Plant Pathology in a One Health World

K1-1

PLANT HEALTH FOR ONE HEALTH IN CENTRAL & WEST AFRICA

PITA Justin. (1)

(1) WAVE, Abidjan, COTE D IVOIRE

Text

One Health is defined as the triad of human health, animal health, and the environment. While the latter is commonly considered the neglected component of the triad, plant health is usually excluded from the One Health concept. To address this important omission, the organizing committee of the 12th International Congress of Plant Pathology chose “Plant Pathology in a One Health world” as the theme of the 2023 conference, to promote the integration of plant health and plant pathology into the One Health concept. But how can this integration be achieved in Central and West Africa if plant health itself is not firmly rooted in the region? We will review the status of the One Health in 10 Central and West African countries and present the approach of the WAVE Regional Center of Excellence to boost Plant Health and One Health across Africa, through the management of transboundary plant pathogens.

K1-2

WHAT IS THE ADDED VALUE OF ONE HEALTH FOR PLANT HEALTH?

MORRIS Cindy. (1), GÉNIAUX Ghislain. (1), NÉDELLEC Claire. (2), SAUVION Nicolas. (3), SOUBEYRAND Samuel. (1)

(1) INRAE, Montfavet, FRANCE; (2) INRAE, Jouy-En-Josas, 0; (3) PHIM, Montpellier, 0

Text

The One Health approach to understanding disease epidemiology and achieving surveillance and prevention is holistic all while currently focusing on zoonotic diseases. Plant health deploys principles of agroecology for holistic goals of plant health management. Nevertheless, One Health offers 4 knowledge challenges that could boost prospects for novel approaches to plant disease surveillance, prediction and prevention: i) uncovering reservoirs and revising pathogen/vector life histories, ii) elucidating drivers of virulence beyond direct host-pathogen interactions, iii) accounting for the natural highways of long distance dissemination, and iv) updating disease forecasts in the face of changing land use, cultivation practices and climate. The implementation of a One Health approach to

surveillance and prevention – for plant and zoonotic diseases alike - will require mobilization of tools to deal with the representation and accessibility of massive and heterogeneous data and knowledge; means for knowledge inference, data science, modelling, and pattern recognition; and multi-actor approaches that unite different sectors of society and different scientific disciplines. The key commonalities, where actors in the efforts to prevent zoonotic and plant disease can work together, are the need to build these tools and related infrastructure for a *bona fide* One Health approach to surveillance and prevention of human, animal and plant disease and sustainable management of biodiversity.

K1-3

ANTIMICROBIAL USE AND RESISTANCE IN PLANT AGRICULTURE: A ONE HEALTH PERSPECTIVE

TEMPELMAN Kim-Anh. (1), **KOUMBA Descartes. (1)**

(1) Food and Agriculture Organization of the United Nations, Rome, ITALY

Text
Antimicrobial Resistance (AMR) is among the top 10 global threats to human health with the highest burdens in low- and middle income countries. AMR in humans is linked to agricultural production of animals, fish and plants and is thereby a perfect example of an issue requiring a One Health approach.

Over the past decades, most AMR-related concerns were raised in the context of intensified animal protein production, including aquaculture, and pig and poultry production. More recently, the use of antimicrobials in crops is seen as an area that needs to be better understood and quantified.

Antimicrobials used in plant production and protection include antibiotics and fungicides. Fungicides are widely used to control fungal plant diseases and fungal resistance has triggered particular attention, due to the link with human health.

The Food and Agriculture Organization of the United Nations (FAO), is developing the International FAO Antimicrobial Resistance Monitoring platform (InFarm). This platform will collect data on antimicrobial resistance in animals, and antimicrobial use in plant production and protection. In parallel, FAO will launch the Reduce the need to use antimicrobials in farms initiative (RENOFARM) in 2023, and establish a list of antibiotics used in horticulture, ranking them according to their importance in plant health.

These new tools will support countries to make sound decisions to reduce AMU in crops and prevent or minimize the development of AMR.

K1-4

EMPOWERING AN INDIGENOUS PERSPECTIVE IN THE RESPONSE TO INVASIVE PATHOGENS

MARK-SHADBOLT Melanie. (1), LAMBERT Simon. (1), SHADBOLT Marcus-Rongowhitiao. (1), FORDYCE Phoebe. (1), HEIMLICK Micheal. (1)

(1) Te Tira Whakamtaki, Rangiora, NEW ZEALAND

Text
Many hundreds of pests and pathogens have been introduced, either deliberately or inadvertently, to Indigenous Peoples lands and waterways the world over. Unfortunately, the current biosecurity and eradication practices and processes implemented to address these incursions employ principles, values and knowledge that often undermine or even oppress local Indigenous Peoples and their extensive practices to sustainably manage biological heritage. So, whilst Indigenous Peoples have a millennia of information and experiences that are valuable in the often urgent response to invasive pests and pathogens, inclusive approaches are needed to ensure those experiences and information are able to inform and lead biosecurity events in a timely and effective manner.

At the same time, public attitudes to novel biosecurity management tactics such as toxins and gene editing need to be explored in advance of their deployment and ways of improving public engagement developed with social researchers and community leaders. We also need to consider ways to improve existing tools to increase the chances of successful eradication of new incursions. Greater use of advanced information technologies will move pest management towards “real time” control. Better understanding of the biology of pests, their interactions with ecosystems, and their impacts on assets that Indigenous Peoples value are required to ensure appropriate and just biosecurity strategies.

Food security in an unsecure future

K2-1

AGRIFOOD SYSTEMS FOR A FOOD AND NUTRITION SECURE WORLD: FROM EFFICIENCY TO RESILIENCE

GOVAERTS Bram. (1)

(1) CIMMYT, Mexico City, MEXICO

Text
The 4Cs – Climate Change, Conflict, COVID-19 and the Cost-of-living crisis – have brought about the worst food security crisis of the 21st Century. Dr. Bram Govaerts, Director General of CIMMYT will discuss strategies to overcome these challenges in his keynote presentation, “Agrifood Systems for a Food and Nutrition Secure World: From Efficiency to Resilience.” Govaerts will talk about early warning and surveillance systems as an important defense to help build resilience to external shocks in food insecure communities and regions. He will share success stories implementing systems that have effectively prevented the spread of prevalent and emerging pests and diseases in sub-Saharan Africa and South Asia. In addition, Govaerts will present CIMMYT’s work with national agricultural research systems and private sector partners on crop breeding programs that every year disseminate dozens

of disease resistant and climate resilient maize, wheat and dryland crop varieties where they are most needed to supplement surveillance efforts. He will describe ongoing efforts to promote the adoption of conservation agriculture-based sustainable intensification practices that transform food systems with a gender and social inclusion approach in the Global South. The training offered and the advisory systems supported by CIMMYT's work aim to empower women and offer more opportunities for fulfilling livelihoods to a new generation of farmers who will grow sustainably nutritious food for all.

K2-2

THE BEAUTY AND COMPLEXITY OF WHEAT DISEASE CONTROL

DOOHAN Fiona. (1)

(1) University College Dublin, Dublin, IRELAND

Text

Wheat has evolved distinct pathways, genes and systems to cope with particular pathogens. Pathogens such as *Fusarium* produce virulence factors, including the mycotoxin deoxynivalenol, to facilitate disease development. In turn, wheat has evolved genomic hotspots associated with disease responses and unique disease control strategies, including those involving taxonomically restricted genes and novel transcription factors. We now have the genomics tools to rapidly introgress these into commercial genotypes. Biocontrol also shows potential for the control of wheat diseases. Pathogens can have an intricate relationship with the host microbiome and endophytic microbes from wild crop relatives show potential for the control of diseases such as Fusarium head blight and Septoria tritici blotch. Now we are moving into an exciting era where we have the affordable tools to evaluate the relationships between the environment, crop biome, disease development and host genetic diversity across diverse ecosystems and this will give us new insights into plant-pathogen evolution and more refined solutions for disease control. Our work now moves to understanding the relationship between deoxynivalenol, wheat and the microbiome, with compelling indications that mycotoxins play an important role in regulating ecosystem interactions.

K2-3

CRISES ABOUND: HEALTH, CLIMATE, ENERGY, FOOD, PANDEMICS... HOW SUPERCOMPUTING, AI, AND LARGE-SCALE SYSTEMS BIOLOGY IN A ONEHEALTH FRAMEWORK CAN HELP ADDRESS THE MAJOR CHALLENGES WE ARE FACING.

JACOBSON Daniel. (1)

(1) Oak Ridge National Laboratory, Oak Ridge, UNITED STATES

Text

The recent flood of data generation has opened a new era of systems biology in which there are unprecedented opportunities to gain insights into complex biological systems. Integrated

biological models need to capture the higher order complexity of the interactions among cellular components. Solving such complex combinatorial problems will give us extraordinary levels of understanding of biological systems. The disease, traits or phenotypes of an organism, including its adaptation to its surrounding environment and the interactions with its microbiome, are the result of orchestrated, hierarchical, heterogeneous collections of expressed genomic variants regulated by and related to biotic and abiotic signals. However, the effects of these variants can be viewed as the result of historic selective pressure and current environmental as well as epigenetic interactions, and, as such, their co-occurrence can be seen as omics-wide associations in a number of different manners. We have developed supercomputing and explainable-AI approaches to find complex mechanisms responsible for all measurable phenotypes as well as an organism's ability to detect and modulate its microbiome. The result is progress towards a comprehensive systems biology model of an organism and how it has adapted to and responds to its abiotic and biotic environment which has applications in bioenergy, precision agriculture, ecosystem studies, precision medicine, and pandemic prevention among other disciplines.

Invasive and Emerging Plant Diseases

K3-1

EMERGING DISEASES IN THE VEGETABLE SECTOR: CHALLENGES AND PERSPECTIVES

GULLINO Maria Lodovica. (1,2), GILARDI GIOVANNA. (1), PUGLIESE MASSIMO. (1,2)

(1) UNIVERSITY OF TORINO, GRUGLIASCO, ITALY; (2) AgriNewTech s.r.l, Torino, ITALY

Text

The vegetable sector is vast and complex. The high volume of trade of products contributes to the vulnerability to contamination by pathogens of the goods in which production is often concentrated in relatively few locations and then marketed all over the world. The vegetable production sector is continuously interested by the emergence of new diseases. The main drivers of such epidemics are a) concentration of few crops and varieties; b) intensive cultivation systems; c) globalisation; d) just in time supply chains; e) climate change. In the vegetable sector new pathogens are often introduced into new areas throughout contaminated seeds. The leafy vegetables represent an interesting case study, also due to their dynamism. Fusarium wilts, Alternaria leaf spot and downy mildews are described as examples of how new pathogens or races can easily and quickly spread, causing severe losses. Reliable diagnostic tools help in controlling seed health, permitting seed treatment when needed. Such tools should be applied already at the industry level. The international trade of agricultural commodities makes the mediation efforts and cooperative research efforts across national barriers critical. The management of these diseases is challenging, since few fungicides are registered on these minor-use crops. However, they are generally grown under protection, often soilless, which is an environment helpful to implement innovative control strategies.

K3-3

RISK ASSESSMENT AND MANAGEMENT OF PESTS AND DISEASES IN THE EU: PAST AND PRESENT

POTTING Roel. (1)

(1) Netherlands Food and Consumer Safety Authority, Utrecht, NETHERLANDS

Text
The number of nonnative insects and pathogens is increasing and these may pose major threats to (agro)ecosystems. Pest risk analysis is the process of evaluating scientific evidence to determine whether a pathogenic agent is a pest, whether it should be regulated, and which official phytosanitary management measures should to be taken against it. Pest risk assessment is the evaluation of the probability of the introduction and spread of a pest and the magnitude of the associated potential economic consequences. In this presentation the evolution of plant health and pest risk assessment in the EU will be discussed.

A Global Plant Health Assessment (GPHA) of the state of Plant Health and its Impact on Ecosystem Services

K4-1

STATE AND EVOLUTION OF PLANT HEALTH GLOBALLY ACROSS PLANT SYSTEMS AND ECOREGIONS

BOVE Federica. (1)

(1) Università Cattolica del Sacro Cuore, Piacenza, ITALY

Text
This presentation is the first talk of the keynote session K4 "Global Plant Health Assessment (GPHA)". The GPHA is an initiative conducted under the aegis of the ISPP undertaken to contribute to the International Year of Plant Health. The general philosophy and the steps taken by the GPHA will be described. The Plant Systems assessed in the different Ecoregions of the world will be mapped. The overall results pertaining to the assessment of plant health status and evolution over the last 10 years will be outlined. Specific results for a limited number of Plant Systems (rice, potato, peri-urban horticulture and household gardens, softwood forests, and oak forests) will be described in more detail, allowing to highlight key findings. These include: plant health as affected by climate change, pathogen invasions, and the issue of pesticide misuse.

K4-2

SYNTHESIS AND IMPLICATIONS OF THE FINDINGS FROM THE GPHA

SAH Sonam. (1,2)

(1) G B Pant University of Agriculture and Teachnology, Pantnagar, INDIA; (2) ICAR-NIASM, Baramati, Pune, INDIA

Text

This presentation is the third talk of the keynote session K4 "Global Plant Health Assessment (GPHA)". This talk will first discuss the outcomes highlighted by the findings of the GPHA and its 26 reports for the [Plant System x Ecoregion] combinations that the project considered. This will be done with respect to the linkages between plant health and crop loss information, food security, biodiversity and conservation of species, climate change, pathogen invasions, and pesticide use and misuse. General insights gained from the GPHA initiative will then be highlighted. Links between the GPHA and the concept of One Health will be discussed. The notion of Ecosystem Services will be revisited and challenged. The talk will emphasise the fact that plant health is a common good, shared by all citizens across the world. The value of the GPHA specific design, as a collective action undertaken by a collective toward a common good, will be delineated. The GPHA recent as well as on-going activities, together with its outputs will be described. Perspectives will be offered, using the GPHA as an example of a collective action undertaken by a collective belonging to a Scientific Society toward common good.

K4-3

IMPACTS OF PLANT HEALTH ON THE SERVICES RENDERED BY PLANT SYSTEMS IN WORLD'S ECOREGIONS

SINGH Manjari. (1)

(1) Alliance of Bioversity International and CIAT Africa Hub – Senegal Office , Dakar, SENEGAL

Text

This presentation is the second talk of the keynote session K4 "Global Plant Health Assessment (GPHA)". The overall results pertaining to the assessment of the impact of disease on ecosystem services (provisioning, regulating, and cultural) and its evolution over the last 10 years will be outlined. Specific results for a limited number of Plant Systems (rice, potato, peri-urban horticulture and household gardens, softwood forests, and oak forests) will be described in more detail, allowing to highlight key findings of the results. These include: the paucity of hard data on crop losses caused by plant pathogens worldwide; the impact of plant diseases on food security; pathogen invasions threatening food security and biodiversity; climate change impacts on crops and crop losses; the challenges of pesticide misuse; and the conservation of plant species that are endangered by diseases, especially in the case of forest species.

Current Topics in Molecular Plant-Microbe Interactions

K5-1

REGULATION OF BACTERIAL GROWTH AND BEHAVIOR BY PLANT IMMUNITY

TSUDA Kenichi. (1)

(1) Huazhong Agricultural University, Wuhan, CHINA

Text

Plants are colonized by commensal, beneficial, and pathogenic bacteria that significantly affect plant health. Plants require bacterial colonization for their survival in nature, but ironically, some bacteria cause disease in plants, pointing to the dilemma that plants face. Therefore, the fundamental question is how plants regulate different bacteria for their benefit. However, we still lack fundamental knowledge of how plants actually regulate bacterial growth and behavior in plants. Through multi-omics and molecular genetics, we uncovered several mechanisms of how plant immunity regulates the growth of the bacterial pathogen Pseudomonas syringae. For instance, we found that plant immunity targets the bacterial iron acquisition system, the type III secretion system, and the bacterial protein MucD, all of which are required for virulence in plants but not their growth in vitro. More recently, we found that reactive oxygen species (ROS) generated by plants directly suppresses the type II secretion system (T2SS) of a potentially pathogenic commensal Xanthomonas isolated from healthy Arabidopsis thaliana plants. ROS-mediated inhibition of the T2SS converted the potentially harmful Xanthomonas into a commensal bacterium that protected plants against P. syringae. Thus, these results suggest that plant immunity targets the virulence mechanisms of bacteria to control their behavior in plants and turns them into beneficial bacteria in some cases.

K5-2

UNCOVERING THE FACTORS THAT SHAPE THE DISTRIBUTION OF VECTOR-BORNE PLANT PATHOGENS

HOGENHOUT Saskia. (1)

(1) John Innes Centre, Norwich, UNITED KINGDOM

Text

Insect vectors of the order Hemiptera, such as aphids, psyllids, leafhoppers and froghoppers, are critical for the transmission of bacterial plant pathogens such as *Phytoplasma* and *Liberibacter* species and *Xylella fastidiosa*. These pathogens, along with their vectors, are invasive and have caused the collapse of fruit and crop production industries and the decline of native flora. However, the drivers of the success of these pathogens are largely unknown.

We shed new light on how these pathogens and their effectors modulate plant processes and interactions with insect vectors. We created genomic and transcriptomic resources for ±40 small hemipteran insects and uncovered the geographic population structure and routes of global dispersal of several invasive insect vectors. Our findings indicate that the successes of the pathogens are due to their abilities to promote insect vector attraction and performance, as well as the migration of insect vectors over long distances.

However, the pathogens' dependence on insect vectors is also their Achilles' heel, and we found that this reliance can be exploited to generate plant resistance. Therefore, it is essential to gather information on sap-feeding insects to build resilience against vector-borne plant pathogens. By understanding the drivers of success of these pathogens and their vectors, we can develop strategies to combat their spread and reduce their impact on crop production and native flora

K5-3

IMPACT OF CLIMATE ON PLANT-PATHOGEN INTERACTIONS

HE Sheng-Yang. (1)

(1) Duke University, Durham, UNITED STATES

Text
The "Disease Triangle" concept states that plant disease outbreaks require not only a susceptible plant and a virulent pathogen, but also conducive environmental conditions. Molecular studies in the past four decades have made major strides in understanding the mechanistic bases of plant resistance and pathogen virulence. However, less effort has been devoted to addressing an increasingly important question - why climatic conditions, such as humidity and temperature, have a profound effect on host susceptibility and disease development. Moreover, current studies often ignore the potentially pervasive effect a plant's endogenous microbiome may have on host-pathogen interactions. In this talk, I will give an example of interplay between disease, environment and microbiota during *Pseudomonas syringae* infection of host plants. Results suggest that future studies should increasingly consider the multi-dimensional nature of "disease-environment-microbiome" interactions, which are likely more reflective of what occur in natural ecosystems.

New Developments in Plant Disease Management

K6-1

DISEASE EARLY WARNING AND ADVISORY SYSTEMS – THE CASE OF WHEAT RUSTS

HODSON David. (1)

(1) CIMMYT, Texcoco, MEXICO

Text
Rust pathogens are one of the main biotic threats to wheat production globally. Highly mobile, constantly changing, and capable of devasting epidemics; they are a priority for disease management and epidemic prevention. Throughout wheat growing areas an increasing number of virulent pathotypes are being detected with rapid evolution and long-distance movements observed. Through a coordinated, large-scale, operational disease surveillance network it has been possible to track emerging threats, notably for stem and stripe rust. This international, multi-disciplinary surveillance and monitoring network is primarily focused on hot spots in developing countries but has global reach and implications. The integration of new technologies is permitting faster accurate detection, improved early warning and widespread dissemination of timely, actionable advice for disease management and reduction of epidemic threats. Over the past 15 years, considerable progress has been made in developing advanced early warning and advisory systems for wheat rusts in East Africa and South Asia. These systems are resulting in the protection of vulnerable wheat crops through early decision-making and on-time deployment of disease management strategies. Progress and status of these early warning and advisory systems will be presented. Future directions, including the expansion to include other important wheat diseases, are also highlighted.

K6-2

ADVANCES IN PLANT VIRUS DISEASE MANAGEMENT IN SUB-SAHARAN AFRICA – THE CASE OF BUNCH TOP DISEASE

KUMAR Lava. (1), NGATAT Sergine. (2), FIABOE Komi. (2), ALABI Tunrayo. (1), MAHUKU George. (3), TRIPATHI Leena. (4)

(1) International Institute of Tropical Agriculture (IITA), Ibadan, NIGERIA; (2) IITA, Yaoundé, CAMEROON; (3) IITA, Kampala, UGANDA; (4) IITA, Dar es Salaam, UNITED REPUBLIC OF TANZANIA

Text
Plant viruses have caused several devastating epidemics to annual and perineal corps in sub-Saharan Africa (SSA). Virus disease management in SSA heavily reliant on host resistance. For the viruses lacking durable resistance management relied on integrated methods, including habitat management, clean seed systems and phytosanitary controls. However, these methods are less efficient in preventing the virus spread.

Production of banana in sub-Saharan Africa is hit by the banana bunchy top virus (BBTV, genus Babuvirus). The virus transmitted by an aphid, Pentalonia nigronervosa, and vegetative propagation is increasingly becoming a serious threat due to the expansion of the virus into new regions in West Africa and, most recently, into East Africa. In the absence of durable host resistance, BBTV management requires integrated approaches to prevent the spread and eradication of infected plants. Progress and status of the recent advances to control BBTV, including the search for host resistance for BBTV and its vector, surveillance using remote sensing and machine learning methods, development of rapid diagnostic tools, biocontrol for aphids, and transgenic approaches will be presented.

K6-3

NLRSEEK: HIGH-THROUGHPUT DISCOVERY PIPELINE FOR FUNCTIONAL RESISTANCE GENES

BRABHAM Helen. (1,2), HERNÁNDEZ-PINZÓN Inmaculada. (2), YANAGIHARA Chizu. (3), ISHIKAWA Noriko. (3), KOMORI Toshiyuki. (3), MATNY Oadi. (4), HUBBARD Amelia. (5), WITEK Kamil. Text

Breeding crop species that are safe from pests and diseases is vital to build sustainable food systems crucial for food security. An effective and environmentally friendly method of disease control is to enhance the plant immune system by introducing functional resistance genes. A major class of plant immune receptors are nucleotide-binding, leucine-rich repeat receptors (NLRs), however identifying NLRs for use in elite crop varieties is time-consuming and resource-intensive. Through analyses of copy number variation and expression data, we identify high expression as an overlooked molecular signature of functional NLRs. Combining this signature with high-throughput crop transformation, we developed an approach that enables rapid identification and in planta validation of NLRs from non-domesticated germplasm. Screening 995 NLRs from 18 grass species identified 19 new resistance genes against wheat stem rust, a critical threat to wheat production. This pipeline facilitates rapid resistance gene discovery from diverse plant species to generate disease-resistant crops.

UTILIZING BIODIVERSITY SCIENCE TO GUIDE SUSTAINABLE CROP MANAGEMENT

LAINE Anna-Liisa. (1)

(1) University of Zurich, Zurich, SWITZERLAND

Text

Pathogens are prevalent across all ecosystems, and an individual's reproductive success and survival will depend on its ability to resist infection. Natural populations have been shown to support considerable diversity in resistance, and theory predicts this diversity to offer an effective means of diluting disease risk at both population and community levels. Analysis of a large natural pathogen metapopulation shows host resistance to be shaped by spatial structure and to have direct consequences on disease dynamics. At the community level we find an association between host trait distribution and pathogen load across a steep environmental gradient. We test these predictions from natural ecosystems in a large field biodiversity trial to identify how undersown species contribute to disease dilution. Our results highlight variation among undersown species in their effectiveness to dilute disease on barley.

C6.7-2

HOW SPECIES MIXTURES SUPPRESS PLANT DISEASES: INSIGHTS FROM A META-ANALYSIS

HOMULLE Zohralyn. (1), LI Wenfeng. (1,3), **DOUMA Bob. (1)**, MAKOWSKI David. (3), VAN DER WERF Wopke. (1)

(1) Centre for Crop Systems Analysis, Wageningen University, Wageningen, NETHERLANDS; (2) Faculty of Mechanical and Electrical Engineering, Yunnan Agricultural University, Kunming, CHINA; (3) University Paris-Saclay, AgroParisTech, INRAE, Unit Applied mathematics and computer science, Paris, FRANCE

Text
There is a strong policy push for the idea that integrating diversity into agricultural systems will reduce the impact of diseases and hence reduce the need for pesticides. It is, however, uncertain how strongly disease pressure is reduced by growing species in mixtures. Here, we present a global meta-analysis on the effect of species mixtures on disease incidence in agriculture. We compiled from the literature a large global dataset of 216 trials reporting disease incidence in intercrops and their corresponding pure stands. Intercropping reduced disease incidence from 35% in pure stands to 21% in mixtures, equivalent to a 52% reduction in the odds of disease, from approximately 1:2 to approximately 1:4. The intercropping effect was consistent across continents but varied for different pathogens and crop species combinations. Mechanisms underlying the suppressive effect were further explored. Among others, we show that: i) the degree of mixing was, surprisingly, not significantly associated with the degree of disease suppression; ii) taller companion crops tended to have a stronger disease suppressive effect compared to smaller companion crops, in particular for aboveground spreading diseases, and iii) intercropping both reduced the initial disease incidence, as well as the disease growth rate. This analysis gives further insight into the mechanisms that underly the disease-suppressive effect of species mixtures and may provide pointers to further optimize agronomic practices

C6.7-3

COMBINING SOURCES OF RESISTANCE IN VARIETAL MIXTURES TO MANAGE THE EVOLUTIONARY DYNAMIC OF PATHOGEN POPULATIONS OF CEREAL CROPS: A WAY TO SOLVE THE EFFICIENCY-SUSTAINABILITY TRADE-OFF?

SUFFERT Frédéric. (1), FOURNIER Elisabeth. (2)

(1) INRAE, Palaiseau, FRANCE; (2) INRAE, Montpellier, FRANCE

Text
Varietal mixtures have been shown to limit plant pathogen expansion in numerous cases. This effect is related to the overall increase of functional diversity within fields, but the mechanisms involved, which are diverse and some of which are specific to the biology of the pathogen, are not all well characterised. Recent results obtained in the rice pathogen Magnaporthe oryzae and the wheat pathogen Zymoseptoria tritici suggested that the combination of resistances within field drives the epidemiological and evolutionary control of pathogen populations, through antagonistic interactions that limit the range of possible adaptations. The aim of this keynote presentation is to highlight most recent body of knowledge on the multi-scale mechanisms of plant-pathogen interactions that play a role on the control of plant diseases in varietal mixtures and drive the evolution of virulence and aggressiveness after the deployment of different resistance genes in neighbouring plants within a canopy. Applying this body of knowledge to control the evolution of pathogen populations would allow the design of “smarter mixtures” reconciling the objectives of efficiency and sustainability of this agroecological practice.

C6.7-4

PLANT-PLANT INTERACTIONS MODULATE WHEAT SUSCEPTIBILITY TO SEPTORIA

MATHIEU Laura. (1), MARTY Soline. (1), DUCASSE Aurélie. (1), METEIGNIER Louis-Valentin. (1), DAVID Jacques. (2), MOREL Jean-Benoît. (1), BALLINI Elsa. (1)

Text

Because of their well-known impacts on yield and diseases, cultivar mixtures are a growing practice and also an increasingly studied research topic. Plant susceptibility to pathogens in mixtures is reduced in fields, notably through epidemiological mechanisms. However, a new mechanism has recently been identified in which plant susceptibility can be modulated by plant-plant interactions, in absence of epidemy. Our objective is to identify the physiological and genetical determinants responsible for such interactions in wheat. We investigated bread wheat susceptibility to Zymoseptoria tritici in 190 two-ways mixtures using a new high throughput image analysis. Overall, the wheat susceptibility to Septoria was identical between mixtures and pure crops, although specific positive and negative plant-plant interactions could be identified, which is consistent with field situations where effects of wheat cultivar mixtures on Septoria susceptibility are highly variable. These results thus allowed the identification of interesting pairs, representing 3% of all tested mixtures, in which neighbours have beneficial effects on focal plant susceptibility after one infection cycle. Using these pairs, we are trying to identify the below-ground signals triggering this modulation of wheat susceptibility by the neighbours and the physiological as well as molecular responses to such neighbours.

