, we demographic histories of worldwide *Pst* populations suggested strong bottleneck events for all *Pst* populations during the wheat formation around 10,000 years ago and during modern agriculture around 100 years ago, suggesting crop domestication and breeding programs could continuously contribute to the decline of pathogen-effective population sizes. Our results highlighted the role of modern agriculture on pathogen demography.

Text

Emerging viral diseases of plants are recognised as a growing threat to global food security. However, little is known about the evolutionary processes and ecological factors underlying the emergence and success of viruses that have caused past epidemics. With technological advances in the field of ancient genomics, it is now possible to sequence historical genomes to provide a better understanding of viral plant disease emergence and pathogen evolutionary history. In this context, herbarium specimens represent a valuable source of dated and preserved material. We report here the first historical genome of a crop pathogen DNA virus, a 90-year-old African cassava mosaic virus (ACMV), reconstructed from small RNA sequences bearing hallmarks of small interfering RNAs. Relative to tip-calibrated dating inferences using only modern data, those performed with the historical genome yielded both molecular evolution rate estimates that were significantly lower, and lineage divergence times that were significantly older. Crucially, divergence times estimated without the historical genome appeared in discordance with both historical disease reports and the existence of the historical genome itself. In conclusion, our study reports an updated time-frame for the history and evolution of ACMV and illustrates how the study of crop viral diseases could benefit from natural history collections.

P2.3-015

DETERMINING THE CONTRIBUTION OF ONION TRANSPLANTS TO THE POPULATION GENETICS OF STEMPHYLIUM VESICARIUM IN NEW YORK, USA USING MICROSATELLITE MARKERS.

PINEROS-GUERRERO Natalia. (1), HAY Frank. (1), HECK Daniel. (1), KLEIN Audrey. (1), HOEPTING Christy. (2), PETHYBRIDGE Sarah. (1)

Text

Stemphylium leaf blight (SLB), caused by the fungus *Stemphylium vesicarium*, is one of the most important foliar diseases affecting onions (*Allium cepa* L.) in the northeastern United States. Bare root transplants imported from the southwestern United States are used to

establish approximately 25% of the onion production area in NY, with the remainder direct seeded. However, there has been no assessment of the contribution of transplants to SLB epidemics. In 2022, bare root transplants (*n* = 120) from each of eight cultivars were obtained prior to planting, incubated in humid chambers, and observed for *S. vesicarium*. *Stemphylium vesicarium* was present in all eight cultivars, with incidence ranging from 11.2 to 100%. Ten isolates of *S. vesicarium* from each of three cultivars collected prior to planting and ten isolates collected from each field at the end of the season were used to characterize genetic diversity using nine microsatellite (SSR) markers. Populations of *S. vesicarium* were highly diverse based on Evenness, Nei's allelic diversity, Shannon-Wiener, and Stoddart and Taylor's genotypic diversity indices. Multiple alleles were found at each locus independently assorting and resulting in 57 multilocus genotypes (MLGs). Minimum spanning networks (MSN) showed that *S. vesicarium* populations sampled from transplants contributed only slightly to the MLGs found at the end of the season, indicating sources of SLB inoculum other than transplants to be more important.

Text

Potato common scab is an important bacterial disease afflicting the potato crop in most potato-growing areas around the world. It is caused by numerous *Streptomyces* species and stains that rely on a myriad of virulence determinants. A better understanding of the genomic diversity of this group of microorganisms would help improving control methods, which remain to this day very limited. Over 300 diseased potato tubers from 23 different varieties were provided by 24 Canadian potato growers. 234 *Streptomyces* isolates were retrieved from scab lesions and over 80 % of these isolates were shown to fall into one of the 12 genetic groups established using digital ERIC-PCR genomic fingerprinting. The genomes of 40 of these isolates, including at least one representative strain per genetic group, were sequenced using PacBio SMRT sequencing technology, generating high quality draft genomes. Phylogenetic analysis, pathogenicity assay and genome exploration were carried out. The isolates were shown to belong to multiple species, including *S. scabiei*, *S. stelliscabiei* and *S. acidiscabies*, and to strongly differ in their virulence towards potato tubers. While only half of the sequenced strains were shown to harbor the biosynthetic operon responsible for the production of the thaxtomin A phytotoxin, the main known virulence determinant in scab-causing *Streptomyces* spp., numerous isolates lacking this cluster instead harbor other less characterized virulence determinants.

P2.3-017

DIVERSITY OF MOBILE GENETIC ELEMENTS AND ASSOCIATED FITNESS FACTORS TO ELUCIDATE THE EVOLUTION OF XANTHOMONAS

WEIS Kylie. (1), POTNIS Neha. (1)

(1) Auburn University , Auburn , UNITED STATES

Text
Recent advances in computational approaches and the abundance of publicly available genomic data have provided the opportunity to investigate the capabilities of fitness factors to be horizontally transferred among resident plant microflora and pathogens. To understand possible methods of genetic exchange, the program MGEfinder was used with genomes of xanthomonads, including both pathogenic and commensal strains from various geographical locations and spanning across group 1 and group 2, to identify putative mobile genetic elements (MGEs). The putative MGEs were subsequently annotated and screened for genetic indicators of mobility, such as transposases, inverted repeats, phage related genes, and att sites. Additionally, screenings identified cargo genes that could be considered fitness factors, including but not limited to virulence factors and antimicrobial resistance genes. Multiple putative MGEs, including one containing the type III secretion system effector XopAD and another MGE showing potentially novel multi-modal mobility and carrying the copper resistance operon CopLAB with significant similarity to Stenotrophomonas, were identified. The methods in this study can further be applied to expand ecological understanding of pathogen evolution via horizontal gene transfer in addition to identifying the extent to which commensals can act as fitness factor reservoirs.

P2.3-018

HIGH GENETIC DIVERSITY FOUND IN EMERGING EUCALYPTUS PATHOGEN ELSINOE NECATRIX

Text
Eucalyptus scab and shoot malformation (ESSM) is an emerging disease and a serious threat to the global forestry industry. The disease appeared in North Sumatra, Indonesia in the early 2000s and the causal agent was only recently determined as a novel species, *Elsinoe necatrix*. In this study, we developed 15 polymorphic microsatellite markers and mating type markers using genome sequences for two *E. necatrix* isolates. We characterized 186 isolates of *E. necatrix* collected from different host varieties at four locations in the Toba lake region of North Sumatra using these markers. These populations were found to have a high level of genetic and haplotypic diversity. Discriminant analysis of principal components, haplotype networks and analysis of molecular variance revealed a lack of population structure related to geographic locations and there was high gene flow among sampling regions. Mating type ratios and linkage disequilibrium analyses suggest that sexual recombination is likely, although a sexual state of the fungus has not been found. The results of this study highlight the fact that new genotypes of *E. necatrix*, likely arising from sexual recombination might challenge efforts to manage the disease, thus breeding and selection for tolerance will require substantial host genetic diversity.

P2.3-019

IS A SHIFT IN PATHOGEN STRUCTURE CAUSING THE INCREASED INCIDENCE OF COMMON BUNT CAUSED BY TILLETIA SPP. IN SWEDISH WINTER WHEAT?

NOVAKAZI Fluturë. (2), BENGTSSON Therése. (2), ANDERSSON Björn. (1), EDIN Eva. (3), HENRIKSSON Tina. (4), **BERLIN Anna. (1)**

Text

Tilletia tritici (syn. *T. caries*) and *Tilletia laevis* (syn. *T. foetida*) cause the seed-borne disease common bunt (CB) in all wheat growing regions around the world. CB can be effectively controlled by chemical seed treatment. Despite this, the CB incidence in recent years has increased all over Europe. For Sweden, possible reasons for this could be the decreasing number of fungicides available for seed treatment, a larger area of organic production, increased use of farm saved seed or new and more virulent pathogen races. The two species, *T. tritici* and *T. laevis*, are genetically related and biologically similar with identical life cycles. One recent study even suggests a conspecific status of the two species. Traditionally, the species identification has been based on morphological features; the teliospores of *T. tritici* have a reticulate surface, whereas *T. laevis* teliospores are smooth. To explain the increasing problems with this disease, we are analysing CB infected wheat spikes from farmers' fields across Sweden to determine disease incidence, the distribution of the two causal species and their respective virulence spectra. The first objective is to understand the distribution of the species complex based on genotyping-by-sequencing. The second objective is to study the biology and evolutionary history of the pathogen to better understand the epidemiology of the disease.

P2.3-020

UNDERSTANDING THE POPULATION STRUCTURE AND PATHOGENICITY OF BIPOLARIS ORYZAE ON COMMERCIAL AND WILD AUSTRALIAN RICES

MORRISON Sabrina ML. (1,2), MCTAGGART Alistair R. (2), TRAN Nga T. (2), GEERING Andrew DW. (2), FURTADO Agnelo. (2), HENRY Robert J. (2)

Text

Rice brown spot caused by *Bipolaris oryzae* is an economically important disease of rice worldwide and was associated with the Bengal famine that resulted in the starvation of over two million people in 1943. *Bipolaris oryzae* is the most common leaf-spotting pathogen found on native wild rices in northern Australia. Water shortages in southern Australia have led to attempts to establish a rice industry in the northern wet tropics. However, the presence

of endemic pathogens, such as *B. oryzae*, on native wild rices threaten the viability of this emerging rice industry. There is little known about the genetic diversity of *B. oryzae* in Australia or its virulence on domesticated rice. This study aims to characterise the genetic diversity of *B. oryzae* on wild rice to determine if geographic distribution or host plant species (*Oryza australiensis* and *O. meridionalis*) affect the pathogen population structure. A high-contiguity reference genome of *B. oryzae* using long-read sequence data is currently being developed and will assist in future studies on the pathogen. A spot inoculation method on detached rice leaves is also being developed to allow pathotyping of the different fungal isolates, and to assist with the identification of disease resistance genes in both domesticated and wild rice. This study will help elucidate the epidemiology of brown spot disease in northern Australia, as well as assist with the formulation of novel disease management strategies.

EMERGENCE AND EVOLUTION OF A NOVEL LINEAGE OF RALSTONIA SOLANACEARUM WITH EXPANDED HOST RANGE

EVSEEVA Daria. (1), PECRIX Yann. (2), POUSSIER Stéphane . (4), WICKER Emmanuel . (3), KUCKA Marek . (1), CHAN Frank. (1), MCCANN Honour . (1)

(1) Max Planck Institute for Biology, Tübingen, GERMANY; (2) CIRAD, Réunion, FRENCH SOUTHERN TERRITORIES; (3) CIRAD, Montpellier, FRANCE; (4) Université de la Réunion, Réunion, FRENCH SOUTHERN TERRITORIES

Text

Members of the Ralstonia solanacearum species complex (RSSC) are historically known to cause brown rot of potato and Moko disease of banana in Central America. A novel lineage detected in the island of Martinique in 1999 exhibited a dramatically different host range and pathogenicity profile. This new lineage, referred to as 4NPB, can infect cucurbits Anthurium and Heliconia spp. and is more aggressive on solanaceous crops than previous variants. We sequenced 500 RSSC strains sampled across Martinique and French Guiana during the emergence of this novel lineage. Pangenome and phylogenetic analyses were performed to identify genomic changes linked with the emergence of the new lineage. This analysis reveals the 4NPB population likely emerged from a population of Moko-causing strains found in association with a tomato host on the mainland, followed by dispersal to Martinique. While 4NPB and Moko-causing strains are closely related, variation in the accessory genome includes the exchange of Type 3 secreted effectors and multiple genes with predicted catalytic activity. Recombination hotspots found between 4NPB and Moko strains include various toxin-antitoxin systems, which are potentially involved in intra-species competition and signaling. These changes may underly the altered pathogenicity and host-range profile of 4NPB, contributing to the dramatic expansion of this lineage across Martinique.

P2.3-024

MORPHOLOGICAL, MOLECULAR AND PATHOGENIC CHARACTERIZATION OF ALTERNARIA SPECIES CAUSING APPLE LEAF AND FRUIT SPOT DISEASE IN CATALONIA (NORTHEASTERN SPAIN)

MORAGREGA Concepció. (1), CAROL Júlia. (1), EL KHATTABI Zohra. (1), LLORENTE Isidre. (1)

(1) UNIVERSITAT DE GIRONA, Girona, SPAIN

Text

Apple tree diseases can cause significant losses in fruit yield and quality. Over the last years, Alternaria leaf and fruit spot disease (ALFS) caused by an *Alternaria* species complex has emerged in Europe.
Since 2013, previously unreported fruit and leaf spot symptoms are being observed in apple tree orchards in Catalonia (Northeastern Spain). Due to its recent detection and particular characteristics, little information is available on the etiology and epidemiology of this disease. This work was aimed at elucidating the etiology of ALFS disease in Catalonia. A morphological, molecular and pathogenic characterization of fungal isolates from apple orchards in Girona province was undertaken.
About one hundred *Alternaria sp*. isolates were recovered from ALFS lesions on apple fruit and leaves. A prevalence of small-spored *Alternaria* species of considerable morphological variation was detected. Isolates from the different *Alternaria* morphotypes were pathogenic on cvs. Golden and Gala apple leaves. Molecular characterization was used to confirm the identity of pathogenic isolates. Results suggest that ALFS disease is present in Northeastern Spain and that a complex of *Alternaria* species belonging to *A. alternata* species group are involved in the disease. Interestingly, *A. mali* was not detected.
This research was supported by Grant PID2021-126505OB-I00 funded by MCIN/AEI/ 10.13039/501100011033 and by “ERDF A way of making Europe” and 2022 FISDU 00051 (Agaur, Generalitat de Catalunya).

Text

Bacterial blast and bacterial canker of almond can affect most parts of the almond tree, including flowers, leaves, trunk, and branches. The plant genus *Prunus* comprises the group of hosts associated with the larger number of polyphyletic pathovars and species within the *Pseudomonas syringae* species complex compared to all other known *P. syringae* host plants. In California, the disease has been mainly attributed to *P. syringae* pv. *syringae*, although few studies have attempted to characterize *Pseudomonas* species affecting almond. In this study, whole genome based phylogenomic and comparative genomics were applied to elucidate the

diversity of almond-associated *P. syringae* species and improve pathogen detection. Of the *Pseudomonas* species isolated from almonds, at least three distinct species including *P. syringae* pv. *syringae*, *P. viridiflava*, and *P. cerasi* were found to cause bacterial blast and/or bacterial canker. Furthermore, genome mining indicated the presence of antibiotic resistance genes, including resistance to copper, tetracycline, and aminoglycoside, the antibiotics commonly used to control these pathogens. *Pseudomonas syringae* pv. *syringae* and *P. cerasi* genomes contained the ice nucleation protein which correlated with their verified ice nucleation ability. Finally, we used bioinformatics tools to design species specific primers for the identified pathogenic species. The general structure of other fluorescent pseudomonads obtained from almonds is also discussed.

Text

The deployment of durable resistances in crops will be decisive to control epidemics of plant pathogens while reducing pesticides use. The quantitative resistance of plants is supposed more durable than the qualitative resistance, but an erosion of this type of resistance has been frequently observed through adaptation of pathogens. It has been the case of new banana hybrids resistant to *Pseudocercospora fijiensis*, a major fungal pathogen of this crop. A more durable deployment strategy would be to combine resistances with specific and antagonistic interactions in order to constrain and limit the adaptation of pathogen populations. To test this hypothesis, we are developing in the pathosystem banana/*P. fijiensis* the following approach. (i) Quantitative traits of interaction between *P. fijiensis* and banana genitors (used for genetic improvement of banana) will be evaluated. (ii) Adaptive architecture of *P. fijiensis* populations to resistance of these genitors will be compare using genome scan approach. (iii) The genotype x genotype interactions between *P. fijiensis* isolates and genitors will be characterized from a cross-inoculation experiment under control conditions. (iv) Then all the data obtained will be used to parameterized a demo-genetic model to find efficient and durable combinations and deployment strategies of resistance. The first results obtained following such an approach will be presented.

COMPARATIVE GENOMIC ANALYSIS OF PSEUDOMONAS SAVASTANOI PV. FRAXINII ISOLATED FROM ASH TREES IN THE UK

HINTON Katherine. (1), RABIEY Mojgan. (1), MCDONALD Megan. (1), BUGGS Richard. (2), JACKSON Robert W. (1)

(1) The University of Birmingham, Birmingham, UNITED KINGDOM; (2) Royal Botanic Gardens, Kew, London, UNITED KINGDOM

Text

Pseudomonas savastanoi pv. fraxinii (*Psf*) causes ash canker and is widespread in the UK. The genetic diversity and variation in virulence of this species is understudied. With the widespread infection of ash dieback, the health of the ash tree population is decreasing. This may alter the *Psf*-ash interaction, leading to loss of the bacterial disease or changes in severity due to a weakened tree immune system. This study aims to establish the genetic diversity of *Psf* in the UK, the impact of disease on the ash microbiome, and the potential for increase in virulence due to progressive tree stress caused by ash dieback. Epiphytic and endophytic populations of *Psf* were isolated from healthy and diseased trees from a range of woodlands in the UK. REP-PCR was used to assess the genetic diversity of collected isolates. A subset was selected for comparative genomics to investigate phylogeny and population structure, using Psf NCPPB 1006 as a reference. Phylogenetic analysis was conducted based on core genome single nucleotide polymorphisms (SNPs), after removal of recombinant regions. The pan-genome will then be characterised, and functionally significant genomic features will be annotated to identify genes with putative involvement in virulence. This information will give insight into the molecular basis of this disease and how the pathogen has evolved within the UK.

P2.3-028

PERILOUS COEXISTENCE: CHILLI LEAF CURL VIRUS AND CANDIDATUS PHYTOPLASMA TRIFOLII INFECTING CAPSICUM ANNUUM, INDIA

PANDEY Vineeta. (1), SRIVASTAVA Aarshi. (1), MALL Smriti. (1), GAUR Rajarshi Kumar. (1)

(1) Deen Dayal Upadhyaya Gorakhpur University, Gorakhpur, Uttar Pradesh, India, Gorakhpur, INDIA

Text

Molecular computing was used to investigate the possible causal agents of chilli crop samples showing mixed symptoms of yellow leaf curl and little leaf type diseases in the Uttar Pradesh, India. Total genomic DNA was extracted from twenty-five samples and amplified by uniplex and duplex PCR using a universal primer pair for begomovirus and phytoplasma. Mixed infection samples show positive amplified products for begomovirus (DNA-A and betasatellite) and phytoplasma (16S rRNA and Sec A). The identified begomovirus was identified as a strain isolate of the previously described Chilli Leaf Curl Virus, which is known to infect *Solanum lycopersicon*, in Oman, whereas the 16S rRNA was identified from the source *Candidatus Phytoplasma trifoli*i, which is known to infect Helichrysum flowering plants in India. Subsequently, molecular computing research based on phylogenetic interweaves, putative recombination, amino acid selection, and genetic diversity were investigated, revealing divergent evolutionary patterns with significant variation and recombination events. The majority of the sequence variations observed in begomovirus and phytoplasma were caused via inter- and intra-specific recombination. These findings could be the first i*n silico* combined infection analysis of ChiLCV and *Ca.P.trifolii* in a chilli crop in India, revealing the potential adaption and evolution of begomovirus and phytoplasma to a new geographic range and crop.

DIVERSITY OF PERONOSCLEROSPORA PHILIPPINENSIS (W. WESTON) C.G. SHAW CAUSING DOWNY MILDEW IN SUGARCANE AND CORN IN THE PHILIPPINES

DELA CUEVA Fe. (1), AGUILAR Ronel. (1), CORTAGA Cris. (1), MICHELMORE Richard. (2), MARTIN Frank. (3)

(1) UNIVERSITY OF THE PHILIPPINES LOS BAÑOS, Los Baños, PHILIPPINES; (2) The Genome Center, University of California, Davis, California, UNITED STATES; (3) USDA-Agricultural Research Station,1636 East Alisal Street, Salinas, California, UNITED STATES

Text

There are four species of Peronosclerospora that cause downy mildew of sugarcane and corn in Asia but Peronosclerospora philippinensis is the most widespread. The pathogen has long been infecting corn and sugarcane in the country but the information regarding its genetic structure and variability is still lacking. In this study, a total of 63 pure isolates were identified and subjected to multi-locus analysis using the partial sequences of three barcoding genes cox2, 28S rRNA, and rps10. Genetic diversity analysis based on concatenated DNA sequences of the three genes (1.3 kbp; n=40) showed a low nucleotide diversity (?) of 0.013, a low average number of nucleotide differences (k) of 1.695, and a moderate haplotype diversity (hd) of 0.604. In the haplotype network and phylogenetic analyses, P. philippinensis population from Cotabato largely formed a separate group from the rest of the PH populations. However, two isolates within the Cotabato populations, and another two isolates from Negros Occidental population formed two independent groups. Overall, the local isolates of P. philippinensis exhibited a low genetic diversity and a rudimentary genetic structure. Furthermore, this study reports the occurrence of two major groups of downy mildew in the country which can have a relevant implication in the management of downy mildew.

Text

Septoria tritici blotch (STB) caused by the hemibiotrophic fungus *Zymoseptoria tritici* is one of the most important foliar diseases of wheat worldwide with yield losses reaching 50% under conducive climate conditions. STB disease control is highly reliant on fungicide application which increases the risk of development of fungicide resistance. Knowledge of pathogen's population structure is important to understand the evolutionary potential of fungicide resistance in *Z. tritici*. To study the influence of fungicide applications on the population structure of *Z. tritici*, 377 pathogen isolates were collected in Denmark, Estonia, France,

Germany, Ireland, Lithuania, Norway, Slovenia, and Sweden in 2019. These isolates were analysed using amplicon based sequenced of housekeeping genes (*actin, BTUB, cal, cyp, EF1, GAPDH, hsp80-1, PKC, TFC1*) supplemented with genes associated with fungicide targets including DMI (*CYP51*), SDHI (*Sdh B*, *C*, and *D*), and QoI (cytochrome *b*). A total of 308 unique genotypes were detected. 274 genotypes were detected only once and were unique to each of the nine populations, while 34 genotypes were reported 2-10 times within the populations from Germany, Denmark, Estonia, Lithuania, Norway, and Ireland. Results of the population structure from the housekeeping genes will be compared to the fungicide resistance gene dataset.

P2.3-031

SPATIAL-TEMPORAL GENETIC DIVERSITY OF NEOSCYTALIDIUM DIMIDIATUM POPULATIONS IN TAIWAN

HONG Cheng-Fang. (1), LIN Yi-Jia. (1), HO Yung-Ching. (1), YE Chung-Yi. (1), LIN Chu-Ping. (2), NI Hui-Fang. (3), WANG Chih-Li. (1), CHUNG Wen-Hsin. (1), HUANG Jenn-Wen. (1)

Text

Neoscytalidium dimidiatum, which causes diseases on several economically important crops, is an emerging plant pathogen worldwide. In this study, 11 simple sequence repeat (SSR) markers were developed to investigate the spatial-temporal genetic structure of *N. dimidiatum* populations in Taiwan. A total of 216 isolates were collected from dragon fruit (*Hylocereus* spp.; n= 205) and Cattleya orchid (n= 11) in 15 Counties/Cities between 2011 and 2021. Eight alien isolates obtained from various hosts were also included, making a total of 224 isolates in the analyses. Among the *N. dimidiatum* populations obtained from dragon fruit (DF) and Cattleya (Ca), 8 and 11 SSR loci were fixed, respectively, and only 2 to 3 alleles were observed in the rest loci. On contrary, only one locus was fixed and 2 to 7 alleles were observed in 10 SSR loci from the alien isolates, suggesting a higher genetic diversity of *N. dimidiatum* populations at the global scale. In addition, 4 and 1 multilocus genotypes (MLG) were identified respectively from the DF and Ca populations whereas all the alien isolates belong to different MLG, again supporting aforementioned observations. Based on the spatial-temporal analyses, a single dominant MLG was identified across space and time in DF populations, suggesting that *N. dimidiatum* may have sustained in Taiwan primarily via asexual reproduction and the DF population may have experienced founder effect, bottleneck effect, or genetic drift in the past.

Text

Watermelon mosaic virus (WMV) is a virus from the genus potyvirus. It is one of the most economically important viral pathogen infecting cucurbits in the world. Several molecular subgroups were reported by Desbiez et al. (2007). The occurrence of WMV in the Czech Republic was first reported by Svoboda (2011) based on ELISA testing. However, no further molecular analyses were done. Currently, and while attempting to update the viral species frequency infecting cucurbits in the Czech Republic, five full-length coding region of WMV isolates were obtained by high throughput sequencing and also by Sanger sequencing (MW188031; OP585149-OP585152) together with 26 more isolates sequenced in the CP coding region. The screening for recombination events in the complete dataset revealed the presence of eighty independent recombination events. The frequency of recombinant WMV isolates reached 96.24%. Therefore, the watermelon mosaic virus showed to have the highest number of recombinants compared to any other potyviruses. Molecular dating analysis suggests that watermelon mosaic virus was originated from northern China at least two thousand years ago, and that the virus moved from non-cucurbit hosts to watermelon one thousand years ago.

Text

In Sub-Saharan Africa (SSA), despite increased potato production, yields have not reached their full potential mainly due to pests and diseases. Late blight caused by *Phytophthora infestans* is a major constraint to profitable potato production in SSA. The genetic structure of *P. infestans* populations is dynamic and new genotypes with different epidemiological characteristics are constantly emerging. To address this challenge, the Feed the Future Global Biotech Potato Partnership has developed biotech potatoes with 3 resistant (*R*) genes to late blight. To evaluate the durability of the 3 R-gene potatoes in SSA, it is important to understand the genetic diversity of *P. infestans* strains in SSA countries. In East Africa, previous work revealed that genotype EU_2A1 dominated *P. infestans* populations. However, little is known about the genetic composition of *P. infestans* populations in West Africa. In this study, samples were collected from infected potato leaves on FTA cards from locations in the main potato growing regions in Kenya and Nigeria in 2022. Nucleic acids (DNA) were extracted from the FTA cards. Genotyping was carried out using standardized multiplex markers (12 SSR markers) and cleaved amplified polymorphisms markers were used to determine mating type. Fungicide sensitivity to metalaxyl-M was carried out on

isolates collected in Kenya. Results from these studies will be presented and will serve as a baseline to inform future deployment of biotech potatoes in SSA.

Text

A new *Emaravirus*, aspen mosaic-associated virus (AsMaV), was identified as the causal agent of the mosaic disease in *Populus tremula*. The genome of AsMaV consists of five negative-sense single-stranded RNA (-ssRNA) molecules. The RNA1 (7.1 kb) encodes for the viral RNA-dependent RNA polymerase (RdRP, 268.2 kDa), RNA2 (2.3 kb), RNA3 (1.6 kb), RNA4 (1.6kb) and RNA5 (1.3kb) encode for the glycoprotein precursor (GPP, 73.5 kDa), viral nucleocapsid protein (N, 35.6 kDa), a putative movement protein (MP, 41.0 kDa) and a protein of unknown function (P28, 28.1 kDa), respectively. Different regions of the virus genome were used to investigate genetic diversity and population genetic parameters. Full-length AsMaV-RNA3, -RNA4, and partial -RNA1 were amplified via RT-PCR with specific primer pairs. Subsequently, the amplicons were investigated by RT-PCR-RFLP and selected variants were subjected to sequencing. The results showed that AsMaV has a conserved genome. However, isolates from Finland and Sweden are belonging to two different phylogenic groups and probably have to be assigned to different populations. AsMaV variants were discriminated better based on RNA3 rather than RNA4 or partial RNA1.

Text

Fusarium head blight (FHB) is an economically important disease on wheat that can result in severe yield losses. In addition, infected grains can accumulate mycotoxins such as the trichothecenes DON, 3ADON, 15ADON and NIV that pose a threat to human and livestock health. F. asiaticum is a major etiological agent of FHB and dominant in Eastern Asian regions including southern China. In order to understand the diversity, population structure

and evolutionary history of F. asiaticum in China, a collection of over 2000 isolates from 127 geographic sites was assembled. Subsequently, we generated a pangenome of F. asiaticum incorporating the 245 high quality F. asiaticum genomes sequences and their phenotypes from selected strains. Population genomic analysis revealed the presence of three distinct opulations. POP1 mainly comprises NIV producing strains from all regions, POP2 is dominated by 3ADON strains from the Yangtze river and Hunan, and POP3 were NIV strains from Sichuan. Ancestral population sizes and populations split time of three populations analyses revealed the evolution of F. asiaticum populations over the last 10,000 years and its correlation with historical documented changes in the crop-rotation system. And POP1(NIV) was the ancestral population. In addition combined analyses of chemotype composition, population structure, spread of spore trajectory and population genomics revealed long-distance (~300 km) migration that was never reported for Fusarium.

Text
Fireblight, a disease of many plant species in the *Rosaceae* family, is caused by *Erwinia amylovora* (*Ea*). Epidemiologically, colonization and infection of blossoms is a crucial stage of the disease. Analysis of the phylogeography and population structure of the species based on minisatellites confirmed presence of high number of diverse haplotypes but also high representation of certain haplotypes during outbreaks (Bühlmann *et al*., 2014). With the aim to ellucidate the basis of the highly abundant *Ea* haplotypes we have selected a number of isolates of both epidemiologically successfull and unscuccessful haplotypes for further characterization. Whole genome sequencing, as well as phenotypic characterization is underway. The preliminary results will be presented

Text
Bacterial leaf spot of cucurbits (BLS) is an emerging disease in the southeastern United States and has also been documented in Serbia. Severe BLS outbreaks, such as were seen in southern Georgia and Florida in the spring of 2013-14, may lead to foliar blighting, reduced yields, delayed fruit maturity, and transplant death, causing significant economic losses for cucurbit growers. Previously believed to be solely caused by Pseudomonas syringae sensu stricto, recent characterization of forty isolates from symptomatic cucurbit foliage from the southeastern U.S. and Serbia has revealed BLS to be associated with multiple Pseudomonas species. Whole genome sequencing, 16S rRNA analysis, average nucleotide identity, and multi-locus sequence analysis were useful in identifying nine Pseudomonas species, spanning three P. syringae phylogroups, as well as four undescribed species outside of the P. syringae species complex. Twelve of forty isolates were identified as P. syringae, twelve as P. alliivorans, nine as P. capsici, one as P. viridiflava, and one as P. lijiangensis. New species were most closely related to P. parafulva, P. corrugata, P. asiatica, and P. cichorii. The discovery and characterization of new causal agents of BLS as well as of new Pseudomonas species may lead to changes in management strategies as well as a greater understanding of the epidemiology of the disease.

P2.3-038

GENETIC DIVERSITY AND VIRULENCE IN A WORLDWIDE COLLECTION OF SUNFLOWER BROOMRAPE (OROBANCHE CUMANA WALLR.) POPULATIONS

(1) Syngenta Spain, Carmona, SPAIN; (2) Syngenta France, Saint Sauveur, FRANCE; (3) Syngenta Argentina, Camet, ARGENTINA

Text
Orobanche cumana Wallr. is a holoparasitic weed that infects roots of sunflower in large areas of Europe and Asia causing serious damages which may reach 90% yield losses. The parasitic interaction between sunflower and *O. cumana* generally follows a gene for gene model, with resistance in sunflower and avirulence in *O. cumana* controlled by dominant alleles at single loci. However, more complex genetic control of resistance has been also reported in some resistance sources. Analysis of genetic diversity of the parasite is important to better understand its evolution and spread. This work presents a study on genetic diversity and population structure, and virulence performed with 78 broomrape populations from Mediterranean and Black Sea areas. Molecular diversity was performed at inter- and intra-population level by genotyping 162 SNP markers on 1700 broomrape individuals. Virulence was evaluated by artificial inoculations in control conditions on eight race differential sunflower genotypes. The present study shed the light on the current distribution, genetic and pathogenic variation in *O. cumana* showing that genetic clusters are associated mostly with the geographical origin of the populations. There are some clusters with relatively high diversity while others present little molecular divergence. Virulence assays showed the presence of races E, F, G and G+ distributed all along the clusters. These results will help to improve resistance breeding and management strategies.

P2.3-039

GENETIC DIVERSITY ANALYSIS OF BROOMRAPE (OROBANCHE CUMANA) POPULATIONS IN SUNFLOWER GROWING AREAS IN EUROPE.

Text

Orobanche cumana or broomrape is an obligate root parasite of sunflower (*Helianthus annuus*) that strongly impacts yield in southern and eastern Europe. The host-parasite system of *O. cumana* and sunflower is characterized by a typical gene-for-gene interaction. The extensive use of sunflower varieties carrying monogenic resistance genes enhanced the selection pressure on the parasite, leading to the emergence of new races. The two most recent races of *Orobanche* that were officially described are referred to as race F and G. This work reviews the results of monitoring broomrape populations in 8 different European countries during the past 10 years. Seeds of *O. cumana* collected in sunflower fields were tested for their virulence on a differential set of sunflower varieties carrying different resistance genes. Race F is still the most predominant in most regions, but in east European countries a wider diversity of races and an increased incidence of the more aggressive race G was observed. The genetic diversity of the isolates was studied using a set of 180 SNPs that allowed to classify them according to their geographic origin and showing higher levels of heterozygosity in eastern Europe populations. These results will be corroborated by more recent GbS data that were obtained for a subset of the collection. All in all, this study provides an overview of the pathogenicity profiles and the molecular diversity of *O. cumana* populations across the major sunflower markets in Europe.

Text

Pyrenophora teres (Pt) f. *teres* (Ptt) and *Pyrenophora teres* f. *maculata* (Ptm) are important fungal pathogens in barley crops, causing substantial economic losses worldwide. France is a major barley producer, but there is a lack of knowledge about the population biology of Pt, making its control challenging. Thus, this work aimed to provide information useful to guide management strategies through the study of Pt population structure. A total of 183 isolates were obtained from nurseries in different barley-producing regions of France. Isolates were characterized using genotyping-by-sequencing, and the analysis of these data showed a

clear differentiation between the two forms of Pt. The most abundant was Ptt (n=177 isolates), the scarcest Ptm (n=3), and three isolates were identified as possible hybrids. The most relevant factor shaping the structure of Ptt was the type of barley, i.e. winter or spring, over geography and barley variety. Furthermore, an analysis using a dataset with samples from Europe, Asia, Africa, and America showed that most of the French isolates cluster independently, but the ones that come from spring barley group with samples from Europe, Asia, and Africa. As a recommendation, special attention should be given to the areas where hybrids are found, as they might have higher virulence. Furthermore, the exchange of barley material with America should be carried out carefully to avoid the introduction of new genotypes.

P2.3-041

POPULATION GENOMIC ANALYSES REVEAL PATTERNS OF HOST SPECIALIZATION AND HYBRIDIZATION IN CERATOCYSTIS FIMBRIATA, C. EUCALYPTICOLA AND C. MANGINECANS

DUONG Tuan A.. (1), HAMMERBACHER Almuth. (2), WINGFIELD Michael J.. (1), SHAW Preston. (1), SEBAPU Lebone. (1), VILJOEN Anien. (1), CHEN Shuaifei. (1,3), CHANG Runlei. (1), LIU Feifei. (1,3), WINGFIELD Brenda D.. (1)

Text

Species of Ceratocystis are important pathogens of forestry and agricultural crops. *C. fimbriata*, the causal agent of black rot of sweet potato, was the first species described in the genus. Two cryptic species closely related to *C. fimbriata*, *C. eucalypticola* and *C. manginecans*, have recently been described causing wilt disease in *Acacia*, *Eucalyptus*, *Mangifera* and *Punica*. Their species boundaries have not been well defined, which has been a source of taxonomic confusion. We sequenced genomes of a large number of isolates of *C. fimbriata*, *C. eucalypticola* and *C. manginecans* from five hosts and 11 counties across five continents. Population genomic analyses revealed three lineages, defined by their patterns of host association. The first lineage included isolates only from sweet potato (member of the Solanales), which represents *C. fimbrita*. The second lineage included isolates infecting *Eucalyptus* and *Punica* (members of the Myrtales), known as *C. eucalytpicola*. The last lineage consisted of isolates infecting *Acacia* and *Mangifera* (members of the Fabales and Sapindales), known as *C. manginecans*. Hybrids of *C. eucalypticola* and *C. manginecans* were identified from regions where they co-occur, but there were no hybrids between *C. fimbriata* and other two species. Overall, our results reveal signatures of host specialization in these fungi. They also provide the basis for our current investigations to identify genomic regions underlining their pathogenicity and host specificity.

P2.3-042

DIVERSITY OF XANTHOMONAS NASTURTII, THE CAUSE OF BLACK ROT OF WATERCRESS

VICENTE Joana. (1,2), ASPIN Andrew. (1), HAYNES Edward. (1), CARTER Brian. (1), BRYNING Adam. (1), COLE Jennifer. (1), CARROLL Sarah. (1), GREER Shannon. (2), GRANT Murray. (2), HARRISON Jamie. (3), STUDHOLME David. (3)

(1) Fera Science Ltd., York, UNITED KINGDOM; (2) University of Warwick, Coventry, UNITED KINGDOM; (3) University of Exeter, Exeter, UNITED KINGDOM

Text

Watercress (*Nasturtium officinale*) is a rapidly growing member of the *Brassicaceae* family that is mainly grown in water beds and is one of the oldest known leaf vegetables. *Xanthomonas nasturtii* causes black rot of watercress, producing lesions around the hydathodes, yellowing and wilting of leaves. This disease was first described in 2017 in samples from Florida, USA, although it has probably been present in crops for much longer. Subsequently, the disease was also found in Hawaii and in Europe, in Spain and Portugal. Isolates were obtained from leaf samples from farms, shop-bought bagged leaves and from seed. Characterisation of isolates was completed using fatty acid profiling, *gyrB* partial gene sequencing and pathogenicity tests. Three watercress accessions were susceptible to all tested isolates, but no symptoms were observed in savoy cabbage.
Whole-genome sequence comparisons showed genetic diversity amongst the isolates, with isolates from Spain being the most diverse. There is some evidence for the presence of genes linked to heavy metal tolerance in some isolates that could be linked to the extensive application of copper based treatments in some farms. Using the genome sequences obtained in this study, we are developing new markers for diagnostics of *X. nasturtii*. Control of the disease is difficult as the bacteria can probably be easily transmitted through water in the water beds. Seed testing should be used to select clean seed lots for each new crop.

Text

Wheat (Triticum spp.) is the most industrially important crop worldwide. In Mexico, the main wheat-producing areas are located in the northwest and center of the country. In these regions, blighted spikes have been observed, causing a loss of commercial quality of the seed due to a typical black lesion at one end of the kernel. Therefore, this study aimed to

identify the causative agents of this symptom through molecular analysis. From 2015 to 2018, 48 spike samples exhibiting this symptomatology were collected on wheat fields in three states of Mexico. From the seeds, 244 isolates were obtained, which were identified via multilocus phylogenetic reconstruction using the entire ITS rDNA region and partial sequences of the lsu, gapdh, and alt a-1 genes. Additionally, the phylogenetic genealogical concordance test calculating the PHI Homoplasia Index (>0.05) recognized new species in the section Alternaria: A. angustiovoidea, A. brassicinae, Alternaria sp., and Alternaria sp. nov. were identified; in the section Infectoriae three new species were described. Additionally, two haplotypes of A. brassicinae and two haplotypes were identified in Alternaria nov. sp. belongs to section Infectoriae. Pathogenicity tests confirmed the disease-causing capacity of all evaluated isolates in the varieties Junco, Cirno, and Borlaug. These results can be used in wheat breeding programs to incorporate resistance into new varieties for Mexico's central wheat-producing regions.

Text
Fusarium musae has recently been described as a cross-kingdom pathogen causing crown rot of banana, a post-harvest disease, keratitis and skin infections as well as systemic infections in immunocompromised patients. To better understand the diversity within strains of the species, the entire genome of 19 *Fusarium musae* strains was obtained through Illumina and Nanopore sequencing assembling short and long reads. The length of the assembled nuclear DNA ranged from 43.04 Mbp to 45.54 Mbp. A similar divergence is shown in mitochondrial DNA ranging from 56493 bp to 59256 bp. Comparative analysis revealed differences in number of secondary metabolites gene clusters (from 41 to 47). A special focus on Enniatin-Beauvericin cluster in *F. musae* identified evolutionary divergences of NPRS gene within the species. Our results are a fundamental step to better investigate phylogenetic relationship within *F. musae* strains with diverse origin and will provide essential knowledge for functional studies of genes involved in the environmental adaptation and in the infection process on humans and banana fruit.

Text
The sudden appearance and rapid spread of pathogen populations can be associated to changes in environmental conditions or to exposures to susceptible hosts (as when introduced to a new geographical region). However, often, these spreads are also associated to genetic changes in the population: mutation or acquisition of new genetic features, that confer the population a fitness advantage. Currently bacterial genomic data is being generated at exponential proportions, and much of it is underexploited. We are developing strategies to integrate methods for genomic analyses in a way that given a set of bacterial genomes and any trait of interest, a user can obtain possible genes or genomic regions associated to said trait. I will show how we have used these startegies to find genes associated to emerging or aggressive bacterial populations. Including how we identifed clusters of genes associated with the emerging *Xanthomonas vasicola* pv. *vasicola* populations infecting corn in South America and the U.S; as well as how we identified candidate genes in *Xanthomonas oryzae* pv. *oryzae* associated to resistance breakdown in field trials.

P2.3-046

POPULATION GENETICS OF TWO INVASIVE FUNGI (CRYPHONECTRIA PARASITICA AND FUSARIUM CIRCINATUM) IN SPAIN

AHMAD Farooq. (1,2), DIEZ CASERO Julio Javier. (1,2)

(1) University of Valladolid, Palencia, SPAIN; (2) Sustainable Forest Management Research Institute, Palencia, SPAIN

Text
Invasive species are known to cause economic as well as ecological damage. Fungal species can invade other territories where they meet naïve hosts and cause diseases or even epidemics. However, why some fungi are successful invaders remains largely unknown, i.e., they become established in a new area while others cannot. One hypothesis is that multiple introductions and sexual reproduction help establish invasive fungi. *Cryphonectria parasitica* and *Fusarium circinatum* are textbook examples of the fungal invasions that were introduced to Europe by accident. These introductions were separated temporally, i.e., *C. parasitica* was introduced almost a century ago, whereas *F. circinatum* is a recently introduced species. We used molecular genetic tools to compare both fungal populations in Spain, considering vegetative compatibility types, mating types and DNA sequencing. We found multiple introduction events of *C. parasitica*, whereas *F. circinatum* was clonal and indicated only one introduction event to Spain. However, we did not find evidence of sexual reproduction in our study area, and it looked like both fungi were still reproducing asexually. Our study also found that quarantine measures are essential to prevent the introduction of new genotypes to an area and to avoid the establishment of invasive species.

Keywords: Population genetics, invasive pathogens, *Fusarium circinatum, Cryphonectria parasitica*

Text

Present study determines the occurrence of anastomosis groups of Rhizoctonia solani on Potato, Tomato, and Chilli with their morpho-molecular characterization. At least 63, 67, and 58 fungal isolates were recovered from potato, tomato, and chilli and identified as R. solani based on nuclear number and morphological characteristics. Restriction analysis of PCR-amplified ribosomal DNA with four discriminant enzymes (MseI, AvaII, HincII, and MunI) revealed recovered isolates belong to; AG-2-1, AG-2-2, AG-3 PT, AG-4 HG I, AG-5, and AG-6. Isolates were further paired with tester strains of R. solani AGs which confirmed the results of AG composition revealed by RFLP analysis. Amplification of ITS region of rDNA with primers ITS1/ITS4 and sequence analysis exhibited 99-100% identity with already reported AGs. Isolates recovered from potato belong to AG-3 PT (76.5%), AG-5 (8.5%), AG-4 HG I (4.2%), AG-2-1 (6.3%), and AG-2-2 (4.2%). AG-3 PT was widely distributed to major potato growing areas while others were confined to distinct locations. Isolates recovered from tomato belong to AG-3 PT (64.2%), AG-2-1 (14.2%), AG-2-2 (9.5%), AG-5 (7.1%), and AG-4-HGI (4.7%). AG-3 PT was widely distributed to major tomato growing areas followed by AG-2-1 while other groups were confined to distinct locations. Similarly, AG-4 HGI (59.4%) was also widely distributed to chilli growing areas. Other AGs recovered from chilli belong to AG-2-1 (16.2%), AG-6 (10.8%), AG-3 PT (8.1%), and AG-5 (5.4%).

Text

There are not many newly discovered viruses infecting agricultural crops in 2023 that are found in ~ 80% of the samples tested; collected across a continent. This is the case of

Blueberry virus L (BlVL), the subject of this presentation. While screening material using high throughput sequencing novel virus-like sequence were identified. Genome sequencing and virus characterization places BlVL in the genus Luteovirus. Luteoviruses encode six or seven proteins including two that are involved in movement. Yet, a small number do not have readily identifiable movement proteins and BlVL belongs to this group, not only based on its genome structure but also its phylogenetic placement. Over 600 samples collected across five US states from both coasts of the continent were screened for BlVL and 79% was found infected. About 300 samples were sequenced and the virus diversity is >18% at the nucleotide level. This is the first luteovirus present in blueberry and its high incidence makes BlVL the most widespread blueberry virus in the USA.

Text

Pectobacterium cacticidum strains can infect cacti and agave. Contrary to the other Pectobacteria, its optimum growth and virulence temperature is much higher (37oC versus 28oC) and exhibits an increased resilience to drought. Since *Pectobacteriaceae* show high potential for environmental spread and adaptation to different hosts, there is a high possibility that a global transmission of this species in an era of climate warming could cause substantial damage to the horticultural and crop industry. It is, therefore, essential to better assess its virulence potential.

We performed whole genome sequencing of five *P. cacticidum* strains. The average genome size was 4.16 MBp, and the GC content of 51%. Genome comparisons with other *Pectobacterium* species yielded 516 unique proteins, most of which were involved in signalling and cellular processes, including quorum sensing mechanism, urea and iron hydroxamate transport, synthesis of rhamnolipids and siderophores. We tested 93 phenotypic characteristics with the BIOLOG system to confirm the activity of the genes present in the genome that can be important contributors to the pathogenicity of this species. We also performed pathogenicity tests to affirm the virulence of the strains. Most of them were virulent towards Opuntia and potato. Based on the genomic data showing that these species differ markedly from other Pectobacteria, we suggest reclassifying *P. cacticidum* into a new genus *Alcornia.*

INTER-CONTINENTAL POPULATION DIFFERENTIATION SPOT FORM OF NET BLOTCH ISOLATES

ELLWOOD Simon. (1)

(1) Curtin University, Bentley, AUSTRALIA

Text
Spot form of net blotch, caused by *P. teres* f. *maculata* (*Ptm*), is a significant necrotrophic fungal disease of barley that spread globally in the 20th century. Genetic relationships were analysed among a geographically diverse collection of 338 isolates from Australia, Southern Africa, North America, Asia Minor and Europe. The results, based on three independent genetic differentiation methods and genome-wide DArTseq data, indicated divergence of *Ptm* populations between continents, although some admixturing was evident. Highest genetic diversity was present among Turkish isolates together with regional sub-structuring. The Australian population was defined by a low genetic diversity; however, genotypic grouping and haplotype data from mutants of *Cyp51A*, which confers insensitivity to triazole fungicides, provided evidence for a recent incursion into Australia, likely involving isolates originating in South Africa.

Text
Fruit, as an important part of people’s diet, provides rich nutrition for human health. However, fungal pathogens frequently cause diseases in fruit during postharvest periods, resulting in huge economic losses. Outcomes of fungal diseases depend on both plant defense responses and fungal pathogenicity. Plant defense responses are highly sophisticated and are generally divided into preformed and induced defense responses. Cell membrane is the first barrier of plant against pathogen infection. Plasma membrane-resided receptor like kinases has also a pivotal role in perceiving and transducing signals into cells to accomplish

defense responses. Our research demonstrate the important roles of cell membrane proteins in disease resistance, immune response, and PCD regulation. Overexpression of tomato SlREM1 increased susceptibility of tomato to Botrytis cinerea, indicating that SlREM1 is a positive regulator of plant cell death and provide clues for understanding the PCD molecular regulatory network in plants. Moreover, we reveal a tomato FERONIA homolog SlFERL involved in immune responses to B. cinerea via a new pattern-triggered immune pathway, that SlFERL recognizes BcPG1 and precisely tuning MAPK signaling. These results provide a new perspective for understanding the molecular mechanism of cell membrane resistance response to fungal pathogens, and are beneficial to giving theoretical guidance for the creation of new technologies of postharvest disease control.

Text

Aspergillus bunch rot is considered one of the most important diseases of grapevines resulting in severe yield losses and, major qualitative deterioration of grape products due to the production of mycotoxins. We investigated, in a two-year field study, the impact of agronomic practices like defoliation to enhance grape microclimate (DF), pruning method to reduce grape bunch density (LBD), and irrigation cut-off (NIR), at three developmental stages of grapevine (Pea size berry, Veraison, and Harvest), on (i) grape composition (TA, pH, and TSS), (ii) on the frequency of occurrence of *Aspergillus* on grape berries and (iii) on the overall composition of grape carposphere microbiome. The density of *Aspergillus* on grape berries was significantly reduced by the applied management practices (DF, LBD, NIR). Amplicon sequencing analysis showed that both the phenological stage and the agronomic practices employed (particularly NIR and DF) imposed significant changes in the α-diversity and β-diversity of the grape carposphere bacterial and fungal communities. The NIR, LBD, and DF treatments which supported lower *Aspergillus* populations, network analysis revealed negative co-occurrence patterns between *Aspergillus* and several bacterial genera (*Streptococcus, Rhodococcus, Melitangium*) reported to have antifungal properties suggesting potential natural attenuation mechanisms for the control of *Aspergillus*.

C2.5-3

THE ASSEMBLY AND DYNAMICS OF THE FRUIT MICROBIOME: WHAT CAN IT TELL US ABOUT BIOLOGICAL CONTROL OF POSTHARVEST DISEASES

DROBY Samir. (1)

(1) ARO, The Volcani Center, Rishon Lezion, ISRAEL

Text

The microbial ecology of fruit associated microbes lags behind that of other plant-associated microbial communities. Determining the host factors that influence fruit surface microbiome assembly and dynamics is crucial to unravel the basic ecological processes involved in the disease process of postharvest pathogens. In our recent studies, we found a greater host effect of fruit stage over genotype in shaping the fruit microbiome structure, characterized by strong community succession. We also see a set of core members that persists throughout the fruit stages and identified some of these members exhibiting differential abundances at specific stages. We demonstrate that the turnover pattern dominates over its antithetic nestedness pattern in driving community succession during the fruit developmental stages and lead to taxonomic homogenization after harvest during storage. We report for the first time, the existence of an underlying universal dynamic model in fruit-associated microbiome assemblies. We provide evidence of microbial cross-domain interactions by showing strong correlations in diversities and community composition and detect some microbe-microbe co-occurrences. Additionally, we show that disease process on harvested fruit is complex and may involve, besides the pathogens, other components of the microbiome.

C2.5-4

IDENTIFICATION OF PUTATIVE NECROTROPHIC EFFECTORS OF MONILINIA SPP. USING A MODIFIED TRV-EXPRESSION VECTOR AS A HIGH-THROUGHPUT INFILTRATION METHODOLOGY

LÓPEZ SANCHEZ-ORTIZ Anselmo. (1), VILANOVA Laura. (1), BEENEN Henriek. (2), VAN KAN Jan. (2), TEIXIDÓ Neus. (1), TORRES Rosario. (1)

(1) Institute of Agrifood Research and Technology (IRTA), Lleida, SPAIN; (2) Laboratory of Phytopathology, Wageningen University, Wageningen, NETHERLANDS

Text

Nowadays, brown rot, caused by the genus *Monilinia* is one of the most important fungal diseases affecting stone fruit. *Monilinia* spp. are necrotrophic plant pathogens, whose life cycle is completed with the gain of nutrients from dead cells through the production of necrotrophic effectors. The recognition of these effectors, which depends on the host genotype, leads to the development of the disease. In this study, we tested the cell death-inducing capacity of 14 putative effector genes, selected by their high expression during plant infection. To test their necrotrophic effect, we used modified *Tobacco Rattle Virus* (TRV) constructs, to express their proteins in host plant tissue by agroinfiltration. Based in our outcomes, this methodology resulted efficient in producing the effector proteins transiently in both *Nicotiana benthamiana* and the non-model plant *Prunus* spp. Our results showed that the effector gene codified as MFRU_030g00190 produced necrosis after infiltration in all *Prunus* genotypes tested, but not in *N. benthamiana*, and two other effectors caused necrosis in both species. Moreover, the *Prunus* individuals codified as 37p15-14 and *Cadaman* seem to be more tolerant to the infiltration; in contrast the 37p15-16 seems to be

quite sensitive to all tested effectors. This procedure could be the basis for genetic analysis of the response generated during the infection and to identify loci in regions that confer susceptibility to the disease in breeding programmes.

C2.5-5

MICROBIOMES: AN IMPORTANT TOOL TO ELUCIDATE THE EPIDEMIOLOGY OF POSTHARVEST PATHOGENS

SPADARO Davide. (1)

(1) University of Torino, Grugliasco, ITALY

Text

Postharvest diseases can be caused by latent pathogens infecting at different phenological phases in orchard. It is of great importance to understand the infection time, in order to intervene with preventive treatments in orchard. Microbiome analysis is a flexible tool to elucidate the epidemiology of plant pathogens. With the introduction of new apple varieties, dry lenticel rot, caused by Ramularia mali, and white haze, associated to Entylomatales and Golubeviales, are emerging. The epidemiology of these pathogens remains unclear. By using metabarcoding, we characterized both epiphytic and endophytic microbiomes of two apple cultivars from early fruit development up to the end of shelf life. R. mali developed in both cultivars as an endophyte at second fruit fall, then white haze symptoms appeared on fruit ripe for picking. This was confirmed in endophytic samples through qPCR specific for R. mali. Among the genera associated to white haze, Golubevia was the most abundant epiphyte from beginning of ripening to the end of shelf life. The analysis of the airborne mycobiome present in the orchard, by using a spore trap in orchard and metabarcoding, permitted to evaluate when fungal pathogen spores are released in orchard: Enylomatales started to occur at the end of the fruit development, whereas R. mali spores were released since flowering. Metabarcoding helps to elucidate the epidemiology of fungal pathogens and to design a targeted crop protection strategy.

Text

Ethylene is a plant hormone that plays important roles in regulating the ripening processes of

fruits. Meanwhile, competitive binding inhibitors, 1-methylcyclopropene (1-MCP), is commonly applied to prevent ethylene perception in the plant for the purpose of delaying or inhibiting the ripening processes, and thus achieving fruit quality preservation. It's noteworthy that ethylene can be also sensed by plant pathogenic fungi to accelerate their infection and disease. However, the molecular mechanisms of responses to ethylene in fungi remain largely unclear. It is also obscure whether 1-MCP can interfere with the recognition of ethylene by pathogenic fungi. In this study, the anthracnose disease pathogen, Colletotrichum gloeosporioides, was investigated via transcriptomic and reverse genetic analysis to reveal that ethylene can cause transcription changes of a large set of genes, which are mainly responsible for appressorium development and virulence expression, and these processes are likely coordinated via GPCRs and MAPK signaling pathways. 1-MCP treatment could inhibit the promoting effect of ethylene on the appressorium development and gene expression. From the perspective of phytopathogenic fungi, this study explores the molecular mechanisms of response to ethylene and the antifungal mechanism of 1-MCP, and provides new ideas for further improving the ethylene-related handlings on harvested fruit crops to reduce the losses caused by fungal diseases.

CITRUS FRUIT POST-HARVEST FUNGAL PATHOGENS AT PAKISTAN'S KHANPUR ORCHARDS

IFTIKHAR Shazia. (1)

(1) Fatima Jinnah Women University, Rawalpindi, Pakistan, Rawalpindi, PAKISTAN

Text

Losses associated with fungal diseases of citrus fruits have been reported in all citrus-growing regions of Pakistan. However, this issue has not been addressed in the Khanpur region. Khanpur is a significant citrus-growing region in Pakistan and significant losses have occurred in this region. Citrus fruits contribute to the income of citrus growers in Pakistan. It is necessary to develop crop management practices to reduce the extent of postharvest losses in citrus fruits. In this study, the fungal pathogens linked to citrus fruit diseases in the orchards of Khanpur were identified, and their pathogenicity was assessed. Fungal isolates were collected from symptomatic citrus fruits from randomly selected orchards within the Khanpur area of production. The fungal isolates, recovered from orchards that were identified morphologically and further confirmed by Internal transcribed spacer (ITS), belong to the genera of Colletotrichum, Alternaria, Aspergillus, Botryosphaeria, Lasiodiplodia, Penicillium, and Fusarium. Research was needed to fully understand the disease development. This knowledge improved the development of management practices to develop cost-effective spray programs. It would also be wise to investigate biological and physical post-harvest management interventions to increase storage and marketability.

USING GENOMICS TO STUDY THE FUNCTION OF THE MICROBIOME IN THE DISEASE PROCESS IN APPLE FRUIT AFTER HARVEST

BARTUV Rotem. (1,2), FREILICH Shiri . (1), DROBY Samir . (1)

(1) Agricultural Research Organization The Volcani Institute, Tel Aviv, ISRAEL; (2) The Robert H. Smith Institute of Plant Sciences and Genetics in Agriculture, Faculty of Agriculture, The Hebrew University of Jerusalem, Rehovot, ISRAEL

Text

The 'pathobiome' concept is highly relevant to the study of postharvest diseases. A shift from native microbiome to a pathobiome occurs during the disease and usually involves transitions in microbial composition leading to pathogen proliferation and disease development. Specific wound-colonizing bacteria taxa may have direct or indirect effects on the development of the disease through positive interactions with the pathogen and taxa that are antagonistic to its function. Genomic data is likely to be the key to deciphering the current "black box" of the trophic exchanges in wound sites. Here, we are representing a set of genome-scale metabolic models of the microbiome based on the recovery of metagenome-assembled genomes to delineate the complex microbial interactions associated with disease progression. 'Golden Delicious' apple fruit-P. expansum pathosystems are using as a model for necrotrophic postharvest disease development. The experimental is based on profiling two wound microbiomes: i. microbiome of uninfected surface wounds; ii. pathobiome of fruits wounds infected with P. expansum. This project aims to construct an in-silico representation of key members of these communities and conduct simulations of the interactions within the two communities. The simulations will predict pathogen-suppressing/enhancing microorganisms and identify the community's metabolic stimulants of positive/negative elements. Experimental systems will validate predictions in-vivo.

Text

Microbes residing on the fruit surface are integral components of the fruit and may play an important role in determining its quality and shelf life. Factors involved in the assemblage of fruit-associated microbial community are just beginning to be studied. In this regard, it has been shown that besides the main drivers like fruit genotype, geographical location and management practices, the microbial assembly and dynamics of the domesticated apple varies greatly between different stages of its development in the field and cold storage after harvest. Additionally, a core taxa was identified persisting across all stages and genotypes tested. This work was designed to explore the effect of application of Aureobasidium sp., one of the core member of the apple microbiome and a known biocontrol agent, applied either as preharvest sprays at different stages starting from the flowering stage or as postharvest

treatment, or both. We present results showing the implications of microbiome disruption on the microbial community structure, assembly and dynamics using culture dependent and high throughput sequencing approaches, consequences on fruit physiological characters and disease status of the fruit at the end of storage. Significant effect on the microbial richness, diversity, temporal dynamics and associations between different taxa were observed in treated fruit in congruent with changes observed in the fruit physiological characters and disease incidence.

P2.5-005

IDENTIFICATION OF FUNGI ASSOCIATED WITH MOULD OF POME FRUIT STEMS AND CALYX SEPALS AFTER CA STORAGE

BLOCK Inge. (1), MEITZ-HOPKINS Julia. (1), **LENNOX Cheryl. (1)**

(1) Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text

Calyx and stem mould is a superficial mould restricted to the pome fruit pedicles and calyx sepals after long-term controlled atmosphere (CA) storage. Markets have reported these moulds on fruit arriving at export destinations. resulting in costly repacking or consignment rejections. This study aims to identify the fungi causing these moulds on stems and calyx sepals of pome fruit. Isolates were collected from symptomatic apple and pear fruit from commercial packhouses in the Western Cape of South Africa. Molecular identification of 100 fungal isolates causing calyx and stem end mould were done using gene areas Alt a 1, OPA1-3 using PCR- RFLP, TEF-1 and RPB2. PCR-RFLP amplification i31 apple isolates classified as A. arborescens and 27 isolates as A. alternata/A. tenuissima. From the 13 pear isolates, five isolates were grouped as A. aborescens and the remaining eight isolates as A. alternata/A. tenuissima. PCR using TEF-1 and RPB2 amplification identified nine isolates as C. cladosporiodes and nine isolates as either Epicoccum nigrum/ layuense. Other fungal genera such as Diplodia, Aureobasidium and Fusarium were also identified, albeit in lower frequencies. In conclusion, a number of fungi were identified as causing stem and calyx mould on pome fruit from CA storage, with the potential for these fungi to occur in complexes, rather than individually. Understanding these complexes and the epidemiology of the members will help in designing appropriate management strategies.

THE IMPORTANCE OF A GOOD RECOVERY OF THE APPLE MICROBIOTA FOR THE ANALYSIS OF ITS MICROBIOME

SÁNCHEZ RUIZ Ana María. (1,2), VILANOVA Laura. (1), OLIVA Jonàs. (2), TORRES Rosario. (1), **TEIXIDÓ Neus. (1)**

(1) IRTA, Lleida, SPAIN; (2) University of Lleida, Lleida, SPAIN

Text

It is essential to know microbiome of apples, one of the most eaten fruits worldwide, in order to understand the interactions of its microbial communities and their effect on pre and postharvest fruit quality. However, the recovery and isolation of these microbial communities from the fruit's surface presents certain challenges due to its low abundance, specially if we compare it with other parts of the plant, such as the rhizosphere. The objective of this study was to identify and establish a reproducible method able to recover the highest possible number of microorganisms from the surface microbiome attached on apple peel. Three different buffer solutions (Tris-EDTA, Tris-EDTA with 2% Tween 80, and Phosphate Buffered Saline (PBS)), three different recovery methodologies (10 minutes of shaking, 20 minutes of shaking, and 20 minutes of shaking plus 5 minutes of sonication) as well as the number of washings needed to extract the largest number of microorganisms possible were evaluated. The results of the investigation showed that the method that recovered the largest number of cultivable microorganisms was the use of two washings with buffer Tris-EDTA with 2% Tween 80 with agitation during 20 minutes at 180 rpm. The present study shows the importance of choosing a good washing method to be able to recover the maximum concentration of microorganisms from the whole surface of apples eliminating possible biases in the results. Financing: PID2020-117607RR-I00

P2.5-007

FUNGAL COMMUNITY DIVERSITY IN CITRUS FRUIT AT DIFFERENT RIPENING STAGE

FU Yanping. (1), ZHAO Ying. (1)

(1) Huazhong Agricultural University, Wuhan, CHINA

Text

Citrus is the most popular fruit around the world. Post harvest decays are often encountered and have great impact on citrus industry. There are diverse fungal communities in citrus fruit under natural conditions. By decoding the sequences of fungal ITS through Illumina MiSeq technologies. the diversity of fungal communities in the rind and flesh of Wanmi No 1 (Citrus reticulata Blanco cv. Ponkan) at the growth, ripening and storage stages was analyzed. A higher degree of fungal diversity was observed in the rind than in the flesh at both the growth and storage stage, on the contrary, the opposite results were found at the ripening stage of citrus fruit. The dominant genera were different at different stage, with Medicopsis and Collectotrichum in the rind at the growth stage, Collectotrichum at the ripening stage, Botrytis, Erythrobasidium and Strelitziana at the storage stage; while in the flesh, Penicillium and Cladosporium accounted for 1/4 of the whole community at the growth stage, Botrytis with more than 50% of the total at the ripening stage, Penicillium and Alternaria accounted for 90% at the storage stage. The population of plant pathogenic fungi Cladosporium, Botrytis, Erysiphe, Penicillium, Alternaria and Fusarium in the rind was larger than in the flesh. The large population of fungi and the change pattern in the flesh suggest that the postharvest fruit decay should be a result of the interaction of fungi.

THE WHITE-COLLAR COMPONENT BCWCL2 REGULATES CITRIC ACID SECRETION TO MAINTAIN REDOX HOMEOSTASIS AND FULL PATHOGENICITY IN BOTRYTIS CINEREA

REN Weiheng. (1), CAI Yunfei. (1), REN Dandan. (1), DENG Zhaohui. (1), ZHANG Ning. (1), WANG Yiwen. (1), **ZHU Pinkuan. (1)**, XU Ling. (1)

(1) East China Normal University, Shanghai, CHINA

Text

Botrytis cinerea, a well-known phytopathogenic fungus, causes gray mold disease in a variety of crops. The pathogenicity of *B. cinerea* depends on a complex network of molecular interactions, which are modulated by various factors such as oxidative stress, metabolic pathways, and morphological changes. In this study, we aimed to investigate the role of the white-collar component BcWCL2 in regulating citric acid secretion to maintain redox homeostasis and full pathogenicity in *B. cinerea*. The results showed that the disruption of BcWCL2 significantly decreased the secretion of citric acid, leading to a reduction in oxidative stress tolerance and pathogenicity. Furthermore, the transcript levels of BcVEL1, BcPacC, transporter Bcin02g07440, pyruvate carboxylase Bcin09g02790, and citrate synthase Bcin02g02750 involved in citric acid metabolism were downregulated in the Δ*bcwcl2* knockout strain. *B. cinerea* produces multicellular appressoria dedicated to plant penetration, named infection cushions (IC). Redox homeostasis regulated by BcWCL2 is critical for IC formation and the early stages of disease. Specifically, These results provide new insights into the molecular mechanisms underlying the pathogenicity of *B. cinerea* and the regulation of citric acid secretion. The discovery of the role of BcWCL2 in maintaining redox homeostasis and full pathogenicity highlights the importance of citric acid metabolism in the pathogenesis of phytopathogenic fungi.

Text

Alternaria postharvest diseases of citrus caused mainly by Alternaria alternata (Fr.) Keissl are a serious worldwide problem leading to significant economic losses. The aim of the present study is to determine the symptomatic, cultural, and pathogenic variability among forty-five Moroccan Alternaria spp. strains based on their hosts. Results showed several disease symptoms on the rind of the infected citrus fruits. Gray and dark-brown to black lesions were produced and developed around the peduncle, end-stem zone, and the surface of the oranges and mandarin fruits whereas other types of lesions spread on lemons surface fruits as dry brown lesions. Symptoms caused by the natural infection of the Alternaria pathogens on mandarins were almost similar, as well as on the lemons fruits. The colony and growth rate characterization of each group of Alternaria spp. on PDA medium revealed clear

and considerable differentiation among isolates. Pathogenicity assays of each isolate were realized on wounded fruits of three commercial varieties, ‘Salustiana’ orange, ‘Ortanique’, and ‘Nadorcott’ mandarins. Findings demonstrate also high significant variations among the isolates in terms of lesion diameter produced on inoculated fruits. The disease severity on ‘Ortanique’ fruits was slightly higher than that observed on fruits of ‘Nadorcott’ and ‘Salustiana’ varieties. In fact, no correlation was found between cultural, pathogenic characters and hosts of the studied Alternaria isolates.

REDUCE THE POST-HARVEST LOSSES IN ORGANIC BEETROOT PRODUCTION

BERNASCONI Alessio. (1), GAMPER CARDINALI Carlo. (1), KOLLER Martin. (2), FLURY Pascale. (3), SCHÄRER Hans-Jakob. (1)

(1) FiBL, Frick, SWITZERLAND; (2) Innoplattform Bio GmbH, Kerzers, SWITZERLAND; (3) University of Basel, Department of Environmental Sciences, Basel, SWITZERLAND

Text
The market for organic agriculture is rapidly growing. In Switzerland, the production of organic Beetroot is particularly renowned. However, their storage until spring has become increasingly difficult in recent years, and losses due to post-harvest rots can lead to over 50 % by March. The causes for the various storage rots in beetroot are currently unclear, and therefore there are few measures to prevent them in organic production. Pathogen infections causing storage rots in beetroot can occur via the seed, in the field, or post-harvest. Understanding the process of infection is, therefore, critical to find preventive solutions. Here, we present the results of a two-year project that aim to reduce post-harvest losses and elucidate the causes of storage rots in organic beetroot production. Analysis of stored beetroot revealed Fusarium and Phoma as predominant pathogens, while Botrytis, Rhizoctonia, and Pythium as additional causative agents of storage rots. Field trials in cooperation with four producers of organic beetroot were performed, where the production from sowing to storage was monitored. Different measures, such as steam sterilization of the seed, the use of biocontrol products in the field and before storage, or processing and cooling methods after harvest, as well as cultivar differences were investigated. The various measures were found to affect seed health, seedling emergence, leaf health, and the quality of beetroot after storage.

Text

Gray mold, also referred to as botrytis fruit rot, is a prevalent postharvest disease that presents a significant threat to a diverse array of fruits and vegetables. The disease is caused by Botrytis cinerea, a fungal pathogen that can infect fruit either during growth or after harvest, ultimately leading to consequential losses in storage, transportation, and marketing. One potential method for managing gray mold is spray-induced gene silencing (SIGS), which utilizes topical dsRNA applications. While SIGS displays considerable potential as an environmentally-friendly and target-specific disease management approach against phytopathogenic fungi, its broad application is hindered by issues regarding the stability, efficacy, and scalability of dsRNA. In the present study, we demonstrated that Escherichia coli-derived anucleated minicells could serve as a scalable and cost-effective platform for dsRNA production and encapsulation. Our research showed that the use of minicell-encapsulated dsRNA (ME-dsRNA) substantially enhanced the stability of dsRNA. ME-dsRNA remained safeguarded from RNase degradation and was stable on strawberry surfaces, making it capable of persisting under field-like conditions. In addition, we found that ME-dsRNAs that targeted chitin synthase class III (Chs3a, Chs3b) and DICER-like proteins (DCL1 and DCL2) genes of Botrytis cinerea selectively silenced the target genes and resulted in substantial fungal growth inhibition in vitro.

C3.3-2

EFFICACY OF ANTAGONISTIC YEASTS IN THE CONTROL OF BROWN ROT OF NECTARINES AND EFFECT ON FRUIT MICROBIOME

REMOLIF Giulia. (1,2), GARELLO Marco. (1,2), SPADARO Davide. (1,2)

(1) Department of Agricultural, Forest and Food Sciences (DISAFA), University of Turin, Grugliasco (To), ITALY; (2) AGROINNOVA - Centre of Competence for the Innovation in the Agro-environmental Sector, Grugliasco (To), ITALY

Text

Monilinia fructicola, the causal agent of brown rot, is one of the most important pathogens affecting nectarines during storage. Current management strategies include preventive treatments with synthetic fungicides, posing technical, environmental and toxicity issues. We aimed to evaluate the efficacy of treatments with antagonistic yeasts to control brown rot of nectarines. A screening trial was set up by treating inoculated fruits with 14 yeast strains. The most effective strains (MS, *Metschnikowia* sp., AP47, *M. fructicola*, FR4A, *Aureobasidium* sp.) were tested in semi-commercial conditions. Fruits were maintained in storage rooms at 1 °C for 28 days, followed by 4 days of shelf-life at 25 °C. After storage, all treatments showed a significant rot reduction compared to the control. The efficacy of MS strain was comparable to

the chemical control treatment, making the antagonist as competitive as fungicides. All strains maintained a significative rot reduction at the end of shelf-life. The evaluation of postharvest quality parameters, including firmness, total soluble solids and titratable acidity showed that none of the three tested yeasts affected nectarine quality. A metabarcoding analysis was conducted to evaluate the effect of the treatments on the microbial population of the nectarines. Results proved that treatments with antagonistic yeasts represents a promising tool for reducing postharvest losses preserving the fruit quality.

C3.3-3

POSTHARVEST DECAY MANAGEMENT OF CITRUS IN THE UNITED STATES WITH CYPROCONAZOLE AND NATAMYCIN, NEW HIGHLY EFFECTIVE CONVENTIONAL AND ORGANIC FUNGICIDES, RESPECTIVELY

ADASKAVEG James. (1), FORSTER Helga. (1), NGUYEN Albert. (1)

(1) University of California, Riverside, Riverside, UNITED STATES

Text

Citrus postharvest decay management is challenging because Penicillium spp., the main postharvest pathogens, are at high risk for fungicide resistance development, few fungicides are effective against sour rot caused by Geotrichum citri-aurantii, and the crop is very susceptible to decay development. The demethylation inhibitor (DMI) cyproconazole was found to have incomplete cross resistance to the DMIs imazalil and propiconazole that are currently registered on citrus in the United States. It was significantly more effective than propiconazole in managing sour rot and more efficacious than imazalil in managing green mold caused by imazalil-resistant isolates of P. digitatum. Mixtures of cyproconazole and propiconazole at half rates were also effective against sour rot and more effective than imazalil to manage imazalil-resistant isolates. Registration of cyproconazole is pending. Packinghouse applications with the polyene natamycin reduced the incidence of sour rot and Penicillium decays to low levels, but for highest decay control, it will be best used in combination with other modes of action. Because the risk for resistance development against natamycin is considered low, its use in mixtures represents an effective anti-resistance measure. With the next-generation DMI cyproconazole and with several formulations of natamycin approved as organic treatments in the United States, a new era in postharvest decay management of citrus is on the horizon.

Improvement Department, Iranian Grape and Raisin Institute, Malayer University, Malayer, IRAN (ISLAMIC REPUBLIC OF)

Text

Reduction of brown rot, caused by *Monilinia fructicola*, is a major challenge in the postharvest storage of fresh Japanese plums (*Prunus salicina* Lindl.), which are highly perishable. The use of plant extracts with antifungal properties could be a sustainable natural alternative to polluting chemical fungicides for brown rot control. An extract obtained from avocado seeds (AVS) was found to completely inhibit the in vitro fungal growth of *M. fructicola*. This extract was then incorporated into composite edible coating matrixes based on hydroxypropyl methylcellulose (HPMC) or Arabic gum (AG) as hydrocolloids and beeswax as lipid. Coated fruits were stored for 5 weeks at 1 °C, followed by 3 days at 7 °C and 5 days of shelf life at 20 °C, simulating cold storage, transportation, and shelf life, respectively. After cold storage, the HPMC-AVS and AG-AVS coatings reduced disease incidence by 30% with respect to uncoated control fruit and disease severity by 50 and 62%, respectively. After shelf life, AG-AVS significantly reduced disease incidence and severity by 13 and 42%, respectively. The coatings also reduced the fruit respiration rate, preserved fruit firmness and alleviated chilling injury symptoms. Additionally, the coatings had no impact on the fruit physicochemical and sensory quality, and AG-AVS improved fruit gloss. These findings show the potential of composite edible coatings incorporating AVS extract to reduce brown rot and preserve plum postharvest quality.

C3.3-5

MANAGEMENT OF BROWN ROT INFECTIONS ON STONE FRUIT USING EPIDEMIOLOGICAL KNOWLEDGE

TORRES Rosario. (1), CASALS Carla. (1), USALL Josep. (1), SEGARRA Joan. (2), DE CAL Antonieta. (3), TEIXIDÓ Neus. (1)

Text

Monilinia spp. is the main pathogen that affects stone fruit causing significant production losses, especially in seasons with favourable climatic conditions for disease development. In the last years, our research has been focused on epidemiological studies of Monilinia spp. in the ‘Valle del Ebro’ (Spain). The epidemiology of this pathogen has been deeply investigated in both under field and postharvest conditions. Studies conducted in the field provided the knowledge to develop a prediction model that define the brown rot epidemic pattern in this area. Likewise, the epidemiology in the packinghouse has shown the importance of the main postharvest handling operations and the influence of temperature and RH on conidia survival to develop the disease. Currently, the standard practices for controlling this disease are conducted by means of spray programs of synthetic fungicides in the field. From the epidemiological model, a practical warning system for fungicide applications in the field has been developed that includes parameters such as: i) fruit susceptibility, ii) the presence of inoculum in the field, and iii) climatological factors. This warning system has been validated for six seasons conducting a total of 38 trials on peach and nectarine crops in the ‘Valle del Ebro’. Our results suggest that the use of the proposed warning system will be an effective tool to control Monilinia spp. in stone fruit and allow a reduction of chemical treatments applied in the field.

C3.3-6

EPIGENETIC CONTROL OF LONG-LASTING DEFENCE PRIMING FOR THE PROTECTION OF FRUIT AGAINST POSTHARVEST DISEASES

STEVENS Katie. (1), ROBERTS Mike. (2), CATONI Marco. (1), **LUNA Estrella. (1)**

(1) University of Birmingham, Birmingham, UNITED KINGDOM; (2) Lancaster University, Lancaster, UNITED KINGDOM

Text

Tomato is a major crop world-wide however its production is heavily limited by Botrytis cinerea. Due to the toxicity of post-harvest pesticide application, alternative control methods such as priming are being investigated. Our work has shown that priming seedlings (2 weeks old) with the chemical β-aminobutyric (BABA) results in long-lasting resistance against B. cinerea in the fruit as well as transgenerational resistance. This work explores how changes in DNA methylation mark long lasting priming in fruit and explores the hypothesis that young plants display a greater epigenetic imprinting capacity. Using whole genome bisulphite sequencing analysis (WGBS), differentially methylated regions (DMRs) specific to the phenotype of long-lasting resistance have been identified. Our results illustrate that BABA treatment impacts CHH context methylation depending on timepoint of application, confirming our hypothesis. Interestingly however, changes in CHH methylation after BABA treatment are not maintained throughout the life of the plant. A transcriptomic analysis on B. cinerea infected fruit BABA treated plants identified differentially expressed genes (DEGs) associated with resistance against B. cinerea. By overlapping our DEGs of interest with our resistance associated DMRs we have identified markers of long-lasting priming in tomato fruit which could serve for targets of durable resistance in other crops.

F3.3-1

COLD AND WILD ENVIRONMENTS: SOURCE OF POTENTIAL BIOCONTROL AGENTS FOR POSTHARVEST FUNGAL DISEASES MANAGEMENT

DI FRANCESCO Alessandra. (1), RUDY Cignola. (1), FIRRAO Giuseppe. (1)

(1) UNIVERSITY OF UDINE, Udine, ITALY

Text

New BCAs (Biocontrol Agents) are urgently needed to reach the ambitious target of reduction of 50% of the pesticide use by 2030. The diversity of the required BCA application promoted the search for strains that best perform in specific environments and conditions, such as the fungal postharvest diseases during the cold storage.
An *Aureobasidium* strain (UC14) isolated from wild environments and sampled during the cold season is under evaluation as an antagonist for postharvest diseases management of stored fruits. According to sequence analysis of ITS, EF1, and ELO, the strain resulted taxonomically distinct from the several concurrently isolated black yeasts that were all identified as *Aurebasidium pullulans*. To verify the effectiveness of the UC14 strain as new BCA to apply during postharvest storage, it was evaluated by *in vitro* (volatile and non-volatile metabolites) and *in vivo* assays against different fungal pathogens (*Monilinia* spp., *Penicillium* spp), and

with several different fruits and storage conditions. Interesting results were obtained by qPCR analysis, that detected the reduction in pathogen abundance on fruit supporting the promise of strain UC14 for postharvest applications.

F3.3-2

CONTROL OF POMEGRANATE POSTHARVEST DISEASES BY IN THE FIELD AND AFTER HARVEST TREATMENTS

MINCUZZI Annamaria. (1), CASETTA Michele. (1), CAPUTO Marika. (1), D'AMBROSIO Pasquale. (1), LEONI Beniamino. (1), IPPOLITO Antonio. (1)

(1) Department of Soil, Plant, and Food Sciences, University of Bari Aldo Moro, Bari, ITALY

Text

In Italy, the demand of fresh/processed pomegranates has recently grown due to the nutraceutical properties. Fruit can be cold stored no more than few months due to fruit rots caused by *Botrytis*, *Alternaria*, *Coniella*, and *Penicillium* fungal genera. The first three genera infect pomegranates during the blooming stage leading to latent infections, instead species belonging to *Penicillium sensu lato* are "wound" pathogens exploiting macro- and microinjuries occurring during harvest and postharvest handling. The scarcity of conventional and alternative fungicides for this minor crop has enhanced the need to find new solutions/strategies for disease control. In the blooming phase, 'Wonderful' plants were treated with low environmental impact compounds: a bio-stimulant made of red algae, a chitosan solution, and two formulations based on *Aureobasidium pullulans* and *Bacillus amyloliquefaciens*. Furthermore, harvested pomegranates with cracking were dipped in ozonated water or in neutral electrolyzed water (NEW) to evaluate the activity of these physical control means against “wound” pathogens. The research disclosed the effectiveness of *B. amyloliquefaciens* and of NEW in reducing postharvest rots due to latent and wound infections, respectively. In pomegranates, the integrated use of low environmental impact products and physical means can represent an ecofriendly alternative to fungicides, fitting into the concept of sustainable agriculture also in organic farming.

P3.3-001

PRE AND POST HARVEST DISEASES OF ONION IS A MAJOR THREAT IN ONION PRODUCTION AND FOOD SECURITY IN BANGLADESH

ISLAM Mohammad Monirul. (1), ALAM Khondoker Mohammad . (1), FARUK Md. Iqbal . (1), KHALEQUZZAMAN K. M. . (1), RAHMAN Md. Matiar . (1)

(1) Bangladesh Agricultural Research Institute, Gazipur, BANGLADESH

Text

In Bangladesh, onion (Allium cepa L.) is generally used as spices and sometimes as vegetables. Area under onion cultivation in the country is 185,000 ha with an annual production of 1954,000 mt and an average yield of 12.34 t/ha. The yield per hectare is very low as

compared to the yield of other onion growing countries. Incidence of pre-harvest diseases like seedling mortality, purple blotch, stemphylium blight, downy mildew and bulb rot is responsible for such low yield. Post-harvest disease may also incur about 30-40% losses in stored bulb. With a view to control both pre and post-harvest diseases a comprehensive study was undertaken, where a series of experiments was conducted for testing some systemic and non-systemic fungicides, botanicals, chemicals and bio-control agents under field conditions and to increase the yield and keeping quality of bulb. Pre-storage bulb curing and improvement of storage methods were tested to control post-harvest diseases. Rovral(Iprodione) and Luna sensation (Fluopyram + Trifloxystrobin) were effective against purple blotch and stemphylium blight, Autostin(Carbendazim) against black mould and Cupravit (Copper) against soft rot. Trichoderma viride and Safeda (botanical) were also effective against black mould. Hydrogen per oxide and low storage temperature (AC room) reduced incidence of black mould and soft rot. Pre-storage bulb curing improved their storage life and keeping quality.

P3.3-002

IMPACT OF UV-C IRRADIATION ON ALTERNARIA LEAF SPOT DEVELOPMENT IN BLUEBERRIES

SCHULENBURG Carl. (1), MALICK Bill. (1), KORSTEN Lise. (1)

(1) University of Protoria, Pretoria, SOUTH AFRICA

Text

Blueberries are regarded as a super food and a crop with the most promising production and commercial prospects worldwide. However, the productivity of blueberry plants is hampered by *Alternaria* spp. causing Alternaria leafspot and fruit rot at the pre-and postharvest stages, respectively. Meanwhile, shortwave ultraviolet (UV-C) light has been successfully used as an alternative treatment to control several pre- and postharvest diseases of fruit. Therefore, this study aimed to investigate the effect of UV-C irradiation as an alternative treatment to prevent Alternaria leaf spot development on artificially inoculated 'Biloxi' and 'Legacy' blueberry leaves. The results of this study indicated that the germination of *A. alternata* spores was inhibited at UV-C dosages between 3.55 and 5.94 kJ/m^2. Furthermore, the findings showed that the UV-C dose of 5.94 kJ/m^2 as a preventative treatment significantly reduced disease severity (lesion diameter) and incidence in artificially inoculated blueberry leaves. This study furnishes evidence that UV-C irradiation at a dosage of 5.94 kJ/m^2 can provide a suitable alternative to the currently adopted commercial Nufarm Azoxy 250 SC applications in preventing Alternaria leaf spot development in ('Biloxi' and 'Legacy') blueberries.

PHYTOPATHOGENS AND POSTHARVEST DISEASE MANAGEMENT: A SUSTAINABLE ALTERNATIVE ANTAGONISTIC YEASTS AS BIOCONTROL AGENTS IN FRUIT

MENSAH Frank Owusu. (1), **FRIMPONG Daniel . (1)**

(1) RURAL EDUCATION AND AGRICULTURE DEVELOPMENT INTERNATIONAL , Kumasi, GHANA

Text
Fruit crop cultivation is a significant component of farmers' agri-horticultural economic activities. Fruit losses from pests and illnesses in the field, storage, transit, and market can account for up to 50% of total production due to a lack of sufficient storage facilities. One reported alternative to the use of synthetic chemical fungicides for controlling postharvest fruit deterioration is biological management employing microbial agents, particularly yeasts. Twenty-nine yeasts were isolated from various sources, and of those, YZ1, YZ7, and YZ27 displayed a wide range of antagonistic activity (mycelial growth inhibition) against the test pathogens in vitro. These isolates' identities as Candida tropicalis YZ1 (CtYZ1), Saccharomyces cerevisiae YZ7 (ScYZ7), and C. tropicalis YZ27 were determined by molecular methods (CtYZ27). When CtYZ1, ScYZ7, and CtYZ27 (1-4108 CFUml1) were applied, the mean lesion diameter of wounds on bananas that had been artificially inoculated with C. musae decreased by 88.7%, 89.3%, and 94.2%, respectively, as opposed to 74.6% in the fungicide-treated fruits (Carbendazim 1.0 g l1) over the control at 4 days. All three yeasts also considerably decreased the latent natural decays brought on by fungi on strawberries, litchis, and bananas. As an alternative to synthetic fungicides, the study's findings could be expanded upon and investigated in the management of post-harvest diseases of fruits.

P3.3-004

POSTHARVEST USE OF NATAMYCIN, A BIOFUNGICIDE TO CONTROL POSTHARVEST DISEASES OF FRESH FRUITS

XIAO Chang-Lin. (1), SAITO Seiya. (1), WANG Fei. (1)

(1) USDA-Agricultural Research Service, Parlier, UNITED STATES

Text
Natamycin is a naturally occurring antimycotic compound. It has been used as an additive in the food industry to reduce the growth of yeasts and molds on certain foods. Natamycin is classified as a biofungicide by the U.S. EPA and has been registered in the U.S. to control postharvest diseases on certain fresh fruits. It has also been certified in 2022 for use on organic fruits. In a series of studies, we evaluated different application technologies to apply natamycin to control postharvest diseases of blueberries, mandarins and table grapes. Natamycin applied either as a spraying or dipping treatment was effective to control gray mold caused by *Botrytis cinerea* and Alternaria rot caused by *Alternaria* spp. on blueberries. On mandarins, natamycin was effective to control *Alternaria* spp. and *B. cinerea*, including those strains that are resistant to other citrus postharvest fungicides as there was no cross resistance between natamycin and other fungicides. Natamycin was effective to control Mucor rot on mandarins caused by *M. piriformis* which is naturally tolerant to most other postharvest fungicides. Natamycin applied as a fog treatment showed as a promising tool to control postharvest diseases of table grapes. Our studies showed that natamycin is an effective tool to control major postharvest diseases of certain fresh fruits and manage fungicide resistance in pathogens such as *B. cinerea* and that it also provides a tool to control postharvest diseases on organic fruits.

P3.3-005

IN VITRO INHIBITION OF FUNGI CAUSING POSTHARVEST GRAY AND BLUE MOLDS ON FRESH HORTICULTURAL PRODUCE BY AGRICULTURAL BY-PRODUCT EXTRACTS

LIMA DE SOUZA Ricardo Felipe. (1), PÉREZ-GAGO María B.. (1), **PALOU Lluís. (1)**

(1) Institut Valencià d'Investigacions Agràries (IVIA), Montcada, SPAIN

Text

Botrytis cinerea (BC) and *Penicillium expansum* (PE), the causal agents of gray and blue molds on several fresh fruits and vegetables, are among the most important postharvest pathogens worldwide. Agricultural by-products can be rich in bioactive compounds, many with antifungal properties. They could be a sustainable alternative to chemical pesticides used to control postharvest fungal diseases. The extraction of value-added compounds from agricultural by-products contributes to circular economy and the EU Green Deal as well. Almond skin (AMS) and avocado seed (AVS) extracts were obtained using ultrasound-assisted extraction and their total phenolic content and total antioxidant capacity were determined. The capacity of extracts to inhibit BC and PE was investigated using a microtiter assay. AVS showed the highest inhibition capacity, with 99% inhibition of both BC and PE, while AMS inhibited BC and PE by 65 and 99%, respectively. The results suggest that the presence of phenols and antioxidants in the extracts may be responsible for the antifungal activity and that these by-product extracts have potential as novel eco-friendly antifungal agents for the management of postharvest diseases. Further in vivo studies are needed to validate these findings.

P3.3-006

GROWTH INHIBITION OF COLLETOTRICHUM MUSAE USING PLANT ESSENTIAL OILS ENCAPSULATED IN METAL ORGANIC FRAMEWORKS NANOPOROUS MATERIALS

ZUNIEGA Johnrell. (1,2,3), GRABULOS Joël . (3), LEBRUN Marc. (3), FARRUSSENG David. (4), BRAT Pierre. (3)

Text

Being highly perishable, ‘Cavendish’ banana fruits are affected by economically important postharvest diseases, like crown rot and anthracnose, which are caused by *Colletotrichum musae*. Fungicide treatment is considered as an effective management strategy however, its repeated applications pose risk to consumers’ health, environment, and even fungal population. The use of plant essential oils (EOs), like thymol and limonene, are extensively studied as an alternative control method due to its antimicrobial properties. In this proof-of-concept study, thymol and limonene were encapsulated in metal organic frameworks (MOFs) nanoporous materials (ZIF-8 and UiO-66) for sustained release that shall limit fungal diseases. An optimized protocol was developed to achieve a high encapsulation efficiency of EOs in

MOFs (EO@MOFs). *In vitro* assays using several concentrations of EO@MOFs were conducted at 14°C and under controlled atmosphere (CA) storage to determine the inhibition capacity against *C. musae*. Encapsulated thymol reduced the growth of *C. musae* better than limonene. Higher concentration of EO@MOFs favorably slowed down the growth of *C. musae* for 11 days at 14°C and CA storage. The data suggest that volatile plant EOs when released from MOFs have the potential to slow down the growth of *C. musae* and may have some utility in banana postharvest disease control.

P3.3-007

POTENTIAL OF ANTAGONISTIC YEASTS, BOTANICALS AND CHEMICALS FOR THE MANAGEMENT OF GREEN MOULD ROT OF KINNOW MANDARIN CAUSED BY PENICILLIUM DIGITATUM

APPUSAMY Aravinthkumar. (1), **RAJ Harender. (1)**

(1) Dr Y. S. Parmar University of Horticulture and Forestry, Solan, INDIA

Text

Post-harvest green mould rot caused by *Penicillium digitatum* is a serious disease in Kinnow mandarin in the northern parts of India. Disease incidence of the post-harvest green mould rot ranged between 14 -27.5 % during 2021-22. Potential of antagonistic yeasts, botanicals and GRAS (Generally Regarded as Safe) chemicals was evaluated against the pathogen first under in vitro conditions and then the effective ones were evaluated for the management of the disease. Different strains of *Saccharomyces cerevisiae* yeast inhibited the mycelial growth of the pathogen by 48.1- 66.6 per cent. Among botanicals, aqueous extracts of *Roylea elegans* (84.81%) was found to be most effective in inhibiting the mycelial growth of the pathogen. In GRAS chemicals, Salicylic acid (0.25 %), resulted in complete inhibition of mycelial growth of the pathogen. Fruit dip with Salicylic acid (0.25 %) was found to be the most effective with complete reduction in disease severity. Fruit dip in yeast isolate *S. cerevisiae* (R) and aqueous extract of *R. elegans* reduced the disease severity by 98.7 and 80.0 %, respectively. However, fruits kept in impregnated wraps with salicylic acid (0.25 %) and aqueous extract of *R. elegans* (10%) reduced the disease severity by 50.0 and 33.3 %, respectively. Yeast treated fruits significantly improved the quality of Kinnow fruits over botanicals and GRAS chemicals with increased levels of titratable acidity, reducing sugar, total solid sugars and ascorbic acid.

P3.3-008

HOT WATER TREATMENT IMPROVES PEACH FRUIT COLD RESISTANCE THROUGH PPHSFA4C-MEDIATED HSF-HSP AND ROS PATHWAYS

ZHAO Liangyi. (1), ZHAO Yaqin. (1), WANG Li. (2)

(1) Nanjing Agricultural University , Nanjing, CHINA; (2) Anhui Agricultural University, Hefei, CHINA

Text

Peach fruit is cold-sensitive and susceptible to chilling injury (CI), and hot water (HW) treatment can reduce their CI. However, the mechanism of HW treatment reduced CI has not been characterized. In this study, HW treatment suppressed the increases in CI index, electrolyte leakage, and malonaldehyde (MDA) content in peach fruit during cold storage. It also decreased reactive oxygen species (ROS) accumulation and increased the activity of ROS-scavenging enzymes. Transcriptome analysis indicated that HW treatment might contribute to the crosstalk between the heat shock factor-heat shock protein (HSF-HSP) and ROS pathways during cold storage. PpHSFA4c was a key transcription factor and could up-regulate defense genes to alleviate the CI of peach fruit during storage. Furthermore, PpHSFA4c could activate the expressions of PpHSP18.5, PpHSP70, PpHSP83, PpAPX1, and PpAPX3 by interacting with their promoters. These studies indicated that HW treatment alleviated the CI, increased antioxidant activity, and maintained ROS homeostasis of peach fruit through the PpHSFA4c-mediated HSF-HSP and ROS pathways. This study provides novel insights into the regulatory mechanisms of HW treatment alleviating CI in postharvest peach fruit, and expands the theoretical basis for commercial application of HW treatment technology to maintain quality and reduce CI in cold-sensitive fruit.

Text

Plant pathogenic fungi are responsible for various diseases affecting agricultural productions both in pre- and post-harvest. With the perspective of reducing environmental pollution and related consequences for human health, nowadays, the research is strongly focused on valorizing waste, especially those largely generated by processing industries. Among these, shrimp waste stands out for their composition, reach in proteins, chitin, calcium and phosphorus, and other substances.

In order to valorize the reuse of waste, this study investigated the in vitro and in vivo antifungal activities of extracts (water-extract, EtOAc-extract, MetOH-extract and nitric-extract) obtained by minimal processing of shrimp waste. In vitro tests were carried out on fungi and oomycetes of the genera *Alternaria*, *Colletotrichum*, *Fusarium*, *Penicillium*, *Plenodomus* and *Phytophthora*, while in vivo tests were conducted on citrus and apple fruit inoculated with *Penicillium* species. The four shrimp extracts were also analyzed by HPLC-ESI-MS-TOF.

Results from the in vitro tests highlighted that the nitric-extract determined, in all the pathogens tested, values of MIC and MFC ranging from 2 to 3.5%; it was also strongly

effective in preventing citrus and apple fruit molds by *Penicillium*. This study could highly contribute to the identification of natural and ecofriendly substances for the control of pre- and post-harvest plant pathogens.

P3.3-010

EFFECT OF SOWING TIME ON DISEASE MANAGEMENT TO INCREASE QUALITY, QUANTITY AND SHELF LIFE OF TOMATO

BANU Salina. (1), ALAM Mohammad. (1), ALAM Khondokar. (1), MOMOTAZ Rumana. (1), ARIFUNNAHAR Mosammat. (1), ARFIN Mosammat. (1), HOSSAIN Mohammad. (1)

(1) Bangladesh Agricultural Research Institute, Gazipur, BANGLADESH

Text

Tomato is one of the important vegetable crop in Bangladesh. Farmers from northern part of Bangladesh identified some economically profitable local varieties for late planting of Tomato. Seedlings were planted at December-January and harvested at April-May. Price of Tomato is higher in May. The optimum sowing and harvesting time of tomato is November and March respectively. This experiment was conducted with three varieties (BARI Tomato 2, BARI Tomato 15 and Dinajpur local) for three sowing time (November, December and January). Incidence of late blight is significantly highest in November sowing for BARI Tomato 15, but no significant difference between varieties in December and January sowing. Incidence of TYLCV is significantly highest for Dinajpur local in January sowing, but no significant difference between varieties in November and December sowing. The harvesting time was March-April for November sowing, April only for December sowing, and April to May for January sowing. Significantly highest fruit yield was obtained in December sowing for all varieties followed by November and January sowing. The Dinajpur local variety showed highest shelf life, firmness, Vitamin C content and soft rot disease tolerance for all sowing dates. Therefore, late sowing of local varieties is a profitable farmer's practice for disease management, quality, quantity and long shelf life of Tomato, and could be a good criterion for varietal development program.

VOLATILE ORGANIC COMPOUNDS ASSOCIATED WITH NEONECTRIA DITISSIMA INFECTION IN APPLES (MALUS PUMILA CV GALA)

YAJI Asoo. (1), COLGAN Richard. (1), HARTE Steven. (1), GOODALL Iain. (2)

(1) Natural Resources Institute, University of Greenwich, Chatham, UNITED KINGDOM; (2) Faculty of Engineering and Science, University of Greenwich, Chatham, UNITED KINGDOM

Text

Post-harvest diseases in apples during long-term storage result in significant amounts (3-10%) of loss. This is mainly caused by fungal pathogens or physiological disorders. The ingress of fungal disease through fruit changes the volatile organic compounds (VOC) profile emitted. This study aimed to identify unique VOCs that can be used as identifiers for fungal infection in

stored apples. Disease-free gala apples were inoculated with *Neonectria ditissima* and sampled weekly. Apples were placed in glass jars, sealed, and incubated at 20°C for 1 hour after which a charcoal-filtered airflow of 1 Lmin-1 was maintained for 1 hour through a Volatile Capture Trap with volatile emissions captured on a porapak-Q absorbent filter. Volatiles were eluted using 1mL of dichloromethane into an Agilent 1.5mL HPLC vial and analysed using Gas Chromatography/Mass Spectrometry. Dodecyl hexanoate and 9-decen-1-yl hexanoate were detected in the early stages of the infection while Styrene, terpinen-4-ol, and 2-methylpentyl formate were detected during decay. The concentration of apple-related volatiles were significantly reduced in diseased apples. Controlled Atmosphere conditions restrict detailed surveys on the incidence of disease spread during storage. Identifying changes in the volatile profile of stored apples in early and later infections may help to provide greater granularity in calibrating the disease progression and help growers make more informed decisions on store management practices.

P3.3-013

CAN ONION STORAGE DISEASES BE DETECTED BY SMELL?

KLEMAN Isabella. (1), BECHER Paul. (1), ROSBERG Anna Karin. (1), GUZHVA Oleksiy. (1), MOGREN Lars. (1)

(1) Swedish University of Agricultural Sciences, Alnarp, SWEDEN

Text

Bulb onion is a vegetable crop that is well suited for post-harvest storage and is often stored up to 8 months. However, a variety of bacterial and fungal diseases can occur during the storage period, causing severe losses. The early development of these diseases may be difficult to detect in storage facilities where large quantities of onions are stored in bins. But onions developing storage diseases give off odors that differ from those of uninfected onions. Deployment of electronic gas sensor arrays, also known as e-noses, could aid in detection of diseases. E-noses for various purposes are commercially available, and can detect the changes in composition of odorant compounds in the air as they develop. To ensure accurate training of these tools, the key odorants that mark the difference between healthy and diseased onions should be identified. To this end, we used solid phase microextraction (SPME) to sample the headspace of uninfected (control) and artificially infected onion bulbs at different time points post infection and analyzed the samples using gas chromatography-mass spectrometry (GC-MS). Both bacterial and fungal pathogens were used. We found differences in the amount of volatiles released between control bulbs and bulbs at different stages of infection. We also found that certain compounds were released only by infected onions.

BIOCONTROL EFFICACY OF WICKERHAMOMYCES ANOMALUS ON TOMATO FIELD DISEASES AND STUDY OF THE RELEVANT MECHANISMS VIA MICROBIOME ANALYSIS

YANG Qiya. (1), ZHANG Hongyin. (1), ZHAO Lina. (1), WANG Kaili. (1), LANHUANG Boen. (1)

(1) Jiangsu University, Zhenjiang, CHINA

Text

Tomatoes are vulnerable to infections by pathogens found in complex field environments. Most infections are triggered by an imbalance between plant growth-promoting microorganisms and pathogens, leading to various tomato rots and high economic losses. This study aimed to test the biocontrol ability of an antagonistic yeast, *Wickerhamomyces anomalus*, towards tomato gray mold disease in the field and explore its relevant mechanisms through microbiome analysis on tomato surface microbial community. The results showed that *W. anomalus* decreased the tomato disease index during the plant growth period, along with changes in the microorganism community composition. *W. anomalus* treatment increased the abundance of some plant growth promotion bacteria, such as *Pantoea* sp. and *Pseudomonas* sp. and biocontrol agents, such as *Golubevia* sp. and *Papiliotrema* sp., and decreased the abundance of some potential pathogens, such as species of *Alternaria*. All these results suggest that *W. anomalus* could control tomato field diseases, and regulating microorganism composition might be a possible mechanism of the yeast.

P3.3-015

BIOCONTROL ABILITY AND ACTION MECHANISM OF AUREOBASIDIUM PULLULANS S2 AGAINST BOTRYTIS CINEREA IN TOMATO FRUIT

ZHANG Hongyin. (1), ZHAO Lina. (1), YANG Qiya. (1), WANG Kaili. (1), SHI Yu. (1)

(1) Jiangsu University, Zhenjiang, CHINA

Text

Gray mold is destructive to the production, transportation, and storage of tomatoes. The application of antagonistic microorganisms to control fruit diseases is a potential alternative to fungicides. This study investigated the effect of *Aureobasidium pullulans* S2 on controlling gray mold in tomatoes and explored the possible mechanisms. The results demonstrated that *A. pullulans* S2 effectively controlled the incidence of gray mold in tomatoes. The response of *Botrytis cinerea* to different components of the *A. pullulans* S2 culture showed that live yeast cells had *B. cinerea* inhibition ability. Host resistance induction, biofilm formation and production of volatile organic compounds (VOCs) with antimicrobial effects could also be important mechanisms of action of *A. pullulans* S2. We identified twelve VOCs; among them, phenylethanol could play a vital role in *B. cinerea* inhibition. These results indicate that *A. pullulans* S2 may be an adequate substitute for fungicides in managing tomato fruit post-harvest diseases.

Text

The most common strategy to avoid post-harvest table grape decay, caused by spoilage fungi such as *B. cinerea* and *A. niger*, is the use of fungicides (preharvest) and of SO_2 generator pads (postharvest). Excessive doses of SO_2 can damage table grapes, causing early browning, berry cracking and fruit injury. Furthermore, SO_2 and fungicide residues on fruit can cause allergies in consumers. Because health authorities also require reducing human and environmental exposure to chemicals, great attention has been recently focused on identifying new Biological Control Agents (BCAs). At CREA-Viticulture and Enology of Turi, 31 different non-*Saccharomyces* yeast were isolated from new table grape genotypes, showing different degrees of tolerance to grey mold. By performing two consecutive in vivo trials, five yeast strains resulted effective to control the grey mold, both when applied at high (10^7 CFU ml-1) and low concentrations (10^5 CFU ml-1). These results we allowed to select them as possible BCAs. The same isolates, applied at low concentrations, were also effective in reducing grape black rot, caused by *A. niger*. In our conditions, the production of soluble enzymes and Volatile Organic Compounds represent the main mechanisms of the antagonistic activity of these yeast strains. Moreover, their inability to lyse red blood cells, make them excellent candidates for the development of new commercial products, which can be used both in organic agriculture and post-harvesting process.

P3.3-017

PHYSICOCHEMICAL PROPERTIES OF PEACH FRUIT ASSESSED BY NON-DESTRUCTIVE METHODOLOGY RELATED TO THE DEVELOPMENT OF MONILINIA FRUCTICOLA DURING POST-HARVEST

ROZWALKA Luciane. (1), **THOMAZI-KLEINA Heloisa. (1)**, ZEVIANI Walmes. (1), BETEMPS Débora. (2), MAY DE MIO Louise Larissa. (1)

Text

The concomitant evaluation of physicochemical properties and development of important diseases, such as brown rot in peaches during post-harvest, is hampered using destructive methods for the physicochemical analysis. This study aimed to evaluate the physicochemical characteristics in wounded and unwounded ‘Chimarrita’ and ‘Maciel’ peaches inoculated with *Monilinia fructicola* assessed by non-destructive methods. Colorimeter, near infrared spectroscopy and portable spectrophotometer DA-meter® were used to evaluate the physicochemical changes that naturally occurred in peaches during post-harvest and due to pathogen development on the same fruit simultaneously. Incidence and severity of brown rot were evaluated at 24, 48 and 60 h post- inoculation. Also, the sporulation of *M. fructicola* on fruit surface was evaluated. Scanning electron microscopy was performed at the 10th d after inoculation. The results indicated that differences between wounded and unwounded fruit

related to soluble solids content (SSC), pulp firmness, titratable acidity, dry matter and IAD index did not affect the incidence of *M. fructicola* in both cultivars. However, *M. fructicola* colonization and consequent lesion size in inoculated wounded 'Chimarrita' fruit was influenced by the interaction between dry matter and color in the inoculation moment. Finally, the pathogen colonization caused the increase of SSC, the reduction of dry matter and titratable acidity and reduction followed by increase of firmness.

P3.3-018

OPTIMIZATION OF TRAGACANTH GUM NANOCAPSULES IMPREGNATED WITH PEPPERMINT ESSENTIAL OIL FOR THE EXTENSION OF SHELF LIFE OF CHILLI PEPPER

ADEOGUN Oluwagbenga. (1,2), MATCHE Rajeshwar. (2)

(1) University of Lagos, Lagos, NIGERIA; (2) CSIR - CENTRAL FOOD TECHNOLOGICAL RESEARCH INSTITUTE, Mysore, INDIA

Text
Chilli pepper fruits' short shelf life necessitates using natural antimicrobials to retain their freshness and extend their shelf life. The impact of peppermint oil-integrated Tragacanth gum nanocapsules on fresh chili pepper fruits was investigated. In this work, the oil sample was analyzed using GC/GC-MS. The nanoencapsulated oil was characterized using selected physicochemical parametres. In addition to the oil's characterization, an in-vitro kinetics study was conducted. The pathogenicity of the fungi isolated from rotten chili pepper fruit was also determined. In addition, the nanoencapsulated oil was employed to evaluate the in-vitro and in-vivo control of anthracnose in the fruits. Fresh chilli pepper fruits were evaluated for quality (pH, electrical conductivity, ascorbic acid, water activity, total phenolic content, antioxidant activity, total soluble solids, respiration, colour, ethylene and browning index) using response surface methodology. The GC/GC-MS analysis revealed that eucalyptol (90.70%) was the most abundant constituent of the peppermint oil. Trichoderrma harzianum, Colletotrichum gloeosporioides, and Aspergillus flavus were isolated from rotten chilli pepper; C. gloeosporioides was proved to be the source of rot in chilli pepper fruits. The nanoencapsulated oil shows that it could be used to control anthracnose disease in chilli pepper fruits, and disparity in the quality assessment indicates the bioactivity of nanoencapsulated peppermint oil.

P3.3-019

EFFICACY OF THE GRAS SALT SODIUM METABISULFITE TO CONTROL CURATIVELY POSTHARVEST FRUIT DECAY

ALLAGUI Mohamed Bechir. (1), BEN AMARA Mouna. (1)

(1) INRAT, Ariana, TUNISIA

Text
The present study evaluate the effectiveness of the GRAS salts, sodium metabisulfite (SMB), ammonium bicarbonate, sodium bicarbonate and potassium dihydrogen orthophosphate

firstly in vitro against the main fungal species of postharvest fruit decay, Alternaria alternata, Botrytis cinerea, Penicillium italicum and Penicillium digitatum. Results showed that SMB at 0.2% inhibited completely mycelium growth of the fungal specie. Ammonium bicarbonate and sodium bicarbonate were less efficient at 0.2 %. The least efficient was potassium dihydrogen orthophosphate with mycelial growth inhibition ranging between 26% to -23% indicating mycelial growth promotion to up 23 %. Experiments were also conducted in in vivo using SMB at concentrations 0.2, 0.5 and 1% preventively and curatively against the most destructive fungus B. cinerea on postharvest apple fruit. Results based on decay length showed that SMB when used as preventive treatment was inefficacy even with the highest concentration. In curative treatment, this salt was highly efficient at 0.5%. Meanwhile, the dose of 1% induced the onset of phytotoxicity observed around the wound in the form of cellular disintegration on the epidermis. To conclude, the appropriate concentration of SMB retained for postharvest treatment is 0.5% used as curative treatment of dipped fruit. Further experiments in semi-commercial trials should be conducted during storage to confirm the effectiveness of SMB. This work was conducted within the framework of the PRIMA StopMedWaste project, which is funded by PRIMA, a programme supported by the European Union.

PLANT VOLATILE ORGANIC COMPOUNDS IN FRUIT PRESERVATION: MICROBIAL INHIBITION, INDUCTIVE DEFENSE AND INNOVATIVE APPLICATIONS

LI Zhenbiao. (1), JIANG Rouwang. (1), XU Yanqun. (1), LUO Zisheng. (1)

(1) Zhejiang University, Hangzhou, CHINA

Text

The postharvest fruit rot caused by diverse pathogens brings severe economic loss to the fresh fruit industry. Conventional chemical preservatives or fungicides are gradually fading away from the interests of both researchers and consumers. Thus, natural products are considered promising substitutes, especially botanical volatile organic compounds (VOCs) with bio-compatibility, accessibility and practicability, which are found versatile in defending against postharvest rot. Based on precise quantification of plant volatiles, we discovered that the plant volatile organic compound (E)-2-hexenal and linalool was the key VOC induced by *Botrytis cinerea* in strawberry and tomato. It is found that VOCs not only directly act on the pathogen but also regulate the defense of fruit with a dose-dependent action pattern. To control the volatility and reactivity of VOC, we created several VOC release control productions. With a cost mentality, we use the cyclodextrin to embed the VOC molecules. We also invented a new kind of sustained VOC release agent by Michael's addition reaction among glutathione and (E)-2-hexenal. This production showed a good environmental responding VOC releasing capability. All of the innovations had sound effects on fruit preservation to control the postharvest disease. These technology innovations in the sustained release of VOCs provided new feasibility in their application in fruit preservation.

P3.3-021

EVALUATION OF CHITOSAN ALONE OR MIXED WITH SODIUM METABISULFITE IN CONTROLLING POSTHARVEST FRUIT DECAY

ALLAGUI Mohamed Bechir. (1), **BEN AMARA Mouna. (1)**

(1) National Institute of Agronomic Researches (INRAT), Ariana, TUNISIA

Text

Fruit decay during postharvest storage is a critical issue that have required efficient biological treatments to reduce waste. In this study, fruit of apple (var. Golden) and of citrus (vars. Maltaise, Thompson and Clementine) were separately inoculated with each of the fungal species Botrytis cinerea, Penicillium italicum and Penicillium digitatum. Results showed that 'Thompson' and to a lesser extend 'Maltaise' were the most sensitive to rots of Penicillium digitatum and Botrytis cinerea. Apple fruit were the least susceptible mainly to Penicillium digitatum. The least pathogenic fungal species was Penicillium italicum whatever the kind of fruit. To reduce decay incidence, aqueous solution of Chitosan (chitoplant at 1%), sodium metabisulfite (at 0.5%) and mixture of both compounds (1% and 0.5% respectively) were applied on 'Maltaise' and 'Golden' inoculated respectively with Penicillium digitatum and Botrytis cinerea. Fruit were disinfected, injured and inoculated with the target pathogen. After 2 h incubation, fruit were dipped for 1 min in the solution already prepared and incubated at room temperature. Results showed that chitosane was slightly effective compared to sodium metabisulfite in decreasing fruit rot diameter. Mixture of both compounds showed a depressive effect compared to each single product.
This work was conducted within the framework of the PRIMA StopMedWaste project, which is funded by PRIMA, a programme supported by the European Union.

Text

High-value trade and favorable climate have encouraged pomegranate cultivation and processing in Italy, where Akko and Wonderful are the most widespread cultivars. In this agro-industrial chain, fungal pathogens are chiefly responsible for product losses. Most of the infections happen in the field during blooming, remaining latent till storage and sale; important losses can be caused also by pathogens getting entrance during harvest and postharvest due to wounds created by "wound" fungi, pests, and abiotic damages. Being a minor crop, conventional and alternative fungicides are scarce, making control of fungal pathogens very difficult. To reduce disease incidence, description of mold symptoms and characterization of fungal etiological agents represent a key-step. Disease incidence of fungal species from symptomatic fruit was assessed according to morphological and molecular features. Main fungal diseases were gray mold, blue mold, black heart, black spot, anthracnose, and dry rot. Results showed latent pathogens as the main cause of rots, being

the most abundant *Alternaria alternata*, *Coniella granati*, and *Botrytis cinerea*. Furthermore, among wound pathogens different species within *Penicillium* and *Talaromyces* genera were recorded. Other genera involved in minor postharvest diseases were *Aspergillus*, *Colletotrichum*, and *Cytospora*. To develop effective control strategies, knowledge of pomegranate fungal pathogens is needed facilitating decision systems to play a leading role.

P3.3-023

EXPLORING THE POTENTIAL OF NATURAL AND SYNTHETIC PHOTOSENSITIZING COMPOUNDS FOR ECO-FRIENDLY MANAGEMENT OF GRAY MOLD IN STRAWBERRIES

RAJAN PREMKUMAR Amos Samkumar. (1), PINKUAN Zhu. (2), SOLHAUG Knut Asbjørn. (1), SUTHAPARAN Aruppillai. (1)

Text

Gray mold is a major menace in fruit crops including cultivable strawberries, caused by cryptic species of fungal pathogen *Botrytis*. Quiescent infection during flowering and fruit ripening resulting in postharvest losses. Persisting usage of fungicides in management of this disease possesses threat to the environment. Photodynamic inactivation of fungi using certain light-absorbing compounds could be an alternative approach. Photosensitizer candidates ranging from compounds of plant origin, food-grade additives, and commercial dyes were screened. These compounds were initially categorized based on its absorption spectra ranging from 250-800 nm wavelengths. The mixture of conidia-photosensitizer candidates was then irradiated with light wavelengths ranges between UV-B (8 µmol/m2/s for 10min) to green, blue, and red (≈120 µmol/m2/s for 30min). Treated samples were inoculated on the surface of potato dextrose agar media and incubated with 18h photoperiod to observe the colony growth, morphology, and intensity over a period of 4 days. Similar experiment was repeated with successful candidates, and germination assays were carried out 6h post-treatment followed by ROS measurement and radical scavenging assays. Preliminary results showed that curcumin, new methylene blue and rose bengal dyes has strong photosensitizing ability in suppressing *B. cinerea* under *in vitro* conditions with blue, red, and green light respectively. The outcomes will be validated further by *in planta* studies.

Text

Nectarines can be affected by many postharvest diseases, leading to production losses. Natural are promising alternatives to pesticides to control storage rots. In this work, the efficacy of biofumigation of essential oils (EOs) through slow-release diffusors was assessed to control postharvest rots of nectarines. A screening test was set up by treating fruits inoculated with *Monilinia fructicola* with EOs of red thyme, fennel, basil, oregano and lemon. Fennel, basil and lemon EOs exhibited the greatest inhibition activity at the end of storage and were selected for setting up a semi-commercial trial, where nectarines were not inoculated. At the end of the storage, all treatments showed a significant rot incidence reduction compared to the control. Quality analyses showed that biofumigation with EOs did non affect nectarine firmness, total soluble solids and titratable acidity. Metabarcoding was used to evaluate the effect of treatments on the nectarine microbiome. The abundance of some fungal genera were modified. Treatments were able to reduce the abundance of *Monilinia* spp. at the epiphytic level, especially in shelf-life. However, basil EO seems to favour the presence of *Penicillium* spp. during shelf-life. Results obtained provide new insights for the development of sustainable strategies for the management of postharvest diseases and the reduction of production losses.

P3.3-025

INHIBITORY ACTIVITY OF COMMERCIAL ESSENTIAL OILS IN VOLATILE PHASE AGAINST BOTRYTIS CINEREA AND MONILINIA LAXA

ÁLVAREZ-GARCÍA Samuel. (1,2), MOUMNI Marwa. (1), **ROMANAZZI Gianfranco. (1)**

(1) Marche Polytechnic University, Ancona, ITALY; (2) Engineering and Agricultural Sciences Department, University of León, León, SPAIN

Text

Gray mold and brown rot, caused by *Botrytis cinerea* and *Monilinia* spp., are postharvest diseases that produce significant losses during fruit and vegetables storage. Natural alternatives to traditional fungicides are being assessed as part of sustainable strategies for postharvest disease control, including the use of volatile organic compounds (VOCs) form plants and microorganisms. In this study, VOC chambers were used to evaluate the antifungal effect of VOCs from commercial essential oils (EOs) of *Melaleuca alternifolia*, *Origanum vulgare*, *Thymus vulgaris*, *Thymus serpyllum*, *Melaleuca alternifolia*, *Lavandula officinalis*, *Lavandula hybrida*, *Citrus bergamia*, *Rosmarinus officinalis*, and *Cinnamomum zeylanicum* against *B. cinerea*, and *M. laxa*. The tested concentration ranged from 2.82 µL/L to 363,64 µL/L, and mycelial growth was measured. Minimum Inhibitory Concentrations (MICs) against *B. cinerea* were 22.73 µL/L for *O. vulgare*, *T. vulgaris*, and *T. serpyllum*; 181.82 µL/L for *M. alternifolia* and *L. officinalis*; and 363.64 µL/L for the rest of EOs. *M. laxa* MICs were 11.36 µL/L for *O. vulgare* and *T. vulgaris*; 22.73 µL/L for *T. serpyllum*; and 181.82 for the other EOs. Overall, *B. cinerea* was less susceptible to the tested EOs than *M. laxa*. Further in vivo research should be conducted to evaluate the potential use of VOCs from these EOs in the control of gray mold and brown rot.

This work was conducted within the framework of the PRIMA StopMedWaste Project

P3.3-026

INTEGRATION OF TRANSCRIPTOMICS AND PROTEOMICS REVEALS THE INHIBITORY EFFECT OF CARVACROL ON POLYSACCHARIDES METABOLISM OF THE CELL WALL IN ALTERNARIA ALTERNATA CAUSING GOJI FRUIT ROT

WANG Junjie. (1), ZHAO Lunaike. (1), ZHANG Huaiyu. (1), ZHOU Yueli. (1)

(1) North Minzu University, Yinchuan, CHINA

Text

Previous studies showed that carvacrol (CVR) significantly inhibited the mycelial growth of *A. alternata* in vitro and reduced Alternaria rot in goji fruits in vivo. However, the antifungal mechanism of CVR against *A. alternata* has not been elucidated. The present study aimed to explore the antifungal mechanism of CVR against *A. alternata* using RNA-seq and 4D-DIA protein quantification methods. The results showed that most genes and proteins of differential expression were largely matched to carbohydrate metabolites. Further investigation found that the contents of cell wall polysaccharides containing chitin and β-1,3-glucan and the activities of the enzymes related to the biosynthesis of these polysaccharides were significantly decreased by CVR treatment, while the activities of chitinase and the β-1,3-glucanase of degrading the two polysaccharides were increased by CVR treatment. Proteomics and transcriptomics together indicated that changes in cell wall polysaccharides metabolism were associated with the expressions of genes and proteins related to β-1,3-glucan, chitin, mannose, and trehalose. Meanwhile, CVR fumigation accelerates the conversion of ethanol to acetaldehyde by up-regulation of the expression of alcohol dehydrogenase, resulting in the accumulation of acetaldehyde which caused toxicity to the pathogenic fungi. In summary, this research explained the general molecular mechanism of the changes of the cell wall polysaccharides in *A.alterntata* in response to CVR.

P3.3-027

STRATEGIES TO OVERCOME STEM END ROT DISEASE IN PAKISTAN MANGOES, A MAJOR THREAT IN EXPORT MARKETS.

REHMAN Abdul. (1), WAQAR Alam. (2), HAMEED Akhtar. (4), MUHMAMMAD Amin. (3)

Text

Stem end rot (SER) a post-harvest disease poses a major threat to mango industry in Pakistan. Efforts were made to understand the infection process of the pathogens involved under Pakistani growing conditions. Fully matured mango fruit cultivar Sindhri were stored in cold storage (12 oC) and at ambient storage (32 oC). After removal of fruits different fungal pathogens were (Lasiodiplodia theobromae, Alternaria alternata, Phomopsis mangifera, Colletotrichum gloeosporioides) were recovered from rotted and decayed mango fruit. On inoculation on healthy fruit L. theobromae produce the largest lesion (63.6 mm) in ambient storage whereas in cold storage again produce largest lesion (44.5 mm). The pathogens are

present as endophytic in developed stems and colonize fruit endophytically through extension of hyphae. Pakistani mango industry is facing a great challenge in post-harvest disease management of mango fruit. For the management of SER fungal pathogens six different fungicides Prochloraz, native, Scholar, Cabrio Top, Tecto®, and Amistar® were evaluated at five different concentrations. Maximum disease inhibition was observed at higher concentrations. When healthy mango fruit was treated with different concentration of Nativo® and cabio Top®, significant disease reduction was observed. In addition to fungicides, plant extracts like Syzygium aromaticum and Moringa oleifera were applied at different concentration of mature healthy mango fruits.

GENOME-SCALE PHYLOGENETIC AND SYNTENIC ANALYSES REVEAL RELATIONSHIP AMONG MONILINIA FRUCTICOLA, MONILINIA LAXA AND MONILINIA FRUCTIGENA WITHIN SCLEROTINIACEAE

DE MICCOLIS ANGELINI Rita Milvia. (2), LANDI Lucia. (1), RAGUSEO Celeste. (2), POLLASTRO Stefania. (2), FARETRA Francesco. (2), **ROMANAZZI Gianfranco. (1)**

(1) Marche Polytechnic University, Ancona, ITALY; (2) University of Bari 'Aldo Moro', Bari, ITALY

Text

The most important fungi causing brown rot and blossom blight on fruit trees are *Monilinia laxa*, *Monilinia fructigena* and *Monilinia fructicola*. They are Ascomycetes included in the *Sclerotiniaceae* family, causing worldwide severe losses on stone and pome fruits production in pre and postharvest. The complete draft genomes of *M. fructicola* strain Mfrc123, *M. laxa* strain Mlax316, and *M. fructigena* strain Mfrg269 have been investigated to clarify the evolutionary history of the *Monilinia* genus within *Sclerotiniaceae*. Phylogenomic analyses suggest *M. fructicola* genetically distant from *M. laxa* and *M. fructigena*, although the three species likely share a common ancestor. *Botrytis* and *Sclerotinia* were the closest related taxa to the *Monilinia* genus in the *Junctoriae* section, and all were in a monophyletic lineage strictly related to *Rustroemiaceae*. The syntenic studies confirm the close relationship among the three *Monilinia* genomes and, even though minor, with *Botrytis cinerea* and *Sclerotinia sclerotiorum* species. The coding sequence divergence (measured by Ks values) confirmed that *M. laxa* and *M. fructigena* are phylogenetically closely related each other, while *M. fructicola* is somewhat divergent. The three *Monilinia* genomes were genetically closer to those of *Sclerotinia sclerotiorum* than *Botrytis cinerea*, and *M. laxa* was the closest to the other tested fungi of the *Sclerotiniaceae* family.

CHITOSAN AND OTHER EDIBLE COATINGS TO EXTEND SHELF LIFE, MANAGE POSTHARVEST DECAY, AND REDUCE LOSS AND WASTE OF FRESH FRUITS AND VEGETABLES

ROMANAZZI Gianfranco. (1), MOUMNI Marwa. (1)

(1) Marche Polytechnic University, Ancona, ITALY

Text
Fresh fruits and vegetables contain high percentage of water and continue metabolic activity after being harvested, resulting in ripening, increased sensitivity to decay-causing fungi, and consequent loss and waste. Edible coatings are prepared from naturally occurring renewable sources and can contribute to reducing waste, respecting environment, and consumer health. Chitosan and other edible coatings (such as shellac, carboxymethyl cellulose, hydroxypropyl methylcellulose, bee wax, and glycerol) form a thin layer surrounding fresh produce that acts as a protective agent, extending shelf life, and have the potential to control their ripening process and maintain nutritional properties of the coated product. Chitosan and other edible coatings can have antimicrobial, film-forming and eliciting activities, that additively or synergistically prevent fungal decay, keep the quality, and reduce fresh product waste.

This work was conducted within the framework of the PRIMA StopMedWaste Project

Text
The in vitro antifungal activity of different natural extracts and essential oils against Monilinia fructicola, the causal agent of brown rot of stone fruits, was evaluated as mycelial growth reduction on amended PDA plates. The most effective agents [lemongrass (LG), geraniol (GE), and Commiphora myrrha (MY)] were selected as antifungal ingredients of composite edible coatings (ECs) formulated with citrus pectin and beeswax. ECs were applied in in vivo curative experiments to 'Lucibella' nectarines artificially inoculated about 24 h before with M. fructicola. The EC with 0.2% GE was the most effective, with disease incidence reductions of 80 and 55% after 3 and 4 weeks of storage at 1 °C and 90% RH, respectively. Furthermore, this GE-EC reduced brown rot severity by up to 93% after 3 weeks. The LG-EC (0.4%) also reduced disease severity by 77% after 3 weeks. Regarding fruit quality, all tested ECs

significantly reduced fruit weight loss and maintained higher firmness than control nectarines after 4 weeks at 1 °C plus 3 days at 20 °C, without adversely affecting the fruit physicochemical (titratable acidity, soluble solids content, and volatiles content) and sensory (overall flavor, off-flavors, firmness, and external aspect) quality. Moreover, the MY-EC provided higher gloss than the rest of ECs. These results can contribute to the development of new safe and eco-friendly commercial antifungal ECs to control major diseases and preserve postharvest quality of stone fruits.

Text

Guava (Psidium guajava) is a tropical fruit that is widely cultivated in many parts of the world, particularly in India, Brazil, Mexico, and Southeast Asia. It is rich source of nutrients with various health benefits. Guava is susceptible to range of pathogen that can affect its growth, yield and quality. One of the most common and devastating diseases of guava is anthracnose cause by colletotrichum gloeosporioides. The goal of the current research was to check the efficacy of synthetic fungicides and medicinal plants extract against Guava anthracnose. For this purpose five synthetic fungicides (Chlorothalonil, Mancozeb, Thiophanate-methyl, Azoxystrobin and Difenoconazole) at three concentrations (100, 200, 300 ppm) and five medicinal plants extract (Ocimum sanctum, Datura stramonium, Curcuma longa L, Piper nigrum and Azadirachta indica) at 5, 10, 15% concentrations were evaluated under in vitro conditions using poisoned food technique. Results revealed that among synthetic fungicides difenoconazole was found highly effective with least mycelial growth (8.75mm) followed by Mancozeb, Azoxystrobin, Thiophanate-methyl and Chlorothalonil, while among medicinal plants maximum growth inhibition was recorded by Piper nigrum (13.45mm) at highest 15% concentration followed by Curcuma longa L, Azadirachta indica, Datura stramonium, Ocimum sanctum. The findings of our study suggested that botanical extracts and fungicides could be efficiently used against anthracnose of guava.

Text
Postharvest losses of fruit, vegetables, and aromatic plants have high economic impact in the Mediterranean area and contribute to food waste. One of the United Nations Priorities, the ZeroHunger Challenge, consists of cutting food waste by half by 2030. StopMedWaste Project (2020-2024) see the interaction of 8 Research Units (UNIVPM, CUT, UNIBA, INRAT, UNITO, UE, IVIA, IKACHEM and DECCO) to join efforts to extend the shelf life of fresh fruit, vegetables, and aromatic plants by applying physical means, natural compounds and biocontrol agents. These treatments are being applied in the laboratory, under semi-commercial conditions, and in the packinghouses. The effects of these treatments on fruit quality, decay, and development of foodborne pathogens are under monitoring during storage, transportation and shelf life, to define their impact on food waste. Results achieved till now showed the beneficial effects of treatment with physical means (ozone, electrolysed water, UVc), natural compounds (chitosan, essential oils, bicarbonates and other antifungal edible coatings), and biocontrol agents in improving the quality of fresh fruit (citrus, pomegranates, peaches, nectarines, apricots, plums, sweet cherries, strawberries, table grapes), vegetables (tomatoes, cucumbers) and aromatic plants (spearmint, basil), that allowed to keep quality and reduce decay, and then waste.
This work was conducted within the framework of the PRIMA StopMedWaste Project

Text
Stone fruits are susceptible to postharvest diseases caused by fungal pathogens able to cause losses and waste. The main pathogens of these crops are *Monilinia* spp., which cause brown rot. The effectiveness of different formulations based on natural compounds and biocontrol agents to manage brown rot on peach fruits (cvs +5Tardibelle and Extreme 486) and nectarines (cv Carene) were evaluated. Commercial formulations of chitosan, sweet orange essential oil, *Bacillus subtilis*, *Bacillus amyloliquefacens*, *Metschnikowia fructicola*, *Aureobasidium pullulans*, COS-OGA, a mixture of thymol, geraniol and eugenol, *Swinglea glutinosa* extract and nettle extract were applied by dipping fruit, using as a reference a synthetic fungicide (fludioxonil) and an untreated control. Fruits were immersed for 30

seconds in the solutions, stored at 2°C for 7-14 days and exposed to shelf life for 10 days. A significant reduction of disease incidence was observed in fruits treated with fludioxonil in all trials. Among alternative compounds, tendency toward disease reduction on +5Tardibelle was observed with application of chitosan and of *B. subtilis*, and on Extreme 486 with application of *Aureobasidium pullulans*. These results suggest that the use of alternative compounds requires a careful evaluation of applicative conditions for different cultivars, and proper application protocols need to be evaluated.

This work was conducted within the framework of the PRIMA StopMedWaste Project

P3.3-034

IN VITRO ANTIMICROBIAL ACTIVITY OF CHITOSAN HYDROCHLORIDE AND COS (CHITO-OLIGOSACCHARIDES)-OGA (OLIGO-GALACTURONIDES) ON FIELD AND POSTHARVEST FUNGAL PATHOGENS

MAKAU Sarah. (1), TUNC Mediye. (1), MOUMNI Marwa. (1), LANDI Lucia. (1), **ROMANAZZI Gianfranco. (1)**

(1) Marche Polytechnic University, Ancona, ITALY

Text

Postharvest infections of fresh produce can cause major economic losses and food insecurity. Synthetic pesticides used in the management of fungi can have detrimental impacts on the environment, then sustainable innovative strategies are required. The use of natural compounds such as chitosan, a natural biodegradable biopolymer, in plant protection is promoted. In this study, in vitro antifungal activity of chitosan hydrochloride (CH; 100%) and COS (chito-oligosaccharides)-OGA (oligo-galacturonides (COS-OGA; 1.25%) was evaluated by monitoring mycelial growth of *Alternaria alternata*, *A. brassicicola*, *Botrytis cinerea*, *Monilinia laxa*, *M. fructigena*, and *M. fructicola*. A list of concentrations of CH and COS-OGA was prepared in PDA. The inhibition increased with the concentration for both formulations, and a different degree of sensitivity was observed. The most sensitive pathogen was *M. fructigena*, that was completely inhibited in the growth at the 0.5%. A continuous decreasing sensitivity to both chitosan formulations was observed by *M. laxa*, *M. fructicola*, *A. alternata*, *B. cinerea* and *A. brassicicola*. At the same concentrations, COS-OGA showed an antimicrobial activity slightly lower than CH. Our results demonstrated antimicrobial efficacy of these compounds and their potential use as innovative sustainable compounds in plant protection. In vivo studies are required to confirm in vitro results.

P3.3-035

PHYSIOLOGICAL CHANGES INDUCED AFTER OZONE TREATMENT ON PEACH FRUITS

LANDI Lucia. (1), D'ORTENZIO Lucrezia. (1), PIANCATELLI Simone. (1), **ROMANAZZI Gianfranco. (1)**

(1) Marche Polytechnic University, Ancona, ITALY

Text
The conservation of high-quality standards for prolonging the shelf life of fruit is a priority for horticultural products. Ozone has been suggested to be an environmentally-friendly method for postharvest storage of fruits, and the effects of ozone on their physiology need to be clarified. This study investigated the effects of postharvest treatment with ozone on peach fruits (*Prunus persica* L.), cultivars 'Summer Royal' and 'Extreme 486' grown in orchards in Marche region (Central-Eastern Italy) in 2020 and 2021. The peach fruits after harvest were stored at 4 °C with or without ozone treatment (45 ppb continuously in 2020 year, and in alternating between 50 and 200 during the day and night in 2021 year) for 10 and 20 days. After treatments the peach samples were collected after 0, 24, 48, 72, 96 and 168 hours of shelf life. The expression of selected target genes involved in signalling pathways regulating plant defence, pathogenesis-related protein, cell wall-degrading enzymes, oxidative and abiotic stress, phenylpropanoid pathway and fruits ripening were assessed by real-time quantitative polymerase chain reaction (RT-qPCR). The result suggests the ozone treatments affects the fruit physiology mainly involved on ripening process and oxidative stress. This study represents a useful approach to understanding molecular basis of peach physiology change induced by ozone treatment.
This work was conducted within the framework of the PRIMA StopMedWaste Project

P3.3-036

EFFECTS OF OZONE EXPOSURE ON BROWN ROT OF PEACH FRUITS IN COLD STORAGE

D'ORTENZIO Lucrezia. (1), MAKAU Sarah Mojela. (1), MUROLO Sergio. (1), LANDI Lucia. (1), **ROMANAZZI Gianfranco. (1)**

Text
Pre and postharvest losses caused by fungal decay affect fresh fruit production globally. Stone fruits are susceptible to brown rot caused by *Monilinia* spp. We evaluated the effects of two sprayers (traditional and innovative with flow control) for preharvest treatments, and postharvest application of gaseous ozone in storage temperature for the control of brown rot. The experiment was carried out in Marche Region, Central-Eastern Italy, on peach cv Royal Summer and Extreme 486, sprayed with fungicides (tebuconazole in 2019 and 2020 and boscalid+pyraclostrobin in 2021) in the field. Immediately after harvest, fruits were stored at 4 °C with or without ozone treatment (45-50 ppb and 200 ppb during the day and night, respectively) for 10, 20 and 25 days. Fruits were removed from cold storage, transferred at 20 °C and decay was measured daily during 10 days shelf life. Concentration of 200 ppm used during the night on cv Extreme 486 induced slight phytotoxic effects on fruits. There were no significant differences between the two sprayers tested for preharvest treatment. Ozone treatment at 50 ppb day/200 ppb night was effective in controlling *Monilinia* spp. The application of ozone can contribute to the management of postharvest diseases of peaches. Further research on different cultivars and ripening stage should be conducted to determine an appropriate concentration of ozone for storage of peaches.
This work was conducted within the framework of the PRIMA StopMedWaste Project

P3.3-037

IN VITRO AND IN VIVO EFFECT OF NATURAL SALTS TO CONTROL POSTHARVEST CITRUS GREEN MOLD DISEASE CAUSED BY PENICILLIUM DIGITATUM IN MOROCCO

HAMRANI Meriem. (1,2,3), ZELMAT Lamyaa. (2), BRHADDA Najiba. (1), AARROUF Jawad. (3), ZIRI Rabea. (1), EL GUILLI Mohammed. (2)

Text

The green mold caused by the wound pathogen *Penicillium digitatum* causes more severe post-harvest citrus damage with significant economic impact.The present study aimed to evaluate the *in vitro* and *in vivo* antifungal activity of certain salts, including potassium sorbate, sodium benzoate, sodium tetraborate and sodium bicarbonate against P. digitatum. In vitro, the PDA medium was supplemented with salt solutions to obtain the final concentrations of 0, 500, 1000, 1500 and 2000ppm before inoculation. The in vivo tests were carried out by inoculating the fruits before or after treatment with salts. The fruits were therefore immersed in saline solutions of 0,2% or 4% for 2min. *In vitro* results showed that potassium sorbate reduced mycelial growth of *P. digitatum* by 71% at 500 ppm, with an IC50 = 2.75 ppm. Complete inhibition of *P. digitatum* was observed with sodium bicarbonate and sodium tetraborate at 1000ppm. The *in vivo* curative treatment showed significant antifungal activity of all the salts tested. However, potassium sorbate and sodium benzoate completely inhibited the development of green mold on ‘Valencia late’ oranges at 2% concentration. This is an efficacy similar to that obtained by the conventional fungicide "Imazalil" used as a positive control. For preventive treatment, sodium tetraborate and sodium benzoate inhibited the development of *P. digitatum* by 67 and 79% respectively at the concentration of 4%.

Text

Tropical fruits are traded worldwide with Latin America as a major global exporting force and Europe and Asia as giant and growing import markets. However, postharvest diseases caused by fungi (e.g. crown rot in bananas) represent important losses for exporters along

the commercialization chain. At present, these problems are mainly treated by the postharvest use of traditional (rather toxic) fungicides that are increasingly restricted in major international markets. We have developed starch-based water-soluble coatings that generate a systemic response in fruits by regulating fruit's respiration process and the incorporation of antifungal agents. Formulations with a reduction of traditional fungicides and with bio-based antifungal agents were tested in vitro and in vivo with the two main strains causing banana crown rot: Fusarium sp and Colletotrichum sp. The in vitro evaluation for the coatings with 60% reduction of traditional fungicide resulted in an antifungal effect equal to the traditional treatment; while bio-based agent formulation achieved a colony-forming units inhibition around 70% for each strain. For the in vivo evaluation, bananas were stored for 20 days at 15°C and 90% RH, matching with typical shipping conditions. Afterward, destructive and non-destructive tests were applied to banana clusters. In all formulations, a reduction of crown rot was observed, and the ripening process was slowed.

POST-HARVEST - Part 3: Eco-epidemiological perspectives generating new concepts on postharvest diseases and mycotoxins

ONE SMALL MOLECULE WITH BIG BIOLOGICAL IMPACTS: NEW ROLES FOR PATULIN IN HOST-MICROBEPLANT INTERACTIONS DURING BLUE MOLD DECAY OF APPLE FRUIT

JURICK II Wayne. (1), BARTHOLOMEW Holly. (1)

(1) USDA, Beltsvile, UNITED STATES

Text

Patulin, a mycotoxin produced by Penicillium spp. during postharvest pome fruit decay, causes acute and chronic effects in humans, withstands pasteurization, and is not eliminated by fermentation. While much is known about the impact of patulin on human health, there are significant knowledge gaps concerning the effect of patulin in postharvest fruit-pathogen-microbe interactions. Inoculation of six apple cultivars with purified patulin reproduced some blue mold symptoms which were cultivar-independent and dose-dependent. Identical symptoms were also observed in pears, Arabidopsis, and mandarins showing the toxin is non-host specific. Six Penicillium spp. isolates exposed to exogenous patulin exhibited delayed germination after 24 hours, yet all produced viable colonies after 7 days. However, four common postharvest fungal pathogens were completely inhibited by patulin, suggesting its role to allow the blue mold fungus to dominate the postharvest infection court. Using clorgyline, a broad-spectrum pump inhibitor, it was demonstrated that active efflux plays a role in Penicillium auto-resistance to patulin. The work presented contributes new knowledge concerning patulin auto-resistance in Penicillium, its function in the decay process, and the toxins exclusionary role in fungal-fungal interactions. Our findings provide seminal work to

explore the mechanisms of patulin action with the long term aim of developing toxin and decay mitigation strategies.

C4.6-2

PREHARVEST FACTORS ASSOCIATED WITH GRAY MOLD DEVELOPMENT IN EUROPEAN PEARS

KC Achala. (1), HERNANDEZ Monica. (1)

(1) Oregon State University, Central Point, UNITED STATES

Text

Postharvest gray mold rot in European pears is caused by *Botrytis cinerea*. The infection by *B. cinerea* in storage leads to huge economic losses to pear packers. To understand pear fruit developmental stages and their association with *B. cinerea* colonization, we designed this study in a commercial orchard in southern Oregon. In addition, we investigated the impact of weather conditions and fungicide sprays on pear infection timing(s). Thirty blossom and fruit samples were collected each during petal fall, fruit set, fruitlet, mid-summer and commercial harvest. The samples were plated on half strength PDA media and data on *B. cinerea* isolation was recorded. In year 1 and year 2, the highest isolation of *B. cinerea* was observed during petal fall and fruit set stages (40% - 73%). The samples collected during fruitlet through commercial harvest had the least *B. cinerea* colonization in both years (4% - 26%). In first year, three precipitation events during the early season resulted in three applications of fungicides and in second year, there were four applications. Relative humidity during early season ranged from 40 to 92%, and during summer months, it ranged from 32 to 65%. The combination of fungicides application during earlier stages of fruit development and drier environment conditions during later stages resulted in least *B. cinerea* colonization during commercial harvest. This subsequently resulted in no gray mold rot incidence in the storage in both years.

C4.6-3

EPIDEMIOLOGY OF GRAIN CONTAMINATION WITH ZEARALENONE AND DEOXYNIVALENOL

PAUL Pierce. (1), MORAES Wanderson. (1), MADDEN Laurence. (1)

(1) The Ohio State University, Wooster, UNITED STATES

Text

Zearalenone (ZEA) and deoxynivalenol (DON), produced by the fungus Fusarium graminearum and related species, are two common mycotoxins that affect the quality, market value, and utilization of cereal crops such as corn and wheat. DON is a type B trichothecene that causes vomiting and feed refusal, among other illnesses, whereas ZEA, which causes various types of cancers and reproductive disorders in mammals, is a class III carcinogen that belongs to the xenoestrogen group of compounds. In wheat, grain contamination with ZEA and DON occurs in the field in association with F. graminearum infection and Fusarium head blight

(FHB), a disease that affects the spikes. DON and ZEA levels may increase in storage and are influenced by complex interactions among host-, pathogen-, and environment-related factors. Efforts to predict grain contamination with, and minimize postharvest losses due to, ZEA and DON must begin in the field, and require a thorough understanding of factors affecting contamination. Results from control-environment and field experiments will be presented and discussed on FHB-DON and FHB-ZEA relationships, the influence of temperature, relative humidity, and rainfall on these relationships, and factors associated with the conversion DON to DON-3-glucoside, a masked form of the toxin that often goes undetected while maintain its toxic effects. In-field, harvest, and postharvest strategies for mitigating DON and ZEA contamination of grain will also be discussed.

C4.6-4

INOCULUM DYNAMICS AND ENVIRONMENTAL FACTORS ASSOCIATED WITH THE PREHARVEST CONTAMINATION OF CITRUS FRUITS BY GEOTRICHUM CITRI-AURANTII

SBRES Mauricio. (1), **PEREZ Elena. (1)**, ALVES Pablo. (1), PALOU Lluís. (2), VICENT Antonio. (3)

(1) Instituto Nacional de Investigación Agropecuaria, Montevideo, URUGUAY; (2) Laboratori de Patologia, Centre de Tecnologia Postcollita (CTP), Institut Valencià d´Investigacions Agràries (IVIA), 46113 Montcada, València, SPAIN; (3) Unitat de Micologia, Centre de Protecció Vegetal i Biotecnologia (CPVB), Institut Valencià d´Investigacions Agràries (IVIA), 46113 Montcada, València, SPAIN

Text

The aim of this study was to establish the methodology and determine the relationships between climatic factors and contamination of citrus fruit by the soil-inhabitant pathogenic fungus Geotrichum citri-aurantii. This pathogen causes sour rot decay of citrus. The field trial was set up in a ‘Murcott’ mandarin experimental orchard in Salto, Uruguay. Fruit sampling was conducted weekly from March to June 2022. Six fruits from 2-3 trees per experimental unit were arbitrarily selected within 50 cm from the orchard floor. Rainfall, air temperature, wetness and relative humidity sensors were placed in the center of the orchard. Wind sensors were placed at each sampling location. The mean number of epiphytic spores of G. citri-aurantii per fruit (abundance) and the proportion of fruits positive for G. citri-aurantii (incidence) were determined in the laboratory by washing and plating serial dilutions. Climatic factors were related to G. citri-aurantii abundance or incidence through generalized linear models specifying the normal or binomial error structure, respectively. For both incidence and abundance, a significant negative relationship was observed with rainfall and wind speed. In contrast, the relationship was significantly positive for wind gusts. The variables wetness and maximum temperature were negatively and significantly related only to abundance. Further field trials are necessary to validate the models and confirm the results obtained in this first year of the study.

C4.6-5

ASSOCIATED TRADE BARRIERS WHILE MANAGING POSTHARVEST DISEASES IN SWEETPOTATO

QUESADA Lina. (1)

(1) North Carolina State University, Raleigh, UNITED STATES

Text

Over the last decade, exports of US grown sweetpotatoes have steadily increased to meet the growing demand in Europe and other countries. Persistence and re-emergence of soilborne pathogens threatens sweetpotato success as a profitable export for US producers, who supply a large share of the global sweetpotato market. Diseases lead to severe yield loss without cultural and chemical management. However, recent changes in fungicide residue tolerances for imported crops by the European Union have reduced chemical control options to manage pathogens. Ceratocystis fimbriata is a fungal pathogen that causes black rot, one of the most devastating diseases afflicting sweetpotatoes. The immense infection potential is due to C. fimbriata being transmissible to sweetpotatoes anytime in its production cycle, from seed roots to postharvest storage, which can result in annual losses as high as $150 million in North Carolina sweetpotato production alone. In this session we will discuss trade barriers associated with sweetpotato production using a black rot epidemic as a case study, and ongoing trans-disciplinary research and extension efforts to ensure the long-term sustainability of US sweetpotato exports.

C4.6-6

RE-EMERGING DISEASE: THE SOUR ROT IRRUPTION ON PEACH PRODUCTION

ZÚÑIGA Erick. (1), TEIXIDÓ Neus. (1), TORRES Rosario. (1), USALL Josep. (1), BORRÀS Júlia. (1), SEGARRA Guillem. (2), CASALS Carla. (1)

(1) IRTA, Lleida, SPAIN; (2) Universitat de Barcelona, Barcelona, SPAIN

Text

In the recent years, stone fruit producing areas in Spain have experienced an outbreak of sour rot (SR) disease affection probably related to climate change, while prior to 2016 SR incidence was low or absent. The main microorganism responsible for SR is *Geotrichum candidum*, and symptoms on fruit are described as a white layer of mycelial growth on fruit with sour smell. Moreover, currently, there are no effective treatments for SR control in stone fruit. In this study we investigated: 1) Potential sources of inoculum in 4 stone fruit orchards; 2) Dispersion of G. candidum artificially inoculated in soil at different conditions of wind, agricultural crop management, or both; and 3) Effect of *Trichoderma asperellum* (strain T34) to reduce the concentration of *G*. *candidum* inoculum in the soil. Our results indicated that *G*. *candidum* was present in all field samples evaluated, and soil presented the highest concentration. Furthermore, we observed that the inoculum of *G*. *candidum* was dispersed at all conditions evaluated, pointing out the dust as an important vehicle for dispersion. Finally, we found that T34 reduced the level of *G*. *candidum* inoculum in the soil in 76% within the two days after inoculation. After 7 days, the reduction of *G*. *candidum* was 47%, and this reduction remained stable for one month. Our study has provided a potential crop management tool to control SR by reducing the main source of inoculum and *G. candidum* dispersion .

SUSCEPTIBILITY TO SOUR ROT (GEOTRICHUM CITRI-AURANTII) IN MANDARIN AND HYBRIDS IN ASSOCIATION WITH FRUIT QUALITY PARAMETERS

PEREZ Elena. (1), SBRES Mauricio. (1), FERNANDEZ Gerónimo. (2), BLANCO Oribe. (1), GUIMARAENS Andrea. (1), ALVES Pablo. (1), MOLTINI Inés. (1), LADO Joana. (1)

(1) Instituto Nacional de Investigación Agropecuaria (INIA), Salto, URUGUAY; (2) Unión de Productores y Exportadores de Fruta del Uruguay (UPEFRUY), Montevideo, URUGUAY

Text

The objective of the work was to evaluate the susceptibility to sour rot (Geotrichum citri-aurantii) in mandarins and hybrids and to explore the association with fruit quality parameters. Disease severity (mean lesion size in 12 fruit) was analysed in 30 samples from 11 cultivars distributed in 7 experiments. Each cultivar was tested at least twice. For each experiment, an analysis of variance between cultivars was performed and the difference between means was evaluated by Tukey's test. Fruit firmness, colour, juice content (%), acidity, and total soluble solids were analysed for all samples. The association between severity and quality parameters, variety, and sample origin (grove) were analysed using a multiple linear model. Significant differences between cultivars were found in each experiment. Cultivars were classified into three groups using an arbitrary scale (more, moderately, and less susceptible). According to our result, Clementine cv "Clemenules" was the most susceptible cultivar, Mor cv. "Moria", Montenegrina, and Ellendalle were moderately susceptible, and Orri, Nankou, and Clementine cv. "Clemendor" were less susceptible. In Satsuma cv. "Owari", and hybrids Tango, Nova, and Afourer mean lesion size varied by experiment and susceptibility could not be established. A total of 58.41% of the variability was predicted by de model. The best quality parameters for predicting aggressiveness were de variety and firmness.

INTEGRATING DIAGNOSTIC TOOLS TO PREDICT DISEASE PRESSURES IN WINTER WHEAT AND REFINE THE APPLICATION OF BIOLOGICAL FUNGICIDES

MALLARD Lucy. (1), VAN DEN BERG Femke. (2), TURNER Judith. (2), SANDERSON Roy. (1), GEORGE David. (1), BOONHAM Neil. (1)

(1) Newcastle University, Newcastle Upon Tyne, UNITED KINGDOM; (2) Fera Science Ltd, York, UNITED KINGDOM

Text
Approximately 70% of fungicide applied on European wheat fields is primarily aimed towards the management of the fungal disease Septoria tritici blotch (STB), although the uptake of biological fungicides (biofungicides) in field-based cropping systems remains poor. The aim of this study was to integrate diagnostic tools into the fungicide decision process to improve disease prediction and refine biofungicide application. Another objective of the study was to investigate the mechanisms of a biofungicide in STB control.
A winter wheat field trial was conducted using traditional agronomy-based risk prediction and a novel method of disease forecasting- spore trapping and weather-based risk modelling- to influence the application rates of synthetic and biological treatments. The effects on STB control were assessed using visual disease assessments, while the data from molecular analyses (qPCR) of spores and symptomless leaves was used to retrospectively forecast disease severity in the crop.
In synthetic fungicide treatments, the diagnostics-based programme showed similar results to the agronomist-lead programme. However, the biofungicides did not effectively control STB, with significantly lower control in the diagnostics programme, prompting an investigation into the biological mechanisms for disease control, or lack thereof. This study will explore the effect of the biofungicide at various stages of STB ingress on the wheat phylloplane and STB control under greenhouse conditions.

Text
Effective management of soilborne pathogens is essential for commercial strawberry production in California. To minimize the impact of these pathogens a site-specific management program is under study that tracks pathogen load, disease incidence, and crop productivity for strawberry and vegetable crops grown in rotation to determine fumigant application rates within a field. Disease risk across the field is assessed by TaqMan soil quantification assays for three of the major lethal pathogens of strawberry (*V. dahliae*, *M. phaseolina* and *F. oxysporum* f. sp. *fragariae*) coupled with prior season disease incidence.

Management decisions on the type of fumigant, a risk-based assessment of rates for different areas of a field, and application methods are based on this information. Plant vigor and disease incidence is monitored during the growing season on a field wide and individual plant basis by drone flights every 1-2 weeks and a tractor mounted sensor system. Two GPS-enabled systems are used to collect precision yield data with cumulative yield maps generated on a regular basis. Correlations between drone/tractor sensor data and yield are explored to evaluate efficacy of the fumigation treatment and develop yield prediction models. An economic analysis of precision pathogen management provides information to support grower decision making. Results from field trials indicate that variable rate fumigant application based on risk can effectively manage disease and maintain yield.

PROGRESS IN DISEASE CONTROL - Part1

C4.1-1

VINE DISEASES AND INTEGRATION OF BIOSOLUTIONS IN CONTROL STRATEGIES

CHANTELOT Eric. (1)

(1) FRENCH VINE INSTITUTE (IFV) , , FRANCE

Text

Downy mildew and powdery mildew are the main diseases affecting grapevines, in terms of impact on production and number of applications during the season. French viticulture is evolving to develop new production models based on agroecological approach for the future. This innovative approach is based on different pillars: resistant varieties, soil management and biosolutions. Biosolutions may include biocontrol (registration as for conventional pesticides) as well as biostimulants. Future strategies may need to combine both categories to achieve complete IPM. Recent work from ITV, the French technical institute of vine, has mostly explored the implementation of biocontrol in vineyards. The relatively low and variable level of efficacy of available products first implied to combine them with lower dose rate of conventional fungicides, which is only a first step to sustainable and resilient IPM strategies. Further work aims at developing strategies based on decision rules (by using DSS) and characteristics of spray products. Such approach strongly relies on spraying quality which has to be perfect (face by face application at all vine stages). Based on the most recent results achieved from trials distributed throughout the French vineyard, this presentation will demonstrate that some of these strategies are highly promising to achieve IPM and identify determinants of its efficacy.

OPTIMIZING FIELD BASED CONTROL OF PHYTOPHTHORA CAPSICI: USE OF MULTIPLEX DROPLET DIGITAL PCR TO QUANTIFY BIOLOGICAL AND PATHOGEN POPULATIONS

VILLANUEVA Oscar. (1), SVIRCEV Antonet M.. (1), CASTLE Alan J.. (2), ZHANG Jinxiu. (3), ELLOUZE Walid. (1)

(1) Agriculture and Agri-Food Canada Research, Vineland-Stn, CANADA; (2) Brock University, St Catharines, CANADA; (3) Agriculture and Agri-Food Canada Research, Ottawa, CANADA

Text

Phytophthora capsici is an oomycete pathogen of vegetable crops with worldwide distribution and serious economic impact. The pesticides currently in use to control P. capsici have limited efficacy, safety concerns and public perception issues. Foretryx®, with active ingredients Trichoderma asperellum and Trichoderma gamsii, has been reported to effectively reduce the severity of phytophthora root and crown rot. The objective of this study was to control phytophthora root and crown rot in pepper by developing integrated pest management practices that incorporate the biofungicide, Foretryx®. Field based experiments in 2021 and 2022 studied the effect of biofungicide, bed type, mulches, and frequency of irrigation on root and crown rot of pepper. Results showed a significant effect of bed type and biofungicide applications in both years. However, the application of Fortryx® alone significantly reduced the incidence of the disease, as compared to the mock-treated plants, but only in 2021. A novel multiplex droplet digital PCR (ddPCR) assay was developed to analyze populations dynamic of T. asperellum, T. gamsii and P. capsici, associated with each treatment. The ddPCR analyses provided population numbers for the pathogen and biologicals in each field season, providing an indication on the apparent result discrepancy between years 2021 and 2022. We expect that this novel technology will have great value in biocontrol management practices of plant pathogens.

C4.1-3

DEVELOPMENT OF MYOSIN INHIBITOR TO CONTROL RICE BLAST AND FALSE SMUT

LIU Songtao. (1), LIU Fei. (1), ZHOU Yuxin. (1), ZHOU Mingguo. (1), **ZHANG Feng. (1)**

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Rice blast and false smut caused by Magnaporthe oryzae(M. oryzae) and Aspergillus oryzae(A. oryzae) respectively cause the devastating loss of rice yield worldwide. At present, two diseases mainly rely on chemical agents for control. Phenamacril is a self-developed fungicide in china and it is proved to be a myosin-5 inhibitor. However, phenamacril only control some species of Fusarium and it has no obvious inhibitory activity against other pathogens. This study is aim to develop new myosin-5 inhibitors to control rice blast and false smut. Firstly, we found that, among the pathogens sensitive and insensitive to phenamacril, the type of residue 375 is only the difference in myosin-5 drug sensitivity site. Second, phenamacril had no inhibitory activity on ATPase of myosin-5 from M. oryzae(MoMyo5), conversely, the ATPase activity of K375M that comprised mutagenesis of K375 to M in MoMyo5 was dramatically inhibited. Next, the residue 375 was the only

difference in crystal structure of MoMyo5 and myosin-5 from F. graminearum. In the sight of K375 in MoMyo5, we designed and synthesized a series of compounds. Ultimately, YJY-22 showed the best activity and its median effective concentration on M. oryzae was 0.5μg/mL, more relevantly, its control effect was equivalent to tricyclazole in the field. YJY-22 also inhibited false smut with high activity. Our discoveries laid a theoretical foundation for the creation of targeted fungicides based on amino acid differentiation in a target.

FUNGICIDE SENSITIVITY OF COLLETOTRICHUM SPECIES CAUSING BITTER ROT ON APPLE IN THE MID-ATLANTIC UNITED STATES

PETER Kari. (1), MARTIN Phillip. (2)

(1) Pennsylvania State University, Biglerville, UNITED STATES; (2) LABServices, Hamburg, UNITED STATES

Text

Bitter rot of apple has triggered losses for apple growers in the Mid-Atlantic United States. We sampled > 500 apples with bitter rot obtained from 38 orchards across PA, VA, MD, DE, and OH. The causal species listed in decreasing abundance were identified as *Colletotrichum fiorninae*, *C. chrysophilum*, *C. noveboracense*, *C. siamense*, *C. fructicola*, *C. henanense*, and *C. gloeosporioides* sensu stricto. A sample of 220 isolates plus 32 reference isolates were tested in an initial fungicide sensitivity screen. A subsample of isolates was tested to obtain EC50 and EC25 values for 22 fungicide active ingredients from FRAC groups 1, 3, 7, 9, 11, 12, and 29. These fungicides varied widely in efficacy both within and between FRAC groups, with our *Colletotrichum* isolates largely insensitive to many of the active ingredients. Comparisons of our *in vitro* results with field trial results conducted in several Eastern U.S. locations suggested that EC25 values (concentrations that reduce growth by 25%) are better predictors of fungicide efficacy in normal field conditions than EC50 values. Benzovindiflupyr (FRAC 7), pyraclostrobin (FRAC 11), trifloxystrobin (FRAC 11), fludioxonil (FRAC 12), and fluazanim (FRAC 29) controlled disease most effectively in the field. Little resistance was found; however, a few *C. siamense* isolates were resistant to FRAC groups 1 and 11 with confirmed β-tubulin E198A and cytochrome-b G143A mutations, respectively.