C6.7-5

SMARTER VARIETAL MIXTURES TO IMPROVE PLANT DISEASE MANAGEMENT

MIKABERIDZE Alexey. (1)

(1) University of Reading, Reading, UNITED KINGDOM

Text

There is a large empirical and theoretical body of knowledge supporting varietal mixtures as an effective and sustainable approach to suppress fungal diseases in crops. Efficacy and durability of mixtures can be improved by adjusting their parameters [1,2]. We can choose the varieties comprising a mixture, thereby adjusting their degrees of disease resistance and tolerance. We can also adjust the number of component varieties and their proportions within the mixture. This optimization requires a detailed understanding of the epidemiology of diseases to be controlled and the population biology of the associated pathogens. I will review recent research on optimizing varietal mixtures drawing from both theoretical and empirical studies. I will discuss promising future directions: the role of new phenotyping technologies in optimizing varietal mixtures and the contribution of plant microbiomes to the efficacy of mixtures.

VARIABLE EFFECTS OF A WHEAT CULTIVAR MIXTURE ON SEPTORIA TRITICI BLOTCH: INVESTIGATING KEY FACTORS INVOLVED IN MIXTURE EFFECT VARIATION BETWEEN EUROPEAN SITES

VIDAL Tiphaine. (1), DUVIVIER Maxime. (2), GAUBRIE Sylvain. (3), HEICK Thies. (4), HELLIN Pierre. (2), KILDEA Steven. (5), SUFFERT Frédéric. (1)

(1) Université Paris-Saclay, INRAE, UR1290 BIOGER, Palaiseau, FRANCE; (2) Plant and Forest Health Unit, Walloon Agricultural Research Center, Gembloux, BELGIUM; (3) Comité de Développement de Plaine et Marais, Luçon, FRANCE; (4) Department of Agroecology, Aarhus University, Slagelse, DENMARK; (5) Teagasc, The Agriculture and Food Development Authority, Carlow, IRELAND

Text

Wheat cultivar mixtures can provide control against numerous diseases such as Septoria tritici blotch (STB) caused by *Zymoseptoria tritici*. One important criterion for mixture design is the contrast in resistance levels between the mixed cultivars, but these resistance levels can vary with local conditions (eg. composition of pathogen populations, climatic conditions). The objective of this work was to assess disease control provided by a cultivar mixture in different locations in Europe, and its relation to factors including the local resistance level of cultivars in pure stand and climatic conditions. A field experiment was carried out in seven sites in Europe (in France, Belgium, Denmark and Ireland) during three successive cropping seasons. In each site, disease severity was measured on each cultivar (Apache and Cellule) in pure stands and in a 50:50 mixture. The resistance level of each cultivar was variable between site x year. Mixture effect, computed as the difference of disease severity of the cultivar in mixture compared to pure stand, ranged from +3% (more disease in mixture) to -3% (less disease in mixture) on Apache and from +1% to -12% on Cellule. The largest disease reductions in mixtures were observed for each cultivar in sites x years where it appeared as susceptible in pure stand. These results show that the efficiency of a particular mixture can vary between sites and years and open perspective to better adapt mixture design to local conditions.

Advances in the use of exotic sentinel trees and novel monitoring programs

to detect incipient threats posed by forest pathogens

C4.5-1

LESSONS LEARNED FROM A RECIPROCAL INTERNATIONAL SENTINEL PLANTING PROJECT

Text

Non-native, invasive tree pathogens and insect pests (PIPs) are among the greatest threats to forest ecosystems worldwide. Prevention and early detection are the most effective management strategies in mitigating PIP impacts. This includes risk analysis of the many possible PIPs in a source locale that can potentially become invasive if introduced into a susceptible sink environment. Ex-patria sentinel gardens can be a significant component of these efforts, as they involve the intentional planting and monitoring of host species of interest in potential source environments, thus exposing them to the local PIPs. In other words, target trees are used as the proverbial canary in the coalmine, i.e. an early warning system. Through an international collaborative study, we established plantations of Asian and European tree species in the U.S.A. and corresponding plantations in Europe, with Asian and North American species, and China, with European and North American species. Sentinel gardens were monitored for symptoms and signs of disease and insect attack over two seasons and fungal and insect species were collected and identified. Preliminary results show that several species of fungi and insects were described for the first time on several of the hosts used. Lessons learned from our experience with this approach so far will be discussed in the context of optimal strategies for invasion prevention.

Text

The main goal of this study was to evaluate the potential of Fisher-Shannon statistical method applied to satellite time series to detect any anomalies happening in the vegetation behavior with particular reference to those related to Xylella fastidiosa and Toumeyella Parvicornis. For the purpose of this study, significant study areas have been selected in Italy focusing both urban forests, affected by Toumeyella Parvicornis, and agricultural areas, affected by Xylella fastidiosa, along with unaffected test areas. To account for the great variability exhibited by the seasonal variations while identifying small multi-year trends and changes, we devised a procedure made up of two steps: (i) firstly, the satellite-based time series has been analysed using the Singular Spectrum Analysis (SSA) to detect and remove the annual cycle including the seasonality and then (ii) the de-trended signals have been analysed using the Fisher-Shannon. The methodological approach has been applied soil-water-atmosphere-plant related satellite products available in the Google Earth Engine cloud database (LAI, NDVI, EVI, ET from MODIS).
In the Fisher-Shannon Information Plane (FSIP), the infected vegetated areas appear well characterized and discriminate from healthy areas. These preliminary results seem to envisage the usefulness of the Fisher-Shannon method as a reliable statistical tool to be included in an operational system for early diagnosis of status of deterioration of vegetation.

FOUR YEARS OF THE EUROPEAN UNION REFERENCE LABORATORY (EURL) FOR FUNGI AND OOMYCETES

PARRA GIRALDO Pedro Pablo. (1), RENAULT Camille. (1), CERF Isabelle. (1), AGUAYO Jaime. (1), IOOS Renaud. (1)

(1) ANSES Plant Health Laboratory, EURL for fungi and oomycetes, Mycology Unit, Malzéville, FRANCE

Text

The European commission approved in 2016 a new Plant Health Act applicable for countries of the European Union (EU). This set of laws implemented in 2019 conferred authorities a greater competence to reduce the risks of introduction and further spread of plant pathogens within the EU. In response to this legislation, a network of EURLs in the main areas of plant health was created. Since 2019, the Mycology Unit of the Plant Health Laboratory of ANSES, has been appointed by the EU to carry this mandate as the EURL for fungi and oomycetes. The main objective of this mandate is to enhance the capacities for pathogens detection of the National Reference Laboratories (NRLs) of the EU member States. This goal is achieved through the organization of trainings, workshops and the validation and development of detection methods, as well as proficiency tests on quarantine or emerging plant pathogens. The latter allows to identify opportunities for improvement and implement corrective actions. Other activities comprise technical assistance and the release of literature reviews and newsletters. The EURL, also maintains a collection of over 100 fungal strains and distribute them as reference material to the NRLs for training purposes. Since its designation, the EURL for fungi and oomycetes has developed its work program on the above-mentioned activities in species such as *Fusarium circinatum*, *Geosmithia morbida*, *Phytophthora ramorum*, *Phyllosticta citricarpa*, *Tilletia indica*, among others.

Text

Early detection of fungi and oomycetes is the key to managing regulated and invasive alien species. These are difficult to study and even more in forest environments. Unlike insects, they can't be lured and requires a more significant sampling effort. Conventional qPCR-based monitoring approaches require a detailed knowledge of the target organisms. High throughput sequencing (HTS) technologies allow us to investigate different types of samples, process large numbers of samples and produce even greater volumes of genomic data. Metagenomics tools combining Ion Torrent sequencing and custom bioinformatic pipelines can be used to evaluate potential sampling methods for pathogens in forestry and agriculture and contribute to identify spreading pathways. Sampling methods exploiting eDNA isolated from insects, air, soil, tissues, and pollen have revealed sources of target pathogens. In addition, pest monitoring activities were evaluated to understand the limitations of the technology in biosurveillance. We aim to provide a framework combining sampling tools with HTS-based methods, appropriate bioinformatic pipelines and qPCR assays for early detection of emerging and invasive alien species. This was applied to *Bretziella fagacearum* responsible for the Oak wilt, *Phytophthora spp*. associated with root rot diseases and other forest pathogens in Canada. We believe that such a framework will help and improve early warning, promote public awareness, and support our regulatory activities.

DORMANT WOODY PLANTS: A PATHWAY OF INTRODUCTION INTO EUROPE OF POTENTIALLY INVASIVE PESTS?

PROSPERO Simone. (1), FRANIC Iva. (1,2), ESCHEN Rene. (2)

(1) WSL, Birmensdorf, SWITZERLAND; (2) CABI, Delémont, SWITZERLAND

Text

Non-native pests (including pathogens) represent one of the major threats for trees worldwide. Most of the recently established non-native pests of trees were not known as harmful organisms or even to science prior to their establishment. Consequently, they were not targeted by practices and measures aiming at minimizing the risk of accidental introduction of harmful organisms.
Recently, new approaches to identify potential harmful invaders before they spread in a new environment have been proposed, including sentinel plantings and horizon scanning. Here

we assessed if the international trade of dormant woody plants may be a pathway of introduction of potentially invasive pests in Europe. For this, we characterized the communities of fungi and insects in and on (insects) asymptomatic dormant twigs of trees from 167 species in 14 genera grown at 49 sites in 33 countries around the globe. Our analyses showed that non-European plant samples hosted 10 fungal species and two specie of herbivorous insects not yet officially present in Europe. Most of these were found or are known to occur in association with tree species which are present in Europe, or which have congeneric species in Europe. Hence, when introduced into Europe such organisms would most likely find appropriate hosts on which, they could become established. To better assess the effective risk that such organisms pose to European tree species, however, specific risk analyses should be carried out in the future.

OBSERVATREE: 10 YEARS OF EARLY WARNING CITIZEN SCIENCE

GOSLING Rebecca. (1), WEST Fritha. (1), CROW Peter. (2), PARRATT Matt. (2), PEREZ-SIERRA Ana. (2), LANE Charles. (3), TURNER Lucy. (2)

(1) Woodland Trust, Grantham, UNITED KINGDOM; (2) Forest Research, Farnham, UNITED KINGDOM; (3) Fera Science Ltd, York, UNITED KINGDOM

Text
Observatree is a successful collaboration between Governmental agencies and NGOs in the UK. The project utilises citizen science to act as an early warning for tree pests and pathogens. Now entering its tenth year, what data has the project generated? Can volunteers submit accurate surveys for early warning and monitoring? By the end of 2022 over 18,000 reports had been submitted by a network of 200 highly trained volunteers. The volunteers reported on 9 priority pathogens identified by the Government, alongside reporting other worrying symptoms and, importantly, negative findings. The network has submitted 1400 new findings of the priority pathogens, contributing greatly to the known distribution of Hymenoscyphus fraxineus, and adding significant new findings for Cryphonectria parasitica and the acute oak decline bacterial complex. Analysis from 2019 reported 85% of the pest or pathogen findings were correct in identification, demonstrating the potential for volunteers in this space. Observatree also has a network of over 600 sentinel trees, consisting of over 30 species, distributed across the UK. The health of this sentinel network is showing decline. Over 50% of the monitored Fraxinus spp. and Aesculus spp. exhibit a damaging pest or pathogen. This data is vital for monitoring the state of the nations trees, aiding statutory action, research, and policy.

Text

The early detection of pests and diseases using sentinel plants has been exploited in some experimental work, to identificaty (unknown) plant pests and pathogens prior to introduction into new countries. Sentinel plantings can have different objectives: in-patria plantings estimate infestation rates of associations of native pathogens and native tree species that may be exported with that particular commodity, whereas ex-patria plantings are relevant to assessing new pest-host associations prior to the introduction of the pests, such as possible host shifts of pests native to the exporting country to hosts native to the importing country. In the frame of the EU project HOMED and an USDA funded project we have implemented this concept, widening the use of this tool. Here we report the results from the sentinel plantations established in Italy.
Eight European (in-patria), seven North American and five South African tree species (ex-patria) were planted in Florence, Italy according to a randomized block design. Over three years, symptomatic trees were sampled twice-a-year and the causal agent identified. The results show that the monitoring techniques developed and used in these trials are extremely effective: regularly monitoring over a period of three years has yielded a multitude of known and previously unknown pest-host associations. Our work presents the associations and discuss them in the context of risks associated with the global movement of live plants.

Text

In the present study, the sentinel arboreta strategy was applied, and its efficacy was evaluated at the Atatürk Arboretum (Istanbul, Turkey), having as a study case the interaction Tubakia spp. – Quercus spp. Thirty-four oak species native of America and Eurasia were sampled within the Fagaceae collection of the arboretum. Isolation trials were conducted from leaf necroses, and High Throughput Sequencing for fungal taxa was carried out from asymptomatic leaf blades. Four *Tubakia* species were identified, *T. dryina*, *T. suttoniana*, *T. hallii*, and *T. macnabbii*. Three out of four are of recent description and the present study contributed to updating their host-range. Thirty-two oak-Tubakia interactions new to science were described. Hypotheses were formulated on the possible movement across geographic areas of these species and on the risk posed in case of introduction in the distribution range of susceptible host species. As a conclusive remark, the present study confirmed the efficacy of the sentinel arboreta strategy to highlight new host-pathogen interactions and the risk of host-shift events.

Text

The causes of broom disease prevalent in Korea are diverse, such as phytoplasma, fungi, and herbicides, and it is difficult to diagnose in the field because pure culture without host cells is impossible. So, we developed a simple quick diagnostic method for the efficient diagnosis of phytoplasmas infection in various hosts at outbreak sites. To do this, we designed a universal LAMP (Loop Mediated Isothermal Amplification) primer set for phytoplasma diagnosis by analyzing the nucleotide sequence of 16s rRNA from phytoplasma-infected *Ziziphus jujuba* var. *inemmis*, *Paulownia coreana*, *Rhus javanica* L., *Hovenia dulcis* Thunb., *Ulmus parvifolia* Jacq., *Elaeocarpus sylvestris* var. *ellipticus* (*Candidatus* phytoplasma malaysianum), *Elaeocarpus sylvestris* var. *ellipticus* (*Ca*. phytoplasma asteris). “Phytoplasma real time quick detection kit (PRTQ kit)” and “KN5 rapid DNA and RNA extraction kit (KN5 kit)” was developed (Speegenebio Co., Ltd). We evaluated both kits’ efficacy together with another portable nucleic acid amplifier (HARU-2000, SM electrical Co., Ltd.). When using PRTQ kit, All the phytoplasmas described above were detected within 14 minutes in “HARU-2000.” Phytoplasma DNA could be extracted by KN5 kit between 1 minute to 10 minutes. KN5 kit enhanced the availability of PRTQ kit in the field by allowing rapid DNA extraction from target samples. Therefore, “PRTQ kit” and “KN5 kit” in addition to “HARU-2000” can solve the difficulties of phytoplasma diagnosis in the field.

Text

Pine wilt disease caused by the pine wood nematode, *Bursaphelenchus xylophilus*, is the most destructive forest disease in Korea. The pine wilt disease first occurred in Busan in 1988 and has spread to 135 regions over the past 30 years. This study was conducted to develop a molecular marker that can analyze the genetic relationship of the pine wood nematode populations by region because identifying the spread route is most important for

controlling pine wilt disease. The genome sequence of the Korean pine wood nematode was prepared, and genetic variations on 6 chromosomes and the mitochondrial genome were confirmed by analyzing the nucleotide sequences of 290 Korean pine wood nematode populations. As a result of phylogenetic analysis with this variation, it was possible to classify into three groups, and the number and location of SNPs by the group were analyzed and genetic markers were selected. Using the six selected SNP markers, hetero-type could be identified, more accurate tracking of the occurrence of pine wood nematode. Analyzing the genetic relationship of pine wood nematodes occurring in Korea and mapping a gene group, KL01, KL02, and KL01-03 groups are mainly distributed, and the KL01-03 hetero-type dominates in Korea. Our results can be useful for epidemiological investigations when pine wood nematodes spread to new areas and can be used as basic data for the development of genetic markers that can be subdivided by populations.

Text

Risk uncertainty limits adoption and effectiveness of preventative forest biosecurity. To gather information on unknown threats, scientists have monitored trees outside of their range (i.e., “sentinel trees”) in new gardens and living botanical collections, where they may be exposed to novel pathogens lurking there. Although most invasive pathogens were known to science, the threat they posed to forest ecosystems in new environments remained unclear until a full-blown epidemic was already underway. In a wider context, Nearctic trees have been planted intercontinentally for > 500 years, resulting in thousands (> 2.7K) of recorded encounters with new pathogens. The analysis of retrospective data on prior knowledge of tree pathogens that became invasive could aid assessment of impending threats by quantifying pre-invasion risk uncertainty. To that end, we assembled chronological records of North American trees outside their range that could have functioned as sentinels for a comprehensive list of established invasive forest pathogens in North America. We then reviewed the biogeographic origins, dates of first observation, and prior records of host range for each pathogen. With this data we found support for the hypothesis that realized impacts of invasive pathogens could be partly accounted for retrospectively by observations from sentinel trees, phylogenetic host range, and human-aided dispersal of hosts to biogeographic regions where pests may be pre-adapted to colonize them.

APP-titude for social media in Plant Disease Research

C7.7-1

ENHANCING SOCIAL MEDIA DELIVERY TO PLANT PATHOLOGISTS

JOHNSON Greg I. (3), MASINO Andrea. (1,2)

(1) International Society for Plant Pathology, Torino, ITALY; (2) Agroinnova - University of Torino, Torino, ITALY; (3) International Society for Plant Pathology, Jamison, AUSTRALIA

Text

Time waster or community of trust? Views differ, but there is no denying the potential of social media to enhance plant disease research progress, record keeping and community engagement. This presentation introduces the use and engagement with social media by plant pathology societies and plant pathologists, and considers how to improve its relevance. The starting point was a 2023 survey of the plant pathology community to gauge the ethical use of social media to

1. improve access to the latest 'hot' findings in plant pathology and food security
2. improve extension and enhance contact with farmers and supply chain people
3. provide services and inspiration through plant pathology societies
4. support mental health and inspire the spirit
5. enhance the impact and access to journals and newsletters
6. promote meetings and report social news about plant pathologists

The survey findings will be summarized under

- topics most important to social media readership
- platforms respondents use to access plant pathology related topics and inspiration
- scientific societies and other sources of plant pathology information and
- the demographic profiles of users and non-users.

Finally, we will suggest opportunities for improving social media use to enhance science outreach, career prospects and well-being of plant pathologists.

C7.7-3

THE INTERNATIONAL YEAR OF PLANT HEALTH: BEING A JOURNALIST HELPS

GULLINO Maria Lodovica. (1,2), MASINO Andrea. (1)

(1) Agroinnova - University of Torino, Grugliasco, Torino, ITALY; (2) Mind the Gap SB S.r.l., Torino, ITALY

Text

The year 2020 offered a unique opportunity to plant pathologist worldwide, having been declared the International Year of Plant Health (IYPH) by the United Nations. Thanks to its activity in the International arena, as well as a very good relationship established with FAO, permitted AGROINNOVA to play a role, with the intent of letting people know the social and economic role of plant pathology. The IYPH indeed permitted to overturn the concept of plant disease into the one of plant health. Did help being a journalist? Of course yes. The celebration of the IYPH provided a very unique opportunity to invest resources in communicating our discipline to a much broader audience. Communicating the results of our research, nowadays considered into the broader field of public engagement, is an important task for researcher. Not all researchers are as good in communication as in research. This happens also because, at least in the past, the traditional *curricula* did not include courses on communication, so that most of us are self-taught. As a researcher active in public engagement, being also publicist journalist, taking courses and working closer to the journalism environment, help in selecting the topics to tell and a better understanding of the timing of journalism. A good relationship among researchers and journalists helps improving researcher's communication, sharing tools, ranking priorities, understanding what indeed matters to the public.

C7.7-4

FROM PHYTOPATHOLOGICAL STROLLS TO SOCIAL MEDIA SCROLLS: AN OPPORTUNITY TO RAISE AWARENESS OF PLANT PATHOGENS

SUFFERT Frédéric. (1), SUFFERT Muriel. (2)

(1) INRAE, Palaiseau, FRANCE; (2) EPPO, Paris, FRANCE

Text

The 2020 International Year of Plant Health was opportune for communication on plant diseases. During this year we illustrated the diversity and beauty of fungal plant pathogens found during “phytopathological strolls”, in which we observed and determined the origin of symptoms on diseased plants found in our garden, in the local streets of a city in the Paris (France) suburbs, and in nearby open spaces. We observed and described fungal pathogens through hundreds of photographs, shared our findings with a large audience on Twitter using the account @wheatpath, and received feedback. The lockdown imposed to control the COVID-19 pandemic created an additional motivation to take up the challenge and to involve our children. This experience was an opportunity to promote phytopathology as a part of our day-to-day life through a combination of classical approaches and digital tools in tune with the times, such as social media, by treating pathogen identification like a detective game and by making use of the addictive nature of collection approaches.

C7.7-5

THE INTERSECTION OF SOCIAL MEDIA AND INDIGENOUS RIGHTS IN PLANT PATHOLOGY

EHAU-TAUMAUNU Hanareia. (1,6), WILLAMS Nari. (2,4,5), MACDIARMID Robin. (3,4,6)

Text

Communication and audience engagement is a key component of the modern science system with a direct benefit to the researcher, research team, organisations, and funding bodies. We now share and like posts of research progress and outputs through social media with the intent of building networks and getting our work out in the world; all with altruistic intentions of making an impact in the field of plant pathology. Yet, this thinking by researchers may not align with the values and practices of Indigenous/First Nations communities and/or could impact their rights. How can social media be used to uplift research projects with equitable benefit for Indigenous/First Nations peoples and rights when appropriate, and on the flip side, how can social media be problematic and unsafe? We will explore social media use and Indigenous/First Nations rights to provide insight and raise possible concerns about engaging in and promoting plant pathology research, and the

opportunities to be guided by strong and shared ethics. In addition to the presentation, we warmly invite you to attend ‘Getting rights right: A roundtable exploration of Indigenous rights and plant pathology’ at ICPP 2023.

(1) Christian-Albrechts University of Kiel, Kiel, GERMANY; (2) Azarbaijan Shahid Madani University, Tabriz, IRAN (ISLAMIC REPUBLIC OF)

Text

The fungal pathogen *Zymoseptoria tritici* causes devastating disease in wheat. The history of this pathogen is tightly correlated with crop domestication and the spread of wheat cultivation with farmers since the Neolithic. We have traced back the origin of *Z. tritici* to the Middle East and identified a large diversity of sister species infecting wild grasses in natural grassland vegetations in Iran. This collection of isolates provides us with a unique resource to study speciation genetics and host specialization in natural and agricultural ecosystems. We have sequenced population genomic data of five *Zymoseptoria* species including populations of *Z. tritici* occurring on the wild wheat relatives, *Aegilops* spp. Plant inoculation experiments prove a strong degree of host specificity, even among closely related linages. In spite of the prominent signature of host specificity, comparative population genomic analyses reveal recurrent introgression including the exchange of functionally relevant traits and transposable elements across species boundaries. Interspecific hybridization may facilitate the rapid evolution of pathogens and new virulence traits in this group of important plant pathogens, and should be considered in the light of emergence of new pathogens in agricultural ecosystems.

C7.3-2

STEMPHYLIUM VESICARIUM CAUSES FOLIAR DISEASE ON CELERY IN MICHIGAN, USA

ABDELRHIM Abdelrazek. (1,2), HIGGINS Douglas. (2,3), HAUSBECK Mary. (2)

(1) Department of Plant Pathology, Faculty of Agriculture, Minia University, El-Minya , EGYPT; (2) Department of Plant, Soil and Microbial Sciences, Michigan State University, East Lansing, Mi 48824, UNITED STATES; (3) Eastern Shore Agriculture Research and Extension Center, Virginia Tech. , Painter, Va 23420, UNITED STATES

Text

Celery (Apium graveolens L) is an important salad vegetable worldwide. Michigan is the second largest supplier of the crop in the United States; the state's crop was valued at $19.5 million USD in 2018. In 2022, foliar symptoms were observed on the lower leaves of celery in a Michigan field that had been previously cropped to onion. Brown spots and conidia were observed on the leaves' adaxial surface and border extending to the petiole. Fungal isolates (25) obtained from symptomatic tissue were identified as *Stemphylium vesicarium* using morphological characteristics. DNA was extracted from three isolates and two primer sets were used for sequencing the internal transcribed spacer (ITS) region (ITS1 and 4) and partial calmodulin (cmdA) gene (CALDF1 and CALDR1). According to a nucleotide BLAST search and multilocus phylogenetic analysis (neighbor-joining tree), the obtained sequences of the three isolates had 100% pairwise identity with *S. vesicarium* sequences MW798751 (ITS) and MK675706 (cmdA) and clustered into a single clade with *S. vesicarium* reference sequences. Selected isolates were tested and found to be pathogenic on celery seedlings. Three *S. vesicarium* isolates from celery incited leaf spot and tip necrosis on 'Bradley' onion seedlings. When two *S. vesicarium* isolates from volunteer onions growing in a celery field were used to inoculate celery seedlings, they caused leaf spots. While onion is a host of *S. vesicarium*, celery has not been considered a host.

C7.3-3

DEMOGRAPHIC AND GENOMIC CONSEQUENCES OF A RAPID ADAPTATION EVENT IN THE POPLAR RUST PATHOGEN

Text

The intense and unidirectional selection pressure caused by the massive deployment of resistant plants can result in rapid adaptation of pathogen populations1. Such rapid evolution was documented for the poplar rust fungus. In 1994, poplar rust populations suddenly overcame the RMlp7 qualitative resistance carried by several poplar cultivars planted widely in Western Europe2,3. This recent event of adaptation from standing genetic variation caused a selective sweep on the rust genome4. We study a 25-year temporal sampling of poplar rust populations to decipher the demographic and evolutionary history of this pathogen while overcoming its host genetic resistance. We examine phenotypic and genetic variations throughout this adaptive event. Our analyses reveal that a unique and homogeneous genetic group overcame RMlp7 resistance and replaced the ancestral genetic group within five years. We then use forward simulations to 1) understand the interplay between demography and genetic evolution underpinning the rapid evolution of poplar rust

populations, and 2) disentangle the polymorphism signatures of selection from that of stochastic processes due to demographic changes. We show high stochasticity in evolutionary trajectories with the notable effect of evolutionary rescue scenarios on polymorphism signatures.Finally, we integrate our simulator in an Approximate Bayesian approach (ABC) to infer the demographic and selection parameters from temporal genetic data.Our statistical framework coupling modelling with temporal data is powerful to understand recent events of rapid adaptation. 1 Saubin et al. HISTORY OF THE LAW OF BARBERRY ERADICATION: - WHY WAS THE LAW REMOVED AND SHOULD IT BE REINSTATED? A CASE STUDY FROM SWEDEN

BERLIN Anna. (1), YUEN Jonathan. (1)

(1) Swedish univeristy of agricultural sciences, Uppsala, SWEDEN

Text

Rust fungi a large group of plant pathogens and are one of the largest threats to plants in the world. Several of the rust fungi infecting grasses have *Berberis* spp. (barberry) as an aecial host, including two important diseases in cereals: stem rust (*Puccinia graminis*) and yellow rust (*Puccinia striiformis*), but also other species such as *Puccinia arrenatheri* and *Puccinia brachypodii*. Since the fungus *P. graminis* that causes stem rust cannot yet survive the winters in Nordic climates, the presence of the barberry bush is required in the landscape for the pathogen to survive. During large parts of the 20th century, the law on eradication of barberry was in force, with the aim of reducing attacks by stem rust. Since the removal of that law in 1994, the number of reported barberry bushes has increased in Sweden. Due to the law and resistant cultivars, Sweden was spared from the disease, but during the last decades stem rust has returned and is now causing disease in all cereal crops. The increased observations of stem rust correlate with an increased number of *Berberis* spp. in the landscape. With help of historical documents and knowledge about the biology of the fungus, we have analysed the importance of *Berberis* spp. in the landscape before, during and after of the law of barberry eradication from an epidemiological perspective. The result increases our knowledge about the management of cereal rust disease and about biological diversity in the agricultural landscape.

Text
A priority goal in pathosystem research is to probe differences in the genetic architecture of defense responses among diverse plant groups, including between crop and wild plants. For crop protection, numerous genome-wide association studies (GWAS) of plant viral disease expression have been conducted in common crops, such as maize and rice. To our knowledge, the only attempts at GWAS in wild plant species have focused on the biennial model plant Arabidopsis thaliana. Moreover, most such studies have been conducted under relatively artificial conditions. Here we report the first large-scale genetic analysis of wild virus interactions with a long-lived wild plant, conducted on Panicum virgatum (switchgrass), a native North American prairie under development as a bioenergy feedstock. We evaluated viral disease expression in a panel of 512 diverse tetraploid accessions originating from populations throughout the broad natural range of switchgrass. Plants were field-grown in Michigan, USA, in unencumbered soil with full exposure to natural environmental factors, including heat, cold, herbivory, and microbial interactions. We focused on naturally-occurring disease caused by switchgrass mosaic virus (SwMV), a wild virus (Genus Marafivirus, Family Tymoviridae) extant to our region that is transmitted by wild leafhoppers. We quantified variation among ecological subgroups in susceptibility to viral disease for three years, and we used GWAS to identify SNPs and candidate genes associated with disease phenotypes. Switchgrass susceptibility to wild viral disease varied among ecological subgroups from highly susceptible to very resistant. Notably, the range of the most susceptible genotypes overlapped the known distribution of switchgrass mosaic virus, suggesting that local interactions have not driven greater resistance in this region. GWAS results found that wild viral disease expression was associated with a broad network of small effect genes implicated in diverse pathways associated with cellular, metabolic, and immune response pathways, with only a small percentage of genes associated with identifiable characteristics of R genes. Among a conservative set of 143 candidate genes associated with 67 pruned SNPs, we found one in common with a candidate gene associated with virus resistance in rice, and 30 unannotated candidate switchgrass genes without known homology to model systems that may represent novel elements regulating plant virus interactions in natural ecosystems. These findings demonstrate the breadth of viral interactions with wild plants and offer opportunities for identifying new genetic mechanisms influencing viral infection dynamics.

Text
Knowledge of the ecological survival niches of *Curtobacterium flaccumfaciens* pv. *flaccumfaciens* (Cff), the causal agent of bean bacterial wilt, is essential for efficient disease management. We study the survival of Cff in the phyllosphere and rhizosphere of 21 weeds,

14 crops, and 4 types of soil. The aerial part of the plant was inoculated by spraying a bacterial suspension of Cff, while the soil of the growing pots and the pots containing only soil was infested with the same suspension. For the soil experiment, we evaluated the survival of one bacterium strain from a common bean and 3 strains from a soybean. The survival of Cff strains was evaluated every seven days until they were not detected and confirmed by PCR. High temperatures and rainfall reduced Cff survival in the phyllosphere, while high temperatures negatively affect survival in the rhizosphere. Our results demonstrated that weeds are potential hosts for Cff and their eradication in common bean fields is recommended. Barley, black oat, canola, forage turnip, maize, pearl millet, ryegrass, sorghum, soybean, sunflower, velvet bean, wheat, and white oat can be potential asymptomatic hosts. In the soil, the survival period ranged from 77 to 154 under laboratory conditions and for a maximum of 91 days under natural field conditions.

Text

Two passion fruit varieties, Purple (*Passiflora edulis* Sims) and yellow (*P. edulis* f. *flavicarpa* Deg), are mainly grown worldwide. *Fusarium solani* (Fo) was important agent to cause collar rot of passion fruit in Brazil, Mainland China, and Japan etc. In Taiwan, Fo could cause collar rot and fruit rot in passion fruit, especially, symptom on fruit showing brown and water soak lesion. Recently, *F. solani* species complex (FSSC) have been classified more than 100 phylogenetic species based on phylogenetic analysis. The objective of this study is to clarify the species of FSSC pathogens causing collar rot and fruit rot of passion fruit in Taiwan and carry out their morphology and characteristics. The FSSC isolates from collar rot and fruit rot of purple or yellow passion fruit from different location in Taiwan were divided into four main molecular groups based on phylogenetic analysis. According to the results, *F. solani-melongenae* (FSSC 21) is dominant species to cause collar rot and fruit rot of passion fruit in Taiwan. Other species are including *F. solani* (FSSC 5), *F. liriodendri* (FSSC 24) and *F. noneumrtii* (FSSC 42). This result demonstrated that FSSC pathogens causing disease in passion fruit are diversities. In addition, *F. solani-melongenae* is homothallic type for perithecium production, and *F. liriodendra* could not produce macroconidia. Moreover, the pathogenicity of these FSSC species showed variation on different cultivars of passion fruit in Taiwan.

Text

Apple is an economically lucrative fruit crop worldwide but can be severely impacted with bitter rot disease caused by multiple species in the *Colletotrichum acutatum* and *C. gloeosporioides* species complexes (CASC and CGSC). Identification of *Colletotrichum spp.* is important due to species-specific differences in life cycle, virulence, temperature requirements and fungicide sensitivity. We collected over 600 *Colletotrichum* isolates from symptomatic apple fruit from 35 locations in Virginia. After morphological examination, in Virginia the species in CGSC dominated with 65.5% of isolates in comparison to the 34.5% of CASC isolates. Using multi-locus phylogenetic analyses of *ITS, GAPDH* and *ACT* for CASC, and *ITS, GAPDH, CAL, ACT, APN2, ApMat* and *GS* genes for CGSC, 82 representative isolates were identified to the species level. In Virginia, we identified *C. fructicola, C. chrysophilum, C siamense* and *C. theobromicola* in CGSC and *C. fioriniae* and *C. nymphaeae* in CASC. The most dominant species in Virginia are *C. fructicola, C. chrysophilum* and *C. fioriniae*. So far, we sequenced 10 new genomes including two isolates of *C. fioriniae,* three isolates of *C. chrysophilum*, three isolates of *C. noveboracense* and three isolates of *C. nupharicola* collected from apple fruit, yellow water lily and *Juglans nigra*. Further work on genome sequencing of other isolates from Virginia is ongoing. Our work contributes to better understanding of *Colletotrichum spp.* diversity in the U.S.A.

Text

Clubroot is a soil-borne plant disease caused by Plasmodiophora brassicae. The current study evaluates the distribution and prevalence of pathogen pathotypes in oilseed rape crops in the Czech Republic, Germany, Poland, and Sweden.
Field information revealed significant differences between disease incidences between

countries. Approximately 52% of infested fields had a low occurrence of the disease, 31% had moderate clubroot incidence, and 17% showed a high incidence of the disease. In total, 84 isolates of P. brassicae were collected in all countries. The pathotypes classification was determined using 17 Brassica hosts, including the European Clubroot Differentials (ECD), the Somé set, and the resistant oilseed rape cv. 'Mendel'.
The virulence analysis of the isolates using the ECD set revealed 42 designated pathotypes, the most prevalent being 16/31/31 in Germany, Poland, and Sweden and 16/06/12 in the Czech Republic, Germany, and Poland. The Somé set identified six pathotypes, with 1-4 per country, with P1 being the most widespread in Germany, Poland, and Sweden and P3 being common in the Czech Republic, Germany, and Poland. The study showed an increase in virulence in the P. brassicae population compared to previous studies, with several isolates overcoming the resistance of cv. 'Mendel' and Brassica rapa genotypes. A negative correlation was found between clubroot incidence and the frequency of oilseed rape in crop rotation and between soil pH and clubroot incidence.

P7.3-005

DIVERSITY AND CHARACTERIZATION OF FUSARIUM OXYSPORUM SPECIES COMPLEX (FOSC) AND FUSARIUM SOLANI SPECIES COMPLEX (FSSC) CAUSING ORCHID DISEASES IN TAIWAN.

Text
The *Fusarium* causing diseases in Orchidaceae are more than eight species, especially, *F. oxysporum* and *F. solani* with wide hosts. The two *Fusarium* species are considered as species complex, FOSC and FSSC. In Taiwan, orchid plants are important flower for export; however, the population and characterization of *Fusarium* pathogens in orchids in Taiwan were obscured. The orchids showed *Fusarium*-like symptoms in garden were collected, including epiphytic orchid (8 species), semi-terrestrial orchid (1 species) and terrestrial orchid (2 species). Results indicated that 88 FOSC isolates and 80 FSSC isolates were obtained and confirmed their pathogenicity in original host. In addition, the terrestrial orchids are major host of FOSC and epiphytic orchids are major host of FSSC. Within phylogenetic analyses, FOSC isolates are divided into *F. nirenbergiae*, *F. curvatum*, *F. contaminatum*, *F. triseptatum* and *F. odoratissimum* based on *cal*, *rpb2*, *tef-1α* and *tub2* genes sequences (Lombard's classification system); meanwhile FSSC isolates could be separated into six molecular groups based on ITS rDNA and *rpb2* and *tef-1α* genes. Among the six groups, three groups were identified as *F. keratoplasticum*, *F. solani* and *F. solani-melongenae*; but another three groups distinguished from knew FSSC species. Moreover, the isolates in two unknow species groups belong homothallic type for perithecium production. Host rang test indicated that FOSC and FSSC isolates showed cross-infection in different orchids.

BIOLOGY OF PENTASTIRIDIUS LEPORINUS AND APPROACHES TO MONITOR THE MAIN VECTOR OF THE SYNDROME ‘BASSES RICHESSES’ IN SUGAR BEET

PFITZER Rene. (1,2), EINI Omid. (1), **VARRELMANN Mark. (1)**, ROSTAS Michael. (2)

(1) Institute of Sugar Beet Research, Göttingen, GERMANY; (2) University of Göttingen, Department of Crop Sciences, Agricultural Entomology, Goettingen, GERMANY

Text

Pentastiridius leporinus is the main vector of Syndrome ‘basses richesses’ (SBR), a fast-spreading sugar beet (Beta vulgaris) disease in Central European sugar beet growing areas. The disease is caused by two procaryotic phloem-limited bacterial pathogens, the γ-3 proteobacterium ‘Can. Arsenophonus phytopathogenicus’, and the stolbur phytoplasma (16SrXII-A subgroup) ‘Can. Phytoplasma solani’. SBR infections in sugar beet can lead up to 5 % sugar content loss and high yield reduction. P. leporinus has adapted from its natural host reed to sugar beet in crop rotation with cereals such as winter wheat or spring barley. Here we present a mass rearing protocol and vector life history data that will help to overcome an important bottleneck in SBR research and enhance efforts in developing integrated pest management tools. More, monitoring of this insect vector based on morphological identification is challenging as two other cixiid species Reptalus quinquecostatus and Hyalesthes obsoletus with similar external characters are known to additionally appear in sugar beet fields. A PCR-based method is provided for simple and reliable detection of P. leporinus collected via nets or traps. This method also detects eggs and all nymphal stages and differentiates this vector from the most common Auchenorrhyncha species occurring in sugar beet fields. Furthermore, the phylogenetic relationship of these morphologically close species was investigated based on cytochrome oxidase I gene.

Text

Highly pathogenic protist-like organism Plasmodiophora brassicae belonging to the infrakingdom Rhizaria is the cause of clubroot, a damaging soilborne disease of brassicas. Sixteen isolates collected in 2017-2021 originating from the roots of winter oilseed rape (Brassica napus) with clubroot symptoms were gathered from nine regions of Poland and

subjected to pathotype studies. using four identification systems (Buczacki, Som?, Strelkov, Williams) and two thresholds of disease index (25%, 50%). There were 10, 3, 6 and 4 pathotypes according to 25% threshold respectively. The systems by Buczacki, Som? and Williams evaluated using 50% threshold resulted in 13, 4 and 6 pathotype designations respectively. Differences in thresholds changed the pathogen designation in 31 out of 48 designations (65%).Twelve isolates were able to infect the cultivar Mendel, which is currently the main source of resistance of oilseed rape to clubroot in Poland. Genome sequencing of two isolates was performed using the Illumina MiSeq platform with 250 bp reading. Studies have shown differences from the reference isolate deposited in the NCBI database (approx. 5000 nucleotide changes). Differences between the tested isolates were also found. Bioinformatic analyses and genome sequencing of the other P. brassicae isolates/pathotypes from Poland are under way.

FIRST REPORT OF RHIZOBIUM RHIZOGENES CAUSING CROWN GALL ON IN CHILE

MILLAS Paz. (1), SANDOVAL Belen. (2), CARRASCO-FERNANDEZ Jorge. (1), BELTRAN Francisca. (1), CORREA Francisco. (1), SAGREDO Boris. (1)

(1) INSTITUTO DE INVESTIGACIONES AGROPECUARIAS, Chillán, CHILE; (2) UNIVERSIDAD ADVENTISTA DE CHILE, Chillan, CHILE

Text

Crown gall is an important disease worldwide caused by several species belonging to the Rhizobiaceae family. In Chile, only Agrobacterium tumefaciens has been reported causing this disease. In the 2018-2019 season a survey was conducted to detect other species causing galls in fruit trees in southern Chile (32°47'S to 49°50'S). Bacterial isolating was made by sowing dilutions of galls macerates from blueberry, raspberry and cherry plants onto Yeast Extract Mannitol with potassium tellurite (YEM+Kt). Twelve bacteria with typical Rhizobiaceae characteristic were isolated. Pathogenicity of the isolates were tested in tomato, kalanchoe, blueberry and cherry plants by injecting the bacterial suspensions (1 x 108 cells ml-1). Strain C-58 and sterile water were used as positive and negative control, respectively. After 30 to 90 d in a greenhouse depending on plant species was evaluated. Of the 12 isolates only the strain RGM (3430) isolated from blueberry and RGM (3422) isolated from cherry were able to induce tumors in four plant species inoculated. Genome sequencing revealed the presence of the tumor inducing (TI) plasmid in both strains. A multilocus phylogenetic analysis (atpD, gyrB, recA, rpoB) clustered both strains with Rhizobium rhizogenes reference strains (95% bootstrap). Average Nucleotide Identity (ANI) of complete genome confirmed the identification with ANI value of 98%. This is the first report of R. rhizogenes causing tumors in blueberry and cherry trees in Chile.

P7.3-009

A COMPREHENSIVE SURVEY OF PREVALENCE OF ROOT-KNOT NEMATODES AND CULTIVAR RESISTANCE ASSOCIATED WITH PEPPERS IN HAINAN, CHINA

CHEN Yuan. (1), LONG Haibo. (1), SUN Yanfang. (1), PEI Yueling. (1), FENG Tuizi. (1), CHE Haiyan. (1)

(1) Environment and Plant Protection Institute, Chinese Academy of Tropical Agricultural Sciences, Haikou, CHINA

Text

Root-knot nematodes (RKNs) are considered as a huge threat to agricultural crops, including pepper in China. Hainan Island is the main producer of pepper, where the climate conditions and crop planting patterns are favorable for infection by RKNs. We first conducted a detailed investigation about the occurrence, severity and population distribution of RKNs infected pepper in 310 fields located in all 18 geographical areas of Hainan. Our results showed that RKNs belonging to *Meloidogyne enterolobii*, *M. incognita* and *M. javanica* were found in Hainan. Notably, *M. enterolobii* is now the dominant population in this area, which were found in 87.5% of RKN infected pepper samples. *M. enterolobii* was first reported in Hainan from the roots of pacara earpod trees. It has caused more concerns worldwide due to its high aggressiveness, increasing geographical distribution, wide host range and pathogenicity in plants carrying resistance genes. We then evaluated the resistance level to common pepper cultivars targeting *M. incognita* and *M. enterolobii*. Among the tested cultivars, about 67% of cultivars showed resistant or highly resistant to *M. incognita*. However, *M. enterolobii* was highly pathogenic on all tested cultivars, which could explain the reason for its rapid expansion throughout Hainan. In conclusion, this study promotes the comprehensive understanding of RKN distribution and host resistance level in Hainan, which will guide the effective control of root-knot nematodes.

P7.3-010

DISEASE EMERGENCE SCENARIOS LINKED TO SPATIAL DISTRIBUTION OF A NOVEL CROP

AKINSANMI Olufemi. (1)

(1) University of Queensland, Brisbane, AUSTRALIA

Text

Disease-ecology studies often address a specific disease scenario. Many crops have evolved natural resistance to diseases and pests in their native environments, but when a novel crop is introduced into a new environment, it can encounter new pathogens, possibly resulting in severe diseases.

The drivers of emerging diseases in macadamia, an evergreen tree nut crop that is native to Australia but now widely produced in several tropical and subtropical regions in the Americas, Asian, and African countries, may be categorised into three distinct disease patterns. These include (i) interplay of novel pathogens and lack natural host resistance resulting in the development of novel diseases, (ii) a spill-over effect from other plant hosts, and (iii) complex interactions of microbial communities with climatic factors that influence or drive disease outbreaks.

Conceptual framework for unravelling host susceptibility and exposure to multiple pathogens that result in various diseases is critical for prevention and management practices. Using fungal and oomycetes diseases in macadamia, this study demonstrated limits of ‘one microbe-one disease postulate”. It revealed a set of drivers of pathogen profiles, disease ecology and transmission dynamics supports each of the three disease emergence categories. It is

important to survey and monitor disease diversity and take necessary steps to prevent disease outbreaks to ensure the long-term sustainability of crop production.

Bacteriophages: ecological roles and potential applications against bacterial plant pathogens

C3.6-1

ECOLOGY AND EVOLUTION OF PHAGE-BACTERIA INTERACTIONS DRIVE BACTERIAL WILT DISEASE DYNAMICS

FRIMAN Ville-Petri. (1)

(1) University of Helsinki, Helsinki, FINLAND

Text
Bacterial viruses - phages - shape the structure of natural bacterial communities via the direct killing of cells and by imposing selection for the evolution of phage resistance. While phages are abundant in soils, their effects on plant-pathogenic bacteria, rhizosphere bacterial communities and associated plants are poorly understood. In this talk, I will present our current work on the role of soil phage communities in constraining the invasions and infections by soil-borne Ralstonia solanacearum plant-pathogenic bacterium. Specifically, I will discuss direct and indirect phage effects in complex rhizosphere microbiomes and how pathogen density regulation could be mediated by complex phage-bacteria interactions. Furthermore, I will highlight how phage selection can rapidly select phage-resistant mutants and how this feature could be used as an evolutionary tool to steer pathogen virulence through costly life-history trade-offs. Together, our findings highlight that soil suppressiveness, which is most often attributed to bacteria, could be determined by the rhizosphere phage communities, highlighting the potential for developing phage therapeutics to control plant pathogen invasions in agriculture.

BIOGEOGRAPHIC DISTRIBUTION IMPACTS XANTHOMONAS ARBORICOLA PV. PRUNI SUSCEPTIBILITY TO BACTERIOPHAGE

DAMICO-WILLMAN Katherine. (1), SMITH Amber. (2), RITCHIE David. (1), HUERTA Alejandra. (1)

(1) North Carolina State University, Raleigh, UNITED STATES; (2) AgBiome, Research Triangle Park, UNITED STATES

Text
Xanthomonas arboricola pv. *pruni* (Xap) is the causal agent of bacterial spot on *Prunus spp*. Lytic phages are being considered to manage bacterial disease due to their ability to infect and kill their bacterial hosts (i.e., Xap); however, bacteria can evolve resistance to phage. Despite the abundance of phage and frequency of phage-bacteria interactions in the environment, there is little knowledge on how biogeography impacts the genetic mechanisms underlying phage infectivity. To examine how geography impacts these mechanisms, 12 phages isolated from symptomatic peach leaves in North Carolina (United States [**US**]) were tested for their ability to lyse Xap strains from Brazil, Uruguay, and the US. The four strains from Brazil and one from the US showed varying levels of susceptibility to the 12 phages tested, while a strain from Uruguay and two from Brazil were moderately and fully resistant to phage lysis. Illumina and PacBio were used to generate closed bacterial genomes and construct a core genome. Phylogenetic analysis revealed the five susceptible strains clustered into one group while the strain from Uruguay and the two resistant strains from Brazil clustered into a second group. Genes unique to the five susceptible strains and the three resistant strains were identified. Predicted annotations include outer membrane and other hypothetical proteins. Understanding phage resistance mechanisms is important if phages are to be used to successfully manage bacterial pathogens.

C3.6-3

COEVOLUTIONARY ANALYSIS OF BACTERIA-PHAGE INTERACTIONS IDENTIFIES POTENTIAL RECEPTOR TARGETS FOR PHAGE INFECTION

RABIEY Mojgan. (1), JACKSON Robert W. (1)

(1) University of Birmingham, Birmingham, UNITED KINGDOM

Text
Bacterial canker, caused by *Pseudomonas syringae* pathovars including pv. *syringae* (*Pss*) and pv. *morsprunorum* (*Psm*), is a major disease of *Prunus* species such as cherry (*Prunus avium*). There is currently no treatment for this disease. One method of control is use of naturally occurring bacteriophage (phage) infective to the bacterial pathogens. We have isolated and characterised phages (MR) with host specificity to *Pss* and *Psm*. Before field application as a biocontrol agent, it is important to assess their efficacy as well as changes occurring in the bacterial population to prevent phage infection. The growth of *Pss* populations co-inoculated with MR phage individually or in combination were measured and showed that either the phages are antagonising one another or that the bacteria evolve differently under multiple phage pressure. In either case, this would reduce the efficacy of phage control of bacterial populations. To understand this interaction further, *Pss* and phage were coevolved over 10 generations and the genomic and behavioural changes in bacterial populations were measured. *Pss* evolved mechanisms of resistance to phages through modifications to lipopolysaccharide (LPS) or mutations in a glycosyltransferase involved in LPS synthesis. Coevolved phages were more potent at reducing the bacterial population. Therefore, understanding the genetic mechanisms of coevolution in generating more infective phages for precise targeting of the bacterial population is essential.

C3.6-4

DO PHAGES HAVE AN IMPACT ON THE DIVERSITY OF PSEUDOMONAS SYRINGAE ON APRICOT TREES?

FELTIN Chloé. (1), MORRIS Cindy. E.. (1), BÉRARD Annette. (2), TORRES-BARCELO Clara. (1)

(1) PV-INRAE, Avignon, FRANCE; (2) INRAE UMR CSE-EMMAH, Avignon, FRANCE

Text

Pseudomonas syringae is diverse and ubiquitous complex of bacteria whose life history is linked to the water cycle. Some strains of *P. syringae* are pathogenic and cause up to 60% of yield losses in a large variety of crops. Recent research suggests that strains from apricot are phylogenetically more closely related to environmental strains than to other plant-associated strains. Neither the pathogenicity nor the phenotypic characteristics of *P. syringae* strains in bacterial canker of apricot are predictable by their phylogenetic position.
Phages play a major role in the evolution of their bacterial host populations by influencing their population size and structure, driving their genetic diversity and also their pathogenic potential.
This project aims to unravel the role of phages and their influence on the population structure of *P. syringae* on apricot. So first, *P. syringae*-specific phages were collected from soils of apricot orchard. Our work reveals a ubiquitous presence of phages and their extraordinary diversity with 10 new genera, 20 new species and 23 new phages have been identified. Their host range on a set of 51 *P. syringae* strains was also characterised. This set of strains was constructed by selecting pairs of *P. syringae* strains isolated from apricot and isolated from the non-agricultural environment from the same phylogroup. This allows the infectivity of phages to be tested on bacterial strains from the same phylogroup but from different isolation sites.

C3.6-5

KEYS AND COST OF THE TOXIC RELATIONSHIP BETWEEN NOVEL PHAGES AND XANTHOMONAS HORTORUM PV. VITIANS : MOLECULAR DETERMINANTS AND TRADE-OFF IN PLANTA

BAUD Anaelle. (1), MORINIÈRE Lucas. (1), TAVEAU Nicolas. (2), CLAVIJO-COPPENS Fernando. (2), COSTECHAREYRE Denis. (2), BERTOLLA Franck. (1)

Text

The use of bacteriophages as biocontrol agents of phytopathogenic bacteria at different stages of the agricultural supply chain has shown promising results in recent years, notably on *Xanthomonas* spp. Bacterial leaf spot of lettuce caused by *Xanthomonas hortorum* pv. *vitians* (*Xhv*) is a major threat for lettuce producers worldwide due to the lack of effective disease control strategies. In order to explore the potential of phages to reduce the severity and incidence of this plant disease, we isolated and characterized several novel lytic phages. Their genome sequences, morphologies, growth kinetic parameters and host ranges were characterized. A transposon insertion sequencing experiment revealed that 36 genes

predominantly involved in lipopolysaccharide biosynthesis were required for successful ΦXhv1 infection of our *Xhv* model strain LM16734. Phenotypic analyses of transposon insertion and deletion mutants resistant to ΦXhv1 suggested that this phage specifically binds lateral branches of the O-antigen to achieve its adsorption. Interestingly, some phage-resistant mutants defective in O-antigen biosynthesis showed a decreased fitness in planta and reduced motility on soft agar assays, resulting in a trade-off unlikely to occur in planta. Altogether, these results would pave the way to the design a phage cocktail combining various infection strategies and complementary host spectra, thus preventing the occurrence of resistances and ensuring the sustainability of the biocontrol.

C3.6-6

EVADING INFECTION: TEMPERATURE AFFECTS INTERACTION BETWEEN DICKEYA FANGZHONGDAI AND ITS BACTERIOPHAGE

ALIC ŠPela. (1), RŽIŠNIK Julija. (2), DREO Tanja. (1)

(1) National Institute of Biology, Ljubljana, SLOVENIA; (2) Biotechnical faculty, Ljubljana, SLOVENIA

Text

Soft rot diseases caused by pathogens like *Dickeya* spp. significantly reduce the yield of agricultural crops used to meet the food needs of the world's growing population. No efficient chemical control strategies exist, and bacteriophage biocontrol has been proposed as a promising alternative. However, complex interactions among phages, bacteria, and their environment are still poorly understood yet critical for efficient therapy applications. In our study, we investigated the influence of temperature and pH on the interactions in the previously described *Dickeya fangzhongda*i and a BF25/12 *Podoviridae* bacteriophage system (Alic et al. 2017).
Different *D. fangzhongdai* strains exhibit different sensitivity phenotypes at 28 °C (standard growth temperature), however all susceptible strains showed reduced bacteriophage susceptibility at higher temperatures (37 °C) including reduction in phage adsorption and absence of bacterial lysis in liquid culture. Other factors, such as pH and bacteriophage concentration, did not affect the observed differences in phage susceptibility. The results of our study demonstrate the ability of *D. fangzhongdai* to evade bacteriophage infection at temperatures relevant to its occurrence in environment and greenhouse production. This is particularly important for bacteriophage biocontrol applications in agriculture and plant health.

CHARACTERIZATION OF NOVEL BACTERIOPHAGES AGAINST ERWINIA AMYLOVORA, A CAUSAL PATHOGEN FOR FIRE BLIGHT DISEASE AND THEIR APPLICATION

HWANG In Sun. (1), VU Nguyen Trung . (2), KIM Hyeongsoon. (1), OH Chang-Sik . (1,3)

(1) Research Institute of Agriculture and Life Sciences, Seoul National University, Seoul, REPUBLIC OF KOREA; (2) Graduate School of Green-Bio Science, Kyung Hee University,

Yongin, REPUBLIC OF KOREA; (3) Department of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, Seoul, REPUBLIC OF KOREA

Text

Fire blight disease caused by *Erwinia amylovora* has been a major problem for cultivation of apple and pear. The development of effective and sustainable strategies for controlling this disease is necessary as alternatives of antibiotics and other conventional agricultural chemicals, which have been widely used. In this study, we focused on bacteriophages that only infect target bacteria as an alternative control agent. Lytic bacteriophages killing *Erwinia amylovora* and *Erwinia pyrifoliae* were isolated from soil and water samples and selected based on their morphology and stability under diverse environmental conditions. Four selelcted bacteriophages, φ13, φ14, φ22, and φ33, were found to be stable under a wide range of temperature (4 °C, 26 °C and 37 °C), pH (pH 3 to pH 11) and UV (λ= 306 and λ= 365). Transmission electron microscopy showed that φ13, φ14, and φ22 belong to the *Podoviridae* family and φ33 belongs to the *Mmyoviridae* family. Using apple seedlings and young apple fruits, we evaluated the control efficacy of these bacteriophages against fire blight. For this assay, *E amylovora* was infected by non-wound inoculation method on plants, and bacteriophages were treated 2 hours before or 6 hours after bacterial inoculation. The disease was significantly reduced by pretreatment of bacteriophages, indicating that selected bacteriophages can be potential candidates as biocontrol agents of *E amylovora*.