Text
Botrytis cinerea and Podosphaera xanthii, the causal agents of the gray mold and the cucurbit powdery mildew diseases, respectively, are one of the main limiting factors of horticultural crops production worldwide, consuming up to 40% of fungicides in its control. However, these fungi have been categorized by the Fungicide Resistance Action Committee as phytopathogens with a high risk for fungicide resistance development, a fact that has been demonstrated in our country. In addition, and according to the "farm to fork" strategy of the recent European Green Deal, the diversity of fungicides available to growers will be reduced by 50% in 2030. For this reason, alternative control tools and molecules with fungicide activity are needed. In our research group, we intend to check if the efficacy of the emerging RNA interference (RNAi) strategy, called "spray-induced gene silencing" (SIGS), could be a valid sustainable solution and an alternative to the use of conventional fungicides for the control of B. cinerea and P. xanthii. For this purpose, several double-stranded RNA (dsRNAs) have been designed against targets genes involved in the virulence/pathogenicity of both pathogens. To improve the application of these oligonucleotides in the field, their encapsulation to create nanoparticles is being carried out. If we succeed, new molecules with fungicidal action, could be included to obtain a sustainable plant protection control programs in the field.

Text
Soybean is one of the most important crops worldwide. Its major foliar disease is Asian soybean rust (SBR) that is caused by the fungus Phakopsora pachyrhizi. Because elite varieties with resistance to all isolates of P. pachyrhizi are not available, current management strategies almost exclusively rely on the utilization of synthetic pesticides. To reduce their application while preserving crop productivity, alternative SBR control measures are needed. Here, we show that nonhost resistance-associated coumarins and phylloplane proteins suppress rust spore germination and illustrate strategies for their utilization. We provide evidence that foliar application of coumarins and combinatorial overexpression of specific coumarin biosynthesis genes in transgenic soybean plants reduces their susceptibility to SBR. Furthermore, screening for molecules which prime the plant immune system for augmented stress responses disclosed natural and near-natural compounds that boost soybean’s resistance to SBR. Combining strategies with differing, but complementary mode of action may provide sustained protection of soybean from SBR.

Text

The ‘Stop the Rot’ project (https://alliumnet.com/stop-the-rot/), funded by the USDA National Institute of Food & Agriculture Specialty Crops Research Initiative, aims to help onion growers reduce losses to bacterial diseases through understanding interactions of the host, pathogens, and environment. Outcomes include improved diagnostic tools and enhanced bacterial disease management strategies. Surveys of >130 locations in 2020-2021 generated isolates of 116 bacterial genera from onion foliage and bulbs in seven regions of the USA, with distribution and pathogenicity varying across regions. Very few strains caused symptoms in onion bulb scale pathogenicity tests. Pantoea, Pseudomonas, Burkholderia, and Enterobacter were the most prevalent genera. Microbiome analyses revealed different complex bacterial communities in asymptomatic vs. symptomatic bulbs. Genomic analyses of Pantoea agglomerans strains showed some carry the HiVir gene cluster associated with virulence to onion. Copper tolerance genes found in ~50% of sequenced P. agglomerans isolates might explain the poor efficacy of copper bactericides in many trials. Trials of bactericides and irrigation, fertility, cultural, and post-harvest practices, evaluated across the USA, demonstrate that irrigation timing and method, and late-season cultural practices can be optimized to reduce losses to bacterial diseases. Economic evaluations of results ensure recommendations are practical, viable, and financially sustainable.

Text

Wheat yellow rust, caused by *Puccinia striiformis* f.sp. *tritici* (*Pst*), is an important disease in France and in Europe. Ten years ago, in 2013, the PstS10 genetic group (Warrior (-)) was detected in France for the first time and became in a short time the dominant genetic group in this area. Its emergence has been associated with the breakdown of different resistant cultivars. In this work, we propose a summary of main evolutions observed in the past decade considering different datasets. We first illustrate the evolution of *Pst* population (based on 1626 pathotyped samples), with 4 variants of PstS10 detected in France since 2013 and the evolution of their frequencies. We then analyse the behaviour of French cultivars exposed to *Pst* at seedling stage under controlled conditions (340 cultivars) and at adult stage in the field (355 cultivars). We first analyse datasets individually, illustrating major tendencies. We then show how combining these different datasets can provide information on possible sources of resistances and their durability. For example, comparing seedling and field behaviour could help detecting adult resistance. Associations between variations in variant frequencies and variations of cultivar resistance level in the field could suggest the presence of specific resistances that could be further investigated. Finally, we expose key perspectives of further investigations aiming at improving the resistance of French cultivars towards recent populations of *Pst*.

Text

Abstract

Root rot disease of cucumber, is the common epidemic fungal diseases causing significantly losses of cucumber plants and their productivity during growing winter season under plastic houses are wilt and root rot diseases. Several nanoemulsions formula of nanoparticles of chitosan, hydroqunone, sorbic and propionic acids compare their native materials were prepared and tested against mycelial linear growth, morphology, of highly pathogenic isolates of fungi causing root rot disease of cucumber Fusarium oxysporum and Fusarium solani. Different rates of nanoemulsion formulations and application methods as soil drench before and after cultivation in plastic houses were tested. Data obtained indicated that application of nanoemulsion formulations of chitosan/hydroquinone by the rate 0.5% as soil drench of transplantings 2 days before cultivation in greenhouse it highly suppress wilt and root rot syndromes on cucumber plant and highly significantly increased morphological characters such as plant hight, fresh weight and yield fruits. So, nanoparticles as eco-friendly agents of environmental resources will be consideration in programme as alternative fungicides for controlling plant diseases and enhance plant growth

and productivity.
Keywords: nanoparticles, chitosan, fungi, root rot, cucumber

Text
The Asian citrus psyllid (ACP) transmits the bacterium Candidatus Liberibacter asiaticus (CLas), the putative cause of citrus Huanglongbing disease (HLB), the most serious threat to citrus production worldwide. A 10 amino acid peptide derived from the Oncocin antimicrobial peptide was evaluated for its ability to control HLB in Carrizo trifoliate citrus through transgenic expression. Detached leaf studies demonstrated up to 80% mortality of CLas+ psyllids when fed for 7 days. Whole plant studies demonstrated a significant delay in nymph development and reduction in nymphs (number/shoot) over 14 days for transgenic cloned lines (TCL) as compared to non-transgenic controls. TCL # 48 caused the greatest delay in nymphal instar development, while also reduced nymphal emergence by 60.4%. TCL #14 reduced insect emergence from nymphs by 54%. The mortality rate for ACP in transgenic plants individually caged with adult psyllids for two weeks was 10X higher than the mortality rate for controls. The antimicrobial effect of oncocin was confirmed by challenging transgenic leaves with citrus canker (Xanthomonas citri). Canker symptoms were reduced >10X in some TCLs compared to the controls. Based on these results, it can be concluded that transgenic expression of the truncated oncocin might provide commercially viable tolerance to HLB by inducing mortality in both the insect vector and the disease associated bacteria, and that it may also provide tolerance to citrus canker disease.

Text
Early detection of pathogens is crucial for enabling the deployment of interventions and can

contribute to reducing synthetic pesticide use, and facilitating more effective use of bio-pesticides.
Vertical farms (VF) have potential to address challenges around global food security and sustainable crop production, in particular growing nutritious crops more closely to where they are consumed. They provide an ideal environment for the proliferation of some pathogens due to highly intensive growing conditions. Disease risk is mitigated by growing short cycle crops, to achieve production in the presence of pathogens. Production of longer cycle and more nutrient dense crops may be limited if sustainable disease control cannot be achieved. In this paper we will present data on remote imaging technologies and machine learning applied to VF grown crops for the detection of biotic and abiotic stress ahead of visual symptoms, facilitating effective interventions. We will also discuss rapid DNA diagnostic methods based on automated disease detection and high throughput sequencing (HTS), exploring how these tools can better target fungicide applications in arable field crops.
It seems unlikely that any one technology can be used to direct crop management interventions, we will likely need to incorporate several technologies, operating at different spatial/temporal scales. Data processing and presentation to growers will increasingly be important to realise impact from these technologies.

ADAVELT ACTIVE (FLORYLPICOXAMID), A NATURALLY INSPIRED SOLUTION FOR BROAD SPECTRUM DISEASE CONTROL

HUFNAGL Andrea. (1), YAO Chenglin. (2)

(1) CORTEVA Agriscience, Guyancourt, FRANCE; (2) Corteva Agriscience, Indianapolis, UNITED STATES

Text
Adavelt™ active (florylpicoxamid) is a second generation picolinamide fungicide (FRAC group 21) from Corteva Agriscience that offers broad spectrum activity against key diseases in a wide range of crops. Adavelt controls major ascomycete pathogens such as powdery mildews, Alternaria spp., Botrytis cinerea, Cercospora spp., Colletotrichum spp., Monilinia spp., Mycosphaerella musicola, Zymoseptoria tritici and more. As a Quinone Inside Inhibitor (QiI), Adavelt inhibits mitochondrial respiration in fungi by blocking electron transfer in the respiratory chain. This is a novel target site in many crops with no cross-resistance to other modes of action. Due to its unique or under exploited mode of action, Adavelt will form a critical new tool to manage fungicide resistance. Quick plant uptake and effective translocation provide Adavelt with excellent acropetal redistribution and translaminar properties on cereals and dicots. Adavelt acts on various life cycle stages of the targeted pathogens with market-leading curative control vs Z. tritici, thus offering growers a flexible solution for managing diseases throughout the season. Adavelt will be offered in a range of formulations either straight or in pre-mixes for use in cereals, row crops, oilseed, top fruit, tree nuts, grapes, tropical fruit, vegetables, turf and ornamentals and others.

Text

Phytophthora species affecting citrus in Morocco are *Phytophthora parasitica* and *Phytophthora citrophthora*. They cause trunk and foot rots, gummosis, branch canker, feeder roots rot, damping-off of seedling and brown rot on citrus fruits. The use of resistant rootstocks is the most economical and sustainable control measure of Phytophthora. Thus, grafting citrus varieties on sour orange may impair the damage caused by Phytophthora. In addition, this rootstock has a high aptitude for grafting and a remarkable compatibility with numerous commercial varieties. For these reasons, Sour Orange is predominantly used as a rootstock. However, this rootstock is highly sensitive to Tristeza disease caused by Citrus Tristeza Virus (CTV). Therefore, Moroccan citrus industry is seeking alternative rootstocks. To address this issue, seeds of several citrus rootstocks were introduced from USA and from France, and they were tested under Moroccan conditions. Seedlings of the rootstocks raised from introduced seeds were inoculated with the fungus directly on the stem of the seedling plant. Inoculated plants were maintained under adequate growth conditions in the greenhouse. The length of the lesions was measured sixty days post inoculation (DPI). This presentation will cover results of the evaluation of two series of rootstock introductions, made by a private producer and by INRA-Morocco.

LORANTHUS LIGUSTRINUS IS AN EMERGING PARASITE CAUSING DECLINING THE YIELD OF CITRUS RETICULATA ORANGE IN INDIA AND ITS SUSTAINABLE MANAGEMENT METHODS

PERIASAMY Raja. (1), HIRAK Jyoti Bhuyan . (2), M Mathiyazhagan . (2)

(1) COLLEGE OF HORTICULTURE AND FORESTRY, PASIGHAT, Pasighat, INDIA; (2) Silapathar Science College, Dhemaji, Assam-787059, India , Dhemaji, INDIA

Text

The production and productivity of Citrus reticulata are mainly affected by the Loranthus stem parasite. It lowers the yield by 47 percent and kills the trees within 4 to 5 years. We have identified two types one is the single-haustoria type, with 6–8 branches at the tip, and the other is the climber type, with multiple haustoria and coils around the stem. The first type of Loranthus has a stem length of 30–42 cm, and it caused a decline within 3–5 years. The second type of Loranthus runs faster and causes a decline within 2 to 3 years. To manage the loranthus foliar spraying of diesel 60% was found to be more effective followed by stem injection with 2, 4-Dicholorophenoxy acetic acid 5%, and foliar spray of diesel 30%. The treatments of diesel 60%, 2, 4-D 5%, and diesel 30% have reduced the loranthus infection by 97.5%, 90%, and 87.5%, respectively. The average yield per tree was increased to 37.5 kg in treated trees compare to the control. We have removed the loranthus by pruner 10 cm away from the base and pasted a 10% Bordeaux mixture. Birds could transmit the parasite through seeds. Birds scaring objects are installed in the field viz. bird deterrents sound ranges from 65-105 decibels, erection of false man-like toys made from stuffing the shirts with straw, and

third is the coiling of colored ribbon in the periphery of the field. Bird deterrents were found to be the best way to keep the birds away from October to March during fruiting time.

Green synthesis of ferrocenyl chalcones and their evaluation against plant pathogenic fungi and root knot nematode

Dinesh K Yadav1,2 *, Najam Akhtar Shakil1, and Jayanta Kumar Saha2
1ICAR-IARI, New Delhi-110 012
2ICAR-IISS, Bhopal-462038, India,
*E-mail: Dinesh.Yadav1@icar.gov.in

A new microwave method (MM) has been developed for the synthesis of a series of thirty-four substituted ferrocenyl chalcones and comparing it with conventional method (CM). Characterization of synthesized compounds was done by different spectroscopic techniques. A series of ferrocenyl chalcones were synthesized and evaluated for fungicidal activity against Sclerotium rolfsii & Alternaria solani and for nematicidal activity against root knot nematode, Meloidogyne incognita. In vitro study revealed that 4-bromophenyl, 2,6-dichlorophenyl, and 5-chloro-2-hydroxyphenyl ferrocenyl chalcones derivatives were found to be most active against S. rolfsii. Based on in vitro study, these three most effective derivatives were chosen for pot experiment. The percent disease incidence was significantly decreased as compared to control & it was found to be minimum in plants treated with 4-bromophenyl derivatives @ 1000 ppm. In case of nematicidal activity, also based on in vitro study, ten most effective derivatives were taken for pot experiment. The activity was highest in 4-methoxyphenyl, 4-methylphenyl, and 3,4,5-trimethoxyphenyl ferrocenyl chalcones derivatives @ 80 ppm.

P4.1-008

FIELD EFFICACY OF VARIOUS SYSTEMIC AND BIOLOGICAL FUNGICIDES AGAINST COFFEE LEAF RUST IN HAWAII

CHENG Zhiqiang. (1), COUGHLIN Julia. (1), BUCHHOLZ Elizabeth. (1), KAM James. (1)

(1) University of Hawaii at Manoa, Honolulu, UNITED STATES

Text

Coffee leaf rust (Hemileia vastatrix, CLR) is considered the world's most devastating pathogen of coffee and is found in nearly all coffee growing regions. Hawaii was one of the

last locations to grow coffee without the disease until CLR was confirmed on Maui in October 2020. Within a year, it spread to all the islands. CLR damage reduces the tree's photosynthetic capabilities and causes premature defoliation of infected leaves. In turn, future growth and yield can be lost, and in severe cases, CLR can cause tree death. Coffee is Hawaii's no. 3 agricultural commodity. Currently Hawaii's coffee growers can only contact fungicides and one translaminar fungicide to battle CLR. Considering the urgent research need, this project aimed to identify effective systemic and biological fungicides against CLR in Hawaii. This was a 2 year project in which we tested 7 systemic fungicides in 2021 and 8 fungicides (6 systemic and 2 biological) in 2022 in replicated field plots (Randomized Complete Block Design) at two major coffee farms in Kona, Hawaii. CLR disease incidence (% infected leaves) and infection severity (0-5 scale) were measured at least 5 months post initial treatment in each year. Our results showed that inpyrfluxam and azoxystrobin were both very effective against CLR. Although both biological fungicides tested showed some efficacy, they were not as effective as inpyrfluxam and azoxystrobin. This research provided critical foundation for CLR management in Hawaii and beyond.

USE OF BIOLOGICAL PRODUCTS-BASE MANAGEMENT PROGRAMS FOR THE CONTROL OF SWEET CHERRY DISEASES

LOVERA Yerko. (1), RUIZ Braulio. (1), GERDING Macarena. (1), BASTÍAS Richard. (1), HIRZEL Juan. (2), **MOYA-ELIZONDO Ernesto. (1)**

(1) Universidad de Concepción, Chillán, CHILE; (2) Instituto de Investigaciones Agropecuarias, INIA Quilamapu, Chillán, CHILE

Text

Bacterial canker and pre- and postharvest fruit rots are diseases affecting sweet cherry worldwide. Use of biological products is a suitable alternative to reduce agrochemical applications. However, there is a lack of information on the interaction between these products and their effect on the population dynamics of these pathogens when incorporated into integrated disease management programs. This study evaluated the phytosanitary impact of biological based management programs on disease control in sweet cherry. Half hectare units were established under two biological-based programs, one based only on chemical control and the other under the local grower program, in a ´Sweetheart´ sweet cherry orchard in Chillán, Chile. Population counts and incidence and severity measurements were made on cherry at specific phenological stages. Results showed that biological-based programs, which included *Pseudomonas protegens, Bacillus* spp. and *Trichoderma* spp., reduced populations of *Pseudomonas syringae* pv. *syringae*; *Botrytis cinerea* and *Alternaria* spp. at specific phenological stages, with no differences, regarding chemical and grower programs. Between programs, no differences in incidence and severity of bacterial canker were detected, but the incidence of *Alternaria* spp. rot was 87% lower in the chemical program compared to biological-based programs, in the ripe fruit stage. These results allow to promote bioproducts inclusion in commercial disease management programs.

P4.1-010

BACTERIAL SPOT INCITED BY XANTHOMONAS CUCURBITAE: A SERIOUS EMERGING DISEASE OF CUCURBITS

BABADOOST Mohammad. (1)

(1) University of Illinois at Urbana-Champaign, Urbana, Illinois, UNITED STATES

Text

Bacterial spot of cucurbits, caused by *Xanthomonas cucurbitae*, is a serious emerging disease in the United States (U.S.) and worldwide. The pathogen infect leaves and fruits. *X. cucurbitae* is identifies based on the colony characteristics on yeast dextrose agar, PCR test using RST 2 and RST 3 primers, and pathogenicity test. Evaluation of isolates of *X. cucurbitae* from the North Central Region of U.S. showed that *X. cucurbitae* isolated from Illinois, Michigan, Kansas, Ohio, and Wisconsin were more virulent than the reference ATCC 23378 strain. In a four-year rotation with nonhost crops, development of bacterial spot was delayed only by two weeks. The pathogen survived for more than 24 months in infected pumpkin debris buried in the field. Although applications of some chemicals reduced incidence and severity of leaf and fruit infection, sprays did not provide effective protection of plants against the pathogen. We screened 81 commercial cultivars of gourds, pumpkins, and squashes, and 300 accessions of *Cucurbita* spp. for their resistance to *X. cucurbitae* under greenhouse and field conditions. All commercial cultivars were susceptible to *X. cucurbitae*. Only 9 and 21 accessions were identified as resistant and less resistant, respectively. Resistant and less resistant accessions belong to the species *Cucurbita maxima*, *C. maxima* subsp. *maxima*, *C. maxima* subsp. *andreana*, and *C. okeechobeensis* subsp. *martinezii*. This is the first report of resistance to the bacterial spot.

P4.1-011

USING RNA INTERFERENCE TO PROTECT CROPS AGAINST FUNGAL PATHOGENS

BELMONTE Mark . (1)

(1) University of Manitoba, Winnipeg, CANADA

Text

Sclerotina sclerotiorum, the causal agent of white mold, infects over 600 species of plants worldwide. Sclerotinia is a persistent problem for global food production that has traditionally been managed using broad-spectrum fungicides. However, current fungicide strategies have proven less effective and crop rotations fail due to the promiscuous host range of Sclerotinia and the formation of durable resting structures known as sclerotia. Thus, there is an immediate need to manage Sclerotinia using novel species-specific control methods. Our strategy exploits the inherent cellular defense process known as RNA interference (RNAi). Upon encountering a double stranded RNA (dsRNA) molecule, the cell processes the dsRNA specifically targeting transcripts with sequence homology. Using a re-designed bioinformatics approach, we identified Sclerotinia-specific target genes. RNAi knockdown was confirmed using quantitative real-time PCR on RNA isolated from fungal liquid cultures. dsRNA molecules were screened for growth inhibition on the plant using a system representative of field conditions that showed up to 85% reduction in lesion spread. We then generated transgenic Brassica napus (canola) over-expressing good quality dsRNA and showed a more profound and prolonged tolerance to the fungus. Finally, I will provide insight into the uptake

mechanisms and utility of next generation molecular fungicides and their applicability to control plant pathogens.

Cercospora beticola causes Cercospora leaf spot (CLS), a devastating disease of sugar beet (Beta vulgaris, L). From 1999 through 2015, growers in Minnesota and North Dakota, USA, used QoI, DMI, and triphenyltin hydroxide to manage sensitive populations of C. beticola. In 2016, US growers lost over $200 million because of fungicide resistance and a CLS epidemic. CR+ cultivars with a C. beticola resistant gene from B. maritima recently became available. Field trials using approved moderately tolerant cultivars (non-CR+) and improved CR+ cultivars were recently conducted in the USA. Fungicide applications were done on a calendar basis, and on an only when needed based on the presence of symptoms and favorable environmental conditions. In a dry and warm 2021 season, fungicides were necessary to provide protection for the non-CR cultivars, but were not necessary for the CR+ cultivars. In 2022, conditions were not favorable for development of C. beticola until late August. One or two timely fungicide applications based on the presence of symptoms and thresholds resulted in low disease severity and recoverable sucrose similar to fungicide applications on a calendar basis. The availability and use of the newer CR+ cultivars will improve the economic viability of the sugar beet industry, and will help to reduce the inoculum load that may facilitate the use of non-CR+ cultivars. However, fungicides will have to be used judiciously to prolong the usefulness of the CR+ cultivars.

Text
During the last years we have identified a new nematode species *Pratylenchus capsici* in Israel leading to devastating damage on pepper crop resulting in stunted growth and significant yield reduction. Molecular phylogeography suggests that contemporary gene flow is prevented among different agricultural farms, while population dispersal from weeds (Chenopodium album and Sonchus oleraceus) to pepper occurs on a relatively small scale. Metabarcoding analysis of soil microbial community from *P. capsici* infested roots indicated that Olpidium species are widely presented in *Pratylenchus* introduced root-lesion, and might be a faithful companion associated with roots infected by *P. capsici*. The migratory potential of these nematodes is still under study. Altogether, results obtained through our research will facilitate with developing innovative management strategies through tailoring them within the agricultural practices and according to *P. capsici* etiology and characteristics.

EVALUATION OF ORGANIC MATERIALS REVIEW INSTITUTE (OMRI) PRODUCTS AND VARIETIES FOR FUSARIUM HEAD BLIGHT (FHB) MANAGEMENT IN ORGANIC WINTER WHEAT IN INDIANA, UNITED STATES OF AMERICA

ROCCO DA SILVA Camila. (1), DEBBINK Kelly. (2), SILVA Erin. (2), MULLER Brian. (2), SMITH Damon. (2), TELENKO Darcy. (1)

(1) Purdue University, West Lafayette, UNITED STATES; (2) University of Wisconsin-Madison, Madison, UNITED STATES

Text
Fusarium head blight (FHB), caused by Fusarium graminearium, is one of the most important wheat diseases in the world. In Indiana, limited information is available regarding the efficacy of OMRI approved products. Field trials were conducted in 2021 and 2022 to investigate the efficacy of four OMRI products in the control of FHB. Treatments consisted of two wheat cultivars (Kaskaskia and Harpoon) as main plot and Reynoutria sachalinensis 12%, Bacillus pumilus QST 2808, Streptomyces lydicus WYEC 108, copper hydroxide, prothioconazole + tebuconazole, and a nontreated control as sub-plots. F. graminearum was inoculated 24 hours after treatment, at Feekes 10.5.1. Disease ratings were assessed at Feekes 11.2. In 2021, FHB incidence, severity, and index were similar for all treatments. The concentration of deoxynivalenol (DON) and percent fusarium damaged kernels (FDK) in Harpoon were reduced by 80 and 43%, respectively, compared to Kaskaskia. Prothioconazole + tebuconazole reduced FDK by 28% over the nontreated control. Yield was similar across all treatments in 2021. In 2022, FHB severity from Harpoon was reduced by 48% compared to Kaskaskia, but no differences were detected for FHB incidence and index. When treated with prothioconazole + tebuconazole, the DON concentration was 43% lower in the variety Harpoon compared to Kaskaskia. There was no difference between treatments and varieties for FDK. The variety Harpoon yielded 14% more than Kaskaskia in 2022.

P4.1-015

MANAGEMENT OF TAR SPOT IN CONVENTIONAL AND ORGANIC CORN SYSTEMS IN INDIANA, UNITED STATES OF AMERICA

ROCCO DA SILVA Camila. (1), DEBBINK Kelly. (2), SILVA Erin. (2), MUELLER Brian. (2), SMITH Damon. (2), TELENKO Darcy. (1)

(1) Purdue University, West Lafayette, UNITED STATES; (2) University of Wisconsin-Madison, Madison, UNITED STATES

Text

Tar spot is caused by Phyllachora maydis, an obligate fungal pathogen that reduces corn grain yield and quality. P. maydis was first reported in the U.S. in 2015 and has since been confirmed in 18 states. Data regarding optimal application timing of foliar fungicides in conventional systems is limited. In addition, efficacy data for tar spot management in organic systems is yet to be published. Conventional corn trials were established from 2020 to 2022 to test the fungicides Mefentrifluconazole + pyraclostrobin and flutriafol + bixafen applied at various timings. Organic corn trials were established in 2021 and 2022 to test Bacillus amyloliquefaciens MBI 600, Streptomyces lydicus WYEC 108, copper oxychloride + copper hydroxide, hydrogen peroxide + peracetic acid, and pyraclostrobin + metconazole, all applied at R1 corn growth stage. Percentage of stromata per ear-leaf was assessed on five plants per plot and used to calculate the area under the disease progress curve (AUDPC). Reductions in tar spot severity reached up to 99.6% after the application of mefentrifluconazole + pyraclostrobin at VT and at R3 fb 3 weeks after first application (WAT). In organic trials, tar spot severity was reduced by up to 52% after the application of pyraclostrobin + metconazole. Yield increases were observed after application of mefentrifluconazole + pyraclostrobin at R3, V8 fb 3 WAT, VT fb 3 WAT, R3 fb 3 WAT and after the application of flutriafol + bixafen at V8 fb 3 WAT.

RESISTANCE TO FUSARIUM OXYSPORUM F. SP. LUFFAE IN LUFFA GERMPLASM DESPITE THE PATHOGEN COLONIZATION

NAMISY Ahmed. (1), CHUNG Wen-Hsin. (1,2,3)

(1) Department of Plant Pathology, National Chung Hsing University, Taichung, TAIWAN; (2) Innovation and Development Center of Sustainable Agriculture (IDCSA), National Chung Hsing University, Taichung, TAIWAN; (3) Master Program for Plant Medicine and Good Agricultural Practice, National Chung Hsing University, Taichung, TAIWAN

Text

Fusarium wilt of *Luffa*, caused by *Fusarium oxysporum* f. sp. *luffae* (Folu), causes great losses in *Luffa* plants worldwide. In this study, 45 accessions of *Luffa* germplasm were used to determine their resistance to Folu isolates (FOLUST, FOLUSC, Fomh16, and Fol114) in two independent trials. In the first trial, only FOLUST was used to preliminarily identify resistant accessions. Nine accessions of *L. acutangular* and five of *L. aegyptiaca* were resistant to the FOLUST isolate. In the second trial, the other three isolates were then used to reevaluate the 14 resistant accessions. The results indicated that the 14 accessions were resistant to FOLUSC but exhibited variable resistance to the Fomh16 and Fol114. Eight accessions of *L. acutangula* and one accession of *L. aegyptiaca* were resistant to Fol114. Seven accessions of *L. acutangula* and one accession of *L. aegyptiaca* were resistant to

Fomh16. Although resistant accessions showed symptomless, the Folu isolates could colonize hypocotyls at 28 days post inoculation, except for isolates FOLUSC and FOLUST on accession LA140. A green fluorescent protein (GFP)-tagged isolates (FOLUSC-A and Fomh16-A) were used to study the Folu distribution and colonization in *Luffa* accessions. In addition, fifteen *Luffa* hybrids were obtained from reciprocal crosses between five resistant lines, four hybrids were successfully grafted with bitter gourd plants and significantly reduced disease incidence caused by *F. oxysporium* f. sp. *momordicae* and Folu.

Text

The ascomycete *Botrytis cinere*a and the oomycete *Phytophthora infestan*s are two important plant pathogens affecting several crops. These phytopathogens are commonly controlled by the frequent use of chemical fungicides with possible detrimental effects to human health and the environment. The present study aims at characterizing the efficacy and mechanism of action of a new biofungicide based on choline pelargonate (TMAP) against these phytopathogens. The chemical properties of TMAP were evaluated at different concentrations in water solution, such as critical micelle concentration, pH, and conductivity. TMAP efficacy was then evaluated against *B. cinerea* and *P. infestan*s at different concentrations *in vitro* and the inhibitory effects were assessed on mycelium growth and spore germination to identify minimum inhibitory concentration and minimum fungicidal concentration. Overall, TMAP reduced pathogen growth at low concentrations. In order to clarify the mechanism of action, TMAP effects on the fungal cell membranes are under evaluation, by analyzing the electrolyte leakage, pH variations, and nucleic acid release from *B. cinerea* and *P. infestans* after TMAP treatment. Results from these experiments will be discussed to further characterize the efficacy of TMAP against the two phytopathogens *in planta*.

STUDY OF THE EFFECT OF DISEASES ON OIL PLANTS: A CASE STUDY OF THE SUNFLOWER PLANT

BOUKABCHA Maamar. (1), EL MILOUDI Khaled. (1)

(1) University of Chlef, Chlef, ALGERIA

Text

The sunflower plant (Helianthus annuus L.) has become among the vital popular sectors in the Mediterranean regions and at the level of most regions of the world, as this type of sunflower plant is characterized by large, easy-to-grow and multi-colored flowers. This descriptive study aims to find out the main diseases that threaten the sunflower plant. The sunflower plant (Helianthus annuus L.) is native to America. Fortunately, many pathogenic microorganisms and insect pests raise the challenge for growing production. If needed, genetic progression can be easily transferred to oil plants. The major diseases that threaten oil plants such as the 'Helianthus annuus L.' type sunflower can affect the leaves, stems, seeds, flowers and cells of the entire plant. Some microorganisms and insects play a major role in protecting oil plants from disease and thus contribute significantly to the increase in vegetable oils across the world.
Keywords: sunflower plant, major diseases, Microorganisms, insects, genetic progress.

P4.1-019

A SNAPSHOT OF SENSITIVITY OF SOUTHEASTERN UNITED STATES MONILINIA FRUCTICOLA ISOLATES FROM PEACH TO PROPICONAZOLE AND THIOPHANATE METHYL

SCHNABEL Guido. (1), GURA William. (1)

(1) Clemson University, Clemson, UNITED STATES

Text

The strategic use and rotation of single-site fungicides during preharvest season is an essential component of IPM practices for control of peach brown rot in the Southeastern United States. However, every management program needs to be assessed over time for efficacy and sustainability. We collected more than 240 Monilinia fructicola isolates from South Carolina, Georgia, and Alabama commercial orchards and investigated sensitivity to propiconazole and thiophanate methyl. Results show that most isolates from South Carolina and Georgia were resistant to propiconazole (78.4%), whereas most isolates from Alabama were sensitive (83.8%) based on relative growth (RG) values at a discriminatory dose of 0.3 mg/L propiconazole. RG values for resistant isolates ranged from 21.1% to 90.0%. Resistant isolates contained the genetic element Mona located upstream CYP51 as determined by PCR and gel electrophoresis. In contrast, the most sensitive isolates (RG ranged from 0% to 18.7%) did not possess Mona. The RG values for our resistant isolates demonstrated no additional shift in sensitivity compared to a similar study conducted 15 years ago likely due to strict compliance of producers to resistance management recommendations. Surprisingly, all isolates from commercial orchards, except for one, were sensitive or reduced sensitive to thiophanate methyl using the discriminatory dose of 1 mg/L, opening the possibility of using this chemistry again carefully and strategically in IPM programs.

P4.1-020

IDENTIFICATION OF 7-HYDROXYTROPOLONE AS AN ACTIVE MOLECULE PRODUCED BY PSEUDOMONAS PA14H7 AGAINST DICKEYA, CAUSAL AGENT OF BLACKLEG ON POTATO.

LEPINAY Euphrasie. (1), MATHIRON David. (3), KHELIFA Mounia. (4), LACLEF Sylvain. (2), PILARD Serge. (3)

(1) inov3PT, Achicourt, FRANCE; (2) LG2A-UPJV, Amiens, FRANCE; (3) PFA-UPJV, Amiens, FRANCE; (4) inov3PT, Amiens, FRANCE

Text

Seed potatoes are subject to a strict control of quality for certification. In France, blackleg, a bacterial disease caused by *Pectobacterium* and *Dickeya*, is regularly the main cause of rejection of seed potatoes during field inspection. So far, neither conventional nor biocontrol product are available on the market to control this disease. *Pseudomonas* PA14H7, a bacteria isolated from potato rhizosphere, was identified as an antagonist agent against *Dickeya*.[1] The objective of this study is to identify the main active(s) molecule(s) produced by PA14H7 in order to understand the mechanism involved in this antagonism. In that way, supernatant of PA14H7 culture was extracted and analyzed by LC/MS, GC/MS and NMR. We have putatively characterized the presence of 7-hydroxytropolone (7-HT). This molecule has already been described in other *Pseudomonas*[2] and is known for antibacterial and antifungal activities. We have synthesized 7-HT[3] in order to determine the amount produced by PA14H7 and to compare its in vitro efficiency vs PA14H7 supernatant one. The final objective is to understand the key role of 7-HT in the antagonist activity of PA14H7 as a potential biocontrol agent.

OPTIMUM TIMING OF FUNGICIDE APPLICATIONS FOR MANAGING KERNEL SMUT OF RICE

ZHOU Xin-Gen. (1), KHANAL Sabin. (2), GAIRE Shankar Prasad. (3)

(1) Texas A&M AgriLife Research Center, Beaumont, UNITED STATES; (2) Texas A&M AgriLife Research Center, Beaumont, UNITED STATES; (3) Texas A&M AgriLife Research Center, Beaumont, UNITED STATES

Text

Kernel smut, caused by *Tilletia horrida*, is an emerging disease of rice that represents a major threat to the U.S. rice industry. Because of the unavailability of resistant cultivars, farmers heavily depend on midseason preventive applications of fungicides. Timely application of fungicides is the key to managing kernel smut and maximizing production returns. The objective of this study was to determine the best timing of fungicide applications for management of kernel smut in rice. A field trial was conducted in 2020, 2021 and 2022 to evaluate the efficacy of applications of Amistar Top (azoxystrobin plus difenoconazole) and Tilt (propiconazole) made at 1) panicle differentiation (PD) + 7 days, 2) mid-boot, 3) heading, 4) PD + 7 days plus mid-boot, 5) mid-boot plus heading, and 6) unsprayed control. Plots were spray inoculated with secondary sporidia of the fungus (10^5 spores/ml) at both boot and

heading stages. Over the years, both fungicides were effective in reducing kernel smut, with Amistar Top being slightly more effective than Tilt. Applications made at the mid-boot stage were most effective with up to 80% control efficacy, followed by those at PD + 7 days. Applications made at the heading stage were ineffective. The results demonstrate that the mid-boot stage is the optimum time to apply a fungicide for managing kernel smut of rice.

P4.1-022

EXPLORING ALTERNATIVES AND SYNTHETIC FUNGICIDES FOR APPLE BITTER ROT MANAGEMENT IN THE MID-ATLANTIC U.S.A.

ACIMOVIC Srdan. (1), BORBA Matheus. (1)

(1) Virginia Tech , Winchester, UNITED STATES

Text

In search of biorational options to manage apple bitter rot caused by different *Colletotrichum* species, we evaluated 18 fungicide treatments on cultivars ‘Idared’ (ID) and ‘Golden Delicious’ (GD). Out of 18 treatments 17 were a single-material spray programs applied throughout the summer. In this inoculated experiment, testing one fungicide with multiple applications until harvest allowed us to determine the whole season protection efficacy. Out of 8 treatments with biorational alternatives, such as giant knotweed extract, *Swinglea glutinosa* extract, acibenzolar-*S*-methyl, laminarin, citric acid, and phosphites none provided satisfactory management of apple bitter rot allowing 37-67% disease incidence on ID and 11-33% disease incidence on GD fruit. In July 2022, all synthetic fungicides including ferbam, captan, ziram, fluazinam, benzovindiflupyr, pyraclostrobin and trifloxystrobin, but not kresoxim-methyl, were effecive with zero to 13% disease incidence on ID fruit and only 0.6 to 3% disease incidence on GD fruit. Untreated inoculated and untreated non-inoculated controls exhibited 63 and 75% disease incidence on ID, respectively. Both controls exhibited 28% disease incidence on GD fruit. Second rating in August confirmed these results, but showed more disease incidence in biorational materials (78-89% on ID; 21-48% on GD) and in synthetic fungicides (12-39% on ID; 6-11% on GD). Future same and new experiments will serve to find new options for bitter rot control.

P4.1-023

EVALUATION OF BURKHOLDERIA GLUMAE CONTROL IN RICE (ORYZA SATIVA) VARIETY 67 WITH SILVER NANOPARTICLES (AGNPS)

MORALES BECERRA Carlos Ernesto. (1), **CHAVES-BEDOYA Giovanni. (1)**, ORTIZ-ROJAS Luz Yineth. (1)

(1) Universidad Francisco de Paula Santander, Cucuta, COLOMBIA

Text

Bacterial panicle blight caused by Burkholderia glumae is one of the world's most serious seed-borne bacterial rice diseases, with an impact on food sustainability in the future. It is a

typical example of the change from a minor plant disease to a major disease due to changes in environmental conditions. Despite their economic importance, effective control measures and rice varieties with complete resistance to this disease are not yet available. In this study, the effect of silver nanoparticles (AgNPs) electrochemically synthesized and applied by spraying in rice plants was evaluated to determine if they constitute an effective control method against B. glumae under greenhouse conditions compared to commercial control. The study was done in a completely randomized design with 5 treatments: T1. Preventive, T2 curative, T3. Positive control, T4. Negative control, T5. Complete control. It was found that the preventive treatment with 5 ppm of AgNPs presents a promising phytoprotective effect for the control of B. glumae in rice variety 67. Further studies are required to assess their effect on field and possible environmental effects.

DEVELOPMENT OF RESOURCES FOR CONTROL OF STRIPE RUST ON WHEAT AND BARLEY IN THE UNITED STATES

CHEN Xianming. (1,2), WANG Meinan. (2), EVANS Kent. (1)

(1) USDA-ARS Wheat Health, Genetics, and Quality Research Unit, Pullman, Wa, UNITED STATES; (2) Department of Plant Pathology, Washington State University, Pullman, Wa, UNITED STATES

Text

Stripe rust, caused by *Puccinia striiformis*, is one of the most destructive diseases of cereals worldwide. To control the disease on a yearly basis, potential yield losses are predicted before stripe rust development based on weather data, field surveys are conducted during the crop season, and recommendations are made for implementing appropriate control measures for individual cultivars based on the yield loss prediction, field surveys, and cultivar resistance. For improving control of stripe rust, various studies have been conducted for new knowledges of virulence, genomics, and population genetics of the pathogen, epidemiology of the disease, host resistance, and measures for integrated control. Races of the pathogen have been identified using a set of differentials, and selected races are used in greenhouse tests, together with field tests, to screen wheat germplasm and breeding lines for developing new resistant cultivars. SSR, SNP, and KASP markers have been developed for monitoring the pathogen populations. To discover more genes for resistance to stripe rust, bi-parental populations and assembled panels of wheat germplasm have been studied using QTL mapping and GWAS approaches, respectively. KASP markers have been developed for new resistance genes, and new wheat germplasm lines have been developed for resistance genes and combinations of genes for more efficiently use in breeding programs.

DETECTION OF ERWINIA AMYLOVORA IN APPLE ROOTSTOCKS: A CASE STUDY IN HIGH-DENSITY APPLE ORCHARDS

ACIMOVIC Srdan. (1), DELGADO SANTANDER Ricardo. (2), MEREDITH Christopher . (3), PAVLOVIC Zaklina. (4)

(1) Virginia Tech , Winchester, UNITED STATES; (2) Washington State University, Prosser, Wa, UNITED STATES; (3) Cornell University, Highland, Ny, UNITED STATES; (4) University of Tennessee, Knoxville, Tn, UNITED STATES

Text

Fire blight infection of apple rootstock can lead to canker development or asymptomatic infections. Cankers can girdle the rootstock leading to tree death and production losses, especially in high-density orchards. Confirming fire blight infection in apple rootstock is a challenge for apple growers because fire blight cankers can be visually misdiagnosed with cankers caused by several Oomycete and fungal pathogens. Accurate fire blight diagnosis is necessary to inform the efforts to remove infected trees from the orchard, can assist in replanting the orchard, and help prevent further pathogen dissemination. We used PCR to detect *Erwinia amylovora* in symptomatic and asymptomatic rootstocks for two years. Rootstock canker incidence and tree death were rated in 3 to 6 infection foci per orchard on 7 farm sites in New York state. Each focus consisted of a central rootstock-cankered tree and the nearest surrounding edge trees with no canker on the rootstock. In the first year, most orchards showed *E. amylovora* detection rates of 10.7 – 45.3% in the asymptomatic rootstocks on the edge trees in infection foci. One year later, 20.8 – 56.3% cankered rootstocks were detected on the edge trees and from zero to 35.4% dead edge trees were recorded. However, PCR showed no pathogen detections in sampled edge rootstocks one year later. Our results elucidate latent fire blight infections in rootstock and indicate that whole trees need to be removed as rootstocks express cankers with delay.

P4.1-026

IN VITRO AND IN SITU ANTIFUNGAL ACTIVITY OF THREE PLANT EXTRACTS AND TWO SYNTHETIC FUNGICIDES FOR THE CONTROL OF VASCULAR WILT OF OIL PALM CAUSED BY FUSARIUM OXYSPORUM F. SP. ELAIEDIS.

MOFORCHA Lilian Zemenjuh. (1), KINGE Tonjock Rosemary. (2), BECHEM Eneke Tambe. (1)

(1) University of Buea, Buea, CAMEROON; (2) University of Bamenda, Bamenda, CAMEROON

Text

The most important oil crop in the world is oil palm whose production is reduced yearly by diseases with a greater percentage being Fusarium oxysporum f. sp. Elaiedis (Foe) which is the causal pathogen for vascular wilt. Plant based fungicides appear to be better alternatives because they are eco-friendly and are not dangerous to consumers in contrast to synthetic pesticides. In an approach towards the development of eco-friendly management schemes, an in vitro and in situ antifungal assay was conducted against four morphotypes of Fusarium oxysporum f. sp. elaiedis with extracts of Tithonia diversifolia, Azadirachta indica and Voacanga africana. The hexane, methylene chloride and methanol extracts of these plants were tested at five concentrations (10%, 15%, 20%, 25% and 30%). Also, Benomyl® and Mancozeb® (synthetic fungicides) were equally tested at five concentrations to do a comparative study of their efficacy. The results revealed that 30% concentration of methanolic extract of Azadirachta indica inhibits all four morphotypes in vitro and in a greenhouse experiment. Since plant extracts are a source of cost effective and non-

hazardous fungicide against Foe, Azadirachta indica is therefore recommended by this study as a good antifungal efficacy, used at 30% concentration for formulating new, safer and ecofriendly fungicides.

INNOVATIVE OPTICAL DEVICE FOR REAL-TIME SPORE DETECTION APPLIED ON GRAPEVINE DOWNY AND POWDERY MILDEW

LEONI Sara. (1,2), BASSO Tessa. (2), BERTI Nicolas. (1), SCHNEE Sylvain. (1), FABRE Anne-Lise. (1), KASPARIAN Jérôme. (2), WOLF Jean-Pierre. (2), DUBUIS Pierre-Henri. (1)

(1) Agroscope Changins, Nyon, SWITZERLAND; (2) University of Geneva, Geneva, SWITZERLAND

Text

Downy and powdery mildews, caused respectively by the oomycete Plasmopara viticola and the ascomycete Erysiphe necator are the major threat for Swiss grapevine. As both polycyclic pathogens, they produce abundant number of spores and cause multiple infections throughout the season.

Decision support systems as infection forecast are only based on weather data and lack biological data such as spores load. For this purpose, an innovative spore detector device was developed. Through holographic imaging, it allows us to detect aerial particles in real time. A trained artificial intelligence identifies and counts Plasmopara viticola and Erysiphe necator spores 24/7. Holographic imaging allows us to be far more specific than classic optical imaging by getting 3D shape, density and weight. An artificial intelligence is trained by a neural network on images of pure spores cultivated in laboratory. Experiments on field during 3 seasons gave satisfactory results, linked to the diseases observed on vineyards. Quantitative spore detection data will be integrated in the decision support system and tested in field trials with the goal to avoid unnecessary sprays.

Aims of the use of this device are to improve performances of the Vitimeteo forecasting model by integrating spore quantitative data, to monitor the first appearance of a target spore and to monitor disease progression on site. Finally, this new technology could be applied to other relevant fungal diseases caused by spore dispersion.

Text

The Brazilian agribusiness supply chains now have an even stronger support for scientific research on diseases, pests and weeds in tropical agricultural systems of grain and fiber crops such as cotton, corn, soybeans, and wheat. A nationwide initiative called Tropical Plant Health Network (RFT) arises to organize, strengthen, and optimize existing collaborative networks. This national cooperative research network has developed a website (https://www.fitossanidadetropical.org.br/) to centralize important information that was previously spread among different research groups. Our work proposal aims to optimize existing collaborate networks for multiple biological targets between research centers to develop applied studies in plant health. The idea was to consolidate almost 20 years of experiences in collaborative research, and at the same time form a basis for the development of future research networks. RFT already brings together more than 34 public and private research centers and several supporters from funding organizations and industry sectors. This document aims to present to the scientists from 12th International Congress of Plant Pathology, in Lyon/France, the advantages and benefits, the potential reach and structuring process of the RFT. **Support:** FAPEAGRO. **Acknowledgement:** National Cooperative Network in Soybean, Corn, Wheat and Cotton.

SCREENING OF BIOCONTROL SOLUTIONS AGAINST BLACK-ROT (GUIGNARDIA BIDWELLII), AMONG REGISTERED ANTI-MILDEWS BIOFUNGICIDES TO DESIGN BLACK ROT CONTROL STRATEGIES FOR CONVENTIONAL AND ORGANIC VITICULTURE AND THE DEPLOYMENT OF RESISTANT VARIETIES.

DUFOUR Marie-Cécile. (1), GUIBERT Antoine. (1), AVELINE Nicolas. (2), BURGUN Xavier. (2)

(1) INRAE, Bordeaux Sciences Agro, ISVV, SAVE/UMT SEVEN, Villenave-D'ornon, France, FRANCE; (2) IFV-Institut français de la vigne et du vin, Pôle Bordeaux Nouvelle-Aquitaine/ UMT SEVEN, Blanquefort, France, FRANCE

Text

Black rot (*Guignardia bidwellii*), considered as a secondary disease may be an emerging problem in the near future in grapevine. It can cause losses of up to 80% at harvest, and may re-emerge owing to the reduction or even withdrawal of chemical compounds, the deployment of varieties resistant to mildews, but also because of climate change.
To date, there is no biocontrol product approved against this disease in France and we have very few candidates for the development of alternative control methods.
As part of the Zero Black-rot project (France Agrimer funding), the aim was to identify active biosolutions and integrating them into the technical itineraries of winegrowers.
To this end, a set of products or substances already approved and marketed in French vineyards against downy and powdery mildews and/or Botrytis) have been selected, preferably from the lists of approved biocontrol products, of basic substances or biostimulants or fertilizers.
Out of a total of 42 products tested under controlled in vitro conditions, only 16 products have

shown a significant efficacy against black rot. At the end of the greenhouse in-vivo further testing, only 8 caught our attention.
Two candidates were further tested for integration into alternative strategies in vineyards: potassium bicarbonate and potassium phosphonate. They displayed significant, yet partial, effectiveness. These products can already be integrated into the vineyard, in combination with sulfur or (modulated) copper.

P4.1-030

BROAD-SPECTRUM CONTROL OF FOLIAR DISEASES WITH AN ENZYME-BASED BIOCHEMICAL PESTICIDE

MAYTON Hilary. (1), BECKER Chris. (2), ELZINGA Dezi. (1), MORSE Nate. (1), MURRAY Matt. (1), HOEPKER Alex. (1), CORGIE Stephane. (1)

(1) Agrynex, Ithaca, UNITED STATES; (2) Barr Scientific LLC, Romulus, UNITED STATES

Text
Field trials were conducted in 2022 to evaluate the efficacy of an enzyme-based biochemical pesticide (AX), with potential for organic registration, for control of foliar diseases on cabbage, cucumber, and pumpkins in Phelps, NY, USA. Plots for all crops consisted of 10 plants using a complete randomized block design with four replicates, and all data were collected from the center 5 plants. Non-treated and commercial controls were included in all trials. Experimental AX formulations and commercial controls were applied with a CO_2 hand-held pressurized sprayer. Cabbage plants were inoculated with *Xanthomonas campestris* pv *campestris* grown from cultures. Cucumber (downy mildew) and pumpkin (powdery mildew) plots were not inoculated; infection was induced from natural field inoculum. On all rating dates, AX formulations and the commercial control Kocide 3000 (Certis, USA LLC) reduced the severity of black rot on cabbage compared to the non-treated control. At 20 days after the first application, the severity of downy mildew on cucumbers treated with each AX formulation was reduced significantly compared to both the non-treated and commercial control Stargus (Pro Farm Group, USA) treated plants. In addition, on all rating dates, AX formulations and commercial control Regalia (Pro Farm Group, USA) significantly reduced the severity of powdery mildew on pumpkins. These trials demonstrate that AX proprietary enzyme formulations have broad-spectrum biocidal activity.

P4.1-031

NOVEL SOURCES OF RESISTANCE TO SOYBEAN SEEDLING DISEASE PATHOGEN PYTHIUM IRREGULARE

DETRANALTES Christopher. (2), MA Jianxin. (2), **CAI Guohong. (1)**

(1) USDA ARS, West Lafayette, UNITED STATES; (2) Purdue University, West Lafayette, UNITED STATES

Text
Soilborne seed rot and seedling diseases of soybean are the number two cause of soybean yield loss in the United States behind soybean cyst nematode. Over 200 soybean varieties

were selected from the USDA soybean germplasm collection for resistance screening against predominant Midwest species *Pythium irregulare*, *P. ultimum* var. *sporangiiferum* and *P. ultimum* var. *ultimum*. Varieties scoring higher on both stand counts and adjusted root weight measures significantly greater than the population mean were discovered in the *P. irregulare* screenings, while no significant resistance was observed in in the *P. ultimum* screenings. A continuous distribution of phenotypes was observed among the selected varieties indicating a likely polygenic quantitative resistance. GWAS uncovered two marker trait associations (MTAs) explaining ~10% each of the variation observed in both emergence and root weight after inoculation. Loci in linkage with these MTAs show both susceptibility and resistance functions. Comparison to the published Williams82 reference genome indicated that the resistance MTA on chromosome 10 is located in a polygalacturanase-like gene in a region also predicted to produce cupins, germins, and polyketide synthesis enzymes. The susceptibility MTA on chromosome 15 was not located within any annotated regions but within 100 kbp of a leucine-rich repeat protein kinase.

EXOGENOUS APPLICATION OF METHYL SALICYLATE INDUCES DEFENSE IN BRASSICA AGAINST PEACH POTATO APHID MYZUS PERSICAE

ALI Jamin. (1)

(1) Keele University, Newcastle Under Lyme , UNITED KINGDOM

Text

Phytochemicals play a critical role in insect-plant interactions, insect herbivores use their sense of smell to detect the volatile compounds released by host plants. The change in phytochemistry of host plants alters the insect-plant tritrophic interactions. Several natural plant derived compounds have been found capable that affect plant's chemistry by activating cascade of defense pathways on their exposure to host plants. Methyl salicylate (MeSA) is a natural plant derived compounds that has been used as a plant defense elicitor on several crop plants. The aim of this study was to investigate the effects of different concentrations (75 mg/l and 100 mg/l) of MeSA treatment of Brassica rapa subsp. chinensis cv. 'Hanakan' on interactions with peach-potato aphid *Myzus persicae* and its natural enemies *Diaeretiella rapae*. To test the responses of *M. persicae* and its natural enemies *D. rapae*, performance and behavioural bioassays were performed. Our results showed that brassica plants treated with MeSA (100 mg/l) significantly reduced aphid performance due to high mortality and low larviposition in cage bioassay. In aphid settlement bioassay, significant lower number of aphids were settled on MeSA treated plants. While parasitoid *D. rapae* spent significant longer time on plants treated with MeSA (100 mg/l) in foraging bioassay. The current findings can be utilised in developing new sustainable approaches for the management of peach-potato aphid.

Text

Mal secco of lemon is a highly destructive tracheomycosis caused by the fungus *Plenodomus tracheiphilus*. The management includes pruning of symptomatic branches and their sanitation by spraying aqueous suspensions of Cu^{2+}-based fungicides. However, these treatments cause the dispersion of Cu^{2+} in the environment, with toxic effects on living organisms and negative impact on soil microbiome and contamination of food.
This study investigated the effectiveness of a super absorbent polymer (SAP) containing copper (SAP-Cu) in controlling mal secco. This new polymer, thanks to its physical properties, acts as reservoir for the controlled release of Cu^{2+} ions ensuring a longer lasting effectiveness of the treatment and preventing, at the same time, the excessive soil and groundwater contamination resulting from the leaching of the metal.
SAP-Cu was characterized by AAS, UV-VIS spectroscopy and ToF-SIMS. *In vitro* tests were performed to determine the inhibitory effects of SAP-Cu against *P. tracheiphilus* on both PDA medium and naturally infected lemon cuttings. Results showed that SAP adsorbed up to 30 times its weight of Cu^{2+} solution at 236 mM; when SAP-Cu was in contact with lemon twigs it transferred Cu^{2+} ions along the xylem vessels. *In vitro*, SAP-Cu significantly inhibited the viability of *P. tracheiphilus* both in PDA medium and in naturally infected lemon twigs. Overall, this study highlighted that the SAP could be a suitable carrier for Cu^{2+} or other antifungal compounds.

P4.1-034

APPLICATION OF YEAST, RESISTANCE INDUCTORS AND MULTI-SITE FUNGICIDES IN THE CONTROL OF DISEASES IN COTTON

BONALDO Solange Maria. (1), TORREZAN Mateus De Aguiar . (1), SANTOS Carlos Guilherme Theodoro Dos. (1)

(1) UFMT/CAMPUS SINOP, Sinop, BRAZIL

Text

Cotton is one of the main products exported by Brazil. But the main production costs is the application of fungicides to control ramularia spot (*Ramulariopsis gossypii*) and target spot (*Corynespora cassiicola*). The present work evaluated the effect of multisite fungicides, resistance inducers and yeast in the control of target spot and ramularia in cotton and their impact on yield. The experiment was conducted in the municipality of Sorriso/MT, in the

2019/20 harvest, experimental design was randomized blocks, consisting of eight treatments and five replications. Multisite fungicides (mancozeb, copper oxychloride and chlorothalonil), resistance inducers (salicylic acid and micronutrient “copper”) and yeast Pichia sp. associated with application of site-specific fungicides. Disease severity was evaluated, and the area under disease progress curve (AUDPC) calculated. To evaluate productivity and measure fiber quality, bolls were collected from all plants in the two central lines of each plot. In the evaluation of the AUDPC of the target spot there was no difference between the evaluated treatments, however for ramularia all treatments differed from the control treatment. The fiber quality was not affected by the evaluated diseases. Increase in yield was observed in the treatment with site-specific fungicide plus the addition of the multi-site fungicide chlorothalonil, providing an average increase of 88.3% in yield.

P4.1-035

IDENTIFICATION AND FUNGICIDE SENSITIVITY OF XYLARIA SP. GROWN ON SHIITAKE WOOD LOG IN TAIWAN

YU Shiang Shiuan. (1), LU Yun Sheng. (1)

(1) Taiwan Agricultural Research Institute, Taichung, TAIWAN

Text

Shiitake is high value mushroom in Taiwan, and usually be planted by sawdust bag or wood log. Because of the climate factors in Taiwan, the diseases, pests or competitors occurred easily during shiitake cultivation. However, the effect of pathogens or competitors on the yield and quality of shiitake remain to be resolved. This study focused on a fungus which was isolated from the shiitake wood log. After comparing the fruiting bodies in the field and data of ITS sequence analysis, the fungus was preliminarily identified as *Xylaria* sp. According to the results of the dual culture assay involving *Xylaria* sp. (CYX-1) and *Lentinula edodes* (Br-1), the mycelium growth of Br-1 was significantly suppressed. After 14 days culturing, mycelium of Br-1 was covered by CYX-1, and the backsides on PDA turned brown. It showed that CYX-1 was detrimental to the mycelial growth of Br-1 and could be the competitor of Br-1 in wood log. In the fungicide sensitivity test, the mycelium of CYX-1 could not grow on PDA with 30 ppm of thiabendazole and be inhibited in filter paper-disk with 1,000 dilution fold of thiabendazole (60% SC). Therefore, thiabendazole can be used as a potential chemical control agent for *Xylaria* sp. Future work will focus on the identification and phylogenetic analysis of CYX-1 by artificial culture of fruiting bodies and multiple-gene sequencing, respectively. The mechanism of pathogenesis in *Xylaria* sp will also further to understand.

P4.1-036

EFFICACY OF INORGANIC CHEMICALS AS PLANT RESISTANCE INDUCER ON THE CONTROL OF POTATO COMMON SCAB DISEASE

LIN Ching Yi. (1), LIN Hui Ju. (1)

(1) Chiayi Agricultural Experiment Branch, Taiwan Agricultural Research Institute, Chiayi City, TAIWAN

Text
Potato common scab caused by several members of the genus *Streptomyces* is an economically important disease worldwide, and can cause significant reduction in the market value of potato. As there are no effective pesticide and limited results of crop rotation and resistant potato cultivars for managing the disease, this study explored the possibility of inducing defense by inorganic chemicals such as salicylic acid (SA) and neutralized phosphorous acid (NPA) to control *S. europaeiscabiei* in the greenhouse. Application of 0.05% SA or 0.1% NPA was conducted on potato by soil drench and tuber treatment, respectively. The results showed that the disease severities of inoculated potato plants by soil-drench with SA and NPA were 20.85% and 39.75%, whereas the disease severity of tuber treatment with SA and NPA were 35.18% and 38.77%. Reduced disease severities of potato common scab were observed in case of both soil drench and tuber treatment, but there was a significant difference only between soil drench with SA and the untreated control (47.30%), indicating that soil drench with SA provided better disease control than tuber treatment.

P4.1-037

AN INTEGRATED PRODUCTION CHAIN FOR CERTIFIED OLIVE, CITRUS AND FIG PROPAGATION MATERIAL IN GREECE

BERIS Despoina. (1), RAMPOU Aggeliki. (1), MALANDRAKI Ioanna. (1), DERVISI Irene. (2), KROKIDA Afroditi. (1), VASSILAKOS Nikon. (1), **VARVERI Christina. (1)**

(1) Laboratory of Virology, Benaki Phytopathological Institute, Kifissia, Athens, GREECE; (2) Laboratory of Bacteriology, Benaki Phytopathological Institute, Kifissia, Athens, GREECE

Text
In the frame of the national “Rural Development Programme 2014 – 2020”, an integrated chain for the production of certified propagating material for olive, citrus and fig trees has been initiated for the first time in Greece. Starting from mother tree plantations of the official plant variety maintainer, the Hellenic Agricultural Organization “Demeter”, pre-basic plantations were established in Chania, Crete and Kalamata, Peloponnese. Basic plantations are being established by two cooperating nurseries and finally certified plantations will be created by the Agricultural Cooperative of Kavousi, Crete. At all stages varietal authenticity and plant health are ensured by appropriate testing. Within this framework, the National Reference Laboratory of Virology of Benaki Phytopathological Institute has applied and verified current molecular detection methodologies for four olive viruses (OLYaV, ArMV, CLRV, SLRSV), seven citrus viruses/viroids (CTV, CVV, CPsV, CLBV, CiVA, CEVd, HSVd), as well as four fig viruses (FMV, FLMaV-1, FMMaV, FFkaV) to meet Commission Implementing Directive (EU) 2020/177 requirements. Virus infected olive and citrus pre-basic or basic trees were only scarcely found. The completion of the proposed integrated production chain promotes the use of certified propagating material of olive, citrus and fig trees, including important local varieties, currently quite limited in the country and thus reduces the necessity for imports of mother plants and seedlings.

P4.1-038

DECIPHERING THE INFLUENCE OF CO-INOCULATION TIMING ON ANTAGONISTIC EFFECTS OF LEPTOSPHAERIA BIGLOBOSA ON L. MACULANS

BINGOL Evren. (1), QI Aiming. (1), RITCHIE Faye. (2), KARANDENI-DEWAGE Chinthani. (1), FITT Bruce D. L.. (1), HUANG Yongju. (1)

(1) University of Hertfordshire, Hatfield/hertfordshire, UNITED KINGDOM; (2) ADAS Boxworth, Cambridge, UNITED KINGDOM

Text

Phoma stem canker is an economically damaging disease of oilseed rape, caused by two co-existing pathogens *Leptosphaeria maculans* and *L. biglobosa*. *L. maculans* produces a phytotoxin called sirodesmin PL. Our previous work showed that *L. biglobosa* has an antagonistic effect on the production of sirodesmin PL if it was simultaneously co-inoculated with *L. maculans*. Here, we investigated the effects of sequential co-inoculation on interactions between the two pathogens in terms of sirodesmin PL production. Clarified v8 broths were inoculated with *L. maculans* first, then *L. biglobosa* sequentially with 1, 3, 5, 7 days in-between, and vice versa. Controls were *L. maculans* only, *L. biglobosa* only, and *L. maculans* & *L. biglobosa* co-inoculated simultaneously. Secondary metabolites were extracted from culture filtrates at 14 days post inoculation and analysed with HPLC. Mycelia were freeze-dried, weighed, and homogenised for DNA extraction and qPCR. Results showed no significant differences in mycelial weight between treatments. Both sirodesmin PL and its precursors were not produced if *L. biglobosa* was inoculated before *L. maculans*, this was due to *L. biglobosa* inhibiting the growth of *L. maculans*, confirmed by qPCR. However, the antagonistic effects of *L. biglobosa* were lost if it was co-inoculated 5 days after *L. maculans*. There is a need to investigate the mechanisms of the antagonistic effects of *L. biglobosa* to develop new strategies for sustainable control of phoma stem canker.

P4.1-040

EARLY BLIGHT COMES LATE IN SWEDISH WARE POTATO

EDIN Eva. (1)

(1) Rural Economy and Agricultural Societies, Västerås, SWEDEN

Text

Early blight is one of the most common foliar diseases in potato and is caused by the fungus *Alternaria solani*. Long-term field inventories revealed that the outbreak of early blight starts in mid-August and can be severe in mid-September in starch potato crops, especially in the south-eastern parts of Sweden. Inventories of the incidence of early blight in ware potato grown in central Sweden showed another pattern as just a few lesions could be found in August and September. However, most of the ware potato haulm are destroyed in late August to early September to ensure desired quality. Since dehaulming often is done at the same time as the epidemic of early blight starts, the effect, and necessity, of fungicide use on ware potato yield were evaluated in four field trials. The fungicide strategy for the two field trials in Skåne (2015) was an alteration of a triazole and a mixture of a strobilurin and boscalid. The treatments in the two field trials in central Sweden (2015 and 2016) were either a strobilurin or a mixture of a strobilurin and boscalid. The fungicide efficacy was compared to an untreated control in all field trials.

There was no effect on yield in neither of the four trials suggesting that fungicide use against *A. solani* is not needed in Swedish ware potato production. One concern for the unnecessary use of fungicides in ware potato is the prevalence of resistance genes toward fungicides based on strobilurins and SDHI in the Swedish population of *A. solani*.

P4.1-041

EVALUATING THE EFFICACY OF PHOSPHITE AND METALAXYL IN PHYTOPHTHORA ROOT ROT CONTROL IN AVOCADO

JOSE Jacob. (1), DANN Elizabeth. (1), DRENTH Andre. (1)

(1) Queensland Alliance for Agriculture and Food Innovation, The University of Queensland , Brisbane, AUSTRALIA

Text

Phytophthora root rot, caused by the oomycete *Phytophthora cinnamomi*, is the most economically important disease in avocado world-wide. Field and glasshouse trials have evaluated effects of timing and method of application of anti-oomycete chemistries phosphite and metalaxyl, for management of Phytophthora root rot in avocado. Tree health and trunk diameter of grafted nursery trees planted in a field site infested with *P. cinnamomi*, were significantly greater as early as 3 months after planting, for trees which had received phosphite as pre-planting drench, phosphite applied as sprays pre- and post-planting, or pre- and post-planting metalaxyl granules applied to the surface of soil, compared with untreated control, and phosphite as standalone pre- and post-planting sprays. In glasshouse trials with seedlings, phosphite foliar sprays applied at 2 time points significantly reduced % root necrosis following inoculation with *P. cinnamomi* in one of the two experiments. However, metalaxyl granules applied on the surface of the potting mix significantly reduced both % root necrosis and % frequency of *P. cinnamomi* recovered from roots, and significantly increased plant height, diameter, leaf number, both above-ground and root biomass, compared to that of *P. cinnamomi*-inoculated control plants in both trials. Further experiments are in progress and results will be presented.

CHEMICAL PRIMING OF DEFENCE IN FOREST HEALTH: OAK DISEASES CASE OF STUDY

SANCHEZ-LUCAS Rosa. (1), BOSANQUET Jack . (1), PASTOR Victoria. (2), LUNA Estrella. (1)

(1) University of Birmingham, Birmingham, UNITED KINGDOM; (2) Universitat Jaume I, Castellon, SPAIN

Text

Plants are continually exposed to (a)biotic stresses potentiated by climate change. One plant defense strategy, to cope with these threats, is priming, a sensitisation of plant defence mechanisms for a faster and/or stronger activation after subsequent attack. Studies on priming in oak seedlings are lacking. We aim to determine whether oak seedlings can

express chemical-induced priming and the potential trade-off in growth. Oak seedlings were treated with salicylic acid (SA), jasmonic acid (JA) and beta-aminobutyric acid (BABA) 7 days before infection with Erysiphe alphitoides, the powdery mildew (PM) causal agent. To investigate the mechanisms behind the specific SA and BABA priming of defence, untargeted metabolome and transcriptome analyses were performed. Metabolites were subjected to LC-MS/MS. Spectra were filtered using the XCMS R script and MarVis was employed to putatively identify metabolites and pathways. Fold changes versus water treatment were applied to isolate primed metabolites. In addition, RNA-seq was performed using the same leaf samples from the PM experiment. Transcriptome data was analysed using the Quercus robur genome as reference (www.oakgenome.fr) with Python (HTSeq) and R (DESeq2) scripts. We have identified molecular markers of priming in oak seedlings. Our results, in terms of enhanced resistance to PM and early/late responses depending on the chemical applied, provide valuable information to fight pathogens in oak seedlings.

P4.1-043

TOMATO SEED PRIMING WITH WATER-SOLUBLE POLYSACCHARIDES FROM JANIA ADHAERENS PROMOTES PLANT GROWTH AND INCREASES PLANT RESISTANCE TO SOILBORNE PATHOGENS

RIGHINI Hillary. (1), ROBERTI Roberta. (1), CETRULLO Silvia. (1), FLAMIGNI Flavio. (1), MARTEL QUINTANA Antera. (3), FRANCIOSO Ornella. (1), PANICHI Veronica. (1), CIANCHETTA Stefano. (2), GALLETTI Stefania. (2)

Text

Marine macroalgae are a source of natural bioactive compounds, such as polysaccharides, that deserve exploitation in the field of plant disease management. Moreover, current European regulations require that priority should be given to alternative products than synthetic pesticides.

In agriculture, algae have been mostly used for their beneficial properties on plant development.

In this study, we showed that tomato seed biopriming with water-soluble polysaccharides (WSPs) from the alga *Jania adhaerens* protects seedlings and adult plants from the soilborne pathogens *Fusarium oxysporum* f.sp. *lycopersici*, *Pythium ultimum* and *Rhizoctonia solani* artificially inoculated in a growing substrate.

First, WSPs were characterized by FT-IR spectroscopy and seedling emergence, disease severity, and expression of genes related to phenylpropanoid, chlorogenic acid, SAR and ISR pathways, and chitinase and *β*-1,3 glucanase activities were investigated after seed priming.

WSPs FT-IR spectra showed typical bands assigned to alduronic acids and glycosidic linkage formation in polysaccharides. Depending on the WSPs dose, seed treatment enhanced seedling emergence, reduced disease severity and increased plant growth. Moreover, HQT, HCT, PAL, PR1 and PR2 genes were significantly upregulated together with β-1,3 glucanase activity.

These results show that algal WSPs have the potential for being considered as natural compounds for soilborne pathogens control in sustainable agriculture.

P4.1-044

STUDY OF ANTHRACNOSE FRUIT ROT & BLACK LEAF SPOT OF STRAWBERRY IN PAKISTAN AND THEIR BIO-MANAGEMENT USING INDIGENOUS PLANTS EXTRACTS

MEHMOOD Nasir. (1), RIAZ Abid. (2), SULTAN Sidrah. (3), GHUFFAR Salman. (4), AZHAR Sohaib. (5)

Text

During 2017-18 and 2019-20 surveys were conducted in 12 strawberry producing districts of Pakistan, of which 8 in Punjab province, 3 in Khyber Pukhtunkhwa province and Islamabad. Disease incidence ranged from 17-55 % for anthracnose fruit rot and 11-32% for black leaf Spot respectively. 90 isolates of *Colletotrichum* spp. (69-*C. acutatum* & 21-*C. gloeosporioides*) and 82 of *A. alternata* were identified morphologically . For molecular identification, PCR of 19 highly pathogenic isolates *C. acutatum* (12); *C. gloeosporioides* (7) & 12 *A. alternata* were amplified by ITS, BT, ACT, TEF1-α and EndoPG primers and submitted in GenBank and subjected to phylogenetic analysis. This is 1st detailed study of these strawberry diseases from Pakistan and these diseases also been reported from almost all major strawberry producing countries. The inhibitory effects of 3 plant extracts viz. *Eucalyptus camaldulensis, Cannabis sativa* and *Polygonum afghanicum* were evaluated against the mycelia growth of these fungal pathogens. Results showed that all plant extracts brought about some inhibition in the mycelial growth. However, the highest concentration caused maximum inhibition followed by lower concentrations of plant extracts. The extract of *P. afghanicum* leaves proved highly effective in inhibiting the mycelial growth of these fungi followed by *E. camaldulensis* & C. *sativa extracts*. These indigenous plants thus may have potential as the new natural fungicide for management of these fungal pathogens

Text

Wheat blast is considered one of the most devastating fungal diseases affecting wheat crops worldwide. The disease is caused by the ascomycetous fungus *Pyricularia oryzae Triticum* lineage (*PoT*l). In Brazil, populations of the pathogen have shown the prevalence of high levels of resistance to fungicides used intensively for managing wheat diseases. To rationalize fungicide inputs, we need high-performance monitoring tools, enabling quantitative measurement of pathogen´s inoculum levels and detection of fungicide resistant alleles. Therefore, using an automated spore sampling device positioned in a major wheat cropping region (Londrina, Paraná), coupled with a real time qPCR assay, our objectives were to i) monitor specific fungal DNA from *PoT*l airborne ascospores continuously released from 2019 to 2021, and ii) reveal the prevalence of QoI resistant (QoI-R) and QoI sensitive (QoI-S) *cyt*B alleles on samples. *PoT*l inoculum was consistently detected during the 2019 and 2020 within wheat cropping seasons with higher amounts detected in 2019. However, high peaks of *PoT*l DNA off-seasons also were continuously detected in both 2020 and 2021. Relative prevalence of QoI resistant (QoI-R) and QoI sensitive (QoI-S) *cyt*B alleles in airborne ascospores samples was detected by a combination of PCR-amplification and pyrosequencing in all the subset of 14 *PoT*l DNA randomly chosen for this assay. **Support:** FAPESP, Araucaria Foundation and IDR-Paraná (Brazil), and BBSRC (UK).

EVALUATING HARD SQUASH CULTIVARS FOR SUSCEPTIBILITY TO POWDERY MILDEW AND FRUIT ROT

PERLA David. (1), **MEDINA-MORA Carmen M.. (1)**, ENGFEHR Cheryl. (1), HAUSBECK Mary K. . (1)

(1) Michigan State University, East Lansing, UNITED STATES

Text

Michigan is an important producer of squash, pumpkins, and cucumbers in the United States. Powdery mildew (PM) (*Podosphaera xanthii* and *Golovinomyces cichoracearum*) affects cucurbits causing foliar blight, defoliation, and reduced fruit yield and quality. Fruit rot (*Phytophthora capsici*) occurs during production and postharvest and is a top grower concern. Pathogen resistance to site-specific fungicides limits mitigation strategies. We evaluated 12 *Cucurbita maxima* and *Cucurbita moschata* hard squash cultivars available for processing and the fresh market in separate, replicated, and controlled field plots under high disease pressure for susceptibility to these destructive pathogens. Age-related resistance (ARR) to *P. capsici* fruit rot occurred for all *C. moschata* cultivars 21-40 days post-pollination (DPP). For the *C. maxima* cultivars evaluated, only the Kabocha type 'Thunder' exhibited ARR at 40 DPP. When foliage was assessed for PM (% diseased foliage), all cultivars developed PM with a final disease assessment of 66 to 97%. The Kabocha type *C. maxima* cultivars Thunder (69%) and Sunshine (66%) had significantly less PM compared to the *C. maxima* cultivar NK-580 (97%) and *C. moschata* cultivar Dickinson (95%) at the end of the season. According to data from the area under the PM disease progress curve, 'Thunder' and 'Sunshine' had significantly less disease than 'Ultra' (*C. moschata*), 'New England Cheddar', and 'NK-580'. Results may inform growers and breeding programs.

IDENTIFICATION OF DEFENCE MECHANISMS IN DORMANT SEEDS

HUBERT Benjamin. (1), MARCHI Muriel. (1), LY-VU Joseph. (1), MOHAMMAD Abdulsatar. (1), LEPRINCE Olivier. (1), BUITINK Julia. (1)

(1) Institut national de recherche pour l'agriculture, l'alimentation et l'environnement (INRAE), Angers, FRANCE

Text

Dormancy is an adaptive strategy that allows seeds to persist in the soil in the face of (a)biotic stresses to ensure germination and dispersal of the species. Our team's work has shown that imbibition of dormant *Medicago truncatula* seeds leads to the activation of a defence response (Bolingue *et al*., 2010). However, the defence pathways and their regulation during dormancy remain poorly understood. Here, we set out to identify the molecular pathways underlying defense activation in dormant tomato (*Solanum lycopersicum*) seeds. As a measure of seed defence, a method was developed that determines the antimicrobial activity in exudate from imbibing seeds against *Alternaria brassicicola* using nephelometry. Exudates from imbibing seeds that are dormant show antimicrobial activity. In contrast, during imbibition of seeds that are germinating, this activity is not detectable and only becomes evident at the seedling stage. Using the accessions of the tomato MAGIC population, we identified a large variation in the level of antimicrobial activity in the dormant seed exudates and this activity appears to be tissue specific. Current research focusses on dissecting the molecular pathways in dormant tomato seeds using transcriptomic and metabolomic analyses. These results will contribute to a better understanding how seed defends themselves and will serve to develop new strategies of seed-borne pathogens management and plant breeding.

A WEATHER-BASED MODEL TO PREDICT THE POPULATION OF AUREOBASIDIUM PULLULANS AND TO IMPROVE GREY MOLD BIOLOGICAL CONTROL

CARISSE Odile. (1), HÉBERT Pierre-Olivier. (1), LEFEBVRE Annie. (1), FALL Mamadou Lamine. (1)

(1) Agriculture and Agri-Food Canada , 430 Gouin Bvl. Saint-Jean-Sur-Richelieu, CANADA

Text

Botrytis cinerea causes countless damages on an exceptionally wide range of crops. This disease is difficult to control because of the ability of the pathogen to survive under adverse environments, to profusely produce wind dispersed spores, to infect different plant tissues under a wide range of environmental conditions, to stay in a quiescent stage for up to several weeks, and to develop resistance to fungicides. Alternatives to synthetic fungicides are available but their optimal use is generally not well documented. One of the barriers to their adoption is that fungicide application recommendations are mainly based on synthetic fungicides. The objective of this study was to develop a weather-based model to predict the population temporal dynamic of the biocontrol agents Aureobasidium pullulans. Controlled

conditions experiments were conducted to determine the influence of temperature (10 to 30oC) on A. pullulans populations, estimated using a qPCR, on both strawberry leaves and flowers. Populations of A. pullulans on flowers parts were monitored under field conditions. These data were used to develop a hydrothermal model to predict the population of A. pullulans. The next step will be to integrate this predictive algorithm into a decision support tool to improve grey mould control by better timing of A. pullulans applications.

MECHANISM OF ?-1,3-GLUCANASE COOPERATING WITH HSAF IN LYSOBACTER ENZYMOGENES TO ANTAGONIZE PYTHIUM

XU Gaoge. (1), LIU Haofei. (1), LIU Fengquan. (1)

(1) Institute of Plant protection, Jiangsu Academy of Agricultural Sciences, Nanjing, CHINA

Text

Plant diseases cause serious crop loss. Biocontrol is one of the effective measures to control plant diseases caused by pathogens. *Lysobacter enzymogenes* is an environmentally ubiquitous bacteria against a variety of pathogenic fungi and oomycetes. Its antagonistic ability mainly comes from the production of secondary metabolites HSAF and extracellular lytic enzymes such as β-1,3-glucanase. In this study, we found that when incubation *L. enzymogenes* OH11 with the pathogen *Pythium aphanidermatum*, the production of HSAF significantly increased. The same results were obtained when incubated with β-1,3-glucan, which is one of the components of oomycete cell wall. Further study showed that *L. enzymogenes* OH11 uses four β-1,3-glucanases (GluA, GluB, GluC, and endoglucanase) to degrade β-1,3-glucan into glucose, then provides energy for itself, thus increasing the production of HSAF. In this process, GluB is the last step degrading β-1,3-glucan into glucose. We also found that when targeting *P. aphanidermatum*, the transcription induction of β-1,3-glucanases genes is earlier than that of HSAF biosynthesis genes, and even the transcription of β-1,3-glucanases genes is inhibited at last. The above results indicated that when *L. enzymogenes* encounters oomycetes, it will preferentially use β-1,3-glucanase as a weapon to degrade oomycetes cell wall to gain more energy, thus launching its ultimate weapon HSAF to kill oomycetes.

Text

Vascular streak dieback (VSD) is the main disease of cocoa in Indonesia that affected the decrease of production until the death of plant. This disease could decrease more than 40 % of photosynthetic activity of cocoa plant. Recently, the technique for controlling VSD was

vary in Indonesia. Good Agricultural Practices implementation in the controlling VSD are the usage of superior cocoa that resistant to VSD, the canopy replacement, shade trees management, specific nutrient application, applying the biological control, and fungicide application. This review shows that the integrated GAP implementation control for VSD needed to reach this goal.

Text

Suspected symptoms of Pierce's disease (PD) of grapevines were first observed in the mountainous vineyards of Nantou, Taiwan in 2002. To monitor potential vectors, sticky yellow cards were used and detected more than 10 species of cicadelline leafhoppers and spittlebugs. Among these species, *Kolla paulula* (Walker) and *Bothrogonia ferruginea* (Fabricius) were confirmed as vectors via transmission assays between 2012 to 2016. Both species are native to Taiwan while their host plant ranges and migration patterns were not identical, and *Bidens pilosa* L. var. *radiate* Sch. is one of their preferred host plant rather than grapevines. The investigations for the relationship between field vector population dynamics and infected grape plants showed the population density of these two vectors was highly correlated to the existence of weed hosts surrounded by the vineyard. The population density can be controlled effectively by using a riding mower regularly. PD infection rate declined effectively through farmers' inspection and removal of infected plants. So far, PD was rarely reported for decades. As to the case in the plain vineyards of Changhua, PD-infected grapevines have not been detected in the area where the grapevines have to renew every 7-10 years because the groundwater level in the area was high which is harmful to the root system development of grapevines.

Text

We have developed a high-throughput screening (HTS) system for the defense gene

expression monitoring system using bioluminescent reporters and for discovery of plant activators. A promoter fragment of a tobacco salicylic acid (SA) inducible pathogenesis-related gene, *PR-1a* isolated from the genomic DNA of tobacco BY-2 cells, was fused to the luciferase reporter gene and introduced into Arabidopsis. To detect the *PR-1a* promoter expression as a luciferase activity, transgenic Arabidopsis seedlings were treated with chemicals with luciferin solution and the bioluminescence levels were monitored *in vivo* using a bioluminescence imaging system. Using the assay system, we have been successfully engaged in the discovery and evaluation of a wide variety of plant defense gene inducing agents (Ono et al. 2011; Watakabe et al. 2011). In this process, we found that the induction pattern of *PR-1a* gene expression changes depending on the nutrition conditions. Specifically, we found that the induction of *PR-1a* gene expression in response to the treatment with SA or acibenzolar S-methyl is strongly suppressed in Arabidopsis seedlings grown under the eutrophic conditions. Furthermore, by using the HTS system, we have succeeded in discovering compounds that have a *PR-1a* gene induction activity even under the eutrophic conditions.

AN OVERVIEW OF ALTERNARIA BLIGHT IN BROCCOLI IN GEORGIA, USA

PETKAR Aparna. (1), PATEL Karan. (1), GANGURDE Sunil. (1), KAUR Navjot. (1), CASSITY-DUFFY Kate. (2), COOLONG Tim. (2), DUTTA Bhabesh. (1)

(1) The University of Georgia, Tifton, UNITED STATES; (2) The University of Georgia, Athens, UNITED STATES

Text

Alternaria leaf blight and head blight (ABHR) caused by Alternaria species complex is an emerging threat to brassica crops in the eastern United States particularly in Georgia. Based on a two-year survey of multiple commercial broccoli fields in Georgia, USA it was found that nearly 85% of the isolates were A. brassicicola and only 15% were identified as A. japonica. Conidial germination assay for a sub-set of isolates on azoxystrobin-amended agar medium indicated that majority of the isolates of both Alternaria species were sensitive at both concentrations (10 and 100 µg/ml). Further field studies indicated that high nitrogen application rates and avoiding overhead irrigation or irrigating in the morning (6 AM) resulted in reduced levels of percent head rot. Interestingly, it was found that older leaves are more susceptible to A. brassicicola infection and is related to reduced wax deposition compared to the younger leaves. Further it was also demonstrated that the pathogen can be seed-borne and seed transmitted under controlled conditions. The pathogenic isolates of Alternaria spp. were recovered from naturally infested commercial broccoli seedlots, which further provide indications of potential movement of pathogen through infested seedlots. Together, these studies provide information for refining management practices to reduce ABHR outbreaks in broccoli.

Text

Since 2013, *Elaeocarpus sylvestris* planted in street trees, native habitats, and natural monuments has turned yellowing leaves, weakening branches, and eventually dying in Jeju Island. It was known as the phytoplasma that causes the decline of *E. sylvestris*, in order to reduce decline symptoms and control phytoplasma, we used oxytetracycline antibiotics including oxytetracycline wettable powder for trees, ultramycin for livestock, and aqua terra for fish, diluted to three concentrations including the standard amount, and applied gravity trunk injection method. From 2018 to 2020, we were conducted trunk injection for 40 trees per test regions in 4 regions of Jeju Island. After trunk injection, we compared vitality of trees, before and after trunk injection using Jun's Meter (PURUMBIO Co.). As a result of measuring vitality, all treatment groups showed 82.2mΩ in April (before injection), and was showed 85.2~95.5mΩ in May (after injection), and these results were indicating that the vitality of trees were improved. In addition, through visual inspection, the symptoms of decline were clearly reduced and the vitality was recovered, but several trees died in the untreated control group. The decline symptoms were recovered in the year of trunk injection, but the symptoms began to recur the following year. It is necessary to discover technology that can control phytoplasma by selecting new antibiotics which are sensitive to phytoplasma.

P4.1-055

PREVENTION OF STOMATAL ENTRY AS A STRATEGY FOR PLANT DISEASE CONTROL AGAINST FOLIAR PATHOGENIC PSEUDOMONAS SPECIES

SAKATA Nanami. (1), ISHIGA Yasuhiro. (1)

(1) University of Tsukuba, Tsukuba, JAPAN

Text

The genus Pseudomonas includes some of the most problematic and studied foliar bacterial pathogens. In Japan, bacterial blight on Brassicaceae crops caused by *Pseudomonas cannabina* pv. *alisalensis* (*Pcal*) are causing severe problems. Generally, in a successful disease cycle, there is an initial epiphytic lifestyle on the leaf surface and a subsequent aggressive endophytic stage inside the leaf apoplast. Leaf-associated bacterial pathogens enter intercellular spaces and internal leaf tissues by natural surface opening sites, such as stomata. Currently, treatments with copper-containing compounds and antibiotics are commonly used against bacterial plant pathogens including *Pcal*. However, *Pcal* strains

resistant to these chemicals already occur in the fields. Therefore, the demand for alternative control strategies has been increasing. We have demonstrated that these three strategies prevent the entry of Pcal into plants, leading to disease reduction: 1) Cellulose nanofibers, 2) Plant activators, and 3) Amino acids. We here would like to discuss these efficient strategies for bacterial disease control to prevent bacterial entry.

GENOME-WIDE ASSOCIATION MAPPING OF RESISTANCE AGAINST RICE BLAST STRAINS IN SOUTH CHINA AND IDENTIFICATION OF A NEW PIK ALLELE

LI Chenggang. (1)

(1) Institute of Plant Protection, Hunan Acadmy of Agricultural sciences, Changsha, CHINA

Text

Background: Effective management of rice blast, caused by the fungus *Magnaporthe oryzae*, requires an understanding of the genetic architecture of the resistance to the disease in rice. Rice resistance varies with *M.oryzae* strains, and many quantitative trait loci (QTLs) affecting rice blast resistance have been mapped using different strains of *M. oryzae* from different areas. However, little is known about the genetic architecture of rice resistance against the *M. oryzae* population in Hunan Province, which is a main rice production area in South China.
Results: In this study, we used three isolates from Hunan Province and the rice diversity panel 1 to perform a genome-wide association study (GWAS) of blast resistance in rice. A total of 56 QTLs were identified. One of the QTLs is localized with the resistance gene *Pik* locus which confers resistance to all three isolates. Genomic sequence analysis of the resistant cultivars led to the identification of a new *Pik* allele, which we named *Pikx*. Yeast two-hybrid and co-immunoprecipitation assays between AvrPiks and Pikx confirmed that *Pikx* is a new allele at the *Pik* locus.
Conclusions: Our GWAS has identified many new blast resistance QTLs. The identified new *Pik* allele *Pikx* will be useful for breeding cultivars with high resistance to blast in Hunan and other South China provinces. Further research on the relationship between *AvrPiks* and *Pikx* will provide new insights into the molecular mechanism of rice resistance to *M. oryzae*.

(1) international Center for Agriculture Research in Dry Area (ICARDA), Zahle, LEBANON; (2) international Center for Agriculture Research in Dry Area (ICARDA), Bhopal, INDIA; (3) international Center for Agriculture Research in Dry Area (ICARDA), Cairo, EGYPT; (4) international Center for Agriculture Research in Dry Area (ICARDA), Rabat, MOROCCO

Text

Chickpea wilt/root rot complexes are the most important yield-limiting factors in spring planted chickpea in the Mediterranean region, south Asia, and East Africa highlands. In WANA, Fusarium wilt caused by *Fusarium oxysporum* f.sp. ciceri (*Foc*) is a dominant pathogen in the disease complex. ICARDA Kabuli chickpea breeding program evaluates breeding lines in sick plots dominated with *Foc* pathogen for global elite lines supplies. In the 2021–2022 growing season, 240 genotypes were evaluated in sick plots at ICARDA research station in Lebanon and naturally infested experimental field at ICARDA research station in Morocco. The experiment was laid out in an alpha lattice design with two replications. Percent plant mortality was scored on plot bases once the average mortality of the susceptible line (ILC482) reached over 95%. The analysis of variance (ANOVA) analysis has indicated that the genetic variation among genotypes was caused by genetic variation as broad sense heritability was high (h2 = 0.76). However, only 51.3% of the changes were attributable to the genotypes, and only 10.0% to the environment (locations). Only four genotypes (S180005, S180022, S180071, and S180079) showed good levels of resistance (<20%) at both locations. These genotypes will be utilized for pyramiding additional resistance genes into other FW races and producing high-yield breeding varieties to be shared with the national chickpea breeding programs in CWANA countries.

Text

Plant extracts can replace chemical fungicides in managing plant diseases due to their antibacterial and antifungal action, low toxicity, and biodegradability. They can inhibit diseases in their early development stages and increase plant defense response to the pathogen. The aim was to evaluate different plant extracts in various concentrations against Botrytis cinerea. Research was carried out at the LAMMC Institute of Horticulture in Lithuania. The essential oils (EO) used in this study Thymus vulgaris, Coriandrum sativum and CO2 plant extracts (PE) Mentha spicata, Nigella sativa. The B. cinerea single spore isolates obtained from infected strawberries. Evaluated concentrations: 200 µl/l, 400 µl/l, 600 µl/l, 800 µl/l, 1000 µl/l. The results showed that T. vulgaris EO achieved highest B. cinerea mycelium inhibition at concentrations from 200 µl/l. The lowest concentrations of C. sativum EO did not affect B. cinerea growth, but 800 µl/l concentration had a slight effect. All evaluated concentrations of N. sativa PE had quite low inhibition of B. cinerea mycelium. A similar tendency observed in M. spicata PE. Our data indicate that PE should be used in higher concentrations. However, essential oils are promising as bio-fungicides against strawberry B. cinerea. Acknowledgement. This project has received funding from European Regional Development Fund (project No 01.2.2-LMT-K-718-03-0035) under a grant agreement with the Research Council of Lithuania (LMTLT).

Text

Long-term and inadequate pesticide use can increase the environmental load and resistance risk. Integrated plant management (IPM) encourages all solutions for environmentally safe plant protection solutions that are effective and efficient. LAMMC Institute of Horticulture evaluates sustainable plant protection management systems for horticulture, reducing the usage of the same active ingredient during horticultural crop's vegetation season and prolonging the preharvest interval up to 1.5 times. Diseases control program was based on internet supported forecasting system iMETOS® (Pessl Instruments, Austria). Forecasting models for diseases are validated and adapted to local conditions. Therefore model-based applications of fungicides are more precise. Every year, crop production area managed by IPM rules increases. However, we observed several variations in national standards for crop protection and control methods, plant nutrition, and soil management. In Lithuania, a lack of resistant/tolerant cultivars and a limited pesticide supply are the major issues in integrated fruit production. Applications based on forecasting models allow reducing plant protection costs, especially when the meteorological conditions are not favourable for disease development. Acknowledgement. This research received funding from the Lithuanian Ministry of Agriculture Research and development project "Development of integrated pest management guidelines for horticultural crops" Contract MT-22-8

INTEGRATED MANAGEMENT TO CONTROL BLAST DISEASE OF WHEAT

BANU Salina. (1), ALAM Mohammad. (1), ALAM Khondokar. (1), ANWAR Babul. (1)

(1) Bangladesh Agricultural Research Institute, Gazipur, BANGLADESH

Text

Field trials were conducted on four components: (i) seed treatment, (ii) splitting of nitrogen fertilizer, (ii) foliar spray of additional fertilizer, and (iv) fungicidal spray, under environmental conditions highly conducive to wheat blast in Bangladesh. Seed treatments with Xelora (Thiophanate-methyl + Pyraclostrobin), Vitaflow (Carboxin + Thiram), and Talc based Trichorderma harzianum were equally effective for reduction of disease severity on susceptible variety BARI Wheat 26 and partially resistant variety BARI Wheat 32. Three split of nitrogen fertilizer (basal 1/2 + crown root initiation 1/4 + maximum tillering 1/4) reduced blast severity for both varieties. Spray of additional fertilizer SiO2 at booting stage reduced disease severity and increased yield in optimum and late planting conditions for both varieties. Fungicidal spray with Opera (Epoxiconazole + Pyraclostrobin) and Cabrio (Pyraclostrobin) were more effective for reduction of disease severity and increase of yield among fifteen fungicides. Finally, two combinations of four components: (i) seed treatment with Xelora, splitting of nitrogen fertilizer, spray of additional fertilizer SiO2 and one spray of Opera (pre-heading) and Cabrio (after heading), and (ii) seed treatment with Vitaflow, splitting of nitrogen fertilizer, spray of additional

fertilizer SiO2 and one spray of Opera (pre-heading) and Cabrio (after heading) were significantly effective for integrated management of wheat blast disease.

STRAWBERRY BOTRYTIS CINEREA CONTROL BY LED-LIGHT

RASIUKEVICIUTE Neringa. (1), DENE Lina. (1), CHRAPACIENE Simona. (1), VASTAKAITE-KAIRIENE Viktorija. (1), SAMUOLIENE Giedre. (1), VALIUSKAITE Alma. (1), VIRSILE Akvile. (1), LAUZIKE Kristina. (1), SUTULIENE Ruta. (1), BRAZAITYTE Ausra. (1)

(1) LAMMC Institute of Horticulture, Babtai, Kaunas Disrt., LITHUANIA

Text

Nowadays, challenges in plant protection demand new solutions. It's known that specific light-emitting diodes (LED) are suitable for targeted plant protection and could resolve pathogen resistance problems. The aim is to evaluate the effects of pulsed LED-light wavelengths on Botrytis cinerea inhibition. Research carried out under controlled environmental conditions. Strawberry B. cinerea single spore isolates maintained in the Petri centre with Potato dextrose agar. Conditions: 22±2°C temp., 4 and 8 h photoperiod, 20±2 µmol m−2s−1 PPFD, 32 Hz, monochromatic LED-light (red 627 nm, yellow 590 nm, cyan 505 nm, blue 470 nm and royal blue 455 nm). Mycelial growth rates (mm) evaluated daily for four days after inoculation (1-4 DAI). Results revealed that B. cinerea acted differently at 4 and 8 h photoperiods. The lowest mycelium growth was at 4 h photoperiod under red after 1 DAI, at 2-3 DAI – under cyan and at 4 DAI – under blue. However, royal blue increased mycelium growth at 2-4 DAI. The development of B. cinerea at 8 h photoperiod suppressed by blue and cyan at 1 DAI, at 2 DAI – royal blue, and at 3-4 DAI under blue. Pulsed light affects B. cinerea growth depending on the photoperiod. Our findings raise new questions about developing B. cinerea control strategy by LED-light. Acknowledgement. This project has received funding from European Regional Development Fund (project No 01.2.2-LMT-K-718-03-0035) under a grant agreement with the Research Council of Lithuania (LMTLT).

Text

Botrytis cinerea is one of the major diseases of strawberry, reducing yields and requiring large amounts of pesticides during the growing season. Therefore, the EU focused on integrated plant protection to decrease pesticide use and recommended preparing IPM guidelines for crops in each country depending on environmental conditions. The aim was to evaluate a conventional plant protection system and based on a forecasting model. Field experiments carried out at LAMMC Institute of Horticulture. First year in conventional and

forecasting where 3 applications in each treatment. Second year, in conventional, was 4 and in forecasting, only one. Fungicides applications based forecasting model were more precise regardless of favourable conditions for disease development and ensured yield and quality of fruits. Results showed that conventional yield increased by an average of 2.3 and 2.7 t ha-1 in different years compared to untreated. In addition, forecasting model showed a yield increase of 4.3 and 3.2 t ha-1 in different years compared to untreated. As a result, the strawberry forecasting model-based plant protection system lowers plant protection expenses, especially when the environment is unfavourable for disease development.

LOCAL CONTROL CASE STUDY FOR FIRE BLIGHT ON APPLES

JUNG Wonkwon. (1), YEON Ilkwon. (1), MINKI Kim. (1), SEOKHEE Park. (1)

(1) GYEONGSANGBUK-DO ARES, Daegu, REPUBLIC OF KOREA

Text
Fire blight (FB), caused by *Erwinia amylovora*, is a fatal disease in pome plant. Based on the case of local control of fire blight on apples, effective managing strategy for first outbreaks area is to remove infected plant after precision monitoring and to follow control manual. In June 2021, FB first occurred in the Gyeongbuk region of the Republic of Korea. Suspicious samples were confirmed using real time(RT)-PCR. All trees in the orchard were buried if the incidence rate was 5% or more. Orchards within a radius of 5 km from the outbreak site were precisely monitored, and infected trees in 6 orchards with FB were removed. Infected trees were found at a distance of up to 1.5 km from the original source. Surveillance was conducted twice more at one month intervals, but no more infected strains occurred. In February and March of the following year, farmers cut suspicious branches and trunk cankers away and then infected trees were removed through RT-PCR test. Including antibiotics, protecting materials were carried out four times from pre-blossom to fruiting period. As a result of epidemiological investigation, it was analyzed that first occurrence was most likely introduced through contaminated seedlings. Rapid spread of inner orchards be caused by frequent pruning at growth initial period.

PERSPECTIVES ON THE APPLICATION OF COLD ATMOSPHERIC PRESSURE PLASMAS IN PLANT PROTECTION AGAINST SOFT ROT PECTOBACTERIACEAE

MOTYKA-POMAGRUK Agata. (1), DZIMITROWICZ Anna. (2), BABINSKA-WENSIERSKA Weronika. (1), ORLOWSKI Jakub. (1), TEREFINKO Dominik. (2), PRUSINSKI Michal. (1), JAMROZ Piotr. (2), POHL Pawel. (2), LOJKOWSKA Ewa. (1), SLEDZ Wojciech. (1)

(1) University of Gdansk, Gdansk, POLAND; (2) Wroclaw University of Science and Technology, Wroclaw, POLAND

Text

Plant pathogenic bacteria belonging to the soft rot *Pectobacteriaceae* (SRP) group are responsible for high economic losses in the production of crops, vegetables and ornamentals. No control methods are available to combat SRP infections. Thus, indirect and direct applications of cold atmospheric pressure plasmas (CAP) were investigated to eradicate these pests. In terms of the indirect approach, we synthetized the post-plasma solutions of antibacterial and plant growth promoting properties by treating mineral salts solutions with direct current atmospheric pressure glow discharge. The application of post-plasma solutions diminished soft rot disease symptoms. The antibacterial properties of these liquids were associated with deeply penetrating, reactive oxygen and nitrogen species. Moving to the direct implementation of CAP, a 2 min dielectric barrier discharge (DBD) plasma exposure eradicated >3.07 logs of SRP cells from the surface of mung bean seeds. The antimicrobial properties of DBD were linked with denaturation and aggregation of bacterial DNA and proteins in addition to rupturing of the cellular membrane leading to outflow of the cytoplasm contents. Also a 3-4% stimulation of seed germination and by 13.4% early seedlings growth were noted in the DBD-exposed seeds. Implementation of the CAP-based innovative and eco-friendly technology into agricultural practice might limit the spread and economic impact of SRP.

EFFECTS OF LIME SULFUR MIXTURE TREATMENT CONCENTRATION AND TIME ON ORGANIC WHEAT SEED DISINFECTION AND SEEDLING GROWTH

MIN-JEONG Kim. (1), CHANG-KI Shim. (1), JAE-HYEONG Lee. (1), YU-MI Han. (1)

(1) National Institute of Agricultural Sciences, Wanju, REPUBLIC OF KOREA

Text

Seedborne pathogens such as fusarium head blight (FHB) and smut are the most problematic and important biotic limiting factors for organic wheat seed production. This study aimed to evaluate the effect of treatment concentration and time of lime sulfur mixture (LSM), an organic agricultural material, on the disinfection effect and seedling growth of Keumgang wheat seeds. The fungal and bacterial infection rates of untreated Keumgangmil seeds were 45% and 0%, respectively, and the germination rate was 80%. When 0.2% LSM was treated for 3, 5, 7, and 10 minutes, the germination rate of the wheat seeds treated for 5 minutes was 100%, and the sterilization effect of fungi and bacteria was 100%, respectively. After 28 days of disinfection with 0.2% LSM, the plant height of the seedlings treated for 5 minutes was significantly longer by 10.4% compared to the untreated ones. When 0.4% LSM was treated for 3, 5, 7, and 10 minutes, the germination rate of the wheat seeds treated for 3 minutes was 100%, and the the sterilization effect of fungi and bacteria was 100%, respectively. After 28 days of seed disinfection treatment with 0.4% LSM, the plant height of Keumgangmil seedlings was examined, and the length of seedlings treated for 3 minutes was significantly longer by 12.0% than that without treatment. Based on the above results, it is considered that immersion treatment with 0.2% and 0.4% lime sulfur mixture is the most effective method for disinfecting Keumgang wheat seeds.

Text

Botrytis cinerea, the causal agent of the gray mold disease, is one of the main limiting factors of horticultural crops production worldwide, consuming up to 40% of fungicides in its control. However, this fungus has been categorized by FRAC (*Fungicide Resistance Action Committee*) as a phytopathogen with a high risk for fungicide resistance development, a fact that has been demonstrated in our country. In addition, and according to the "farm to fork" strategy of the recent European Green Deal, the diversity of fungicides available to growers will be reduced by 50% in 2030. For this reason, alternative control tools and molecules with fungicide activity are needed to *B. cinerea* control. In this study, the efficacy of emerging strategies using oligonucleotides with antifungal effect has been explored. Preliminary results, obtained in *in vivo* assays, have shown a significantly reduction of the fungal development, demonstrating the potential of these oligonucleotides to be novel candidates to include in the different strategies of integrated control programs of the gray mold disease.

Text

Grapevine trunk diseases (GTDs) are an unsolved problem in the disease management of grapevine. In the present study we aimed to screen, identify and characterize grapevine endophtic bacteria with biocontrol potential against GTD pathogens.
A total of 54 bacterial isolates were obtained from 15 healthy trunks and screened for antifungal activity against the Esca pathogen P*haeomoniella chlamydospora*. Ten positive isolates were further tested in dual culture assays against *P. chalymdospora*, *Eutypa lata*, *Botryopshaeria dothidea* and *Diaporthe eres* pathogens. One isolate (ID: 3/1) with efficient antibiosis against the above mentioned pathogens was identified as a member of *Bacillus*

amyloliquifaciens species group according to 16S rDNA sequence. Experiments with the steril culture filtrate of this isolate pointed out its fungistatic and fungicide activity, while no phytotoxicity was detected in leaf disk assays. The antifungal effect could be recovered in both the organic solvent extracts and ammonium sulfate precipitate of the culture filtrate, suggesting that the active agent is a lipoprotein.
According to the above results, isolate 3/1 can be an efficient biocontrol agent against GTDs with a special emphasis on its ability to grow in the host tissues and the secretion of effective antimycotic molecules.

EVALUATION OF WILDFIRE DISEASE CONTROL EFFECT BY VARIETY ACCORDING TO BORDEAUX MIXTURE TREATMENT IN ORGANIC SOYBEAN SEED PRODUCTION

JAE-HYEONG Lee. (1), MIN-JEONG Kim. (1), CHANG KI Shim . (1), YU-MI Han. (1)

(1) National Institute of Agricultural Sciences, Wanju, REPUBLIC OF KOREA

Text
It is necessary to develop control technologies for problematic diseases such as wildfire for organic soybean cultivation. This study evaluated the efficacy of 4-4 formula Bordeaux mixture (BM) treatment on wildfire disease control efficacy by soybean variety before and after the rainy season. The soybean varieties announced in the test were Daewon, Daechan, and Nogpoong, and 4-4 BM was prepared and used in the laboratory. 4-4 BM was sprayed three times at 7-day intervals from the end of July, the rainy season, and was additionally treated once after seed formation. The occurrence of wildfire disease was significantly lower in the three soybean cultivar fields treated with 4-4 BM than in the non-treated field until harvest season. Among the three soybean cultivars, Nogpoong soybean was found to be susceptible to wildfire disease. The incidence of wildfire disease in the Nogpoong soybean block treated with 4-4 BM was significantly lower than that in the untreated block. Through the above results, it was revealed that 4-4 Bordeaux mixture treatment will be an organic agricultural material that can effectively control wildfire disease in the organic Daechan and Daewon soybean farming.

Text

The reduction of copper-based fungicides has a high priority in European policy as well as in organic agriculture. To successfully reduce copper use, preventive strategies have to be fully implemented, and several substitution products need to be brought to the market. Plant-derived plant protection products could provide sustainable and environmentally friendly alternatives. As part of a project aiming at the discovery of such new products, we screened a library of more than 3000 plant extracts against important plant pathogens. One of the extracts with promising activity against grapevine downy mildew (*Plasmopara viticola*) was an 96% ethanolic extract from the leaves of *Inga sapindoides* (*in vitro* MIC_{100} 25 µg/mL). On grapevine plantlets under controlled conditions, compared to non-treated plants, the *I. sapindoides* ethanolic extract reduced grapevine downy mildew by 96%-97% at 0.5 mg/mL, and its efficacy was comparable to a standard copper treatment (two independent experiments). Targeted isolation of the active constituents resulted in the characterization of three acacic acid-type bidesmosidic saponins with high antifungal activity (in vitro MIC_{100} values of 3 - 6 µg/mL). *I. sapindoides*, a tree which is often cultivated for shading coffee plantations in Central America, may represent a sustainable source of fungicidal products to be used in the replacement of copper.

OZONATED WATER APPLICATION AS AN INNOVATIVE TOOL FOR ELICITATION OF PLANT DEFENSE RESPONSE: THE CASE OF BEGONIA HYBRIDA-BOTRYTIS CINEREA PATHOSYSTEM

PISUTTU Claudia. (1), FERRARIN Matteo. (1), MARIOTTI Lorenzo. (1), NALI Cristina. (1), PELLEGRINI Elisa. (1)

(1) University of Pisa, Pisa, ITALY

Text

Ozonated water (OW) represents an innovative and eco-friendly solution for inhibiting pathogens in pre- and post-harvest. When bubbled into water, ozone dissolves partially forming reactive oxygen species, that can exert positive effects against microorganisms and contaminants. It can be directly applied as soil drench or sprayed on leaves by controlling plant diseases and avoiding chemical residues. Ozone-treated products are safe and sustainable, and this makes OW a promising approach when low impact management practices are requested. This is the case of edible flowers, known to be highly perishable and susceptible to several fungal pathogens. Here, the application of OW at different concentrations (200-800 ppb) was firstly tested in vitro on *Botrytis cinerea*, *Fusarium oxysporum*, and *Verticillium dahliae* showing a high inhibitory effect on spore germination in liquid solution (-60% at 400 and 600 ppb). According to these preliminary results, in *Begonia hybrida* plants artificially inoculated with *B. cinerea*, pot irrigation supplemented with OW (400 ppb, for 2 weeks) resulted increased number of flowers (+50 compared to uninoculated and untreated ones) with higher water content (+32%). Considering the scarce development of visible injuries associated with *B. cinerea* on petals, the obtained data indicate the priming effects of OW treatment and the potential of this sustainable technique in limiting the damage of necrotrophic fungi in edible flowers.

P4.1-071

SUSTAINABLE STRATEGIES TO MANAGE YELLOW RUST IN NORWEGIAN SPRING WHEAT

FICKE Andrea. (1), **GRIEU Chloé. (1)**, BRODAL Guro. (1)

(1) Norwegian Institute of Bioeconomy Research (NIBIO), Aas, NORWAY

Text
Yellow rust, caused by the fungus *Puccinia striiformis*, f.sp. *tritici* (*Pst*), is one of the most yield-reducing diseases in wheat. Employment of resistant varieties has been an effective and sustainable strategy to manage this disease. However, new *Pst* races emerged and infected previously resistant varieties in Norway in 2014. Since then, *Pst* races were monitored every year until 2022. A three-year field trial was established to test the effect of variety resistance, fungicide timing and dosage, and a combination of these factors to develop sustainable and practical management strategies in Norwegian spring wheat. We registered *Pst* infections on the digital information platform VIPS (www.vips-landbruk.no) and the RUSTWATCH crowdsource app (https://arcg.is/1zTHTS). Infected leaf samples were sent to the Global Rust Reference Center (https://wheatrust.org) for race typing. Results showed that the Norwegian *Pst* population has been dominated by PstS10 since 2014. Field trials were conducted at three different locations in the southeast of Norway over three years. We chose three varieties with different levels of *Pst* resistance, three different spraying times (early, late, and at 1% infection) and two different dosages (1/2 and ¾ dose) of fungicides. We assessed *Pst* and leaf blotch diseases, yield quantity and quality. Varieties and location had a strong effect on *Pst* development over all years. Timing and dosage of fungicides appeared less important.

P4.1-072

TEMPERATURE IMPACTS THE PROTECTIVE EFFICACY OF MICROBIAL BIOCONTROL AGENTS

GRIMONPONT Margot. (1), TURC Estelle. (1,2), LIES Adrien. (2), MONNIER Noadya. (2), NICOT Philippe. (1), BARDIN Marc. (1)

(1) INRAE, Avignon, FRANCE; (2) Elephant Vert, Serris, FRANCE

Text
The development of biocontrol agents could be a promising option to decrease reliance on fungicides for the control of white mold caused by Sclerotinia sclerotiorum on oilseed rape . Two bacterial strains have shown promising activities against this pathogen. Their effective use in the field requires that various factors be considered, which may interfere with their protective efficacy. For example, knowledge of the impact of temperature on treatment efficacy could guide recommendations for more reliable application in the field.
The aim of this study was to determine the level of efficacy of these two bacteria against S. sclerotiorum under different temperature conditions. To this end, detached leaves of oilseed rape were treated with the bacteria and incubated during 6 or 24 hours at temperatures

representative of those encountered in the field at the time of flowering, the favorable period for pathogen infection (5, 13, 21 or 28°C). Two strains of S. sclerotiorum with different levels of aggressiveness were inoculated on the leaves 24 hours after treatment and incubated at 21°C, a temperature favorable to the development of the pathogen. Temperature at the time of treatment had a substancial effect on the protective efficacy of biocontrol, depending on the strain of S. sclerotiorum. These results emphasize the need to know the factors modulating the efficacy of biocontrol agents before their use in the field.

Text

The Soybean Cyst Nematode (SCN), *Heterodera glycines*, is the greatest yield-limiting biological factor in North American soybean production. This is due in part to low active management of SCN among soybean growers. In 2015, “The SCN Coalition,” a public-private partnership (PPP) of agro-chemical and seed companies, soybean grower organizations and universities formed. The SCN Coalition utilizes the multi-media strength of its partners to inform soybean growers about the increasing threat of SCN, with the objectives to increase active SCN management and reduce yield losses. Since 2018, The SCN Coalition generated over 70 million potential impressions in the U.S. agricultural media, 2 million video views, and millions of social media and personal contacts. To measure the impact of The SCN Coalition, U.S. national market research of soybean grower awareness and behavior was conducted in 2015 and 2020. In that time, over 50% of growers recalled all primary SCN Coalition messages and reported 6% to 18% increases in use of SCN management tools. Using conservative economic estimates, grower-reported increases in management and yield impacts suggest The SCN Coalition resulted in financial gains to U.S. soybean growers far exceeding $100M USD. The SCN Coalition serves as a model of a how a University-led PPP can facilitate national changes in grower behavior and economics when public and private sector partners are committed to a common vision and goal.

Text
Phoma black stem (PBS), caused by *Phoma macdonaldii* Boerema (teleomorph *Leptosphaeria lindquistii* Frezzi), is an important sunflower disease in North America, South America, Europe and Asia. Active management of PBS in the United States is rare, due partially to grower perception that PBS does not cause yield loss and limited available information on the efficacy of modern fungicides. The objectives of this study were to determine fungicide efficacy and optimal application timing for management of PBS on sunflower. Efficacy of ten fungicides from FRAC groups 3, 7, and 11 were evaluated in four field experiments in 2018 and 2019. Fungicide timing was evaluated by applying single and/or sequential applications of pyraclostrobin fungicide at three sunflower growth stages in six field experiments between 2017 and 2019. All experiments were arranged in a randomized complete block design with four replications. Efficacy was determined by calculation of PBS disease severity index (DSI) and harvested yield. Efficacy of nine of the ten fungicides evaluated, and all fungicide timings that included an early bud application, resulted in a DSI reduction when compared to the non-treated controls. The DSI was negatively correlated to sunflower yield only in high-yield environments. Results of this study provide information about the yield impact and fungicide management of PBS to sunflower growers and the sunflower industry.

P4.1-075

REAL TIME ADAPTED CANOPY VIGOR APPLICATION OF COPPER IN VINEYARD

FURIOSI Margherita. (1), DAMBROSIO Roberto. (1), GATTI Matteo. (1), **CAFFI Tito. (1)**

(1) Università Cattolica del Sacro Cuore, Piacenza, ITALY

Text
Adaptation of canopy sprays based on the real vine vigor, determined by proximity sensors, is a promising solution to reduce fungicide use. This solution must provide a crop protection at least equal to conventional sprayers to be widely adopted. The aims of this study were to: i) test the on-the-go system for variable rate application, and ii) optimize copper distribution in vineyard. The trial was carried out within the PSR-project RIPRESO in a commercial vineyard in Colli Piacentini (Italy) area, using a low-volume sprayer. Conventional spraying (C) was compared to a variable rate (VR) application, reducing the volume by 50%, based on Canopy Index (CI) value, measured by MECS-Vine sensor. Vines growth, downy mildew incidence and severity were assessed at stages BBCH 59,73 and 79. Water sensitive papers were used to evaluate ground spray drift and spray efficacy, in terms of canopy coverage (%) and spray deposit (µg cm-2). VR allowed 15.4% reduction of Cu solution compared to C, keeping a similar canopy coverage (25-30%) and ground drift. Moreover, VR provided a similar disease control, both in terms of incidence and severity, on both leaves and bunches, of C. At harvest, yield and grape composition were not affected by treatment. This study adapted a traditional sprayer for real-time spraying adjustment based on actual CI; and

demonstrated the effectiveness of VR spray in reducing PPP use, maintaining similar crop protection, yield and fruit composition than C spray.

P4.1-076

OPTIPLASM : OPTIMISATION OF THE OFFICIAL EVALUATION OF OILSEED RAPE VARIETIES AGAINST CLUBROOT (PLASMODIOPHORA BRASSICAE).

ORGEUR Geoffrey. (1), **PERROT Sophie. (1)**, JESTIN Christophe. (2), LOR Mathilde. (1), MANZANARES-DAULEAUX Maria. (3)

(1) GEVES, Beaucouzé, FRANCE; (2) Terres Inovia, Thiverval-Grignon, FRANCE; (3) IGEPP, Le Rheu, FRANCE

Text
OPTIPLASM project, started in 2019, is a project funded by CASDAR. The main objective of this project led by GEVES, in partnership with Terre Inovia and IGEPP, is to optimise the official CTPS tool for evaluating oilseed rape varieties under controlled conditions against Plasmodiophora brassicae (cruciferous clubroots). The current tool is based on a set of population isolates corresponding to the main pathotypes (P1*/P1/P2*/P3) identified in France in 2010-2013. These pathotypes tend to evolve during successive multiplications, which requires repeated characterisation to provide a robust result. The production of genetically homogeneous single-spore isolates that are stable over time is the chosen approach to overcome this difficulty. These have been produced and characterised for the different pathotypes during the 3 years of the project.
In parallel, a study of the correlation between the official CTPS test conducted under controlled conditions and the varietal response observed in the field was carried out. The idea was to evaluate the capacity of the test carried out in the laboratory to predict the behaviour of varieties in the field by comparing the behaviour of a panel of varieties under controlled conditions and in the field. As an exploratory measure, the possibility of evaluating the level of partial resistance of varieties should also be explored in order to enhance the value of genetics currently classified as sensitive.

(1) GEVES, Beaucouzé, FRANCE; (2) ACTIFOL Coordinator, CTIFL, Prigonrieux, FRANCE

Text
Fusarium oxysporum f. sp. lactucae on lettuce creates a serious threat for growers and a challenge for breeders with three main topics: emergence of a new race, the possibility or not of seed transmission and treatment.
The Actifol project, funded as CASDAR by the French Ministry involving 9 partners, studies

among other things, the possibility of seed transmission of Fusarium oxysporum f. sp. lactucae and the experimentation of alternatives methods of treatment against Fusarium on lettuce. The evaluation of seed transmission is conducted on commercial seed lots and on seeds harvested from artificially inoculated plants (from susceptible, intermediate resistant and resistant varieties). To date, of the 49 seed lots tested for detection of Fusarium, all have been negative (even those from artificially inoculated mother plants). Other seed lots are still being harvested.
Eight marketed products from different companies have been tested in controlled conditions with inoculation by Fusarium on a susceptible variety of lettuce to define the level of protection at the stage of transplantation of plantlets in 2021. After various results obtained race 1, new assays on same products are planned in 2023 and adapted to race 4 tested on two different genotypes. Results of the task will be present to the posters.

INSIGHTS TOWARDS THE CONTROL OF RAMULARIA LEAF SPOT — AN INVESTIGATION OF THE RELATIVE ROLES OF BARLEY VARIETY, SEED SOURCE, FUNGICIDE TREATMENT, AND GEOGRAPHIC LOCATION

ZIA Rabisa. (1,2), DOYLE Deirdre . (2), POPPER Zoë A.. (1), KILDEA Steven. (2)

(1) Botany and Plant Science and Martin Ryan Institute, School of Natural Sciences, College of Science and Engineering, University of Galway, Galway, IRELAND; (2) Teagasc, Crops, Environment and Land Use Programme, Carlow, IRELAND

Text
Ramularia leaf spot (RLS) caused by Ramularia collo-cygni (Rcc) is an emerging disease of barley in temperate regions including Europe. Although the disease results in a yield loss of ~30%, and reduces grain quality, there are currently no effective controls. To address knowledge gaps about the disease and identify approaches for its control we investigated the interactions between RLS and barley variety, seed source, fungicide treatment, and geographical location. Our approach was to select two barley cultivars, sourced from three different sites, and cultivate them at two locations with differing disease pressure. To evaluate the role of seed in RLS pathogenesis, seed samples were analysed for Rcc biomass through qPCR, further grown under controlled conditions, and the seedlings quantified for pathogen biomass. For the field trials, all treatments except the untreated controls, received two applications of fungicides in addition to a fungicide seed treatment. Specifically, the treatment comprised of QoI (GS 29) followed by either an RLS-targeted and non-RLS-targeted fungicide (GS 49). Treatment plots were sampled before and after the second fungicide application. Plots were scored for visual RLS symptoms, quantified for pathogen biomass, and yield data was recorded. Preliminary data suggest correlations between environment and fungicide in RLS pathogenesis. Future work will focus on interactions between plant microbiome, RLS and fungicide treatment.

REDUCTION OF EUTYPA LATA IN CABERNET SAUVIGNON WOOD BY BIOCONTROL AGENTS NATIVE TO CENTRAL CHILE

LOLAS Mauricio. (1), DONOSO Eduardo. (2), GUTIERREZ Mauricio. (1), GONZALEZ Paulina. (1), DÍAZ Gonzalo A.. (1)

(1) University of Talca, Talca, CHILE; (2) Bio Insumos Nativa SPA, Talca, CHILE

Text

The Maule Region in central Chile is one of the main producing areas of wine grapes, which is a significant commercial activity supporting economic and social development. Grape Trunk Diseases have been recognized as limiting vineyard longevity and productivity in the last 12 years. Since the first detection of *Eutypa lata* in 2020, efforts have been made to comprehensively know its epidemiology under Chilean edaphoclimatic conditions and develop sensible management practices. This study investigated the antagonistic activity of formulated biological control agents native to Chile against *E. lata*. Mamull® (*Bionectria ochroleuca* strain Mitique; *Trichoderma gamsii* strain Volqui; *T. virens* strain Ñire) and Coraza® (*T. virens* strain Ñire; *Bacillus licheniformis* strain Copihue; *B. ochroleuca* strain Mitique) were tested under field conditions, spraying or painting on wounds made by pruning 1-year-old Cabernet Sauvignon wood. Each wound was inoculated on the day of pruning with a mycelial plug of *E. lata* isolate 2B including those pruning cuts of the control plants without any treatment. Inoculations were made in August 2021 and the extent of stained wood was assessed in June 2022. Our results showed a 60 and 69% reduction in staining spread for Mamull® (sprayed) and Coraza® (painted) respectively. No foliar symptoms were observed at that time. Biological control agents could be integrated with other management strategies to control *E. lata* and Grape Trunk Diseases efficiently.

P4.1-080

INFLUENCE OF SOIL-BORNE INOCULUM FO PLASMODIOPHORA BRASSICAE MEASURED BY QPCR ON DISEASE SEVERITY OF CLUBROOT-RESISTANT CULTIVARS OF WINTER OILSEED RAPE

Text

Brassica oilseeds have been valuable crops in Sweden for the past 80 years, and injuries of clubroot caused by the soil borne pathogen Plasmodiophora brassicae constitute a permanent threat due to the persistence of the resting spores in the soil. Access to resistant cultivars is considered the most effective tool in managing clubroot, and guidelines for managing clubroot as a part of IPM were developed based on soil analysis of P. brassicae DNA. Three clubroot resistant (Cr) commercial cultivars of winter OSR and a susceptible ´Cultivar mix´ were evaluated for disease severity (DSI) and yield performance in field soils, selected for varying abundance of natural inoculum of P. brassicae in seven field experiments 2017-2019. For cultivar mix a negative correlation (y=-252.4ln(x) + 58897.6) was found between inoculum density and seed yield, whereas no correlation was found for resistant cultivars. In comparative bioassays performed in a growth chamber ´Cultivar mix´ exhibited a high correlation between DSIb and number of gene copies g-1 soil (R2=0.72). For resistant cvs. Mentor and Alister results indicate that resistance was under pressure. The best long term control strategy for clubroot is an extensive soil testing based on DNA

technology and to use Cr cultivars in situations where the abundance of P. brassicae exceeds 1300 gene copies per g -1 soil but < 100 000 gene copies per g -1 soil, as there is a risk of losing efficacy of resistance at high inoculum densities.

Text

An important goal of the European Green Deal strategy is to reduce use of chemical plant protection products, including fungicides. The purpose of the project in a consortium with Grupa Azoty Zaklady Azotowe Pulawy S.A. (POLAND) and the Institute of Plant Protection – NRI in Poznan (POLAND) is to develop and implement fertilizing products based on bioactive compounds of microbial and plant origin and liquid nitrogen fertilizers that will stimulate the growth and development of plants in the initial period of plant growth and increase their resistance to biotic and abiotic stresses. The tests conducted under laboratory conditions were aimed at the efficacy of selected bioproducts in limiting the growth of mycelium of economically important pathogenic fungi. Selected bioactive compounds were then verified in terms of their compatibility with urea-based liquid fertilizers (including RSM® - urea-nitrate solution and RSM®S - urea-nitrate solution with sulfur). In the next stage, the effect of selected bioproducts applied together with appropriate liquid fertilizers on the development of oilseed rape, wheat and corn plants and the efficacy of diseases control in greenhouse and field experiments was analyzed. Works were carried out as part of the project "Supporting the development and resistance of plants using liquid fertilizers enriched with bioactive compounds", POIR.01.01.01-00-1265/20, co-financed by the NCBiR, Operational Program - Intelligent Development 2014-2020.

EFFECT OF CEREAL-PULSE ROTATIONS ON FUSARIUM AVENACEUM PATHOGENICITY

ERANTHODI Anas. (1), OVERY David. (2), HARRIS Linda J. (2), HUBBARD Michelle. (3), SCHWINGHAMER Timothy. (1), CHATTERTON Syama. (1), **FOROUD Nora A. (1)**

(1) Agriculture and Agri-Food Canada, Lethbridge, CANADA; (2) Agriculture and Agri-Food Canada, Ottawa, CANADA; (3) Agriculture and Agri-Food Canada, Swift Current, CANADA

Text
Pulse root rot is caused by oomycete and fungal species, of which Fusarium avenaceum (Fa) is an important fungal pathogen. Since Fa is a common pathogen of pulse root rot and cereal head blight, we hypothesized that cereal-pulse rotations can influence Fa pathogenicity. As a first step to test this, we are assessing the natural variation in aggressiveness of Fa isolates collected from wheat, pea and lentil. Isolates collected from wheat (16) and pea (19) were screened for aggressiveness in wheat (cv Langdon) by point inoculation and pea and lentil (cvs CDC Meadow and CDC Proclaim) by soil and seed inoculations. Point inoculation of Langdon, soil inoculation of CDC Meadow and seed inoculation in CDC Proclaim had higher disease severity for pea isolates compared to wheat isolates. A similar difference in disease was not observed for a repeated trial of CDC Proclaim seed inoculation. Likewise, CDC Proclaim soil inoculation did not have a statistically significant difference between pea and wheat isolates. Thus, the general trend is that the pea isolates evaluated are more aggressive in pulses and wheat. Currently, we are screening 7 lentil isolates for aggressiveness in pulses and wheat as described above. The next step will be to select a subset of isolates which will be evaluated for altered aggressiveness after serial passage through wheat spikes or pulse roots, to determine whether passage through one crop type can influence pathogenicity on another crop type.

REPEATED APPLICATIONS OF POTASSIUM BICARBONATE SUPPRESSES DOLLAR SPOT ON AMENITY TURFGRASS

BANYAI Zoltan. (1), KOCH Paul. (1)

(1) University of Wisconsin-Madison, Madison, UNITED STATES

Text
Dollar spot (Clarireedia jacksonii) is the most economically important disease of amenity turfgrass in temperate climates. Increasing fungicide resistance and the declining number of novel chemistries entering the market has led to widespread interest in more integrated dollar spot control strategies. Past research has indicated that C. jacksonii requires an acidic leaf environment for infection and that there may be a metabolic cost to the fungus to modify the leaf surface pH. Our study attempted to suppress C. jacksonii infection by increasing leaf surface pH through repeated applications of potassium bicarbonate. The study was conducted at the OJ Noer Turfgrass Research Facility in Madison, WI during the summer of 2022. The results demonstrated that high rates of potassium bicarbonate applied every 7 days effectively suppressed dollar spot to a commercially acceptable level. Lower rates of potassium bicarbonate, including those found in the commercial formulation Kaligreen, demonstrated little to no suppression of the disease. Future work will focus on optimizing the application rate, reapplication interval, and water carrier volume for potassium bicarbonate and other compounds to support the development of more sustainable disease management strategies.

Text

Huanglongbing (HLB), putatively caused by *Candidatus* Liberibacter asiaticus (CLas), and citrus canker, caused by *Xanthomonas citri* subsp. *citri* are the two most devastating bacterial diseases in Florida, USA. Yet, there is no HLB control and only limited control measures against canker. Thus, there is a pressing need to develop novel therapeutics for long-term disease control in citrus orchards. This study assessed new strategies for combating HLB and canker with novel class plant defense inducers (PDIs) and antimicrobials. Foliar spray applications of several PDIs on the two-year-old healthy citrus trees a week before exposure to CLas-infected Asian citrus psyllid (ACP) effectively delayed CLas infection and HLB symptoms for six months. All non-treated trees and those treated with bacteriostatic oxytetracycline were infected with CLas, two to four months after ACP exposure, with high bacterial titers. In separate experiments, PDIs and Actigard (acibenzolar-S-methyl) significantly reduced leaf canker lesions relative to non-treated control and were comparable to copper sulfate pentahydrate. Additional experiments with trunk injection of an antimicrobial compound into the CLas-infected trees reduced CLas titers and HLB symptoms in the greenhouse and field 3-6 months after injections. The disease prevention mechanisms and potential use of PDIs and antimicrobials for simultaneous management of economically important citrus diseases are currently being evaluated.

Text

Electrolyzed water has recently been used due to its potential use for controlling various plant diseases including cucurbits powdery mildew. However, developing proper application technique and efficiency for farmers are becoming a concern. This study aimed to investigate the future potential of slightly acidic electrolyzed water (SAEW) using the volatilized method focusing on the capability to suppress the disease severity of cucurbits powdery mildew and HOCl distribution inside the greenhouse. The greenhouse was divided into four (4) blocks consisting of volatilized SAEW, mist nozzle + SAEW, volatilized tap water, and mist nozzle + tap water. Cucurbit plants such as melon, cucumber, and squash were used as samples. The samples were sprayed automatically for 60 seconds during nighttime, intervals of 5 minutes for 3 hours long (only for volatilized, the continuous spray was conducted). The results indicated that SAEW using the volatilized method still effectively suppressed the disease severity only on cucumber and melon for 3 weeks consecutively, compared to tap water treatment. The concentration of HOCl inside the greenhouse showed a range of 1.4 – 5.8 μg m-2min-1. Moreover, this study revealed that SAEW has no impact on chlorophyll content, and also no water droplets were found on the leaves. This study demonstrates the possibility of controlling powdery mildew on cucurbit in a wide area using a volatilized SAEW as an alternative to pesticide use.

Text

Preparation of nano sustained release fungicide based on ZIF-8 materials to control strawberry anthracnose

Fuxin L, Junyuan S, Gaoming Z, Yitong Y, Yang B*
Beijing University of Agriculture, Beijing, 102206, PR China
* Correspondence: biyang0620@126.com.

Zeolitic imidazolate framework-8 (ZIF-8) is a rhombic dodecahedral crystal type cage coordination compound formed by the reaction of zinc ions as transition metals with 2-methylimidazole. In this study, prochloraz was loaded in ZIF-8 by a one pot method (Pro@ZIF-8), due to the acidic degradation of ZIF-8, making it pH responsive for drug release to control strawberry anthracnose. Dynamic light scattering results showed the particle size of Pro@ZIF-8 was 129.6 ± 14.8 nm, and scanning electron microscopy indicated the crystal structure was not changed after drug loading observed. TGA tests showed the loading capacity of prochloraz was 10.8%, the quantity of prochloraz released under pH 5.0 was 89.8 ± 4.6%, significantly higher than that pH 7.0 conditions (20.4 ±1.1%). In vitro results showed that the EC50 of Pro@ZIF-8 was 0.0150 ± 0.006 μg/mL, which was significantly different from that of prochloraz (0.0429 ± 0.01 μg/mL) in 4 days. Pot experiments showed that Pro@ZIF-8 could effectively postpone the occurrence of strawberry anthracnose in 14 days, which was better than prochloraz. Fruit preservation experiments indicated Pro@ZIF-8 could inhibited the spread of pathogen and relatively safe for fruits.

INJECTING OXYTETRACYCLINE: AN EFFECTIVE APPROACH FOR MANAGING HLB DISEASE IN CITRUS

KUNWAR Sanju. (1), REDONDO Ana. (1), ARCHER Leigh. (1), ALFEREZ Fernando. (1), ALBRECHT Ute . (1), BATUMAN Ozgur. (1)

(1) University of Florida, Immokalee, UNITED STATES

Text

Huanglongbing (HLB) is a destructive bacterial disease associated with Candidatus Liberibacter asiaticus and vectored by the Asian citrus psyllid, for which there are no effective control measures. It is challenging for growers to manage HLB with foliar sprays since the pathogen lives within the trees' vasculature. Trunk injection ensures treatments are delivered directly into the tree's vascular tissue, allowing for improved uptake and transport. This study assessed the efficacy of injecting Oxytetracycline (OTC) in managing HLB and its effects on tree health parameters, including yield and fruit quality. We also assessed its efficacy against citrus canker (Xanthomonas citri subsp. citri), which causes disease on leaves, fruits, and twigs. In a field study where both diseases are prevalent, mature 'Duncan' grapefruit trees were injected with OTC (0.79 g active ingredient/tree) in the spring and/or fall of 2021 and 2022, and tree health and bacterial titer were assessed. OTC injection increased fruit yield and improved tree health relative to the water-injected control; however, it did not reduce the incidence of citrus canker. These findings suggest that OTC injection could be a promising tool for citrus growers to combat HLB and maintain tree health and productivity when combined with other best management practices, such as vector control and proper nutrition. The long-term effect of injection on tree wounding and recovery is currently being investigated.

CONTROL OF CHICKPEA ASCOCHYTA BLIGHT USING CURATIVE FUNGICIDE STRATEGIES AND CULTIVAR RESISTANCE

FANNING Joshua. (1), BRAND Jason. (1), MUNOZ SANTA Isabel. (2,3), MCDONALD Linda. (1), MAWALAGEDERA Sundara. (1), TAYLOR Julian. (2), HOLLAWAY Grant. (1)

(1) Agriculture Victoria, Horsham, AUSTRALIA; (2) School of Agriculture, Food and Wine, University of Adelaide, South Australia, AUSTRALIA; (3) Department of Statistics and Operations Research, University of Valencia, Valencia, SPAIN

Text

Worldwide chickpea production is constrained by the fungal disease Ascochyta blight (*Ascochyta rabiei*). Disease management is often reliant on foliar fungicides to reduce grain yield losses, due to limited cultivar resistance. To develop management strategies to reduce the impact of Ascochyta blight this study, across nine experiments, investigated: 1) cultivar resistance, 2) applying fungicides preventatively (before rainfall events), or curatively (after the first signs of disease), and 3) interrow sowing in standing or slashed cereal residue. Four experiments showed a significant benefit of cultivar resistance where the moderately susceptible cultivar had grain yield losses of 38-64% as compared to 74-96% in the susceptible cultivar. In most seasons, all fungicide strategies reduced disease severity.

Comparisons between preventative or curative applications of dual active fungicides produced mixed results for grain yield. In drier environments, there was no significant difference in grain yield, but in wetter environments, yield losses were significantly greater with the curative compared to the preventative treatments. In both environments there was greater disease severity observed with curative fungicide strategies. Sowing chickpeas in standing cereal residue significantly reduced grain yield losses to disease.
This study highlighted the benefits of cultivar resistance, curative fungicide applications in drier environments, and interrow sowing in standing cereal residue.

P4.1-089

SMALL PEPTIDES AS POTENTIAL ENHANCERS OF A PLANT'S RESPONSE TO PATHOGEN ATTACK – INVESTIGATING THEIR UPTAKE INTO PLANT CELLS FOLLOWING EXOGENOUS APPLICATION.

WOOD Marion. (1), TAYLOR Annalise. (1,2), HIGGINS Colleen. (2)

(1) Plant and Food Research, Auckland, NEW ZEALAND; (2) Auckland University of Technology (AUT), Auckland, NEW ZEALAND

Text
Small peptides (<100 amino acids) are involved in a wide range of biological responses in plants to both biotic and abiotic stimuli, including Programmed Cell Death (PCD). In the presence of the exogenously applied, plant-derived small peptide Kiss of Death (KOD_{pep}), *Arabidopsis thaliana* root hairs undergo a morphological PCD-like response at low KOD_{pep} concentrations and/or limited incubation periods. The efficacy of two cell penetrating peptide (CPP) fluorescein isothiocyanate (FITC) labelled tags was also investigated: a classic CPP tag (RQIKIWFQNRRAKWKK) and the more recently discovered amoeba-derived CPP tag (RRVQIWFQNKRAKVKR). The presence of either CPP tag resulted in increased intracellular uptake of KOD_{pep} as indicated by an increase in fluorescence activity. However, this was associated with a loss of a PCD-like morphological response which was superseded with a necrotic-like response at high peptide concentrations and/or longer incubation periods. Biological activity of the KOD_{pep} to induce a PCD-like morphological response in the absence of a CPP tag was detected, with novel intracellular uptake of KOD_{pep} observed. The potential role of KOD_{pep} in a plant's response to a pathogen and the utility of small peptides to participate in the arsenal of plant defence strategies will be presented.

FUNGICIDE APPLICATION METHOD IMPACTS ON MAIZE GRAIN FILL DURATION, KERNEL DYNAMICS, AND GRAIN YIELD

BARTABURU Malena. (1), TELENKO Darcy. (1), LEE Chad. (3), STEINKE Kurt. (2), OLMEDO PICO Lia. (1), QUINN Daniel. (1)

(1) Purdue University, West Lafayette, UNITED STATES; (2) Michigan State University, East Lansing, Michigan, UNITED STATES; (3) University of Kentucky, Lexington, Kentucky, UNITED STATES

Text
Climatic variability and emerging maize (Zea mays L.) disease has driven farmers toward using multiple fungicide applications to enhance grain yield. Despite observed fungicide yield increases, minimal research has addressed the physiological mechanisms behind observed yield increases. Specifically, how does disease control impact grain fill duration and kernel formation. Trial objective(s) were to assess how fungicide application methods can impact maize grain fill, kernel formation, and yield. In 2022, 6 trials were initiated in Indiana, Kentucky, and Michigan, USA. Treatments include: 1) control (C), no fungicide applied, 2) C + starter fungicide (Flutriafol) applied at planting, 3) C + foliar fungicide (prothioconazole, trifloxystrobin, and fluopyram) applied at the R1 growth stage, and 4) C + starter fungicide and foliar fungicide. Preliminary results observed yield increases at 2 of 6 site-years and 4 of 6 site-years from starter fungicide and R1 fungicide, respectively. In addition, starter fungicide and R1 fungicide increased kernel number at 3 of 6 and 4 of 6 site-years, respectively. Furthermore, starter fungicide, R1 fungicide, and their combination increased grain fill duration by 4, 5, and 4 days, respectively and increased maximum kernel weight by 5, 5, and 10%, respectively. Overall, preliminary data shows the ability of different fungicide application methods to reduce leaf disease severity, increase kernel number, grain fill duration, and kernel weight.

Text
Biological agents can control brown spot (Bipolaris oryzae) in rice (Oryza sativa), increasing sustainability and food quality. Our aim was characterize biochemically and identify the most effective microorganism antagonist to B. oryzae. Two assays (E1 and E2) were conducted, composed of twenty-two treatments and three replications in completely randomized design. E1 characterized all 21 isolates for production of extracellular enzymes, siderophores, biofilm, indoleacetic acid (AIA) and phosphate solubilization. E2 tested in vitro antagonism between 21 isolates and B. oryzae. All isolates produced Lipase, N-fixation, phosphorus, sideophere, AIA and biofilm, Protease produced twenty isolates (95.24%), Pectinase and cellulose produced sixteen isolates (76.20%), Amilase produced fourteen isolates (66.67%), Potassium produced eight isolates (38.10%) lacase produced four isolates (19.05%), zinc produced two isolates (9.52%) while ligninase produced only isolate (4.8%), the antagonist results showed that Bacillus cereus (BRM65921 and BRM65922) and Prestia megaterium (BRM65915) reduced radial colony growth of B. oryzae by 98.28, 98.28 and 90.35 % respectively

EFFICACY OF A ZERO-RESIDUE STRATEGY AGAINST FIELD AND POSTHARVEST DISEASES ON STRAWBERRIES

GARELLO Marco. (1), SCHIAVON Giada. (1), ROSATI Marco. (1), **SPADARO Davide. (1)**

(1) University of Torino, Grugliasco, ITALY

Text

In recent years, growing concerns associated to pesticide residues in fruit have led to develop alternative crop protection strategies, including zero-residue strategy (ZeR). We assessed the impact of a ZeR strategy on fruit quality and postharvest microbiota of strawberries (Fragaria x ananassa), compared to a conventional IPM strategy. Data on fungal pathogen incidence was gathered over two years in two Italian farms. Fruit picked from treated farms were sampled for yield, quality parameters and microbiota composition at harvest, after storage and at the end of shelf-life, while pesticide residues were quantified by accredited laboratories. Disease incidence showed no significant difference between the adopted strategies for either farm in both year. No systematic impact of the strategy was found on yield (commercial production, average fruit weight, number of fruit per plant), titratable acidity, total soluble solids. Minor differences were observed for fruit firmness and colour parameters. Quantification of residues on fruit returned lower levels for the ZeR strategy, although a long-term contamination by fosetyl-Al was noticed. Microbiota composition was unaffected by the crop protection strategy and resulted in very high levels of Botrytis at the end of shelf-life. The ZeR strategy showed comparable efficacy to the conventional strategy.

Text

In 2019, the scientific community of plant pathologists reflected on major scientific questions that remained to be solved in our field in the coming years (Harris, Balint-Kurti et al. 2020). Among these questions, the following had been identified: what is the impact of abiotic stresses on plant/microbe interactions, and more generally, how does the knowledge gained on simple interactions hold up in an ecological context? Indeed, for most interactions, we have very little idea of how interactions between plants and microbes are affected by the ecological environment in which they live. At the same time, the concept of eco-immunity has been described (Schulenburg et al., 2009). Broadly speaking, this concept aims to understand and explain variation in immune response, in other words, to determine why and how biotic and abiotic factors contribute to variation in the immunity of a living organism (Nobori and Tsuda 2019). In this presentation, we will elaborate on the effects of five factors in combination or not on the establishment of the septoria (Zymoseptoria tritici) infection cycle in wheat seedlings. Thus, we studied the impact of the partial resistance of the host variety, the water stress undergone by the seedling during the infection, two types of

treatments: a root biostimulant at sowing to promote host growth and a plant defense stimulator applied before inoculation to reinforce host defenses and finaly we tested the effect of a neighboring co-cultivated plant .

PROGRESS IN DISEASE CONTROL - Part2

THE AUSTRALIAN WAY OF CROP DISEASE CONTROL IN AGRICULTURE AND HORTICULTURE

KISS Levente. (1)

(1) University of Southern Queensland, Toowoomba, AUSTRALIA

Text

The history of extensive crop production in Australia only goes back to 1788 when the first British settlers set up their first colony in Sydney Cove. Since then, many broadacre and horticultural crops have been introduced to Australia from overseas and grown extensively there; in fact, all but one of the important crops grown in Australia are introduced species (macadamia, an Australian native, being the only exception). Inadvertently, many of the pathogens of those crops were also introduced to Australia before efficient plant biosecurity measures were set up and applied rigorously as part of border control and to prevent the spread of plant diseases within the country. As of today, the Australian crop production industry is valued at over AU$20 billion per year. Crop disease control is shaped by the climate, soil characteristics, technology, and other specific conditions, including the lack of important plant pathogens such as Xylella fastidiosa, Puccinia striiformis f. sp. hordei and Guignardia bidwellii that are kept out of the country as a result of the plant biosecurity system. This presentation will provide an overview of crop disease control practices in Australia; fungicide use; plant biosecurity; technology; and the research and development sector in this field.

INTEGRATED CONTROL OF STRAWBERRY POWDERY MILDEW INCORPORATING THE USE OF A PREDICTION SYSTEM AND A BIO-AVAILABLE SILICON NUTRIENT

LIU Bo. (1), HALL Avice. (1), WILEMAN Hannah . (1), ASIANA Ifeoma. (1)

(1) University of Hertfordshire, Hatfield, UNITED KINGDOM

Text
Strawberry powdery mildew (*Podospheara aphanis*) is the most serious epidemic disease of protected strawberries in many parts of the world. In order to control this disease many growers are spraying with fungicides every 7 or 8 days, resulting in up to 22 sprays in a 6 months season. This heavy use of fungicides may prevent epidemics developing but it has some deleterious consequences, for example expense, lack of appropriate active ingredients and the accumulation of a high number of pesticide residues in the fruit. The work presented here will demonstrate how the use of an on-farm, real-time decision support system can prevent epidemic development but also reduce the number of fungicides used by half. This system has now been in operation on commercial farms for 5 years and shows not only disease control but also a reduction in labour and fuel use which gives a financial saving. Furthermore the paper will demonstrate how the regular use of a bio-available silicon nutrient in the fertigation system enhances the passive defence pathway of strawberries and thus gives increased resilience to powdery mildew. This integrated use of different approaches enables strawberry growers to achieve their goal of increasing yield from each plant and also achieving sustainable production with reduced environmental impact.

FUNGICIDE RESISTANCE MANAGEMENT, MONITORING AND ALTERNATIVES INVESTIGATED IN THE SOUTH AFRICAN CITRUS INDUSTRY

VAN NIEKERK Jan. (1), BASSON Elaine. (1), VAN DYK Meagan. (1), DU PLOOY Wilma. (1), MOYO Providence. (1)

(1) Citrus Research International, Nelspruit, SOUTH AFRICA

Text
South Africa is one of the largest exporters of fresh citrus fruit. Production of high quality fruit is therefore critically important. Effective management of economically and phytosanitary fruit pathogens are therefore important. Preharvest and postharvest fruit pathogens such as *Alternaria alternata*, *Phyllosticta citricarpa*, *Penicillium digitatum* and *Geotrichum citri-aurantii* are managed using a combination of orchard practices, packhouse sanitation and fungicide applications. As these pathogens are prone to developing resistance to fungicides, resistance management practices include the application of fungicides with different modes of action either in tank mixtures or at different points in the packhouse. Resistance monitoring include regular testing of pathogen isolates for reduced sensitivity and characterisation of fungicide sensitivity within the populations of abovementioned pathogens. In cases where reduced sensitivity is detected, and a molecular resistance assay is not available, these assays are developed through research projects. However, with increasing pressure to reduce fungicide residues on fruit, research is also done into alternative, non-chemical management options. The resistance management and monitoring practices followed in the South African citrus industry will be described while some preliminary results of research into alternative management options will be outlined.

Text

Trichoderma spp. represent a rich source of bioactive molecules for controlling plant pathogens. As bioactive molecules, antimicrobial peptides (AMPs) are gaining interest as candidates for new eco-friendly plant protection products. Peptaibols are a peculiar class of AMPs with a well-defined helical structure but poor water solubility, which hampers their use in crop protection. Based on these premises, we used a biorational approach to synthesize peptide analogs of the natural peptaibol trichogin GA IV with Gly-to-Lys substitutions to enhance water solubility and antimicrobial activity. We obtained several water-soluble analogs with *in vitro* fungicidal and bactericidal activity. Some of these analogs completely inhibited the growth of the fungus *Botrytis cinerea* and the sporulation of the oomycete *Plasmopara viticola* at low micromolar concentrations. The peptide analogs also exerted bactericidal activity against the bacteria *Xanthomonas campestris* pv. *campestris* (Xcc), *Pseudomonas syringae* pv. *tomato* and *P. syringae* pv. *actinidiae*. In growth chamber experiments, the most effective peptides protected grapevine from *P. viticola* and *B. cinerea* and cauliflower from Xcc without phytotoxic effects. The microscopic analysis showed different alterations of the cell membrane and the cytoplasm depending on the examined plant pathogen. Finally, in a two-year field trial, one selected peptide resulted as effective as a cupric fungicide in protecting the vineyard from downy mildew.

C6.1-5

THE EVOLUTION OF FUNGICIDE RESISTANCE IN EUROPEAN CEREAL PATHOGEN POPULATIONS

HAWKINS Nichola. (1), FRAAIJE Bart. (2)

(1) National Institute of Agricultural Botany, Cambridge, UNITED KINGDOM; (2) Wageningen University & Research, Wageningen, NETHERLANDS

Text

Cereal disease control in Europe relies heavily on fungicides, combined with some varietal resistance. However, some pathogens that are key targets of control programmes, such as *Zymoseptoria tritici* on wheat, *Ramularia collo-cygni* and *Pyrenophora teres* on barley, and cereal rusts and powdery mildews, have proven to be highly adaptable in the face of crop protection measures. *Z. tritici* has evolved resistance against MBC and QoI fungicides and ongoing slides in sensitivity to azole and SDHI fungicides, as well as breakdown of host resistance such as that in Cougar-derived varieties.

The differing nature of resistance against the various fungicide classes has had different impacts on disease control. In some cases, a single mutation conferring high levels of resistance has spread rapidly through the pathogen population resulting in control failures

and the effective loss of that fungicide class for the control of that pathogen. In other cases, the gradual accumulation of mutations each contributing only partial resistance has been countered by the development of new, more active fungicides within that class. We will present data on the ongoing shifts and associated genotypes in *Z. tritici* sensitivity to azoles and SDHIs. We are also developing in vitro selection approaches to improve predictions of future resistance evolution, enabling more pre-emptive resistance monitoring and management.

INTEGRATED PLANT DISEASE MANAGEMENT OF CEREALS IN FRANCE: FROM RESEARCH TO PRACTICE

VALADE Romain. (1), THIBIERGE Jérôme. (1), COULEAUD Gilles. (1), DU CHEYRON Philippe. (1), MAUMENE Claude. (1), VERJUX Nathalie. (2)

(1) ARVALIS, Boigneville, FRANCE; (2) ARVALIS, Montardon, FRANCE

Text

Cereal diseases are numerous and need to be controlled for worldwide food safety from both quantitative and qualitative perspectives. This control must be effective, environmentally friendly, economically sustainable, and socially suitable. Integrated Plant Disease Management (IPDM) aims to answer those complex expectations by combining all solutions which are already available or to be developed. These strategies are based on three principles: prevention, risk assessment and control for which many researches are carried out in order to provide such innovative solutions for farmers. We can mention genetic resistances, decision support system, biocontrol products, diseases monitoring, remote sensing instruments, companion plants, new technical practices…
Here, we purpose to make a state of the art of the main diseases of cereals in France, the principal means of control available and how IDPM is currently implemented by farmers and stakeholders. We will focus on how characterizing the methods of integrated protection to help the producer to choose the best combination for him? How do producers adopt these new practices to deal with plant diseases as well as to face climate changes? What research should focus on the most to complement current solutions?
Such answers will highlight the significant advances arising in IPDM in France but also outline the gap we still need to fulfill by strengthening research and supporting farmers towards a successful agroecological transition.

P6.1-001

EFFICACY OF FOLIAR FUNGICIDES FOR THE MANAGEMENT OF FUSARIUM HEAD BLIGHT OF WHEAT AND MYCOTOXIN ACCUMULATION IN WHEAT GRAIN

ROSE Lindy. (1), CRAUSE Jenny. (1), VAN COLLER Gert. (2), VILJOEN Altus. (1)

(1) Stellenbosch University, Cape Town, SOUTH AFRICA; (2) Western Cape Department of Agriculture, Cape Town, SOUTH AFRICA

Text
The chemical control of F. graminearum s.s., causal pathogen of Fusarium head blight (FHB) of wheat and the mycotoxins it produces, is an integral disease management strategy. However, no fungicides are currently registered against FHB in South Africa. This study aimed to determine the efficacy of several foliar fungicides to control FHB and mycotoxin contamination in different production regions of South Africa. Commercial fungicides were evaluated during 2021 in a field trial each in the Western Cape (WC) and Free State provinces, respectively. Five wheat cultivars were evaluated in a randomised complete block design with three replicates at each location. Fungicides were applied to flowering wheat heads, two days prior to inoculation with F. graminearum s.s. Additional treatments included a fungicide only, fungus only and water only controls. Disease incidence, DON contamination and thousand kernel weight (TKW) was measured. All fungicides effectively reduced disease incidence and DON levels in field trials compared to the control while also increasing TKW. Significant differences between locations, cultivars and treatments for parameters were determined. All fungicide applications significantly reduced DON levels at Napier (WC) for inoculated bunches. The results obtained in this study confirms that foliar fungicides can effectively contribute to managing FHB and mycotoxins in wheat grain and thus represents a feasible disease management strategy.

P6.1-002

EFFECTS OF SEED PRETREATMENTS WITH MIXED BIOPRODUCTS FOR IMPROVING DISEASE TOLERANCE AND GROWTH OF PEPPER SEEDLINGS

PETRISOR Cristina. (1), ZAHARIA Roxana. (1), OLTENACU Viorel. (3)

(1) Research and Development Institute for Plant Protection, Bucharest, ROMANIA; (2) Research and Development Institute for Plant Protection, Bucharest, ROMANIA; (3) Research and Development Station for Tree Fruit Growing Baneasa, Bucharest, ROMANIA

Text
Pre-sowing treatment of seeds is a very simple method for farmers' to increase growth, yield and also for pathogens management. Pepper seeds were subjected to combined application of Trichoderma isolate(T), chitin(CH) and salicylic acid(SA) for assessment of growth promotion and defense induction against Rhizoctonia solani, an important destructive soil-borne phytopathogenic fungus that causes severe loss of agricultural crops around the world. Effects of combined treatments with T+SA+CH, T+CH, T+SA, CH+SA on growth parameters, polyphenols, chlorophylls and carotenoids concentrations and on the activities of antioxidant enzymes, peroxidase (POX) and polyphenoloxidase (PPO), were examined in pepper seedlings leaves. The treatment of pepper seeds with all combinations used had a beneficial effect on the growth and development of pepper plants, both in the absence or in presence of the pathogen. Among treatments, the sequential applications of T+CH and T+SA+CH most effectively stimulated the plant's antioxidant system and thus resistance to the pathogen. The combination of SA+CH had no significant effect on plant growth nor on the antioxidant system. The use of natural compounds in combination with microbial suspensions may be recommended for application particularly to seeds in order to produce high quality crops due to the induction of disease resistance.

P6.1-003

VIRULENCE AND AZOXYSTROBIN SENSITIVITY ANALYSIS OF THE STRAWBERRY NEOPESTALOTIOPSIS CROWN ROT PATHOGENS FROM CHINA

WU E-Jiao. (2), QIAO Yu-Shan . (2), ZHAN Jiasui. (1), ZHAO Mi-Zhen . (2)

(1) Swedish University of Agricultural Sciences, Uppsala, SWEDEN; (2) Jiangsu Academy of Agricultural Sciences, Nanjing, CHINA

Text

In recent years strawberry crown rot caused by *Neopestalotiopsis spp* has occurred in many places in China, leading to an increasing economic loss. In order to understand their virulence and fungicide resistance profiles, 71 isolates of *Neopestalotiopsis spp* pathogens collected from six provinces (Fujian, Yunnan, Inner Mongolia, Sichuan, Jiangsu and Shandong) over China were determined for pathogenicity and sensitivity to azoxystrobin by a detached leaf assay and mycelial growth rate. The results showed that virulence differed significantly among the isolates from different geographical sources and was positively correlated to the annual mean temperature of the sampling sites. The EC50 values of azoxystrobin to the 71 *Neopestalotiopsis* isolates ranged from 2.89 µg/mL to 52.80 µg/mL, with an average of 44.57 µg/mL. Association between azoxystrobin sensitivity and conidia production was dose-dependent but there was no correlation between azoxystrobin sensitivity and virulence of the pathogens. The results of this study provide useless information for the formulation of azoxystrobin control plan for strawberry *Neopestalotiopsis* crown rot in China.

DYNAMICS OF TOTAL, VIABLE AND CULTURABLE STATES OF TWO BACTERIAL BIOLOGICAL CONTROL STRAINS APPLIED TO GRAPEVINE AND FRUIT-TREE CROPS

DARANAS Núria. (1), BADOSA Esther. (1), MONTESINOS Emilio. (1), **BONATERRA Anna. (1)**

(1) Plant Pathology-CIDSAV-CeRTA, Institute of Food and Agricultural Technology, University of Girona (Spain), Girona, SPAIN

Text

The population dynamics of the biological control strains *Bacillus velezensis* A17 and *Lactobacillus plantarum* PM411 were evaluated after their release into grapevines in Penedès area (Catalunya, Spain) and apricot and peach trees in Torreilles (France). The population levels were quantified by viability qPCR, qPCR, and dilution-plate counting in leaves, flowers, and fruits over two growing seasons. *B. velezensis* A17 showed high survival rates in all crops. The viability of all A17 cells was confirmed since qPCR and viability qPCR estimations did not differ significantly. However, higher levels were estimated by dilution-plate counting due to the non-selective characteristics of the growth medium used. In contrast, the viability of *L. plantarum* PM411 was conditioned depending on the plant tissue, crop, and climate conditions.

In general, the viable population level of PM411 was higher in apricot than in grapevine. In general, the PM411 survival declined some days after application, indicating difficulties in its establishment. The population level of PM411 was made up of dead, culturable, and/or viable but non-culturable cells since significant differences between the three methods were observed. The size of each portion changed depending on the sampling time point and the field trial. In conclusion, A17 and PM411 differ strongly in their colonization and survival in grapevine, peach, and apricot.
Funding was provided by INTERREG POCTEFA EFA182/16/PALVIP.

P6.1-005

POTENTIAL OF AN EXPERIMENTAL BACILLUS VELEZENSIS STRAIN AS A BIOCONTROL AGENT TO CONTROL GRAPEVINE BLACK ROT DISEASE

RAVEAU Robin. (1), ILBERT Chloé. (2), DURAND Solène. (1), HELOIR Marie Claire. (2), ADRIAN Marielle. (2), FERMAUD Marc. (1)

(1) INRAe, UMR SAVE, Bordeaux Science Agro, ISVV, F-33882, Villenave D'ornon, FRANCE; (2) INRAe, Agroécologie, Institut Agro Dijon, CNRS, Univ. Bourgogne Franche-Comté, F-21000, Dijon, FRANCE

Text

Guignardia bidwellii (Ellis; anamorph *Phyllosticta ampelicida*), a hemibiotrophic fungus responsible for black rot (BR) disease in grapevine, could turn into a serious threat in the near future. Causing potential severe crop loss, it currently benefits from the withdrawal of several synthetic fungicides and the lack of commercial specific biocontrol alternatives. Within the framework of the French research project VITAE, combinations of management options, such as biocontrol and vine genetic resistance, are investigated.
To evaluate the efficiency and mode(s) of action of a biocontrol experimental candidate, *i.e*. a *Bacillus velezensis* strain, culture supernatants were tested via *in planta* efficacy bioassays in greenhouse (cv. Artaban & Marselan), and *in vitro* direct confrontation assays. The application of the bacterial supernatant significantly reduced both BR incidence and severity, with protection rates reaching 90% *in planta*. Two major modes of action accounting for the supernatant efficiency are put forward and deeply investigated: a direct effect against the pathogen and the elicitation of grapevine defense responses.
Thus, the *B. velezensis* supernatant could act as an efficient biocontrol tool in a future strategy of grapevine protection. The mechanisms of action and their relative importance will be further discussed by quantifying the antibiosis capacity under different conditions and at different infection stages, as well as deciphering the defense induction pattern.