P3.6-002

DEVELOPMENT OF PHAGE COCKTAIL FOR PREVENTING SOFT ROT DISEASE CAUSED BY PECTOBACTERIUM SPECIES IN KIMCHI CABBAGE

VU Nguyen-Trung. (1), KIM Hyeongsoon. (2), HWANG In-Sun. (2), **OH Chang-Sik. (2,3)**

(1) Department of Green-Bio Science, Kyung Hee University, Gyeonggi-Do, REPUBLIC OF KOREA; (2) Research Institute of Agriculture and Life Science, Seoul National University, Seoul, REPUBLIC OF KOREA; (3) Department of Agriculture Biotechnology, Seoul National University, Seoul, REPUBLIC OF KOREA

Text

Chemical bactericides such as antibiotics and copper-based agents have been extensively used to control plant pathogens. However, antimicrobial resistance has emerged that are recognized as serious threats in human health as well as agriculture. To overcome this problem, phages have been in the spotlight as alternative antimicrobial agents to replace chemical bactericides. Pectobacterium species causes soft-rot disease in various crops by producing plant cell wall-degrading enzymes (PCWDEs). The aim of this study is to develop phage cocktail for preventing soft rot disease caused by Pectobacterium. Two virulent Pectobacterium phages (phiPccP-2, and phiPccP-3) were isolated from rotten cabbage, and had 171,484 bp, and 107,777 bp genome, respectively. Lytic activities of phiPccP-2 and phiPccP-3 were maintained after incubation under various environmental conditions such as pH ranging from 4 to 11, -80°C to 50°C, UV-A, and UV-B. Phage cocktail consisting of phiPccP-2 and phiPccP-3 could suppress the emergence of phage-resistant Pectobacterium in killing curve assay and efficiently prevent soft rot disease in detached mature leaves of Kimchi cabbage. Phage phiPccP-1 was added to phage cocktail to enhance the antimicrobial effect, and phage cocktail treatment effectively protected Kimchi cabbage seedlings from soft rot disease, compared to single phage treatments. These results suggest high potential of phage cocktail as alternative antimicrobial agents to control Pectobacterium.

P3.6-003

DEVELOPING PHAGE THERAPY TO REDUCE PLANT PATHOGEN VIRULENCE IN RALSTONIA SOLANACEARUM

NARINO ROJAS Daniel. (1), FRIMAN Ville. (1,2), HARPER Andrea. (1)

(1) University of York, York, UNITED KINGDOM; (2) University of Helsinki, Helsinki, FINLAND

Text

Ralstonia solanacearum is a devastating plant pathogen which causes bacterial wilt and brown rot disease, leading to huge economic losses worldwide. Several factors contribute to this: a large host range, persistence in soil and water, and broad geographical distribution. Moreover, there is no effective method of plant protection against this pathogen, making it imperative to develop novel control approaches. Bacteriophages have been proposed as biocontrol agents for *R. solanacearum*, as they are highly specific to the pathogen and propagate rapidly in soil. Phage efficacy at reducing bacterial densities has been reported, but over time bacteria evolve resistance to phages. Resistance is highly costly however, compromising both bacterial fitness and virulence. Therefore, phages could provide durable control of *R. solanacearum*, by reducing pathogen densities and leading to evolutionary trade-offs that make resistant bacteria less pathogenic. This study aims to understand how phage resistance reduces pathogen virulence. We will create a library of phage-resistant mutants using experimental evolution to identify genes linked with resistance. The effects of resistance mutations on pathogen fitness will be tested in plant rhizosphere microcosms, focusing on pathogen metabolic versatility, root colonization capability, and ability to evade plant immunity. Transcriptomic analyses will also be conducted to elucidate phage-bacteria interactions and the role of phage defence systems.

P3.6-004

CHARACTERISATION OF PHAGE THAT LYSE BRENNERIA GOODWINII AND GIBBSIELLA QUERCINECANS, THE CAUSATIVE AGENTS OF BLEEDING CANKERS ASSOCIATED WITH ACUTE OAK DECLINE

GRACE Emily. (1), RABIEY Mojgan. (1), BROCKHURST Michael. (2), JACKSON Robert. (1)

(1) University of Birmingham, Birmingham, UNITED KINGDOM; (2) University of Manchester, Manchester, UNITED KINGDOM

Text

Acute oak decline (AOD) is an emerging disease of oak trees (*Quercus* spp.), that includes the production of dark bleeding cankers on bark and potential tree mortality within 3 to 5 years. AOD is caused by a polymicrobial complex of several bacterial species, the most important of which are the gram negative phytopathogens *Brenneria goodwinii* and *Gibbsiella quercinecans*. No treatments are yet available against AOD, and environmental impacts restrain the use of antimicrobial treatments . However, a potential avenue for biocontrol of

these bacteria species is the use of bacteriophage (phage), which have proven effective in treating several other bacterial tree diseases. Multiple phages from diseased lesions of oak trees have been isolated that can lyse *G. quercinecans* and *B. goodwinii* in England. A subset of unique phages has been characterised via several assays, including killing curve assays, one-step growth curves, and temperature and UV survival assays to determine their suitability as biocontrol agents. In addition, their genomes have sequenced in order to perform taxonomic characterisation and comparative genomic analysis. The results of this study will help identify phages or phage cocktails to treat bacterial cankers and reduce the impact of AOD. It will also form the basis of research on phage identification and dynamics within the AOD pathosystem.

P3.6-005

ISOLATION AND CHARACTERISATION OF VIRULENT PHAGES AGAINST EUROPEAN XYLELLA FASTIDIOSA SUBSPECIES

LEBRUN Caroline. (1), GRAILLOT Benoit. (1,2), ANSALDI Mireille. (1)

(1) CNRS, Marseille, FRANCE; (2) Bioline AgroSciences, Biot, FRANCE

Text
Xylella fastidiosa (Xf) is ranked in the world top 10 most important bacterial plant pathogens [1] and its host range is estimated at 638 plant species [2]. This bacterium colonizes the xylem vessels and forms biofilms that block water flow, resulting in plant wilting and death [3]. *Xf* is transmitted by biting-sucking insects but also by the trading of plants.
The most spread and damaging subspecies *(Xf fastidiosa, Xf pauca, and Xf multiplex)* are present in many countries and infect plants of agricultural interest [4]. Therefore its potential economic, environmental and social impact are considered the most serious in the Union [5]. Since 2013, *Xfp* has been identified in Europe on olive trees in Italy. In Spain, clusters of infection on olive and almond trees have been detected, and in France heavy infection have been reported on olive trees in the PACA region. Corsica is entirely infected by *Xfm*.
Phages are a promising mean of biocontrol and our objective is to develop a cocktail targeting Mediterranean strains. For this, Xf-associated and non-Xf-associated environments were tested to find phages. To bypass the difficulties of experimentation on *Xf*, a surrogate host *Xanthomonas albilineans* was used to isolate phages whose efficacy is then tested on *Xf* [6]. We have now about twenty characterized phages having efficiency on *Xfm*, some being also efficient on *Xff*.

P3.6-006

BACTERIOPHAGE AS A BIOCONTROL AGENT IN BACTERIAL BLOOD DISEASE OF BANANA IN INDONESIA

SAFNI Irda. (1), LISNAWITA Lisnawita. (1), MURTHI Raju Surya. (1)

(1) Universitas Sumatera Utara, Medan, INDONESIA

Text
Blood disease of bananas caused by Ralstonia syzygii subsp. celebesensis (Rsc) has been one of the limiting factors for banana production in Indonesia. The current disease management has not yet provided effective results to supress the spread of the disease. This study was aimed to examine the potential of bacteriophage as a biocontrol agent in controlling Rsc in several banana cultivars in a Greenhouse and in the large field. Four isolates of bacteriophage (?BTF1, ?BTF 2, ?BTF 3, and ?BTF 4) were applied on four cultivars (Barangan, Cavendish, Raja Bulu, and Kepok Putih) infected by Rsc. The treatments of four bacteriophage isolates did not show any symptoms on all infected cultivars. Furthermore, the four bacteriophage isolates were able to supress the disease incidence and disease intensity on the fourth week of observation in the Greenhouse and on the tenth month of observation in the large field. No disease incidence and disease severity was appeared until the end of the observation, compared with 100% of disease incidence and disease severity in the control treatments. The weight of fresh fruits per bunch of the treated cultivars increased from the range of 19.26-30 kg, compared to no fresh fruits were harvested in the control treatments. This study suggests the application of bacteriophage has a great potential to reduce the infection of banana blood disease.

P3.6-007

PHAGE BIOCONTROL OF BACTERIAL LEAF BLIGHT ON RICE CAUSED BY XANTHOMONAS ORYZAE PV. ORYZAE IN VIETNAM

NGUYEN Nga. (1), DOAN Tien. (1), HOLTAPPELS Dominique. (2), LAVIGNE Rob. (2), VALLINO Marta. (3), KAMEI Kaeko . (4), JØRGENSENS Hans J. L. (5), WAGEMANS Jeroen. (2), JONES Jeffrey B. . (6)

Text
Rice bacterial leaf blight (BLB), caused by Xanthomonas oryzae pv. oryzae, is a serve disease in in many rice-growing countries. Bacteriocides such as antibiotics and copper compounds have mainly been used for managing this disease. However, this is not considered good methods in sustainable agriculture. In this study, we used phage therapy for control the disease. One hundred seven bacteriophages were isolated from six provinces in the Mekong Delta of Vietnam. Five promising phages, designated ΦVL12, ΦDT63c, ΦHG48b, ΦDT60b and ΦAG68a, were selected based on their ability to lyse more than 45 out of 62 tested Xoo strains and produced large plaques. ΦDT60b produced the largest plaques. Under greenhouse conditions, four phages (ΦVL12, Φ?T60b, Φ?T63c and ΦAG68a) at a titre of 108 pfu/ml were most effective in reducing BLB infection, with ΦDT60b being the most effective. The four phages belonged to the lytic Xiphoviridae, so they are safe for applying in open fields. In the field, four phage treatments, i.e. ΦDT60b (107 pfu/ml or 108 pfu/ml) or mixtures of four phages (107 pfu/ml or 108 pfu/ml) showed efficacy in disease

reduction. Two treatments, i.e. ?DT60b (108 pfu/ml) and the mixture of 4 phages (108 pfu/ml) provided excellent disease protection and increased yield compared to other phage treatments and were equally efficient as the control bactericide treatment, Starner 20WP.

URBAN TREE INVENTORIES - AN EFFECTIVE TOOL IN BIOSECURITY?

ÖSTBERG Johan. (1)

(1) Nature Based Solution Institute AB, Malmö, SWEDEN

Text
Tree inventories are thereby one of the most fundamental components of planning, managing and developing urban forestry. Inventories are therefore being conducted all over the world, often with huge costs involved. However, many of these inventories contain too much information, with little focus on keeping the content updated, and are often conducted without a clear purpose. Nevertheless, inventories can be a huge resource that, with correct application, can have a significant impact on how urban forestry is governed and how it is perceived by the public. This presentation will have an international focus, looking at examples of how tree inventories are being used to tackle one of the main problems that urban forestry is facing, pests and pathogen. The presentation include examples of how managers have used urban tree inventories for communication, monitoring and prognosis of how future pests and pathogen might affect the urban tree population, the ecosystem services they provide and the nature based solutions they provide.

C1.5-2

COMPLEX HEALTH ISSUES FACED BY URBAN TREES

BELKA Marta. (1), AUGUSTINUS Benno A.. (2)

(1) Poznan University of Life Sciences, Poznan, POLAND; (2) Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, SWITZERLAND

Text
Trees growing in cities survive in a harsh environment, often with limited access to light, soil, and water and exposure to strong winds and elevated temperatures. These factors negatively impact health and vigour, influencing the various ecosystem services they provide. Additional to abiotic factors, biotic factors can adversely affect urban tree health. The ease with which goods and people move in cities reflects in elevated introduction and spread of harmful pests and pathogens. For these reasons, resistance to pests and diseases is particularly important for trees planted in urban environments. Assessment of the threat level and accurate diagnosis, along with optimally selected management measures that consider legal restrictions and the safety of inhabitants, are absolute necessities. Diagnostic facilities are required, along with systems and standards for monitoring threats from biotic factors. All such activities should aim to preserve the existing structure of parks and city gardens in a healthy, vigorous condition, minimizing costs. In Europe, tree species richness is higher in urban environments compared to the surrounding forests, with a different species assemblges as a result. Therefore, the interface between urban and surrounding forest creates opportunities for invasive species and pathogens to establish and spread.
This work will review the most critical issues impacting urban tree health.

C1.5-3

THE VALUE OF BOTANICAL GARDENS FOR GLOBAL PLANT HEALTH RESEARCH: A SOUTH AFRICAN CASE STUDY

PAAP Trudy. (1), WILSON John R.u.. (2,3), BALOCCHI Felipe. (1), WINGFIELD Michael J.. (1)

(1) Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, SOUTH AFRICA; (2) South African National Biodiversity Institute, Cape Town, SOUTH AFRICA; (3) Centre for Invasion Biology, Department of Botany and Zoology, Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text
Worldwide there is a growing number of damaging invasive plant pests, introduced largely by international trade and the movement of plant material. Notably many of these pests are not problematic in their native range or were unknown to science prior to their arrival in novel environments. It is challenging to respond to such incursions but improving surveillance, and in particular global cooperation in surveillance, is likely to have significant benefits. Sentinel plantings are increasingly being used to identify future threats before widespread invasions occur. Botanical gardens contain diverse plant collections, providing unique opportunities for sentinel research. Moreover, as they are often close to likely points of entry, botanical gardens are often among the first sites of establishment of new invasive pests. In 2016, a sentinel project was initiated in South African botanical gardens to improve surveillance and identification of new and emerging pest risks. The project has led to multiple first reports for the country, including the detection of the polyphagous shot hole borer. It has also provided opportunities for training activities with botanical garden staff and supported the development of novel management options for existing pest issues. By raising plant health and biosecurity best practice awareness and capacity, the intention is to provide increased opportunities for the detection of invasive plant pests in a country with a limited surveillance budget.

TREE INSECT PESTS AND PATHOGENS: SOCIO-ECONOMIC AND ENVIRONMENTAL IMPACTS IN URBAN AREAS

RAUM Susanne. (1), PAULEIT Stephan. (1), EGERER Monika. (2)

(1) Technical University of Munich, Chair for Strategic Landscape Planning and Management, Freising, GERMANY; (2) Technical University of Munich, Chair of Productive Urban Ecosystems, Freising, GERMANY

Text

Trees contribute greatly to urban environments and human well-being, yet relatively little is known about the extent to which a rising incidence of tree insect pests and pathogens may be affecting these contributions. To address this issue, we undertook a systematic review and synthesis of the diverse global empirical evidence on the impacts of urban tree insect pests and pathogens, using bibliographic databases. Following screening and appraisal of over 3000 articles from a wide range of fields, 100 studies from 28 countries, spanning 1979–2021, were conceptually sorted into a three-part framework: (1) environmental impacts, representing 95 of the studies, including those reporting on tree damage, mortality, reduced growth, and changes in tree function; (2) social impacts were reported by 35 of studies, including on aesthetics, human health, and safety hazards; and (3) economic impacts, reported in 24 of studies, including on costs of pest management, and economic losses. There has been a considerable increase in urban impact studies since 2011. Evidence gaps exist on impacts on climate-regulating capacity, including temperature regulation, water retention, soil erosion, and wind protection, but also on specific hazards, nuisances, human well-being, property damages, and hazard liabilities. As a knowledge synthesis, the findings will enable us to better forecast how growing threats will affect the urban forest and plan for these eventualities.

C1.5-5

REPORTING SYSTEMS AND CITIZEN SCIENCE FOR THE DETECTION OF REGULATED TREE PESTS AND PATHOGENS IN BRITAIN

PEREZ SIERRA Ana Maria. (1)

(1) Forest Research, Farnham, England, UNITED KINGDOM

Text

Early detection of pests and pathogens is critical for their management, allowing rapid response and helping to prevent their establishment and spread. The approach from the UK government is to respond to plant pest and disease threats by focussing on a biosecurity continuum to minimise their potential impact, that includes increasing vigilance and prevention measures; better enforcement and responses to threats, and more public awareness and engagement with biosecurity. Active surveillance for pests and pathogens consists of regular and ongoing monitoring by official bodies. However, additional data (passive surveillance) on tree health from citizen scientists (including the general public, landowners and tree professionals) can support national surveillance programmes, and the detection of new threats in the wider landscape. TreeAlert was developed to allow

submissions of tree health reports in Britain. This was complemented with citizen science and the Observatree project, launched in 2013. Since then, Observatree volunteers have been trained to identify priority tree pests and diseases of concern and have carried out thousands of tree health surveys, some of which have led to eradication or mitigation measures. Now more than ever, there is a need to be vigilant to ensure that the benefits that trees provide to us are maintained for future generations. This is a good example of how working together with active and passive surveillance can help to build tree resilience.

C1.5-6

THE EPIDEMIC SPREAD OF PHYTOPHTHORA NICOTIANAE IN A MEDITERRANEAN PARK IN ATHENS IS ASSOCIATED WITH HIGH SITE INVASIBILITY AND PATHOGEN INVASIVENESS.

VANNINI Andrea. (1), MORALES-RODRIGUEZ Carmen. (1)

(1) Universita'' degli Studi della Tuscia, Viterbo, ITALY

Text

In the summer of 2016, extensive decline, and mortality of multiple species of Mediterranean shrubs and trees were recorded in a park in Athens (Greece). The progressive crown decline of shrubs and trees was occasionally associated with collar and stem bleeding cankers, and root necrosis. *Phytophthora nicotianae* was found to the responsible for such decline in the park. The possible drivers of this extensive decline were investigated and discussed with a specific focus on pathogen invasiveness and site invasibility. The pathogen was probably unintentionally introduced from commercial nurseries. Its spread was likely favored by intrinsic traits such as polyphagy, adaptation to warm climate, potential of recombination and reproduction, long persistence of inoculum in the soil, which determine the high invasiveness in the Mediterranean climate. A multiple linear regression model was elaborated that evidenced a significant association of the level of inoculum in the plant beds with specific site traits such as total host richness and the quote of susceptible hosts. Furthermore, a multivariate model evidenced that specific host taxa were the drivers of inoculum build-up. Based on the results of the present study, the strategies to reduce the site invasibility by the polyphagous *P. nicotianae* without sensibly affecting the park's ornamental value must consider the choice of plant taxa and their combination in the plant beds.

P1.5-001

BIOSECURITY SURVEILLANCE FOR EARLY DETECTION OF INVASIVE SPECIES IN URBAN FORESTS IN AUSTRALIA

CARNEGIE Angus. (1), TOVAR Francisco. (2)

(1) NSW Department of Primary Industries, Parramatta, AUSTRALIA; (2) Australian Forest Products Association, Canberra, AUSTRALIA

Text

Protection of Australia's forests from invasive species has recently been enhanced with the establishment of a National Forest Biosecurity Surveillance Program, funded by a forest

industry and government partnership. Governance of the Program is managed through a committee of government and industry stakeholders, with technical experts developing operational aspects of the Program. Locations for surveillance are identified through a risk-categorisation process both across Australia and within each State, with resources allocated accordingly. Insect traps with semiochemicals are used to monitor for invading or recently established insect pests. Sentinel trees are assessed annually for signs and symptoms of pest or pathogen attack. Stakeholder engagement and awareness is used to increase general surveillance, with workshops and field days held for local councils, arborists, botanic gardens. An app (MyPestTrees) has been developed to assist in general surveillance and reporting. Research (funded by the forest industry and government) has been undertaken, and is ongoing, to improve risk and pathway analysis, biosecurity surveillance, diagnostics, and response processes. Transformative technologies are being utilised: remote sensing and machine learning to semi-automatically detect and map key hosts in high-risk areas; metabarcoding and high throughput sequencing for diagnosis of samples and eDNA. Examples of responses to recent exotic pathogen invasions are provided.

P1.5-003

MONITORING EMERGING PATHOGENS IN HORSE CHESTNUT TREES ACROSS EUROPE AND THEIR CORRELATION TO THE LEAF MINER INFESTATION

KORKMAZ Yasin. (1), BLUMENSTEIN Kathrin. (1)

(1) UNIVERSITY OF FREIBURG , Freiburg, GERMANY

Text

Horse Chestnut trees (*Aesculus* spp.) are a crucial component of urban ecology, but their health is facing numerous challenges from the effects of climate change and the ongoing emergence of non-native pests and pathogens. To investigate the fungal communities causing disease symptoms, Horse Chestnut leaves were collected from a European transect covering POR, ESP, GER, DEN, and SWE. The fungi were identified using molecular markers (ITSu1/4, LSU/LR6, ELF1-α). Some fungi were present in all locations (*Alternaria* sp. or *Cladosporium* sp.), while others were found in specific regions (*Epicoccum* sp., *Biscogniauxia* sp., and *Leptosphaerulina* sp.). A field trial was conducted to investigate the role of the Leaf Miner (*Cameraria ohridella*) as a vector of the pathogens. Symptomatic leaves with Leaf Miner pupae were stored over the winter and following arranged with healthy saplings in net cages to prevent external interactions. Results showed that the Leaf Miner could play a significant role in transmitting fungal pathogens to healthy hosts. The Horse Chestnut trees are critical for the urban environment and provide ecological benefits such as air purification, carbon sequestration, and biodiversity. However, their health is threatened by the combination of climate change and the impact of the Leaf Miner and fungal pathogens. This study highlights the need for ongoing monitoring and management efforts to protect Horse Chestnut trees and their ecosystem benefits.

PREVALENCE OF ASAV-INFECTED FLOWERING ASH (F. ORNUS) TREES OF TWO GERMAN METROPOLES

KÖPKE Kira. (1), BEHREND Niklas. (1), VON BARGEN Susanne. (1), BANDTE Martina. (1), RYBAK Malgorzata. (2), BÜTTNER Carmen. (1)

(1) Humboldt-Universität zu Berlin, Berlin, GERMANY; (2) Plant Protection Service Hamburg, Ministry of Economy and Innovation, Free and Hanseatic City of Hamburg, Hamburg, GERMANY

Text

Viral diseases play a particular role in tree health as predisposing factors (Büttner et al, 2013, 2023). Therefore, the virus infection could counteract trees resilience, especially in cities with anticipated extreme climate conditions. Flowering ash (Fraxinus ornus L.) infected by the ash shoestring-associated virus (ASaV) develop characteristic leaf symptoms (Gaskin et al., 2021). The tree species is considered as a potential “climate tree” in urban environment. The prevalence of ASaV in this tree species should be assessed in the cities of Hamburg and Berlin.

In the vegetation periods 2019 and 2020, a survey on the occurrence of ASaV-associated symptoms was carried out in selected street sites of Hamburg considering 50 % of the 466 flowering ash trees planted in the city state. The trees were visually inspected twice per year. A selection of symptomatic and symptomless leaves was sampled and tested for an ASaV-infection by virus-specific RT-PCR.

In 2021, we examined 65% of the 1150 flowering ash trees grown in Berlin for ASaV symptoms. Visual scoring of the trees was followed by sampling of 82 symptomtic leaves, 85 samples without virus suspected symptoms, and 32 with ASaV-atypical discoloration and deformation, and 14 samples with mild ASaV-symptoms were taken and tested by ASaV-specific RT-PCR. The occurrence and distribution of ASaV-infected trees in these two cities make aware that viruses have to be listed as a considerable member of potential pathogens in trees.

P1.5-005

A DIVERSE RANGE OF PHYTOPHTHORA SPECIES RECOVERED FROM TWO SOUTH AFRICAN BOTANICAL GARDENS

PAAP Trudy. (1), BALOCCHI Felipe. (1), BOSE Tanay. (1), WINGFIELD Michael J.. (1)

(1) Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, SOUTH AFRICA

Text

The genus *Phytophthora* contains many destructive and globally important plant pathogens. In the last decade, targeted sampling efforts have resulted in a dramatic increase in the number of known species, as well as a better understanding of the global distribution of these important pathogens. Routine activities undertaken in botanical gardens, combined with great numbers of local and international visitors, place botanical gardens at risk with regard to the accidental introduction and establishment of pathogens. In this study, the

occurrence of *Phytophthora* was investigated in two South African botanical gardens. Symptomatic collar and stem tissues were collected, and root and rhizosphere soil samples were taken from trees exhibiting symptoms of decline. Standard baiting techniques and direct plating of symptomatic tissues revealed the presence of seven species of *Phytophthora* residing in four phylogenetic clades. Five of these species were already known to be present in South Africa. However, *P. aquimorbida* was recorded for the first time, and an undescribed species residing in *Phytophthora* clade 5 was detected. A novel host-pathogen association where *P. citrophthora* is causing tar-spot on indigenous *Celtis africana*, was also identified. This study highlights the importance of monitoring botanical gardens for the detection and discovery of pathogens, and emphasises their value as sites for the discovery of novel host-pathogen associations

Text

Phytophthora comprises numerous invasive plant pathogens threatening natural and anthropized ecosystems. Botanical gardens hosting diverse plant species of various origin may be ideal sites to study the diversity of communities associated to the plants, intercept exotic species and investigate the potential host range of species of this oomycete genus. In this respect, botanical gardens can be regarded as sentinel plant collections in surveillance and monitoring schemes. From 2016 to 2019, it was investigated the diversity of *Phytophthora* species associated with the rhizosphere soil of exotic and enedemic plant species in the Botanical Garden of Catania, Sicily. Isolations were carried out from plants with symptoms suggestive of *Phytophthora* infections using standard techinques and the NARPH agar selective medium. Samples were taken from soil, roots and stem bark of *Araucaria cookii*, *Phytolacca dioica*, *Sterculia diversifolia*, *Zelkowa sicula*, *Quercus suber*, *Olea europea*, *Coffea arabica*, *Pistacia atlantica* and *Morus alba*. Isolates were identified based on both morphological characters and the analysis of the ITS regions of rDNA. *Phytophthora multivora*, the prevalent species, was recovered from all hosts, except *C. arabica*. *Phytophthora nicotianae*, the second most frequent species, was recovered from *A. cookii*, *P. dioica*, *Q. suber* and *O. europaea*. *Phytophthora parvispora* was recovered from *C. arabica*. Some of these pathogen/host associations are first records worldwide.

Text

The current phase of climate and environmental changes demands actions that enhance available resources and preserve the forest heritage to reduce biodiversity loss and safeguard socio-economic systems. Digitization, especially remote sensing, has emerged as an innovative tool for sustainable management of forest ecosystems. Smart Urban Forest Monitoring (SUFM) program proposes a multidisciplinary approach to detect alterations in vegetation indices caused by pests on trees and forests in urban areas. Multi/hyperspectral RGB-NIR and SAR images from PRISMA satellite will be interpolated with ground data derived by the Greenery Scanner developed at the Massachusetts Institute of Technology; further data will derive from additional aerial images, Tree Talkers sensors and traditional visual inspections for assessing the state of infestation. A data lake will be created to collect data, and models of data analysis that will be developed to correlate images to the degree of infestation. The platform will be developed firstly on a remote sensing system measuring the degree of infestation of the pine tortoise scale Toumeyella parvicornis on Pinus pinea in urban parks and forests in Rome, with the aims at extending the remote sensing system to the spectral anomalies caused by other biotic or abiotic stresses of forest systems in both urban and non-urban contexts.

THE NOVI SAD POPLAR TREE DIE-BACK AND DECAY LINKED TO FUSARIUM SOLANI, GRAPHIUM PENICILLIOIDES, AND CYCLOCYBE AEGERITA

DJILAS Milutin. (1), ORLOVIC Sasa. (1), MARKOVIC Miroslav. (1), PAP Predrag. (1), KESIC Lazar. (1), KOVACEVIC Branislav. (1), ZLATKOVIC Milica. (1)

(1) Institute of Lowland Forestry and Environment (ILFE), Novi Sad, SERBIA

Text

Since the introduction of poplar (Populus spp.) hybrids in Serbia in the 1960s, Populus euramericana cl. I-214 and cv. "Robusta" have been widely planted in Novi Sad, which is the capital of the Vojvodina Province. Apart from sporadic infections of Plagiostoma populinum (syn. Dothichiza populea) on P. euramericana, the poplars planted in this city over the years have remained healthy. However, these trees have recently begun to show symptoms of die-back and decay, making them vulnerable to windthrows and windbreaks. Urban tree vulnerability is important for the risk management strategies used by city authorities, but it also attracts the attention of environmental NGOs, academic institutions, citizen groups and

other stakeholders that want to create safe, green, and habitable cities. Therefore, Novi Sad has begun an intensive health monitoring of poplars which has been carried out by the Institute of Lowland Forestry and Environment in accordance with a city directive for the maintenance of urban tree's health. Several fungi were isolated during the surveys and were preliminary identified as Fusarium solani species complex, Graphium penicillioides species complex, and Cyclocybe aegerita using the ITS rRNA. Moreover, it was common to find C. aegerita mushrooms at the base of symptomatic trees. The study calls for the restoration of greenery in Novi Sad after documenting for the first time F. solani and G. penicillioides species complexes in urban environments in Serbia.

Text
Arborvitae (Thuja occidentalis L.) is native to eastern North America and is widely grown in Europe as an evergreen ornamental. In Serbia, T. occidentalis is typically planted as a screen or hedge in private gardens and public green spaces like city parks and cemeteries. Moreover, T. occidentalis cultivars (e.g. "Woodwadii", „Smaragd", "Globosa", "Aurea Nana") are the most commonly produced ornamentals in Serbian nurseries. During the last decade, T. occidentalis has been endangered due to a canker disease caused by Botryosphaeriaceae fungi. However, T. occidentalis plants in Serbian nurseries as well as in urban and rural areas have recently displayed new, unique symptoms of a foliar blight disease, according to the plant health inspection service of the Institute of Lowland Forestry and Environment. The leaves had symptoms of tip blight with numerous pycnidia on the brown necrotic areas at the edge of the leaves and these symptoms differed from those caused by Botryosphaeriaceae. The fungus consistently isolated from the infected tissues was preliminary identified as Pestalotiopsis thujae using morphology and DNA sequence data for the internal transcribed spacer (ITS) rRNA. P. thujae is known to be opportunistic and recent stressful conditions caused by drought and heat waves might have weakened T. occidentalis, making it vulnerable to pathogens. The study is the first report of P. thujae in Serbia and it raises concerns regarding the impact of P. thujae on these trees.

BIOLOGICAL CONTROL - Part 1: The importance of augmentative biocontrol and plant microbiome function for plant health

C1.1-1

BENEFICIAL BACTERIA-FUNGI INTERACTIONS TO INCREASE PLANT GROWTH AND HEALTH

DEL BARRIO DUQUE Alejandro. (1,3), ANTONIELLI Livio. (1), SESSITSCH Angela. (1), NYBROE Ole. (2), **COMPANT Stéphane. (1)**

Text

Fungi and bacteria cohabit in the plant environment. Separately they have been intensively studied for their impact on plant health. Except some particular cases, little attention has however been paid to the intricacy of fungi-bacteria interactions. Using different models, we described that specific multipartite interactions between fungi and bacteria can lead to an increase or reduction of plant growth and/or health.
For instance, we used *Serendipita indica* (syn. *Piriformospora indica*), which is a root colonizing endophytic fungus that holds capabilities to enhance plant growth and to confer resistance to different stresses. This fungus is further known as hosting a bacterial endosymbiont, *Rhizobium radiobacter*, living inside its hyphae. However, there was still a gap of knowledge if other bacteria can also have positive effects on the fungus. We analyzed how co-inoculations of endophytic bacteria and *S. indica* influence plant growth and increase protection against different fungal pathogens. Possible mechanisms behind these interactions were described based on genome and advanced microscopic analyses, using fungal and bacterial strains tagged with fluorescent markers. Bacteria-fungus seem to cooperate in the process of fungal root colonization and establishment, e.g., by increasing fungal sporulation and hyphae expansion. Genome analysis of positive bacteria revealed many genes potentially involved in fungal and plant growth stimulation, biocontrol and root colonization.

C1.1-2

THE ROLE OF SMALL RNAS IN REGULATING MYCOPARASITIC INTERACTIONS

EDOARDO Piombo. (1), VETUKURI Ramesh R. . (1), BROBERG Anders. (1), KALYANDURG Pruthvi B. . (1), SUNDARARAJAN Poorva. (1), KUSHWAHA Sandeep. (1), FUNCK JENSEN Dan. (1), KARLSSON Magnus. (1), **DUBEY Mukesh. (1)**

Text

Small-RNAs (sRNAs) are emerging as key players in host-microbe interactions, although their role in mycoparasitic interactions remain understudied. We used the mycoparasitic

fungus *Clonostachys rosea* and plant pathogenic mycohosts *Botrytis cinerea* and *Fusarium graminearum* and investigated the role of sRNAs in mycoparasitism. Deletion of dicer genes in *C. rosea* resulted in mutants with reduced antagonism towards *B. cinerea*, reduced biocontrol of fusarium foot rot disease on wheat, and reduced production of sorbicillin secondary metabolites. Transcriptome and sRNA sequencing of *C. rosea* strains (wild type and *dcl1* and *dcl2* deletion strains), *B. cinerea* and *F. graminearum* during *in vitro* interactions identified 61 novel microRNA-like RNAs (milRNAs) in *C. rosea*. Eleven of those were downregulated in the Δ*dcl2* mutant. In addition to putative endogenous gene targets, these 11 milRNAs were predicted to target *B. cinerea* and *F. graminearum* virulence factor genes, as these showed an increased expression during interaction with the Δ*dcl2* mutant incapable of producing the targeting milRNAs (cross-species RNA silencing). In summary, our work constitutes the first step in elucidating the role of sRNA-mediated RNAi in regulating mycoparasitism and poses the base for future studies focusing on the role of cross-species RNAi in interspecific fungal interactions. This also indicate an important mechanistic role of RNAi in biological disease control using *C. rosea* as a biocontrol agent.

C1.1-3

TRICHODERMA IN THE BIOCONTROL OF NON-CONVENTIONAL TARGETS: NEMATODES AND INSECT PESTS

MONTE Enrique. (1), HERMOSA Rosa. (1)

(1) University of Salamanca, Salamanca, SPAIN

Text

Trichoderma is a multipurpose, plant-beneficial fungus of importance in agriculture as a direct biological control agent (BCA) that, because of its interaction with plants, has become an indirect BCA (inducing resistance in plants against pathogens and their vectors) and a biostimulant, which can reduce the application of agrochemicals, thus promoting an eco-sustainable agriculture (Woo et al. 2023). The direct action of *Trichoderma* as a BCA against phytopathogenic fungi and oomycetes is well documented. However, there is much less information on the biocontrol and mechanisms of action of non-conventional targets, such as nematodes and insects. *Trichoderma* has long been noted to have suppressive effects on *Meloidogyne* root-knot nematodes (RKN) and other phytopathogenic nematodes via parasitism, egg lysis by proteases and chitinases, or suppression of egg hatching by secondary metabolites (Woo et al. 2023). Furthermore, *Trichoderma* exhibits direct biocontrol of insect pests, and vectors of viral and bacterial diseases, through enzymatic activity on the midgut peritrophic matrix, inhibition of cuticle formation or displaying antifeedant effects mitigating herbivore attack. In addition, extracts of secondary metabolites can have inhibitory effects on insect larvae and attract predators and parasitoids (Di Lelio et al. 2023; Monte, 2023).

PLANT MODIFIES FUNGAL NON-SELF RECOGNITION TO FACILITATE MYCOVIRUS TRANSMISSION

HAI Du. (1), JIANG Daohong. (1), CHENG Jiasen. (1), FU Yanping. (1), **XIE Jiatao. (1)**

(1) Huazhong Agricultural University, Wuhan, CHINA

Text

Horizontal transmission of mycovirus is strictly limited by hyphal anastomosis that is regulated by fungal non-self recognition system. However, mycovirus transmission between vegetative incompatible groups occurs in nature despite of the non-self recognition system. Understanding the mechanism of mycovirus transmission in nature would facilitate using hypovirulent-associated mycoviruses (HAV) to combat plant diseases. Here, we show that the horizontal transmission efficiency of mycoviruses between vegetatively incompatible individuals of Sclerotinia sclerotiorum is significantly higher in planta than in vitro. Furthermore, plant proline is increased upon S. sclerotiorum infection, and results in suppressing expression of genes responsible for the fungal non-self recognition reaction. Additional in vitro experiments and genetic evidence confirmed that proline facilitates mycovirus transmission between fungal isolates via inhibition of non-self recognition reaction. The Application of HAV-mediated hypovirulent strain together with proline substantially improved the virocontrol efficiency of fungal plant pathogens in multiple agricultural fields. This work provides mechanism by which plants defend themselves against pathogenic fungi by enhancing mycovirus transmission and opens up a future strategy to promote HAV horizontal transmission efficacy for the biocontrol of plant diseases.

C1.1-5

INTRASPECIFIC PHENOTYPIC AND GENETIC VARIATION IN BIOCONTROL INTERACTIONS: CHALLENGES AND OPPORTUNITIES

KARLSSON Magnus. (1), CHAUDHARY Sidhant. (1), PIOMBO Edoardo. (1), DUBEY Mukesh. (1), FUNCK JENSEN Dan. (1)

(1) Swedish University of Agricultural Sciences, Uppsala, SWEDEN

Text

In augmentative biocontrol, individuals from a single species typically display high variation in biocontrol efficacy. In order to investigate the basis for this phenomenon, we evaluated 63 genome-sequenced strains of the biocontrol fungus Clonostachys rosea for their ability to control fusarium foot rot disease on wheat, in vitro antagonism, plant growth promotion and growth rate on a range of different fungicides. There were significant ($P < 0.05$) differences between C. rosea strains in all investigated traits, and typically low correlations ($R2 < 0.27$) between traits. This suggests a mechanistically different basis for these biocontrol-related traits, allowing for genotypic adaptation. A transcriptome analysis further identified induction of distinct gene sets in C. rosea following interaction with Fusarium graminearum or Botrytis cinerea, suggesting different mechanisms of antagonism towards different pathogens. In parallel, 200 genotyped wheat varieties were evaluated for their responsiveness towards C. rosea-mediated biocontrol of septoria tritici blotch disease. There was significant ($P < 0.05$) variation among wheat genotypes for biocontrol responsiveness, which allowed the

identification of two genomic regions associated with the trait. In summary, we show a high degree of genotype-by-genotype effects on the outcome of biocontrol interactions, which opens opportunities for designing optimal biocontrol agent – crop combinations as well as biocontrol breeding programs.

C1.1-6

AUREOBASIDIUM PULLULANS: UP-AND-COMING BIOCONTROL AGENT AGAINST CROWN ROT, ROOT ROT, AND GREY MOULD

IQBAL Mudassir. (1), ANDREASSON Erik. (1), STENBERG Johan. (1)

(1) Swedish University of Agricultural Sciences, Alnarp, SWEDEN

Text

Wild populations of woodland strawberries (*Fragaria vesca*) typically host the beneficial yeast fungus *Aureobasidium pullulans*, which protects the wild plants (incl. fruits) from pathogens. We isolated *A. pullulans* (AP-SLU6) from wild strawberries and tested its potential as a biocontrol agent against several diseases on cultivated garden strawberry (*Fragaria* × *ananassa*) in a greenhouse setting as well as in open field plantations. Both traditional spray applications and a bee vectoring system (Flying Doctors®) for high-precision application were tested. In controlled greenhouse tests, we found that spray applications of *A. pullulans* significantly reduced crown rot, root rot, and grey mould caused by *Phytophthora cactorum* and *Botrytis cinerea*, respectively. However, the high-precision application of *A. pullulans* using the bee-vectoring system was most efficient against grey mould, leading to significantly reduced grey mould development on the harvested fruits by 45 % and increased shelf life by 100 % in comparison to control treatments. The field experiment in a commercial strawberry plantation confirmed the significant effects of *A. pullulans* on grey mould infestation and shelf life and furthermore showed that *A. pullulans* was more efficient than other established biocontrol products. We conclude that *A. pullulans* shows high potential for successful biological control of several strawberry diseases and discuss opportunities for further optimization of this beneficial fungus.

BIOLOGICAL CONTROL - Part 2: The importance of augmentative biocontrol and plant microbiome function for plant health

C2.2-1

MICROBIOME CONCEPTS FOR BIOCONTROL OF PLANT AND HUMAN PATHOGENS

BERG Gabriele. (1,2)

(1) TU Graz, Graz, AUSTRIA; (2) Leibniz-Institute for Agricultural Engineering ATB, Potsdam, GERMANY

Text

Understanding and managing microbiomes offers promising perspectives for all kind of health issues. The synergistic impact of anthropogenic factors on the inter-linked plant microbiome such as biodiversity loss, pollution, ozone depletion, climate change and changing biogeochemical cycles is less understood. Recent studies indicated a general shift of the plant microbiota characterized by a decrease of evenness and specificity, and an increase of r-strategist and hypermutator prevalence as well as antimicrobial resistance. This typical microbiome signature of the Anthropocene is often followed by a dysbiosis, which leads to missing symbionts on one hand and outbreaks of pathogens in the other. Managing the microbiome and controlling pathogeny can provide solutions for sustainable agriculture. Beyond, the plant microbiome is connected across systems and crucial for human and planetary health issues as well. Examples will be discussed. In conclusion, diversity within the microbiome and resistome are interconnected, and should be managed by microbiome management together.

C2.2-2

THIRTY YEARS OF RESEARCH ON BIOLOGICAL CONTROL OF POTATO COMMON SCAB USING PLANT-BENEFICIAL BACTERIA: WHAT WE HAVE LEARNED, WHAT'S NEXT…

FILION Martin. (1), BIESSY Adrien. (1), ZBORALSKI Antoine. (1), ST-ONGE Renée. (2), NOVINSCAK Amy. (1), CIOTOLA Marie. (1), CADIEUX Mélanie. (1)

(1) Agriculture and Agri-Food Canada, Saint-Jean-Sur-Richelieu, CANADA; (2) Université de Moncton, Moncton, CANADA

Text

Potato common scab in an important disease caused by several *Streptomyces* species that significantly reduces potato tuber quality and market value. Management of common scab is difficult, and no conventional method can reliably control this disease. An alternative approach is the use of plant-beneficial bacteria as biocontrol agents, whose application in the field can significantly reduce common scab incidence and severity. However, inconsistencies in efficacy have been reported and yet no durable control has been achieved. In this presentation, the potato common scab disease, the diversity and distribution of scab-causing *Streptomyces* species and their phytotoxins and pathogenicity determinants will first be reviewed. Then, we will describe the diversity of bacterial strains successfully used to date to suppress potato common scab under controlled and field conditions, their biocontrol mechanisms and the factors influencing the biocontrol success. Finally, we will discuss the use of phenazine-producing *Pseudomonas* spp. as promising biocontrol agents against

potato common scab, an attractive approach supported by ten years of continuous research in our laboratory.

C2.2-3

BACTERIAL BIOPROTECTANTS IN NATURAL AND AUGMENTATIVE BIOLOGICAL CONTROL

HÖFTE Monica. (1)

(1) Ghent University, Gent, BELGIUM

Text

The three most commonly studied bacterial genera in the biocontrol of plant pathogens are Bacillus, Pseudomonas and Streptomyces. In Europe, most commercial bioprotectants used for augmentative biological control are based on Bacillus, with a predominance of closely related cyclic lipopeptide-producing Bacillus velezensis (amyloliquefaciens) strains. In contrast, only two active substances based on Streptomyces and two based on Pseudomonas (2) strains are listed in the EU pesticides database showing that their commercial potential is insufficiently exploited. Streptomyces and Pseudomonas, however, play key roles in natural biological control as observed in disease-suppressive soils and produce secondary metabolites that directly or indirectly impact plant pathogens. In our lab, we are interested in the drivers of taxonomic and metabolic diversity in Pseudomonas populations in disease-suppressive soils. Our data from tropical soils suggest that the main drivers for Pseudomonas diversity are soil quality, plant age and interbacterial competition. This results in a diverse Pseudomonas population that produce a range of bioactive compounds, including structurally diverse cyclic lipopeptides and type VI secretion systems, that suppress plant pathogens.

C2.2-4

FROM BCA DISCOVERY IN CEREALS TO BIOLOGICAL CONTROL OF FUSARIUM HEAD BLIGHT

COLLINGE David B. (1), KHAIRULLINA Alfia. (1,2), JØRGENSEN Hans Jørgen Lyngs. (1), JENSEN Birgit. (1)

(1) University of Copenhagen, Frederiksberg C, DENMARK; (2) Lund University, Lund, SWEDEN

Text

Fusarium head blight disease in cereals is feared as much for mycotoxins as for direct yield loss. Neither disease resistance nor chemical control are effective or efficient in controlling disease or mycotoxin accumulation. Biological control based on beneficial filamentous fungi is receiving increasing attention for controlling this disease [1]. We have isolated plant-associated fungi from the rhizosphere and endophytes from healthy cereal tissues and demonstrated their potential as biological control agents to combat Fusarium head blight in oats (*Avena sativa*) and wheat (*Triticum aestivum*). Disease control works both in controlled environments and/or the field. Studies of mechanisms using RNAseq and microscopy

implicate induced resistance as the primary disease reducing mechanism [2,3,4]. Furthermore, disease control by the BCAs *Penicillium olsonii* and *Clonostachys rosea* is associated with reduced accumulation of mycotoxins [2,4], and we have seen substantial stimulation of detoxification of DON (deoxynivalenol) in oats by glycosylation by *C. rosea* and direct treatment with DON itself [2].

PSEUDOMONAS PROTEGENS: BACTERIAL SWISS ARMY KNIVES FOR FUTURE PROSPECTS IN PLANT PROTECTION AGAINST PEST INSECTS

VACHERON Jordan. (1), HEIMAN Clara. (1), GARRIDO-SANZ Daniel. (1), KEEL Christoph. (1)

(1) Department of Fundamental Microbiology, University of Lausanne, Lausanne, SWITZERLAND

Text

Root-associated bacteria of the *Pseudomonas protegens* subgroup are well known for their plant-beneficial activities, which include the suppression of plant pathogenic fungi and protists and priming of plant immune defense. These bacteria can also exhibit potent insecticidal activities towards plant-feeding larvae of certain Lepidopteran and Dipteran pest insects. The disease and pest control capacities of these *Pseudomonas* are enabled by the production and release of various antimicrobial metabolites and insecticidal toxins. *P. protegens* are highly competitive and capable of efficiently colonizing different ecological niches and hosts, notably plants and insects that are densely populated by competing bacteria. We identified several molecular determinants important for the modus operandi of these insecticidal *Pseudomonas* once ingested by pest insects. Among them are contractile phage tail related-structures, specifically the type VI secretion system and tailocins, that are important weapons for the invasion of the insect gut microbiome, competition with dominant microbiome members and related *Pseudomonas*, and consequently for insect pathogenicity. The in-depth understanding of the molecular basis of the insect pathogenic activities of these fascinating bacteria and of their role in the microbial ecology of plants and insects are a prerequisite to generate knowledge for the potential future implementation of such bacteria in agricultural pest management strategies.

C2.2-6

MECHANISM BY WHICH SELECTED BACILLUS STRAINS THAT CONFER TOLERANCE TO VERTICILLIUM WILT IN POTATO AND STIMULATE GROWTH

LI Min. (1,2), YANG Jianfeng. (1), WANG Yating. (1), TANG Fang. (1), ZHANG Jian. (1), CHENG Xu. (3), HAN Guodong. (1), BISSELING Ton. (2), ZHAO Jun. (1)

Text

Potato Verticillium wilt caused by *Verticillium dahliae* is a vascular disease, that seriously affects potato yield and quality worldwide. Once the pathogen enters the vascular bundle, the use of chemicals as control is not only ineffective but also the polluting environment. Therefore, it is of great importance to find environmentally friendly biological control methods. In this study, five strains from potato-growing fields, with good antagonistic activity were selected. These strains had an antagonistic activity against the other three pathogens, *Fusarium oxysporum*, *Rhizoctonia solani* and *Phytophthora infestans*. Among five strains, *Bacillus velezensis* XS142 showed the highest biocontrol effect on *V. dahliae*, even higher than that of the SynCom of the 5 strains. XS142 colonize intercellular spaces within roots and also stimulated the growth of the potato. To study the mechanism of XS142, by which tolerance to *V. dahliae* is created, the genome of XS142 was sequenced and showed that eight gene clusters were involved in the production of secondary metabolites with potential antimicrobial properties. Further, the transcriptomes of potatoes treated with XS142 were analyzed and the mechanisms underlying the increased resistance and growth promotion will be discussed. Conclusion: This study showed that *B. velezensis* XS142 has a high potential to be used as a biocontrol agent for potato Verticillium wilt and/or plant growth-promotion agriculture.

F1.1-1

INSIGHTS INTO THE GENERALIST LIFESTYLE AND BIOCONTROL ACTIVITY OF FUNGAL SPECIES OF CLONOSTACHYS THROUGH ANALYSIS OF THEIR PREDICTED SECRETOMES

PIOMBO Edoardo. (1), GUASCHINO Micol . (1,2), JENSEN Dan Funck. (1), KARLSSON Magnus. (1), DUBEY Mukesh. (1)

(1) Department of Forest Mycology and Plant Pathology, Swedish University of Agricultural Sciences, Uppsala, SWEDEN; (2) Department of Agricultural, Forest and Food Sciences (DISAFA), University of Turin, Grugliasco, ITALY

Text

The fungal secretome comprises proteins that are involved in many aspects of fungal lifestyles, including adaptation to ecological niches. The aim of this study was to investigate the composition and function of predicted fungal secretomes in mycoparasitic and beneficial fungal-plant interactions of *Clonostachys rosea*, *C. byssicola*, *C. chloroleuca*, *C. rhizophaga*, *C. solani* and one unidentified *Clonostachys* species. The predicted secretomes of the analyzed species comprised around 8% of their proteomes. Mining of transcriptome data collected during previous studies showed that 18% of the genes encoding predicted secreted proteins were upregulated during the interactions with the mycohosts *Fusarium graminearum* and *Helminthosporium solani*. Functional annotation of the predicted secretomes revealed that the most represented protease family was subclass S8A, often involved in the response

to nematodes and mycohosts, while the most numerous lipases and carbohydrate-active enzyme (CAZyme) groups appeared to be potentially involved in eliciting defense responses in the plants. Comparison with three *Trichoderma* spp., another genus known for its mycoparasitic activity, revealed profound differences in secretome composition, such as differences in the dominant CAZyme classes. This work sheds light on the role of the secretome in the interaction of *Clonostachys* spp. with plants and fungi, and highlights differences with *Trichoderma* spp. sharing similar lifestyles and ecological niches.

F1.1-2

ISOLATION AND IDENTIFICATION OF BACTERIAL STRAINS FROM APPLE FLOWERS IN TRENTINO AND THEIR EVALUATION AS BIOCONTROL AGENTS OF ERWINIA AMYLOVORA

PEDRONCELLI Anna. (1), MARIAN Malek . (1), PUOPOLO Gerardo. (1)

(1) UNIVERSITY OF TRENTO, San Michele All'adige (Tn), ITALY

Text

Fire blight caused by *Erwinia amylovora* (*Ea*) represents a great threat to apple and pear production worldwide. For instance, the outbreak of fire blight occurred in Trentino caused a relevant reduction of crop yield in 2020. It is now widely accepted that apple flowers may harbor bacterial taxa that might hinder the ability of *Ea* to colonize apple flower. Based on this body of knowledge, we aimed at investigating the microbiota of apple flowers to select new potential biocontrol agents active against *Ea*. Flowers of *Malus domestica* cv. *Golden Delicious* from Trentino apple orchards were sampled at the 'Baloon stage' and surface sterilised to isolate only bacteria residing within the flowers. According to the 16S rRNA gene sequencing, the bacterial isolates mainly belonged to the *Enterobacteriaceae*, *Pseudomonadaceae*, and *Microbacteriaceae* families. One member of each bacterial family was selected and tested against *Ea* both on newly open apple flowers and on pear slices. *Pantoea agglomerans* AFF2001 and *Curtobacterium flaccumfaciens* AFF2009 effectively controlled *Ea* in both conditions. To characterize their mode of action, these bacterial strains were grown in a specific medium mimicking the apple stigma nutrient conditions and their cultural filtrates were tested to evaluate their impact on the growth and virulence of *Ea*. In the future, we will investigate the molecular mechanisms involved in the biocontrol activity of these bacterial strains.

F1.1-4

BIOLOGICAL CONTROL OF POTATO SCAB BY PSEUDOMONAS SP.

VITOR Lucas. (1), FERREIRA-TONIN Mariana. (1), DESTEFANO Suzete. (1)

(1) Instituto Biológico, Campinas, BRAZIL

Text

Potato scab, caused by *Streptomyces* spp., is a complex disease widespread in the main producing regions of the world. The control of this disease is very difficult and therefore a set

of techniques is required for effective management. Biological control represents an alternative measurement and the bacteria *Pseudomonas* can be the solution. In the present study two strains of *Pseudomonas* sp. (IBSBF 3420 and IBSBF 3423), which are resistant to Fluazinam (fungicide widely used by potato growers), were tested with this chemical *in vitro* and *in vivo* against S*treptomyces scabiei*. *In vitro* assays, halos of inhibition with average of Ø 4.4 cm were observed in treatment with the two control agents (biological+chemical) while that those treatments with only one agent showed averages of Ø 2.8 cm. In greenhouse assays, tubers treated with *Pseudomonas* sp. IBSBF 3420 and IBSBF 3423 resulted in the reduction of incidence (85 and 75%, respectively) and severity of disease (63.9 and 60.8%, respectively). Fluazinam treatment showed better performances when used together with *Pseudomonas* IBSBF 3420 (reduction of 79.6% incidence/64.1% severity) or *Pseudomonas* IBSBF 3423 (75.7% incidence/56.1% severity), while the treatment with only fungicide the reduction of incidence and severity were 68.5% and 50%, respectively. The results obtained herein showed that *Pseudomonas* strains can be used to reduce potato scab disease and the combination with Fluazinam does not affect the biological agent action.

P1.1-001

MICROBIAL BIOLOGICAL CONTROL AGENTS (MBCAS): CONSUMERS' FRIENDS OR FOES?

DEVASAHAYAM Bennet Rohan. (1), UTHE Henriette. (3), POESCHL-GRAU Yvonne . (4), DEISING Holger B. (2)

(1) Agricultural and Nutritional Sciences, Halle (Saale), GERMANY; (2) Agricultural and Nutritional Sciences, Halle (Saale), GERMANY; (3) German Centre for Integrative Biodiversity Research (iDiv), Leipzig, GERMANY; (4) German Centre for Integrative Biodiversity Research (iDiv), Leipzig, GERMANY

Text

Microbial biological control agents (MBCAs) are used as an alternative to synthetic chemistries and the application of MBCAs implies that these confront microbial communities, including plant pathogenic fungi. The competitions for ecological niches are decided by the toxicity of secondary metabolites (SMs) produced by the microbes. The SM compounds produced and secreted by a microbe are taken up and are further modified by another, creating a SM cocktail, which might be highly toxic and putatively have an adverse effect on human health.

In order to test the hypothesis that confrontations between pathogenic fungi and MBCA transcriptionally de-regulate SM gene clusters (SMGCs) and SM synthesis, we established confrontation experiments with maize fungus Colletotrichum graminicola and the MBCA Bacillus amyloliquefaciens. Microscopy showed that large hyphal swellings are formed in the vicinity of B. amyloliquefaciens. To elucidate the response of SMGCs, transcriptome studies were performed, and we observed differentially regulated genes belonging to PKS and NRPS clusters. Of the 42 SM clusters in Colletotrichum, more than 30 clusters harbor genes that were differentially regulated in confrontations. The metabolites extracted from the fungus-bacterium interface were analyzed by LC-MS/MS to reveal the chemical interaction and these studies showed that confrontations between microbes induce the production of a large number of chemistries belonging to various classes.