P6.1-006

EFFECTS OF FLUBENETERAM ON INHIBITING THE DEVELOPMENT OF PUCCINIA STRIIFORMIS F. SP. TRITICI IN WHEAT LEAVES

JI Fan. (1), HUANG Lili. (1), KANG Zhensheng. (1), **ZHAN Gangming. (1)**

(1) State Key Laboratory of Crop Stress Biology for Arid Areas, Yangling, CHINA

Text
Stripe rust caused by *Puccinia striiformis* f. sp. *tritici* (*Pst*) is a serious threat to wheat production, and the application of fungicides is one of the most important means of controlling the disease. The purpose of this study is to determine effects of a new succinate dehydrogenase inhibitor (SDHI) fungicide, flubeneteram. Results showed that flubeneteram displayed significantly inhibitory effects on SDH enzymes of *Pst*. The baseline sensitivity of 173 *Pst* isolates from 13 provinces of China to flubeneteram was determined. Histological observations showed that after flubeneteram application, the formation and development of *Pst* hyphae and haustoria were significantly inhibited, and the structures were destroyed. The biomass of *Pst* in wheat leaves was significantly reduced at 18 h after flubeneteram application. Finally, it was found that flubeneteram could induce the upregulation of genes related to callose synthesis in wheat, thus increasing the number of callose deposition; moreover, flubeneteram also primed wheat for SA-induced defenses via upregulating pathogenesis-related genes (*PR1* and *PR2*), which play roles in preventing *Pst* infection. Altogether, our study is the first to provide evidence that flubeneteram induces wheat defense against *Pst* infection. The findings indicate that flubeneteram could be an effective fungicide for managing stripe rust.
Additional keywords: wheat stripe rust, flubeneteram; ultrastructure, histo chemistry, induced systemic resistance

P6.1-007

EVALUATION OF FUNGICIDES AND FUNGICIDE APPLICATION METHODS TO MANAGE PHYTOPHTHORA BLIGHT OF PIGEONPEA

GAVIYAPPANAVAR Ramanagouda. (1), SHARMA Mamta. (1)

(1) International Crops Research Institute for the Semi-Arid Tropics, Hyderabad, INDIA

Text
Phytophthora blight of pigeonpea caused by Phytophthora cajani has been significantly increasing in major pigeonpea production regions of India. Limited information on pathogen infection, epidemiology and lack of adequate resistant cultivars is hampering the P. cajani management significantly. Therefore, five fungicides viz. metiram + dimethomorph, mancozeb + cymoxanil, cymoxanil + famoxadone, mancozeb and, mancozeb + metalaxyl-M were evaluated against P. cajani under control condition to control zoospore induction as well as infection of zoospores at seedling stage. Half maximal effective concentration (EC50) of fungicides for mycelial inhibition was calculated. Lowest EC50 was recorded in metiram + dimethomorph (0.17µg/ml) followed by mancozeb + metalaxyl-M (2.49µg/ml) and mancozeb + cymoxanil (8.23µg/ml) fungicides. The sporangium and zoospore formation significantly affected by mancozeb + metalaxyl-M followed by metiram + dimethomorph and mancozeb + cymoxanil on sporangia viability, zoospores germination and encystment. Further, under glasshouse conditions, different fungicide application methods (e.g. seed-treatment, soil-drench, foliar-spray either singly or in combinations) were evaluated with fungicides on susceptible (ICP 7119) moderately resistant pigeonpea (ICPL 99010, ICPL 20135 and ICPL 99048) cultivars. Among fungicide application methods seed-treatment + soil-drench, soil-drench + foliar-spray and soil-drench are effective in controlling of Phytophthora blight.

CONTROLLING CUCUMBER POWDERY MILDEW AND ANTHRACNOSE BY BACILLUS VELEZENSIS STRAIN TCB43

KUO Chien-Chih. (1,2), HUANG Yi-Chiao. (2), WANG Chao-Jen. (1), DENG Wen-Ling. (2)

(1) Taichung District Agriculture Research and Extension Station, Council of Agriculture,Executive Yuan, Changhua, TAIWAN; (2) National Chung Hsing University, Taichung, TAIWAN

Text

Powdery mildew and anthracnose are important diseases during the harvest period of cucumbers, which could cause yield reduction, quality decline or shorter harvest period in severe cases. A bacterial strain, designated Tcb43, capable of inhibiting the germination of fungal spores was isolated from an organic red dragon fruit field. The phenotypes of Tcb43 cultured on nutrient agar was changeable, quite different from other *Bacillus* species. The Tcb43 strain was identified as *Bacillus velezensis* using whole genome sequencing. In the fungal inhibition tests, the Tcb43 could inhibit the mycelial growth of *Colletotrichum orbiculare* in confrontation assays, and the germination rate of the conidia of *Podosphaera xanthii* was significantly reduced by more than 85% after treating with the 200-fold dilution (200X) Tcb43 fermentation broth. Greenhouse assays revealed that treating cucumber plants with 200X Tcb43 reduced the incidence of anthracnose disease by 50% after treatment for three consecutive weeks. In field trial, the cucumber plant treated with 200X of Tcb43 fermentation broth by spraying continuous 5 weeks, reduced the incidence of powdery mildew disease up to 68% compared to the mock treatment. This work revealed that the effectiveness of the rhizobacterium *B. velezensis* Tcb43 to antagonize the anthracnose and powdery mildew fungus in greenhouse or field trial, indicating that Tcb43 is a potential biocontrol agent.

Text

In nature, plants have evolved several mechanisms to protect themselves from pathogens. Agriculture limited the defense possibilities by reducing the genetic variability of the plant and selecting the cultivated varieties, based more on quality traits than on pathogen resistance. This is particularly true for grapevine (*Vitis vinifera* L.), a woody plant that is susceptible to several diseases, such as downy mildew. In the past, the search for disease management tools has been focused on fungicides to target the pathogen primarily, and secondarily on introgressing resistant traits of other *Vitis* species into the cultivated grapevine. No attention has been paid to *V. vinifera* as a source of resistance. The recent discovery of a resistant

cultivar (Mgaloblishvili) in a grapevine collection of the *V. vinifera* domestication center (Georgia, South Caucasus), that possesses a high genetic variability, changed our perspectives on breeding. Moreover, it led to the development of biotechnological and natural fungicides from susceptibility/resistance mechanisms. dsRNA was designed to trigger RNA interference and transiently silence candidate susceptibility genes (*e.g.*, *VviLBDlf7*), and antifungal compounds (terpenes) were identified in Mgaloblishvili. An effective disease protection was achieved in both cases. Further implementations of these and other findings will shape a new era in grapevine downy mildew control, that will be possible thanks to the efforts in germplasm conservation.

P6.1-010

BISMUTH SUBSALICYLATE, A FUNGISTATIC COMPOUND AND PLANT DEFENCE STIMULATOR WITH POTENTIAL FOR MANAGEMENT OF GRAPEVINE TRUNK DISEASES.

MERLEN Loriane. (1,2,3), TARNUS Céline. (1,2), DELAITE Christelle. (1,3), GELLON Mélanie. (1,2)

Text

Since use of sodium arsenite was banned in 2001, increasing numbers of grapevines affected by grapevine trunk diseases (GTDs) have been observed, and lack of highly effective control products has led research on bismuth subsalicylate (BSS). The antifungal capacity of BSS (which contains salicylic acid) was assessed against GTD pathogens, and for ability to stimulate plant defence genes. An objective was to design an appropriate formulation for BSS which had water solubility. A suitable formulation based on a liquid polymer was developed, with small particle size which increased the bioavaibility of the compound, an extremely important feature for eventual developments. Antifungal potency of the formulated BSS against GTD pathogens was confirmed, through growth inhibition of *Neofusicoccum parvum* (isolates Bt 67 and Bourgogne), *Diplodia seriata* (98.1) and *Fomitiporia mediterranea* (PHCO36). Stimulation of defence genes was analysed by RT-qPCR on grapevine callus (*VvPAL, VvEDS1, VvHSR1* overexpressed), and the non toxicity of BSS on grapevine cells was confirmed by fluorescence microscopy. BSS was then evaluated *in planta* using vertical plant endotherapy laboratory technique, where BSS was injected directly into grapevine rotten wood where mycelium complexes are concentrated. Preliminary observations will be presented for symptomatic grapevines treated (n=100) with BSS for 2 years in Alsace, taking into account the complexity of GTD symptom expression.

P6.1-011

COMBINED EFFECT OF ABIOTIC PARAMETERS ON TRICHODERMA SP. GROWTH WITH BIOCONTROL POTENTIAL ON STORED GRAIN PHYTOPATHOGENS

ZAHARIA Roxana. (1), PETRISOR Cristina. (1), FATU Viorel. (1), LEVEANU Ion. (1), BOTEA Mihaela Carmen. (1)

(1) Research and Development Institute for Plant Protection Bucharest, Bucharest, ROMANIA

Text

Temperature, pH, and water activity are key factors in the growth behavior, development and biocontrol activity of the fungal strains. These abiotic factors are relevant for different application in agriculture and biotechnology. *Trichoderma* spp. is well known as very effective biological mean for plant disease management. The present work aimed to establish the effects of environmental factors on the mycelial radial growth of *Trichoderma* sp. strain (isolate Tr.1) and its biocontrol capacity against stored grain phytopathogens. Also, it was evaluated the antagonistic effect of an isolate of *Trichoderma* sp. on five strains of *Penicilium* spp., *Fusarium* spp and *Botritys* sp. phytopathogens, by dual culture method. The pH used were 4, 5, 6 7, 8 and incubation temperatures were 10°C, 15°C, 25°C, 30°C, 35°C. The results of experiments showed that the most favorable pH was between 5 and 6, while pH 8 and pH 4 showed significant reduction in the growth parameters of *Trichoderma* sp. The results revealed that tested strain has grown better between 25°C and 30°C. Mycelial growth was reduced at 15°C and inhibited at 10°C. After six days of incubation at 28°C, the antagonistic capacity of *Trichoderma* sp. isolate was recorded. The results showed that *Trichoderma* sp. has high biocontrol potential as it inhibited the growth of all tested fungal strains associated with grain seeds, in percentage between 59.52% and 84.71%.

P6.1-012

BIOCIDAL ACTIVITY OF PLANT BY-PRODUCTS TO CONTROL PLANT DISEASES USING FOLIAR APPLICATIONS

MIRMAJLESSI Mahyar. (1)

(1) University of Ghent, Ghent, BELGIUM

Text

Using substances of natural origin is a promising alternative to synthetic pesticides. The biocidal activity of organic extracts derived from waste streams of tomato shoots, chicory roots, wheat bran, celery, fennel, and sunflower stems was investigated against plant pathogens Phytophthora infestans, Botrytis cinerea, Blumeria graminis, Alternaria solani and A. alternata in the greenhouse. The dry waste sources were mechanically grinded for solid-liquid extraction using different types of solvents (water, ethanol, ethyl acetate and hexane). Foliar applications were implemented, at 10,000 ppm and 100,000 ppm dilutions of concentrated extracts on potato, tomato and wheat plants 24 h before inoculation. Disease assessment was measured based on disease severity index (DI). From a total of 58 extracts, water solvent-based extracts at 100,000 ppm exhibited the best inhibitory effect. Celery extract showed the best inhibitory effect (DI 11.11%) against P. infestans, followed by chicory root, wheat bran and fennel with DIs 20.74%, 22.96% and 23.70%, respectively. These extracts also displayed a moderate effect against B. graminis and A. alternata with DI ≈ 55%. A significant disease control (p-value < 0.05) was observed against B. cinerea on tomato plants using sunflower extract (DI 5.56%). The protective activity of these extracts against tested plant pathogens can be further processed as biopesticides to be applied alone or in combination with other disease management strategies.

Text

Rice blast is an important limiting factor for rice growth. Deploying resistant varieties is an effective, economical, and eco-friendly way to manage rice blast. However, most resistant varieties possess only one major resistance gene, making the resistance easily to be broken down by field isolates after 3-5 years of monoculture on large scales. ‘Kaohsiung 145 (KH145)’ is an elite Taiwanese japonica rice cultivar with good rice quality and high yield, but moderate susceptibility to blast disease. To improve the resistance of KH145 and achieve durable resistance, this study aimed to develop KH145 multilines and pyramid lines by marker-assisted breeding and evaluate their blast resistance under field conditions. In farmers’ fields in Daliao and Meinong, Kaohsiung and Guanshan, Taitung in 2021 and 2022, a mixture of three KH145 monogenic lines carrying *Pi9*, *Pik-h*, and *Ptr* showed a much higher leaf and panicle resistance than the KH145 pure line. By testing the disease severity and genotypes of individual plants, we found susceptible-type lesions on some plants with Pik-h, indicating that this gene is being overcome. The three-gene pyramided lines, which were developed by hybridization of the KH145 monogenic lines, also exhibited high resistance to leaf and panicle blast in the upland and paddy blast nurseries. The lines are being selfed to increase the homozygosity. Also, lines with good agronomic traits and rice quality will be selected for commercial cultivation.

P6.1-014

EFFECT OF NANO ZINC LOADED PGPR BIOACTIVE FORMULATION ON PHYSIOCHEMICAL PROPERTIES AND ITS RELEASE EFFICIENCY AGAINST RHIZOCTONIA SOLANI KUHN

DUMPAPENCHALA Vijayreddy. (1), DUTTA Pranab. (1)

(1) College of Post Graduate Studies in Agricultural Sciences, Central Agricultural University (Imphal), Umiam, INDIA

Text

Rhizoctonia solani Kuhn is an ubiquitous in its distribution in worldwide and in India causing 8-50% yield losses to the farmers. Zinc oxide nanoparticles are generally regarded as GRAS materials due to its safe application and having antimicrobial activity. The present study focussed on the study of physiochemical properties by exploring the enzymatic activity on Superoxide dismutase (SOD), Catalase (CAT) and Malondialdehyde (MDA) and on the release efficiency against R. solani against different concentrations of green engineered nano zinc loaded PGPR bioactive formulation (En-ZnO-NP-BF) from 1, 5, 10, 20, 50, 100, 150 and 200 ppm. The release efficiency was found to be increasing after treating the rice seeds with En-ZnO-NP-BF and placed in MS media. 200 ppm possessed the highest release efficiency with 47.46% followed by 150 ppm with 32.28% after 24 hrs. Sclerotia treated with En-ZnO-NP-BF showed highest mycelial inhibition of 98.81% at 200 ppm followed by 84.81% for 150 ppm compared to control 0.00%. No sclerotia was found to formed at 200 ppm of En-ZnO-NP-BF. This was followed by 150 ppm (11.67). In control maximum (53) sclerotia was found to form. The present study conclude that En-ZnO-NP-BF at 200 ppm was showing highest enzymatic activity against fungus and sclerotia formation and mycelial growth also reduced after treating sclerotia with En-ZnO-NP-BF.

THE EFFECT OF SOIL MICROBIAL INOCULANTS ON THE SUSCEPTIBILITY OF GRAPEVINE TO PLASMOPARA VITICOLA INFECTION.

TAIBI Othmane. (1), SCAGLIA Fabio. (2), BOVE Federica. (1), CAFFI Tito. (1), ROSSI Vittorio. (1)

(1) Universita cattolica del sacro cuore-campus di piacenza, Piacenza , ITALY; (2) Horta srl, Piacenza, ITALY

Text

The control of Grapevine Downy mildew (GDM), caused by the oomycete Plasmopra viticola, strongly relies on applications of chemical fungicides, with negative impacts on the environment and human health. The use of beneficial microorganisms rises as an alternative in GDM management, in form of both microbial pesticides (biocontrol agents) and soil microbiota. The interest in the application of soil microbial inoculants (SMIs), including mycorrhizal fungi, has been increasing in recent years as biostimulants increase the growth and development of agricultural and horticultural crops, and mitigate environmental stresses. The effect of SMIs to augment the plant defense against pathogens has also been demonstrated. In 2021 and 2022, we implemented a RCB design experiment in a five-year vineyard in northern Italy, in which 7 commercial SMIs were applied at the rhizosphere level at the start of each season, in comparison with a nontreated test (NT). Between flowering and veraison, leaves were inoculated with a sporangial suspension of P. viticola in the field and under lab inoculations, and the resulting GDM severity was assessed; the inoculation experiment was repeated three times. Some SMIs were able to reduce disease severity compared to NT, with a maximum of 56 % efficacy. The results support the potential interest in SMIs to potentiate plant resistance against P.viticola in the frame of sustainable management of GDM in viticulture.

P6.1-016

EFICACY AND COMPATIBILITY OF BIOLOGICAL AGENTS AND CHEMICAL FUNGICIDES FOR THE MANEGEMENT OF SCLEROTINIA SCLEROTIORUM ON SOYBEAN.

HAMADA Natasha Akemi. (1), AGOSTINI João Alesi. (1)

(1) IFPR - Instituto Federal do Paraná, Palmas, BRAZIL

Text

The white mold caused by *Sclerotinia sclerotiorum* cause reduction of 20% to 70% of production of soybean in the South of Brazil and the control is based on fungicide sprays. Nowadays, biological control has been emerging in the manegement of the disease. The aim of this study was to evaluate the eficacy of *Trichoderma harzianum* (ESALQ1306), *Bacillus subtilis* (QST713) and *B. amyloliquefaciens* (CPQBA 040-11DRM 01) in the control of *S. sclerotiorum* isolates, alone and in combination with chemical fungicides. First, the sensitivity of biological agents to Bixafem+Protioconazol+Trifloxistrobin and Methyl tiofanate+Fluazinam was evaluated in vitro. This was followed by in vitro assays that evaluated the eficacy of biological agents and chemical fungicides (alone and in combination) in reduction the micelial growth of three isolates of *S. sclerotiorum*, by direct contact and pairing. *T. harzianum* inhibited the pathogen 70 to 90% (direct contact) and 100% (pairing) but was not compatible with fungicides; *B. subtilis* and *B. amyloliquefaciens* inhibited the pathogen just when paired (80 to 100%) and were compatible whit Methyl tiofanate+Fluazinam but not with Bixafem+Protioconazol+Trifloxistrobin. Fungicides inhibited 100% of pathogen micelial growth independently of isolate. These results are important for the adequacy of the disease management program, mostly about the simultaneous application of products, and should be validated in field tests.

Text
The reduction of copper-based plant-protection products with the final aim of phasing out has a high priority in European policy, as well as in organic agriculture. The aim of this survey was to provide an overview of the current use of these products in European organic agriculture and the need for alternatives to allow policymakers to develop strategies for a complete phasing out. Since there is a lack of centralized databases on pesticide use, we combined expert knowledge on permitted and real copper use per crop and country, with statistics on organic area in 12 European countries covering 83% of the organically managed horticultural area. We calculated that approximately 3258 t copper metal per year is used by organic agriculture in these countries, equalling to 53% of the permitted annual dosage. This amount is split between olives (1263 t y^{-1}, 39%), grapevine (990t y^{-1}, 30%), and almonds (317 t y^{-1}, 10%), followed by other crops with much smaller annual uses (< 80 t y^{-1}). In 56% of the allowed cases (countries × crops), farmers use less than half of the allowed amount, and in 27%, they use less than a quarter. At the time being, completely abandoning copper fungicides would lead to high yield losses in many crops. To successfully reduce or avoid copper use, all preventive strategies have to be fully implemented, breeding programs need to be intensified, and several affordable alternative products need to be brought to the market.

P6.1-018

EVALUATION OF MYCOPARASITIC FUNGI AS POTENTIAL BIOLOGICAL CONTROL AGENTS FOR WATTLE RUST (UROMYCLADIUM ACACIAE)

POSWA Nonkululeko . (1), BANCOLE Bernice. (2), SIVPARSAD Benice. (2), LAING Mark. (1)

(1) University of KwaZulu Natal, Pietermaritzburg, SOUTH AFRICA; (2) Institute for Commercial Forestry Research, Pietermaritzburg, SOUTH AFRICA

Text
Wattle rust, caused by *Uromycladium acaciae* (*Cooke*) *P. Syd. & Syd*), is the most economically important disease currently affecting black wattle (*Acacia mearnsii*) plantations in South Africa. Available control measures for wattle rust consist of rust tolerant clones, azoxystrobin- based fungicides and difenoconazole fungicides. There is an urgent need to find alternative chemical and biological control measures that will comply with Forest Stewardship Council (FSC) regulations in the management of wattle rust. *Sphaerellopsis filum* and *Lecanicillium lecanii* are well known mycoparasites of rust. This study aims to evaluate the efficacy of S. filum and L. lecanii for the control of wattle rust through a series of potted nursery trials. Early results have shown that biweekly applications of S. filum significantly reduced rust disease progression. Although applications with *L. lecanii* did reduce rust disease progression, it did not produce a significant reduction relevant to the untreated rust control. This study demonstrates that *S. filum* has the potential to control wattle rust and could be used as part of an integrated pest management strategy for the disease.

Text

Developing chemicals with antifungal activity from agricultural wastes is a promising approach to reduce the environmental impact of disease management strategies in plant protection and potentially a valuable source of novel modes of action. Pyricularia oryzae is able to infect rice plants at all stages of development such as leaves, stems, nodes and panicles. The almost exclusive use of chemical fungicides, e.g. strubilurins, for rice blast managements increases the risk of emergence of fungicide resistant strains. The goal of our study was to extract bioactive compounds from grapevine wastes assessing their efficacy against P. oryzae strobilurin-resistant and -sensitive strains. We tested 28 compounds on two strobilurin-resistant and two sensitive P. oryzae strains, both on spore germination and mycelium growth inhibition. One compound inhibited the mycelial growth of resistant strains by 32% and that of sensitive strains by 58% at 0.06 mM concentration. Other two compounds completely inhibited spore germination of the resistant strains at 1mM without inhibiting mycelium growth. This preliminary work will pave the way for the synthesis of nature-derived compounds possibly acting on diverse cellular targets, exhibiting dual or multiple modes of action.

P6.1-020

EFFICACY OF IN-FURROW FUNGICIDE APPLICATION TO MANAGE SOUTHERN BLIGHT IN MISSISSIPPI PEANUT FIELDS.

TRIPATHI Subina. (1), WILKERSON Tessie. (1), ALLEN Tom. (1)

(1) Mississippi State University - Stoneville, MS, Stoneville, UNITED STATES

Text

Southern blight (SB), caused by Athelia rolfsii (AR) is a soil-borne fungus that can cause losses of up to 80%. Symptoms are water-soaked lesions, yellowing, wilting, and plant death. Currently, fungicides are used to manage the disease. This study was conducted to test the efficacy of in-furrow fungicide applications to control SB. In 2022, a field study was conducted in Stoneville, MS to evaluate the effect of in-furrow fungicides on the severity of AR, in peanut. Seven fungicides (Quadris, Solatenol, Omega, Velum, Proline, Elatus, Revytek) and a non-treated control were evaluated in a RCBD with four replications. Each plot was planted to four rows of ‘Georgia-06’ in Bosket fine sandy loam. During planting, two rows of each plot were inoculated with sterilized millet colonized by AR, and two rows were left non-inoculated. Stand counts, vigor, and phytotoxicity were collected at 15 and 30 DAP, and disease severity was recorded at 90 and 110 DAP. The data collected were analyzed using ANOVA in R studio software. No significant differences were observed in the severity of AR among the treatments; however, there was a numerical reduction of 11% in the incidence of AR in the plot treated with Elatus compared to the control. Despite no significant differences in yield, an average increase of 13% was observed in plots treated with Omega.

Further research is needed to assess the potential of in-furrow fungicide applications as a management strategy for SB in peanuts.

Text

Natural compounds isolated from macroalgae are promising, ecofriendly, and multifunctional bioinoculants, which have been tested and used in agriculture. We have characterized for the first time an arabinogalactan protein-like (AGP-like) from Ulva lactuca, which exhibits several features associated to land plant AGPs. In land plant, AGPs were shown to play a role in several plant biological functions, including cell morphogenesis, reproduction, and plant-microbe interactions. Here, we have evaluated its ability to (i) protect oilseed rape cotyledons against Leptosphaeria maculans, and (ii) its ability to activate immune responses. Preventive application of the Ulva AGP-like enriched fraction on oilseed rape, followed by cotyledon inoculation with L. maculans, resulted in a major reduction of infection propagation. The noticed reduction correlated with an accumulation of H2O2 in treated cotyledons and with the activation of SA and ET signaling pathways in oilseed rape cotyledons. In parallel, an ulvan was also isolated from Ulva lactuca. Preventive application of ulvan also enhanced plant resistance against L. maculans. Surprisingly, reduction of infection severity was only observed at high concentration of ulvan. Together, this study indicates that U. lactuca AGP-like glycoproteins exhibit promising elicitor activity and that plant eliciting properties of Ulva extract, might result not only from an ulvan-originated eliciting activities, but also AGP-like originated.

Text

During their evolution, plants have developed mechanisms to adapt to their growth environment and deal with various types of stresses. The mechanisms that determine the composition of each environmental niche largely involve the creation of chemical heterogeneity by harnessing the metabolic flux from primary metabolism. Following this, plants produce species-specific chemical compounds through the exploitation of a network of interconnected biosynthetic steps. Eminent molecules of this are the compounds resveratrol and hydroxytyrosol both of which are directly connected to human health protection. Resveratrol, a stilbenoid, is mainly produced in grape skins, and hydroxytyrosol, a phenylethanoid, is produced in olive leave tissues and fruits. Various studies over the past decades have led to the identification of the genes involved in their biosynthesis. The latter, allowed the heterologous reconstitution of their biochemical pathways making possible their bulk production in microbial factories. After certain purification steps, such bioactive compounds of plant origin have been proven to be equally beneficial when they are utilized as antibiotics both in in-vitro as well as in-planta experimentation. Formulations of both types of compounds were able to inhibit either fungal or bacterial growth. Thus, their use as plant protection agents is investigated to replace existing commercial pesticides and contribute to environmental protection and consumer safety

Text

Pseudomonas syringae pv. *actinidiae* (Psa) is the causal agent of kiwifruit bacterial canker disease, currently, the disease management relies on copper-based compounds, which could force the insurgence of copper-resistance Psa strains, as already observed with other plant pathogens. Thus, new control strategies should target bacterial virulence mechanisms, such as the type III secretion system, to weaken pathogens rather than prevent their growth *in planta*. Exploiting a reporter system based on the GFP expression driven by the promoter region of the *hrpA1* gene, which encodes one of the major components of the T3SS, a chemical library was screened to seek molecules capable of reducing T3SS induction in the most aggressive Psa biovar 3. Among selected candidates, dicumarol was further characterized for its ability to dampen Psa virulence *in planta*. Moreover, a proteomic analysis suggested that dicoumarol could interfere with a regulatory mechanism common to

both ‘injectisome’ and flagellum-related T3SS.

SPECTROSCOPIC DETECTION OF CROP AND FOREST DISEASES

QUARATIELLO Giuseppe. (1), COUTURE John J. (2), CRUZ Christian D. (3), FIACCADORI Ivan. (1), **COTROZZI Lorenzo. (1)**

(1) University of Pisa, Department of Agriculture, Food and Environment, Pisa, ITALY; (2) Purdue University, Departments of Entomology, and Forestry and Natural Resources, West Lafayette Wi, UNITED STATES; (3) Purdue University, Department of Botany and Plant Pathology, West Lafayette Wi, UNITED STATES

Text

Sustainable agriculture and forest management require advancements in high-throughput techniques to early and accurately detect plant stresses. Spectroscopy has emerged as a promising tool to monitor vegetation status (from leaf to landscape level), being a non-destructive, rapid, and relatively low-cost technique: it relies on the interaction of light with plant chemical/structural composition and water content. The present work highlights the potential of this technology for detecting and monitoring crop and forest diseases. First, it briefly reports basic concepts of vegetation spectroscopy. Then, it shows the capability of hyperspectral data to detect and monitor crop diseases, focusing on a case study on wheat blast disease [e.g., inoculated leaves were well discriminated by the analysis of spectral profiles (accuracy >0.75), even before the onset of visible symptoms]. Finally, it highlights that although the use of such spectral approaches has risen sharply, most studies have been carried out for agricultural applications, while the utilization for detecting and monitoring forest diseases has been less investigated. Indeed, although a number of forest diseases have been detected and quantified using optical sensors, some major issues need to be addressed, such as the lack in exploring several major diseases and geographic areas, and in the use of this approach for long-term monitoring.

Text

Grapevine (Vitis vinifera L.) is one of the most economically important crops worldwide, and the increase in wine production rate demand requires changes in the agricultural processing and manufacturing practices to make them sustainable. Issues associated with the large use of agrochemicals and consumer needs for residue free products have stimulated research

into new and eco-friendly tools for sustainable pest management and vine protection. The aim of the present study (supported by Kwizda Agro GmbH) was to characterize at functional level the “indirect” protective mechanisms induced by the application of a yeast extract formulate (YE) through the induction of defense responses in V. vinifera cv. Sangiovese plants artificially inoculated with Botrytis cinerea (Bc). In YE+/Bc+ leaves, germ tubes did not elongate well, and their hyphae were slightly spread over the leaves after 2 days. The hydrogen peroxide induction (observed from 1 h post inoculation; +40% compared with YE-/Bc- ones) triggered a production of ethylene and a concomitant accumulation of jasmonic acid (7 fold-higher and +34%, respectively). These results confirm a synergistic action in the regulation of defense reactions. The absence of oxidative stress (as confirmed by the unchanged values of malondialdehyde by-products) and the early activation of a signaling pathway suggest the capability of YE to induce resistance in grapevine against necrotrophic pathogens.

Text

Bacterial wilt, caused by Ralstonia solanacearum (Rs), is a major constraint to key cash crops in West Africa. In Benin, BW is particularly problematic in traditional leafy vegetables (Gboma and amaranth) and on key vegetable crops (tomato and pepper). In this study, the distribution of Rs across the main vegetable-growing regions in Benin was characterized for the first time, which is critical to implement targeted regional management. Overall, 27 localities were surveyed, and 50 strains were isolated and confirmed to be Rs-positive by species-specific primers. Rs diversity was broad, and strains from 3 phylotypes I, II & III were isolated. Most isolates (43) identified by PCR using a phylotype-specific primer were phylotype I and were isolated from tomato, pepper, bitter leaf, African basil, and weed. There were 1 strain in phylo I & II (tomato), 2 in phylo II (tomato), 1 in phylo III (pepper), and 3 in phylo II & III (tomato). The presence of Asian (phylo I) strain may be due to accidental introductions from humans. Sequevar analysis using egl primers showed that most strains belonged to sequences 17 and 18, while few others belonged to sequevars 14, 23, and 31. Given that peanuts are a significant source of protein for people in West Africa, greenhouse trials validated the pathogenicity of the seq. 14 strains on peanuts. The targeted approaches to control Rs, can help protect economically important crops and improve livelihood of subsistence farmers in Benin.

P6.1-028

INTEGRATED MANAGEMENT TO CONTROL BARLEY DISEASES

HAVIS Neil D . (1), REES Helen J. (1), YOXALL Tracy. (1), CREISSEN Henry . (1), BURNETT Fiona J. (1)

(1) SRUC, Edinburgh, UNITED KINGDOM

Text

Barley (*Hordeum vulgare*) is the major cereal crop in Scotland. Many common barley varieties have only moderate resistance to the major foliar and ear diseases, especially in winter barley crops. Diseases can have significant impact on both the yield and quality of barley crops. Ramularia leaf spot has been increasingly difficult to control with one of the most effective plant protection products losing its registration in 2020.
Investigations into control of barley diseases in replicated field trials in both winter and spring barley crops using a combination of biologicals, elicitors and fungicides has been conducted over several years. Elicitors and biologicals were applied to seed and growing crops at the T0 timing (GS 24-30). Management programmes were designed to combine the use of the elicitors and biologicals with reduced rates of conventional fungicides.
Results indicate there is potential for new programmes and new products to maintain barley production whilst reducing our dependence on agrochemicals. Programmes with elicitors as a seed treatment and a T0 treatment followed by quarter dose rate fungicides gave significant yield increases over untreated crops and were only just behind a normal commercial fungicide programme in winter barley crops. Additionally, in Laminarin seed treated plots, the biological spray outperformed the fungicide and gave a significant reduction in disease and an increase in yield.

NEW FUNGICIDE ALTERNATIVES TO FUMIGATION FOR MANAGING POTATO EARLY DIE

MALEK Katie. (1), MALEK Alan. (1), LUFF Kelly. (2), WHARTON Phillip. (1)

(1) University of Idaho, Aberdeen, UNITED STATES; (2) Bayer Crop Science Division , Kimberly , UNITED STATES

Text

Potato Early Die Complex (PED) is an annual concern in potato growing areas worldwide causing up to 40% yield losses. The primary causal agent is Verticillium dahliae. However, several other pathogens may contribute, including root lesion nematodes (Pratylenchus spp.) and Colletotrichum coccodes. Pre-plant application of metam sodium has been the standard chemical practice for managing PED. However, high cost, worker safety and increasingly stringent regulations are motivating growers to look for alternative practices. New non-fumigant approaches are being developed to manage the various pathogens responsible for PED. Among these is fluopyram, developed by Bayer CropScience as Velum® Prime. To investigate the efficacy of fluopyram for managing PED, a study was carried out in grower fields in S Idaho from 2019 to 2022. Stems were collected from plants in grower fields treated with either Velum Prime or the grower standard three times (late July, mid-August and early September) and levels of V. dahliae and C. coccodes were quantified using qPCR. Plants treated with fluopyram showed a significant reduction in both V. dahliae and C. coccodes compared to the grower

standard. The plants treated with fluopyram also showed significant yield increases compared to the grower standard. This studysuggests that it is possible to manage PED using low dose at-planting and post-emergence applications of fluopyram.

EVALUATION OF FUNGICIDE PROGRAMS FOR THE MANAGEMENT OF AERIAL STEM ROT IN POTATO.

MALEK Alan. (1), MALEK Katie. (1), NEWBERRY George. (2), WHARTON Phillip. (1)

(1) University of Idaho, Aberdeen, UNITED STATES; (2) Gowan Company, Yuma, UNITED STATES

Text

Aerial stem rot (ASR) is an important foliar disease of potato worldwide and is predominantly caused by the pectolytic soft rot bacteria Pectobacterium carotovorum. It differs from black leg (caused by P. atrosepticum) as it is found later in the season after row closure. The pathogen primarily enters through wounds in the stem and expands outward leaving a distinct black lesion. These lesions spread down the stem as opposed to black leg lesions which spread up the stem from diseased tubers. Decaying stems appear watery and gooey and optimal conditions can spread lesions quickly and desiccate the entire stem. Ten years of field trials were conducted using susceptible varieties in a randomized complete block design. Treatments consisted of different formulations of copper containing fungicides starting at row closure and continuing on a 7-day schedule until vine kill. Plots were inoculated with P. carotovorium two weeks after the initial treatment. When disease symptoms started to show up in untreated plots, disease incidence was rated visually as the number of infected stems per plant every four days over a a two-to-three-week period. These results were used to calculate the Relative Area Under the Disease Progress Curve, showing the rate of disease progress. Results showed that treatments with the copper containing fungicides Previsto and Badge SC significantly reduced the incidence and severity of aerial stem rot compared to the non-treated control.

Text

UV-C light (200-280nm) can combat a variety of microorganisms, including necrotrophic fungi like *Botrytis cinerea* (grey mould), offering a viable alternative to agrochemical control. Yet a balance must be struck between controlling infection and causing damage to plants. We exposed *B. cinerea* conidia and early vegetative mycelia to increasing UV-C doses (up to 8 minutes), logging survival data, and colony-forming units. We also applied a unique grey-

scale imaging method to measure melanin phenotypic changes post-treatment. Following that, we applied a non-toxic UV-C treatment (4 minutes) with incubation at 4°C (postharvest conditions) and 21°C (production conditions). We then analysed changes in gene expression in the melanin biosynthetic pathway. Melanogenic genes both up- and downstream in the pathway are targets for ongoing mutation survival studies. Initial survival trials confirm significant lethality in conidia with increasing UV-C dose, but that mycelial-stage *B. cinerea* not only demonstrated lower lethality rates but also a darker phenotype compared to untreated. Gene expression moreover shows significant and rapid upregulation in upstream gene (*YGH1*) within 30 minutes of UV-C treatment with an associated lag in upregulation of downstream genes (*BRN1*, *BRN2*). Adaptive melanisation to non-lethal UV-C treatment highlights the need for a more comprehensive understanding of grey mould pathogenic biology under current commercial UV-C treatment.

Text

Apple scab caused by the fungus *Venturia inaequalis*, is the most important disease of apples in temperate countries. The main commercial apple varieties are susceptible to this disease and the phytosanitary treatments applied in the orchard to get rid of it represent a considerable economic and environmental cost (up to 30 fungicide applications/year). To combat apple scab, we are developing a totally new biocontrol strategy combining two inventions. The first invention which can be linked to autocidal control makes the fungus non-virulent. We target the sexual phase of *V. inaequalis* by forcing it to reproduce with non-pathogenic strains on apple belonging to the *forma specialis* pyracanthae of *V. inaequalis* (PYR strains), resulting in the generation of non-virulent progeny on apple the following spring. The second invention consists of applying the PYR strains in the spring to protect young apple leaves against a subsequent scab attack. It is expected that this breakthrough technical itinerary will cause a collapse in the size of the pathogen population in the orchard and thus allow reduction in the use of fungicides. This project involving phytopathologists, geneticists, orchards experimenters, economists and professionals of apple sector aims to prove the concept of this innovative strategy, to evaluate its sustainability as well as the conditions of acceptance and appropriation of the inventions by the apple sector

CROSS-PROTECTION IN PLANT VIRUSES: HOW CLOSELY RELATED DO PROTECTING AND CHALLENGING VIRUSES NEED TO BE?

SICARD Anne. (1), VIGNE Emmanuelle. (1), LEMAIRE Olivier. (1)

(1) INRAE, Colmar, FRANCE

Text
Cross-protection is a biocontrol method to protect plants from damage caused by pathogenic viruses. This strategy of cross-protecting a plant with a mild strain to prevent subsequent infection by related severe strains was first described in 1926. Although cross-protection was first evidenced nearly a century ago, the underlying mechanism(s) remain(s) poorly understood. In particular, although the genetic relatedness between cross-protective and challenge strains has been emphasized in a number of papers, the percentage of identity required for cross-protection remains unknown. This lack of data has led to a long and sometimes unsuccessful empirical search for cross-protective strains against some viral pathogenic ones. Recent papers have shown that cross-protection occurs only among variants of the same strain and not between variants of different strains for the citrus tristeza virus (Closterovirus) and the pepino mosaic virus (Potexvirus). In order to determine the percentage of identity required between the cross-protective and the challenge strains for cross-protection to be effective against the grapevine fanleaf virus (GFLV, Secoviridae), different cross-protective variants with decreasing sequence homology with respect to the challenge variant were selected and inoculated on Nicotiana benthamiana. Our results suggest that in addition to the genetic relatedness, the entry point of the cross-protective and challenge strains impacts the cross-protection success.

MANAGEMENT OF WHITE RUST (ALBUGO CANDIDA) DISEASE OF RED AMARANTH FOR SEED PRODUCTION

AHMMED Abu Noman Faruq. (1)

(1) Sher-e-Bangla Agricultural University, Dhaka, BANGLADESH

Text
Experiments were conducted for management of white rust disease of red amaranth (Amaranthus tricolor L.) for seed production during 2018 and 2019 at Dhaka, Bangladesh by following RCBD design with three replications. Eight treatments including chemicals, botanicals, bio-pesticides viz. Ridomil gold 68WG (Mencozeb + Metalaxyl @ 0.2%), Autostin 50 WP (Carbendazim @ 0.2%), Dithane M 45 (Mancozeb @ 0.2%), Goldton 50WP (Copper oxychloride @ 0.2%), Bordeaus mixture (CaO + CuSO4 @ 1%), G-Derma (Trichoderma sp.) @ 0.3%, Garlic bulb extract 1:1 (w/v) (Allium sativum @ 2%), and Allamanda leaf extract 1:1 (w/v) (Alamanda cathertica @ 2%) were considered for the management of white rust disease of Red amaranth (Amaranthus tricolor L.). Four foliar sprays were done at seven days interval, started from 7 days after disease appeared. Among the treatments, Ridomil gold 68WG gave best result. Moreover, Allamanda leaf extract showed better effect and Autostin 50WP had moderate effect against the disease. Growth and seed yield of red amaranth varied significantly among the treatments. In Rabi season of 2018, After 4th spray, the lowest plant incidence and severity were recorded in Ridomil Gold (24%; 1.83%) followed by Allamanda leaf extract (31%; 2.43%). Similar results also found in kharif season of 2019 where after 4th spray, the lowest plant incidence and severity were recorded in Ridomil Gold (18.66%; 1.93%) which was statistically identical with Allamanda leaf extract (22%; 2.23%).

P6.1-036

COMPARATIVE EVALUATION OF CHEMICAL FUNGICIDES AGAINST SHEATH BLIGHT DISEASE OF RICE IN AMAN SEASON

AHMMED Abu Noman Faruq. (1)

(1) Sher-e-Bangla Agricultural University, Dhaka, BANGLADESH

Text

Two experiments were conducted to evaluate the efficacy of chemical fungicides for the management of sheath blight disease of rice in Bangladesh during 2019-20, RCBD design with 3 replications. Sheath blight disease susceptible variety BR 11 was used in these experiments. Fifteen treatments viz. T1 (Tilt 250 EC), T2 (Contaf 5 EC), T3 (Folicur 250 EC), T4 (Score 250 EC), T5 (Combi 230 EC), T6 (Filia 525 SE), T7 (Amister Top 325 SC), T8 (Acibin 28 SC), T9 (Awal 72 WP), T10 (Nativo 75 WP), T11 (Autostin 50 WP), T12 (Dithane M-45), T13 (Sunvit 50 WP), T14 (Control1 with inoculation) and T15 (Control2 without inoculation) were evaluated against Rhizoctonia solani causing sheath blight disease of rice (BR 11) in aman season. In field experiment, after the 4th spray the lowest disease incidence per hill (30%), disease incidence per tiller (10.80%), disease severity (10.80%) and percent relative lesion height (%RLH), (2.44%) was found in T2 treated plot (Contaf 5 EC). However the highest disease incidence per hill (93.33%), disease incidence per tiller (44.71%), disease severity (48.36%) and % RLH (9.11%) was found in T14 after the final spray. Similarly in case of yield contributing characters, the highest yield (6.94 ton/ha) and straw yield (7.12 ton/ha) was found in T2 treated plot while lowest yield (3.49 ton/ha), straw yield (4.32 ton/ha) observed in T14. Moreover, T3 (Folicur 250 EC) and T4 (Score 250 EC) were also significantly effective against this disease.

CROSS-PROTECTION, A VIABLE METHOD TO FIGHT FANLEAF DEGENERATION? STUDY OF 14-YEAR-OLD PRIMARY-INFECTED VINES IN A VINEYARD PLOT

KUBINA Julie. (1), HILY Jean-Michel. (2), MUSTIN Pierre. (1), GERTZ Claude. (1), DEMANGEAT Gérard. (1), SICARD Anne. (1), LEMAIRE Olivier. (1), VIGNE Emmanuelle. (1)

(1) INRAE, Colmar, FRANCE; (2) IFV, Le Grau-Du-Roi, FRANCE

Text

Fanleaf degeneration is a worldwide disease causing a severe decline of vineyards with serious economic losses. Its main causal agent is the grapevine fanleaf virus (GFLV), a virus transmitted from grapevine to grapevine by an ectoparasitic nematode. While GFLV is depicted as one of the most severe viruses of grapevines, infected-vines are not always symptomatic and show a wide range of symptoms with varying degrees of severity. The lack of effective measure to control this disease led us to explore mild strain cross-protection (MSCP) as a biocontrol method. In MSCP, primary infection with a mild isolate is used to prevent secondary

infection(s) by related severe variant(s). Efficient and long-term MSCP relies on the selection of isolates causing mild symptoms on the cultivar of interest and able to prevent subsequent infection by challenger variants present in its growing environment. In this study, the efficacity of MSCP was assessed by monitoring 2000 vines primary-infected with local mild GFLV isolates implanted in a severely diseased commercial plot. After 14 years, most vines remained mildly symptomatic. NGS analyses of 200 representatives of these vines (in terms of symptoms severity), suggest a great resilience of the primary infection and a moderate level of superinfection. We will discuss our results with the aim at developing MSCP as a workable approach to prevent fanleaf degeneration and its deleterious impact on viticulture.

P6.1-038

SIDE EFFECTS OF D-LIMONENE ON THE MEALYBUG DESTROYER , CRYPTOLAEMUS MONTROUZIERI MULSANT (COLEOPTERA: COCCINELLIDAE)

EL AALAOUI Mohamed. (1), SBAGHI Mohamed. (1)

(1) National Institute of Agricultural Research, Settat, MOROCCO

Text

Before incorporating a pesticide into IPM programs, it is necessary to evaluate its impact on the main natural enemies. The lethal and sublethal effect of d-limonene (60 g/L) on adults and larvae of Cryptolaemus montrouzieri (Mulsant) were evaluated under laboratory conditions (26°C) through topical application and ingestion of treated individuals of Dactylopius opuntiae (Cockerell) female (a scale pest that caused damage to Opuntia spp. cactus crops in Morocco and many countries worldwide). The toxicity of this insecticide was compared to that of chlorpyrifos-methyl (480 g/L) and pyriproxyfen (100 g/L), which are both commonly known to be harmful to C. montrouzieri larvae and adults. D-limonene was slightly harmful when applied directly to C. montrouzieri adults (Percent reduction (E)= 66%) and moderately toxic to larvae (E= 88%). Chlorpyrifos-methyl was classi?ed as moderately toxic to the predator adults (C. montrouzieri) due to its effects on fecundity, egg hatching, and offspring survival (E= 90.7%). Pyriproxyfen was classi?ed as harmful to larvae because of its acute effect on pupal mortality (E= 100%). When C. montrouzieri adults were fed treated prey, d-limonene was classified as slightly harmful (E= 44.7%) and when the predator larvae were fed treated prey, d-limonene was classified as harmless (E= 9.8%). The results of this study indicate that D-limonene (60 g/L) may be compatible with augmentative releases of C. montrouzieri to control D. opuntiae in cactus crop.

Text

Chilli production is significantly harmed by the interruption of fungal pathogens i.e., Fusarium oxysporum f.sp. capsici. In recent years application of green synthesized nanomaterials is documented as the best performer against various plant diseases. However, the knowledge about the application of green-synthesized Ag and CuNMs for the management of Fusarium oxysporum and its impact on the components of antioxidant defense system especially in chilli plant is still unknown. Therefore, in the current study, green synthesized silver and copper NMs were applied at three different concentrations to check their efficacy against fusarium wilt of chilli and the components of the antioxidant defense system of chilli plants. Results revealed that AgNMs were found most effective and exhibited disease incidence of F. oxysporum (22.79%) with a significant increase in chilli production (13.13%) along with number of fruits/plant (15%). Moreover, the application of AgNMs improved the concentration of ascorbic acid (1240, 997 µg/mL), total phenolic contents (950, 800µg/mL), flavonoids (111, 88mg/g), hydrogen peroxide (0.0013, 0.001U/mg), amylase (110, 89U/mL), chlorophyll a (0.31, 0.25mg/g), chlorophyll b (0.22, 0.16 mg/g) and total chlorophyll (0.61, 0.50 mg/g) in treated plants of resistant and susceptible varieties of chilli respectively than that of control. It is concluded that the application of green synthesized AgNMs may be a viable approach for disease management.

NANOPARTICLES AS HAMMER OF THOR AGAINST PSEUDOMONAS SYRINGAE CAUSING APICAL NECROSIS IN MANGO

ARIF Asif Mahmood. (1,2), ATIQ Muhammad. (1), RAJPUT Nasir Ahmed. (1), SAHI Shahbaz Talib. (1), USMAN Muhammad. (1), IQBAL Shahid. (1), KACHELO Ghalib Ayyaz. (1)

(1) University of Agriculture Faisalabad, Faisalabad, PAKISTAN; (2) Institute of Plant Protection, MNS University of Agriculture Multan, Multan, PAKISTAN

Text

Apical necrosis disease of mango is becoming a potential threat for mango industry throughout the world. It causes severe yield loss depending on disease triangle. Various chemical, antibiotic, phytoextracts and biological management strategies have been adopted to overcome this malady. These control measures are either having adverse effects on environment or in slow action. Nanotechnology is one of the rapidly advancing and most fascinating science in the field of Agriculture. Use of nanoparticles (NPs) is an environment friendly and effective approach to control bacterial diseases of plants. Silver and copper nanoparticles have excellent antibacterial properties and used as an alternative to pesticides in management of bacterial plant diseases. NPs directly affect the bacterial pathogen and activate defense system of host plant through altering its nutritional status. Silver and copper can be directly toxic to bacterial pathogens while manganese, boron, silicon and zinc act as fertilizer in host defense. As demand for food production is increases globally under changing climate, nanoparticles will play a key role to mitigate new challenges in plant disease management by reducing chemical pesticides.

P6.1-041

DEVELOPMENT OF AN ASCOCHYTA BLIGHT SCREENING SYSTEM FOR THE SELECTION OF RESISTANT PEA (PISUM SATIVUM L.) ACCESSIONS

SCHAERER Hans-Jakob. (1), PETER Nadine. (1), THUERIG Barbara. (1), **OBERHAENSLI Thomas. (1)**, VONZUN Seraina. (1), SCHEINER Christine. (2), DOLDER LAARAÏCHI Barbara. (2), KUSSMANN Sebastian. (2), MESSMER Monika M.. (1)

(1) Research Institute of Organic Agriculture FiBL, Frick, SWITZERLAND; (2) gzpk Getreidezüchtung Peter Kunz, Feldbach, SWITZERLAND

Text

The cultivation of pea (*Pisum sativum* L.) among other leguminous crops has become more and more important in respect to biological nitrogen fixation for sustainable cropping systems and as important plant-based protein source for human nutrition. However, pea production is challenged by many biotic stresses, such as fungal and viral pathogens and insect pests. Among fungal pathogens, *Didymella pisi*, *D. pinodes* and *D. pinodella* contributing to the Ascochyta blight complex are causing severe yield losses in pea production. The disease is stubble-, air-, soil- and seed-borne, hence disease control includes certified seed production and fungicide applications. However, particularly in organic agriculture the latter is not available and disease resistant varieties are needed. In collaboration with an organic pea breeder, we have established a reproducible screening system for selection of resistant pea lines using artificial inoculation. Main achievements are the isolation and identification of *Didymella* strains which contribute most to Ascochyta blight under local conditions, and differential scoring scales of pea leaf or tendril symptoms caused by the different Didymella species used for inoculation. This screening system is fundamental for phenotypic selection of resistant breeding lines independent of the disease pressure in the field. Moreover, it can be employed for identification of resistance genes using genome-wide association studies or genomic prediction approaches.

PHYTO-BIOPOLYMERS FOR INDUCING RESISTANCE AGAINST PEARL MILLET DOWNY MILDEW DISEASE AND TRANSCRIPT PROFILING OF DEFENSE GENE EXPRESSION

SATHYANARAYANA Niranjan Raj. (1), SIDDIAH Chandra Nayaka. (2)

(1) Karnataka State Open University, Mysuru, INDIA; (2) University of Mysore, Mysuru, INDIA

Text

The year 2023 is recognized as the International Year of Millets underscoring the importance of millets. Pearl millet (*Pennisetum glaucum* (L) R. Br.) is projected to be one of the climate change compliant future crop. Pearl millet is a globally important cereal whose production is severely constrained by downy mildew caused by *Sclerospora graminicola* (Sacc.). In this

study, gum biopolymers of *Anogeissus latifolia, Gardenia resinifera, Lannea coramandelica, Buchanania lanzan, Boswwalia* spp., *Canarium strictum*, and T*erminalia tomentosa* were evaluated for their downy mildew disease resistance inducing efficiency and also their synergistic effects when combined with Metalaxyl (Apron 35 SD). Gum exudates of *Terminalia tomentosa* induced disease resistance against pearl millet downy mildew and reduced the disease up to 72% in comparison to the untreated control. *Terminalia tomentosa* gumbiopolymer elicited enzyme activities and transcript accumulation/gene expression of defense enzymes such as ß-1,3-glucanase, Phenylalanine ammonia lyase (PAL), Peroxidase (POX), Polyphenol oxidase (PPO), Lipoxygenase (LOX), and defense protein Hydroxyproline-rich glycoproteins (HRGPs). The very rapid and large changes in elicitor-treated seedlings, in contrast to the delayed, smaller changes in the untreated suscpeptible control seedlings suggests that rate and magnitude of defense gene expressions are important for the effective manifestation of defense.

Text

The potato cyst nematodes (PCN), Globodera rostochiensis is a major quarantine pest of potato (Solanum tuberosum L.)in Kenya, it was reported in Kenya in 2015, with contrywide surveys showing it was widespread in all potato growing regions.In this study, field experiments were conducted to evaluate the population dynamics of PCN under vegetable and potato crops rotation. Seven treatments, three African Indegenous vegetable crops, Solanum scabrum, Solanum villosum and Amaranths dubious, and three potato varieties 'Shangi', 'Mayan Gold' and 'Dutch Robin'and a Fallow (weed free) were established and replicated six times. Treatment were maintained on the same plots for first two seasons, the third season potato plots, S. scabrum A. dubius were maintained. Cyst density and viable eggs at planting and at harvest was evaluated. Results showed PCN populations declined significantly on vegetable crops,a significant natural decline noted under fallow. In S. villosum and S. scabrum, the viable eggs reduced by over 50% in season one and by 60 % and 70% in season two and three respectively.The number of cyst and viable eggs reduced by 30% in season 2 and 35% in season 3 in both dubius and weed free fallow. In potato plots increased by over 70% in potato plots in season 1 and 2,and dobled in season 3. The results indicate that African nightshade has potetial in capturing thus reducing PCN juveniles and eggs thus can be used as a trap crop in PCN management rotational programs.

EFFICIENCY OF ELICITORS ON INDUCED RESISTANCE AGAINST CASSAVA ROOT ROT DISEASE

SAENGCHAN Chanon. (1), BUENSANTEAI Kumrai. (1)

(1) School of Crop Production Technology, Institute of Agriculture Technology, Suranaree University of Technology, Nakhon Ratchasima , THAILAND

Text

Cassava root rot disease (CRRD) is caused by one or several fungal genera. Fusarium species are an important component of the fungal complex that causes root rot disease in Thailand. Therefore, the aims of this study were to evaluate the efficacy of salicylic acid formulation and the mechanism of induced resistance in cassava plants against the CRRD. Zacha elicitor formulations at a concentration of 500 ppm and JN2-007 could reduce mycelial growth of F. solani. Also, the accumulation of hydrogen peroxide and activity of some enzymes related to plant defense mechanisms (peroxidase, polyphenol oxidase and catalase) revealed that the 500 ppm Zacha treatment showed an increased regulation in cassava plants at 24 hours after inoculation (HAI) compared to that of the noninfected plants. Cassavas sprayed with Zacha11 elicitor and inoculated with Fusarium suspension had a slight increase of β-1,3-glucanase activity at 24 HAI (15.62 µg min-1 mg-1 protein) compared to that of the negative control. For chitinase activity, the increase was similar to that of the β-1,3-glucanase. Likewise, the accumulations of salicylic acid increased at 24 hours after inoculation of 69.95 µg g-1 fresh weight. Moreover, cassava treated with Zacha11 showed the biochemical components of lignin and pectin in the cassava cell wall. Thus, it is possible that elicitors could be used to reduce Fusarium root rot disease severity by inducing signals mediating defense responses in cassava.

P6.1-045

USE OF AGRICULTURAL WASTE AND INDIGENOUS ANTAGONISTIC FUNGI FOR CONTROLLING ROOT KNOT NEMATODES (MELOIDOGYNE SPP.) ON POTATO IN NORTH SUMATRA, INDONESIA

LISNAWITA Lisnawita. (1), TANTAWI Ahmad Rafiqi. (2), SAFNI Irda. (1), LUBIS Khairunnisa . (1)

(1) Universitas Sumatera Utara, Medan, INDONESIA; (2) University of Medan Area, Medan, INDONESIA

Text

Root knot nematode (Meloidogyne spp.) is one of the important pathogen on potato in North Sumatra, especially in Karo District as a center for potato production in North Sumatra, Indonesia. Lack of information and knowledge about this nematode has resulted in no effective control methods to control this nematode in North Sumatra. The research aims to obtain an effective control method based agricultural waste and indigenous antagonistic fungi for improving plant health towards sustainable agriculture. 14 indigenous antagonistic fungi from the potato rhizosphere consisting of the genera Aspergillus (28.6%), Mucor (21.4%), Trichoderma (21.4%), Gliocladium (14.3%), and Penicillium (14.3%) was obtained from exploration results at 4 potato planting locations in Karo District. Further tests were carried out on the 14 indigenous antagonistic fungi isolates using agricultural waste, each of the Solanaceae, Leguminoceae, and Brassicaceae singly and in combination in suppressing the

population of Meloidogyne spp. in the greenhouse. The results showed that the combination of Leguminoceae waste with Trichoderma 1 isolate gave the best results in increasing plant growth, number of leaves, number of branches of potato plants, and decreasing number of galls. The same result got in the demonstration plot test in the field. Molecular identification of Trichoderma 1 isolate was Trichoderma viride.

EUGENOL, ISOEUGENOL, THYMOL, CARVACROL, AND ESTER DERIVATIVES AS AN ECOFRIENDLY OPTION TO CONTROL COLLETOTRICHUM CHRYSOPHILLUM AND COLLETOTRICHUM NYMPHAEAE

SCHORR Renan R.. (1), BALLESTEROS Meira. (1), SALES MAIA Beatriz. (1), RAFAELE Moreira. (1), PETERMANN Débora. (1), FRANCISCO Marques. (1), **MAY DE MIO Louise Larissa. (1)**

(1) UNIVERSIDADE FEDERAL DO PARANÁ, Curitiba, BRAZIL

Text
Glomerella Leaf Spot (GLS) and Bitter Rot are severe diseases of apple and *Colletotrichum nymphaeae and Colletotrichum chrysophillum* are the main species in Brazil. To control GLS in Brazilian apple orchards, mancozeb and thiophanate-methyl fungicides are still largely used. In recent years Colletotrichum resistance to these active ingredients has been reported and, in addition, mancozeb has been banned by some apple-importing countries. So, this study aimed to search for alternatives to control the diseases. We assessed the antifungal activity of eugenol, isoeugenol, thymol, carvacrol, and some of their ester derivatives formulated in DMSO. The best results obtained in two in vitro assays were using thymol, thymol butyrate, and carvacrol. These compounds completely inhibited mycelial growth at 125 mg·L-1 and conidial germination at 100 mg·L-1. In ex vivo assay, carried out with detached leaves of apple trees, all tested compounds significantly reduced GLS symptoms but do not differ from DMSO. In detached apple fruit, eugenol significantly reduced Bitter Rot symptoms caused by *C. nymphaeae* but the effect varied with *C chrysophillum.* Eugenol is a promising alternative to replace fungicides to control *C. nymphaeae* on apple fruit, but new formulations are needed for GLS control.

P6.1-047

HETEROMURUS NITIDUS (COLLEMBOLA) GRAZES THE WHEAT PATHOGENIC FUNGUS ZYMOSEPTORIA TRITICI ON INFECTED TISSUES: OPPORTUNITIES AND LIMITATIONS FOR BIOREGULATION

BOURGEOIS Thomas. (1), PRADO Soizic. (1), SUFFERT Frédéric. (2), SALMON Sandrine. (1)

(1) Muséum national d'Histoire naturelle, Brunoy, FRANCE; (2) INRAE, Palaiseau, FRANCE

Text

Septoria tritici blotch is a worldwide wheat disease caused by the fungal pathogen *Zymoseptoria tritici* that damages leaves through multiple infection asexual cycles and survive through sexual reproduction in crop residues left on the ground during the interepidemic period. Springtails (Collembola) are cosmopolitan soil arthropods and mycophagous species largely contribute to structure fungal communities and could interact with pathogens present on crop residues. In this study, we investigated the interaction between *Heteromurus nitidus*, a common Collembola species, and wheat tissues (leaves and plant residues) infected or not infected by *Z. tritici*. A short time of interaction allowed to test the preferences of springtails among the two types of wheat tissues, while a longer time (for two to ten weeks) allowed to test spore grazing in fungal fruiting bodies by counting springtails and remaining spores. *H. nitidus* was attracted by infected leaves and reduced tenfold the number of pycnidiospores compared to controls (absence of springtail). Results obtained on wheat residues consisting in older dried plant tissues were more contrasted as no spore emission was observed, although springtail populations thrived on them. Our results show the attraction of *H. nitidus* towards *Z. tritici* infecting leaves and suggest that springtails could contribute to reduce the pathogen inoculum. Microcosm experiments should be conducted to further assert this bioregulation potential.

THE OCCURRENCE OF ALTERNARIA SPECIES INVOLVED IN DIEBACK OF PINUS PINEA IN TUNISIA.

HLAIEM Sawssen. (1), YANGUI Islem. (1), EZZINE Olfa . (1), DELLA ROCCA Gianni. (2), BARBERINI Sara. (2), DANTI Roberto. (2), BEN JAMAA Mohamed Lahbib. (1)

(1) Institut National de Recherches en Génie Rural, Eaux et Forêts (INRGREF), Ariana, TUNISIA; (2) National Research Council, Institute for Sustainable Plant Protection of Italy (IPSP-CNR), Firenze, ITALY

Text

Fungal pathogens are among the main causes of forest trees decline including *Pinus pinea* due to dynamic interactions between the plant host and several abiotic and biotic factors. Recently during our surveys, symptoms of branch canker and canopy transparency have been monitored on *P. pinea* trees in Tunisian Nabeul forest. Nevertheless, this phenomenon has been less well-studied in Tunisia. The aim of this study was to identify the causal agent of *P. pinea* trees dieback and to evaluate the factors influencing its occurrence. Ecological factors (rainfall, temperature, and altitude), dendrometric parameters (crown width, total height, and trunk circumference) of pine trees, and the incidence of the pathogen were detected. For diagnosis, 10 symptomatic branches were collected from each declining tree and transferred to the laboratory for fungal isolation. Two *Alternaria* species were identified: *Alternaria alternata* and *A. infectoria* by means of morphological features and phylogenetic analysis of the internal transcribed spacer (ITS) region of the nuclear ribosomal DNA. The incidence of *Alternaria* species on *P. pinea* trees appeared to be significantly correlated to the trunk parameters and ecological factors. Our findings show that the decline in stone pine trees could be mainly linked to the environmental factors. To our knowledge, data from the present work provide the first record of the species of *Alternaria* associated with *P. pinea* branch dieback in Tunisia.

MODELING MULTIPLE PESTS FOR AGROECOLOGICAL PROTECTION OF RICE IN CAMBODIA

DIONISI Mathilde. (1,2), AUBERTOT Jean-Noël. (2), SESTER Mathilde. (1), ADAM Myriam. (1)

(1) CIRAD, Montpellier , FRANCE; (2) INRAE, Toulouse, FRANCE

Text

Damages caused by various pathogens, animal pests, and weeds in rice crops can result in important yield losses (Oerke, 2006). In order to limit these damages, farmers use large amounts of pesticides, especially in Cambodia (Flor et al., 2019). This leads to high health and ecological risks. Two major challenges must be completed to support farmers in the agroecological transition, and to limit the use of pesticides on rice crops: i) to link pest populations and pest injuries with the associated risks of crop losses (yield and/or quality) in a given production situation and for given cropping practices; ii) to understand which agroecological levers can prevent pest development and damages. We calibrated the Decision Support System DSSAT using the CERES-Rice model to simulate the impact of different cropping systems (e.g. number of cycles per year, cultivars, fertilization practices) representing various farming systems (e.g. conservation agriculture) on rice growth and yield in Cambodia. The simulated growth dynamics represent potential crop growths in the considered agro-environmental conditions. The impacts of multiple pests are then integrated using coupling points and damage functions. This presentation introduces the structure, parameterization, model's goodness of fit, and potential use of the model to help adapt crop management strategies in different environments.

Text

Diseases are still a major constraint to crop production despite the great efforts made by multiple stakeholders interested in sustainable food production. Specialists in breeding, pathology, agronomy, plant genetics, among others, are working towards the same goal of improved varieties for effective on-farm disease management. This effort could advance faster if a strategy involving multiple actors in the same production chain is designed. Currently, under the new research scheme in the CG centers, we have defined a work plan that integrates researchers not only from the system but also strategic partners from national programs in the regions where diseases are limiting production. Here we present our strategy that will enable us to 1) know the diversity of races of Anthracnose and Angular Leaf

Spot affecting the cultivation of beans in Southeast Africa, 2) highlight a key component of the strategy which, is the vast genetic diversity held by advanced lines from breeding programs, and 3) showcase the capacity and expertise of regional partners. These components will convene on sentinel trials deployed at multiple sites representative of the producing areas to generate data that will be used to identify genotypes resistant to local races of different diseases, identify resistance genes associated with resistance, and their corresponding molecular markers to facilitate the improvement of market-class varieties.

A PLANT-BASED COMPOUND AS A NON-CHEMICAL NEMATICIDE OF CITRUS NEMATODE TYLENCHULUS SEMIPENETRANS

SAEIDI NAEINI Farhad. (1), FARAHBAKHSH Mohammad-Hossein. (1)

(1) Iranian Research Institute of Plant Protection, Tehran, IRAN (ISLAMIC REPUBLIC OF)

Text
Different types of citrus were planted in the north and south of Iran. The citrus nematode Tylenchulus semipenetrans, the cause of the slow decline of citrus can cause serious damage to the roots of citrus trees alone or together with other soil-borne pathogens. The efficacy of Nemakob® compound with the active ingredient obtained from several types of wood vinegar at the rate of 60 and 80 liters per hectare in two orange orchards in Fars province, Darab city, in two sections of Jannat and Forg were investigated. Nemakob treatments considered in this experiment included simple Nemakob 60 and 80 liters per hectare, and Nemakob plus 80 liters per hectare. The Fosthiasate and Bio-nematon were considered as reference nematicides and the treatment without nematicide was considered as control. In terms of the efficacy of Nemakob treatments compared to Fosthiasate reference nematicide, an increase of 7.9%, 8.7%, and 13.5% efficiency was observed in Jannat section, and 62%, 87.8%, and 62.8% increase in Forg section respectively. In terms of comparing the efficacy of different Nemakob treatments with Bio-nematon biological nematicide, an increase in efficacy of 19.5, 20.4, and 25.7 percent was observed in Jannat section and 23, 42.3, and 23.4 percent in Forg sector. Therefore, taking into account all the dependent variables investigated, Nemakob simple and plus 80 liters per hectare treatments are recommended to control the citrus nematode population, especially in early infections.

P6.1-052

ENCAPSULATED FUNGUS-BASED COMPOUND OF POCHONIA CHLAMYDOSPORIA AGAINST ON ROOT-KNOT NEMATODE OF OLIVE

SAEIDI NAEINI Farhad. (1), NEGAHBAN Maryam. (1)

(1) Iranian Research Institute of Plant Protection, Tehran, IRAN (ISLAMIC REPUBLIC OF)

Text
The olive root-knot nematode Meloidogyne javanica is considered one of the most important soil-born pathogens of olive trees in Iran. The use of non-chemical methods, especially in the control of plant parasitic nematodes, plays an important role in managing the population and

the damage caused by the pathogen in a sustainable and environmentally friendly manner. Among the infected trees of the Aliabad Mother Garden, a number of olive trees infected with M. javanica, the efficiency of encapsulated fungus-based (Pochonia chlamydospora) suspension, SP2, (5 x 1023 CFU) in the amount of 5 l/ha were compared to Trevigo SC 1.8% 10 l/ha, Nemakob 80 l/ha, and Bio-nematon powder 10 kg/ha in controlling root-knot nematode population. Unsprayed trees were used as controls. Based on the reproduction factor and efficiency percentage, SP2 contains spores and mycelium of P. chlamydosporia with an efficiency percentage of 63.78 and a reproduction factor of 0.58. Bionmaton, Nemakob, and Trevigo were ranked with an efficacy of 27.4, 22.7, and zero, and in terms of reproduction factor of 1.7, 5.3, and 4.7 respectively. Therefore fungus-based compound (SP2) was the best treatment for controlling the root-knot nematode population of olive trees.

Text

Liposomal forms of glycans (termed TRG) containing rhamnolipids and methylthiosulfanilate as structural elements of liposomes were investigated as plant resistance regulators in wheat infected with wheat streak mosaic virus (WSMV) at different developmental stages: 1) stalk-shooting; 2) ear emergence from the upper leaf boot; 3) earing; 4) flowering; 5) grain formation; and 6) milky ripeness. To assess the modulating properties of TRG, the activity of enzymes involved in the detoxification of reactive oxygen species (superoxide dismutase (SOD), catalase (CAT), peroxidase (POD) and ascorbate peroxidase (ARX)) was examined. Enzyme-linked immunosorbent assay (ELISA) was used to confirm WSMV infection in wheat samples. ELISA data showed that plants inoculated at the first 4 developmental stages were successfully infected with the virus, while older plants either contained much less virus or have not been infected at all. After pre-sowing treatment of wheat seeds with TRG, the activity of the enzymes was reduced (18-29%) or remained at the control level. SOD activity in plants inoculated with WSMV at stages1-4 was reduced by 43%. All infected plants showed sharp decrease of CAT activity, whereas the activity of POD showed no dependency on TRG. However, TRG reduced ARX activity up to 30% in both infected and intact plants. Obtained data indicate the involvement of the studied enzymes in plant pathogenesis/virus resistance and possible protective effect of TRG in WSMV-infected wheat

P6.1-054

MICROCARBON PLANT-BASED NEMATICIDE PROMAX® AGAINST MELOIDOGYNE JAVANICA ON GREENHOUSE CUCUMBER

SAEIDI NAEINI Farhad. (1), KARIMI POUR FARD Hadi. (1)

(1) Iranian Research Institute of Plant Protection, Tehran, IRAN (ISLAMIC REPUBLIC OF)

Text

Among the pathogenic factors of vegetable plants, Meloidogyne javanica has great importance. The use of non-chemical nematicides has been considered. In the present study, a broad-spectrum soil-powerful fungicide, and nematicide are made with thyme oil active ingredient, Huma Gro® PROMAX® with micro carbon technology was used to control greenhouse cucumber in two locations, Tehran with "VIOLA cv." and Kohgiluyeh and Boyer Ahmad with "PHYTO cv.". The amounts ??of 5, 10, and 15 l/ha were evaluated three times at 20-day intervals. Fenamiphos granules 10% as control and at 15g/m2. Before the experiment, soil samples were taken from each experimental plot for the second-stage juveniles, and at the end of the experiment, nematode variables including the number of galls, the number of egg masses on the root, the second juvenile population in the soil, and the root were determined. The efficacy of Promax nematode at 5 l/ha in both greenhouses was more than 90%. The difference between the efficacy of this Promax compared to Fenamiphos in Tehran province with a high initial nematode population was more than seventy percent. The reproduction factor was less than zero in both locations. Therefore, to control the population of root-knot nematode of greenhouse cucumber, Promax 5 l/ha hectare alone at least three times, one at the time of transplanting and the others at 20-day intervals is advisable.

EFFICACY OF FUNGICIDE ROTATION ON POTATO LATE BLIGHT (PHYTOPHTHORA INFESTANS, (MONT.) MANAGEMENT

ACHARYA Basistha. (1), KHADKA Rambahadur. (2), K.C Sujata. (3)

(1) National Plant Pathology Research Center, NARC, Khumaltar, Kathmandu, NEPAL; (2) National Plant Pathology Research Center, NARC, Khumaltar, Kathmandu, NEPAL; (3) National Wheat Research Programme, Bhairahawa, Rupandehi, Bhairahawa, NEPAL

Text

Potato late blight caused by *Phytophthora infestans* is major threats for potato production in Nepal.Due to high risk of resistance development and high cost associated with the fungicides pressed to find the alternatives by spray rotation with other fungicides.Field experiments were conducted for two consecutive years (2019 and 2020) cropping seasons to evaluate the effect of fungicides rotations for the management of potato late blight in Western Nepal. Three fungicides: mancozeb, dimethomorph and fenamidone + mancozeb were evaluated in different rotations to suppress late blight. The experiment composed of eight treatments was arranged in a randomized complete block design with three replications.The lowest mean AUDPC (221.67) was obtained from first spray with mancozeb followed by two spray of fenamidone + mancozeb right after first spray with mancozeb followed by two spray of dimethomorph (233.33) whereas, the highest mean AUDPC was obtained from untreated control plot (522.08) right after mancozeb only treated plot (373.33).The highest tuber yield (14.46 mt/ha) was

obtained from first spray with mancozeb followed by two sprays of fenamidone + mancozeb.The study confirmed that the rotation in fungicide application plays a crucial role to reduce the cost of fungicide applications, risk of development of fungicide resistance by late blight even under high late blight pressure.

STUDIES ON THE PATHOGENICITY OF METARHIZIUM ANISOPLIAE VAR. ACRIDUM AGAINST DESERT LOCUST, SCHISTOCERCA GREGARIA (ORTHOPTERA: ACRIDIDAE) NYMPHS AND ADULTS

SAID Fazal. (1), ALI Hussain. (1,2)

(1) Abdul Wali Khan University Mardan Khyber Pakhtunkhwa Pakistan, Mardan, PAKISTAN;
(2) Agricultural Research Institute, Tarnab Peshawar, PAKISTAN

Text
The current study was carried out to tested the efficacy of different entomopathogenic fungi (EPF) formulations i.e. Metarhizium anisopliae against the nymphs and adults of the desert locust, Schistocerca gregaria Forskål under field as well as laboratory conditions. Four different concentrations were applied against different instars of the nymphs and adults of desert locust. Susceptibility was found to be greatest in 3rd-instar nymphs, followed by 5th instars, and then adults. Along with lethal effects, sublethal doses of EPF reduced the number of egg pods/female, total eggs/pod, and egg hatching, while extending nymphal developmental time and reducing adult longevity; again, Metarhizium anisopliae performed well. Sublethal doses not only retarded reproduction, but also caused behavioral changes, like reduction in food consumption, fecal production, and weight gain. All EPF formulations not only showed significant mortality in laboratory conditions, but also performed very well under the field conditions. The maximum mortality against 3rd-instar (81.7% and 74.0%), 5th-instar (73.3% and 65.1%), and adult locusts (67.5% and 58.9%) was observed when using Metarhizium anisopliae under greenhouse and field trials, respectively. The current study showed that all of the EPF formulations have the potential to reduce pest populations, and could be used in the integrated pest management program.

P6.1-057

EFFECT OF PLANT EXTRACTS AGAINST SOME SEED-BORN PATHOGENS IN VITRO

AFANASIEVA Oksana. (1), SHEVCHUK Olga. (1), GOLOSNA Lesia. (1)

(1) Institute of Plant Protection NAAS , Kyiv, UKRAINE

Text
Given the need to apply environmental strategies in agriculture, there is growing interest in studying the possibilities of plant extracts. Alternaria spp. and Fusarium spp. are the most common pathogens on cereal seeds. Objective of this study was to investigate the fungistatic effect of plant extracts against Alternaria tenuissima (Kunze) Wiltshir and Fusarium culmorum (Wm.G. Sm.) Sacc. in vitro. Plant extracts were made on the basis of the raw

materials of medicinal plants: Salvia officinalis L., Macleaya cordata (Willd) R. Br., Echinacea purpurea (L.) Moench, Mentha piperita L., Thymus vulgaris L., Matricaria recutita L., Datura stramonium L., Origanum vulgare L., Datura metel L., Achillea millefolium L., Apocynum cannabinum L., Artemisia annua L., Artemisia absinthium L., Chelidonium majus L. Agar-disk diffusion method was used. The radial growth and the percentage of growth inhibition were determined. According to our results, extracts of Salvia officinalis, Artemisia annua and Macleaya cordata showed fungistatic effect against both pathogens. Higher inhibition of colony growth was observed against A. tenuissima – 84,3-99,5%. For F.culmorum the maximum effect was obtained when extract of Artemisia annua was used – 82,3%. Results obtained suggest that extracts of these plants can be used in the future to develop plant protection products.

THE PERFORMANCE OF THE BACTERICIDAL AND PLANT DEFENCE ELICITOR PEPTIDE BP178 IN DIFFERENT PLANT HOST PATHOSYSTEMS

BADOSA Esther. (1), BARÓ Aina. (1), MOLL Luís. (1), MONTESINOS Laura. (1), GASCÓN Beatriz. (1), MONTESINOS Emilio. (1), **BONATERRA Anna. (1)**

(1) Universitat de Girona, Girona, SPAIN

Text

Functional peptides are low-risk and sustainable plant protection products that provide several mechanisms of action against pathogens. Peptide BP178 was engineered for expression in plants, and consists of a BP100 moiety (1-11), an AGPA hinge (12-15), a magainin sequence (16-25) (GIGKFLHSAK), and a terminal end KDEL sequence (26-29) for secretion through the endoplasmic reticulum of the plant cells. The peptide BP100 has a potent bactericidal activity but did not induce plant defense responses, whereas peptide BP178 retained the bactericidal activity of BP100, but in addition induced defenses in tomato, almond, and *Nicotiana benthamiana* and can be produced heterologously in plants. Specifically, it has been assayed against plant pathogenic bacteria such as *Xylella fastidiosa*, *Xanthomonas campestris* pv. *campestris* and *Pseudomonas syringae* pv. *tomato* and the fungus *Botrytis cinerea*, among others. The peptide has been applied in planta following different strategies depending on the pathosystem such as spray, endotherapy, or transient expression. In these different scenarios, BP178 was able to limit infections total or partially due to its dual mechanism of action. Formulation of the peptide are under field testing against diseases caused by fastidious bacteria (e.g. citrus greening) and fire blight of apple and pear. Funding was provided by: 101060593 and 817526 EU projects, RTI2018-099410-B-C21 MCIN/AEI/FEDER, TED2021-130110B-C43 MCIN/AEI/ Unión Europea NextGenerationEU/PRTR.

ANTIBACTERIAL ACTIVITY OF SOME SUBSTANCES AGAINST CITRUS BACTERIAL CANKER CAUSED BY XANTHOMONAS CITRI PV. CITRI IN BURKINA FASO

ZERBO Kevin Ben Fabrice. (1,2), WONNI Issa. (1), SOMDA Irénée. (2)

(1) Institut de l'Environnement et de Recherches Agricoles, Bobo Dioulasso, BURKINA FASO; (2) Unuversité Nazi BONI, Bobo Dioulasso, BURKINA FASO

Text

Bacterial canker of citrus is a disease with high social and economic impact. The present study was conducted to evaluate the antibacterial activity of copper hydroxide and sulfate, Bacillus subtilis, Ocimum gratissimum essential oil, aqueous extracts of Azadirachta indica, Cymbopogon citratus and Eucalyptus camaldulensis leaves, and two formulations based on thymol and eugenol against this bacterial disease. Thus, the method of dilution in solid medium and the macromethod of dilution in liquid medium were used in vitro. Through foliar spraying, in vivo greenhouse trials and in vitro trials were conducted respectively on plans and trees of Citrus reticulata×Citrus sinensis species. From the in vivo and in situ trials, it was found that copper hydroxide at 2.5 g/L; Bacillus subtilis at 5 ml/L and Ocimum gratissimum essential oil at 1 ml/L reduced the severity of citrus bacterial canker by 86.39%, 44.71% and 59.13%, respectively, compared to the untreated control.

SILICON DELAYS THE SPREAD OF VASCULAR STREAK DIEBACK OF COCOA

ASAMOAH Frederick Osei. (1), MOHD NOZANI Norfaezah. (1), MOHAMED SIDIQUE Siti Nordahliawate. (1)

(1) Universiti Malaysia Terengganu, Kuala Terengganu, MALAYSIA

Text

Silicon (Si) has been proven to control fungi infections, primarily in monocots, with fewer studies in dicots. Little is therefore known about its effectiveness in controlling vascular streak dieback (VSD) diseases of cocoa (*Theobroma cacao* L.) caused by *Ceratobasidium theobromae*. VSD is a major systemic disease of cocoa, lethal to seedlings under 10 months old, and kills mature tree branches. Often, fungicides and resistant cocoa varieties are used to curb VDS. This study thus observed the growth of cocoa seedlings under different Si concentrations in its bio-available form [silicic acid ($Si(OH)_4$)] to understand its effect on the physical features that promote the plants' defence and inhibit the progression of *C. theobromae* after inoculation. $Si(OH)_4$ was applied weekly as root applications of 0.25% $Si(OH)_4$ (v/v), 0.15% $Si(OH)_4$ (v/v), and 0.10% $Si(OH)_4$ (v/v) for seven months. The thickest cuticle (1.99 µm) and bark, with better growth parameters, were measured in seedlings given 0.15% $Si(OH)_4$ (v/v), whereas the control seedlings' leaf cuticle thickness averaged 1.10 µm. The $Si(OH)_4$ treatments also inhibited the growth of *C. theobromae* in the stems after inoculation. The improved leaf cuticle thickness, coupled with thicker barks and VSD inhibition, positively correlated with the amount of silicon in the leaves after inductively coupled plasma atomic emission spectroscopy (ICP-OES) analysis. Silicon thus has the potential as a viable alternative for controlling VSD of cocoa.

Text

Viticulture is affected by several abiotic and biotic stresses causing huge yield losses and deterioration of berry quality. Due to climate change drought has become one of the major threats to grapevine production. Among biotic stresses, diseases caused by the oomycete *Plasmopara viticola* and the fungal pathogen *Botrytis cinerea*, causal agents of downy mildew and grey mold, respectively, are major concerns for grapevine. The management of these diseases mostly relies on chemical control with the application of copper-based products and/or synthetic fungicides that determine negative effects on the environment and on the health of vine growers and consumers. Therefore, the searching for sustainable alternatives to the use of chemical control is crucial. On this basis, we tested different cell wall extracts from the yeast *Saccharomyces cerevisiae* for the capacity to induce grapevine tolerance to water deficit and resistance to *P. viticola* and *B. cinerea* infection. One of the yeast extracts that proved effective in inducing tolerance to the pathogens was selected to evaluate its efficacy in promoting internode elongation rate and stomatal conductance under well watering and water deficiency conditions. Our results showed that the yeast extract applied to grapevine did not promote internode elongation but determined a positive impact on stomatal conductance after water deprivation during the recovery phase.

P6.1-062

INTEGRATED PEST MANAGEMENT SMART TECHNOLOGIES TO PRECISELY DETECT AND CONTROL PLANT DISEASES

TSITSIGIANNIS Dimitrios. (1)

(1) Agricultural University of Athens, Athens, GREECE

Text

The ever-increasing demands of international markets for safe food have led to the development of integrated plant protection strategies (IPMs) for a more efficient and sustainable agriculture and to more robust certification and control systems for agricultural products. Novel IPMs of particularly serious plant diseases and mycotoxin contamination of plant products are being developed using innovative smart agricultural systems. The purpose is to: (a) accelerate the prognosis of disease outbreaks through prediction models; (b) develop methods of artificial intelligent diagnosis using imaging techniques or mass spectrometry sensors; (c) evaluate novel biocontrol and chemical PPPs to control effectively the diseases; (d) develop innovative prototype sprayers actuating different nozzle types and adopting variable rate control based on canopy characteristics and disease development.

Decision Support Systems (DSS) are also developed and validated based on computer-based knowledge systems that enable disease prediction and monitoring and determine the critical stages of the various plant protection spray interventions. The ultimate goal of smart technologies is to reduce the European agriculture reliance on agrochemicals resulting in lower residues and reduced impacts on human health.

The presented research has received funding from the European Union's Horizon 2020 research and innovation programmes under grant agreement No 773718 (OPTIMA) and No 778219 (OchraVine Control).

AN INVESTIGATION OF WAYS TO REDUCE PHYTOTOXICITY CAUSED BY COPPER-BASED FUNGICIDES IN CITRUS

THANGAVEL Tamilarasan. (1), SMITH Malcolm. (2), GALLAGHER Brian. (1), BRANSGROVE Kaylene. (1), COOKE Tony. (1), PERESSINI Tamaya. (1), REID Michael. (1), COATES Lindy. (1)

(1) Queensland Government, Australia, Bundaberg, AUSTRALIA; (2) Citrus Monitoring Services Pty Ltd., Gayndah, AUSTRALIA

Text

In Australia, export-quality mandarins, lemons and limes are predominantly grown in Queensland's subtropical regions. Queensland citrus production in 2021/2022 totalled almost 87,440 tonnes (from 4360 ha) with a farmgate value of around $200 million. Since 1920, the management of citrus fungal diseases has always presented challenges for mandarin growers, including 'Emperor' Brown Spot (EBS) and Citrus Black Spot (CBS) caused by Alternaria sp. and Phyllosticta citricarpa, respectively. Queensland's citrus industry routinely exports premium quality mandarins to more than 30 countries, and exporters are required to meet specific markets' Maximum Residue Limits (MRL) to enable international trade. Copper-based products and dithiocarbamates are broadly used fungicides to protect against various citrus diseases, however, the current dithiocarbamate fungicides face an uncertain future globally due to human health concerns. When over-applied, copper-based fungicides can be toxic to citrus trees. Under certain conditions, they may also cause darkening of existing fruit blemishes and stipple marks, which are significant issues for exports. As copper-based fungicides are essential for citrus disease management in the absence of dithiocarbamates, there is a need to investigate ways to reduce phytotoxicity. These complex investigations are currently underway

EVALUATING HISTONE ACETYLTRANSFERASES IN PARASTAGONOSPORA NODORUM TO DEVELOP NOVEL FUNGICIDES

SHARMA Anjana. (1), TAN Kar-Chun. (1), KNIGHT Noel. (1), TURO Chala. (1), LOPEZ-RUIZ Francisco J.. (1)

(1) Curtin University, Bentley, AUSTRALIA

Text
Sustainable crop disease management requires an integrated approach, including the use of chemicals. However, the loss of chemicals to both resistance and regulation, combined with no new fungicide modes of action in the market is posing a serious threat to the global food security. This study applies the genomic approaches for identifying the novel targets to potentially develop them into new fungicide mode of actions. We have characterised two histone acetyltransferase encoding genes in a model crop pathogen Parastagonospora nodorum and has demonstrated that they could be targeted for fungal inhibition. Targeted deletion of PnGcn5 resulted significant reduction in the growth. Attempts to delete PnEsa1 were unsuccessful. In contrast, knock down approach using a long hairpin RNAi showed successful silencing with transformants exhibiting reduced sporulation and pathogenicity. Results suggest an essential function for PnEsa1. Further studies aim to determine the processes disrupted by PnGcn5 and PnEsa1 gene deletion in P. nodorum. This will facilitate the identification of fungal inhibition pathways that could be targeted for the control of plant pathogens

P6.1-065

IMPACT OF FUNGICIDE TANK-MIXING ON CERCOSPORA LEAF SPOT OF SUGARBEET AND GENETIC DIVERSITY OF CERCOSPORA BETICOLA

LIEN Austin. (1), **CHANDA Ashok Kumar. (1)**

(1) University of Minnesota, St. Paul, UNITED STATES

Text
Cercospora leaf spot (CLS) caused by Cercospora beticola is the most destructive foliar disease of sugar beet worldwide. Use of fungicides remain critical for managing CLS because most of the commercial sugar beet varieties are susceptible to CLS. Currently Demethylation inhibitor (DMI) fungicides are used along with a broad-spectrum tank-mix partner to manage CLS. However, it is not clear how tank-mix partners interact with DMI fungicides for managing CLS under field conditions. A two-year field study was conducted to evaluate the efficacy of DMI fungicides with multiple tank-mix partners for managing CLS. Treatments included DMI fungicides (prothioconazole, tetraconazole, difenoconazole + propiconazole, and mefentrifluconazole) and tank-mix partners (mancozeb, copper oxychloride + copper hydroxide, sodium bicarbonate, sulfur, potassium phosphite, and Bacillus subtilis). Significant differences were observed for the tank-mix partners with mancozeb, copper, potassium phosphite, and sulfur resulting in increased recoverable sucrose compared to DMI fungicides alone. Interactions among DMI fungicides and tank-mix partners for CLS severity were also observed. We also collected 763 C. beticola isolates before and after fungicide applications. Based on 8 microsatellite markers, an estimated 93 MLGs identified before fungicide applications and 250 MLGs identified following exposure to fungicide treatments. Interestingly, only 37 MLGs were observed in both collection periods.

P6.1-066

INFLUENCE OF SOWING TIME ON THE OCCURRENCE OF ALTERNARIA LEAF SPOT AND RUST ON SUNFLOWER

RADU Ioan. (1,2), GURAU Lorena-Roxana. (1,2)

(1) Research - Development Institute for Plant Protection Bucharest, Bucharest, ROMANIA;
(2) University of Agronomic Sciences and Veterinary Medicine of Bucharest, Bucharest, ROMANIA

Text

The occurrence of Alternaria leaf spot (*Alternaria helianthi*) and rust (*Puccinia helianthi*) on six sunflower hybrids were assessed to notice the effect of sowing time (ST). ST was set taking into account the Celsius degrees at the soil depth of 7 cm: ST1 at 5ºC, ST2 at 7ºC and ST3 at 9ºC. The research was performed in the field experiments in Tulcea county in 2021 under rainfed conditions. Observations on the attack intensity (% of the leaves area) have done after the flowering period. For *A. helianthi* similar results were at ST1 and ST2 (46,7% and 48,7%) while at ST3 the intensity was lower (33,1%). Only one hybrid was attacked by *P. helianthi* at SD1 and four hybrids were attacked at SD2. The attack intensity increased upon the sowing delay from 0,5% (SD1) to 7,9% (SD2) and to 16,1% (SD3).

ANTAGONISTIC PROPERTIES OF RHAMNOLIPID BIOSURFACTANT OF PSEUDOMONAS AERUGINOSA RS6AGAINST PATHOGENIC FUNGI OF CUCUMBER AND MELON

ADNAN Adieya Atyrrah. (1)

(1) Universiti Putra Malaysia, Serdang, MALAYSIA

Text

The application of chemical pesticides in vegetable and fruit crops has been commonly practiced over the years in combating pests, insects, weeds and diseases. Rhamnolipids (RLs) biosurfactant produced from biodiesel side stream-waste glycerol and extracted from P. aeruginosa RS6 are known to possess antifungal effect against several phytopathogens and has the potential to be used as biopesticides for crop protection in the agriculture industry. The efficacy of RLs as a biopesticide in controlling widespread airborne and soilborne diseases was studied. The field planting study of cucumber and melons was conducted. There was no significant difference observed on the plant's height and leaves when using different treatments, however, a significant difference in fruit weight was observed. It shows that the application of RLs had a significant effect on plant growth and therefore suggested that RLs are an efficient control towards fungi pathogen as the observation of the diseases infections during the field trial showed that the time taken to the diseases infected plant with the RLs treatment took long time compare the plant with other treatments with optimal concentration of RLs at 0.5 g/L. Therefore, the efficiency of RLs as a biopesticide in controlling fungal pathogens widespread especially soilborne and airborne diseases also equally good to control. Hence, RLs are the possible environmentally friendly alternatives to partially substitute commercial chemical pesticides.

P6.1-068

HOW TO IMPROVE THE PERFORMANCE OF MINERAL OIL TO CONTROL POTATO VIRUS Y IN SEED POTATO PRODUCTION?

MOUNIER Camille. (1), MATHIRON David. (2), PILARD Serge. (2), **KHELIFA Mounia. (1)**

(1) inov3PT, 43-45 rue de Naples. 75008 Paris/ Bâtiment Serres-Transfert, UFR-Sciences, Université de Picardie Jules verne, 33 Rue St Leu.80039, Amiens, France, Paris, FRANCE; (2) Plateforme Analytique, Bâtiment Serres-Transfert, UFR-Sciences, Université de Picardie Jules verne, 33 Rue St Leu.80039, Amiens, France, Amiens , FRANCE

Text

Mineral oil is the main alternative treatment identified to limit the spread of Potato Y virus (PVY) in seed potato production, this plant protection product is a part of the biocontrol list according to the French plant health authorities. Because there are currently no exact recommendations for its use, the mineral oil is commonly spread by farmers on potato plants every 2-3 days during the active plant growth and every 7 days when the vegetation is stabilized.
Our main objective is to better understand the duration of the oil protection in order to give recommendations to farmers with regard to the frequency of applications for optimal performance against the virus transmission and being consistent with the environmental recommendation of the French Ecophyto II+ program.
High resolution mass spectrometry using an electrospray ionization source (ESI-HRMS) was selected to detect the mineral oil with a high sensitivity and an experimental protocol was developed to distinguish the fraction of oil which penetrates the leaf from the surface fractions.
The results of kinetic study demonstrated that oil persists on treated leaves surface after 7 days. The relationship between this persistence and the oil ability to protect the leaves against virus transmission by aphids will be discussed.

Text
Reducing the use of copper fungicides with the aim of phasing out has a high priority in

European policy as well as in organic farming. To reach this goal without compromising yields, all preventive strategies have to be implemented and several affordable alternative products need to be brought to the market. Within the EU-funded project RELACS (2018-2022), we investigated alternative compounds that had reached a high technology readiness level. We focused on major copper-relevant crops/pathogens (grapevine/*Plasmopara viticola*, apple/*Venturia inaequalis*, vegetables/downy mildews/late blight, oil-producing roses). As alternatives, two plant extracts including licorice leaf extract (*Glycyrrhiza glabra*) and a larch bark extract (*Larix decidua*), a rare sugar (tagatose) as well as a test product based on fatty acids (NEU 1143F in apple) were evaluated.
Refined strategies with these alternatives were tested, adapted and validated under practical conditions in different European countries, and further aspects of importance (e.g. mode of action, wine fermentation, compatibility with other plant protection products) examined. All alternatives proved to be effective in one or more of the investigated crops. In some cases, their efficacy as stand-alone treatment was comparable to that of copper. In other cases, the combination of the alternatives with reduced amounts of copper or in combination with other standard methods provided effective protection of the crops.

Text
Chitin soil amendment improves soil quality, plant growth and plant stress resilience, but the underlying mechanisms are not well understood. To gain a deeper understanding on the effects of chitin, several omics approaches were applied in a multidisciplinary project.
We studied the growth promoting effects on lettuce upon treatment with chitin in two different soil types (potting and greenhouse). In both soils, lettuce grew bigger with chitin amendment. Lettuce grew generally better in the potting soil compared to the greenhouse soil.
The rhizobiome composition was analyzed using metabarcoding. A decrease in α-diversity was observed upon chitin treatment in both soils. Based on β-diversity, chitin amendment had a stronger effect on the fungal community compared to the bacterial one. Both soils contained different genera significantly altered upon chitin treatment. In potting soil, a known plant-growth promoting fungus was significantly more abundant and associated with other chitin degraders. Such association was not observed in the greenhouse soil.
The transcriptional reprogramming of lettuce roots in response to chitin treatment was studied using RNA-Seq. Over 300 genes were significant differentially expressed with chitin amendment.

Our results suggest that chitin soil amendment promote plant growth indirectly by changing the rhizobiome, induce transcriptional and metabolomic changes in lettuce roots, and might activate induced resistance by priming lettuce plants.

P6.1-071

MULTICRITERIA ANALYSIS, A POWERFUL TOOL TO SELECT CONTROL METHODS AND DESIGN A CONTAINMENT STRATEGY AGAINST THE PLANE TREE CANKER DISEASE

GACHET Emmanuel. (1), . FONTAINE Florence. (2), THARREAU Didier. (3,4), TOMBETTE Hélène. (5), SACHE Ivan. (6), GENTZBITTEL Laurent. (7)

Text

In France, *Ceratocystis platani*, the fungus responsible of the plane tree (*Platanus acerifolia*) canker, is a quarantine pest that must be eradicated. In some regions, namely Provence-Alpes-Côte d'Azur and Occitanie, the disease is out of control in some areas. In 2020, Anses (French Agency for Food, Environmental and Occupational Health & Safety) was requested by the French Ministry in charge of Agriculture to identify different strategies to contain the disease by taking account of the specificity of the outbreak locations (urban or landscape environments, proximity with a river).

To address this question, a multicriteria analysis methodology has been used to design containment strategies relevant to these epidemic situations. The approach has been developed in 3 steps: i) the life cycle of a plane tree contaminated by C. platani has been divided in 4 sequences (standing plane tree, tree stump, contaminated residues after the removal of a plane tree and new planting of a plane tree), ii) 21 control methods against C. platani have been selected and considered as single actions that could be positioned on one of 4 sequences of the tree life cycle, and iii) 13 criteria were selected to evaluate the efficacy, cost, innocuity, scale of implementation (spatial and time) and social acceptability of each method.

Eleven ready-to-use methods (among the 21 control methods and the prophylaxy method) have been ranked by considering the specificity of the 3 outbreak environments.

P6.1-072

EVALUATING BIO-PRODUCTS, FUNGICIDES AND SAR CHEMICALS IN INTEGRATED MANAGEMENT OF ALTERNARIA BRANCH ROT OF CARNATION

CHANDEL Sunita. (1), SIDANA Sumit. (1)

(1) Dr Yashwant Singh Parmar University of Horticulture and Forestry, Nauni, Solan, Solan, INDIA; (2) Dr Yashwant Singh Parmar University of Horticulture and Forestry, Nauni, Solan, Solan, INDIA

Text
Alternaria leaf spot or branch rot of carnation is a serious disease in carnation causing maximum disease severity of 26.25% in Chail of Solan district in H.P. Considering to the heavy losses annually and the adverse effect of the chemicals on environment, the present study was formulated to include alternative strategies in managing this disease . Various bioresources and SAR chemicals were exploited .Out of the bio-products, neemazal, cow urine were found superior and gave 95.37% inhibition at 30% compared to 10, 20% conc .Cloves extract of garlic suppressed the growth upto 60.80% .The latex of agave and fruit rind of the soapnut gave 50.60 and 47.09 per cent inhibition in mycelia growth. Maximum inhibition (91.42%) in mycelia growth was obtained with neem and mint oil (88.52%). Systemic fungicides, score and contaf completely inhibited the growth at all concentrations followed by fungicide, dithane M-45 (mancozeb) a non-systemic in nature under *in vitro* assessments. In field trail, the best treatments along with SAR (systemic acquired resistant) chemicals revealed the minimum extent of the disease severity with four applications of the sprays in score, which was followed by Contaf and combined treatments of BABA (β amino butyric acid)+ neemazal+garlic extract + neem oil and Chitosan+ neemazal+garlic extract + neem oil .The combined treatments also enhanced all the plant growth parameters in addition to lowering of the disease level to minimum threshold.

COURGETTE GENETIC BACKGROUND MODULATES DEFENSE MECHANISMS INDUCED BY REGALIA® AGAINST THE FUNGAL PATHOGEN PODOSPHAERA XANTHII

MARGARITOPOULOU Theoni. (1), BAIRA Eirini. (1), ANAGNOSTOPOULOS Christos. (1), VICHOU Katerina-Eleni. (1), KIZIS Dimosthenis. (1), MARKELLOU Emilia. (1)

(1) Benaki Phytopathological Institute, Kifissia, GREECE

Text
The biotrophic fungus *Podosphaera xanthii* (*Px*) has evolved adaptive mechanisms to various environments causing powdery mildew diseases leading to yield losses. The appearance of resistant to pesticides *Px* isolates and EU goals for fungicide reduction has made crucial the development of alternative control means. Here, we discuss the interaction of courgette hosts, sensitive (S) or with moderate resistance (IR) to *Px*, after the application of Regalia® (RS), a plant inducer of resistance. In depth transcriptomic and metabolomic analyses, gene and protein expression, and chromatin immunoprecipitation assays were combined with physiological and morphological studies to investigate plant's responses after Regalia® application and/or spore artificial inoculation. Our results demonstrated that RS enhances glycerophospholipid accumulation at the plasma membrane and phospholipid signaling especially in S courgette genotype, while the IR genotype showed practically no response due to inherent level of resistance. The water treated IR plants were characterized by accumulation of salicylic acid, defense metabolites and enriched epigenetic H3K4me3 marks on Pm-0 locus genes (a genomic region that confers resistance to Cucurbits against *Px*). Additionally significant enrichment of Gene Ontology terms related to response to fungi, fatty acids and lipids, was observed on S plants after Regalia® application.

Text

Citrus is a high demanding fruit across the globe due to its nutritional and economic values. In Pakistan, it is regarded as an important source of foreign earning and has promising position in country's GDP. But per hectare yield of citrus is reducing from previous two decades due to a number of biotic and abiotic factors. Citrus gummosis (Phytophthora

nicotiana) is one among the biotic factors affect the quality as well as quantity of produce. That's why in current research seven chemical namely Aliette, Score, Topsin-M, Kocide 3000, Diathane M-45, Ridomil gold, Novice ultra were assessed at three concentrations (200, 250 and 300 ppm) under lab conditions through poisoned food technique while two best performed chemicals (Topsin-M and Ridomil gold) their combinations were evaluated in field trial through soil drenching method under RCBD design. Findings of this study showed that Topsin-M gave the best results with min. mycelial growth (5.3mm) followed by Ridomil (7.46mm) during lab experiment while in field conditions combination of (Topsin-M+ Ridomil gold) showed the most promising results with minimum incidence of disease (19 and 23%) followed by Topsin M and Ridomil as compared to control treatment (77%).

STEAMING CAN DISINFECT SOIL AND ONION WASTE CONTAMINATED WITH STROMATINIA CEPIVORA CAUSAL AGENT FOR WHITE ROT OF ONION AND GARLIC

ASALF Belachew. (1), JUSTAD Tor-Arne. (1)

(1) NIBIO, Ås, NORWAY

Text

Sclerotinia cepivorum (Teleomorph: Stromatinia cepivora) is an economically important pathogen of Allium species worldwide. The sclerotia can survive in the soil for many years, and it is difficult to manage. White rot is a quarantine disease in Norway. As a result, onion waste is not used as a resource for composting because of the risk of spreading the pathogen with compost. Furthermore, the disposal of onion waste is costly in Norway. The objective was to determine the lethal dose (temperature and duration) that kills the pathogen. A stationary soil steaming machine that has several thermocouples were used for the experiments. The temperatures tested were 60, 70, 80, 90, and 98 °C with a duration of 3 minutes, and 60 °C with 3 minutes of steaming followed by storage in Styrofoam boxes for 24 hours. Untreated sclerotia were used as control. The viability of S. cepivorum were tested by surface disinfecting the sclerotia and plating on potato dextrose agar. The germination and sclerotia production were determined after incubating at room temperature. The experiment had four replications and was repeated twice. There was no germination of sclerotia in the steam-treated groups with the exception that one sclerotium germinated in the treatment at 60 °C for 3 minutes, whereas the majority of sclerotia in the control group germinated. Steaming is promising for disinfesting soil and onion waste contaminated with S. cepivorum, so onion waste can be composted and used as a resource.

P6.1-078

DIFFERENTIAL INDUCTION OF DEFENSE MECHANISMS BY COMMERCIAL BIOPESTICIDES IN CARROT VARIETIES AGAINST THE PHYTOPATHOGENIC FUNGUS ALTERNARIA DAUCI

KAVROUMATZI Charikleia. (1), **TSITSIGIANNIS Dimitrios. (1)**

(1) Laboratory of Plant Pathology, Department of Crop Science, Agricultural University of Athens, Athens, GREECE

Text
Plant Resistance Inducers (PRIs) could allow a plant to combat a pathogen infection, by activating the transcription of certain defense genes. As such products are not currently available to control *Alternaria dauci* on carrot, the approach of this study consisted in evaluating the ability of 3 commercial products, *Sonata*® (*Bacillus pumilus* QST 2808), *Helioterpen Soufre*® (Sulphur co-formulated with pine terpenes) and LBG-01F34® (Potassium phosphonates) to induce plant defense response in two carrot varieties, with different resistance response to Alternaria leaf blight disease (Presto: susceptible; Boléro: intermediate resistant). For the analysis of carrot defense induction, a field experiment was carried out that included 5 treatments of the three bio-PPPs and infection of the carrot plants with *A. dauci*. Analysis of plant defense induction was followed by studying overexpression of marker defense genes using the qPFD® platform (Quantitative Low-Density Chip). The qPFD® technology is a molecular diagnostic tool that allows the simultaneous study of 28 different defence genes. The results showed that that not all the varieties are receptive to the three PRIs and that the level of protection can, in precise situations, be related to an over-expression of certain defence genes and at different time points depending on the variety. For some bio-PPPs protection is not due to induction of plant defense but probably due to direct effect on pathogens.

P6.1-079

DEVELOPMENT OF AN INFECTIOUS CLONE OF BLACKBERRY CHLOROTIC RINGSPOT VIRUS

SIERRA MEJIA Andrea. (1), VILLAMOR Dan E. V.. (1), TZANETAKIS Ioannis. (1)

(1) University of Arkansas System Division of Agriculture, Fayetteville, UNITED STATES

Text
Blackberry chlorotic ringspot virus (BCRV), genus Ilarvirus, is one of the most prevalent viruses in the blackberry yellow vein disease (BYVD) complex, which currently hinders blackberry production in the southeastern United States. In efforts to study the virus biology, the three genomic RNA were cloned into a PJL89 Agrobacterium binary vector. Additionally, an extra construct coding for the viral coat protein, hypothesized to be required for replication, was developed. Leaf agroinfiltrations of indicator plants with either the genomic RNAs or the genomic RNAs and the coat protein binary vectors in combination with the tomato bushy stunt virus p19 silencing suppressor construct were conducted. RTqPCR assays using systemic tissues of agroinfiltrated plants revealed positive virus infection on Nicotiana benthamiana and N. occidentalis. Mechanical transmission experiments, carried out using sap from BCRV-positive agroinfiltrated plants, resulted in systemic infection of N. benthamiana, N.occidentalis, and Chenopodium quinoa. The generation of a full-length infectious clone of BCRV facilitates future studies on the biology of this virus, particularly those aimed to dissect its contribution in mixed infections with other viruses in the BYVD complex.

Text

Pseudocercospora leaf and fruit spot is a citrus disease caused by Pseudocercospora angolensis resulting in 50 to 100% yield losses. It also causes fruit quality decline and significantly reduces the juice content. Carbendazim has proven an effective disease management option. However, the safety of chemical control needs investigation to prevent health hazards resulting from chemical poising. Study was undertaken to determine the chemical regimes offering effective disease control with minimal chemical residue accumulation. Four farmers were selected from each district for the studies with seven experimental plots set per farm, representing different chemical treatments. The pseudocercospora fruit and leaf spot scores at different timepoints determined the effectiveness of treatments, while lab analyses determined the effect of chemical regimes on fruit quality and chemical residues. The different chemical regimes reduced disease variably. The brix content of the fruits under different treatments were measured against the national standard of 8 with fruits mostly having Brix of 7 to 8 degrees although chemical regimes didn't significantly influence the Brix content. The detectable carbendazim in the fruits under different treatments was <0.01 ppm below the acceptable limit of 1 ppm. This implies the different regimes of carbendazim deployed are effective in pseudocercospora disease management and safe if deployed within two to three months.

Text

In a context of sustainable agriculture aiming to reduce the use of synthetic pesticides, the discovery of new plant defense stimulators or biofungicides, which can be used in the biocontrol of cryptogamic diseases, represents a major research challenge. Plants synthesize many phenolic compounds involved in different metabolisms and in particular in defense responses. Certain phenolic compounds, such as phenylpropanoids derived from p-coumaric acid, have shown direct antifungal activities to fight against pathogens. The p-

coumaric acid was functionalized with fatty acid chains of different lengths to determine whether these new molecules possessed direct antimicrobial activities and were able to stimulate defenses in rapeseed. The production of around twenty functionalized derivatives of p-coumaric acid was developed through chemo-enzymatic synthesis in order to improve their physico-chemical properties. The evaluation of these molecules for their direct antimicrobial activity against *Sclerotinia sclerotiorum* and their ability to stimulate defenses in rapeseed was carried out. The molecules having presented the most important biological activities are those displaying a fatty acid chain of 10 and 12 carbons with a strong hydroxylation, thus increasing their amphiphilic property. The optimization of the functionalization of the molecules has made it possible to improve their biological activities for potential use in biocontrol.

Text

Fire blight caused by *Erwinia amylovora* (Ea) is a plant disease threatening apple production worldwide. As honeybees mediate the spread of Ea in apple orchards, a qPCR-based detection protocol was developed for the early detection of Ea from corbicular pollen. To do that, uninfected pollen was inoculated with cell suspension of strain Ea21 (rifampicin-resistant) at different concentrations (from 1×10^8 to 1×10^0 CFU/mL). Pollen not inoculated with Ea21 cells was used as untreated control. One gram of spiked samples was serially diluted and plated on Nutrient Agar amended with rifampicin. Concurrently, 30 g of spiked samples were homogenized in 120 mL of 0.85% (w/v) NaCl and 0.001% (v/v) TWEEN®80 and incubated on ice under orbital shaking (140 rpm). After 1 h, samples were centrifuged (3,000 rpm, 30 s) and the supernatants were collected and centrifuged (5,000 rpm, 10 min). The pellets were resuspended in Tris-HCl pH 8 buffer (2.25 mL) and exposed to thermal shock (95°C for 15 min and ice for 10 min). Products from the extraction were used directly in qPCR according to EPPO standard PM 7/20 using primer pairs hpEaF/hpEaR and the FAM Taq-man® minor-groove-binder (MGB) nonfluorescent quencher probe hpEaP.
In future, the detection protocol developed in this study might be used to monitor the presence of Ea in pollen collected from hives located close to apple orchards.

CHARACTERIZATION OF THE PHYSICAL MODE OF ACTION OF AN ESSENTIAL OIL-BASED PRODUCT AGAINST GRAPEVINE DOWNY MILDEW CAUSED BY PLASMOPARA VITICOLA

FITTIPALDI BROUZZARD Monica. (1), FURIOSI Margherita. (1), **CAFFI Tito. (1)**

(1) Università Cattolica del Sacro Cuore, Piacenza, ITALY

Text

Despite the advantage of Plant Protection Products application in agriculture, the massive use of chemicals has caused severe damage to human and environmental health. Within 2030 the EU Commission targets to reduce the use of pesticides by 50%, including those in the list of candidates for substitution such as copper-based products. To cope with this goal there is a crucial need to find non-chemical alternatives for disease management. In this study, the Physical Mode of Action (PMoA) of the botanical product EO41106 based on essential oils was characterized, in particular, for its preventative and eradicant efficacy against grapevine downy mildew caused by the Oomycete *Plasmopara viticola*. Trials were carried out under semi-controlled conditions at BBCH stages 51, 71 and 81. For preventative efficacy, different potted grapevines were sprayed with a copper reference, the EO41106 product and bi-distilled water as control. Inoculations with a sporangia suspension of *P. viticola* have regularly performed leaf discs in the lab, until 18 days after treatment. Incidence was evaluated at symptom appearance. For the eradicant efficacy, leaf disks with symptoms were sprayed with the same products on plates from 24 to 72 h after sporulation. Damaged sporangia were counted. Essential oil-based product EO41106 showed preventive protection comparable to copper in pre-flowering and the highest percentage of damaged spores with eradicant application.

Text

Plants are subject to many bacterial diseases that affect its productivity. For most of them, no cure is available, and producers use products such as copper-based mixtures and antibiotics to control them. New, sustainable and effective management options for plant bacterioses are urgently needed. Bacterial wilt of potatoes (BWP) and bacterial canker of grapevines (BCG) are examples of such diseases. Producers can only use kasumin and copper, respectively, to control such diseases. We developed different formulations using the modified amino acid N-acetylcysteine (NAC), an antioxidant that can improve plant-responses to microorganisms, helping to control some diseases. Previously, we have obtained good control results for citrus diseases such as CVC, citrus canker and greening. For BWP we obtained similar control results as those obtained for kasumin, in both disease

control and productivity. It is important to highlight that NAC is not an antibiotic, and therefore, is a more sustainable alternative to be used in field. For BCG, our tests conducted in a commercial field showed an increase of 35% in productivity, with no differences observed for fruit quality. Also, the number of infected leaves was reduced in 40%, indicatingdisease control was the main driver for productive increase. We here present other diseases that can be controlled with the NAC, a naturally found modified amino acid that is a promising alternative for large scale control of bacterial diseases in field.

P6.1-085

IDENTIFICATION AND CHARACTERIZATION OF FUNGI ASSOCIATED WITH LEMON WOOD ROT IN ARIZONA

HU Jiahuai. (1)

(1) University of Arizona, Tucson, UNITED STATES

Text

Canker and wood rots are economically important preharvest diseases of lemons in south-western Arizona, where commercial lemon production is concentrated. However, the aetiology and epidemiology of canker and wood rots are not well understood. This study comprised a large survey of canker and wood rot incidence and severity in Arizona and the characterization of fungal species associated with the disease. A total of 5431 trees with ages ranging from 1 to 20 years old in 10 lemon orchards were surveyed from 2018 to 2020. Our survey results revealed that canker and wood rot occurred in all 10 lemon orchards studied. Canker and brown rots of twigs, branches, and trunks were the most prevalent symptoms of affected trees ranging from 1 to 20 years old. In contrast, canker and white rots of twigs and branches were observed mostly on 1- to 5-year-old trees. Disease incidence for both diseases was less than 2% on 1- and 2-year-old trees. Brown rot increased significantly in older trees, ranging from 62.9% to 100%. Fungi were isolated from canker and wood rot samples and identified based on morphological characters and DNA sequences. *Fomitopsis meliae* and *Hypoxylon macrocarpum* were the primary canker and wood rot pathogens, at frequencies of 89% and 11%, respectively. In pathogenicity tests, both fungi were capable of causing canker and wood rots on lemon cv. Lisbon branches and the necrotic length caused by *F. meliae* was twofold greater than that caused by *H. macrocarpum*.

NEW EVIDENCE ON ADVANCED TECHNIQUES FOR THE EARLY DETECTION OF PLANT DISEASES ON SOLANUM LYCOPERSICUM AND CAPSICUM ANNUUM

FOLLADOR Alessia Regina Vera. (1), PASSERA Alessandro. (1), ROBERTO Oberti. (1), COCETTA Giacomo. (1), MANENTI Daniele. (1), CASATI Paola. (1)

(1) UNIVERSITA DEGLI STUDI DI MILANO, Milano, ITALY

Text

Every year agricultural production is affected by losses that can reach 20-40% of the global

harvest due to plant diseases. Reliable and early detection is crucial to minimise economic and field losses. To identify pre-visual or emerging symptoms enable acting earlier with protection treatments or by targeted removing infected plants to prevent the spread of disease. The most widely used detection methods are lab-based assays. Detection of DNA or RNA is reliable and accurate, but also expensive, time-consuming, and destructive. Optical sensing techniques have the potential to alleviate these problems. The aim of this project is to validate a method for the early detection of specific pathogens including TMV WT, TMV gfp-marked, Pseudomonas syringae, on Solanum lycopersicum and Capsicum annuum. Classical lab-methods including DNA/RNA extraction and the evaluation of pathogen concentration and distribution with qPCR were supplemented by the use of hyperspectral imaging, and non-destructive optical estimation of leaf pigments and measurements of chlorophyll fluorescence-related parameters. In addition, the expression of specific infection-related genes over time was evaluated and some tests with resistance inducers were also carried out to evaluate the plant's response against pathogens. These preliminary results show how the use of advanced sensor solutions has potential to increase the sustainability of crop-management systems and ensure plant health protection and food safety.

P6.1-087

BIOCONTROL OF RHIZOCTONIA SOLANI ON STRAWBERRY IN GREENHOUSE BY EXPERIMENTAL ANTAGONISTS

PUGLIESE Massimo. (1)

(1) University of Torino, Grugliasco, ITALY

Text

There are several soil-borne pathogens that affect strawberry crops, such as *Verticillium, Pythium, Phytophthora, Neopestalotiopsis* and *Rhizoctonia*, with production losses that can be huge. As part of the European project Excalibur, experimental trials have been carried out on strawberry plants cv Olimpia, Portola, Clery and Elodiè in greenhouse with the aim to evaluate the efficacy of microbial antagonists, obtained from suppressive soils, substrates and compost, to control *Rhizoctonia solani.* Results showed a good efficacy of some microorganisms such as antagonistic Fusaria and Trichoderma that significantly reduced *R. solani*, while all remaining tested microorganisms provided similar protection to the commercial mixture of *Trichoderma asperellum* and *Trichoderma gamsii* (64-75% efficacy). However, the differences in efficacy varied according to the strawberry cultivar used in the study.

P6.1-088

CRANBERRY FRUIT ROT: CHARACTERIZATION AND NOVEL MANAGEMENT

UPPALA Leela. (1), SULLEY Salisu. (1)

(1) Unviersity of Massachusetts-Amherst-Cranberry Station, East Wareham, UNITED STATES

Text
Cranberry fruit rot (CFR) complex which is associated with over a dozen taxonomically diverse fungi, has been described as the most yield-limiting and economically significant disease in cranberry production since the late 1800s. To this date, CFR stands as a significant threat to North American cranberry cultivation. CFR could result in 100% losses if not managed with rigorous cultural and fungicide regimes. Even with fungicides, fruit rot in Northeastern (NE) US ((New Jersey (NJ) and Massachusetts (MA)) ranges from 1-15%. Fruit rot infected lots beyond 12% are heavily discounted and lots with >20% are not accepted by many cranberry handlers (processing industry). Growers are also dealing with a new challenge of losing the most commonly used multi-spectrum mode of action fungicides (chlorothalonils and mancozebs) owing to perceived negative impacts on pollinators, human and environmental health. These changes and associated restrictions are prompting the industry to shift towards the only two available single-site mode of action (FRAC Group 3 & 11) fungicides which are now at the risk of fungicide resistance. We would like to take this opportunity to present on the current status of CFR research in MA. We will present data from CFR fungal characterization studies focusing on year-to-year fungal population variations from wild, conventional and organic systems, and multi-year efforts towards novel and integrated CFR management in organic and conventional production systems.

P6.1-089

INTEGRATED AND BIOLOGICAL PROTECTION STRATEGIES AGAINST POWDERY AND DOWNY MILDEWS ON GRAPE: RECENT RESULTS FROM TRIALS CARRIED OUT IN ITALY.

PUGLIESE Massimo. (1)

(1) University of Torino, Grugliasco, ITALY

Text
Powdery (causal agent *Erysiphe necatrix*) and downy (causal agent *Plasmopara viticola*) mildews are the most important grape diseases, causing relevant losses both in terms of quality and quantity. Climate changes may further favour the development of these diseases in the future, in a context where policies are limiting the use of chemical fungicides, copper included. Low environmental impact products, such as oligosaccharides derived from chitin, essential oil from sweet orange, *Ampelomyces quisqualis* and *Bacillus pumilus* showed to be effective in trials carried out on “Arneis” and “Nebbiolo” both on potted plants and in field conditions, demonstrating to be applicable in vineyard to reduce, at least partially, the use of traditional fungicides and to respect recent restrictions in the use of copper in Europe. In the trials on potted plants, acibenzolar-s-methyl was the most effective, among the other tested products, against both pathogens, followed, on downy mildew, by potassium phosphonates.

CELLULOSE NANOCRYSTALS AS AN INNOVATIVE TOOL TO CONTROL X. PERFORANS

SCHIAVI Daniele. (1), JAIN Mukesh. (2), MINSAVAGE Gerald V.. (2), JONES Jeff B.. (2), BALESTRA Giorgio M.. (1)

(1) University of Tuscia, Viterbo, ITALY; (2) University of Florida, Gainesville, UNITED STATES

Text

Xanthomonas perforans (Xp) is one of the main responsible for bacterial leaf spot on tomato, leading to dramatic crop losses. New tools are required to limit its spread in field and its introduction in new areas, since traditional strategies, such as the use of cupric salts, are losing effectiveness. Among the original approaches proposed in crop protection, nanomaterials could represent a sustainable way to control bacterial disease. In this work we evaluated the antimicrobial mechanisms of cellulose nanocrystals (CNC) on Xp. The obtained results suggested that CNC do not damage the bacterial cells, but they are able to decrease in vitro swarming and swimming motility, with a significant reduction of 30% in motility when supplemented in agar media. CNC presence in liquid media prevent cell adhesion to surfaces; as a result lower level of EPS have been recorded. Moreover, comparison with carboxymethylcellulose pointed out that CNC cannot be attacked by bacterial cellulases. All this combined effects played a major role in tomato plants, where foliar treatment with CNC reduced Xp epiphytic survival and leaf ingress after 7 days from spray inoculation. These interactions were confirmed by looking at the molecular expression of the bacterial cells on plants by RT-qPCR, which showed a down-regulation of pilA, rpfG and engXCA genes. These results highlight the potential of cellulose nanomaterials to develop innovative agrochemicals for controlling bacterial plant pathogens.

P6.1-091

STUDY ON EFFICACY OF ETHANEDINITRILE AGAINST PLASMODIOPHORA BRASSICAE, THE CAUSAL AGENT OF CLUBROOT DISEASE OF CRUCIFERS

PATAR Usha Rani. (1), MANASOVA Marie. (1), HNATEK Jonas. (2), WENZLOVA Jana. (1), ZOUHAR Miloslav. (1)

(1) Czech University of Life Sciences, Prague, CZECH REPUBLIC; (2) Lučební závody Draslovka a.s., Tchéquie, CZECH REPUBLIC

Text

Clubroot disease, caused by *Plasmodiophora brassicae* Woronin, an obligate biotrophic protist, has been a global challenge for oilseed rape farmers to control effectively. The current study investigated the potential of ethanedinitrile (EDN), a cyanogen-based fumigant as an effective tool to control clubroot disease at different concentration rates and durations of exposure. Clubroot-susceptible oilseed rape plants were grown in EDN-fumigated soil and evaluated for clubroot disease severity and plant growth parameters in a greenhouse setting. The results demonstrated a reduction in clubroot disease severity by 81.39% as compared to the control, and complete control was achieved at concentration rates of 42 g/m^3 and 50 g/m^3 and in the 35 g/m^3-48 h variant. EDN was also found to improve plant health, with a 58.24% increase in shoot weight. However, higher concentration rates and longer exposure durations had potential adverse residual effects on the plants, including a decline in seedling emergence rate and plant shoot weight. This suggests that there is a need to find a balance between efficacy and sustainability in terms of plant health. Overall, the results of the study show the

potential of EDN as an effective tool to control clubroot, offering hope for minimizing yield loss due to clubroot disease in oilseed rape and other crucifer crops.

P6.1-092

APPLICATION PROSPECTS FOR THREE BACTERIAL ENDOPHYTES AGAINST SOIL BORNE DISEASES AND CROP YIELD IMPROVEMENTS IN ORGANIC PRODUCTION OF VEGETABLES.

MMBAGA Margaret. (1), DEMISSIE Daniel. (1), EYEGHELEME" Peter . (1), HALL Richard. (1), ROBINSON Jamille. (1), OLAWUNI Mustapha . (1)

(1) Tennessee State University, Nashville, UNITED STATES

Text

Naturally abundant microorganisms which colonize plants internally without causing harm to their host plants often provide plant protection against pathogens and improvements in plant growth and soil health. However, results from greenhouse studies do not often translate to consistent field efficacy. In our studies, three isolates of bacterial endophytes (PRT, PSL and IMC8) were efficacious against multiple pathogens in vitro, in greenhouse and in repeated fields trials against Phytophthora capsici and Sclerotium rolfsii. Seed treatment allowed early plant colonization prior to plant exposure to pathogen-infested soil. Plastic mulch was used to control weeds and drip irrigation provided water; no fertilizer was used. Data on tomato and sweet pepper plant vigor, number of fruits, fruit size, disease scores, percent of diseased fruits, and total yield per plant were collected. Analysis of variance displayed significant differences between the bacteria-treated plants and the non-treated control. The three strains performed better than two commercial bio-fungicides, Double Nickel® and Serenade® on disease control and fruit yield following label recommendations. Strain PRT gave the best results for most of the traits followed by PSL. IMC8 was best for plant vigor and larger fruit size, but with a smaller number of fruits per plant. The selected bacterial isolates will be good additions in organic farming disease control and yield improvements.

P6.1-093

MITIGATION OF GREY MOULD DISEASE IN STRAWBERRY PLANTS THROUGH EXOGENOUS APPLICATION OF PHYTOHORMONES

MURENA Chiara. (1,2), MARIZ-PONTE Nuno. (1,2), LUNA Estrella. (3), RIBEIRO FERNANDES Tânia. (1), MARIA PINTO CARVALHO Susana. (1,2)

(1) Faculty of Sciences-University of Porto, Porto, PORTUGAL; (2) GreenUPorto-Sustainable Agrifood Production Research Centre, Vairão, PORTUGAL; (3) School of Biosciences-University of Birmingham, Birmingham, UNITED KINGDOM

Text

Grey mould (GM) disease, caused by the necrotrophic fungus *Botrytis cinerea*, is a devastating disease for strawberry plants (*Fragaria* x *ananassa*) and its control requires intensive application of synthetical fungicides. Bio-based products, eliciting plants' defense mechanisms, are promising alternatives for disease mitigation. To combat fungal infections,

plants rely on their innate immune responses, where phytohormones play a critical role. Although some previous studies have evaluated the effect of exogenous application of a given phytohormone on strawberry resilience to GM, a more comprehensive analysis is still missing. This study aimed to evaluate and understand the impact of salicylic acid (SA) and jasmonic acid (JA) and their methylated forms (MeSA and MeJA) on the progression of GM. Six treatments (Control-water, Control-EtOH, SA, MeSA, JA and MeJA) were applied four times (every two weeks) to strawberry plants cv. '*San Andreas*' grown in a greenhouse. Our results demonstrated that JA significantly inhibited *B. cinerea* infection in leaves, as well as MeJA and MeSA. Moreover, it was found that SA and JA inhibited *B. cinerea* mycelial growth when tested *in vitro*. These results suggest that both phytohormones may play a key role on the activation of plant defense mechanisms and/or the inhibition of *B. cinerea* pathogenicity. Understanding these mechanisms may be critical for integrating these compounds for GM management.

P6.1-094

BURKHOLDERIA SP. SSG – A POWERFUL NEW MANAGEMENT TOOL FOR CROP HEALTH AND PRODUCTION

KONG Ping. (1), **HONG Chuan. (1)**

(1) Virginia Tech, Virginia Beach, UNITED STATES

Text

Burkholderia sp. SSG was an endophyte isolated from boxwood blight-reverted leaves of *Buxus sempervirens* 'Suffruticosa'. This endophyte provided excellent control of boxwood blight caused by *Calonectria pseudonaviculata* (*Cps*). Specifically, SSG at 10^7 cfu/mL lysed all conidia in mixed broth culture. SSG at 10^8 cfu/mL reduced blight of container-grown Justin Brouwers boxwood by >98% when applied 1 day before or 3 hours after plants were inoculated with *Cps* under controlled environments. Its blight control decreased with decreasing bacterial concentration and increasing lead time. When applied on diseased leaf litter under boxwood plants, SSG reduced *Cps* sporulation and consequently mitigated blight incidence by 90%. When applied monthly onto boxwood plants in production fields, SSG provided a similar level of blight control as the fungicide standard – Concert II. SSG also was effective against a variety of other diseases caused by five fungi (*Alternaria tenuissima, Botrytis cinerea, Colletotrichum fructicola, C. gloeosporioides, Pseudonectria rouselliana*), three Oomycetes (*Phytophthora capsici, P. nicotianae, P. ramorum*), plus *Xanthomonas campestris* and tomato spotted wilt virus on eight crops. Additionally, SSG promoted boxwood growth. These properties together make this endophyte a powerful management tool for crop health and production. SSG was identified as a new member of the *Burkholderia cepacia* complex with distinct characters from known clinical strains.

Raising awareness of plants and ways of teaching plant pathology

C8.7-1

TEACHING PLANT PATHOLOGY

GULLINO Maria Lodovica. (1)

(1) UNIVERSITY OF TORINO, Grugliasco, ITALY

Text

In the past forty years teaching plant pathology changed significantly, both from a student and professor perspectives. Which have been the driving forces? The agricultural sector did change during the past few decades: environmental protection and food safety became more relevant and different needs of the stakeholders emerged. Unfortunately, not always departments and colleges have been able to keep the pace, adapting the content of the courses to societal needs. In the period 1975-1990 plant pathology was taught in Agricultural Sciences as a main course plus several others: physiological plant pathology, plant disease management, generally followed by most students. Others were offered as optional courses. In the early 2000, plant pathology remained as the only mandatory course for students in the agricultural science *curriculum*, and specific courses disappeared. During 2001-2020 the number of *curricula* offered increased, with a growing importance of the agro-food sector. The Internet in the early 2000 permitted much faster access to information and images for both students and instructors, resulting useful also for life-long programmes. Instructional technology, providing tools tools for classroom presentations and communication with students, became crucial during the Covid-19 pandemics. Nowadays, hybrid forms of teaching help reaching a broader audience. The many changes encountered in teaching is described as a kind of journey and critically discussed.

C8.7-2

TEACHING PLANT PATHOLOGY IN THE LARGER CONTEXT OF SCIENCE AND THE HUMANITIES

ARENZ Brett. (1)

(1) University of Minnesota, Twin Cities, UNITED STATES

Text

In 2013 a class was first developed at the University of Minnesota called “Plague, Famine, and Beer”. This class has gone on to achieve great success in attracting a large and consistent pool of students (100-200 each year) by linking plant pathology to the historical perspective liberal education requirement. The course discusses the history development of the science of microbiology including the study of plant pathogens in the larger context of the history of science and medicine and the development of germ theory. Additionally, both negative and positive effects of microbes on the course of human civilization are covered. In the middle “famine” portion of the class, historically important plant disease epidemics such as the Irish Potato Famine, Ergot of Rye, Chestnut Blight are also discussed considering their respective impacts on human history. Students also gain experience doing the work of historians by directly analyzing primary sources from these events. By including plant pathogens with human pathogens and innovations such as microbial food and drink fermentation, antibiotics, biotechnology, etc., students gain an additional context of the overall importance of the discipline of plant pathology to their lives.

C8.7-3

GRADUATE EDUCATION IN PLANT PATHOLOGY: PREPARING SCHOLARS TO ADVANCE THE DISCIPLINE

STACK James. (1), FLETCHER Jacqueline. (2), GAMLIEL Abraham. (3), MCKIRDY Simon. (4), SMITH Grant. (5)

(1) Kansas State University, Manhattan, UNITED STATES; (2) Oklahoma State University, Stillwater, UNITED STATES; (3) Volcani Institute, Rishon Lezion, ISRAEL; (4) Murdoch University, Perth, AUSTRALIA; (5) New Zealand Institute for Plant and Food Research Limited, Lincoln, NEW ZEALAND

Text

Over the past few decades, we've experienced a rapid expansion in knowledge fueled in part, by the rapid evolution of the technologies that underpin science. Growth in disciplines and subdisciplines coincident with the rapid expansion in scientific journals over this same period leads to important questions regarding the education of the next generation of plant pathologists: what is enough for a student to know and achieve in-order to fulfill the requirements for a graduate degree? Have we become too focused on the acquisition of technological skills at the expense of developing a broad and deep knowledge base essential to advancing plant pathology? Is the steady decline in the number of plant pathology departments an indication of the evolution of our discipline through integration into other disciplines or a reflection of the fragmentation of disciplines into more specialized areas of study? Is the decline in taxon-based courses a result of careful deliberation as to the best approach to graduate education or a consequence of the fragmentation of the discipline? There have been periodic discussions as to whether a Ph.D. program should require coursework or be solely focused on research. The increase in knowledge in all areas of science affords the opportunity for deeper understanding but, is it at the expense of breadth of knowledge? Our goal should be to generate scholars to advance our discipline. The challenge is to determine the best way to achieve that goal.

C8.7-4

A STEP FORWARD IN THE APPLICATION AND TEACHING OF MODERN STATISTICAL METHODS FOR PLANT PATHOLOGY

MARCIANÒ Demetrio. (1), TOFFOLATTI Silvia Laura. (1)

(1) Dipartimento di Scienze Agrarie e Ambientali (DISAA), University of Milan, Milan, ITALY

Text

Ex vivo and in vivo assays are routinely employed by plant pathologists to evaluate the effects of a certain treatment on Plant-Pathogen Interactions (PPI). Unfortunately, PPI is a complex phenomenon affected by many factors, which dramatically increases the variability associated with experiments. Therefore, the use of appropriate statistical analyses is essential for the positive exploitation of data, thus limiting the risk of misinterpretation of results. For this reason, appropriate handling of statistics is crucial for phytopathologists. However, traditional techniques, such as ANOVA or non-parametric tests, are often

inappropriate or even deleterious for PPI datasets but are still common in scientific publications. The increasing availability of open-source tools for statistical analyses represents an opportunity for researchers, professionals, and students; However, the adoption of uncommon techniques still represents an obstacle because of limited knowledge from potential users. Teachers must address these needs during their lessons. Exploiting real datasets from recent publications, easy-to-interpret and appropriate analyses and instruments (e.g., generalized linear models, beta regressions, machine learning, and effective data visualization) should be considered for plant pathology classes, thus shaping a new generation of plant pathologists that can efficiently exploit information derived from laboratory and field trials.

C8.7-6

A CONVENIENT BIBLIOMETRIC PIPELINE TO SNAP-SHOT LARGE RESEARCH FIELDS - AN EXAMPLE OF APPLICATION WITH THE FIELD OF MOLECULAR PLANT IMMUNITY

PETRE Benjamin. (1), LOUET Clementine. (1), LINTZ Julie. (1), DUPLESSIS Sebastien. (1)

(1) Unité Mixte de Recherche Université de Lorraine/INRAE Interactions Arbres-Microorganismes, Nancy, FRANCE

Text
To quickly gain an analytical and conceptual knowledge of a large research field is complex and daunting. Yet, academics of all levels critically need such knowledge to make educational- and career-related strategic decisions, to develop creative and sound research projects, to train students, or to mentor colleagues. Over the last three years, our group developed, used, and published a bibliometric pipeline that allows to snap-shot large research fields in an objective, data-driven manner (Petre et al., 2022; doi.org/10.1094/MPMI-05-22-0112-CR). On the one hand, junior academics, such as early-career scientists and graduate students, can use this pipeline to quickly and effectively apprehend a given research field and to build solid dissertations, thesis introduction, literature reviews, or context parts of grant proposals; and to ultimately make strategic career-related decisions. On the other hand, senior scientists, such as higher education teachers and mentors, can use this pipeline to prepare comprehensive courses and lessons, to explore fields that are outside of their area of expertise, and to effectively advise students and colleagues. At the ICPP, we propose to present an example of application of our bibliometric pipeline to analyze the field of molecular plant immunity, as well as a follow-up study focused on the research community in France. The presentation will highlight the value of our approach for training and mentoring graduate students.

FARMER FIELD SCHOOLS AS A MEANS OF ENHANCING FARMER KNOWLEDGE IN COMMON BEAN PRODUCTION AND DISEASES MANAGEMENT IN UGANDA

PAPARU Pamela. (1), MUKANKUSI Clare. (2), KAYONGO Allan. (1), CANDIRU Agnes. (1), NAKIBUULE Justine. (1), KATO Fred. (2), OTIM Michael Hillary. (1)

(1) National Agricultural Research Organization (NARO-NaCRRI), Kampala, UGANDA; (2) Centro Internacional De Agricultura Tropical (CIAT), Kampala, UGANDA

Text

The Farmer Field School (FFS) is a Farmer Participatory Research approach that can be used to determine end-user acceptance of new technologies. In 2019, we initiated a program of FFSs in 5 districts of Uganda to promote biofortified beans and crop management practices including chemical disease management, use of NPK, row planting and weed management. We established six 1-acre FFSs in each district run by pre-existing Farmer Groups. Key FFS activities included land preparation, variety selection, row planting, fertilizer application, seedling and foliar diseases assessment, application of Ridomil Gold and harvest of beans. Farmer knowledge of introduced technologies was assessed at the onset of the FFSs and at the end of the season Thirty-five, 15 and 36% of the participants said they understood fertilizer application, row planting and disease identification and control using Ridmil Gold, respectively. Better still, 29, 64 and 18% said they got full knowledge of the practices above, respectively. Similarly, 40, 29, and 11% participants reported to have acquired new knowledge on proper chemical dosages, use of protective clothing and proper disposal of used chemical containers, respectively. Participants acknowledged positive impact of FFSs on pre-existing Farmer Groups as FFSs offered access to new knowledge and technologies, motivated participation and unity, provided access to information and increased their visibility and chances of benefiting from Government programs.

ADDRESSING THE GLOBAL GAP IN SEED PATHOLOGY EDUCATION

DU TOIT Lindsey. (1), MUNKVOLD Gary. (2), HIDDINK Gerbert. (3), DUNKLE Ric. (4)

(1) Washington State University, Mount Vernon, UNITED STATES; (2) Iowa State University, Ames, UNITED STATES; (3) Enza Zaden, Enkhuizen, NETHERLANDS; (4) American Seed Trade Association, Alexandria, UNITED STATES

Text

Seeds are foundational to production of most plant species. Efficient cultivar development, seed production, and seed distribution require a global effort, representing a $50+ billion industry annually. As a result, regional and global movement of seeds is a critical component in the seed supply. Because seeds, in some cases, can be a pathway for dissemination of plant pathogens, phytosanitary restrictions on seed movement are enforced increasingly in most countries. This fuels the demand for education and training in seed science and seed pathology, including knowledge needed to address rapid technological advances, phytosanitary concerns, and evolution of seed trade policies. However, very few university programs are dedicated to seed pathology. Many seed companies have had to create in-house training programs to develop expertise in seed pathology that is essential to seed production and management, and government agencies have difficulty hiring staff with relevant seed pathology expertise. To help address the global gap in educational resources and training in seed pathology, a 12-week, 1 h/week, online, introductory course is being developed by seed pathologists from academia, industry, and government agencies in various countries to provide a high-level perspective on seeds and seed pathology. We will discuss this course as the first in a series of seed pathology educational events being developed to address the global demand for seed pathology education and training.

DON’T RISK IT! - AN EPPO COMMUNICATION CAMPAIGN TO RAISE AWARENESS OF INTERNATIONAL TRAVELLERS ABOUT THE RISKS OF CARRYING PLANTS IN THEIR LUGGAGE

ROY Anne-Sophie. (1), SUFFERT Muriel. (1), **GRIMAULT Valérie. (1)**, **GRIMAULT Valérie. (1)**, **GRIMAULT Valérie. (1)**

(1) EPPO, Paris, FRANCE

Text

Travelling long distances with plants or plant products of unknown phytosanitary status can present serious risks to agriculture, forestry and the environment, as these plants may carry pests and diseases. International travellers are generally unaware of these risks, in particular when travelling between continents which have quite distinct floras and faunas. In order to raise public awareness about the risks of moving plants during international travels, EPPO launched a communication campaign in 2013 with the slogan 'Don't Risk It!'. A poster and its accompanying leaflet were provided to National Plant Protection Organizations of EPPO countries (in Eurasia and the Mediterranean Basin). They were designed as templates so that they could be easily translated and adapted. The main objective was that these documents should be displayed in airports or any other sites where travellers would easily see them. So far, more than 20 EPPO countries have used this communication material in airports, train stations, border inspection points, travel agencies, websites, international fairs, etc. Countries have also been quite creative and used the slogan or the visual material to prepare videos, luggage tags, bookmarks and other goodies. It is hoped that the ‘Don’t Risk It!’ campaign will continue to contribute to a better understanding of the general public about the importance of protecting plant health and ultimately reduce the risks of introducing dangerous diseases into new areas.

Text

Yields of cocoa have stagnated despite decades and millions of dollars spent on research and farmer training. In Indonesia and Papua New Guinea we have shown that labour availability and productivity is the major constraint to cocoa production, due to poor education, aging and poor health of farming families, narrow income diversification and increasing dependency on off-farm and remittance income. Conventional farmer training programs focus on technical aspects of cocoa farming and ignore the capacity of individual households to invest in improved technologies, usually requiring available healthy, educated and productive labour. On the cocoa growing island of Bougainville we addressed labour

productivity through transdisciplinary training on family nutrition and health, gender equity, income diversification, local leadership and goal setting to complement conventional farmer training. Dietary diversity and food security improved, food crop and cocoa production increased. The importance of educated, healthy labour was confirmed by when the local demand for food in remote rural communities stimulated innovation and the adoption of new technologies and increased local food and cocoa production when relatively young, healthy and well-educated labour returned from urban centres during the COVID-19 pandemic. Healthy crops require healthy farmers

Re-emergence of tobamoviruses threatening global vegetable production

C8.4-1

GLOBAL EMERGENCE OF TOMATO BROWN RUGOSE FRUIT VIRUS IN TOMATO AND PEPPER AND ITS MANAGEMENT

LING Kai-Shu. (1)

(1) USDA Agricultural Research Service, Charleston, UNITED STATES

Text

Tomato brown rugose fruit virus (ToBRFV) is an emerging tobamovirus that was first identified in 2014 infecting greenhouse tomato in the Middle East (Jordan and Israel). Due to its ability to break the popular resistance gene (*Tm-2*^{2}), this seed-borne and mechanically transmitted virus quickly spread around the world, causing disease outbreaks on tomato and pepper in over 30 countries in just few years. Most of the outbreaks occurred on tomato in a greenhouse, field-grown tomato and pepper are also susceptible. ToBRFV can be transmitted through hands-on activities during transplanting, pruning, de-leafing or fruit harvesting. With increasing activities in global seed production and trade, seed health testing will ensure a seed lot free of ToBRFV to be used for planting. In nursery propagation, it is necessary to monitor seedlings for symptoms, followed by a confirmation test. In greenhouse production, it is important to establish a strong cleaning, disinfecting and sanitizing program. Several effective disinfectants (Clorox, Virkon S, and Virocid) capable of inactivating virus infectivity have been identified. However, the most effective means of management would be to develop a new tomato cultivar with resistance to the virus. In screening the USDA tomato germplasm, a new source of resistance to ToBRFV was identified in a tomato relative, *Solanum pimpinellifolium*. QTL analysis, SNPs identification and their applications for marker-assisted selection will be discussed.

Text

The recent emergence of tomato brown rugose fruit virus and tomato mottle mosaic virus (ToBRFV and ToMMV, *Tobamovirus, Virgaviridae*) poses a significant threat to global tomato and pepper production. Tobamoviruses have highly stable virions and are mainly transmitted through infected seeds, planting material and mechanically, but other transmission routes should not be neglected. Our objective was to determine the possible transmission routes of emerging tobamoviruses via infested water or soil. Results of our study indicate that ToBRFV can remain infectious in water stored at room temperature for up to four weeks, while its RNA can be detected in water for at least four months. We have shown that ToBRFV-contaminated water used for irrigation in hydroponic or soil-based cropping systems can infect tomato plants through the roots after one to six months of exposure. In addition, soil infested with ToBRFV or ToMMV was confirmed to be an inoculum source for planted tomato seedlings and seedlings grown from seeds. These results indicate new epidemiological pathway of ToBRFV and ToMMV via water and soil. The results fill existing knowledge gaps and point to the need to control the presence of emerging tobamoviruses and to disinfect irrigation water and soil in tomato and pepper production if contamination occurs.

C8.4-3

IMPROVING STRATEGIES FOR TOMATO BROWN RUGOSE FRUIT VIRUS SURVEILLANCE IN TOMATO FRUIT PRODUCTION

FOX Adrian. (1,2), FOWKES Aimee . (1), LOH Yue Lin. (1), MEHLE Natasa. (3,4), MAKSIMOVIC Olivera. (3,5), VAN GEMERT Jerom. (6), BOTERMANS Marleen. (6), SKELTON Anna. (1)

Text

Tomato brown rugose fruit virus (ToBRFV) is a member of the genus Tobamovirus. Since it was first detected in Jordan and Israel in 2014/15 it has spread to the major tomato production regions of the world. It has become a major constraint on commercial tomato production in the Northern Hemisphere impacting yield and marketability of tomato fruit from

affected crops. Since 2018, National Plant Protection Organisations have focused on stringent biosecurity measures, such as seed testing, to minimise the risk of transnational spread. Strategies for containment at the national level have focused on crop surveillance, however, visual inspection is inadequate for detection of the virus. Laboratory diagnostic protocols are limited in being able to handle adequate numbers of plant samples, especially for testing young plants.
Studies have been conducted to investigate the optimum sampling strategy to detect the virus from plants including both inoculation trials and outbreak sampling exercises. These have identified that sepals and young leaves give the most reliable detection irrespective of plant age. Additionally, non-invasive, non-crop based monitoring approaches have been investigated including swab and irrigation water testing, using both laboratory and onsite methods. These approaches could offer early detection of the virus from an infected glasshouse. Approaches for integrating these approaches into monitoring both pre- and post-outbreak will be discussed.

Text

The tomato *Tm-2*^{2} gene was considered one of the most durable resistance genes in agriculture, protecting against viruses of the *Tobamovirus* genus. However, an emerging tobamovirus, tomato brown rugose fruit virus (ToBRFV), has overcome *Tm-2*^{2}, damaging tomato production worldwide. *Tm-2*^{2} encodes a plant immune receptor that recognizes its effector, the tobamovirus movement protein (MP). Recently, we have established that ToBRFV MP (MP^{ToBRFV}) enabled the virus to overcome *Tm-2*^{2}-mediated resistance. Yet, it was unknown how *Tm-2*^{2} remained durable against other tobamoviruses (e.g. TMV and ToMV) for over 60 years. Here, we show that a conserved cysteine (C68) in the TMV MP (MP^{TMV}) is both sufficient to trigger *Tm-2*^{2} resistance and essential for intercellular movement of the virus. Substitution of MP^{ToBRFV} amino acid H67 with the corresponding amino acid in MP^{TMV} (C68) activated *Tm-2*^{2}-medited resistance. Phylogenetic and structural prediction analysis revealed that C68 is conserved among all Solanaceae-infecting tobamoviruses except ToBRFV, and localizes to a predicted β-barrel fold common to various viral MPs. Cell-to-cell and systemic movement analysis showed that C68 is required for the movement of TMV and ToMV, by determining the MP subcellular localization and targeting it to plasmodesmata. The double role of C68 in viral movement and *Tm-2*^{2} immune activation could explain how TMV and ToMV were unable to overcome *Tm-2*^{2} for such a long period.

Text

Studies of early stages of cucumber green mottle mosaic virus (CGMMV) disease could be affected by extreme diurnal temperatures. Our studies disclosed a new phenotypic description of CGMMV disease initiation, characteristic of cucumbers grown under extreme environmental temperature fluctuations. We have revealed two new phenotypes that developed gradually, preceding severe symptoms of post-recovery CGMMV infection. 'Early post-recovery stage' bright yellow islands ('early BYIs') with defined boundaries amid asymptomatic leaf blades were first emerging followed by 'late post-recovery stage' ('late BYIs') with diffused boundaries. Profiling ontology of cucumber differentially expressed genes in BYIs vs the associated dark-green surrounding tissue disclosed activation of jasmonic acid (JA) pathway in 'early BYIs'. JA signaling was inactivated in 'late BYIs' concomitant with increasing expressions of JA signaling inhibitors and downregulation of the phenylpropanoid pathway. Regarding RNA silencing we have found that specifically at the 'early BYIs', RDR1c was significantly upregulated. Knockdown of cucumber rdr1c1 and c2 genes using CRISPR/Cas9 system increased viral accumulation. Plants with a homozygous mutation in rdr1c were highly susceptible to coinfection of soil-mediated CGMMV and necrotrophic pathogen Pythium spp. leading to plant collapse.

C8.4-6

THE ROLE OF THE WEED SPECIES AMARANTHUS VIRIDIS IN THE EPIDEMIOLOGY AND SURVIVAL OF CUCUMBER GREEN MOTTLE MOSAIC VIRUS

Text

Amaranthus viridis is a weed host of cucumber green mottle mosaic virus (CGMMV) that can occur in and around Australian cucurbit crops. Experimentally, it has been shown to be a viable host for CGMMV and mechanical inoculation with infected A. viridis was used to successfully transmit the virus to susceptible cucurbit species. CGMMV can be difficult to detect in field collected A. viridis, which might be associated with virus titre and distribution

within the plant. It is not known if CGMMV reaches the seeds and if it can be successfully vertically transmitted in this weed host. This raises questions about the importance of A. viridis as virus reservoir and its contribution to the CGMMV disease cycle. Using a series of pot trials this study examined the systemic movement and virus titre of CGMMV across the life cycle of A. viridis. Seeds collected from virus positive plants were tested for presence of virus using quantitative RT-PCR. Seed transmission of CGMMV was analysed by testing second-generation plants propagated from collected seeds. Preliminary results indicate systemic movement of the virus within A. viridis. The results of this study will inform CGMMV management in Australian cucurbit crops.

P8.4-001

AFRICAN EGGPLANT-ASSOCIATED VIRUS: CHARACTERIZATION OF A NOVEL TOBAMOVIRUS IDENTIFIED FROM SOLANUM MACROCARPON AND ASSESSMENT OF ITS POTENTIAL IMPACT ON TOMATO AND PEPPER CROPS

GIESBERS Anne. (1,2), ROENHORST Annelien. (1,2), SCHENK Martijn. (1), WESTENBERG Marcel. (1,2), BOTERMANS Marleen. (1,2)

(1) National Plant Protection Organization (NPPO-NL), Netherlands Food and Consumer Product Safety Authority (NVWA), Wageningen, NETHERLANDS; (2) Netherlands Institute for Vectors, Invasive plants and Plant health, Wageningen, NETHERLANDS

Text

A novel tobamovirus was identified in a fruit of *Solanum macrocarpon* imported into the Netherlands in 2018. This virus was further characterized in terms of host range, pathotype and genomic properties, because many tobamoviruses have the potential to cause severe damage in important crops. In the original fruit, two different genotypes of the novel virus were present. The virus was able to infect multiple plant species from the *Solanaceae* family after mechanical inoculation, as well as a member of the *Apiaceae* family. These species included economically important crops such as tomato and pepper, as well as eggplant and petunia. Both tomato and pepper germplasm were shown to harbor resistance against the novel virus. Since most commercial tomato and pepper varieties grown in European greenhouses harbor these relevant resistances, the risk of infection and subsequent impact on these crops is likely to be low in Europe. Assessment of the potential threat to eggplant, petunia, and other susceptible species needs further work. In conclusion, this study provides a first assessment of the potential phytosanitary risks of a newly discovered tobamovirus, which was tentatively named African eggplant-associated virus.

DIAGNOSIS AND CHARACTERIZATION OF SEED BORNE VIRUSES IN CUCURBITACEOUS CROPS: HIDDEN THREAT FOR GLOBAL CROP PRODUCTIONS AND SEED INDUSTRIES

BASAVARAJU Mahesha. (1), SAMUEL Duleep Kumar. (1), TALAGAVADI RAMAMOORTHY Usha Rani. (1), HESARAHALLI SHANKALINGAPPA Yogeesha. (1)

(1) INDIAN INSTITUTE OF HORTICULTURE RESEARCH, Bangalore, INDIA

Text
Cucurbitaceous crops are one of the important groups in the vegetable crops that are rich in neutraceuticals and pharmaceutical value. However, investigations during 2017-2023 revealed that seed borne viruses are most significant because of its survivability, persistent nature, transmission potentiality, contagiousness, severity, loss of yield and quality of the produce. In the current investigations, collected the virus infected cucurbit host plants viz., ashgourd, bitter gourd, bottle gourd, chow-chow, cucumber, gherkin, muskmelon, pumpkin, ridge gourd, snake gourd, spiny gourd, squash, teasle gourd and watermelon and seeds; further, developed the diagnostics through molecular, serological, and biological techniques. The sequencing results concluded that Cucumber green mottle mosaic virus and whiteflies transmitted Tomato leaf curl New Delhi virus is predominantly detected in bottle gourd and ridge gourd seed coat, respectively. Further, confirmed the CGMMV and ToLCNDV easy transmission through sap on bottlegourd and ridgegourd, respectively. Finally, developed and demonstrated the integrated virus disease management strategies for ridgegourd, cucumber and muskmelon. Indeed, seed borne viruses might be entered to India through escapes while importing from other countries through commercial seed industries; hence, vigilance and stringent seed quarantine measures to be implemented globally.

REMOTE REAL-TIME RT-PCR FOR MONITORING AND EARLY DETECTION OF TOMATO BROWN RUGOSE FRUIT VIRUS IN TOMATO CROPS IN SICILY

PANNO Stefano. (1), MATIC Slavica. (2), **CARUSO Andrea Giovanni. (1)**, DAVINO Salvatore. (1)

(1) University of Palermo, Palermo, ITALY; (2) Institute for Sustainable Plant Protection, National Research Council of Italy, Turin, ITALY

Text
Tomato brown rugose fruit virus causes destructive disease on tomato. Following its first outbreak occurred in Italy, it has become a serious threat to tomato crop.
For that purpose, 600 tomato samples were directly analyzed in field in 3 Sicilian different areas with the bCUBE® system (Hyris Ltd). The bCUBE® was integrated within a network of mini-lab, established and monitored in real time by the Plant Virology Lab located at the University of Palermo.
A quick in-field sample preparation procedure was used. In detail, ~100 mg of tissue were homogenized in a sample bag with 3mL of extraction buffer. Five µL of extract was spotted on a 1 cm2 hybridization membrane, dried at RT for 5 min, and placed in a 2 mL tube with 250 µL of glycine buffer. After manual mixing of the tubes for 20 sec, 3 µL of the extract were used for the RT-qPCR assay according to the procedure developed by Panno and co-workers (2019). The results were visualized on a smartphone directly in the field and at the University of Palermo using the webApp developed by Hyris.
To confirm the RT-qPCR analyses in field, 125 samples were also analyzed at the Plant Virology laboratory of ISPP-CNR (Turin) using routine procedures such as RNA extraction and a RT-qPCR. All samples resulted positive in-field for ToBRFV were confirmed by the laboratory analyses. The developed mini-laboratories network, data visualization, and

analysis confirmation allowed remote and continuous virus monitoring and in-field ToBRFV detection.

P8.4-005

LATENT INFECTION BY TOBAMOVIRUSES

ILYAS Rabia. (1), RICHERT-PÖGGELER Katja. (1), ZIEBELL Heiko. (1)

(1) Julius Kühn-institut, Braunschweig, GERMANY

Text

Tobamoviruses are among the most well-studied plant viruses and yet there is still a lot to uncover about them. On one side of the spectrum, there are damage-causing members of this genus: such as the tobacco mosaic virus (TMV), tomato brown rugose fruit virus (ToBRFV) and cucumber green mottle mosaic virus (CGMMV), on the other side, there are members which cause latent infection in host plants. New technologies, such as high-throughput sequencing (HTS), have enabled us to discover viruses from asymptomatic plants, viruses in mixed infections where the disease etiology cannot be attributed to a single entity and more and more researchers are looking at non-crop plants to identify alternative virus reservoirs, leading to new virus discoveries. However, the diversity of these interactions in the virosphere and the involvement of multiple viruses in a single host is still relatively unclear. For such host–virus interactions in wild plants, symptoms are not always linked with the virus titer. Although latency has been observed for many tobamoviruses, the mechanisms underlying this phenomenon are still elusive. While there are multiple definitions of latent infection in the literature, there are even more explanations that use this umbrella term. It is important to study new and emerging tobamoviruses that are threatening horticulturally important crop plants, as well as those that cause a latent infection, which can go unchecked and potentially cause diseases on other hosts.

P8.4-006

SEARCHING FOR A MILD ISOLATE TO USE IN CROSS-PROTECTION STUDIES FOR TOBRFV

ROHDE Mareike Johanna. (1), NIEHL Annette. (1), ZIEBELL Heiko. (1)

(1) Julius Kühn-Institut, Braunschweig, GERMANY

Text

Tomatoes and other solanaceae are among the most important food crops in the EU and worldwide. The tomato brown rugose fruit virus (ToBRFV) is a recently emerged tobamovirus that has quickly spread since its discovery in 2016 and can be a severe threat to pepper and tomato cultivation. ToBRFV can overcome established resistances against tobamoviruses, such as the Tm-2^2 gene in tomato (Luria et al. 2017) and L genes in pepper plants (Fidan et al. 2022).
The use of cross-protection presents the possibility to establish resistance without the necessity for time-consuming breeding approaches and thus without affecting established

cultivar traits.
Different approaches are applied in the VIRTIGATION project to screen for mild isolates that can be used in cross-protection studies. Here we employed the application of nitrous acid and we investigate mutagenesis in tissue culture for its suitability to generate ToBRFV mutant isolates. This method has been recently established for potato virus Y, where attenuated mutants were found after regeneration of shoots from leaf discs of infected plants (Ogawa et al. 2013).
Using these methods, we look for candidates with attenuated ToBRFV disease phenotypes. The virus isolates present in the plants will be sequenced and evaluated for their potential to be used as cross-protection agents against infection of tomato with the severe wild-type ToBRFV.

THE ABILITY OF ELISA, REAL-TIME RT-PCR, AND BIOASSAY IN THE QUANTIFICATION OF THE VIRUCIDAL EFFICACY USING MENNO FLORADES DISINFECTANT AND TOMATO BROWN RUGOSE FRUIT VIRUS AS AN EXAMPLE

NOURINEJHAD ZARGHANI Shaheen. (1), EHLERS Jens. (1), MONAVARI Mehran. (2), VON BARGEN Susanne. (1), HAMACHER Joachim. (3), BÜTTNER Carmen. (1), BANDTE Martina. (1)

(1) Humboldt-Universität zu Berlin, Albrecht Daniel Thaer-Institute for Crop and Horticultural Sciences, , Berlin, GERMANY; (2) Section S.3 eScience, Federal Institute for Materials Research and Testing, Berlin, GERMANY; (3) INRES - Plant Pathology, Universität Bonn, Bonn, GERMANY

Text
Tomato brown rugose fruit virus (ToBRFV) is a new emerging tobamovirus considered to be one of the biggest threats to tomato production. It is a regulated/quarantined plant pathogen in many countries including Germany. The virus has been reported in more than 35 countries in tomato, pepper, and herbaceous plants. It overcomes the Tm-2 resistance genes in tomatoes and outbreaks caused by ToBRFV have been reported in several countries since the first outbreak in 2014. Tobamoviruses are easily transmitted by mechanical contact and remain infectious for serval years outside of the host cells making their eradication from infected areas very difficult. Therefore, the application of an effective disinfectant is mandatory. MENNO Florades is an authorized plant protectant in Germany showing very promising results in the deactivation of ToBRFV on different surfaces. We compared three different quantification methods including quantitative ELISA, RT-qPCR, and bioassays as methods based on virus proteins, viral genomic nucleic acids, and virus pathogenicity, respectively, for their suitability to quantify the virucidal efficacy of MENNO Florades. Finally, only the bioassay could estimate the efficacy of the disinfectant with satisfying accuracy.

Resilience in soil health and disease suppression

AN INTERNATIONAL COLLABORATION FOR THE DEVELOPMENT OF A BIOLOGICAL NEMATICIDE FOR USE IN SUB-SAHARAN AFRICA

JENSEN Jared. (1)

(1) AgBiome, Research Triangle Park, UNITED STATES

Text

Farmers of root and tuber crops, such as yam (Dioscorea spp.), are particularly affected by plant-parasitic nematodes; due to economic losses caused by decreased crop yields and crop quality. The lack of nematicide availability and selection across Sub-Saharan Africa (SSA) severely limits farmers' productivity and profitability. Backed with grant funding from the Bill and Melinda Gates Foundation, AgBiome is leading a multinational team of researchers to discover, develop, and commercialize a bacteria-based nematicide for use across SSA on root and tuber crops.This team of researchers, formed in 2018, includes scientists from national research organizations (Tanzania Agricultural Research Institute - TARI), academic institutions (University of Abomey-Calavi and University of Ibadan), and non-governmental organizations (International Institute for Tropical Agriculture -IITA). AgBiome and the research and development team will partner with local commercial organizations to deliver a safe, effective, and affordable tool for farmers; enabling them to better reach their full economic potential.

Text

Agricultural mulching films made of polyethylene, a petrochemical product, are widely used in agricultural fields to increase crop yields. However, removal and disposal of the Agricultural mulching has become a challenge, the plastic pollution in farming soil is increased, similar to that seen in the ocean. Accumulated agricultural plastics in soil affect the physicochemical properties of soil, soil microbiota, and plant growth. Moreover, recent study indicated that nano-plastics in the soil can be taken up by plants. However, knowledge about tripartite interactions among plastic, microorganism, and plant remains unclear. Here we showed their interaction at the transcriptome level in the model plant, *Arabidopsis thaliana*. Plants were incubated in the 0 and 5 % meso-plastics (mechanically pulverized forms of low-density

polyethylene films)-contaminated soils that had been pre-incubated for 120 days under dark conditions (25? and 80% relative humidity). The transcriptome analysis revealed that certain genes were down-regulated or up-regulated when plants were exposed to high concentrations of meso-plastics. On the other hand, plastic contamination also affected the community structure of the rhizosphere microbiome. These results showed that agricultural plastic remnants caused physiological changes in plants and the change of microbiota in soil and propose the potential impact of agricultural plastic pollution on phytobiome.

C3.4-3

A CULTUROMICS APPROACH IDENTIFIES RHIZOSPHERIC BACTERIAL STRAINS INVOLVED IN LEGUMES PROTECTION AGAINST THE ROOT ROT AGENT APHANOMYCES EUTEICHES

ZOUAOUI Mohamed. (1), BAZERQUE Quentin. (1), REY Thomas. (1), DUMAS Bernard. (1)

(1) Université Toulouse III - Paul Sabatier, Toulouse, FRANCE

Text
In recent years, using a consortium of selected bacteria from the root microbiota, also known as a "synthetic community" (SynCOM), to promote plant health has become increasingly common. The objective of this study is to elaborate a model SynCOM from the rhizosphere of Medicago truncatula (Mt) to unravel the role of root microbiota in mediating plant-microbe interactions in the context of biotic stress caused by Aphanomyces euteiches, a devastating oomycete that causes root rot in legume plants. A high throughput culturomics protocol was used to obtain 1364 isolates from the rhizosphere of Mt. The collection of isolated bacteria was genotyped using Illumina 16S metabarcoding sequencing. The UCLAST algorithm was employed with a 97% identity to select 812 pure isolates with 79 unique OTUs. The relative abundance analysis of the collection showed that the uppermost taxa were similar to those observed in molecular identification obtained from soil DNA. Among the selected 812 pure isolate 12 were found to inhibit A. euteiches growth in a dual culture assay. In planta testing, only one strain of Pseudomonas sp. showed significant difference from the untreated control. This collection of 79 unique OTUs was used to constitute a synthetic community as a model of the root microbiota of Medicago plants. A multi-omics approach will be used to analyze the behavior of this SynCOM in a gnotobiotic system to study its role in plant microbe interactions.

SHIFT OF BACTERIAL COMMUNITIES IS INVOLVED IN THE STIMULATION OF PLASMODIOPHORA BRASSICAE RESTING SPORE GERMINATION

WANG Yao. (1), ZHENG Xiaorong. (1), SARENQIMUGE Sarenqimuge. (1), VON TIEDEMANN Andreas. (1)

(1) Georg August University of Göttingen, Göttingen, GERMANY

Text

Clubroot, caused by *Plasmodiophora brassicae*, is a severe soil-borne disease in cruciferous crops worldwide. *P. brassicae* can survive in the soil as resting spores for many years. The germination of resting spores is a key process for successful infection leading to disease and thus identifying germination stimuli is imperative. Previous studies reported that root exudates of host and non-host plants were able to stimulate the germination of *P. brassicae* resting spores. In contrast, our studies showed that pure root exudates collected under sterile conditions cannot stimulate resting spore germination. Instead, various bioassay results demonstrated that *P. brassicae* resting spore germination is likely influenced by the microbial communities rather than being simply induced by root exudates. 16s rRNA gene amplicon sequencing results showed clear shifts in the abundance and composition of bacterial communities in the samples with higher germination rates compared to the initial community. The initial microbial community can be regulated to one that induces resting spore germination under suitable conditions (e.g. soil moisture, nutrients and carbon sources). Root exudates could be one of the carbon sources modulating the microbial community. This study presents novel insights significantly improving our understanding about the interaction of soil microbiota with *P. brassicae* and its host plant, which may enable to develop novel strategies of clubroot disease control.

C3.4-5

THE INTEGRATION LEVEL OF MICROBIOME STUDIES DETERMINES POTENTIAL DETECTION OF GLYPHOSATE-ASSOCIATED DYSBIOSES ON/IN PLANTS AND ANIMALS AND SUBSEQUENT DISEASE DEVELOPMENT.

VAN BRUGGEN Ariena. (1), FINCKH Maria. (2)

(1) Department of Plant Pathology, University of Florida, 32611 Gainesville, UNITED STATES; (2) Faculty of Organic Agricultural Sciences, Ecological Plant Protection, University of Kassel, 37213 Witzenhausen, GERMANY

Text

Glyphosate is the most used pesticide worldwide. It interferes with the shikimate pathway in plants and, depending on the genetic make-up, in many microorganisms, impeding the production of aromatic amino acids. Research results of glyphosate effects on microbial communities have been contradictory. We show that contrasting results are mostly due to differences in the integration levels studied. Thus, short-term treatment effects on microbial biomass or composition at higher taxonomic levels usually are minimal. In contrast, when using more detailed DNA sequencing techniques it was shown that especially chronic glyphosate treatments resulted in changes in the prevalence of specific genera or species as well as biological processes. Plant growth promoting rhizobacteria and beneficial intestinal bacteria often are negatively affected, while pathogenic bacteria and fungi are enhanced. Thus, by selectively weakening bacteria, fungi and protozoa, repeated exposure to glyphosate may change microbiome compositions in rhizo- and endospheres of plants, as well as animal guts. Such shifts in microbial composition have been implicated in enhanced susceptibility of plants to *Fusarium* and *Rhizoctonia*, of birds and mammals to toxic *Clostridium* and *Salmonella* species, and of bees to *Serratia* and Deformed Wing Virus. For the determination of health effects via dysbiosis there is a need to define the correct level of integration needed in microbial community analyses.

C3.4-6

EXPLORING SUSTAINABLE SOILBORNE DISEASE MANAGEMENT SOLUTIONS FOR SPECIALTY CUT FLOWER PRODUCTION

GUTIERREZ YANEZ Daniela. (1), TESTEN Anna L.. (2), **HAND Francesca. (1)**

(1) The Ohio State University, Columbus, UNITED STATES; (2) USDA-ARS-ATRU, Wooster, UNITED STATES

Text

Specialty cut flowers are produced in diverse systems, ranging from crates, raised and in-ground beds in high tunnels, or open fields. Agricultural soil and soilless substrates are often repurposed for production, introducing the risk of many soilborne diseases. Commercial growers have historically relied on soil fumigants for disease control, but the global phase-out of methyl bromide has left them with limited chemical options. At the same time, an increasing number of growers choose to adopt more sustainable practices due to concerns for human and environmental health. In this study, we explored the use of a non-pesticide-based soil disinfestation technique known as anaerobic soil disinfestation (ASD) for its potential to reduce incidence and severity of Rhizoctonia stem rot in zinnia. Wheat bran, soybean meal, and tomato pomace were incorporated as carbon sources in soilless and soil-based substrates, which were then irrigated to saturation, covered, and incubated for 4 weeks. Zinnia plugs were then transplanted in the substrates and monitored for disease development. Incidence and severity of stem rot were significantly reduced in all carbon source treatments when soil-based substrate was used, and in the tomato pomace and wheat bran treatments when soilless substrate was used. These results indicate that ASD is a suitable option for control of *Rhizoctonia solani* in specialty cut flowers and should be further investigated under a variety of production conditions.

PHYTOPATHOGENIC FUNGI MODIFY THE BACTERIAL DIVERSITY OF THE WHEAT RHIZOSPHERE GROWN IN CONVENTIONAL AND ORGANIC AGRICULTURAL SOILS UNDER AMBIENT AND FUTURE CLIMATE SCENARIOS

GIONGO Adriana. (1), BRAUN-KIEWNICK Andrea. (1), REITZ Thomas. (2), BUSCOT François. (2), SMALLA Kornelia. (1)

(1) Julius Kühn Institute, Braunschweig, GERMANY; (2) Helmholtz Centre for Environmental Research, Halle (Saale), GERMANY

Text

Due to their specific indigenous microbial communities, soils vary in suppressiveness towards pathogens. To explore the effects of climate change and agricultural management on the ability of soil microbiota to suppress phytopathogenic fungi, we collected soils from conventional and organic farming (CF and OF, respectively) plots exposed to ambient (A) or future (F) climatic conditions at the "Global Change Experimental Facility" (Bad Lauchstädt, Germany). The preconditioned soils were cultivated with wheat at the greenhouse and tested

for their suppressiveness towards Fusarium graminearum (Fg-1) and Gaeumannomyces tritici (Ggt). The soils inoculated with Fg-1 or Ggt presented a significantly lower microbial diversity ($p<0.05$) in the rhizosphere than the respective control soils. The preconditioning under ambient or future climatic conditions caused community differences in the conventional farming soil (CF-A vs. CF-F; $p<0.001$) for both inoculated treatments, while no such differences were observed for the organic farming soil. Overall, taxa affiliated with Actinobacteria and Proteobacteria were most abundant in all treatments and the most differentially abundant between CF-A and CF-F after inoculation with Fg-1. These taxa may contribute to disease suppressiveness and consequently support crop health. The study further revealed that soils preconditioned under different climatic conditions can help understand the impact of climate change on the functioning of soil microbiota.

P3.4-001

THE ROLE OF SOIL BACTERIA AND ROOT EXUDATES IN REGULATING DORMANCY AND GERMINATION OF MICROSCLEROTIA OF VERTICILLIUM LONGISPORUM

SARENQIMUGE Sarenqimuge. (1), VON TIEDEMANN Andreas. (1)

(1) Plant Pathology and Plant Protection Division, University of Göttingen, Göttingen, GERMANY

Text

Verticillium longisporum is a soil-borne, vascular pathogen on many brassicaceous plants. It produces dormant structures, microsclerotia, on the stems of host plants at crop maturity, which are very persistent in the soil. Previous reports speculated on two potential causes of soil suppressiveness to soil-borne pathogens, competition between microorganisms for nutrients or antagonistic interactions among them. Our study showed that compared to water control, none of the tested nutrient solutions showed any significant enhancement of microsclerotia germination. Hence, to reveal possible antifungal compounds, bacteria were isolated from soil and tested for their effects on microsclerotia. The results confirmed that bacterial volatiles have significant suppressive effects on microsclerotia, and volatile fatty acids are likely to be important factors determining dormancy of microsclerotia. Earlier research indicated an effect of plant root exudates on soil-borne pathogens, but this has been tested without considering the impact of soil microorganisms. In this study, microsclerotia were first suppressed by treatment with soil bacteria and exposed to plant root exudates. The results indicate that root exudates of both host and non-host plants can off-set the suppressive effect of soil bacteria on microsclerotia. Furthermore, our study indicated that the rescuing effect of root exudates is not owing to the reduction in bacterial viability but to changes in system metabolites.

P3.4-002

ORGANIC AMENDMENTS TRANSFORMED THE APPLE (MALUS DOMESTICA BORKH.) RHIZOSPHERE FUNGAL, BUT NOT BACTERIAL, COMMUNITY IN AN ORCHARD REPLANT SOIL.

MOYO Lindani. (1), MAZZOLA Mark. (1,2), BEETS Rochelle. (1), MCLEOD Adele. (1)

(1) Stellenbosch University, Stellenbosch, SOUTH AFRICA; (2) United States Department of Agriculture – Agricultural Research Service, Tree Fruit Research Laboratory, Wenatchee, UNITED STATES

Text
Apple replant disease (ARD) is caused by a complex of soilborne pathogens and suppresses yields in apple orchards. Long-term applied organic soil amendments have potential for sustainable disease management. Our study investigated changes in the composition of the apple rhizosphere microbiome under glasshouse conditions in response to the long-term application of organic soil amendments (mulch, mulch+compost, or untreated) in an ARD apple orchard. All treatments possessed a highly similar bacterial assemblage dominated in relative abundance by the phylum Proteobacteria (32- 33%) and genus *Conexibacter* (7%). The ascomycota was dominated by fungal phyla within the apple rhizosphere with the control having a lower relative abundance (67%) than the mulch (84%) and mulch+compost (79%). Differential abundance was also observed for the phylum chytridiomycota which had the highest relative abundance in the control (14%), followed by the mulch+compost (4%) and mulch (3%). As expected, the cellulolytic genera *Coniochaeta* and *Zopfiella* occurred at higher abundance in the mulch (8% and 5%) and mulch+compost (5% and 3%) than in the control (1% and 0.3%). The composition of the fungal communities of the soil treatments were significantly different (R^2 = 0.16, $P_{PERMANOVA}$ = 0.001) based on a beta diversity analysis. The study has increased our knowledge on transformation of the apple rhizosphere microbiome induced by long-term application of organic amendments.

P3.4-003

BIOLOGICAL SUPPRESSION OF SOILBORNE FUNGAL PATHOGEN VERTICILLIUM DAHLIAE IN COTTON SOILS

VADAKATTU Gupta. (1), MORRISON Sabrina. (2), HICKS Marcus. (1), KROKER Stasia. (1), **SMITH Linda. (3)**

Text
Verticillium dahliae Kleb. is causes wilt diseases in >200 plant species worldwide and verticillium wilt has a significant impact on cotton production in Australia. The control of soilborne plant diseases involves management of the pathogen at different microsites in soil at different time periods (pre-season or in-crop) and the control of infection and incidence. We demonstrate efficacy of two short-term soil-based lab-assays using a GFP-transformed non-defoliating (ND) strain of V. dahliae or qPCR technique (ND and defoliating strains, D) to quantify pathogen suppression capacity (PSP) of Australian cotton soils. Surface 10cm soil samples collected from established field experiments at ACRI, Narrabri and NorthStar in NSW were used. GFP assays indicated the biological nature of PSP capacity in soils from ACRI fields with varying disease incidence history. PSP estimates from qPCR assays showed significant differences in the growth pattern of both the D and ND strains in soils under different rotation treatments. Pathogen growth was higher in soils from continuous cotton and fallow rotations & lowest in Corn-Cotton rotation. These assays also detected changes in PSP upon addition of C and N (crop residues, chitin, N fertilizer), and bacterial amendments to soils, and distinguish between suppressive and conducive soils. A rapid soil

diagnostic tool would not only help understand the soil microbiome role in PSP, but how it can be enhanced to increase cotton production.

P3.4-004

WOODCHIP AMENDMENT CAN ALTER BANANA SOIL MICROBIAL ABUNDANCE AND DISEASE SUPPRESSIVE POTENTIAL

GAZA Hazel. (1), O' NEILL Wayne. (2), SHUEY Tim. (2), PATTISON Tony. (1)

(1) Centre for Wet Tropics Agriculture, South Johnstone, AUSTRALIA; (2) Eco Sciences Precint, Brisbane, AUSTRALIA

Text

Long-term banana cultivation alters soil microbial communities compared with areas of native vegetation. Specifically, the fungal microbial communities in banana soils are less abundant and less diverse, allowing potentially pathogenic groups of fungi, such as *Fusarium oxysporum* complexes, to dominate. Woodchip amendments could potentially increase soil fungi, leading to greater disease suppression in banana soil. We tested three rates equivalent to 2, 20 and 100 t/ha of woodchips from leguminous trees, *Erythrina* sp. and *Leucaena* sp., incorporated into the soil used for commercial banana production. One month after adding woodchips, Ducasse (Musa ABB) was planted into the soil. One month later, the plants were inoculated with a spore suspension of *Fusarium oxysporum* f. sp. *cubense* (Foc) Race 1 (VCG 0124). Results indicated that the incorporation of woodchips did not significantly impact the growth of banana plants. Woodchip amendment significantly increased the abundance of bacteria, archaebacteria and fungi in the soil compared to non-amended soil. Fungal biomass was significantly increased following the application of *Leucaena* sp., whereas bacterial biomass was enhanced following the incorporation of *Erythrina* sp. An increase in the rate of woodchip application increased the proportion of omnivorous nematodes and decreased the proportion of bacterivores. Woodchip amendment can increase the soil microbial biomass, which reduces FocR1 colonisation of the banana corm.

P3.4-005

EFFECTS OF SOIL PHYSICOCHEMICAL PROPERTIES ON FUSARIUM OXYSPORUM F. SP. ELAEIDIS DISEASE INCIDENCE AND SEVERITY IN OIL PALM PLANTATIONS OF CAMEROON DEVELOPMENT CORPORATION (CDC).

MOFORCHA Lilian Zemenjuh. (1), KINGE Tonjock Rosemary. (2)

(1) University of Buea, Buea, CAMEROON; (2) University of Bamenda, Bamenda, CAMEROON

Text

Oil palm is one of the tree crops that utilize a high amount of soil nutrients for optimum growth and development and is one of the leading cash crops in the economy of Cameroon. This study was carried out to evaluate the effect of soil physiochemical properties of Foe disease incidence and severity on oil palm estates of CDC (Bota, Debundscha, Idenau and Mondoni). Twelve bulked soil samples were collected from each estate and analysed using standard procedures. Tolerant oil palm hybrid seedlings were planted in soils collected from CDC estates and some in sterilized soil (control experiment). All soil physicochemical parameters negatively influenced the disease incidence and severity of Foe on the seedlings in prenursery. Soil samples from Idenau had highest pH value 6.3±0.03 while Debundscha had lowest pH of 5.5±0.1. Mondoni recorded high amount of total nitrogen; carbon/nitrogen ratio (40.8±12.8), organic matter (OM) (5.3±0.08), organic carbon (3.0%) and cation exchange capacity (CEC) (18.0±0.7). Soils from Idenau were the opposite. After planting disease free seedlings, soils from Mondoni had the lowest disease severity index (4.55%) meanwhile that of Idenau was the highest (12.02%). Therefore, appropriate nutrient management such as the application of organic and inorganic fertilizers should be used for soils that are deficient and low like that of Idenau.

P3.4-006

CROPPING SEQUENCES THAT REDUCE PATHOGEN INOCULUM AND MAINTAIN OVERALL SOIL BIOLOGICAL HEALTH REDUCE DISEASE INCIDENCE OF VERTICILLIUM WILT OF COTTON

SMITH Linda. (1), SCHEIKOWSKI Linda. (2), KAFLE Dinesh. (1), VADAKATTU Gupta. (3)

(1) Department of Agriculture and Fisheries, Dutton Park, AUSTRALIA; (2) Department of Agriculture and Fisheries, Toowoomba, AUSTRALIA; (3) Commonwealth Scientific and Industrial Research Organisation, Urrbrae, AUSTRALIA

Text

Verticillium wilt (VW) is a major economic constraint to cotton production in Australia. The causal agent, *Verticillium dahliae* Kleb (Vd), is a soilborne fungus that has a wide host range and survives long-term in soil by producing microsclerotia. Management of VW requires an integrated approach that reduces soil inoculum and maintains soil biological health.

A field trial was conducted to examine the impact of crop rotation on suppression of VW and overall soil biological health. Four treatments (sorghum, corn, fallow, and cotton) were examined. Disease incidence was assessed late season. Surface soil samples collected pre-plant and late season were analysed for Vd population and microbial abundance and catabolic diversity.

Disease incidence and soil inoculum levels were reduced following 2-year rotations with non-hosts or fallow compared to continuous cotton. The fallow-fallow (FF) rotation had the lowest abundance of fungal populations and overall catabolic diversity of soil microbial communities, whereas crop sequence that included sorghum had the highest values. Although FF rotation reduced Vd level and disease incidence, the decline in overall microbial populations and activities in the long-term could potentially make soils more conducive to soilborne diseases. Results suggest that management of VW in cotton through crop sequences that include other crops, may be a better option as they not only reduce disease incidence but also maintain overall soil biological health.

P3.4-007

THE RELATIONSHIP BETWEEN SHIFTS IN THE RHIZOSPHERE MICROBIAL COMMUNITY AND ROOT ROT DISEASE IN A CONTINUOUS CROPPING AMERICAN GINSENG SYSTEM

BI Yan-Meng. (1,2), ZHANG Xi-Mei. (2,3), JIAO Xiao-Lin. (2,4), LI Jun-Fei. (2), PENG Na. (2), TIAN Gei-Lin. (2,5), WANG Yi. (2), GAO Wei-Wei. (2)

(1) School of Environmental and Municipal Engineering, Tianjin, CHINA; (2) Institute of Medicinal Plant Development, Chinese Academy of Medical Sciences and Peking Union Medical Q5 College, Beijing, China, Beijing, CHINA; (3) School of Biology and Brewing Engineering, Taishan University, Tai'an, CHINA; (4) Biomedicine School, Beijing City University, Beijing, CHINA; (5) College of Agricultural and Biological Engineering, Heze University, Heze, CHINA

Text

The root rot disease causes a great economic loss, and the severity usually increases as ginseng ages. However, it is still unclear whether the disease is related to changes in microorganisms during the entire growing stage of American ginseng. The present study examined microbial community in the rhizosphere and chemical properties of the soil in 1–4-year-old ginseng plants grown in different seasons . Additionally, the study investigated ginseng root rot disease index (DI). Results showed that the DI of ginseng increased 2.2 times in one sampling site and 4.7 times in another during the 4 years. As for the microbial community, bacterial diversity increased with seasons in the first, third, and fourth years but remained steady in the second year. The seasonal changing of relative abundances of bacteria and fungi showed the same trend in the first, third, and fourth years but not in the second year. The Mantel test showed that soil chemical properties, including available nitrogen, phosphorus, potassium, calcium, magnesium, organic matter, and pH, were significantly correlated to microbial composition. The contents of available potassium and nitrogen were positively correlated with DI, while pH and organic matter were negatively correlated with DI. In summary, we can deduce the second year is the key period for the shift of the ginseng rhizosphere microbial community. Disease aggravation after the third year is related to the deterioration of the rhizosphere microecosystem.

IMPACTS OF ELEVATED CO2 ON INTERACTIONS WITH ROOT MICROBES FOR ENHANCED OAK GROWTH AND DEFENCE AGAINST PATHOGENS

PLATT Emma . (1), PASTOR Victoria. (2), **SANCHEZ-LUCAS Rosa. (1)**

(1) University of Birmingham, Birmingham, UNITED KINGDOM; (2) Universitat Jaume I, Castellon, SPAIN

Text

Symbiosis between plants and beneficial soil microorganisms like mycorrhizae are known to promote plant growth and defence against (a)biotic stresses in plants. Climate change (CC) is increasing the number of plant stress factors, such as increasing atmospheric CO2 (eCO2). Therefore, understanding the role of mycorrhizal in plant responses facing environmental changes is critical. However, mycorrhizae role is largely underappreciated, and field experiment research is scarce. This project will test the mycorrhizae effects on oak,

the eCO2 impact on mycorrhizal colonization and their role in mediating growth-defence trade-offs. For this, microscopy and untargeted metabolomic analyses were performed in oak seedlings grown under ambient CO2 (aCO2) and eCO2 and then infected with powdery mildew at the Free Air CO2 Enrichment (FACE) facilities of the Birmingham Institute of Forest Research (BIFoR). Powdery mildew infection was monitored and mycorrhizae staining was performed by ink-acid method in 20 seedlings/CO2 level. Root-extracted metabolites were subjected to LC-MS/MS analysis. Spectra were filtered by using XCMS R scripts. Statistical analysis, using METABOANALYST, showed statistical differences among treatments. Identification and functional pathway analysis was performed using MARVIS to select putative biomarkers. Data showed a protective role of mycorrizhae that can be limited by future CO2 atmospheric levels, endangering the forest health under climate change conditions.

P3.4-009

EFFECT OF RESIDUE MANAGEMENT ON CERCOSPORA LEAF SPOT OF TABLE BEET AND SOIL MICROBIOME.

SHARMA Pratibha. (1), MURPHY Sean. (1), KIKKERT Julie. (2), PETHYBRIDGE Sarah. (1)

(1) Cornell University, Geneva, Ny, UNITED STATES; (2) Cornell Cooperative Extension, Canandaigua, Ny, UNITED STATES

Text

Cercospora leaf spot (CLS), caused by *Cercospora beticola*, can detrimentally affect foliar health in table beet leading to significant economic loss. CLS management currently relies on fungicides, but the high genetic diversity of *C. beticola* can rapidly develop fungicide resistance. Management of infested crop residue can help to delay the onset of the disease by reducing the primary inoculum in soil. A replicated field experiment was conducted to assess the impact of different residue management techniques on CLS in table beet. The experiment was a completely randomized block design with four replications of each treatment and nontreated controls. Infested beet leaves were used as the source of inoculum. Treatments were applied in fall 2021 and table beet was planted in summer 2022. Heat treatment of residue significantly reduced the CLS severity and AUDPS by 45.3% and 51.8%, respectively, compared to the no residue management control. Treatments with CaCO3 and a combination of chopping and plowing had significantly higher CLS severity and AUDPS than plots with no residue control by 92.8% and 149.3%, respectively. Other treatments were not statistically different from either control. *C. beticola* density and the structure of soil microbiome will be determined by qPCR and next generation sequencing of soil DNA, respectively. Identification of alternative CLS management strategies can help reduce the crop loss and frequency of fungicide applications for enhanced profitability.

P3.4-010

IS THE PLANTING OF PESTICIDE-TREATED SEED PROFITABLE? RESULTS FROM A LARGE-SCALE FARMER-LED ARABLE CROPPING SYSTEM EXPERIMENTS IN NORTH-EAST FRANCE

LAMICHHANE Jay Ram. (1), LAUDINOT Véronique . (2)

(1) INRAE, Castanet-Tolosan, FRANCE; (2) Chambre d'Agriculture du Grand Est, 9 rue de la Vologne Bâtiment I 54520 LAXOU, France, Laxou, FRANCE

Text

Farmers and policy makers rely on crop management data to evaluate socio-economic and environmental sustainability of cropping practices. The use of pesticide-treated seed is a widely used practice worldwide to control seed- and soil-borne pathogens affecting crop establishment and yield. In Europe, farmers raise concern about risks of yield losses due to a lower or no availability of chemicals previously used for seed treatment due to tighter restrictions imposed by the EU pesticide regulation 1107/2009, including the ban of several widely used fungicides (e.g. thirams, Metalaxyl-M). Within this context, research needs to provide a clear answer as to whether the economic viability of arable farms will be jeopardized when there is no access to pesticide-treated seeds. To respond to this concern, a 6-year specific project has been set up within the framework of French national action plan Ecophyto aiming at assessing economic and environmental sustainability of cropping systems without pesticide seed treatment compared to commonly used pesticide-treated seed. Large-scale farmer-led experiments using sequences of key arable crops (wheat, barley, maize, oilseed rape etc.) were put in place across contrasted environmental conditions of NorthEast France. Preliminary results show no significant yield differences between pesticide-treated and non-treated seeds raising questions on the prophylactic use of pesticide-treated seeds to yield gains.

Text

Root-associated microbiomes are critical to the growth and health of wheat. Long-term trends in wheat-root microbial community dynamics are poorly understood. We characterized the growing season and long-term population dynamics of bacterial communities in the rhizosphere and endosphere of wheat grown for eight years in dryland and irrigated plots in Washington State, USA with less than 305 mm annual precipitation. The diversity and richness of bacterial communities declined from the bulk soil to the rhizosphere, and to the endosphere. Bacterial richness and diversity were significantly greater in irrigated wheat. Some genera showed a consistent periodicity in their population trends during the growing season from March to August. Over eight growing seasons, Proteobacteria and Bacteroidetes (*Pseudomonas*, *Variovorax*, *Chryseobacterium*) maintained stable rhizosphere

populations in both dryland and irrigated wheat. Populations of some Bacteroidetes and Proteobacteria (*Mucilaginibacter*, *Sphingomonas*, *Massilia*, *Burkholderia*) were dryland adapted and persisted or increased in the dryland rhizosphere whereas others (*Rhizobium*, *Acidovorax*, *Terremonas*, *Hyphomicrobium*, *Bdellovibrio*) increased on irrigated wheat. In contrast, some taxa, including many Actinobacteria, declined in abundance over eight years in both the endosphere and rhizosphere regardless of irrigation. Our results provide insight into how water and monoculture impact the population dynamics of the wheat-root microbiome.

P3.4-012

EXAMINING THE IMPACT OF SOIL ON TREE HEALTH AND DISEASE PROGRESSION

MILENKOVIC Vanja. (1), RABIEY Mojgan . (1), GAUCI Vincent. (1), JACKSON Robert W.. (1)

(1) University of Birmingham, Birimingham, UNITED KINGDOM

Text
Forests are globally important ecosystems that provide goods and services to the planet. They have a crucial role in supporting biodiversity, storing carbon, and regulating the climate. The forests around the world, including temperate European forests, are under threat by the global increase in temperature and unpredictable climate conditions caused by climate change. These climatic changes are also causing the spread of new pests and diseases northwards as the planet warms. In recent years, some devastating diseases have affected trees and forests in continental Europe and the UK. To understand the role of soil, both its biotic and abiotic components, in tree health and disease development, we are analysing the effects of soil treatment on diseased and healthy trees. Using the study system of Oaks affected by Acute Oak Decline and Horse Chestnuts affected by Bleeding Canker, we investigated if the treatments successfully reduce disease or help recover existing diseased trees by analysing phenotypic measurements of the tree, the soil and tree microbiome and the tree metabolome. The initial assessments have revealed differences between diseased and healthy trees in the baseline measurements. So far, no effect of the treatment has been detected, and no difference between the treatments has been observed, but measurements over two further years will continue.

P3.4-013

EFFECTS OF TERMINATION TIME OF LEGUMINOUS COVER CROPS ON ROOT DISEASES OF SUCCEEDING PEAS

SISIC Adnan. (1), BARESEL Jörg Peter. (1), **FINCKH Maria. (1)**

(1) University of Kassel, Witzenhausen, GERMANY

Text
Many long-lived soil borne legume pathogens also persist in leguminous cover crops, making the intensification of legume production for biological N-fixation as well as grain production a

challenge. An open question is if the pathogen load of the cover crops can be influenced by the method and timing of the cover crop termination. In a two-year model crop rotation consisting of overwintering legume cover crops (CC) followed by maize in the first year and grain peas in the second year, the phytopathological risks of legume CC in minimum tillage systems were examined. CC were terminated either very early in spring in March, in late spring (May) or as control not at all (no maize) in the rotation. The pathogen load in the soil after maize was tested with peas as a model crop under field and controlled conditions. In the CC roots, by May, the load of *Didymella pinodella* was usually significantly higher than in March. Vetch favored *Fusarium culmorum* in the following maize, clover *F. avenaceum* independent of termination time. In the field, the following pea crops were mainly symptom free but with moderate incidences of *F. avenaceum* (40%) and *F. redolens* (30%). In the greenhouse, emergence of peas compared to sterile sand was reduced in all field soils but disease symptoms on the emerged peas were lower than in sand. Symptoms were slightly higher in soils where the CCs had been terminated late compared to early terminated CCs. but much less than in sterile sand.

UNDERLYING MONOCULTURE SOIL CONDITIONS CAUSES OF THE DURIAN PHYTOPHTHORA STEM CANKER ESCALATION

CHONG Sok Leng. (1), MOHAMED SIDIQUE Siti Nordahliawate. (1), MOHAMED NOR Nik Mohd Izham. (2)

(1) Research Interest Group (RIG) Biointeractions and Crop Health, Laboratory for Pest, Disease and Microbial Biotechnology (LAPDiM), Faculty of Fisheries and Food Science, Universiti Malaysia Terengganu, Kuala Terengganu, MALAYSIA; (2) School of Biological Sciences, Universiti Sains Malaysia, Penang, MALAYSIA

Text

The increased local demand and international export to China have caused rapid expansion of monoculture durian plantations. Consequently, durian stem canker escalation in Malaysia may occur without proper disease management strategies comprising both biotic and abiotic risk factors. This study aims to obtain the current disease status in Malaysia and to know soil conditions at various infected orchards. Each sampling plot (2500m^2) had been evaluated for stem canker disease incidence (DI) and disease severity index (DSI). Composite soil samples were collected for pH, texture (particle size) and nutrient availability. All eleven durian orchards were infected and most of the old orchards (≥10 years) DI was 77%. The orchard less than 10 years had the greatest DI (71%) and DSI almost 50% whereas 4 years orchard; 40% stem canker incidence and 16% DSI. The soil pH of both orchards 6.47 (<10 years) and 4.85 (4 years) and at the old orchards between 3.46 to 6.70. Most of the orchards were 80% of clay and silt that retain water. Also, a 2 years old durian orchard showed 2% DSI and 7% DI may risk of stem canker with 87% clay and silt. New durian orchards were relatively richer in nutrients than old orchards especially Ca, Mn and Zn. These soil conditions favour by Phytophthora pathogen during wet seasons could lead to escalation of stem canker particularly new durian area. Thus, this study will aid the agronomic practices i.e. irrigation and fertiliser to reduce stem canker infection.

ASSESSMENT OF DISEASE THREATS AND BIOFUNGICIDE EFFICACY IN WOOD SUBSTRATES

POLEATEWICH Anissa. (1), MICHAUD Isobel. (1), JACKSON Brian. (2), DEGENRING Liza. (1)

(1) University of New Hampshire, Durham, UNITED STATES; (2) North Carolina State University, Raleigh, UNITED STATES

Text

In greenhouse production, plants are grown in soilless growth substrates. For decades, peat moss has been the primary substrate for container-grown ornamental and some vegetable crops. Substrate manufacturers have identified wood byproducts to be some of the most promising alternative sources of raw materials for use in substrate formulations. Unfortunately, a change in substrate can be very disruptive to a grower's production system affecting everything from water to pest control. Our objective was to evaluate how wood components (1) affect severity of soilborne disease and (2) affect biopesticide efficacy. Wood components are manufactured in multiple ways with the three most common being hammer milled, twin-disc refined, and single or twin-screw extruded. In this study we evaluated the three differently processed WFs for natural suppression and biopesticide efficacy against damping-off on radish and crown and root rot on chrysanthemum caused by *Rhizoctonia solani*. Our findings provide evidence that the inclusion of wood components, regardless of blend ratio or type, does not impact severity of damping-off disease on radish and may lessen the effect of crown and root rot on chrysanthemum. We also found that blending of wood components with peat did not affect efficacy of *Trichoderma harzianum* T-22. Additional research is needed to determine if the trends we observed hold true for other plant species or other pathogens.

RESILIENT CIRCULAR GROWING MEDIA FOR THE FUTURE

GORTER Florien. (1), HOFMAN Marco. (1), GRIEKSPOOR Yvonne. (1), NIJHUIS Els. (1), RUSS Lina. (1), VAN DER WOLF Jan. (1), BLOK Chris. (1)

Text

Growing media used in horticulture currently largely consist of peat. Due to environmental concerns associated with peat use, there is a rising demand for alternative growing media. Alternatives often contain high proportions of organic materials such as coconut coir, wood fibers and compost, which are associated with increased microbial activity. However, it is unclear what the effect of such increased activity is on the growth and health of the plant. We are developing a reference method for assessing the quality of alternative growing media. To this end, we cultured birch, lavender, Pelargonium and chrysanthemum on one conventional and five alternative mixes of growing media components. We measured changes in physico-chemical properties, such as EC and elemental composition, of the growing media over time. We also determined changes in the bacterial and fungal microbiome using a combination of amplicon sequencing and metagenomics. Finally, we determined plant weight and asked which of the above properties (physical, chemical and/or microbiological) drove this measure. The developed method will be further optimized and used to determine the quality of

alternative growing media. Research was supported by Glastuinbouw NL (via foundation KIJK), RHP, LTO Vakgroep Bomen, Vaste Planten en Zomerbloeiers, Tree Centre Opheusden, Kekkilä BVB, Lensli, Legro, Jiffy and BVOR.

P3.4-018

EFFICIENCY OF BIOCOMPOST ON THE GROWTH OF TOMATO PLANTS AND INCIDENCE OF FUSARIUM WILT IN NURSERY

GORASHI Naiema. (1), MODAWI Hanan. (1), HASSAN Rania. (1), ABDELJABAR Ezzaldin. (1), ELNASIKH Maria. (1)

Text

Diseases affect productivity and quality of tomato, of which Fusarium wilt caused by Fusarium solani is considered one of important diseases of tomato in greenhouseand field. Syntheticpesticides used for disease management have known negative impacts and risks. In this regard, efforts are directed to ecofriendly, efficient sustainable tools. This study was conducted in a completely randomized block design in the nursery of Agriculture College, University of Bahri, Alkadaro. The objectives of this study are; To evaluate the effect of compost enriched with combinations of compatible isolates of Trichoderma harzianum Th and T. viride, TV with Bacillus thuringiensis Bt Wh-5 JX674041; B t St-6 JX841104, Paenibacillus papillae Pp Om-4 JX841101; Pp Ab-4 KC107788l and Lactobacillus sp. (R4) on seeds germination and other growth parameters. and on the incidence of Fusarium wilt disease of tomato. Tomato Seeds were sown directly into the treated soils and the control ones in plastic buckets in the nursery arranged in a randomized block design with 4 replications. Significant differences (P≤0.05) were existed between treatments in seeds germination, plant height, leaves, flowers and fruits numbers and disease incidence. It is concluded that, combination of microbial antagonist with compost is better solution for enhancing tomato growth and suppressing Fusarium wilt disease than using the compost alone or using chemical fertilizers. QFurthers studies are mandatory.

Text
Steaming of the soil is proposed as an alternative to synthetic chemical fumigants, but little is known concerning its effect on soil health and how to combine it with biocontrol agents (BCAs). We tested the effect of steaming on soilborne pathogens, soil health indicators and the colonization of the soil with BCAs. The pathogen systems under study were *Rhizoctonia solani* on lettuce, *Sclerotinia sclerotiorum* on chicory and *Pythium sylvaticum* on lamb's lettuce. Greenhouse experiments were set-up and soil samples were taken at several time points to measure following soil health indicators: (i) phospholipid-(derived) fatty acids to monitor the microbial biomass, (ii) hot-water extractable carbon to monitor the easily available carbon as a proxy for microbial biomass-C and (iii) DNA metabarcoding to monitor relative changes in microbial community. The BCAs were commercially available products based on *Trichoderma* spp. Steaming was highly efficient in killing the survival structures of the three pathogens. A similar or higher yield and plant health were observed for the following crop cultivations in the steam-treated plots as compared to the control. The effect of steaming on the soil health indicators and the survival of BCAs was depending on the experiment and the duration of the steaming. Moreover, steaming seems to improve the establishment of BCAs in the soil, probably due to the release of easily available carbon immediately after steaming.

P3.4-020

WILLOW CHIPS SUPPLEMENTATION IN SOIL ENHANCES RESISTANCE AGAINST POTATO LATE BLIGHT

RASTAS Marika. (1)

(1) Luonnonvarakeskus, Jokioinen, FINLAND

Text
Willows (Salix) have bioactive components, salicylates being the most characteristic compouds. Willow extracts are used as biostimulants and willow bark infusion is also listed as a basic substance in EU pesticide legislation against fungal diseases. Also, use of wood as soil amendments has been shown to promote the growth of saprophytic fungi and retain excess nitrogen. The aim of the study was to test the ability of willow chip supplementation in soil to increase the resistance against potato late blight pathogen *Phytophtora infestans*. The trial was conducted in greenhouse conditions. Fresh willow chips or dried willow bark was added to peat 6 % v/v. Infection rate was tested by inoculating leaf discs (cv. King Edward and Melody) with sporangia of *P. infestans.* Willow chip supplementation in soil caused no adverse effects on the crops in visual observation. With King Edward, after five weeks growing period, the average decrease in the infection rate was 7 % with fresh willow chips and 9 % with dry willow chips. With Melody, there were no differences between the treatments. When the growing period was seven weeks, the effect of the treatment was only minimal for both cultivars. It seems that, in the trial conditions, soil supplementation with willow chips increased resistance against potato late blight for a susceptible variety, but for a moderately susceptible variety Melody, there were no considerable effect.

P3.4-021

USING RNA-SEQ TO ASSESS THE META-TRANSCRIPTOME OF MICROBIOME OF FIELD CROPS

LI Leli. (3), RADHA SIVARAJAN Sajeevan. (1), GISEL Andreas . (2), **ALEXANDERSSON Erik. (1)**

(1) SLU, Lomma, SWEDEN; (2) IITA, Ibadan, NIGERIA; (3) Lund University, Lund, SWEDEN

Text

A better understanding of microbes living in the phyllosphere and rhizosphere of crops is important as they regulate aspects of plant performance, and can significantly improve crop yield and quality. The structure and diversity of the microbiota is influenced by the host as well as the growth environment.
Since there are many influencing factors determining the microbiome, a large amount of data needs to be analysed to determine the set of common microorganisms of certain crops have. A large body of data that remains relatively unexplored, and which could help us better understand plant-microbe interactions, are RNA-seq data obtained from different crops and environments.
In this study, the metatranscriptome was explored by analysing RNA-seq obtained from crops grown in field conditions, with potato and cassava as examples. After the removal of transcripts related to the crop genomes, meta-transcriptomics was performed using either unassembled short reads or assembled contigs.
We identified both previously characterised and novel microbes interacting with potato and cassava. For potato, there was a clear difference in the fungal microbiome based on growth site, irrespectively of genotype. In cassava roots, we found microbes varying depending on the carotenoid content of the root. In conclusion, we show that RNA-seq data provides an untapped resource to identify and better understand the microbiome of crops and that the microbiome is both site and genotype dependent.

P3.4-022

MONITORING THE PRESENCE OF ENTOMOPATHOGENIC NEMATODES IN MAIZE FIELDS: TOWARDS BIOLOGICAL CONTROL BY CONSERVATION BIOCONTROL

DEPUYDT Elisabeth. (1,2), OGIER Jean-Claude. (1), MAHIEU Patrice. (3), VILLENAVE Cécile. (4), **NGUEMA-ONA Eric. (2)**, GAUDRIAULT Sophie. (1)

Text

Biological control by conservation is based on the use of native organisms to manage the population of pests in fields, and contrast with biological control by augmentation (inoculation of exogenous organisms). However, the conservative approach in biological control requires a good description of the agents present. Entomopathogenic nematodes (EPNs) are ubiquitous since they are distributed in all continents except in Antarctica. In agricultural soils, they offer a high potential for crop protection against insect pest. The classical method used to detect EPNs in soils is the Galleria mellonella-baiting method. But this method allows to detect only 20-40% of EPNs present in soils.

The objective of this study is to compare several methods of EPN detection in order to describe the distribution of EPNs in agricultural soils. In this goal, we assumed that multi-method approach would allow to obtain the most accurate picture of the presence and diversity of EPNs in agricultural soils. We used two techniques of detection: multiple G. mellonella-baiting cycles to increase the efficiency of capture of EPNs in soils and an extraction of soil nematodes followed by morphological identification. Using these methods, we obtained 35% of positive plots instead of 14% with only the classical baiting method. We showed that the depletion trapping method and the extraction of soil nematodes increase both the number of EPN isolates and the EPN species diversity.

P3.4-023

RESPONSE OF THE SOIL MICROBIAL COMMUNITY, DRY ROOT ROT AND COMMON BEAN YIELD TO COVER CROPS IN A NO-TILLAGE FIELD.

LOPES FILHO Luiz. (2), BASÍLIO Juliana. (2), BARBOSA Elder. (1), TORMEN Nédio. (4), NUNES Rafael. (3), **LOBO Murillo. (1)**

Text

No-tillage and cover crops have been recommended to improve soil health in Brazilian intensive farming systems, but their effects on the soil microbiome need to be better understood. This work investigated in 2021 the metagenome of soil fungi and bacteria in a field experiment and their relation with common bean root rot severity and yield. Fall cover crops were grown from 2017 to 2021 after the summer cropping of soybean or maize and were succeeded by common beans in the winter, under center pivot irrigation. The cover crops consisted of millet, oat, Congo grass, oat, crotalaria and a mix of millet + crotalaria + fodder radish + buckwheat, while fallow plots served as a control. All plantings had the support of GPS RTK equipment, ensuring plot overlap and cumulative results. Rhizospheric 0-10 cm topsoil was sampled in triplicates during common bean flowering. The extracted DNA was subjected to metagenomic analysis according to the 16S and ITS gene sequencing, respectively, to identify which bacteria and fungi responded to the treatments. The cover crops affected 67 taxonomic groups ($p<0.05$). Oat, Congo grass and the cover crop mix recruited arbuscular mycorrhizal fungi (*Glomus* sp.), most Actinomycetes and plant growth-promoting bacteria. These favored common beans with higher yields, despite higher root lesions. Regardless of a lower root disease severity, fallow resulted in the lowest yields throughout the experiment and a poor environment for beneficial microorganisms.

P3.4-024

FORTIFICATION OF COMPOST WITH BIOAGENTS FOR GROWTH IMPROVEMENT AND SUPPRESSION OF WILT DISEASE ON CHICKPEA PLANTS

MUDAWI Hanan. (1), GORASHI Naiema. (1), ELNASIKH Maria. (1), ABDALLA Ishag. (2), IBRAHIM Essa. (2), MOHAMMED Rabab. (2)

Text

Fusarium wilt caused by *Fusarium solani* is the major constraints to Chickpea (*Cicer areitinum*) productivity in the Sudan. Fortifying compost with bioagents can manage pests and diseases, improve soil fertility and sustain productivity. Bioagents-fortified compost was assessed for its ability to control *F. solani* and increase chickpea. A greenhouse experiment was conducted using a randomized complete block design with four replications. Shandi cultivar was used for its susceptibility to Fusarium wilt and root rot disease. Treatments consist of not infected, infected controls, standalone compost and Trichoderma harzianum (Th) or T. viride (Tv) each solo mixed with compatible strains of *Bacillus thuringiensis* (OM4, Wh5, St6, and Ab4 strains) or Lactobacilli strain rb4. Well-matured compost was fortified with each microbial consortium before application. Control plants were given the recommended doses of fertilizers (urea and superphosphate). In the presence of *F. solani* as soil infection, treatments significantly (*P<0.05*) reduced the disease index (DI). The fortified compost with Tv mixed with *B. thuringiensis* strain Wh5 and Th mixed with *B. thuringiensis* strain St6, OM4 and Wh5 each alone, were the best in improving plant growth. Fortified compost with Th mixed with B. thuringiensis strain St6 suppressed disease development by 96% compared to control uninfected and standalone compost. Integrated disease management strategies may benefit from bioagents-fortified compost.

P3.4-025

BIOCHAR AMENDMENT WITH ALTERNATE WETTING-DRYING IN RICE FIELD: AN UNIQUE COMBINATION OF CROP DISEASE MANAGEMENT AND QUALITY ENHANCEMENT

MAJUMDAR Arnab. (1,2), DUBEY Pradeep Kumar. (3), UPADHYAY Munish Kumar. (4), GIRI Biswajit. (2), ROYCHOWDHURY Tarit. (1)

Text

Over a decade, sustainable and resilient soil amendments are proposed and biochar stands high in global acceptance (**1**). Several research has been carried out to show its potential in plant disease management and tolerance (**2, 3**), although its combination with another sustainable practice, alternate wetting and drying, has not been researched in terms of plant disease management and tolerance. Here we tried this unique combination to show how

efficient it can be in rice cultivation. The dry-wet cycle and biochar alone can reduce waterlog conditions and thus minimize water-borne pathogens, root-knot nematodes and other harmful microbes in the soil (**4, 5**). To suppress these disease-causing microbes furthermore, biochar amendment in the field at 1% (w/w) is highly efficient as proved by the rice plant stress-responsive enzyme assessments. Further metagenomics and high throughput sequencing showed the prominent difference in the microbial diversity where the disease-causing microbial community and root-knot nematode have been substantially minimized in the biochar-amended dry-wet fields with greater nutrients to promote plant health and tolerance. **1.** Majumdar, A, et al, 2023. IMPACT OF DIFFERENT TILLAGE SYSTEMS ON NET CARBON EXCHANGE RATES (NCER) AND WINTER WHEAT INFECTION A LONG-TERM STUDY

SAWINSKA Zuzanna. (1), BLECHARCZYK Andrzej. (1), RADZIKOWSKA-KUJAWSKA Dominika. (1), ?WITEK Stanis?aw. (1)

(1) Poznan University of Life Sciences, Poznan (Poznan-Jezyce), POLAND

Text

The research was conducted during the years 2021–2023, on the base of a long-term study established in 1998, at the Experimental Station Brody (52°26′ N; 16°18′ E), belon ging to the Pozna? University of Life Sciences. The purpose was to evaluate the impact of different tillage systems on net carbon exchange rates (NCER) and severity of plant infection by pathogenic fungi in whinter wheat. A randomized complete block design was set up with four replicates per treatment (conventional, strip till and no-tillage systems). The results demonstrated higher net carbon exchange rates (NCER), in flag leaf phase and no-tillage systems. Fusarium spp. and Gaeumannomyces graminis occurring on stem base s and roots were the main pathogens found in winter wheat. The incidence of stem base and roots was shown to increase under no-tillage in comparison with phloughing tillage system. Puccinia recondita and Septoria nodorum predominant on leaves. The conven-tional tillage increased the incidence of leaf diseases of winter wheat as related to theploughless tillage systems.

P3.4-027

IMPACT OF SOIL MANAGEMENT ON DISEASE SUPPRESSION OF SOIL BORNE PATHOGENS IN ARABLE FIELDS

POSTMA Joeke. (1), SCHILDER Mirjam. (1), VAN DE VOORDE Tess. (1)

(1) Wageningen University and Research, Wageningen, NETHERLANDS

Text

Enhanced soil suppressiveness against plant pathogens is a promising strategy to control diseases and crop losses. Improved management practices are developed, however, the

effect of soil management treatments on the level of suppressiveness is mostly unknown. To acquire this knowledge, samples from several field experiments comparing different soil treatments have been evaluated for soil suppressiveness.
Field soils were tested in pot experiments with garden cress and sugar beet by scoring the disease rate after artificial infection of the soils with respectively *Pythium ultimum* and *Rhizoctonia solani* AG2-2IIIB. These two pathogens are known to react differently on the biotic and abiotic factors in soil, being more or less conducive to general and specific suppressiveness. Pythium suppressiveness was in general enhanced by reduced tillage and the addition of several organic products. Rhizoctonia suppressiveness was not consistently influenced by tillage. And although chitin- and keratin-rich products stimulated Rhizoctonia suppressiveness in pot experiments, this effect could not be attained in field trials up to now. Nevertheless, Rhizoctonia suppressive soils did occur among arable fields of farmers, but how to create such suppressiveness is unclear. One of the factors involved could be the presence of the pathogen itself in the field being a precondition to evoke disease suppression, since Rhizoctonia decline is a well-documented phenomenon for several crops.

P3.4-028

CHITIN-FORTIFIED BLACK SOLDIER FLY COMPOSTED ORGANIC FERTILIZER AS AN EFFECTIVE TOOL FOR MANAGING POTATO CYST NEMATODES AND IMPROVING POTATO YIELDS

ANEDO Emmanuel Onyekwelu. (1), BENSON Mochoge. (1), NICHOLAS Korir. (1), BEESIGAMUKAMA Dennis. (1), HAUKELAND Solveig. (1), TANGA Chrysantus. (1)

(1) International Centre of Insect Physiology and Ecology, P.O. Box 30772-00100 Nairobi, Kenya, Nairobi, KENYA

Text

Soil degradation and nematode infestation are major challenges to potato production. Synthetic fertilizers and nematicides are costly, less effective, and harmful to the environment. This study explored the potential for use of chitin-fortified black soldier fly composted organic fertilizer (BSFCOF) as a multipurpose organic fertilizer for improved potato yield, and suppression of potato cyst nematodes under greenhouse conditions. The BSFCOF was applied at a rate equivalent to 150 kg N ha-1 and fortified with chitin from black soldier fly pupa exuviae at inclusion rates of 0, 0.5, 1, 2, 3, 4, and 5%. Potato growth, yield, cyst population, number of eggs/J2 g soil-1, and potato cyt nematode (PCN) reproduction rate were monitored. Results revealed that soil amendment with chitin-fortified BSFCOF significantly increased potato growth and yield compared to the control. The number of marketable tuber yields achieved using chitin-fortified BSFCOF was 63 – 169% higher than the control. Chitin-fortified BSFCOF caused a significant reduction in the cyst nematode population (37 – 87%) and the number of cyst eggs/J2 g soil-1 (50 – 96%) compared to the control. Potato yield and PCN suppression increased with an increase in chitin inclusion. Our findings demonstrate that chitin-fortified BSFCOF is a high-quality and multipurpose soil booster for improved soil health and PCN management.

Text

Low phosphorus (P) bioavailability in soils is a major constraint for optimal wheat growth. Because of high fixation rates of phosphates on surface soil minerals, phosphate fertilizer use-efficiency can be very low. Iron (Fe) oxides, including goethite, have a strong adsorption capacity and intensely influence the availability of phosphorus for wheat crop. When phosphorous deficiency occurs, wheat is more susceptible to diseases, such as Septoria tritici blotch caused by the hemibiotrophic fungus *Zymoseptoria tritici*. To acquire Fe, some plant growth promoting rhizobacteria produce siderophores, ligands with a high affinity and specificity for iron. The present study aims at deciphering the effect of goethite dissolution provoked by the siderophore isopyoverdine, from *Pseudomonas putida* BTP1, on the co-solubilization of phosphates, to enhance soil P availability and to activate the plant immune system of wheat against *Z. tritici*. The experiments were performed in the greenhouse using a hydroponic system and modified Hoagland medium containing no P or soluble Fe, but with the addition of goethite sorbed with phosphate ions and supplemented or not with isopyoverdine, inoculated or not with the pathogen. Growth traits, plant vigour, and plant defence makers, were assessed. The expected results will provide new knowledge on the valorisation of bacterial siderophores for crop health and nutrition.

SORGHUM-SUDANGRASS AS AN ORGANIC AMENDMENT IN ANAEROBIC SOIL DISINFESTATION DECREASES DISEASE SEVERITY AND PROMOTES PLANT VIGOR

OUMA Wilson. (1), DEE Mary. (1), BUTLER David . (1), SHRESTHA Utsala. (1), RICE John . (1), LITTRELL James. (1), OWNLEY Bonnie. (1)

(1) University of Tennessee, Knoxville, Tn , UNITED STATES

Text

Anaerobic Soil Disinfestation (ASD) is a non-chemical control used against soilborne pathogens. The technique uses organic amendments, soil saturation, and tarping to create an anaerobic environment for soilborne pathogens that reduces their survival. The choice of organic amendment used in the ASD procedure can make a difference in reduction of

Fusarium oxysporum (Fo) populations, and in plant health. Many studies on ASD have used wheat bran as the organic amendment for control of Fo, which has been only partially effective against Fo populations. In this study, we evaluated ASD with sorghum-sudangrass (SoSu) residue as the organic amendment and compared it to wheat bran. Soil treatments were ASD + wheat bran and ASD + SoSu. Controls were wheat bran and SoSu amendments, without ASD. Polyethylene mesh bags with 2 g Fo inocula were buried in 5-cm depth soil in pots. After 3 weeks of ASD treatment, Fo populations were assessed from the mesh bags. Strawberry plug transplants were planted in ASD and non-ASD treated soils in pots and evaluated for disease incidence and severity after 2 months. Fo populations were assessed from soil at 3 weeks after ASD treatment, and at 2 months after transplant with standard dilution plating. Plants in ASD + SoSu-treated soil exhibited greater vigor and less disease severity in comparison to plants in soil treated with ASD + wheat bran and control plants with no ASD. Our results suggest that SoSu as an organic amendment improves ASD efficacy.

P3.4-031

GRAPEVINES WITH ESCA SYMPTOMS HAVE LOWER OR HIGHER COLONIZATION BY NATIVE ARBUSCULAR MYCORRHIZAL FUNGI?

LANDI Lucia. (1), MUROLO Sergio. (1), ROMANAZZI Gianfranco. (1)

(1) Marche Polytechnic University, Ancona, ITALY

Text

The native arbuscular mycorrhizal fungi (AMF) community was investigated in vine roots affected by esca, a complex and devastating grapevine trunk disease. The AMF symbiosis was analysed on roots of adjacent plants (symptomatic and asymptomatic to esca) in 14 sites of three vineyards in Marche regions (Italy). The whole AMF community in the roots samples was investigated by light microscopy after non-vital staining and by amplicon sequencing of internal transcribed spacer of nuclear ribosomal DNA (ITS2). The non-vital staining identified higher value of AMF colonization, in all esca symptomatic plants (ranging from 24.6% to 61.3%) than neighbouring asymptomatic plants (from 17.4% to 57.6%). The largest number of operational taxonomic units (OTUs) associated to *Glomeromycota* phylum, related to the AMF species, was detected on roots from symptomatic plants (0.42%), compared to asymptomatic ones (0.29%). The native *Rhizophagus irregularis* and *Funneliformis mosseae* species quantified by droplet digital PCR (ddPCR) technology displayed a higher number of 28S rRNA gene of both fungal species more frequently in symptomatic than asymptomatic vines. This work showed that esca infection affect the AMF microbial community associated with roots and suggest an interaction of canopy symptoms with microorganisms inhabiting the rhizosphere.

P3.4-032

EFFECT OF COMPOST AND BIOCONTROL AGENTS ON LETTUCE AND TOMATO FUSARIUM WILTS AND ON RHIZOSPHERE MICROBIOME

PUGLIESE Massimo. (1)

(1) University of Torino, Grugliasco, ITALY

Text
Suppressive composts and biocontrol agents are considered among the alternatives to soil fumigants for controlling soil-borne pathogens. Different mechanisms of action are involved, including competition for space and nutrients, plant resistance induction, bioactive compounds, and direct parasitism. The objective of the present work is to summarize the results achieved by evaluating green composts and biocontrol agents (*Trichoderma* spp., *Bacillus amyloliquefaciens, Pseudomonas* sp.) efficacy against *Fusarium oxysporum* on lettuce and tomato, as well as the effect on the rhizosphere microbiome. Experimental trials were carried out in field conditions, by transplanting plants previously grown using potting substrate containing compost or applying the biocontrol agents in nursery. RT-qPCR and the next generation amplicon sequencing technologies were applied on rhizosphere samples. Composts and biocontrol agents reduced the diseases by 50-70%, compared to the untreated controls. Moreover, a reduction of the abundance of the soil-borne pathogens was observed in the treated soils. The abundance of beneficial microorganisms, such as *Bacillus* and *Trichoderma*, increased in the rhizosphere of plants treated. However, treatments did not affect the microbial diversity according to NGS. Compost and biocontrol agents can be used to reduce plant diseases caused by soil-borne pathogens, most probably improving the abundance of beneficial microorganisms and reducing that of pathogens.

Risk assessment for plant pathogens, a key tool for biosecurity under global changes

C3.2-1

AN OVERVIEW OF THE IPPC GLOBAL FRAMEWORK ON PEST RISK ANALYSIS INTERNATIONAL STANDARDS

MOREIRA Adriana. (1)

(1) FAO, Roma, ITALY

Text
It is known that the introduction and spread (or outbreak) of plant pests significantly affects food security, biodiversity and economic prosperity. A vast range of plant pests threaten global food production, the productivity and biodiversity of forests and the wild flora of the natural environment. The impacts of transboundary plant pests and diseases vary from region to region and from year to year. In some cases, they result in total loss of the crop. Globally, annual crop losses caused by plant pests are estimated at 20 to 40% of production (IPPC 2020). In terms of economic value, plant diseases alone cost the global economy around US$220 billion annually (Agrios, 2005) and invasive insects around US$70 billion (Bradshaw et al., 2016).

Preventing those pests spreading and establishing in new countries and regions is the aim of national plant protection organizations (NPPOs) and the International Plant Protection Convention (IPPC). And pest risk analysis (PRA) is a core process within the scope of the IPPC. With an increasing and more diversified trade, with structural and operational changes in the way NPPOs work, continuing developments in molecular biology and genetic sequencing, and the mitigation of climate-change related impacts on agriculture and plant health will present a major challenge to NPPOs and international organizations (IPPC Strategic Framework 2020-2030). In this scenario, the IPPC international standards global framework on pest risk analysis plays a more important role in preventing the introduction and spread of plant pests, while facilitating safe international trade.

Text

The emergence and spread of plant pathogens is an increasing problem, creating an important challenge for ensuring sustainable global agriculture. An urgent issue faced by the international plant health community is where to prioritize proactive phytosanitary responses. We address this problem by identifying priority locations based on geographic risk assessments of pathogen spread through cropland and trade networks of twelve crops key to global sustainability. Our analysis identifies locations having or connecting to croplands with large host populations, and countries with high imports or acting as trade intermediaries, which are likely high risks for pathogen spread. Globally, these locations are candidate priorities for epidemic surveillance. We then analyzed the geographic distribution and ecological niche of over 930 pathogen species affecting the twelve crops. Pathogen richness and community composition, which tend to group geographically into hotspots and distinct “epidemiological regions,” are multicausal phenomena, with the most important predictors in this analysis being cropland connectivity and climate variability. The low association between host range, temperature tolerance and mode of transmission indicate how a crop’s pathogen communities occupy diverse ecological niches, a challenge for the development of epidemic management strategies. These findings provide new components for designing global surveillance and mitigation strategies.

C3.2-3

THE APPROACH OF THE EUROPEAN AND MEDITERRANEAN PLANT PROTECTION ORGANIZATION (EPPO): FROM EARLY WARNING TO RISK MANAGEMENT

SUFFERT Muriel. (1), MUSOLIN Dmitrii. (1), PICARD Camille. (1), ROY Anne-Sophie. (1), TANNER Rob. (1), GRIMAULT Valérie. (1), PETTER Françoise. (1)

(1) EPPO, Paris, FRANCE

Text

One of EPPO's main priorities is to prevent the introduction of dangerous pests from other parts of the world, and to limit their spread within the EPPO region should they be introduced. The emergence of new pests has always been a challenge for the National Plant Protection Organizations. Based on horizon scanning, the EPPO Secretariat initiated the EPPO Alert List in 1999 to provide an early warning to its member countries on pests that may present a risk. In the EPPO Alert List, potential emerging risks are identified on a pest-based approach. A Pest Risk Analysis (PRA) is carried out for selected pests to evaluate in detail the risk for the EPPO region and to identify phytosanitary measures which can be taken against these pests. EPPO also has identified potential emerging risks on a commodity-based approach. Dedicated EPPO Expert Working Groups conduct PRAs on specific pests or groups of pests. PRAs are critically reviewed by different groups of experts. National or multi-national PRAs are also reviewed. Formal recommendations are made to EPPO member countries. Sharing information is essential and several databases have been established by EPPO including the Platform on PRAs. The EPPO approach to early warning and risk assessment and management will be illustrated in the context of global changes for plant pathogens (e.g. ToBRFV, Meloidogyne sp.)

C3.2-4

PRIORITIZATION OF INVASIVE ALIEN PESTS WITH THE POTENTIAL TO THREATEN AGRICULTURE, BIODIVERSITY, AND FORESTRY IN AFRICA THROUGH HORIZON SCANNING

MULEMA Joseph. (1), CHARLES Lucinda . (1), DAY Roger. (1), MAKALE Fernadis. (1), RWOMUSHANA Ivan . (1), KENIS Marc. (1)

(1) CABI, Nairobi, KENYA

Text

Sub-Saharan Africa (SSA) is at crossroads especially from attack by invasive alien species (IAS). A multitude of invasions that have significantly impacted economies, livelihoods, and biodiversity have been recorded. Although countries in SSA have weak border biosecurity systems, availing adequate and timely information on the highest risk species enables planning and implementation of sustainable management options that can avert some likely invasions. Such options include prevention through early detection, containment and eventual eradication where possible. Prevention is achieved through constricting pathways by reducing and limiting the means of entry, intercepting movements at border points, and assessing risk of planned imports. Horizon scanning provides an opportunity in generating such information. It is the systematic search for potential biological invasions and an assessment of their potential socio-economic impacts and potential impacts on biodiversity, considering possible opportunities for mitigating the impacts. CABI has developed a horizon scanning tool that utilises information from the Crop Protection Compendium to select pests that have been reported in other countries but not the countries at risk. The tool has been used to generate pests lists for assessment in Burundi, Ghana, Kenya, and Zambia. Actions such as detection surveillances, regulation, deregulation, pest-initiated Pest Risk Analysis have been suggested for the prioritised lists.

C3.2-5

COMMODITY RISK ASSESSMENT AS A TOOL TO IDENTIFY NEW PLANT PESTS: CHALLENGES, FUTURE PERSPECTIVES AND LINKS TO HORIZON SCANNING AND PEST RISK ASSESSMENT

KACZMAREK Agata. (1), MIKULOVA Alzbeta. (2), GARDI Ciro. (1), STREISSL Franz. (1), KARIAMPA Paraskevi. (1), ANTONIOU Alexia. (1), TRAMONTINI Sara. (1), STANCANELLI Giuseppe. (1)

Text

A key component of biosecurity is the early identification of the risks associated with a plant commodity to ensure its safe trade as well as to monitor the emergence of new potential threats. The European Food Safety Authority (EFSA) currently performs commodity risk assessment to support with scientific and technical evidence the phytosanitary decision-making process in the European Union (EU). Commodity risk assessment is conducted based on dossiers submitted by Third Countries for the so- called High Risk Plants commodities but also for derogation requests to particular provisions of the EU plant health law. Many plant pests not included in the EU legislation are identified each time a new commodity is assessed. These pests are evaluated for their presence in the exporting country, their association with the commodity and their potential impact in the EU. Pests for which there is insufficient information are further monitored through the EFSA Horizon Scanning activities. New plant pests identified as potential threats for the EU, by the commodity risk assessment as well as by the horizon scanning processes, undergo pest categorisations or, when needed, quantitative pest risk assessments. This presentation will summarise the challenges and future perspectives related to the early identification of new plant pests by commodity risk assessment and the links to the horizon scanning and pest risk assessment processes.

INTERDISCIPLINARY ANALYSIS AND MODELLING OF PLANT HEALTH THREATS TO SCOTLAND

BEBBER Daniel. (1), GURR Sarah. (1), KARLEY Alison. (2), LOZADA-ELLISON Luz-Maria. (2)

(1) University of Exeter, Exeter, UNITED KINGDOM; (2) James Hutton Institute, Dundee, UNITED KINGDOM

Text

We have taken an interdisciplinary approach combining biophysical modelling with social science methods to analyse the threat from emerging crop pests and pathogens (CPPs) to agriculture in Scotland. By building on horizon scanning research with agricultural stakeholders, we have co-constructed future scenarios of risks from CPPs, climate change, and socioeconomic factors. These scenarios are compared with a comprehensive biophysical modelling analysis based on CPP distribution data, climate projections, and trade

flows. Our results identify emerging CPPs of greatest interest, and highlight areas of agreement and disagreement between biophysical models and expert stakeholder opinion to identify knowledge gaps in focal CPP biology and other key parameters required for risk modelling. Areas of disagreement are highly instructive in improving models and in signposting potential threats which are not currently considered by stakeholders. Recent examples of invasive pathogens which were not expected to become problematic in the UK include the tree pathogen Phytophthora pluvialis and wheat stem rust (Puccinia graminis). We have conducted a multi-species analysis rather than focussing on one or a few CPPs, allowing us to draw wider conclusions regarding the application of interdisciplinary methods to pest risk assessment.

Text

Fusarium oxysporum (*Fo*) is a ubiquitous soilborne fungus that can cause Fusarium wilt (FW) in 100+ crops. Uncertainties in aspects of its epidemiology and a lack of global distribution data have historically challenged monitoring and containment efforts. Our NASA Interdisciplinary Sciences project seeks to address this need by integrating remote sensing, aerosol transport modeling, and comparative genomics to build a global disease surveillance system for FW incidence and *Fo* dispersal risk in aerosolized agricultural dust. As foundation, we released an interactive, global web map documenting 4500+ FW incidences reported in peer-reviewed literature. Here, we developed a global susceptibility assessment that integrates all three aspects of the disease triangle. We identified agricultural production zones conducive to FW, noting subsets capable of serving as dust sources, by overlapping the MODIS Deep Blue algorithm with a Landsat-based cropland product. We then restricted this assessment to only regions with reported *Fo* in the past 30 years. Conducive disease environment was modeled using multiple satellite-derived products with species distribution modeling. Results from this assessment along with aerosol transport modeling can inform how related incidence sites on opposite ends of dust events may be. This integrated approach to disease surveillance can provide key insights about drivers for current and future FW distribution and the spread of *Fo* on global dust currents.

P3.2-001

NUTRITIONAL MANAGEMENT AND PREDICTION OF TOMATO LEAF CURL VIRUS DISEASE

ZESHAN Muhammad Ahmad. (1)

(1) University of Sargodha, Sargodha, PAKISTAN

Text

Tomato leaf curl virus (TLCV) is a notable constraint for the cultivation of tomato worldwide. It causes 70-100% crop losses in case of severe attacks. Whitefly Bemisia tabaci (Genn.) transmits TLCV persistently and circulatively. As no viricides are available, different insecticides are commonly used for the management of TLCV disease. Frequent use of insecticides creates serious environmental issues and resistance in insects. In present study, plants were sprayed with aqueous solution of nutrients and salicylic acid as an eco-friendly approach for the management of TLCV. Furthermore, a disease predictive model was developed based upon environmental factors to find out the possibility of disease outbreaks. Predictive modelling is an efficient tool for accurate TLCV disease management. TLCV disease predictive model was formulated on the basis of weather variables through regression analysis. Nutrients and salicylic acid gave significant reduction in TLCV disease incidence i.e. 49% and 51%, respectively. A disease predictive model based on 2 years of ecological and meteorological data was formulated y= 0.541+ 0.049x1+0.91x2-0.079x3+0.11x4 R2= 0.85. This would aid the farmers to identify, assess and select appropriate disease management methods.

P3.2-002

ADAPTING TO THE PROJECTED EPIDEMICS OF FUSARIUM HEAD BLIGHT OF WHEAT IN KOREA UNDER CLIMATE CHANGE

JUNG Jin-Yong. (1), KIM Jin-Hee. (3), PAVAN Willingthon. (2), **KIM Kwang-Hyung. (1)**

(1) Seoul National University, Seoul, REPUBLIC OF KOREA; (2) International Fertilizer Development Center, Muscle Shoals, UNITED STATES; (3) National Center for Agro-Meteorology, Seoul, REPUBLIC OF KOREA

Text

Fusarium head blight (FHB) of wheat, mainly caused by *Fusarium graminearum*, is an emerging threat to wheat production in Korea under a changing climate. The disease occurrence and accumulation of associated mycotoxins in wheat kernels strongly coincide with warm and wet environments during flowering. In this study, we adopted GIBSIM, an existing mechanistic model developed in Brazil to estimate the infection risk of wheat FHB, to simulate the potential FHB epidemics in Korea using the 6th Coupled Model Intercomparison Project (CMIP6) climate change scenarios. An integrated modeling combining the results of wheat suitability, heading dates, and FHB infection risks from the CMIP6 scenarios showed a gradual increase in FHB epidemics towards 2100, with different temporal and spatial patterns of varying magnitudes depending on the scenarios. These results indicated that proactive management strategies are needed in the near future to minimize the potential impacts of the FHB epidemic in Korea. Therefore, available wheat cultivars with different heading dates, FHB resistance, market preference, and other characteristics were used in the model simulations as a potential and realistic adaptation measure. As a result, wheat cultivars with the combination of specific characteristics showed significant decreases in FHB epidemics in

future periods, emphasizing the importance of effective adaptation measures against the projected increase of FHB epidemics in Korea under climate change.

P3.2-003

A GENERIC PROCESS-BASED SIMULATION MODEL WITH TWO-WAY COUPLING OF EPIDEMICS AND CROP GROWTH

WILLOCQUET Laetitia. (1,2), SAVARY Serge. (2,3)

(1) INRAE, Biot, FRANCE; (2) GBPUAT, Pantnagar, INDIA; (3) UC Davis California, Davis, UNITED STATES

Text

Plant disease epidemiological models often simply account for the effect of crop growth through change in the carrying capacity of epidemics. Agrophysiological yield loss models incorporate effects of "pests" (pathogens, insect pests, and weeds), represented as time-dependent drivers, on physiological processes involved in crop growth according to damage mechanisms. Explicit two-way couplings of epidemiological and agrophysiological processes in dynamic simulation models are very rare. Here, we describe a generic, transparent, simple, model structure, with emphasis on polycyclic epidemics affecting the canopy of a crop. Simulated crop growth affects epidemics dynamics in altering the carrying capacity for epidemics. Simulated epidemics, in turn, affect crop growth through damage mechanisms incorporated in the agrophysiological model. The coupled model enables comparing dynamics for biotrophic and necrotrophic pathogens. Outputs from sensitivity analyses show the interplay between damage mechanisms (light stealer, accelerated leaf senescence, assimilate diversion) and their impact on crop growth, which in turn determines the carrying capacity for epidemics through a feedback loop. Potential uses and expansions of this modelling approach are outlined, including risk assessment under global and climate changes.

Text

The pine wilt disease (PWD) is the result of the success of three main events, inoculation of the pine wood nematode (PWN) to the host tree by the insect vector, *Monochamus galloprovincialis*, during its maturation feeding; multiplication of the nematode within the host tissues and development of the insect in the infested trees. Within this conceptual framework, we combined literature and expert knowledge to document the interactions between the nematode, its insect vector and 75 coniferous species.
We ended up with 5 categories of risk of development of PWD (1, no risk to 5, high risk). No pine species in Europe seems completely resistant to PWN, although some species are less favorable to the multiplication of the PWN. In case of an epidemic, the risk of spread of the disease is then directly related to the ability of the insect vector to transmit the nematode from tree to tree. It is recommended that priority be given to eliminating the pine species on which *M. galloprovincialis* is able to complete its life cycle, i.e., with certainty those of category 5 (*P. pinaster*, *P. sylvestris*, *P. nigra* and *P. radiata*) and probably those of category 4 (*P. halepensis* and *P. taeda*). However, for *P. taeda*, uncertainties remain in the literature, both regarding the multiplication of the nematode, the expression of wilt symptoms and the ability of the insect to feed and reproduce on this species. In particular, it cannot be excluded that *P. taeda* acts as a 'healthy carrier' of the disease.

P3.2-005

PEST RISK ANALYSIS, AN EFFECTIVE TOOL TO ENHANCE CRISIS PREPAREDNESS TOWARDS EMERGING PESTS: THE CASE OF TOBRFV IN FRANCE

TAYEH Christine. (1), GENTIT Pascal. (1), STEYER Stéphan. (3), WETZEL Thierry. (4), VERDIN Eric. (2)

Text
In 2019, Anses (French Agency for Food, Environmental and Occupational Health & Safety) was aware of an alert concerning an emerging tomato virus: tomato brown rugose fruit virus (ToBRFV) and initiated an express pest risk analysis of ToBRFV for France. The probabilities of entry, establishment and spread of ToBRFV in France were evaluated and scored as high. The magnitude of the impact of ToBRFV in the area of potential establishment in France was also estimated as high, especially in the endangered area. The latter include areas of large-scale production of tomatoes (in protected conditions and open-field), as well as areas of pepper production. Several phytosanitary measures were recommended. If infected plants are reported in a production unit, eradication was recommended by taking immediate action to destroy all the plants and fruits, coupled with strict hygiene measures including a crop-free period. Based on these recommendations, the French Ministry of Agriculture immediately issued technical instructions for professionals to be applied against ToBRFV. This pest risk analysis performed by ANSES, together with the development of a detection method of ToBRFV by the National Reference Laboratory, and the implementation of quick and drastic measures to eradicate the first outbreak in Brittany by the risk manager, allowed a successful management of the epidemic of ToBRFV in 2020. Today, ToBRFV is considered as transient in France, with only one outbreak under eradication.

P3.2-006

THE RISK ASSESSMENT OF SHARP EYESPOT CAUSED BY CERATOBASIDIUM CEREALE ON CEREALS IN KOREA

JEONG Min-Hye. (1), JANG Seol-Hwa. (1), JO Miju. (1), AN Sunmin. (1), PARK Jiyoon. (1), PARK Jiwon. (1), KIM Seoyeon. (1), **PARK Sook-Young. (1)**

(1) Sunchon National University, Suncheon, REPUBLIC OF KOREA

Text

Cereals including barley (Hordeum vulgare L.), wheat (Triticum turgidum), and oat (Avena sativa) are major winter crops in Korea. The level of the total production of cereals is not sufficient. Furthermore, climate change is increasing the threat of fungal disease in the cereals as well as newly emerged pathogens. One fungal disease is sharp eyespot disease. The fungal disease is caused by Ceratobasidium cereale. In this study, we collected fungal isolates and assessed the risk of the disease according to the effect of temperature and humidity. To identify fungal disease, the internal transcribed spacer (ITS) region of the ribosomal DNA was amplified using the primer pairs ITS4/5, producing a 686 bp amplicon. Their sequences showed 99.7% identity to that of C. cereale strain WK137-56 (99.7%; KY379365) and Ceratobasidium sp. AG-D (99.8%; KP171639). Maximum likelihood phylogenetic analysis based on the ITS sequences placed the representative isolates within a clade comprising C. cereale. As a result of examining the optimal growth conditions, the fungus can grow in the range of 10 to 25? with pH 6-7 on a PDA medium and showed the highest growth at 20-25?. Moreover, in the temperature-dependent pathogenicity test, C. cereals showed the highest level of pathogenicity in the crops at 20?. Further studies will be displayed. [This work was supported by a grant from the Rural Development Administration (PJ0149952023).]

P3.2-007

THE EPPO PLATFORM ON PEST RISK ANALYSIS, A HUB FOR RISK ASSESSMENTS OF PLANT PATHOGENS

SUFFERT Muriel. (1), GRIESSINGER Damien. (1)

(1) EPPO, Paris, FRANCE

Text

The EPPO Platform on Pest Risk Analysis (https://pra.eppo.int/) was launched in September 2018. It allows to share work done on the evaluation of pest risk within the EPPO region and beyond. It includes Pest Risk Analyses (PRAs) produced by national plant protection organizations of countries in the European and Mediterranean region. Documents cover all types of organisms harmful to plants including pathogens, as well as commodity risk assessments. PRAs are prepared for different reasons: for example when a pathogen is intercepted on imported commodities or found during official surveillance activities, to assess the risk of a specific traded commodity, or before allowing the import of pathogens for research purpose. Sharing assessments done in one country may help identify emerging plant pathogens. Checking existing PRAs is a useful first step when preparing a new

assessment. It may help reducing the workload e.g. to produce a risk assessment for the same pest in another area.
The Database is regularly updated with new documents being posted. As of February 2023, more than 1900 documents are available. A number of relevant open access scientific articles are also included. Most of the documents are publicly available but registered users may also choose to share documents to a defined group of users to help collaboration at an early stage. Documents are indexed and can be retrieved by pest or commodity of concern, date, country, as well as with keywords.

P3.2-008

THE EPPO ALERT LIST, A TOOL TO RAISE AWARENESS ON EMERGING PESTS IN THE EPPO REGION

SUFFERT Muriel. (1), ROY Anne-Sophie. (1)

(1) EPPO, Paris, FRANCE

Text
New plant pests and invasive plants with negative impacts on food security and the environment are regularly reported. Some of these emerging species are new to science, while many others have been introduced into new areas where they become damaging. Early warning is crucial to allow rapid action against emerging pests and invasive plants. The emergence of new pests has always been a challenge for the National Plant Protection Organizations (NPPOs). At the request of its member countries, the EPPO Secretariat started to develop the EPPO Alert List in 1999. This list of pests, pathogens and invasive alien plants has two aims:
- to draw the attention of EPPO member countries to certain organisms possibly presenting a risk to them and achieve early warning,
- to identify possible candidates for Pest Risk Analysis.
The poster will present the triggers to support addition to the Alert List, the information gathered to support this addition and the general maintenance to keep the Alert List focused and relevant. The Alert List is available on EPPO website https://www.eppo.int/ACTIVITIES/plant_quarantine/alert_list. When pests are added to the Alert List, this is marked by an article in the EPPO Reporting Service (4500 readers), as well as by publications on social media. The objective is to raise awareness among different audiences (e.g. scientists, NPPOs, professional operators, general public).

P3.2-009

DISTRIBUTION AND DIVERSITY OF ABACA BUNCHY TOP VIRUS AND BANANA BUNCHY TOP VIRUS CAUSING BUNCHY TOP OF ABACA IN CARAGA, PHILIPPINES

RIVAREZ Mark Paul. (1,2), PORRAS Jezmeir. (1), MAGADAN Cristal Mae. (1), GAGULA Arnaldo. (1), BORINES Rezel. (1), **PARAC Elizabeth. (1)**

(1) CARAGA STATE UNIVERSITY, Butuan City, PHILIPPINES; (2) NORTH CAROLINA STATE UNIVERSITY, Raleigh, UNITED STATES

Text

The Philippines contributes more than 80% to the world production of abaca (*Musa textilis*) fiber or 'Manila hemp' that is used in various industrial products. However, abaca industry growth is significantly hampered by the bunchy top disease (BTD) caused by abaca bunchy top virus (ABTV) and banana bunchy top virus (BBTV). Herewith, we surveyed major abaca plantations in Caraga region, Philippines using mapping tools complemented with molecular diagnostics, to generate a distribution map for the incidence of abaca BTD. We showed that BTD is present in all Caraga provinces where a total of 395 samples were collected. A subset (n=120) were tested for ABTV/BBTV using duplex PCR tests where 84 samples were positive for BBTV and 66 samples for ABTV. Interestingly, there is a high rate of ABTV/BBTV co-infection, where 49 samples (41%) tested positive for both viruses. Diversity analyses revealed moderate levels of nucleotide diversity for both viruses with evidence of recombination and phylogenetic lineages showed correspondence with the geographic origin of the global isolates. Furthermore, data from PCR tests were used for the MaxEnt analyses that provided predictive insights on the possible spread of the disease in the region. Overall, we contributed novel information on the distribution and diversity of ABTV and BBTV. By using predictive analyses, we advanced of the understanding of the epidemiology of abaca bunchy top disease in a major growing region of the Philippines.

P3.2-011

AUSTRALIAN PLANT BIOSECURITY

AZZOPARDI Stacey. (1), WALKER James. (2), COLLINS Susie. (2)

(1) Department of Agriculture, Fisheries and Forestry, Mascot, AUSTRALIA; (2) Department of Agriculture, Fisheries and Forestry, Canberra, AUSTRALIA

Text

Australia's biosecurity system helps prevent, detect and manage exotic invasive pests that threaten agriculture and natural ecosystems.

Targeted pest lists strengthen agricultural and environmental biosecurity. There are 27 priority plant pathogens targeted by monitoring, surveillance and diagnostic activities across the Australian borders and post-border by ?governments, industry, and the community. Surveillance is conducted by trained officers and aided using innovative methods including remote sensing and drones?, hyperspectral cameras, suction traps, eDNA sampling and lures.

Diagnostic laboratories receive plant samples and insect specimens for testing, from monitoring, surveillance and inspection activities. The diagnosticians in these laboratories identify pests and diagnose diseases though microscopy, high throughput sequencing and spectrophotometry to stop pests of biosecurity concern from entering and establishing in Australia.

The surveillance and diagnostic techniques used by scientists delivering Australian biosecurity and the tools and systems supporting these activities enables our capable workforce to operate competently and consistently while working in an effective, safe, modern and efficient diagnostic system.

This paper demonstrates how continuously enhancing diagnostic capability and capacity has resulted in greater accuracy, identification of intercepted pathogens to higher taxonomic

levels and greater confidence in Australian plant biosecurity outcomes.

WHEN FINDING A SOLUTION IS NOT SUFFICIENT: ECONOMIC VIABILITY OF CITRUS DISEASE MANAGEMENT AND THE ROLE OF EXTREME ENVIRONMENTAL FACTORS

AL ABRI Ibtisam. (1), AL SADI Abdullah. (1), GROGAN Kelly. (2)

(1) Sultan Qaboos University, Al-Khod, OMAN; (2) University of Florida, Gainesville, UNITED STATES

Text

Countries located in arid and semi-arid regions in the world do not only face constraints due to the limited availability of arable lands, but major crops in these countries are continuously attacked by destructive diseases like Witches' broom disease of lime (WBDL). In Oman, more than one million lime trees were damaged due to WBDL. Consequently, Omani lime production and cultivated area have declined over the past two decades by 75%. Several studies have been carried out to address the citrus disease in crop science, very few, and non in the case of Oman, have addressed the economic loss associated with the disease risk or economic gain resulting from disease management strategies. Given these and the lack of a detailed and thorough economic analysis of possible environmental factors that may influence the occurrence and spread of WBDL, the first objective of this study is to derive a bioeconomic model to simultaneously determine optimal disease treatment timing, frequency, and level to optimize tree value and inform growers about best practices to mitigate the risk associated with citrus diseases. This study also aims to investigate environmental factors that affect the occurrence and spread of citrus diseases and present comparisons between infected and non-infected trees. This would help government agencies develop more effective educational and treatment programs in order to align governmental interests and farmers' interests to maximize citrus profit and economic value.

P3.2-013

IDENTIFYING PRIORITY QUARANTINE PESTS BASED ON ASSESSING THEIR ECONOMIC, SOCIAL AND ENVIRONMENTAL RISKS

SANCHEZ Berta. (1), BARREIRO HURLE Jesus. (1), **RODRIGUEZ-CEREZO Emilio. (1)**

(1) European Commission-JRC, Sevilla, SPAIN

Text

The world is witnessing an increased number of plant pests' outbreaks driven by both globalization of trade and effects of climate change. With scarce resources, setting up systematic controls for all potential pests would become inefficient and extremely expensive. Therefore, efforts should be prioritised on those pests with higher risk of having economic,

environmental and social impacts in the EU. In this spirit, the new EU Plant Health Law (PHL) [Regulation (EU) 2016/2031] calls for the identification of quarantine pests that qualify as "priority pests". Priority pests identified as such will have to be the of subject of annual surveys, contingency plans, simulation exercises, and designed action plans at national level.
We have developed a composite index that translates the legislative criteria defining a priority pest into measurable indicators. The composite index has 25 indicators combining both quantitative and qualitative data. These are grouped into 3 domains and 10 sub-domains to cover the most important potential economic, social and environmental impacts. We have applied it to an initial list of 28 quarantine pests in a scenario of pests' maximum potential spread across the EU. The methodology adds to the normally neglected aera of research on economic and social risk assessment of pests. The indicator has been used to derive the first official list of EU priorty pests published in 2020.

FIG MOSAIC DISEASE IN TUSCANY (ITALY): MOLECULAR CHARACTERIZATION AND INVESTIGATION OF VIRUS-HOST INTERACTION

PEDRELLI Athos. (1), NALI Cristina. (1), PANATTONI Alessandra. (1), PELLEGRINI Elisa. (1), COTROZZI Lorenzo. (1)

(1) University of Pisa - Department of Agriculture, Food and Environment, Pisa, ITALY

Text

Fig mosaic disease (FMD) represents the main threat to global fig production. It has been associated to several viruses and viroids, but only *Fig mosaic virus* (FMV) has been identified as etiological agent. Here, 15 fig trees 'Dottato' were investigated in Tuscany (Central Italy). In February 2022, winter branches were sampled. On July, as leaf visible symptoms occurred in 14 trees, fully developed symptomatic and asymptomatic leaves were collected. Among the FMD-associated viruses we tested, only *Fig fleck-associated virus* (FFKaV) was identified in branches (73% of samples). Differently, not only FFKaV, but also FMV was reported in both symptomatic and asymptomatic leaves (93 and 63% of samples, respectively), with all 15 and 14 trees tested positive to FMV and FFKaV, respectively. FMV amplicons provided nucleotide sequences corresponding to partial RdRp genomic region, among which three new variants (GenBank: OQ291242, OQ291243, and OQ291244). The FMV phylogenetic analysis showed low bootstrap values, and the new variants resulted near to their closest counterparts at GenBank. Investigation of phytopathological responses showed an FMV-induced reduction of carbon dioxide assimilation due to stomatal and no-stomatal limitations, as well as of leaf pigment concentrations. Harsher effects were reported in positive symptomatic leaves, but alterations occurred also in positive asymptomatic ones. This study represents the first investigation of FMD in Central Italy.

P3.2-015

A spatio-temporal database of first introductions of plant pests in the EU

ROSACE Maria-Chiara. (1), CENDOYA Martina. (2), MATTION Giulia. (1), BATTISTI Andrea. (3), CAVALETTO Giacomo. (3), MARINI Lorenzo. (3), VICENT Antonio. (2), ROSSI Vittorio. (1)

(1) Università Cattolica del Sacro Cuore, Piacenza, ITALY; (2) Instituto Valenciano de Investigaciones Agrarias (IVIA), Valencia, SPAIN; (3) University of Padua, Viale Dell'Università, Legnaro, ITALY

Text

World trade of plants and plant products has highly increased in the last decades, together with a higher risk of introduction of new pests, including bacteria, fungi, viruses and arthropods. Identifying plant pests' introduction points in the European Union (EU) territory may offer some insights for early detection to prevent new plant pest invasions as well as supporting the surveillance and risk assessment activities carried out in the EU. A key challenge in analysing patterns of pests' introductions is the frequently limited historical record with data on the time and location of the appearance of new species in certain countries. As part of the HoPPI (Hotspot for Plant Pest Introduction) project, data were collected on plant pest first introduction records along the EU between 1999 and 2019, drawing upon a range of published literature and online databases, such as EASIN and EPPO, in order to determine pests' introduction trend over the years and spatial aggregation among EU regions. The database contains expert-revised data on 278 pests: it is estimated that on average around 10 new pests are detected within the EU territory each year, and in some years, there are as many as 25 introductions of new pests. Some of the most high-profile cases included, comprehend the insidious bacterium Xylella fastidiosa, causing serious diseases in a wide range of plants around the world, the fungus Fusarium circinatum, considered one of the most important pathogens of conifers worldwide, or the Pepino mosaic virus, which can cause severe yield losses and reduced fruit quality in affected crops.

DISEASE SYSTEMS ANALYSIS FOR PROTECTING GLOBAL FOOD SECURITY: AN INTRODUCTION TO THE R2M TOOLBOX

ETHERTON Berea. (1,2,3), MOUAFO TCHINDA Romaric . (1,2,3), PLEX SULÁ Aaron. (1,2,3), CHOUDHARY Manoj. (1,2,3), KRAISITUDOMSOOK Nattapol. (1,2,3), ADHIKARI Ashish. (1,2,3), GARRETT Karen. (1,2,3)

(1) University of Florida Plant Pathology Department, Gainesville, UNITED STATES; (2) University of Florida Global Food Systems Institute , Gainesville , UNITED STATES; (3) University of Florida Emerging Pathogens Institute, Gainesville, UNITED STATES

Text

Epidemic modeling and forecasting are key to improving global food systems. As food security is challenged by pest and pathogen invasions, natural and manmade cataclysms, and climate change, digital agriculture can support informed decision making and mitigate the impacts of disasters. Digital agriculture uses farm and disease models to provide decision support about potential epidemic outbreaks. Here we describe three computational tools in the Rapid Risk and Mitigation (R2M) toolbox for agricultural stakeholders and policy makers, to support the mitigation of diseases and pests. i) Impact network analysis (INA) is a scenario analysis framework, designed to simulate epidemic and socioeconomic networks and to identify strategies for regional disease management. ii) GeoPathome is an interactive web data scraper, informing users about the geographic distribution of pests and pathogens

and the potential for invasions through international trade. iii) The R2M meta-tool for expert knowledge elicitation is an interactive interface that generates a survey for experts based on a curated set of disease-risk questions. These three tools use R, an open-source language, to harness observed or speculative data to help agricultural stakeholders streamline data collection and scenario analyses of potential disease outbreaks. Effective use of these disease modeling and risk analysis tools will support disease management for a more secure and sustainable future for food systems.

P3.2-017

ESTIMATION OF TYLENCHULUS SEMIPENETRANS POPULATION ON DIFFERENT CITRUS VARIETIES GROWN IN THE NATIONAL AGRICULTURAL RESEARCH CENTER, ISLAMABAD, PAKISTAN

MUHAMMAD Sohail. (1), TARIQ Mukhtar. (1), SHAHID AHMED Khanzada. (2)

(1) PMAS Arid Agriculture University, Rawalpindi, Rawalpindi, PAKISTAN; (2) National Agricultural Research Center (NARC), Islamabad, PAKISTAN

Text

Citrus is an important agricultural fruit crop. Pakistan holds a leading position in citrus production, with a production area of 204.4 thousand hectares. Tylenchulus semipenetrans is an important and widespread plant-parasitic nematode that affects citrus worldwide and can cause citrus slow decline disease in all citrus growing areas of Pakistan. A study was conducted to determine the nematode population on six different citrus varieties: Arnold blood (Carrizo), Cara Cara (Troyer), Daisy Manadarin (Troyer), Mc Mahon (Carrizo), Ryan Navel (Carrizo), and Salustiana (Troyer), grown in orchards of the National Agricultural Research Center, Islamabad. Nematodes were extracted from soil and roots of 10-year-old citrus plants using Hemming's Tray method. The quantitative data for nematode population in 100ml of soil sample for each plant was calculated. The study revealed that the majority of the extracted nematodes were T. semipenetrans based on their peculiar morphological characteristics. The maximum nematode population was observed in Arnold blood, followed by Daisy Manadarin, Cara Cara, Ryan Navel, Mc Mahon, and Salustiana, while the minimum nematode population was observed in Harvard blood. This information is important for citrus growers in Pakistan, as citrus slow decline disease can significantly reduce citrus production. Therefore, appropriate measures should be taken to manage the nematode population, prevent the disease, and maintain healthy citrus orchards.

P3.2-020

VIRUS DISEASES OF VEGETABLES IN MALI AND NORTHERN COTE D`IVOIRE, WEST AFRICA

WUBETU BIHON Legesse. (1), CHAN Yuan-Li. (2), KENYON Lawrence. (2), RAMASAMY Srinivasan. (2)

(1) World Vegetable Center, Eastern and Southern Africa, Addis Ababa, ETHIOPIA; (2) World Vegetable Center, PO Box 42, Shanhua Tainan 74199, Shanhua, TAIWAN

Text
Virus disease is among the major constraint to vegetables production in sub-Saharan Africa including Mali and cote d`Ivoire. Vegetable diseases caused by geminiviruses and more specifically species under the genera begomovirus are among the major production constraints. To assess what were the predominant and emerging virus diseases of major vegetables in Mali and northern Cote d`Ivoire, a field survey was conducted during the major vegetable growing seasons. Virus like disease samples from tomato, pepper, okra and African eggplant were collected and the virus(es) present in each was diagnosed by ELISA and PCR. The survey and diagnosis analysis using PCR amplification of Begomovirus universal primers and ELISA analysis identified several viruses in both countries. In Mali of the 12 okra samples tested, 11 were positive to Geminiviruses and from 29 pepper samples 16 were positive using PCR amplification. Moreover, ELISA test detected 3 PMV, 1 PMMV, 3 WSMOV and 5 PoTV viruses from 11 plants tested. In the northern Cote d`Ivoire both the ELISA and PCR test identified pepper yellow vein Mali virus, African eggplant yellowing virus, pepper veinal mottle virus, Capsicum chlorosis virus and tomato chlorosis virus. The presence of these viral diseases in vegetables at different levels of frequencies calls an attention to develop virus resistant varieties.

P3.2-021

BUILDING GLOBAL SURVEILLANCE AND MITIGATION STRATEGIES FOR LAUREL WILT

MOUAFO-TCHINDA Romaric A.. (1,2,3), PLEX SULÁ Aaron I.. (1,2,3), ETHERTON Berea A.. (1,2,3), CHOUDHARY Manoj. (1,2,3), CHOUDHURY Robin A.. (1,2,3,4), GAZIS Romina. (1,5), CRANE Jonathan. (5), GARRETT Karen A.. (1,2,3)

(1) Plant Pathology Department, University of Florida, Gainesville, Fl, Usa, UNITED STATES; (2) Food Systems Institute, University of Florida, Gainesville, Fl, Usa, UNITED STATES; (3) Emerging Pathogens Institute, University of Florida, Gainesville, Fl, Usa, UNITED STATES; (4) University of Texas, Rio Grande Valley, Tx, Usa, UNITED STATES; (5) Tropical Research and Education Center, University of Florida, Homestead, Fl, Usa, UNITED STATES

Text
Laurel wilt, caused by the fungus *Harringtonia lauricola* and vectored by ambrosia beetles, is a devastating disease of avocado and many species in the Lauraceae. Laurel wilt is not yet present in all regions where Lauraceae are present, including some important avocado production regions. We evaluated which locations are particularly useful for surveillance and mitigation to slow the future spread of laurel wilt and to warn areas that are at particular risk to prepare management strategies. We analyze global wood trade, Lauraceae host connectivity, and climate suitability to identify candidate priority locations for early surveillance of laurel wilt. Analysis of the international wood trade network showed that disease-free countries such as Mexico, Brazil, and Australia have multiple trade links to countries with laurel wilt. Potential epidemic networks were based on maps of host landscape connectivity for Lauraceae and cultivated avocado. For avocado, locations in southern Mexico and Central America were important locations to monitor for laurel wilt, while for the Lauraceae, locations in Amazonia, and western Europe were important. Maps of global climate suitability for laurel wilt identify locations with current and future climate suitable for the establishment of laurel wilt, including locations in southern Brazil, southeastern China, and eastern Australia. These results can inform regional, national, and global monitoring and mitigation strategies for laurel wilt.

P3.2-022

RISK ANALYSIS OF THE CUT FLOWER TRADE AND GEOGRAPHIC HOTSPOTS TO PROTECT GLOBAL AGRICULTURE FROM INVASIVE PESTS AND PATHOGENS

CHOUDHARY Manoj. (1,2,3), PLEX SULÁ Aaron Isaí . (1,2,3), PENCA Cory. (4), MENDOZA Laurent C. Lagos . (1,2,3), MOUAFO-TCHINDA Romaric Armel . (1,2,3), ETHERTON Berea A. . (1,2,3), GARRETT Karen A.. (1,2,3)

(1) Department of Plant Pathology, University of Florida, Gainsville, UNITED STATES; (2) Global Food Systems Institute, University of Florida, Gainsville, UNITED STATES; (3) Emerging Pathogens Institute, University of Florida, Gainesville, UNITED STATES; (4) USDA-APHIS, Raleigh, UNITED STATES

Text

The international trade of cut flowers reached $21.3 billion in 2021, growing 28% in the last decade. Most cut flowers are traded fresh with limited sanitation options available, increasing the risk of pest and pathogen introductions. High rates of invasive pests have been found in inspected cut flowers, and rates are expected to increase with growth in international trade. Strategies for early surveillance and detection for pests and pathogens are needed. Here, we analyzed formal international trade and the geographical distribution of pests and pathogens associated with cut flowers to identify candidate priorities for surveillance locations. Trade networks highlight the risk posed to the USA, the largest importer (20%), and the Netherlands, exporting more than half of global cut flowers, as well as other countries. In the absence of adequate phytosanitary measures, the role of Uganda and the Netherlands in trade networks for rose planting materials could pose a risk for dissemination of associated pests and pathogens. Similarly, in the absence of adequate phytosanitary measures, the role of the Netherlands and Colombia in chrysanthemum flower trade networks could pose a risk for introduction of chrysanthemum white rust, a quarantine pathogen in the USA. These network-based analyses can guide phytosanitary measure prioritization globally for effective use of resources to protect agriculture from invasive pests and pathogens.

P3.2-023

QUICK ASSESSMENTS OF THE POTENTIAL FOR ESTABLISHMENT OF QUARANTINE PESTS IN SWEDEN

BOBERG Johanna. (1), BJÖRKLUND Niklas. (1)

(1) Swedish University of Agricultural Sciences, Uppsala, SWEDEN

Text

The environmental conditions and availability of plant hosts in a country greatly influence the potential for establishment of new plant pests and have important implications for their management. In the EU, regular surveys for all union quarantine pests shall be carried out on a regular basis in all member states according to the plant health regulation ((EU) 2016/2031)). However, surveys are not required if the ecoclimatic conditions or the absence of hosts prevents the establishment or spread of the pest. For some quarantine pests it is

uncertain whether the ecoclimatic conditions or host availability in Sweden allow an establishment. Quick assessments of the degree to which the conditions are suitable for the establishment were performed for 82 quarantine pests to support management decisions by the Swedish National Plant Protection Organization. Depending on the biology of the pest species, different factors affect the potential for population development and the uncertainties associated with the assessments. The assessments were based on the likelihood of the pests to survive and reproduce in Sweden both outdoors and in protected cultivation. The following factors were considered i) the presence of host plants, ii) the presence, or potential establishment, of vectors if required for transmission of pathogens and iii) the prevailing ecoclimatic conditions. Assessments were done using a four-level scale and the uncertainty was included as plausible min and max options.

P3.2-024

BACTERIAL LEAF STREAK OF MAIZE CAUSED BY XANTHOMONAS VASICOLA PV. VASCULORUM, A DISEASE THAT MIGHT THREATEN EUROPEAN MAIZE PRODUCTION

ASPIN Andrew. (1), VICENTE Joana. (1), HAYNES Edward. (1), CARTER Brian. (1), BRYNING Adam. (1), COLE Jennifer. (1), CARROLL Sarah. (1), KENNEDY Marc. (1), SMITH Julian. (2), STUDHOLME David. (3), MURRAY Grant. (4)

(1) Fera Science Ltd., Sand Hutton, UNITED KINGDOM; (2) Rothamsted Research, Harpenden, UNITED KINGDOM; (3) College of Life and Environmental Sciences, University of Exeter, Exeter, UNITED KINGDOM; (4) The School of Life Sciences, University of Warwick, Coventry, UNITED KINGDOM

Text

Plant diseases caused by *Xanthomonas* species affect many different crops worldwide. The species *Xanthomonas vasicola* currently includes four pathovars: *arecae*, *musacearum*, *vasculorum* (Xvv), and *holcicola* (Xvh). Of these only Xvh has a validly published name, although the others have been proposed.

Maize (*Zea mays*) is the most widely grown cereal in the world. Bacterial leaf streak of maize caused by Xvv was first reported in South Africa in 1948 and was not reported anywhere else until 2014 when it was identified in Nebraska, USA; this disease then spread rapidly and is now present in 10 US states. Recently it has also been reported in some regions of Argentina and Brazil. This disease is not currently present in Europe, but should be considered as a potential theat to maize crops. At Fera, artificial inoculations on a range of maize varieties grown in the UK indicate wide susceptibility to this pathogen. The main host of Xvv is maize, but evidence has shown that other monocot species like oat and rice are also hosts.

The most likely pathway of entry in Europe will be on seed, although there are only a few reports of seedborne infections. By sequencing Xvv isolates from South Africa, the US, Brazil, and Argentina, and comparing sequences with publicly available data, we aim to determine what is the most likely origin of the infections observed in South America and use this to inform a plant protection strategy for the UK.

P3.2-025

IMPACT OF CLIMATE CHANGE ON POTENTIAL DISTRIBUTION OF DICKEYA ZEAE CAUSAL AGENT OF STALK ROT OF MAIZE IN SIALKOT DISTRICT PAKISTAN

SHAHID Humaira. (1), **HYDER Sajjad. (1)**, NAEEM Muhammad. (2), GONDAL Amjad Shahzad. (3), RIZVI Zarrin Fatima. (1)

(1) GC Women University Sialkot Pakistan, Sialkot, PAKISTAN; (2) Department of Zoology, Riphah International University, Faisalabad Campus, 38000 , Faisalabad, PAKISTAN; (3) Department of Plant Pathology, Bahauddin Zakariya University, Multan, PAKISTAN

Text

Zea mays L. is the 3rd most influential crop by its bulk production all over the world. Bacterial stalk rot of maize caused by Dickeya zeae result into significant crop yield reduction, thus need to be addressed. Further, to produce the epidemiological evidence for the management of the disease outbreaks in the hot spot region, extensive field surveys during 2021 revealed that out of 266 visited areas, high disease incidence was observed in Bhoopalwala (78.5 %) followed by Bangla Chowk (76 %), Suraj (74 %), and Bakhray wali (68.5 %), while the lowest disease incidence was recorded from Pasrur (20 %), Chawinda (15 %) and Head Marala (9 %). The Maxent algorithm modelling was used to predict areas at risk of disease outbreaks in Sialkot regions and, to predict and forecast the disease outbreaks in coming years. Among the nineteen bioclimatic/environmental variables, four factors including temperature seasonality (standard deviation*100) (bio-4), mean temperature of wettest quarter (bio-8), annual precipitation (bio-12), and precipitation of driest month (bio-14) were found to be the most critical factors influencing the disease distribution in current and coming years. It is predicted that high risk area and disease distribution will increase across the four tehsils of Sialkot Pakistan over the years 2050 and 2070. These results are important for policymakers and researchers to take effective disease control measures against bacterial stalk rot of maize disease outbreak.

P3.2-026

HORIZON SCANNING FOR PLANT HEALTH THREATS: 7 YEARS OF SUPPORT TO EU RISK MANAGERS

ANTONIOU Alexia. (1), TRAMONTINI S.. (1), **LARENAUDIE M.. (2)**, LINGE J.. (3)

(1) The European Food Safety Authority (EFSA), Parma, ITALY; (2) ANSES, Angers, FRANCE; (3) Joint Research Centre (JRC), Ispra, ITALY

Text

In December 2016 EFSA was mandated by the European Commission to carry out a horizon scanning exercise on emerging plant pests. From that moment, and in close collaboration with the Joint Research Centre, EFSA started its monitoring and extraction of news and scientific data on plant pests using the Medisys platform (https://publications.jrc.ec.europa.eu/repository/handle/JRC53155).
Medisys retrieves continuously relevant items from the web by searching on more than 21,000 media and scientific literature sources from around 200 countries for keywords (more than 13,000) from the pre-defined ontology and classifies them according categories. The retrieved items are then reviewed and filtered by a group of experts who selects the most relevant ones. The result of this activity is compiled and presented in freely available monthly

newsletters (https://efsa.onlinelibrary.wiley.com/doi/toc/10.2903/(ISSN)1831-4732.Horizon-scanning-for-plant-health).
In case of non-regulated pests, further analysis of potential risks is carried out by applying a fast-track procedure that allows identifying the most relevant “emerging pests of the month”. The results of this analysis are also included in the newsletter, whose content is presented and discussed each month by the EU Commission and Member State representatives. During these seven years of activity the process and quality of outputs have been refined and the contribution of this activity to the timely reaction to emerging threats by EU risk managers and risk assessors is fully acknowledged.

P3.2-027

EFSA ACTIVITIES ON RISK ASSESSMENT AND PREPAREDNESS FOR INVASIVE ALIEN PLANT PATHOGENS IN EUROPE

CROTTA Matteo. (1), CZWIENCZEK E.. (1), GARDI C.. (1), GOBBI A.. (1), KACZMAREK A.. (1), KARIAMPA P.. (1), KERTESZ V.. (1), MAIORANO A.. (1), MERCADAL J.. (1), MIKULOVA A.. (1), PAUTASSO M.. (1), ROSSI E.. (1), SFYRA O.. (1), STREISSL F.. (1), STANCANELLI G.. (1)

(1) European Food Safety Authority, Parma, ITALY

Text
The European Food Safety Authority (EFSA) is the Agency of the European Union responsible for risk assessment in food safety, animal health and welfare and plant health. EFSA conducts risk assessment for individual plant pests with a two-phase fit for purpose approach, a simpler and narrative pest categorisation first, followed by a quantitative probabilistic pest risk assessment for more complex questions, where quantification of the risk allows the comparison of outputs under different scenarios, including risk mitigation options and climate change scenarios. EFSA is also funding research projects to reduce key uncertainties and knowledge gaps by generation and collection of observational and experimental evidence. Trends and examples from risk assessment of invasive alien plant pathogens are presented.

Keywords: pest categorisation, pest risk assessment, quantitative, probability

Text

Society is confronted by interconnected threats to ecological sustainability. Among these is the devastation of forests by destructive non-native pathogens and insects introduced through global trade, leading to the loss of critical ecosystem services and a global forest health crisis. We argue that the forest health crisis is a public good social dilemma and propose a response framework that incorporates principles of collective action. This framework will enable scientists to better engage policymakers and empower the public to advocate for proactive biosecurity and forest health management. Collective action in forest health will feature broadly inclusive stakeholder engagement to build trust and set goals; accountability for destructive pest introductions; pooled support for weakest-link partners; and inclusion of intrinsic and non-market values of forest ecosystems in risk assessment. We provide short-term and longer-term measures that incorporate the above principles to shift the societal and ecological forest health paradigm to a more resilient state.

C7.6-2

NGA RAKAU TAKETAKE - CONTROL, PROTECT, CURE NOVEL. TOOLS AND TECHNOLOGIES FOR DETECTION AND MANAGEMENT.

WOOD Marion. (1), **MILNER Dave. (2)**

(1) Plant and Food Research, Auckland, NEW ZEALAND; (2) Kahu Environmental, Wellington, NEW ZEALAND

Text

Aotearoa New Zealand’s BioHeritage Challenge is leading the development and implementation of a programme, known as Ngã Rãkau Taketake (NRT) – Saving our Iconic Trees. The name Ngã Rãkau reflects the historical connections that Mãori and other New Zealanders have with our kauri and myrtaceae trees, whilst Taketake refers to the permanence of that relationship. This programme aims to protect and restore that relationship and connection. Kauri dieback is threatening Aotearoa New Zealand’s taonga (treasured) kauri with extinction, whilst myrtle rust (and its associated offshore strains) is threatening many iconic native species as well as plants important to primary industries. New Zealanders have strong emotional and cultural attachments to kauri and the native estate,

the loss of which is having a major impact on our communities. The myrtle rust and kauri dieback spaces desperately need a suite of fully integrated management tools and approaches to saving our ngahere (forest). To address this, Ngã Rãkau Taketake is investing in research and related activities in the field of 'Tools and Technologies for Detection and Management'. Our team has been using an innovative co-development, co-design outreach process with local indigenous tribes to socialise new technologies, assess important values and concerns, and ensure research, operations and case studies are fully integrated, of which examples and learnings will be presented.

C7.6-4

INDIGENOUS SEED BANKING TO PROTECT AGAINST PLANT PATHOGENS IN AOTEAROA NEW ZEALAND

FORDYCE Phoebe. (1), **SHADBOLT Marcus. (1)**

(1) Te Tira Whakam?taki, Rangiora, NEW ZEALAND

Text

This paper considers the dangers that plant pathogens represent for native plants in Aotearoa New Zealand, and how Indigenous M?ori seed banking can help to save them. The growing impacts of climate change and environmental instability increase the risk of the introduction, adaptation, and spread of plant pathogens in Aotearoa. As Indigenous people of the land, M?ori have a special relationship with and responsibility for the natural environment including native plant species which can be endangered by pathogens. For example, austropuccinia psidii is one such pathogen which affects many native trees including p?hutukawa, manuka, and r?t? all species of cultural significance. While the introduction of such pathogens is not easy to control, the preservation of native plants through methods such as seed banking can act as insurance against incursions. Preserving these plants through seed banking is essential to M?ori, but it is complicated by colonisation and the Crown's (illegal) ownership of native flora and fauna which is perpetuated through government-owned seed banks both in Aotearoa and overseas. Te Tira Whakam?taki, home of Aotearoa's M?ori Biosecurity Network, is seeking to provide a much-needed alternative; an Indigenous-owned M?ori seed bank programme. The programme already has provided training and equipment to iwi/hap? to start their own seed banking at-place, but an Indigenous Seed Banking Declaration and a national M?ori seed bank are the next steps.

C7.6-5

MEDIA COVERAGE OF FOREST SURVIVAL IN TURKEY

GÜRSOY Akile. (1), KARBI Bilge. (1)

(1) Beykent University, Istanbul, TURKEY

Text

Public opinion plays a significant role in shaping policies that impact forest and tree health directly or in the long run. This paper explores media coverage of news related to tree and forest health in the years 2021-2023 in two daily newspapers that have the widest reading

coverage in Turkey: “Sözcü” with an opposition and “Hürriyet” with a pro-government stand. Unprecedentally widespread forest fires witnessed in the summer of 2021 in Turkey have once again opened debates related to forest survival and the role of human action in shaping nature. News related to forests have been firstly about forest fires and secondly about the transfer of state-owned forest lands for development and tourism. We see that the survival of forests is reflected in relation to the survival and the well-being of wildlife. Ecological concerns are openly voiced or implied as overriding priorities and decisions to designate forest lands for other purposes is deemed to be detrimental. News is given of local protests. The disastrous earthquakes that took place in February 2023 in Turkey have accelerated the media coverage and debates over the country-wide planning of land designated for agriculture, forestry and urban dwelling usage. Amidst such agonized debates we perceive a novel sensitivity about land use that also embraces concerns over forest health and survival.

AN INDIGENOUS SOLUTION TO A PLANT PATHOGEN IMPACTING AN ICONIC TREE SPECIES IN AOTEAROA-NEW ZEALAND

ASHBY Tohe. (1), PARATA H. (2), COOPER J. (1), ATARIA Jamie. (3)

(1) Nga Tirairaka o Ngati Hine, Whangarei, NEW ZEALAND; (2) Kahui Kaumatua Ngatiwai Trust, Whangarei, NEW ZEALAND; (3) Te Tira Whakamataki, Rangiora, NEW ZEALAND

Text
The pathogen Phytophthora agathidicida is having a devastating impact on the kauri (Agathis australis), a tree species that is a paramount symbol of M?ori, Indigenous peoples of Aotearoa, cultural identity. M?ori across regions have mobilised, motivated by deep cultural responsibilities to restore and protect kauri and surrounding environments, encapsulated in the proverb “Ko au ko te kauri – ko te kauri ko au, I am the kauri and the kauri is me”. In 2019 M?ori knowledge and practitioner experts were afforded a rare opportunity to employ their own epistemological frameworks, implement their experience and apply their customary practice to conceptualise, develop and then trial treatment and holistic management systems to combat the impacts of this pathogen. Termed the ‘rongoa approach’ this uniquely M?ori approach employs M?ori knowledge and M?ori traditional practices and has proven to offer a credible pathway forward in reversing the physical manifestations of this disease in infected trees and provide ongoing protection against reappearance of symptoms. We will present an overview of the epistemological construct that has been a unique collaboration between knowledge holders from different tribal areas that informed the ‘rongoa’ approach to improve tree health, and how this work was conducted without compromising M?ori cultural norms and expectations. Results will be discussed within the context of tree and wider biodiversity health, and the empowering outcomes for M?ori.

P7.6-001

M?TAURANGA — AN INDIGENOUS RESPONSE TO MYRTLE RUST.

MARSH Alby. (1,2), WOOD Waitangi. (4), WAIPARA Nick. (3), ROPATA Hone. (3), GARNER Gary. (5)

(1) NZ Institute for Plant and Food Research, Palmerston North, NEW ZEALAND; (2) Better Border Biosecurity (B3), Palmerston North, NEW ZEALAND; (3) NZ Institute for Plant and Food Research, Auckland, NEW ZEALAND; (4) Wai Communications, Kaeo, NEW ZEALAND; (5) Gary Garner Ltd, Leeston, NEW ZEALAND

Text

M?ori (Indigenous peoples of New Zealand) have traditionally used ‘m?tauranga (traditional knowledge), to articulate a knowledge system that encompasses inherent and acquired knowledge. While western science has demonstrated an appetite to identify opportunities to align or integrate m?tauranga of the Ngahere (native forests), wai (water) and moana (sea), M?ori have been reluctant to share their knowledge, and the protection of m?tauranga and ‘knowledge holders’ has become fundamental in any engagement with western science, agents and/or enterprise.

M?tauranga M?ori, used to describe a whole M?ori system, is not western science and research . M?ori knowledge systems are made up of observations and intimacy with our world over millennia and these systems inform the way we make decisions.There are obvious distinctions between the two systems. Western science doesn’t require that you do anything with knowledge, while M?ori knowledge requires that you take action and are accountable for that action. Western scientists seek expertise in singular fields, while M?ori knowledge is acquired across a range of domains which allows M?ori to better respond to the needs of the natural environment and their people. Using the myrtle rust incursion, we explored Maori expectation of the inclusion of m?tauranga in the response and how science and research has enabled kaitiakitanga (guardianship) and rangatiratanga.(decision making) solutions and approaches in the biosecurity system.

P7.6-002

INDIGENOUS FRAMEWORK TO RECOGNISE AND GIVE EFFECT TO CULTURAL AND DATA SOVEREIGNTY TO ELEVATE INDIGENOUS PEOPLES INTO SCIENCE AND BIOSECURITY SYSTEMS

WOOD Waitangi. (1,2), LUSTIG Audrey. (3), LATHAM Maria C. (3), ANDERSON Dean P. (3), BIDOIS Carlton. (4)

(1) Wai Communications Ltd, Northland, NEW ZEALAND; (2) Tau Iho I Te Po Trust, Ngatirua, NEW ZEALAND; (3) Manaaki Whenua Landcare Research, Christchurch, NEW ZEALAND; (4) Manaaki Te Awanui, Tauranga, NEW ZEALAND

Text

Surveillance in Aotearoa New Zealand is part of a biosecurity response that protects our borders and landscapes and our natural biological heritage and economy. Prioritisation of investment and resourcing in surveillance is determined by an ‘ecosystem approach’ that values nature as much as it contributes to the needs or values of people. The Matauranga Maori Framework (for surveillance of for plant pathogens) informs research in the Biological Heritage, National Science Challenge in New Zealand that addresses the impact of plant pathogens, phytophthora agathidicida and austropuccinia psidii on native species. Both pathogens are destroying native species culturally significant to Maori. The Framework aims to enable better engagement of Hapu/Iwi (indigenous tribes) across central and local

government agencies, including the Ministry for Primary Industry (MPI), Department of Conservation (DOC), regional councils, stakeholders and communities engaged in a surveillance effort. Seeking to normalise 'cultural licence' and to inform systemic change, the Framework encourages early engagement with indigenous tribal authorities and knowledge holders in the development and design of research, and recognises the importance of indigenous peoples relationship with their lands and possessions.

Soil-borne plant viruses

VIRUSES INTERACT WITH SOIL AND PLANT MICROBIOMES

SIERADZKI Ella Tali. (1), NICOLAS Alexa. (2), PETT-RIDGE Jennifer. (2,3,4), BLAZEWICZ Steven. (3), FIRESTONE Mary. (2)

(1) École Centrale de Lyon, Écully, FRANCE; (2) University of California Berkeley, Berkeley, UNITED STATES; (3) Lawrence Livermore National Laboratory, Livermore, UNITED STATES; (4) University of California Merced, Merced, UNITED STATES

Text

Plants depend on the soil microbiome for mineralization of nutrients. Soil viruses outnumber the soil microbiome 10-1000-fold. Therefore, they can serve as a lineage-specific top-down control on the soil microbiome. While largely understudied, we know that soil viruses can affect soil carbon sequestration, the rhizosphere environment and plant health. Many soil viruses carry horizontally transferred genes that code for plant polysaccharide degradation or methanotrophy, which may resolve metabolic bottlenecks experienced by their microbial hosts during infection.

Advances in sequencing technology combined with methods for enrichment of viruses and tracing isotope flow through the microbial community allow us to probe the diversity and effects of viruses on their hosts over different stages in the life cycles of plants and soil. Recent work suggests that up to half of the mortality of soil bacteria in the week following wet-up is due to viral lysis. During the winter there is a positive correlation between virus activity and host activity, implying continued effect of viruses in wet soil. Presence of plant litter in soil during the growing season propels viruses of fungi. Finally, there is evidence for consistent presence of viruses in legume nodules, where they may control population size of nitrogen fixing symbionts.

Soil viral ecology is a nascent field highly relevant to plant health and carbon storage under global climate change

Text

Benyviruses have multipartite RNA genome. Several exoribonuclease-resistant RNAs (xrRNAs) are associated with benyvirus infections. Recently it has become evident that xrRNAs are produced by many viruses. Whereas xrRNAs contribute to pathogenicity of these viruses, the role of xrRNAs in virus infectious cycle remains elusive. We will present evidence that xrRNAs produced by a benyvirus are involved in formation of monocistronic coat protein-encoding chimeric RNAs (chRNAs). Naturally occurring chRNAs, we discovered, are composed of 5´-end of RNA 2 and 3'-end of either RNA 3 or RNA 4. Using computational tools and site-directed mutagenesis we addressed the mechanism chRNAs biogenesis. Moreover, knock-down of the expression of exoribonuclease-encoding gene *XRN4* inhibited biogenesis of both xrRNAs and chRNAs. We will present a model to explain the mechanism of the chRNAs biogenesis. This model integrates our findings and data into a broader picture on the role of intermolecular RNA-RNA base-pairing interactions of xrRNAs with genomic RNAs in template switching during virus replication cycles to yield formation of chRNAs. Furthermore, we found that chimeric RNAs are biologically active as the coat protein is translated from chRNAs and they move systemically in the infected plants. Our results suggest an additional level of organization and expression of viral RNA genomes (i.e. formation of functional chimeric RNAs) beyond classical genomic and sub-genomic RNA species.

VIRUS-NEMATODE–PLANT INTERACTIONS DURING TRANSMISSION OF GRAPEVINE FANLEAF VIRUS

RITZENTHALER Christophe. (1)

(1) CNRS Université de Strasbourg, Strasbourg, FRANCE

Text

Many animal and plant viruses rely on vectors for their transmission from host to host. Grapevine fanleaf virus (GFLV) is a picorna-like virus from plants responsible of a severe grapevine degeneration observed in vineyards worldwide. GFLV is specifically transmitted from grape to grape by the ectoparasitic nematode Xiphinema index. Structurally, GFLV is an icosahedral virus of 30 nm of diameter with a pseudo T = 3 symmetry composed of 60 identical coat protein subunits (CP) of 54 kDa. The capsid of GFLV, carries the determinants of this specificity.

Over the past years, structure-function studies have provided important insight in the specificity of transmission. We could show that a GFLV strain poorly transmissible by nematodes possess a single Gly297Asp mutation responsible of the defect in transmission. This mutation maps to an exposed loop at the outer surface of the capsid that does not affect the conformation of the assembled capsid, nor of individual CP molecules. The loop is part of a positively charged pocket with essential function in GFLV transmission by X. index which is also mutated in escape variants isolated from plants that express a Nanobody specifically

recognizing GFLV that are naturally resistant to the virus. Our data suggest that perturbation of the electrostatic landscape of this pocket affects the interaction of the virion with specific receptors of the nematode's feeding apparatus, and thereby severely diminishes its transmission efficiency.

SOIL-BORNE MULTIPARTITE BNYVV DIFFERENTIALLY CONTROLS ITS SEGMENT COPY NUMBER

GUO Yi. (1), DALL'ARA Mattia. (1), GILMER David. (2), RATTI Claudio. (1)

(1) University of Bologna, DISTAL, Bologna, ITALY; (2) Institut de biologie moléculaire des plantes (IBMP), Strasbourg, FRANCE

Text

Multipartite virus genomes are composed of two or more segments each packaged into independent viral particles. A potential benefit for multipartitism is the regulation of gene expression through segment copy number variations. The soil-borne beet necrotic yellow vein virus (BNYVV) containing four or five genomic RNAs may be considered as a model of multipartitism among RNA viruses. Here, we investigate the relative frequency of the four genomic RNAs of BNYVV during infection of different host plants by a validated protocol of dual step reverse transcriptase droplet digital PCR. We show that some viral genomic segments accumulate at low frequency, whereas others dominate. BNYVV genome formula reaches a different setpoint in distinct host plant species and organs. Moreover, the vector, Polymyxa betae, seems to affect the accumulation of BNYVV genomic RNAs in its hosts. We characterized as well the BNYVV genome formula within zoospores and resting spores of P. betae taking into account contamination issued from infected Beta vulgaris roots. Results show the virus reaches a dedicated set-point genome formula also in each of the two forms of the protozoan life cycle. Hence, our results indicate that BNYVV can differentially control the copy number of its segments.

TOWARDS A BETTER UNDERSTANDING OF FUROVIRUS-HOST INTERACTION – IDENTIFICATION OF FACTORS INFLUENCING INFECTION

GAUTHIER Kevin. (1), SPROTTE Nico. (1), STRAUCH Claudia Janina. (1), **NIEHL Annette. (1)**

(1) Julius Kühn-Institut, Braunschweig, GERMANY

Text

The *Polymyxa graminis*-transmitted viruses can cause extensive losses in cereal crops. We are studying the interaction between virus and host plant with the aim to better understand the molecular mechanisms underlying infection, to better characterize the threat virus infection poses in a changing climate, and to derive resistance strategies complementary to resistance breeding approaches.

To obtain insight into the mechanisms underlying virus intercellular transport and transmission, we identify and characterize interaction partners of furovirus CP-RT and movement proteins using protein biochemical and cell biological methods. We obtained evidence that the endoplasmic reticulum may be important for virus transmission and identified a pentatricopeptide repeat-containing protein and a heat shock protein 70 as interacting partners of the Japanese soil-borne wheat mosaic virus (JSBWMV) movement protein.
By investigating furovirus infection under specific environmental conditions, we identify, which parameters specifically influence infection and the stability of resistance. These parameters can then be used to derive strategies for virus control and thus contribute to a sustainable and environment-adapted agriculture.

C6.5-6

ADAPTION OF BNYVV TOWARDS RZ1 RESISTANCE IN SUGAR BEET

LIEBE Sebastian. (1), MAISS Edgar. (1), **VARRELMANN Mark. (1)**

(1) Institute of Sugar Beet Research, Göttingen, GERMANY

Text
The beet necrotic yellow vein virus (BNYVV) causes rhizomania in sugar beet, which is controlled since more than two decades by the Rz1 resistance gene. The development of resistance-breaking strains has been favoured by a high selection pressure on the populations. Resistance-breaking is associated with mutations at amino acid positions 67-70 in the pathogenicity factor P25 and the presence of an additional RNA component (RNA5). However, natural BNYVV populations are highly diverse with more than 25 known tetrad variants and different RNA5 species making investigations on the resistance-breaking mechanism rather difficult. We refined our previously developed reverse genetic system for BNYVV (A type) to study the Rz1 resistance-breaking mechanism by agroinoculation of seedlings. This allowed a clear discrimination between genotypes. A screen for resistance-breaking revealed that multiple tetrad variants allow BNYVV to overcome Rz1. Furthermore, certain mutations impaired the viral pathogenicity in the susceptible genotype. Finally, the supplementation of an additional RNA5 species, either from the J or P type group, allowed virus accumulation in the Rz1 genotype independent of the P25 tetrad. However, this effect was impaired in a genotype carrying Rz2, which is another resistance gene against BNYVV. Our infection system enables a rapid identification resistance-breaking mutations and highlights the plasticity of the BNYVV genome allowing adaption towards Rz1.

VIRUSES TRANSMITTED TO RICE BY POLYMYXA GRAMINIS : A TRIPARTITE INTERACTION

JAFFRÉ Emma-Louise. (1), DESBIEZ Cécile. (2), ALBAR Laurence. (1), HEBRARD Eugénie. (1)

(1) Institut de Recherche pour le Développement IRD, Montpellier, FRANCE; (2) INRAE, Avignon, FRANCE

Text

The rice stripe necrosis virus (RSNV, *Benyvirus*) is a bipartite virus, present in West Africa and emerging in South America. It is transmitted to rice by a soil protist, obligate endoparasite of rice roots, *Polymyxa graminis* (*Pg*). The diversity, biology and specificity of this tripartite interaction are poorly known, and no effective means of control are available to date. Our objective is to improve knowledge on the infection process of rice by RNSV. To better control the inoculation, we are developing cDNA infectious clones by homologous recombination in yeast and fusion PCR. Introns are inserted to prevent the toxicity of the Triple Gene Block proteins previously observed for another benyvirus, namely BNYVV. Different inoculation methods of the RSNV clones will be tested in controlled conditions, and compared to *Pg*-mediated inoculation. The symptomatology, multiplication rate and viral movement will be monitored in plants. The specificity of the rice/*Pg*/RSNV interaction will be evaluated using different lineages of both the vector and the virus. Based on the methodologies developed, we will characterize the single resistance source identified so far and screen for others in representative accessions of rice. The results obtained here will contribute to the development of tools for the study of the tripartite interaction as well as the identification of efficient and durable control methods.

Text

The plasmodiophorid Polymyxa graminis, an obligate endoparasite, transmits several phytoviruses on major crops worldwide. In this study, the diversity of P. graminis associated with Rice stripe necrosis virus (RSNV) infested areas and the host range of a monosporosorus isolate of P. graminis f. sp. colombiana were assessed. Four soil samples from Burkina Faso and Mali, collected in sites where RSNV was detected, have been selected. The diversity of Polymyxa associated with these soils was tested using a set of plant species identified as natural hosts of Polymyxa. In this study, P. graminis was detected in roots of rice, wheat and sorghum grown on the four soils and in roots of barley and millet on two of the four soils. Molecular characterization revealed the effective presence of several formae speciales associated with P. graminis f. sp. tropicalis, P. graminis f. sp. colombiana on rice or with another group associated with the ribotype associated with the isolate BF209 (Legrève et al. 2002)[CB1] .The host range of P. graminis f. sp. colombiana, revealed that these isolates can infect other cereal species grown on P. glaucum, S. bicolor as well as some weed species which are D. horizontalis and A. viridis.

SOIL TRIPARTITE INTERACTIONS BETWEEN HOST PLANTS, VIRUSES AND THE PROTIST VECTORS POLYMYXA

GENARD Margaux. (1), DECROES Alain. (1), BRAGARD Claude. (1), LEGREVE Anne. (1)

(1) UCLouvain/ELIM/SAVE, Louvain-La-Neuve, BELGIUM

Text

Viral diseases transmitted by Polymyxa involve complex soil-borne pathosystems involving three actors: a plant host, a root obligate endoparasitic protist vector (Polymyxa spp.) and viruses. These pathosystems are spread worldwide, in both temperate and tropical areas. They affect numerous host plants (both monocotyledons and dicotyledons) due to the large diversity of the Polymyxa-virus pathosystems. Our research aims to assess how the host plant, Polymyxa and the viruses they vector interact, mainly focusing on two Polymyxa-virus models for which genomic data are available : (1) the Polymyxa betae – Beet necrotic yellow vein virus (BNYVV) pathosystem on sugar beets and (2) the Polymyxa graminis – Rice stripe necrosis virus (RSNV) pathosystem on rice. Recent genomic and transcriptomic data regarding the vector Polymyxa open new opportunities to understand the nature and specialization of the Polymyxa-host interactions. It allows a better understanding of how Polymyxa manage to by-pass host defenses and paves the way for identifying effectors involved in host defenses manipulation. Additionally, the first transcriptomic data of in vivo transmission of virus by Polymyxa clarify how the virus impacts plant defenses and therefore Polymyxa-host interactions. These transcriptomic results also give insight on the specificity Polymyxa-virus interactions.

POTATO MOP-TOP VIRUS SHAPES A DEFENCE-RELATED TRANSCRIOPTOME THROUGH SUPPRESSION OF CHLOROPLAST-MEDIATED IMMUNITY GENES

ROY Shweta. (1), NEMES Katalin. (1), SARIPELLA Ganapathi Varma. (2), VETUKURI Ramesh. (2), SAVENKOV Eugene. (1)

(1) Department of Plant Biology, Swedish University of Agricultural Sciences, Uppsala, SWEDEN; (2) Department of Plant Breeding, Swedish University of Agricultural Sciences, Alnarp, SWEDEN

Text

Potato is major non-cereal food crop. Potato mop-top virus (PMTV), the causal agent of ´potato spraing´ disease, severely deteriorates the quality of potato tubers. PMTV is transmitted by spores of a soil-borne protist Spongospora subterranea. Efficient approach for controlling the disease is not available to date. Therefore, new genetic information on disease development is crucial to obtain disease resistant varieties. To reveal the novel genetic regulators of viral defense, we performed an RNA-seq of PMTV infected Nicotiana benthamiana plants. Altogether, 2291 host genes were found to be differentially regulated after PMTV infection. Photosynthesis, enzymatic activity, cell wall organization, and cell-to-cell communication were found to be the major affected gene ontology categories. Interestingly, chloroplast localized protein encoding genes were especially affected. In total,

258 choloroplastic genes were differentially regulated where 145 were downregulated. These suggest a putative viral strategy to suppress the chloroplast-mediated defense to gain advantage in replication and movement. Localization of PMTV RNA and a movement protein to chloroplasts further reinforces the hypothesis Thus, RNA-seq data has provided insight into chloroplast defence genes exploited by PMTV to accelerate systemic infection. Further characterization of these candidate genes can be useful for genetic intervention to develop strategies for sustainable control of PMTV and will be discussed.

Synergism/antagonism between microbial pathogens and disease complexes: implications in epidemiology and management

C9.6-1

TOMATO PITH NECROSIS: A BACTERIAL DISEASE COMPLEX CAUSED BY ENDOPHYTIC PSEUDOMONADS

CATARA Vittoria. (1)

(1) University of Catania, Catania, ITALY

Text

The spread of tomato pith necrosis (TPN) in the late 1970s led to the description of a new bacterial species, *Pseudomonas corrugata*, later demonstrated to include strains of another species, *P. mediterranea*. The diagnosis by duplex PCR has made it possible to detect the presence, in some cases, of multiple infections of the two bacterial species. In the past 50 years many pseudomonads have been associated with this syndrome. Also called FPTPN (fluorescent pseudomonads associated with TPN) some of them have been attributed to new genomospecies or identified as *P. chicorii*, *P.marginalis*, *P. viridiflava*, alone or in mixed infections even with *P. corrugata* e *P. mediterranea*. In the latter two species a role in the development of TPN is due to the production of the cyclic lipopeptides (CLP) cormicin A and corpeptins. Genome sequencing of species representatives and transcriptomic analysis have helped to improve the knowledge of CLP production. Regulation mediated by the Quorum Sensing system of CLPs suggests that there are conditions in which bacterial concentration exceeds the quorum leading to the development of symptoms. Bacteria of the genus *Pseudomonas* are among the major constituents of the tomato microbiota's endorhizosphere. The presence and interaction of endophytes, also of species not yet described, could support the hypothesis that endophytes, that are potentially harmless, interact so contributing to the development of the pathobiome which leads to conduct to TPN.

Text

The disease triangle is usually focused on one host/one pathogen model. However, pathosystems can also involve co-infection by several pathogen species. Co-infection may exhibit disease symptoms dissimilar to infections by each pathogen alone and may increase the damage to the host. The current case study describes the synergistic effect of co-infection by the C*ucumber green mottle mosaic virus* (CGMMV) and *Pythium* spp. The late-wilting syndrome has lately increased in cucumber greenhouses during CGMMV outbreaks. As wilting appears in patches and is accompanied by root rot, we hypothesized that the co-infection of soil-borne pathogen/s and CGMMV causes this phenomenon. The Greenhouses survey showed that 69% of the wilting plants were colonized simultaneously by *Pythium* spp. and CGMMV, whereas only 20 and 6.6% of the wilting plants were colonized only with Pythium spp. or CGMMV, respectively. Artificial inoculation of cucumber plants showed that co-infection with *P. spinosum* or *P. aphanidermatum* and CGMMV resulted in a significant synergistic wilting effect and reduced growth parameters. Moreover, the synergistic effect was detected under a wide range of (optimal and suboptimal) temperatures, and P*. spinosum*, which mostly prevails in mild temperatures, caused high mortality incidence at an extended temperature range as high as 32°C. The extended damage was accompanied by a sharp downregulation of genes related to the host defense mechanism against the necrotrophic pathogen.

LIFE HISTORY TRAITS, COINFECTION AND EPIDEMIOLOGICAL DYNAMICS IN A PARASITIC COMPLEX: THE CASE OF ASCOCHYTA BLIGHT OF PEA

LE MAY Christophe. (1), DUTT Agathe. (1), LECLERC Melen. (2), BARANGER Alain. (2), ANDRIVON Didier. (2)

(1) Institut Agro Rennes-Angers, Rennes, FRANCE; (2) INRAE UMR IGEPP, Le Rheu, FRANCE

Text

Any host plant is subjected, throughout its life, to the simultaneous or sequential pressure of infection by various pathogens, whose coexistence leads to competitive interactions able to affect epidemiological dynamics. The main objective of this work is to assess the impact of

the coexistence of Peyronellaea (ex Didymella) pinodes (Dp) and Phoma medicaginis var. pinodella (Pmp), two key agents of pea Ascochyta blight, on their epidemic development. Our results suggest that the coexistence of both fungal species derives from three distinct life history and host exploitation strategies. Most Dp strains are 'pioneer colonizers', allowing them to develop first on young hosts. These early attacks weaken the plant, and favor later infection by Pmp and rare Dp strains boasting a 'scavenger' strategy on vulnerable host tissue. The remaining Pmp and Dp strains display an 'intermediate' strategy, and act as opportunists. We also showed that both direct and indirect competition alter these life strategies. However, for each type of competition, host exploitation strategies vary in the same direction irrespective of the kind of competitor, although the intensity of the variation depends on the genetic relatedness between competitors. We therefore show the strong impact of competitive interactions on coexistence and virulence, so that the management of epidemics would benefit from a full understanding and use of underlying mechanisms.

INTERACTIONS OF TWO PHLOEM LIMITED VIRUSES IN THEIR HOST PLANT AND VECTOR AND IMPLICATIONS FOR VECTOR FITNESS AND EPIDEMICS

SRINIVASAN Rajagopalbabu . (1), GAUTAM Saurabh. (1), GADHAVE Kiran. (4), DUTTA Bhabesh. (2), ADKINS Scott. (3)

(1) University of Georgia, Griffin , UNITED STATES; (2) University of Georgia , Tifton, UNITED STATES; (3) USDA-ARS, Fort Pierce, UNITED STATES; (4) Texas A & M University , Amarillo, UNITED STATES

Text

Mixed-virus infection is common in agricultural settings. Viruses in mixed-infection can synergistically/antagonistically interact, and differentially alter host phenotype and vector fitness than individual viruses. Mixed-virus infection in a vegetable pathosystem in the United States has two facets: 1. Mixed-infection in hosts due to multiple viruses transmitted by the same vector, whitefly *Bemsia tabaci* Gennadius; and 2. Acquisition of multiple viruses from multiple hosts by the vector. Facet 1: Begomovirus (cucurbit leaf crumple virus, CuLCrV) and Crinivirus (cucurbit yellow stunting disorder virus, CYSDV) interactions in squash and on *B. tabaci* fitness was assessed. Mixed-infection of CuLCrV and CYSDV in squash resulted in an antagonistic interaction. This interaction differentially affected virus acquisition by whiteflies and settling than single (CuLCrV or CYSDV) infection. Facet 2: Combined acquisition of tomato infecting -tomato yellow leaf curl virus(TYLCV) and squash-infecting CuLCrV by whiteflies was examined. Combined whitefly acquisition of CuLCRV and TYLCV enhanced settling towards non-infected tomato and squash plants. Viruliferous (CuLCrV and/or TYLCV) whitefly fitness study conducted on a virus non-host (cotton) revealed that the mere presence of virus in the vector influenced its fecundity positively. Overall, mixed-virus infection in hosts and acquisition of multiple viruses by the vector could potentially exacerbate epidemics than a single virus.

SYNERGISM BETWEEN VIRUSES IN THE WHEAT STREAK MOSAIC DISEASE COMPLEX IN WHEAT

WEGULO Stephen. (1), HEIN Gary. (1), TATINENI Satyanarayana. (2), BYAMUKAMA Emmanuel. (3)

(1) University of Nebraska-Lincoln, Lincoln, UNITED STATES; (2) United States Department of Agriculture–Agricultural Research Service, Lincoln, UNITED STATES; (3) United States Department of Agriculture–National Institute of Food and Agriculture, Houston, UNITED STATES

Text

The wheat streak mosaic disease complex causes significant yield losses in the Great Plains of the US. It consists of three wheat curl mite (Aceria tosichella Keifer)-vectored viruses: Wheat streak mosaic virus (WSMV), Triticum mosaic virus (TriMV), and High Plains wheat mosaic virus (HPWMoV). The majority (91%) of TriMV-positive wheat samples from field surveys were co-infected with WSMV whereas WSMV and HPWMoV were mainly (60-80%) detected singly. Double inoculation of a susceptible winter wheat cultivar with WSMV+TriMV in the field exacerbated symptoms and reduced yield by >87% compared to single virus infections. Double inoculation of susceptible winter wheat seedlings with WSMV+TriMV induced disease synergism that resulted in severe stunting, leaf deformation, and bleaching. In co-infected plants, accumulation of both viruses increased by up to 7.4 fold compared to single infections at 14 days post-inoculation. In TriMV-infected wheat seedlings, WSMV showed accelerated long-distance movement with increased accumulation of genomic RNAs compared to buffer-inoculated wheat, which indicated that TriMV-encoded proteins complemented WSMV for efficient systemic infection. In WSMV-infected wheat seedlings, TriMV exhibited delayed systemic infection, but in the late stages of infection, it accumulated rapidly with accelerated long-distance movement compared to buffer-inoculated wheat, indicating asymmetrical interactions between synergistically interacting WSMV and TriMV.

Fitosanidad-Fitopatología (Plant Diseases), and Recursos Genéticos y Productividad, Montecillo, MEXICO

Text

Since 2005 in Íxtaro, Michoacán, symptoms of *Harzia ixtarensis* **sp. nov.** infection have been observed on immature *Annona cherimola* fruit with *Colletotrichum fragariae*-induced anthracnose lesions and mummified fruit. This study aimed to evaluate *H. ixtarensis* pathogenicity and its synergistic behavior with *C. fragariae*. During 2019 and 2020 in an *A. cherimola* tree, two randomized experiments were conducted on previously disinfected

healthy immature fruit and on fruit with 14-day-old anthracnose lesions caused by prior *C. fragariae* inoculations. The conidia inoculations treatments (T) plus a control were: T1, *C. fragariae*; T2, *H. ixtarensis*; T3, *C. fragariae* plus *H. ixtarensis* (simultaneous inoculation); and T4 (derived from T1), *H. ixtarensis* inoculation on fruit with anthracnose lesions. The inoculum (20 µL drop of a conidial suspension from 7-day-old cultures containing a mean of 1×10^6 mL^{-1}) was deposited on the fruit surface (with and without a wound). There were significative differences. In situ, inoculations showed that fruit with wounds developed larger lesions than those without wounds. *H. ixtaresis* inoculation on anthracnose lesions produced larger anthracnose lesions than *C. fragariae* alone. When *C. fragariae* or *H. ixtarensis* was inoculated alone, the lesion size was 51 and 99% smaller, respectively, indicating synergy between these species. Thus, *H. ixtarensis* may have a parasitic-synergistic and necrotrophic lifestyle and exhibited symptoms on anthracnose lesions.

Text

Pathogens actually share host plants with a myriad of other microbes, some of them being pathogenic. Multiple infections, or ‘co-infection’, occur when a single host plant is infected by various pathogen species, or genotypes. This is known to affect symptom expression and pathogen multiplication in various pathosystems. However, the population-scale consequences remain poorly explored. We consequently aimed at integrating each pathogen in the microbial community of its host, with a particular focus on evolution and epidemiology. Our focus is on rice in Sub-Saharan Africa, a crop of strong agronomic importance because of human population growth and change in food habits, and two major rice pathogens: the Rice yellow mottle virus (RYMV) and the bacteria Xanthomonas oryzae (Xo). These two pathogens were shown to interact reciprocally in experimental co-infection. We monitored these two diseases over an eight-years period in 2-6 sites from western Burkina Faso. We aimed at testing whether multiple infections impact the evolutionary trajectories of pathogen populations and drive epidemiological outcome. We show that the viral population evolved over the period, in terms of genetic and pathogenic diversity. Levels of virus-bacteria co-occurrence and co-infection were estimated in the fields. Evidence of intra-species co-infection is shown as well, both for the virus (multiple viral isolates) and the bacteria (various bacterial strains).

The ecology plant viruses and epidemiology of the disease they

cause: How fundamental ecological research in natural systems can inform and advance plant pathology

Text

Plant virus ecology began to be explored at the end of the 19th century. Since then, major advances have revealed complex virus–host–vector interactions in a variety of environments. These advances have been accelerated by development of new technologies for virus detection and characterization, the latest of which being high-throughput sequencing (HTS). HTS technologies have proved to be effective for non-targeted characterization of all or nearly all viruses present in a sample without requiring prior information about virus identity, as would be needed for virus-targeted tests. Plant virus metagenomics studies have thus made important advances, including characterization of the complex interactions between phytovirus dynamics and the structure of multi-species host communities, and documentation of the effects of anthropogenic ecosystem simplification on plant virus emergence and diversity. However, such studies must overcome challenges at every stage, from plant sampling to bioinformatics analysis. Results of two recent studies will be presented. While the first study aimed at systematically evaluate plant-associated viromes across broad agro-ecological interfaces, the second study aimed at using a predator-enabled metagenomics strategy to sample the virome of a remote and difficult to access densely forested African tropical region.

C4.4-2

ALTERATION OF PLANT SPECIES MIXTURES BY VIRUS INFECTION

JONES Roger. (1)

(1) University of Western Australia, Crawley, AUSTRALIA

Text
What occurs when virus infection is spreading within a mixed plant species population? This question is important not only for environmentally significant mixed wild species populations but also for economically significant, mixed species managed systems. This contribution re-interprets examples of past research on mixed species managed pasture done over two decades on three continents that demonstrated plant species balance changes arising from virus infection. These examples showed that plants belonging to susceptible pasture cultivars sensitive to systemic virus infection are sufficiently weakened that their ability to withstand competition from non-host plants of other pasture species, or weed species, was decreased sufficiently to alter the plant species balance. Also, a similar alteration occurred when they were competing with virus-resistant or virus-tolerant host plants of the same or other pasture species, or a virus-resistant weed species. Such competition also diminished seed production, which decreased their ability to regenerate. Notably, when two different pasture species infected by the same virus compete with each other, growth of the more sensitive species is suppressed. Because managed mixed species pastures constitute an important component of regenerative agriculture, retaining an optimal balance of pasture species and delaying pasture decline from weed invasion both require effective management of virus diseases.

Text
The increase in human-mediated introduction of plant species to new regions due to global travel and globalization has resulted in a rise of invasive exotic plants (IEPs) that can have significant effects on biodiversity, ecosystem processes, and food production. The introduction of IEPs to new regions often occurs through seed dispersal, and most pathogens

are not vertically transmitted, leading to low viral loads in these plants. Also, most pathogens are not evenly distributed across the Earth, meaning that IEPs colonizing a new territory are unlikely to encounter pathogens from their native range. This situation, referred to as the "enemy-release hypothesis" suggests that decreased pathogen-mediated selective pressures on IEPs in colonized territories will result in increased IEP populations, densities, and geographical distributions. To test the enemy-release hypothesis, the virome of an invasive cane bluestem (Bothriochloa barbinodis) was compared to that of four or more indigenous grass species in both naturalized and native ranges. The results showed that the IEPs had lower viral infection loads than the native grasses, providing evidence that supports the enemy release hypothesis. Novel viruses associated with Bothriochloa barbinodis were further partially or fully sequenced and the phylogenetic relationships of these viral sequences and representative sequences of corresponding virus families were analyzed.

OCCURRENCE AND PREVALENCE OF SCHLUMBERGERA VIRUS X IN DRAGON FRUIT CROPS IN ECUADOR

ESPINOZA-LOZANO Lisbeth. (1), SUMBA Martha . (1), CAÑADA-BAUTISTA Gabriela. (1), QUITO-AVILA Diego. (1)

(1) Escuela Superior Politécnica del Litoral - ESPOL, Guayaquil, ECUADOR

Text

Dragon fruit is a unique and highly sought-after fruit grown in many parts of the world, including Ecuador. In recent years, its cultivation has grown in popularity among farmers, as it is a highly profitable crop due to its domestic and international demand. Despite the growth in dragon fruit production, Ecuador faces challenges such as emerging pests and diseases and the lack of knowledge on their management and prevention. Emerging viruses are responsible for reductions in yields in many crops if they are not prevented and adequately managed. Cladodes exhibiting symptoms of irregular and ring-shaped chlorotic spots and mild chlorotic yellow spots were collected from farms in three coastal provinces and the main production area in the Amazon region of Ecuador. Schlumbergera virus X (SchVX), a potexvirus, was detected in more than 90% of tested cladodes, including symptomatic and asymptomatic samples of the two major dragon fruit species (Hylocereus undatus and H. megalantus) cultivated in the country. The symptoms presented differed among the species and were more severe on H. undatus. Phylogenetic inferences based on the partial nucleotide sequence of the RNA-dependent-RNA-polymerase (RdRp) showed that SchVX isolates found in H. undatus and H. megalantus, regardless of the field location, share a most recent ancestor with isolates from Spain and Portugal. Additional assays on the mechanical transmission of the virus are underway and will be further discussed.

C4.4-5

FACTORS INFLUENCING EPIDEMIOLOGY AND SPREAD OF WHITEFLY-TRANSMITTED CUCURBIT VIRUSES IN THE UNITED STATES VARY AMONG PRODUCTION REGIONS

WINTERMANTEL William. (1), MONDAL Shaonpius. (1)

(1) USDA-ARS, Salinas, UNITED STATES

Text
Viruses transmitted by the whitefly, *Bemisia tabaci*, threaten cucurbit production in the United States (US) and throughout the world, reducing yield and fruit quality. This threat increases with elevated whitefly populations, prevalence of mixed infections, and the introduction of new viruses. Large whitefly populations occur in summer and fall cucurbit production throughout much of the southwestern and southeastern US, including in areas that once had limited whitefly pressure. Recent surveys conducted in these regions demonstrated that mixed virus infections, which create challenges for disease management and plant breeding, are now common. These mixed infections often include the criniviruses, cucurbit yellow stunting disorder virus (CYSDV) and cucurbit chlorotic yellows virus (CCYV), and the begomovirus, cucurbit leaf crumple virus (CuLCrV) along with other viruses. Epidemiological research to clarify factors driving the perennial threat these viruses pose to production, including identification of weed and non-cucurbit reservoir hosts, impact of timing of infection, and competitiveness of viruses in mixed infections, varies by region. This research is highly dependent on multiplex RT-PCR assays to identify mixed infections. Additional efforts by the Emerging Viruses in Cucurbits Working Group (ecucurbitviruses.org), established in 2022, are underway to improve communication regarding virus threats throughout the industry with the goal of reducing virus spread and impact.

EPIDEMIOLOGY OF YAM VIRUSES IN GUADELOUPE: ROLE OF CROPPING PRACTICES AND SEED-TUBER SUPPLY

DIOUF Mame Boucar. (1,2), **GUYADER Sébastien. (1)**, GASPARD Olyvia. (1), FRANCIUS Eric. (1), TEYCHENEY Pierre-Yves. (3,4), UMBER Marie. (1)

(1) INRAE, UR ASTRO, Petit-Bourg, GUADELOUPE; (2) CIRAD, UMR AGAP Institut, Capesterre-Belle-Eau, GUADELOUPE; (3) CIRAD, UMR PVBMT, Saint-Denis, REUNION; (4) Université de la Réunion, UMR PVBMT, Saint-Pierre, REUNION

Text
Among the 25 viruses recognized officially in yams (*Dioscorea* spp.) worldwide, nine have been reported in yams in Guadeloupe. Since the epidemiology of these viruses remains largely unexplored, we undertook a large-scale epidemiological study of yam viruses in Guadeloupe based on the analysis of 1124 leaf samples collected from yams and weeds. We assessed the prevalence of cucumber mosaic virus (CMV), Cordyline virus 1 (CoV1), Dioscorea mosaic associated virus (DMaV), yam asymptomatic virus 1 (YaV1), yam mosaic virus (YMV), yam mild mosaic virus (YMMV), badnaviruses, macluraviruses and potexviruses, and evaluated the effects of key epidemiological drivers of these viruses. We identified several weed reservoirs of YMMV and provide evidence that YMMV isolates infecting weeds cluster together with those infecting yams, pointing to the role of weeds in the epidemiology of YMMV. We report on the occurrence of yam chlorotic necrosis virus (YCNV) in Guadeloupe, the introduction of YMMV isolates through the importation of yam tubers, and the absence of vertical transmission of YaV1. We identified specific effects of some cropping practices, such as weed management and the use of chemical pesticides, on the occurrence of several yam viruses, but no crop-related factor had a strong or general

effect on the overall epidemiology of the targeted viruses. Overall, our work provides insights into the epidemiology of yam viruses that will help design more efficient control strategies.

F4.4-1

STRIVING TO STAY CLEAN: DETECTION OF SWEETPOTATO VIRUSES ON MULTIPLE SEED GENERATIONS IN NORTH CAROLINA

ALMEYDA Christie. (1), LI Chunying. (1), PECOTA Kenneth. (1), YENCHO Craig. (1)

(1) North Carolina State University, Raleigh, UNITED STATES

Text

Under the National Clean Plant Network (NCPN) economic study, the sweetpotato clean centers started an experiment aiming to assess the value of clean seed in comparison to older generation seed. The goal of this study was to evaluate the performance and quality of foundation seed after it had been integrated into commercial sweetpotato operations. In NC, trials started in 2021 with Covington and Beauregard as evaluated varieties. G1 seed was used as a reference to compare the yield and virus incidence of growers' generation 2 (G2), generation 3 (G3) and generation 4 (G4) seed roots. This experiment was repeated in 2022 with Averre and Bayou Belle added to the initial pool of varieties as well as older generations (G5 and G6). It is known that the accumulation and perpetuation of viruses in sweetpotato is a major constraint for production of seed and the commercial crop. The potyvirus complex is prevalent in North Carolina and comprises Sweet potato feathery mottle virus (SPFMV), Sweet potato virus G (SPVG), Sweet potato virus C (SPVC) and Sweet potato virus 2 (SPV2). In 2021, virus data suggested a low incidence of viruses (mainly SPFMV) on G1 material. Potyviruses (mainly SPVG, SPVC and SPFMV) started to be prevalent on G2 and G3 material. In the older generation evaluated (G4), all potyviruses (SPVG, SPVC, SPFMV and SPV2) were detected. In 2022, the same trend was observed as the prevalence of four potyviruses was associated to higher seed generations.

P4.4-001

CHARACTERIZATION OF A NOVEL ORTHOTOSPOVIRUS FROM MACADAMIA IN SOUTH AFRICA

ROBERTS Ronel. (1), ROBBERTSE Nicola. (2), **READ David. (3)**

(1) Agricultural Research Council - Tropical Subtropical Crops, Mbombela, SOUTH AFRICA; (2) Agricultural Research Council Plant Health and Protection, Pretoria, SOUTH AFRICA; (3) FABI, Pretoria, SOUTH AFRICA

Text

South Africa is the largest producer of macadamias in the world. In order to ensure the continuation of the industry, it is important that research focuses on the control and eradication of economically-important pests and diseases. Macadamia trees in Mpumalanga show symptoms of severe chlorosis. This chlorosis coincides with a significant drop in production, with losses of up to 60% being recorded. In an attempt to determine whether the chlorosis may

be associated with a virus, high throughput sequencing analyses was performed on RNA extracted from both diseased and healthy trees collected from six different farms. Subsequent data analyses could not find a specific virus being linked to chlorotic trees, however, reads spanning the full genome of a novel virus belonging to the Orthotospovirus genus were obtained from a number of samples. A RT-PCR assay was optimised for the detection of this virus and subsequent surveys linked the virus to ringspot symptoms which are commonly observed on different macadamia cultivars. The virus has been identified from orchards in three provinces. Viruses described in the genus are known to cause severe crop losses. It is therefore important that the virus, provisionally named macadamia ringspot associated virus (MRSV), be further studied to determine whether association with this virus can lead to yield losses, as well as determine the vector of the virus so that control strategies can be implemented to limit the spread of MRSV.

P4.4-002

INCIDENCE AND OCCURRENCE PATTERN ON KIWIFRUITS IN KOREA

KIM Hyo Jeong . (1)

(1) Jeju special self governing province agricultural research and extension services, Jeju Special Self Governing Province, REPUBLIC OF KOREA

Text

The occurrence of viruses in Kiwifruits in Jeju Island were investigated between the period of 2020 and 2022. The result showed that 3.3 and 6.7% of trees in Jeju Island were infected with AcVA and ASbLV, respectively. Viruses that specifically infect kiwifruit are mostly from Betaflexiviridae family, such as Actinidia virus A, Actinidia virus B, and the Actinidia seedborne latent virus. Infected kiwifruits usually show bright leaf vein, chlorotic ringspots, and spot. However, the symtoms tend to not be detected during the season of vitality restoration, even when infected. Other kiwifruits viruses include cucmber mosaic virus, apple stem grooving virus, potato virus X, cucumber necrosis virus, alfalfa mosaic virus, and citrus tatter leaf virus. But, It does not occur in Jeju Island. Incidence of major viruses varies from year to year, with most cases occurring in the form of multiple. It was found that the damage to kiwifruits in Jeju Lsland caused by the virus was not significant. However, there is a possibility of damage occurring when new varieties are introduced or developed in the future. To prevent fruit damages, continuous monitoring for fruit infecting viruses and viroids will be necessary.