P1.1-002

IN-VITRO EVALUATION OF BIOAGENTS AGAINST CLAVICEPS FUSIFORMIS CAUSING ERGOT OF PEARL MILLET

JAGTAP Gajendra. (1), **KUMAR Sathish. (1)**

(1) VNMKV,PARBHANI- MAHARASHTRA, Buldana, INDIA

Text

Aims- Among the bajra ailments, ergot presents a severe problem, but scant research has been done on it by using bioagents. **Methods**:For the objective of pathogen isolation With the help of a sterilized procedure these dried drops of honeydew were inoculated on the autoclaved solidified and cooled PDA media. After a week of incubation, the well-developed mycelial growth was purified using the hyphal tip techniques. By using a dual culture approach, eight bioagents were examined in vitro for their antagonistic vigour against pearl millet ergot. The inhibitory zone was ultimately quantified by measuring the distance between the two sides of the Petri dish under test. **Results**- The pathogen was isolated on Potato dextrose agar (PDA) media. Results revealed that all the bioagents that were evaluated, exhibited fungistatic/antifungal activity against C. fusiformis and significantly inhibited its growth over untreated control. Among bioagents tested T. asperellum was found to be the most effective highest mycelial growth inhibition (59.73%) followed by T. harzianum (57.51%).
Conclusion- Among the bioagents, Trichoderma asperellum showed promising results for the control of ergot under invitro conditions and has the potential zone of inhibition growth than other bioagents. Additionally, it reduces the cost of production by means of reducing chemical application in fields, so it derives maximum benefits to farmers in an eco-friendly manner.

P1.1-003

TRICHODERMA AFROHARZIANUM – A NEW PATHOGEN IN MAIZE

PFORDT Annette. (1), VON TIEDEMANN Andreas. (1)

(1) Georg-August-University of Goettingen, Goettingen, GERMANY

Text

Trichoderma spp. are ubiquitous soil fungi occurring worldwide. Due to their mycoparasitic and endophytic properties, Trichoderma species are used in agriculture as biocontrol agents. However, in 2018, a massive occurrence of T. afroharzianum on maize cobs was observed for the first time in Germany. Since then, Trichoderma ear rot has been observed at several locations in Germany, France, and Italy, especially in dry and hot seasons. Symptoms of Trichoderma ear rot consist in massive production of green to gray-green conidia on infected cobs leading to significant reduction of cob weight and quality as well as reduced germination rate and malformed seedlings. In addition, several Trichoderma strains used in approved biological fungicides and soil additives were pathogenic and caused heavy cob infection. In inoculation trials in the greenhouse with barley, rye, sorghum and wheat, T. afroharzianum caused visual symptoms of infection, such as browning and discoloration on the ears of wheat and barley, leading to high colonization rates and reduction of grain weight. Climate chamber experiments confirmed that growth rate and disease severity of pathogenic T. afroharzianum isolates is increased above 25°C and show a broader temperature optimum,

especially in the high temperature range.

P1.1-004

BIOLOGICAL CONTROL OVER SOURCES OF POWDERY MILDEW INOCULUM (ERYSIPHE NECATOR), GRAY ROT (BOTRYTIS CINEREA) AND ARM DEATH (DIPLODIA SERIATA), IN PERIODS OF WINTER DORMANCY OF VITIS VINIFERA.

DONOSO Eduardo. (1), HETTICH Walter. (1), ROMERO Luis. (1), TORRES Carlos. (1), GARCIA Consuelo. (1)

(1) bio insumos nativa spa, Maule, CHILE

Text

The use of biological control agents, allow a more ecological management for plant diseases, using population ecology. This study evaluates the effect of applications of biological agents, in dormancy of Vitis vinifera, aiming to evaluate the effect of formulations of Trichoderma spp, (Mamull ®) and Bacillus spps (Nacillus pro), during the pruning period, on the control of wood diseases (Diplodia spp) incidence and parasitism of pycnidia's, incidence of powdery mildew (Erysiphe necator), as well as incidence of gray rot (Botrytis cinerea) and parasitism in sclerotia. A field trial was established, with random blocks, with 5 replications by treatments, Control, pruning paste and chemical fungicides and winter biological, to foliage 24 hours post pruning and pruning debris. The results showed a significant effect (P< 0,05) of the treatments, both chemical (3.5%), and biological (0.5%) showed reduction damage to wood with respect to control (15.8%), only the biological showed a parasitism of pycnidia 73.4%, in Botrytis the control showed an 82.5% incidence, chemical 3.5% and the winter biological of 56.5% and 60% of sclerotia parasitism. In oidium, control 100% of incidence in clusters and 74% in leaves in veraison, while the chemical 5.2% in bunches, 1.2% in leaves, the biological reached 45% in clusters and 34% in leaves. This study shows the possibility to use biological control agents, in dormancy to reduce inoculum with significative effect in full season diseases.

P1.1-005

IN VITRO EFFICACY OF SOME PLANT EXTRACTS ON THE INHIBITION OF PECTOBACTERIUM CAROTOVORUM, THE CAUSATIVE AGENT OF BACTERIAL SOFT ROT

MIRZAEI Mahdi. (1), MIRZAIE Sara. (2)

(1) University of Tehran, Tehran, IRAN (ISLAMIC REPUBLIC OF); (2) Department of Agriculture, Iranian Research Organization for Science and Technology (IROST), Tehran, IRAN (ISLAMIC REPUBLIC OF)

Text

Pectobacterium carotovorum, is one of the most important and widespread bacterial pathogens of a variety of plant products in storage. The aim of the present study was to evaluate the efficacy of some plant extracts on Pectobacterium carotovorum in the laboratory conditions. For this purpose, flower, leaf and seed hydroethanolic extracts of cloves (Syzygium aromaticum), savory (Satureja hortensis) and fennel (Foeniculum vulgare) respectively were prepared. Overnight culture of Pectobacterium carotovorum (PTCC 1675) in nutrient agar was cultured into nutrient broth and standardized with 0.5 McFarlands. The minimum inhibitory concentrations (MIC) of the plant extracts were determined by a serial two-fold dilution method in 96- well plates. The plates were incubated at 25ºC for 48 h with the lid on. The wells were then examined for evidence of growth and MIC values were determined as the lowest antimicrobial concentration that inhibited visible growth of the test microorganism. Experiment was repeated two times. MIC value for the fennel and savory extracts was 1/32 while the value for clove extract was 1/16; hence, according to our results, fennel and savory showed stronger antimicrobial activity against Pectobacterium carotovorum as comparison with clove. These results in overall are promising to use some plant extracts as potential botanical tools to control microorganisms in plant and their products.

P1.1-006

INSIGHT OF THE BACTERIA COMMUNITIES IN THE PHYLLOSPHERE OF COFFEA ARABICA CATIMOR7963 ASSOCIATING WITH GEOGRAPHICAL DIFFERENCES

LI Le. (1), YI Kexian. (2,3,4), XIA Qianfeng. (1)

(1) NHC Key Laboratory of Tropical Disease Control/ Key Laboratory of Tropical Translational Medicine of Ministry of Education/ College of Tropical Medicine, School of Tropical Medicine, Hainan Medical University, Haikou, Hainan, CHINA; (2) Key Laboratory of Tropical Agriculture Pest Monitoring and Control, Hainan Province/ Environment and Plant Protection Institute, Chinese Academy of Tropical Agricultural Sciences, Haikou, Hainan, CHINA; (3) Sanya Research Institute of Chinese Academy of Tropical Agricultural Sciences, Sanya, Hainan, CHINA; (4) Hainan University, Haikou, Hainan, CHINA

Text
Coffee is one of the most important economic crops. Bacteria have been considered as the most abundant inhabitants of the phyllosphere while it is unknow for Coffea arabica Catimor7963, one of the main coffee cultivars in China. The objectives of this study were to reveal the status of the bacterial communities in the phyllosphere of Catimor7963 through sequencing by the Illumina HiSeq2500 of the 16S rDNA V4-V5 regions across 6 representative sampling sites located in the main cropping areas of China, including YN_HGGL, YN_ZFXH, YN_PE, YN_WS of Yunnan and HN_WN, HN_FS of Hainan. To the best of our knowledge, the current study revealed the status of the bacteria communities in the phyllosphere of Catimor7963 for the first time. The dominant family was Chloroplast norank followed with Mitochondria. PCoA based on Bray-Curtis dissimilarities displayed the differences of the phyllosphere bacteria communities were positively correlated with the geographical distances. RDA analysis of the alpha diversity index with geographical parameters demonstrated that the diversity and abundance of the phyllosphere bacteria communities in high altitude and high latitude were relatively higher than those in low altitude and low latitude. We aim to gain a better understanding of the biocontrol resources suitable for realizing ecological cultivation under different agroecological systems. Moreover, the ecological cultivation management should be adapted to the local conditions.

P1.1-007

A POTENTIAL BIOCONTROL AGENT FOR MANAGING POTATO COMMON SCAB IN TAIWAN

LIN Tsung-Chun. (1), HUANG Siang-Shan. (1), YU Ching-Shang. (1), CHEN Yi-Nian. (1), CHEN Chun-Wei. (1), SU Jiun-Feng. (1), HSIEH Ting-Fang. (1)

(1) Taiwan Agricultural Research Institute, Taichung City, TAIWAN

Text

Potato scab is widely distributed in major potato producing areas in the world, and can be transmitted through the infested soil and seed potatoes. Potato scab mainly harms the underground part of potatoes, and due to the properties of the soil are complicated, the effect of chemical pesticides on controlling potato scab is not good. This study developed a biocontrol agent (BCA) that can control potato scab. The naturally and artificially infested seed potatoes were used for preliminary field experiments. Both naturally and artificially infested seed potatoes were cut into pieces, coated them with wettable powder formulation of BCA (50-fold diluted with diatomaceous earth), planted them in the field, and then drenched them with suspension concentrate formulation of BCA (400-fold diluted with water). The results showed that drenching the naturally and artificially potatoes with BCA could reduce the diseased area of potato scab by 33.57 and 62.72% as compared with the control group, respectively. If the naturally and artificially potatoes coated with BCA alone, the diseased area of potato scab could be reduced by 7.99 and 47.3% as compared with the control group, respectively. In the future, if healthy seed potatoes can be used in conjunction with field sanitation to avoid discarding previously diseased potatoes in the field, the success rate of biological control of potato scab can be further increased.

P1.1-008

APPLICATION OF A BIOCONTROL AGENT FOR MANAGING ROOT-KNOT NEMATODE, MELOIDOGYNE GRAMINICOLA

LIN Tsung-Chun. (1), YU Ching-Shang. (1), HUANG Siang-Shan. (1), CHEN Yi-Nian. (1), CHEN Chun-Wei. (1), SU Jiun-Feng. (1)

(1) Taiwan Agricultural Research Institute, Taichung City, TAIWAN

Text

Most plant parasitic nematodes attack the underground parts of plants, and their life cycle can be completed in the soil. Because of the complex properties of soil, chemical pesticides are not effective in controlling plant parasitic nematodes. This study developed a biocontrol agent (BCA) that can control root-knot nematode (*Meloidogyne graminicola*) of green onion. The result of first preliminary field trial showed that treatment of green onion seedlings with 200-fold diluted BCA can reduce the nodulation rate by 65.5% as compared to the control group. The result of the second preliminary field trial showed that treatment of green onion seedlings with 200-fold and 400-fold diluted BCA can reduce the nodulation rate by 48.36% and 45.95% as compared to the control group, respectively. In addition, the effect of BCA on controlling *Meloidogyne incognita* of cucumber was evaluated in the greenhouse. Cucumber

seedlings treated with 200 and 400-fold diluted BCA can reduce the nodulation rate by 65.2% and 59.4% as compared to the control group, respectively. At present, there is no BCA registered for managing root-knot nematode in Taiwan. This study develops a BCA that is easy to mass-produce, has a long shelf life, and has a good effect on the control of root-knot nematodes. It will provide an alternative method to control the nematode diseases for organic and conventional farming in Taiwan.

P1.1-009

BACILLUS MEGATERIUM STRAINS ISOLATED FROM RHIZOSPHERE AS PROMISING AGENT FOR BIOSTIMULANTS

KIM Yangseon. (1)

(1) Center for Industrialization of Agricultural and Livestock Microorganisms, Jeongeup, REPUBLIC OF KOREA

Text

Global climate change affects plant growth deficiency and yield loss with abiotic stresses such as drought, salinity, greenhouse gases and extreme temperature. In this regard, it is necessary to develop biostimulants to enhance tolerance to abiotic stress, uptake nutrients and promote plant growth. The aim of this study is utilizing of plant growth promoting rhizosphere microorganism as microbial biostimulants. *Bacillus megaterium* GEB3 and GEB13 were isolated from the rhizosphere of ginseng and identified by sequencing 16S rRNA. GEB3 and GEB13 has been showed plant growth related activity such as nitrogen fixation, siderophore secretion, and indole-3-acetic acid production. In addition, rice seeds were treated with GEB3 and GEB13 culture solutions, and seed germination rates were measured by culturing the seeds under drought conditions of 0 Mpa, -0.15 Mpa, and -0.49 Mpa. In drought conditions, the seed germination rate was higher in the GEB3 and GEB13 treatment groups than in the microbial-free control group. In greenhouse, GEB3 and GEB13 were treated to rice seedlings under drought conditions. As a result, the chlorophyll content was 34.1 SPAD for GEB3 treatment and 33.4 SPAD for GEB13 treatment after 4weeks, which was significantly increased compared to the control value of 21.6 SPAD without microbial treatment. These results indicate that *B. megaterium* GEB3 and GEB13 can be used as biostimulants that promote plant growth and abiotic stress resistance in crop cultivation.

P1.1-012

A LAB TO LAND EXPERIENCE ON TRICHODERMA BASED TECHNOLOGY FOR BETTER PLANT HEALTH MANAGEMENT IN TRIBAL REGIONS OF NORTH EAST INDIA

DUTTA Pranab. (1)

(1) Central Agricultural University (Imphal), Umiam, INDIA

Text

Indigenous Trichoderma strains were isolated and characterized. Potential strains of

Trichoderma spp. effective against six soil-borne fungal phytopathogens identified through a series of studies. The mode of action of Trichoderma spp. was studied against the targeted phytopathogens. PGP, enzyme release activity, the ability for siderophore production, P and Zn solubilization, tolerance to Al and Fe toxicity, and compatibility with soil microbiome studies showed a positive result for better plant health management. Through a continuous effort of 15 years in different agroecological conditions of NER of India, standardized bio-intensive strategies and popularized among the farming communities. More than 5000 farmers, FPOs, extension personnel, and tea garden managers were trained on technical aspects of the technology and its field use. Technology adopters gained more profit due to the result of higher yield with nutritious farm produce. The farmers could fetch more income compared to the non-adopters and bankability increases. The success opens a hope that the technology may create a revolution among the farming communities of the nearby areas. Moreover, the low-cost technology has opened up a new vista for plant disease management and is likely to be a boon for seed industries that would like to provide protection to seeds as well as plants against a large number of seed, soil-borne, and foliar diseases.

P1.1-013

EVALUATION OF MULTI-BACILLUS STRAINS ON CONTROL OF SOUTHERN BLIGHT IN PEPPER

SRIPRASERT Kornkamon. (1), STRITONGKAM Benjapon. (1), **CHUNG Wen-Hsin. (1)**

(1) National Chung Hsing University, Taichung, TAIWAN

Text

Southern blight caused by Sclerotium rolfsii is a major fungal and soil-borne disease damaging the economic crops worldwide. The management of southern blight relies primarily on the strategic application of synthetic fungicides. However, chemical fungicides are responsible for environmental pollution, health hazards, pest resurgence, development of resistance in pathogens, destruction of non-target species, and deterioration of natural habitats. Here, endophytic Bacillus spp. were evaluated the efficacy on control of southern blight. Results revealed that R8-25, R8-43, and PS6-2 strains showed best ability against S. rolfsii isolates with 59.1% to 71.1% mycelia inhibition rate. Moreover, these three strains could produce volatile organic compounds (VOCs) to inhibit mycelia growth and sclerotia germination. Characteristics analyses indicated that the three strains have abilities secrete amylase, cellulase, gelatinase, protease, iturin A, bacillaene and IAA. For the seed germination and plant-growth-promoting tests, the strains R8-25 and R8-43 have the best efficacy to induce seed germination and promote bell/chili pepper growth in greenhouse. In the control test, single strains or mixture of R8-25 and R8-43 could reduce the severity of southern blight in bell pepper based on seed coating combined with drenching method in greenhouse, especially two strains mixture. According to these results, the two strains have the potential to be agents on control of southern blight.

P1.1-014

PRESENT STATUS, CHARACTERIZATION & BIOLOGICAL CONTROL USING NATIVE BACTERIAL STRAINS FOR DIEBACK & BLACK ROOT ROT DISEASES OF STRAWBERRY IN PAKISTAN

MEHMOOD Nasir. (1), RIAZ Abid. (2), SULTAN Sidrah. (3), GHUFFAR Salman. (4), AURANGZEB Wajid. (5), AZHAR Sohaib. (6)

(1) Rawalpindi Women University, Rawalpindi, PAKISTAN; (2) PMAS-Arid Agriculture University Rawalpindi, Rawalpindi, PAKISTAN; (3) Government Associate College for Women, Rahwali, Gujranwala , Gujranwala , PAKISTAN; (4) Vegetable Research Station, Sahiwal, Punjab, Pakistan, Sahiwal, PAKISTAN; (5) Agri-food and Forestry Systems-DIBAF, University of Tuscia, Italy, Tuscia, ITALY; (6) Ministry of Climate Change, Islamabad, Pakistan, Islamabad, PAKISTAN

Text

During 2017-18 and 2019-20 surveys were conducted in 12 strawberry-producing districts of Pakistan. Out of 12, 08 districts of Punjab province, 03 of Khyber Pukhtunkhwa province and Islamabad for disease assessment and samples collection. Mean % disease prevalence and incidence ranged from 0-100% and 5-8% for dieback whereas, 0-100% and 0-16% for black root rot (BRR) respectively. Dieback symptoms appeared as wilting and dieback with collapsing of the entire plant. The BRR appeared as black discolorations on entire root and plant look stunted and collapsed. Purified cultures were identified on morpho-molecular basis. Total of 30 Lasiodiplodia theobromae (dieback) and 47 of Rhizoctonia solani (21), Macrophomina phaseolina (11) & Fusarium solani (15) isolates of (BRR) were studied. Pathogens were by culturally & morphologically identified. For molecular studies, nucleotide sequencing of 20 highly pathogenic isolates (5 each of L. theobromae, R. solani, M. phaseolina & F. solani were done by ITS, TEF1-α & EndoPG primers & phylogenetically analyzed. This is 1st detailed study of these diseases in Pakistan. For biological control 30 native bacterial isolates were processed of which 3 isolates viz. Bacillus subtilis (1) and Pseudomonas fluorescens (2) showed the highest antagonistic effectiveness (>70%) against the dieback and BRR pathogens during bioassays. The selected bacterial isolates were further tested in the greenhouse and also showed promising disease control of 21-57%

P1.1-015

ISOLATION AND IDENTIFICATION OF PENICILLIUM CORYLOPHILUM AS ANTIBACTERIAL-PRODUCING FUNGI IN THE SOIL ENVIRONMENT OF KOYA PROVIN

IBRAHIM Rebeen. (1), **ZRARY Taha. (2)**

(1) Rapain University, Ranya, IRAQ; (2) Koya University, Koya, IRAQ

Text

The study was carried out to isolate and identify several fungi from Koya soil. (48) soil samples were collected from four different locations in Koya district. 6 fungal genera which include: *P. spp., Asp. spp., Rh. spp., Aur. spp., Cl. spp. and Dip. spp.* were isolated by used SDA, PDA, and MEA. Serial dilution plate method was used for isolation of soil fungi. the results, reveal that the most predominant genera and highest number of colonies were Pen. and Asp. sp.. the result showed that the of occurrence of Asp. and Pen. were very high among the fungal isolates . Different species of Pen. obtained from soil samples especially from Shewashok soil. The P. coryl had significant antagonistic activity against five out of six (G-) and (G+) pathogenic ATCC . P. coryl. from Shewashok location was the best isolate for antibacterial production and it had more antagonistic activity against pathogenic bacteria than the other Pen.spp. this isolate was used for antibacterial production. Ethanol solvent was used for the extraction of the antibacterial substances form

fermented P. corylm. The crude extract was dried in rotary evaporator , centrifuge at 35?C. The antibacterial obtained was highly effective against Y. enterocolitica and S. aureus. (GC-MS) was used for analysis of the fungal extract obtained from P. coryl. The result had determined thirteen compounds from crude extract . Some of these compounds have antibacterial activity against some pathogenic microbes .

P1.1-016

A BIOLOGICAL AGENT SERENADE FOR PROMOTING THE BANANA GROWTH AND MODIFYING RHIZOSPHERE SOIL MICROBIAL DIVERSITY AND COMMUNITY COMPOSITION

ZHENG Sijun. (1)

(1) Yunnan Academy of Agricultural Sciences, Kunming , CHINA

Text

Fusarium wilt of banana is becoming a serious challenge to the banana industry globally. Biological control is one of the most effective measures for this disease. In order to explore the biocontrol effects of a biological agent Serenade on banana plants, two different cultivars ‘Brazilian’ and ‘Yunjiao No.1’ were used in greenhouse pot experiments. Results showed that the plant height and pseudostem diameter of banana susceptible cultivar Brazilian increased by 11.68% and 11.94% respectively after Serenade application, while the plant height and pseudostem diameter of resistant cultivar Yunjiao No.1 increased by 14.87% and 12.51% respectively. The fresh weight of two cultivars increased by 20.66% and 36.68% respectively, these indicating that Serenade has positive effects on plant growth promotion. TR4 infection and Serenade application changed the bacterial community composition of two banana cultivars, and the fungal community composition of Yunjiao No.1 also changed significantly. Correlation analysis showed that the relative abundance of Bacillus and Pseudomonas in the rhizosphere of both cultivars increased significantly after Serenade application, which had significant positive correlation with plant height, psedustem girth, above ground fresh weight, leaf length and leaf width. Therefore, the outcome of this study suggests that Serenade could be used in banana field application for promoting plant growth and modification of soil microbial communities.

SIMPLICILLIUM AS THE DOMINANT MYCOPARASITES OF HEMILEIA VASTATRIX REVEALING REGIONAL GENETIC DIVERSIFICATION

LI Le. (1), YI Kexian. (2,3,4), TANG Tianle. (1)

(1) NHC Key Laboratory of Tropical Disease Control/ Key Laboratory of Tropical Translational Medicine of Ministry of Education, School of Tropical Medicine, Hainan Medical University, Haikou, Hainan, CHINA; (2) Key Laboratory of Tropical Agriculture Pest Monitoring and Control, Hainan Province/ Environment and Plant Protection Institute, Chinese Academy of Tropical Agricultural Sciences, Haikou, Hainan, CHINA; (3) Sanya Research Institute of Chinese Academy of Tropical Agricultural Sciences, Sanya, Hainan, CHINA; (4) Hainan University, Haikou, Hainan, CHINA

Text
?Coffee leaf rust (CLR) as one of the most devastated diseases of *Coffea arabica*, caused by the obligate fungal parasite *Hemileia vastatrix* (Hv). Mycoparasites frequently follow Hv in the field, interfering with the reproductive structures to stop further growth and dissemination of Hv, to offer a chance to potentially limit CLR. Here, we applied high throughput sequencing of the rDNA ITS1-ITS2 regions of coffee phyllosphere microbiota with 3 leaves symptoms (C, HV, PHV) across 6 sampling sites located in China coffee regions. Simplicillium was evaluated as the dominated mycoparasites of Hv in all the investigated populations through a series approach of metabarcoding analysis, revealing genetic diversity of associating with the geographic differences. At the 0.97 clustered threshold, 22 OTUs were 98-100% homologous to *Simplicillium* spp., of which, 11OTUs identified as *S. lanosoniveum*, 6 OTUs identified as *S. subtropicum*, others identified as *S. lamellicola, S. obclavatum* and *Simplicillium* sp. These sequences had 68 segregating sites and Pi of 0.05305. The MJ haplotype networks were built from a total of 17 haplotypes produced by 22 OTUs of *Simplicillium* spp. while divided into 2 groups, demonstrating great diversification with 0.996 Hd and 0.00023 VarHd and displaying genetic divergence with clear geographic patterns and leaf symptom selectivity. All in all, the current study is helpful for developing management biocontrol measures against CLR.

P1.1-018

POTENTIAL GROWTH SUPPRESSION AND BACTERIOSTATIC ACTIVITY OF PLANT-ASSOCIATED LACTIC ACID BACTERIA (LAB) AGAINST PANTOEA STEWARTII OF THE JACKFRUIT BRONZING DISEASE

JAFFAR Nur Sulastri. (1), JAWAN Roslina. (1), **CHONG Khimphin. (1)**

(1) Universiti Malaysia Sabah, Kota Kinabalu, MALAYSIA

Text
Pantoea stewartii subsp. stewartii is the causative agent of "Jackfuit Bronzing," an emerging disease in jackfruit crops (Artocarpus heterophyllus L.). The disease was first discovered in Malaysia in 2017, affecting the J33 variety, Tekam Yellow. This disease degrades the quality of fresh jackfruit, leading to economic losses, and has remained a serious problem for the Malaysian jackfruit trade. In this study, 58 lactic acid bacteria (LAB) isolated from fruits and vegetables were screened and characterized for their antagonistic potential against P. stewartii subsp. stewartii. Fourteen cell-free supernatants (CFS) of the LAB isolates were found significantly inhibit the growth of P. stewartii subsp. stewartii in vitro ($P<0.05$). They were morphologically, biochemically, and genetically identified and based on the 16S rDNA sequencing analysis, the 6 LAB isolates showing the greatest antagonism are Lactiplantibacillus pentosus, Lactiplantibacillus argentoratensis, Leuconostoc holzapfelii, Weisella cibaria and Weisella paramesenteroides. CFS of the 6 potential LABs was extracted using ethyl acetate, diethyl ether, dichloromethane, and n-hexane solvents to examine their bioactive metabolites qualitatively and quantitatively. Gas chromatography-mass spectrometry (GC-MS) and liquid chromatography-mass spectrometry (LC-MS) identification of the purified bioactive metabolites from the extract that possessed the greatest effect against P. stewartii subsp. stewartii will be presented.

P1.1-019

INDUCTION OF PEPPER RESISTANCE AGAINST PEPPER MILD MOTTLE VIRUS BY BACILLUS VELEZENSIS TREATMENT

CHENG Ying-Huey. (1), CHEN Chin-Chih. (2), LIN Feng-Chyi. (2), WANG Jau-Yueh. (2), LIN Mei-Ju . (2)

(1) Fengshan Tropical Horticultural Experiment Branch, Taiwan Agricultural Research Institute, Kaohsiung , TAIWAN; (2) Taiwan Agricultural Research Institute, Taichung, TAIWAN

Text

Pepper mild mottle virus (PMMoV), a member of genus Tobamovirus, is the major viral pathogen of peppers (Capsicum annuum L.) in Taiwan. Symptoms caused by PMMoV include various degrees of mottling and curling of leaves, distortion of fruit and dwarfing. PMMoV is a rigid rod shaped virus that can be easily transmitted via mechanical inoculation when primary inoculum was present. The primary inoculation of PMMoV is difficult to prevent because it often comes from contaminated cultivation media or seeds. In our study, Bacillus velezensis was tested as a biocontrol agent for inducing systemic resistance of sweet pepper against PMMoV under nethouse conditions. Foliar application and soil irrigation of B. velezensis was performed once a week when the seedlings germinated. Treatment and control sweet pepper plants were inoculated with PMMoV after 2 treatments. For challenge inoculation, diseased sweet pepper leaves were ground into 50 times (W/V) phosphate buffer, and the ground juice was mechanically inoculated on sweet pepper leaves. The virus infection and virus concentration were detected by ELISA. All control plants were infected with PMMoV, and only 40% plants in the B. velezensis treatment were infected by the virus, and the virus concentration was lower than control plants. In our results on sweet pepper, B. velezensis can be used as a biocontrol agent for induction of resistance against PMMoV or reduction of symptoms caused by this virus.

PROSPECTS FOR THE USE OF MICROBIAL PREPARATIONS TO PROTECT FRUIT CROPS FROM FIRE BLIGHT

SHEMSHURA Olga. (1), ISMAILOVA Elvira. (1), SADANOV Amankeldy. (1), ALIMZHANOVA Mereke. (1), MOLZHIGITOVA Asel. (1), BAIMAKHANOVA Gul. (1)

(1) LLP “Research and Production Center for Microbiology and Virology”, Almaty, KAZAKHSTAN

Text

Fire blight is a dangerous disease of fruit crops and causes enormous economic damage to fruit growing. The bacterium Erwinia amylovora, the causative agent of the disease, belongs to quarantine objects.

In order to reduce the spread of morbidity, screening of microorganisms isolated from garden cenosis of various regions of Kazakhstan was carried out against the causative agent of bacterial burn of fruit crops.

It was established that the MB-40 and 17M isolates showed the highest antagonistic activity against E. amylovora (the zones of pathogen growth inhibition were 48 mm and 30 mm,

respectively).
It was determined that acetoin and 2,3-butanedione produced by B. amyloliquefaciens MB-40, as well as lactic and acetic acids produced by L. plantarum 17, are the components responsible for the inhibitory activity against E. amylovora.
It has been shown that double application of the culture broth of strains B. amyloleguefaciens MB-40 and L. plantarum 17M, containing inhibitory components, protects fruit trees from bacterial burn by 70%.
The study of the virulence properties of the B. amyloliguefaciens MB-40 and L. plantarum 17 M strains showed that they are not pathogenic for warm-blooded organisms and can be used as the basis of biological preparations against bacterial burn of fruit crops.

P1.1-021

LECANICILLIUM AS THE PRINCIPAL NATURAL ENEMY OF HEMILEIA VASTATRIX DISPLAYING GENETIC DIVERGENCE WITH GEOGRAPHIC PATTERNS AND LEAF SYMPTOM PREFERENCES IN FIELD SETS

LI Le. (1), YI Kexian. (2,3,4), XIA Qianfeng. (1)

(1) NHC Key Laboratory of Tropical Disease Control/ Key Laboratory of Tropical Translational Medicine of Ministry of Education, School of Tropical Medicine, Hainan Medical University, Haikou, Hainan, CHINA; (2) Key Laboratory of Tropical Agriculture Pest Monitoring and Control, Hainan Province/ Environment and Plant Protection Institute, Chinese Academy of Tropical Agricultural Sciences, Haikou, Hainan, CHINA; (3) Sanya Research Institute of Chinese Academy of Tropical Agricultural Sciences, Haikou, Hainan, CHINA; (4) Hainan University, Haikou, Hainan, CHINA

Text

Hemileia vastatrix (Hv) Berk & Broome is one of the greatest threats to the global coffee industry causing coffee leaf rust (CLR). *Lecanicillium* can naturally parasitize rust pustules which is highlighted in the biological control of CLR. Here, we explore the genetic diversity of *Lecanicillium* spp. across the main coffee cropping areas of China through high-throughput sequencing of ITS1-ITS2 regions of rDNA in a series of complex leave field samples. At the 97% clustered threshold, 15 OTUs were 98–100% homologous to *Lecanicillium* spp. with Pi of 0.13356 and 187 segregating sites. These OTUs were classified as *L. lecanii, L. antillanum, L. muscarium, L. fusisporum* and *Lecanicillium* sp. They generated 15 haplotypes with Hd of 1.000 and VarHd of 0.00059 and constructed MJ haplotype networks. Populations from various sample sites showed distinct geographic trends in their haplotype diversity. The highest Pi?0.47886?and the highest VarHd?0.07407?presented in WN, while the genetic variants of FS and PE was not observed. MJ network based on the leave symptoms presented leave symptom preferences. Of which, 12 haplotypes presented in symptom HV with VarHd of 0.00116, and 9 haplotypes detected in symptom PHV with VarHd of 0.00274. Specific haplotypes were observed in HV and PHV. Our results demonstrated that it is essential to underline the need for strategies to forge alliances between various components to convert these biocontrol agents into workable commercial product.

REDUCTION OF PATHOGENS CAUSING FUSARIUM HEAD BLIGHT IN WHEAT GRAIN BY AUREOBASIDIUM PULLULANS STRAINS PRODUCING AUREOBASIDIN A

WACHOWSKA Urszula. (1), GIEDROJC Weronika. (1), PLUSKOTA Wioletta. (1), WACHOWSKA Agata. (1), STUPER – SZABLEWSKA Kinga. (1)

(1) University of Warmia and Mazury in Olsztyn, Olsztyn, POLAND

Text

Modern European agriculture increasingly relies on organic farming methods and ecological approaches, or conventional pesticides are partially replaced with biocontrol agents such Aureobasidium pullulans. Some strains of A. pullulans produce aureobasidin A, a cyclic antifungal peptide, catalyzed by an amino acid complex encoded by the aba1 gene. The aim of this field experiment, conducted in 2021 and 2022 in north-eastern Poland, was to select A. pullulans strains with the use of molecular markers linked to the aba1 gene, and to analyze the inhibitory effect of selected strains on trichothecenes concentrations in wheat grain. In 2021, all biological treatments reduced the severity of Fusarium head blight (FHB), and their effectiveness reached 62.6% (Ap CC2) and 57.1% (Ap 15). Wheat grain was contaminated with type-B trichothecenes: deoxynivalenol (DON), Fus-X, 3ADON, 15ADON, and nivalenol (NIV), and type-A trichothecenes: STO, HT-2 toxin, T-2 toxin tetraol, T-2 toxin triol, and diacetoxyscirpenol (DAS). Biological treatments involving a cell suspension of A. pullulans strain Ap 15 decreased the NIV content of grain from 11 mg/kg to 8 mg/kg in the first year of the study, and completely eliminated this mycotoxin from grain in the second year. When FHB severity was low, a A. pullulans treatments did not decrease DON concentrations in grain, although it reduced disease symptoms and the abundance of selected Fusarium species.

Text

ε-poly-L-lysine (ε-PL) produced by microorganisms has broad antimicrobial spectrum and good stability. miRNAs play an important role in various plant processes such as growth and development, defense stress and disease resistance. To investigate the antiviral mechanism of action of ε-PL in plants, we analyzed the expression profile of microRNA (miRNA) in tobacco mosaic virus (TMV)-infected *Nicotiana tabacum* after ε-PL treatment. The results showed that expression levels of 328 miRNAs were significantly altered by ε-PL. Some miRNAs were screened, and joint network analysis was performed on their target genes and gene-enriched GO/KEGG pathways. The results indicated that ε-PL regulates expression of miRNAs involved in pathways such as plant hormone signal transduction, host defense response and plant pathogen interaction, such as nta-miR6146, nta-miR1446 and nat-

miR319a. Subsequently, TRV-VIGS gene silencing method combined with the short tandem targets mimic technology were used to functionally analyze these miRNAs and their target genes. The results of northern blot and RT-qPCR showed that the accumulation of TMV in *N. benthamiana* were increased after silencing miR1446 and miR6146. Meanwhile, the silencing of miR172, miR164, and miR319 reduced the content of TMV, indicating that these miRNAs may play diverse roles during ε-PL- mediated antiviral responses. Collectively, these results provide theoretical basis for further elucidating antiviral mechanisms of ε-PL.

BIOLOGICAL SOIL CRUST MICROALGAE AS A NOVEL SOURCE FOR THE DEVELOPMENT OF BIOCONTROL AGENT

NAGENO Bernard. (1), ECKSTEIN Dikla. (1), **RAANAN Hagai. (1)**

(1) Agricultural Research Organization of Israel (ARO) - The Volcani Center, Gilat, ISRAEL

Text
Soil-borne pathogens pose a significant threat to crops globally, leading to significant economic losses. These pathogens can survive without a host by producing resting structures that are resistant to environmental stress and pesticides. Pesticides are toxic and their accumulation in soil and plants is dangerous to the environment and humans. Hence, researchers are focused on developing sustainable solutions such as biocontrol agents (BCA). However, the complex interactions between BCAs and the environment pose a challenge in developing effective solutions. Biological soil crusts (BSCs) are the natural cover of many arid and semi-arid lands. The microorganisms inhibiting BSCs developed unique mechanisms to survive harsh environmental conditions such as desiccation, heat, and radiation. Green algae isolated from desert crusts show a remarkable ability to withstand harsh environmental conditions. Surprisingly, it is also one of the fastest-growing phototrophs known. Preliminary results show that co-culturing this alga significantly inhibits the growth as well as the production and viability of resting structure in various soil-borne pathogenic fungi, including *Verticillium dahliae* and *Rhizoctonia solani*. The combination of fast-growing (i), resilience (ii), and the observed antifungal activity (iii) make it a promising candidate for the development of a BCA against soil-borne pathogenic fungi, specifically for arid and semi-arid regions and in the face of climate change.

FIGHTING LETTUCE BACTERIAL PATHOGENS WITH BENEFICIAL PSEUDOMONAS STRAINS

ZBORALSKI Antoine. (1), BIESSY Adrien. (1), CIOTOLA Marie. (1), CADIEUX Mélanie. (1), ALBERT Daphné. (1), FILION Martin. (1)

(1) Agriculture and Agri-Food Canada, Saint-Jean-Sur-Richelieu, CANADA

Text
Lettuce is a popular vegetable crop worldwide, accounting for a production value of more

than US$20 billion in 2020. It is threatened by several bacterial pathogens, including *Xanthomonas hortorum* pv. *vitians*, *Pseudomonas cichorii*, and *Pectobacterium carotovorum*. These pathogens cause bacterial leaf spot, varnish spot, and bacterial soft rot, respectively. Control methods are limited and often ineffective. It is therefore important to develop and implement novel, effective, durable, and low environmental impact control methods, such as biocontrol. With this in mind, we screened a collection of 1,200 *Pseudomonas* strains for their ability to inhibit the growth of the three pathogens under study. In total, 35 effective antagonistic *Pseudomonas* strains where identified. Their genomes were fully sequenced and annotated, revealing their phylogenetic affiliation and potential genetic determinants involved in their antagonistic activity. These *Pseudomonas* strains belong to 27 different species distributed among the *P*. *fluorescens* and the *P*. *putida* phylogenomic groups. Only 15 of these species have been described to date. The presence of genes involved in microbial competition and antibiosis, including the biosynthesis of pyochelin, type VI secretion systems, tailocins, and hydrogen cyanide, correlated with their inhibition abilities. Some of these strains show promise for the development of efficient biocontrol products against lettuce bacterial diseases.

Text

Soil salinity is a prevalent environmental stress in agricultural production. Microbial inoculants could effectively help plants to alleviate salt stress. However, there is little knowledge of the *Pseudomonas alcaliphila* Ej2 mechanisms aiding rice plants to reduce the adverse effects caused by salt stress. We performed integrated field and greenhouse experiments, microbial community profiling, and rice proteomic analysis to systematically investigate the Ej2 mechanism of action. We found an increase in shoot/root lengths and fresh/dry weight in inoculated plants under salt stress. In the meantime, the strain Ej2 has important roles in controlling diseases and promoting rice growth. Furthermore, the alpha diversity of Ej2-inoculated plants was higher than the control plants, expect the Shannon index of the bacterial microbiome. The Ej2 inoculated samples clustered and separated from the control samples based on beta diversity analysis. Importantly, the enriched and specific OTUs after Ej2 inoculation at the genus level were *Streptomyces*, *Pseudomonas*, *Flavobacterium*, and *Bacillus*. Moreover, we observed that Ej2 inoculation influenced the rice proteomic profile, including metabolism, plant-pathogen interactions, and biosynthesis of unsaturated fatty acids. These results provide comprehensive evidence that Ej2 inoculation affects the rice endophytic microbiome and proteomic profiles under salt stress.

Text

The rhizosphere microbiome is vital for maintaining plant growth/development and expressing resistance/tolerance responses to (a)biotic stresses. Plant growth-promoting rhizobacteria (PGPR) can confer resistance/tolerance on plants against stressed conditions, e.g., through liberating volatile organic compounds (VOCs). On the plant's side, plants employ root exudates as attractants to recruit root-associated beneficial microorganisms. Thus, artificial manipulation of plant-microbe interaction in the rhizosphere would be an efficient way to cope with various (a)biotic stresses. Yet, the remote crosstalk among VOCs emitted by a donor strain, microbiota, and plants and their root exudates have been challenging to unravel. The present study investigated the direct impact of VOCs emitted by the *Bacillus zanthoxyli* HS1 strain for boosting induced systemic resistance (ISR) and the indirect impact on plant nutrient uptake. Cabbage and cucumber seedlings exposed to bacterial VOCs showed ISR in infected leaves with phytopathogenic microbes. A split root approach revealed that bacterial VOCs change the root exudates composition, altered microbiome diversity, and increase nutrients uptake by plants. In conclusion, the study of the tripartite interaction among pathogen-infected plants, bacterial VOCs, and root exudates proposes a possibility that VOCs released by *B. zanthoxyli* HS1 modulate the microbiome and composition of root exudate to suppress pathogen attack and promote plant growth.

Text

Potential of consortial application of bioagents against fungal, bacterial and nematodes can be utilized to fullest extent by selecting most potential strains and not by arbitrary use of consortia. Cumin (Cuminum cyminum L.) is an important seed spices crop in India is majorly infected by Fusarium oxysoprum f. sp. cumini (Fusarium wilt) and aphid (Myzus persicae (Sulzer)).The multi-location field trials were conducted at Zone III A semi-arid eastern plain zone (Jaipur- Jobner) and zone IVB southern humid zone (Banswara)to evaluate the efficacy biocontrol agents and insecticide against major pests of cumin (Variety: RZ19) at two different agroclimatic conditions for the years of 2017, 2018 and 2019 rabi seasons. The combined application of biocontrol agents for the management of wilt of cumin by soil application with T. harzianum Th3 and M. anisopliae Ma1 enriched FYM (1:20). Seed

treatment with Th3 and Ma1 @ 8g/kg seeds also drenching at 30 and 60 days after sowing and three foliar spray with Flonicamid at 0.015 % clearly shows the maximum reduction of disease (62.16%) compared to control and also maximum yield of 570.94 kg/ha at Jaipur agroclimatic conditions. The maximum disease reduction of 60.22 per cent and increased yield up to 541.50 kg/ha was observed at Banswara agroclimatic conditions. Based on the bliss independence hypothesis, the synergy factor was >1 (1.01) which demonstrated the interaction was synergistic in both pests of cumin.

P1.1-029

CONTROL OF ANTHRACNOSE AND THRIPS IN CUCUMBER BY BACILLUS SUBTILIS WITH PRODUCTION OF VOLATILE COMPOUNDS

Text

Cucumis sativus L. is one of the most important vegetables worldwide. Cucumber anthracnose caused by *Colletotrichum orbiculare* can incite anthracnose symptoms on leaves, stems and fruits causing serious yield loss. *Thrips palmi* not only causes damage by sucking, but also transmits Tospovirus virus diseases. Here, we aimed to evaluate the potential of *Bacillus subtilis* for controlling cucumber anthracnose and thrip's population, and to reveal potential mechanism in plant health management. *B. subtilis* WMA1 and *B. subtilis* 151B1 were isolated in native Taiwan. Both strains showed antagonistic activity to *C. orbiculare* COC3 by dual culture assay. Application of culture broth of either *B. subtilis* WMA1 or *B. subtilis* 151B1 exhibited preventive and curative efficacy against cucumber anthracnose. Culture filtrates of *B. subtilis* WMA1 and *B. subtilis* 151B1 inhibited conidial germination of *C. orbiculare* COC3 to 26.7 and 22%, respectively, compared to 70.7% of the SYB medium control. Additionally, both *Bacillus* strains promoted the growth of cucumber seedlings, inhibited the mycelium growth of *C. orbiculare* COC3, and reduced oviposition and modulated the development and reproduction of thrips, which may be due to the volatile compounds produced by *B. subtilis* WMA1 and *B. subtilis* 151B1. Our findings suggested that *B. subtilis* strains WMA1 and 151B1 exhibited potential for the control of cucumber anthracnose, and significantly reduced the fecundity and development rate of thrips.

Text

During 2006 to 2007, cucumber (*Cucumis sativus* L.) was infected by melon yellow spot virus (MYSV) with symptoms of mosaic, yellow and necrotic spots on the leaves, and transmited by melon thrips. So, the viral disease control mainly on preventing vector by insecticides. On this study, we develop a system to screen induced resistance microorganisms for cucumber virus disease control. Among 130 microorganisms, 23 exhibited good proteolytic activity with cleared more than >2.0 cm zone on milk agar plate. Bioassays of induce resistance to viral disease was conducted on indicator host quinoa (*Chenopodium quinoa*) and zucchini yellow mosaic virus (ZYMV). After spreading the lower five leaves with the culture filtrate of the above-mentioned microorganisms for 4 hours, the upper five leaves were inoculated with freshly prepared ZYMV inoculum. The local lesions were account at 7 days post inoculation (dpi). Results showed that *Bacillus velezensis* (B34) and *Bacillus* spp. (FYC14) is effective in inducing plant resistance. In vivo screening of endophytic, *B. velezensis* was selection for MYSV control in screenhouse cucumber. The results showed an approximately 47% reduction in disease incidence compared to the control after 4 weeks of planting and a 22% increase in total cucumber yield. In summary, *B. velezensis* is effective control with ability to cleave proteins, induce plant resistance, promote plant growth and endogenously. So far, the molecular mechanism is still under investigation.

Text

The present investigations were carried out to assess the interaction of rhizobacteria and target pathogen in soybean ecosystem at Molecular Genetics Lab,UAS,Dharwad to gain the insights into molecular basis of host-pathogen interaction during 2022. Defence related genes were analysed for their expression levels in response to pathogen (Sclerotium rolfsii Sacc.) and rhizobacterial isolates (AUUB209 Streptomyces enissocaesilis and AUDT626 (Streptomyces racemochromogenes) through quantitative real time polymerase chain reaction. A total of five defence related genes viz., Pathogenesis related protein 1 (PR 1), Pathogenesis related protein 2 (PR 2),Pathogenesis related protein 2 (PR 10), Polyphenol oxidase (PPO) and Chalcone synthase (CHS) were selected and analysed for

their expression levels under different treatments where rhizobacteria were applied as seed treatment (10g/kg seeds) and drenching at 35-40 days after sowing. The results revealed that the highest expression levels of PR 1 (2.75 fold),PR 2 (7.88 fold), PR 10 (4.16 fold) and PPO (8.50 fold) observed in the treatment (Host + Pathogen + AUUB 209 + AUDT 626) and the highest (3.27 fold) CHS gene expression was recorded in the treatment (Host + AUDT 626). The positive check (Host + Pathogen + Trichoderma harzianum) recorded 2.42, 5.74, 4.15, 6.33 and 1.34 fold change of PR 1, PR 2, PR 10, PPO and CHS genes respectively.This is the first report on rhizobacteria and root rot pathogen interaction in soybean in India.

Text

Haematococcus pluvialis is a unicellular freshwater microalga cultivated industrially to produce astaxanthin, a sought-after antioxidant for nutraceutical and feed industries. Its mass culture is hindered by the fungal pathogen *Paraphysoderma sedebokerense* (Blastocladiomycota)[1,2]. The complex life cycle of this fungus and its resistance to most disinfection methods lead to a difficult control of the disease. Like for plants, there is increasing evidence that the algal microbiota plays a role for host health, including defense against pathogens[3]. To investigate the potential protection of *Haematococcus* by its bacterial microbiota against *P. sedebokerense* we combine metagenomics with a culture-based approach where we isolate the cultivable bacteria and prepare axenic algal strains. We show first results of our metagenomic analysis of the *Haematococcus* spp. microbiome in presence or absence of *P. sedebokerense*, revealing insights into the taxonomic diversity and potential functions of bacteria linked to fungal infection. These results guide us in choosing bacteria from the cultivable microbiota which are re-inoculated on axenic algae with or without the pathogen *P. sedebokerense*. First results of the impact of these synthetic bacterial communities on the alga-fungus interaction are shown. Altogether, this work allows to set the bases for development of biocontrol tools in industrial *Haematococcus* production.

CHARACTERIZATION OF THE MODE OF ACTION OF A BIOCONTROL PRODUCT THROUGH THE PATHOSYSTEM TOMATO MICRO-TOM AND PHYTOPHTHORA INFESTANS

PENAUD Valentin . (1,2), ALAHMAD Abdel-Rahman. (1), BERNARDON-MERY Aude. (2), LAVAL Karine. (1), GAUTHIER Adrien. (1)

(1) Institut Polytechnique UniLaSalle , Mont-Saint-Aignan , FRANCE; (2) GAIAGO SAS, Saint-Malo, FRANCE

Text

The tomato is the most consumed fruit in France and in the world. Among the different diseases affecting tomatoes and potatoes, the late blight caused by the oomycete, *Phytophthora infestans*, is one of the most devastating pathogens. The oomycete causes significant yield losses, involving the repeated use of phytopharmaceutical products harmful to the environment and public health. In order to reduce the use of pesticides, the use of biocontrol agents is one of the possible alternatives for crop protection.
In this context, my research project aims to characterize the mode of action of a biocontrol product (GA342) developed by the company Gaïago in order to improve its effectiveness against the late blight, using the pathosystem *Phytophthora infestans* (A36_A2 strain) - Micro-Tom, model cultivar for tomato. Preliminary results showed that 1) GA342 had a direct effect on the oomycete, decelerating or inhibiting totally the mycelial growth, in a dose dependent manner; 2) in planta, the treatment with GA342, prior to the infection, showed to reduced significantly the symptoms. The results of further studies will be presented on the direct effect of GA342 and more particularly on sporangia, zoospores and mycelia. In addition, targeted transcriptomic and biochemistry approaches in planta will be shown.
The promising results related to the action mode of GA342 will allow us to optimize the efficiency of the product for field application.

P1.1-034

CHARACTERIZATION AND IDENTIFICATION OF FUSARIUM SPP. SPECIES THAT AFFECT ORANGE CROPS (CITRUS X SINENSIS L.) IN CHILE

GARZÓN NIVIA María Alejandra . (1), MÁRTIZ Johanna . (1), VALDÉS Héctor . (1)

(1) Pontificia Universidad Católica , Santiago , CHILE

Text

In Chile, there are a few studies about the etiology and level of damage caused by *Fusarium* spp. species in citrus. Among the symptoms described in literature caused by these pathogens are foliar chlorosis, epinasty, dry root rot, wilting, branch dieback, and decreased growth. Most of these symptoms have been observed during the last years in commercial citrus orchards in the central region of Chile. For this reason, this study aims to identify morphologically and molecularly *Fusarium* species that affect orange trees in Chile. Therefore, from three orange commercial orchards of "Lane late" and "Fukumoto" cultivars, twelve *Fusarium* isolates were obtained, which were identified as *F. solani* and *F. oxysporum.* These isolates were characterized by yellow to purple colonies and the micro and macroconidia were organized in false mucilaginous heads. The pathogenicity tests carried out

on eight-month-old plants of the Robidoux rootstock confirm that the two identified *Fusarium* species colonize the root and generate necrosis after eight months of evaluation. However, no significant symptoms have yet been evidenced in the canopy. Only plants inoculated with *F. solani* grew 11% less than the control during a nine-week evaluation period. For this reason, plant growth measurements continue in order to demonstrate the pathogenicity level of these species on orange trees. The previous results are promising and will allow the evaluation of *Fusarium* biocontrol strategies in orange orchards.

(1) Federal University of Mato Grosso, Sinop, BRAZIL; (2) Fasipe, Sinop, BRAZIL

Text

Fungi are the main decomposers of nature. They can live in different environments, especially in the soil, live in decaying organic matter. Also collaborate to renew and recycle materials, playing a very important role in sustainable development. Studies on conidial fungus saprobes in tropical areas are developed mainly in South America. Amazon region is considered to have the greater biodiversity of species with great relevance in the medical and economic areas, highlighting the possibility of new biocontrol agents and resistance inducers. The objective of this study was to determine the potential of the saprobic conidial fungi of the Amazon region in control of *Colletotrichum truncatum*, *C. musae*, *Fusarium udum*, *Fusarium* sp., *Aspergillus clavatus*, *Sclerotinia sclerotiorum* and *Rhizoctonia solani.* For this, we used the conidial fungi *Beltrania rhombica*, *Brachysporiella* sp., *Dictyochaeta* sp. and *Gonytrichum* sp. In the pairing test and evaluation through the note scale proposed by Bell et al. (1982). It was verified that in the direct comparison, there was a significant interaction, and the conidial fungi studied showed different degrees of growth inhibition of *A. clavatus*, *C. truncatum*, *C. musae* and *F. udum*, with scores of 1 to 2, being very efficient and efficient, showing promising antagonists to phytopathogens. We concluded that the saprobic conidial fungi studied have potential in the control of phytopathogens, and these relationships should be better studied.

Text

Soybean (*Glycine max*) is one of the main crops globally, but various diseases, such as Anthracnose (*Colletotrichum truncatum*) and root rot (*Fusarium* spp.), have a significant impact on grain yield and quality. Traditional control strategies rely mainly on chemical fungicides, but the emergence of fungicide-resistant pathogen strains requires a new approach. Biocontrol methods with a focus on sustainable agriculture have gained attention, particularly the use of the genus *Streptomyces*. Despite numerous studies on crops and biotic stress, research on the immune response to environmental and biological stress is limited. Our previous studies found that *Streptomyces bacillaris* S8 and *S. globisporus* SP6C4 exhibit excellent antifungal and antibacterial activities and suppress plant diseases. In this study, we aim to demonstrate the feasibility of using these strains as biological control agents. Genome sequencing revealed the presence of antibiotic-producing gene clusters in SP6C4 and S8. To verify the antifungal properties of these clusters, CRISPR/Cas9 was used to create biosynthesis knockout mutants. Results showed that the mutants lost antifungal activity against the Anthracnose and root rot pathogens. These findings demonstrate the potential of *S. bacillaris* S8 and *S. globisporus* SP6C4 as biocontrol agents, warranting further research in this field to promote sustainable disease management in soybean crops.

Text

During the noble rot (NR) process not only *Botrytis cinerea* but the complex interaction dynamics of other filamentous fungi and yeasts play a role enabling the production of botrytized wines. Metatranscriptomic data was analyzed from healthy berries (H) and berries representing the four NR phases (I-IV) from the Tokaj wine region in Hungary over three months. Since a previous, DNA metabarcoding study has indicated that the most abundant fungal genera in NR grape berries are the filamentous fungi belonging to the genera *Alternaria*, *Botrytis*, *Epicoccum* and the yeasts *Aureobasidium* and *Rhodotorula*, RNAseq reads were aligned to the reference genomes *Alternaria alternata*, *Botrytis cinerea*, *Epicoccum nigrum* and *Aureobasidium pullulans* and *Rhodotorula graminis*. The main antagonistic strategy for B. cinerea is by means of reactive oxygen species (ROS) synthesis, but it also degrades complex carbohydrates, making nutrients available for the rest of the microbiome. For *E. nigrum*, *A. pullulans* and *R. graminis*, the main antagonistic and synergistic interaction strategy is by competing for and liberating nutritional resources respectively. *A. pullulans* and *R. graminis* express genes involved in alcohol biosynthesis, which has an antagonistic effect on filamentous fungi. *A. pullulans* also expresses genes involved in sulfate biosynthesis, but this

appears to be countered by *E. nigrum* which synthesizes enzymes which lower the sulfate concentration.

DETERMINING THE MICROBIOTA CONTRIBUTION ON CROP PERFORMANCE BY COUPLING IN SITU AND IN VITRO APPROACHES

KEMMERLING Rosa. (1)

(1) INRAE- l'Institut national de recherche pour l'agriculture, l'alimentation et l'environnement, Le Rheu Cedex, FRANCE

Text
The negative impact of chemical inputs used in agriculture on the environment and human health calls for the development of more sustainable agricultural managements. Recent studies have highlighted that host-associated microbial diversity has an effect on plant resistance to biotic stresses. Biological processes related to this adaptation include microbiota-pest interactions (competition, antagonism, parasitism) and/or modulation of plant immunity. The objective of the presented work is to use microbiota-pest interactions to estimate Synthetic Microbial Communities (SynComs) composed by bacterial and fungal strains with protective effects on crops against a pathogen. The study focuses on two different pathosystems: Rhizoctonia solanii infecting Brassica napus and Fusarium graminearum infecting Triticum aestivum. During this congress, I propose to present the first results obtained during my PhD program. A microbial collection has been established and characterized to identify the microbiota of the two crops grew under contrasted agronomic and pedoclimatic conditions in France. The first SynComs could be formed quickly to be able to do in vitro tests on B. napus in the presence of R. solanii. These results could be presented at the congress in August.