P4.4-003

FIRST VIRUSES INFECTING COCKSPUR CORAL TREE (ERYTHRINA CRISTA-GALLI L.): DISCOVERY OF A NOVEL CAPILLOVIRUS AND A NEW HOST FOR THE PRUNE DWARF VIRUS

ŠKORIC Dijana. (1), ŠERUGA MUSIC Martina. (1), GRBIN Dorotea. (1), MASSART Sébastien. (2)

(1) University of Zagreb Faculty of Science, Zagreb, CROATIA; (2) Plant Pathology Laboratory, TERRA-Gembloux Agro-Bio Tech, University of Liège, Gembloux, BELGIUM

Text

Erythrina crista-galli L. (*Fabaceae*) or cockspur coral tree is a South American deciduous woody ornamental spread worldwide. One out of three *E. crista-galli* plants from the collection of the Botanical Garden in Zagreb exhibited virus-like symptoms such as stunting, white striations of flowers, leaf asymmetry, bleaching, white speckles and striations. Total nucleic acids were extracted from leaves by CTAB method, DNase treated and subjected to HTS (Illumina, 2x150 nt). Total of 4.2 million reads obtained from ribodepleted RNA-seq were analysed by Geneious Prime software and VirHunter. Complete sequence (2129 nt) of prune dwarf virus (PDV, *Ilarvirus, Bromoviridae*) segment RNA3, encompassing CP and MP genes, was obtained (GenBank Acc.No. OP503942). Moreover, almost complete genome (acc. no. OQ067396) was obtained for an unknown virus (*Betaflexiviridae*) spanning 6,483 nts and containing all expected ORFs. Phylogenetic analyses revealed the maximum nucleotide identity was 41% with ASGV (sequence LC143387), far below the threshold for species delimitation making it a candidate for a new *Capillovirus* genus member. Besides PDV, only this new virus was found and validated by RT-PCR in symptomatic *E. crista-galli*, an unexpected fabaceous host with no viruses recorded so far. As asymptomatic plants were not positive for the two viruses in RT-PCR, this makes them “prime suspects” as the disease etiological agents.

P4.4-004

EFFECTS OF TEN SERIAL PASSAGES OF TOMATO SEVERE RUGOSE VIRUS (TOSRV) BY DIFFERENT HOSTS ON THE EVOLUTIONARY DYNAMICS OF THE VIRAL POPULATION

FERRO Camila Geovana. (1), FAVARA Gabriel Madoglio . (2), **KRAIDE Heron Delgado. (1)**, REZENDE Jorge Alberto Marques. (1)

(1) ESALQ- USP, Piracicaba, BRAZIL; (2) UNESP- Campus de Botucatu, Botucatu, BRAZIL

Text

Tomato severe rugose virus (ToSRV) is the most important begomovirus in Brazilian tomato crops. Many weeds and other solanaceous are associated with tomatoes, and some are hosts of begomoviruses. Here we tried to access the population dynamics of ToSRV after ten serial passages throughout different hosts. The ToSRV-TF isolate, initially maintained on tomato, was transmitted by *Bemisia tabaci* Middle East-Asia Minor 1 (MEAM1) for ten successive generations to tomato (control), soybean, and *Nicandra physalodes* plants. The ToSRV-TF isolate could infect the three hosts but with different efficiency. There was a higher infection rate in tomato plants compared to other hosts. There was genetic differentiation in the ToSRV population obtained from the different hosts. The seventh serial passage showed genetic differentiation in the viral population from *N. physalodes* plants. This viral subpopulation is possibly better adapted to the host because the virus’s infection rate increased in these plants. In tomatoes, the infection rate was nearly 100% in all passages. The variation in this viral population was constant, and despite this, two separate lineages emerged. Furthermore, the viral population's “disappearance” scenario was observed in soybean plants during serial passages, but the level of diversity remained constant. Therefore, there are differences in the evolutionary dynamics of the ToSRV population over generations in different hosts.

P4.4-005

A GLIMPSE INTO THE GERMAN HOP VIROME

PASHA Ali. (1), **ZIEBELL Heiko . (1)**

(1) Julius Kuehn Institute, Braunschweig, GERMANY

Text
In summer 2019, citrus bark cracking viroid (CBCVd) was reported for the first time in Germany. CBCVd is a pathogen of citrus plants that causes mild and often tolerated infections of different citrus species, whereas it causes severe disease in hop plants. The project “HopfenViroid” is addressing practical and scientific questions regarding CBCVd. As a part of this project, high-throughput sequencing (HTS) is being applied to investigate the viro-diversity in different German hop-growing sites. In 2021, we started with a pilot study targeting three fields in Hallertau (southern Germany), where CBCVd was previously detected. The samples were collected from hop, non-hop inside the field, and non-hop outside the field. Samples were pooled, double-stranded RNAs were extracted as a viral and viroid enrichment approach, and followed by Illumina sequencing. The bioinformatic analysis showed that all identified viruses and viroids in hops across the three fields were previously described as hop pathogens. In 2022, this study was extended to cover three different hop-growing sites in Germany. The same sampling and pooling strategies were used in 2022. The HTS-data analysis revealed common hop viruses and a viroid infecting the German hops. CBCVd was identified in hops in one site. A non-hop virus was identified in hops in three fields across the targeted sites. This study is still ongoing in 2023 to get a comprehensive understanding of the viro-diversity in German hops.

P4.4-006

SURVEYS FOR THE RESISTANCE-BREAKING ORTHOTOSPOVIRUSES IN TOMATO FIELDS IN FLORIDA

YILMAZ Salih. (1), HUTTON Samuel. (2), ADKINS Scott. (3), **BATUMAN Ozgur. (1)**

(1) University of Florida, SWFREC, Immokalee, UNITED STATES; (2) University of Florida, GCREC, Wimauma, UNITED STATES; (3) USDA-ARS, Fort Pierce, UNITED STATES

Text
Members of the genus Orthotospovirus such as tomato spotted wilt virus (TSWV) and tomato chlorotic spot virus (TCSV), are thrips-transmitted and highly destructive tomato viruses. The *Sw-5* gene is a single dominant resistance gene for TSWV and is also effective for TCSV; thus, the use of Sw-5 tomatoes is a critical IPM component. Amino acid (aa) mutations in the TSWV nonstructural movement protein (NSm) result in *Sw-5* resistance-breaking. In 2019-2023, high incidences of orthotospovirus-like symptoms were observed in Sw-5 tomato fields in south Florida. Symptomatic field samples from resistant and susceptible tomato plants were collected, and the *Sw-5* gene and orthotospovirus infection in all samples was verified by PCR and RT-PCR assays, respectively. Sequences of NSm from 131 Florida orthotospovirus isolates were analyzed for novel and known resistance-breaking aa substitutions (C118Y/T120N/D122G). The known aa substitutions were not present in any Florida isolates. However, novel aa substitutions (D17E, C118S, and I135V) in NSm were observed predominantly in TCSV isolates from resistant tomatoes. Furthermore, infection by TCSV^{C118S} isolate was systemic in an Sw-5-resistant tomato and in *N. tabacum* ‘Turk,’ whereas other isolates remained localized or did not infect inoculated plants. Our ongoing

inoculation experiments will help determine these mutations' association with the emergence of potential resistance-breaking virus isolates.

P4.4-007

CAN YOU RESIST ME? SCREENING HEMP LINES FOR RESISTANCE TO EMERGING VIRUSES AND VIROIDS UTILIZING THE HEMP VIROME

HACKENBERG Laine. (1), HAN Jinlong. (1), KAPUSCINSKI Marylee. (1), STENGLEIN Mark. (1), NACHAPPA Punya. (1)

(1) Colorado State University, Fort Collins, UNITED STATES

Text

Cannabis has been an emerging industry worldwide within the past decade with a global market valued at 4.71 billion USD for hemp alone, yet the diversity and distribution of associated pathogens have yet to be adequately studied. As production increases and the crop diversifies, the emergence and spread of these pathogens are imminent. The goal of this study is to describe the diversity and distribution of viruses/viroids infecting hemp in Colorado to help prevent crop loss due to diseases. In this study, four major hemp-producing regions in Colorado were analyzed. Tissue samples were collected from two cultivars of hemp from each farm visited in these regions at three timepoints throughout the growing season. These samples were submitted for Next Generation Sequencing and upon bioinformatic analysis, candidate virus/viroid sequences were validated. With metagenomic data from previous work, 26 different lines of hemp were screened for resistance to the top 2 predominant viruses/viroids found in the hemp virome, beet curly top virus and hop latent viroid. These 26 lines are genetically diverse which will facilitate the discovery of candidate genes involved in virus resistance. This work aims to further integrated pest management strategies in the hemp industry to promote sustainable agriculture.

P4.4-008

INTEGRATED MANAGEMENT STRATEGY FOR THRIPS-BORN DISEASE IN TAIWAN AND IMPLICATIONS

CHEN Yi-Ju. (1), CHENG Ying-Huey. (2), LIN Feng-Chyi. (1)

(1) Taiwan Agricultural Research Institute, Taichung, TAIWAN; (2) Taiwan Agricultural Research Institute, Fengshan Tropical Horticultural Experiment Branch, Kaohsiung, TAIWAN

Text

The insect-born disease management strategy includes using insect vector control, field sanitation, and resistant crops. Thrips transmit Orthotospovirus and Machlomovirus in different manners. However, strategies for viral disease management in Taiwan were rarely adjusted to the intricate virus-thrips interactions, cropping systems, and geographical areas. Due to this fact, the study evaluated the crop management regarding melon yellow spot orthotospovirus (MYSV) transmitted by melon thrips (*Thrips palmi* Karny.) on greenhouse cucumber and maize chlorotic mottle machlomovirus (MCMV) transmitted by maize thrips

(*Frankliniella williamsi* Hood) on field maize for better strategies. Removal of initial inoculum including weeds and plant debris from the greenhouse is recommended rather than removing infected plants for MYSV management on protected crops. Chemical control of thrips was effective to eliminate the thrips population and disease infection rate; spinetoram had less fatal effect on the natural enemy Orius species for MCMV management in open fields. The results implied the importance of sanitation and knowing the effect of chemicals for vector control on its beneficial enemy. For various cropping systems, we attend to clarifying inoculum sources, monitoring viruliferous thrips, and developing resistant traits on crops to adapt to the coming impacts of climate change.

P4.4-009

VIRUSES ARE ASSOCIATED WITH BUFFALO GRASS YELLOWING IN AUSTRALIA

TRAN Nga. (1), TEO Ai Chin. (1), MCTAGGART Alistair. (1), THOMAS John. (1), CAMPBELL Paul. (2), PERSLEY Denis. (2), GEERING Andrew. (1)

(1) The University of Queensland, Queensland Alliance for Agriculture and Food Innovation, Centre for Horticultural Science, Dutton Park, AUSTRALIA; (2) Queensland Department of Agriculture and Fisheries, Dutton Park, AUSTRALIA

Text

Stenotaphrum secundatum (Buffalo grass or St Augustinegrass) is a hardwearing and vigorous warm season turfgrass popular in many countries including the USA and Australia. In Australia, buffalo grass ranks first in importance based on farmgate value. Buffalo grass yellowing is an emerging disease syndrome that affects both the appearance and vigour of the turf. We tested the hypothesis that buffalo grass yellowing is caused by one or more viruses. We surveyed turf farms in NSW, QLD and WA and found sugarcane mosaic virus (SCMV) to be widespread, while panicum mosaic virus (PMV) was only detected in cultivar Palmetto and a new cultivar recently imported from the USA. Satellite panicum mosaic virus was not associated with these PMV isolates. Network analyses of the coat protein gene indicated that there are two strains of SCMV on buffalo grass in Australia, one matching that found in panicoid grasses in Florida and the second on *Digitaria didactyla* (blue couch) in Queensland. The Australian PMV isolates from buffalo grass have only 86% nucleotide identity across the entire genome sequence to the exemplar isolate from pearl millet in Kansas, confirming that it is a very distinct strain. A new virus named Stenotaphrum nepovirus was also identified by high-throughput sequencing and it was common in all regions and cultivars but symptoms of infection were not obvious. We conclude that SCMV is a major cause of the buffalo grass yellowing disease syndrome.

Text

In 2021, an international project on raspberry and strawberry viruses was launched (KAPPA project TO01000295). Twenty-nine and fifteen raspberry plants from the Czech Republic and Norway, respectively, were tested by NGS during 2021. The following known raspberry viruses were detected in the plants: BRNV, RBDV, RLBV, RLMV and RVCV. A DNA virus, RYNV was detected in several samples. Further research is needed to establish whether this is a virus infection, or a plant genome associated DNA sequence. Six viruses were detected in raspberry for the first time. Additionally, two novel viruses were identified, tentatively named raspberry enamovirus and raspberry rubodvirus. More than 400 raspberries samples and 200 insect samples have been collected and successively tested for viruses by RT-PCR. RBDV and BRNV had the highest prevalence in the raspberry samples. The most common aphids infesting raspberries in both countries are Aphis idaei and Amphorophora sp. Promising genotypes and new cultivars were introduced in vitro. Of the 7 in vitro genotypes screened, the ´Tulameen´ cultivar was infected with BRNV. The cryopreservation procedure as a “cryoknife” for virus eradication and for safe backup of selected raspberry genotypes was tested. The plant vitrification solution PVS3 was used as a vitrification mean. The first results indicate successful eradication of BRNV virus from ´Tulameen´.

Text

Yellow dwarf viruses (YDVs) are distributed worldwide and can significantly reduce grain yield in economically important cereal hosts such as wheat, barley and oats. YDVs and their aphid vectors are frequently found in cereals and grasses in south-eastern Australia. The serological detection methods most commonly used to identify YDVs in Australia are unable to differentiate between closely related species and are not available for all YDV species. As a result, information about the diversity and distribution of YDVs in Australia, and their relationships with their aphid vectors and alternative hosts, is limited. To begin addressing

this knowledge gap, we used high-throughput sequencing (HTS) to examine the diversity and distribution of YDVs in cereals and grasses in south-eastern Australia. Our results show that Australian YDV isolates are much more complex and diverse than is currently suggested in the literature, both between and within species. Based on these results, new diagnostic tests are being designed to further examine the distribution of different YDV species in Australia, which will help us better understand this complex group of viruses. The information obtained in this study is critical for the more targeted development of virus-resistant cultivars.

Text

In recent decades, a legion of monopartite begomoviruses transmitted by the whitefly has emerged as serious threats to vegetable crops in Africa. Recent studies in Burkina Faso reported the predominance of pepper yellow vein Mali virus (PepYVMLV) and its frequent association with a previously unknown DNA?B component. To understand the role of this DNA?B component in the emergence of PepYVMLV, we assessed biological traits related to virulence, virus accumulation, location in the tissue and transmission. We demonstrate that the DNA?B component is not required for systemic movement and symptom development of PepYVMLV, but that its association produces more severe symptoms including growth arrest and plant death. The increased virulence is associated with a higher viral DNA accumulation in plant tissues, an increase in the number of contaminated nuclei of the phloem parenchyma and in the transmission rate by B. tabaci. Our results suggest that the association of a DNA?B component with the otherwise monopartite PepYVMLV is a key factor of its emergence. To assess the impact of this DNA-B component on the structure of the geminivirus community, grid-based sampling and the use of metagenomic protocols allowed obtaining of complex networks. Further analysis of our networks using genome sequences showed the presence of nestedness and modularity. This support the need to continue studies of the virus-plant system.
Keywords: Begomovirus,disease, etiology, Tomato, Burkina Faso.

Text

Plant breeders generally choose resistance genes based on their immediate efficacy and spectrum of action. One question that remains is which parameters of pathogen evolution should be targeted to promote plant resistance sustainability. Experimental evolutions of potato virus Y (PVY) in pepper (Capsicum annuum) genotypes contrasted in terms of resistance mechanisms allowed us to explore this question. These plant genotypes carried the same major-effect resistance gene encoding an eIF4E (eukaryotic initiation factor 4E) combined with different sets of resistance QTLs (quantitative trait loci).
We showed that the evolutionary trajectories of PVY were highly contrasted across plant genotypes. Some PVY evolutionary lineages showed more or less rapid adaptations linked to parallel nonsynonymous mutations in the VPg cistron, others showed losses of adaptation or even extinctions and some showed no significant change.
These varied trajectories can be explained by the level of resistance of the pepper genotype and by the intensity of the genetic drift imposed by the plant on the viral population. The intensity of selection, on the other hand, explains little of the diversity of evolutionary trajectories. In particular, we show that it is possible for breeders to combine high resistance efficiency and durability, even with strong selection on virus populations by a major-effect resistance gene, by using plant genotypes where viruses undergo strong genetic drift during infection.

P4.4-014

GENETIC DIVERSITY OF BARLEY YELLOW DWARF VIRUS (BYDV) ACROSS THE UK

BRAMHAM Lawrence. (1), SANDOVAL-CARVAJAL Izayana. (1), HAMMOND-KOSACK Kim. (1)

(1) Rothamsted Research, Harpenden, UNITED KINGDOM

Text

Sap-sucking aphids impact plants through direct feeding and the secretion of exudates, promoting saprophytic fungi whilst reducing the photosynthetic ability of a host. The capacity to also transmit plant viruses renders aphids a threat to important crop species. Wheat is one such host affected by aphids and the viruses they transmit, most prominently Barley yellow dwarf virus (BYDV). In terms of both worldwide distribution and economic significance, BYDV is one of the most important viral diseases affecting cereals, reducing yield by up to 80%. Genetic sources of resistance to aphids and/or or BYDV may provide an attractive control solution; this forms the basis for much of our work.

The presence and variation of BYDV strains across the UK has not been thoroughly explored with few key strains reported. This is despite knowledge of BYDV diversity being crucial for robust monitoring, effective disease management, the development of improved diagnostics, and identification of resistance-breaking viral variants. Here, work has explored UK BYDV diversity via viral coat protein sequencing and phylogenetic analyses using viruliferous aphid

samples collected from suctions traps across the nationwide Rothamsted Insect Survey.

Besides those already known to be prevalent across the UK, our results suggest the widespread occurrence of unreported BYDV strain(s) and substrain variation; this has potentially significant ramifications and may be a key finding for improved disease management.

P4.4-015

POTATO VIRUS Y STRAIN CHARACTERIZATION, DETECTION AND ANALYSIS

RUSHTON Jennifer. (1), NALAM Vamsi. (1)

(1) Colorado State University, Fort Collins, UNITED STATES

Text

Potato Virus Y (PVY) is an economically important virus affecting the potato industry worldwide. PVY belongs to the largest family of RNA plant viruses, Potyviridae. The single-stranded RNA virus has a monopartite genome that encodes for a single polyprotein. The genome properties and organization of PVY are important to its nature of recombination. Recombinant junctions at the functional protein sites allow PVY to recombine easily. A recombinant event can occur if there is more than one strain of PVY present in a host plant. PVY exists as a complex of strains and variants: five non-recombinant genotypes with 36 unique recombinant strains. This work evaluates strains of PVY in San Luis Valley (SLV), Colorado based on current detection methods. Sampling of potato leaf tissue was done in the 2021 and 2022 growing seasons. The field samples were tested for PVY and further analysis was performed using NGS. Bioinformatic analysis revealed new insights into mixed infections, possible recombinants, and current detection methods.

P4.4-016

FACTORS AFFECTING THE POPULATION DYNAMICS AND EPIDEMIOLOGY OF VIRUSES INFECTING POTATO.

LACOMME Christophe. (1), BACK Emma. (1), DAVIE Kim. (2), THOMSON Catherine. (1)

(1) SASA - The Scottish Government, Edinburgh, UNITED KINGDOM; (2) RESAS - The Scottish Government, Edinburgh, UNITED KINGDOM

Text

Potato virus Y (PVY), Potato Leafroll virus (PLRV) and Potato virus A (PVA) are the most prevalent species in symptomatic plants of seed potato crops. The molecular diversity of PVYN isolates indicated that ~85% belong to the recombinant European (EU)-NTN group. Overcoming innate host resistance appears to be an essential factor in shaping intra-species virus populations. Transmission studies indicate that PVYEU-NTN has the highest transmission rate, a higher propensity of to infect older plants by out-compete other variants and overcoming host resistance mechanisms [1]. Transmission studies revealed. While far less diverse, PVA genome analysis suggest that polymorphism between severe and mild

isolates define novel pathogenicity determinants. A novel potyvirus Potato yellow blotch virus (PYBV) was identified in breeding lines [2]. PYBV elicits characteristic bleached symptoms on leaves and is closely related to PVA. PYBV is a rare virus and has not been found in commercial seed and ware potato crops in Scotland. Further analysis of potato and alternative hosts are on-going to further study their epidemiology. We are currently implementing nanopore next generation sequencing to study the etiology of potato disease in leaves and tubers and identifying potential emerging virus threats to potato and other Solanaceaous hosts.

P4.4-017

EMERGENCE OF CACAO-INFECTING BADNAVIRAL SPECIES IN THE TROPICAL AMERICAS AND WEST AFRICA

BROWN Judith K.. (1)

(1) The University of Arizona, Tucson, UNITED STATES

Text
At least eight badnaviral species associated with cacao swollen shoot disease have emerged or re-emerged as damaging pathogens of cacao in West Africa since ~2000. In the neotropics, the endemic Cacao mild mottle virus (CaMMV) and Cacao yellow vein-banding virus (CYVBV), once eradicated from cacao farms in Trinidad where they emerged during the 1940's, have been identified in cacao germplasm repositories and commercial cacao farms in Brazil, Trinidad, USA-Puerto Rico. Although CaMMV and CYVBV are distributed more widely than previously expected, symptomatic trees experience minimal damage. Phylogenomic surveillance of cacao-infecting badnavirus species indicate that the West African badnaviral species are distributed phylogeographically while others are widely distributed, collectively, due to mealybug vector dispersal patterns. For CaMMV and CYVBV, infected germplasm collections are the primary inoculum sources of inoculum, and viruses will not spread in the absence of endemic mealybug vector(s). Recent research has provided new insights into factors driving re-emergence and spread of badnaviruses in West Africa and the tropical Americas in commercial cacao and germplasm collections, respectively, grounded in improved molecular detection assays to enable identification of badnaviral phylodynamic-epidemiological predictors and support plant breeding efforts focused on species-specific disease tolerance in parallel with optimum production traits.

P4.4-018

RISK FACTORS ASSOCIATED WITH CASSAVA BROWN STREAK DISEASE DISSEMINATION THROUGH SEED PATHWAYS IN EASTERN D.R. CONGO

BISIMWA Kwibuka. (1,2), NYIRAKANANI Chantal. (2), BIZIMANA Jean-Pierre. (2), BISIMWA Espoir. (1), BROSTAUX Yves. (2), LASSOIS Ludivine. (2), VANDERSCHUREN Hervé. (2), MASSART Sébastien . (2)

(1) Université Catholique de Bukavu, Bukavu, THE DEMOCRATIC REPUBLIC OF THE CONGO; (2) University of Liège, Gembloux, BELGIUM

Text
Vegetatively propagated crops are particularly prone to disease dissemination through their seed systems. Strict phytosanitary measures are important to limit the impact of diseases, as illustrated by the European potato seed system.

Cassava brown streak disease (CBSD) is a devastating disease caused by two viral species (CBSVs). After 100 years of research, a disease's westward and eastward spread is threatening people's livelihood in new areas. A better understanding would be an asset to properly managing it. This study tested the efficiency of a multidisciplinary framework in surveying the epidemiology of CBSVs in Uvira territory, Eastern D.R. Congo, and its drivers. Results revealed that three epidemic clusters, among which one potentially interesting for seed multiplication, could be identified in the study area using the five most significant factors: (i) symptom incidence, (ii) number of whiteflies, (iii) types of foliar symptoms, (iv) cutting pathways and (v) plant age. Through risk assessment, we also identified several key socio-economic determinants of disease epidemy: (i) factors related to farmer's knowledge and awareness (knowledge of cassava pests and diseases, knowledge of management practices, support from extension services and management strategies applied), (ii) factors related to the geographical location of farmer's fields (proximity to borders, proximity to a town, distance to acquire cuttings), as well as (iii) the pathways used to acquire cuttings.

P4.4-019

EFFECTS OF SOWING CMV-INFECTED LENTIL SEED ON GROWTH AND YIELD

AFTAB Mohammad. (1), **TREBICKI Piotr. (2)**, SHUNMUGAM Arun. (1), NANCARROW Narelle. (1), RODONI Brendan. (1)

(1) Agriculture Victoria, Horsham, AUSTRALIA; (2) Macquarie University , Sydney, AUSTRALIA

Text
Lentil (*Lens culinaris*) is an important food crop and is considered to be one of the main protein sources in many countries. Lentils are vulnerable to several viral diseases, but cucumber mosaic virus (CMV) is one of the most important. CMV is transmitted through seeds and by aphid vectors. CMV is common in lentils in south-eastern Australia, but data is lacking on its effect on growth and yield. In this study, field trials were conducted to quantify the yield risk of planting CMV-infected lentil seed. In preparation for field trials, 143 seed lots were sown in the greenhouse, then seedlings were tested for CMV using tissue blot immunoassay (TBIA) one month after sowing. CMV was detected in seeds of three lentil varieties SP1333, Eston and Indianhead with infection levels of 0.7%, 2% and 3% respectively. These varieties were sown in field trials in a randomised complete block design at four locations. Field plots were tested for CMV infection during the season to assess virus presence. The mean incidence of CMV across all the sites in SP1333, Eston and Indianhead was 24%, 13% and 8% respectively while the mean incidence in control plots did not exceed 1%. Plots were machine harvested and the grain yield from each plot was measured.

Overall, mean yield across all trial sites was higher in the control plots than the virus-infected treatment plots. In general, in the virus infected SP1333 treatment plots, the higher the incidence of CMV, the lower the yield from that plot.

P4.4-020

MOLECULAR CHARACTERIZATION AND PREVALENCE OF A NOVEL STRAWBERRY CRINIVIRUS IN IRAN

HAJIZADEH Mohammad. (1,2), ZANDAN Nasrin. (2), KOLONIUK Igor. (3), **TZANETAKIS Ioannis. (1)**

(1) University of Arkansas System Division of Agriculture, Fayetteville, UNITED STATES; (2) University of Kurdistan, Sanandaj, IRAN (ISLAMIC REPUBLIC OF); (3) Biology Centre CAS, ?eské Bud?jovice, CZECH REPUBLIC

Text

A new crinivirus was detected in strawberry plant (Fragaria × ananassa Duchesne) using high-throughput sequencing. The consensus genome was validated using RT-PCR, cloning and RACE. The complete genome sequence consists of two single-stranded RNAs of 8.8 and 7.1 Kb. The virus shares 37 – 56% nucleotide identity to previously described criniviruses. The RNA-depended RNA polymerase was most similar to tetterwort vein chlorosis virus with 66% aa identity whereas the heat shock protein 70 homolog showed the highest sequence identity to the lettuce chlorosis virus ortholog with 74% aa identity. Given the low sequence similarities with known criniviruses the virus should be considered a new member of the genus. Phylogenetic analysis of the RdRP placed the virus in Crinivirus Group 2 and supported its assignment to a new species within the genus Crinivirus. The virus was detected at high prevalence in the two main strawberry growing areas of Iran and verified to be whitefly-transmissible.

P4.4-021

STUDYING ROSE ROSETTE EMARAVIRUS REPLICATION IN ITS VECTOR PHYLLOCOPTES FRUCTIPHILUS.

DRUCIAREK Tobiasz. (1,2), ROJAS Alejandro. (1), **TZANETAKIS Ioannis. (1)**

(1) University of Arkansas System Division of Agriculture, Fayetteville, UNITED STATES; (2) Section of Applied Entomology, Department of Plant Protection, Institute of Horticultural Sciences, Warsaw University of Life Sciences, , Warsaw, POLAND

Text

Genus Emaravirus (Family Fimoviridae; Order Bunyavirales) is an emerging group comprising over 20 classified and putative species with a worldwide distribution and economic impact. Amongst them, rose rosette emaravirus (RRV, virus species Emaravirus rosae) is probably the most devastating due to its lethality on rose in North America. Emaraviruses are assumed to be exclusively transmitted by eriophyoid mites (Acari: Eriophyoidea), the smallest and most elusive among the arthropod vectors. Despite the

significance of emaraviruses, there is no understanding of the mode and mechanisms of their transmission. We used direct RT-qPCR to estimate the number of viral RNA copies within individuals of Phyllocoptes fructiphilus, and P. adalius, a confirmed and non-vector species respectively. After a 24 h acquisition period, mites were transferred daily to new, non-RRV-infected tissue. RRV copies in P. fructiphilus significantly increased with peak of virus titer recorded on day five, whereas it remained stable in P. adalius. Our results suggest that RRV replicate in P. fructiphilus, a finding of significance as it contributes to virus spread. These findings provide essential insights into a better understanding of intricate interactions between emaraviruses and eriophyoid mites.

P4.4-022

A NOVEL AMPELOVIRUS INFECTS BLUEBERRY

VILLAMOR Dan E.v.. (1), **TZANETAKIS Ioannis. (1)**

(1) University of Arkansas System Division of Agriculture, Fayetteville, UNITED STATES

Text
A novel ampelovirus-like sequence was detected from a blueberry selection from the National Clonal Germplasm Repository of USDA-ARS in Corvallis, Oregon, United States using high throughput sequencing (HTS). The authenticity of this ampelovirus-like sequence was validated and subsequently, a near complete genome was assembled using HTS contigs and amplicon sequences from overlapping RT-PCR. Sequence comparisons and phylogenetic analyses of several proteins confirmed distinct speciation of the novel blueberry ampelovirus within the genus Ampelovirus, with pistachio ampelovirus A being the closest relative amongst members of the genus. A triplex RT-PCR that targets two regions of the virus and a host gene was developed. An additional isolate of the virus was detected in Arkansas, USA. The source plant was co-infected with blueberry green mosaic-associated virus and exhibited stunting and yellowing. Grafting onto virus-tested plants verified transmissibility of the novel ampelovirus onto blueberry but also validated the symptomology observed. An extensive survey is underway to determine the distribution of the ampelovirus on major blueberry growing regions, blueberry germplasm, breeding programs, and nurseries.

P4.4-023

IDENTIFICATION OF APPLE LUTEOVIRUS (ALV-1) AND POTENTIAL ASSOCIATION WITH DIEBACK OF APPLE TREES IN NORTHERN ITALY

GUALANDRI Valeria. (1), VICELLI Bianca. (1), ANGELI Gino. (1)

(1) Fondazione Edmund Mach, Center for Technology Transfer, San Michele All'adige Trento, ITALY

Text
Apple tree (*Malus domestica* L.) is the most cultivated fruit crop in Trentino, in northern Italy.

For the last several years, an unusual problem of dieback of young apple trees is normally associated with wood pathogens and has never been associated with the presence of viruses. In the apple tree, commonly viruses include apple stem pitting virus (ASPV), apple stem grooving virus (ASGV), and apple chlorotic leaf spot virus (ACLSV) and apple mosaic virus (ApMV). During 2018-2022 RT-PCR was performed for the detection of apple luteovirus 1 (ALV-1) in symptomatic and asymptomatic apple trees and rootstock collected during spring. Total nucleic acids were extracted from leaf and bark tissues and the presence of a named apple luteovirus 1(ALV-1) was performed using specific primers AluDetF6/R6 in RT-PCR. The obtained amplicon was purified and sequenced. The analyzes confirm the absence of ACLSV, ASPV, ASGV and ApMV both on the plant and on the rootstock. Instead, it confirms the presence of ALV-1 especially in the symptomatic plant and in the rootstocks. These reports suggest a possible association with ALV-1 and apple dieback and that rootstocks may be a source of infection spread in an apple tree. To our knowledge, this is the first report of ALV-1 of apple trees and rootstocks in Italy and can be applied for further epidemiological and diagnostic investigations to evaluate the phytosanitary status of the plant material and to control and prevent the spread of the disease.

IDENTIFICATION AND DISTRIBUTION OF VIRUSES ASSOCIATED WITH BAMBARA GROUNDNUT PLANTS IN BURKINA FASO.

ZONGO Aboubié Elisabeth. (1), NEYA Bouma James. (1), PALANGA Essowé. (1,2), SEREME Drissa. (1), KOALA Moustapha. (1), BARRO Nicolas. (2), TRAORE Oumar. (3)

(1) Institute of Environment and Agricultural Research , Ouagadougou, BURKINA FASO; (2) Joseph Ki-Zerbo University, Ouagadougou, BURKINA FASO; (3) National Biosafety Laboratory, Ouagadougou, BURKINA FASO

Text

Plant viruses are a major constraint to the production of bambara groundnut [Vigna subterranea (L.) Verdc.] and can considerably reduce its production and hamper the nutritional quality of the seeds. Indeed, viral diseases cause yield losses of 15 to 87%. The objective of the study is to identify the viruses responsible for the diseases in the main production areas of bambara groundnut in Burkina Faso.
Thus, surveys and collection of samples of infected plants from the three agro-ecological area of Burkina Faso were carried out and submitted to molecular RT-PCR testing.
A total of 135 samples were collected, including 35 samples from the Sahelian area, 50 from the Sudano-Sahelian area and 50 from the Sudanian area. Molecular RT-PCR tests carried out on the collected samples and sequence analyses revealed the presence of three species of potyvirus, including one already described in Bambara groundnut, Cowpea aphid born mosaic virus (CABMV), and two new species provisionally named Bambara groundnut potyvirus 1 (BGVP1) and Bambara groundnut potyvirus 2 (BGVP2), reported for the first time in the country. The distribution of isolates shows that CABMV isolates were most frequent in the Sudano-Sahelian area (71.42%) compared to the Sudanian area (28.58%). In contrast, most BGPV2 isolates (92.31%) and all BGPV1 isolates were found in the Sudanian area. The Sudanian area was the most infected zone with 75% infection rate followed by the Sudano-Sahelian area (25%).

P4.4-025

EVALUATION OF BAMBARA GROUNDNUT ACCESSIONS FOR RESISTANCE TO COWPEA MOSAIC VIRUS (CABMV) IN BURKINA FASO.

ZONGO Aboubié Elisabeth. (1), KOALA Moustapha . (1), NEYA Bouma James. (1), TRAORE Valentin Stanislas Edgar . (1,3), BARRO Nicolas. (2), TRAORE Oumar. (3)

(1) Institute of Environment and Agricultural Research , Ouagadougou, BURKINA FASO; (2) Joseph Ki-ZERBO University, Ouagadougou, BURKINA FASO; (3) National Biosafety Laboratory, Ouagadougou, BURKINA FASO

Text

Cowpea aphid born mosaic (CABMV) is a prevalent virus on legumes and particulary on Bambara groundnut in Burkina Faso. Its impact has been recorded also on Cowpea and caused some significant yield losses. The main of this study is to investigate the sources of resistance to CABMV in order to develop control strategies. Thus, eight accessions of Bambara groundnut were assessed in the greenhouse in pots by mechanical inoculation method in two replicates.
Infected plants showed characteristic symptoms of CABMV virus such yellow mosaic, leaf deformation followed by leaf drop and stunting. The results of yield parameters showed that CABMV had an impact on flowering, pod and seed formation. A1 and A6 accessions were less affected with pods losses estimated between 21.71% to 35.74% and 24.44-32.35% for grain yield. These accessions (A1 and A6) were tolerant to CABMV virus and could be used in Bambara groundnut varietal improvement program in order to control effectively and sustainably CABMV virus.

PREVALENCE AND SPATIAL DISTRIBUTION OF BADNAVIRUS IN THE BANANA (MUSA SPP) MAJOR GROWING AREAS IN BURKINA FASO

OUATTARA Bakary. (1)

() Institut de l'Environnement et de Recherches Agricoles, Ouagadougou, BURKINA FASO; (1) Burkinabè, Ouagadougou, BURKINA FASO

Text

Banana streak virus (BSV) and Sugarcane bacilliform virus (SCBV) are two badnaviruses commonly found in all banana growing areas of the world. It is a threat to the production and improvement of Musa germplasm. In Burkina Faso, the presence of badnaviruses was reported in banana producing regions. The objective of this study was to determine the prevalence of BSV and SCBV in banana production areas of Burkina Faso. A survey followed by a symptomatologic study was conducted in banana plantations in 27 localities of the nine main banana producing regions from July to October 2018 and September to December 2020. In all, 251 leaf samples were collected and analysed for BSV and SCBV infection by Indirect Antigen Coated Plate Assay-ELISA followed by amplification of the RT/RNase H region using Polymerase chain reaction with Badna FP/RP and SCBV F/R primers, respectively. A variety of symptoms were observed on almost all plant organs which were revealed due to BSV by symptomatologic study. The results of serological and

molecular diagnosis revealed a high overall prevalence of BSV in 80.48% of the samples tested. BSV was distributed in seven survey regions out of nine with prevalence ranging from 10% to 100% in North, Centre, Centre West, Hauts Bassins, Cascades, Centre East and Boucle of Mouhoun regions. Very low prevalence was recorded for SCBV in Cascades and East Centre region with 4.35 and 12.5%, respectively. Species detection using specific primers to each species revealed three main species: Banana streak Obino l'ewaï virus (BSOLV), Goldfinger virus (BSGFV) and Imové virus (BSIMV) in the samples tested, respectively in the proportions of 23%, 8% and 0.8%. Co-infection between BSV species was also detected. Keywords: Banana streak virus, Sugarcan baciliform virus, Indirect Antigen Coated Plate Assay, Polymerase Chain Reaction, Musa spp.

The future of disease surveillance and prediction: Beyond the usual suspects.

LANDSCAPE ECOLOGY OF RICE YELLOW MOTTLE VIRUS ALONG THE NIGER VALLEY AND IMPLICATIONS FOR DISEASE SURVEILLANCE AND ANTICIPATION

TRAORE Oumar. (1), FARGETTE Denis. (2)

(1) Institut de l'Environnement et de Recherches Agricoles (INERA), Ouagadougou, BURKINA FASO; (2) Institut de Recherche pour le Dévéloppement, IRD, Montpellier , FRANCE

Text
Rice yellow mottle caused by Rice yellow mottle Sobemovirus (RYMV) is the major rice disease in Africa. RYMV spread was inferred based on regular sampling of virus isolates taking into account the rice growing ecologies and the hydrographic network in the River Niger Valley. RYMV disease outbreaks started with changes in rice agroecosystem particularly when irrigation schemes started in the early 1980s, allowing double cropping per year. The disease underwent a rapid spread over hundreds of kilometers along the River Niger except the outmost northern loop part where the ecology is dominated by floating rice. Spatial and temporal host continuity and inoculum build-up led to the development of severe epidemics. There was no evidence of long-distance dissemination of the virus through natural water. The progressive reduction in host habitat fragmentation may be a key driver in the RYMV spread and need continuous disease surveillance.
Keywords: Rice yellow mottle, virus spread, Niger Valley, ecology

THE ROLE OF VINEYARD CHARACTERISTICS, TECHNOLOGY AND CULTIVATION IN THE GRAPE DISEASES PREVALENCE: FIRST LECTURES OF A LARGE-SCALE CITIZEN SCIENCE

KOCSIS Ivett. (1), PETRÓCZY Marietta. (1), MARKÓ Gábor. (1)

(1) Hungarian University of Agriculture and Life Sciences, Budapest, HUNGARY

Text

The grape production dynamically evolves under the pressure of technological innovation, increasing consumer expectations and regime of global climatic challenges. The role of specific climatic and technological factors in the occurrence and spread of grape diseases might be a well-known issue. However, only a few studies applied a complex methodological approach to the relationship among the vineyards' local properties, cultivation practices and infection severity, although these factors could explain the temporal and spatial variation of the plant diseases. In this citizen science study, we aimed to test the relative importance of the most relevant vineyard characteristics (e.g., inclination, row orientation), crop technology and grape cultivar features on the long-term infection prevalence of primary grapevine pathogens, such as *Botrytis cinerea*, *Plasmopara viticola* and *Erysiphe necator*. We found certain factors that could predict and determine the prevalence of pathogens, which could interfere with the cultivar-specific features. Our results indicated that vineyard characteristics, crop technology, and cultivars features could highly determine the production efficiency via the level of disease control on a long-term basis. In future, these findings may play a key role in plantation establishment and applying precision technologies (i.e., differential spraying), which become increasingly intense due to the general pesticide reduction and global climatic changes.

C9.4-3

COMBINING NETWORK ANALYSIS AND MACHINE LEARNING FOR DESIGNING SURVEILLANCE STRATEGIES

SOUBEYRAND Samuel. (1)

(1) INRAE, Avignon, FRANCE

Text

Surveillance in plant health consists in collecting direct or indirect information on the presence, the distribution and the dynamics of diseases and pests. Surveillance actions are expected to be improved in terms of efficiency if they are designed based on knowledge or assessment of the risks. This talk will illustrate with several case studies (e.g., Xylella fastidiosa and sugarbeet yellowing) how the construction and analysis of networks associated with machine learning may be used to identify new indicators of risks, to build integrated indicators, to assess spatial interconnections and, finally, to design improved spatio-temporal surveillance strategies.

Text

Airborne plant pathogens pose an existential threat to regions naïve to their impact. There are many examples where such pathogens are detected too late; when entire forests are dying (ash dieback - *Hymenoscyphus fraxineus*), stands have been decimated (chestnut blight - *Cryphonectria parasitica*), or keystone ecosystems all but destroyed (myrtle rust – *Austropuccinia psidii*). Once established, pathogen eradication becomes exceedingly difficult as they continue to spread, and management resources are allocated in a reactive manner. Here, we present a surveillance technique that co-opts existing air pollution monitoring infrastructure for the early detection and monitoring of airborne plant pathogens. For this, we used *A. psidii* as a case study and verified its presence in the air of southeast Queensland, Australia using a new species-specific TaqMan qPCR assay. We also present metagenomic results from the same air filters that extend beyond targeting specific plant pathogens to include other potential biosecurity threats. *Austropuccinia psidii* has not established in Western Australia. Routine monitoring for spores from the eastern Australian states using the technique proposed here, will enable more efficient allocation of resources thereby enhancing our ability to predict, find and contain *A. psidii*, and other pathogens like it, before disease is established. A proactive, rather than reactive response.

Text

Interest in agricultural robots for data-driven decision making and improved efficacy has grown significantly in recent years. However, advancements in robotics for disease management have lagged. Labor shortages present a grand challenge for not only agricultural production and disease management, but also breeding programs and academic research. Scouting robots can help ameliorate this challenge by providing accurate disease incidence information at greater temporal and spatial resolutions than humans can feasibly and cost-effectively provide. The PhytoPatholoBot (PPB) is a fully autonomous robotic imaging rover optimized for deployment in trellised crops. PPB autonomously traverses vineyards using an RTK-GPS system and collects side canopy imagery with a custom multispectral camera. PPB employs a semantic segmentation model for near real-time identification and severity estimation of Grapevine Downy Mildew and Grapevine Leafroll

Virus. Experimental results show high correlation between PPB and human ratings for both diseases. PPB ratings correlate well with remote sensing measurements from UAVs, airborne, and spaceborne platforms, which could be further developed into a closed-loop autonomous training system between ground and remote sensing systems. The PPB could one day provide stakeholders and academic users with large-scale disease incidence data to strategically deploy limited mitigation resources and validate remote sensing-based disease warning systems.

HOW REACHABLE IS EUROPE FOR THE JAPANESE BEETLE: TRACKING PLANES, TRAINS AND TRUCKS TO INFORM SURVEILLANCE STRATEGIES

BORNER Leyli. (1), MARTINETTI Davide. (2), POGGI Sylvain. (1)

(1) INRAE, Institut Agro, Univ Rennes, IGEPP, 35653, Le Rheu, France, FRANCE; (2) INRAE, UR 546 BioSP, Avignon, France , FRANCE

Text
The Japanese beetle (*Popillia japonica*) is a polyphagous insect listed as priority pest by the EU phytosanitary legislation. The beetle was first detected in Continental Europe in 2014, in the Italian regions of Piedmont and Lombardy. Since then, it has quickly invaded a large portion of Northwestern Italy and Southern Switzerland, despite the eradication effort of regional phytosanitary services. Furthermore, several interceptions of living adults have occurred in distant locations as a result of unintended passive transport of the beetle. Indeed, it is well established in the literature that *Popillia japonica* is capable of being dispersed over large distances via passive human transportation (hitchhiking behavior). In this work we analyzed how the invaded areas of Northern Italy and Switzerland are connected to the rest of Europe via three main transportation networks: planes, trains and trucks. We built reachability maps from the invaded zone highlighting sites that are likely to act as stepping stones or entry points for the beetle, both close and further away from the currently infested zone. Combined with a suitability map, this allows to prioritize sites for early-detection surveillance based on how likely they are to be reached, as well as their potential for being a future outbreak of infestation. This is crucial, as experiences in North America proved that early detection followed by effective eradication protocols can prevent the establishment of the beetle.

APPLE SCAB FORECASTING: AN INSIGHT INTO PREVAILING AND PROSPECTIVE METHODS

SINGH K P. (1), KUMAR J. (2), PRASAD R K. (3)

(1) G B Pant University of Agriculture & Technology, Pantnagar, INDIA; (2) Graphic Era Hill University, Dehradun, INDIA; (3) B C G University of Horticulture and Forestry , Ranichauri, Tehri Garhwal, INDIA

Text
Apple scab is the most devastating important disease that has invaded almost all apple-growing regions worldwide, causing economic losses in terms of fruit quality and yield. It is a complex disease that develops following two phases, a monocyclic phase caused by ascospores produced in pseudothecia originating from leaf lesions present the previous fall is usually large and is released over a period of 1 to 2 months following bud break, and a polycyclic phase produced by conidia originating from lesions on leave and fruits. PAD is a useful tool to forecast the total amount of inoculum in an orchard and has been shown to effectively improve apple scab management. In IPM programs, the control of apple scab is based on the use of fungicides, and these programs are developed to improve fungicide efficacy using procedures to estimate potential ascospore dose, weather-based models to estimate ascospore maturity, leaf growth, and risk of infection periods. ? In orchards managed according to advisory information, a significant increase in yield was obtained relative to the common management policy. ?During some years, the complete management of the scab by applying 3-4 fungicides and 2 percent urea spray at the time of leaf fall was obtained. Warnings are issued mainly via a call-in telephone, SMS, WhatsApp, Agriculture Govt. department, and broadcasted through radio stations.

(1) Griffith University, Nathan, AUSTRALIA; (2) Department of Primary Industries and Regional Development, Perth, AUSTRALIA

Text
Ascochyta blight of chickpea poses a major risk to the chickpea industry in Australia and worldwide and therefore significant efforts are invested to better understand and monitor the populations of *Ascochyta rabiei*, the causal agent. However, the outputs of these efforts often remain within the domain of researchers and plant pathologists and are not made available to the industry and public outside of internal reports and scientific publications.
Here we introduce the **Asco dashboard** (http://bit.ly/asco-dashboard), an online interactive tool that was developed to provide a visual and intuitive spatio-temporal overview of a comprehensive collection of 1,155 *A. rabiei* isolates collected in Australia between 2013-2022. The dashboard consists of an interactive map with pins representing the location of collected isolates, along with collection metadata, aggressiveness assessment and genotypic information (when available). The dashboard provides summary tables and plots highlighting the risk to common chickpea varieties used in Australia. Dashboard users have access to the underlying data, which can be downloaded. Further work is underway to improve the interface and allow users to select isolates out of the map and to expand this work to other worldwide *A. rabiei* collections.
Feedback from the community and early adopters proves that this is a useful tool for researchers, agronomists, and growers trying to understand the risk of Ascochyta blight in their region and nationwide.

Text

Climate change and international trade intensification has increased health issues for plants. Governments and representatives of EU citizens have agreed to protect the economic, social and environmental resources related to plant health by adopting the plant health regulation 2016/2031 (EU). A major aspect of these regulations is to strengthen, prioritize and harmonize plant pest surveillance based on common scientific technical principles. Epidemiological surveillance is essential to prevent and control health risks, particularly emerging diseases. In July 2018, France signed an agreement whereby public and private organizations constitute the first dedicated network to plant health surveillance by creating the Epidemiological Plant Health Surveillance Platform (ESV Platform).
Various missions are entrusted to the platform such as international plant health media and scientific monitoring system, the provision of pest recognition sheets, assessments of the territory's health and surveillance systems or the proposal for improvements in surveillance based on the risk. We are working on several pathosystems including Xylella fastidiosa, HLB or the pine wood nematode. From the centralization of surveillance data of the territory as well as research and operational works, we assess and improve the surveillance of the health status of plants. The ESV Platform provides methodological and operational support for public policies and the supervisors of monitoring systems.

PREDICTION OF SCLEROTINIA SCLEROTIORUM OCCURRENCE USING SMARTPHONES AND AN IMAGE ANALYSIS PROGRAM

LEE Eunji. (1), WON Hye Sue. (1), KIM Dong Sub. (1)

(1) Kongju National University, Yesan, REPUBLIC OF KOREA

Text

Previous studies have reported that crops infected by phytopathogens can be detected using image analysis techniques. Our studies have shown that image analysis using smartphones can determine the efficacy of soil disinfection techniques and pesticides, but prediction of disease occurrence has not been actively progressed due to difficulty of detection until symptoms or signs appear. The objective of this study was to predict *Sclerotinia sclerotiorum* occurrence based on RGB changes in the image data from pictures taken with two smart phones, Galaxy Note10 and iPhone13 mini. A nitrogen fertilizer and commercial fertilizer for

red lettuces were applied with twice the recommended amount at 10-day intervals. The negative control was applied with no fertilizer. *S. sclerotiorum* was injected 25 days after fertilization and pictures were taken twice a week. RGB proportion was significantly different for each treatment. Signs were detected on 11/28 but the proportion of a black color (RGB 0 0 0) in the infected red lettuces on 11/24 was higher than that of the uninfected red lettuces. The phenomenon appeared in all the treatments regardless of the smartphone models. If more image data is collected, at least, *S. sclerotiorum* occurrence can be predicted using just a smartphone in commercial farms. Furthermore, a combination of the image analysis and drone technologies may contribute to predicting the occurrence in the case of large-scale farms with less time, labor, and cost.

Text

A key challenge in plant disease management is achieving early detection of invading pathogens, which requires effective surveillance through the implementation of monitoring programmes. However, when monitoring relies on visual inspection as a means of detection, surveillance is often hindered by a long incubation period during which plants may be infectious but not displaying visible symptoms. 'Sentinel' plants - alternative susceptible host species that display visible symptoms of infection more rapidly - could be introduced to at-risk populations and included in monitoring programmes to act as early warning beacons for infection. However, while sentinel hosts exhibit faster disease progression and so allow pathogens to be detected earlier, this often comes at a cost: faster disease progression typically promotes earlier onward transmission. Here, we will construct a computational model of pathogen transmission to explore this trade-off and demonstrate how including sentinel plants in monitoring programmes could facilitate earlier detection of invasive plant pathogens. Using *Xylella fastidiosa* infection in *Olea europaea* (European olive) as a current high profile case study, for which *Catharanthus roseus* (Madagascan periwinkle) is a candidate sentinel host, we will demonstrate that including sentinel plants in monitoring programmes can reduce the expected prevalence of infection upon outbreak detection substantially, increasing the feasibility of local outbreak containment.

Text
Grapevine downy mildew (GDM), caused by the oomycete *Plasmopara viticola*, plagues humid production regions and can cause 100% yield loss and vine death under conducive conditions. Growers currently rely on frequent fungicide applications for control, but this practice has led to widespread resistance. Rapid remote detection and mapping of GDM outbreaks would enable precision pesticide applications to target high performing but resistance-prone fungicides where and when most needed, while relying on less resistance-prone protectants elsewhere. To actualize this vision, we investigated two platforms for GDM surveillance: high resolution, multispectral satellite imagery and a terrestrial robotic imaging system at the Cornell Pathology Vineyard in Geneva, New York. We evaluated several supervised and unsupervised methods to predict disease severity using satellite spectral features as input. Spectra and vegetation health indices derived from Planet Labs SkySat imagery (50cm pixel size) could differentiate between healthy and diseased vines even at low GDM severity (10% symptomatic leaf area). Automated severity ratings derived from rover-based imagery also correlated well with human scout ratings ($r > 0.75$). Our next step is to integrate the two systems by training satellite imagery on rover generated severity maps. Our results thus far indicate that both satellite and terrestrial robotic platforms are promising methods for mapping GDM incidence and severity.

VALIDATION OF THE SCLEROTINIA STEM ROT FORECASTING MODEL (SKLEROPRO) UTILIZING SCLEROTIA-DEPOTS

ZAMANI-NOOR Nazanin. (1), BRAND Sinja. (1)

(1) Julius-Kuehn-Institute, Braunschweig, GERMANY

Text
Sclerotinia stem rot caused by Sclerotinia sclerotiorum is one of the important diseases of oilseed rape. SkleroPro is a forecasting model offers recommendations regarding the optimal time for fungicide application during flowering stage. However, validation is an integral part of the model development process if the model is to be used in decision support systems. Investigations were carried out on oilseed rape fields to assess the variables related to the germination of sclerotia and the production of apothecia. The emergence of sclerotia and the release of ascospores were monitored using sclerotia depots, and a data logger was used to record soil temperature and humidity. Further controlled experiments were performed to determine the influence of weather variables on the carpogenic germination of sclerotia. The monitoring reveals that the infestation strength varies yearly. The depots' monitoring showed that apothecia's appearance ranged from 13 May to 10 June 2021, significantly after the oilseed rape flowering stage. In the following year, 2022, the appearance of apothecia ranged from 20 April to 1st May, which was shortly before plant flowering time. Additionally, the findings indicated a significant correlation between the development of apothecia and ascospores with the soil temperature and moisture. In both years, initial germination of

sclerotia and production of the apothecia occurred after 3-5 days of mean soil temperature of 15°C and 55 to 60% soil humidity.

Text

Powdery mildews cause $42.8B in damage annually and are notoriously ubiquitous with 10,000+ host species on all crop producing continents. Grapevine (*Vitis vinifera*) Powdery Mildew (GPM; *Erysiphe necator*) is responsible for >90% of negative environmental consequences associated with vineyard management globally as effective control necessitates high frequency fungicide application. While mechanistic models to predict GPM incidence and spread exist, their accuracy is limited by uncertainty in underlying initial disease distribution. The overall goal of this work is to develop a quantitative index for GPM rooted in disease physiology that can be used to parameterize epidemiological models with NASA Airborne Visible and Infrared Imaging Spectrometer Next Generation (AVIRIS-NG) hyperspectral imagery collected over Napa Valley, CA. We compared Normalized Difference Vegetation Index (NDVI), Red-Edge NDVI (NDVIre), Plant Senescence Reflectance Index (PSRI), and others as viable early indicators of GPM-induced stress and compared their accuracy when derived from hyperspectral and multispectral (Sentinel-2) sources. We found NDVIre derived from AVIRIS-NG to be the most accurate indicator of grapevine health and vigor as relates to potential GPM-stress, especially once vines have amassed significant foliar chlorophyll. The next step for this work is to compare the distribution yielded by our quantitative index to simulations from the Gubler-Thomas.

Text
Early, rapid and accurate detection of plant disease is critical in deploying effective management strategies. The application of multispectral imaging in plant disease diagnosis is getting priority due to ease of application in a large area, high confidence, and considerably low cost. Considering the significant variation in the spectral response of leaf tissues due to impact of huanglongbing (HLB) infection in citrus plants, this study is focused on determining the potential application of multispectral imaging in HLB detection. Multispectral imaging system mounted on UAV was utilized to acquire images from PCR confirmed HLB-infected and healthy plants in farmers' fields in Tanahu district of Nepal. The image acquired with UAV at flight height-30 m, are stitched, and post-processed to generate the geo-referenced reflectance map. The plant pixels were segmented from soil followed by extraction of regions of interest of healthy and infected with a polygon shapefile to prepare the training samples for machine learning methods. The dataset was divided into train and test split in 8:2 ratio. We employed a support vector machine as a classifier. The support vector machine as a classifier produced an accuracy in the range of 72–75% for HLB detection on test samples. The results indicate the potential application of multispectral imagery for rapid detection and pre-screening of HLB-infected trees in citrus orchards where PCR facilities are unavailable or prohibitively expensive.

SIMPLE MODELS FOR COMPLICATED EPIDEMICS: EXPLORING THE USE OF EPIDEMIOLOGICALLY RELEVANT PARAMETERS IN PARSIMONIOUS MODELS TO INFORM EARLY DETECTION SURVEILLANCE

TAYLOR Thomas. (1), PARNELL Stephen. (2), YATES Katherine. (1)

(1) University of Salford, Salford, UNITED KINGDOM; (2) University of Warwick, Conventry, UNITED KINGDOM

Text
The Food and Agricultural Organisation of the United Nations estimated that between 20 and 40 percent of global crop production is lost to pests annually, these losses to plant disease costed the global economy approximately $220 billion annually (FAO, 2021). In the UK, the estimation of the cost of invasive species is £1.7 billion per year (Spence, 2020). To manage plant disease outbreaks, biosecurity measures against plant pathogens must consider risk-based decision making. Risk-based decision making is supported by a framework of surveillance and predictive modelling. Predictive modelling is useful for early detection, increasing the likelihood of extinction and decreasing the cost of management. For early detection to be effective, the efficient use of sparse data sets to inform models is necessary. Therefore, investigation of parsimonious models that are transferable across disparate emerging plant disease epidemics is a research priority. In this study, a model was used to estimate an epidemics discovery-prevalence (labelled the "rule of thumb" approximation) using epidemiological parameters. The results indicated that decreased surveillance efforts and increased growth rate of disease led to a reduction in the accuracy of the rule of thumb approximation. Further research is being conducted to investigate the landscape aggregation of host plants on the accuracy of this simple model and how this interacts with the dispersal capacity of the pathogen.

ESTIMATING STRIPE RUST SEVERITY IN WHEAT USING RGB AND THERMAL IMAGING WITH MACHINE LEARNING MODELS

SINGH Rn. (1,2), KRISHNAN Prameela. (2), SINGH Vaibhav. (2)

(1) ICAR - National Institute of Abiotic Stress Management, Pune, INDIA; (2) ICAR - Indian Agricultural Research Institute, New Delhi, INDIA

Text

Accurate estimation of the severity of wheat stripe rust in a field is crucial for controlling the disease and reducing field losses. Field experiments were carried out during 2017-18 and 2018-19 to collect RGB and thermal images of wheat varieties with different disease resistance levels at critical growth stages. Machine learning (ML) models were developed using the combinations of indices and partial least square regression (PLSR) scores of indices with disease severity and Yeo-Johnson (YJ) transformed values of disease severity. The performance of ML models was the best with indices, while the PLSR scores of indices and YJ transformations of disease severity were unable to improve model performance. In training, the models achieved an R2 and d-index value of greater than 0.95, while in the validation, the models produced R2 and d-index values up to 0.67 and 0.87, respectively. Cubist model developed using indices was the most effective in predicting disease severity. In contrast, the Gaussian process regression model developed using PLSR scores of indices and the YJ-transformed disease severity was the least effective. The findings of this study demonstrated the capabilities of machine learning models in providing predictions of stripe rust severity in the field through the use of RGB and thermal images.

Text

Fungicides are crucial for global grape production, but overuse has financial and resistance consequences. If growers had a way to monitor fungicide activity non-destructively, they could reduce use and expense through more targeted applications and lengthened intervals. We previously found that handheld hyperspectral sensing can predict fungicide concertation with moderate-high accuracy. Here, we developed our “BlackBird” high-throughput imaging platform into an automated hyperspectral imaging platform (HyperBird) to quantify fungicide

concentration on grape leaves. The system consists of a hyperspectral camera (MSV500, Middleton Spectral Vision; 400-1000nm, 8nm resolution), a diffused dome light, X-Y sample positioning, and Z-axis focusing movement. The HyperBird acquires line images at 200 frames per second, equivalent to 20 seconds per 10-mm leaf disc sample (about 2 hours per 351-sample tray). Greenhouse-grown grape leaves are treated with known volumes of strobilurin fungicides, processed into discs, and monitored for up to 21 days. Leaf discs are sampled from varying distances from the point of deposition to examine systemic movement. Concentration is validated for a subset of samples with GC-MS/MS. The next step is evaluating machine and deep learning models to identify the most accurate method for concentration prediction. Our platform enables high throughput fungicide activity monitoring of thousands of samples daily, which can inform application timing.

Text

Classical hand-made measurements of plant phenotype are precise but destructive. The aim of this work was the search for high-throughput technique that can effectively describe the shape and size of oilseed rape plants, with the main focus on its potential yield, expressed as the number of siliques. We were mainly interested in the effect of Sclerotinia stem rot on plant yielding potential. The study used Light detection and ranging technique (LiDAR) to count the number of siliques and compare the results with the traditional method.
Scans were done using FARO LS Focus 3D X 130 scanner in the ‘multi scan’ mode, mostly from three angles and 25% of full resolution capacity. We have proved that disease progression had an increasing effect on the phenotype of oilseed rape plants. Statistically significant differences between healthy and infected plants were found at BBCH 79 – BBCH 80 and this effect was progressing till plant maturity. Infected plants were shorter, with smaller number of side branches, the plants were prematurely dry and many of siliques fell off. The laser scanning gave inaccurate results for healthy plants but was reasonably effective for infected plants. The highest mean correlation between the hand-made and LiDAR-based measurements was 76.5%, but it was up to 92.1% for a single plant. In this study, the traditional method of manual measurements proved its superiority, but it was destructive, which makes it of limited use in plant breeding.

DISEASE SPREAD DYNAMICS FROM MONITORING AT DIFFERENT SPATIAL AND TEMPORAL SCALES

CAMPBELL Rebecca. (1), BERESFORD Robert. (2)

(1) The New Zealand Institute for Plant & Food Research, Motueka, NEW ZEALAND; (2) The New Zealand Institute for Plant & Food Research, Auckland, NEW ZEALAND

Text

Apple canker (AC) is a fungal disease caused by Neonectria ditissima that is primarily rainsplash dispersed and has a variable latent period from weeks to years. These features help to promote a non-random spatial pattern of disease incidence within and across orchard blocks, with hot-spots that can persist in the same location over several years. Spatial disease incidence dynamics were analysed from empirical data varying in temporal and spatial resolution. Temporal comparisons were made between yearly and monthly tree level disease incidence records. Incidence over time was also related to environmental factors, seasonal availability of wounds and expected latent periods. One set of incidence data was recorded at a precise spatial scale by recording the location of individual trees, whereas the other data set approximated location to the orchard 'bay' (± 10 m within a tree row). Disease spread patterns were also analysed both within-block (single cultivar and uniform management) and across-blocks (multiple apple cultivars; differing plant spacing and age). Spatial models were developed using empirical and mechanistic approaches incorporating the spatial and temporal differences in data resolution. Implications of spatial modelling with different resolutions of spatial and temporal scales are discussed for application to efficiently manage and predict the spread of AC in New Zealand apple orchards.

EFFICIENCY OF ANTI-SHARKA CONTROL STRATEGIES

DAURELLE Norman. (1), QUILLEVERE-HAMARD Anne. (2), COTTO Olivier. (1), THEBAUD Gaël. (1)

(1) INRAE, Montpellier, FRANCE; (2) ANSES, Lyon, FRANCE

Text

Plum pox virus is an aphid-transmitted virus responsible for sharka, a disease of trees belonging to the Prunus genus that can cause significant economic losses for growers whose trees are infected. Sharka used to be classified as a quarantine pest (QP). Without an effective curative method, for several decades the French State organized a collective control based on the surveillance and uprooting of symptomatic trees. However, sharka recently became a regulated non-quarantine pest (RNQP) according to European regulations. As a result, the French State is progressively disengaging from the management of this disease. Currently, the intensity of the regulated control is decreasing, and in the medium term it is planned that sharka control in orchards will be deregulated (target system). This transition raises questions on the efficiency (i.e. the ratio between results and resources used) of the future of sharka management: will the level of commitment of growers compensate for the State's disengagement? Will their organization enable an efficient monitoring of the disease and control of its transmission?
To address these questions, the functioning and performance of sharka surveillance systems (present, future) will be analyzed using the OASIS method. The results will be used to make recommendations to improve system efficiency. We will also use a model to simulate the spread and management of sharka in realistic landscapes, in order to compare the two systems' efficiency.

UNDERSTANDING THE USE OF MULTISPECTRAL UAV DATA AND DEEP LEARNING FOR QUANTITATIVE RESISTANCE AND DISEASE CONTROL: CASE OF CERCOSPORA LEAF SPOT IN SUGAR BEET

BARRETO ALCANTARA Abel Andree. (1), ISPIZUA YAMATI Facundo Ramon. (1), MAHLEIN Anne-Katrin. (1)

(1) Institute of Sugar Beet Research, Göttingen, GERMANY

Text

Deep learning in computer vision is currently the principal pillar for image analysis in diverse application fields including disease monitoring in agriculture. Techniques for object detection, semantic segmentation and instance segmentation allow extracting image-based features to replace visual estimations on-site. In crop protection, one of the most time-consuming activities is quantifying disease damage. This work addresses the case of a relevant foliar disease in sugar beet cultivation, Cercospora leaf spot (CLS). We aimed automatic disease quantification using unmanned aerial vehicle (UAV), multispectral imagery, and deep instance segmentation networks. An UAV imagery pipeline is proposed and evaluated in time-series in two experimental fields. The first trial was arranged for a resistant test and considered a comparison of automatic and manual determination of disease severity (DS) in five sugar beet varieties. As second trial, a CLS spot-inoculated experiment was led with the objective to access the parameter for control, disease incidence (DI). Results of resistance test emphasized the robustness the automatic determination of DS, crucial for breeding programs; nevertheless, in the second experiment, a limited use of UAV-based DI was observed for the implementation of control activities. These results allow a better understanding of the practical use of UAV platforms and novel sensing technologies, crucial for replacing the very laborious work of visual assessments.

Text

Working with researchers and scientists, indigenous tribes in New Zealand have developed and adopted (the) Te Whakahononga, an approach that recognises the value of indigenous knowledge and its contribution to improve surveillance approaches and solutions. Indigenous tribes with this approach are encouraged to work with scientists,

researchers and agencies to understand the pathogens that are threatening native species and apply their own indigenous knowledge and observations for better research and surveillance outcomes. 13 indigenous tribes across New Zealand, with researchers from the Biological Heritage, National Science Challenge are working to address *phytopthera agathadicida* and *austropuccinia psidii*, plant pathogens that are a risk to New Zealands native species and significant to the retention of Maori language, culture, identity and traditions. Using traditional methods of observation and new technologies, the approach recognises and gives effect to the role of traditional knowledge in a surveillance effort by elevating indigenous and traditional knowledge holders into the science and research system and tribal authorities alongside local and central government agencies, into the biosecurity and surveillance systems. This presentation will discuss this approach and the outcomes of its application for surveillance on *phytopthera agathadicida* and *austropuccinia psidii* research.

PATHOGEN ISOLATION RATE OF SESAME WILT DISEASE AND QUANTITATIVE RESISTANCE EVALUATION OF MACROPHOMINA PHASEOLINA

DO Jiwon. (1), LEE Sung-Hee. (1), PARK Jae-Ho. (1)

(1) Chungcheongbuk-do Agricultural Research&Extension Services, Goesan, REPUBLIC OF KOREA

Text

Sesame is one of the crops that suffer the most damage from repeated cropping, and is exposed to various diseases. In particular, sesame wilt disease appears in farms where most of the sesame is continuously cultivated. So it is necessary to find a control according to accurate pathogen identification.

Therefore, in this study, 23 farmhouses in 5 regions with wilting symptoms were collected, pathogens were separated by part, and quantitative resistance evaluation of Macrophomina phaseolina, a major pathogen by cultivar, was conducted in vitro. As a result, the pathogen isolation frequency was different depending on the separated organs, Fusarium spp., M. phaseolina, etc. were observed as isolated pathogens. The ratio of pathogen isolation from roots was 30% for M. phaseolina and 73.6% for fusarium sp. and 1% of Didymella. The pathogens isolated from the stem root were more diverse than the pathogens isolated from the roots, with M. phaseolina 27.5% and fusarium sp. 67.0%, Alternaria sp. 16.5%, Didymella 3.3% and so on. The pathogens isolated from the leaves were Alternatia sp., but most of them were saprophile, and only a few of the sesame pathogens, A. sesami, were isolated. Quantitative resistance evaluation of M. phaseolina was conducted on 36 varieties, a piece with a diameter of 5 mm was removed from the tip of strain 17-034 and inoculated together with seeds. As a result, Areum and Gangheuk sesame showed sensitivity, and Geumok sesame showed resistance.

Text

Early warning systems for plant disease based on remote sensing can provide rapid and accurate information for efficient resource management, thus reducing losses, expenses, and unintended negative environmental impacts. We previously found that deploying Machine Learning (ML) on spectroscopic imagery (SI) from NASA's Airborne Visible and Infrared Imaging Spectrometer Next Generation (AVIRIS-NG) yields accurate maps of grapevine leafroll-associated virus 3 (GLRaV-3) at multiple spatial resolutions. Providing these maps to agricultural stakeholders would reduce time, expenses, and uncertainty associated with management, however, both storing SI and training/deploying ML models require significant computing and storage resources. This challenge will magnify tenfold as global SI from the forthcoming satellite Surface Biology & Geology satellite becomes available. We present a cloud-native architecture for plant disease detection to address this challenge using SI from NASA's AVIRIS-NG with GLRaV-3 as a model system. Our system processes SI into disease incidence maps using simple ML (Random Forest, optimized through SMOTE) and easily accommodates new additions and improvements, as well as shifting data modalities, without retaining potentially proprietary stakeholder information. We present an innovative system that empowers stakeholders to make data-driven plant disease management decisions informed by cutting-edge SI while preserving reproducibility and user privacy.

Text

Rhizoctonia crown and root rot (RCRR) caused by *Rhizoctonia solani* AG2-2IIIB can cause severe yield and quality losses in sugar beet. The development of resistant varieties by identifying the genotypes that excel in resistance attributes is one of the principal strategies for disease management. Selecting resistance requires extensive and labor-intensive field trials and breeding work. This situation opens the potential use of unmanned aerial vehicles (UAV) and imaging sensors. From 2019 to 2022, field trials with 17 varieties artificially

inoculated with RCRR were carried out in Göttingen, Germany. The field plots were scored three times during each session, and the fields were monitored biweekly by UAV with multispectral cameras. A digital scoring model was trained and implemented based on multispectral cameras and artificial intelligence. The model first classifies the number of diseased plants within plots and then assigns an overall plot score. A significant relationship was observed between the model's prediction and the one manually obtained by the experts for each plot. The presented approach allows continuous large-scale monitoring during the growing season and could support breeders in determining differences between RCRR resistant varieties.

Text

Aphids pose a significant threat as pests of citrus fruit crops worldwide. They feed directly on plant sap, they damage crops and reduce yields, but most importantly, they are being vectors of plant viruses. The transmission of these viruses depends on the movements of aphids between different parts of a plant, between nearby plants, and further afield. The movement of aphids influences the timing of virus epidemics.
Detection of Aphids in flight is difficult due to their size and weak-flying abilities. We present optical devices that record their wingbeat and machine learning techniques that automatically classify species based on analyzing their wing beat frequencies and harmonics during flight. The species we studied are Aphis spiraecola and Aphis gossypii (Sternorrhyncha: Aphididae) feeding on tender citrus stems.
We further show examples of how this approach can be embedded in electronic insect traps. We also discuss their prospect in being integrated in mobile platforms such as tractors and drones that scan the field and derive flying-insect densities. New optoelectronic devices illuminate up to 2m away and as the aphids fly, they modulate and backscatter light with their wingbeat that is collected and turned to an audible recording that is subsequently analyzed and classified to discern insect species.
The end goal of this effort is to develop monitoring devices that automatically quantify the risk to a crop and guide the process of taking informed preventative measures.

A MODELLING APPROACH TO MAP THE RISK OF HLB IN THE IBERIAN PENINSULA

ELLIS John. (1), LAZARO HERVAS Elena. (3), VICENT CIVERA Antonio. (3), PARNELL Stephen. (2), CUNNIFFE Nik. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM; (2) University of Warwick, Coventry , UNITED KINGDOM; (3) Instituto Valenciano de Investigaciones Agrarias, Valencia, SPAIN

Text

Huanglongbing (HLB), or citrus greening, is a devastating citrus disease, currently found in Asia, Africa and North and South America. At present, no cases of HLB have been found in Europe, but in the past decade one of the disease vectors, the African citrus Psyllid (AfCP), has been found in several locations in North-Western Spain and Portugal. The presence of an established vector population means there is a high risk of transmission between citrus if HLB is subsequently introduced.

We present the findings of a 1 km^2 computational model of vector and pathogen spread in the Iberian Peninsula. The density of citrus in residential areas and commercial orchards, as well as climate suitability, influence the pattern of spread. The majority of vectors disperse locally and are dependent on the availability of citrus plants, but we also account for long-distance dispersal via mechanisms such as wind or human transportation. Using the current estimated distribution of AfCP as an initial condition, results often show a pattern of slow growth of the psyllid in the North-West. However, once long distance dispersal or new introduction of psyllid into the densely populated commercial citrus regions in the South or East of Spain occurs, the population quickly increases. There is subsequently a high risk of rapid spread of HLB upon the introduction of an infected plant in this region.

Text

The collective action of individuals is key for protecting food systems when managing disease. We evaluate how information exchange about epidemic and economic outcomes can influence the management decisions of individuals and the resulting epidemic, in the context of the avocado laurel wilt epidemic in south Florida. In scenario analyses, we

addressed how social and epidemic networks, policy incentives, and social behaviors combine to influence growers' management decisions and regional avocado health. We built an agent-based model to simulate epidemic expansion using parameters specific to the laurel wilt epidemic in south Florida. We found that increased social connections resulted in decreased crop health since increased sharing of information reinforced the selection of less expensive and less effective management choices. Information exchange was most impactful during the lag phase of epidemic expansion, when the cost of disease management outweighed the cost of disease. Managers who were "stubborn" against adopting these cheaper and less effective management strategies contributed to greater regional health. Growers responded to policies that penalized individuals more than to policies which offered financial benefits. This agent-based model represents key aspects of decision making, demonstrating the caveats of information exchange across social networks, and can be used to inform the decisions of avocado growers in regions at risk like Mexico and California.

Text

In the past, air in cities and agricultural fields has been tested for pathogenic microorganisms, revealing important information on potential risks to human and plant health. However, surprisingly, such tests are far less common in greenhouses, while the risk of pathogen dispersal forms a considerable threat to the crop. As a part of a project on air monitoring in greenhouses, our aim is to investigate if high throughput metabarcoding approaches can play a role in early detection of airborne fungal and bacterial pathogens, such as powdery mildew (*Podosphaera xanthii*) and cucumber angular leafspot (*Pseudomonas amygdali* pv. *lachrymans*) in commercial greenhouses. In order to detect potential biases in DNA extraction as well as during PCR and sequencing that might result in failure to detect certain pathogens a custom mock-community of bacteria and fungi, relevant for greenhouse crops, was created. In addition, aerosols were collected with an air sampler in a greenhouse where airborne pathogens were known to be present. These samples and the mock community were subjected to Illumina amplicon sequencing. In addition, the presence of *P. xanthii* and *P. amygdali* pv. *lachrymans* were quantified in the air samples by TaqMan qPCR. Here, we will present results on the sequencing results and comparison to the TaqMan assay and discuss their relevance early detection and monitoring of greenhouse pathogens.

Text

Introductions of invasive plant pests and pathogens are rising sharply. For example, in Europe, ash (*Fraxinus excelsior*) has been impacted by ash dieback disease (causal agent *Hymenoscyphus fraxineus*) and is now threatened by the spread of Emerald ash borer (*Agrilus planipennis*). Early detection increases the efficacy of control measures, however the ability to survey large areas is resource limited. Citizen scientists provide an invaluable resource to increase the survey area, but to provide surveillance metrics, such as the confidence of pathogen absence or the estimated pathogen prevalence, the sensitivity (probability of correctly identifying a pathogen when present) and specificity (probability of correctly declaring a pathogen absent when absent) of surveyors must be known. In 2022, 23 volunteers surveyed up to 176 oak (*Quercus*) trees in two long-term monitoring sites in the UK that have been expert assessed for three acute oak decline symptoms. Volunteer sensitivity and specificity was calculated using the expert data as a reference. This revealed substantial variation in volunteers' ability to recognise different disease symptoms accurately. This dataset was then used to examine the utility of Bayesian models to calculate the sensitivity and specificity of citizen scientists in the absence of an expert assessor as a reference. These methods enable inference of surveillance metrics from citizen science data and optimisation of risk-based surveillance in plant health.

Text
Leaf curl is one of the most important fungal diseases of peach, caused by the pathogen *Taphrina deformans*. The disease has been particularly pronounced in recent years in Greece, causing extensive damage characterized by hyperplasia of host leaves. Aiming to develop an approach towards early diagnosis and knowledge of the pathogenesis of the causal agents of leaf curl disease in Greek peach orchards, innovative -omics technologies were used to optimize the integrated management of the disease. Leaf samples were collected from four main peach producing areas in Greece and 44 strains were isolated using the “spore fall” method. Sequencing with species specific primers led to the molecular identification of the strains as *T. deformans*. Specific primers were also used for the successful detection of the pathogen in the extracted DNA of artificially and naturally infected leaves. Genomic DNA was extracted from isolated fungal strains and underwent HRM analysis, SSR genotyping and Illumina re-sequencing in order to assess the genetic polymorphism of the isolates. Quantification and detection threshold of the pathogen in artificially and naturally infected leaves was achieved by real time PCR using specific primers created for this purpose. This study concluded in a robust and repeatable method for detection and quantification of the pathogen *T. deformans* and indicated a higher genetic polymorphism between strains from different Greek peach producing areas than within each area.

Text
Plant disease detection and quantification depend on accurate visual observations by human experts. However, human rater subjectivity along with labor- and time-intensive disease ratings reduce the reliability and accuracy of disease detection and the throughput needed for the surveillance of emerging diseases. Tar spot of corn, originally endemic to Mexico and Latin America, is an emerging fungal disease in the United States. To accurately detect and track this disease, the Stromata Contour Detection Algorithm (SCDA) v1.0 was developed in 2021, which detects and quantifies tar spot stromata using Red-Green-Blue (RGB) images of infected maize leaves. However, the performance of SCDA is dependent on optimal input parameters that require empirical analyses of numerous images within a specific dataset. Here, we combined the capabilities of the SCDA and Convolutional Neural Network (CNN) to eliminate the empirical search for optimal input parameters while automating the stromata detection process. A preliminary dataset of 9000 tar spot images generated by the SCDA was annotated by a human rater and then used as testing and validation datasets (8:2 rule) to train the binary CNN classifier. The trained CNN model achieved high accuracy (> 93 %) and minimal loss (> 0.15 %) for both testing and validation sets. Our approach will be critical for building an effective, high-throughput, and efficient detection and surveillance platform for

tar spot of corn.

HIGH-THROUGHPUT MONITORING OF PLANT-PATHOGEN INTERACTIONS BASED ON LOW-COST IMAGING

CORDIER Mathis. (1), RASTI Pejman. (1), TORRES Cindy. (1), DAVID Rousseau. (1)

(1) Université d'Angers, Angers, FRANCE

Text

Imaging systems enable to monitor in parallel population of plants during their development. Most Agtech commercial systems to achive this goal are very expensive. This limits the diffusion of such technologies. Cost is specially important for plant pathogen interactions since the imaging systems have to be deployed in confined environment, cannot be moved from these environments and therefore have to be replicated, i.e. be affordable. We recently proposed such low-cost network of imaging systems which operate day and night and are based on raspberry-pi nanocomputers coupled with RGB and Depth cameras (1). In (2,3) the value of these systems were illustrated on the monitoring of abiotic stress. We extend the use of these imaging systems in this communication to biotic stress.

Text

Abstract text
Onset of diseases is affected by several factors, including (among others) weather, soil pathogens, crop genetics, and different management decisions. These factors impose an immense parameter space that needs to be explored and understood to allow mitigation efforts. Addressing this task necessitates a collaborative approach between researchers and other stakeholders, which can be hampered by a myriad of data sources, formats and notations used by the participating groups. Data standardization platforms can streamline collaborations, enable more efficient research progress, and help capitalize on a big-data approach. This presentation will present the role of data standardization in creating high quality data for modeling. Using the Axiom platform (by Agmatix) as an example, observational data of sudden death syndrome (SDS) in soybean crops from 7 states in the US and Canada (2472 observations), collected between 2012-2016, was used to develop a machine learning prediction model. The model, built as an ensemble of decision trees, was able to predict SDS occurrence with an accuracy of 80% across the different production environments. Sensitivity analysis found the key factors affecting SDS in our data: i) crop genetics, ii) precipitation during specific growth periods, and iii) seed treatments. This analysis demonstrates the usefulness of standardization to foster collaborative efforts, and to leverage the collective power to cover critical research gaps.

Text
Leaf spectral reflectance (LSR) has been studied in several pathosystems as a tool for early detection of the infection, before symptoms' appearance, which is key for an effective disease management. However, this technology has been poorly explored in kiwifruit bacterial canker (KBC), and other diseases, through a dynamic monitoring after artificial inoculation. Here, *Actinidia chinensis* var. *deliciosa* plants grown in a climate chamber were mock- (control) and *Pseudomonas syringae* pv. *actinidiae* (Psa)-inoculated and monitored with a hyperspectral spectroradiometer (350-2500 nm) for measuring LSR at 1, 2, 5, 7, 9 and 14 days post inoculation (dpi). At 2 dpi (prior to symptoms' appearance) and 5 dpi (initial symptoms) LSR of Psa-infected plants was significantly lower compared with control plants in the following regions: ultraviolet (UV) (350-364 and 350-400 nm, respectively); violet, blue and green (400-502 nm, at 5 dpi) and red (660-686 nm at 5 dpi and 671-688 nm at 2 dpi). A lower LSR in the UV region was found in infected plants throughout the experiment (except at 1 and 7 dpi), whereas lower LSR in the red region was only related to early infection (<7

dpi). Moreover, higher LSR in the infrared region (>700 nm) was related to symptoms' progression, with Psa-infected leaves showing this alteration only at 14 dpi, when all plants had heavy KBC foliar symptoms. Hence, LSR analysis seems to be a valuable tool for early detection of Psa, allowing anticipated sanitary measures

(1) Canola Council of Canada, Winnipeg, CANADA; (2) Saskatchewan Ministry of Agriculture, Regina, CANADA; (3) Government of Alberta, Agriculture and Forestry, Rosemary, CANADA; (4) Manitoba Agriculture, Carman, CANADA

Text

Canola (Brassica napus and B. rapa) is Canada's most valuable crop, contributing $29.9 billion CAD to the Canadian economy. But recently verticillium stripe, a new disease caused by the fungus Verticillium longisporum, may threaten this success.
Verticillium stripe is a soil-borne disease that was found first in Canada in 2014, and a survey in 2015 found this pathogen present in all Canadian provinces.
Currently canola disease surveys conducted independently in each of the Prairie Provinces (Manitoba, Saskatchewan and Alberta), have reported the presence of this disease.
From 2020 to 2022, the prevalence of verticillium stripe has risen 8% in Manitoba and in 2022 the province saw an average incidence of 23%. In 2022, Saskatchewan coordinated a targeted survey on the eastern side of the province revealed a 9.7% average incidence in canola fields. Alberta found two suspected cases of verticillium stripe in 2020 and reported seven cases in 2022.
Overall, the results from the disease surveys highlight that verticillium stripe could be an increasing problem for the canola growing region of Western Canada and emphasize the importance of ongoing survey efforts to track this disease.

Text
Fusarium root rot of soybean, dry bean and field pea is of concern in Manitoba, Canada, as there have been increasing numbers of reports of significant losses in plant stand and yield caused by this disease. Therefore, annual field surveys of soybean, dry bean, and field pea have been conducted to determine the prevalence and severity of root rot, identify the common root pathogens and detect the presence of any new root diseases. Since 2015, approximately 40 crops each of soybean, bean and pea have been sampled per year where roots were rated for the incidence and severity of root rot disease and causal fungal species were identified. The results have shown that root rot of soybean, bean and pea in Manitoba is primarily caused by several species of *Fusarium*. The *Fusarium* species isolated in each year included *F. oxysporum*, *F. graminearum*, *F. redolens*, *F. avenaceum*, *F. acuminatum* and *F. solani*, with some *Fusarium* spp. common to all three crops. A notable finding was the identification of *F. graminearum* in dry bean and soybean. With increasing acreages of these crops in Manitoba, *F. graminearum* may be problematic in current crop rotation regimes given its cross-pathogenicity and as a source of inoculum. Collectively, the findings from this research will support the development of effective management strategies for root rot disease associated with the *Fusarium* spp. complex affecting soybean, dry bean and field pea in Manitoba and across Canada.

Text
Compatible plant-pathogen interactions result in diverse visible plant disease symptoms. Assessing these symptoms is the basis for identifying plant disease and quantifying disease severity, such as in plant breeding programs for disease resistance. But before the appearance of visible symptoms, the interaction has already triggered fundamental changes in the plant. Optical sensors can non-invasively detect such changes, and therefore enable early disease detection and quantification as well as provide insights into processes underlying symptom development. This can be particularly useful for pathogens that induce visible symptoms only late in the disease cycle, for example obligate biotrophs like the oomycete downy mildews. We found that lettuce leaf tissue that is colonized by the downy mildew pathogen Bremia lactucae emits increased UV-A-excited blue-green fluorescence before the appearance of other visible signs and symptoms. Transcriptome and metabolome analysis suggest that this fluorescence originates mainly from the accumulation of phenolic acids, potential precursors for pathogen-induced lignin biosynthesis. We also show that UV-fluorescence imaging can be applied for early and accurate downy mildew disease severity estimation. In combination with automatic image segmentation, this can provide a tool for sensor-based phenotyping in downy mildew resistance breeding. Keywords: Fluorescence, Phenotyping

DEEP LEARNING BASED IDENTIFICATION OF CUCURBIT DISEASES AT THE MICROIMAGING SCALE WITH EXPLAINABLE SALIENCY ANALYSIS

SENTIL Sruthi. (1), PARET Mathews. (1)

(1) University of Florida, Quincy, UNITED STATES

Text

The timely diagnosis of plant diseases plays a crucial role in integrated pest management and decision-making to enhance agricultural yields. Still, rapid disease classification and thereafter management remain difficult for smallholder farmers lacking robust resources. Existing deep learning models for on-site plant disease classification from image inputs at the macroscopic scale suffer from confounding variables in their backgrounds and limited capabilities in a field setting. We present the CUCMicroNet pipeline for the visual classification of biotic and abiotic stresses in five cucurbit species. Images were collected from a smartphone camera and attachable 30x microscopic lens, focusing on disease lesions of cucurbit leaves. We compared an array of data separation and backend neural network architectures on their prediction abilities, quantified by their mean average precision and F1 Scores. The approach merging all classes of plant condition together regardless of the cucurbit species yielded the highest prediction capabilities, with an average precision of 93.2%, and recall of 82.9%. To understand and interpret the CUCMicroNet classification reasoning, GradCAM and t-SNE saliency metrics were analyzed to display regions of interest in the image. This tool is expected to aid farmers, especially in remote places in the world, to make reliable decisions regarding disease management treatments.

O. Box 30197-00100 , Nairobi, KENYA

Text

A remote PLANT HEAlth Diagnostic (PLANTHEAD) network is being developed within The H2020 EWA-BELT project (https://www.ewabelt.eu/), based on a platform hosting photographic database and geroreferentiation. An image repository is being built-up with vouchered pictures of symptoms of the most relevant diseases and pests affecting major crops in african countries. The local farmer sends an alert by mobile phone directly to the central HUB, providing relevant information such as localization, crop management, pesticide treatments, along with pictures (macro- or microscopic) and a short description of the problem. If the HUB can solve the problem, the platform sends the diagnosis and suggested actions

directly to the farmer. If not, the platform sends the request to the first node, which takes charge of it. The request goes to a higher node if the lower one is unable to provide a solution. The node can be local, national or international. Once the solution is found, the competent node formulates a diagnosis and the farmer receives a notification of successful response. This response is stored in the database for future use and the images feed an AI-based image recognition system. The shared database will represent an extremely valuable tool for epidemiological studies, real time monitoring, modelling, and forecasting the progression of a pathogen or any pest that may raise serious food security/ safety concern.

The Potential of Seed Microbiomes

C5.6-1

SEED MICROBIOTA: DIVERSITY, ASSEMBLY AND TRANSMISSION

BARRET Matthieu. (1)

(1) INRAE, Angers, FRANCE

Text

Seed can act as a primary inoculum source for the plant microbiota. Understanding the processes involved in the seed microbiome assembly and dynamics during seed germination and seedling emergence has the potential to be used to improve crop establishment. This presentation will summarize current knowledge on the diversity of microbial communities associated with seeds of about 50 plant species. Particular attention will be paid to the stable bacterial fraction shared across multiple plant species at a large scale. The origin, timing of arrival and succession of these core seed-associated bacterial taxa will be detailed using common bean and radish as study models. The relative importance of selection in seed microbiota assembly will be discussed as well as the bacterial genetic determinants potentially involved in seed transmission. Finally, strategies to limit seed transmission of plant pathogens through seed microbiota engineering will be addressed.

C5.6-2

FUTURE OF SEED PATHOLOGY IN THE METAGENOMICS ERA

Text

Seeds are a cornerstone to US agriculture as the beginning steps to production of most plant species. These plant reproductive vehicles are also habitats for microorganisms, ranging from the symbiotic to pathogenic. Historically, seed has been moved without many

phytosanitary barriers. However, a growing concern in plant-based agriculture and trade is the risk of transporting pathogens with seed. Rapid advancements in metagenomics, the collective DNA in an environment, is revealing that a normal plant microbial community can contain diverse microorganisms, including saprophytes, pathogens, and beneficial microorganisms. This includes the possibility of finding microorganisms of emerging risk to human, animal, and plant health that were not previously known to occur in plant tissues. This is particularly poorly understood for seed health across most cropping systems, including elucidating the biological risk of seed transmission. Metagenomics is beginning to be used in seed health screening, so there is an urgent need to define the core seed microbiome as an overall indicator of seed health and for determining relevant metrics for plant pathogen identification and risk assessment. This presentation will discuss how research can advance agricultural and economic security by defining healthy seed microbiomes in the context of plant diseases and provide guidance on biologically-relevant risk assessment for seed transmission of plant pathogens.

C5.6-3

NEW INSIGHTS INTO TREE SEED MYCOBIOMES – A BIOSECURITY PERSPECTIVE

FRANIC Iva. (1), CLEARY Michelle. (1), ESCHEN René. (2), PROSPERO Simone. (3)

(1) Swedish University of Agricultural Sciences, Alnarp, SWEDEN; (2) CABI, Delémont, SWITZERLAND; (3) Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, SWITZERLAND

Text

Tree seeds have been considered as a low-risk introduction pathway for plant pathogenic fungi, and their movement is, thus, mostly unregulated from a phytosanitary point of view. This is despite historical evidence of some harmful fungi, such as *Diplodia sapinea* or *Fusarium circinatum*, being introduced to new areas via seed import, and recent discoveries about high diversity of seed-associated fungi. Here we present the results of large-scale studies in which we use traditional plating and RNA- and DNA-based high-throughput amplicon sequencing to characterise all and viable fungi associated with traded tree seeds and seeds from botanic gardens. In these studies, we assess 1) the diversity, 2) main drivers of species composition, and 3) vertical transmission of tree seed-associated fungi. Our results show that tree seeds carry highly diverse fungi, including potential plant pathogens, and that fungal species composition is mostly determined by the host tree species, possibly due to high prevalence of vertical transmission. These results suggest high risk of introduction and establishment of seed-borne fungi in new environments and highlight the need for additional studies regarding spread and impact of tree seed-borne fungi, as well as for improved risk assessment and management.

C5.6-4

SOYBEAN AND COTTON SPERMOSPHERE SOIL MICROBIAL DYNAMICS

OLOFINTILA Oluwakemisola. (1), **NOEL Zachary. (1)**

(1) Auburn University, Auburn, UNITED STATES

Text

The spermosphere is the transient, immediate zone of soil around imbibing and germinating seeds. It represents a habitat where there is contact between seed-associated microbes and soil microbes, but is studied less compared to other plant habitats. Thus, the objectives of this study were to develop an efficient strategy to collect spermosphere soils around imbibing soybean and cotton in non-sterile soil and investigate changes in microbial communities. The method employed sufficiently collected spermosphere soil as initially defined in space by constraining the soil sampled with a cork borer and confining the soil to a 12-well microtiter plate. Spermosphere prokaryote composition changed over time and depended on the crop within six hours after seeds were sown. By 12 to 18 hours, crops had unique microbial communities in spermosphere soils. Prokaryote evenness dropped following seed imbibition with the proliferation of copiotrophic soil bacteria. Due to their long history of plant growth promotion, prokaryote OTUs in *Bacillus*, *Paenibacillus*, *Burkholderia*, *Massilia*, *Azospirillum*, and *Pseudomonas* were notable genera enriched. Fungi and prokaryotes were hub taxa in networks. Additionally, the enriched taxa were not hubs in networks. Overall, this study advances knowledge in the assembly of the plant microbiome early in a plant's life.

Text

Agriculture Victoria Research, a state government department, has a role in research to support the pasture-based dairy industry of Victoria, as well as a role in biosecurity. Metatranscriptomic studies have been done on commercial seeds of the pasture species *Lolium perenne* and *Medicago sativa*, and the diversity of viruses seen in these data sets will be presented. Viruses present include known viruses and novel viruses. Data on the presence of some of the viruses in seedlings grown from these seed will also be discussed. Using metatranscriptome data enables other members of the microbiome present to be estimated, and this data will be examined with respect to the diversity of viruses present in the samples. The viral diversity in pasture seeds will be compared to that in a set of 9 horticulture species, including *Capsicum annuum*, *Raphanus sativus* and *Cucurbita pepo* which have been profiled for viruses. Viruses detected in select public sequence runs from the NCBI short read archive will used to compare viral seed diversity across countries.

Text

Seed germination is drastically decreased by biotic and abiotic stresses. The improvement of seed germination efficiency is, hence, a strategic priority to increase food production. There exists a need for environmentally-friendly solutions to compensate for chemical treatments currently used. A way to enhance seed performance is to exploit the beneficial impact of endophytes on plant fitness. The current view is that such protection relies on chemical mediations using the large variety of molecules produced by endophytes.
Tomato is one of the most important crop worldwide undergoing important periodic losses due to abiotic and biotic stresses. Tomato seed germination and seedling establishment are particularly sensitive to salt and water stress as well as fungal pathogens. Recent studies support the potential of endophytes to improve tomato tolerance to salt stress or pathogens. The objective of BIOSTIM is to develop sustainable agronomic solutions based on metabolites produced by fungal seed-borne endophytes. We investigate the diversity of seed-borne fungal endophytes in tomato cultivars used worldwide and test the potential of their metabolites to stimulate tomato seed germination under abiotic and biotic stress conditions.
So far, 60 fungal endophytes have been isolated and taxonomically identified from 15 tomato varieties and their metabolites extracted. Their impact on seed germination under abiotic and biotic stresses are currently investigated.

Text
Inheritance of microbes is crucial for the persistence of host-associated microbial communities. Although the inheritance of seed microbes has been reported from diverse plants, temporal dynamics of microbial communities from parent to progeny remain scarce. Little is known concerning intra-plant variations in progeny seed microbiota at the single-seed level. In this study, we addressed the veiled dynamics of the transmission and variation of seed bacteria and fungi in rice. We identified 29 bacteria and 34 fungi vertically transmitted across generations. Abundance-based regression models allow us to classify the colonization types of the microbes. We found that they are late colonizers dominating each community at the ripening stage. Source-sink modeling showed that parental seeds and stem endosphere are major origins of progeny seed microbiota. We further investigated the heterogeneity of progeny seed microbiota using 70 single-seed samples from a single field-grown rice. We found that high heterogeneity of seed bacteria and fungi at the single-seed level. The observed variation patterns could be clustered according to the originating panicle branch. Null modeling-based statistical analysis revealed that homogeneous selection, dispersal limitation, and ecological drift governed the heterogeneity of seed microbiota. This study gives empirical evidence for the drivers and dynamics of seed bacterial and fungal communities as an ecological continuum.

ANALYSIS OF TOMATO SEED MICROBIOME AND ITS BIOLOGICAL ACTIVITIES

CHOI Kihyuck. (1), YANG Seongeun. (1), CHOI Heeyun. (1)

(1) Dong-A University, Busan, REPUBLIC OF KOREA

Text
Microbiota associated with plants plays a critical role in promoting plant health. Especially, seed endophytes play an important role in the germination and growth of seedlings at an early stage. To analyze the bacterial endophytes inhibiting the tomato seeds we isolated metagenomic DNA from tomato seeds of resistant (Hawaii 7996) and susceptible (Moneymaker) cultivars to bacterial wilt disease after removing microbiota on the surface of them. The comparison of bacterial endophytes in both cultivars of seeds revealed the identification of several operational taxonomic units (OTUs) as core microbiota in the resistant cultivar. Furthermore, the culture collection of seed endophytes was established under various cultural conditions. Among the isolated seed endophytes, *Moraxella osloensis* YHT4-1 and *Paenibacillus peoriae* YHR2-1 showed growth-promoting and antimicrobial effects against tomato plant pathogens, respectively. To verify the effect of the isolates the synthetic community (SynCom) including YHT4-1 and YHR2-1 strains was constructed based on in vitro and in silico analysis. The capability of disease suppression of SynCom was tested on Fusarium wilt disease in a susceptible cultivar of tomato plant using seed-soaking treatment. Results showed significant disease suppression and taxonomic profiling confirmed the presence of the inoculated SynCom. In conclusion, core microbiota from the resistant cultivar demonstrated beneficial effects on tomato plant health.

Text

The community of microorganisms associated with a plant (the microbiome) is critical to plant fitness. However, little is known on how plants recruit the microorganisms. Here, we study the extent to which maternal trees transmit their microbiome to their offspring during seed development; a process that will lead to differences among clones that are caused by microbiome differences rather than the action of ash genes themselves. We used metabarcoding of the ITS1 intergenic region and the 16S rRNA gene to compare the seed microbiome of European ash (Fraxinus excelsior). Seeds were dissected and organ-specific microbiomes of each seed were profiled. We also profiled the microbiome of mother (seed stalk) and father (pollen) trees. This data will improve our understanding of how intrinsic factors shape the development of the seed microbiome from mother and father tree to their offspring.

Text

Seed-borne diseases are a growing concern on crops of economical and social interest around the world. To control these diseases, some strategies can be applied having in mind the necessity to consider the high diversity and specific characteristics of seed borne agents in addition to several other factors. Two common sanitary measures, seed health testing and seed health treatment may be considered key measures to successfully control important seed-borne diseases in practice. Studies on those topics have been demonstrating that the combination of those practices for crops like soybean, maize, etc is responsible to produce great impact on yields and on quality of their products. Studies on seed health treatment in soybean and maize were carried out to evaluate the efficacy of chemical seed treatment and to quantify the effects of pathogens like C. truncatum and R. solani, S. maydis and F. verticillioides on their hosts. Impacts of the seed-borne inoculum of those pathogens and the efficacy of seed health treatment on plant development and on yields varied according to the fungal species, but in average each 1% incidence of the pathogen in seed lots was able to cause yield reduction in the range of 1.0 to 2.5 %. Chemical seed treatment was able to reduce losses in the range of 80 to 100 %. Effects of the seed-borne inoculum of all pathogens could be more drastic as the environmental conditions in the present case were not well favorable for the diseases development.

Text

Nucleotide-binding and leucine-rich repeat domain proteins (NLRs) are the predominant class of disease resistance proteins. They are intracellular receptors that detect pathogen-secreted virulence effectors. In addition to singleton NLRs, plants possess NLR pairs composed of one sensor and one helper (sNLR and hNLR) that cooperate for effector detection and disease resistance.
The NLR pair RGA4/RGA5 from rice recognizes the effectors AVR-Pia and AVR1-CO39 from the fungus *Magnaporthe oryzae*, which causes the devastating blast disease on rice. The unconventional Heavy Metal-Associated (HMA) domain of RGA5 is critical for effector binding, and we identified the surfaces that mediate complex formation. Using detailed knowledge on other rice sNLRs, we created a new high-affinity binding surface for the *M. oryzae* effector AVR-PikD. RGA5 variants with this engineered binding surface perceived the new ligand, AVR-PikD, and still recognized AVR-Pia and AVR1-CO39 in the model plant *N. benthamiana*. However, these modifications were insufficient to create a novel blast resistance specificity in transgenic rice plants. This pinpoints significant knowledge gaps that limit the full deployment of this NLR-ID engineering strategy and provided hypotheses that we are testing by studying the structure and dynamics of RGA4/RGA5 complexes at the resting and the active state.

C6.6-3

RECOGNITION OF PATHOGEN EFFECTORS BY NON-CANONICAL DOMAINS IN PLANT NLR IMMUNE RECEPTORS

BANFIELD Mark. (1)

(1) John Innes Centre, Norwich, UNITED KINGDOM

Text
Nucleotide-binding leucine rich repeat (NLR) proteins activate plant defences on perception of pathogen effectors. These innate immune receptors are a critical line of defence against plant disease and are a major component of crop breeding programs for disease resistance. A molecular mechanistic and structural understanding of their function underpins efforts to engineer these proteins with enhanced/extended activities that have potential for deployment in agriculture. One route by which NLR immune receptors detect effectors is through non-canonical integrated domains that directly bind these proteins. These integrated domains likely have their evolutionary origin in virulence-associated targets of effectors, but have been genetically incorporated into NLRs to act as bait domains. In the context of the full-length receptors, binding of effectors to integrated domains likely induces conformational change and oligomerisation to generate a signalling platform. Studies of the interaction between the integrated HMA domain of the rice NLR pair Pik and the rice blast pathogen effector AVR-Pik has enabled engineering of novel disease resistance profiles in rice. Recently, the Pik NLR chassis has been used to incorporate novel domains that bind different effectors, opening new opportunities for engineering resistance to pathogen strains that infect different cereal crops. Structure-led approaches continue allow for optimisation of effector recognition potential by integrated domains.

REVIVE BROKEN NLR-GENES

ZENDLER Daniel. (1), TAKKEN Frank L. W.. (1)

(1) Molecular Plant Pathology, SILS, Universiteit van Amsterdam, Amsterdam, NETHERLANDS

Text
Besides changing environmental and climatic conditions plant pathogens are one of the major threats to food security worldwide. A major aspect of plant breeding involves introgression of natural genetic resistances that arose from co-evolution of plants with their respective pathogens. The process of identifying novel resistances and their subsequent introgression into elite cultivars is a time consuming and labor-intensive process. Typically, these dominant resistance traits, often encoded by NB-LRR-like receptor genes (NLRs), exert only temporarily resistance in the field. Fast evolving pathogens such as viruses can overcome such resistances, sometimes by a single amino-acid change in their recognized effector proteins. One example of the latter is the interaction of the non-structural movement (NSm) protein of the tomato spotted wilt virus (TSWV) with the Sw5b coiled-coil NLR protein. A single amino-acid change in NSm (C118Y or T120V) breaks Sw5b resistance. To counteract the evolutionary adaption of pathogens we propose a high-throughput screening pipeline using in vitro molecular evolution to identify gain-of-function mutations in NLR proteins to resurrect broken resistances.

Text

RGA5/RGA4 and Pik1/Pik2 are two paired nucleotide-binding leucine-rich repeat (NLR) receptors conferring blast resistance in rice. RGA5 and Pik1 function as sensor receptors that recognize, respectively, the corresponding Magnaporthe oryzae Avrs and ToxB-like (MAX) effectors AVR-Pia/AVR1-CO39 and AVR-Pik through their integrated heavy metal-associated (HMA) domains, leading to helper NLR RGA4 and Pik2-mediated blast resistance. Previous studies have determined the crystal structures of RGA5-HMA/AVR1-CO39 complex, Pik1-HMA/AVR-PikD and Avr-Pib, and shown that RGA5-HMA and Pik1-HMA are structurally similar and yet recognize the effectors through distinct interfaces. Based on the structures, we engineered the AVR1-CO39-recognizing interface in the RGA5-HMA domain and its following C-terminal lysine-rich tail, and generated a mutant of RGA5, named RGA5HMA2, which can recognize the noncorresponding MAX effector AvrPib and confer complete resistance in transgenic rice to the M. oryzae strains expressing AvrPib. In addition, we generated another RGA5 mutant RGA5HMA5 that confers resistance to M. oryzae strains expressing AVR-PikD, in which the HMA domain harbors three resurfaced interfaces, including one corresponding to the AVR-PikD/Pik-HMA interface. Altogether, our work demonstrates that a synthetic RGA5 sensor NLR requires a concerted action of multiple interfaces within and outside the HMA domain to both recognize MAX effectors and activate helper NLR-mediated blast resistance.

Text

A Canadian biovigilance platform is under development aiming to entail inadvertent repercussions of pest migration arising from cultural practices and climate change and ultimately mitigate fungal disease threats to agricultural productivity. Over the past 15 years and through multiple developmental phases, this platform now consists of local and nationwide spore sampling networks (AeroNET), DNA-based diagnostic toolboxes, and trajectory modeling of pathogen inocula. As a proof of concept, we investigated aeromycobiota in western Canada using weekly air-sampling over four growing seasons at three mixed-use sites in British Columbia and one season at five sites in southern Alberta. Metabarcoding via rust-enhanced ITS2 amplicons generated from air-borne fungal spores and novel bioinformatic pipelines to curated known cereal rust fungal sequences, was used for species-level identification. Wind trajectory simulations predicted the potential sources of rust urediniospores and their airborne transmission pathways. We showed that the Canadian Rocky Mountains created a geographic barrier to upper wind flow to prevent the spread of rusts and other plant pathogens. Regional climate and crop diversification conditions also explained some pronounced changes in the diversity and abundance of wheat rust pathogens. This study paves the way for pathogen monitoring and disease risk forecasting as part of the design and development of enhanced biovigilance systems in Canada.

SURVEILLANCE OF DISPERSAL AND PATHOGENICITY VARIATION OF CORN RUSTS

LIANG Junmin. (1), LI Yuanjie. (1), CAI Lei. (1)

(1) Institute of Microbiology, Chinese Academy of Sciences, Beijing, CHINA

Text

Corn rusts, caused by *Puccinia polysora* and *P. sorghi* have posed an increasing risk for global corn production. However, knowledge of their population structure, dispersal patterns, and virulence dynamics is limited. Here, we built a pipeline using HiFi reads and Hi-C data, and successfully assembled two pathogens to haplotype-phased and chromosome-level. The genome size of *P. polysora* (GD1913) and *P. sorghi* (LN2104) is 1.71 Gbp and 320 Mbp, respectively, with a similar sized 18 chromosomes in each haplotype. Genome resequencing of 79 additional isolates revealed a clonal population structure of *P. polysora* in China with low geographic differentiation. Nevertheless, a minor population differentiated from the major population by having mutations on secreted proteins including *AvrRppC*, indicating the ongoing virulence evolution to evade recognition by *RppC*, a major resistance gene in Chinese corn cultivars. Some *P. polysora* strains showed different phylogenetic positions when maped to the phased genome and single nuclei, suggesting that somatic recombination could contribute to lineage differentiation. Combined with the mantel test and lineage distribution along typhoons, we considered that the dispersal pattern of *P. polysora* in China was not simply from south to north but affected by multiple possible origins, e.g., southeast Asia. The population genomics of *P. sorghi* and its comparison with *P. polysora* were also studied.

A METACOMMUNITY MODEL FOR ENTANGLED AIRBORNE PATHOSYSTEMS: APPLICATION TO BROWN ROT SPREAD IN PEACH ORCHARDS

RADICI Andrea. (1), MARTINETTI Davide. (1), CUNNIFFE Nik. (2), VANALLI Chiara. (3), BEVACQUA Daniele. (1)

(1) INRAE, Avignon, FRANCE; (2) University of Cambridge, Cambridge , UNITED KINGDOM; (3) Pennsylvania State University, State College, UNITED STATES

Text

Plant disease dynamics are driven by concurrent host susceptibility, pathogen presence, and environmental conditions favourable to infection. While host susceptibility and environmental conditions have been widely studied, pathogen presence, in case of wind dispersal, is particularly complex to investigate. In this study we conceive a metacommunity model where local communities composed by plant hosts and the pathogen are connected through airborne pathogen dispersal, to describe the spatio-temporal dynamics of a fungal disease, attacking stone fruits, in continental France. We explicitly consider climatic drivers affecting pathogen dispersal and survival, host phenology and epidemic processes. We demonstrate the model against a real pathosystem, brown rot spread in French peach orchards, using measures of disease incidence and weather reanalysis. We eventually produce maps of risk distinguishing site vulnerability (inclination to be affected by secondary infections) and dangerousness (inclination to be generate secondary in other sites). Our results satisfactorily match past observations of brown rot incidence in France. Moreover, we found that most vulnerable regions are placed along the Rhône Valley, in the Roussillon and the Montauban plain, the first two being also the most dangerous. Our work represents a first step to use air-masses movements to inform plant protection strategies, and could be adapted to perform optimization under future climate projections.

Text

Understanding the origins and migration routes of phytopathogen inoculum is essential in predicting disease development and formulating control strategies. Puccinia striiformis f. sp. tritici (Pst), the causal agent of wheat stripe rust, is an airborne fungal pathogen threatening wheat production by long-distance migration. Due to large variation in geographic features, climatic conditions, and wheat production systems, inter-regional Pst dispersal routes in China remain largely unknown. In the present research, we sequenced 154 Pst isolates

sampled from all the major wheat-growing regions in China to study the Pst population structure. Western Qinling Mountains, Himalayan region, and Guizhou Plateau were found to be centers of Pst origin in China. Combined with trajectory tracking and field disease surveys, long-distance Pst migration routes from individual origins were proposed. The present findings will improve current understanding of Pst origin and migration in China and emphasize the need for managing stripe rust at the national scale.

Text

Soilborne pathogenic fungi are a leading cause of crop disease and are primarily spread through microscopic, durable spores adapted differentially for both persistence and dispersal via soil, animals, water and atmosphere. While intracontinental aerial dispersion of soilborne fungal spores has been well established, transoceanic and intercontinental atmospheric transport of these spores entrained with aerosolized agricultural dust is understudied and may contribute to disease spread. Our NASA ROSES project seeks to address this need by integrating remote sensing, aerosol transport and comparative genomics to assess the long-distance atmospheric dispersal of the plant pathogenic, soilborne fungus *Fusarium oxysporum* (*Fo*) on global dust currents. The CAM6-MIMI climate model was modified to incorporate spore traits that influence dispersal and atmospheric survival, and was parameterized using the 2020 Godzilla dust event. We found modeling evidence of transoceanic and intercontinental atmospheric transport of viable *Fo* spores and offered a danger index for *Fo* spore deposition on susceptible agricultural zones. The main long-distance transport of viable spores and the highest danger for deposition on cropland are between the regions of Eurasia, North Africa, and Sub-Saharan Africa. This study provides key insights about Fusarium wilt epidemiology and lays the groundwork to build an operational, real-time global surveillance system of long-distance plant pathogen transport risk.

USE OF SPATIO-TEMPORAL AEROBIOLOGICAL DATA OF SPORE ABUNDANCE TO UNDERSTAND THE LARGE-SCALE EPIDEMIOLOGY OF THE ASH DIEBACK DISEASE

GOMEZ GALLEGO Mireia. (1), AGUAYO Jaime. (2), MULLER Elodie. (1), GILLET Anaïs. (1), MARÇAIS Benoit. (1)

(1) INRAE, Champenoux, FRANCE; (2) ANSES Laboratoire de la Santé des Végétaux, Unité de Mycologie, Malzéville, FRANCE

Text

Aerial dispersal of pathogenic fungi is a key process in disease epidemiology and an effective long-distance dispersal method. Quantification of airborne inoculum at different spatial scales can then inform disease epidemiology and management. Here, we use pollen-monitoring permanent aerobiological networks in Europe to inform large-scale epidemiology of the ash dieback disease. We focused on the ongoing epidemic in France as case study. Captured Hymenoscyphus fraxineus spores were estimated by qPCR on 696 samples from 2015 to 2018 from 31 locations with a duration of disease presence of 0 to 9 years, and were aligned with the nation-wide database of disease occurrence.
We detected H. fraxineus spores in disease-free locations, up to a distance of 318 km from the nearest recorded outbreak. Number of spores linearly increased with the distance to the closest disease record. The maximum number of spores was recorded six years after disease arrival, and then decreased, with a strong effect of the sampling year. The proportion of positive samples per year linearly increased with the time of disease presence (9-year range). While pathogen detectability increased with time of disease presence, inoculum load peaked at six years of disease presence. The use of mass air movement probability in our models will be discussed. Our results suggest an attenuation of pathogen load with time. Aerobiology proves a powerful tool to monitor pathogen colonization in airborne invasive pathogens.

P3.5-001

SINKS, SOURCES AND BOTTLENECKS OF ATMOSPHERIC CONNECTIVITY NETWORKS

MARTINETTI Davide. (1)

(1) INRAE, Avignon, FRANCE

Text

Tracking and monitoring airborne plant pathogens pose serious challenges to plant epidemiologists since the dispersal medium, atmospheric air, is constantly moving in unpredictable and untraceable ways. Nonetheless, it is well known that both short- and long-distance dissemination events can occur as pathogenic propagules (fungal spores or bacteria) are released in to the air and passively transported from infected to susceptible hosts. From the epidemiological perspective, we still miss a formal description of the connectivity network that emerge from air mass movements. In this work we propose a new methodological framework to reconstruct these networks across large geographical areas. Our method relies on the analytical transformation of dynamical systems (atmospheric air circulation patterns) into network objects using a trajectory-based formulation of the node degree, an essential property of networks. The method is based on the computation of the

backward- and forward-in-time Lyapunov exponents and allows to identify critical nodes of the dynamic connectivity network that shall be prioritized for monitoring and surveillance, such as source, sink and bottleneck nodes. We compare our results to pollen count data from the French Aerobiology Surveillance Network and we test the hypothesis that bottleneck nodes, i.e., nodes with higher network betweenness, corresponds to those trapping stations where pollen diversity is higher across all seasons.

P3.5-002

PATHOTYPIC AND MOLECULAR CHARACTERIZATION OF XOC IN SENEGAL

TALL Hamidou. (1)

(1) Senegalese Institute of Agricultural Research (ISRA), Kolda, SENEGAL

Text
Bacterial streak of rice (BLS), is a disease caused by Xanthomonas oryzae pv. oryzicola (Xoc), was first reported in Senegal by Trinh in 1980 and confirmed by H. Tall in 2022. BLS poses a serious threat to rice cultivation in West Africa. Characterization of the pathotypic and genetic diversity of bacterial populations is essential for the management of pathogen-resistant varieties. Pathogenicity tests show that all strains are virulent on the susceptible rice variety Kitaake. Phenotyping of Kitaake RXo1, Carolina Gold and IRBB1 showed that the Xo1 and Xa1 genes control 99% of the isolates tested, and that MLVA analysis identified 10 haplotypes grouped into 3 clonal complexes that are defined by a single locus variant (SLV) and 4 singletons differing from each other by 2 to 7 loci. In the St. Louis area where the largest number of strains were isolated, the genotypic diversity of the Podor Xoc collection is greater than the Dagana collection based on the richness estimated by the rarefaction procedure with MLG values of 4.056 and 2.517 respectively. The strains collected in 2014 are much more diverse than those collected in 2015, and progeny links are observable between haplotypes 8 and 9, and 1 and 2.

P3.5-003

SEASONAL SPORE PRODUCTION, GERMINATION AND FUNGICIDE RESISTANCE SHIFTS OF CERCOSPORA BETICOLA IN COMMERCIAL SUGAR BEET FIELDS IN THE USA

SECOR Gary. (1), RIVERA Viviana. (1), WYATT Nathan. (2), BOLTON Melvin. (2)

(1) North Dakota State University, Fargo, Nd, UNITED STATES; (2) Schafer Agricultural Research Center USDA ARS, Fargo, Nd, UNITED STATES

Text
Cercospora leaf spot (CLS) caused by Cercospora beticola (Cb) is the most important foliar sugarbeet disease. Management includes cultural practices, resistant varieties and timely fungicide applications. Disease prediction models monitor conditions for disease spread and fungicide application, but do not include spore production and germination that may be important for predicting protective fungicide application prior to disease. Laboratory

experiments indicate spore germination begins in two hours at 10°C, is higher in free water and increases with time and temperature. Spores from fungicide resistant isolates tend to have a lower germination rates compared to fungicide sensitive isolates at lower temperatures. Field studies were conducted in 2021 and 2022 to study timing of Cb spore detection in commercial sugarbeet fields. Spore trap (Spornado) contents were tested for Cb DNA by PCR three times weekly from May to August. Asymptomatic leaves were tested for the presence of Cb DNA by PCR and monitored for first appearance of CLS. In both years, Cb spores were detected before sugar beet emergence and Cb DNA was detected in asymptomatic plants before CLS was observed. Continued seasonal testing showed changes in fungicide resistance to QoI and DMI fungicides. We conclude that forecasting models for CLS should include spore detection and early wetness conditions, and adjusted to recommend fungicide applications earlier in the growing season before infection by Cb.

P3.5-004

QUANTIFICATION OF AIRBORNE BASIDIOSPORES OF GANODERMA ZONATUM AT DIFFERENT ALTITUDINAL GRADIENTS AND THEIR RELATIONSHIP WITH ENVIRONMENTAL CONDITIONS IN OIL PALM

LÓPEZ Juan. (1), ZUÑIGA Franky. (1), CASTILLO Sandra. (1), SARRIA Greicy. (1)

(1) COLOMBIAN OIL PALM RESEARCH CENTER - CENIPALMA, Santa Marta, COLOMBIA

Text

Basal Stem Rot, caused by *Ganoderma zonatum*, is one of the most limiting emerging diseases of oil palm crops located in northern Colombia. The hourly concentrations of *G. zonatum* basidiospores in the air were quantified using four 7-day Burkard volumetric samplers at different heights (1, 4, 7, and 10 m) installed on a scaffold-type structure located inside an 18-year lot of African palms (*Elaeis guineensis*) highly affected by the disease. Hourly records of air temperature, rainfall, and relative humidity at the capture site were also collected. The results obtained indicated that there are no significant differences in the concentration of basidiospores captured at different altitudinal gradients, which suggests a great dispersal capacity of *G. zonatum* when reaching higher altitudes or close to the palm canopy. The concentration of inoculum in the air varies according to the seasonality of the year. The highest concentrations of captured basidiospores occurred several hours after a rain event >5mm, being more frequent during the wet season. Regarding the seasonal patterns, a higher concentration of basidiospores was found at night (absence of solar radiation) between 5:00 p.m. and 4:00 a.m., when the air temperature was 20 to 23°C and the relative humidity was >80%. These concentrations decrease considerably during daylight hours, especially between 11:00 a.m. and 2:00 p.m., when the air temperature was 27 to 30°C and the relative humidity was <65%.

P3.5-005

DISPERSAL KERNELS ARE STEEPER THAN THE OBSERVED GRADIENTS

KARISTO Petteri. (1), SUFFERT Frédéric. (2), **MIKABERIDZE Alexey. (3)**

Text

Measuring dispersal is important for understanding how pathogen populations change in time and space, since capacity for dispersal is a fundamental fitness component. We measured rain splash-driven dispersal of the major fungal wheat pathogen Zymoseptoria tritici (Zt) and estimated its dispersal kernel in field conditions for the first time. We inoculated field plots of wheat (Triticum aestivum) with two distinct Zt strains and measured the disease intensity as counts of fruiting bodies using automated image analysis. These measurements characterized primary disease gradients, which we used to estimate effective dispersal of the pathogen population. Genotyping confirmed the conclusions drawn from phenotypic data. While analysing the dispersal gradient data, we realized that our assumption of a point-like source was flawed. Although dispersal gradients contain information on dispersal, they are influenced by the spatial extent of the source. We solved that challenge with a theory that incorporates the spatial extent of sources to estimate dispersal kernels from dispersal gradients. We analysed the collected data using this spatially explicit mathematical model, which allows for a more accurate estimation of dispersal kernels. Additionally, we re-analysed published dispersal gradients for two other plant pathogens (stripe rust of wheat, potato late blight) and concluded that all three pathogens disperse over substantially shorter distances compared to conventional estimates.

Understanding emergence of pathogens in commercial and public forest ecosystems

PATHOGEN EMERGENCE IN CHANGING ECOSYSTEMS: CASE STUDY WITH PHELLINUS NOXIUS IN EASTERN ASIA, AUSTRALIA, AND THE PACIFIC ISLANDS

KOZHAR Olga. (1), IBARRA CABALLERO Jorge. (1), KIM Mee Sook. (2), KLOPFENSTEIN Ned. (3), CANNON Phil. (4), STEWART Jane. (1)

(1) Colorado State University, Fort Collins, Co, UNITED STATES; (2) USDA Forest Service, Pacific Northwest Research Station, Corvallis, Or, UNITED STATES; (3) USDA Forest Service, Rocky Mountain Research Station, Moscow, Id, UNITED STATES; (4) USDA Forest Service, Forest Health Protection, Vallejo, Ca, UNITED STATES

Text

In recent decades, brown root rot disease (BRRD), caused by *Phellinus noxius* of unknown origin, has emerged to cause extensive damage to diverse trees in tropical/subtropical regions. Understanding the population structure, demographic history, and potential pathways of spread is essential to determine if BRRD emergence was caused by invasion

of *P. noxius*. In this study, we characterized genetic relationships, pathways of spread, and evolutionary histories of *P. noxius* collected from 15 locations in eastern Asia, Australia, and the Pacific Islands. We analyzed patterns of genetic variation by measuring correlations in allele frequencies and genetic drift. Also, we applied the coalescent-based analyses using approximate Bayesian computation (ABC) with supervised machine learning. Population structure analyses revealed five distinct genetic groups of *P.noxius* with signatures of complex migration histories among study locations. ABC analyses indicated that the pathogen was most likely spread from a “ghost population” to Malaysia and the Pacific Islands, with subsequent spread to Taiwan and Australia. Major pathogen spread likely occurred 1,000s of generations ago, contradicting previous assumptions that *P. noxius* was recently introduced into many areas. Our results suggest that *P. noxius* has a long evolutionary history in the study region, and recent disease emergence is likely driven by anthropogenic and natural disturbances in many regions, rather than by recent introductions.

C2.6-2

CAN ALIEN FOREST PATHOGENS REPLACE NATIVE ONES? THE CASE OF HETEROBASIDION IRREGULARE AND H. ANNOSUM IN EUROPE

GONTHIER Paolo. (1), LIONE Guglielmo. (1), MARTINIUC Alina V.. (1), GARBELOTTO Matteo. (2)

(1) University of Torino, Grugliasco, ITALY; (2) University of California - Berkeley, Berkeley, UNITED STATES

Text

Heterobasidion irregulare and *H. annosum* are destructive pathogens of pines in North America and Europe, respectively. The former was introduced in central Italy during WWII and has been spreading in the range of the native *H. annosum* causing high mortality of *Pinus pinea* in natural forests, artificial plantations and urban parks. Based on its current and potential impacts, *H. irregulare* is recommended for regulation by EPPO. While *H. irregulare* is clearly fitter that *H. annosum* based on some key traits, one intriguing question is whether the alien species has the potential to replace the native congener in Europe.
We addressed this issue by using an aerobiological assay replicated ten years apart in a forest in central Italy were both *Heterobasidion* species have been coexisting. Replacement index (RI), Markov chains and geometric progressions were used to model the interspecific interaction between the two species and to assess the invasiveness of *H. irregulare*. Results showed that, in 10 years, the incidence of *H. annosum* dropped from 39.4 to 6.1%, while that of *H. irregulare* increased from 57.6 to 81.8%, with the alien pathogen replacing the native one (RI = 84.6%) and spreading at a maximum rate of 139 ha/year. This study adds new pieces of information on the invasiveness of *H. irregulare*. In addition, modelling results clearly support a potential for replacement of *H. annosum* in Europe, although the extinction of the native species appears unlikely.

C2.6-3

BOTRYOSPHAERIACEAE ASSOCIATED WITH BAOBAB (ADANSONIA DIGITATA L.) AND MARULA (SCLEROCARYA BIRREA A. RICH.) IN AGROFORESTRY SYSTEMS IN KENYA

CHEROTICH Sheillah. (1), NJUGUNA Jane. (2), MUCHUGI Alice. (3), MUTHAMIA Japheth. (4), OTAYE Daniel. (4), IGNAZIO Graziosi. (1), KINYANJUI Zakayo. (1)

(1) World Agroforestry (ICRAF), Nairobi, KENYA; (2) Kenya Forestry Research Institute, Nairobi, KENYA; (3) International Livestock Research Institute, Addis Ababa, ETHIOPIA; (4) Egerton University, Njoro, KENYA

Text

Cultivation of Indigenous fruit trees such as baobab and marula provide key nutrients and income for smallholders and enhance diversification of agroforestry systems in the drylands of Sub-Saharan Africa. Cankers and diebacks are increasingly observed impacting baobab and marula in domestication trials and farms in Kenya, but little is known on disease occurrence and associated pathogens. Field disease incidence and severity was assessed. Fungal isolation and molecular identification were performed, and pathogenicity of isolates was evaluated on baobab, marula and additional agroforestry trees; *Vachelia xanthophloea* and *Calodendrum capense*. Nine taxa morphotypes belonging to genera *Lasiodiplodia*, *Neofusicoccum* and *Dothiorella* were identified co-occurring in both symptomatic and asymptomatic plant material. Seedlings inoculated with isolates of *L. pseudotheobromae*, *L. theobromae* and *N. parvum* showed similar symptoms with various degree of virulence ($p<0.001$). These findings suggest that species of Botryosphaeriaceae may occur as endophytes and also act as a disease complex, with the potential of infecting a wide range of trees in Eastern Kenya. Further investigation of ecology and impact of this potential threat to agroforestry systems in the African drylands, need to be performed in order to develop mitigation strategies. Further, their occurrence as endophytes may complicate disease management hence and exchange of disease free germplasm is important for stakeholders.

Text

Myrtle rust, caused by *Austropuccinia psidii*, is responsible for significant economic, and environmental impacts. Brazil is the center of origin for *A. psidii*, an obligate biotroph, that has its asexual dikaryotic stage associated with epidemic outbreaks on a wide global host range. Thus far, four main genetic groups of the pathogen, with specialization to different

hosts and/or geographic regions, have been reported worldwide: two biotypes showing a strong relationship with different hosts in Brazil; a polyphagous biotype restricted to South Africa, and a polyphagous pandemic biotype, widely spread globally. In order to facilitate our understanding of the genetic relationship and evolution of the different biotypes, we sequenced the genome of three Brazilian isolates with evidence of host adaptations to *Eucalyptus* spp., *Syzygium jambos* and *Psidium guajava*. The new genomes were HiC-phased and annotated, in order to compare haplotypes with the genome of the pandemic biotype. We identified specific and shared groups of genes related to pathogenicity among the four isolates. These results are important resources to better decipher host adaptation processes to different species in the Myrtaceae family. Moreover, these results provide insights into the genetic relationships and evolutionary history of the pathogen, which are key to preventing new incursions of the pathogen around the world.

PHYTOMONAS SP. CAUSING SUDDEN WILT DISEASE ON YELLOW BLEEDING HEART (DACTYLICAPNOS SCANDENS) (D. DON) IN INDIA

PERIASAMY Raja. (1), TANTULUNG Tatan. (1), T.S. Mehra. (1)

(1) COLLEGE OF HORTICULTURE AND FORESTRY, PASIGHAT, Pasighat, INDIA

Text

We have noticed sudden wilting of Dactylicapnos scandens and found that it is an aflagellate Phytomonas sp. The disease incidence was recorded at 72 percent and 50% yield loss. The symptom begins at the leaf margin as a water-soaked brown lesion. It spreads through the vine and branches. Dieback is also observed. Vines are dried and die within three weeks. The symptoms are also observed on the outer petal of the flower, which turns brown and flaccid, followed by drying and dropping of the flower. The cross-sectioning of one-week-old infected tubers shows dark brown symptoms, followed by blackening and hollowness within two weeks. In the third week, the tuber becomes empty and rotten. Aflagellate protozoa were found in the tubers, leaves, and inflorescences of infected plants. It measures 19.2 µm to 36 µm in length and width of 4.4µm to 9.6 µm. The pathogenicity of the protozoa was proved by inoculating 1 ml of 4 x 108 protozoa cells on the healthy tubers with a 0.45 mm syringe and then keeping them in a humid chamber at 24.2 °C and 90% relative humidity for 72 hours. It was observed that after 48 hours, the incubated tubers started showing brown discoloration upon dissection, and after 72 hours, they became dark brown and soft. After five days, it turns black and becomes mummified. The pathogen remains viable in the infected tubers for months. Phytomonas sp. can cause disease and yield losses of up to 50%, and it is transmitted through infected tubers.

Text

Cryptostroma corticale is an ascomycete responsible for the sooty bark disease (SBD) on maples. Native from eastern North America, the pathogen has spread over the last few decades in Europe and in the Pacific Northwest of North-America. The spores of *C. corticale* can be also pathogenic for humans causing hypersensitive pneumonitis. *C. corticale* can remain asymptomatically in host tissues, and its development has been linked to drought conditions. Here, we study the conditions of emergence and the aerobiology of the SBD in Europe. We analyzed two-year aerobiological and epidemiological data in France, and one-year aerobiological data from six European countries. Additionally, we modelled disease outbreaks and climatic data in France and Switzerland from 1990. Aerobiological detection of the pathogen was successful in countries within the host native area and with longer disease presence, such as France, Switzerland and Czech Republic, and absent in countries where the pathogen has not been reported yet. The disease was frequently reported in France and Switzerland after the severe drought and heat waves of 1990-1991, 2003 and especially 2018-2020. SBD occurrence was strongly related to the water balance in the vegetative season (April-August) of the year preceding disease report. Aerobiological surveillance can inform the spatial distribution of the SBD, and contribute to early detection in pathogen-free countries.

(1) University of Helsinki, Helsinki, FINLAND; (2) Natural Resources Institute of Finland (Luke), Helsinki, FINLAND

Text
Heterobasidion annosum species complex is a major threat to the forestry industry. Fungal and bacterial communities in *Heterobasidion-infected* trees have been extensively studied for disease management, but less is known about the inter-kingdom interactions. The inter-kingdom analysis has revealed significant findings in recent studies by providing insights into the pathobiology of the disease as well as ecologically meaningful data. In this study, we aim to 1) Unravel the contribution and development of the bacteria and other fungi in the *Heterobasidion* infected wood decay process; 2) Uncover how the environmental factors and conifer pathogen drive the microbiome community structure and function changes; 3) Identify the core microbiome during the *Heterobasidion* mediated wood decay process. ITS and 16S amplicon sequencing data from Heterobasidion fruiting body and its associated woody tissue were applied in this analysis. Samples collected from managed forests and nature-reserved forests were classified into four decay classes based on the extent of decay of the wood. Our result shows that the abundance, activeness, and environmental response sensibility of bacteria and fungi are different in study materials. The *Heterobasidion* ecological correlation network is conservative. The core microbiome defined in our analysis showes huge potential in the microbiome community functioning. Forest management shows the biggest impact on the microbiome assembly.

Text
Despite advances in disease management, the bacterial phytopathogen *P. syringae* remains a threat to commercial cherry production. Aside from the known causes of canker, pathogenic potential has also been found in *P. syringae* strains from diverse environments. This study investigates regional and temporal variations in epiphytic *P. syringae* populations in cherry orchards in four regions of the UK across two years. In addition, to enrich insights into the prevalence of *P. syringae* in non-agricultural environments, we also sampled wild cherry and related plant species in woodlands nearby. A total of 12,000 bacterial strains were isolated from leaves and shoots in May and September of both 2021 and 2022. Multiplex PCR was used to identify *P. syringae* and detect the presence of genes encoding the Type 3 Secretion System (T3SS), a hallmark of pathogenicity, followed by whole genome sequencing. Intriguingly, a distinct reduction in the frequency of T3SS+ strains has been found in strains isolated from Scotland. These results indicate the reduced prevalence of potentially pathogenic strains in Scotland, and equally importantly, an interesting regional variation in *P. syringae* populations. Through further analysis of these environmental isolates,

we will improve our understanding of how evolution of epiphytic populations leads to new outbreaks of cherry canker.

CERIPORIA LACERATA MAY BE A POTENTIAL TREE PATHOGEN

CHUANG Wei-Ting. (1), CHEN Che-Chih. (2), CHUNG Chia-Lin. (1)

(1) Master Program for Plant Medicine, National Taiwan University, Taipei , TAIWAN; (2) Department of Biology, National Museum of Natural Science, Taichung , TAIWAN

Text

Ceriporia species are well-known saprotrophic fungi that cause wood decay in the forest. Although some endophytic *Ceriporia* spp. have been isolated from living plants, none of them was considered a pathogen. However, a weakly grown tree of *Delonix regia* with the white resupinate basidiocarps of *Ceriporia lacerata* (syn. *Irpex laceratus*) covered on its roots and stem base suddenly toppled over in October 2021 at the campus of National Taiwan University. *C. lacerata* was isolated from the interior white rot wood tissues and confirmed for its identity using multi-locus phylogenetic analysis based on ITS, 28S, *rpb1*, *rpb2* and *tef1* genes. To investigate the pathogenicity of *C. lacerata*, wounded and nonwounded inoculations were conducted on the stem of 1-m-high *D. regia* seedlings. Although none of the infected plants showed visible symptoms within 122 days post inoculation, *C. lacerata* caused browning of the interior wood at the inoculation site, and *C. lacerata* re-isolated at the frequency of 80% from the bark and 25% from the wood tissues. The results indicated that *C. lacerata* is able to infect living woody plants and caused wood degradation. Considering that *C. lacerata* is a potential tree pathogen, the inhibitory effects of 13 fungicides with 9 modes of action were evaluated on the mycelial growth of *C. lacerata*, and tebuconazole and propiconazole were the most effective. How *C. lacerata* affects the health of living plants and its management are worthy of further investigation.

P2.6-005

TOP DOWN AND BOTTOM UP: HOW THE INTERACTION OF TWO PATHOGENS FUELS MORTALITY OF COMMON ASH (FRAXINUS EXCELSIOR) IN EUROPE

HEINZELMANN Renate. (1), SPIEGEL Philipp. (1), HINTZE Thomas. (2), QUELOZ Valentin. (1), PROSPERO Simone. (1)

(1) Swiss Federal Research Institute WSL, Birmensdorf Zh, SWITZERLAND; (2) Robinia Baumbüro, Aadorf, SWITZERLAND

Text

Since the early 1990s, the invasive pathogen *Hymenoscyphus fraxineus* has been causing severe dieback of common ash (*Fraxinus excelsior*) and narrow-leaved ash (*Fraxinus angustifolia*) in Europe. Recently, several cases of windfall of ash trees with green foliage were reported in Switzerland. The uprooted trees frequently showed signs of Armillaria root disease. To shed light on the interaction of *H. fraxineus* and *Armillaria* spp. and to develop

criteria to identify potentially hazardous ash trees, we investigated frequency and severity of Armillaria root disease on common ash trees showing varying degrees of crown dieback. In addition, we conducted non-invasive static pulling experiments on a subset of the investigated ash trees to estimate their resistance to uprooting and stem breakage. We found that the probability of Armillaria root disease increases with crown dieback severity. Most *Armillaria* infections were caused by *A. gallica* and *A. cepistipes*, which primarily act as opportunistic pathogens on weakened trees. Ash trees with a reduced resistance to uprooting were more often infected by *Armillaria* spp. than trees resistant to uprooting or stem breakage. Based on these results, we are developing recommendations for practicians to assess the safety of ash trees infected by *H. fraxineus* and/or *Armillaria* spp.

P2.6-006

A CASE STUDY OF EXPANSION OF HETEROBASIDION PARVIPORUM GENOTYPES IN A NORWAY SPRUCE STAND ON PEAT SOIL

SILBAUMA Lauma . (1), **KLAVINA Darta. (1)**, PIRI Tuula. (2), LEGZDINA Liva . (1), JANSONS Jurgis . (1), GROSBERGA Magdalena . (1), GAITNIEKS Talis. (1)

(1) LSFRI Silava, Salaspils, LATVIA; (2) Natural Resources Institute Finland LUKE, Helsinki, FINLAND

Text

The aim of the study was to analyse the long-term expansion of root rot fungus Heterobasidion spp. genets in a 72-year-old, Norway spruce (Picea abies (L.) H. Karst.) stand on drained peat soil (Oxalidosa turf. mel. forest type. The stand was for the first time sampled for Heterobasidion root rot in 2009 and for the second time in 2019. Heterobasidion was isolated from 142 trees/stumps (28%) in 2009 and from 159 trees/stumps (30%) in 2019. In total, 29% of the analysed spruces were infected by Heterobasidion spp. In 2019, 65 Heterobasidion genets were identified. Single-tree genets represented 45% and multi-tree genets (expanded through mycelial growth via root contacts) 55% of all genets. Over a ten-year period, the total number of genets had increased by 10 and the mean number of trees infected by one genotype increased from 3.7 to 4.2. Moreover, 18 genets had expanded while 12 had disappeared. Our result indicates that rapid degradation of stumps and roots on peat soils related to shading and high moisture may limit secondary infection of Heterobasidion spp. Therefore, it is important to prevent primary spore infections, particularly reducing aboveground root damage during selective thinning.
This research was funded by JSC Latvian State Forests project No. 5-5.9.1_007q_101_21_79, “Investigation of the impact of root rot and reducing risks caused by root rot”.
Key words: Picea abies; root rot; genets; secondary infection; drained forests.

ENVIRONMENTAL REGULATION OF THE HYMENOSCYPHUS FRAXINEUS LIFECYCLE

COMBES Matt. (1,2,3), WEBBER Joan. (1), BODDY Lynne. (2)

(1) Forest Research, Alice Holt Lodge, Farnham, UNITED KINGDOM; (2) School of Biosciences, Cardiff University, Cardiff, UNITED KINGDOM; (3) Warwick Crop Centre, School of Life Sciences, University of Warwick, Wellesbourne, Warwick, UNITED KINGDOM

Text

Ash dieback disease symptoms were first noticed in Europe in the 1990s, although it now transpires the pathogen, *Hymenoscyphus fraxineus*, was present at least a decade earlier. The pathogen infects ash (*Fraxinus*) foliage via ascospores ejected from apothecia formed on fallen ash leaves shed the previous year. Mortality of European ash (*F. excelsior*) is widespread across the continent due to the disease. Our study investigated environmental effects on apothecia development and ascospore ejection, and examined the relationship between ascospore density, host litter colonisation, and disease severity. Apothecia development was monitored at six sites in 2018, and seven sites in 2019, along with temperature, relative humidity, canopy closure and ground cover data. Additionally, aerial ascospore density was measured at one site in 2018 and six sites in 2019, with colonisation of *F. excelsior* litter and crown dieback severity recorded in 2020. Results revealed that temperature positively affects apothecia development, with most effect at higher relative humidity or under a sheltered litter layer. Ascospore ejection was positively affected by both temperature (with greater effect in more exposed litter layers), and relative humidity. Ascospore density was also positively related to colonisation of host litter, which in turn was related to disease severity. Our study demonstrates environmental regulation of the *H. fraxineus* lifecycle and suggests consequences for disease progression.

POPLAR RUST NEVER SLEEPS: EVOLUTIONARY CHARACTERIZATION OF THE FIRST AVIRULENCE GENE IN THE POPLAR RUST FUNGUS MELAMPSORA LARICI-POPULINA

LOUET Clémentine. (1), SAUBIN Méline. (1), DUPLESSIS Sébastien. (1), HALKETT Fabien. (1), **FREY Pascal. (1)**

(1) INRAE, Nancy, FRANCE

Text

Poplar rust, caused by the pathogenic fungus *Melampsora larici-populina* (Basidiomycota, Pucciniales), is the main phytosanitary constraint for commercial poplar cultivation in Europe and other parts of the world. In the last 50 years, many rust-resistant cultivars were bred and released, but all the qualitative resistance genes released were overcome by pathogen evolution within a short period. In 1994, breakdown of the *RMlp7* resistance gene was detected in Belgium and Northern France. New virulent *M. larici-populina* individuals spread all over Western Europe in less than five years, causing very destructive epidemics, and lead to a complete replacement of the pathogen's populations. Through a genome-wide association study (GWAS), we identified a locus in the genome of *M. larici-populina*, that corresponds to the candidate avirulence gene *AvrMlp7*, whose mutation is responsible for RMlp7 resistance breakdown. To further characterize this effector, we used a population genetics approach on a set of almost 300 individuals collected throughout a 28-year period encompassing the resistance breakdown event. Genotyping at the avirulence locus highlighted two different mutations: a non-synonymous mutation and a complete deletion of this locus. The temporal survey at the candidate locus revealed that both mutations pre-

existed long before the breakdown, but at a heterozygous state. Using a reverse ecology approach, we identified the first candidate avirulence gene in this rust fungus.

Viral modification of plants and vectors

C2.4-1

MODELLING VIRAL MANIPULATION OF PLANT-VECTOR INTERACTIONS

CUNNIFFE Nik. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text
Diseases caused by plant viruses threaten food security and ecosystem services worldwide. Almost all plant viruses are spread by insect vectors. Over the past decade or two, extensive experimental evidence has accumulated indicating plant viruses can manipulate their host to cause vectors to prefer to visit infected plants. More recent experimentation has shown how the direction and magnitude of such effects can depend on the infection status of the vector itself. There are further interactions between the infection status of the plants upon which vectors feed and vector population dynamics. Complexities also follow from distinctions between persistent and non-persistent transmission, which are expected to have significant effects on the optimal strategy for viruses to manipulate their host. Mathematical modelling offers a framework to make sense of complex interactions such as these, identifying key principles affecting spread of plant viruses when viruses can manipulate vectors and/or hosts. In this talk, I will describe some recent progress in this area.

C2.4-2

WHITEFLY-BORNE CASSAVA VIRUSES AND THE ESTIMATION OF VIRAL RETENTION PERIOD FROM ACCESS PERIOD EXPERIMENTS

DONNELLY Ruairí. (1), GILLIGAN Christopher A.. (1)

(1) Epidemiology and Modelling Group, Cambridge, UNITED KINGDOM

Text
Estimation of the duration that a pathogen is retained in an insect vector - i.e., viral retention period - is of particular importance for understanding plant virus epidemiology. This is typically investigated in access period experiments in which the duration of access of insects to plants is experimentally varied. In this presentation I will discuss new modelling advances for estimating viral retention period from access period experiments.

In recent decades a cassava mosaic begomovirus epidemic (CMV) spread by Bemisia tabaci whitefly has severely affected cassava yield in sub-Saharan Africa, and this was followed by

a regional cassava brown streak ipomovirus epidemic (CBSV) spread by the same vector.

I will discuss the use of the two modelling approaches for estimating viral retention period in relation to CBSV and CMV. In addition, I will discuss how low insect survival from manual transfers of insects in the laboratory may have influenced existing retention period estimates.

THE ACROSTYLE, A CUTICULAR MICRO-TERRITORY WITHIN APHID MOUTHPARTS INVOLVED IN VIRUS-VECTOR AND PLANT-INSECT INTERACTIONS

UZEST Marilyne. (1)

(1) INRAE, Montpellier , FRANCE

Text

Aphids are among the most frequent and economically important vectors of plant viruses in the world. The majority of aphid-vectorized viruses are transmitted in a non-circulative manner and are retained transiently on specific receptors on the surface of the stylets as the insects move from plant to plant. In order to identify receptors and explore the binding properties of aphid stylets, our team has developed various approaches, including "omics", microscopy techniques and 3D imaging, or gene function validation.
We have shown that the proteins are not uniformly distributed in the stylets conferring local functionalization of cuticular micro-territories such as the acrostyle, a discrete structure at the apex of the maxillary stylets hosting virus receptors. Interestingly, some viruses have adapted to use this structure and hijacked the acrostyle from its original function for their own benefit. Our data recently highlighted the role of the acrostyle in the retention of a saliva effector known to modulate plant responses in the early phases of aphid feeding. The acrostyle thus acts as a platform for multiple interactions capable of binding both self and nonself molecules. Furthering our knowledge of the properties of the acrostyle and the mechanisms of interaction on its surface offers avenues for disease control strategies.

MULTI-INFECTION MODIFIES APHID TRANSMISSION AND PLANT TISSUE LOCALIZATION OF SUGAR BEET INFECTING VIRUSES

KHECHMAR Souheyla. (1), BRAULT Véronique. (1), DRUCKER Martin. (1)

(1) Institut National de Recherche pour l’Agriculture, l’alimentation et l’Environnement (INRAE) Colmar France, Colmar, FRANCE

Text

Aphids transmit multiple plant viruses separately or simultaneously to a new host. Sugar beet is frequently infected by several viruses transmitted by aphids. Some of the viruses infecting sugar beet (the closterovirus BYV and the poleroviruses BChV&BMYV) are restricted to the plant phloem while a potyvirus (BtMV), invades all cells of the plant. Here we investigate how BYV co-infections with the other viruses change aphid transmission and virus localization.

First, we optimized a detection method, SABER fluorescent in situ hybridization, to localize all sugar beet viruses simultaneously within co-infected tissues and cells. Using this technique, we started with BYV/BChV co-infection. Our results showed co-localization of the two viruses in the phloem cells. This correlated with a higher transmission of BYV and a lower one of BChV. Changes in viral load explain lower transmission of BChV but not higher transmission of BYV. Currently, we are testing whether changed aphid behavior on co-infected plants is responsible for higher BYV transmission. Co-infection of BYV&BtMV resulted in different localization of the two viruses in the plant tissue, compared to mono-infection, but this time it correlated with lower transmission of BYV. Other selected multi-infections are presently tested for correlation between localization, transmission, accumulation & aphid behavior, in order to understand the mechanisms behind the cellular localization and how they impact transmission.

Text

Potato virus Y (PVY) is the most economically devastating plant virus affecting the potato production worldwide. To complete its infection cycle the virus reprograms the intracellular environment of the host and a complex and dynamic interaction network is established between viral and plant proteins. This study aims at better understanding the role of viral and host proteins in such interconnected pathways. We focused in particular on two viral proteins: viral genome-linked protein (VPg) and coat protein (CP). We prepared a PVY clone with the VPg fluorescently tagged and followed the localisation of the protein during the infection cycle. Supporting the fact that VPg is a multitasking protein, the preliminary results showed that it can be observed in several plant cell organelles i.e nucleus, cytoplasm, plasma membrane and endoplasmic reticulum. We also searched for VPg interacting partners using pull-down assay. Several plant proteins have been identified and we are confirming the interaction using Yeast 2-hybrid system. Within this project we are also studying the involvement of the CP protein in the viral cell-to-cell movement. Using a PVY clone tagged with GFP we confirmed the N-terminal residues of the CP are crucial for the viral movement. We are now introducing short deletions at the N-terminus to identify the critical amino acids for the cell-to-cell movement. The knowledge acquired in this study will help developing effective agricultural management strategies.

AN APHID-BORNE POLEROVIRUS SWITCHES ITS VECTOR TO THE WHITEFLY BEMISIA TABACI: AGRONOMIC IMPORTANCE, EPIDEMIOLOGY AND VIRUS-VECTOR MOLECULAR RELATIONSHIPS

GHANIM Murad. (1), KONTSEDALOV Svetlana. (1), LEBEDEV Galina. (1)

(1) Volcani Institute, Rishon Lezion, ISRAEL

Text

Poleroviruses, like all other members of Luteoviridae are phloem-limited RNA viruses, which are exclusively transmitted by aphids. In the last decade, poleroviruses have been on the rise due to frequent recombination events between members of this group. Outbreaks with vein yellowing, leaf rolling, fruit discoloration and change in fruit taste in pepper cultivations in Israel, despite low aphid populations, led to reinvestigating the disease and its transmission by vectors. A new recombinant polerovirus was discovered, and strikingly demonstrated a shift in its insect vector from aphids to the whitefly Bemisia tabaci. Full genome of this new virus, named as Pepper whitefly borne vein yellow virus (PeWBVYV) was characterized. PeWBVYV shares homology (>95%) with Pepper vein yellows virus (PeVYV) described from Israel and Greece on its 5' end half while being homologous to African eggplant yellow virus (AeYV) on the 3' half. The recombinant PeWBVYV was not transmissible by aphids but was transmitted by B. tabaci MEAM1 species and not MED. Parameters for acquisition and transmission of the new virus by B. tabaci, competitive interactions with PeVYV inside aphids and whiteflies, proteins interacting with the new virus in aphids and whiteflies, and geographical distribution of both viruses were investigated. PeWBVYV is the first report of a whitefly-transmitted polerovirus.

Text

Several plant viruses manipulate their hosts to modify the attractiveness of their insect vectors, in a way that enhances their own spread. Cucumber mosaic virus (CMV) emit volatile organic compounds (VOC) that attracts its main vector, *Aphis gossypii*. However, it is not known how aphids respond to plants double infected with additional viruses such as Cucurbit aphid-borne yellows virus (CABYV). Furthermore, plants often emit volatiles after aphid feeding that attract natural enemies to limit pest damage ("call for help"). However, few studies have been conducted on how aphid parasitoids react to VOC emitted by virus-infected plants. Thus, we conducted Y-tube olfactometer assays to understand how simple and double infection (CMV+CABYV) can modify volatile cues involved in aphid-attraction and in aphid-plant-parasitoid interactions. Our results confirmed that VOC emitted by CMV-infected melon attracted *A. gossypii* but when plants became infected with CMV+CABYV aphid attraction was suppressed. We also found that in the presence of aphids, *Aphidius colemani* was attracted to mock-inoculated plants but rejected VOC emitted by CABYV-infected plants. Thus, our work reports for the first time that a plant virus can counteract the "call for help" plant defense response involved in parasitoid attraction to its aphid host. This could ultimately induce lower rates of parasitism on CABYV-infected plants reducing the effectiveness of biological control of *A. gossypii* by *A. colemani*

IMPACT OF 'CANDIDATUS LIBERIBACTER ASIATICUS' ON THE EXPRESSION AND ACTIVATION OF TOLL SIGNALING PATHWAY GENES IN DIAPHORINA CITRI, THE VECTOR OF CITRUS GREENING DISEASE

RASHIDI Mahnaz. (1), KILLINY Nabil. (1)

(1) Citrus Research and Education Center - University of Florida, Lake Alfred, UNITED STATES

Text

Citrus greening disease, (Huanglongbing; HLB), is putatively caused by the phloem-restricted bacterium '*Candidatus* Liberibacter asiaticus'. HLB is an economically important disease of citrus worldwide. In Florida, HLB is endemic causing huge damage to the citrus industry. HLB is transmitted by the Asian citrus psyllid, *Diaphorina citri*. To date, the disease management mainly depends on insect vector control by insecticides. Toll signaling pathway proteins and receptors play crucial roles in embryonic development and immunity in insects. In the current study, we identified and performed *in silico* analyses of toll-related proteins in *D. citri*. Our findings indicate that the relative expression of Toll pathway genes was altered in the '*Ca*. L. asiaticus'-infected compared to healthy *D. citri*. Furthermore, we knockdown *pelle* and *tube*, two key genes in the Toll system using RNA interference technology. Silencing of the *pelle* and *tube* increases nymphal mortality and shortens the adult lifespan. Currently, we are investigating the effect of silencing the dorsal gene in the embryonic development of *D. citri*. In addition, we are evaluating the effect of silencing Toll genes on the susceptibility of *D. citri* to Gram-positive and Gram-negative bacteria. Ultimately, targeting Toll system by RNAi may help in mitigating the HLB disease by misfunctioning the development process, limiting the vector immunity, and interfering with the '*Ca*. L. asiaticus' transmission by *D. citri*.

P2.4-003

PLANT BACTERIAL PATHOGEN MANIPULATES THE FATTY ACIDS METABOLISM OF THE INSECT VECTOR TO FULFILL ITS NUTRITIONAL NEEDS

KILLINY Nabil. (1), RASHIDI Mahnaz. (1)

(1) University of Florida, Lake Alfred, UNITED STATES

Text

Diaphorina citri is the main vector for the '*Candidatus* Liberibacter asiaticus' pathogen, which is associated with citrus greening. *D. citri* transmits '*Ca*. L. asiaticus' during its feeding on the phloem sap of citrus. The mode of transmission is circulative, propagative, and persistent. '*Ca*. L. asiaticus' has a small genome (1.2 mbp). Therefore, it acquires most of its nutrients

from its hosts. We assessed the effect of '*Ca*. L. asiaticus' infection on the level of the free fatty acids in its vector. The fatty acids and triglycerides were extracted from adult *D. citri* using ethyl acetate, derivatized with boron trifluoride-methanol, and analyzed using GC-MS. Nine fatty acids were identified in the extract of *D. citri* adults. Oleic acid was the most predominant fatty acid followed by stearic acid and palmitic acid, whereas the rest of the fatty acids were present in low amounts. In general, the levels of the detected fatty acids in '*Ca*. L. asiaticus'-infected *D. citri* were lower than those found in healthy psyllids. Our findings showed that, the reduction of fatty acids in '*Ca*. L. asiaticus'-infected psyllids resulted from the higher activity of the β-oxidation to generate acetyl-CoA, which could be converted to citrate or used to convert alanine to proline in the fat body and to produce more ATP. In conclusion, our results indicated that '*Ca*. L. asiaticus' may enhance the β-oxidation of fatty acids in its vector insect to fulfill its nutrient requirements.

Text

The tomato golden mosaic disease, caused by the tomato severe rugose virus (ToSRV), is considered one of the most important diseases in tomato fields. The ToSRV is transmitted by *Bemisia tabaci*, from a wide range of hosts. The ToSRV arrival in commercial fields and the epidemic development are highly related to the presence of near inoculum sources. In that context, monitoring studies can be a helpful tool to understand the spread dynamic of the vector and, consequently, the disease. This study evaluates the short-range fly distance of *B. tabaci* MEAM1 through recaptures in yellow stick traps and the transmission of ToSRV by viruliferous adults through the release in an arena with tomato plants placed in knowing distances. Of the two proteins source tested (albumin and lecithin), albumin was efficiently detected by PTA-ELISA. There were no effects on mortality rates when the insects were labeled. The field tests showed that a label reduces the number of recaptured insects compared with unmarked ones. Due to its easy detection, dye labeling was considered more straightforward. Most whiteflies only achieved a 30 m distance, which was the maximum of ToSRV-infected plants detected. The results of this study reinforce the suspects that the epidemic-supporting source of ToSRV inoculum must be in the close range of commercial fields and provides new tools to understand the *B. tabaci* MEAM1 movement, based on different labeling methods.

IRIS YELLOW SPOT ORTHOTOSPOVIRUS-THRIPS COMPLEX IN ONION PRODUCTION AREAS IN THE USA: PROGRESS TOWARD DEVELOPING MANAGEMENT TACTICS

IFTIKHAR Romana. (1,3), GHOSH Amalendu . (2), **PAPPU Hanu. (3)**

(1) University of Agriculture, Faisalabad, Faisalabad, PAKISTAN; (2) Advanced Center for Plant Virology, ICAR-Indian Agricultural Research Institute, New Delhi, INDIA; (3) Department of Plant Pathology, Washington State University, Pullman, UNITED STATES

Text

Iris yellow spot orthotospovirus (IYSV) is predominantly transmitted by onion thrips (Thrips tabaci Lindeman, Thysanoptera: Thripidae) and continues to be a production constraint for seed and bulb onion crops in several onion producing states in the USA. Ongoing research over the last several years was directed toward understanding the epidemiology including the role of thrips vectors, diversity of onion thrips populations and screening of onion breeding lines for virus resistance. Onion thrips is a major pest of onion and serves as IYSV vector, however, there is limited information available on the genetic variation within and between T. tabaci populations in the USA. A total of 92 COI gene sequences of T. tabaci from A. cepa were analyzed including 83 T. tabaci specimens were collected from A. cepa from 15 locations comprising four states of the USA. 7 distinct haplotypes of T. tabaci were identified from the current collection, while 9 T. tabaci sequences retrieved from GenBank comprised 5 haplotypes. Overall, 15 haplotypes of T. tabaci infesting A. cepa were identified in the world that includes the ten haplotypes in the USA. In the phylogenetic analysis, all the populations collected during the study clustered with thelytokous lineage. Results suggested that haplotypes 1 and 7 are more frequently prevailing haplotypes in the northwestern USA, with haplotype 1 being the predominant all over the country. The eastern USA appears to have a more diverse group of haplotypes.

BIASED POLLEN TRANSFER BY BUMBLEBEES FAVORS THE PATERNITY OF VIRUS-INFECTED PLANTS IN CROSS-POLLINATION

MURPHY Alex. (1), JIANG Sanjie. (1), ELDERFIELD James. (1), PATE Adrienne. (1), HALLIWELL Chay. (1), GLOVER Beverley. (1), CUNNIFFE Nik. (1), CARR John. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text

Volatile organic compounds emitted by virus-infected bean and tomato plants attract bumblebees. Bumblebees vibrate tomato flowers to extract pollen (‘buzz pollination’) and, in doing so, maximize seed production by increasing the self-pollination rate. CMV infection decreases tomato seed yield, except in the presence of bumblebees; buzz pollination activity rescues infected plant seed yield. We proposed that this may have resulted from pollinator preference for flowers of CMV-infected plants that increased their success as female parents, by increasing the probability of ovule fertilization, and that this constituted a ‘payback’ from the virus to its susceptible hosts. Here, we used a GFP marker gene for paternity analysis to determine if virus infection affected male reproductive success in bee-mediated cross-pollination. We found that bees that first visited flowers of infected plants showed a strong preference to subsequently visit flowers of non-infected plants; suggesting

the insects either find infected plant pollen distasteful, or direct contact with infected flowers repellent. The behavior of the bees to move towards non-infected plants after pollinating the infected, appears to explain the paternity data, which show a statistically significant ~10-fold bias for fertilization of non-infected plants with pollen from infected parents. Thus, in the presence of bumblebee pollinators, CMV-infected plants exhibit enhanced male, as well as female, reproductive success.

Text

With an expansive host range of over 1000 plant species across 90 families, tomato spotted wilt virus (TSWV) — since its first report in 1915 in Australia — has become a pandemic virus with an estimated economic impact over $1 billion annually. Current management strategies for TSWV heavily rely on growing single gene resistant cultivars of tomato ('*Sw-5b*' gene) and pepper ('*Tsw*' gene) deployed worldwide, combined with multiple pesticide applications to control thrips, a supervector of TSWV and a cosmopolitan pest. However, the increased virulence of TSWV through emergence of resistance breaking (RB) strains in recent years has significantly escalated what is already an unparalleled dual threat to agricultural production worldwide. Our lab reported new, more virulent TSWV RB strains, with novel RB mutations capable of swiftly disrupting single-gene resistance in all tested commercial tomato and pepper cultivars. Data on comprehensive genomic analysis, characterization, and transmission biology of three tomato-infecting RB strains from Texas, California, and Mexico and one pepper-infecting RB strain from Texas will be presented. Our progress in developing TSWV reverse genetic system (led by Dr Verchot's lab at Texas A&M University) and a potential of novel RNAi-based approach to manage the dual threat of TSWV and thrips will be discussed.

Text
Vectors play an important role as sentinel in *Xylella* spp. transmission. The vectors of *Xylella* spp. belong to taxonomic groups of three different superfamilies (Cercopoidea, Cicadoidea, and Membracoidea) within the order Hemiptera worldwide. An overview of the categories of vector distribution shows contrasting results in different continents. In the Americas, sharpshooters (Cicadellidae: Cicadellinae) are major vectors while spittlebugs (Aphrophoridae) are minor; in Europe, spittlebugs and cicadas (Aphrophoridae and Clastopteridae) are main vectors. As to Asia, Africa, and Oceania, where vector information was relatively limited, sharpshooters are major vectors as well. Despite the invasion of exotic vectors, many cases of Xylella spp. transmission were taken via local insects, suggesting the inoculum source might come from imported infected plants and plant materials. For instance, both vectors in Taiwan are native insects whereas the sequence data of the pathogen is identical to America. Since there is still no effective treatment for *Xylella* spp.-caused disease, the infectious rate can be reduced by controlling vectors, detecting and removing infected host plants to prevent further spread. To prevent global transmission, preventive measures must be taken by increasing the intensity and frequency of host plant products quarantine in high risks countries to block out infected vectors and pathogens.

Text
Cucumber mosaic virus (CMV) is vectored by aphids, including Myzus persicae. Tobacco (Nicotiana tabacum ‘Xanthi’) plants infected with a mutant of the Fny strain of CMV (Fny-CMVΔ2b, which cannot express the CMV 2b protein) exhibit strong resistance against M. persicae, which is manifested by decreased survival and reproduction of aphids confined on the plants. Previously, we found that the Fny-CMV 1a replication protein elicits aphid resistance in plants infected with Fny-CMVΔ2b, whereas in plants infected with wild-type Fny-CMV, this is counteracted by the CMV 2b protein; a counter-defence protein that, among other things, inhibits jasmonic acid (JA)-dependent immune signalling. We noted that in nontransformed cv. Petit Havana SR1 tobacco plants aphid resistance was not induced by Fny-CMVΔ2b, suggesting that not all tobacco varieties possess the factor(s) with which the 1a protein interacts. To determine if 1a protein-induced aphid resistance is JA-dependent in Xanthi tobacco, transgenic plants were made that expressed an RNA silencing construct to diminish expression of the JA co-receptor CORONATINE-INSENSITIVE1. Fny-CMVΔ2b did not induce resistance to M. persicae in these transgenic plants. Thus, aphid resistance induction by the 1a protein requires JA-dependent defensive signalling, which is countered by the CMV 2b protein.

EFFECTS OF A VIRAL COUNTER-DEFENSE PROTEIN ON PLANT-INSECT INTERACTIONS IN ARABIDOPSIS THALIANA

BERLINGER Arden. (1), MURPHY Alex. (1), PATE Adrienne. (1), LEWSEY Mathew. (2), CARR John. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM; (2) La Trobe University, Bundoora, AUSTRALIA

Text

Cucumber mosaic virus (CMV) infection of a host plant has been shown to induce changes in plant secondary metabolism. In *Arabidopsis thaliana* these include altered emission of volatile organic compounds (VOCs) and soluble molecules such as glucosinolates, which influence the interactions of a host plant with aphids, important viral vectors. For example, aphids confined to plants infected with Fny-CMV showed reduced growth and reproduction. The multifunctional CMV-2b protein disrupts signalling mediated by key defense and stress-related phytohormones such as jasmonic acid and has been implicated in modulating changes in VOC emission that lead to altered insect behaviour and viral spread. My research explores the mechanisms behind this phenomenon. Aphid growth rate and reproduction experiments were conducted as measures of aphid health and behaviour on *2b*-transgenic plants, which revealed that the growth and reproduction of generalist aphid *Myzus persicae* was significantly reduced when aphids were confined to plants expressing the 2b protein, while two species of specialist aphids were not significantly impacted by *2b* expression. Choice tests are also being conducted to determine the settling preferences of these aphid species on non-transgenic and *2b*-transgenic plants. This research clarifies the mechanisms behind CMV's effective manipulation of an infected host plant to accelerate its spread, with significant implications in understanding an agronomically important pathogen.

Text

Begomoviruses transmitted by the Sweetpotato whitefly, Bemisia tabaci Gennadius, are major constraints to vegetable production in the United States. Monopartite tomato yellow leaf curl virus (TYLCV) and bipartite cucurbit leaf crumple virus (CuLCrV) and sida golden mosaic virus (SiGMV) affect crops such as tomato, cucurbits, and snap bean. Bemisia tabaci cryptic species B (MEAM 1) is predominant outdoors, and B. tabaci Q (MED) cryptic species is limited to greenhouses. However, in recent years, B. tabaci Q has been found colonizing outdoor ornamentals and field crops in Florida and Georgia. This has raised concerns on whether the dispersal of B. tabaci Q cryptic species into the landscape could exacerbate the virus epidemics situation. Competence in the transmission of CuLCrV,

SiGMV, and TYLCV was compared between B. tabaciB and Q. Bemisia tabaci B efficiently transmitted all three viruses, whereas the Q did not transmit the two bipartite viruses. TYLCV loads in both cryptic species following acquisition was similar, but bipartite virus levels were substantially lower in B. tabaci Q than in B. Virus loads in various whitefly tissues revealed a similar trend. A series of molecular and Omics approaches were undertaken to decipher the differences in interactions between monopartite and bipartite viruses with both cryptic species. An exciting number of transmission-influencing candidates were identified, and some were functionally validated. These findings will be discussed.

(1) Department of Plant Pathology, National Chung Hsing University, Taichung, TAIWAN; (2) Advanced Plant and Food Crop Biotechnology Center, National Chung Hsing University, Taichung, TAIWAN

Text

Virus-virus interaction is a common phenomenon that causes recombination, host range change, virus transmissibility, and fluctuation of virus titer. It makes the management of virus control in the field more complicated. In this study, we tried to identify interactions between RNA viruses and DNA viruses and its implications to DNA viruses' mechanical transmissibility. Two tobamoviruses and four begomoviruses were used for analysis. TMV, ORSV, ToLCNDV-OM, and TYLCTHV are mechanically transmissible viruses, but ToLCNDV-CB and ToLCTV are not. Coinfection of one tobamovirus and one begomovirus was conducted by coagroinfiltration in Nicotiana benthamiana. Symptoms were observed at 8 dpi and systemic leaves of N. benthamiana were used for mechanical inoculation to new plants. Results showed that TMV abolished mechanical transmissibility of ToLCNDV-OM and TYLCTHV, but TMV helped ToLCNDV-CB and ToLCTV for mechanical transmission to N. benthamiana. Mechanical inoculation of TMV and ToLCNDV-OM coinfection revealed that only ToLCNDV-OM but not TMV could be detectable in oriental melon. TMV failed to inhibit the ToLCNDV-OM in non-host oriental melon. ORSV also helped ToLCNDV-CB and ToLCTV for mechanical transmission, but it didn't alter mechanical transmissibility of ToLCNDV-OM and TYLCTHV in N. benthamiana. In oriental melon, ORSV didn't help ToLCNDV-CB for mechanical transmission. Analysis of virus accumulation and the interaction mechanisms of this phenomenon is ongoing.

IDENTIFICATION OF PLANT VIRUS RECEPTORS IN THE STYLETS OF THEIR INSECT VECTORS USING CRISPR-CAS9 MUTANT APHID LINES

FU Yu. (1), DESHOUX Maëlle. (1), CAYROL Bastien. (1), LE BLAYE Sophie. (1), COLELLA Stefano. (1), UZEST Marilyne. (1)

(1) INRAE, Montpellier, FRANCE

Text
Aphids are the only known vectors of stylet-borne non-circulative viruses comprising hundreds of species in the genera *Caulimovirus*, *Potyvirus* and *Cucumovirus*. These viruses can be acquired and inoculated from one plant to another within seconds when aphids feed. They are retained on receptors located at the surface of the cuticle of insect mouthparts. The *Cauliflower mosaic virus* (CaMV) was shown to bind the acrostyle, an organ at the tip of aphid stylets. Stylin-01, a cuticular protein from the CPR family directly accessible at the surface of the acrostyle, was shown to play a role in CaMV transmission. To characterize Stylin-01 role in viruses transmission as a receptor for CaMV and other viruses, stable Stylin-01 mutant lines were generated via CRISPR-Cas9 technology in the pea aphid *Acyrthosiphon pisum*. Our work focuses on two Stylin-01 mutant lines: one with a complete knockout of the protein and another with an alteration at the cuticle/fluid protein interface. While demonstrating a major role of Stylin-01 in CaMV transmission, our results show that at least a second cuticular protein is involved in the retention of this virus at the surface of the acrostyle. In addition, our data indicate that the transmission efficiency of *Turnip mosaic virus* (TuMV, *Potyvirus*) is poorly affected in aphid mutant lines, thus showing that Stylin-01 is not the main receptor for TuMV. All together, our data demonstrate the existence of at least two virus receptors in aphid stylets.

Text
Diaphorina citri, the insect vector of citrus Huanglongbing (HLB) disease, transmits *Candidatus* Liberibacter asiaticus (*C*Las) between plants. Insect virus provides an effective target-specific method to decrease the *C*Las transmission. The influence of insect viruses on psyllid biology and the interaction between these viruses and *C*Las remain unclear. Here, *D. citri* flavi-like virus (DcFLV), one of four associated viruses in the gut virome, was identified by high throughput sequencing and selected for further study. We show that DcFLV systemically infects *D. citri* and is vertically transmitted to the offspring. On the cellular level, dark necrotic portions were observed in DcFLV-exposed midguts that are similar to the *C*Las-exposed midguts of psyllids. We also measured significant differences on the expression level of apoptosis- and endoplasmic reticulum (ER) stress-related genes in DcFLV-infected psyllids compared to DcFLV-free psyllids. *C*Las and DcFLV co-occurred in field-collected psyllid populations and co-localized in the guts and salivary gland cells of *D. citri*. Moreover, DcFLV infection increased *C*Las acquisition in nymphs. Our study identified a *D. citri*-associated virus that localized and showed pathogenicity on *D. citri* guts. The virus modulates *D. citri* cellular functions and may affect the efficiency of *C*Las transmission.

P2.4-015

THE TRANSMISSION OF BARLEY YELLOW DWARF VIRUSES BY FOUR CEREAL APHID SPECIES

NANCARROW Narelle. (1,2), LAM Shu Kee. (1), RODONI Brendan. (3,4), **TREBICKI Piotr. (1,5)**

(1) The University of Melbourne, Parkville, AUSTRALIA; (2) Agriculture Victoria, Horsham, AUSTRALIA; (3) Agriculture Victoria, Bundoora, AUSTRALIA; (4) La Trobe University, Bundoora, AUSTRALIA; (5) Macquarie University, Sydney, AUSTRALIA

Text

Barley yellow dwarf viruses (BYDVs) infect cereals such as wheat, barley and oats worldwide, causing significant yield and quality losses. BYDVs are frequently found in south-eastern Australia, where BYDV-associated yield losses of up to 84% in wheat and 64% in barley have been observed. They are persistently transmitted from plant to plant by aphids. The most common cereal aphids in south-eastern Australia are *Rhopalosiphum padi* (bird cherry-oat aphid), *Rhopalosiphum maidis* (corn aphid), *Metopolophium dirhodum* (rose grain aphid) and *Diuraphis noxia* (Russian wheat aphid). In this study, a glasshouse experiment was conducted to examine the efficiency with which these four cereal aphid species transmit two BYDV species (BYDV PAV and BYDV PAS-like) to wheat. Each plant was inoculated with a single viruliferous adult aphid. Plants were tested for virus presence using tissue blot immunoassay four weeks after inoculation. While there were differences in transmission efficiency between aphid species, no obvious differences were observed between BYDV species. *R. padi* was the most efficient vector of both BYDV species. Further experiments have been conducted on other hosts. This information improves our understanding of the relationship between BYDV diversity and epidemiology in an Australian context.

CHARACTERISING THE INTERACTION OF THE CUCUMBER MOSAIC VIRUS 1A AND 2B PROTEINS

CRAWSHAW Sam. (1), WATT Lewis. (1), MURPHY Alex. (1), CARR John. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text

The cucumber mosaic virus (CMV) 2b viral suppressor of RNA silencing (VSR) is a potent counter-defense and pathogenicity factor that inhibits antiviral silencing by titration of short double-stranded RNAs. It also disrupts microRNA-mediated regulation of host gene expression by binding ARGONAUTE 1 (AGO1). But in Arabidopsis thaliana complete inhibition of AGO1 triggers another layer of antiviral silencing against CMV mediated by AGO2, de-represses strong resistance against aphids (the insect vectors of CMV), and exacerbates disease symptoms.

Recent work showed that the CMV 1a protein, a component of the viral replicase complex, regulates the 2b-AGO1 interaction (Watt et al., 2020). By binding 2b protein molecules and

sequestering them in P- bodies, the 1a protein limits the proportion of 2b protein molecules available to bind AGO1. This ameliorates 2b-induced disease symptoms, and moderates induction of resistance to CMV and to its aphid vector but does not appear to inhibit the 2b protein's VSR activity. The amino acid sequence between residues 56-60 in the CMV 2b protein has been shown to be essential for its interaction with the CMV 1a protein.

The interaction between the CMV 1a and 2b proteins represents a novel regulatory system in which specific functions of a VSR are selectively modulated by another viral protein. The finding also provides a mechanism that explains how CMV, and possibly other viruses, modulates symptom induction and manipulates host-vector interactions.

TIMING OF IN-SEASON PLANT-TO-PLANT SPREAD OF POTATO VIRUS Y IN POTATO IN IDAHO, UNITED STATES

DUELLMAN Kasia M.. (1), LENT Melinda A.. (1), LIU Cong. (1), MCKINNEY Lindsey F.. (1), WENNINGER Erik J. . (2)

(1) University of Idaho - Idaho Falls Research and Extension Center, Idaho Falls, UNITED STATES; (2) University of Idaho - Kimberly Research and Extension Center, Kimberly, UNITED STATES

Text

Potato virus Y (PVY) is vectored in a non-circulative, non-persistent manner by many aphid species. Knowing when PVY is moved from plant to plant may inform optimal timing of PVY mitigation strategies such as mineral oil applications. Such knowledge may also indicate whether age-related resistance (ARR), a phenomenon that is inconsistently observed in the field, can be successfully harnessed. In 2021 and 2022, a small-plot experiment to exclude alatae at various times during the growing season via a mesh barrier was established in a randomized complete block design with four replications. Six treatments included 1. no barrier, 2. barrier from before emergence (BE) to vine beating (VB), 3. barrier only from BE to presumed onset of ARR (4 weeks post-emergence), 4. barrier only from onset of ARR to VB, 5. barrier from BE to tuber bulking (12-13 weeks after planting), and 6. barrier from BE to chemical vine kill. All plots were treated with a systemic insecticide. Based on a combined analysis using a generalized linear mixed model, PVY pressure in 2021 was higher than 2022, but for both years the lowest incidence of PVY in daughter tubers was observed in treatments where alatae were excluded either all season, from BE to bulking, or from BE to vine kill. These results support recommendations for PVY mitigation efforts to extend at least to onset of tuber bulking, and that onset of ARR may not contribute substantively to PVY management in a field setting until later in the season.

Text

Wheat dwarf disease is commonly occurring in many parts of Europe and Asia. The disease is caused by wheat dwarf virus transmitted by the leafhopper Psammotettix alienus. In Sweden, there have been outbreaks of the disease in winter wheat for more than 100 years with sometimes great crop losses. The primary virus infection of winter wheat occurs in autumn with adult leafhoppers followed by a secondary spread in spring by wingless nymphs. This study aimed at evaluating factors contributing to the incidence of wheat dwarf disease in Swedish fields of winter wheat and the correlation with population size of the leafhopper vector as well as weather conditions. A significant correlation between the size of the adult leafhopper population in autumn to disease incidence in the following year was found in some counties. PCR tests of pools of collected P. alienus leafhoppers revealed that they frequently were carriers of WDV, especially in autumn after a high incidence of wheat dwarf disease. The weekly average temperature as well as weekly averages of maximum and minimum temperature in autumn were found to be significantly related to the number of adult leafhoppers per field. This study shows the constant presence of WDV and wheat dwarf over the years and that autumn temperature is an important factor determining the number of leafhoppers in the field and the incidence of disease. The result provides insights that can be useful for improving management strategies of the disease.

P2.4-019

TRANSMISSION EFFICIENCY OF TOMATO CHLOROSIS VIRUS (TOCV) TO POTATO PLANTS BY BEMISIA TABACI MEAM1 AND MED AND DAMAGE CAUSED BY THIS CRINIVIRUS ON THIS VEGETABLE

FAVARA Gabriel Madoglio. (1), MARTINES Caroline Da Cruz. (1), MARUBAYASHI Julio Massaharu. (1), OLIVEIRA Cíntia Sabino. (1), SOUZA Suyanne Araújo. (1), HAYASHI Pedro. (3), SOUZA-DIAS José Alberto Caram. (2), KRAUSE-SAKATE Renate. (1)

Text

Tomato chlorosis virus (ToCV), transmitted by whiteflies, causes significant damage to solanaceous crops. This study aimed to evaluate the efficiency of ToCV transmission to potato plants by B. tabaci MEAM1 and MED and the damage caused by ToCV in potato plants. Transmission efficiency was evaluated exposing B. tabaci MEAM1 and MED to ToCV-infected potato leaves for 24-h, then transferred (10 whiteflies/plant) to healthy plants (n=20) of the cultivars Agata and Asterix for a 24-h inoculation period. To measure the damage, healthy or ToCV-infected plants of the cultivars Agata and Asterix (n=15) were grown, separately, in field conditions within insect-proof cages. The infected plants were inoculated 30 days after emergence. The damage caused by ToCV was assessed by comparing the productivity and the number of tubers produced by healthy or infected plants. The transmission efficiency of ToCV to Agata plants by MEAM1 and MED was 5% and 30%, and to Asterix plants were 20% and 55%, respectively. Healthy and infected plants of the cv. Agata produced an average of 325 g and 307 g of tuber and means of 8.4 and 8.2 tubers per

plant, respectively. Healthy and infected plants of the cv. Asterix produced an average of 207 g and 160 g of tuber and means of 7 and 6.4 tubers per plant, respectively. As potatoes are vegetatively propagated using seed tubers, further studies are necessary to evaluate the secondary damages caused by ToCV on this vegetable.

P2.4-020

FIRST REPORT OF BIDENS MOSAIC VÍRUS INFECTING PATCHOULI PLANTS (POGOSTEMON CABLIN BENTH.) IN BRAZIL.

MARTINES Caroline. (1), FAVARA Gabriel. (1), MARUBAYASHI Julio. (1), OLIVEIRA Cíntia Sabino. (1), KRAUSE-SAKATE Renate. (1)

(1) Universidade Estadual Paulista "Júlio de Mesquita Filho"., Botucatu, BRAZIL

Text

Patchouli (Pogostemon cablin) is a plant belonging to the Lamiaceae family, used for medicinal purposes and in the cosmetics industry. In 2022, 6 patchouli plants exhibiting mosaic and leaf deformation were found in a flower shop in Botucatu municipality, São Paulo state, Brazil. Total RNA was extracted from leaves of all symptomatic plants and subjected to RT-PCR using the potyvirus universal primers WCIEN/PV1. Amplicons of the expected size (800 bp) were obtained for all samples analyzed and sent for nucleotide sequencing. The nucleotide sequences obtained showed 95.83%-98.90% identity with the corresponding nucleotide sequence of an isolate (Genbank AY960151.1) of bidens mosaic virus (BiMV) identified in plants of Bidens pilosa in Brazil. Symptomatic patchouli leaves were macerated in phosphate buffer and mechanically inoculated into 9 healthy plants of B. pilosa. The inoculated plants were kept in a greenhouse for symptom observation and the viral infection was confirmed by RT-PCR using the BiMV-specific primers 8331/9046. The B. pilosa inoculated plants showed mosaic symptoms 10-15 days after inoculation, and molecular analyses confirmed the infection with BiMV in all inoculated plants. In Brazil, four viruses have been reported infecting patchouli, patchouli X virus (PatVX), tobacco necrosis virus (TNV), pepper ringspot virus (PepRSV), and an unidentified potyvirus. To the best of our knowledge, this is the first report of BiMV infecting patchouli plants in Brazil.

P2.4-021

TRANSMISSION EFFICIENCY OF BEGOMOVIRUS BY DIFFERENT POPULATIONS OF BEMISIA TABACI MED IN SÃO PAULO STATE

OLIVEIRA Cíntia Sabino. (1), NOGUEIRA Angélica Maria. (1), MARTINES Caroline Da Cruz. (1), FAVARA Gabriel Madoglio. (1), MARUBAYASHI Julio Massaharu . (1), ALVAREZ Daniel De Lima . (1), BUENO Regiane Cristina Oliveira De Freitas. (1), REZENDE Jorge Alberto Marques . (2), KRAUSE-SAKATE Renate. (1)

Text

Begomoviruses transmitted by cryptic species of *B. tabaci* cause losses to several crops of agricultural importance. This study aimed to evaluate the transmission efficiency of the begomovirus tomato severe rugose virus (ToSRV), tomato rugose mosaic virus (ToRMV) to tomato plants, and bean golden mosaic virus (BGMV) to common bean plants by *B. tabaci* MEAM1 and MED. The experiments were conducted with one population of *B. tabaci* MEAM1 and three populations of *B. tabaci* MED collected in different municipalities in São Paulo state. Inoculum source plants were placed in separate cages with MEAM1 or MED whiteflies for a 24-h acquisition access period (AAP). At the end of the AAP, the insects were transferred, according to the virus acquired, to cages containing healthy plants of tomato and common beans for an inoculation access period (IAP) of 24-h. Total DNA was extracted 21 days after the inoculation and virus infection was confirmed by PCR using begomovirus universal primers. The transmission rates of ToSRV, ToRMV, and BGMV by MEAM1 were high and ranged from 66.5%-93.3, 46.7%-80%, and 53.3%-100%, respectively. MED populations did not transmit ToSRV and ToRMV to tomato plants. Only one MED population transmitted BGMV to a bean plant (1/15), indicating that MED is able to transmit begomovirus. The results suggest that the MED populations from São Paulo State are not good vectors of these viruses.

COLLECTION AND IDENTIFICATION OF POTENTIAL XYLELLA FASTIDIOSA VECTORS - ASSESSMENT OF BACTERIA TRANSMISSION IN POLAND

KALUZNA Monika. (1), SOIKA Grazyna. (1), WARABIEDA Wojciech. (1)

(1) The National Institute of Horticultural Research , Skierniewice, POLAND

Text

A quarantine organism, the bacterium Xylella fastidiosa (Xf), is a xylem-inhabiting, vector-transmitted, Gram-negative, and very slow-growing bacterium in the Lysobacteraceae (earlier Xanthomonadaceae) family. Spread for the long distances of X. fastidiosa occurs mainly via import/export human-mediated transportation of mainly latently or symptomatically infected plant material. Short-distance distribution is usually by xylem sap-feeding insects. Until now the presence of bacterium Xf was not reported nor studied in our country. During this study over 500 individuals of insects belonging to four families: Cicadellidae, Aphrophoridae, Delphacidae and Membracidae were collected in different geographical regions of Poland. The application of real-time PCR with TaqMan probe and nested PCR for the detection of Xf, using DNA extracted directly from selected insects known as potential vectors of X. fastidiosa, allowed to predict the potential threat of bacteria transmission in our country. The results of the conducted research will be presented. This study was financed by the National Science Centre, Poland (Narodowe Centrum Nauki), grant UMO-2017/26/M/NZ9/01024.

P2.4-023

TRANSMISSION OF CUCURBIT LEAF CRUMPLE VIRUS (GEMINIVIRIDAE: BEGOMOVIRUS) BY VECTOR BEMISIA TABACI WITH DIFFERING SECONDARY ENDOSYMBIONT COMPOSITION

ANDREASON Sharon. (1), KOUSIK Shaker. (1)

(1) USDA-ARS U.S. Vegetable Laboratory, Charleston, UNITED STATES

Text
Cucurbit leaf crumple virus (CuLCrV), a bipartite begomovirus transmitted by the sweetpotato whitefly (*Bemisia tabaci*; Hemiptera: Aleyrodidae), is a limiting factor in the production of cucurbits in the United States. Virus transmission is in a persistent, circulative manner, and whitefly secondary endosymbionts, such as *Rickettsia*, may affect transmission efficiency. Virus transmission tests were performed from susceptible versus resistant watermelon varieties using *B. tabaci* MEAM1 harboring the maternally inherited secondary endosymbiont *Rickettsia* versus MEAM1 deficient of this endosymbiont. Results demonstrated CuLCrV transmission from susceptible watermelon to the same susceptible variety in 50% of tests using *Rickettsia*-harboring or *Rickettsia*-deficient whiteflies. CuLCrV was not detected in susceptible watermelon after transmission test whiteflies acquired virus from the resistant watermelon variety. Quantification of virus titers in leaves after whitefly acquisition access demonstrated significantly lower titers in leaves fed on by *Rickettsia*-deficient versus *Rickettsia*-harboring whiteflies. Virus titers in whiteflies post-inoculation access were not significantly different. These results highlight the importance of using resistant watermelon varieties in CuLCrV management. Studies to better understand how vector secondary endosymbiont composition affects virus transmission and viral titer in host plants are ongoing.

Text
Genome-wide association studies (GWAS) have revolutionized scientific insight and potential to examine complex diseases. Huanglongbing (HLB), or citrus greening disease, threatens the citrus industry at a global scale. HLB results from the growth of “Candidatus Liberibacter asiaticus” (CLas) in the phloem of Citrus species and is spread by the hemipteran insect vector, Diaphorina citri. GWAS of 600 adult D. citri collected from four citrus groves in southeast Florida, USA, was used to identify genetic loci associated with pathogen acquisition, a quantitative trait. The acquisition phenotype for each insect (absolute titer of CLas) was estimated using quantitative PCR. After shallow sequencing (1-7x coverage), haplotyping, imputation, quality filtering, and kinship analysis were performed to establish a marker panel. An association model identified hundreds of single nucleotide polymorphisms significantly associated with CLas acquisition and genomic loci. A separate reference-free K-mer based analysis was compared to the initial reference-based GWAS to cross-examine

loci deemed biologically important. Loci of interest were further assessed with Gene Ontology pathway analysis. This study provides novel insight into the genetics underlying vector biology and promotes further research to identify therapeutics which prevent insect-vector disease acquisition and transmission.

P2.4-025

HOW MIGHT MANAGEMENT INTERVENTIONS BE MATCHED TO THE STAGE OF EPIDEMICS FOR CASSAVA VIRUSES?

DONNELLY Ruairí. (1), TANKAM Israel. (1,2), GILLIGAN Christopher A.. (1)

(1) Epidemiology and Modelling group, Department of Plant Sciences, University of Cambridge, Cambridge, UNITED KINGDOM; (2) Central and West African Virus Epidemiology for Food Security (WAVE), Abidjan, COTE D'IVOIRE

Text

In recent decades a cassava mosaic begomovirus epidemic (CMV) spread by Bemisia tabaci whitefly has severely affected cassava yield in sub-Saharan Africa, and this was followed by a regional cassava brown streak ipomovirus epidemic (CBSV) spread by the same vector.

Both viruses are spread by B. tabaci - but infection also occurs in contaminated plant stock. But it is essential to understand how the relative importance of the transmission routes depends on the temporal phase of the epidemic.

In this poster we indicate how the efficacy of managing infected cuttings vs. whitefly-borne transmission changes as the temporal phases of epidemics change. We contrast findings for CMV and CBSV using recent published results on retention period for these viruses.

Text

Philaenus spumarius L., the main vector of *Xylella fastidiosa* (Wells) in Europe, is a univoltine species that overwinters in the egg stage, and its nymphs emerge in late winter or spring. Predicting the time of egg hatching is essential for determining the precise times for deploying control strategies against insect pests. Here, we monitored *P. spumarius* eggs from oviposition to egg hatching together with the daily temperatures and relative humidities at four field locations located at different altitudes in central Spain. The collected data were used to build a growing degree day (GDD) model to forecast egg hatching in the Iberian Peninsula. Furthermore, the model was validated with field observations on the presence of newly born nymphs in different regions of Spain. The model was then used as a decision-support tool to calculate the optimum timing for applying control actions against *P. spumarius* nymphs. Our results suggest that controlling nymphs at two different dates would target the highest percentage of nymphal populations present in the field. Our model represents a first step for predicting the emergence of nymphs and adopting timely control actions against *P. spumarius*. These actions could limit disease spread in areas where *X. fastidiosa* is present.

CURRENT SITUATION OF XYLELLA FASTIDIOSA IN FRANCE

LEGENDRE Bruno. (1), CUNTY Amandine . (1), FORVEILLE Aurélie . (1), DOUSSET Christèle . (1), BOUTIGNY Anne-Laure . (1), RIVOAL Carène . (1), BRUNET Anaël . (1), OLIVIER Valérie . (1)

Text
Xylella fastidiosa (*X. f.*) has been detected for the first time in France, in Corsica and PACA region during the summer 2015. Since 2020, *X. f.* has been also highlighted in Occitanie region with a significant number of new outbreaks discovered during the summer 2022. Only the subspecies *multiplex* has been reported so far in these regions, although *X. f.* subsp. *pauca* was previously reported and eradicated in one outbreak in Menton (PACA). In France, the sequence-types (ST) ST6 and ST7 were identified, but new ST88 (Var) and ST89 (Alpes-Maritimes) were recently identified in PACA on two different areas with a limited host range. In Occitanie, only ST6 has been identified but MLVA analyses suggested theses strains are genetically different from ST6 strains from PACA, Corsica and Spain. Since 2015 in France, only 5 olive trees (*Olea europaea*) have been found infected with low titer. No grapevine (*Vitis vinifera*) and no *Citrus* sp. were found infected with *X. f.*.
Official *X. f.* detection is based on the real-time PCR Harper *et al.*, 2010. The new version of the French method MA039 v6 includes an internal PCR control 18S (Ioos *et al.*, 2009) for the detection in plant and a new DNA extraction method based on the Maxwell® HT Environmental TNA kit (Promega). Compared to the traditional CTAB-Chloroform method, this new automatized protocol allows an improved sensitivity on *Olea europaea* and *Quercus* spp., safer working conditions for operators and the automatization of the process.

AUSTRALIA PREPAREDNESS: XYLELLA FASTIDIOSA AND ITS INSECT VECTORS – POTENTIAL CONTROL AND MANAGEMENT OPTIONS APPROPRIATE TO AN AUSTRALIAN CONTEXT

(1) CSIRO, Montferrier Sur Lez, FRANCE; (2) CSIRO, Brisbane, AUSTRALIA; (3) CSIRO, Canberra, AUSTRALIA; (4) Department of Agriculture, Fisheries and Forestry, Canberra, AUSTRALIA

Text
The spread of Xylella fastidiosa (Xf), one of the most detrimental plant pathogens currently affecting the Americas and Europe, is a reality that will likely continue due to globalisation. As such, effective preparedness of countries where the pathogen does not yet occur is paramount to shield both native flora and commercial plant-based industries from an incursion and spread.
As a first step for being prepared for a robust response should an incursion take place, a comprehensive and critical review of the existing literature regarding available control and management strategies was undertaken.
Here we will present the results of this review which was a response to the Australian National Xylella Action Plan and specifically Action 3.4 which is to Analyse literature and overseas experience to identify control and management options relevant to the Australian context.
Our results indicated that current mitigation strategies are largely deployed across those that target Xf in the host plant and those which focus on the insect vectors with the aim to minimise the impact of Xf, its vectors and the associated plant diseases caused by the bacterium. Furthermore, integrating these results, we have identified several research gaps that could limit Australia's capacity to respond to a Xf incursion. We have therefore proposed a set of 24 research recommendations that will increase Australia's preparedness to control and manage a Xf outbreak and these recommendations will be discussed.

SURVEY ON THE PRESENCE OF XYLELLA FASTIDIOSA IN OAK TREES IN FRANCE AND ASSESSMENT OF SEED-TRANSMISSION

CESBRON Sophie. (1), GRILLOTON Killian. (1), JACQUES Marie-Agnès. (1)

(1) Univ Angers, Institut Agro, INRAE, IRHS, SFR QUASAV, F-49000 Angers, France, Angers, FRANCE

Text

Xylella fastidiosa (*Xf*) is a plant xylem-inhabiting bacterial pathogen that may colonize a wide range of plants and cause diseases in various crops of economic importance. According to climate model predictions, most French area could be suitable to *X. fastidiosa* subsp. *multiplex* (*Xfm*). Strains of this subspecies are likely to cause serious damages to various plant species including forest and shade tree species such as oak. A sampling campaign was therefore conducted in 2020 and 2021 in French state forests exploited for the quality of their oak trees and in woods. Quantitative PCR was used to detect *Xf*. None of the samples taken from oak trees during these two years revealed any *Xf* contamination. Whereas *Xf* introduction through contaminated plant material (horizontal transmission) most probably already occurred into Europe, *Xf* vertical transmission through seed is poorly documented. The transmission of *Xf* to the acorn was studied by inoculating stems at different vegetative stages (from flower to fruit). Transmission from acorn to seedling was also analysed by acorn inoculation before sowing. In both types of analyses, no *Xf* transmission was demonstrated, while stem colonization was observed. However, the question of seed transmission for other plant species remains an important issue for a better understanding of the mechanisms underlying the epidemiological dynamics and control of diseases caused by this European priority pathogen.

DIRECT XYLELLA FASTIDIOSA WHOLE GENOME SEQUENCING FROM PLANT USING TARGETED ENRICHMENT

Text

Xylella fastidiosa is a gram-negative plant pathogenic bacterium with a broad host range, which causes important diseases. Endemic to the Americas, this bacterium was recently introduced to the European continent where it has been detected since 2013 in various plant species in Italy, France, Spain, and Portugal. Precise genetic characterization of *X. fastidiosa* diversity can be obtained using whole genome sequencing, but isolation of the bacterium from contaminated plant material is not always successful. In order to access the bacterial genome directly from plant infected samples, a SureSelect targeted enrichment method was developed. Enrichment was very efficient to retrieve *X. fastidiosa* genome sequence with genome coverage significantly improved for all enriched plant samples, whatever the plant species or the contamination level. Whole genome sequencing data are useful to study the epidemiology and the origin of *X. faxtidiosa* introductions, and to give new insights for surveillance and management of this quarantine bacterium.

PROJECTING CLIMATE SUITABILITY OF XYLELLA FASTIDIOSA, AN IMPORTANT GLOBAL BIOSECURITY THREAT

Text

Xylella fastidiosa (XF) is a plant pathogen that can cause disease in a wide range of plants, making it a serious global threat to plant health. The outbreak of XF in Italy and its subsequent spread in Europe has raised serious concern about its potential impact on the production of food crops. To better understand the potential distribution of this pathogen, a Maximum Entropy (MaxEnt) model was developed using long-term climate data and data on the current global distribution of XF. The model found that annual mean temperature and precipitation of the coldest quarter were the most significant contributors to XF's potential distribution, accounting for 90.1% of the model projection. The optimal temperature for pathogen establishment was identified as 16°C. The model projected that most of New Zealand is suitable for XF establishment, and by overlaying the model output with areas where potential vectors are present, hotspots for XF establishment were identified. The model also highlighted areas where the climate is highly conducive to XF establishment, including most parts of Italy, southern France, southwestern Spain, and large areas in Portugal. These findings may be valuable for countries such as China, Australia, New Zealand, and South Africa, where the pathogen has not yet established. Overall, the MaxEnt model provides important insights into the potential global and local distribution of XF, which could aid in developing strategies to manage and control its spread.

NO NEED TO KILL XYLELLA FASTIDIOSA

ZHANG Heng. (1)

(1) xinjiang Tuozheng Agricultural Technology Co.,Ltd., Aksu, CHINA

Text

Regarding the symbiotic relationship between pathogens and plants, I propose that it is not necessary to use targeted killing or isolation methods to combat Xylella fastidiosa. Instead, we can control the relationship between the pathogen and the plant in a mutually beneficial way that does not harm the host by enhancing the tree's vitality, improving its immunity, and providing drug treatments. We have already achieved success in date palms, where the relationship between the pathogen and the plant can be mutualistic, and this phenomenon can be compared to traditional Chinese medicine's approach to dealing with viruses. I believe that studying the symbiotic relationship between pathogens and plants can provide new ideas and methods for agriculture, environmental management, and biological control, and promote the development of new agricultural technologies. In the future, international cooperation needs to be strengthened to explore the mechanisms and applications of the

symbiotic relationship between pathogens and plants, providing new avenues and possibilities for achieving sustainable development.

EVALUATION OF A NEW BIOLOGICAL SOLUTION COMBINING ANTIMICROBIAL PEPTIDES AND A DELIVERY SYSTEM BASED ON AGROBACTERIUM TUMEFACIENS FOR THE CONTROL OF XYLELLA FASTIDIOSA

TANNIERES Melanie. (1), SHATTERS Robert. (1)

(1) European Biological Control Laboratory - USDA-ARS, Montferrier Sur Lez, FRANCE

Text

Xylella fastidiosa (Xf) is a quarantine bacterium that can infect the xylem of a wide range of cultivated, ornamental, and wild host plants. Xf is the causal agent of Pierce's disease in grapevine in North America, citrus variegated chlorosis in South America, and olive quick decline syndrome, notably in Southern Italy. There is currently no method that effectively prevents or cures host plants from infection. The current approaches for Xf disease management mainly rely on eradication of infected plant to reduce inoculum source, the use of insecticides to control the vector populations, and the use of healthy plant propagation material. Therefore, there is a need for new and safe biological solutions. Protecting and/or curing mature fruit trees infected by *Xf* remains a challenge but would be the best possible solution to avoid eradicating infected trees and replanting. The use of antimicrobial peptides (AMPs) represents an interesting approach due to their broad spectrum of activity against bacterial pathogens, low environmental impact, and limited evolution of resistance. EBCL will test an innovative approach combining the use of AMPs and a delivery system based on Agrobacterium tumefaciens. The main advantage of this method is that it can potentially confer resistance to mature fruit trees. Preliminary tests will thus be performed to evaluate proof of concept of this strategy for the control of Xf.

NOVEL TARGET-ORIENTED PEPTIDES WITH POTENTIAL FOR INFECTION CONTROL STRATEGIES AGAINST XYLELLA FASTIDIOSA

Peptides can be promising candidates against *X. fastidiosa* due to their broad spectrum of activity and low environmental impact. They can be targeted towards the pathogen by affecting its viability or by hampering processes such as biofilm formation or motility. Peptides can also be directed towards the host by acting as plant defense elicitors, which would induce a priming state.

In our studies, a screening platform was developed to assess the bactericidal and antibiofilm

activity of peptides using viability qPCR and crystal violet, respectively. Peptides were selected or newly designed, synthetized and tested, resulting in the identification of the peptides **1036** and **RIJK2**, which possess dual activity (high bactericidal and antibiofilm activities). In addition, a screening platform for the identification of plant defense elicitors on *Prunus dulcis*, host of *X. fastidiosa*, was set up with the peptide **flg22** using RNAseq and RT-qPCR. From the peptide library studied, we identified the peptide **FV7** as a novel plant defense elicitor. In addition to the bifunctional peptide **BP178** with bactericidal and plant defense elicitor activities, several of the above new peptides are currently being tested in the almond platform to evaluate their efficacy of infection control against *X. fastidiosa.*

Text

Efficient delimitation of a newly detected area infested by a quarantine pest is a key element to enhance the effectiveness of phytosanitary measures. Xylella fastidiosa subsp. multiplex was first detected in the department Aude (Occitanie, France) in September 2020. In the following months, the reinforced surveillance implemented in accordance with Regulation (EU) 2020/1201 resulted in numerous detections close to the first outbreak, while an extra survey plan made it possible to detect several new and separate infested areas in the same department. Then, in 2021 a multidisciplinary working group in the framework of the Epidemiological Plant Health Surveillance Platform was appointed to support the risk manager with the further delimitation of the contaminated area. On-site observations, expertise and risk maps using eco-climatic data were used to define a risk-based and sequential survey plan and provide guidelines to improve the surveillance. The implementation of this survey plan resulted in findings of both contaminated and non-contaminated areas. The risk manager strongly relied on the results of this survey plan to adapt the surveillance and management strategy. This approach could be generalised to other outbreaks of Xylella fastidiosa or any other pest. It highlights the benefits of bringing together researchers (bacteriologists, entomologists, epidemiologists), inspectors, agronomists and stakeholders to devise a delimiting survey.

XYLELLA FASTIDIOSA: ACTION OF THE ENZYME LESA ON PLANT LIPIDS

Text

Xylella fastidiosa is classified as a global threat for agriculture. After inoculation by xylem sap-feeding insects, *Xylella fastidosa* colonizes plants by different strategies including an enzymatic arsenal. Among these molecules, LesA[1] is the major enzyme among the proteins secreted by the bacteria. According to its sequence and its structure, this protein is supposed to be a member of lipase/esterase family. LesA is structurally close to LipA of *Xanthomonas oryzae* that is also involved in virulence. We produced LesA in *E. coli* and performed a number of experiments of characterization by in-vitro tests based on selected substrates to verify its activity. In a second step, we performed an untargeted lipidomic approach using total lipid extracts from *Arabidospis thaliana* leaves. The results obtained on the activity tests confirm the esterase activity of LesA but only on short carbon chains. The lipidomic results show 172 compounds significatively differents ($p<0,05$) between treated and untreated samples. Some have been identified by mass-spectrometry, suggesting that LesA could have an impact on some phospholipids. More investigations are needed to better know biological substrates of LesA and its role in plant colonization and symptoms expression in plants infected by *Xylella fastidiosa*.

[1]Nascimento, R. et al. The Type II Secreted Lipase/Esterase LesA is a Key Virulence Factor Required for *Xylella fastidiosa* Pathogenesis in Grapevines. Sci. Rep. 6, 18598 (2016)

In 2018, *Xylella fastidiosa* (Xfas) was detected at a Belgian arboriculture wholesaler, in olive plants imported from Spain. Despite this being a sole finding, its capacity to establish under regional environmental conditions was investigated. Colonisation of Xfas was assessed in 20 perennial woody plant species, common in the urban landscape and natural environment, under both greenhouse (10-35°C) and outdoor conditions. In three consecutive years, shoots were pin-prick inoculated with strain CFBP 8431 (ST6) from the subsp. *multiplex*. The fate of the bacterium was monitored by Harper TaqMan PCR and dPCR after 5, 12, 24 and 36 months. Overall, plants maintained a healthy appearance. Xfas detection in the inoculated part of the shoots did not indicate multiplication. Indoors, bacterial titres remained fairly constant over time, whereas they were generally lower and less stable in outdoor plants. There was

also no clear evidence of bacterial movement as detections in non-inoculated twig parts were mostly in the grey zone of quantification, except for *Castanea sativa*, *Populus nigra* and *Quercus robur*. Although a slow coloniser, xylem microbiome analyses of *Salix alba* revealed that the presence of Xfas can significantly alter resident endophytic bacterial communities at a local scale. This study shows that under the regional climatic conditions, establishment and proliferation of Xfas is unlikely, yet the pathogen may remain latent in infected tissue for an extended period of time.

FLUORESCENCE IN SITU HYBRIDIZATION COUPLED TO FLOW CYTOMETRY AND CELL IMAGING ANALYSES AS POTENTIAL TOOLS FOR XYLELLA FASTIDIOSA RESEARCH AND DIAGNOSTICS.

Text

Fluorescence in situ hybridization (FISH) is used to directly identify microorganisms within complex samples in a few hours having a widespread application in environmental microbiology, including reports for Xylella fastidiosa detection in plant xylem vessels and insect honeydew. In Costa Rica, X. fastidiosa subsp. fastidiosa is endemic, with high bacterium prevalence and seldom disease manifestations in coffee plantations throughout the central valley, where most of the coffee is grown. We study the extent of the bacterial infection in coffee and its insect vectors. For this purpose, we implemented two FISH-based tools coupled to (i) flow cytometry (Flow-FISH), and (ii) cell imaging analyses, to study specific events of the X. fastidiosa life cycle in vitro and in vivo; as well as for the direct detection of X. fastidiosa with potential diagnostic value. For this purpose, we tested an X. fastidiosa-specific probe (KO210) and a universal probe (Eub338), using flow cytometry and microscopy. We standardized the hybridization conditions using an X. fastidiosa pure culture, we determined the detection limits of each tool, and confirmed the specificity of the KO210 probe for X. fastidiosa. Applications of the tools include detection of bacteria from plant and insect material, and in vitro cultures, with an in-depth qualitative and quantitative resolution, broadening the existing tools for research and diagnostics in X. fastidiosa.

IMPROVING THE DIAGNOSTIC CAPABILITY FOR XYLELLA FASTIDIOSA SUBSP. MULTIPLEX USING ADVANCED NANOTECHNOLOGY AND PCR-BASED ASSAYS

Text

Xylella fastidiosa subsp. *multiplex* (Xfm) is an emerging threat to the southern U.S. pecan

and peach growing regions, causing pecan bacterial leaf scorch and phony peach disease, respectively. The current lack of reliable diagnostic tools for Xfm causes uncertainty in the specialty crop industry in the U.S. The research objective is to improve diagnostic capability for Xfm. We validated different diagnostic tools for Xfm using enzyme-linked immunosorbent assay (ELISA) and molecular-based assays, including traditional PCR and real-time quantitative PCR (qPCR). New Xfm-specific primers were generated and validated, producing expected amplicons specific to Xfm. We also developed a TaqMan qPCR assay protocol for the detection of Xfm in pecan and peach. The results of the qPCR experiments based on plant genomic DNA from petioles were equivalent to the traditional PCR amplification based on crude sap. Further improvement in detection methods is critical for the early diagnostics and subsequent timely intervention for Xfm. To address this, advanced nanotechnology was used to improve diagnostic capability. Antibody-conjugated immunomagnetic carbon nanotubes were developed to improve sensitivity and reliability of PCR-based diagnostics for Xfm. The improved PCR diagnostic methods will support production and distribution of clean plant materials during national and international movement of plant materials.

COMPARATIVE GENOMICS OF XYLELLA FASTIDIOSA SUBSP. MULTIPLEX STRAINS FROM FRANCE REVEALS PATHOGEN DYNAMICS AFTER ITS INTRODUCTION

Text

Xylella fastidiosa is a plant pathogen responsible for numerous crop diseases worldwide. It specifically colonizes the xylem of plants and is transmitted exclusively by sap-feeding insects. X. fastidiosa has a significant adaptive capacity, as evidenced by its great genetic diversity and frequent recombination events between subspecies. Originating from the Americas, X. fastidiosa is now present in several European countries (Italy, France, Spain and Portugal) due to accidental introductions of contaminated plant material. This situation calls for a better understanding of the evolutionary dynamics of the pathogen in its new areas of distribution. Herein, we present a comparative genomics analysis of strains belonging to the subspecies multiplex that have been isolated from various host plants in France since the first detection of the pathogen in 2015. High-quality genome sequences were obtained using the PacBio sequencing technology, which allowed the identification of numerous plasmids, in contrast to American strains of this subspecies which rarely possess plasmids. We further employed a metagenomic sequencing approach combining both long- and short-read technologies to sequence additional genomes directly from infected plants in a new focus of infection. This strategy simplifies the sequencing of new strains detected in the field by eliminating the time-consuming isolation step, thereby providing access to strains that could not have been sequenced previously.

DETECTION OF XYLELLA FASTIDIOSA BY COLORIMETRIC LAMP AND DROPLET DIGITAL PCR ASSAYS

Text

Xylella fastidiosa (Xf) is a bacterium that inhabits the xylem vessels of over 600 plants. The entry of Xf subsp. *pauca* ST53, causing the olive quick decline syndrome in Italy, represents the first outbreak in field on UE territory.
Prompt field-based and sensitive laboratory assays are urgently required for the containment strategies of the Xf spreading. A cLAMP and ddPCR assays, based on widely validated primer (Harper *et al.,* 2010), were used for Xf detection in a crude alkaline sap obtained from incubation of thin olive stem slices in NaOH-based buffer. cLAMP assay can be performed at any location in a portable isothermal block at 65°C, providing a naked-eye detectable amplification result in 40-minutes. Both assays detected the target DNA up to 10^2 CFU/mL of bacterium in crude alkaline sap without any inhibition effect. Moreover, a ddPCR assay was implemented to detect Xf in purified DNA extracts prepared from different plant and insect matrices artificially contaminated with Xf suspension..
An exstensive validation of both assays on naturally infected samples, using crude extracts and purified DNA, proved that cLAMP has remarkable potential as first screening test for a timely detection of Xf at the point of care due to its simplicity, low cost, and portability; conversely ddPCR, although requires expensive reagents/equipment and is time-consuming, is more sensitive, especially using purified DNA extracts and solves some results recorded as doubtful by the qPCR assay.

XVETORES.PT: BIOLOGY OF XYLEM-SAP FEEDING INSECT VECTORS AND POTENTIAL VECTORS OF XYLELLA FASTIDIOSA IN PORTUGAL

Text

Xylella fastidosa was reported for the first time in Portugal in 2019; since then, this phytopathogenic bacteria was progressively spread throughout the country, and currently, 17 demarcated regions of infection have been established. This constant spread may lead to devastating economic and environmental problems, threatening Portugal's agricultural sector and plant diversity. Since there is no cure for this bacterium, vector control is perceived as the main tool to limit the spread of *X. fastidiosa*. In Portugal, some studies developed in the

Northeast region demonstrated the importance of the main and potential vectors and clarified aspects of biology, diversity and abundance; however, there is a lack of knowledge about these aspects at the national level. Therefore, the project Xvetores.pt: Biology of xylem-sap feeding insect vectors and potential vectors of *Xylella fastidiosa* in Portugal, funded by EFSA (call GP/EFSA/ALPHA/2021/07), aims to study the biology, abundance, and diversity of insect vectors and potential vectors in different agrosystems such as olive groves, cork oak forests, and urban and semi-natural areas in different regions of Portugal with different agroclimatic conditions. Furthermore, preference studies for host plants and studies on the biology of vectors under microcosm conditions will also be carried out. The Xvectors.pt project is led by IPB and integrates five other Portuguese partners, namely ISA/ULisboa, INIAV, DGAV, UP, and InPP.

MEDITERRANEAN AGRICULTURAL SPECIES, THEIR VOLATILES, AND THE POTENTIAL IMPACT ON PHILAENUS SPUMARIUS

Text

Philaenus spumarius (Linnaeus, 1758) (Hemiptera, Aphrophoridae) is Europe's most common and widespread xylem-sap feeder insect. This insect has become a serious threat to European agriculture due to its recognized role in transmitting the phytopathogenic bacterium Xylella fastidiosa (Xanthomonadales: Xanthomonadaceae). Therefore, understanding the factors that influence the host plants' choice by this insect vector could be an important tool to manipulate the vector behaviour and implement sustainable control strategies. Therefore, in this work, the volatile profile of the leaves of three important Mediterranean crops, almond, olive, and vine were assessed. Moreover, the P. spumarius olfactory response towards two of the most abundant and common Volatile Organic Compounds (VOCs) (cis-3-hexenyl acetate and cis-3-hexen-1-ol) present in the crop leaves were evaluated. From the three plant species, in total, 83 compounds were identified. Although the plant species showed a distinct volatile profile, cis-3-hexenyl acetate and cis-3-hexen-1-ol were common and abundant. Furthermore, females of P. spumarius were significantly attracted to cis-3-hexenyl acetate and cis-3-hexen-1-ol, whereas males did not respond to the VOCs. Our results can help future implementation of approaches to manage the vector and the spread of X. fastidiosa.

XYLELLA FASTIDIOSA: A EUROPEAN THREAT UNDER CLOSE SURVEILLANCE ON THE MEDISYS PLATFORM

Text

In December 2016 EFSA was mandated by the European Commission to carry out a horizon

scanning exercise on emerging plant pests. From that moment, and in close collaboration with the Joint Research Centre, EFSA started its monitoring and extraction of news and scientific data on plant pests based on the Medisys platform (https://publications.jrc.ec.europa.eu/repository/handle/JRC53155).
Classification is automatically and continuously carried out by the system on more than 21,000 media and scientific literature sources, from around 200 countries, using a set of more than 13,000 pre-defined keywords. The result of this activity is presented in freely available monthly newsletters (https://efsa.onlinelibrary.wiley.com/doi/toc/10.2903/(ISSN)1831-4732.Horizon-scanning-for-plant-health).
With its 54 keywords, the European situation of Xylella fastidiosa has been monitored over the last 6 years on media and scientific publications, from outbreaks to vectors, from subspecies to hosts, from detection methods to epidemiology. Since the beginning of this activity, X. fastidiosa was the pest providing the largest number of items on Medisys and the most represented pest in the horizon scanning publications (in 94 outputs over the total 108 accessible by March 2023).

ENDOPHYTIC MICROBIOMES OF WILD PLANTS SUSCEPTIBLE TO XYLELLA FASTIDIOSA INFECTION

Text
Xylella fastidiosa (Xf) is a phytopathogenic bacterium responsible for a wide range of diseases with high economic, environmental and social impacts. The plant-associated microbiome plays a central role in maintaining fitness, but little is known about the diversity and structure of these endophytic microbial communities. It is therefore essential to study this diversity and the interactions between endophytes and plants in order to understand the biotechnological potential of these microorganisms. In this context, we aim to characterise the structural diversity of endophytic microorganisms in wild plant species susceptible to Xf infection and present in the demarcated area of Portugal. Plant samples were selected and tested by qPCR for the presence of Xf. The microbiome was analysed in plants with and without Xf using a long-read sequencing approach. The results suggest a functional importance of some core microbiome groups, namely related to the ability to degrade toxic substances, fix nitrogen and promote plant growth. They may also help to explain the lack of visible symptoms and signs of decline in these wild plants, suggesting that certain taxonomic endophyte groups may contribute to modelling the infection. Notably, this is the first study in wild plants and the identification of relevant clusters is a contribution to the understanding of the impact of Xf on microbiome dysbiosis in nature.
This work was financed by FCT (PTDC/ASP-PLA/3145/2021).

LONG-READ METABARCODING APPROACH FOR DIAGNOSIS AND EPIDEMIOLOGY IN GENETICALLY HETEROGENEOUS PRUNUS SP. ORCHARDS

Text

Diagnostic challenges are increasing as globalisation and climate change favour the introduction of new plant pests. Xylella fastidiosa, Xanthomonas arboricola, Pseudomonas syringae and Monilinia fructicola are important pests affecting Prunus production with significant losses. Two different Prunus production systems were analysed: old orchards of P. dulcis and coexisting orchards of P. avium and P. persica, where significant areas of P. dulcis have recently been established. The high density of genetically heterogeneous Prunus sp. in which pests can coexist favours the development of highly adapted strains and/or the occurrence of coevolutionary phenomena associated with the spread and emergence of new diseases. This coexistence of phylogenetically close strains with drastically different phenotypes is a critical diagnostic challenge. In this context, molecular epidemiological studies were conducted by characterising the leaf and flower bacteriome and mycobiome of Prunus sp. using a long-read sequencing approach to assess the occurrence, distribution and impact of pests. Preliminary results showed that, in contrast to the leaf microbiome among Prunus species, significant differences were found between the flower and leaf microbiomes. Important pathogen-related groups were detected with significant impact on the microbiome structure, supporting the use of this approach for large screening phytosanitary surveys.
This work was financed by FCT (PTDC/ASP-PLA/3145/2021).

PHENOLOGY AND ECOLOGY OF PHILAENUS SPUMARIUS L. INFORM RISK ASSESSMENT FOR XYLELLA FASTIDIOSA WELLS IN SWITZERLAND

Text

The meadow spittlebug *Philaenus spumarius* L. (Hemiptera: Aphrophoridae) has been identified as the main vector of *Xylella fastidiosa* Wells in Europe. With a proactive approach toward a potential arrival of *X. fastidiosa* in Switzerland, we are studying the phenology and ecology of *P. spumarius* in the southern Alps so as to inform risk assessment for *X. fastidiosa* and suggest timely and effective management measures. The study of phenology allowed to identify the developmental periods, the host plants and their specificity for the nymphs in the Insubric climate. The ecology was studied across Canton Ticino according to

a stratified design that considered different combinations of environmental factors (climate, geology and topography, summarized by the Swiss Environmental Domains), habitat (vineyards, olive groves, orchards, hay meadows and pastures) and management (intensive vs. extensive). This provided information about host plants preference and specificity within different regional pools, and estimates of the density of *P. spumarius* in different habitats. Nymphs select preferentially host plants from Asteraceae, Plantaginaceae, Caryophyllaceae, Fabaceae families, in particular *Taraxacum officinale*, *Plantago lanceolata*, *Silene vulgaris*, *Trifolium pratense*. Nymphs' host preference varies according to regional pools and habitat type. Density of spittle nests is significantly higher in hay meadows compared to the other surveyed habitats and in extensively-managed habitats.

VECTORS AS SENTINELS OF PLANT DISEASES IN A CHANGING WORLD: RISING TEMPERATURES INCREASE THE RISK OF XYLELLA FASTIDIOSA OUTBREAKS

Text

Not much is known about how a changing climate will affect the epidemiology of generalist vector-borne diseases. We developed a high-throughput screening method to test for the presence of *Xylella fastidiosa*, in its insect vectors. Based on a four-year survey in climatically distinct areas of the island of Corsica (France), we found a significant positive correlation between the frequency of vectors positive for the bacterium and temperature. Higher prevalence corresponded with milder winters. Climate projections show that the risk for *X. fastidiosa* outbreak will increase in the future. Besides calling for research efforts to limit the incidence of plant diseases in temperate zones, our work reveals that recent molecular technologies could and should be used for massive screening of pathogens in vectors in order to scale-up surveillance and management efforts. Such methods could for example target multiple plant-pathogens in vectors communities. This will contribute to better understand the drivers of plant pest spread and establishment such as the influence of climate change or ecosystem degradation or to better evaluate environmentally sound control solutions over large geographical and temporal scales.

ABILITY OF GLASSY-WINGED SHARPSHOOTER TO ACQUIRE XYLELLA FASTIDIOSA SUBSP. PAUCA FROM RIPE OLIVE VARIETIES GROWN IN CALIFORNIA, USA.

BURBANK Lindsey. (1), KRUGNER Rodrigo. (1), ROGERS Elizabeth. (2)

(1) USDA-ARS, Parlier, UNITED STATES; (2) USDA-ARS, Ft. Detrick, UNITED STATES

Text

Xylella fastidiosa subsp. *pauca* (*Xfp*) is not currently present in North America but could have significant impacts on the United States olive industry if it were introduced. The state of California (CA), which has historically dealt with disease outbreaks caused by *X. fastidiosa* in

other crops, produces 70-80% of olives grown in the US. Several insect species present in CA, including the glassy-winged sharpshooter (*Homalodisca vitripennis*, GWSS) are known vectors of *X. fastidiosa* in grapevine, and could drive spread of *X. fastidiosa* in olive if *Xfp* strains were introduced. This study evaluated the susceptibility of three CA ripe olive varieties (Mission, Manzanillo, and Sevillano) to olive-pathogenic *X. fastidiosa* strain DeDonno, as well as ability of GWSS to acquire this pathogen from infected olive plants. GWSS caged on *X. fastidiosa*-infected olive seedlings for 3 days tested positive by PCR for *X. fastidiosa* at a rate of 4.8%. This shows that GWSS can acquire *Xfp* from CA ripe olive varieties and could potentially act as a vector of *X. fastidiosa* in this crop. Although overall acquisition rates were low, acquisition occurred as soon as 30 days post-inoculation of the plants in all three olive cultivars tested. Potential for GWSS to serve as a vector of *Xfp* in olive is relevant to scenarios where this subspecies is introduced to North America, or where GWSS is introduced to areas where *Xfp* is already present such as the Mediterranean.

EARLY DETECTION OF XYLELLA FASTIDIOSA INFECTION USING REFLECTANCE PROXIMAL SENSORS IN ALMOND AND OLIVE TREES

Text

Asymptomatic infection, long incubation period and non-specific symptoms hamper early detection of *Xylella fastidiosa* (*Xf*), which is essential to successfully eradicate, contain and manage *Xf* epidemics. Our objective was to assess the response of *Xf*-infected plants by physiological traits using proximal sensors at leaf level in (i) artificially infected olive plants and (ii) naturally infected almond trees in Mallorca Island. Olive leaves were measured, sampled and tested for *Xf*-infection for 18 months. Almond *Xf* symptoms were evaluated in 150 trees in May, June and July 2022. One branch was selected per tree and leaves measured and tested each month. Our results identified, in both species, physiological traits related to anthocyanins, carotenoids, xanthophylls content as the best indicators to discriminate between plants *Xf*-infected (even in absence of visible symptoms) from those non-inoculated or testing *Xf*-negative. Hierarchical clustering and discriminant analyses showed distinct groups differentiating symptomatic from asymptomatic leaves. Moreover, machine learning algorithms revealed the predictive capability of the visible and infrared spectral information to detect *Xf* infection in asymptomatic almond leaves 1 or 2 months before symptoms appearance with overall accuracies >87%. These results allow the application of imaging techniques, which is being used in a phenotyping platform.

Text

Plants activate an enhanced defense response when challenged by a pathogen in a mechanism called priming. Molecular signatures of microorganisms known as microbe-associated molecular patterns (MAMPs) can activate priming. The bacterium, *Xylella fastidiosa* (*Xf*), is a xylem-limited pathogen containing lipopolysaccharides (LPS) considered as a MAMP. LPS isolated from *Xf* elicits a priming response from *Vitis vinifera* grapevines. Primed grapevines experienced lower pathogen titer and significantly less disease compared to naïve vines.

During the priming phase (PP) and post-pathogen challenge phase (PPCP), analysis of differential gene expression revealed considerable transcriptional reprogramming. Unlike naïve vines during the PPCP, primed vines revealed an increased number of differentially expressed genes temporally and spatially.

We identified that *VviCP1*, which is a cationic peroxidase, was upregulated during the PP and PPCP. This suggests that *VviCP1* may link the PP to the PPCP. Constitutive expression of *VviCP1* demonstrated significant disease resistance suggesting that a mechanism relying on a peroxidase mediator is important during defense priming to the immune memory. Compared to naïve vines, weighted gene co-expression analysis revealed that more genes were co-expressed in primed vines of local and systemic petioles. This signifies that in primed plants there exists an innate synchronization of the systemic response to combat *Xf*.

MOBILE DIGITAL DATA COLLECTION TOOLS: XYLELLA FASTIDIOSA OUTBREAK PREPAREDNESS & PLANT HEALTH SURVEILLANCE

LINES Alex. (1)

(1) Animal and Plant Health Agency, Weybridge, UNITED KINGDOM

Text

Xylella fastidiosa poses a significant threat to UK plants, with the potential to cause widespread damage. As infected hosts may have long asymptomatic periods, it is crucial to have effective tools for early detection and rapid response to Xylella outbreaks. We developed a digital data collection system to coordinate Plant Health Inspectors during a rapid response to Xylella outbreaks. The system uses ESRI ArcGIS Online applications to generate survey grids around positive findings and allocate grid squares directly to inspectors. Barcodes attached to samples and scanned into the ESRI Field Maps mobile app provide full traceability and controlled data entry ensures consistency. All collected data is available on ESRI Dashboards for immediate analysis, ensuring that policy decisions and data analysis are always based on the latest data. Full deployment and training for 400+ inspectors were completed in 10 months. The system has proved to be effective in directing sample collection and providing real-time information to management teams during simulated outbreaks. These digital tools are essential for mitigating the impact of Xylella on UK agriculture and horticulture.

USE OF PLASMID PROFILES IN EPIDEMIOLOGICAL SURVEILLANCE OF XYLELLA FASTIDIOSA OUTBREAK IN THE VALENCIAN COMMUNITY, SPAIN

Text

In the *Xf* Demarcated Area (DA) of the Valencian Community (VC), Spain, all infected plants and insect vectors harbor the same sequence type (ST) as identified by MLST analysis (*Xf* subsp. *multiplex* ST6). However, *Xf* strains harboring three plasmid profiles have been isolated to date in this DA: strains harboring one (pUCLA-ESVL) or two (pXF64-Hb_ESVL and pUCLA-ESVL) plasmids, or no plasmids. In this study, we used a PCR-based plasmid-typing approach as a tool in the epidemiological surveillance of this *Xf* outbreak. A set of hundreds of DNA samples testing positive by qPCR including infected almond trees (86% of samples), 20 plants species including crops and landscape plants identified as *Xf* hosts in this DA, as well as three species of *Xf* insect vectors (3% of samples) were typed for the presence of the two plasmids. Results revealed that four plasmid profiles were present in this DA, with a new plasmid profile being identified, that did not match any strain isolated to date. The plasmid profile most abundant was pXF64-Hb_ESVL(-)/pUCLA-ESV(-) (55%), followed by pXF64-Hb_ESVL(+)/pUCLA-ESVL(+) (24%); however, its distribution differed among municipalities being some of them more prevalent in specific regions. The geospatial associations of the different plasmid profiles and the implications in the surveillance of the *Xf* epidemic in the DA of the VC will be discussed.

Text

Xylella fastidiosa (Xf) and Verticillium dahliae (Vd) are plant vascular pathogens that threaten global olive and almond production, restricting the flow of water and nutrients. Previous studies have demonstrated that hyperspectral and thermal imagery acquired at high spatial resolution successfully detected early symptoms of infection. Here, we assessed the feasibility of scaling-up Xf- and Vd-detection algorithms to high-resolution multispectral satellites Worldview-2 and -3 (WV 2&3) against airborne hyperspectral imagery in olive and almond orchards acquired across countries and seasons. Machine learning algorithms were trained using as inputs model-inverted plant traits, solar-induced fluorescence (SIF), and a thermal indicator (CWSI). Results obtained with multispectral satellite and airborne hyperspectral datasets reached similar accuracies for detecting advanced stages of disease development (OA=0.81/0.91; k =0.63/0.81, respectively). However, the detection of the early stages of disease development was outperformed by hyperspectral data (OA=0.74 and k=0.47 for WV 2&3) due to the inability of WV 2&3 to track critical plant traits such as NPQI, xanthophyll proxy PRIn, SIF, or anthocyanin content. Adding the thermal CWSI indicator to satellite data improved OA by 10%–15%, but the early detection of symptoms still requires specific narrow bands sensitive to Xf- and Vd-induced symptoms. Comparisons across species (almond, olive) and pathogens (Xf, Vd) will be discussed.

GENOMIC CHARACTERIZATION OF XYLELLA FASTIDIOSA SUBSP. PAUCA STRAINS ISOLATED FROM OLIVE (OLEA EUROPAEA L.) AND ALMOND (PRUNUS DULCIS MILL.) TREES IN ARGENTINA

Text

In Argentina, *X. fastidiosa* (Xf) subsp. pauca is considered a regulated non-quarantine pest that is causing serious phytosanitary problems in traditional olive plantations over 50 years old, especially in cv. Arauco grown in La Rioja province. Using the MLST typing system, two sequence types (ST) exclusive to Argentina were identified; ST69 and ST78 being detected in olive and ST78 in almond. In this study the complete genomes of two strains of *Xf* subsp. *pauca* isolated from olive (La Rioja region) and one from almond (Catamarca region) were obtained using a hybrid assembly approach combining data from Illumina and Oxford Nanopore sequencing platforms. The assemblies were generated with Trycycler, polished with medaka + pilon and evaluated with BUSCO. All strains were assembled at the chromosomal level (~2.6 Mb) and one plasmid was found in each strain. A Maximum Likelihood tree including a worldwide collection of *Xf* genomes indicated a closer relationship of isolates from Argentina with those from Brazil. These genomes represent a valuable resource in comparative genomic studies to extend the knowledge of *Xf* outbreaks, providing

data to determine potential *Xf* origin, virulence, and evolution. These are the first *Xf* genomes obtained from olive and almond trees in Argentina.

Text
Xylella fastidiosa although not present in Australia is a destructive plant pathogenic bacterium, with several subspecies affecting many plant species including grapevines, almonds, peaches, apricots, and olives in many countries worldwide. It is xylem limited, and transmitted mainly by spittlebugs, sharpshooters, leafhoppers and froghoppers. Xylella and its exotic vectors have been identified by the Plant Health Committee as the number one National Priority Plant Pest for Australia, by New Zealand MPI as an 'unwanted organism' and by the European Commission as one of most dangerous plant bacteria worldwide. Our research aims to provide biosecurity agencies with tools and knowledge which can be effectively implemented to rapidly eradicate Xylella fastidiosa, or prevent and suppress its spread if there is an incursion in Australia. This project focuses on potential insect vectors of Xylella, biology, physiology and ecology in targeted horticultural crops across three states of Australia. Efforts, methodology, results, and its significance to Australian food production will be communicated and discussed.

DECIPHERING XYLELLA POTENTIAL PATHOSYSTEMS IN THE BELGIAN FLORA : A STUDY ON NORTHERN EUROPEAN TEMPERATE REGIONS WITH EMPHASIS ON RIPARIAN AREAS

Text
The discovery of various strains belonging to three subspecies of *Xylella fastidiosa* in Europe has raised concerns about the potential spread of the bacteria to Northern regions. It is crucial to evaluate the susceptibility of European flora, which has not been exposed to this pathogen before. In a biosafety facility, we mechanically inoculated KLN59.3 GFP-labelled *X. fastidiosa* at 22°C and 28°C to assess the susceptibility of *Salicaceae*, including *Populus tremula, Populus canescens, Salix alba,* and *Salix caprea*. The movement and multiplication

of bacteria in plants were examined using PCR, real-time PCR, confocal or scanning electron microscopy. After nine months, all plants tested positive for *X. fastidiosa*, except for 57% of *P. canescens* under the 22°C growing conditions. Bacteria were detected up to 120 cm from the inoculation point for *S. alba* and were found in the roots of all species. Successful isolation was achieved for *S. alba* and *P. tremula*. The average CFU/g of plant tissue per species ranged from 1.5E+03 to 3.5E+06, with the highest figures for *P. tremula*, which also showed a high number of totally obstructed vessels observed by confocal microscopy. Additionally, more than 400 endophytic bacterial isolates obtained from *Salicaceae* xylem sap, extracted using a Scholander pressure chamber, are currently under investigation as potential antagonist agents.

XYLELLA FASTIDIOSA INFECTION ALTERS THE XYLEM MICROBIOTA IN WILD AND CULTIVATED OLIVE TREES

Text

Nowadays, there are no tools available to cure *Xylella fastidiosa* (*Xf*) once a plant becomes infected. Research on plant-associated microorganisms is gaining increasing interest as an innate natural defense of plants to cope against infection by pathogens. In this study we have characterized the xylem-inhabiting bacterial communities in olive trees infected or not by *Xf* under natural field conditions in the Balearic Islands (Spain) by using a NGS approach. We have also evaluated the potential differences in the xylem microbiota associated to wild and cultivated (native or introduced) olive genotypes. For that, 244 samples from leaf petioles of *Olea europaea* plants were sampled and fingerprinted using an EST-SNP marker analysis to identify the olive accession. Alpha and beta-diversity measures of bacterial communities indicated that the main significant differences were associated to *Xf* infection, followed by the origin of the olive genotype (wild or cultivated) within each island (Mallorca, Menorca and Ibiza). Also, we have identified different bacterial genera significantly enriched according to *Xf* infection and olive genotype. The relationship between the genetic closeness of cultivated versus wild olive genotypes along with their differences in the xylem microbiome will be addressed.

Text

Xylella fastidiosa is a priority quarantine pathogen in the EU. As laid down in the EU legislation, after an outbreak, a demarcated area is established delimiting the infested zone surrounded by a buffer zone, where intensive surveillance and control measures are applied. The spread of almond leaf scorch disease (ALSD) in Alicante, Spain, was simulated with a spatial individual-based epidemiological model, comparing the performance of different surveillance and control designs for outbreak management. Two survey designs were compared where the survey effort was estimated based on the population size, or in two-steps, first the sample size per hectare, and second the hectares to be inspected. Two confidence levels, buffer zone sizes and eradication radii were compared, including those set by the regulation. The effect of vector control and inoculum removal was considered in the model by reducing the transmission rate parameter in the buffer zone, greatly decreasing the number of infected trees. Without the reduced transmission rate, the number of infected trees was similar to that obtained without any intervention, even with the eradication measures in place. No major effects were observed with the different buffer zone sizes and eradication radii. Higher confidence levels resulted in better disease control but increased survey efforts. The two-step approach had the greatest survey efforts but, did not improve disease control substantially.

IS A 'HIGH QUALITY' PLANT ALWAYS HEALTHY? CHARACTERISING PERCEPTIONS OF 'QUALITY' ACROSS THE LIVE PLANT TRADE IN THE CONTEXT OF XYLELLA FASTIDIOSA.

MARZANO Mariella. (1), POLLARD Christopher. (1)

(1) Forest Research, Midlothian, UNITED KINGDOM

Text

The movement of plants through the ornamental plant trade presents a major source of risk for the introduction and spread of *Xylella fastidiosa (Xf*). Prevention is crucial and involves understanding how trading bodies assess the risks associated with procurement of host plants. We focus on how key businesses define whether a plant is 'healthy' or not. We interviewed 44 businesses across the UK such as garden centres, nurseries, growers, and wholesalers and surveyed a further 100 in one specific county identified as a potential entry point for *Xf*. 'Quality' was consistently presented as a characteristic used to judge the health of a plant. We unpacked this further to identify what quality means and how this may influence purchasing decisions. Three main themes emerged: the quality of the plant (e.g. appearance, colour), quality of the supplier (e.g. relationships, response to queries), and quality of processes (e.g. on-site husbandry, record keeping, biosecurity checks). Each of these themes presents challenges to ensuring that Xf is detected or detectable. For example, assessing plant quality is largely informed by visual inspection, which may miss vital clues that a plant is infected. Long-term relationships with suppliers may lead to (mislaid) trust that their biosecurity processes are sufficient to prevent or detect Xf. By clearly outlining factors influencing current purchasing behaviours, we will present opportunities for improving biosecurity across the supply chain.

IDENTIFICATION AND CHARACTERIZATION OF A XYLELLA FASTIDIOSA RESISTANT ALMOND GENOTYPE

Text

Almond leaf scorch (ALS) caused by *Xylella fastidiosa* is an emerging disease in the EU and the Mediterranean that lack effective management tools. To identify *X. fastidiosa* resistance in almond, we grafted seven genotypes on infected almond trees in a commercial orchard, using the commercial cultivar 'Um ElFahem' (UEF) as a susceptible control. Each genotype was grafted on at least 10 trees with 3-4 grafts per tree. Disease incidence and severity were determined visually at 170 days post grafting. Six of the grafted genotypes including UEF, were similarly susceptible to *X. fastidiosa* with 65 to 82% of the grafts showing ALS symptoms. On the other hand, one genotype was clearly more resistant with only 12% symptomatic grafts. In the following year, none of resistant genotype grafts expressed ALS symptoms, while 87% of the UEF grafts were symptomatic. Furthermore, only 12% of the resistant genotype grafts were positive for *X. fastidiosa* in the second year, compared with 50% in the first year. We also measured *X. fastidiosa* migration and relative concentration in the grafts using quantitative-PCR and found that while *X. fastidiosa* migrated to similar distances in UEF and in the resistant genotype, its population was significantly lower in the resistant genotype. This indicates that this genotype is resistant to *X. fastidiosa* and that its resistance intensifies over time. Further characterization of the resistant genotype is underway and will be presented at the meeting.

CAN A PATHOGENIC PLANT GALL BECOME A BENEFICIAL SYMBOINT? ROLE OF AGROBACTERIUM IN DEVELOPING SOLUTIONS TO PLANT VASCULAR BACTERIAL DISEASES.

Text

Plant vascular diseases due to infection with bacteria, like Xylella fastidiosa (Xf), are difficult to treat due to inefficient therapeutic molecule delivery. We used Agrobacterium tumefaciens (At) as a therapeutic molecule delivery tool by converting the pathogenic gall into a beneficial symbiont. This was accomplished by creating a T-DNA that included four genes from T-DNA of pathogenic At that encode cytokinin and auxin biosynthetic enzymes together with a therapeutic gene of interest (gene for production of antimicrobials) . The plant growth regulators induced cell division/gall formation. The T-DNA also encoded a

visual marker molecule (mCherry or GFP fluorescent proteins or betalain a small red colored betacyanin molecule) to observe production in symbionts. The symbiont T-DNA vector was inserted in the disarmed At EHA105 strain for plant inoculation. Our proof of concept focused on citrus greening disease, caused by the phloem-limited bacterium 'Candidatus Liberibacter asiaticus' (CLas). Upon symbiont formation, marker proteins were expressed in the symbiont, and movement into neighboring plant tissues was detected by western blot. When antimicrobial peptides were expressed, symbionts produced on CLas-infected citrus reduced foliar symptoms and CLas titer. We present that symbionts can be used as a screening tool or as a field deployable solution to deliver therapeutics for plant vascular bacterial diseases such as Xf Induced diseases.

THE SECOND MESSENGER C-DI-GMP: VIRULENCE AND BIOFIM FORMATION BY XYLELLA FASTIDIOSA

RAMOS GONZÁLEZ María Isabel. (1), BACCARI Clelia. (2), TRAVIESO HUERTAS María Luisa. (1), LINDOW Steven E.. (2)

Text

The vascular pathogen *Xylella fastidiosa* subsp. *fastidiosa* Temecula1 causes Pierce's Disease in grape plants. Bacterial proliferation blocks the transport of sap through the xylem, causing water and mineral nutrient alterations in the aerial parts of the plant. The pathogenicity mechanisms involve biofilm formation in the xylem vessels of infected plants. In the genome of Temecula1 there are few genes encoding GGDEF/EAL domain-containing proteins potentially involved in the turnover of c-di-GMP. It is known that this second messenger regulates the multicellular life style in bacteria. In *Xylella*, low levels of c-di-GMP are associated to acquisition of bacteria by the insect vector, while high levels of the second messenger are associated with the exploratory phase in plants (virulence). These phenotypes are contrary to the accepted canonical framework of c-di-GMP influencing the lifestyle of most phytopathogenic bacteria including other *Xanthomonadaceae*. We have generated mutants in GGDEF/EAL domain-containing proteins which were unavailable, investigated their role in virulence of grapevines and implemented a protocol to quantify c-di-GMP in these bacteria with the aim of certainly testing whether the c-di-GMP paradigm has an exception in *Xylella*, as it is suggested by the mutants' phenotypes. Identifying compounds which may inhibit biofilm formation by *Xylella fastidiosa* strains and unveil the mechanisms involved is also a goal.

FACTORS DRIVING INSECT VECTOR PRESENCE, ABUNDANCE AND PATHOGEN TRANSMISSION: THE CASE OF PHILAENUS SPUMARIUS AND NEOPHILAENUS CAMPESTRIS

LÓPEZ-MERCADAL Júlia. (1), SANZ-AGUILAR Ana. (1), MIRANDA Miguel Angel. (1)

(1) Universitat de les Illes Balears, Palma, SPAIN

Text
Global trade routes have increased the risk of new disease outbreaks and enhance the invasive species spreading worldwide. *Xylella fastidiosa* is one of the vector-borne plant pathogens that provokes huge economic impact. To understand its epidemiology, it is crucial to unveil the ecological factors affecting its insect vectors. *Philaenus spumarius* and *Neophilaenus campestris* are the most important vectors in the Balearic Islands. To shed light on the ecological drivers that influence vector seasonality, a three-year macrocosm study was conducted in olive, vineyard and almond crops in Majorca. Also, transmission tests were conducted under laboratory conditions. We used Generalized Linear Models (GLMs) to assess the effect of different ecological factors (e.g., type of crop or vegetation structure) on the presence and abundance of the vectors. Moreover, we evaluate the differences in transmission of *X. fastidiosa* between both vector species using Generalized Mixed Linear Mixed Models (GLMMs) and Pearson correlation. Our results highlight that the most influential variables explaining the presence and abundance of *P. spumarius* were the vicinity of canopy and cover and for *N. campestris* cover and border vegetation compartments. On the other hand, results on transmission trials showed no correlation between the number of positive insects and the number of plants infected, and that percentage of plants infected did not depend on the species of vector.

USE OF APTAMERS AS A DIAGNOSTIC TOOL FOR XYLELLA FASTIDIOSA

KLETT-MINGO José Ignacio . (2), **ROMAN ECIJA Miguel. (1)**, VELASCO-AMO Pilar. (1), BARRAGÁN-USERO Miriam . (3), PASCUAL-MELLADO Manuel . (2), LANDA Blanca B.. (1), NAVAS-CORTÉS Juan A.. (1), GONZÁLEZ Víctor M. . (2,3)

Cardenal Herrera Oria 298, 28035, Madrid, SPAIN

Text
Aptamers are single-stranded nucleic acids capable of adopting defined three-dimensional structures that allow them to interact with high affinity and specificity with their target molecule. To identify aptamers that specifically and differentially recognize bacterial cells of *Xylella fastidiosa* (*Xf*), 12 rounds of selection against a mixture of five *Xf* strains belonging to different subspecies were performed, and counter-selection was carried out in all rounds against bacteria belonging to 20 genera that are common inhabitants of the plant xylem. The enrichment in *Xf*-specific aptamers of the populations obtained in successive rounds of selection was analyzed by real-time PCR and rounds 11 and 12 were cloned to obtain individual aptamers and analyzed by Next Generation Sequencing (NGS). The ability of six aptamers identified to recognize *Xf* bacteria cells was studied by slot-blot and ELONA and their structural characterization was performed with m-Fold (secondary structure) and QGRS mapper (possible G-quadruplex) software. Two aptamers have been identified (X11-5F and X136699R) able to recognize with a high affinity a set of 15 *Xf* strains belonging to four subspecies being their binding capacity significantly higher than that shown against other common xylem-inhabiting bacteria. The potential use of these aptamers as a diagnostic tool for *Xf* will be discussed.

ESTABLISHMENT OF AN IN VITRO COLLECTION OF OLIVE CULTIVARS

BORROTO FERNANDEZ Eduviges Glenda. (1), JOSEPH Judith. (1), LAIMER Margit. (1)

(1) University of Natural Resources and Life Sciences, Vienna, AUSTRIA

Text

As part of the UN-programme for development of integrated techniques for inducing genetic diversity and improvement of vegetatively propagated and horticultural tree crops (CRP D24014) genotypes of Olea europaea were established in vitro. The research focused on developing and validate tissue culture protocols as a first step to reach induced stable mutants with tolerance to Olive Quick Decline Syndrome Disease. The cultivars ‘Coratina’, ‘Favolosa’ ‘Frantoio’, ‘Leccino’ and ‘Ogliarola‘ were kept under greenhouse conditions. Single node explants of juvenile branches from trees were used for the initiation of the cultures. The aim of this work is to study the influence of factors such as explant maturity, position within the branch on the establishment of an in vitro shoot culture of Olea europaea.The basal medium Olive medium (OM) was supplemented with different cytokinins. Significant differences in the survival percentages were found between the cultivars with SPPS statistics 27. Interestingly, the response of explants from two different donor plants of ‘Leccino’ indicates the importance of the physiological state on the establishment process. Also explants from the two branch parts showed different survival rates with apical branch part performing better. However, significant differences were found in the shoot lengths after three months. Here explants from the basal branch part produced significant longer shoots in most cultivars.

APPLICATION OF A WEB-BASED APP (CLASNIP:WWW.CLASNIP.COM) FOR THE IDENTIFICATION AND CLASSIFICATION OF FASTIDIOUS PLANT PATHOGENS

Text

Fastidious plant pathogenic bacteria inhabit either the xylem or phloem of the vascular tissues of plants. They are usually transmitted from plant to plant by insect vectors, which also serve as hosts for reproduction and overwintering. These pathogens either resist to growth in any available media such as ‘Candidatus Liberibacter solanacearum’ (CLso), or require specific and enriched media such as Xylella fastidiosa (Xf), which makes identification and classification challenging. Here we introduce Clasnip (www.clasnip.com), a web-based platform implemented with a state-of-art classification algorithm by deriving the Maximum Likelihood estimation of the Hidden Markov Model (HMM) parameters, for rapid and reliable interspecific and intraspecific interpretation of sequences reads. To date, Clasnip has newly curated databases for the classification of potato zebra chip (CLso), grapevine pierce disease (Xf), bacterial ring rot (Clavibacter sepedonicus), soft rot and blackleg

pathogens such as Dickeya and Pectobacterium spp, and potato virus Y phylogroups. We will demonstrate the high accuracy of Clasnip in classifying CLso haplotypes and Xf subspecies from pure culture and environmental samples using Sanger, genome and metagenomics sequencing data. This intuitive platform also allows users to customize their own reference databases for expanded detection coverage. Clasnip is a decision-making tool that can facilitate disease containment and control disease outbreaks or invasions.

WHAT IS THE RISK OF XYLELLA FASTIDIOSA TO ESTABLISH IN TEMPERATE EUROPEAN REGIONS - A SCENARIO INVESTIGATED IN BELGIUM

Text

To prepare for the potential spread of *Xylella fastidiosa* in northern Europe, where the bacterium has not yet been evidenced, addressing data gaps on both potential host plants and insect vectors is crucial. A pilot sentinel plantation was established in the infected region of Majorca to enhance knowledge for pest risk assessment. *Prunus domestica* cv. Opal, *Quercus petraea* and *Salix alba*, identified as potential keystone host polant species, along with a network of rosemary 'spy plants,' were used for symptomatic and molecular detection over four years, emphasizing the complexity of conducting sentinel plantation assays and stressing the need for long-term investigations. In addition, the potential of *Salicaceae* as an alternate host for Xylella in Belgium and Northern Europe was investigated. The flight capacity of *Philaenus spumarius* and *Aphrophora salicina* was also studied through mark-release-recapture and flight mill experiments, highlighting a possible association with riparian areas and spread over rather long distances.

Text
The species of the genus *Clastoptera* are xylem-feeder, can be potential vectors of *Xylella fastidiosa*. In olive orchards in southeastern Brazil, individuals of an as yet unidentified species of *Clastoptera* were frequently observed in association with olive plants. Then, surveys of regions and times of occurrence of nymphs and adults, natural infectivity by *X. fastidiosa*, and association with host plants of *Clastoptera* were carried out to understand their potential involvement in the dissemination of *X. fastidiosa* in olive orchards. Surveys with yellow sticky cards and visual observations in different locations in southeastern Brazil showed that *Clastoptera* occurs only in olive orchards above 1000 m altitude in the Mantiqueira Mountain Range, with population peaks of adults and nymphs between February and April. *Clastoptera* adults collected in cards were positive for *X. fastidiosa* by qPCR, indicating that individuals are naturally carrying the bacterium in olive orchards. By visual observation, adults and nymphs of *Clastoptera* were detected in shoots of olive trees and other shrub or tree plants close to olive orchards, such as *Duranta erecta*, *Salvia rosmarinus*, *Rhododendron* sp., *Tibouchina mutabilis*, and *Prunus persica*. New studies are underway to identify or describe the species of Clastoptera (apparently a new species) collected from olive trees and alternative host plants, as well as to assess their ability to transmit X. fastidiosa to olive trees.

IMPROVING PLANKTONIC GROWTH OF XYLELLA FASTIDIOSA SUBSP. PAUCA, STRAIN DE DONNO BY SUPPLEMENTING LIQUID MEDIA WITH POLYSORBATE SURFACTANTS

DEL GROSSO Carmine. (1), SURANO Antony. (1), SALDARELLI Pasquale. (1), SAPONARI Maria. (1)

Text
Xylella fastidiosa (*Xf*) is a fastidious and slow growing bacterium, difficult to grow *in vitro*. Isolates of *X. fastidiosa* subsp. *pauca* (*Xfp*) recovered from diseased olive trees in Apulia (Italy), are notoriously difficult to be cultivated in common media (PD3 and PW or PWG), and growth in liquid cultures is very limited, most likely for the abundant formation of biofilm that promotes the aggregation of the bacterial cells, forming the typical and visible ring of biofilm and cell aggregates. Such behaviour poses major constrains for testing the effects of different growth conditions or compounds on the bacterial multiplication. In this study, we tested the effect of two polysorbate surfactants, Tween-20 (TW20) and Tween-80 (TW80) at different concentrations, on the growth and biofilm formation of *Xfp* in different liquid media. TW20 and TW80 are widely used in microbiology, biochemistry, and molecular biology due to their excellent solubilization properties and low toxicity. Our results showed that TW20 positively affects the planktonic growth of *Xfp* and reduce the biofilm formation. Whereas, when TW80 was used an increase of the planktonic growth rate was recorded, but not a decrease in the biofilm formation. Overall, our results showed that by adding the two surfactants, *Xfp* planktonic growth can be significantly increased, allowing to improve *in vitro* tests aimed at evaluating the inhibition effects of compounds and antimicrobial formulations.

INTERPLAY BETWEEN BIOTIC AND ABIOTIC STRESS EXACERBATES LEAF SCORCH DEVELOPMENT IN ARABIDOPSIS INFECTED WITH XYLELLA FASTIDIOSA

VIEIRA Filipe. (1), ROBATZEK Silke. (1)

Text

Abiotic stresses, as drought, can induce xylemic vessel emboly and loss of water potential. While these responses are essential for plant survival during drought, some bacteria may evolve to explore these host responses for their own gain. Xylella fastidiosa, a vector borne xylem pathogen, specifically colonizes more than 500 different plant species. Through feeding, insects transmit the bacterium to the xylem. Xylella cells form a biofilm attached to the cell walls. Interestingly, within these plant species some develop disease symptoms, as leaf scorch, while others remain symptomless. The underlining molecular mechanisms, and the relative importance of the host response to the abiotic stress vs biotic stress as of outcome for bacterial growth and/or disease development remains unexplored. Here, we investigated the effect of drought stress on the establishment and development of symptoms in Arabidopsis infected with Xylella. Plants were exposed to drought stress for 10 days after Xylella infection. 75% of the Xylella infected leaves show rapid development of symptoms after watering, compared to either, mock infected, or normally raised Xylella infected leaves. This effect was independent of the Xylella subspecies used. Our data suggests that the host response to drought stress may increase the ability of Xylella to colonize the host. Studying the interface between drought and infection may reveal useful molecular mechanisms to create plants resistant to infection.

SCREENING AN ALMOND GENOTYPE COLLECTION FOR RESISTANCE TO XYLELLA FASTIDIOSA AND IDENTIFYING DNA MARKERS ASSOCIATED WITH THIS TRAIT

Text

Xylella fastidiosa causes almond leaf scorch (ALS) disease in North America, the EU and the Mediterranean. Controlling the disease once trees have been infected is practically impossible, and therefore finding resistant genotypes can be an elegant solution to reduce ALS damage. We have recently identified a resistant almond genotype by conducting a small-scale screen of our almond genotype collection. In the current study we have expanded this screen to test 50 different almond genotypes. From each genotype 8 seedlings were generated by grafting genotype scions on GF677 rootstocks. Seedlings will be inoculated with *X. fastidiosa* using the needle prick method during the spring and evaluated for disease incidence, severity, and *X. fastidiosa* colonization during the summer.

The Unit of Fruit Tree Sciences in Newe Yaar has established a map of ~5000 SNP markers, evenly spread across the genome of these almond genotypes. Using this map, the Unit of Fruit Tree Sciences will lead the research to link *X. fastidiosa* resistance to specific DNA markers, which represent a region of approximately 40K bp. This will allow to identify not only markers linked to almond resistance but also candidate genes which may be relevant for the resistance phenotype. Hence, results from these experiments are expected to advance breeding efforts to generate *X. fastidiosa* resistant almond cultivars and to help understand the genetic basis of resistance to ALS.

EVALUATION OF MOLECULAR TESTS FOR THE DETERMINATION OF THE XYLELLA FASTIDIOSA SUBSPECIES: RESULTS FROM AN EUROPEAN TEST PERFORMANCE STUDY (TPS) AND THE ORGANIZATION OF A PROFICIENCY TEST (PT)

RAAYMAKERS Tom. (1), VOGELAAR Martijn. (1), **BERGSMA-VLAMI Maria. (1)**

(1) Netherlands Institute for Vectors, Invasive plants and Plant health (NIVIP) / European Union Reference Laboratory for Pests of Plants on Bacteria (EURL), Wageningen, NETHERLANDS

Text
The European Commission has identified Xylella fastidiosa (Xf) as a priority pest to be addressed in the activities of the European Union Reference Laboratory for Pests of Plants on Bacteria (EURL). The detection of Xf has been harmonized among the national reference laboratories (NRLs). Currently, Xf subspecies determination requires a laborious multilocus sequence typing (MLST) test (Annex IV B of Commission Implementing Regulation (EU) 2020/1201). Over the past few years, two real-time PCR tests have been published that focus on the Xf subspecies designation. These real-time PCRs offer several advantages when compared with the implemented MLST test: firstly, they should increase the sensitivity of detection, and secondly, they should decrease the time required for subspecies designation. However, available validation data is currently rather limited. Therefore, the EURL (Netherlands Institute for Vectors, Invasive plants and Plant health-NIVIP) has scheduled a TPS on the Xf subspecies determination by these real-time PCRs. The TPS consists of 38 blind samples containing DNA from different Xf subspecies (either mixed with plant DNA or in buffer), or plant DNA and 6 controls. The results obtained from this TPS will be discussed, as well as the organisation of a PT on the subspecies designation of Xf in 2023. Results will support the addition of one or both real-time PCR tests to the Annex IV B of Commission Implementing Regulation (EU) 2020/1201.

HOW EUROPEAN VINEYARDS ESCAPED PIERCE'S DISEASE DURING THE XIX AND XX CENTURY

MORALEJO Eduardo. (1), GIMÉNEZ-ROMERO Alex. (2), MATÍAS Manuel. (2)

Text
Pierce's disease (PD) of grapevine caused by *Xylella fastidiosa* (Xf) exhibits a limited global

distribution compared to other grapevine diseases, e.g. powdery and downy mildews. Why European vineyards were not affected by PD during the 19th and 20th centuries is a matter of scientific debate, but no clear answer has yet been provided. Here we gather phylogenetic, epidemiological, and historical evidence indicating that (i) the spread of Xf in vineyards of the southeastern USA likely occurred after the *Phylloxera* crisis in Europe (~1868-1890) and that (ii) most of American-vine species exported to Europe came from nurseries located in areas without PD risk in the USA, according to our epidemiological model. Once in France, American vines were multiplied and distributed mainly from Montpellier and Bordeaux. Using reanalysed temperature data from 1950 to 1980 we show how Montpellier would be located in an epidemic-risk zone with potentially low to very low growth rates, while temperatures between 1870 and 1900 would be below the threshold for PD epidemics (T_{av} ~ 0.5ºC lower). Our temperature-driven epidemiological model suggests moderate PD risks only in Mediterranean islands and some coastlands areas before 1980. However, global warming is accelerating since 1990 the extent and risk levels of PD in continental areas of the Mediterranean basin (e.g. Rhone valley, central Italy) and the Atlantic face of Portugal and southern France.

NANOPORE AMPLICON SEQUENCING: RAPID, SENSITIVE AND SPECIFIC DIAGNOSTIC SYSTEM TO MONITOR AND INTERCEPT XYLELLA FASTIDIOSA

Text

Xylella fastidiosa (Xf) is a quarantine bacterium causing important diseases in various host plants. Since 2013 it has been intercepted in several European countries, starting from Italy. The recent rise in minimum winter temperatures, due to climate change, has extended the range of areas suitable for its establishment, in fact cold temperature is one of the main deterring factors for Xf establishment. The spread of this bacterium often comes from asymptomatic plant materials for which sensitive detection is needed. Moreover, in case of new outbreak or new host plant, the identification of the subspecies and the Sequence Type (ST) is required. With this purpose, an amplicon-Nanopore sequencing was developed for Xf detection and identification at the subspecie/ST level, even in asymptomatic conditions. The workflow foresees the amplification of seven housekeeping genes (MLST) and the sequencing based on MinION from Oxford Nanopore Technology, a portable, fast and easy-to-use device, paired with an ad hoc bioinformatics pipeline. Two host plants, grape and olive, have been spiked with
the Xf subspecies fastidiosa and pauca respectively, at different known concentrations (from 10^7 to 10 cfu/mL). Preliminary results indicate that this approach is a promising tool to precisely detect and identify Xf and therefore can be used to monitor the spread and the evolution of this bacterium. Finally this workflow could be applied for the correct identification of other priority pathogens.

GENETIC VARIATION WITHIN ALMOND POPULATIONS DO NOT IMPEDE LEAF SCORCH OUTBREAK IN MALLORCA

Text

Genetic variation within host populations decreases disease risk and spread in annual crops, but this central prediction in evolutionary ecology remains largely untested in perennial crops. Around 30 years ago, two subspecies of Xylella fastidiosa (Xf) were introduced to the island of Majorca and subsequently dispersed by the insect vector, Philaenus spumarius, mainly in almond crops. During this time, almond germplasm banks distributed in various locations on the island have been naturally exposed to the pathogen. Between 2019 and 2021, the symptoms of 95 mostly local varieties of almond trees exposed to the pathogen were analyzed and monitored each year in the germplasm collections. Xf have been detected in 82 of the 95 almond varieties analyzed. In general, a good correspondence was observed between varietal response to the pathogen in the germplasm almond collection and in the field. Despite the great spatial and genetic heterogeneity found in Mallorcan almond orchards, Xf has been effectively transmitted among almond trees and orchards, causing almond leaf scorch disease in more than 1.5 million trees (83% incidence) across the island. Analysis of the data suggests that although transmission rates may be higher in host populations with genetic uniformity, vector movement is sufficient to bridge the spatial gaps between orchards containing with more resistant varieties.

SURVEYS ON XYLELLA FASTIDIOSA AND ITS VECTORS IN MONTENEGRO

PEROVIC Tatjana. (1), HRNCIC Snjezana. (1), ADAKALIC Mirjana. (1), LAZOVIC Biljana. (1)

Text

Xylella fastidiosa (Xf) causes various diseases on important crops such as olives, grapevines, citrus fruits, almonds, but also forest trees, ornamental plants and plants of spontaneous flora. Since the olive is the most widespread fruit species in Montenegro, possible presence of the Xf bacterium would cause great economic losses. The paper presents the results of a three-year survey of olive trees and other host plants carried out in olive groves, nurseries, home and public gardens. With visual inspections a special attention was paid to the presence of typical and atypical symtoms. A total of 120 samples were colected and analyzed by the LAMP method (Yaseen et al., 2015), dominantly Olea europaea (39.2%), followed by Citrus spp., Prunus spp., Nerium oleander, Laurus nobilis, Magnolia grandiflora, Rosmarinum officinalis and other host plant. In the analyzed plant material phytopathogenic bacteria Xf was not detected. Bearing in mind the importance of vectors in the transmission of Xf from infected host plants to healthy ones the presence of

insect vectors in olive groves on the Montenegrin coast was monitored as well. Insects were collected on weeds, using sweep-net sampling at three locations in the area of Valdanos and two locations in the area of Radanovici. The insect population in the area of Valadanos compared to population in Radanovici was richer in number of species and more abundant in number of individuals.

A PHYSIOLOGICALLY-BASED POPULATION MODEL OF PHILAENUS SPUMARIUS

Text

The meadow spittlebug, *Philaenus spumarius* L. (1758) (Hemiptera: Aphrophoridae), is the main vector of the plant pathogen bacterium *Xylella fastidiosa* in Europe. Effective disease containment strategies are mainly based on uprooting infected plants and control of the vectors. The vector control strategy focuses on suppressing juveniles in the herbaceous cover and preventing colonization of the olive canopy by newly-emerged adults. The design and implementation of vector control strategies can take advantage of properly calibrated population models describing and predicting the phenology and abundance of P. spumarius populations in agroecosystems.

We developed a temperature-driven physiological-based model to predict the phenology and population dynamics of P. spumarius. We parametrized model functions describing the diapause termination and age-distribution of overwintering individuals, and the temperature-dependent development and mortality rates by integrating data collected in lab experiments and literature. The model has been calibrated and validated with field data collected in Northern and Southern Italy (in the Liguria and Apulia regions).

The model can be used for a proper definition of effective Integrated Pest Management strategies to control P. spumarius populations and thus to support Xylella fastidiosacontainment.

HOST PLANT RELATIONSHIPS OF POTENTIAL INSECT VECTORS OF XYLELLA FASTIDIOSA

Text

Xylella fastidiosa is a bacterial pathogen that causes disease symptoms in plants, such as leaf scorch and plant dieback. The outbreak of *X. fastidiosa* in Italy has affected 80% of all olive plantations and incurred a loss of €6.3 billion a year. *X. fastidiosa* has spread globally

through transport of infected plant material. Consequently, there is a high chance that *X. fastidiosa* could enter the UK from continental Europe in the future. *Philaenus spumarius* is the main insect vector of *X. fastidiosa* locally in agricultural habitats in southern Europe. The *X. fastidiosa* bacterium is transmitted from infected plants to healthy plants by *P. spumarius* feeding. My research is focussed on understanding the feeding behaviour of P. spumarius, specifically the host plant preferences of the insect in the UK.

XYLEM SAP RECOVERED FROM DIFFERENT CROP SPECIES AFFECTS IN VITRO GROWTH OF XYLELLA FASTIDIOSA SUBSP. PAUCA, STRAIN DE DONNO

Text

Mechanisms driving *Xylella fastidiosa* lifestyle and the host susceptibility are still largely unknown. An example of successful host adaptation is given by *X. fastidiosa* subsp. *pauca* (*Xfp*) infecting olives, with a large number of cultivars (cvs) being susceptible, and resistance traits identified only in the olive cvs Leccino and FS17. In this study, the in vitro growth and gene expression of *Xfp* were evaluated in artificial liquid media enriched with xylem sap from: olive cvs Leccino (resistant) and Cellina di Nardò (susceptible), and from citrus and grapes representing *Xfp* immune species. The results show that the sap of Cellina di Nardò promoted a greater planktonic growth than Leccino. Conversely, a higher biofilm formation was detected when the sap of Leccino was used. Media supplemented with citrus sap produced the lowest values, both for biofilm formation and planktonic growth. Unexpectedly, values similar to those recorded for Cellina di Nardò were obtained using the sap from grapes. The level of expression of 15 *Xfp* genes involved in several biological processes was assessed. The multivariate analysis yielded two clusters, one including Cellina di Nardò and grapevine, and the second Leccino and citrus. These results suggest that the xylem sap composition contributes to the resistance/susceptibility of olive cvs, but as showed by the contrasting results gathered with citrus and grapes, most likely this is only one of the components of the multifactor response to *Xfp*.

CHARACTERIZATION OF THE AMYLOIDOGENICITY OF REP-WH1 DOMAINS IN PLASMIDS FROM XYLELLA FASTIDIOSA

LUCERO Leticia. (1), GIRALDO Rafael. (1)

(1) National Center for Biotechnology (CNB-CSIC), Madrid, SPAIN

Text

We have been working for many years with a plasmid replication protein from *Pseudomonas savastanoi* (RepA), achieving its structural and functional characterization[1]. Such knowledge has lent to prove that its WH1 dimerization domain has amyloidogenic traits[2]. Thus, we were able to trigger the formation of amyloid aggregates, eliciting toxicity in *E. coli* by targeting the bacterial inner membrane, disrupting PMF and hampering transport through membranes, central metabolism and ATP/nucleotide synthesis and generating ROS[3,4].

Here we report the use of the homologue Rep-WH1 domains from two plasmids of *Xylella fastidiosa* (*spp. pauca* and *multiplex*) to trigger an amyloid proteinopathy. In *E. coli*, depending on the Rep-WH1 variant, it forms distinct amyloid aggregates (according to Th-S staining), drastically changing bacterial morphology, growth rates and viability. DnaK (Hsp70) chaperone overexpression, which shifts the aggregative behaviour of *P. savastanoi* RepA-WH1[5,6], also altered the aggregation pattern in one of the variants from *X. fastidosa*. Our goal is to use these Rep-WH1 variants as a control strategy against *X. fastidiosa*.

EPPO DIAGNOSTIC PROTOCOL ON XYLELLA FASTIDIOSA: HOW NATIONAL AND TRANSNATIONAL RESEARCH FEED INTO REGIONAL STANDARDS

GIOVANI Baldissera. (1), **GRIMAULT Valérie. (1)**, PETTER Françoise. (1)

(1) EPPO, Paris, FRANCE

Text
EPPO is one of the Regional Plant Protection Organizations recognized under the International Plant Protection Convention. One of its functions is to develop Regional Standards. EPPO has a long standing and active program for Standard setting in several areas and started a program to prepare diagnostic Standards in 1998. The objective of this program is to achieve a harmonized approach to detection and identification for regulated pests. The work is conducted by the Panel on Diagnostics and Quality Assurance in collaboration with specialized Panels (including one in Bacteriology). Panels are composed of specialists from member countries. As of March 2023, 145 Pest-specific diagnostic protocols and horizontal diagnostic Standards have been developed. The first version of the Diagnostic protocol on Xylella fastidiosa (Xf) was approved in 2003 and focused on Vitis and Citrus hosts. After the introduction of the bacterium in Italy a first revision of the protocol was prepared to include information on the different hosts of Xf (including symptoms), details on sampling and sample preparation and new tests for detection and identification. Further revisions have been initiated to incorporate outcomes of transnational research projects (e.g. Euphresco PROMODE, POnTE and XFActors). The fifth version of the diagnostic protocol was approved in 2023-02. The EPPO Secretariat is a partner in BeXyl and relevant outcomes will be considered for inclusion in the EPPO protocol.

UPDATE ON THE EUROPEAN FOOD SAFETY AUTHORITY DATABASE OF XYLELLA SPP. HOST PLANT SPECIES

DELBIANCO Alice. (1), GIBIN Davide. (1), PASINATO Luca. (1), STANCANELLI Giuseppe. (1)

(1) EFSA, Parma, ITALY

Text
Following the X. fastidiosa oubreak in Italy in 2013, EFSA was requested by the European Commission to provide scientific assistance on this plant pathogenic bacterium. EFSA conducted a pest risk assessment and published several scientific opinions on this topic, that are all included in the EFSA Journal virtual issue on X. fastidiosa (https://efsa.onlinelibrary.wiley.com/doi/toc/10.1002/(ISSN)1831-4732.XylellaVI). EFSA also released a database of host plant species of Xylella spp.. A systematic literature review allowed the compilation of lists of host plant species, along with collection of information on infection conditions, geographic locations, pathogen taxonomy and tolerant/resistant response of host plants. The database is regularly kept up-to-date with information retrieved through a comprehensive search of the latest scientific literature and EUROPHYT outbreaks notifications by Member States. The raw data are published in Zenodo platform in the EFSA Knowledge Junction community (https://doi.org/10.5281/zenodo.1339343) and interactive reports are available in the freely accessible Microstrategy platform (https://www.efsa.europa.eu/en/microstrategy/xylella). The EFSA database of Xylella spp. host plant species represents a key tool for research, risk assessment and risk management. The main findings will be presented, particularly focusing on plant hosts of Xylella fastiosa recently reported.

COMMUNITY STRUCTURE AND SEASONAL ABUNDANCE OF POTENTIAL XYLELLA FASTIDIOSA VECTORS AND RELATED TAXA IN XYLELLA-SUSCEPTIBLE CROPS IN SOUTHERN NEW SOUTH WALES, AUSTRALIA

HOSKINS Jessica. (1), TREBICKI Piotr. (2,3), STEVENS Mark. (1)

(1) New South Wales Department of Primary Industries, Yanco, AUSTRALIA; (2) Macquarie University, Sydney, AUSTRALIA; (3) The University of Melbourne, Melbourne, AUSTRALIA

Text
Xylella fastidiosa (*Xf*) and its vectors (xylem-feeding leafhoppers and spittlebugs) are considered the single greatest threat to Australian plant biosecurity and Australian horticultural industries. Despite this, potential native vectors of *XF* in vulnerable crops in Australia are unknown. Thus, the aim of our study is to examine the diversity and seasonal abundance of leafhoppers and spittlebugs present in *XF* vulnerable crops and to discover if any have the potential to be vectors of *XF*. We did this by trapping and sweep netting, every two to three weeks, in *XF* vulnerable crops (wine grapes, citrus, olives and cherries) and surrounding native vegetation in one of the main horticultural areas of southern NSW. The results of this trapping effort and possible implications for the transmission of *XF* and other plant pathogens in Australia are discussed here.

THE POTENTIAL DIRECT ECONOMIC IMPACT AND PRIVATE MANAGEMENT COSTS OF AN INVASIVE ALIEN SPECIES: XYLELLA FASTIDIOSA ON LEBANESE WINE GRAPES

FREM Michel. (1,2), FUCILLI Vincenzo. (1), NIGRO Franco. (1), ELMOUJABBER Maroun. (3), ABOU KUBAA Raied. (4), LA NOTTE Pierfederico. (4), BOZZO Francesco. (1), CHOUEIRI Elia. (2)

Text

Xylella fastidiosa subsp. *fastidiosa* (Xf) has not been reported in Lebanese vineyards. The average gross revenue generated by Lebanese wine growers is estimated as close to US$22 million/year for 2015-2019. The potential quantitative economic impacts of an Xf outbreak and particularly, the private control costs have not been assessed yet for this country as well as for others which Xf may invade. Using Partial Budget approach at the farm gate, we estimated that a hypothetical full spread of Xf on Lebanese wine grapes would lead to maximum potential gross revenue losses of almost US$ 11 million for an average recovery period of 4 years, to around US$ 82.44 million for an average grapevine life span period of 30 years in which infected plants are not replaced at all. The first yearly estimated additional management cost is US$853 per potentially infected hectare. For a recovery period of 4 years, the aggregate estimated additional cost would reach US$2374/ha, while the aggregate net change in profit would be US$-4046/ha. The observed costs in this study support the concerned policy makers and stakeholders to implement a set of reduction management options against Xf at both national and wine growers' levels. This re-emerging alien biota should not be neglected in this country. This understanding of the potential direct economic impact of Xf and the private management costs can also benefit further larger-scale studies covering other potential infection areas and plant hosts.

REPRODUCTIVE BIOLOGY AND EGG PARASITOIDS OF PHILAENUS SPUMARIUS

BODINO Nicola. (1), VOLPE Francesco. (2), DEMICHELIS Stefano. (2), CAVALIERI Vincenzo. (4), GIORGINI Massimo. (3), BOSCO Domenico. (2)

(1) Institute for Sustainable Plant Protection (IPSP-CNR), Torino, ITALY; (2) University of Torino, Grugliasco, ITALY; (3) Institute for Sustainable Plant Protection (IPSP-CNR), Portici, ITALY; (4) Institute for Sustainable Plant Protection (IPSP-CNR), Bari, ITALY

Text

The control of *Philaenus spumarius* (Hemiptera: Aphrophoridae), the main vector of *Xylella fastidiosa*, currently relies on measures against nymphs and adults. We studied the reproductive behavior of this insect and its egg parasitoids with the aim of providing new targets and approaches for control strategies against the vector. Main investigations intended to describe: i) a molecular marker of the reproductive phase in females, ii) the duration of ovarian parapause and timing of egg maturation in different climatic areas, iii) the variations in association with the symbiotic bacterium *Wolbachia*, iv) egg parasitoid communities. The results showed that: i) the expression level of the vitellogenin gene is a good marker of egg development phase, ii) the maturation of eggs and the duration of the ovarian parapause is highly dependent on the environmental conditions, iii) the prevalence of *Wolbachia* is highly variable among populations and seems to follow an increasing trend toward colder areas, iv) egg parasitoids [*Ooctonus* spp. (Hymenoptera: Mymaridae)] are present in both North and South Italy. These results start shedding light on some poorly known biological aspects of *P. spumarius*, thus providing useful information for designing new and more effective control strategies that take into consideration the reproductive biology of the main vector of *X. fastidiosa*.

PHILAENUS SPUMARIUS VIROSPHERE: THE BEXYL PROJECT

The use of virus-based biocontrol technologies as sustainable alternatives to pesticides in pest management has been extensively discussed for decades. The application of next-generation sequencing (NGS) to viral metagenomic analyses of insect populations has significantly increased the discovery rate of viruses, leading to the identification of new virus-based tools for pest management. In this perspective, the Horizon Europe-funded BeXyl project includes a task, within the work package 5, which aims at identifying potential biocontrol agents from the virosphere of the *Xylella fastidiosa* vector *Philaenus spumarius* (Hemiptera: Aphrophoridae). Eight European *P. spumarius* populations were sampled from fields characterized by distinct ecological traits, and their transcriptomes were analyzed using NGS. In this work, we present the preliminary composition of the European virome assigned to *P. spumarius*. Beside the evaluation of potential pathogenic viruses to be exploited as bio control agent, the most recurrent viruses will be further characterized alone or in combination with other stress factors to ascertain if they produce fitness cost for the vector and can be regarded as potential tools in an integrated pest management perspective. In conclusion, the identification and characterization of virus-based biocontrol agents can contribute to the development of more efficient and environmentally friendly pest management strategies.

CHARACTERIZATION OF THE METABOLIC DIVERSITY OF XYLELLA FASTIDIOSA STRAINS BY HIGH-THROUGHPUT PHENOTYPING

ROMAN ECIJA Miguel. (1), CORBÍN Paola. (2), ÁLVAREZ Miguel. (2), TORTAJADA Marta. (2), PERETO Juli. (2), LANDA Blanca B.. (1)

Text

Xylella fastidiosa (*Xf*) is a fastidious-growing bacterium with a wide range of host plants, being able to live with a commensal or pathogenic life style in hundreds of plant species depending on the association among specific *Xf* strains and host genotype. *Xf* phenomic characterization is key to establish potential alternative or adaptative metabolic pathways changes on certain host plants. A metabolic network using the sequences of 22 different *Xf*-strains has been proposed, and a high-throughput phenotyping approach was used to characterize the metabolic fingerprinting of seven *Xf* strains belonging to the three main subspecies isolated from several hosts. The number of carbon sources used ranged from 35 to 75, while compounds used as nitrogen sources varied from 12 to 37; with only between 14 and 22 % of the compounds being used by all the strains studied. The model developed with the *Xf* core gene set identified several key functions and the results obtained with the phenotyping microplates supported the proposed metabolic network. Different new defined minimal media have been designed based on the metabolic network and results from metabolic fingerprinting indicating that growth and biofilm formation differed according to the

type of carbon and nitrogen source used, although in general all strains had lower growth compared to that obtained in PD3 medium.

Text
EPPO is one of the Regional Plant Protection Organizations recognized under the International Plant Protection Convention. One of its functions is to develop Regional Standards. EPPO has a long standing and active program for Standard setting in several areas including inspection. Inspection Standards are developed to provide information to phytosanitary inspectors on when and how to inspect consignments or places of production of plants for planting and include sampling guidance (how lots are identified, and what is the unit of inspection). The EPPO Inspection Standards PM 3/81(3) Inspection of consignments for *Xylella fastidiosa* and PM 3/82(3) Inspection of places of production for *X. fastidiosa* were developed by the EPPO Panel on Phytosanitary Inspections following the introduction of *X. fastidiosa* in the EPPO region. Both Standards, were first approved in 2016 and have been revised twice, with the most recent update in 2022 incorporating additional sampling guidance (e.g. pooling of samples) from the EU H2020 project XF-ACTORS. Both Standards include common sections, e.g. information on vectors of *X. fastidiosa*, host plants, symptom description and general elements for phytosanitary inspections. The EPPO Secretariat is a partner in BeXyl and relevant outcomes will be considered for inclusion in the EPPO Standards.

DYNAMIC MODEL OF THE XYLELLA FASTIDIOSA PATHOSYSTEM: AN EXAMPLE ON ALMOND TREES FROM SOUTH-EAST SPAIN

Text
The almond tree is one of the most widely grown species around the Mediterranean basin, in

southern Spain alone it generates an estimated net economic impact of €9 billion/y. However, since 2016, the xylem-feeder bacteria *Xylella fastidiosa* has spread and infected crops from the Balearic Islands to peninsular Spain. The main transmission vectors of *X. fastidiosa* in the Spanish Mediterranean are the spittlebugs *Philaenus spumarius* and *Neophilaenus campestris*. Despite all the management measures taken, the situation has become critical in certain areas, such as the northern part of the province of Alicante, Spain. As an alternative to the institutionally-sanctioned use of pesticides and crop eradication campaigns, other strategies which are currently in preliminary experimental stages are being sought out that directly target the pathogen stages. One such approach currently being investigated in our laboratory, involves the use of antibacterial endolysins, which are peptidoglycan-lysing enzymes derived from bacterial viruses.
To support these efforts, we present a dynamic model of the entire *X. fastidiosa* pathosystem. Our model is based on field data and literature. This model allows us to develop simulations of diverse scenarios, which help to identify where different measures should be implemented. By incorporating laboratory data, our results show a first insight into the required effectiveness of lysins to control the spread of the bacteria.

XYLELLA FASTIDIOSA AFFECTS THE ALMOND TREES IN THE PROVINCE OF ALICANTE (SPAIN). SINCE WHEN?

SIGNES-PONT Maria Teresa. (1), CORTÉS-PLANA José Juan. (1), MORA MORA Higinio. (1)

(1) University of Alicante, San Vicente Del Raspeig, SPAIN

Text
In 2017, Xylella fastidiosa (Xf) reaches the almond trees of the province of Alicante (Spain). Our project (AICO 2021/331) funded by valencian government consists of developing mathematical-computational models that incorporate environmental variables. For validation, our model representing the spread of the plant pest must be fitted to the actual data available. Here we ran into a difficulty, because we are not sure the date of the analysis of the samples coincides with the date on which the tree was infected. The origin (time and coordinates) of the infection is unknown. So, the question is, when and where did the contagion of the almond trees really begin in the province of Alicante?
Our hypothesis is Xf has been around long before 2017. It is based on the observation and analysis of the production of almonds both in the province of Alicante and in Spain. Since almost twenty years ago, we observe a decline in almond production and cultivated area due to abandonment by farmers that suffer low crop yields, while production has increased in other areas in Spain. Despite new plantations have a higher yield, the permanent decrease in the harvest confirms the unstoppable destruction, if not remedied, of the traditional Valencian almond tree.
Although there are several causes such as inclement weather, scant help from agricultural insurance and disproportionate increase in production costs, the downward trend being almost 50% in some varieties could confirm our hypothesis.

POTENTIAL ALTERNATIVE WOODY PLANTS FOR THE RENEWAL OF “POST-XYLELLA” AGRICULTURE IN SALENTO (ITALY)

KOKIÇI Hysen . (1), BARONE Vito. (1), LABBATE Antonella. (1), BOSCIA Donato. (1), BOZZO Francesco. (2), PANTALEO Piccinno. (3), LA NOTTE Pierfederico . (1)

Text

Since its first discovery in 2013, the epidemic of Xylella fastidiosa subs.pauca ST53 in few years devastated the olive orchards of 3 provinces in Salento (Puglia, Italy) causing huge economic, landscape and environmental problems as well raising the need to rebuild the main and almost unique arboreous coverage, increasing biodiversity and resilience of the agro-ecosystem. The identification/evaluation of alternative woody agricultural and agro-forestry crops/species, both native and potentially adaptable to the soil/climatic conditions of Salento, is the starting point to regenerate and reconvert the future agriculture living together the bacterium. In the framework of a wider national project, the research is aimed to study the main aspects of alternative plants in term of agronomic requirements, characteristics, cultivation, protection, uses, investments and market. The information will be available as a “reasoned catalogue” that draws data/info from bibliographical research, specialist consulting, small farming experiences and pilot projects intercepted in the infected area. Furthermore, for the species not present in Salento, pathogenicity tests will be carried out, by controlled artificial/vector inoculation and periodic qPCR analyses, to verify their immunity or the level of resistance of the selected species. The results are addressed to producers/technicians to guide investments or pilot field trials as well to policy makers to plan strategies and funding measures.

KNOWLEDGE ON VECTOR’S FAUNA FOR XYLELLA FASTIDIOSA INVASION PREPAREDNESS: XYLEM FEEDERS IN ALBANIAN OLIVE ORCHARDS

Text

Since its first occurrence in Southern Italy, *Xylella fastidiosa* (hereafter Xf) has gained importance, especially in matters of its management and limiting its transmission. In regions non-affected by the bacterium, such as Albania, it is necessary to assess the risks of spread, notably by understanding the ecology of its vectors. Surveys took place over 12 months from August 2015 and July 2016 in two Albanian regions (Vlora and Tirana), where olive production is important covering 14 olive orchards. The aim was to investigate the presence of Auchenorrhyncha species with particular attention to xylem feeders. Identified Auchenorrhyncha species belonging to families Aphrophoridae, Cercopidae, Cicadellidae, Issidae, Flatidae were found. In Vlora, 4 out of 11 species captured were xylem feeders, whereas, in Tirana, 3 species were captured. The most abundant xylem feeder species was *Philaenus spumarius* in both regions. Vlora showcased a higher presence of *P. spumarius* in olive trees than in Tirana. Adults of *P. spumarius* and *Neophilaenus campestris* were the most frequent in August, September, and October 2015. The agroecological analysis noted that the Vlora area shows a higher richness of Auchenorrhyncha in terms of the number of

species. Further, the analysis of real-time Lamp assay confirmed the absence of *Xf* in the tested individuals. This study has public implications and pointed out that this country is still a free territory from *Xf*, at least in the surveyed areas.

TRANSLOCATION OF QUORUM SENSING MOLECULES FROM TRANSGENIC ROOTSTOCKS TO NON-TRANSGENIC SWEET ORANGE SCIONS INCREASES RESISTANCE AGAINST BACTERIAL DISEASES

Text

One of the greatest challenges for sustainable food production is the decrease of productivity due to pathogens, which makes urgent studies on plant-pathogen interactions regarding disease management. Previously, we developed a genetically modified citrus variety, carrying rpfF gene from *Xylella fastidiosa*, which was able to produce diffusible signaling factor (DSF), a quorum sensing molecule, and cause “pathogen confusion” to *X. fastidiosa* and *Xanthomonas citri*, thus attenuating CVC and citrus canker (CC) symptoms. Currently, we are investigating whether RpfF-expressing GM rootstocks could translocate DSF and improve the disease tolerance to non-transgenic scions. Hence, we verified that RpfF was produced at high levels in “Carrizo” rootstocks and triggered tolerance to CC in non-transgenic scions. Based on this, we also transformed “Swingle" rootstock, resulting in 3 GM lines (GM-SR1- 3), onto which non-GM “Valencia” sweet orange (NGM-SO) was grafted. To prove DSF translocation, *X. citri* was used as a biosensor due to its rapid infection process. Thus, leaves from each NGM-SO/GM-SR and control (NGM-SO/NGM rootstock) were challenged with *X. citri*-GFP. Genes regulated by DSF were monitored through RT-qPCR. The lines showed significantly lower symptoms and bacterial titer compared to the control. Furthermore, significant modulation of DSF-responsive genes demonstrated the potential use of GM-rootstocks to translocate DSF and confer disease tolerance to non-transgenic scions.

AGRUSAVER PUGLIA XYLELLA FIELD TRIAL

Text

Agruresina(AgruSaver) Organic
Fertilizer

For year 2021, the percentage of desiccated shoots for the year 2021 varied from as low as 3% for the treated trials compared to the control trees that exhibited on average 50% desiccated shoots.

? The comparison of molecular analysis results in terms of CFU/ml, considering the end of the treatments period for both years of experimentation (November 2021 and 2022), shows a percentage reduction for the treated trials up to 98% and for the control up to 43% for the low experimental test.

? For the low experimental Xylella field there was a production of olives, vegetative season 2022.. The treated olive trees produced significantly more olives compared to the control trees. Even the average weight of the olives seems to reach the highest values for some of the treated trials (e.g., OS-SW-F) as compared to the control trees . The Agru-S-F treatments produced 18 times more fruit compared to control trees in 2021 and in 2022 the OliveSaver-SW treatments produced 45 times more fruit compared to the control trees.

Hence, these natural biostimulant/organic fertilizer products seem to have the potential to stimulate the plants immune system and make the plants "cohabit/disease tolerant" in an environment where the Xylella fastidiosa disease is endemic.

Big Ideas in Agricultural Microbiome Science: A Community-based Interactive Workshop

COMPARATIVE FUNGAL DIVERSITY AND DYNAMICS IN PLANT COMPARTMENTS AT DIFFERENT DEVELOPMENTAL STAGES UNDER ROOT-ZONE RESTRICTED GRAPEVINES

ZAHID Muhammad. (1), XU Wenping. (1), WANG Shiping. (1), ZHOU Xuhui. (2)

Text

The root-zone restriction cultivation (RR) technique is used to achieve superior fruit quality at the cost of limited vegetative and enhanced reproductive development of grapevines. Fungal interactions and diversity in grapevines are well established, but fungal diversity under RR is unexplored. DNA from rhizosphere, plant compartments, including white roots ,leaves, flowers, and berries of rr and control plants (c) was extracted at full bloom, veraison, and maturity stage. QIIME2 performed analysis based on the ITS1 region. RR primarily affected the fungal communities of the soil and plant compartments at different growth stages. Fusarium, Ilyonectria, Cladosporium and Aspergillus spp observed in the rhizosphere overlapped with the phyllosphere at all phenological stages, having distinctive abundance in grapevine habitats. Peak richness and diversity were observed in the rhizosphere at the full bloom stage of C, white roots at the veraison stage of RR, leaves at the maturity stage of RR, flowers at the full bloom stage and berries at the veraison stage of C. Except for white roots, the diversity of soil and plant compartments of treated plants tended to increase until maturity. At the maturity stage of the RR & C, the abundance of Aspergillus spp. was 25.99 and 29.48%, respectively.

Moreover, the total soluble sugar content of berries was 19.03 obrix and 16 obrix in RR and C plants, respectively, at the maturity stage.

DO SPERMOSPHERE IS ESSENTIAL TO CROP PROTECTION?

FERREIRA Thiago Costa. (1)

(1) UNIVERSIDADE ESTADUAL DA PARAIBA, Lagoa Seca, BRAZIL

Text
Crops are carriers of microbiome communities, these have different biological functions and are still dynamic in time and space. Among these spermosphere communities, the microbial community present in the seeds at the time of germination has been studied as an essential form of production of healthy and resistant plants. Therefore, the objective of this research was to describe information about the biology and handling of the spermosphere and in relation to cultivated plants. For this, an analysis of Web of Science was conducted for resuming the principal's pieces of information about it. However, some fresh thirty articles were selected. In this paper, the microbial diversity in seeds is also dependent on the place of origin and the cultivated variety and is regulated by environmental factors. Therefore, the modulation of this ecological niche can be useful in relation to several work processes, including the treatment of seeds with the use of microorganisms, which can promote resistance to abiotic and abiotic factors and plant growth. understanding at the molecular level of the community and, therefore, the production sites with microbiomes that can favor the resilience of commercial crops. Research can be carried out to understand biology and ecology, as well as the correct management of the microbial community.

Biological induced resistance in plants against pathogens using beneficial microbes and natural substances

POTENTIAL OF DUCKWEED EXTRACTS TO CONTROL THE ANTHRACNOSE AND STIMULATE GROWTH OF BEAN PLANTS

DA SILVA Ariana K.. (1), **STADNIK Marciel J. . (1)**

(1) UNIVERSIDADE FEDERAL DE SANTA CATARINA, Florianópolis, BRAZIL

Text
Duckweed species are small free-floating aquatic plants belonging to the Lemnoideae subfamily which are found in a wide variety of climates worldwide. They have been mainly exploited for bioremediation, but several properties (fast growing, easy harvest, etc.) make them highly attractive for other applications. In this work, the duckweeds *Landoltia* sp. (La), *Lemna* sp. (Le) and *Spirodela* sp. (Sp) were cultivated under nutritionally controlled conditions and yields measured during 5 weeks. Ethanolic extracts at 25 and 50 $mg.mL^{-1}$

were tested in vitro against *Colletotrichum lindemuthianum*. Bean plants (*Phaseolus vulgaris*) grown in greenhouse were sprayed 3 days before challenging with the fungus and disease severity assessed at 7 and 12 days after inoculation (dai). The effect of extracts on length and dry weight of shoot and root was determined at 9 days after seed treatment. Landoltia, a recently segregated genus from Spirodela, exhibited the highest fresh yield, *i.e.* 239 g/ m^2/ week. All extracts reduced the mycelial growth of *Colletotrichum* by c. 32%. Although all of them did not significantly affect conidial germination, Sp-extract reduced the formation and markedly the melanization of appressoria after 48 h of incubation. All extracts reduced anthracnose severity locally and systemically at 7 dai. Systemic effect at 12 dai lasted only on La-treated plants. No extract affected elongation and dry weight of roots, but La- and Sp-treatments enhanced these variables on shoots.

DEHYDROASCORBATE INDUCES RESISTANCE AGAINST ROOT-KNOT NEMATODES IN THE SAME AND A SUBSEQUENT RICE GENERATION

KYNDT Tina. (1), CHAVAN Satish Namdeo. (1), TUMPA Farzana Haque. (1), DE KOCK Karen. (1), DEGROOTE Eva. (1)

Text

Ascorbic acid is a plant antioxidant that regulates various physiological processes. Exogenous treatment with its oxidized form, dehydroascorbic acid (DHA) induces systemic resistance in rice against root-knot nematode Meloidogyne graminicola. Transcriptome analysis on roots of DHA-treated plants revealed induction of genes related to plant immunity, antioxidant activity, salicylic acid (SA) and diterpenoid production. Biochemical measurements, combined with use of chemical or genetic inhibitors confirmed that H_2O_2, SA and diterpenoid accumulation contribute to DHA-induced resistance. DHA was observed to protect plants from nematode infection for up to 14 days after treatment. Based on this knowledge an experiment in a naturally nematode-infected rice field in Bangladesh was executed using biweekly applications, and significant control efficacy was observed.
In an intergenerational experiment, the offspring of lifelong DHA-treated plants was also found to be less susceptible to M. graminicola than offspring of mock-treated control plants. The transcriptional changes in the offspring showed remarkable similarities to those of their parents. This intergenerational acquired resistance was found to be dependent on ARGONAUTE 4, an important player in the RNA-directed DNA methylation pathway. This resistance phenotype was however not inherited further.
Taken together, our results reveal interesting potential for DHA to be used as novel nematode control agent in rice.

COMPLEMENTARY PEPTIDES REPRESENT A CREDIBLE ALTERNATIVE TO AGROCHEMICALS BY ACTIVATING TRANSLATION OF TARGETED PROTEINS

COMBIER Jean-Philippe. (1,2)

(1) CNRS, Auzeville Tolosane, FRANCE; (2) Micropep Technologies, Auzeville Tolosane, FRANCE

Text

The current agriculture main challenge is to maintain food production while facing multiple threats such as increasing world population, temperature increase, lack of agrochemicals due to health issues and uprising of weeds resistant to herbicides. Developing novel, alternative, and safe methods is hence of paramount importance. Here we show that complementary peptides (cPEPs) from any gene can be designed to target specifically plant coding genes. External application of synthetic peptides increases the abundance of the targeted protein, leading to related phenotypes. Moreover, we provide evidence that cPEPs can be powerful tools in agronomy to improve plant traits, such as growth, resistance to pathogen or heat stress, without the needs of genetic approaches. Finally, by combining their activity they can also be used to reduce weed growth.

ACTIVATION OF SEED DEFENSES THROUGH DEFENSE PRIMING

Text

Yield losses due to seedborne pathogens have a major economic impact on the global food market. We attempted to develop sustainable strategies to stimulate pathogen resistance from the seed that have a negligeable impact on seed quality parameters, such as germination rate and homogeneity. Our approach consisted in applying defense priming treatments using plant resistance inducers (PRI) such as methyl jasmonate (MeJA) and β-aminobutyric acid (BABA) on developing or mature seeds. After a first stage of technique optimization, results from tomato and bean treated seeds showed extensive transcriptome reprogramming, with a strong effect on defense pathways. To correlate these data with pathogen resistance, we analysed developing and germinating seeds treated with different PRIs and their effects on the growth of different pathogens including bacteria and fungi. First results obtained on tomato showed a marked growth inhibition on A. brassicicola from specific PRI-treated seeds, while the effect on C. michiganensis was minor. Our next step is, now, the identification of the molecules responsible of the fungistatic effect present in treated seeds.

DESIGN AND APPLICATION OF A PLANT-IMMUNE BIOSENSOR FOR SCREENING AND DISCOVERY OF BIOCONTROL AGENTS AGAINST NECROTROPHIC FUNGAL PATHOGENS

Text
To date, the screening of most microbial biocontrol agents has been conducted *in vitro* thereby restricting our ability to predict biocontrol behaviour in planta. Here we developed a novel approach, non-destructively capturing plant immune-biosensor output (via gene-based reporter system) in real-time for screening of beneficial microbes with plant immunity inducing properties. We focused on biocontrol agents capable of suppressing disease caused by destructive necrotrophic fungal pathogens such as *Sclerotinia sclerotiorum* and *Rhizoctonia solani*, both for which limited host resistance exists. Searching transcriptomic databases for genes of the model plant *Arabidopsis thaliana* responsive to necrotrophic fungi and to beneficial microbes, we identified the *GLUTATHIONE S-TRANSFERASE PHI7* (*GSTF7*) gene. We designed a *GSTF7:luciferase* reporter system in stably transformed Arabidopsis for non-destructive observation of *GSTF7* expression in planta, and used this system to screen in high-throughput a collection of candidate microbes. We identified a *Streptomyces* isolate which protected plants against *S. sclerotiorum* and *R. solani*, but not against a bacterial pathogen. Treatment of plants with either the *Streptomyces* culture or its cell-free fermentation extract induced a range of stress and defense related genes and hormone signaling pathways. Our study demonstrates that *GSTF7* is a suitable marker for the rapid and preliminary screening of beneficial microbes for crop protection.

EVIDENCE OF CROSS-PROTECTION BETWEEN GEMINIVIRUSES IN TOMATO AND THE ESCAPE PHENOTYPE OF THE INVASIVE RECOMBINANT TOMATO YELLOW LEAF CURL VIRUS -IS76

JAMMES Margaux. (1), URBINO Cica. (1), **PETERSCHMITT Michel. (1)**

(1) CIRAD-PHIM, Montpellier Cedex 5, FRANCE

Text
Whereas cross protection was extensively studied and applied in plant protection strategies (PPS) with RNA viruses, this phenomenon was rarely reported with ssDNA viruses of the family Geminiviridae. Using tomato yellow curl virus (TYLCV), a worldwide economically important tomato geminivirus belonging to the genus Begomovirus, we formally demonstrated the existence of cross protection in geminiviruses. When a TYLCV clone is inoculated in susceptible tomato plants already infected with a mutated version of the clone (8 CG deletion in the intergenic region), its accumulation is at least 100 times lower than its accumulation in non-pre-infected plants. The protection effect persists at least two months after superinfection and was also observed in isogenic plants carrying the resistant gene Ty-1, irrespective of the super-inoculation mode, mediated by agrobacterium or the whitefly vector Bemisia tabaci. As TYLCV is not mechanically transmitted, cross protection is not easily implementable in PPS. However, as of now, it sheds new light on the unusual fitness of TYLCV-IS76, a TYLCV recombinant that easily superinfect TYLCV infected plants in spite of its high nucleotide identity with TYLCV (98 %). Indeed, considering that another TYLCV recombinant, exhibiting the same recombination pattern and the same genetic distance with TYLCV, is unable to establish an infection in tomato plants already infected with TYLCV, TYLCV-IS76 seems to exhibit a cross-protection escape phenotype.

SYMBIOTIC COMPATIBILITY BETWEEN ORYZA SATIVA AND ARBUSCULAR MYCORRHIZAL FUNGI GENOTYPES IMPACTS RICE'S

GROWTH AND MYCORRHIZA-INDUCED RESISTANCE AGAINST XANTHOMONAS ORYZAE PV ORYZAE

GUIGARD Ludivine. (1), JOBERT Léa. (1), CZERNIC Pierre. (1), MOULIN Lionel. (1)

(1) PHIM Plant Health Institute, Univ. Montpellier, IRD, CIRAD, INRAE, Institut Agro, , Montpellier, FRANCE

Text

Arbuscular mycorrhizal fungi (AMF) are beneficial to their plant hosts in many ways. By increasing nutrient availability, AMF can improve the growth and tolerance of their host to abiotic stresses. AMF symbiosis can also reduce symptoms and pathogen load on infected plants, both locally and systemically, through a phenomenon called Mycorrhiza-Induced Resistance (MIR). However, there are few reports on rice mycorrhization, despite the high potential of this symbiosis in a context of rational water use.
We analysed the symbiotic compatibility (mycorrhization & arbuscules rate) between six rice genotypes (Nipponbare, IR64, Kitaake, Zhongua 11, Phka rumduol, Azucena) and three AMF species (*Funneliformis mosseae, Rhizophagus irregularis* and *R. intraradices*). Using both phenotypic and rice gene expression studies, we analysed the impact of AMF on rice growth and defence responses to *Xanthomonas oryzae pv oryzae* (Xoo) infection. Our results show differences in symbiotic compatibility depending on the combination studied. AMF induced either beneficial, neutral or negative effects on rice growth, but also on the extent of Xoo symptoms. Overall, *R. irregularis* induced the most beneficial effects, both by stimulating rice growth and by reducing symptoms caused by Xoo. To further investigate MIR at the molecular level in rice leaves, we analysed by qPCR a set of plant marker genes (development, hormones, nutrient transport, defence) of two rice genotypes with contrasting responses to AMF.

MULTIOMICS IDENTIFIES KEY ANTIFUNGAL COMPOUNDS AND BIOSYNTHETIC GENE CLUSTERS DURING LIQUID-STATE FERMENTATION OF A BIOCONTROL STREPTOMYCES

Text

New, safe and sustainable fungicides are required to fill a growing gap in the crop protection market left by a decline in public acceptance or increasing regulation of synthetic chemical controls. An opportunity exists to exploit bacteria such as *Streptomyces*, well known for their ability to produce antimicrobials but where up to 90% of their metabolic potential is yet to be discovered and characterised. From a unique terrestrial and plant-associated collection of Actinobacteria we identified through traditional in vitro bioactivity screens a *Streptomyces* strain linked to potent antifungal activity against a broad range of necrotrophic fungal pathogens in crops. Whole genome sequencing revealed the strain encodes a predicted repertoire of over 50 biosynthetic gene clusters and has the capacity to produce up to 35 novel compounds. To facilitate identification of causal gene clusters and develop fermentation strategies for improved industrial scale antifungal compound production, we undertook a simultaneous targeted metabolomics and untargeted transcriptomics (RNAseq) approach to subsample *Streptomyces* cells, cell-free extracts and

volatiles during a fermentation time-course and link differential gene expression and metabolic profile to antifungal bioactivity. The process enabled rapid identification of candidate biosynthetic gene clusters underpinning activity, including PKS and volatiles.

THE ROLE OF DEFENSE PHYTOHORMONES IN INTERACTIONS WITH ENVIRONMENTS

TSUDA Kenichi. (1)

(1) Huazhong Agricultural University, Wuhan, CHINA

Text

In nature, plants are constantly surrounded by diverse microbes called plant microbiota that promote plant health and are attacked by microbial pathogens that threaten plant health. At the same time, plants are exposed to fluctuations in physical factors, including abiotic stresses. Phytohormones are small molecules produced and perceived in plants that govern coordinated plant responses to the environment. Signaling pathways mediated by phytohormones intimately interact antagonistically or synergistically to form phytohormone signaling networks, which enable plants to activate appropriate and effective defense responses as well as to balance defense and growth. However, the intricated hormone signaling network is also exploited by pathogens by interfering with hormone signaling or producing hormones (mimic) to benefit pathogen fitness. I will discuss the role of phytohormone signaling networks in interactions with environments, including biotic and abiotic factors.

FACILITATING THE LAB-TO-FIELD TRANSACTION OF AGRICULTURAL BIOLOGICALS

ALEXANDERSSON Erik. (1)

(1) SLU, Lomma, SWEDEN

Text

Crops are confronted with numerous abiotic and biotic stresses that affect productivity and quality. In response, crops can activate defence mechanisms with varying specificity. Stresses can also be alleviated by biologicals, which are compounds derived from dead or living organisms that can mimic cues to promote defence and growth. Even if biologicals have been shown to reduce rates of disease by activating host defence or by direct toxicity, safeguard yield and improve product quality, there are, nevertheless, hurdles in converting these findings into field practice.

In this talk, I will discuss new techniques, which can be used to screen and assess biologicals, such as automated phenotyping and spectral analysis. This could help in accelerating a sustainable adaptation of biologicals. I will present data on crop fitness, yield and product quality in potato and tomato and discuss the incorporation of biologicals in future breeding strategies and their role in the agro-ecological system.

Farmer and societal acceptance is another important step to transfer findings regarding biologicals from lab to practice. We have therefore assessed the knowledge, attitude and practice (KAP) of biologicals among small-holder farmers, agro-dealers and policymakers in Ethiopia, Kenya and South Africa.

In general, a better understanding - both regarding molecular mechanisms and stakeholders' perceptions - is necessary for biologicals to be efficiently integrated in future agricultural practices.

IDENTIFICATION OF A STREPTOMYCES NECROTIC ELICITOR INVOLVED IN ANTIFUNGAL ACTIVITY, PLANT DEFENSE STIMULATION AND BACTERIA FITNESS IN THE RHIZOSPHERE

NICOLLE Clément. (1), GAYRARD Damien. (2), AMIEL Aurélien. (2), NOEL Alba. (3), LONG Maya. (3), LAUTRU Sylvie. (3), REY Thomas. (2), DUMAS Bernard. (1)

Text

Rhizospheric microbiota harbors bacterial strains participating in plant immunity and resistance to root diseases. Recently, we identified a *Streptomyces* strain AgN23 isolated from grapevine rhizosphere, which produce a broad spectrum of antifungal metabolites and activates hypersensitive responses (HR) in *A. thaliana*. A metabolomic approach lead to the identification of a candidate compound produced by AgN23 which may impair sphingolipid metabolism in plants. Sphingolipid metabolism of plants is involved in HR, thus we characterized the role of this metabolite through a reverse genetic approach, based on the construction of AgN23 knock-outs strains. These mutants showed a reduced antifungal activity and are unable to inhibit Inositol Phosphorylceramide Synthase activity, a crucial enzyme in plant sphingolipid pathway. The induction by AgN23 of markers associated with HR or immune responses was compromised in AgN23 knock-out strains: nuclear calcium influxes, necrotic lesions, defense gene expression, and production of camalexin. Finally, we explored the role of the candidate metabolite in the soil and found that it is involved in the rhizosphere colonization by AgN23. Thus, we identified a specialized metabolite produced by a *Streptomyces* strain which is involved in antifungal activity, plant defense stimulation and strain fitness in the plant environment. Further work will aim to investigate how this strain and its cognate metabolite structure the rhizospheric microbiota.

BIOSURFACTANT-PRODUCING BACTERIA AS RESISTANCE-INDUCERS IN PLANTS

HÖFTE Monica. (1)

(1) Ghent University, Gent, BELGIUM

Text

Biosurfactants, which are secreted by a range of bacterial genera including *Pseudomonas* and *Bacillus*, play an important role in bacterial motility and attachment to surfaces, biofilm formation, and antimicrobial activity against a broad range of microorganisms. The most extensively studied biosurfactants are rhamnolipids, which are glycolipids mainly produced by *Pseudomonas aeruginosa* strains, and cyclic lipopeptides (CLPs), which are produced by selected taxonomic groups within the *Pseudomonas* and *Bacillus* genus. CLPs consist of a

hydrophobic fatty acid tail linked to an amphipathic oligopeptide that is partly or completely organized in a cyclic structure. Plant-associated *Bacillus* strains produce three main families of CLPs: surfactins, iturins, and fengycins. *Pseudomonas* CLPs are much more diverse and are currently classified into at least 17 different groups.
Biosurfactants also play a vital role in the interaction of their producers with plants, either as resistance inducers or as phytotoxins contributing to plant pathogenesis. They achieve these effects by interacting with the lipids in the membranes of microorganisms and plants. In particular, the role of rhamnolipids and selected *Pseudomonas* and *Bacillus* CLPs in resistance induction in rice will be further discussed. Evidence will be presented that some biosurfactants may induce resistance in plants by releasing elicitors from pathogens and other microorganisms rather than through direct interactions with the plant.

CROSS-PROTECTION: MILD STRAINS AS A PROMISING BIOCONTROL TOOL OF PLANT DISEASES

Text
Until recently, plant virus management strategies have largely been limited to controlling the viral insect vectors, using resistant or tolerant varieties, and the implementation of hygiene protocols. However, these approaches are often insufficient. Especially newly emerging mechanically transmitted viruses are difficult to control as they do not rely on insect vectors for their transmission. In this lecture, we focus on cross-protection (also known as superinfection exclusion) as a biocontrol strategy to combat viral diseases in crops. Cross-protection is the underlying mechanism of plant vaccination against viral infection, in which plants are ‘vaccinated’ at an early stage of plant development using a mild or attenuated viral isolates to protect the plants against a subsequent infection with a more aggressive isolate belonging to the same viral species or genotype. Efficiency of protection depends largely on genome sequence homology between the protective and challenging isolates. Although the phenomenon of cross-protection was already described in late 1920s, its practical use in biocontrol is much more recent. In 2015, the first mild plant virus for plant vaccination (PepMV CH2 isolate 1906) was approved as active substance for plant protection in Europe. Since then, vaccination has been widely used for protecting greenhouse tomato crops against pepino mosaic virus (PepMV). Research is ongoing to translate this methodology to other emerging viruses in important crops.

CROSS-PROTECTION IN PLANT VIRUSES: HOW CLOSELY RELATED DO PROTECTING AND CHALLENGING VIRUSES NEED TO BE?

SICARD Anne. (1), VIGNE Emmanuelle. (1), LEMAIRE Olivier. (1)

(1) INRAE, Colmar, FRANCE

Text

Cross-protection is a biocontrol method to protect plants from damage caused by pathogenic viruses. This strategy of cross-protecting a plant with a mild strain to prevent subsequent infection by related severe strains was first described in 1926. Although cross-protection was first evidenced nearly a century ago, the underlying mechanism(s) remain(s) poorly understood. In particular, although the genetic relatedness between cross-protective and challenge strains has been emphasized in a number of papers, the percentage of identity required for cross-protection remains unknown. This lack of data has led to a long and sometimes unsuccessful empirical search for cross-protective strains against some viral pathogenic ones. Recent papers have shown that cross-protection occurs only among variants of the same strain and not between variants of different strains for the citrus tristeza virus (Closterovirus) and the pepino mosaic virus (Potexvirus). In order to determine the percentage of identity required between the cross-protective and the challenge strains for cross-protection to be effective against the grapevine fanleaf virus (GFLV, Secoviridae), different cross-protective variants with decreasing sequence homology with respect to the challenge variant were selected and inoculated on Nicotiana benthamiana. Our results suggest that in addition to the genetic relatdeness, the entry point of the cross-protective and challenge strains impacts the cross-protection success.

ESSENTIAL OILS AS POTENTIAL ALTERNATIVE BIOCONTROL PRODUCTS AGAINST FUNGAL PLANT PATHOGENS AND WEEDS

JULIEN Langrand. (1), ROBIN Raveau. (1), FRÉDÉRIC Laruelle. (1), JOËL Fontaine. (1), **LOUNES - HADJ SAHRAOUI Anissa. (1)**

Text

Since sustainability of farming systems, and the environment preservation are crucial issues, it appears mandatory to offer farmers feasible alternatives to synthetic pesticides. Owing to their natural richness in active principles, essential oils (EO), biosourced products with a high added-value, display a wide range of biological properties, which could find applications in crop protection. Within the framework of PhytEO & DEPHYTOP phytomanagement projects (funded by ADEME) and carried out on trace element-polluted soils, the *in situ* cultivation of 3 aromatic plant species, namely *Coriandrum sativum* L., *Salvia sclarea* L. and *Angelica archangelica* L., led to the obtention of different EO. Thus, the main goals of this study were, on one side, to evaluate the in vitro direct effect of these molecules, against several phytopathogenic fungi, among which *Fusarium culmorum* and *Zymoseptoria tritici* are of major concern, due to the resulting foliar diseases, that may cause yield losses up to 70%. On the other side, the study focused on *in vitro* herbicidal effects of the different EO, against *Lactuca sativa* L. and *Lolium perenne* L., two plant species commonly used for phytotoxicity assays. Our first results demonstrate the antifungal effect of all the tested EO against the target fungal phytopathogens, as well as their potential to inhibit seed germination, and root elongation of the two tested plant species. EO from coriander and angelica, in particular, displayed higher efficiency.

CONSERVED DOWNY MILDEW-ASSOCIATED MICROBIOMES REDUCE PLANT DISEASE AND FUNCTION AS TRANSFERABLE RESISTOBIOMES

GOOSSENS Pim. (1), SPOOREN Jelle. (1), LAPIN Dmitry. (1), PIETERSE Corné. (1), VAN DEN ACKERVEKEN Guido. (1), **BERENDSEN Roeland. (1)**

Text

Plant microbiomes can protect plants against microbial attackers as is evidenced by the existence of disease suppressive soils. These are thought to be created by the plant in response to pathogen attack. Plants have been shown selectively promote a plant-protective microbiome in response to infection by e.g. the downy mildew of *Arabidopsis thaliana*, *Hyaloperonospora arabidopsidis* (Hpa). However, microbiomes are complex, microbiome studies have infamously poor reproducibility and evidence for protective microbiomes is often anecdotal. In this study, we show that distinct cultures of the obligate biotroph Hpa have accumulated the same bacteria that together reduce disease and can be vertically transmitted to a next population of plants growing on the same soil. We found that during routine maintenance of laboratory cultures Hpa typically is co-inoculated with an Hpa-associated bacterial microbiome (HAM) that is formed by a small number of bacterial species and subsequently dominates the phyllosphere of infected plants. Remarkably, bacterial isolates of the same abundantly-present species were found to be isogenic even when obtained from distinct and segregated cultures across Europe. We show that the HAM members benefit from Hpa infection, but that reversely HAM reduces Hpa sporulation when co-inoculated with Hpa spores. Our results thus suggest that infections with Hpa can over time result in the formation of 'resistobiomes' that contribute to plant disease resistance.

INDUCTION OF RESISTANCE IN SUGARCANE AGAINST RED ROT THROUGH PLANT DEFENSE ACTIVATORS.

Text

Red rot caused by Colletotrichum falcatum globally challenging disease of sugarcane growing countries. Colletotrichum falcatum could decrease weight of cane by up to 29% and sugar loss by 31%. The emergence of new races of pathogen ultimately breakdown the resistance. In this study five plant defense activators salicylic acid (SA), citric acid (CA), K_2HPO_4, benzoic acid (BA), and KH_2PO_4 were evaluated at three levels of concentrations under randomized complete block design (RCBD). Biochemical analysis of catalase (CAT), superoxide dismutase (SOD), Hydrogen peroxide (H2O2 peroxidases (POD),) and total phenolic contents (TPC) of treated and un-treated leaves were performed. Amount of CAT, SOD, H2O2, POD was estimated in moderate susceptible variety. Maximum impact of management was recorded by salicylic acid with 16.15% disease incidence, followed by benzoic acid (21.32%), K_2HPO_4 (27.85%), citric acid (32.37%), KH2PO4 (38.40%) and control (78.83%) under field condition. The range of CAT activity was estimated as (3.20-3.86 µg/g), SOD (1.61-1.97 µg/g), H_2O_2 (0.84-1.05 µg/g) and POD was (1.81-2.16 µg/g) while, TPC concentration was higher in treated (15688 µg/g) as compared to untreated (12823 µg/g). In treated leaves, all of these altered biochemical contents were observed more or less to be restored which helped the plants in disease recovery.

Key words: biochemical, CAT, challenging disease, salicylic acid, H2O2

INDUCTION OF RESISTANCE BY PANTOEA ANANATIS AND PERCEPTION OF GLYCOLIPIDS IN TOMATO

Text

In a context of sustainable agriculture aiming to reduce the use of synthetic pesticides, studying PGPR (Plant Growth Promoting Rhizobacteria) bacterial strains or molecules derived from these microorganisms (used in the biocontrol of fungal diseases) represents a major research challenge. A large number of studies have shown that microorganisms produce biomolecules that can be perceived by the plant and induce an innate immune response. For example, natural amphiphilic glycolipids from microorganisms, such as rhamnolipids, can induce resistance against pathogens in several plants. Recently, new glycolipids have been identified in *Pantoea ananatis*. The objective of the project is to test this new strain and its glycolipids for their ability to induce resistance against phytopathogenic fungi in tomato.
We demonstrated that this strain had direct in vitro antifungal activity against *Botrytis cinerea*. Root bacterization of tomato plants with *P. ananatis* allowed us to observe foliar protection against *B. cinerea*, demonstrating the establishment of an ISR (Induced Systemic Resistance). In addition, a stimulation of the growth of the aerial part of tomato plants was highlighted, showing the potential of *P. ananatis* as a PGPR strain. Using different markers of perception and signaling, such as extracellular ROS production and MAPK phosphorylation, we observed that glycolipids were perceived by plant cells and could therefore participate in defense responses in tomato.

THE USE OF NATURAL BIOSTIMULANTS APPLIED BY SEED COATING ON WHEAT TO IMPROVE TOLERANCE AGAINT FUNGAL PATHOGENS

HAMADA Walid. (1)

Text

Coating seeds with beneficial microorganisms appear to be as a promising approach to maintain the productivity of plants under stressed conditions. Their effect in inducing defense response of the plant to foliar or soil borne fungal diseases was evaluated. In this study, we tested the bacteria Burkholderia, the fungus Trichoderma and the yeast Meyerozyma, for their ability to control fungal disease both under controlled conditions. These biostimulants were tested on seedlings driven in a hydroponic medium in an oxygenated nutrient solution.

Daily sampling of the leaves made it possible to carry out biochemical analysis (peroxidase, phenolic compounds and H2O2 levels). On the other hand, infections by pathogenic fungi (Septoria tritici) can reveal the induction of defense reactions according to the evolution of the necrotic spots on leaves. Later on, inoculations are made by a soil borne pathogen through the injection of a suspension of Fusarium spores into the nutrient solution on wheat roots. Biochemical analysis performed in an infectious context revealed an increase of markers linked to defense response. This was also confirmed through molecular analysis performed at the leaf level which revealed the presence of acquired systemic resistance through the overexpression of genes involved in defense response. Alltogather these results showed the presence of both an inducing and priming effect of the microorganisms tested leading to the protection of the target plant.

NEIGHBOR MEDIATED SUSCEPTIBILITY, TOWARDS AN ECOLOGICAL VIEW OF PLANT IMMUNITY

BALLINI Elsa. (1), MATHIEU Laura. (2), METEIGNIER Louis Valentin. (2), PELISSIER Rémi. (1), MOREL Jean-Benoit. (2)

Text

Among the major scientific questions that remain to be solved in plant pathology is how plant-pathogen interactions hold up in an ecological context? Indeed, for most interactions, we have very little idea of how interactions between plants and microbes are affected by the ecological environment in which they live. At the same time, the concept of eco-immunity has been described. Broadly speaking, this concept aims to understand and explain variation in immune response, in other words, to determine why and how biotic and abiotic factors contribute to variation in the immunity of a living organism. An ecological context that seems interesting to study for its positive impact on the control of epidemics is varietal mixtures. However, this general benefit is not systematic and can be suppressed by specific allele combinations. This highlights the need to know the genetic basis of neighbor-regulated immunity in order to make better use of mixtures. According to our first results, the plant immunity regulated by the neighborhood relies on inter-root communication events. One of our hypotheses is that this inter-root communication would be ensured by specialized metabolites exuded into the rhizosphere that has been described in the context of allelopathic mechanisms. Other phenomena that could be involved include nutrient competition in the root compartment, but the molecular mechanisms by which immunity is regulated under mixed conditions have yet to be described.

NEWLY SYNTHESIZED BENZIMIDAZOLE–2–CARBAMATE MOLECULES SHOW SUPPRESSIVE ACTIVITIES AGAINST PLANT PATHOGENIC FUNGI AND OOMYCETES

AL-SUDAIRY Omar. (1), RETHINASAMY Velazhahan. (1), ABDEL-JALIL Raid. (1), MOGHADAM Ebrahim. (1), AL ANSARI Aliya. (1), AL-SADI Abdullah. (1)

Text
Most bioactive compounds are designed and synthesized by heterocyclic chemistry. Benzimidazole and its derivatives are important heterocycles that are critical subunits for pharmaceutical and biological molecules. This study was carried out to investigate the effect of 44 newly synthesized benzimidazole compounds on Alternaria, Rhizoctonia, Cochliobolus, Fusarium, Lasiodiplodia and Pythium, which are pathogens of major crops worldwide. Well diffusion method was done using 100 mL of two different concentrations of benzimidazole compounds (1000 and 5000 ppm). The molecules designated as EBI.bB4, EBI.eB1, EBI.fB2, EBI.gB1, EBI.gB2, EBI.aB4.S, EBI.aB5.S, EBI.eB1.S and EBI.gB1.S showed suppressive effects on fungal and oomycete growth at 1000 and 5000 ppm. When these fungicides were tested against Trichoderma harzianum, a beneficial biocontrol fungus, the fungus was not affected. This suggests that these newly synthesized fungicides may work synergistically with T. harzianum in suppressing growth of the pathogenic fungi. Scanning electron microscopy showed that the fungicides resulted in malformation, bursting, swelling and hyphal tip collapse of the mycelia. The study shows that nine new fungicides show promising results in reducing growth and resulting in deformations of the mycelia of A. alternata, R. solani, C. hawaiiensis, F. solani, L. pseudotheobromae and P. aphanidermatum pathogens. The benzimidazole compounds had no effect against the biocontrol agent T. harzianum

APPLICATION OF RNA-BASED BIOPROTECTANTS AGAINST VIRUSES FOR SUSTAINABLE CROP PRODUCTION IN A CHANGING CLIMATE

Text
The European ERA-NET SusCrop Project BioProtect aims to contribute to reducing the application of chemical pesticides through the creation of a platform for the development and cost-effective production of nature-friendly dsRNA-based bioprotectants. dsRNA is a natural and environmentally safe molecule originating from RNA interference (RNAi) pathways involved in gene regulation and pathogen defense. Its exogenous application to plants leads to the activation of the RNAi pathway which can be programmed against specific pathogens according to the designed dsRNA nucleotide sequence. In addition, dsRNA has the potential to trigger pattern-triggered immunity (PTI) thereby reinforcing crop protection through a second host defense pathway. In this project, high-quality (hq) dsRNA with homology to TMV and TuMV were formulated to increase leaf uptake and stability. The antiviral protection effect triggered by spraying the formulated hq-dsRNAs is tested in crops infected with GFP-tagged target viruses. Moreover, non-specific hq-dsRNAs are used to determine the contribution of PTI, which may influence target specificity. In the light of climate change, the effect of increased temperature on virus replication and movement and on the efficiency of hq-dsRNAs is determined. Our results show that the treatment with hq-dsRNA results in plant protection by programming the ability of plants to defend themselves against target pathogens with their own native defense mechanisms.

EFFICIENCY OF THAI MEDICINAL PLANT EXTRACT, MICRO-ORGANISM AND SALICYLIC ACID FOR CONTROL OF ANTHRACNOSE DISEASE OF CASSAVA

THANAPHON Phuangkheaw. (1), RUNGTHIP Sangpueak. (1), **KUMRAI Buensanteai. (1)**

(1) Institute of Agricultural Technology, Mueang Nakhon Ratchasima District, THAILAND

Text

This study was to evaluate the efficiency of Thai medicinal plant extract, micro-organisms, and salicylic acid for controlling the anthracnose disease of cassava caused by *Colletotrichum gloeosporioides*. Three Thai medicinal plant extracts including garlic (*Allium sativum*), Wildbetal leaf bush (*Piper sarmentosum*), and curry paste at concentrations of 5000, 10000 and 15000 ppm compared with 3 isolates of *Bacillus subtilis* at concentrations 10^6 cfu.ml^{-1} and salicylic acid at concentration 500 ppm by using the poisoned food technique method compare with Mancozeb fungicide and water control. The results showed that Mancozeb 80% WP has the highest antifungal activity at 100%, which non-significance difference with *B. subtilis* CaSUT 008–2 with 98.24%. The curry paste extract at 15000 ppm has an inhibition of 73.05%, followed by Wildbetal leaf bush extract and Garlic extract at 15000 ppm can inhibit 64.73 and 42.32% respectively, and salicylic acid at 500 ppm can inhibit 42.07%. After that, all 7 treatments were tested in the greenhouse condition. The results show that Mancozeb 80% WP has high inhibitory activity against anthracnose disease at 7 and 14 days at 13.50 and 14.33% respectively, curry paste at 15000 ppm can inhibit at 11.67 and 11.33%, and salicylic acid at 500 ppm can inhibit at 11.83 and 10.33%, respectively. In conclusion, curry paste and salicylic acid have the ability as an alternative solution for managing anthracnose disease in cassava.

LESSONS FROM VIRUSES: HOW TO INDUCE RESISTANCE TO INSECT PESTS

CARR John. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text

Many plant viruses have evolved the ability to susceptibility or to trigger mild resistance their insect vectors. Certain viral mutants trigger antibiosis. For several geminiviruses and several RNA viruses, specific viral gene products have been identified that modify plant biochemistry and physiology in ways that influence their plant hosts' interactions with, respectively, whiteflies and aphids. Experiments with cucumber mosaic virus (CMV) and several potyviruses indicate that the induction of resistance to aphid settling can enhance the dispersal of viruliferous aphids and promote dissemination of viruses that utilise the 'non-persistent' mode of transmission. Modification of the host phenotype occurs through a combination of virus-induced changes in emission of volatile organic compound and in accumulation of repellent substances in plant tissue. Work with CMV in arabidopsis and tobacco has shown that this re-tuning of plant defense depends on interactions of several viral proteins with each other and with host factors influencing the pattern-triggered immunity pathway and signalling that is largely dependent upon jasmonic acid. Understanding how viruses and their gene products modify plant-insect relations will lead to more effective means of inducing natural resistance mechanisms that protect crop plants against insects

and, in the case of insects that vector pathogens, provide indirect but potentially highly effective protection against infectious disease.

EFFECT OF BROCCOLI RESIDUES INCROPORATION INTO FIELD UNDER DIFFERENT TIMES ON THE OCCURRENCE OF COTTON VERTICILLIUM WILT, STRUCTURE AND FUNCTIONAL PATHWAYS OF RHIZOSPHERIC MICROBIAL COMMUNITY

ZHAO Weisong. (1), LI Shezeng. (1), LU Xiuyun. (1), SU Zhenhe. (1), GUO Qinggang. (1), MA Ping. (1)

(1) Plant Protection Institute, Hebei Academy of Agriculture and Forestry Science, Baoding, CHINA

Text

Cotton verticillium wilt (CVW) is widespread and is responsible for serious economic losses. Crop residues incorporated into soil is an important measure for controlling soil-borne diseases in agricultural management practices. The objective of this study was to evaluate the influence of broccoli residues incorporated into soil under different years (BRF, BRS and BRT) on the incidence of CVW, the population of *V. dahliae* in soil, and the soil microbial community structure and functional genes using metagenomics analysis. Results demonstrated that the disease indices dramatically decreased by 34.67%, 66.67%, and 62.67%, respectively, compared with that under the CK treatment. The *V. dahliae* populations also decreased, by 40.89%, 61.64% and 36.74%, respectively. Principal component analysis (PCA) showed that significant changes were found on the bacterial communities composition among treatments. Redundancy analysis (RDA) revealed that the structures of microbial communities were driven mainly by NH_3^--N and NH_4^+-N. Spearman's correlation analysis showed that function pathways of bacterial community was negatively correlation with OM, NH_3^--N and NH_4^+-N, and positively correlation with AP in fungal community. In addition, nitrite reductase (*NarGHI*, *NirBD* genes) were decreased in the nitrogen cycle, sulfate adenylyltransferase (*PAPSS*, *CysNCD*, *Sat* genes) and serine O-acetyltransferase (*CysE* gene) were decreased in the sulfur cycle compared with CK.

STRUCTURE-ACTIVITY OF THE LIPOPEPTIDE SURFACTIN AS ELICITOR OF PLANT IMMUNITY

DING Ning. (1,2), PRSIC Jelena. (1), DONG Hansong. (2), **ONGENA Marc. (1)**

(1) University of Liège, Gembloux, BELGIUM; (2) Shandong Agricultural University , Taian, CHINA

Text

Cyclic lipopeptides (CLPs) are amphiphilic secondary metabolites produced by plant beneficial rhizobacteria such as *Pseudomonas* and *Bacillus* that are important for the biocontrol activity of the producing strains. This is due to their strong antimicrobial activity but also to their plant immunity eliciting potential leading to a systemically-expressed higher resistance to subsequent infection (ISR). We have recently shown that CLP perception by plant cells relies on a unique process based on docking into specific lipid domains of the plasma membrane rather than being recognized via high-affinity protein receptors. In this

work, we show that immunity activation by a particular CLP is fine-tuned by precise structural traits in the molecule. We compared natural variants of the *Bacillus* CLP surfactin for their potential to stimulate early plant immune-related events such as ROS and RNS, for activation of specific transcription factors and for ISR triggering in *Arabidopsis*. Altogether our data revealed that slight structural changes in the fatty acid length and single amino acid substitutions at key positions in the peptide cycle strongly impact the activity and are thus of unsuspected importance in triggering both immune responses and ISR. We discuss these results in the context of co-evolution assuming that *Bacillus* species have adapted the structure of their CLPs (e.g. surfactin) according to their endophytic or epiphytic life style.

IDENTIFICATION OF RESISTANCE LOCI FOR FOLIAR DISEASES IN THE COMMON WHEAT LINE 'KIJIL'

YAN Shanshan. (1)

(1) HuaZhong Agricultural University, Wuhan, CHINA

Text
Wheat is one of the world's most important cereal crops. With climate change in recent years, fungal diseases caused by wheat stripe rust, leaf rust and powdery mildew have had a significant impact on the safe production of wheat. The cimmyt strain ‘KIJIL’ has good resistance to wheat rust and powdery mildew, but the genetic mechanism of resistance is not known. In this study, we used the F5 RILs to identify diseases at multiple environments over a number of years, and combined with Genotyping-by-sequencing (GBS) genotyping to locate disease resistance QTL. The new seedling powdery mildew resistance locus *QPm.hzau-7BL* and the adult stage concurrent resistance locus *QYr/Lr. hzau-5DL* were identified in 'KIJIL'.The adult disease resistance genes *Lr46*, *Yr30* and *Yr27* were also localized. In response to the identification of new disease resistance loci, a variety of molecular markers were developed for breeders to use.

CLONING AND FUNCTIONAL ANALYSIS OF AN ADULT PLANT RESISTANCE GENE LR68 FOR WHEAT LEAF RUST

WANG Liang. (1)

(1) Huazhong Agricultural University, Wuhan, CHINA

Text
Wheat is the second largest food crop in the world. Leaf rust disease caused by Puccinia triticina (Pt) is one of the important disease factors affecting the global wheat yield, which can cause the loss of wheat yield up to 50% in epidemic years. Breeding resistant wheat varieties is the most economical, environmentally friendly and effective way to control wheat leaf rust. Therefore, it is particularly important to continuously explore and utilize excellent resistance loci to breed durable resistant varieties. According to previous studies, the adult resistance gene Lr68 was initially located on chromosome 7BL, which showed good resistance to wheat leaf rust at adult stage and was widely used in CIMMYT and even global wheat breeding. In this study, F5 RIL population containing 674 and 696 Lr68 single gene lines and 27 γ-ray mutants of 10 families were constructed respectively. The markers designed by RNA-seq

were used for fine mapping of Lr68. At the same time, the 7B chromosome of Arula was separated, deeply sequenced and spliced without reference. The candidate interval of Lr68 was determined by combining the fine mapping markers sequence, and the functional verification and related mechanism analysis of the candidate genes were carried out. This study will provide new markers, new genes and new germplasm for breeding wheat varieties resistant to leaf rust in the future, and providing theoretical basis for revealing the inheritance of adult plant resistance to wheat rust.

INDUCTION OF PLANT DEFENCE AGAINST MYCOSPHAERELLA IN CUCUMBER

DE GRAAF Esmée. (1), TILLI Floortje. (1), ISBILIR Zeynep. (1), BAC-MOLENAAR Johanna. (1), LEISS Kirsten. (1)

(1) Wageningen University and Research, Bleiswijk, NETHERLANDS

Text

In cucumber cultivation systems, *Mycosphaerella* has been a common problem for years. It can infect the plants through lesions in the leaf or stem and often penetrates through a fresh flower into the fruit. This results in loss of production, quality reduction, and poorly marketable products. Controlling *Mycosphaerella* is difficult as the disease has often spread in the greenhouse before being visible. We have set up a method to investigate induction of plant defence against this fungus. Infecting flowers in vitro with *Mycosphaerella* and examining the degree of fungal infestation in the developing fruit can be linked to the plant's defence. Plant treatment of young plants with methyl jasmonate lead to an increase in plant defence metabolites in the flowers with subsequent lower disease severity or even absence in the fruits. Besides, we detected a *Bacillus* strain inhibiting fungal growth in vitro. Applying foliar spray with *Bacillus* may be used additionally as a treatment against *Mycosphaerella*. Essential is the early and preventive application in young plants.

A NEW APPROACH FOR THE DESIGN OF CROSS-PROTECTION TRIAL IN THE FIELD

Text

Cross-protection is a biocontrol method whereby the primary-infection of a plant with a mild (cross-protective) virus strain prevents it from the damage caused by the subsequent infection by another (challenge) strain of the same virus. Among the factors influencing the effectiveness of cross-protection in the field, the steady mild symptoms induced by the cross-protective strains and the genetic relatedness between the cross-protective and challenge strains seem to be crucial. To our knowledge, when developed in the field, the complex genetic diversity of

the cross-protective and challenge virus strains is rarely considered at a local scale before implementation. Hence, our strategy is to implement cross-protection against grapevine fanleaf virus (GFLV, *Nepovirus*) using a combined phenotypic and genetic approach in a long-term vineyard experiment. Our first campaigns in a highly GFLV infected plot in Burgundy led to the selection of candidates, i.e. GFLV-infected vines displaying mild symptoms while producing similar fruit yields compared to GFLV-free vines. Using high throughput sequencing, consensus sequences of GFLV RNAs found in these mildly symptomatic vines were compared to those of the challenge isolates found in a specific area of this plot where the trial will be designed. This experiment should eventually lead to the identification of key features responsible for the success of cross-protection and guide its implementation in the field.

GRAPEVINE DECLINE DUE TO THE 161-49 C ROOTSTOCK SEEN AS A DYSFUNCTION OF THE ROOT HOLOBIONT

Text

The grapevine rootstock 161-49 C (Vitis berlandieri x Vitis riparia) is a "qualitative" rootstock which has been widely used in France. However, for the past ten years, serious and unexplained problems of 161-49 C decline have been reported. In the plot, the affected vines show a reduction in vigor, with in particular a clear reduction in the height of vegetation and in the diameter of the stems. In Burgundy, it is not uncommon to find plots affected by more than 50%, generating considerable yield losses, impacting both the production and the sustainability of the vineyard. In this context, we wanted to test the hypothesis that soil nutrient biodisponibility can impact the level of this decline (prevalence), and the root system is analyzed as a holobiont.
Our results reveal major modifications of the vine holobiont during the decline of this rootstock. The mineral composition of the rootlets as well as their anatomical structure are strongly modified. This also has repercussions at the scale of microbial communities. Moreover, modulations in the accumulation of certain metabolites are also observed.
Obtaining bioindicators of grapevine holobiont dysfunction in a situation of root decline will allow us (i) to better understand these risks, particularly in a context of climate change which generates abiotic stresses such as water stress and (ii) to better characterize root immunity as a component of the grapevine holobiont functioning.

The induction of crop resistance to cryptogamic diseases by Plant Defense Elicitors (PDE) is an attractive strategy to reduce chemical pesticide use. However, the variability of its effectiveness in the field limits its development. One of the reasons is that, unlike fungicides which act directly on pathogens, PDE solicit plant immunity, the performance of which may depend on the plant physiological status. In addition to PDE, other products used in agriculture, biostimulants (BS), are described to improve certain functions of the plant. In this context, the objective of this work was to determine whether a BS, via effects on grapevine physiology, could increase effectiveness of a PDE.
We have developed an experimental methodology (on vitroplants) to characterize the effects of a BS (plant extract). Added to the culture medium, it (i) accelerates the start of the plant growth, (ii) has an impact on the plant aerial and root development and (iii) has an effect on the metabolome and the phytohormone content of leaves, stems and roots. Moreover, in response to a PDE (another plant extract, applied on leaves), the plant defense responses are induced and a protection against Plasmopara viticola (the downy mildew agent) is obtained only for biostimulated vines. Therefore, the biostimulant may act by priming the plant defense elicitor action. Thus, this study demonstrates the relevance of the use of BS to optimize the effectiveness of a PDE.

Text
Bread (BW) and durum (DW) wheats are both challenged by Zymoseptoria tritici, the hemibiotrophic fungus responsible for septoria triciti blotch (STB) disease. Developing more eco-friendly control strategies is needed in order to move towards a more sustainable plant protection approach. This study aims at investigating the ability of chitosan to induce

resistance in the two wheat species against Z. tritici. Leaf spraying of this compound provided a strong reduction of necrosis area, by 63 and 66% on BW and DW, respectively. No direct antifungal activity was observed in vitro against Z. tritici. In planta monitoring of the infection process revealed that chitosan did not prevent fungal epiphytic growth nor leaf colonization, but strongly inhibited stomatal penetration. Moreover, significant reduction of fungal cell-wall degrading enzymes and protease activities were observed in both wheat species. During the early stages of infection, chitosan induced defense responses on both wheat species, such as stimulation of endo-β-1,3-glucanase, peroxydase, phenylalanine ammonia lyase and lipoxygenase activities. Moreover, H202 and phenolic compound accumulation at the site of fungal penetration attempts were observed. Although few differences were recorded, the patterns of the defense responses induced were overall similar in the two species. These results clearly suggest that chitosan could be an interesting resistance inducer that could be used to control STB on both BW and DW.

THE ROLE OF PLANT VOLATILES IN ACTIVATING NATURAL DEFENSES AGAINST HLB AND ITS VECTORS

Text

Huanglongbing (HLB), also known as citrus greening, is a bacterial disease that severely restricts citrus production in citrus-growing regions across the globe. Recent research has demonstrated that activating the immune system of citrus plants can help to limit HLB. This activation is primarily achieved through the salicylic acid (SA) signaling pathway by triggering plant defenses. Our research team has developed a new method for activating the immune system of citrus plants using organic volatiles that act as an alert signal for imminent attacks, prompting the plants to induce their defenses. By exposing eight citrus species to six different volatiles using a polymer diffuser, we found that almost all combinations of volatiles and citrus species could activate the SA pathway. The most potent volatile was (Z-)3-hexenyl propanoate [(Z)-3-HP], which was further investigated for its impact on the biology of both HLB vectors in defensively activated plants. We observed that exposing plants to (Z)-3-HP reduced the oviposition of the two psyllid vectors, *Trioza erytreae* and *Diaphorina citri* by more than 50%. We also studied the behavior of their parasitoids, *Tamarixia dryi* and *Tamarixia radiata*, in response to this defensive activation and found that both parasitoids were attracted to plants activated by (Z)-3-HP exposure. Finally, we present preliminary results on the effect of defensive activation through exposure to (Z)-3-HP on the acquisition and multiplication of HLB.

ANTAGONISTIC POTENTIAL OF DIFFERENT RHIZOSPHERIC BACTERIA FOR THE MANAGEMENT OF PECTINOLYTIC PATHOGENS CAUSING BLACKLEG OF POTATO

SARFRAZ Sohaib. (1)

(1) University of Agriculture Faisalabad, Faisalabad, PAKISTAN

Text
Blackleg, a bacterial disease caused by a group of pathogens belonging to Pectobacterium and Dickeya species inflicts incredible losses to potato crops in major potato growing areas of Punjab. The aim of this study was to isolate, identify and evaluate the quorum quenching (NAHL degrading) bacterial strains from potato rhizosphere against Pectinolytic bacteria causing infections in potato. A total of 78 morphologically different isolates were retrieved from 50 potato rhizosphere samples. Therefore, after initial screening of 78 isolates, only 24 isolates showed NAHL degradation activity in a 96 well plate biosensor based assay. Furthermore, remaining 24 strains were passed through different NAHL degradation assays like plate streak and TLC plate assays but providentially all showed NAHL degradation less or more. Finally, all these NAHL degrading test strains were evaluated under QQ tuber assay to agonize Pectobacterium based QS-regulatory processes. Thus, on the basis of QQ tuber assay, 2 test strains did not reduce maceration, 6 partially reduce maceration while 16 test strains exhibited complete degradation or inhibition of the NAHLs with no maceration in tubers as compared to positive and negative control. Out of 16 QQ strains, 6 were identified as Bacillus spp., 3 as Pseudomonas spp., 2 as Variovorax spp., 2 as Arthrobacter spp. and 1 each as Rhodococcus erythropolis, Commomonas and Delftia species.

DESIGN OF SUSTAINABLE BIOCONTROL STRATEGIES AGAINST SEPTORIA TRITICI BLOTCH OF WHEAT

Text
Limiting the use of synthetic pesticides is critical to increase sustainability in agriculture and food security. Wheat is the main staple food in Europe and one of the top-3 in the world. Wheat production is challenged by diseases, being septoria tritici blotch (STB) the most damaging one in Europe. The control of this foliar disease is extremely challenging since it is caused by the fast-evolving pathogen Zymoseptoria tritici, and the methods traditionally used to control it, mainly genetic resistance and fungicides, are losing their efficacy. We propose that the strategic use of microorganisms as biological control agents (BCAs) inhibiting fungal growth and interfering with the infection of pathogens is a sustainable and effective method to control diseases, including STB. The main goals of our work are to identify BCAs adapted to wheat in Spain and the Mediterranean basin, and to determine the evolutionary potential of Z. tritici to erode BCA-based control. To achieve the first objective, we are currently generating a collection of endophytic microbes of wheat leaves from the field, and we are screening these endophytes for their antagonistic activity to Z. tritici. This work will bring applied solutions for the biocontrol of STB of wheat in the Spanish fields, as well as providing important knowledge about wheat endophyte communities and their mechanisms as BCAs.

ULVANS INDUCE RESISTANCE IN WHEAT AGAINST FUNGAL LEAF DISEASES

Text

Ulvans are water-soluble sulfated polysaccharides extracted from green seaweeds that have previously been reported to induce resistance in plants against various pathogens. This study investigated their ability to induce resistance against two major foliar fungal diseases in wheat, Septoria leaf blotch (SLB) and powdery mildew (PM). Wheat plants were sprayed with an ulvan solution and subsequently inoculated with either *Zymoseptoria tritici* or *Blumeria graminis* f.sp. *tritici*, which are responsible for SLB or PM, respectively. Results showed that ulvan-treated plants exhibited both reduced disease severity, by 45% for STB and 42% for PM, with a clearly impact on the fungal colonization compared to control plants. Moreover, the expression levels of defense-related genes in wheat plants were analyzed using qRT-PCR. Ulvan treatment upregulated the expression of several defense-related genes involved in the phenylpropanoid pathway and pathogenesis-related protein synthesis. In the case of the *Z. tritici*-wheat interaction, ulvans reduced disease severity and the density of asexual fruiting pycnidia, while positively regulating several defense-related genes. Interestingly, the treatment did not substantially alter the wheat leaf metabolome, suggesting a low metabolic cost associated with induced resistance. These findings suggest that ulvans have potential as a natural and environmentally friendly tool for plant disease management.

ENHANCING SOIL PHOSPHORUS AVAILABILITY AND WHEAT IMMUNITY AGAINST ZYMOSEPTORIA TRITICI USING THE PSEUDOMONAS SIDEROPHORE ISOPYOVERDINE

Text

To promote agroecology and sustainable agriculture, looking for eco-friendly alternatives to chemical fertilizers and pesticides is encouraged. The aim of the present study was to evaluate the potential of isopyoverdine, a siderophore from *Pseudomonas putida* strain BTP1, to enhance the bioavailability of iron and phosphorus in the soil and to induce resistance in wheat against the hemibiotrophic fungal pathogen *Zymoseptoria tritici*. *In vitro* assays revealed that isopyoverdine co-solubilizes both iron and phosphorus from goethite (iron oxides), thus revealing the interest of this siderophore to increase the available amount of these nutrients. *In planta* experiments were also performed to validate these findings and to assess the ability of isopyoverdine to stimulate the wheat immune system through the roots. The bioassays were

carried out in a hydroponic system containing modified Hoagland medium with the addition of goethite sorbed with phosphate ions, supplemented or not with isopyoverdine, and inoculated or not with *Z. tritici*. Disease severity, fungal sporulation, as well as plant growth traits were assessed. More specifically, plant defence mechanisms potentially induced by isopyoverdine in both priming and eliciting conditions were explored using cytological, molecular and biochemical markers. The expected results will provide new knowledge about the valorisation of bacterial siderophores for crop health and nutrition.

Text

Plant induced immunity is a valuable eco-friendly tool that fits with sustainable agriculture and healthy food. Here, we reveal that mycosubtilin, a lipopeptide from the bacterium *Bacillus subtilis*, protects wheat against the hemibiotrophic fungal pathogen *Zymoseptoria tritici* through dual (direct and indirect) mode of action and that the indirect one relies mainly on priming rather than the elicitation of plant defense mechanisms. Foliar application of the biomolecule primed, during the early stages of infection, the expression of 80 genes associated with sixteen functional groups, including responses to pathogens, abiotic and oxidative stresses, secondary metabolism, cell-wall structure and function, and primary metabolic pathways (carbohydrate, amino acid, protein, lipid, and energy metabolisms). Interestingly, mycosubtilin also primed the accumulation of several flavonoids during the period preceding the fungal switch to the necrotrophic phase. This priming-based bioactivity of mycosubtilin against a biotic stress could result from its interaction with leaf cell plasma membranes that may mimic an abiotic stress-like stimulus in wheat plants, as supported by cytological bioassays, as well as the regulation of genes associated with abiotic stress-responses and early signal transduction in the treated plants. This study provides new insights into the use of mycosubtilin as a biocontrol compound with two distinct modes of action against *Z. tritici*.

RESISTANCE IN WHEAT AGAINST ZYMOSEPTORIA TRITICI INDUCED BY ULVAN REQUIRES THE FLAVONOID TRICIN

DE FREITAS Mateus B.. (1), SIAH Ali. (2), **STADNIK Marciel J. . (1)**

(1) Laboratory of Phytopathology, Federal University of Santa Catarina, Florianópolis, BRAZIL; (2) Joint Research Unit 1158 BioEcoAgro, Junia, Université de Lille, Université de Liège, UPJV, Université d'Artois, ULCO, INRAE, Lille, FRANCE

Text

Ulvan, a heteropolysacharide from green seaweed, can induce resistance against a wide range of fungal plant pathogens. However, the defense responses and signaling mechanisms are not yet fully understood. Therefore, our work aimed at investigating the role of wheat metabolites in ulvan-induced defense responses against *Zymoseptoria tritici* by using an inhibitory approach. For that, the third leaf of three-week-old wheat plants (cv. Alixan) was infiltrated with water (control), 1-aminobenzotriazole (ABT; 0,1mM), 2-(difluoromethyl)arginine (DFMA; 2mM) or trinexapac-ethyl (TXPE; 0,1mM) using a needless syringe. ABT, DFMA and TXPE inhibit enzymes involved in the biosynthesis of HDMBOA-Glc (benzoxazinoid), putrescin (polyamine) and tricin (flavonoid), respectively. Three hours after infiltration, plants were sprayed with water (control) or ulvan (10mg·mL^{-1}) and, two days later, inoculated with *Z. tritici*. Then, wheat plants were incubated under high humidity condition (>90%) for 48h and kept at 20±4°C and 16h of light for further 21 days when the percentage of necrotic leaf area was visually estimated on the third leaf. The percentage of necrotic third leaf area recorded for control plants (infiltrated and treated with water) was 27%. Ulvan spraying reduced this variable by 37% in leaves infiltrated with water, ABT and DFMA but failed to do so in those infiltrated with TXPE, suggesting that tricin may play an important role in ulvan-induced defense responses against *Z. tritici*.

NEW BIO-SOURCED ELICITORS FROM A SUGAR BEET BYPRODUCT INDUCE RESISTANCE IN WHEAT AGAINST ZYMOSEPTORIA TRITICI

Text

The current context of agroecology requires the discovery of new ecofriendly plant protection compounds. Plant resistance inducers are considered as one of the most promising alternatives satisfying such requirements. Here, we assessed the efficacy and the modes of action on wheat against *Zymoseptoria tritici* of a set of 31 molecules, including γ-aminobutyric acid (GABA), pyroglutamic acid (PGA, bio-sourced from sugar beet byproducts), M1 (derived from PGA), and 28 other molecules functionalized from M1 using green chemistry. Foliar application of the molecules provided significant protection rates (up to 63 % disease severity reduction) for GABA, M1 and 15 molecules functionalized from M1. A structure-activity relationship study highlighted the importance of all chemical groups of the M1 pharmacophore in the activity of the molecules. In vitro bioassays revealed that they did not exhibit any direct activity towards the pathogen, indicating that the protection conferred by the molecules is due to host defense activation. Further characterization of the most efficient molecules (M1, M2 and GABA) confirmed this finding and revealed that these three molecules up-regulate the expression of genes encoding for lipoxygenase, phenylalanine ammonia-lyase, peroxidase) and pathogenesis-related protein 1. This study reports a new

family of bio-sourced elicitors inducing resistance in wheat against *Z. tritici*, hence providing new insights into the sustainable control of this pathogen.

MORINGA FROM SUSTAINABLE CULTIVATION IN SOCIAL COMMUNITY

BRUNNER Robert Ingo. (1)

Text
Plants have developed an array of mechanisms to protect themselves against pathogen invasion. The deployment of defense mechanisms is imperative for plant survival, but can come at the expense of plant growth, leading to the “growth-defense trade-off” phenomenon. Following pathogen exposure, plants can develop resistance to further attack. This is known as induced resistance, or priming. Here, we investigated the growth-defense trade-off,

examining how defense priming via Systemic Acquired Resistance (SAR), or Induced Systemic Resistance (ISR), using microbial and chemical priming agents, affects tomato development and growth. We found that defense priming can promote, rather than inhibit, plant development, and that defense priming and growth tradeoffs can be uncoupled. Cytokinin response was activated during induced resistance, and found to be required for the observed growth and disease resistance resulting from ISR activation. ISR was found to have a stronger effect on plant development than SAR. Taken together, our results suggest that growth promotion and induced resistance can be co-dependent, and that defense priming can, within a certain developmental window, not necessitate a trade-off on growth, but rather, encourage and drive developmental processes and promote plant yield.

MENOAGE WITH MORINGA

BRUNNER Robert Ingo. (1)

(1) MoringaVerde & partners, Augsburg, GERMANY

Text
„MenoAge":

Anti-aging is the subject of our century. Proteins are the key to solve it.
Glycosylation is one of the most important posttranslational modifications found in organisms from bacteria to humans.
Moringa seeds contain the antibiotic pterigospermine and fatty acids such as linoleic acid, linolenic acid and behenic acid, as well as secondary plant substances such as tannins, saponins, phenolic compounds, phytates, flavonoids and lectins. In addition, there are fats, fiber, proteins, minerals, vitamins A, B and C, and amino acids.
Determining exact glycosylation patterns is not only important in research and development but also in clinical settings where they can serve prognostic as well as diagnostic purposes.

Glycosylation is one of the most important posttranslational modifications found in organisms from bacteria to humans.
The addition of glycans, branched oligosaccharides, determines the structure and function of proteins and other macromolecules.
However, unlike the other three types of macromolecules (nucleic acids, lipids, and proteins), glycans are still on the margins of contemporary science.

MARVIC's partner GENOS is specialized in high-throughput glycan analysis using methods developed over 15 years of experience in academia and partnerships with clients in the clinical, pharmaceutical, and biotech industries.

Why glycans?
Glycosylation is one of the most important posttranslational modifications found in organisms from bacteria to humans.

TRANSCRIPTOMIC AND FUNCTIONAL ANALYSES REVEAL THE DIFFERENT ROLES OF VITAMINS C, E AND K IN REGULATING VIRAL INFECTIONS IN MAIZE

Text

Maize lethal necrosis (MLN), is caused by maize chlorotic mottle virus combined with a potyvirid, such as sugarcane mosaic virus. However, the host response as well as the resistance mechanism of maize to MLN remains largely unknown. Here we obtained four complete gene expression profiles from PBS, SCMV, MCMV and S+M inoculated maize plants via comparative analysis of SMRT and Illumina based RNA sequencing. Both single infection and co-infection of SCMV and MCMV had significant effects on photosynthesis, reactive oxygen species scavenging, and some pathways related to disease resistance in maize. Through CMV-VIGS assays, we demonstrated that silencing *ZmGalDH* or *ZmAPX1*, two vitamin C biosynthesis related genes, promoted viral infections. However, MCMV and S+M infections were inhibited when *ZmTAT* or *ZmNQO1*, the genes involved in vitamin E or K biosynthesis, were silenced. Furthermore, we tested 54 maize inbred lines for MCMV and SCMV resistance, and two MLN-resistant inbred lines, S766 and Shen137, were identified. Moreover, we demonstrated that exogenous application of vitamin C solutions could effectively suppress viral infections and relieve the symptoms of MLN, while spraying vitamin E and K had the opposite effects. The antiviral roles of these three vitamins probably depended on their regulatory effects on the expressions of salicylic acid responsive pathogenesis-related genes. These findings the roles of vitamins C, E and K in conditioning viral infections in maize.

IDENTIFICATION OF POTENTIAL TARGETS OF A NEW ANTI-TMV COMPOUND GLY-15 CONTAINING PYRIMIDINE HETEROCYCLE AND MOROXYDINE SKELETON

YU Miao. (1), LIU He. (1), LI Xinghai. (1), AN Mengnan. (1), WU Yuanhua. (1)

Text

We have previously reported that the new compound GLY-15 containing pyrimidine heterocycle and moroxydine skeleton structure has good anti-TMV activity (Yu et al., 2022. Pest Management Science). The combination of chemical molecular probes and mass spectrometry is used to identify the potential target proteins of the compounds. Here, we constructed a biotin modified active probe by covalent bonding biotin with GLY-15 using an active small molecule probe, and thereafter confirmed its e anti-TMV activity in Nicotiana glutinosa. Total proteins extracted from TMV infected N. tabacum plants were incubated with biotin probes P-GLY-15, and then, using the interaction between biotin and avidin, we enriched and purified the GLY-15 binding protein using an avidin coated solid phase carrier. Finally, after separation by SDS-PAGE gel, we selected specific bands for LC-MS/MS mass spectrometry analysis. The results showed that major host proteins pulled down by the XX probes include Glyceraldehyde-3-phosphate dehydrogenase (GAPDH), Fructose-bisphosphate dehydrogenase (FBA), Malate dehydrogenase (MDH), Mannose-binding lectin (MBL1), Annexin, Form dehydrogenase, mitochondrial (FDH), and Germin-like protein (GLP). Nevertheless, more precise verification of this molecular interaction between GLY-15 and

viral proteins should be performed in a subsequent study using methods such as molecular dynamics simulation or Tobacco rattle virus (TRV)-based virus-induced gene silencing (VIGS).

PSEUDOZYMA APHIDIS SUPPRESSES MAMP-TRIGGERED IMMUNITY AND ACTIVATES LOCAL AND SYSTEMIC INDUCED RESISTANCE

LEVY Maggie. (1), ALSTER Shanee. (1), HARRIS Raviv. (1), DAFA-BERGER Avis . (1), BUXDORF Kobi. (1), ROTEM Neta. (1)

(1) Hebrew University of Jerusalem, Rehovot, ISRAEL

Text

Beneficial microorganisms need to overcome the plant defense system to establish on or within plant tissues. Like pathogens, beneficial microbes can manipulate a plant's immunity pathways, first by suppressing and hiding to establish on the host and then by inducing resistance to protect the plant. In the current study, we demonstrated that although *Pseudozyma aphidis* can activate microbe-associated molecular pattern (MAMP)-associated genes, it does not activate MAMP-triggered callose deposition and can, moreover, suppress such deposition triggered by Flg22 or chitin. While MAMPs associated gene activation by *P. aphidis* was not dependent on salicylic acid, jasmonic acid, or ethylene signaling, suppression of MAMP-triggered callose deposition required the salicylic acid and jasmonic acid signaling factors JAR1-1 and COI1 yet did not rely on EIN2, NPR1, or the transcription factor JIN1/MYC2. Later on, *P. aphidis* or its secreted metabolites prime plants' defense machinery via local and systemic induction of PR genes in a manner independent of SA, JA, and NPR1. Finally, *P. aphidis* fully or partially reconstituted PR1 and PDF1.2 expression in SA related mutants, but not in a JA related mutant, after *B. cinerea* infection, suggesting that *P. aphidis* can bypass the SA/NPR1, but not JA, pathway to activate PR genes. Thus, either partial gene activation is sufficient to induce resistance, or the resistance can be directed through other pathogen-resistance genes or pathways as well.

METABOLOME ANALYSIS OF ARECANUT PALM RESPONSE TO YELLOW LEAF DISEASE

MENG Xiuli. (1), SONG Weiwei. (1), TANG Qinghua. (1)

(1) Coconut research institute of chinese academy of tropical agricultural sciences, Wenchang, CHINA

Text

The arecanut palm, Areca catechu L., family Palmae is an important herbal medicine which has potential for the treatment of parasitic diseases, digestive function disorders and depression. Yellow leaf disease (YLD) caused by phytoplasmas is a destructive disease of arecanut palm. Leaves of 6 diseased palms and 6 healthy ones were collected in Baoting, Hainan, China(109.67°E, 18.41°N) and sent to BGI (https://www.bgi.com/) for untargeted metabolome analysis. Compared to healthy palms, 71differential metabolites (DMs)were detected in diseased palms and 46 ones were up-regulated. By KEGG pathway rich analysis, 6 DMs were involved metabolic pathways; 4 DMs were involved biosynthesis of secondary

metabolites; 3 DMs were involved phenylpropanoid biosynthesis. Besides, there are 8 pathways which enriched 2 DMs including cyanoamino acid metabolism, aminoacyl-tRNA biosynthesis, phenylalanine metabolism, glucosinolate biosynthesis, purine metabolism, biosynthesis of amino acids, 2-Oxocarboxylic acid metabolism, phenylalanine-tyrosine and tryptophan biosynthesis. The result providing important information for analyzing the mechanism of pathogen-plant interaction.

CHITOSAN: A COMPLEX SUBSTANCE WITH GREAT POTENTIAL FOR GLOBAL INTEGRATED PEST MANAGEMENT AND FOR REDUCING FARMERS' DEPENDENCE ON SYNTHETIC FUNGICIDES

HENRY Judie. (1), **DUBREU Ophélie. (1,2)**, PAGNOUX Anaëlle. (1), PAJOT Emmanuel. (1)

(1) Green Impulse, Angers, FRANCE; (2) UMR 1345, INRAe, Université d'Angers, Institut Agro Rennes-Angers, SFR 4207 QuaSaV, Beaucouzé , FRANCE

Text

Due to its numerous biological properties, its absence of toxicity and its biodegradability, chitosan is well studied and already used in various fields of application such as nutraceuticals, water treatment and plant protection. The interest of chitosan in agriculture, and more particularly in crop protection, has been known for decades and has allowed it to obtain the status of basic substance in Europe. Despite its strong potential as tool for reducing the use of pesticides, its development has been hindered by its complex nature and a lack of knowledge on the parameters influencing its biological efficacy. The knowledge obtained in recent years on the structure-activity relationship of chitosan as well as the technological advances that have taken place at the same time have allowed the industrial development of new well-characterized chitosans called of "second generation" and consequently the emergence of new chitosan-based products specifically designed for their application in agriculture. Thanks to an optimized composition and a controlled inter-batch reproducibility, these natural products have demonstrated interesting plant resistance inducer and fungistatic activities, and therefore represent promising solutions in the objective of reducing the use of pesticides, in a strategy of integrated pest management (IPM).

SELECTION BY PLANT OF PLANT-PROTECTING PSEUDOMONAS POPULATIONS EVIDENCED VIA AN EXPERIMENTAL EVOLUTION APPROACH

MULLER Daniel. (1), **PRIGENT-COMBARET Claire. (1)**

(1) University Claude Bernard Lyon 1, Villeurbanne, FRANCE

Text

Plant interacts with multiple microbial players, together constituting the plant holobiont. At the level of their roots, a specific rhizospheric microbiota is shaped by their exudates. Within this microbiota, certain bacteria are capable of stimulating the growth of the plant and protecting it against plant-pathogens. Today, most molecular studies on plant-microbe cooperation are performed on one plant inoculated by one bacterium, and despite the multitude of strategies developed, plant-beneficial bacteria generally have very low efficacy in protecting plants grown in the field. This might be largely related to the fact that we do not know how plant-

beneficial bacteria may interplay with other members of the rhizomicrobiota and with the plant. To understand the adaptive mechanisms involved in plant-bacteria cooperation, our group has developed an experimental evolution approach, carried out on a synthetic community, made up of 10 cooperative bacteria belonging to distinct species from the Pseudomonas group, evolving in presence and absence of plants, for 400 generations. A metabarcoding analysis allowed us to investigate the evolutionary dynamic of the synthetic community. We observed rapid changes of the community composition and a clear effect of the plant in controlling the direction of changes in Pseudomonas populations' assembly. We are now exploring the genomic and phenotypic modifications of evolved populations, especially concerning their plant protection traits.

IDENTIFICATION OF COMMON FUNGAL EXTRACELLULAR MEMBRANE (CFEM) PROTEINS IN FUSARIUM SACCHARI THAT INHIBIT PLANT IMMUNITY AND CONTRIBUTE TO VIRULENCE

YAO Wei. (1), HUANG Zhen. (1), DUAN Zhenzhen. (1), ZHANG Muqing. (1)

(1) Guangxi University, Nanning, CHINA

Text

Fusarium sacchari is one of the primary pathogens causing pokkah boeng disease (PBD) in sugarcane in China. Common Fungal Extracellular Membrane (CFEM) domain-containing proteins only exist in fungi and play a significant role in the interaction of pathogens and plants. However, the CFEM proteins in F.sacchar were not identified and functionally resolved.

Of the 20 FsCFEM proteins identified from the genome of F. sacchari, 16 FsCFEM genes were cloned while 4 FsCFEM proteins (Fs06761, Fs08184, Fs10706, and Fs13617) were identified as effector proteins that could suppress the programmed cell death (PCD) triggered by BCL2-associated X protein (BAX) in Nicotiana benthamiana. Subcellular localization analysis revealed that these four effectors could enter plant cells and mainly located in the cell membrane and nucleus. By the yeast YTK12 secretion system, the signal peptides of four CFEM proteins were functionally verified. The expression levels of these four effector proteins were significantly increased in the Fs-infected sugarcane plants. Through fungal gene knockout, three genes (Fs06761, Fs08184, and Fs13617) were found to be important pathogenic factors for pathogens.

Our results support that the FsCFEM effector proteins were virulence effectors and might be involved in regulating plant immunity.

ENDOPHYTIC STENOTROPHOMONAS MALTOPHILIA D1B AND TRICHODERMA ASPERELLUM AAUTLF PRODUCES ANTIFUNGAL COMPOUNDS AND EXHIBITS ADDITIVE PLANT GROWTH-PROMOTING EFFECTS

SAIKIA Bandana. (1), **BHATTACHARYYA Ashok. (1)**

(1) ASSAM AGRICULTURAL UNIVERSITY, Jorhat, INDIA

Text
Present study was carried out to isolate 177 bacterial endophytes and 57 fungal endophytes, out of which; 143, 51 and 40 isolates were obtained from roots, stems and leaves, respectively, of the tomato crop in decreasing order. A maximum of 112 endophytes were isolated during monsoon followed by 64 and 58 isolated during pre-monsoon and post-monsoon periods, respectively, indicating the rich diversity in bacterial and fungal endophytes of tomato crops from different locations of Assam, India. Bacterial endophytic isolate D1B and fungal isolate AAUTLF showed the highest antifungal activity against the pathogen *Fusarium oxysporum* f. sp. *lycopersici in vitro* and *in vivo*. Based on 16S rRNA gene of bacteria and 5.8r DNA of fungal endophytes the most effective bacterial and fungal isolates against FOL were identified as *Stenotrophomonas maltophilia* D1B and *Trichoderma asperellum* AAUTLF, respectively. The bacteria produced antifungal compounds including Benzotiazole, Oleic acid, Phenyllactic acid and 3-(Hydroxy-phenyl-methyl)-2,3-dimethyl-octan-4-one. However, *Trichoderma asperellum* AAUTLF produced an antifungal compound, 6-pentyl-2H-pyran-2-one, which also possesses growth-promoting characteristics. This would be highly important for the source of antagonistic strains and biocontrol of tomato Fusarium wilt, as well as other plant fungal diseases.

Fusarium wilt disease of banana: how to tackle a pandemic?

ORNAMENTALS AS ALTERNATIVE HOSTS OF FUNGAL PATHOGENS CAUSING FUSARIUM WILT IN BANANA

MARTÍNEZ DE LA PARTE Einar. (1,2), MEIJER Harold J.g. . (3), GUZMÁN QUESADA Mauricio. (4,5), CARR RODRIGUEZ Claudiana. (5), MASIS JIMENEZ Silvia. (5), PÉREZ VICENTE Luis. (2), KEMA Gert H.j. . (1)

Text
Fusarium wilt, caused by a suite of *Fusarium* spp. formerly known as *F. oxysporum* f. sp. *cubense*, is a major threat to the cultivation of bananas globally. In addition to persistent chlamydospores, the fungus likely survives in the field between crop cycles in alternative hosts like grasses and weeds. However, it is unknown if other Zingiberales, grown as ornamentals in the same geographical areas as bananas, are hosts of *Fusarium* spp.. We conducted greenhouse assays to test whether a Race 1 (R1, aka *F. phialophorum*) and Tropical Race 4 (TR4, aka *F. odoratissimum*) strains, can infect ornamentals. *Ensete ventricosum*, *Stretlizia reginae* and *Musella lasiocarpa* showed no external symptoms with either strain. In contrast, *Heliconia latispatha* and *Musa coccinea* displayed external symptoms after inoculation with TR4. Inoculation of *H. latispatha*, *H. psittacorum*, *M. coccinea* and *M. velutina* with R1 also resulted in wilting leaves. We recovered isolates from distinct organs of all studied plant species and confirmed their identity by PCR. Re-isolated

strains caused disease symptoms on Gros Michel or Grand Naine banana plants. The susceptibility of some ornamental species and the presence of *Fusarium* strains as asymptomatic endophytes in others, with remaining pathogenicity, calls for a revision of current containment protocols for Fusarium wilt. The relevance of these species as reservoirs and potential vehicles for dissemination, should be further examined under natural conditions.

EVALUATION OF RESISTANCE OF MUSA CULTIVARS TO FUSARIUM OXYSPORUM F. SP. CUBENSE TROPICAL RACE 4 IN COLOMBIA

LEON Rommel. (1), GÓMEZ-CORREA Juan Camilo. (1), CARMONA Sandra L.. (1), LOVERA-SOTELO Andrea. (1), BURBANO-DAVID Diana. (1), IZQUIERDO-GARCÍA Luisa Fernanda. (1), OROZCO-GUERRERO Alfonso Rafael. Text

Fusarium oxysporum f. sp. cubense Tropical race 4 (TR4) has severely curtailed banana production in the tropical regions of the world. In 2019, TR4 was reported in Colombia, and more recently in Peru and Venezuela. TR4 is virulent to all Cavendish type banana cultivars, including Cavendish clones, which are the source of 99% of banana exports. However, the production of traditional cooking bananas plays an important role in food security in many developing countries. The response of traditional plantain cultivars from Colombia against TR4 is still largely unknown. In this study, we have assessed the TR4 resistance response of 10 Musa cultivars with plants grown under semi-controlled conditions. The incidence and severity of the disease were calculated. The banana accessions evaluated showed different degrees of susceptibility to TR4 with incidence values from 25 to 100% for Manzano and Pelipita, respectively; and severity values between 6 and 35%. Additionally, the quantity of pathogen DNA was compared between inoculated cultivars using ddPCR technology, showing a correlation between the quantity of pathogen DNA and the Fusarium wilt disease severity rating. The traditional cooking bananas of Colombia are susceptible to TR4 under semi-controlled conditions, this result, raise alarms up for all cooking banana farmers, the establishment of strict containment and biosecurity measures are fundamental.

EARLY DETECTION OF FUSARIUM WILT IN BANANAS USING RAMAN SPECTROSCOPY: A PROMISING NON-DESTRUCTIVE DIAGNOSTIC TOOL

JO Young-Ki. (1), KUROUSKI Dmitry . (1)

(1) Texas A&M University, College Station, UNITED STATES

Text

Fusarium wilt caused by *Fusarium oxysporum* f. sp. *cubense* (FOC) is a serious threat to banana production worldwide, particularly with the spread of the tropical race 4 (TR4) strain. With no cure for the disease and popular banana varieties such as Cavendish having high

susceptibility, early detection and timely control measures are crucial. Recent research has focused on developing advanced diagnostic techniques such as polymerase chain reaction (PCR) and next generation sequencing (NGS) technology. One promising method is Raman spectroscopy (RS), which can detect FOC infection in banana plants with minimal or no damage. Our research found that Raman signals from banana leaves can reliably indicate FOC infection, particularly early at the asymptomatic stage. The key vibrational bands of RS from carotenoids allowed for the early detection of FOC, up to 40 days after inoculation and 35 days before characteristic wilting symptoms appeared. As the disease progressed, the accuracy of FOC detection improved to over 90% by 61 days after infection. The speed of processing time, ease of use, and non-destructive nature of data collection make RS an ideal early detection tool, improving the effectiveness of mitigation practices to eliminate, contain, and quarantine FOC.

EVALUATION OF THE BIOCONTROL CAPACITY OF NATIVE MICROORGANISMS AGAINST FUSARIUM OXYSPORUM F. SP. CUBENSE

TRIGOSO Carla. (1), ARIE Tsutomu. (2), **ARAGON Liliana. (1)**

(1) UNALM, Lima, PERU; (2) TUAT, Tokyo, JAPAN

Text
Fusarium Wilt is an economically important disease of bananas caused by the fungus *Fusarium oxysporum* f. sp. *cubense* (Foc). It causes severe losses in the yield and quality of bananas and is extremely difficult to control conventionally using chemical fungicide. Biological control offers an eco-friendly alternative for sustainable plant disease management. In this context, the objective of this research is the determination of the biocontrol capacity of native microorganisms against *Fusarium oxysporum* f. sp. *cubense*. For the isolation of native rhizospheric microorganisms, samplings were carried out in the region of Perené and Satipo in the central jungle of Peru. Thirty rhizobacterial isolates were screened for antagonistic activity in dual culture, and isolate 27 showed the highest antagonistic activity (81,52% mycelial growth inhibition) against Foc. The metabolites of isolate 27 inhibited mycelial growth of Foc by 80%. Based on the morphological, physiological and phylogeny analysis with 16S rRNA sequence the isolate 27 was identified as *Burkholderia sp*. This is a preliminary study of the SATREPS project (Japan - Peru): "The Project on establishment of an alert system for *Fusarium oxysporum* f. sp. *cubense* the banana and plantain wilt pathogen, and biological mitigation strategy of the pathogen"

GENETIC RESISTANCE FOR LASTING CONTROL OF FUSARIUM WILT

AITKEN Elizabeth. (1), CHEN Andrew. (1)

(1) The University of Queensland, St Lucia, AUSTRALIA

Text
The first Fusarium wilt pandemic of banana ended with genetic resistance; Cavendish was found to be resistant to Race 1. In the same way we predict that TR4 will be halted by genetic resistance but, this time more persistently if resistance genes are pyramided. Resistance to TR4 exists in wild diploid lines. Analysing these resistance sources allows

development of molecular markers for use in breeding programs. If these resistance sources prove to be independent of each other, the markers will permit selection of combined resistant traits in future cultivars.
Molecular markers are used routinely in crop breeding, enabling early selection of germplasm and, for resistance breeding, reducing the need for pathogenicity testing at each generation. In banana, the sterility of cultivated lines and requirements for parthenocarpy increases the complexity of breeding. We have identified molecular markers for resistance from a Malaccensis source and these markers are being used for selection in international breeding programs. Additional segregating populations have been generated using the resistant diploid Calcutta 4 and a Pisang Jari Buya-derived line, to determine if these traits map to the same or different chromosome locations from that of the Malaccensis resistance locus. The ultimate molecular marker is an actual resistance gene itself and once identified, such a gene can be used as a perfect marker in breeding programs or alternatively be deployed by genetic manipulation

SPECIFIC DETECTION OF FUSARIUM OXYSPORUM F. SP. CUBENSE AND ITS RACES BY LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP)

Text
Loop-mediated isothermal amplification (LAMP) can be used for rapid, simple and easy detection of plant pathogens. In this study we established LAMP for specific detection of the banana wilt pathogen *F. oxysporum* f. sp. *cubense* (*Foc*) and its races, based on the genomic information. *Foc*-specific detection primer set was designed on a candidate effector gene *ce15*. The gene was present in all *Foc* isolates tested, but absent in other formae speciales of *F. oxysporum* and non-pathogenic *Fusarium* spp. A *Foc* race 1 isolate 160527 possessed *ce15* on the contig 2, and its contig 2-partly-deficient mutant lost pathogenicity to banana (cv. Shima-banana; Matsui 2022). Races of *Foc* can be distinguished by the retention pattern of the putative effector genes. Race SR4 (subtropical race 4) possesses *SIX7* and *SIX8*, TR4 (tropical race 4) possesses only *SIX8*, and race 1 has neither. We designed primer sets for the specific detection of *SIX7* and *SIX8*, respectively. We could propose the rapid detection of *Foc* and its races by combination of LAMP with these primer sets. Extraction of genomic DNA, used as a template, from plant tissues and fungal mycelial cake took about 10 min using Template Prepper kit, LAMP reaction was completed in about 30 min and the determination can be made immediately after the reaction. The detection limit of the template DNA was 0.5 x 10^{-2} ng/µl reaction mixture for all the primer sets.

IMPROVING RESISTANCE TO FWB IN EAST AFRICAN HIGHLAND BANANAS

BROWN Allan. (1)

(1) International Institute of Tropical Agriculture, Arusha, UNITED REPUBLIC OF TANZANIA

Text

Breeding for fusarium resistance in East Africa has been accomplished through a collaboration between the International Institute of Tropical Agriculture (IITA) and national partners in Tanzania and Uganda. These breeding efforts have produced a number of promising hybrids with resistance to both race 1 and TR4. Four of these hybrids have been advanced to multilocational trials and release is expected within the next two years. Integrating fusarium resistance, however, is only a single consideration as new hybrids must also meet consumers demands and perform at least as well as commonly grown check varieties in both consumer preference trials and in terms of agronomic performance. The described hybrids display up to a 60% yield increase and have consumer preference scores comparable to commonly grown varieties. A new methodology for incorporating recombinant breeding into banana improvement has been developed and deployed. This should decrease the time required to produce new varieties combining multiple desired traits.

FUSARIUM OXYSPORUM F. SP. CUBENSE TR4 INTERACTIONS WITH BANANA AND ALTERNATE HOSTS, AND ORIGIN OF THE PATHOGEN IN THE MIDDLE EAST

MAYMON Marcel. (1), SHPATZ Uri. (1), GALPAZ Navot. (2), **FREEMAN Stanley. (1)**

(1) ARO, The Volcani Institute, Rishon Lezion, ISRAEL; (2) R & D Migal, Kiryat Shmona , ISRAEL

Text

Fusarium oxysporum f.sp. *cubense* tropical race 4 (TR4), the causal agent of wilting and plant mortality of Cavendish banana varieties, is considered one of the most devastating soilborne fungal pathogens of this crop worldwide. The pathogen was first detected in South East Asia in the 1990s, and has since spread worldwide, being discovered in Jordan and Lebanon in 2014, and Israel in 2016. Disease symptoms include leaf chlorosis and wilting, with internal vascular discolorations of rhizomes and pseudostems and eventual plant mortality. TR4 isolates from Israel were tested for pathogenicity, and identification from symptomatic plants was reconfirmed by PCR. Resistance/susceptibility screening of banana germplasm, included 6-7 resistant, 6-8 tolerant, and 15-16 susceptible genotypes. In inoculated resistant plants, TR4 was not detected within the vasculature while in susceptible wilted plants conidia and mycelia were observed within these tissues. TR4 colonization of roots and shoots of certain weed species growing in infested soils of banana plantations indicated systemic infection of these hosts without disease symptoms. Artificial inoculation of citrus, mango, avocado and grapevine seedlings indicated symptomless seedling root colonization by TR4. Genome sequencing of TR4 isolates (two from Israel, one from Jordan, Philippines, and Indonesia each) and comparison to 11 additional worldwide isolates by SNP analyses indicated that TR4 in Israel originates from Jordan.

Harnessing Culture Collections for Improved Plant Health

THE NATIONAL COLLECTION OF PLANT PATHOGENIC BACTERIA (NCPPB)

ASPIN Andrew. (1), MUSTAFA Syed Moin. (1)

(1) Fera Science Ltd., Sand Hutton, UNITED KINGDOM

Text

The NCPPB is one of the longest-established collections of its type; its aims are to maintain representatives of all known culturable bacterial plant pathogens and exemplify the standards for housing and supply of reference and type strains.
In 1947 bacterial plant pathogens from the National Collection of Type Cultures, some dating back to the early 1900s, were combined with a collection maintained by W J Dowson at the Botany School, Cambridge, for the Agricultural Research Council.
On his retirement in 1956 the collection of 200 isolates moved to the Plant Pathology Laboratory of the Ministry of Agriculture, Fisheries & Food and was recognised as a National Collection.
The NCPPB, funded by the Dept. for Environment, Food & Rural Affairs since 2002, continues its primary role of providing scientific support to the UK Plant Health Service. It houses circa 4000 lyophilised strains. Each batch is checked for purity, authenticity and viability immediately after lyophilisation. Enough ampoules are made to ensure that supply demands are met before the end of the batch's shelf life – measured in decades – and for some accessions examples of each previous batch continue to be housed, so comparisons can be made between the earliest lyophils and those made today.
The NCPPB is a founder collection of the United Kingdom Biological Resource Network (UKBRCN), is a member of the European Culture Collections' Organisation (EPPO) and is an affiliate member of the WFCC.

High-throughput sequencing in plant virology: from discovery to diagnostics

USE OF HIGH THROUGHPUT SEQUENCING FOR PLANT MATERIAL CERTIFICATION AND RELEASE OF QUARANTINED PROPAGATIVE PLANT MATERIAL AT FOUNDATION PLANT SERVICES IN DAVIS, CALIFORNIA, USA.

AL RWAHNIH Maher . (1)

(1) Foundation Plant Services, UC-Davis, Davis, Ca, UNITED STATES

Text
High throughput sequencing (HTS) is an important component of routine testing procedures at Foundation Plant Services (FPS) at the University of California, Davis for plant material certification and quarantine import programs. The US Department of Agriculture-Animal and Plant Health Inspection Service, Plant Protection and Quarantine (USDA-APHIS-PPQ) and California Department of Food and Agriculture (CDFA) have approved the use of diagnostic testing protocol that replaces biological indexing with a combination of HTS and polymerase chain reaction (PCR) testing for release of plant material. Research conducted at FPS indicates that this protocol results in more accurate test results compared to biological indexing using woody and herbaceous indicators for virus detection. FPS scientists conducted side-by-side studies comparing the efficacy of indexing to PCR and HTS testing in grapevine, Prunus, and rose. The results of these studies indicate that biological indicators give false negative results a significant percentage of the time and do not provide sufficient sensitivity in detecting target viruses or unknown viral pathogens. Similar results were obtained in studies conducted on Prunus and pome fruits by other clean plant centers. The streamlined testing methods yield the most accurate information about the phytosanitary status of material, expedite release times, and reduce potential risks from the transmission of vector-mediated viruses in the field.

HIGH-THROUGHPUT SEQUENCING IDENTIFIES CO-INFECTION OF TURNIP YELLOWS VIRUS AND ASSOCIATED RNAS IN SWEDISH OILSEED RAPE

PUTHANVEED Vinitha. (1), SINGH Khushwant. (1,2), POIMENOPOULOU Efstratia. (1), PETTERSSON Josefin. (1), SIDDIQUE Abu. (1), **KVARNHEDEN Anders. (1)**

(1) Swedish University of Agricultural Sciences, Uppsala, SWEDEN; (2) Crop Research Institute, Prague, CZECH REPUBLIC

Text
In autumn 2018, the presence of green peach aphids (Myzus persicae) in southern Sweden presented a risk for infection of winter oilseed rape (OSR; Brassica napus) with turnip yellows virus (TuYV; genus Polerovirus, family Solemoviridae). Therefore, a survey was carried out in spring 2019 with random leaf samples from 46 OSR fields in southern and central Sweden using DAS-ELISA. TuYV was detected in all fields except one, and in the counties of Skåne, Kalmar and Östergötland, the average incidence of TuYV-infected plants was 75% and reached 100% for nine fields. Analyses of the CP gene of nine Swedish TuYV isolates revealed highest identity to TuYV isolates from the UK. One OSR sample was selected for high-throughput sequencing using rRNA-depleted total RNA and Illumina technology. The assembled TuYV sequence of 5661 nt covered the complete genome except for the terminal ends. A phylogenetic analysis showed a close relationship between the Swedish TuYV isolate from OSR and European isolates from pea. In addition, near full-length sequences were obtained for TuYV-associated RNA (TuYVaRNA; 2841 nt) and TuYVaRNA2 (2795 nt), which both shared highest nt identity with German pea isolates of TuYVaRNAs. Similar to other polerovirus-associated RNAs, the two TuYVaRNAs had two ORFs encoding proteins for replication. Potentially, co-infection with TuYVaRNAs could increase the severity of disease and more studies are required to study their incidence and effect on crop plants.

METATRANSCRIPTOMICS APPROACH TO STUDY THE VIROME OF ECONOMICALLY IMPORTANT CROPS

ESCALANTE Cesar. (1), JACOBSON Alana. (1), BALKCOM Kipling S. . (2), CONNER Kassie . (3)

(1) Auburn University, Auburn, UNITED STATES; (2) United States Department of Agriculture - Agricultural Research Service, Auburn, UNITED STATES; (3) Alabama Cooperative Extension System, Auburn University, Auburn, UNITED STATES

Text

The use of high throughput sequencing (HTS) has expanded our perspective on the distribution and diversity of plant viruses. Furthermore, due to the increasing number of versatile and improved HTS technologies and the decrease in the cost per sample, implementing HTS has facilitated the diagnosis and discovery of novel viruses. This study aimed to examine the putative virome of economically important crops. Leaf samples were collected from vegetables, ornamentals, and row crops. Information on different nucleic acid extraction methods for HTS, including double-stranded RNA and total RNA, will be presented. Library preparation was performed from pooled samples before sequencing in an Illumina platform. The sequenced libraries were mapped to the host's reference genome, and the resulting sequences were de novo assembled. Both nucleic acid extraction methods successfully yielded sequences of good quality. A metatranscriptomics analysis revealed complete genome contigs of a variety of known and unidentified putative RNA and DNA plant viruses co-infecting the same host. The information obtained in this investigation will help develop a broader perspective on other viruses present in the tested plant species to determine whether co-infections with other viruses are a factor that might influence (negatively or positively) plant physiology, product quality, and yield.

THE ADDED VALUE OF PREPUBLICATION HTS DATA SHARING FOR THE DISCOVERY AND CHARACTERIZATION OF A NEW POTATO TORRADOVIRUS

MOLLOV Dimitre. (1), ALVAREZ-QUINTO Robert. (2), AMAO Melody. (3), MULLER Giovanna . (3), FUENTES Segundo. (3), GRINSTEAD Samuel. (5), FUENTES-BUENO Irazema. (5), ROENHORST Annelien . (4), WESTENBERG Marcel. (4), BOTERMANS Marleen . (4), KREUZE Jan. (3)

Text

High throughput sequencing (HTS) is a powerful technology for the detection of plant viruses. In 2014, the U.S. Customs and Border Protection intercepted potato tubers originating from South America. In 2016 the Netherlands Food and Consumer Product Safety Authority also intercepted potatoes from S. American origin. In both cases these samples were subjected to HTS and viral contigs most similar to torradoviruses were identified. These contigs showed

high similarity to an isolate of an undescribed isometric virus, coded SB26/29, which has been previously associated with a disease named potato rugose stunting in southern Peru. Tentatively the virus was named potato rugose stunting virus (PotRSV). Additional sequences obtained from cultivated potatoes in Peru, as part of the CIP potato virome project confirmed that all of these isolates from US, Peru, and the Netherlands belong to PotRSV. PotRSV like other torradoviruses has two polyadenylated RNA segments. RNA1 ranges between 7,086-7,089 nt and RNA2 from 5,228 to 5230 nt. The closest torradovirus species to PotRSV is squash chlorotic leaf spot virus sharing 41% (query coverage 48%) identity at the amino acid level. The prepublication data sharing enabled us to combine our efforts and with compiled data we tracked potential high risk virus movement out of its exotic range. The benefit is a better understanding of the virus genomic diversity and the ability to develop reliable detection assays for this new virus.

AUTOMATED AND REAL-TIME PROFILING OF PLANT VIRUS INFECTIONS TO SUPPORT DIAGNOSTICS AND QUICK RESPONSE IN OUTBREAK EVENTS

High-throughput sequencing (HTS) technologies are transforming our means to detect pathogens and perform disease diagnosis. Recent advances in genomic sequencing, as the ones pioneered by Oxford Nanopore Technologies (ONT), are enabling extremely rapid and effective detection, and quick transition from research to adoption in diagnostics settings is already occurring. The pocket-size of the sequencer, ease of library preparation, low sequencing costs and (long) read data generated in a short turnaround time are key characteristics of the ONT platforms, with substantial benefits for point-of-care testing and on-time reactions in response to a disease. Here we present the application of ONT for rapid, semi-automated profiling of (multiple) virus infections in plant samples. An amplicon-sequencing based approach was established by combining VolTRAX, a compact USB-powered device for automated sample and library preparation, with MinION sequencing and subsequent real-time analysis of the sequence reads. We demonstrate that the workflow – from RT-PCR amplification of total RNA to taxonomic assessment of pathogen sequences – can be accomplished in less than 5 hours, with a minimal need of human intervention, enabling a sensitive and rapid identification of viruses in diseased plant material.

FULL-LENGTH SEQUENCING OF CONCATENATED CIRCULAR DNA VIRUS GENOMES USING ROLLING CIRCLE AMPLIFICATION AND OXFORD NANOPORE SEQUENCING

Text
Geminiviruses are plant-infecting viruses with a mono- or bipartite single-stranded DNA genome, approximately 2.5-3.1 kb in size. Reliable and accurate detection of virus species and subspecies level sequence types can be performed by modern sequencing methodologies, however the percentage of virus-derived reads is often very low. Here we present a species-independent method to enrich viral sequence data and to generate a consensus sequence from Oxford Nanopore Technologies sequencing reads. Rolling Circle Amplification based on the phi29 polymerase was used to generate concatemers of the circular virus genomes in DNA samples from various infected crop plants, including melon, pepper, eggplant, tomato and okra. Multiplexed sequencing of debranched and linearized amplification products displayed an enrichment of the viral sequence content. Some samples showed up to 83% of the read data derived from Begomoviruses, far more than the values found in non-enriched samples: typically 0-2% of the read data. Moreover, the concatenated DNA molecules generated during the Rolling Circle Amplification step resulted in concatemer reads, ranging from 3 to 20+ fold, that allowed generation of a reliable consensus sequence of the viral genome from a single Nanopore read. Cost-effective and reliable detection, description and sequence typing of geminiviruses and other pathogenic viruses with a circular ssDNA genome can be performed very efficiently and reliably with this method.

APPLICATION OF HIGH-THROUGHPUT SEQUENCING (HTS) FOR ROUTINE PLANT VIRUS DETECTION IN THE SOUTH AFRICAN CITRUS IMPROVEMENT SCHEME

Text
The South African Citrus Improvement Scheme (CIS) is responsible for the production of pathogen-free propagation material for the southern African citrus industry. The CIS provides certified budwood and seed to local and international nurseries to produce trees. Budwood are produced under strict phytosanitary guidelines and multiplication trees are regularly re-tested. Before admission into the CIS new accessions are subjected to pathogen elimination (heat therapy and shoot-tip grafting) and rigorous testing for viruses and viroids. To reduce the timeline without an increase in risk, a high-throughput sequencing detection assay was validated for implementation in the CIS. The credibility of HTS as pathogen detection assay was measured using specific parameters, including repeatability, specificity, sensitivity, and reproducibility. The sensitivity of the HTS assay was compared to routinely used RT-PCR assays in a time course experiment. Controls were introduced at sampling and data analyses levels. Expectedly, both extraction method and sequencing platform resulted in significant differences between the data sets. However, even though the limit of detection of HTS was influenced by pathogen concentration, sample processing method and sequencing depth, HTS detection in this study was found to be equivalent or more sensitive than RT-PCR.

VALIDATION OF A HIGH THROUGHPUT SEQUENCING TEST WITHIN AN ISO17025 ACCREDITED PLANT HEALTH LABORATORY

Text

The use of High Throughput Sequencing (HTS) for the detection and identification of plant viruses and viroids is widely used. So far, validation of HTS mainly focussed on the bioinformatics pipeline. We described and validated an HTS test from biological material till the reporting of the identified viruses and viroids within an ISO 17025 diagnostic framework. This includes the analysis of multiple first line controls and visual assessment of assemblies to further substantiate the reliability of the results.
Performance criteria analytical sensitivity, repeatability and reproducibility were determined similarly as for traditional molecular methods using tomato brown rugose fruit virus in infected tomato leaves as a model system. Analytical specificity, selectivity and robustness were assessed in a more generic way. This allowed addition of the detection and identification of viruses by HTS to the scope of accreditation. Using this validation approach, the HTS test was demonstrated to be fit for purpose for at least 180 viruses and viroids, including viruses with both DNA and RNA genomes, in a variety of hosts. The ISO 17025 accredited HTS test allows us to detect and identify potentially all EU-regulated viruses and viroids, instead of implementing and validating specific tests (ELISAs, PCRs) for each regulated pest.
We will present challenges and practical solutions in implementing and validating an HTS test within an ISO 17025 accredited plant health laboratory.

Text
High-throughput sequencing (HTS) based methods have revolutionised plant virus discovery and virome studies. To facilitate a wide employment of the methods, build capacity and bring new advances to the field we joined forces within a Marie Sklodowska-Curie Innovative Training Network (MSCA-ITN) called INEXTVIR (Innovative Network for Next Generation Training and Sequencing of Virome). Fourteen PhD students, from 11 countries, were trained within the project over 12 European academic and industrial partners from 5 countries. Within INEXTVIR we aimed to generate a better understanding of viral communities and their role in agricultural ecosystems by using the latest advances in HTS technologies coupled with modern big data analytical approaches and socioeconomic analysis. The outputs of the project, which will be presented bring new advances overarching several natural and social science fields, including: comprehensive virome studies with detection and discovery of numerous new viruses in diverse crops (e.g., tomato, carrots, cucurbits, fruit trees); characterization of newly discovered viruses; insights into the interactions between virome and the environment (e.g., effects of habitat biodiversity); development of novel approaches for bioinformatics analysis of HTS-derived virome data; and societal perceptions of the risks and benefits related to the virome in agriculture.

WHAT CAN VIRAL METAGENOMICS BRING TO OUR UNDERSTANDING OF THE DIVERSITY AND ECOLOGY OF PLANT VIRUSES IN AGRO-ECOLOGICAL LANDSCAPES ?

MACLOT Francois. (1)

(1) University of Liège, Gembloux, BELGIUM

Text
High throughput sequencing (HTS) gave access for the first time to the viral metagenome or virome, by allowing to characterize, without a priori, all or nearly all viruses in a given sample. This broad-spectrum capability of HTS is raising a growing interest to study the diversity and ecology of plant viruses, in particular the richness and composition of viral communities at the agro-ecosystem scale, as well as the virus circulation among host reservoirs and the discovery of new and emerging viruses.
Recent viromics studies revealed diversified and largely unknown phytoviromes in natural ecosystems, with high rates of co-infection and the abundance of so-called persistent (or cryptic) viruses representing more than half of the viruses identified in wild plants. The influence of plant traits (e.g., lifespan, height, occurrence) on the virome richness, and the relationships between host-pathogen richness in cultivated and non-cultivated plant communities were also unravelled. In particular, the richness and diversity of plant communities appeared as influencing the richness and composition of phytoviromes, especially the distribution of persistent and acute viruses. Other results demonstrated the stability of virome richness over time but the large viral intraspecific variability within and among plant communities. Thus, HTS technologies have highlighted and will continue to serve the exploration of the complex network of viral communities in nature for the times to come...

DATA MINING-BASED DISCOVERY OF NOVEL TOBAMOVIRUSES AND VIRUSES ASSOCIATED WITH MACROPHYTES

Text

The search for new viral sequences provides an opportunity to improve early detection of pathogens, and to predict viral hosts and environmental reservoirs. Accelerated use of high-throughput sequencing has led to an increased amount of publically available sequencing data, which often remains unexplored. Here we present two distinct examples of how data mining can be used either to search for sequences belonging to a group of viruses in various samples or to identify novel viruses associated with a certain group of host organisms. Firstly, we searched for known and novel tobamoviral sequences in a set of published sequence datasets, selected based on Serratus infrastructure. Preliminary results show that novel tobamovirus-like sequences can be found in diverse sets of environments. For novel tobamovirus-like sequences, we presented associations with source environments (e.g., wastewater, human gut) and viral hosts (e.g., sugarcane) and performed phylogenetic analyses. Secondly, we mined publically available transcriptomes of aquatic plants (macrophytes) for viral sequences, utilizing data from the 1000 Plant Transcriptomes Initiative (1KP). Similar experiments have previously revealed the presence of new viral species in a water moss, and a perennial creeping herb. Likewise, we have found that many of the analysed macrophyte transcriptome data sets contain known and novel plant viral sequences, including crop pathogens.

DISCOVERY OF RINGSPOT VIRUSES IN NEW HOSTS BY HTS

Text

Columbine (Aquilegia sp.) and violet (Viola sp.) are landscape perennial plants. Columbine and violet plants with ringspots and mosaic symptoms were observed in a garden in Syracuse, NY. A combined sample was used for RNA extraction and high throughput sequencing (HTS). BLASTN analysis of seven contigs spanning between 3877 and 7480 bp revealed similarity to tobacco ringspot virus (TRSV) (94-96%), and to tomato ringspot virus (ToRSV) (93-97%). HTS results were confirmed by RT-PCRs using RNA from each sample and primers specific for TRSV and ToRSV. Columbine tested positive for ToRSV and TRSV, while violet tested positive for TRSV. Dagger nematode (Xiphinema sp.) was found in soil samples. ToRSV has been reported infecting columbine in Lithuania. Here we show evidence of ToRSV infecting columbine for first time in the U.S. Columbine and violet are new host for TRSV worldwide.

TOWARDS THE INCORPORATION OF HTS IN THE CONFIRMATORY DIAGNOSTICS PROCESS FOR QUARANTINE PLANT VIRUSES IN THE US

Text

High-throughput sequencing (HTS) has advanced from research use to a powerful diagnostic tool for plant viruses. Efforts to develop and improve validation metrics, interlaboratory comparability studies, and quality measures established in the diagnostics workflow have facilitated its acceptance in diagnostics. The USDA APHIS PPQ, Plant Pathogen Confirmatory Diagnostics Laboratory (PPCDL), an ISO17025 certified facility, provides the official federal diagnostic determination for regulated plant pathogens in the United States. PPCDL relies on various molecular technologies for the detection and identification of plant pathogens. PPCDL scientists have joined national and international efforts to optimize and validate HTS processes for diagnostics and incorporate this technology in the diagnostics workflow. The PPCDL has used HTS to confirm the presence of quarantine viruses in plant samples, examine the genome-wide diversity of emerging plant viruses and detect novel viruses. This presentation will discuss the progress to incorporate HTS as a diagnostic tool that include optimization and validation of processes, and the results of its incorporation for the detection of emerging plant viruses in the United States.

INCIDENCE OF VIRUS INFECTING TOMATO AND PEPPER PLANTS AND SEEDS IN SOUTHEAST ASIAN COUNTRIES BY METATRANSCRIPTOMICS

Text

Virus infection caused by insect vector from Southeast to East Asia is one of important constraints to the production of solanaceous crops, such as tomato (*Solanum lycopersicum*) and peppers (*Capsicum* spp.). However, limited information is available for incidences of viruses in vegetable crops in many Southeast Asian countries. Here, we report metatranscriptomics using RNA sequencing followed by bioinformatics analyses to determine viruses and viroids in solanaceous plants and/or seeds from Asian countries, including

Vietnam, Cambodia, Laos, Thailand, and Indonesia. We prepared a total of 21 libraries from virus infected pepper and tomato plants derived from different geographical regions in Vietnam, Lao PDR, and Cambodia. Also, we collected commercial or informal tomato and pepper seeds from several Asian countries and prepared 17 libraries in this study. We identified a total of 1,008 virus-associated contigs, which were assigned to 33 different virus species belonging to 13 different viral genera. In commercial pepper seeds, pepper cryptic virus 2 and pepper vein yellows virus were frequently detected. Multiple viral infections were detected in common in both plants, moreover, geographical region and host plant were two major factors to determine viral populations in Vietnam samples. Thus, our results provide the comprehensive overview of viral pathogens infecting two economically important plants in the family *Solanaceae* grown in Asian countries.

EPIDEMIOLOGICAL INSIGHTS WITH NEXTSTRAIN: LESSONS LEARNED FROM APPLICATION IN PLANT HEALTH AND FUTURE PERSPECTIVES

VAN DE VOSSENBERG Bart. (1), DE KONING Pier. (1), WESTENBERG Marcel. (1), VISSER Michael. (1), BOTERMANS Marleen. (1)

Text
With new high-throughput sequencing techniques, assembling complete plant pest genomes is becoming the new standard. Particularly for plant viruses this is the case. When faced with outbreaks of priority regulated pests, pest genomes and associated metadata can be put to work to gain insights in the diversity, spread and epidemiology. Managing the large amount of various data and interpreting their interconnectedness is a grand challenge. At present, typically a plethora of static phylogenic trees is produced focusing on a limited set of traits.

Nextstrain is a collection of bioinformatic tools that creates an interactive webpage enabling interactive visual analytic. Genomic diversity of the pest under investigation is presented in the context of geographic distribution and associated multi-layered epidemiological traits. We present three cases in which Nextstrain has been used at the Dutch National Plant Protection Organization to better understand novel findings of plant pests: Tomato brown rugose fruit virus outbreaks, *Thaumatotibia leucotreta* host range expansions and the occurrence of *Synchytrium endobioticum* strains with increased virulence.

Lessons learned from these cases, which are relevant for all organism groups, and future perspectives to increase the impact of the Nextstrain tool will be presented.

NANOPORE SEQUENCING FOR THE ANALYSIS OF OFFICIAL SAMPLES FOR THE PRESENCE OF (QUARANTINE) PLANT VIRUSES

Text

Climate changes and increased international trade are accelerating the spread of plant viruses, increasing the chance of introduction of new pathogens into new areas, and their persistence in new host species. Accurate identification of plant viruses is crucial for planning an effective prevention of new disease spread and its eradication. Targeted diagnostic tests are not available for many viruses, including some on quarantine lists. Development and validation of individual targeted tests could be time-consuming and costly. In this case, the use of the generic high-throughput sequencing (HTS) approach is sensible. HTS, using Illumina platform, has been used in our laboratory for selected official samples since 2017, resulting in detection of several new viruses for Slovenia. Recently, we introduced nanopore sequencing for the same aim, and shown that it gives comparable results to Illumina sequencing. Comparative studies were performed for detection of plant viruses in bulk plant samples, detection of various begomoviruses, and detection of unexpected plant viruses. Nanopore sequencing has been found to provide comparable results to Illumina sequencing, while being faster and better suited for small laboratories. Thus, nanopore technology was selected in our laboratory for a full validation according to EPPO standard PM 7/98, considering the specific guidelines of EPPO PM 7/151. The output of this process and our experiences obtained during it will be presented.

BIOVALON: A BIOINFORMATICS PIPELINE ADAPTATION AND VALIDATION FOR PLANT VIRUS DETECTION USING HTS METHOD.

BAZIN Sarah. (1), TOUZAIN Fabrice. (2), GERBAULT Jean-Emmanuel. (1), RENVOISÉ Jean-Philippe. (1), BELVAL Lorène. (1)

(1) ANSES-Quarantine unit, Lempdes, FRANCE; (2) ANSES-Unit of Viral Genetics and Biosafety, Ploufragan, FRANCE

Text

Due to important and rather frequent EU and French regulation evolution, the Anses Quarantine Unit needs to develop targeted and non-targeted tests to detect plants pests. The BioValON project aims to develop a bioinformatics pipeline, part of a HTS test, to detect simultaneously all viruses and viroids in plants in quarantine.
Datasets obtained from total ribodepleted RNAs using Illumina sequencers were used: serial dilutions of virus-infected potatoes (analyzed with another pipeline in 2018) and potentially healthy or known to be infected Citrus, Prunus and Vitis.
The pipeline, resulting from the PrepMedVet project (Anses- Ploufragan), is divided into five steps: quality control, plant’s sequences subtraction, regulated pests detection, other pests detection and unassigned reads identification.
To validate the pipeline, five objectives were foreseen: successive and correct execution of the different steps, similar detection level obtained with data processed in 2018, negligible plant host remaining reads, validated interpretation criteria for viruses and viroids and identification confirmation of all expected pests.
The three first objectives have been achieved. For the analyzed samples, the expected pests (viruses and viroids) were detected and identified reliably. The interpretation criteria establishment and validation is still underway, notably to evaluate cross contaminations. The results are promising and give hope in the pipeline validation.

DISCOVERY OF THREE NOVEL SPECIES OF CARLAVIRUS AND ONE POTEXVIRUS IN MIXED INFECTION IN HIBISCUS ROSA-SINENSIS IN COLOMBIA USING HIGH THROUGHPUT SEQUENCING

Text

The genus Hibiscus consists of numerous species of herbs, shrubs, and trees. Although hibiscus is not native to Colombia, it is well suited to its arid soil and dry climates which makes it ideal for cultivating in gardens and grows wild in tropical rainforests. Plant viruses in the genera Betacarmovirus, Begomovirus, Cilevirus, Higrevirus, Ilarvirus, Soymovirus, and Tobamovirus have been reported to infect hibiscus. Hibiscus is a well-known host for Brevipalpus transmitted viruses (BTVs) and, during surveys in the citrus growing regions in Colombia, several hibiscus samples were collected for virus testing. One of the hibiscus leaf samples from Risaralda, showing black spots on upper and lower sides, was selected for virome analysis using High-throughput sequencing (HTS) followed by bioinformatic analysis. BLASTn/BLASTx searches of assembled contigs revealed three novel sequences resembling carlaviruses and one presumed potexvirus. In addition, several contigs of Betacarmovirus, Cilevirus, Nepovirus, and Tobamovirus were also identified. All four novel viruses shared less than 70% nucleotide and 50% amino acid identities with each other and virus sequences available in the GenBank. To confirm the presence of Nepovirus and novel species of carla- and potexviruses in the same sample, RT-PCR specific primers were designed, and amplified products were sequenced. To our knowledge, this is the first report of carla-, nepo-, and potexvirus infection in hibiscus.

A NOVEL AUTOMATED WORKFLOW FOR PLANT VIRUS DIAGNOSTICS FROM HIGH-THROUGHPUT SEQUENCING DATA

Text

Several workflows have been developed for the diagnostic testing of plant viruses using high-throughput sequencing methods. Most of these workflows require considerable expertise and input from the analyst to perform and interpret the data when deciding on a plant's disease status. The most common detection methods use workflows based on de novo assembly and/or read mapping. Existing virus detection software mainly uses simple deterministic rules for decision-making, requiring a certain level of understanding of virology when interpreting the results. This can also result in inconsistencies in data interpretation between analysts which can have serious ramifications. To combat these challenges, we developed an

automated workflow using machine-learning methods, which can decrease human interaction while increasing sensitivity, specificity, and consistency. Our workflow involves three steps: sequence data mapping, feature extraction, and machine learning model training. Using real data, we compared performance of our method with other popular approaches, and show our approach increases sensitivity and specificity while decreasing the detection time for most types of sequencing data.

APPLICATION OF HIGH THROUGHPUT SEQUENCING METHODS FOR A GRAPEVINE IMPORT, EXPORT AND DOMESTIC CLEAN PLANT PROGRAMS IN CANADA

Text

Virus disease in Canadian vineyards has become a serious problem, resulting in decreased quality and yield of grapes. The only effective solution is the removal and replacement of infected plants. Growers propagating their own grapevine material can perpetuate the problem, with some recent planting testing 100% positive for unwanted virus diseases. Imported and domestically produced grapevine cuttings for planting are primarily check visually for disease which can be unreliable. Audit testing shows that this material can be infected. Growers can request lab testing, but this is expensive and/or limited and the Canadian Food Inspection Agency also has a limited capacity for audit testing of imported material. To improve testing of planting material to ensure a disease free status, rapid and comprehensive testing methods need to be developed. A collaborative project between Canadian universities, government and industry, with funding coming from Genome Canada, is developing methods, based on high throughput sequencing, for large scale testing to ensure that new grapevine planting material are free of harmful viruses. An update on this project will be presented.

Text

High-throughput sequencing (HTS), more specifically RNA-seq of plant tissue, has become an indispensable tool for plant virologists to detect and identify plant viruses. During the data analysis step, plant virologists typically compare the obtained sequences to reference virus databases only, which lead to our hypothesis that they might be missing possible traces of other pathogens in the data. In this study, we set up a community effort to re-analyze existing RNA-seq datasets used for virus detection to check for the potential presence of non-viral pathogens or pests. In total 101 datasets from 15 participants derived from 51 different plant species were re-analyzed, of which 37 were selected for subsequent in-depth analyses. In 29 of the 37 selected samples (78%), we found convincing traces of non-viral plant pathogens or pests (>100 reads per million). The most observed organism categories were fungi (15/37 datasets), insects (13/37) and mites (9/37). Nematodes were not observed and only a few samples showed the presence of plant pathogenic phytoplasmas (1/37), bacteria (3/37) and oomycetes (4/37).
In conclusion, we were able to show that it is possible to detect non-viral pathogens or pests in these metatranscriptomics datasets, in this case primarily fungi, insects and mites. With this study, we hope to raise awareness among plant virologists that their data might be useful for fellow plant pathologists in other disciplines (bacteriology, mycology, entomology) as well.

IDENTIFICATION AND CHARACTERIZATION OF RESISTANCE-BREAKING BARLEY YELLOW MOSAIC VIRUS AND BARELY MILD MOSAIC VIRUS ISOLATES IN GERMANY

STRAUCH Claudia J.. (1), NIEHL Annette. (1)

(1) Julius Kühn-Institute, Braunschweig, GERMANY

Text
Barley yellow mosaic virus and barley mild mosaic virus cause the yellowing disease in barley and lead to yield losses of 50% in infested fields. The soil-borne vector *Polymyxa graminis* transmits both viral species and forms resting spores containing infectious virus particles. Noteworthy, against *P. graminis* no environmental or economical useful treatment is known. To avoid crop losses due to the two virus species, resistant barley cultivars are used by farmers. Interestingly, even by using cultivars carrying known resistant genes, plants can be found to show virus symptoms and are tested positive in ELISA for either one or both viruses. The aim of this newly started project is to identify resistance-breaking virus-isolates by using field trials and then to characterize the virus isolates by high throughput sequencing. We hope to find characteristic changes in the virus-isolates and want to use this information to further monitor the presence of these resistant breaking virus-isolates in fields in Germany.

HIGH THROUGHPUT SEQUENCING: RESEARCH TO REALITY – THE AUSTRALIAN POST ENTRY QUARANTINE JOURNEY.

PATTEMORE Julie. (1), DINSDALE Adrian. (1), ELLIOTT Candace. (1), GAUTHIER Marie-Emilie. (2), LELWALA Ruvini. (2), BARRERO Roberto. (2)

Text
The ability to detect all viruses and viroids present in plants undergoing post-entry quarantine is the ‘holy grail’ for both plant health scientists and regulators alike. For the Australian Government Post Entry Quarantine (PEQ) facility, the aspiration has become a reality after a near-decade long journey from proof-of-concept and validation through to operationalisation. In December 2022, small RNA sequencing and VirReport bioinformatics were deployed as the primary screening tool for virus and viroid detection in imported Prunus, Rubus, Fragaria and clonal grass species at PEQ. The outcomes from this deployment include the potential to reduce quarantine lag times, thousands fewer PCR tests per year, reduced use of biological indexing, and increased capacity for higher volumes of plant imports as a result of increased availability of glasshouse bench space. We anticipate that adopting high throughput sequencing (HTS) will enable plant industries to remain competitive and access more rapidly emerging high-value market opportunities.

EXPLORING PRACTICAL APPLICATIONS OF METABARCODING WITH MINION TO SUPPORT THE SURVEILLANCE OF THE PHLOEM BACTERIA “CANDIDATUS PHYTOPLASMA” AND “CANDIDATUS LIBERIBACTER”

EVERAERT Ellen. (1), DE JONGHE Kris. (1), SLOS Dieter. (1), HEYNEMAN Maaike. (1), **HAEGEMAN Annelies. (1)**

Text
“*Candidatus* Phytoplasma” and “*Candidatus* Liberibacter” are non-culturable, wall-less phloem bacteria linked to various plant diseases. Some species are quarantine pathogens

while others are regulated non-quarantine pathogens (RNQPs). Hence, a fast detection and correct identification is key for both farmers and authorities. In currently available methods, after detection, additional molecular analyses are needed to identify the correct species and its haplotype or (sub)group. Moreover, both pathogens are known to occur together sometimes making detection and identification dependent on several PCR assays.
In the METAMINSURV project, MinION metabarcoding targeting multiple loci will be evaluated to combine broad detection and identification of both types of phloem bacteria in one test. In silico analyses will be done to evaluate and select barcode(s) and primers to be able to target and distinguish as many species, haplotypes and/or (sub)groups as possible. Mock and spike communities will be prepared by mixing DNA, plant or insect samples with gBLOCKs from known species in different concentrations. MinION metabarcoding protocols and data analysis pipelines will be optimized. Besides phloem bacteria, another case study on fungal forest pathogens from spore traps or seeds will be evaluated. METAMINSURV will hence provide insights in the usefulness of MinION metabarcoding for the detection and identification of these pathogens in terms of cost, speed, sensitivity and specificity.

APPLICATION OF NANOPORE SEQUENCING AS A VIRAL DIAGNOSTIC TOOL: THREE ACCESSIONS, THREE OUTCOMES

AMOIA Serafina Serena. (1,3), ABOU KUBAA Raied. (1), VENERITO Pasquale. (2), CILLO Fabrizio. (1), LOCONSOLE Giuliana. (1), MINAFRA Angelantonio. (1), **CHIUMENTI Michela. (1)**

Text
Traded plants for planting must be free from harmful systemic pathogens which may determine economic damages in the considered species or behave as a reservoir for further host change and crop infection.
In this context, we evaluated the sanitary status of a *Jasminum officinalis*, a *Ficus carica* and a *Solanum lycopersicum* using the nanopore MinION device (Oxford Nanopore Technologies). A cDNA-PCR, cDNA and RNA-direct sequencing protocols were used to sequence dsRNA or rRNA-depleted total RNA extracted from leaf tissues from *Jasminum* and fig. In the case of tomato, a targeted approach, with the use of virus complementary primers for the cDNA synthesis was tested. The ONT produced long-reads allowing the identification of a carlavirus (Jasmine virus C), two closteroviruses (fig virus A and fig virus B) for *Jasminum* and fig, respectively, while the full-length genome reconstruction of tomato brown rugose fruit virus and pepino mosaic virus was possible for tomato. As per other high-throughput sequencing technology, the ONT demonstrated to be suitable as an early and generic diagnostic tool before symptom onset or in symptomless plants. However, the different approaches tested produced non-comparable results in terms of coverage and number of viral reads, suggesting the need of further improving the available protocols to be more suitable for plant specimens.

DEVELOPMENT OF PCR-BASED ASSAYS FOR GRAPEVINE BADNAVIRUS 1 USING HTS DATA OBTAINED FROM INFECTED GRAPEVINES

Text

Grapevine badnavirus 1 (GBV-1; family *Calimoviridae*, genus *Badnavirus*) was detected for the first time in 2018 by high-throughput sequencing (HTS) from Croatian autochthonous grapevine varieties 'Ljutun' and 'Vlaška'. Recently, a screening of the grapevine virus collection (University of Zagreb Faculty of Agriculture) by HTS confirmed the presence of GBV-1 in four additional grapevine accessions. The collected HTS data were used to select the genomic region for primers and probe construction and to develope robust detection assays based on end-point polymerase chain reaction (PCR) and real-time PCR (qPCR). The qPCR showed 100-fold higher sensitivity compared to end-point PCR, regardless of the method of nucleic acids isolation (column-based from Qiagen or GES). Both detection methods (qPCR detectability down to a dilution of 1:10,000,000 and end-point PCR of 1:10,000) were more sensitive with nucleic acids isolation by column-based method than with GES (1:100,000 and 1:100, respectively). Using GES GBV-1 was efficiently detected by qPCR throughout dormancy and most of the growing season, with false negatives at the beginning of vegetation (April/May). The survey, conducted in 93 commercial vineyards and five grapevine collections on 4,327 vines, found that GBV-1 infections occurred only in autochthonous grapevine varieties with an overall infection rate of 13.4% and infections at specific sites/vineyards ranging from 1.9% to 96%.

QUADS INTER-LABORATORY EVALUATION OF HIGH THROUGHPUT SEQUENCING METHODS FOR PLANT VIRUS DETECTION

Text

Members of the Quadrilateral (QUAD) Working Group for Diagnostic Tools Collaboration, organized an inter-laboratory exchange to evaluate high throughput sequencing (HTS) methods for plant virus detection. A set of Prunus and Malus freeze-dried leaf samples were sent to each participating laboratory. Participants performed multiple nucleic acid extractions and sequencing of each sample using method(s) of their choice. Total, small and double stranded RNA extraction methods were represented. The datasets were evaluated for reproducibility and accuracy using several bioinformatic workflows. The individual laboratories analysed the datasets using their own bioinformatic workflows, then all four country data sets were analysed using an independent bioinformatic workflow. While each sequencing method was able to detect the viruses and viroids present, indicating that HTS is an effective screening method for plant virus diagnostics, some differences were observed and noted. While the amount of sample background or contamination was not fully evaluated, it was present to various degrees in many of the data sets and the patterns were unique to each laboratory. The exception, however, was a consistent low level of contamination in one sample detected across all the labs. These results indicate the importance of appropriate QC standards (control) and protocol validation and confirmation of HTS virus detections with a secondary test method.

TRANSCRIPTOME SEQUENCING ANALYSIS AND FUNCTIONAL VERIFICATION REVEALED THE ROLE OF EXOGENOUS MAGNESIUM IN TOBACCO ANTI-PVY INFECTION

Text

Potato virus Y (PVY) infection causes necrosis and curling of leaves, which seriously affect the yield and quality of Solanaceous crops. The role of nutrient elements in the regulation of plant resistance to virus infection has been widely reported. Previous studies in our laboratory have demonstrated that foliar spraying of MgSO4 could induce Nicotiana tabacum resistance to PVY infection by increasing the activity of defense-related enzymes. Consistent with the results, we found that exogenous magnesium (Mg) had a certain effect on Nicotiana tabacum anti-PVY infection. Meanwhile, Illumina RNA sequencing revealed that Mg induced resistance to PVY infection mainly by regulating carbohydrate metabolism and transportation, nitrogen metabolism, Ca2+ signal transduction and oxidative phosphorylation. Further more, we used TRV vector to verify the function of homologs of five Nicotiana tabacum genes involved in above pathways in Nicotiana benthamiana. The results showed that NtTPS and NtGBE were the key genes related to PVY infection, NtPPases and NtNiR were related to resistance to PVY infection, while NtCML36 did not play a role in PVY infection. Our transcriptome database and candidate genes functional verification suggested a novel strategy for resistance to PVY infection and provided a theoretical basis for virus-resistance breeding.

CHARACTERIZATION AND FUNCTION ANALYSIS OF SCMV-DERIVED VSIRNAS IN MAIZE RESISTANT AND SUSCEPTIBLE INBRED LINES

Text

RNA silencing plays an important role in plant antiviral responses, which triggered production of virus-derived small interfering RNAs (vsiRNAs). Sugarcane mosaic virus (SCMV) infection causes serious economic losses worldwide in maize (*Zea mays* L.). In this study, the maize inbred lines Chang7-2 (resistant to SCMV) and Mo17 (susceptible to SCMV) were inoculated with SCMV (SC, SM) and phosphate buffer (MC, MM), respectively. The systemically infected leaves were harvested to perform whole-transcriptome RNA-seq and degradome sequencing. The results showed that the distribution of vsiRNAs on the sense strand of SCMV genome was higher than that on the antisense strand in both SC and SM libraries. The accumulation level of 21-nt vsiRNAs was higher in SM libraries, while more 22-nt vsiRNAs were accumulated in SC libraries. Through degradome sequencing, we identified 706 transcripts targeted by 204 vsiRNAs. The competing endogenous RNA (ceRNA) networks in SCMV-infected Chang7-2 and Mo17 were constructed and verified. Our results also showed that the transcripts of *DCLs*, *AGOs* and *RDRs* were differentially accumulated in resistant and susceptible maize plants after SCMV infection, which were associated with the production and function of vsiRNAs. These findings provide novel insights into the relationship between SCMV-derived vsiRNAs and potential ceRNA networks in resistant and susceptible maize materials.

TRANSCRIPTOMIC AND BISULFITE SEQUENCING IN PAPAYA PLANTS INFECTED WITH BABACO MOSAIC VIRUS (BABMV)

Text

Babaco mosaic virus (BabMV) infects babaco plants (Carica pentagona). Due to genetic similarities with babaco, papaya plants (Carica papaya) were used to identify the transcriptomic and methylation responses occurring after BabMV infection. We performed RNA and Bisulfite sequencing of 32 samples of papaya leaves from plants infected with the BabMV evaluated at -2, -10, 15- and 30-days post-infection. Illumina reads quality for each sample was checked using FASTQC in Galaxy and mapping to papaya genome was performed with HiSat2 for transcriptomic reads and Bissmark tool for mapping and global cytosine methylation level for DNA sequences. Statistical analysis was carried out by multi-contrast test using Deseq2 for the transcriptomic analysis and logistic regression using the Methylkit package in Rstudio for the DNA reads, For the differential analysis FDR corrected p value <0.05 and log2 fold change > 0.5 criteria were used to select the differentially expressed genes and regions per CpG sites. In addition QTC clusters were constructed to

identified the gene patterns in both analyses. 1585 genes were differentially expressed in the RNA and 508 methylation sites in the DNA samples, GO overrepresentation analysis indicate changes in protein synthesis, oxidative stress and polysaccharide metabolism at 15- and 30-dpi. The use of both next generation sequencing techniques represents an important contribution to understanding the response of the plant to the virus infection.

How to combine remote sensing with epidemiological modelling to improve plant disease management?

CAN REMOTE SENSING DATA IMPROVE MATHEMATICAL MODELS FOR TACTICAL DECISION MAKING AND FUNGICIDE APPLICATION?

FEDELE Giorgia. (1), SALOTTI Irene. (1), CAFFI Tito. (1), **ROSSI Vittorio. (1)**

Text

Remote sensing has supported applications on crop fertilization and irrigation, weed management and yield estimates. Applications for disease control, however, are still at small-scale, pilot development. How to use remote sensing data in decision making for tactical crop protection needs further investigation. These tactical decisions include (i) whether and when a fungicide application is needed, (ii) which fungicide(s) should be used, and (iii) at what dosage, which are supported by disease and fungicide models. Disease models provide information on infection events and their severity, and on the length of incubation and latent periods, so they guide fungicide timing and the activity the fungicide may have (pre- or post-infection, pre- or post-symptoms). Fungicide models define the degree and the duration of the fungicide activity; these models can be complemented by plant growth models that help estimating the fungicide dilution after application. Remote sensing data have the potential to supplement disease, plant and fungicide models in order to improve models' outputs and, finally, decision making. For instance, early detection of infection can be used to validate disease model predictions and support pre-symptom application of fungicides. Assessment of plant growth and development through vegetational indexes can improve the accuracy of fungicide models and support better (and spatially variable) definition of the fungicide dosage. Examples are provided for vineyards.

PAIRING HIGH RESOLUTION SATELLITE IMAGERY AND TERRESTRIAL ROBOTICS TO DETECT AND MONITOR GRAPEVINE DOWNY MILDEW EPIDEMICS

Text

Grapevine downy mildew (GDM), caused by the oomycete *Plasmopara viticola*, plagues humid production regions and can cause 100% yield loss and vine death under conducive conditions. Growers currently rely on frequent fungicide applications for control, but this practice has led to widespread resistance. Rapid remote detection and mapping of GDM outbreaks would enable precision pesticide applications to target high performing but resistance-prone fungicides where and when most needed, while relying on less resistance-prone protectants elsewhere. To actualize this vision, we investigated two platforms for GDM surveillance: high resolution, multispectral satellite imagery and a terrestrial robotic imaging system at the Cornell Pathology Vineyard in Geneva, New York. We evaluated several supervised and unsupervised methods to predict disease severity using satellite spectral features as input. Spectra and vegetation health indices derived from Planet Labs SkySat imagery (50cm pixel size) could differentiate between healthy and diseased vines even at low GDM severity (10% symptomatic leaf area). Automated severity ratings derived from rover-based imagery also correlated well with human scout ratings ($r > 0.75$). Our next step is to integrate the two systems by training satellite imagery on rover generated severity maps. Our results thus far indicate that both satellite and terrestrial robotic platforms are promising methods for mapping GDM incidence and severity.

INTEGRATING REINFORCEMENT LEARNING AND EPIDEMIOLOGICAL MODELS FOR DISEASE CONTROL OPTIMISATION WITH LIMITED INFORMATION

TRIMBLE Rachel. (1), CUNNIFFE Nik. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text

Epidemiological modelling is well established as a method to evaluate options for control of epidemics across human, animal and plant health. Those advising stakeholders may simulate the model to trial management strategies or use analytical techniques to optimise control. However, trial and error analysis risks selecting suboptimal strategies and analytical models require significant approximations to be tractable for realistic systems. Reinforcement learning is an approach to optimise sequential decision making which has been used in fields as wide ranging as chess, robotics and control of fusion reactors. The target problem is framed as interactions between an agent and an environment (in this case, a simulated epidemic) and the algorithm learns to optimise the outcome (e.g. the number of plants lost to disease) by targeted exploration of the state space. A key challenge for any control optimisation is acting in situations with partial observability — where parts of the system can be observed but the underlying state of the system is not known. This work applies reinforcement learning to a model of landscape level plant disease spread and breaks down how different elements of model observability and environment formulation make the learning more or less effective. In the context of remote sensing, this work may provide insights into how improving different types of observability in landscape scale epidemic control can improve our ability to optimise epidemic outcomes.

INTEGRATING REINFORCEMENT LEARNING AND EPIDEMIOLOGICAL MODELS FOR OPTIMISATION OF INVASIVE PLANT DISEASE CONTROL

In the context of remote sensing, this work may provide insights into how improving different types of observability in landscape scale epidemic control can improve our ability to optimise epidemic outcomes.

COMBINING IMAGING AND SPATIALLY-EXPLICIT MODELLING FOR THE STUDY OF PLANT DISEASES : LESSONS LEARNED FROM THE STUDY OF PLANT PATHOGEN LESIONS

LECLERC Melen. (1)

(1) INRAE, Le Rheu, FRANCE

Text
The use of mathematical models offers a mean to analyse epidemiological data. Despites the recent development of imaging technologies to monitor plant diseases at various scales, these new data are still seldom used to fit mechanistic models and estimate key parameters.

In this presentation we present how combining image-based phenotyping with reaction-diffusion models provides new insights into the spread of plant pathogen lesions. The proposed approach consists in i) monitoring inoculated leaflets through imaging, ii) using computer vision methods to align images to each other and segment symptomatic tissues, and iii) fitting a reaction-diffusion model to image sequences with a variational data assimilation approach. This modelling framework was used to analyse data obtained on several pathosystems for a range of pathogen isolates and plant cultivars. It enables one to disentangle the processes involved in host-pathogen interactions and gives new quantitative traits for assessing host resistance and/or pathogen aggressiveness.

Similar approaches may be implemented by plant disease epidemiologists to understand the

spread of pathogens at larger spatial scales using remote sensing data. Besides the methods used for processing images produced by remote sensing, modellers will have to integrate image-data assimilation methods and perhaps, take into account the errors produced by computer vision algorithms to better estimate the parameters of mechansitic models.

PREDICTING STRESS CAUSED BY GRAPEVINE POWDERY MILDEW WITH NASA AIRBORNE IMAGING SPECTROSCOPY IN NAPA VALLEY, CALIFORNIA

Text

Powdery mildews cause $42.8B in damage annually and are notoriously ubiquitous with 10,000+ host species on all crop producing continents. Grapevine (Vitis vinifera) Powdery Mildew (GPM; Erysiphe necator) is responsible for >90% of negative environmental consequences associated with vineyard management globally as effective control necessitates high frequency fungicide application. While mechanistic models to predict GPM incidence and spread exist, their accuracy is limited by uncertainty in underlying initial disease distribution. The overall goal of this work is to develop a quantitative index for GPM rooted in disease physiology that can be used to parameterize epidemiological models with NASA Airborne Visible and Infrared Imaging Spectrometer Next Generation (AVIRIS-NG) hyperspectral imagery collected over Napa Valley, CA. We compared Normalized Difference Vegetation Index (NDVI), Red-Edge NDVI (NDVIre), Plant Senescence Reflectance Index (PSRI), and others as viable early indicators of GPM-induced stress and compared their accuracy when derived from hyperspectral and multispectral (Sentinel-2) sources. We found NDVIre derived from AVIRIS-NG to be the most accurate indicator of grapevine health and vigor as relates to potential GPM-stress, especially once vines have amassed significant foliar chlorophyll. The next step for this work is to compare the distribution yielded by our quantitative index to simulations from the Gubler-Thomas.

COMBINING REMOTE SENSING AND EPIDEMIOLOGICAL MODELLING TO IMPROVE MANAGEMENT OF RED NEEDLE CAST OF RADIATA PINE IN NEW ZEALAND

FRASER Stuart. (1), MCLAY Emily. (1), CAMARRETTA Nicolò . (1), PEARSE Grant. (1)

(1) Scion, Rotorua, NEW ZEALAND

Text

Red needle cast (RNC), primarily caused by Phytophthora pluvialis, is one of the most

important diseases of Pinus radiata (radiata pine) in New Zealand. The disease causes reddening and premature cast of needles, leading to growth loss. The disease predominantly affects the lower crown but extends to the whole of the crown in severe cases. Disease expression generally begins in autumn, with disease severity developing rapidly and peaking in winter or spring. Remote Sensing approaches are being used to investigate several aspects of RNC, including epidemiology, growth impacts, and control options, with an aim to support the development of management options. High resolution imagery from fixed cameras, UAV, fixed-wing aircraft, and satellites is used to manually score trials in mature forests. A combination of terrestrial and aerial LiDAR has been used to map mature trees to allow aerial assessments of individual trees to be combined with on-ground weather, disease, and growth data. Frameworks have also been developed for the use of high- and low- resolution satellite imagery to automatically map and monitor outbreaks of RNC. Simultaneously, data on the environmental tolerances of the different pathogen life stages are being used to develop a process-based infection risk model, for which a range of remote sensing data will be used for calibration and validation. The benefits of this multi-disciplinary approach and the specific challenges of this system will be discussed.

DETECTION OF CERCOSPORA LEAF SPOT DISEASE IN TABLE BEETS FROM UAS MULTISPECTRAL IMAGES

SAIF Mohammad . (1), CHANCIA Robert. (1), SHARMA Pratibha . (2), MURPHY Sean. (2), PETHYBRIDGE Sarah. (2), VAN AARDT Jan . (1)

(1) Rochester Institute of Technology, Rochester, UNITED STATES; (2) Cornell University, Geneva, UNITED STATES

Text

Cercospora leaf spot (CLS), caused by the fungus *Cercospora beticola* Sacc., is a severe foliar disease that affects the health of table beet crops. To effectively combat CLS, remote sensing techniques, specifically unmanned aerial systems (UAS), could offer a valuable solution for early detection and efficient fungicide application. Between June and August of 2021 and 2022, we conducted UAS flights over C. beticola inoculated table beet plots at Cornell Agritech in Geneva, NY, USA. Five bands (475, 560, 668, 717 and 840 nm) multispectral images were collected at a spatial resolution of 1 cm. CLS severity was assessed based on the percentage area of leaves affected by the disease. The severity level was evaluated by manually inspecting 20 random leaves from each plot. Vegetation indices, derived from multispectral imagery, are known to be effective in assessing plant health and disease determination. Texture features also have been reported to be effective in determining plant traits since they provide additional spatial information to the model. An initial analysis of a subsample of 2021 data produced an R2 = 0.71 using a combination of vegetation indices, reflectance values, and texture features, hinting at the possibility of CLS severity estimation from UAS multispectral images. We aim to further analyze and scrutinize our results by incorporating four flights' worth of data collected at various stages of disease severity.

HIGH RESOLUTION MULTISPECTRAL UAV IMAGERY FOR DISEASE QUANTIFICATION: AN ALTERNATIVE FOR LEAF DISEASE MANAGEMENT IN SUGAR BEET

BARRETO ALCANTARA Abel Andree. (1), ISPIZUA YAMATI Facundo Ramon. (1), MAHLEIN Anne-Katrin. (1)

(1) Institute of Sugar Beet Research, Göttingen, GERMANY

Text

In sugar beet production, managing leaf diseases is one of the most relevant activities to safeguard yield. To initiate a control measure, exhausting visual scoring activities must be conducted to release a warning signal based on disease quantification parameters such as disease incidence (DI). By the end of the growing season, a georeferenced estimation of disease severity (DS) can deliver spatial information on yield and pathogen distribution; this last aspect is crucial to track epidemics in the following years. Unmanned aerial vehicle (UAV), multispectral imagery, and deep instance segmentation networks enable an in-field detection and quantification of plant disease. The extraction parameters improve the knowledge of temporal and spatial development of disease. For determining DI and DS, the concept of scoring unit was transferred from practical use to an image-based perspective to analyze recorded fields at leaf and plot level. The results give an overview of how the accuracy of deep learning models and image-based “decision-making” criteria affects the performance of DI. Moreover, a better understanding of the disease spread is available by analyzing various metrics of DS, such as number of clusters, cluster area, and ratio of damaged leaf regions. The results of this work will deliver a possible solution to reduce the so far very laborious work of visual disease assessments in the field and thereby automate warning systems for disease management itself

CLOUD-NATIVE, MACHINE LEARNING BASED DETECTION OF GRAPEVINE LEAFROLL VIRUS IN VITIS VINIFERA WITH NASA IMAGING SPECTROSCOPY IN CALIFORNIA, USA

ROMERO GALVAN Fernando. (1), RUBAMBIZA Gloire. (1), PAVLICK Ryan. (2), WEATHERSPOON Hakim. (1), GOLD Kaitlin. (1)

Text

Early warning systems for plant disease based on remote sensing can provide rapid and accurate information for efficient resource management, thus reducing losses, expenses, and unintended negative environmental impacts. We previously found that deploying Machine Learning (ML) on spectroscopic imagery (SI) from NASA’s Airborne Visible and Infrared Imaging Spectrometer Next Generation (AVIRIS-NG) yields accurate maps of grapevine leafroll-associated virus 3 (GLRaV-3) at multiple spatial resolutions. Providing these maps to agricultural stakeholders would reduce time, expenses, and uncertainty associated with management, however, both storing SI and training/deploying ML models require significant computing and storage resources. This challenge will magnify tenfold as global SI from the forthcoming satellite Surface Biology & Geology satellite becomes available. We present a cloud-native architecture for plant disease detection to address this challenge using SI from NASA's AVIRIS-NG with GLRaV-3 as a model system. Our system processes SI into disease incidence maps using simple ML (Random Forest, optimized through SMOTE) and easily accommodates new additions and improvements, as well as shifting data modalities, without retaining potentially proprietary stakeholder information. We present an innovative system that empowers stakeholders to make data-driven plant disease

management decisions informed by cutting-edge SI while preserving reproducibility and user privacy.

MAPPING GLOBAL RISK OF FUSARIUM WILT IN A CHANGING CLIMATE WITH REMOTE SENSING AND AEROSOL TRANSPORT MODELING

Text

Fusarium oxysporum (*Fo*) is a ubiquitous soilborne fungus that can cause Fusarium wilt (FW) in 100+ crops. Uncertainties in aspects of its epidemiology and a lack of global distribution data have historically challenged monitoring and containment efforts. Our NASA Interdisciplinary Sciences project seeks to address this need by integrating remote sensing, aerosol transport modeling, and comparative genomics to build a global disease surveillance system for FW incidence and *Fo* dispersal risk in aerosolized agricultural dust. As foundation, we released an interactive, global web map documenting 4500+ FW incidences reported in peer-reviewed literature. Here, we developed a global susceptibility assessment that integrates all three aspects of the disease triangle. We identified agricultural production zones conducive to FW, noting subsets capable of serving as dust sources, by overlapping the MODIS Deep Blue algorithm with a Landsat-based cropland product. We then restricted this assessment to only regions with reported *Fo* in the past 30 years. Conducive disease environment was modeled using multiple satellite-derived products with species distribution modeling. Results from this assessment along with aerosol transport modeling can inform how related incidence sites on opposite ends of dust events may be. This integrated approach to disease surveillance can provide key insights about drivers for current and future FW distribution and the spread of *Fo* on global dust currents.

ASSESSING LONG-DISTANCE, TRANSOCEANIC AND INTERCONTINENTAL ATMOSPHERIC TRANSPORT OF SOILBORNE PLANT PATHOGENS ENTRAINED WITH AEROSOLIZED AGRICULTURAL DUST

Text

Soilborne pathogenic fungi are a leading cause of crop disease and are primarily spread through microscopic, durable spores adapted differentially for both persistence and dispersal via soil, animals, water and atmosphere. While intracontinental aerial dispersion of soilborne fungal spores has been well established, transoceanic and intercontinental atmospheric transport of these spores entrained with aerosolized agricultural dust is understudied and may contribute to disease spread. Our NASA ROSES project seeks to address this need by integrating remote sensing, aerosol transport and comparative genomics to assess the long-distance atmospheric dispersal of the plant pathogenic, soilborne fungus *Fusarium oxysporum* (*Fo*) on global dust currents. The CAM6-MIMI climate model was modified to incorporate spore traits that influence dispersal and atmospheric survival, and was parameterized using the 2020 Godzilla dust event. We found modeling evidence of transoceanic and intercontinental atmospheric transport of viable *Fo* spores and offered a danger index for *Fo* spore deposition on susceptible agricultural zones. The main long-distance transport of viable spores and the highest danger for deposition on cropland are between the regions of Eurasia, North Africa, and Sub-Saharan Africa. This study provides key insights about Fusarium wilt epidemiology and lays the groundwork to build an operational, real-time global surveillance system of long-distance plant pathogen transport risk.

COMBINING DATA AND KNOWLEDGE FOR DISEASE SPREAD MODELING AND SIMULATION SHOWN FOR CERCOSPORA LEAF SPOT IN SUGAR BEET

GÜNDER Maurice. (1), ISPIZUA YAMATI Facundo Ramón. (2), MAHLEIN Anne-Katrin. (2), BAUCKHAGE Christian. (1)

Text

For an efficient and sustainable management of plant diseases, knowledge about their temporal and spatial occurrence and development is crucial.

To enable targeted and site-specific management measures such as site-specific application, the development of models for large-scale fields is necessary. Traditional models are based on environmental parameters and knowledge on the pathogen's epidemiology, integrating management practices. More recent technologies and innovations from the field of optical sensors and artificial intelligence provide the potential to improve data- and knowledge-based models.

In this work, we present a use case of a simulation model for Cercospora Leaf Spot (CLS) in sugar beet, caused by the fungal agent Cercospora beticola. Therefore, we combine data from optical sensors mounted on drones, weather, and environmental data with epidemiological knowledge to establish a simulation model for the occurrence and development of CLS. Furthermore, we integrate and simulate different fungicide applications

and spread scenarios. As an outcome of our study, we are able to model the disease spread by Spatio-temporal Point Processes (STPPs). This approach will support the generation of risk maps and to establish specific fungicide application maps for CLS and other diseases on the field level.

MONITORING BUTT AND ROOT-ROT DISEASES USING UNMANNED AERIAL VEHICLES

DUTECH Cyril. (1), SEGURA Raphaël. (1), SAINT-JEAN Gilles. (1), BELOUARD Thierry. (2), MONNET Jean-Matthieu. (3)

(1) INRAE, Cestas, FRANCE; (2) Forest Health Department, Cestas, FRANCE; (3) INRAE, Grenoble, FRANCE

Text

Forest stands are threatened by numerous pathogens and insect pests. However, it is often difficult to estimate the dieback and mortality they cause at the scale of several stands, as well as their progression over time. Mapping of each tree in forest plots impacted by pests is necessary to estimate the epidemiological dynamics over several years. These maps are now possible on several hectares thanks to the use of high resolution aerial pictures obtained by unmanned aerial vehicles. We have developed an automated analysis of these pictures to obtain these maps and the identification of dying or decaying trees. This analysis was applied to maritime pine plots impacted by butt and root rot disease in the Landes de Gascogne massif (southwestern France). These analyses allowed to characterize the associated mortality and to test whether these telluric diseases present on the stands were associated with specific spatio-temporal structures compared to other types of mortality (bark beetles, hydric stress, ...). This method could be used to identify the emergence of new diseases associated with introductions such as pinewood nematode, and to rapidly implement eradication measures in the identified areas.

QUANTITATIVE INVERSION OF WHEAT STRIPE RUST DISEASE INDEX BASED ON UNMANNED AERIAL VEHICLE HYPERSPECTRAL IMAGERY AND PIXEL-LEVEL REGRESSION ALGORITHM

JIE Deng. (1), JUNZHENG Shi. (1), **ZHANHONG Ma . (1)**

(1) Department of Plant Pathology, China Agricultural University, Beijing, CHINA

Text

There have been many research achievements in the detection of wheat stripe rust disease based on UAV multispectral/hyperspectral remote sensing images and deep learning methods. In this study, 1,920 local wheat varieties were selected as experimental materials in Henan Province, with a planting area of 13,350 square meters. High-resolution hyperspectral images were obtained by drones at a height of 100 meters at different infection stages. Deep learning methods were used to achieve end-to-end quantitative inversion of disease index by adding a Sigmoid activation function and using continuous loss functions such as Laplacian Loss. The study also compared the model performance with different loss functions, model architectures, with or without the addition of the PSA module, and different datasets. The results showed that the LaplacianLoss+MSELoss loss function and the

HRNet_W18 algorithm model had the best performance, with an R2 of 0.875 and an mean average error(MAE) of 0.0129 on the test set. After adding the PSA module, the R2 reached 0.880, and the MAE was 0.0123. When using a few feature indices for modeling (such as 6 feature indices modeling), the model recognition effect decreased significantly to 0.829 compared to the full-band modeling. The results showed that end-to-end modeling based on deep learning algorithms can be directly carried out on the full band to reduce data analysis steps and achieve better inversion effects.

CLASSIFICATION OF SOUTHERN CORN RUST SEVERITY BASED ON LEAF-LEVEL HYPERSPECTRAL DATA COLLECTED UNDER SOLAR ILLUMINATION

JIANMENG Gao. (1), YUE Ma. (1), **ZHANHONG Ma . (1)**

(1) Department of Plant Patholoy, China Agricultural University, Beijing, CHINA

Text

Maize is one of the most important crops in China, and it is under a serious, ever-increasing threat from southern corn rust (SCR). SCR has spreaded northward to northeast China, causing severe yield loss. Thus, a cost-effective, real-time detection method is required. The identification of wheat rust based on hyperspectral data has been proved effective. For SCR research, the reliability and usability of spectra collected under solar illumination (SCUSI) need to be explored.In this study, full-range hyperspectral data (350~2500 nm) were collected under solar illumination, and SCUSI were separated into several groups according to the disease severity, measuring height and leaf curvature. Ten indices were selected as candidate indicators for SCR classification, and their sensitivities to the disease severity, measuring height and leaf curvature, were subjected to analysis of variance (ANOVA). The better-performing indices according to the ANOVA test were applied to a random forest classifier, and the classification results were evaluated by using a confusion matrix. The results indicate that the PRI was the optimal index for SCR classification based on the SCUSI, with an overall accuracy of 81.30% for mixed samples. The results lay the foundation for SCR detection in the incubation period and reveal potential for SCR detection based on UAV and satellite imageries, which may provide a rapid, timely and cost-effective detection method for SCR monitoring.

INTEGRATING UAS-BASED MULTISPECTRAL IMAGING AND EPIDEMIOLOGICAL MODELING IN CEREAL CROPS

GONGORA-CAUL Carlos. (1), ZHANG Chongyuan. (1), OH Sungchan. (1), **CRUZ Christian. (1)**

Text

Detecting and estimating disease intensity at the plant population level primarily rely on visual sign and symptom assessments. This traditional approach can be reliable if done correctly but labor-intensive, low-throughput, and prone to human subjectivity. Evidence suggests that sensor-based technologies offer a new opportunity to quantify disease intensity. Our group seeks to combine imagery and epidemiological modeling using wheat

blast and corn tar spot as model systems. Through manuscripts published in 2020 and 2021, we demonstrated that the intensity of wheat blast or corn tar spot could be quantified using UAS-based multispectral imagery with varying levels of accuracy ($0.69<\rho_c<0.92$). In 2023, we demonstrated that image-based features and machine learning could be used to estimate tar spot epidemiological parameters from UAS-based multispectral images collected in field efficacy trials. Disease severity was assessed visually at three canopy levels within micro-plots for two years, while aerial images were gathered with UASs equipped with multispectral cameras. The developed models estimated disease severity at distinct canopy levels ($r\geq0.93$; $\rho_c\geq0.97$), and data were used to model disease progression. Parameters y_0 and AUDPC derived from visual and estimated disease severity were similar, but significant differences ($\alpha=0.05$) between K_{max} or r_L were found. Further studies are required to improve or transfer methods.

THE UTILITY OF PROXIMAL SENSING AND DEEP LEARNING IN THE DETECTION AND CHARACTERIZATION OF TAR SPOT EPIDEMICS ON CORN IN THE UNITED STATES

Text

In recent years, the widespread incorporation of image sensors through proximal or aerial remote sensing has proven their utility as an alternative approach to conventional, human-vision-based disease estimation. Nevertheless, from a disease management standpoint, obtaining objective, accurate, and high-throughput measurements of signs and symptoms during the growing season are critical in sensor-based phenotyping. Since its first identification in 2015 in the United States., tar spot of corn caused by *Phyllachora maydis* has rapidly spread from Illinois and Indiana through the corn belt and south to Florida. The detrimental impact on yield and the polycyclic nature of tar spot epidemics have made this disease one of the most significant emerging diseases of corn in the United States. In my talk, I will share our work towards developing a pipeline consisting of the previously developed Stromata Contour Detection Algorithm (SCDA v1) and the generation of a Convolutional Neural Network (CNN). Our approach allows high-throughput and automated detection and quantification of tar spot stromata in Red-Green-Blue (RGB) images of corn leaves collected at multiple experimental sites in Indiana in 2021 (onset to later stages of tar spot development). Our work will serve as a foundation for building an accurate and reliable standardized approach that can be utilized nationally and internationally for tar spot research, disease management, surveillance, and epidemiological modeling.

QUANTIFYING VCMAX AND PLANT TRAITS TO MONITOR FOREST DECLINE SYMPTOMS BY COUPLING SATELLITE IMAGES AND BIOPHYSICAL MODELS

Text

As climate change and globalization are changing forest pathogens and pests distributions and dynamics, accurate forest health monitoring (FHM) systems are increasingly sought after by forest managers to detect and prevent forest disturbances. We developed a hybrid machine learning approach that couples the SCOPE radiative transfer model with Sentinel-2 (S2) satellite time series to estimate maximum carboxylation rate (Vcmax) and leaf biochemical constituents. We found that our predictions matched with the estimates of gross primary productivity better in deciduous broadleaf forests than in forests dominated by needle-leaved evergreen trees. To verify the effectiveness of the proposed FHM system, we explored its capacity to estimate key plant physiological traits and red-edge spectral indicators in the Pinus pinea L. (Stone pine) forest stand monitored through the San Rossore 2 ICOS Ecosystem station in Italy, where an outbreak of a parasitic fungal infection occurred in the summer of 2020. The results reveal that the Vcmax, pigments, leaf water content and the red-edge indicator S2 showed to be more effective than conventional indices (e.g., NDVI) for the early detection of this fungal infection. Our work demonstrates the potential of coupling radiative transfer models and S-2 images to monitor plant physiological traits in support of FHM activities, particularly in the context of pest epidemics

REMOTE SENSING IN SUPPORT OF PLANT DISEASE DETECTION AT DIFFERENT SPATIAL SCALES

DELALIEUX Stephanie. (1), TITS Laurent. (1)

(1) VITO, Mol, BELGIUM

Text

For an efficient Integrated Pest Management (IPM), the ability to monitor the plant’s health status to early spot diseases has proven essential. Among the methods to monitor plant diseases, remote sensing (RS) stands out as an excellent tool. However, along with a wide diversity of plant monitoring needs, there is also a wide variety of RS-based plant disease monitoring tools, each tailored to specific needs within the IPM. Within-field monitoring tools, such as sensors mounted on tractors, are critical in many production systems for which disease symptoms cannot be properly detected from a top-view perspective. This has been demonstrated in pear orchards for fire blight detection. Drones on the other hand, provide detailed information at the field level, enabling the monitoring of individual leaves and plants. This has proven to be useful in the detection of, e.g., Powdery Mildew in sugar beets, or Banana Wilt Disease. The downside of this technology is however the revisit time as well as the scalability to the regional level. To this end, satellites have demonstrated their potential in providing frequent and large-scale information on the phenological stages of crops as well as on their general health condition, both essential for a proper disease spread modelling.

Based on VITO's long-standing research in the use of RS technology for disease detection and monitoring, an overview of these technologies will be presented, together with their merits and pitfalls.

SPREAD OF NEOPESTALOTIOPSIS SP. CONIDIA FROM STRAWBERRY UNDER CONTROLLED CONDITIONS

GAMA Andre. (1), BAGGIO Juliana. (1), ALONZO Galvin. (1), **PERES Natalia. (1)**

(1) University of Florida, Wimauma, UNITED STATES

Text

The Florida strawberry industry has been recently affected by a new species of Neopestalotiopsis that is more aggressive and has caused significant losses. Since the fungus had been considered of secondary importance, little is known about its life cycle. Thus, experiments were set up in a wind tunnel to evaluate the dispersal of the pathogen from symptomatic strawberry leaves, fruit, as well as dried senescent leaves, and inoculated sandy soil. Plates with selective media for Neopestalotiopsis spp. were placed at 0.6, 1, 3, 5, and 7 m away from the inoculum sources, and the following treatments were tested: 5 m/s, 5 m/s + water, 7 m/s, and 7 m/s + water. To describe the dispersal gradients, an exponential model was fitted to the number of colony-forming units of Neopestalotiopsis sp. found on the plates and to the distance from the inoculum source. The exponential model described the dispersal gradient for treatments with water, although a few colonies were found in the treatments without water. The highest number of CFU were found in plates where strawberry fruit and strawberry dried leaves were the inoculum sources. Most inoculum moved less than 1 m, regardless of the inoculum source. The 7 m/s wind + water moved the inoculum further than 5 m/s + water. Our data suggest that Neopestalotiopsis dispersal occurs within short distances, but higher wind speeds, which commonly occur during storms in Florida, may move conidia longer distances.

VOLATILE ORGANIC COMPOUNDS -CHEMICAL SIGNALS TO COMMUNICATE PLANT HEALTH

FICKE Andrea. (1), ASALF Belachew. (1), NORLI Hans Ragnar. (1)

(1) Norwegian Institute of Bioeconomy Research (NIBIO), Aas, NORWAY

Text

Plants and their respective pests, including pathogens, communicate their physio-chemical status to their surroundings by emitting volatile organic compounds (VOCs). The specificity and uniqueness of these VOCs could be utilized as "infochemicals" to detect, identify and monitor diseases. Pre-symptomatic detection would allow more targeted and less resource intensive pest control strategies to be employed. In addition, the release of pathogen-related VOCs might elicit defense responses in neighboring plants that delay the spread of the disease within the crop stand. As such, the study of VOCs holds an untapped potential in plant pathogen epidemiology and management. We have collected VOCs emitted from wheat grown both in the greenhouse and in the field exposed to different fungal pathogens and identified those compounds emitted from infected plants by GC-MS. Concentrations of VOCs were very low, but the target diseases could be identified based on the VOC profiles of

the infected host plants. The project ‘PurPest- Plant Pest Prevention through technology-guided monitoring and site-specific control', currently funded by EU’s Horizon Europe program, is exploring the most recent sensor technology to detect and identify pathogens and insect pests based on their VOC signature in host plants to limit their spread, target control measures and better understand the drivers of pest invasion.

A MODELLING APPROACH TO MAP THE RISK OF HLB IN THE IBERIAN PENINSULA

ELLIS John. (1), LAZARO HERVAS Elena. (3), VICENT CIVERA Antonio. (3), PARNELL Stephen. (2), CUNNIFFE Nik. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM; (2) University of Warwick, Warwick, UNITED KINGDOM; (3) Instituto Valenciano de Investigaciones Agrarias, Valencia, SPAIN

Text

Huanglongbing (HLB), or citrus greening, is a devastating citrus disease, currently found in Asia, Africa and North and South America. At present, no cases of HLB have been found in Europe, but in the past decade one of the disease vectors, the African citrus Psyllid (AfCP), has been found in several locations in North-Western Spain and Portugal. The presence of an established vector population means there is a high risk of transmission between citrus if HLB is subsequently introduced.

We present the findings of a 1 km^2 computational model of vector and pathogen spread in the Iberian Peninsula. The density of citrus in residential areas and commercial orchards, as well as climate suitability, influence the pattern of spread. The majority of vectors disperse locally and are dependent on the availability of citrus plants, but we also account for long-distance dispersal via mechanisms such as wind or human transportation. Using the current estimated distribution of AfCP as an initial condition, results often show a pattern of slow growth of the psyllid in the North-West. However, once long distance dispersal or new introduction of psyllid into the densely populated commercial citrus regions in the South or East of Spain occurs, the population quickly increases. There is subsequently a high risk of rapid spread of HLB upon the introduction of an infected plant in this region.

AN EPIDEMIOLOGICAL MODEL TO ASSESS THE EFFICACY OF MONITORING TECHNOLOGIES FOR EARLY DETECTION OF TREE PESTS AND PATHOGENS AT LOCAL AND TREESCAPE LEVELS

MCMENEMY Paul. (1), KLECZKOWSKI Adam. (1), GAULTON Rachel. (2), POCOCK Michael. (4), BROWN Paul. (3)

(1) University of Strathclyde, Glasgow, UNITED KINGDOM; (2) University of Newcastle, Newcastle, UNITED KINGDOM; (3) FERA, York, UNITED KINGDOM; (4) UK Centre for Ecology and Hydrology, Bangor, UNITED KINGDOM

Text

Trees are an essential natural resource that stores carbon, provides habitats and food for wildlife and is an important ecosystem service. Nevertheless, they are under increasing threat from pests and pathogens. Efficient monitoring of tree conditions is needed to respond

efficiently to plant health threats and minimise the risk of new outbreaks. Monitoring of tree health through visual inspection alone is prone to error and bias and consumes time, monetary and human resources. Thus, it would be in the interest of stakeholders if tree health could be assessed and monitored rapidly while utilising sensors and technologies, from Internet of Things (IoT) devices through drones and satellite imagery which in addition offer continuous monitoring. However, each of the technologies comes with limitations and costs. We assess their monitoring potential with a spatially-extended metapopulation model of a landscape consisting of woodland parcels, incorporating both local and long-distance spread. We include the IoT/visual inspections, which are potentially able to detect low levels of stress but at a high cost and low frequency. We contrast this approach with satellite imagery which offers continuous monitoring over large areas, but with a significantly lower resolution. The detection process is quantified by the time from the start of the epidemic to the first detection. We then relate the efficacy to the total cost of the monitoring programme.

ESTIMATING BEET YELLOWS SEVERITY AT PLOT RESOLUTION WITH SATELLITE OBSERVATIONS

SOUBEYRAND Samuel. (1), JOUDELAT François. (2), RYNKIEWICZ Joseph . (3), GABRIEL Edith. (1)

(1) INRAE, Avignon, FRANCE; (2) ITB, Paris, FRANCE; (3) Université Paris 1 Panthéon-Sorbonne, Paris, FRANCE

Text

Beet yellows is now perceived as a major problem in plant health in Europe due to the modification of the regulations concerning the use of phytosanitary products. An agro-ecological approach to this issue requires actions at multiple levels, via prophylaxis, treatments and insurance systems in particular. To implement these actions effectively, we need an increased level of information. With this in mind, we are interested in a way to estimate the severity of beet yellows at plot resolution over large territories. We have thus developed an approach combining field observations (precise but partial) and satellite observations (less precise but with a high coverage rate). We tested different supervised approaches exploiting raw images or indices calculated on the basis of images, as well as a post hoc approach allowing to integrate multi-scale dependencies between observations.

A COMPARTMENTAL MATHEMATICAL MODEL BASED ON APHID FEEDING BEHAVIOURS ALLOWS MORE REALISTIC MODELLING OF NON-PERSISTENTLY TRANSMITTED PLANT VIRUSES

FALLA Elin. (1), CUNNIFFE Nik. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text

Plant viruses threaten global food security and are often transmitted by arthropod vectors. Non-persistently transmitted (NPT) plant viruses are characterised by a very short virus retention time in the vector and are transmitted almost exclusively by aphids. Compartmental models using ordinary differential equations to capture the course of an epidemic have been used in plant virus epidemiology for decades. However, the underlying model structure, in

which the infective period of vectors is fixed, omits a key feature of non-persistent transmission: probing or feeding on a plant is often what causes an aphid to lose its infectivity. A recent model by Donnelly et al. (2019) captures this behaviour via a Markov chain that tracks the behaviour of individual aphids. We introduce a new compartmental model which replicates this model, while allowing the easy extensibility characteristic of compartmental models. It is comprised of linked Susceptible-Infected models for the plants and aphids, where loss of aphid infectivity is conditioned upon its probing and feeding behaviour, rather than occurring at a fixed rate. This additional biological realism means our model behaves differently to previous compartmental models of NPT viruses, therefore allowing us to more accurately investigate virus transmission dynamics for all NPT systems. We focus on the case of viral manipulation of host plant phenotype, which changes aphid landing and feeding behaviour to enhance virus spread.

DISEASE CLIMATIC RISK MODEL INTERPRETATIONS AT MULTIPLE SPATIAL SCALES

CAMPBELL Rebecca. (1), BERESFORD Robert. (2)

(1) The New Zealand Institute for Plant & Food Research, Motueka, NEW ZEALAND; (2) The New Zealand Institute for Plant & Food Research, Auckland, NEW ZEALAND

Text

Climatic risk models are often used to help understand the areas and seasons where invading organisms will have the greatest risk of establishing and causing a negative impact. These risk models often make predictions for a large spatial scale using inputs of time-averaged climatic data (e.g. annual). However, many organisms respond to, or have mechanisms influenced by, much shorter time scales (e.g., diurnal effects) and finer spatial scales (e.g., microclimate effects). Large-scale averaging may hide important information and could lead to misrepresentation of the dynamics of pathogen and pest populations and their spread in time and space. This risks misinterpretation of risk and errors in surveillance and management efforts. We use the existing myrtle rust (*Austropuccinia psidii*) climatic risk model in conjunction with field data, as an example to explore the scale of variability in microclimate variables across forest edges and what that could mean for risk model interpretations. These are compared to risk predictions from the national forecast grid, regional weather stations and local weather stations. We discuss the implications of these comparisons to risk predictions for future incursion responses, for example *Xylella fastidiosa*, and what resolution is ‘good enough’ for what particular purpose.

MEASURING PLANT STRUCTURE AND FUNCTION USING OPTICAL REMOTE SENSING – CURRENT STATUS AND RECENT ADVANTAGES OF AIRBORNE AND SATELLITE REMOTE SENSING AND THEIR POTENTIAL FOR DISEASE DETECTION

RASCHER Uwe. (1)

(1) Forschungszentrum Jülich, Jülich, GERMANY

Text

We have experienced a great increase of earth observation satellites in the past years and

nowadays a large number of satellite earth observation products are available on user-friendly plattforms. Despite this large number of remote sensing products it remains a challenge to early detect plant diseases from satellite data. The main challenges are related to the small symptoms that often are hidden in the large satellite imagery and insufficient revisiting time of many satelllite platforms.
In this didactical presentation an introduction on the basis of optical remote sensing is given and recent advances in Earth Observation will be highlighted. Existing multi-spectral mission, recently launched hyper-spectral mission concepts, as well as fluorescence and thermal approaches will be reviewed on their potential for disease detection.

HIGH-RESOLUTION HYPERSPECTRAL AND THERMAL IMAGING FOR THE EARLY DETECTION OF PLANT DISEASES. PROSPECTS AND LIMITATIONS.

ZARCO-TEJADA Pablo J.. (1), POBLETE Tomas. (1), CAMINO Carlos. (2), CALDERON Rocio. (3), HORNERO Alberto. (4), HERNANDEZ-CLEMENTE Rocio. (5), GONZALEZ-DUGO Victoria. (4), LANDA Blanca B.. (4), NAVAS-CORTES Juan A.. (4)

Text
Progress in the last 20 years in thermal and imaging spectroscopy has advanced tremendously, allowing the large-scale monitoring of crop physiological processes. Successes have been obtained in biotic and abiotic stress detection, particularly through sensor miniaturization and innovative physically- and artificial intelligence-driven modelling techniques. These developments have enabled the screening of subtle physiological changes through spectral analysis. Remote sensing efforts as part of European initiatives (POnTE, XF-ACTORS and recently BeXyl), and through regional programs have focused on the development of algorithms for the early detection of Xylella fastidiosa and Verticillium dahliae -induced symptoms. These studies have shown that using specific spectral plant traits successfully reveals infections at early / pre-visual stages. Nevertheless, several issues remain to be addressed, such as i) lack of high spatial resolution hyperspectral satellite images to detect subtle physiological changes on individual tree crowns; ii) lack of high-resolution thermal imagery to detect changes linked to transpiration reduction in infected vegetation; iii) lack of suitable multispectral bandsets in commercial satellite sensors; and iv) limited scale coverage of airborne hyperspectral and thermal sensors (i.e. drones and piloted platforms). These aspects will be discussed in the context of global detection and monitoring of harmful organisms causing plant diseases.

OMGN: Oomycete Molecular Genetics Network Annual Meeting

WHOLE GENOME SEQUENCING AND PHYLOGENOMIC ANALYSIS SHOW SUPPORT FOR THE SPLITTING OF GENUS PYTHIUM

NGUYEN Hai. (1)

(1) Agriculture and Agri-Food Canada, Ottawa, CANADA

Text

The genus *Pythium* (nom. cons.) sensu lato (s.l.) is composed of many important species of plant pathogens. Early molecular phylogenetic studies suggested paraphyly of *Pythium*, which led to a formal proposal by Uzuhashi and colleagues in 2010 to split the genus into *Pythium* sensu stricto (s.s.), *Elongisporangium*, *Globisporangium*, *Ovatisporangium* (= *Phytopythium*), and *Pilasporangium* using morphological characters and phylogenies of cox2 and 28S rDNA. Although the split was fairly justified by the delineating morphological characters, there were weaknesses in the molecular analyses, which created reluctance in the scientific community to adopt these new genera for the description of new species. In this study, this issue was addressed using phylogenomics. Whole genomes of 109 strains of *Pythium* and close relatives were sequenced, assembled, and annotated. Phylogenomic analyses were performed with 148 single-copy genes represented in at least 90% of the taxa in the data set. The results showed support for the division of *Pythium* s.l. The status of alternative generic names that have been used for species of *Pythium* in the past (e.g., *Artotrogus*, *Cystosiphon*, *Eupythium*, *Nematosporangium*, *Rheosporangium*, *Sphaerosporangium*) was investigated. Based on our molecular analyses and review of the *Pythium* generic concepts, we urge the scientific community to adopt the concepts proposed by Uzuhashi and colleagues in 2010 in their work going forward.

AN OPEN-ACCESS T-BAS PHYLOGENY FOR EMERGING PHYTOPHTHORA SPECIES

COOMBER Allison. (1), SAVILLE Amanda. (1), CARBONE Ignazio. (1), **RISTAINO Jean. (1)**

(1) NC State University, Raleigh, UNITED STATES

Text

Phytophthora species cause severe diseases on food, forest, and ornamental crops. We developed an open access phylogenetic tool using the Tree-Based Alignment Selector Toolkit (T-BAS) for 192 formally described species of Phytophthora and 33 informal taxa in the genus *Phytophthora*. The phylogenetic tree uses sequences of eight nuclear genes and was inferred using the RAxML maximum likelihood program. A search engine was developed to identify microsatellite genotypes of *P. infestans* based on genetic distance to known lineages. The T-BAS tool provides a visualization framework allowing users to place unknown isolates on a curated phylogeny of all *Phytophthora* species. The tree can be updated in real-time as new species are described. The tool contains metadata including clade, host species, substrate, sexual characteristics, distribution, and reference literature, which can be visualized on the tree and downloaded for other uses. This phylogenetic resource will allow data sharing among the global *Phytophthora* community and the database will enable users to upload sequences and determine the phylogenetic placement of an isolate within the larger phylogeny and download sequence data and metadata. The database will be curated by *Phytophthora* researchers and is housed on the T-BAS web portal in the Center for Integrated Fungal Research at NC State. The T-BAS web tool can be

leveraged to create similar metadata enhanced phylogenies for other Oomycete, bacterial or fungal pathogens.

DNA METABARCODING AS A SUPPORT TOOL OF TRADITIONAL ISOLATION METHODS TO DESCRIBE THE COMPLEXITY OF PHYTOPHTHORA COMMUNITIES

Text

With the advent of the new millennium, traditional PCR has become the most reliable tool for the identification of cultured microorganisms. Recently, advancements in molecular technologies paved the way to 'omic sciences', new disciplines leading to the description and interpretation of communities of microorganisms in complex biological samples. Among these sciences, the DNA metabarcoding is emerging as the best support tool for the surveillance of *Phytophthora* communities within environmental samples carried out by traditional isolation. In this study, leaf baiting isolation and DNA metabarcoding were used to describe *Phytophthora* communities from soils of a nature reserve, a botanical garden and a citrus orchard. Overall, 155 baited isolates and the 32 metabarcoding-ASVs leaded to the identification of 21 *Phytophthora* taxa, including species exclusively recorded by baiting (*P. bilorbang*, *P. cryptogea*, *P. gonapodyides*, *P. parvispora* and *P. pseudocryptogea*), species exclusively detected by metabarcoding (*P. asparagi*, *P. occultans*, *P. psycrophila*, *P. syringae*, *P. aleatoria*/*P. cactorum*, *P. castanetorum*/*P. quercina*, *P. iranica*-like, and 5 unknown *Phytophthora* taxa) and species in common with both techniques (*P. citrophthora*, *P. multivora*, *P. nicotianae* and *P. plurivora*). Results suggested that the combination of leaf baiting and metabarcoding is the best approach to gain the most comprehensive diversity of *Phytophthora* communities in soil samples from different environments.

HEAVY RAINFALL HAS GIVEN RISE TO SEVERE CROP DISEASES CAUSED BY PHYTOPHTHORA SPP. IN TAIWAN

HUANG Jin Hsing. (1), YUAN Chin Ya . (1)

(1) Taiwan Agricultural Research Institute, Taichung City ,, TAIWAN

Text

In Taiwan, heavy rainfall has been the most typical severe weather event in summer, causing various crop diseases. Most diseases were caused by *Phytophthora* spp., including Phytophthora blight of Welsh onion, Phytophthora blight of cucurbits, Phytophthora heart rot of pineapple, Phytophthora blight of orchids, Phytophthora blight of passion fruit, Phytophthora leaf blight, and fruit and root rot of papaya, and so on. Since 2009, continuous heavy rainfall has been a big problem in the summer in Taiwan, often causing flooding in the

fields. It usually led to poor growth, the death of large areas of Welsh onion, as well as severe fruit rot of melon. The crop yield loss was initially thought to be the poor water tolerance of the cultivars in the rainy season. Later studies proved it was a severe disease caused by *Phytophthora nicotianae*, *P. melonis*, and other *Phytophthora* spp. induced by continuous heavy rainfall. Because Phytophthora blight develops fast and can cause severe infections in several days, it will be too late to apply pesticides after the rainy season. Field trial results show that the regular application of phosphite weeks before the rainy season or/and the precise application of fungicides before and during the rainy season could significantly reduce the disease severity. In addition, healthy seedlings and weather forecasting are also crucial for disease prevention.

A QTL MAPPING APPROACH LEADS TO THE IDENTIFICATION OF CANDIDATE AVIRULENCE GENES OF GRAPEVINE DOWNY MILDEW

Text

Plasmopara viticola is a biotrophic oomycete responsible for grapevine downy mildew, one of the most destructive diseases in viticulture. Breeding efforts for new resistant cultivars are based on the introgression of *Resistance to Plasmopara viticola* (*Rpv*) factors from wild grape species. However, in recent years, a number of isolates able to overcome the resistance conferred by different *Rpv* genes have been reported. The risk of rapid breakdown of resistance makes it urgent to understand the genetic factors underlying the virulence of the pathogen.

We carried out a QTL mapping study focused on *P. viticola* adaptation to three major resistance genes: *Rpv3*, *Rpv10* and *Rpv12*. Sexually compatible strains were crossed to generate two F1 progenies, on which targeted genotyping-by-sequencing was performed. We built a set of unprecedented linkage maps of the *P. viticola* genome, with a consistent number of seventeen linkage groups that likely correspond to chromosomes.

Each offspring was cross-inoculated on a panel of grapevine cultivars carrying one of the aforementioned *Rpv* genes or none. Linkage analysis shows that resistance breakdown is under the control of one major QTL for each *Rpv* gene. These QTLs map to regions enriched in predicted secreted effectors, in which large deletions are observed for strains virulent on *Rpv3* and *Rpv12*. These results pave the way for the functional validation of the interaction between *Rpv* genes and candidate P. viticola avirulence genes.

A CULTUROMICS APPROACH IDENTIFIES RHIZOSPHERIC BACTERIAL STRAINS INVOLVED IN LEGUMES PROTECTION AGAINST THE ROOT ROT AGENT APHANOMYCES EUTEICHES

ZOUAOUI Mohamed. (1), BAZERQUE Quentin. (1), REY Thomas. (1), DUMAS Bernard. (1)

Text

In recent years, using a consortium of selected bacteria from the root microbiota, also known as a "synthetic community" (SynCOM), to promote plant health has become increasingly common. The objective of this study is to elaborate a model SynCOM from the rhizosphere of Medicago truncatula (Mt) to unravel the role of root microbiota in mediating plant-microbe interactions in the context of biotic stress caused by Aphanomyces euteiches, a devastating oomycete that causes root rot in legume plants. A high throughput culturomics protocol was used to obtain 1364 isolates from the rhizosphere of Mt. The collection of isolated bacteria was genotyped using Illumina 16S metabarcoding sequencing. The UCLAST algorithm was employed with a 97% identity to select 812 pure isolates with 79 unique OTUs. The relative abundance analysis of the collection showed that the uppermost taxa were similar to those observed in molecular identification obtained from soil DNA. Among the selected 812 pure isolate 12 were found to inhibit A. euteiches growth in a dual culture assay. In planta testing, only one strain of Pseudomonas sp. showed significant difference from the untreated control. This collection of 79 unique OTUs was used to constitute a synthetic community as a model of the root microbiota of Medicago plants. A multi-omics approach will be used to analyze the behavior of this SynCOM in a gnotobiotic system to study its role in plant microbe interactions.

INSIGHTS INTO THE GENOME OF PHYTOPHTHORA AGATHIDICIDA, THE KAURI DIEBACK PATHOGEN

TARALLO Mariana. (1), GUO Melissa. (1), BRADLEY Ellie. (2), SHILLER Jason. (3), MESARICH Carl H.. (2), BRADSHAW Rosie E.. (1)

Text

Phytophthora agathidicida is the main causal agent of a devastating dieback disease that kills iconic and ancient kauri (*Agathis australis*) in New Zealand. Like for so many other *Phytophthora* pathogens, there is no simple way to control or eradicate it. Studying the genomes and genes of species such as *P. agathidicida* will provide a much deeper understanding of how *Phytophthora* pathogens work and, ultimately, how we might combat them. We recently assembled the genome sequence of *P. agathidicida* to chromosome level - one of the first for any *Phytophthora* species (Cox et al. 2022 Frontiers in Microbiology 13: 1038444). The complete genome sequence shows the extent of duplication and diversification of genes such as effectors that are predicted to have roles in virulence. Here we describe recent progress in analysing the *P. agathidicida* genome and assessing effector gene expression *in planta*, as well as functional studies of both cytoplasmic and apoplastic effectors. The *P. agathidicida* genome sequence shows many similar genomic and gene features to those of other sequenced *Phytophthora* species. Because of this, it is anticipated that this genome sequence will be a useful resource for the broader *Phytophthora* research community as we make a collective global effort to control these plant killers.

A MULTIPURPOSE TOOLKIT OFFERED PRACTICAL ASSISTANCE TO ADVANCED FUNCTIONAL ANALYSIS OF PHYTOPHTHORA SOJAE GENES

TAN Xinwei. (1), HE Zheng. (1), **WANG Qunqing. (1)**

(1) Shandong Agricultural University, Taian, CHINA

Text

Oomycetes, represented by *Phytophthora*, have a threat of serious injury to natural and farm ecosystems due to complex pathogenic mechanism. Recently, CRISPR/Cas9-based gene-editing strategy has been established in *Phytophthora sojae*, becoming a powerful tool for oomycete functional gene research. However, an integrated gene research system needs functional complementation and reintroduction of target gene(s). Currently, lacking efficient selection marker for complementation becomes the short board of gene function research. Here, we report that the gene *NAT1* (GenBank: CAA51674.1), which encodes Nourseothricin acetyltransferase and confers resistance to antibiotic Nourseothricin, can be used as a selection marker for Phytophthora transformation. Therefore, a new genetic manipulation toolkit is developed based on vectors containing NAT1 or NPT II, offered practical assistance to advanced functional analysis of *P. sojae* avirulence genes. In this study, we demonstrated that the NAT gene can be used as a screening marker and constructed a complete functional genetic research system in *P. sojae*. This report will greatly accelerate the functional genomics of oomycetes.

A PHYTOPHTHORA SOJAE RXLR EFFECTOR IMPACT HOST DEFENSE-ORIENTED TRANSCRIPTOME REPROGRAMMING BY TARGETING SOYBEAN MEDIATOR SUBUNIT 21

TAN Xinwei. (1), HE Zheng. (1), XU Qian. (1), **WANG Qunqing. (1)**

(1) Shandong Agricultural University, Taian, CHINA

Text

Upon pathogen infection, plant-activated defense systems undergo dramatic transcriptome reprogramming. In eukaryotes, conserved mediator complex bridges transcription factors and RNA polymerase II to regulate the transcription of specific genes. Mediator complex affects almost all stages of transcription and plays an essential role in the transition from normal development to immune response. However, pathogens may manipulate host transcription by delivering effectors into plant cells. Here, we report that the nucleus-localized RxLR effector PsAvh109 of *Phytophthora sojae* regulates plant immunity by interacting with the soybean (*Glycine max*) mediator subunit 21 (GmMED21). We further showed that GmMED21 is a positive regulator of plant resistance to pathogen. Silencing of *MED21* in *Nicotiana benthamiana* suppresses the expression of salicylic acid (SA) signaling pathway genes, leading to increased pathogen infestation. Consistent with this, over-expression of *PsAvh109* in soybean also suppressed the genes response to SA signaling pathway and significantly enhanced the invasion by *P. sojae*. In addition, we found that the nuclear localization of the effector PsAvh109 is crucial for its action. The further research reveals Avh109 blocks the function of host core Mediator. As a result, our study identifies a regulatory mechanism by which pathogen effectors target the mediator complex to regulate the transcription of plant defense genes.

UNDERSTANDING THE EARLY EVENTS OF PLANT INFECTIONS BY OOMYCETES, AT NEW SPATIO-TEMPORAL SCALES: FROM ATTRACTION AND AGGREGATION OF ZOOSPORES TO HOST PENETRATION

LE BERRE Joëlle. (1), MINET Naïma. (1), KUHN Marie-Line. (1), RANCUREL Corinne. (1), LUPATELLI Carlotta. (1), THOMEN Philippe. (2), COHEN Céline. (2), NOBLIN Xavier. (2), FRÖSCHEL Christian. (3), GALIANA Eric. (1), DROEGE-LASER Wolfgang. (3), **ATTARD Agnes. (1)**

Text

Plant pathogens have evolved a wide range of strategies enabling surface colonization and invasion of host despite the plant defense mechanisms. Current knowledge of small spatio-temporal scales on mechanisms allowing attraction toward hosts and progression across each first plant cell layer remains sparse. To characterize which host signals and plant cell functions regulate zoospore attraction and penetration, we developed a multidisciplinary study of the rhizospheric dialogue between the telluric oomycete, *Phytophthora parasitica* and Arabidopsis. On the one hand, we generated new phenotyping tools dedicated to the short time-scale quantification of both zoospores behavior swimming in the presence of ionic signals and aggregation on the root surface. On the other hand, we defined the transcriptome of roots and zoospores during attraction of *P. parasitica* and the translatome of each root cell layer during the penetration of zoospores. Thus, we showed that (1) the zoospores aggregated on root in the first minute after inoculation, (2) both roots and zoospores stimulated transcriptomic changes during attraction, and (3) when *P. parasitica* penetrated the rhizodermis, the translatomes were also modulated beyond in the cortex, the endodermis and the stele while these cell layers are not yet colonized. The implication of these results in understanding the early stages of infection, at short spatio-temporal scales, and their use for disease control will be discussed

REVEALING PRINCIPLES OF PHYTOPHTHORA ZOOSPORES SENSING AND MOTION PROPERTIES THROUGH A BIO-PHYSICAL APPROACH

Text

In the soil, early infection events of *Phytophthora* species are mediated by sensory and propulsion capabilities of biflagellate unicellular zoospores, orchestrated by rhizospheric

guidance factors. Lack of detailed information on zoospores plasma membrane proteins prevents a comprehensive understanding of how they contribute to the perception of rhizospheric environment, particularly during migration toward host plant. A bio-physical approach was developed to identify the molecular key-players mediating host-driven taxis. At first, the membrane protein repertoire of *Phytophthora parasitica* zoospores was investigated through LC-MS/MS approach, resulting in a distinct peptide signature between zoospores cell body and flagella plasma membranes. Then, using a microfluidic set-up, functional biomechanics analyses were developed to quantify both zoospore motion (velocity, trajectory and cell rotation) and flagella beating (frequencies and oscillation amplitude) in response to distinct rhizospheric stimuli. The set-up further enabled to discriminate zoospores specific stimuli response among other rhizospheric microbial species. Altogether, the obtained results contribute to elucidate the mechanism of protein-mediated sensing and motion response of *Phytophthora* zoospores and improve the understanding of the complex rhizospheric interaction network driving oomycete dispersal.

GENOMIC INVESTIGATIONS REVEAL ATYPICAL DYNAMIC MITOTIC VARIATION CAN RAPIDLY DRIVE DIVERSITY IN SPINACH DOWNY MILDEW

Text

Spinach (*Spinacia oleraceae*) downy mildew (SDM), caused by the oomycete pathogen *Peronospora effusa*, is the most important disease of spinach worldwide. Breeding resistant spinach cultivars is a critical management strategy. Race typing of SDM has been an important approach for tracking the evolution of the pathogen. Our objective was to investigate plasticity of the whole genome under controlled and field conditions for multiple race types. Genomic DNA was extracted from putative single lesions and PCR-free libraries were sequenced using Illumina HiSeqX in a 2x150bp configuration. Data were processed and heterozygous allele frequencies estimated using BWA and GATK as well as CLC Genomics Workbench. Heterozygous allele frequencies were visualized at the chromosome level. Most heterozygous allele frequencies were inconsistent with the expectations for a diploid organism and proved unstable between isolates as well as locations in the genome. Race type did not correlate with genotype and the SDM pathosystem appears to be dynamic. The plasticity of the genome has broad implications.

NUCLEOTIDE-SUGAR BIOSYNTHESIS PATHWAY IN OOMYCETES: FROM GENOME TO FUNCTION

Text

Oomycetes are fungi-like microorganisms and pathogenic to many plant and animal species. Our study evaluates the distribution and molecular level diversity of the nucleotide-sugar (NTS) biosynthetic enzymes within the oomycetes domain. The NTS are essential polymerizing units of carbohydrates and their conjugates in all living organisms. A comprehensive phylogenetic analysis and metabolic pathway reconstruction were performed based on the sequence-structure-functional analysis and genome mining approaches. The phylogenetic result shows that a total of 24 unique NTS-related enzymes producing different types of nucleotide-sugar units are present within oomycetes. The overall phylogenetic analysis demonstrated that each clade represents a particular enzyme family. Moreover, sequence diversity was found between the members of each clade with sequence identities from 25-99.99 %. Here we postulate that one clade can represent one enzyme family associated with a particular function. The paraphyletic clade in the phylogenetic tree indicates the presence of either isoform or species/strain-specific enzyme. The complete NTS pathway reconstruction provides detailed information about the presence and absence of NTS enzymes or an alternate route for synthesizing activated sugar nucleotide units. This information will help to understand the NTS enzymes and their role in the composition of the oomycetes cell wall, which can further assist in developing anti-oomycetes agents.

PHASE-SPECIFIC TRANSCRIPTIONAL PATTERNS OF THE OOMYCETE PATHOGEN PHYTOPHTHORA SOJAE UNRAVEL GENES ESSENTIAL FOR ASEXUAL DEVELOPMENT AND PATHOGENIC PROCESSES

QIU Min. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Oomycetes are filamentous microorganisms easily mistaken as fungi but vastly differ in physiology, biochemistry, and genetics. This commonly-held misconception lead to a reduced effectiveness by using conventional fungicides to control oomycetes, thus it demands the identification of novel functional genes as target for precisely design oomycetes-specific microbicide. The present study initially analyzed the available transcriptome data of Phytophthora sojae and constructed an expression matrix of 10,953 genes across the stages of asexual development and host infection. Hierarchical clustering, specificity, and diversity analyses revealed a more pronounced transcriptional plasticity during the stages of asexual development than that in host infection, which drew our attention by particularly focusing on transcripts in asexual development stage to eventually clustered them into 6 phase-specific expression modules. Three of which respectively possessing a serine/threonine phosphatase expressed during the mycelial and sporangium stages, a histidine kinase expressed during the zoospore and cyst stages, and a bZIP transcription factor exclusive to the cyst germination stage were selected for down-stream functional validation. In this way, we demonstrated that PP2C, HK, and bZIP32 play

significant roles in P. sojae asexual development and virulence. Thus, these findings provide a foundation for further gene functional annotation in oomycetes and crop disease management.

SCREENING OF ALFALFA VARIETIES RESISTANT TO PHYTOPHTHORA CACTORUM AND RELATED RESISTANCE MECHANISM

YANG Bo. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Alfalfa is one of the most important legume forages in the world. Root rot caused by soil-borne pathogens severely restricts the production of alfalfa. The knowledge of the interaction between alfalfa and root rot-pathogens is still lacking in China. Phytophthora cactorum was isolated from symptomatic seedlings of an alfalfa field in Nanjing with high levels of damping-off. We observed the different infection stages of P. cactorum on alfalfa, and found that the purified P. cactorum strain was aggressive in causing alfalfa seed and root rot. By evaluating the resistance of 37 alfalfa cultivars from different countries to P. cactorum, we found Weston is a resistant variety, while Longdong is a susceptible variety. We further compared the activities of various enzymes in the plant antioxidant enzyme system between Weston and Longdong during P. cactorum infection, as well as gene expression associated with plant hormone biosynthesis and response pathways. The results showed that the disease-resistant variety Weston has stronger antioxidant enzyme activity and high levels of SA-responsive PR genes, when compared to the susceptible variety Longdong. These findings highlighted the process of interaction between P. cactorum and alfalfa, as well as the mechanism of alfalfa resistance to P. cactorum, which provides an important foundation for breeding resistant alfalfa varieties, as well as managing Phytophthora-caused alfalfa root rot.

PECTIN METHYLESTERASES INHIBITOR MODULATE PLANT HOMOGALACTURONAN STATUS IN DEFENSES AGAINST THE PHYTOPHTHORA SOJAE

XIA Yeqiang. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Pectin Methylesterases Inhibitor Modulate Plant Homogalacturonan Status in Defenses against the *Phytophthora sojae*

Hosts and pathogens are engaged in a continuous struggle for physiological dominance that drives the evolution and specialization of key defense and virulence proteins. A major site on the struggle is the plant cell wall. Here, we show the involvement of the dynamic remodeling pectin methylesterification of cell wall in the co-evolutionary struggle between host and microbe. Pathogen-secreted apoplastic pectin methylesterases, PsPME1, that loosening the plant cell wall and synergizing the activity of pathogen secreted endo-polygalacturonases by decreased the degree of pectin methylesterification. However, GmPMEI, a soybean

produced pectin methylesterases inhibitor protein, expression controlled by PME-related damage-associated molecular patterns that binds to both soybean and P. sojae pectin methylesterases and inhibits them enzyme activity to remodeling the pectin to high methylesterification status for protecting themselves from enzymatic degradation. Totally, our work highlights that plants exploit induced defense mechanisms based on biochemical modification on the cell wall in shaping the balance of the arms race in the co-evolutionary conflict between host and microbe.

THE SOYBEAN (GLYCINE MAX) LYSM RECEPTOR KINASES GMNFR5A AND GMCERK1 MEDIATE CHITOOLIGOSACCHARIDES-TRIGGERED IMMUNITY

SUN Guangzheng. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text
Chitin is a major component of fungal cell walls and serves as a molecular pattern for the recognition of potential pathogens in the innate immune systems of plants. Previous research suggested that chitin has different immune signaling pathways in Arabidopsis and rice, including extracellular receptor recognition and intracellular signal transduction. The mechanism of induced resistance of chitin oligosaccharide (COSNAC) and its deacetylated product chitosan oligosaccharide (COS), collectively referred to as chitooligosaccharides, is not clear in soybean. Herein, we report that chitooligosaccharides trigger immune responses and plant disease resistance in soybean. GmNRF5a and GmCERK1 are required for chitooligosaccharides recognition in soybean. Unexpectedly, COSNAC is directly recognized by GmNFR5a and GmCERK1, whereas COS only binds GmNFR5a. In addition, we confirmed that GmCERK1 and GmRLCK5 transduce intracellular signals of chitooligosaccharides through proteins interaction and phosphorylation. Taken together, our results suggest GmNFR5a and GmCERK1 play a key role in the perception of chitooligosaccharides elicitors, and the existence of a complete phospho-signaling transduction pathway from GmNFR5a and GmCERK1 mediated chitooligosaccharides recognition to GmRLCK5 activation in soybean.

ABPP-MS METHOD IDENTIFIES ORIGINAL MODULAR EXTRACELLULAR PROTEASES FROM A. EUTEICHES IN PEA APOPLAST DURING INFECTION

Text
In the field *A. euteiches* causes the root rot disease of legume crops as pea and alfalfa and interacts in the lab with the legume model *Medicago truncatula.* During infection, *A.*

euteiches secrete myriad of proteins to both combat the host plant defense mechanisms and to survive in adverse environmental conditions [1]. Microbial proteases are predicted to be crucial components of these systems. Here, we identified an overrepresentation of tandemly repeated proteases within *A. euteiches* genome, which are upregulated during host infection. We developed an Activity Based Protein Profiling and mass spectrometry (ABPP-MS) approach [2,3] on apoplastic fluids isolated from pea roots infected by the pathogen. We characterized 35 active extracellular microbial proteases, which represents around 30% of the genes expressed encoding serine and cysteine proteases during infection. Notably, eight of the detected active secreted proteases carry an additional C-terminal domain [4]. This work demonstrates ABPP-MS as an efficient tool to quickly substantiate genomics prediction of oomycete pathogenicity factors. This system can be easily translated to other pathosystems and will facilitate the selection of microbial candidate genes for functional analysis.

PHYTOPHTHORA DIX DOMAIN-CONTAINING PROTEINS: AN ENERGY DISTRIBUTION PLATFORM?

KOSTARELI Myrto. (1), WESTERINK Timo. (1), WEIJERS Dolf. (2), **EVANGELISTI Edouard. (1)**

(1) Wageningen University, Laboratory of Phytopathology, Wageningen, NETHERLANDS;
(2) Wageningen University, Laboratory of Biochemistry, Wageningen, NETHERLANDS

Text

In animals, the DIshevelled and aXin (DIX) domain favours the aggregation of essential regulators of the Wnt-beta-catenin signalling cascade. DIX domains also occur in SOSEKI proteins that localize to specific corners of plant cells. Interestingly, oomycete genomes encode DIX-containing proteins with unique combinations of functional domains, suggesting their role differs from those identified in animals and plants. Using the cacao killer *Phytophthora palmivora* as a model system, we investigate the contribution of DIX domain-containing proteins in oomycete plant pathogens. *In vivo* imaging and interaction studies suggest these proteins contribute to energy distribution in hyphae. Our work aims to exploit oomycete genetic specificities to provide inroads for crop protection against this class of plant pathogens.

A LAB-ON-A-CHIP DEVICE TO STUDY THE GROWTH OF OOMYCETES IN O2 GRADIENTS

TAYAGUI Ayelen. (1), SUN Yiling. (1), NOCK Volker. (1), GARRILL Ashley. (1)

(1) University of Canterbury, Christchuch, NEW ZEALAND

Text
Diseases caused by oomycetes impact ecosystems with loss of biodiversity, and in the agricultural, horticultural, forestry and aquaculture sectors cause huge economic losses. It is

thus important to understand how they grow and infect their hosts. The energy required for growth and infection is presumed to come from oxidative respiration, despite the fact that the infection structures and hyphae may be exposed to oxygen concentrations as low as 1 – 2% in and around the host. Pathogenic fungi, which utilize similar infective strategies, have been shown to sense and adapt to these hypoxic conditions, significantly altering their gene expression. As far as we are aware, there are as yet no reports of how oomycetes respond to differing oxygen concentrations. With a view to investigating this, we are developing oxygen sensor Lab-on-a-Chip (LOC) devices that expose oomycetes to oxygen gradients. Made from gas-permeable polydimethylsiloxan (PDMS), the devices comprise a central channel along which hyphae can grow and two side channels, one on each side of the central channel. These are filled with oxygen or nitrogen that diffuses through the PDMS. This creates an oxygen gradient in the central channel that can be measured with the hypoxia-sensing dye Pt(II) meso-tetrakis(pentafluorophenyl)porphine (PtTFPP) which is embedded in PDMS. I will describe experiments using these devices and the tropic responses of several oomycete species, including Phytophthora and Achlya.

PERFORMANCE OF COMMERCIAL VARIETIES AGAINST PHYTOPHTHORA SOJAE

GRIJALBA Pablo. (1), PALMUCCI Hemilse. (1), PUCHETA Juan. (1)

(1) Universidad de Buenos Aires, Caba, ARGENTINA

Text

Phytophthora stem and root rot of soybean, caused by Phytophthora sojae, is mainly managed with single or stacked qualitative disease resistance genes. As pathotype complexity of the population increases, management through the tolerance of the commercial varieties would be advisable. The goal of this study was to evaluate the response of commercial genotypes against the pathogen. We used the hypocotyl inoculation and infected rice techniques. Six commercial genotypes were used together with “Sloan” variety as susceptible control, and 3 pathotypes of P. sojae (which differed in virulence on 1 to 6 Rps genes and are the most representative on the pampeana region). In the first technique, the response of the genotypes was identified as susceptible (70 % or more seedlings killed) or resistant (30% or less seedlings killed). The infected rice technique was carried out in a Randomized Design with 3 repetitions per treatment. The total length of the roots of the surviving plants in the pots was evaluated 21 days after sowing. The data obtained were subjected to ANAVA and Fisher's LSD test ($p<0.05$). The variety identified as commercial 4 is the only one that presented significant differences compared to the control and the rest of the varieties. It was classified as resistant and reached 316% more growth in length. We conclude that it could be possible to use this variety as a tolerant control for future field resistance trials against Phytophthora sojae in Argentina.

GENOME-WIDE ASSOCIATION STUDIES IDENTIFY THE OOMYCETE MATING-TYPE LOCUS SEQUENCE AND AVIRULENCE CANDIDATE GENES IN GRAPEVINE DOWNY MILDEW (PLASMOPARA VITICOLA)

PAINEAU Manon. (2), DUSSERT Yann. (3), MINIO Andrea. (2), FABRE Frédéric. (1), COUTURE Carole. (1), DEMEAUX Isabelle. (1), CANTU Dario. (2), MESTRE Pere. (4),

DELMOTTE Francois. (1)

Text
The availability of high-quality reference assemblies for oomycetes enables genome-wide association studies (GWAS) to link genotype and phenotype variation, identifying the genomic architecture of pathogens' life-history traits. In P. viticola, mating can occur only between individuals of different mating types (heterothallism). Using GWAS, we identified a genomic region of 570 kb associated with the mating-type phenotype (Dussert et al. 2020). P2 individuals were homozygous for the MAT-a allele at the mating-type locus, whereas P1 individuals were heterozygous, carrying the MAT-a and MAT-b alleles. The mating-type region features a gene that encodes a transmembrane protein that might act as a hormone receptor; this is noteworthy since hormones have previously been identified as mating-type factors in Phytophthora spp. Our subsequent research delved into the genomic factors that drive the breakdown of grapevine's partial resistance to downy mildew, specifically focusing on Rpv3. Using GWAS, we discovered a distinct structural variation exclusively present in the genomes of strains that are virulent on grapevines carrying the Rpv3 locus. The structural variation consisted of in a deletion of 30 kb encompassing two closely-related genes that encode proteins of 800-900 amino acids with a signal peptide. The predicted structures of both proteins contain repeats that form structural elements typical of the LWY-fold, a conserved structural module in oomycete effectors.

TWO INDEPENDENT CLEAVAGE EVENTS ARE INVOLVED IN RXLR-EER EFFECTOR PROCESSING

XU Lin. (2), WANG Shumei. (3), PHAM Jasmine. (2), WANG Wei. (2), WANG Haixia. (2), WELSH Lydia. (1), WHISSON Stephen. (1), **BOEVINK Petra. (1)**, BIRCH Paul. (2)

Text
Phytophthora plant pathogens are a serious and continuing threat to agriculture and the natural environment. Secreted effectors are critical to their infection success and the translocated RXLR class are a key set of these. We have shown that RXLR effectors are secreted from *Phytophthora* in a non-conventional fashion, despite having typical signal peptides. We have been investigating what this secretory pathway involves. It was shown, first with Avr3a, and subsequently for other RXLRs, that there is cleavage at the RXLR motif during secretion from the pathogen. Using a range of RXLR effector variants and mutations we show consistent cleavage at the RXLR, including at some degenerated motifs. Furthermore, we reveal that the EER motif represents a second cleavage site. We propose a model for how the RXLR motif may function in the secretory pathway selection.

Text

Oomycete genome editing using CRISPR/Cas9 system represents the most promising and powerful technique to study genes involved in pathogenicity such as effectors. However, most of the reported successful studies have been obtained on *Phytophthora sp*. using polyethylene glycol-mediated protoplast transformation to insert Cas9 DNA plasmids for gene disruption. This method presents some disadvantages. Firstly, PEG-mediated transformation protocol needs strain adaptation and includes difficulty in obtaining high concentrations of viable protoplasts, high transformation efficiency or stable transformants. Secondly, the random integration of foreign DNA can lead to undesired gene disruption or reduced transcription rates. Furthermore, the transgene overexpression of Cas9 can result in off-target cleavage or toxicity. Here, we propose to circumvent these problems by adapting a protocol previously described on brown algae. By combining microprojectile bombardment for delivery of ribonucleoprotein complexes, we successfully transformed for the first time *Aphanomyces euteiches*, the root rot pathogen of legumes. We report that mutations at specific target sites are generated following the introduction of CRISPR-Cas9 ribonucleoproteins into *A. euteiches* cells. By transposing the positive selection system described for algae, we next propose a double mutation approach on a selected effector gene. Potentially, this method should be readily transferable to other oomycete species.

MITOCHONDRIAL GENOMICS – A SYSTEMATIC APPROACH FOR PHYLOGENETICS, TAXONOMY AND DEVELOPMENT OF DIAGNOSTIC MARKERS

MARTIN Frank. (1)

(1) USDA-ARS, Salinas, UNITED STATES

Text

A database of approximately 800 oomycete mitochondrial genomes representing 260 species in 19 genera has been assembled and used in a systematic approach for phylogenetic studies, design of a new barcode locus for species identification and development of diagnostic assays. Extracting the same gene from a broad range of taxa helps identify the most useful loci for phylogenetic analysis; the ability to examine flanking regions from a range of taxa for genes of interest also helps in the design of conserved amplification primers. Comparison of gene order differences facilitated development of a new barcode locus for species identification. In oomycetes the *rps10* gene is flanked by a unique order of tRNAs that enabled design of conserved amplification primers. Since this gene order is not observed in plants or Eumycotan fungi there are low levels of nonspecific amplification from environmental samples. Comparison of *rps10* with *cox1* sequences from the same isolates indicate an equal level of discrimination among taxa. The Grunwald lab developed a metabarcoding approach for oomycetes using this locus (Phytobiomes 6:214-226). Unique gene order differences among genera have also proved useful for design of diagnostic assays for *Phytophthora, Plasmopara, Aphanomyces* and current work with *Pythium* spp. For some taxa the identification of unique putative open reading frames by BLAST analysis of the entire database were useful for development of diagnostic assays.

AN AGO PROTEIN IS REQUIRED FOR AVIRULENCE GENE SILENCING IN AN OOMYCETE PLANT PATHOGEN

SHU Haidong. (1), YIN Guoyu. (1), FANG Yujie. (1), **CHEN Han. (1)**, DONG Suomeng. (1)

Text

Successful pathogens can rapidly overcome host resistance through epigenetic silencing, but the underlying mechanisms of epigenetic variation are largely elusive. Based on genome-wide association study, we identified a natural allele of an Argonaute protein in Phytophthora sojae that confers adaptability to resistance soybean cultivar. Knockout of PsAGO2 impaired avirulence gene Avr1b silencing and the psago2 mutants were recognized by soybean cultivar carrying Rps1b. Further data revealed that PsAGO2 can bind 24-26 nt sRNAs and recruit the histone methyltransferase complex PRC2 to establish H3K27me3 at Avr1b loci. Our finding supports a model in which H3K27me3 formation is mediated by sRNA in oomycete, highlighting the role of a new function of AGO protein in epigenetic gene silencing in a plant pathogen.

XEG1: A CASE STUDY OF MICROBIAL ATTACK AND PLANT IMMUNITY IN THE APOPLAST

WANG Yan. (1), MA Zhenchuan. (1), XIA Yeqiang. (1), **WANG Yuanchao. (1)**

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

The apoplast constitutes a major interaction niche in plant-microbe interactions. During infection, microbial pathogens secrete a large repertoire of effectors that act in the apoplast to modulate host conditions for infection. Plants respond to microbial attack via perception of conserved molecular patterns or apoplastic effectors using cell surface immune receptors to mount defense. The apoplastic effector XEG1 is a glycoside hydrolase 12 protein secreted by the soybean root rot pathogen Phytophthora sojae. XEG1 displays hydrolase activity toward xyloglucans and essential for Phytophthora infection. As a countermeasure, soybean secretes the inhibitor GmGIP1, which binds directly to XEG1 and inhibits its hydrolase activity, to increase soybean resistance. P. sojae secretes a paralogous XEG1-like protein, XLP1, with no enzyme activity. XLP1 binds GmGIP1 more tightly than XEG1, and acts as a decoy protecting XEG1 from the inhibitor GmGIP1. XEG1 is degraded by host aspartic protease GmAP5 in the apoplast. However, XEG1 undergoes N-glycosylation, which protects XEG1 from GmAP5 degradation. In addition, XEG1 can be recognized by a plant membrane-localized receptor-like protein RXEG1 to mount defense. Structural analyses revealed that RXEG1 inhibits the hydrolase activity of XEG1 and plays a dual immunogenic role in plant defense. Together, these studies revealed that co-evolutionary arms race tailored the multi-layered defense and counter-defense in plant-microbe interactions.

DETECTION AND MANAGEMENT OF APHANOMYCES ROOT ROT OF SUGAR BEET

(1) University of Minnesota NWROC, Crookston, UNITED STATES; (2) Department of Plant Pathology, University of Minnesota, St. Paul, UNITED STATES; (3) USDA-ARS, Salinas, UNITED STATES

Text

Aphanomyces cochlioides is the causal agent of seedling damping-off and Aphanomyces root rot (ARR) of sugar beet. The pathogen can persist in the soil as dormant oospores. It is essential for the growers to know the risk of Aphanomyces prior to planting so that they can develop a suitable disease management approach to mitigate yield losses. Aphanomyces root rot can look very similar to root rots and seedling diseases caused by other fungi and oomycetes, so developing a diagnostic assay would be of great value to the sugar beet industry. A specific quantitative PCR (qPCR) assay targeting mitochondrial DNA was developed to detect and quantify *A. cochlioides* DNA in infested field soils and infected sugar beet samples. The assay has a detention limit of 0.1 pg of pathogen DNA and was able to detect A. cochlioides in naturally infected sugar beet root samples. Currently seed treatments offer protection during the first few weeks after planting. However, if the soil moisture remains high later in the season, significant yield losses can occur due to chronic root rot. Precipitated calcium carbonate (PCC), a byproduct of the sugar beet factories is very effective in protecting plant stands and reducing ARR severity up to 12 years after a single application. Use of PCC is widely adopted by the growers in Minnesota and North Dakota. A strong positive correlation between soil extractable calcium (SEC) and root yield suggesting that calcium is playing a vital role in reducing ARR.

SERENDIPITOUS OBSERVATION LED TO PRACTICE OF USING PRECIPITATED CALCIUM CARBONATE IN CONTROLLING APHANOMYCES COCHLIOIDES IN SUGAR BEET

KHAN Mohamed. (1)

(1) North Dakota State University, Fargo, UNITED STATES

Text

Sugar beet (*Beta vulgaris* L.) major crop worldwide for sugar production. Minnesota and North Dakota, adjoining states in the US produce 57% of the US sugar beet production that results in $5 billion in total economic activity. One of the major limiting factors for sugar beet production is *Aphanomyes cochlioides* that causes seedling damping off and Aphanomyces root rot. Tachigaren/hymexazol as a seed treatment is the only fungicide labeled for and widely used on sugar beet for protecting seedlings from *A. cochlioides*. In the 2003, research conducted in Minnesota to determine whether precipitated calcium carbonate (CaCo3) could help to reduce the time that sugar beet could be grown in fields with carryover herbicide showed that the CaCo3 reduced the impact of root with symptoms of Aphanomyces root rot. Further research using 11 to 44 tonnes per hectare of precipitated CaCo3 significantly reduced damage caused by *A. cochlioides.* As a result, sugar beet growers in the USA with fields identified with A. cochliodes have used the practice of applying 7 to 16 tonnes per hectare of CaCo3 before planting sugar beet for a high quality crop. Research further showed that the CaCo3 provided protection from *A. cochlioides* for over 12 years.

CONSERVATION AND DIVERGENCE OF RAR1-MEDIATED NONHOST RESISTANCE DURING LAND PLANT EVOLUTION

JEONG Hyeonmin. (1), CARELLA Philip. (1)

(1) John Innes Centre, Norwich, UNITED KINGDOM

Text
Session 4
Over 450 million years of co-evolution, plants and pathogens have developed sophisticated strategies to manipulate one another. In plants, nonhost resistance (NHR) describes a collection of molecular and cellular mechanisms that neutralize non-adapted pathogens. Although NHR has been extensively studied in angiosperms, the origin and evolution of NHR in land plants is largely unknown. Here, we demonstrate the conservation of a NHR mechanism mediated by the RAR1-SGT1-HSP90 chaperone complex and identify lineage-specific divergence in terrestrial ferns. The RAR1-SGT1 interaction is highly conserved among lineages and even occurs between distantly related ortholog pairs. Intriguingly, we identified a single exception in the C-fern, whose homologs were incapable of interactions outside of its lineage. We hypothesize that lineage-specific differences in the SGT1-interacting CHORD2 domain determines this specificity, which is supported by protein-modeling studies. To determine a role for RAR1-mediated NHR in divergent lineages, we generated a liverwort (*Marchantia polymorpha*) *Mprar1* mutant and screened it against 28 diverse *Phytophthora* isolates. Excitingly, the *Mprar1* mutant exhibited significant defects in NHR to candidate pathogens that we are now examining in more detail. Overall, our findings suggest that the core mechanism of RAR1-mediated NHR is conserved in land plants, while plant lineages have fine-tuned the system during their evolutionary histories.

POPULATION STRUCTURE OF CACAO PATHOGEN PHYTOPHTHORA MEGAKARYA

Text
Phytophthora megakarya is an aggressive and extremely destructive pathogen that causes black pod disease of cacao, significantly limiting yield in the world's leading cacao producing region in West and Central Africa. To effectively use genetic breeding to improve cacao resistance to black pod disease, the genetic diversity of both host and pathogen populations must be considered. We examined genetic diversity and population structure of *P. megakarya* using genomic data from 166 isolates collected from Cameroon, Nigeria, and Ghana. We used reads from genotyping by sequencing of 150 isolates and from published whole genome sequences of 15 isolates to call 2,644 high quality SNPs relative to the reference genome Pm1/GH34 from Ghana. Isolates could be assigned to one of two major clades. One clade contained isolates from Nigeria and Ghana and the other contained isolates collected in all three countries. The two major clades showed differing degrees of genetic variation among isolates and heterozygosity of SNPs. Genomic data will be integrated with isolate phenotypes determined using experimental inoculations of cacao pods to evaluate variation in genetic determinants of virulence in *P. megakarya*.

POTENTIAL ANTI-PYTHIUM INSIDIOSUM THERAPEUTICS IDENTIFIED THROUGH SCREENING OF AGRICULTURAL FUNGICIDES

Text

Pythiosis is a life-threatening infectious disease of humans and animals caused by the oomycete microorganism Pythium insidiosum. Clinical manifestations of pythiosis include blood vessel, eye, skin, or gastrointestinal tract infections. According to geographical distribution analysis, pythiosis has been increasingly reported in 23 countries across the world, with an overall mortality rate of 28%. Pythiosis is treated with a combination of surgery, immunotherapy, and antimicrobial drugs. Radical surgery, which usually results in a handicap, is often required to save patients' lives due to the limited efficacy of conventional antimicrobial drugs. Immunotherapy could reduce the need for surgeries and improve recovery rates in a few cases. However, new and effective medical treatments are urgently needed for pythiosis. This study aims to find potential anti-P. insidiosum agents by screening 17 agricultural fungicides that inhibit plant-pathogenic oomycetes and validating their efficacy and safety. We found that cyazofamid, fenamidone, and fluopicolide could effectively inhibit P. insidiosum and showed relatively low toxicity to human cells. Cyazofamid was the most promising chemical with the highest calculated therapeutic ratio, and its mode of action may involve binding cytochrome c reductase of P. insidiosum. In conclusion, pythiosis still lacks effective treatment. This study demonstrates some agricultural fungicides that could be repurposed for treating pythiosis.

KIWIFRUIT VINE DECLINE SYNDROME: ARE WE CLOSING THE CIRCLE?

Text

The Kiwifruit Vine Decline Syndrome (KVDS) is a disease that severely affects the root system of kiwifruit plants, causing their sudden collapse. While the causes behind KVDS are still being debated, previous work shows that this syndrome has a biotic origin, and it is potentially induced by oomycetes. In this context, our work focused on clarifying causes and mechanisms behind KVDS. Our field surveys identified three major sites where we isolated several oomycetes identified as Phytophtora spp., Pythium spp., and Phytopythium spp. Amplicon metagenomics focused on bacterial, fungal, and oomycete communities show marginal differences in the diversity and structure of microbial communities between

symptomatic and asymptomatic plants. However, more detailed analyses showed a clear presence of Phytopythium sp. only in presence of KVDS symptoms. Furthermore, Phytopythium vexans was the most frequently isolated pathogen using a baiting approach. Then, we performed the high-throughput isolation of potential biocontrol agents, which yielded a pool of bacterial isolates with a strong antagonistic activity against representative isolates of Phytophtora sp., Pythium sp. and Phytopythium sp.. Collectively, our results strongly support the biotic origin of KVDS, potentially caused by Phytopythium spp. through a complex interaction with the environment, the plant, and the plant microbiome, building up the base for sustainable control strategies.

INVESTIGATION OF THE ROLE IN VIRULENCE OF PHYTOPHTHORA INFESTANS EFFECTOR PI06099

MCLELLAN Hazel. (1), SUNNY Sherin. (1), LIU Xinyu. (1), WELSH Lydia. (2), GILROY Eleanor. (2), BIRCH Paul. (1,2)

Text
Plant pathogens secrete many effector proteins which are translocated inside plant cells and act to suppress host defences and promote pathogen colonisation. The RxLR effector Pi06099 from potato late blight pathogen *Phytophthora infestans* interacts with the plant red light receptor Phytochrome B (PhyB). Red light promotes plant immunity by accelerating cell death in response to the *P. infestans* MAMP INF1. Silencing the *Pi06099* effector using Host Induced Gene Silencing (HIGS) and stable RNAi transgenic lines demonstrated that it contributes to the virulence of *P. infestans* on Potato and *Nicotiana benthamiana*. Furthermore, domain swapping and mutagenesis of Pi06099 has been used to investigate the disruption of the interaction with PhyB and phenotypes associated with effector virulence.

DISCOVERY OF PROTEIN MARKERS OF OOMYCETE EV'S

Text
Session 1: Cell Biology, Signaling and Metabolism

The movement of effector proteins and RNAs from pathogen into host cells during infection is known to occur. However, the exact mechanisms facilitating this movement are still being widely studied. One possible delivery route involves the secretion and uptake of extracellular vesicles (EVs) between organisms.

In this study we isolated EVs from the oomycete Phytophthora infestans, cause of potato late blight, with the aim of identifying oomycete-associated EV markers and investigating the cargo of these bodies. This is being achieved by a proteomics approach to identify both

secreted and vesicular proteins during in vitro growth. We have identified some known EV proteins found widely in EV proteomes, supporting our methodology and approach. Additionally, we have identified some oomycete-specific proteins that have as yet unknown functions but appear to be transmembrane proteins, including TMP1 (Trans-Membrane Protein 1). TMP1 accumulates in the same density fraction in sucrose gradients as the RXLR effector protein, PITG_04314, during EV isolation implying they could be associated with the same EV. The overall aim of this work is to find markers of EVs that we can use to determine how these EVs are secreted and taken up into the plant cell and whether this is a mode of transport for pathogenicity factors such as RXLR effectors.

NEW APPROACHES TO EXPAND OUR UNDERSTANDING OF CRYPTIC OOMYCETE ELICITIN PROTEINS

KHAREL Aayushree. (1), ROOKES Jim. (1), ZIEMANN Mark. (1), ADCOCK Jacqui. (1), CAHILL David. (1)

Text

Phytophthora cinnamomi, one of the most devastating plant pathogens, poses a serious threat to the biodiversity and has a host range of almost 5000 plant species. Belonging to the class Oomycetes, *P. cinnamomi* is a sterol auxotroph and relies on external sterol sources for completion of its life cycle. Our recent review paper on elicitins of *Phytophthora* outlined the importance of these highly conserved proteins in recruiting sterols and providing it to the pathogen, however, the process is largely unknown. Research on the dependency of *P. cinnamomi* on plants for sterols, the process following sterol recruitment and thereafter, sterol signalling, will help us better understand the importance of sterols for oomycete survival. Thus, through a targeted metabolomics technique, we explored the dynamics of sterol acquisition by *P. cinnamomi*. We have also begun to explore gene editing which, in a limited *Phytophthora* species has assisted in gene functionalisation. Thus, to expand the possibilities of gene editing in *P. cinnamomi*, we have optimized a protoplast isolation process from the multinucleated hyphae of this pathogen. To understand the cell biology of the protoplasts, we utilized various vital stains to visualize internal structures, along with fluorescent dye to quantify viable protoplasts. These methodologies provide an opportunity to establish CRISPR/Cas-mediated gene editing of elicitins in *P. cinnamomi* to expand our fundamental knowledge of these proteins.

IDENTIFYING PROTEIN-PROTEIN INTERACTIONS WITH TURBOID IN PHYTOPHTHORA INFESTANS

WELSH Lydia. (1), WHISSON Steve. (1)

(1) James Hutton Institute, Dundee, UNITED KINGDOM

Text

Determining how proteins function and interact with one another is a key step in understanding how cellular systems function. There are a variety of methods for determining protein-protein interactions, such as co-immunoprecipitation, yeast-2-hybrid, and proximity labelling methods. One of the most recent developments is TurboID, a proximity labelling

method that uses a high efficiency biotin ligase to tag interacting or nearby proteins with biotin, followed by streptavidin purification and mass spectrometry. We have adapted TurboID for use in the potato late blight pathogen, Phytophthora infestans, with the aim of identifying proteins interacting with effectors as they are secreted. We have generated transgenic lines of P. infestans expressing effector-TurboID fusions. These have been assessed for correct protein localisation, conditions for biotin labelling, and protein purification. Progress towards identifying proteins involved in secretory pathways will be presented.

RE-EMERGENCE OF THE POTATO LATE BLIGHT THREAT IN EUROPE DRIVEN BY AN EVOLVING POPULATION OF PHYTOPHTHORA INFESTANS

Text

Successful integrated pest management (IPM) is dependent on knowledge of the pathogen, its host and the environment and how each influences management practices. Late blight, caused by Phytophthora infestans, continues to threaten potato and tomato crops on a global scale. An evolving pathogen population and increasingly rigorous regulations on chemical use are driving a transition from prophylactic fungicide use to more integrated approaches combining host resistance, knowledge of pathogen spread and infection risk with smarter use of fungicides and biological products. The evolving population of P. infestans prompted the EuroBlight consortium to collect data on the diversity of P. infestans, analysed with simple sequence repeat genetic markers. Surveys of late blight infected crops by many collaborators from 2013–2022 has resulted in over 16 thousand genotyped samples from across Europe held in an isolate database with associated analysis tools and a mapping interface. The population is dominated by relatively few clonal lineages that we have tracked over time and space (www.euroblight.net). We have identified traits such as fungicide resistance that drive the emergence, evolution and spread of some clones and share the knowledge with the industry to tailor IPM practices. In contrast to the clones, 20-30% of the European population comprises genetically diverse strains consistent with oospore-derived sexual populations and their evolving traits are challenging to predict.

COMPARATIVE GENOMICS OF EUROPEAN APHANOMYCES EUTEICHES STRAINS

Text
The plant pathogen Aphanomyces euteiches causes root rot in its broad host range of various legume species. The homothallic oomycete is known for its low genetic diversity due to predominant clonal reproduction. In a recent study using short sequence repeat markers, three genetically distinct groups were identified in pea-infecting A. euteiches strains from Europe. A central European population differed significantly from genetically distinct groups comprising strains from the most northern (eastern Sweden and Finland) and most southern (Italy) sampling regions. From this strain collection, 69 strains representing the three groups were genome sequenced and the genomes assembled and annotated. Initially, a genealogical concordance phylogenetic species recognition analysis will be performed to establish the species status of the northern and southern groups. We will further perform a comparative genomics analysis of A. euteiches with focus on gene content and gene family evolution. Effectors, CAZymes and proteases have been shown to play important roles in oomycete virulence, and these gene families will be characterised in detail. Further, the data set offers the possibility for scanning the genomes for signatures of positive selection using selective sweep analysis. This project will improve our understanding of the genetics underlying diversity and virulence in European A. euteiches populations. The annotated genomes will be made available through AphanoDB

EVOLUTION OF LWY EFFECTOR REPERTOIRE IN PHYTOPHTHORA

LI Yufei. (1), SHU Haidong. (2), ZHANG Zhichao. (2), ZHANG Fan. (2), LI Hui. (1), TANG Bozeng. (1), FENG Li. (1), YE Wenwu. (2), DONG Suomeng. (2), WANG Yuanchao. (2), KAMOUN Sophien. (1), MA Wenbo. (1)

Text
Effectors are deployed to manipulate host cellular processes and promote infection by pathogens. Many *Phytophthora* effectors consist of tandem repeats of (L)WY motifs, each containing a conserved 3-5 α-helical bundle. Some of these (L)WY effectors have the WY1-(LWY)n arrangement in which neighboring (L)WY-LWY units are concatenated by a conserved linkage, resulting in an overall non-globular shape. Despite the structural conservation, the (L)WY units show divergence in surface-exposed residues, leading to the hypothesis that the shuffling of (L)WY units may contribute to the diversification of *Phytophthora* effector repertoire. To investigate potential (L)WY shuffling, we developed a bioinformatic pipeline, which identified 74-155 LWY sequences from five *Phytophthora* genomes. Many of these genes are arranged in multi-LWY gene clusters in the genome, which may serve as hotspots for effector evolution. Interestingly, up to ~64% of the LWY genes encode putative proteins without the canonical N-terminal secretion Signal Peptide, indicating the presence of a dynamic sequence reservoir that could promote effector evolution. Comparison of sister *Phytophthora* species revealed LWY effectors as recombined products, lending support to a recombination-based mechanism that could contribute to the birth of novel virulence activities. This study offers important insight into the functional diversification of an effector repertoire driven by modular protein architecture.

A PHYTOPHTHORA INFESTANS MYB TRANSCRIPTION FACTOR INVOLVED IN SPORULATION AND HOST PENETRATION

WELSH Lydia. (1), OSPINA-GIRALDO Manuel. (2), SQUIRES Julie. (1), PHAM Jasmine. (3), BIRCH Paul. (3), HUITEMA Edgar. (3), VETUKURI Ramesh. (4), **WHISSON Steve. (1)**

(1) James Hutton Institute, Dundee, UNITED KINGDOM; (2) Lafayette College, Easton, Pa, UNITED STATES; (3) University of Dundee, Dundee, UNITED KINGDOM; (4) Swedish University of Agricultural Sciences, Alnarp, SWEDEN

Text

Completion of the *Phytophthora* lifecycle involves the precise expression of thousands of genes, typically regulated by the action of transcription factors. We aimed to identify transcription factors that bound to conserved sequence motifs in the promotors of infection-regulated genes from the potato late blight pathogen, *Phytophthora infestans*. Using a motif found in the promotors of many effector coding genes, we conducted a yeast-1-hybrid screen, which identified a single *P. infestans* candidate MYB transcription factor. Silencing of this transcription factor revealed that it regulated sporulation and pathogenicity phenotypes. In particular, silenced lines were unable to penetrate intact leaves, but could colonise wounded leaves. Transcriptome analysis of silenced lines, compared to wild type, identified over 1000 differentially expressed genes, including 42 RXLR effectors and 79 carbohydrate active (CAZy) proteins. Additional transcription factors and kinases were also discovered and, when silenced, also led to loss of pathogenicity.

CONTROL OF PYTHIUM PATHOGENS IN HYDROPONIC GREENHOUSES

BURKEY Carren. (1), OSAMIKA Sunday. (1), **MORRIS Paul. (1)**

(1) Bowling Green State Unoiversity , Bowling Green, UNITED STATES

Text

Hydroponic greenhouses are more efficient in their use of water than conventional soil-based systems. With the use of energy efficient light, and elevated CO2 conditions, these production systems enable the year-round production of leafy greens in northern climate zones. However, this novel environment is also ideally suited for the spread of pythium pathogens in the recirculating water. These pathogens can be introduced via air dust, contaminated water, insects, foot traffic, contaminated soil etc. In the US, Pythium pathogens have emerged as particularly economically impactful pathogens of spinach, and other leafy greens. Our research has identified a group of Pseudomonas fluorescens strains capable of contact-dependent killing of isolates obtained from greenhouse operations from California, Indiana, Ohio, and New Jersey. To identify species-specific virulence factors, we have implemented a sequential strategy of bioinformatic analysis; DNA synthesis of boundary regions containing in-frame deletions of target genes, electroporation of the vector containing gene KOs; selection of vector and assays of virulence following operon disruption by integration of vector; counter-selection for removal of vector; and finally, verification of gene deletion events and changes in gene virulence.

GENOMIC BIOSURVEILLANCE OF SUDDEN OAK DEATH PATHOGEN PHYTOPHTHORA RAMORUM REVEALS VARIANTS, HYBRIDS AND SUPER-SPREADER EVENTS

Text

Invasive alien tree pathogens often have complex invasion histories. Understanding the source and pathways of invasion is crucial to improve prevention. Genomic biosurveillance can help untangle the invasion history. The BioSAFE project sequenced and analysed more than 500 genomes of a global collection of the pathogen responsible for the sudden oak death, the sudden larch death and Ramorum blight (*Phytophthora ramorum*). Variants within clonal lineages of P. ramorum were often geographically and/or chronologically restricted. We detected a shift in variants of the EU1 and NA2 lineages of *P. ramorum* in nurseries in British Columbia, Canada. One of the EU1 variants replaced all previous variants and spread to many nurseries, a signature of a potential super-spreader event. We also identified interlineage hybrids that are F1 progenies. They produce viable sporangia and chlamydospores and are infectious to rhododendron, a common host. Comparison of variant composition in nurseries, following treatment, revealed instances of eradication success and failure. For rapid and high-throughput biosurveillance, we have developed SODseq, a tool that generates high-throughput sequence data for 355 informative amplicons that recapitulate the patterns obtained with whole genome sequencing. This tool can be used with DNA extracted from cultures or directly from environmental samples or infected host tissues and provide useful genomic data that can inform mitigation approaches.

THE COEVOLUTIONARY RACE BETWEEN HYALOPERONOSPORA ARABIDOPSIDIS AND ARABIDOPSIS THALIANA AT A TRANSCONTINENTAL SCALE

Text

Plants and their pathogens are locked in a perpetual coevolutionary battle for survival. We present a transcontinental investigation of coevolution in the Hyaloperonospora arabidopsidis – Arabidopsis thaliana pathosystem. We generate whole genome sequences of over 400 host-pathogen pairs from natural infections collected throughout both the native eurasian range and the human-commensal colonisation of North America, as well as new near-complete long-read genome assemblies with evidence-based annotation. We investigate the demographic history of both host and pathogen, examine coevolution both generally and of individual gene pairs, and describe variation in the genetic networks of interacting host and pathogen genes. Our results show that the negative-frequency dependent selection on both the pathogen and host genomes leads to the presence of balanced polymorphisms in the wild pathosystem, in contrast to the directional selection generally experienced by pathogens of crop pathosystems.

SYNCHROSPORA GEN. NOV., A NEW PERONOSPORACEAE GENUS WITH AERIAL LIFESTYLE FROM A NATURAL CLOUD FOREST IN PANAMA

JUNG Thomas. (1,2), BALCI Yilmaz. (3), BRODERS Kirk. (4,5), MILENKOVIC Ivan. (1,6), JANOUSEK Josef. (1), KUDLACEK Tomas. (1), DORDEVIC Biljana. (1), **HORTA JUNG Marilia. (1,2)**

Text

During a survey of *Phytophthora* diversity in Panama fast growing oomycete isolates were obtained from naturally fallen leaves of an unidentified tree species in a tropical cloud forest. Phylogenetic analyses of ITS, LSU, beta–tubulin, cox1 and cox2 sequences revealed they belong to a new species of a new genus, officially described here as *Synchrospora* gen. nov., which resided as basal genus within the *Peronosporaceae*. The type species *S. medusiformis* has unique morphological characters. The sporangiophores show de-terminate growth, multifurcating at the end forming a stunted, candelabra-like apex from which multiple (8 to >100) long, curved pedicels are growing simultaneously in a medusa-like way. The caducous papillate sporangia mature and are shed synchronously. The breeding system is homothallic, hence more inbreeding than outcrossing, with smooth-walled oogonia, plerotic oospores and paragynous antheridia. Optimum and maximum temperatures for growth are 22.5 and 25–27.5 °C, consistent with its natural cloud forest habitat. It is concluded that *S. medusiformis* is adapted to a lifestyle as canopy-dwelling leaf pathogen in tropical cloud forests. More oomycete explorations in the canopies of tropical rainforests and cloud forests are needed to elucidate the diversity, host associations and ecological roles of oomycetes and, in particular, *S. medusiformis* and possibly other *Synchrospora* taxa in this as yet under-explored habitat.

SESSION 7:Taxonomy, Nomenclature, New Taxa

MICROTUBULE-MEDIATED NUCLEAR POSITIONING IN P. PALMIVORA

KASTEEL Michiel. (1), EVANGELISTI Edouard. (1), KETELAAR Tijs. (1), GOVERS Francine. (1)

(1) Wageningen University, Wageningen, NETHERLANDS

Text

Oomycetes of the genus Phytophthora are filamentous plant pathogens. They are coenocytes, possessing multiple nuclei in a single cytoplasm. Like other tip-growing

organisms, proper nuclear organization is likely to be paramount in maintaining hyphal growth, a process in which the microtubule cytoskeleton is often strongly involved. Using fluorescent reporters, we investigate microtubule dynamics in relation to nuclear positioning in the broad range plant pathogen Phytophthora palmivora. We previously found clues for microtubule-mediated force generation, and now show how microtubules associated with nuclei impose strict inter-nuclear distancing. Oryzalin-mediated microtubule depolymerization shows how nuclear disorganization leads to growth deficiencies, and we explore how microtubule overlaps could provide the force required to distance nuclei.

BIOCONTROL OF POTATO LATE BLIGHT BY NATURAL COMPOUNDS FROM TRAMETES VERSICOLOR WITH POTENTIAL ANTIMICROBIAL AND BIOSTIMULANT EFFECTS

FRATINI Rosita Silvana. (1), BECCACCIOLI Marzia. (1), CECCHETTI Valentina. (1), FAINO Luigi. (1), REVERBERI Massimo. (1)

Text

Potato late blight is a devastating disease infecting cultivated potato (*Solanum tuberosum*), caused by the oomycete *Phytophthora infestans*. The use of biocontrol agents and plant resistance inducers are sustainable and alternative ways to fungicides to contrast the disease in field. These can include microorganisms capable to contain the pathogen or compounds derived from them that act as plant defense biostimulants. In this study we tested the effect of natural compounds derived from the liquid culture of the fungus *Trametes versicolor*, known for antioxidant and antimicrobial properties, against potato late blight. For this purpose we conduced both *in vitro* and *in planta* assays in which we also tested chitosan and ß-aminobutyric acid (BABA), known respectively as antimicrobial against *P. infestans* and biostimulant on potato. In the first assay, the oomycete growth was analyzed via spectrophotometer and microscopy, whereas the *in planta* effect was investigated via gene expression and mass spectrometry. We showed that the cultural filtrate (CF) of *T. versicolor* inhibits the growth of *P. infestans* with an effect comparable to chitosan. Moreover, when sprayed on potato leaves, both CF and BABA are capable to enhance plant defense hormones. Further studies will focus on the mode of action of CF based on its chemical components (mainly polysaccharides and peptides) and the use of natural compounds are promising for small-scale field trials in order to control potato late blight.

PHYTOPHTHORA: TAXONOMY AND PHYLOGENY AND ASPECTS OF MORPHOLOGICAL AND MOLECULAR CHARACTERIZATION BASED ON THE TYPES

Text
Phytophthora with 212 species contains many members that cause diseases of economic and environmental impact in nurseries, horticulture, agricultural and natural ecosystems; many species are of regulatory concern. This status requires the implementation of robust tools for morphological and molecular identification based on the reference specimen (type), which has been designated to represent the name for each described species. Since 2014, members of the USDA S&T Plant Pathogen Confirmatory Diagnostics Laboratory and Pest Identification Technology Laboratory have been collaborating with national and international experts to implement robust systems for species identification. In September 2019, the "*IDphy*: morphological and molecular identification based on the types" international resource with Lucid and Tabular Keys was launched online to cover the 161 species described until 2018 and in 2021 the *IDphy* app with Lucid key for morphological characterization. In 2023, we are working on *IDphy* version 2 to cover the 212 species described, and the innovative molecular toolbox with seven genes, and databases for Sanger sequencing and metabarcoding high-throughput sequencing technologies. In addition, a manuscript for the Revision of the Taxonomy and Phylogeny of *Phytophthora* based on the types is in progress and implemented to operate in conjunction with *IDphy* V2. We expect that these resources will be of great benefit for the international community working with *Phytophthora*.

Text

During surveys of global *Phytophthora* diversity 40 new species were detected mainly in natural forests and streams in Europe, Asia and the Americas and assigned to the five subclades of *Phytophthora* Clade 2 based on a multigene phylogeny of nine nuclear and three mitochondrial gene regions. The evolutionary history of the Clade appears to have involved the pre-Gondwanan divergence of three extant subclades, 2c, 2d and 2e, all having disjunct natural distributions on separate continents and comprising species with a soilborne and aquatic lifestyle and a few partially aerial species in Clade 2c; and the post-Gondwanan evolution of subclades 2a and 2b in South-/East Asia and South America, respectively. Clade 2b comprises soil inhabiting and aerial species whereas Clade 2a has evolved further towards an aerial lifestyle comprising only species which are predominantly or partially airborne. The 74 described Clade 2 species result from both allopatric non-adaptive and sympatric adaptive radiations. They represent most morphological and physiological characters, breeding systems, lifestyles and forms of host specialism found in the genus *Phytophthora* demonstrating the strong biological cohesiveness of the genus. The finding of 40 previously unknown species from a single *Phytophthora* clade highlights a critical lack of information on the scale of the unknown pathogen threats to forests demonstrating the anachronism of plant biosecurity protocols based on lists of named organisms.

SEVERE DIEBACK AND MORTALITY OF WILD OLIVE TREES ASSOCIATED WITH PHYTOPHTHORA SPECIES IN ITALY

DEIDDA Antonio. (1), BRANDANO Andrea. (1), ANGIUS Francesca. (1), SATTA Gabriele Giuseppe Antonio. (1), **SCANU Bruno. (1)**

(1) University of Sassari, Sassari, ITALY

Text

Wild olive (*Olea europaea* var. *sylvestris*) is a drought-tolerant and disease-resistant tree, often used as rootstock on which cultivated olive varieties are grafted. However, since 2022, extensive dieback and mortality of wild olives trees have been reported in an area of ca 4000 ha in central Sardinia (Italy). Infected trees showed severe leaf chlorosis, wilting or

defoliation often associated with root rot and necrotic lesions on the feeder roots. In the investigated areas, estimated tree mortality and disease incidence were 60 and 80%, respectively. Rhizosphere soil was sampled from over hundred unhealthy trees and subjected to the baiting technique, using fresh Ceratonia siliqua leaves as baits and SMA as *Phytophthora* selective medium. The isolates obtained were identified by analyses of their morphological traits and sequences of ITS and cox1 genes. Five homothallic *Phytophthora* species from Clades 2 and 6 were consistently isolated from symptomatic trees. Their pathogenicity was tested using 6-month-old wild olive seedlings and the soil infestation method. These findings highlight as *Phytophthora* may represent an emerging pathogen to the genus Olea. Investigations are ongoing to better understand the epidemiology of the disease and other possible factors involved in the outbreak. In addition to the ecological impact, a consequence of this damaging new disease is that further use of wild olive as a source of rootstock for grafting olive varieties could be limited.

PHYLOGENETIC DIVERSITY OF THE OAK PATHOGEN PHYTOPHTHORA QUERCINA FROM EUROPE AND NORTH AFRICA

BRANDANO Andrea. (1), TOMI? Zeljko. (2), KUDLACEK Tomas. (3), MULLETT Martin. (3), SEDDAIU Salvatore. (4), HORTA-JUNG Marilia. (3), JUNG Thomas. (3), SCANU Bruno. (1)

Text

Phytophthora quercina was first reported causing root rot on oak trees in central Europe. Since then, this oak-specific pathogen has spread across Europe mainly associated with chronic decline on Quercus cerris, Q. faginea, Q. ilex, Q. petrea, Q. pubescens and Q. robur, and more recently Q. suber. Since distinct phenotypes were observed amongst the isolates detected from oak trees, thus morphological and phylogenetical analyses were conducted in this thesis to assess the intraspecific variability of P. quercina. Overall, 64 different isolates of P. quercina from several European countries and oak species were analysed. Colony morphology and growth rates were compared, and nuclear and mitochondrial DNA sequences were investigated by phylogenetical analyses. The results show a high variability within the P. quercina population both in terms of colony features and growth rates. The phylogenetical analyses (Bayesian Inference and Maximum Likelihood) have enabled discrimination of 12 different lineages into the European P. quercina population, with clear association between host and geographic area. In addition, a putative new species, closely related to P. quercina, was isolated from Chamaecyparis lawsoniana var. globosa in Croatia.

EXPLORING NUTRITIONAL RELATIONSHIPS BETWEEN PLANTS AND PATHOGENIC OOMYCETES

MCDOWELL John. (1), DINKELOO Kasia. (1), SONAWALA Unnati. (1), PILOT Guillaume. (1)

(1) Virginia Tech, Blacksburg, UNITED STATES

Text
All plant pathogens obtain nutrients from the plant host to fuel their own growth. At the same time, plants must reprogram their own metabolic pathways to fuel their immune responses and withhold nutrients from pathogens. These critically important functions are accomplished in environments where key nutrients are either limiting, sufficient, or in excess. Physiological experiments have demonstrated that changes in host nutrient status either promotes or retards pathogen growth or plant resistance. However, these data are fragmentary, particularly for plant interactions with oomycetes (e.g., Phytophthora species, downy mildews) that account for tens of billions of dollars in annual crop losses. This presentation will focus on the interaction between Arabidopsis and the oomycete pathogen Hyaloperonospora arabidopsidis (Hpa). Hpa is an obligate biotroph and establishes putative feeding structures, called haustoria, in plant mesophyll cells. We have developed a new system for transcriptomics, based on Translating Ribosome Affinity Purification, in which we can analyze the transcriptome of haustoriated plant cells to understand how their metabolism and immune responses are altered by the direct interaction with Hpa haustoria. We will describe this system and summarize the initial insights into the biology of plant cells that are actively parasitized by oomycetes.

THE TELOMERE-TO-TELOMERE REVOLUTION: UNVEILING OOMYCETE GENOMES

FLETCHER Kyle. (1), **MICHELMORE Richard. (1)**

(1) University of California, Davis, Davis, UNITED STATES

Text
Oomycetes include diverse pathogens that include obligate biotrophs, hemibiotrophs, and necrotrophs that result in foliar and root diseases. Technological advances in genome sequencing have enabled the generation of near complete genome assemblies of diverse species; these are foundational resources that can be used to study how the pathogen rapidly adapts to evade control. We have generated telomere-to-telomere assemblies from several oomycete genera, focusing on the obligately-biotrophic oomycetes that cause downy mildew diseases as well as Phytophthora and Pythium spp. Comparative genomics determined that downy mildew causing oomycetes are polyphyletic and share a 17-chromosome ancestral state along with many Phytophthora clades. Annotation of these assemblies has identified horizontal gene acquisition events from phytopathogenic fungi and defined high-identity gene clusters that encode putative effectors. Sequencing of multiple isolates revealed hallmarks of allo- and auto-heterokaryosis. Alloheterokaryons are believed to arise by somatic fusions of distinct genotypes, while autoheterokaryons are believed to arise via somatic mutations in a single founding genotype; both result in distinct genotypes sharing a common cytoplasm. Heterokaryosis increases the adaptability of the pathogen and has consequences for determining virulence pathotypes and population genomic inferences.

THE ROLE OF THE OOMYCETE PHYTOPYTHIUM VEXANS AS A BIOTIC STRESS COMPONENT OF KIWIFRUIT VINE DECLINE SYNDROME IN ITALY

GUASCHINO Micol. (1,2), GARELLO Marco. (1,2), NARI Luca. (3), SPADARO Davide. (1,2)

Text
Several soilborne oomycetes belonging to the genus Phytopythium have been associated to kiwifruit vine decline syndrome (KVDS) which is defined as a multifactorial syndrome where both abiotic and biotic stressors are involved. Phytopythium vexans is one of the main species isolated in affected orchards also revealing several interactions with other taxonomic groups composing the microbiome associated to the syndrome. Microbiome network analysis between taxa revealed strain-specific interactions, requiring further studies on the genomics of involved oomycetes. Furthermore, plant response to the presence Phytopythium vexans in Actinidia deliciosa roots, characterized through gene expression analysis approach, revealed an upregulation of ROS scavenging pathways and hormonal stress signaling in response to the pathogen presence and flooding at specific time points. Further transcriptomic studies on Actinidia roots will reveal a major understanding of all the involved pathways in oomycete pathogenesis on fruit trees. The model of KVDS as a multifactorial syndrome, where climate change plays an important role in defining the onset of the syndrome, requires the application and combination of different omics techniques for reaching a wider comprehension of oomycete pathogenesis in complex systems.

Pectobacteriaceae: soft rot pathogenesis and symbiosis

INTRODUCTION TO CLASNIP (WWW.CLASNIP.COM), A WEB-BASED APPLICATION FOR IDENTIFICATION AND CLASSIFICATION OF DICKEYA AND PECTOBACTERIUM SPP.

CHUAN Jiacheng (Eric). (1,2), **LI Xiang (Sean). (1)**

(1) Canadian Food Inspection Agency, Charlottetown, CANADA; (2) Department of Biology, University of Prince Edward Island, Charlottetown, CANADA

Text
Bioinformatic approaches for the identification of microorganisms have evolved rapidly, but existing methods are either time-consuming, complicated or expensive for massive screening of pathogens and their non-pathogenic relatives. A rapid and reliable classification at interspecies and intraspecies levels can facilitate the early detection of plant pathogens, and is important for disease containment and cost effective, timely action for outbreaks or invasions. Clasnip (www.clasnip.com) is a web-based platform, initially designed for haplotyping potato zebra chip disease caused by 'Candidatus Liberibacter solanacearum'. The platform integrates a state-of-art classification algorithm based on Hidden Markov Model (HMM) and maximum likelihood. It has curated databases for the classification of bacteria ring rot pathogen (Clavibacter sepedonicus) and associated Clavibacter spp, soft rot and blackleg pathogens such as Dickeya and Pectobacterium spp, and potato virus Y phylogroups for the classification and similarity evaluation of closely related microorganisms

at interspecies and intraspecies levels. In this presentation, classification of Pectobacterium spp from pure culture and environment samples were tested with 100% accuracy based on sanger sequence, genome sequence, and metagenomic NGS data. In addition, users with less bioinformatics training can build custom databases for their own applications under the Clasnip system. Detailed applications on Clasnip will be discussed.

RELATION BETWEEN TUBERS TESTING FOR SOFT ROT PECTOBACTERIACEA AND THE BLACKLEG EXPRESSION IN SUBSEQUENT FIELDS

LEPINAY Euphrasie. (1), CIGNA Jérémy. (3), BEURY Amélie. (1), HÉLIAS Valérie. (2)

(1) inov3PT, Achicourt, FRANCE; (2) inov3PT, Le Rheu, FRANCE; (3) inov3PT, Gif-Sur-Yvette, FRANCE

Text

Blackleg is one of the major potato diseases subjected to strict tolerances for seed production. Its presence may result in downgrading or rejection of seed potato fields. Voluntary seed tubers detection tests of latent infections by soft rot *Pectobacteriacae* prior to planting have recently increased. However, the correlation between the predictive tests with blackleg expression is poorly documented. Herein, the aim was to determine if evaluated latent infections in tuber could predict the risk of blackleg in the following year. Quantification of *Pectobacterium atrosepticum*, *P. parmentieri*, *P. brasiliense*, *Dickeya dianthicola* and *D. solani* in lots of 200 tubers, was performed thanks to inov3PT qPCR Taqman assays specific. Lots were then distributed in fields and blackleg incidence was monitored by inspectors during growing season. Then, relationships between estimated level of latent infections in seed lots and blackleg incidence in field were studied. Results revealed that latent infection levels could not unequivocally predict the occurrence of blackleg in the field. The predictive value of latent infection on blackleg expression differs with the bacterial species. *Dickeya* latent infection is significantly related with increased expression of symptom. Conversely, for *Pectobacterium*, which is frequently detected, no correlation was shown. That's why tuber testing has to be integrated in a global blackleg risk management as disease emergence depends on several factors.

PECULIAR EVOLUTION OF TWO PECTOBACTERIUM SPECIES, P. AQUATICUM AND P. QUASIAQUATICUM, SUGGESTING AN ADAPTATION TO A NEW ENVIRONMENTAL NICHE.

BEN MOUSSA Hajar. (1), PEDRON Jacques. (1), HUGOUVIEUX-COTTE-PATTAT Nicole. (2), BARNY Marie-Anne. (1)

(1) Sorbonne Université, INRAE, Institut d'Ecologie et des Sciences de l'Environnement de Paris, Paris, FRANCE; (2) Université de Lyon, CNRS, UCBL, INSA, Microbiologie, Adaptation et Pathogénie, Lyon, FRANCE

Text

Historically, research on Soft Rot Pectobacteriacea (SRP) has focused on economically important crops and ornamentals and knowledge of these bacteria outside the plant context remains poorly investigated. Recently, two closely related species Pectobacterium

aquaticum and Pectobacterium quasiaquaticum were isolated from water and have not been isolated from any plant yet. To identify the distinctive characteristics of these two species, we performed a comparative genomic analysis of 80 genomes representing 19 Pectobacterium species and performed an evolutionary reconstruction. Both water species underwent a reduction in genome size associated with a high pseudogene content. A high gene loss was predicted at the emergence of both species. Among the 199 gene families missing from both P. aquaticum and P. quasiaquaticum genomes but present in at least 80% of other Pectobacterium genomes, COG analysis identified many genes involved in nutrient transport systems. In addition, many type II secreted proteins were also missing in both species. Phenotypic analysis revealed that both species had a reduced pectinolytic activity and a biofilm formation defect associated with a reduced virulence on several plants. These genomic and phenotypic data suggest that the ecological niche of P. aquaticum and P. quasiaquaticum may differ from that of other Pectobacterium species.

INTRASPECIES VARIATION AND MALDI-TOF MS-BASED PHYLOPROTEOMIC STUDY OF AN ECONOMICALLY IMPORTANT PLANT PATHOGEN DICKEYA SOLANI

MOTYKA-POMAGRUK Agata. (1), BABINSKA-WENSIERSKA Weronika. (1), SLEDZ Wojciech. (1), KACZOROWSKA Anna-Karina. (1), LOJKOWSKA Ewa. (1)

Text

Dickeya solani, a pectinolytic phytopathogen from the *Pectobacteriaceae* family, is responsible for soft rot and blackleg diseases threatening global potato production. There are still no effective control methods against this bacterium. After studying and closing the pangenome of *D. solani*, an in-depth phenotypic characterization of 20 *D. solani* strains of various origin and year of isolation was conducted. Two *D. solani* strains, *i.e.* IFB0223 and IFB0455, of diminished abilities to macerate plant tissues, which coincided with their limited cellulolytic activity, lack of proteases action, reduced motility, lower siderophores production and impaired growth *in vitro* in contrast to the other *D. solani* isolates, were described. Notably, the pectinases action of IFB0223 and IFB0455 was only slightly reduced. Next, phyloproteomic analysis on 449 MALDI-TOF MS spectra recorded for 20 strains disclosed variation in the *D. solani* population with the low virulent strains IFB0223 and IFB0455 grouping together. Some similarities in the topologies between phyloproteomic- and core genome-based dendrograms were furthermore revealed. In addition, we disclosed four representative MALDI-TOF MS spectra for this species. The presented insight into biodiversity of *D. solani* adds to knowledge on this economically-significant pathogen and suggests that rather than genomes, the proteomes should be searched for explanations of intraspecies variation in the pathogenic potential of *D. solani*.

DOES THE MICROBIOME OF SOIL INFLUENCE DEVELOPMENT OF BLACKLEG AND SOFT ROT DISEASES CAUSED BY PECTOBACTERIACEAE?

BABINSKA-WENSIERSKA Weronika. (1,2), MOTYKA-POMAGRUK Agata. (1,2), FONDI Marco. (3), MENGONI Alessio. (3), LOJKOWSKA Ewa. (1,2)

Text

In the recent years, scientists started to suspect that development of disease symptoms in crops is related to the so-called suppressiveness of the soil. In this regard, suppressive and non-suppressive soils are distinguished. Their microbiological composition either inhibit or favor development of certain disease symptoms on the there-grown plants. Therefore, the aim of this project was to investigate whether there is a relation between the soil type, composition of soil microbiota and progression of the *Pectobacteriaceae*-driven infections.

The herein studied suppressive and non-suppressive soils were selected basing on long-term monitoring data on the occurrence of *Pectobacteriaceae*-triggered infections on potato fields in Poland, collected since 1996, in addition to the current blackleg and soft rot incidences from 2021. The insight into the soil microbiome was achieved by analysis of 16S rDNA gene amplicons sequenced on the MiSeq machine, with a paired-end approach using the Illumina v3 set. Based on the metagenomic approach relying on R programming language including the DESeq2 package, it turned out that *Bacillus, Acidobacterium* and *Actinobacterium* spp. were more frequently identified in the suppressive than the non-suppressive soil samples.

This research provided evidence that the composition of soil microbiota is an important factor determining the prevalence of blackleg and soft rot diseases in potato fields.

Blackleg causes high economic losses for the seed potato industry worldwide. The disease is caused by bacteria belonging to the genera Pectobacterium or Dickeya. Recent developments in sequencing technology led to refine their taxonomy. Since 2016, the number of described species has increased from 12 to 33, highlighting their great genetic diversity. To date, few data are available about their specific behavior on potato host.
In order to compare the aggressiveness of 5 different Pectobacterium and 2 Dickeya species, we inoculated the pathogens on tubers just before plantation in trial fields. Each inoculum consisted in a mix of 5 strains belonging to a same species. Then, different parameters reflecting the aggressiveness and fitness of the inoculated strains were observed, as blackleg expression or vertical transmission in harvested tubers.
The results showed differences between species for all the parameters studied, highlighting different colonization strategies on potato host. Moreover, the qPCR analysis of blackleg symptoms obtained after inoculation with a mix of strains belonging to two different species can reveal a possible antagonistic relation between pectinolytic bacteria species association. Finally, a metabarcoding sequencing approach performed to monitor each inoculated strain revealed the predominance of one strain in each analyzed symptom, not always the same,

highlighting a pioneer effect during the symptom development.

T3SS INHIBITORS AS ANTIBIOTIC ALTERNATIVES IN FIRE BLIGHT MANAGEMENT

YANG Ching-Hong. (1), YU Manda. (1), HUANG Jian. (2), YUAN Xiaochen. (3)

Text

Fire blight, caused by Erwinia amylovora, is the top two most devastating diseases of apples and pears. Floral spray of antibiotics such as streptomycin is one of the few options that can effectively suppress blossom infection of fire blight in commercial orchards. However, the long-term use of streptomycin facilitated the evolution of the pathogen to develop resistance. Since the initial report in 1971, streptomycin resistance has been constantly observed in almost all apple-producing regions in the U.S. We identified a series of small phenolic compounds that can potently inhibit the expression of key type III secretion system (T3SS, a major pathogenicity factor) genes in the fire blight pathogen without affecting its growth. We proved that virulence suppression could lead to effective control of fire blight in our pilot field study. Most importantly, as the virulence inhibitors do not impose selective pressure, we anticipate less chance for the pathogen to mutate to develop resistance to the virulence inhibitors as they do to antibiotics.

INSIGHTS FROM THE INTERACTION OF BACTERIOPHAGES AND SOFT ROT PECTOBACTERIACEAE BACTERIA

CZAJKOWSKI Robert. (1)

(1) University of Gdansk, Intercollegiate Faculty of Biotechnology UG and MUG, Gdansk, POLAND

Text

Pectinolytic Soft Rot Pectobacteriaceae (SRP – *Pectobacterium* spp. and *Dickeya* spp.) cause soft rot diseases on various crops and ornamentals worldwide, leading to losses of up to 250 million Euro annually in crop production. Lytic bacteriophages able to infect and kill SRP bacteria can be readily isolated from virtually all SRP-containing environments, yet little is known about the selective pressure those viruses exert on their hosts. This presentation will cover the topic of receptors used by lytic bacteriophages to interact with *Pectobacterium* spp. and *Dickeya* spp. cells, spontaneous phage-resistance building up in the phage-full environment and the role of prophages (viral sequences) present in the SRP genomes in the ecology and environmental fitness of these bacteria. With these independent approaches, we investigated a trade-off hypothesis that phage infections may cause fitness advantages/disadvantages for the SRP bacteria in the environment.

Text

Dickeya and Pectobacterium species are necrotrophic pathogens that macerate stems (blackleg disease) and tubers (soft rot disease) of Solanum tuberosum. They proliferate by exploiting plant cell remains. They also colonize roots, even if no symptoms are observed. The genes involved in pre-symptomatic root colonization are poorly understood. Here, transposon-sequencing (Tn-seq) analysis of D. solani living in macerated tissues revealed 126 genes important for competitive colonization of tuber lesions and 207 for stem lesions, including 96 genes common to both conditions. In root colonization, Tn-seq highlighted 83 genes, all different from those in maceration conditions. They encode the exploitation of organic and mineral nutrients, including glucuronate, and synthesis of metabolites: cellulose, aryl polyene and oocydin. Overall, this work distinguished two metabolic networks supporting either an oligotrophic lifestyle on roots or a copiotrophic lifestyle in lesions. This work revealed novel traits and pathways important for understanding how the D. solani pathogen efficiently survives on roots, persists in the environment and colonizes progeny tubers.

GENOTYPIC AND PHENOTYPIC ANALYSES ON PECTOBACTERIUM ATROSEPTICUM ASSOCIATED WITH POTATO SOFT ROT AND BLACKLEG DISEASES IN POLAND

Text

Among the soft rot Pectobacteriaceae (SRP) the P. atrosepticum (Pba) species is responsible for serious damages affecting both potato yield and tuber quality especially under temperate climate condition. As limitation of the spread of SRP is solely prevention-based, we undertook broad characterization on both genotypic and phenotypic levels of the Pba isolates acquired during monitoring of potato fields in Poland in 2013, 2014 and 2016. Of REP, ERIC and BOX-based genomic fingerprinting, the BOX-PCR allowed for classification of 118 Pba strains into six groups. Finally, 23 Pba strains representing all BOX

groups and originating from various growing seasons were selected for genotypic, phylogenetic and phenotypic studies. rpoS-based phylogeny revealed intraspecies variation (16 SNP sites) among the studied Pba strains, in contrast to the analyses relying on gyrA (1 SNP) and recA (0 SNP) sequences. Pba strains showed higher potency to macerate potato tissue at 20°C than 28°C. Characterized isolates exhibited rather uniform production of plant cell wall degrading enzymes (pectinases, cellulases and proteases), lipases, siderophores and biofilm, however in majority of cases inferior in comparison to Dickeya solani and Pectobacterium carotovorum strains.
In conclusion, this study revealed genotypic and phenotypic uniformity in addition to high virulence potential of Pba strains isolated from potato fields during several growing seasons in Poland.

LC-MS-MOLECULAR NETWORKING TO PROFILE THE METABOLOME OF PECTOBACTERIUM BRASILIENSE 1692

BOKHALE Mamokete. (1,4,5), MHLONGO Msizi Innocent. (2,6), MADALA Edwin Ntakadzeni. (3,7), MOLELEKI Lucy Novungayo. (1,4,5)

Text

Pectobacterium brasiliense is an economically important pathogen that infects potatoes and causes significant economic loss of crops worldwide. Although metabolites against *P. brasiliense* produced by potato tubers and stems have been identified, information on the metabolites that *Pbr*1692 secretes in the host environment to manipulate host defenses or for cell growth is lacking. Therefore, this study aimed to employ untargeted liquid chromatography coupled with mass spectrometry and molecular networking to understand the cell metabolism of *Pbr*1692. The molecular networking results indicated that *Pbr*1692 produces metabolites, some of which are involved in virulence and cell growth. Among these, the derivative phytotoxin N-coronafacoyl-valine was detected in the exometabolome in the exponential growth phase, suggesting a role of N-coronafacoyl-valine in *Pbr*1692 virulence. Furthermore, the molecule lumichrome was detected at the exponential growth phase of growth in both the exo- and endometabolome suggesting a possible role in cell growth and proliferation. Additionally, siderophores were detected in the endo and exometabolome of the exponential and stationary growth phase, suggesting siderophores are required for the growth of *Pbr*1692 and their production is population density-dependent. This study will assist in further identifying metabolites and their role in *Pbr*1692 growth and virulence.

A NATURAL SINGLE NUCLEOTIDE MUTATION IN THE SMALL REGULATORY RNA ARCZ OF DICKEYA SOLANI SWITCHES OFF THE ANTIMICROBIAL ACTIVITIES AGAINST YEAST AND BACTERIA

Text

The necrotrophic plant pathogenic bacterium *Dickeya solani* emerged in the potato agrosystem in Europe. All isolated strains of *D. solan*i contain several large polyketide synthase/non-ribosomal peptide synthetase gene clusters. Analogy with genes described in other bacteria suggests that the clusters *ooc* and *zms* are involved in the production of secondary metabolites of the oocydin and zeamine families, respectively. A third cluster, named *sol* produces a new antibiotic, solanimycin, capable of killing many yeasts, including the human pathogen *Candida albicans*. In our study, we analysed the antimicrobial functions of these three PKS/NRPS clusters against bacteria, yeasts or fungi in different wild-type *D. solani* isolates. Phenotyping and comparative genomics revealed that the small regulatory RNA ArcZ plays a major role in the control of the clusters *ssm* and *zms*, but not *ooc*. A single-point mutation, conserved in some *Dickeya* wild-type strains, including the type strain IPO 2222, impairs the ArcZ function by affecting its processing into an active form. Our study showed that single-nucleotide polymorphisms of sRNA encoding genes can have huge impacts on bacterial phenotypes. It is thus critical to pay attention to the allele diversity of sRNA genes.

DYNAMIC AND DIVERSIFIED BACTERIAL COMPLEX CAUSING POTATO BLACKLEG AND SOFT ROT IN THE NORTHEASTERN UNITED STATES

Text

Potato blackleg and soft rot (BSR) has caused substantial economic losses to potato production in the Northeastern region of the United States since the 2015 outbreak. To understand the disease epidemiology, pathogens were isolated from potato plants and tubers showing BSR symptoms from various locations in multiple years. The isolates were identified using a polymerase chain reaction. Representative bacterial species were compared in infection and pathogenicity using whole genome sequencing analysis. The bacterial complex recovered from single disease lesions was examined using metagenomic sequencing. Dickeya dianthicola genotype I was the predominant species in the outbreak, as observed in the field. Pectobacterium parmentieri has been frequently associated with tuber

damage in storage. In addition, several other bacteria were found associated with BSR including D. polaris, D. dadantii, D. atroseptica, D. zeae, P. brasilliense, and P. versatile. The frequency of the species has changed dynamically. Noticeably, P. versatile is now the most frequently isolated species among all the pathogens in 2022. D. aquatica, isolated from surface water ,caused severe BSR on potatoes, and could be a potential inoculum source. Multiple bacterial species synergistically caused higher disease severity than that caused by any single species. Tubers had a much higher infection incidence when they were contaminated/inoculated at harvesting or before storage than inoculated at planting.

ROLE OF LRP IN DICKEYA DADANTII

Text

Bacterial pathogenic growth requires a swift coordination of pathogenicity function with various kinds of environmental stress encountered in the course of host infection. Among these, nutritional deficiency is one of the major stresses that pathogenic bacteria must face. The nucleoid Associated protein (NAP) LRP play a key role in bacteria genome regulation in response to nutritional stress. LRP is widely distributed in Bacteria and Archaea and was shown to control, in addition to basic metabolism genes, various adaptation processes, including virulence genes in animal pathogens. No study has been conducted to determine the role of LRP in plant-pathogenic bacteria. Therefore, we investigate the role of LRP in the model phytopathogen *Dickeya dadantii*. We inactivated LRP and determined both phenotypic effects of *lrp* null mutation on *D.dadantii* virulence and the transcriptional response under various conditions of growth. We show that *lrp* null mutation reorganizes the genomic expression affecting the main virulence genes involved in both symptomatic and asymptomatic phases of infection, these regulations being dependent on the availability of nutrients. Thus, LRP allows the bacterium to optimize the use of energy to colonize the host plant.

THE CHROMOSOME-ENCODED TYPE II TOXIN-ANTITOXIN SYSTEMS OF DICKEYA DADANTII 3937.

Text

Type II toxin-antitoxin (II TA) systems are the intracellular modules consisting of 2 non-secreted proteins: a stable toxin and an antitoxin, which binds the toxin and neutralizes its toxic effect. The disturbance in the intracellular toxin and antitoxin ratio typically leads to inhibition of bacterial growth or even cell death. A number of studies suggests that chromosome-encoded TA modules are engaged in important processes including maintenance of mobile genetic elements and bacteriophage defence, but possibly also biofilm formation and stress response.

The *Dickeya dadantii* 3937 strain serves as a model for pathogens causing the soft-rot disease in a wide range of angiosperm plants. In 2011 Glasner *et al*. published the DNA sequence of *D. dadantii*, and identified in silico over 20 putative II TA systems. However, the computational analysis does not provide proof of a TA systems activity in a living bacterial cell. Therefore, in this study we determined which of II TA systems of *D. dadantii* is functional *in vivo*. We were able to establish that among 24 putative II TA modules, 7 were active in vivo, while the activity of 17 was excluded, either on the basis of DNA sequence analysis or after experimental validation. Among 7 bona fide TA systems, one was described previously as the $ccdAB_{Ech}$ module of *E. chrysanthemii*, while the remaining 6 were newly validated by our group. Among them the *dhiTA* system probably encodes proteins belonging to the novel T/A superfamilies.

CHARACTERIZATION OF A NEW GENUS OF THE PECTOBACTERIACEAE FAMILY AND RECTIFICATION OF THE OUTLINE OF THIS FAMILY

Text

The bacterial order *Enterobacterales* is currently divided into eight recognized families: *Budviciaceae*, *Enterobacteriaceae*, *Erwiniaceae*, *Hafniaceae*, *Morganellaceae*, *Pectobacteriaceae*, *Thorselliaceae*, *Yersiniaceae*, and the not yet recognized family *Bruguierivoracaceae*. The *Pectobacteriaceae* family comprises plant pathogens able to provoke diverse diseases, including plant maceration due to the production of pectinases disrupting the plant cell wall. To better understand their natural diversity, a survey of pectinolytic bacteria was performed in lakes of the French region La Camargue near the Mediterranean Sea. Sixteen atypical pectinolytic isolates were obtained from brackish water of three lakes. In phylogenomic trees, the novel strains formed a new clade of *Pectobacteriaceae*, separate from the previously described genera of this family: *Affinibrenneria*, *Brenneria*, *Dickeya*, *Lonsdalea*, *Musicola*, *Pectobacterium*, and *Samsonia*. Phylogenomic study of representative members of the order *Enterobacterales* clearly indicated that *Acerihabitans* does not belong to *Pectobacteriaceae* and should be reclassified in the *Bruguierivoracaceae* family. In contrast, the relative position of *Symbiopectobacterium* in the *Enterobacterales* tree supports its appurtenance to *Pectobacteriaceae*. Finaly, based on phenotypic, genomic and phylogenetic characteristics, we propose the creation of a new genus including the sixteen pectinolytic isolates from Camargue brackish lakes.

METALS AT THE BACTERIAL/PLANT INTERFACE, CASE OF A PHYTOPATHOGENIC BACTERIUM AND ZINC

Text
Metals are increasingly recognized as playing an essential role in bacterial/host interaction, and in particular in pathogenicity phenomena. In this work, we investigated the role of the metalloregulator Zur in the interaction between the plant pathogenic bacterium Dickeya solani and plants. Zur senses zinc and regulates the transcription of genes involved in zinc homeostasis. However, a growing number of studies show that the Zur regulon is not restricted to genes involved in the maintenance of homeostasis but that some of these genes are involved in the pathogenicity of the bacteria. We constructed a mutant deleted from the zur gene in D. solani. As expected, this mutant showed increased sensitivity to Zn. We also showed that deletion of zurcaused an increased sensitivity to polymyxin B, an antimicrobial peptide. Interestingly, the mutant dispalyed a very attenuated virulence. This attenuated virulence was not related to a developmental defect of the mutant in the plant. We also showed that the production of pectate lyases, major virulence factors, was induced by Zn, but that Zur did not directly control these genes. Finally, real-time monitoring of the expression of the znuAgene, encoding a Zn acquisition system, during the infection of the plant, revealed that Zn acquisition is important in the early phases of the infection.

PBR1692 SECRETOME ANALYSES

MAPHOSA Silindile. (1), **MOLELEKI Lucy. (1)**

(1) Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, SOUTH AFRICA

Text
Pectobacterium brasiliense (Pbr) are important phytopathogens affecting potato and other crop plants, globally. To enhance our understanding of the biology of P. brasiliense, the Pbr1692 secretomes of outer membrane vesicles (OMVs) and the Type 6 Secretion System (T6SS) were determined using mass spectroscopy. Functional annotation of OMV proteins revealed that OMVs harbour cargo associated with other secretion systems such as phospholipase A1 and A2, polygalacturonase, peptidase, cellulase and Avirulence L (AvrL). Furthermore, the role of Pbr 1692 OMV-mediated competitive fitness against Dickeya dadantii, virulence on potato tubers, and elicitation of a hypersensitive response (HR) in Nicotiana benthamiana leaves was demonstrated. This study further used in silico computational prediction tools to identify T6SS-secreted proteins. To validate these in silico predictions, secretomes of Pbr1692 wild type (T6SS-active strain) and tssBC sheath mutant (T6SS-inactive strain) secretomes were compared to each other as well as to the predicted substrates. A combined total of 449 proteins were secreted by the T6SS-active and inactive Pbr 1692 strains. Of these, a total of 19 proteins were secreted by the T6SS-active Pbr 1692 strain only, suggesting that these proteins are secreted in a T6SS-dependant manner. These included T6SS hallmarks such as VgrG and Hcp, and HNH endonuclease. Overall, our results suggest that OMVs and the T6SS potentially share substrates with each other.

IDENTIFICATION AND CHARACTERIZATION OF BACTERIA FROM THE GENUS PECTOBACTERIUM ISOLATED FROM THE SOIL, WATER, AND INSECTS

Text

Bacteria of the *Pectobacteriaceae* family are widespread plant pathogens that are being isolated globally from a wide range of plants but also from water, soil, or insect guts. We decided to check whether Soft Rot Pectobacteriaceae strains isolated from soil, water, and insects exhibit equally strong pathogenicity as pectinolytic strains isolated from diseased plants. We isolated 85 pectinolytic strains from 46 water, soil, and insect samples. The strains were identified by species-specific PCR, and *recA* gene sequencing. The isolated bacteria were assigned to the eight species, *P. atrosepticum, P. aquaticum, P. brasiliense, P. carotovorum, P. polonicum, P. quasiaquaticum, P. versatile* and *Dickeya zeae*. The species *P. versatile* was most abundant.

To perform the characteristics of isolated strains, comprehensive biochemical analyzes were carried out, and the adaptive potential to adverse environmental conditions such as high salinity, extreme pH and limited water availability was examined. In addition, susceptibility to selected antibiotics and possible resistance mechanisms were examined.

We have found that *Pectobacterium* strains that do not originate from plants are characterized by a very large adaptation potential to harsh environmental conditions and exhibit equally strong virulence as strains isolated from plants with disease symptoms. Moreover, some strains revealed the ESBL and KPC type of resistance to antibiotics.

Text

Surface architecture and its effect on bacterial attachment, colonization, and micro-environment, are poorly understood. Our aim is to unravel the complex interaction of leaf surfaces with bacterial cells and explore the mechanism by which microstructures influence bacterial behavior and gene regulation. For that purpose, two closely related ornamental species of the genus Zantedeschia were chosen as model hosts for the soft rot pathogen *Pectobacterium brasilense*. While *Z. aethiopica* (ZA) has a relatively smooth, less competent surface for bacterial cell attachment, the hybrid cultivar 'Captain Romance' (CR) has a rough surface, which is highly compatible with bacterial colonization. Using biomimetic replicas of leaf surfaces, we were able to associate the phytopathogen attachment patterns and the surface microstructure, by this to establish a direct linkage between bacterial behavior and the microstructure. Our hypothesis is that the microstructure also affects the microenvironment and by this differential regulation patterns of the colonizing bacteria. Our research combines multidisciplinary approaches such as biomimetics, microscopy, and

molecular microbiology to study the events that affect microbes' interaction with natural and artificial surfaces.

ROLE OF ANAEROBIC RESPIRATIONS OF CARBON SOURCES ON SURVIVAL AND ECOLOGICAL FITNESS OF DICKEYA GENUS

HAICHAR Feth El Zahar. (1)

(1) INSA Lyon, Villeurbanne, FRANCE

Text

Bacteria are ubiquitous and occupy a very wide range of ecological niches where oxygen can be rapidly limited. In this case, bacteria develop flexible metabolic respiration. Therefore, demonstrating the possibility of using carbon sources as alternative terminal electron acceptors (TEAs) and elucidating the underlying genetic pathways has great potential to help understand bacterial strategies to adapt and persist in the environment. This question is more relevant in the case of phytopathogenic bacteria which face many specific challenges to infect plants. It is the case for Dickeya, an emergent pathogen, found in various ecological niches, such as plant apoplast, and responsible for soft rot disease in a wide variety of plants. Understanding anaerobic respiratory pathways involved in Dickeya persistence and colonization will allow us to better understand its pathogenicity, and thus better counter it. In this study, we demonstrated that D. dadantii is able to use malate and asparagine as TEA. By constructing metabolic model of D. dadantii, we predicted pathways involved in anaerobic growth using asparagine and malate. Mutants affected in asparagine pathway were constructed and we evidenced the role of asparagine respiration in D. dadantii virulence. We also tested whether asparagine pathway is conserved among Dickeya and Pectobacterium genus.This study demonstrated that anaerobic respiration is an important trait involved in D. dadantii virulence.

DIVERSITY AND BIOLOGICAL FEATURES OF PECTOBACTERIUM BRASILIENSE, CAUSATIVE AGENT OF POTATO BLACKLEG

VAN DER WOLF Jean Martin. (1), VAN DUIVENBODE Inge. (2), KRIJGER Marjon. (1), MENDES Odette. (1), BRANKOVICS Balazs. (1), VAN DER LEE Theo. (1)

Text

In the last decade, *Pectobacterium brasiliense* has become the dominant blackleg causing soft rot Pectobacteriaceae (BL-SRP) in seed potatoes in the Netherlands and *P. brasiliense* is now responsible for over 90% of all blackleg incidences. The genetic diversity of *P. brasiliense* in potato is high, but only a limited number of haplotypes is able to cause blackleg. Most strains belonging to these virulent haplotypes can cause disease. To detect the various blackleg causing haplotypes of *P. brasiliense*, enrichment TaqMan assays were developed.

Seed potato cultivation starts with minitubers (PB1) which are free of BL-SRP. However, surveys conducted at different Dutch farms, showed that already during the growing season a PB1 crop can become infected with BL-SRP, with incidences of over 40%, depending on

growing season and location. In most cases one of the virulent *P. brasiliense* haplotypes was detected. In surveys performed to identify possible infection sources, BL-SRP were not detected in rain water, but 2.3% of the insects sampled in a potato field carried BL-SRP, in most cases a virulent haplotype. In field experiments, spray-inoculation of haulms of young potato plants with *P. brasiliense* resulted in tuber infections even at a low inoculum density of approximately 100 cfu per plant, indicating the risks of contamination of haulms.

Text
Dickeya dadantii is a bacterium causing soft rot disease in a wide range of plant species. During the infection process, D. dadantii undergoes environmental stresses: acidic stress during penetration in the apoplast, oxidative stress due to the plant immune response, and osmotic and oxidative stresses during plant maceration and disease generalization. Interestingly, these stresses affect DNA supercoiling (SC): acid and oxidative stresses lead to DNA relaxation and osmotic stress induces an increase in SC level. Deciphering the mechanisms of SC-related transcriptional regulation in that species is thus crucial for our understanding of the mechanisms of virulence. As far as we know, the SC level is mainly regulated by topoisomerase I and DNA gyrase. Inhibiting either of these enzymes with antibiotics leads to global SC modifications and subsequent changes in global gene expression. We analyzed the first transcriptomic response of a Gram-negative bacterium to topoisomerase I inhibition by an antibiotic. We detected distinct patterns of expression level and spatial organization along the chromosome. Particularly, we found that all SC variations affect the expression of two major virulence genes, encoding pectate lyases (destroyer of the cell wall, causing the soft rot symptom), pelE and pelD.

VIRULENCE REGULATORY NETWORK OF DICKEYA DADANTII: WHAT IS THE ROLE OF POSTTRANSCRIPTIONAL REGULATION?

Text

The genus *Dickeya* are enterobacterial plant pathogens responsible for soft rot disease in a wide range of plant species, including economically important crops e.g. potato and rice. The infection process is divided into two main phases: the asymptomatic phase where *Dickeya spp.* produce early virulence factors to colonize the apoplastic spaces between plant cells; and the symptomatic phase, which is associated with the secretion of late virulence factors, i.e. plant cell wall degrading enzymes that macerate the plant tissue. Therefore, the spatial and temporal production of the virulence factors must be precisely controlled to ensure the efficient colonization and degradation of the host. While many transcriptional regulators are involved in controlling *Dickeya*'s virulence factors, knowledge of post-transcriptional regulation is still in infancy. Our first results on *Dickeya dadantii* RNA chaperons suggest a post-transcriptional regulation of virulence. Additionally, the obtention of *D. dadantii* transcriptional landscape allowed us to identify RNAs predicted to interact with the mRNAs of virulence factors regulators that play a role in response to oxidative stress and changing metabolic content in the apoplast. Ongoing work aims to establish a link between regulatory RNAs, virulence factors, and environmental changes encountered by bacteria during infection, which will lead to a better comprehension of the complex virulence regulatory network of *D. dadantii*.

COMPARISON OF THE ACTIVITY OF THE VFM QUORUM SENSING SYSTEM IN DIFFERENT STRAINS OF THE GENUS DICKEYA.

Text

The Vfm Quorum Sensing (QS) system is preponderant for the virulence of different species of phytopathogenic bacteria of the genus *Dickeya*. The *vfm* gene cluster includes 26 genes involved in the biosynthesis, sensing or transduction of the Vfm signal. The transduction of the Vfm signal was shown to result into the activation of the promoter of the gene *vfmE* encoding a transcriptional regulator of the AraC family which itself activates the promoter of genes encoding the plant cell wall degrading enzymes (PCWDEs). The transcriptional regulator VfmE was shown to also activate promoters of the *vfm* gene cluster, allowing an exponential auto-induction of the Vfm QS system. Additionally, the activity of the transcriptional regulator VfmE was shown to also be controlled by Vfm-independent regulatory pathways involving the secondary messenger c-di-GMP and/or transcriptional regulators encoded outside of the *vfm* gene cluster. Here, we used a reporter gene fused to the promoter of the gene vfmE and compared the activity of the *vfmE* promoter among strains of *Dickeya*.

Phytobiomes Research for Plant Health

MODULATION OF PLANT DEFENSE GENE EXPRESSION IN BARLEY BY RUSSIAN WHEAT APHID HONEYDEW AND HONEYDEW-ASSOCIATED BACTERIA

LUNA Emily. (1), HARDIN Janet. (1), PINEDO Santiago. (1), LEACH Jan. (1)

(1) COLORADO STATE UNIVERSITY, Fort Collins, UNITED STATES

Text

Plant health outcomes are largely based on the dynamic interactions of multiple organisms in the phytobiome. Our previous work demonstrated that variation in Russian wheat aphid (RWA, *Diuraphis noxia*)-induced chlorosis on wheat is determined, in part, by aphid-associated bacteria. Aphids with high titers of bacteria induced expression of salicylic acid (SA) biosynthetic genes and accumulation of SA, a hormone that inhibits insect resistance, in susceptible wheat. High, sustained expression of SA biosynthetic genes was followed by downregulation of jasmonic acid (JA) biosynthetic genes; JA is associated with insect resistance. These trends in plant defense gene modulation are also evident in barley, an alternate host for RWA with considerable genetic resources. We hypothesize that aphid-associated bacteria contribute to aphid virulence by modulating the plants' insect defense mechanisms. Although saliva from aphids contains culturable bacteria, scanning electron microscopy (SEM) studies did not detect bacteria in high numbers in the aphid salivary glands or foreguts. However, the same genera of bacteria were detected in aphid honeydew as in saliva; thus, we are focusing on the role of honeydew in induction of plant defense. In this presentation, we will report on the impact of honeydew and honeydew-associated bacteria on plant defense response pathways in barley.

UNRAVELLING THE EPIPHYTIC MICROBIOME OF RASPBERRIES: HOW FRUIT AGE AND POLYTUNNEL LOCATION IMPACT PATHOGENIC AND BENEFICIAL FUNGI AND BACTERIA ON THE SURFACE OF RASPBERRIES

FARWELL Lauren. (1,2), MAGAN Naresh. (2), XU Xiangming. (1)

Text

Raspberries are a profitable crop, susceptible to fungal diseases. In the UK, *Cladosporium* fruit rot is becoming more prevalent. For many fungal pathogens, inoculum is spread via airborne spores that land on the surface of plant tissues. *Cladosporium* is reported to be an abundant component of aero-inoculum, and is likely to land on the fruit surface. It is not known if more *Cladosporium* may germinate and grow as the fruit ages, or if beneficial organisms may inhibit such fungal growth. Hence understanding how fruit age impacts the microorganisms on the fruit surface may provide insight into how they cause or prevent disease.

The aero-microbiome is also impacted by air movement, which may be impeded by the presence of polythene plastic. The gradient of temperature and humidity associated with large polythene tunnels may also impact the aero-microbiome composition.

In this study, we sampled green, ripening and ripe fruit at two time points, and two locations

(the outer edge and centre of polytunnels). We then performed metabarcoding to profile the microbiome on the surface of raspberry fruits.
Preliminary results show that sampling date, fruit age, location within the polytunnel and the polytunnel location all have significant effects on the epiphytic microbiome of raspberries. Differential analyses revealed that multiple pathogenic species (including *Cladosporium*) increased and decreased across fruit ages and between fruit sampled in the inner and outer sections of polytunnels.

THE RULES BEHIND PLANT MICROBIOME ASSEMBLY: A BIG DATA APPROACH

MALACRINO Antonino. (1), FRANCOMANO Edda. (1), ZAKARIA Nesma. (1), SCHENA Leonardo. (1)

(1) University of Reggio Calabria, Reggio Calabria, ITALY

Text
The study of plant microbiomes is increasingly attracting a large interest worldwide, generating groundbreaking knowledge on the composition, function, and origin of the plant-associated microbial communities. However, we are only beginning to understand the rules behind the assembly of plant microbiomes. In this study, we leverage on the massive amount of publicly available data generated by over thousands of studies (timespan 2017-2021), which we collected and re-analyzed under a common framework. Using a variety of metrics and approaches, we tested several questions, including: (i) which are the major factors contributing to the assembly of plant microbiomes? (ii) do specific stressors (e.g., pathogens, drought) generate unique changes in the plant microbiomes? (iii) does plant phylogeny reconciliate with the diversity/structure of plant microbiomes? We also carefully searched each article, highlighting important methodological limitations that need to be considered in the future research endeavors. Our results contribute to a more general understanding of plant-microbiome interactions, which are thought to be key towards eco-sustainable plant protection, ecosystems conservation, and successful ecological restoration

DRY LENTICEL ROT – AN EMERGING POSTHARVEST DISORDER ON APPLES IN NORTHERN ITALY

PRIMISSER Stefanie Maria. (1,2), DELTEDESCO Evi. (1), OETTL Sabine. (1)

(1) Laimburg Research Centre, Bolzano, ITALY; (2) University of Turin, Torino, ITALY

Text
Symptoms of dry lenticel rot, also known as Ramularia spots, were first observed 2012 on apples after long-term conservation in the cold storage in South and Tyrol Piedmont (Northern Italy). Since then, only few notifications of this postharvest disorder were made from the fruit growers cooperatives. However, since 2019, a notable increase of dry lenticel rot, has been observed in South Tyrol and recently, occurrence of similar symptoms has been reported from other apple growing areas in Austria and France. A collection of more than 100 fungal isolates from affected fruit and originating from various orchards was established. Subsequent multi locus sequencing analysis of five gene loci identified Ramularia mali as causative agent of this postharvest disease. Nevertheless, isolates of

deviating morphology and genetic variability were identified and thus, their impact on the disorder needs to be investigated. Ramularia mali is able to switch from endophytic to epiphytic lifestyle, however, the trigger for this switch remains to be elucidated. Symptom development might be linked to the apple peels' microbiome composition, thus, metabarcoding of the fruits' endo- and epiphytic microbiome shall provide further information and contribute to the identification of potentially antagonistic or beneficial microorganisms for further applied research.

GENETIC ANALYSIS OF STRIPE RUST RESISTANCE IN CIMMYT COMMON WHEAT LINE KFA/2*KACHU UNDER CHINESE RUST ENVIRONMENT

YIN Yuruo. (1), YUAN Chan. (1), **ZHANG Yichen. (1)**

(1) HuaZhong Agricultural University, Wuhan, CHINA

Text

Breeding resistant wheat variety is the most economic and efficient way to manage wheat stripe rust, while identification of new stripe rust resistance gene and development the molecular markers will be very useful for wheat breeder in the breeding program. In the present study, a recombinant inbred line (RIL) population derived from a cross of the resistant parent KFA/2*KACHU and susceptible parent Apav#1 was used to map stripe rust resistance loci. In combination of GBS genotyping platform and BSR-Seq method, we mapped a new race-specific stripe rust resistance gene on wheat chromosome 5BL at the seedling stage, temporarily named as *YrK*. *TraesCS5B02G330700* encoded a receptor-like kinase was considered as the key candidate gene of *YrK* based on virus induced gene silencing (VIGS) method. Its expression showed a significant up-regulated at 24h after inoculation and the functional molecular markers were developed based on the polymorphic SNPs in the CDS region. In addition, a total of four adult plant resistance (APR) loci were identified on wheat chromosome 1BL, 2AS, 2BS and 4AL, respectively. Among these, *QYr.hazu-1BL* and *QYr.hazu-2AS* was verified as the known resistance genes *Lr46/Yr29/Pm39* and *Yr17*, respectively. *QYr.hazu-2BS* was a new APR locus and the closely linked SNP markers were converted into breeder-friendly KASP markers.

IS THE PLANT RHIZOBIOME ENGAGED IN INTERACTIONS BETWEEN PECTOBACTERIUM AND PLANTS?

Text

Phytopathogens, to infect a host, must bypass the host's defence system and the additional barrier their plant microbiome provides. To determine whether the plant microbiome affects

the pathogen and determines its interactions with the plant or vice versa, we investigated the changes in the plant rhizobiome composition during plant-bacteria interactions.
Using the 16S rRNA amplicon sequencing approach, we determined the microbiome composition of soil and rhizosphere of Arabidopsis, Chinese cabbage, Calla lily and Turmeric before and after inoculation with Pectobacterium. First, we counted the number of cultivable bacteria in each sample, and pure bacterial strains were isolated. Then the interaction between the strains from the rhizosphere and *Pectobacterium* was studied.
The sequence analysis of the 16S rRNA gene showed that the biodiversity of the soil microbiome is significantly lower than those observed in the case of plants' rhizosphere. The microbiome of each plant has different species composition.
Interestingly, it was observed that *Pectobacterium* significantly reduced the number of taxa in the rhizosphere of each plant. However, no antagonism between strains isolated from the rhizosphere and *Pectobacterium* was found. The obtained results indicate the negative impact of *Pectobacterium* on the biodiversity of the plant microbiome, which in turn may lead to the breakdown of their protective barrier and the development of disease symptoms.

Text
Late wilt disease, caused by the fungus *M. maydis,* threatens commercial maize production in high-risk areas. Thus, searching for control options against the pathogen is one of the top priorities in Israel, Egypt, and other countries. Disease-resistant maize genotypes can reduce yield loss. Yet, aggressive variants of the fungus can overcome host resistance. The current study aimed at inspecting *Trichoderma asperellum*, a maize endophyte, and its secreted metabolites, particularly the purified 6-pentyl-α-pyrone (6-PP), against the pathogen. First, adding *T. asperellum* directly to seeds with sowing provides significant protection to sprouts (up to 42 days) in a growth room, with more than two-fold growth promotion and reduced pathogen root infection (detected by real-time PCR). The same procedure applied in a commercial field reduced the cobs' symptoms by 11%, resulting in nine-fold lower pathogen DNA levels in the stem tissue. Second, the *T. asperellum* secreted 6-PP compound (30 µg/seed) was used in seed coating and tested against the *T. asperellum* secretory metabolites' crude (diluted to 50%). At the season's end, these treatments improved plant biomass by 90–120% and cob weight by 60%. Moreover, the treatments significantly ($p < 0.05$) reduced the symptoms (up to 20%) and pathogen infection (94–98%). The current study's results reveal the potential of 6-PP as a new fungicide against *M. maydis*. Such a treatment may protect maize plants from other soil diseases.

DECIPHERING THE ACTIVE STRAWBERRY MICROBIOME ASSOCIATED WITH ROOTS AND RHIZOSPHERE SOIL

ADHIKARI Tika. (1), PHILBRICK Ashley. (1), LOUWS Frank. (1)

(1) North Carolina State University, Raleigh, Nc, UNITED STATES

Text

Plants recruit diverse microbial communities from the soil. Plant-microbiome interactions confer multiple beneficial impacts on crop plants. Understanding of such interactions in strawberry production systems is still obscure. Using a strawberry crop model, we conducted a 3-year field experiment at Castle Hayne, North Carolina to test the hypothesis that carbon sources (molasses, mustard meal, and mixtures) when used in anaerobic soil disinfestation (ASD) procedures can improve soil health and impact microbial communities. Our results demonstrate that ASD, particularly with the mixture of molasses and mustard meal significantly produced higher marketable yield, and reduced soil-borne pathogens. Microbiome data analysis showed increased relative abundance and structure of both bacterial and fungal communities and influenced the α-diversity and β-diversity compared with the non-treated control. We discovered shifts in the assembly of beneficial microbiome members such as *Arthrobacter, Bacillus*, *Paraburkholderia*, *Bradyrhizobium* and *Trichoderma harzianum*. Collectively, this study adds to our understanding of the eminent roles of beneficial microbiomes and uncovering mechanisms that can lead to potential biologically based solutions for disease resilience in strawberry, and enhanced productivity, consistent with a sustainable agriculture.

Powdery mildews: phylogenetics, phylogenomics, and molecular host-pathogen interactions

AN AVIRULENCE EFFECTOR FROM BARLEY POWDERY MILDEW FUNGUS CAN SUPPRESS MILDEW LOCUS A RESISTANCE.

Text

The barley powdery mildew fungus *Blumeria hordei* (*Bh*) relies on a huge repertoire of effectors for successful infection and the development of disease symptoms on the barley host. In resistant lines, the *Bh* AVRA effectors are recognised by cognate barley nucleotide-binding leucine-rich repeat receptors encoded at the *Mildew locus A* (MLA NLRs). For example, AVRA13-1 is recognized by MLA13. The effector-receptor interaction activates host cell death, and this terminates powdery mildew disease development. We demonstrate that a virulent form of AVRA13, called AVRA13-V2, escapes MLA13 recognition by substituting a serine for a leucine residue at the C-terminus. Counterintuitively, this substitution in AVRA13-V2 results in an enhanced MLA13 association and prevented the detection of AVRA13-1 by MLA13. Therefore, AVRA13-V2 is a dominant-negative form of AVRA13. Our interaction

analysis involving effector and receptor mutant variants constitute an important step to define intermediate receptor conformations during NLR activation and implies that the dominant-negative function of AVRA13-V2 has contributed to the breakdown of Mla13 resistance.

HOST PHOSPHOLIPIDS ARE INVOLVED IN RESISTANCE AND SUSCEPTIBILITY TO FUNGAL INVASION INTO EPIDERMAL CELLS OF BARLEY

Text

ROP GTPases regulate cell-polarity in plant growth processes. The barley ROP RACB is involved in susceptibility towards infection by the barley powdery mildew fungus Blumeria hordei. To improve our knowledge on cellular pathways that connect RACB-signaling to disease susceptibility, we used an untargeted CoIP-LC-MS/MS screening from Bh-infected barley plants, that expressed constitutively activated (CA) GFP-RACB. Thereby, we uncovered new RACB interaction partners of plant and fungal origin. At least three of those proteins, a plant phosphoinositide phosphatase, a plant phosphoinositide phospholipase and one putative Bh-effector protein, are involved in the interaction outcome. The candidate interactors and RACB are able to interact with overlapping anionic phospholipid species in vitro, and in case of RACB, this lipid-interaction is mediated by its polybasic region (PBR). In planta, the PBR appears to be essential for RACB's plasma membrane localization and recruitment to the haustorial neck region during Bh-invasion. Other canonical interaction partners of RACB are also targeted to this fungal interface in a RACB-dependent manner. Phosphatidyl-4-phosphate and phosphatidylserine show a distinct enrichment at the haustorial neck region, suggesting a connection to subcellular targeting of RACB at this site. We suggest that the interplay of ROPs with anionic phospholipids steers subcellular enrichment of components that are pivotal for fungal penetration success or failure.

POWDERY MILDEW IN AUSTRALIAN MUNGBEAN CROPS: IDENTIFICATION OF THE PATHOGENS, THEIR HOST RANGE AND EPIDEMIOLOGY

KELLY Lisa. (1), VAGHEFI Niloofar. (1,2), KISS Levente. (1)

(1) University of Southern Queensland, Toowoomba, AUSTRALIA; (2) The University of Melbourne, Melbourne, AUSTRALIA

Text

Since the 1970's, powdery mildew has been a consistent threat to mungbean (Vigna radiata) production across Australia. Powdery mildew can reduce yields by more than 40% without fungicide management. Despite its economic importance, the precise identification of the pathogens and many aspects of their disease has been unclear. This study was designed to validate the identification and taxonomy of the species causing powdery mildew in Australia, and improve our understanding of their host range, virulence and climatic factors that favour

disease. In this study we identified Podosphaera xanthii and Erysiphe vignae, a newly recognised taxon, as the causal agents of the disease based on cross-inoculation studies and the examination of internal transcribed spacer sequences of the nuclear ribosomal DNA and/or morphology of freshly collected and herbarium specimens. Further examination of fresh and historical herbarium specimens was conducted to investigate the host range of these pathogens. Cross-inoculation experiments were performed to determine whether P. xanthii isolates that infect mungbean are different to the P. xanthii isolates that infect cucurbits. We also report on the effect of temperature on conidial germination, infection and sporulation in the two species. The outcomes of this study significantly improve our understanding of powdery mildew in Australian mungbean crops and assist in the development of better control strategies for these diseases.

COORDINATED ROLE OF CHITIN-TRIGGERED IMMUNITY SUPPRESSION MECHANISMS OF PODOSPHAERA XANTHII

BAKHAT Nisrine. (1), FERNÁNDEZ-ORTUÑO Dolores . (1), PÉREZ-GARCÍA Alejandro. (1)

(1) Instituto de Hortofruticultura Subtropical y Mediterránea “La Mayora”, Universidad de Málaga, Consejo Superior de Investigaciones Científicas (IHSM–UMA–CSIC), Malaga, SPAIN

Text

Fungal pathogens are the main destructive microorganisms for terrestrial plants and pose increasing challenges for global agricultural production. Chitin is a vital building block for fungal cell walls and a widely effective inducer for plant immunity that, through chitin-triggered immunity, can defend against fungi attack. That is why the phytopathogenic fungi have developed different virulence factors that allow them to suppress the activation of this defensive response. In this study, the molecular mechanisms of chitin-triggered suppression, previously identified in the cucurbit powdery mildew *Podosphaera xanthii*, have been evaluated in detail. These mechanisms consist of the modification of chitin immunogenic oligomers (CDA), the binding to these oligomers (CHBE) and their degradation (EWCAs). For this, the RNA interference (RNAi) technology, which consists of the application of double-stranded RNA (dsRNA) designed to suppress the expression of target genes, was used. The preliminary results obtained using this strategy significantly reduces the development of the fungus and the symptoms of powdery mildew disease in melon, suggesting that chitin signaling suppression mechanisms are essential for the development of *P. xanthii*.

This work was supported by AEI (PDC2021-121373-C21).

CONSERVED AND NON-ANNOTATED PROTEINS OF PODOSPHAERA XANTHII: NEW TARGET CANDIDATES FOR THE CONTROL OF POWDERY MILDEWS BY SPRAY-INDUCED GENE SILENCING

RUIZ JIMÉNEZ Laura. (1,2), POLONIO Álvaro. (1,2), VIELBA FERNÁNDEZ Alejandra. (1,2), PÉREZ GARCÍA Alejandro. (1,2), FERNÁNDEZ ORTUÑO Dolores. (1,2)

Text

One of the most important limiting factors for cucurbit production worldwide is the powdery mildew fungus *Podosphaera xanthii*. Despite the efforts invested in plant breeding programs and chemical companies, effective control of this pathogen remains elusive to growers. In this work, we examined the potential of RNAi technology called spray-induced gene silencing (SIGS) for controlling cucurbit powdery mildew. For that, we first developed a new and simple gene silencing method for *P. xanthii* based on the application of dsRNAs to the plant surface. Moreover, to identify new target candidate genes, we focused on the study of a set of sixty conserved and non-annotated proteins (CNAPs) deduced from the *P. xanthii* transcriptome. After protein modeling and ligand prediction studies, six proteins presumably involved in respiration, glycosylation and efflux transport, were selected. Functional analysis of these CNAP coding genes by dsRNA-induced gene silencing resulted in strong silencing phenotypes with large reductions in fungal growth and disease symptoms. Due to their important contributions to fungal development, three of these *CNAP* genes were selected as targets to conduct SIGS assays under plant growth chamber conditions. The spray application of these dsRNAs induced high levels of disease control, supporting that SIGS could be a promising tool for controlling powdery mildews.

This work has been funded by AEI (AGL2016-76216-C2-1-R; PID2019-107464RB-C21).

IDENTIFICATION, PHYLOGENY AND GEOGRAPHIC AND HOST RANGE EXPANSIONS OF POWDERY MILDEWS INFECTING CROPS AND WILD PLANTS

KISS Levente. (1)

(1) University of Southern Queensland, Toowoomba, AUSTRALIA

Text

Powdery mildew fungi (Erysiphaceae) are widespread obligate biotrophic pathogens of many dicots and monocots, including important agricultural and horticultural crops. Over 900 species representing 19 genera belong to the Erysiphaceae, a monophyletic lineage within Helotiales, Ascomycota. Recent comprehensive phylogenetic analyses based on nuclear ribosomal DNA (nrDNA) sequences and single-copy orthologous amino acid sequences confirmed earlier results on the phylogeny and phenotypic evolution of powdery mildews, which served as the basis for the identification of species and genera. Host range and geographic expansions of some species have also been recently confirmed with genetic and genomic analyses. This presentation will provide an overview of recent advances in understanding the evolutionary history of powdery mildews infecting crops and wild plants in different parts of the world.

CHALLENGES IN WHOLE GENOME SEQUENCING OF POWDERY MILDEW FUNGI AND USE OF PHYLOGENETIC SIGNAL TO ASSESS GENOME QUALITY

VAGHEFI Niloofar. (1,2), KUSCH Stefan. (3), KISS Levente. (2)

Text

Genome-scale phylogenetic analyses of powdery mildew fungi corroborate earlier phylogenies based on sequences of the nuclear ribosomal DNA (nrDNA) but also reveal several contaminations and mis-assembly issues in publicly available genomes. The obligate biotrophic nature of powdery mildews makes genome sequencing and assembly challenging. This is complicated by the fact that research groups working on genomics of powdery mildew fungi often do not make specimens publicly available, making re-sequencing and further scrutiny of the results difficult. Providing multiple examples from publicly available genome datasets, we demonstrate that, while assessment of Benchmarking Universal Single-Copy Orthologs can provide important information regarding genome quality, it needs to be complemented by additional quality control analyses. We recommend that the presence of nrDNA sequences in whole genome datasets be investigated to evaluate the quality of genome assemblies. We also discuss the importance of depositing specimens in internationally accessible herbaria to facilitate their safeguarding as well as availability to the research community to confirm findings and extend previous studies, especially where detailed plant-pathogen interaction studies and analyses of effector repertoires are conducted without providing phylogenetic analyses to confirm the identity of the sequenced powdery mildew specimens.

NEW INSIGHTS INTO THE GENETIC STRUCTURE OF GRAPE POWDERY MILDEW POPULATIONS IN ISRAEL AND THEIR ECOLOGICAL ATTRIBUTES

Text

Plant pathogens usually originate and diversify in geographical regions where hosts and pathogens co-evolve. *Erysiphe necator*, the causal agent of grape powdery mildew, is a destructive pathogen of grapevines worldwide. Although Eastern US is considered the center of origin and diversity of *E. necator*, previous reports on resistant native wild and domesticated Asian grapevines suggest Asia as another possible origin of the pathogen. By using multi-locus sequencing, microsatellites, and a novel application of amplicon sequencing (AmpSeq), we show that the population of *E. necator* in Israel is composed of three genetic groups: Groups A and B that are abundant worldwide, and a new group IL, which is genetically different from any known group in Europe and Eastern US. Group IL showed distinguished ecological characteristics: it was dominant on wild and traditional vines (95%); its frequency increased along the season; it was more aggressive than A and B isolates on both wild and domesticated vines; and its mating types ratio was different from

group B ratio. Conidial morphology and adaptation to microclimate were also significantly different across the different genetic groups. The low genetic diversity within group IL suggests that it has invaded Israel from another origin. Therefore, we suggest that the Israeli *E. necator* population was founded by at least two invasions, of which one could be from a non-East American source, possibly from Asian origin.

CRACKING THE CODE OF POWDERY MILDEW ANCIENT DNA

SMITH Reannon. (1), Ll Tongda. (1), SAWBRIDGE Tim. (1), EDWARDS Jacqueline. (1,2)

Text

From the establishment of reliable DNA extraction and sequencing protocols to application – an overview of working with powdery mildew reference collection specimens in a molecular era. Through this research it was recognised that powdery mildew reference collections should be considered as ancient DNA (aDNA) due to the degraded and fragmented nature of the specimen. This work included a methods comparison study in which 13 DNA extraction were tested on 25-year-old powdery mildew specimens to identify a consistent method which can recover high quality aDNA. Following this we investigated standard PCR, alongside next-generation library preparation and sequencing. Our results demonstrate that fragmented DNA library preparation together with Next Generation Sequencing (NGS) to be the best platform for analysing degraded aDNA. These methods were then applied to resolve taxonomic questions in two important horticultural crops for Australian biosecurity. Our findings clarified the pathogen status of these species in Australia and resulted in the description of a new powdery mildew species. Finally, genomic sequence data from powdery mildew specimens over a 116-year period was analysed to understand how powdery mildew DNA degrades over time in plant pathogen reference collections.

MOLECULAR CO-EVOLUTION OF POWDERY MILDEW FUNGI WITH THEIR HOST PLANTS

KUSCH Stefan. (1), QIAN Jiangzhao. (1), SPANU Pietro. (1), PANSTRUGA Ralph. (1)

(1) RWTH Aachen University, Aachen, GERMANY

Text

The powdery mildew fungi (*Erysiphaceae*) are globally occurring fungal pathogens of more than 10,000 plant species and pose a constant threat for agriculture. These pathogens are intimately connected with their host through their haustoria, where plant-fungus communication presumably takes place. Powdery mildew fungi deliver a range of effector proteins and likely also small interfering RNAs and transfer-RNA fragments to subvert plant immunity. Ubiquitously distributed transposable elements seem to play key roles in powdery mildew evolution. They make up >60% of the genomes of most powdery mildews and thus can be a powerful source of genetic variation and genome instability. Multiple sequence analysis of paralogous transposons in powdery mildew species for which high quality genome assemblies are available revealed recent and lineage-specific bursts of transposon activity. We found that transposable elements are transcriptionally active in the barley

powdery mildew pathogen (*Blumeria hordei*) at specific stages of infection. The pathogen dynamically regulates its abundant transposable elements via epigenetic mechanisms, RNA interference, and antisense lncRNAs. Antisense lncRNAs could be a mechanism to repurpose transposable elements and give rise to novel genes. Thus, transposable elements are the likely key drivers of adaptive evolution in powdery mildew fungi.

GENETIC ANALYSIS OF AVIRULENCE GENES IN POWDERY MILDEW

BERNASCONI Zoe. (1), **KELLER Beat. (1)**

(1) University of Zurich, Zürich, SWITZERLAND

Text
Race-specific resistance against wheat powdery mildew depends on the specific recognition of mildew avirulence genes by the host Pm (powdery mildew) resistance genes. To understand the molecular and evolutionary aspects of this interaction, we have isolated in the last years several *AvrPm3* and *Pm3* genes from the pathogen and the host, respectively. We have used map-based cloning in biparental mapping populations of diverse isolates, as well as genome-wide association analysis to isolate Avr genes. Recently, we have established an efficient protocol for UV mutagenesis in mildew. Using host plants with specific resistance genes as selective hosts, loss-of-avirulence mutants were isolated for a number of alleles of the *Pm3* resistance gene. Based on whole-genome sequencing we identified the underlying mutations and we found a diversity of molecular changes, including point mutations, as well as smaller and larger delections. The mutagenesis protocol can now be applied to additional avirulence genes. In particular, we want to study the avirulence components of the powdery mildew pathogen recognized by the recently described race-specific immune receptors which do not belong to the NLR type of proteins.

STANDING GENETIC VARIATION IN AVIRULENCE EFFECTORS UNDERLIES THE RAPID RESISTANCE BREAKDOWN OF TWO INTROGRESSED RYE RESISTANCE GENES IN WHEAT

MÜLLER Marion. (1,2), KUNZ Lukas. (2), KELLER Beat. (2)

(1) Chair of Phytopathology, Technische Universität München, Freising-Weihenstephan, GERMANY; (2) Department of Plant and Microbial Biology, University of Zurich, Zürich, SWITZERLAND

Text
Crop wild and domesticated relatives are valuable sources of new resistance gene specificities against fungal plant pathogens. The durability of such resistance gene introgressions is highly variable, a phenomenon that remains poorly understood mainly because the corresponding avirulence effectors are unknown. Until their breakdown, the resistance genes *Pm8* and *Pm17*, located on independent rye to wheat translocations, conferred resistance against the wheat powdery mildew disease caused by *Blumeria graminis* f.sp. *tritici*. We used genome-wide association studies (GWAS) and quantitative trait loci (QTL) mapping in mildew to identify the corresponding *AvrPm8* and *AvrPm17* effectors both encoding small, secreted proteins that are highly expressed during the early stages of

infection. Diversity analysis in powdery mildew collections from major wheat growing areas as well as related powdery mildew lineages revealed that several gain-of-virulence variants of *AvrPm17* and one variant of *AvrPm8* are likely ancient and predate the introgressions of *Pm17* and *Pm8* from rye to wheat. We concluded that standing genetic variation can underlie rapid resistance breakdown of introgressed resistance genes. Our studies demonstrate the relevance of pathogen-based genetic approaches to understand resistance gene durability. We, therefore, argue that the effort to identify durable resistance genes cannot be dissociated from studies of pathogen avirulence genes.

HYDROXYCINNAMIC ACID AMIDE ACCUMULATION AND PR-PROTEIN ENCODING GENE EXPRESSION ARE MAJOR RESPONSES OF WHEAT DURING THE EARLY STAGES OF POWDERY MILDEW INFECTION

Text

Blumeria graminis f.sp. *tritici* (*Bgt*) is an obligate biotrophic fungal pathogen responsible for powdery mildew in bread wheat (*Triticum aestivum* L.). During the first steps of this pathogenic interaction, basal defense mechanisms take place in wheat leaves. We used RT-qPCR and metabolomic approaches to analyze these early stages of the interaction between *Bgt* and the moderately susceptible wheat cultivar Pakito. The expression of genes encoding pathogenesis-related (PR) proteins (PR1, PR4, PR5 and PR8), known to target the pathogen, increased during the first 48 hours post-inoculation. Moreover, RT-qPCR and metabolomic analyses pointed out the importance of the phenylpropanoid pathway in quantitative resistance against *Bgt*. Among metabolites of this pathway, hydroxycinnamic acid amides containing agmatine and putrescine as amine components accumulated from the second to the fourth day after inoculation. This suggests the involvement of these metabolites in quantitative resistance via cross-linking processes in cell wall for reinforcement, what is supported by the up-regulation of PAL (phenylalanine ammonia-lyase), PR15 (encoding an oxalate oxidase) and POX (peroxidase) further inoculation. This study increases knowledge on basal resistance in wheat, giving new targets to investigate induced resistance in wheat towards *Bgt*.

POWDERY MILDEW ON BLUEBERRIES: TRACKING THE WORLDWIDE SPREAD OF A FUNGAL PATHOGEN IN SPACE AND TIME

Herbarium specimens can be an opportune source of genetic material that can shed light on the recent past, and sequencing them can be a valuable tool for reconstructing the spread of pathogens. In response to a novel epidemic, it is not always known what the causative agent is and, in the case of a newly introduced pathogen, there is often a lag between detection and identification, and between identification and ascertaining the pathway of movement.

Erysiphe vaccinii is a North American powdery mildew species that infects *Vaccinium* species and up to the present, has never been reported outside of North America. *E. vaccinii* is an important obligate pathogen since it can cause damage to the blueberry industry, especially in an era of reduced fungicide availability/activity. Recent inquiries, in collaboration with a proprietary breeding, marketing and distribution berry company, has found *E. vaccinii* in all other parts of the world (China, Morocco, Mexico, Peru, Portugal, and South Africa) where it is causing damage to blueberries by reducing yields, and causing an increased need for fungicide applications. Understanding the pathogen diversity and geospatial distribution is also key for successfully deploying host genetic resistance.

In this study we took a multi-locus phylogenetic approach on herbarium and fresh specimens collected throughout the world to ascertain the spread of this pathogen in space and time as well as to determine its resistance to commonly used fungicides

Rice diseases

FUSARIUM INCARNATUM AND EQUISETI SPECIES COMPLEX ASSOCIATED WITH RICE BAKANAE DISEASE

Text
Symptomatic rice plants were found with adventitious roots, thin stems, yellowish leaves, and tall plant-like bakanae disease during a series of surveys conducted in rice-growing areas of peninsular Malaysia and Bangladesh from 2019 to 2022. The pathogens were identified using morphological characteristics, DNA sequences, and phylogenetic analyses of two genes, namely, tef1-α and rpb2. A total of 50 isolates recovered from diseased stems of rice, adventitious roots, roots, leaves, and grains showed morphological features that resembled Fusarium incarnatum-equiseti species complex (FIESC). The identity of the isolates was further determined up to the species level by comparing DNA sequences and phylogenetic analyses of two genes. The phylogenetic analyses of the combined dataset of tef1-α and rpb2 clarified that all the isolates obtained were species within FIESC. The results of

pathogenicity tests revealed that isolates of Fusarium incarnatum are pathogenic toward rice. Leaves of inoculated plants became yellowish, and plants stunted. Mostly FIESC is typical saprophytes, endophytes, or opportunist pathogens associated with plants. Species delimitation and their pathogenic traits within the FIESC are still lacking. The aims of the present study were to identify the species, determine the phylogenetic linkage among the different species of FIESC commonly occurring in rice and assess their ability to cause diseases in rice.

COMPARED ANALYSIS OF PATHOGENICITY OF RICE BLAST FUNGUS MAGNAPORTHE GRISEA

To master pathogenic characteristics of *Pyricularia oryzae* is the premise and foundation of screening germplasm, breeding resistance, and deploying rice varieties resistant to blast. In this study, total the 166 isolates of rice blast fungi were collected from Japonica rice planting area in Jilin Province, northeast China, and were inoculated to the 7 Chinese Differentials Varieties (CDVs) and the Monogenic Differential Varieties (MDVs) which harbored 23 resistance genes in greenhouse condition.Those isolates were categorized into 7 groups and 44 races according to the CDVs'phenotypes, the dominant Chinese race group was ZA, and the frequency was 45.18%, the dominant races were ZA17(19.28%), ZG1(9.64%), ZB31(7.83%), and ZA25(6.63%), respectively. No dominant race types were demonstrated according to the MDVs' phenotype data, but the sub-groups data were prominent, and the higher sub-groups and frequency were U73(47.0%), i5(31.9%), i7(31.9%), U53(24.7%), k177(21.5%), and ta330(21.7%), respectively. Based on the avirulent gene(s) frequency of Avr*Pi12* (74.70%), Avr*Pi20* (72.29%), Avr*Pi19* (68.67%), Avr*Piz-t* (68.07%) and Avr*Piz* (60.45%), it presented that broad spectrum genes were *Pi12*, *Pi20*, *Pi19*, *Piz-t*, and *Piz*, respectively. The information of dominant avirulent genes type of blast fungi not only presented the pathogenicity, but also reflects the varieties broad spectrum resistance gene types, so it would be benefit for breeding resistant to rice blast.

VARIABILITY AND EVOLUTION INSIGHTS IN XANTHOMONAS ORYZAE PV. ORYZAE TO DETERMINE THE SUSTAINABILITY OF GENETIC RESISTANCE

Text

Study of diversity and dominance pattern within existing pathogen population helps to identify, select, and deploy effective and sustainable resistance genetics in target

geographies for better and long-lasting product performance. Xanthomonas oryzae pv. oryzae (Xoo) is a major rice pathogen, and its genome harbors extensive inter-strain and inter-lineage variations. We studied pathotype variation in rice bacterial leaf blight pathogen-Xoo strains from India, and performed population based whole genome sequencing and analysis of 100 diverse Xoo strains to understand relationship between pathotypes and genomic lineages. Pathotype analysis of 1024 Xoo strains revealed 11 distinct groups, dominated by 4 major ones while others have restricted distribution. Genomic analysis revealed a major clonal lineage with predominant population and four minor but highly diverse lineages among Indian Xoo strains. This study allowed us to gain insights into the origin of lineages, pathotypes and highly pathogenic strains from India, and further, we were also able to identify core effector genes in Xoo strains. Specific mutations in the effector genes are clearly associated with an ability to cause disease on corresponding resistance genes containing cultivars. Such mega-genomic studies and resources are highly valuable in surveillance of the plant pathogen and to track their diversity and movement, thereby effective deployment of durable resistance genetics.

CHARACTERIZATION OF VIRULENCE FACTORS POTENTIALLY INVOLVED IN HOST-SPECIFICITY OF MAGNAPORTHE ORYZAE ISOLATES

(1) Institute Plant Physiology RWTH Aachen, Aachen, GERMANY

Text

The blast fungus *Magnaporthe oryzae* is a threat to global food security causing high yield losses in rice and wheat production. Molecular analyses identified multiple divergent lineages and sub-divisions within the pathogen population, which are preferentially associated with particular host genus.[1] Understanding the molecular basis for host preferences is crucial to improve disease management and prevent future spread to new hosts. Comparative genomic analysis has been used to enquire for differences within the genomes of different isolates and this led to the identification of potential host-specific genes. However, experimental proof for these virulence factors and their molecular function is mainly lacking. To close this gap, we established a toolbox for in-depth characterization of such candidate genes. Actually, we investigate two gene candidates: a Nudix-hydrolase present in most *Magnaporthe*-isolates except those infecting wheat, and a trehalase solely present in wheat-isolates. Confocal laser-scanning microscopy confirmed that both genes are secreted and qPCR pointed to a precise regulation during the infection process. To determine a contribution to host specificity of *M. oryzae*, we utilized CRISPR/Cas9 mediated marker-free genome editing and generated mutants with gene deletion, complementation, *in locus* mRFP-tagging and overexpression. Impact of these genetic modifications on fungal virulence was observed for both genes.

Text

Blast rice caused by Pyricularia oryzae Cavara, is the main fungal disease of rice (Oryza sativa L.), which has been widely studied due to its vast distribution and destructiveness throughout the world. In Cuba, blast rice affects during all planting seasons and the high variability of cultivars to the breeds of this phytopathogenic fungus confirms that in our country there are cultivars resistant to certain breeds. At present, the western zone, specifically the province of Pinar del Río is the one with the highest incidence of the disease. That is why the improvement strategy to minimize escape includes the selection of lines and new cultivars are traditionally carried out in this province, where its populations and inoculum pressure remain high as well as pathogenic diversity. In this work, the behavior of 14 rice cultivars that are currently used in Cuba with a variable behavior before the attack of this disease compared to resistant controls was evaluated in beds of infection. The isolation and morphological characterization of isolates of Pyricularia oryzae was performed. The in vitro effect of a chitosan on mycelial growth of the fungus was observed. The results showed that three cultivars behaved as highly susceptible. The isolates were characterized morphologically.

EVALUATION OF THE INCIDENCE OF PIRICULARIA ORYZAE ON RICE PLANTS TREATED WITH CHITIN DERIVATIVES AT A HOT SPOT SITE IN CUBA.

Text

Pyricularia oryzae is one of the most important diseases in rice crop in the world and Cuba. In this work, seeds of rice (Oryza sativa L.) from J-104, a Cuban susceptible cultivar to Pyricularia oryze, were treated with partially acetylated chitosan at 100 and 250 mg L-1 and hydrolyzed chitosan at 100 mg L-1 and then planted in the field at "Caribe" rice farm, a high hot spot site for Pyricularia oryzae infestation. Plant cultivation was done in favorable conditions for disease development. Blast incidence on rice leaves in the vegetative stage at 35 days after planting and blast incidence in the panicle neck at 85 days were evaluated according to the standard scale proposed by the International Rice Research Institute. No chitosan derivative was effective to protect plants from treated seeds at vegetative stage, however, hydrolyzed chitosan at 100 mg L-1 made plants tolerant to P. oryzae at reproductive stage, which was associated with the size of chitosan. Several symptoms of infection by P. oryzae were shown in both stages, so different strains occurred in this hot spot site.So, this site can be a good place for conducting assessments of rice cultivar resistance to P. oryzae and evaluating in vivo elicitors against this fungus in the future.

POST-TRANSLATIONAL MODIFICATION OF OSWRKY31 ARE INTEGRAL TO OSMKK10-2-MEDIATED PATHOGEN DEFENSE OVER GROWTH IN RICE

Text

The mitogen-activated protein kinase (MPK) cascade plays vital roles in plant innate immunity, growth, and development. Here, we report that the activation of OsMKK10-2 enhances resistance against the rice blast pathogen *Magnaporthe oryzae* and suppresses root growth through the increase of jasmonic and salicylic acid accumulation and decrease of indole-3-acetic acid levels. The transcription factor gene *OsWRKY31* is a key component in OsMKK10-2-OsMPK3-OsWRKY31 cascade involved in plant disease resistance and root growth in rice, as knockout of *OsWRKY31* transcription factor gene compromises most of the responses activated by OsMKK10-2. Phosphomimetic OsWRKY31 has an elevated DNA-binding activity and confers enhanced resistance to *M. oryzae*. In addition, OsWRKY31 stability is regulated by phosphorylation and ubiquitination for fine-tuning the defense and growth balance. Taken together, our findings indicate that OsWRKY31 can physically interact with OsMPK3 and its upstream OsMKK10-2, forming a ternary complex, and OsWRKY31 modified by phosphorylation and ubiquitination functions in OsMKK10-2 mediated signaling pathway for defense priority.

THE GENETIC VARIATION OF FUNGAL EFFECTOR AVR-PIK AND COMPARATIVE PATHOGENICITY OF RICE BLAST FUNGUS POPULATIONS IN THAILAND.

PARINTHAWONG Nonglak. (1), CHANNUAL Pennapar. (1)

(1) King Mongkut's Institute of Technology Ladkrabang, Bangkok, THAILAND

Text

The blast fungal effector *AVR-Pik* in Thailand exhibits high variability, with 4 of 6 alleles identified (*AVR-PikA*, *D*, *E*, and a novel allele *F*). Isolates containing 2 alleles, *D/F*, are also detected. Allele *F* is unable to recognize by any *PiK* resistance allele, while the *D/F* combination can only infected rice harboring *Piks*. In this study, isolates carrying *AVR-Pik*, those carrying *AVR-PikA*, *D*, *F*, or more than 1 allele (THL794, UBN207129, RBR55004), showed similar pathotype as previous results. The isolates UBN207129 and RBR55004 carry *AVR-Pik* alleles that are recognized by all *Pik* alleles. Therefore, PCR product of *AVR-Pik* from each isolate containing more than 1 allele was cloned and 10 white colonies/isolate were sequenced and analyzed. Sequence analysis showed that UBN207129 and THL794 encoded AVR-PikD, while RBR55004 encoded 9 AVR-PikD and 1 AVR-PikA, which is the first report of this combination in Thailand. Analysis of pathotype in 41 isolates from different regions showed that 9 isolates had a similar pathotype to isolates containing *AVR-PikD*, *F*, and *D/F*, while 32 isolates showed different pathotypes from previously reported. Future research will focus on the role of *AVR-PikD* in isolates containing *D/A* combination in relation to *Piks* resistance gene.

RELIABLE INOCULATION PROTOCOL FOR STUDYING PANTOEA ANANATIS IN RICE

(1) COLORADO STATE UNIVERSITY, Fort Collins, UNITED STATES; (2) Dale Bumpers National Rice Research Center, Stuttgart, UNITED STATES

Text

Bacterial leaf blight-like symptoms were observed on several rice genotypes (*Oryza sativa*) in research field plots of global rice germplasm grown in Arkansas, USA in August of 2021 and 2022. We demonstrated that the disease, which was characterized by spreading lesions on leaves, panicle sterility and reduced yield, was caused by *Pantoea ananantis*, a pathogen not previously described on rice in the USA. The bacterial pathogen isolated from symptomatic plants forms uniform, distinct, yellow-colored bacterial colonies on nutrient agar. Amplicons of the 16S rRNA and *gyrB* genes of the rice *P. ananatis* isolate are 100% identity with the corresponding regions of the *P. ananatis* PA13 reference genome. Pathogenicity of *P. ananatis* to rice was confirmed by scissor-clip inoculations of leaves from seedlings (cultivar Kitaake), and re-isolation of *P. ananatis* from the symptomatic inoculated leaves. While leaf blight disease associated with *P. ananatis* on rice has been reported in other regions of the world, studying the disease interaction in rice plants has proved difficult because methods for inoculating and consistently surveying symptoms are lacking. Here, we report a reliable assay for inoculating plants with *P. ananatis* and characterizing symptom development throughout disease progression on several commonly grown rice cultivars.

SPATIOTEMPORAL MONITORING OF MULTIPLE RICE DISEASES IN WESTERN BURKINA FASO: HIGH FREQUENCY OF CO-OCCURRENCES AND RAPID TURNOVER OF VIRAL POPULATIONS

BARRO Mariam. (2), KASSANKOGNO Abalo Itolou. (2), SEREME Drissa. (3), WONNI Issa. (2), BILLARD Estelle. (1), BANGRATZ Martine. (1), POULICARD Nils. (1), **TOLLENAERE Charlotte. (1)**

Text

Understanding the spatiotemporal dynamics of diseases and identifying risk factors is of paramount importance in guiding the deployment of effective control measures.
We conducted the present study between 2016 and 2019 in western Burkina Faso in three geographical areas, each of which included one irrigated perimeter, and a nearby lowland. Symptom monitoring annually at the same developmental stage showed that bacterial leaf streak (BLS) disease and rice blast were preferentially found in irrigated areas, compared to rainfed lowlands. High levels of co-occurrences were found between the four rice diseases under study, particularly in irrigated areas.
The rice yellow mottle disease, due to the RYMV, is not affected by the rice production system, but instead by the specific site. Partial sequencing of a set of 132 samples revealed a very high genetic diversity, with the co-occurrence of four distinct lineages at small geographical scale. One of these lineages results from a recombination event between two others. Temporal dynamics suggest an evolution of the relative frequencies of each genetic lineage within the studied period. Aggressiveness estimates were obtained from

experimental infections, and differences between isolates likely contribute to explain observed RYMV population evolution.
The implications of these results, including the potential consequences of co-occurrences and co-infections for the evolution of pathogen populations, will be discussed.

EVALUATION OF THE BEHAVIOR OF 49 LINES OF RICE (ORYZA SATIVA L) INTROGRESSED WITH KNOWN RESISTANCE GENES AGAINST RICE BLAST IN IRRIGATED AND RAINFED RICE GROWING SYSTEMS IN BURKINA FASO

Text
Rice blast caused by Magnaporthe oryzae is one of the major rice diseases in Burkina Faso with losses up to 77% under favorable disease conditions. For the management of this disease, the use of resistant cultivars remains the most economical, and most protective method for the environment. This study focuses on the evaluation of the resistance of 49 lines of rice resulting from crosses between popular cultivars of different countries of Sub-sahara against blast. The experimental design used is a 7 x 7 Alpha lattice with 3 repetitions. The study was conducted in two rainfed sites (Farako-Bâ and Karfiguela) and two irrigated sites (Bagré and Tengrela) in Burkina Faso. The results showed that the rice genotypes developed the disease differently depending on their developmental stages andRice growing systems. In rainfed rice cultivation, 32 genotypes were resistant to leaf blast and 03 (AR-67, IR 130412 and CSR 36) were resistant to leaf and panicle blast. In irrigated conditions, 44 genotypes were resistant to leaf blast and 06 (TZLR-74, IR 133136-B, NERICA 4, NERICA 10, NERICA 11 and CSR 36) were resistant to leaf and panicle blast. The genotype (CSR 36) was disease resistant in both ecologies. The results of this study will make it possible to choose the best rice cultivars, tolerant or resistant to blast, and to identify the effective resistance genes in their genomes.

THE SUSTAINABILITY OF THE RESISTANCE OF ORYZA SATIVA VAR CHHOMRONG DHAN TO PYRICULARIA ORYZAE AND ITS IMPACTS ON RAINFED RICE CULTIVATION IN THE VAKINANKARATRA REGION.

RABAKOMANANTSOA Landry Richard Gabriel. (1), RAVELOSON Harinjaka. (1), RAKOTONANAHARY M. Natolotra. (1), THARREAU Didier. (2)

Text
In Madagascar, rice is the staple food of the population. With the increase in population, rice cultivation in lowlands has become insufficient. Therefore, rainfed upland rice farming has

gained importance.
Since the 1990s, different varieties of rainfed upland rice have been made available to farmers. Unfortunately, their resistance to blast disease was overcome by Pyricularia oryzae populations after a few years of cultivation. But since 2006, a Nepalese variety called Chhomrong Dhan (ChD), which was first tested at the FOFIFA Antsirabe research station in the mid-1990s, has been massively deployed. Thanks to its resistance to blast disease, it was quickly adopted by farmers and covers 85% of the land dedicated to rainfed upland rice in 2017.
Studies conducted by Raveloson et al. from 2014-2017 suggest that ChD displays resistance to P. oryzae, that the strains attacking ChD panicles come from neighboring varieties by spill-over at late stage, but no pathogen population has yet adapted to ChD.
The resistance of ChD reduces the pressure of the disease on rainfed upland rice cultivation in the Vakinankaratra region. Rice blast incidence survey on ChD and neighboring varieties will be continued. The genetic diversity of P. oryzae will be characterized to monitor the evolution of its population structure over the years, on ChD and neighboring varieties. Finally, the genetics of resistance of ChD will be characterized by crossing with susceptible varieties and genetic mapping.

GENE PYRAMIDING FOR ENHANCED BLAST RESISTANCE INTO SPANISH RICE CULTIVARS

DOMINGO Concha. (1), GARCÍA-ROMERAL Julia. (1)

(1) Instituto Valenciano de Investigaciones Agrarias, Moncada, SPAIN

Text
Blast disease, caused by the fungus Magnaporthe oryzae, greatly reduces yield and grain quality and can ruin field crops. Blast disease is a complex trait and preventive treatment with fungicides is the most common method to control the disease, but this is coming to an end due to the restrictions in the use of phytosanitary products and the increasing social demand for a healthier agriculture. Integrated management of crop diseases relies on varietal resistance, agronomic practices, and application of pesticides. In this sense, varietal resistance has a crucial role. Race specific resistance is mediated by R-genes. Breeding for resistance is carried out for a long time and there are a few examples of durable resistance to blast, combining several specific resistance genes and some level of partial resistance. Results from previous research projects allowed us to identify effective R-genes in Spain and served as the basis for a breeding program to introduce R-genes into local varieties. We have generated two highly yielding varieties, displaying long and medium grain size each, by pyramiding the R-genes Pi-ta, Pi-b and Pi-km. Field trials under favourable infection conditions during several years in two different regions of the country, showed that these new varieties are resistant to the blast races present in Spain. These new varieties will contribute to reduce the impact of disease by minimizing the use of fungicides and to the sustainability of the crop.

DISTINCT ALLELIC AND GENOTYPIC STRUCTURES FEATURED BY XIAN/GENG TYPE RESISTANCE GENES RESPONSIBLE FOR RICE BLAST BETWEEN THE SOUTHERN AND NORTHEASTERN REGIONS OF CHINA

JINYAN Wang. (1), JIANQIANG Wen. (1), XING Wang. (1), YALING Zhang. (1), YONGXIANG Yao. (1), XUEMEI Ye. (1), LIPING Lin. (1), LING Wang. (1), **QINGHUA Pan. (1)**

Text

Rice blast, caused by *Magnaporthe oryzae*, it is a major hurdle in the productivity of rice (*Oryza sativa*). Asian rice includes two major subspecies: *Xian*/*indica* and *Geng*/*japonica*, resistance genes (*R*) have been recognized in both subspecies, which can provide a foundation to breed improved cultivars with better invulnerability against the pathogen.Having employed a set of updated comprehensive functional nucleotide polymorphic (FNP) marker systems for deeper allele mining at nine loci, at least 37 candidate functional alleles were identified in both Southern and Northeastern populations in China. As for the functional/non-functional haplotypes at the nine *R* gene loci, *Pid2*, *Pid3*, *Pit*, *Pib*, and *Pi63 w*ere strictly diverged into *Xian* type cvs in the Southern population, and *Pid4*, *Pi54*, *Pi36*, and *Pi37* into *Geng* type cvs in the Northeastern population. Similarly, the candidate functional alleles at the former five loci were almost predominant in the *Xian*, and those at the latter four loci in *Geng* populations. The distinct allelic and genotypic structures between the Southern and Northeastern rice populations in China, which were featured by such *Xian* and *Geng* type *R* genes, will be discussed.

MOLECULAR IDENTIFICATION OF XANTHOMONAS ORYZAE PV. ORYZAE AND BACTERIAL LEAF BLIGHT RESISTANCE GENES XA5, AND XA21 IN BENIN

NANOUKON Chimène Nadège Mahoussi. (1), DJEDATIN Lambert Gustave. (1), HAVIVI Amed. (1), LOUMEDJINON Pamela. (1)

Text

In Benin, Xanthomonas oryzae pv. Oryzae (Xoo) causing bacterial leaf blight (BLB) was first described in 2013 on wild rice. So far, no study has been done on Beninese Xoo strains to better characterize these strains. We do not know whether the pathogen has already passed into the cultivated rice varieties and what the disease index is.This study aims to identify Beninese Xoo strains and screen rice varieties grown in Benin for the major BLB resistance genes Xa5, and Xa21. Diseased rice leaves collected from different rice fields in the three phytogeographic areas of Benin were analyzed by PCR for Xoo-specific sequence identification. Furthermore, collected rice accessions were screened by PCR to identify resistance genes Xa5 and Xa21. The results reveal that Xoo was identified in Banikouara and Malanville. Sphingomonas Sp has been identified in several rice fields in Benin. Rice fields infected with Xoo are also coinfected with Sphingomonas Sp. Of the 61 rice accessions screened for the Xa5 resistance gene, 10% are resistant, 53 87% are susceptible and 3% lack the xa5 resistance gene. For Xa21, 60.65% were found to be resistant of which 28 were homozygous (Xa21/Xa21) and 9 were heterozygous (Xa21/xa21). Three accessions possess both xa5 and Xa21 genes. These results indicate that Xoo has moved from the wild rice variety to the cultivated variety in northern Benin. Consequently, a varietal improvement program must be put in place to prevent a BLB pandemic in Benin.

GENOMEWIDE ANALYSIS OF TRANSCRIPTIONAL NETWORKS UNDERLYING RICE RESPONSES TO THE DISEASE BACTERIAL PANICLE BLIGHT AND HIGH NIGHT TEMPERATURES

DAHAL Shilu. (1,3), ORTEGA Laura. (2), LIEW Chia Sin. (4), RIETHOVEN Jean-Jack. (4), **ROJAS Clemencia. (1,2,3)**

Text

Bacterial Panicle Blight (BPB) caused by Burkholderia glumae has impacted rice production worldwide. Outbreaks of BPB have been associated with high night temperatures, suggesting that BPB incidence can be exacerbated by the increases in global temperatures. To understand the effect of high night temperature on BPB, this work screened 20 accessions from the USDA mini-core collection to evaluate BPB disease symptoms in rice panicles in response to B. glumae inoculation under low and high night temperatures. The screening revealed a wide spectrum of disease symptoms in the panicle among accessions. Interestingly, depending on the accession, the severity of symptoms was temperature-dependent or temperature-independent. Within the temperature-independent accessions, we identified susceptible and moderately resistant accessions. To further understand the transcriptional networks controlling rice resistance or susceptibility to BPB, one susceptible accession and one moderately resistant accession were chosen for RNA-sequencing analyses. Comparative transcriptomics analyses between the moderately resistant and the susceptible accession after B. glumae inoculation, uncovered jasmonic acid (JA) biosynthetic and JA-regulated genes, as well as genes involved in cell wall remodeling and disease resistance. These findings highlight the function of these genes and pathways regulating and executing rice responses to BPB in combination with heat stress.

MULTIPLE MUTATIONS IN SDHB AND SDHC SUBUNITS CONFER RESISTANCE TO THE SUCCINATE DEHYDROGENASE INHIBITOR CYCLOBUTRIFLURAM IN FUSARIUM SPP.

Text

Fusarium fujikuroi is one of the dominant phytopathogenic fungi causing rice bakanae disease worldwide. Cyclobutrifluram is a novel succinate dehydrogenase inhibitor (SDHI) developed by Syngenta, which shows strong inhibitory activities against *Fusarium* spp. The baseline sensitivity of 112 *F. fujikuroi* to cyclobutrifluram was determinated with a mean EC_{50}

value of 0.025 µg/mL. A total of 17 resistant mutants were obtained by fungicide adaptation and displayed equal or slightly weaker fitness than parental isolates, which suggests that the resistance risk of *F. fujikuroi* to cyclobutrifluram is medium. A positive cross-resistance was detected between cyclobutrifluram and fluopyram. The amino acid substitutions H248L/Y of FfSdhB and G80R or A83V of $FfSdhC_2$ conferred cyclobutrifluram resistance in *F. fujikuroi*, which was validated by molecular docking and protoplast transformation. We also found the point mutations H248Y in FpSdhB and A83V or R86K in $FpSdhC_1$ conferred the resistance of *F.pseudograminearum* to cyclobutrifluram. The results indicate that the affinity between cyclobutrifluram and Sdhs obviously decreased after point mutations, therefore multiple mutations in SDHB and SDHC subunits confer resistance to cyclobutrifluram in *Fusarium* spp.

MULTIPLE INFECTION STRATEGIES UNCOVERED BY FUNCTIONAL STUDIES OF EFFECTOR PROTEINS IN USTILAGINOIDEA VIRENS

Rice false smut is a devastating disease caused by the fungal pathogen *Ustilaginoidea virens*. Effector proteins are known to play a critical role in pathogen virulence, but molecular mechanisms underlying virulence functions of *U. virens* effectors remain largely unknown. Our results identify three *U. virens* core effector proteins SCRE1, SCRE4, and SCRE6 via large-scale screening and knockout analyses. We reveal that SCRE6 is a tyrosine phosphatase, which represents the first identified phosphatase in fungal effector proteins. The effector targets the rice immune negative regulator OsMPK6 and specifically dephosphorylates OsMPK6. The dephosphorylation inhibits OsMPK6 degradation and promotes the accumulation of the negative immune regulator, and thus suppressing plant immunity. Additionally, we show that the SnRK1A-XB24 phosphorelay module positively contributes to plant immunity. SCRE1 inhibits the ATPase activity and phosphorylation of XB24 mediated by SnRK1A, thereby suppressing the rice immune response. We also demonstrate that SCRE4 is an essential virulence effector that transcriptionally suppresses the expression of *OsARF17*, a positive immune modulator in rice, and thus inhibiting plant immunity and promoting pathogen invasion. These studies reveal previously unidentified fungal infection strategies and provide insights into potential targets for improving rice disease resistance.

SOWING DATES INFLUENCE INCIDENCE OF BACTERIAL LEAF STREAK AND RICE YIELD UNDER IRRIGATED PRODUCTION SYSTEMS IN BURKINA FASO

Text
Bacterial leaf streak caused by Xanthomonas oryzae pv. oryzicola is a disease that is prevalent in the main rice-growing sites of Burkina Faso. It causes foliar incidences of up to 100% on some crop varieties and is variable from season to season. Control methods include the use of resistant varieties, integrated pest management and good cultural practices, including sowing dates. Indeed, data of the influence of sowing dates on the disease incidence are not well known, especially under the rice cultivation conditions in Burkina Faso. In order to identify sowing dates that would reduce BLS incidence on irrigated plains, we set up a trial in the Kou Valley and Di, using a split-plot design with three rice varieties with susceptibility contrasting levels, at three different date of transplantation. The results show that among the three evaluation dates, the sowing in June is the best because it avoids a high incidence of BLS and allow to obtains a better average yield of the three varieties with 8.10 t/ha and 7 t/ha respectively in the both sites. At June sowing date, infection is less severe for the two susceptible varieties FKR62N and TS2, ranging from 0.33 to 1.93 at Kou Valley compared to 8.06 to 10.16 at Di. However, when sown in August, BLS incidence was higher with a yield reduction of at least 3t/ha compared to June sowing. Therefore, the early planting dates can be recommended for effective control of BLS under irrigated rice growing conditions in Burkina Faso.

EMERGENCE OF XANTHOMONAS ORYZAE PV. ORYZAE IN MADAGASCAR: EPIDEMIOLOGY AND IDENTIFICATION OF RESISTANCE SOURCES TO CONTROL BACTERIAL LEAF BLIGHT OF RICE

Text
In Madagascar rice is the staple food grain. In this country where the consequences of climate change are dramatic, rice production represents a major challenge for food security. Bacterial Leaf blight (BLB), caused by *Xanthomonas oryzae* pv. *oryzae* (*Xoo*), is a devastating disease of rice crops in many countries of Asia and West Africa. In Madagascar, despite a continuous monitoring for rice diseases since the 1980s, BLB had never been reported until recently. In 2019, BLB-like symptoms were observed in two fields in the Central Highlands of Madagascar. Strains were isolated and their identity confirmed as *Xoo*. Since then, regular surveys allowed to observe the dispersion of the disease in different geographical areas of the island and a sharp increase in incidence. 92 malagasy strains collected between 2019 and 2022 were genotyped with the aim to 1) evaluate if this outbreak results from one or several introductions, 2) define its origin and 3) date the introduction. A Multilocus VNTR Analysis (MLVA-14 scheme) suggests a recent unique introduction from Asia and highlights a large clonal expansion from primary founders. Whole genomes of 2 malagasy strains confirm and precise the Asian origin. Strains representative of the diversity were selected for pathogenicity tests, which allowed to identify 4 potentially effective resistance genes. Overall, we show that efficient surveys, genotyping, effector sequencing and phenotyping provide tools to rapidly react to new outbreaks.

ALLELE SPECIFIC RECOGNITION OF THE MAGNAPORTHE ORYZAE EFFECTOR AVR-PITA BY THE UNCONVENTIONAL RICE RESISTANCE PROTEIN PTR

Text

Blast disease caused by the fungus *Magnaporthe oryzae* is one of the most devastating rice diseases. To secure rice production from losses by blast, disease resistance genes are critical. *Pi-ta* is a widely used blast resistance gene. Published work reports that it codes for a nucleotide-binding and leucine-rich repeat protein (NLR) and recognizes the fungal protease-like effector AVR-Pita. However, this model was challenged by the recent finding that another rice gene named Ptr, which codes for a membrane protein with a cytoplasmic Armadillo repeat domain is required for AVR-Pita recognition. Using *NLR Pi-ta* and *Ptr* RNAi knock-down and CRIPSR-Cas9 mutant rice lines, we found that AVR-Pita recognition relies only on *Ptr* and that the *NLR Pi-ta* has no role. Analysis of the natural diversity of AVR-Pita, showed that different alleles of *Ptr* have different recognition specificities. While the Ptr allele B recognizes a restricted set of AVR-Pita alleles, PtrA detects all natural sequence variants of the effector. We confirmed the escape of certain AVR-Pita alleles from detection by PtrB using mutant and transgenic isolates of the fungus and identified one specific polymorphism that controls the break-down of PtrB-mediated resistance.
Taken together, our work establishs that the *M. oryzae* effector AVR-Pita is detected in an allele-specific manner by the unconventional resistance protein Ptr and that the NLR Pi-ta has no function in Pi-ta resistance and the recognition of AVR-Pita.

Tn-Seq to reveal microbial lifestyles along plant interaction processes

IDENTIFICATION OF BACTERIAL PLANT COLONIZATION GENES AT THE GENOME SCALE

Text

Bacteria are critical drivers of plant health and performance, and therefore can make key contributions to sustainable agriculture. However, the molecular mechanisms enabling them to effectively colonize plants remain poorly understood. Traditional methods of studying

plant-bacteria interactions have sought to characterize the function of one gene at a time, but the slow pace of this work means that the functions of the vast majority of bacterial genes remain unknown or poorly understood.

Recently developed high-throughput techniques such as transposon sequencing (TnSeq) have been used to identify which are the genetic determinants that are involved in a function of interest. In our study we use RB-TnSeq (random barcode transposon-site sequencing), which combines the advantages of TnSeq and rapid quantification of each transposon mutant using unique barcodes that can be amplified by PCR, in order to identify a comprehensive set of microbial genes that control or influence root colonization.

We found numerous genes that, when mutated, affect the ability of bacteria to competitively colonize the rhizosphere of plants. Interestingly, several genes seem to be important for colonization across different bacterial species, while other genes seem to be specific for a given plant-bacteria interaction. The identification of bacterial genes shaping plant colonization will pave the way for the future development of innovative biostimulants for sustainable agriculture.

TN-SEQ REVEALED DIFFERENT LIFESTYLES OF PLANT PATHOGENS

FAURE Denis. (1)

Text
Agrobacterium tumefaciens is a biotrophic pathogen that colonizes the galls (plant tumors) it causes, as well as the roots of host and non-host plants. Dickeya and Pectobacterium species are necrotrophic pathogens that macerate stems (blackleg disease) and tubers (soft rot disease) of Solanum tuberosum. They proliferate by exploiting the remains of plant cells. They also colonize roots, even if no symptoms are observed. In this review, we present our results on the use of Tn-Seq to reveal the different lifestyles of these pathogens when they colonize roots (pre-symptomatic lifestyles) or lesions (pathogenic lifestyles).

THE MAKING OF A PATHOGEN: HOW XANTHOMONAS CAMPESTRIS PV. CAMPESTRIS ADAPTS TO PLANT ENVIRONMENTS

Text
Xanthomonas campestris pv. *campestris* (*Xcc*) is a bacterial pathogen causing black rot disease on wild and cultivated Brassicaceae. *Xcc* starts its disease cycle on the surface of the leaf, after which it gains entry to the plants via the hydathodes. Next, *Xcc* colonizes the underlying epithem, xylem vessels, mesophyll and finally the plant seeds, which allow it to travel through plant generations. Despite the fact that the virulence mechanisms of *Xcc* have been studied since the early eighties, little is known about the genetic determinants that allow *Xcc* to adapt to the various environments it encounters during its disease cycle. In order to identify the genetic determinants of bacterial adaptation to the different plant environments, we performed high-throughput randomly barcoded-transposon insertion site sequencing (RB-TnSeq) screens i*n vitro* and *in planta*. Here, we discuss the results of these screens, which lead to a better understanding of the physiological state of the bacteria in different stages of the disease cycle.

Understanding the ecology and evolution of bacterial wilt disease in the plant microbiomes

HOST RANGE OF A NEW RALSTONIA PSEUDOSOLANACEARUM (PHYLOTYPE I) STRAIN DETECTED IN DUTCH SURFACE WATERS AND BITTERSWEET

Species of the *Ralstonia solanacearum* species complex (RSSC) cause bacterial wilt and are aggressive, contagious and persistent. As such, all species within the RSSC, including *Ralstonia pseudosolanacearum* (phylotype I), have a quarantine status. Until recently, *R. pseudosolanacearum* (phylotype I) was only sporadically found within the European Union, and the pathogen was absent from the aquatic environment within this region. However, starting from 2020, the bacterium has repeatedly been found in Dutch surface waters, as well as in bittersweet, a known host of *R. solanacearum* (phylotype II). Here, we used one of the original isolates from 2020 to determine the host range of this novel pathogen. We introduced a rifampicin resistance marker via homologous recombination and used the transformed strain to inoculate 24 different plant species from the *Solanaceae*, *Rosaceae*, and other plant families that are known or suspected hosts of the RSSC. Both cultivated crops and weeds were included in the assays. Young plants were stem inoculated, grown under controlled conditions and monitored for 8 weeks. In case of symptomatic or asymptomatic infection, the assays were repeated using soil inoculation. Research was supported by the Dutch Food and Consumer Product Safety Authority, Naktuinbouw, the Nederlandse Algemene Keuringsdienst, Glastuinbouw NL (Stichting Kennis in je Kas),

Text

Members of the *Ralstonia solanacearum* species complex (RSSC) are historically known to cause brown rot of potato and Moko disease of banana in Central America. A novel lineage detected in the island of Martinique in 1999 exhibited a dramatically different host range and pathogenicity profile. This new lineage, referred to as 4NPB, can infect cucurbits *Anthurium* and *Heliconia* spp. and is more aggressive on solanaceous crops than previous variants. We sequenced 460 RSSC strains sampled across Martinique and French Guiana during the emergence of this novel lineage. Pangenome and phylogenetic analyses were performed to identify genomic changes linked with the emergence of the new lineage. This analysis reveals the 4NPB population likely emerged from a population of Moko-causing strains found in association with a tomato host on the mainland, followed by dispersal to Martinique. While 4NPB and Moko-causing strains are closely related, variation in the accessory genome includes the exchange of Type 3 secreted effectors and multiple genes with predicted catalytic activity. Recombination hotspots found between 4NPB and Moko strains include various toxin-antitoxin systems, which are potentially involved in intra-species competition and signaling. These changes may underly the altered pathogenicity and host-range profile of 4NPB, contributing to the dramatic expansion of this lineage across Martinique.

CONTACT DEPENDENT GROWTH INHIBITION IN RALSTONIA PSEUDOSOLANACEARUM

GOPALAN NAIR Rekha. (1), EVSEEVA Daria. (1), MCCANN Honour. (1)

(1) Max Planck Institute for Biology, Tübingen, GERMANY

Text

Ralstonia pseudosolanacearum is a deadly bacterial plant pathogen known to infect many plant species. Comparative genomics of a South Korean population of *R. pseudosolanacearum* revealed that recombination frequently targets secreted gene products including type III secreted effectors and CdiA proteins, similar to hemagglutinin. CdiA proteins vary in the presence of a C-terminal toxin domain that inhibits the growth of adjacent cells lacking cognate immunity protein CdiI, a phenomenon called contact-dependent growth inhibition (CDI). CDI mediates both antagonistic and cooperative contact-dependent interactions, contributing to the formation of populations sharing identical CDI loci. *R. pseudosolanacearum* carries an expanded set of CDI loci compared to Burkholderia spp.,

where their function is better characterized. My work examines whether these loci mediate contact-dependent interactions and contribute to phenotypes associated with virulence and cooperative behavior in *R. pseudosolanacearum*.

COMPARISON OF RHIZOSPHERIC BACTERIAL COMMUNITIES OF POTATO GENOTYPES WITH DIVERSE DEFENSE RESPONSES AGAINST RALSTONIA SOLANACEARUM.

Text

Potato (Solanum tuberosum) is one of the most important widespread hosts of Ralstonia solanacearum, the causal agent of bacterial wilt. In Uruguay, germplasm with resistance to R. solanacearum has been identified and advanced clones with different responses to R. solanacearum infection were selected and characterized. Previous results showed that plant resistance was correlated with differential bacterial colonization patterns and induced defense responses after infection. The aim of this work is to study the correlation between plant resistance and rhizosphere microbiome in selected genotypes with different responses to bacterial wilt. Plants were grown in a macrotunnel greenhouse with soil collected from a potato field. Pathogen colonization effects on rhizosphere microbiota were evaluated in healthy and infected plants. Disease progression was recorded and pathogen was quantified in rhizosphere samples. A resistant genotype showed delay in pathogen colonization and high final pathogen concentration in the rhizosphere, comparable to the susceptible genotype. These results suggest that the resistant genotype restricts rhizosphere pathogen colonization, preventing root and stem infection. Bacterial community composition is being analyzed in 76 samples comparing the sequence of V3-V4 region of 16S rARN. It is expected to identify potentially beneficial microbial groups related with resistant plants, contributing to an integrated disease control.