STUDY ON PHENOLIC SUBSTANCES IN POPLAR ANTHRACNOSE

ZHANG Linxuan. (1)

(1) Beijing Forestry University, Beijing, CHINA

Text
Phenolic substances are one of the important secondary metabolites of plants, which are of great significance in the resistance to the infection of pathogens and metabolic regulation. The early symptoms of poplar anthracnose are the oxidative allergic reactions of phenolic compounds, indicating that phenolic compounds play an important role in the occurrence and development of poplar anthracnose. Therefore, we determined the concentrations of phenolic compounds and their antifungal activities in three poplar species. The results showed that: (1) Three poplar species showed different resistance to poplar anthracnose: P. canadensis was resistant, P. tomentosa was susceptible, and P. beijingensis showed intermediate resistance; (2)This study selected 11 phenolic secondary metabolites with large difference and high content from three poplar species before and after inoculation. The results showed that these 11 substances showed different degrees of effects. Most of the

substances showed the lowest and highest concentrations to inhibit the growth of pathogen, while the intermediate concentrations promoted the growth of pathogen; (3) The kinds and content of phenolic substances in P. tomentosa are low, but P. tomentosa show resistance in the field. Therefore, we believe that phenolic substances do not play a major role in the interaction between P. tomentosa and Colletotrichum gloeosporum, but other structures, such as waxy layers, are important in antifungal activities.

HARNESSING THE INNER BEAST: DEVELOPMENT OF BIOCONTROL AGENTS FOR SWEET ACACIA (VACHELLIA FARNESIANA)

LIMBONGAN Amelia. (1,2), YOUNG Anthony. (2), CAMPBELL Shane. (2), GALEA Victor. (2)

(1) Musamus University, Merauke, INDONESIA; (2) University of Queensland, Gatton campus, Gatton, AUSTRALIA

Text

Sweet acacia (*Vachellia farnesiana*) is a woody weed in Australia requiring Integrated Pest Management. Prospective biocontrol agents were sought among diseased plants from north and central Queensland. Symptoms were documented, samples collected, and stems were prepared for isolation using ½ strength Potato Dextrose Agar. Internal Transcribed Spacer sequencing and phylogenetic analysis revealed 53 fungal strains, several of which are undergoing formal description. Several isolates were also pathogenic on sweet acacia seedlings and were selected for use in a field study aimed to investigate the interaction between the fungi and a stress enhancer, glyphosate. The fungal inoculum was encapsulated and implanted into stems, while several were encapsulated with a sub-lethal dose of glyphosate. Untreated control and encapsulated glyphosate applications were included for comparison. All fungus-only and fungus+glyphosate treatments displayed significant stem lesions compared to control and glyphosate-only treatments. However, the canopy recovered and it is concluded that glyphosate addition did not increase fungal infection of sweet acacia within the year-long trial period. Investigation of these treatments is still ongoing to evaluate their long-term effect on sweet acacia. Further study on incorporating these isolates and investigating their pathogenicity as a potential biocontrol agent is also ongoing, particularly for the long-term management of sweet acacia.

ACTION OF PYTHIUM OLIGANDRUM ON GRAPEVINE TRUNK DISEASES AND ITS IMPACT ON MICROBIAL COMMUNITIES

LOPEZ Séverine. (1), CHATAIGNER Alexandre. (1), DUFOUR Marie-Cécile. (1)

(1) INRAE, Bordeaux Sciences Agro, ISVV, SAVE, Villenave-D'ornon, FRANCE

Text

Grapevine trunk diseases (GTD) have become a major concern in viticulture. Since the ban in 2001 of sodium arsenate, the use of alternative methods, such as biocontrol, has become

a major issue. Among the promising microorganisms, the oomycete *Pythium oligandrum* is known to improve the plants health by increasing their natural defenses and reducing diseases to up than 40%.
The BIOBESTicide project, funded by the European Commission, aims to industrialize the production of a biopesticide solution to fight GTD. Efficiency evaluation of the product formulated from *P. oligandrum* will be carried out, and the environmental impact of this solution will be assessed.
Thus, an experiment was carried out in greenhouse for assessing the impact of the biopesticide on microbial communities by a high-throughput sequencing approach. Vines were treated with a *P. oligandrum* formulation and were inoculated with a fungus involved in Esca disease: *Phaeomoniella chlamydospora*. A three-month follow-up was carried out with samples from wood and rhizosphere environment to allow the evaluation of potential changes on microbial communities, whether as part of grapevine trunk disease or after the action of *P. oligandrum*.
The results obtained revealed that the biopesticide acts efficacy against *P. chlamydospora* with a reduction in the size of induced necrosis. Moreover, it had few effect on the rhizosphere microbial communities, which may suggest that the biopesticide is environmentally safe.

Text
Fusarium Head Blight is a devasting disease in cereals caused mainly by *Fusarium* spp. (Fspp). Despite being primary inoculum sources, soil and crop residues have been less studied than grains. Knowledge of the diversity and dynamics of microbiota and Fspp populations in these compartments is relevant to elaborate efficient biocontrol strategies. Six min-till wheat fields were thus monitored for two years, with soil, maize residues, and wheat grains collected at four stages, before metabarcoding using 16S, ITS2, EF1α markers, and qPCR using Fspp-specific primers. *F. graminearum* (Fg) and *F. avenaceum* were dominant in both grains and residues. Despite similar Fspp loads in residues in both years, grains of 2021 were more severely infected than in 2022, most probably because of less conducive conditions (drier and hotter) at flowering for Fspp. Following metabarcoding, co-occurrence network analyses revealed significant negative correlations between Fg and *Epicoccum nigrum* as well as *Sphingomonas* sp.. In parallel, a collection of 1670 bacterial and fungal isolates from collected samples was built using two methods (culture on classical media or after confrontation with Fg using the double layer method). High throughput screening of their anti-Fg activities on wheat grain-based medium, followed by a taxonomic identification of positive isolates, is in progress and shows a high prevalence of *Trichoderma* spp. in soil, while *Epicoccum* spp. have also been found but to a lesser extent.

Text

The subtropical race 4 of *Fusarium oxysporum* f. sp. *cubense* (*Foc*-STR4) causes Panama disease in bananas crops of the Canary Islands. Hitherto, there is no effective control methods, thus the selection of biological control agents from the native microbiota could help to find a sustainable solution. Our objectives were: to analyse the diversity of biocontrol genes in the native Trichoderma collection and to evaluate the in vitro biocontrol capacity on *Foc*-STR4. Rhizospheric soil of infected and healthy plants were collected in 14 farms of Tenerife. It was obtained 109 isolates of the genus *Trichoderma*, in which 12 species were identified by phylogenetic analysis of the tef1 gene. Specific primers were designed to detect 9 genes involved in the biocontrol process: proteases (*p6281, tvps1)*, glucanases (*bgn13.1, glyc, lam1.3, egl1*), chitinases (*tv-ech1, 42-kDa, chit36Y*). Showing that 55.5 % of the isolates have genes involved in protease synthesis and most of them belong to the *Harzianum-Virens* lineage. In relation to glucanases (39.2% positive isolates) and chitinases (21.4% positive isolates), most of them belonging to the *Longibrachiatum* (glucanases) and *Trichoderma* (glucanases and chitinases) lineages. In vitro biocontrol tests were carried out in a Petri dish with PDA, evaluating the inhibitory capacity of *Trichoderma* isolates against *Foc*-STR4. Obtaining a percentage of Foc-STR4 inhibition up to 35 %, demonstrating the biocontrol potential of the native strains.

Text

Ralstonia solanacearum causes disease in more than 200 plant species including bacterial wilt of tomatoes and brown rot of potatoes. This bacterium is part of the EPPO A2 list of quarantine pathogens due to its soilborne and waterborne nature, worldwide distribution and lack of effective control measures. The use of bacteriophages as biocontrol agents is promising, as they exhibit high specificity to individual bacterial species, and do not affect eukaryotic cells. However, one aspect of the use of phage should not be underestimated: the

quick ability of the bacteria to become resistant to the phage. This often leads to a trade-off, whereby in becoming resistant, bacteria lose virulence. This may be exploited to reduce the overall pathogenicity of *Ralstonia* populations, and can also help us to better understand plant-pathogen interactions. We have successfully identified phages which are effective at controlling *R. solanacearum*, and are now focused on understanding the transcriptome response of a susceptible tomato cultivar over time when inoculated with either a virulent ancestral strain, in-vitro evolved strains (non-virulent), or an ancestral strain plus phage treatment, which models co-evolution in the soil. The transcriptomic analysis reveals that there are clear differences in the immune response of the plant in each of the treatments. This work sheds light on the key genes activated in susceptible plants when phage resistance mutations occur in the bacteria.

EFFICACY OF BIOPESTICIDE LIFEGARD® WG FOR CONTROLLING PLASMOPARA VITICOLA AND ERISIPHE NECATOR IN EUROPEAN GRAPEVINE (VITIS VINIFERA)

PAUL Angela. (1), COMBS David. (1), WILCOX Wayne. (1), GOLD Kaitlyn. (1)

(1) Cornell Agritech, Geneva, UNITED STATES

Text

Fungicides are critical for modern grapevine (Vitis vinifera) production, but overuse has undeniable financial, environmental, and pathogen resistance consequences. This has led to a growing interest in biopesticides; however, it is yet unclear how best to integrate them into management programs. We conducted a metastudy of 7 years (2016-2022) of trial reports from the Cornell Pathology Vineyards (Chardonnay & Chancellor) in Geneva, NY to evaluate LifeGard® WG (Bacillus mycoides isolate J; BmJ) efficacy against grapevine downy mildew (Plasmopara viticola) and powdery mildew (Erysiphe necator). Disease incidence and severity was measured on leaves and clusters using the Horsfall-Barratt scale at harvest. We found that treatments containing LifeGard (e.g. alone, tank mix, or rotation), provided significantly greater protection compared to untreated control for both diseases. Generally, LifeGard provided better cluster control than foliar control. As expected, conventional materials provided more control than LifeGard when used alone, however, LifeGard provided exceptional control, beyond the commercial standards, when used in rotation. Overall, we find that integrating LifeGard into vineyard disease management can reduce conventional chemistry use while maintaining effective control. From these results, we speculate that increased biopesticide adoption can lengthen the useful life of highly effective yet resistance-prone fungicides by reducing resistance development pressure.

P1.1-047

RESPONSE OF CUCUMBER PHYLLOSPHERE MICROBIOME TO THE APPLICATION OF SYNTHETIC AND ENVIRONMENTALLY FRIENDLY FUNGICIDES IN MANAGING POWDERY MILDEW

WU Ping-Hu. (1), CHANG Hao-Xun. (1), SHEN Yuan-Min. (1)

(1) National Taiwan University, Taipei, TAIWAN

Text

Reducing the use of synthetic fungicides and implementing environmentally friendly alternatives are pivotal to achieving sustainable agriculture. However, the impact of these environmentally friendly fungicides on plant microbiomes has received limited attention. This study compared the effectiveness of two environmentally friendly fungicides (neutralized phosphorous acid (NPA) and sulfur) and one synthetic fungicide (tebuconazole) in controlling powdery mildew in cucumber. The differences in the phyllosphere microbiome are analyzed using high-throughput amplicon sequencing methods. The results showed that all three fungicides significantly reduced disease severity and the incidence of powdery mildew. However, while the α-diversity showed no significant differences of the phyllosphere microbial communities among treatments, tebuconazole had a significantly impact on the fungal community, as revealed by β-diversity analysis. The differential abundance analysis showed that tebuconazole altered the phyllosphere fungal composition by reducing the abundance of fungal OTUs, primarily from the Dothideomycetes and Sordariomycetes groups, which include potentially beneficial endophytic fungi. In contrast, NPA and sulfur had minimal effects on the phyllosphere fungal microbiome compared to the control. These findings indicated that the use of NPA and sulfur can effectively control powdery mildew while having fewer impacts on the phyllosphere fungal microbiome compared to tebuconazole.

GROEL PROTEIN FROM THE POTENTIAL BIOCONTROL AGENT RHODOPSEUDOMONAS PALUSTRIS ENHANCES RESISTANCE TO RICE BLAST DISEASE

CHEN Yue. (1), WU Xiyang. (1)

(1) Institute of Plant Protection, Hunan Academy of Agricultural Sciences, Changsha, CHINA

Text

GroEL, which is a chaperone, plays a key role in maintaining protein homeostasis and, among other functions, serves to prevent protein misfolding and aggregation. In addition, the GroEL protein also has a significant effect on enhancing plant resistance and inhibiting plant diseases. However, the function of the GroEL protein in the inhibition of rice blast remains unknown. Field experiment results show that photosynthetic bacteria PSB-06 have a good control effect on M. oryzae. PSB-06 also can promote rice growth and enhance the stress resistance. A GroEL protein which was separated and purified from photosynthetic bacteria had a significant antagonistic effect on appressorial formation and pathogenicity of M. oryzae, meanwhile transcriptional analysis demonstrated that the GroEL protein could improve the expression of defense gene of rice. Our results show that the photosynthetic bacteria Rhodopseudomonas palustris significantly controls rice blast disease. Its action involves an extracellular GroEL protein, which inhibits appressoria formation, antagonizes the pathogenicity of Magnaporthe oryzae and promotes a host defense response. The research results provide evidence of the potential of this photosynthetic bacterium as biocontrol agent at least for rice blast control.

MANAGEMENT OF ALMOND CANKER DISEASES WITH THE BIOCONTROL AGENT TRICHODERMA ATROVIRIDE STRAIN SC1 IN CALIFORNIA.

JAIME FRIAS Rosa. (1), TRAVADON Renaud . (2), HERNANDEZ Alejandro Ivan. (2), TROUILLAS Florent Pierre . (1)

(1) University of California Davis, Parlier, UNITED STATES; (2) University of California Davis, Davis, UNITED STATES

Text

Almond is the most extensive crop in California producing about 80% of the world production. Canker diseases caused by *Botryosphaeriaceae*, *Ceratocystis destructans* and *Eutypa lata* are the main limiting factor for almond production in California. Currently, management of canker diseases relies mainly on chemical treatments, which constitute a concern for environmental contamination in California. The efficacy of the biocontrol product Vintec (*Trichoderma atroviride* SC1) and benefits a spreader-sticker adjuvant to protect almond pruning wounds from infection by canker pathogens was evaluated using different spray application technologies [Solo 425 4-gallon backpack sprayer (Solo®); 25-gallon brushbuster spot sprayer Ag Spray Equipment and 100-gallon Pak-Blast air blast sprayer (Rears Manufacturing)]. Vintec treatments were compared to a water control and the chemical fungicide thiophanate-methyl. All treatments were applied on fresh pruning wounds 24 hours prior to inoculation with 100 µl of a spore suspension (1×104 spores/ml) of the fungi *Botryosphaeria dothidea*, *Neofusicoccum parvum*, *E. lata* and *C. destructans*. Results indicated that the efficacy of *T. atroviride* SC1 to protect pruning wounds was greater or equal to that of Thiophanate-methyl for *E. lata* and *Botryosphaeriaceae* fungi. Wound protection was improved when Vintec was amended with a spreader-sticker adjuvant and using the Solo 425 backpack sprayer and the brush spot sprayer.

P1.1-051

EFFECT OF ADDITIONAL ARBUSCULAR MYCORRHIZAL FUNGI (AMF) APPLICATION INTO PLANTING HOLE FOR GANODERMA DISEASE MANAGEMENT IN OIL PALM PLANTATION

MD NOH Normahnani. (1), AHMAD RAFIE Meor Badli Shah. (1), AMIT Samsudin. (1)

(1) Sime Darby Plantation Research Sdn Bhd, Selangor, MALAYSIA

Text

Oil palm remains to be vulnerable to basal stem rot disease caused by *Ganoderma boninense*, the most severe oil palm disease in Malaysia. Arbuscular mycorrhiza fungi (AMF) are ubiquitous in the soil and well known to play an essential role in plant growth, plant protection and soil amendments. Although the success of research in oil palm has been variable, this paper reports the benefits of additional AMF application observed in two field trials in coastal

area estates in Malaysia; after 13 and 20 years of evaluation for *Ganoderma* management in oil palm plantations. Several AMF treatments were evaluated. Data on *Ganoderma* incidence in the same planting point was compared before replanting and then, after 13 and 20 years with AMF treatment. Overall results showed that 50g AMF inoculated during seed sowing is highly recommended for timely contact of the fungus to the root cells for vigorous colonization in oil palm roots. A single application of 50g AMF onto 3-month-old oil palm seedlings (T5) and 100g AMF into the planting hole only (T2) seems not sufficient to control *Ganoderma*. A combination of 50g AMF either during seed sowing or to 3-month-old oil palm seedlings with an additional of 100g or 500g of AMF applied into the planting hole demonstrates a positive significant result in *Ganoderma* control. Subsequent application of 500g AMF at the 6-monthly interval, for the first 3 years of planting also showed an effective control of *Ganoderma* disease in the oil palm field.

SCREENING BIOCONTROL AGENTS FOR CASH CROP FUSARIUM WILT BASED ON FUSARIC ACID TOLERANCE AND ANTAGONISTIC ACTIVITY TO FUSARIUM OXYSPORUM

GUO Qinggang. (1), LI Shezeng. (1), SU Zhenhe. (1), ZHAO Weisong. (1), MA Ping. (1)

(1) Institute of Plant Protection, Baoding, CHINA

Text

Fusarium wilt caused by Fusarium oxysporum is one of the most notorious diseases for cash crops. Using of microbial fungicides is one of the effective measures for controlling crop Fusarium wilt, and the genus of Bacillus is an important resource to develop microbial fungicides. Fusaric acid (FA) produced by F. oxysporum can inhibit the growth of Bacillus, thus affecting the control efficiency of microbial fungicides. Therefore, screening biocontrol Bacillus with FA-tolerant ability is hopeful to improve the biocontrol effect for Fusarium wilt. In this study, the method for screening biocontrol agents against crops Fusarium wilt was established based on the tolerant to FA and antagonism to F. oxysporum, three promising biocontrol bacteria, named as B31, F68 and 30833 were obtained to successfully control tomato, watermelon and cucumber Fusarium wilt. Strain B31, F68 and 30833 were identified as B. velezensis by phylogenetic analysis of 16S rDNA, gyrB, rpoB and rpoC genes sequences. Co-culture assays revealed that strain B31, F68 and 30833 enhanced the tolerance to F. oxysporum and its metabolites, when compared with B. velezensis strain FZB42. Further experiments confirmed that 10 μg/mL FA could completely inhibit the growth of FZB42, while strain B31, F68 and 30833 kept normal growth at 20 μg/mL of FA and partial growth at 40 μg/mL of FA. Compared with strain FZB42, strain B31, F68 and 30833 significantly improved the tolerance to FA.

A NATURAL METABOLITE, REJUAGRO, TO CONTROL APPLE FIRE BLIGHT, CITRUS CANKER, AND CITRUS GREENING DISEASES

HUANG Jian. (2), YU Manda. (1), EFFINGER Robert. (2), **YANG Ching-Hong. (1)**

(1) University of Wisconsin, Milwaukee, Milwaukee, UNITED STATES; (2) T3 Bioscience, Milwaukee, UNITED STATES

Text

Since 2017, our research team has built an extensive collection of microbes from different orchards and natural environments in Wisconsin and other states of the U.S. in order to identify natural metabolites produced from microbes for plant disease control. A novel metabolite named "RejuAgro" produced from Pseudomonas soli strain T3-07 was discovered. RejuAgro has been commercially formulated with a two-year shelf-life when stored at room temperature. RejuAgro shows high potency in suppressing multiple bacterial and fungal crop pathogens with large economic impact, including pathogens causing apple fire blight, citrus greening, and citrus canker. External field trials of RejuAgro have been performed to assess its inhibition efficacy on apple fire blight and citrus canker. RejuAgro was benchmarked against streptomycin, a commercial antibiotic that is considered the gold standard for controlling crop diseases such as fire blight in the U.S. A treatment of RejuAgro at 10-20 ppm can effectively control the fire blight and citrus canker in field trials.
There is no cure once a tree is infected with citrus greening. USDA predicted that citrus greening could destroy the entire U.S. citrus industry during our lifetime. RejuAgro suppresses Candidatus Liberibacter asiaticus, the cause of citrus greening by foliar spray. In addition, we observed a higher expression of pathogenesis-related defense genes PR1 and PR2 when RejuAgro was applied to the citrus.

Text

Kordyana brasiliensis, an obligate biotrophic fungal pathogen native to South America, was deliberately introduced to Australia as a classical biological control agent for the environmental weed Tradescantia fluminensis. A field-based monitoring study was established in New South Wales at 14 sites where K. brasiliensis was released across a broad latitudinal (~ 1000 km) and climatological gradient. The study's objective was to evaluate the climatic conditions conducive to K. brasiliensis establishment and severe disease development as well as the ecological impacts of sustained disease on T. fluminensis. Sites were monitored 6, 18 and 24-months post release, assessing K. brasiliensis disease incidence (number of stems infected per plot) and severity (percentage of leaf area covered by lesions) and T. fluminensis abundance (cover and volume). Kordyana brasiliensis established at all release plots 6-months post release with an average disease incidence of ~ 80% at release plots. At 6, 18 and 24-months post release, disease severity was lower at southern, cooler, and drier sites compared to sites in the northern region with warmer, humid climates. At 18-months post release, K. brasiliensis high disease severity was strongly correlated with a significant negative decline in T. fluminensis abundance, with greatest reductions observed in the northern region.

BIOCONTROL ACTIVITY AGAINST SOIL-BORNE PLANT PATHOGENS BY BACILLUS SPP.

CHEN Jin, Tong. (2), LIN Mei, Ju. (1), CHU Che, Wei. (2)

(1) Taiwan Agricultural Research Institute, Taichung, TAIWAN; (2) Floriculture Research Center, Taiwan Agricultural Research Institute, Yunlin, TAIWAN

Text

Soil-borne diseases are plant pathogens worldwide that cause disease in many economically important crops. Soil-borne pathogens are notoriously difficult to control. However, people using insecticides to control soil-borne diseases have developed pathogens that are resistant to the fungicides. Here, Bacillus spp. is used to control strawflowers stem rot caused by Sclerotinia sclerotiorum and cucumber damping-off caused by Pythium aphanidermatum. Seven strains of Bacillus spp. isolated from mushroom compost, it has the ability to promote plant growth. Among them, B13 and B36 inhibited the mycelial growth of S. sclerotiorum and P. aphanidermatum on PDA (potato dextrose agar) plates. In the greenhouse experiments, B13 and B36 bacterial cultures were irrigated on 5-week-old strawflowers and 14-day-old cucumber seedlings. After 7 dpi, plants inoculated with mycelium blocks of S. sclerotiorum which grew on PDA for 7 days, or inoculated with zoospores solution (10^8 CFU/ml) of P. aphanidermatum. The disease incidence was recorded after 3 weeks and 10 days, respectively. Results showed that the incidence of plant irrigated of B36 were reduced 27% compared to control. The incidence of Pythium damping-off of cucumber seedlings was reduced from 92% of the control to 32% of Bacillus spp. B36 treatment. B36 was identified as B. velezensis and B13 was B. aryabhattai of 16S rDNA sequence. The strain B36 has the potential to control stem rot of strawflower and Pythium damping-off of cucumber.

SELF-RESISTANCE MECHANISMS DURING THE BIOSYNTHESIS OF ANTIMICROBIAL N-OXIDE PHENAZINE IN LYSOBACTER ANTIBIOTICUS

ZHAO Yangyang. (1), LIU Fengquan. (1)

(1) Jiangsu Academy of Agricultural Sciences, Nanjing, CHINA

Text

Phenazines are redox-active compounds exhibiting broad antibiotic activity. *Lysobacter antibioticus* OH13, a soil bacterium emerging as a potential biocontrol agent, produced phenazine 5,10-dioxides myxin with outstanding antimicrobial activity. Antibiotic-producing microbes always employ self-resistance mechanisms, mainly including efflux, target modification, sequestration, and enzymatic inactivation to escape self-toxicity. A monooxygenase encoding gene *LaPhzX*, located in myxin biosynthetic gene cluster, deletion of which caused the mutants more sensitive to myxin and prolonged existence of myxin. Meanwhile, myxin decreased significantly in the LaPhzX protein reaction, and heterologous expression of LaPhzX in *Xanthomonas* increased its resistance to myxin. So LaPhzX is a

myxin detoxification enzyme for protecting *L. antibioticus* from suicide. In addition, we found a RND (resistance-nodulation-division) efflux pump encoding gene cluster *lexABC* in strain OH13, and their deficiency resulted in strains increased myxin susceptibility and reduction of myxin yield. Moreover, *lexABC* expression was induced by myxin and directly activated by a LysR type transcriptional regulator LexR. Myxin bound with LexR at valine (146) and lysine (195) residues. These results indicate a RND pump with regulation mediated self-protection strategy in *L. antibioticus*. The discovery of two self-resistance mechanisms against myxin in *L. antibioticus* is important for obtaining high-yield myxin strains.

DOPING IN P. RADIATA: CAN PLANT GROWTH PROMOTING BACTERIA ENHANCE MORPHO-BIOCHEMICAL TRAITS

LEITÃO Frederico. (1,2), HENRIQUES Isabel. (2), PINTO Glória. (1)

(1) University of Aveiro, Aveiro, PORTUGAL; (2) University of Coimbra, Coimbra, PORTUGAL

Text

Pine pitch canker (PPC), caused by Fusarium circinatum, is an alarming forest disease that affects pine species differently. Pinus radiata is susceptible to PPC, while Pinus pinea is resistant. Previous work has shown that the Pinus pinea microbiome may be a source of plant growth promoting bacteria, which may also enhance resistance to PPC.
In this study, bacterial isolates were obtained from P. pinea and characterized. These were mixed into bacterial consortia (A1-A5 and B1-B5) presenting a progressively higher number of beneficial characteristics: IAA production, phosphate solubilization, siderophore production and ACC-deaminase. Pinus radiata seeds were soaked for 2 hours in solutions containing the bacterial consortia and sown in a peat:vermiculite (1:1, v/v) soil mixture. After 30 days of germination, seedlings' height, biomass and biochemical parameters (i.e. pigments, sugars and starch (STA), free amino acids (FAA), phenolics, flavonoids and malondialdehyde (MDA)) were assessed.
Concerning germination, B3 and A4 consortia increased germination up to 20%. The A4 group displayed significantly more adventitious roots, and higher STA and FAA content. B1 and A5 showed higher MDA content.
All in all, this study points to a high potential of the selected bacterial consortia to affect the germination and primary metabolism of P. radiata. Further experiments with larger numbers of plants and subsequent inoculations are needed to fully assess the impact of these bacteria.

Text

Pea root rot, caused by the oomycete, *Aphanomyces euteiches*, is considered to be the most damaging pathology, as it can lead to significant losses in pea fields and there are currently no effective treatments for it. Studying plant microbiomes, such as bacterial endophytes present in pea nodules, can be a basis for valorizing them as potential biocontrol agents. For this purpose, nodules of three spring and three winter pea cultivars were investigated to isolate bacterial endophytes and test their potential biocontrol ability against *A. euteiches*. Moreover, a metabarcoding approach was performed to comprehensively assess the diversity of bacterial endophytes, with a particular emphasis on the biocontrol genera that are already described. Screening tests revealed 17 isolates, from five out of six cultivars, with an *in vitro* antagonist effect towards *A. euteiches*. High-throughput sequencing showed a predominance of *Rhizobium lusitanum* followed by *Rhizobium leguminosarum* in the nodules of all cultivars. High-throughput sequencing revealed a higher diversity of minor endophytes in the two winter cultivars, which are more resistant to frost, and known antagonist genera were more abundant in winter cultivars, making them better suited for biocontrol against *A. euteiches*. This research is the first to explore the microbiomes of nodule-inhabiting bacteria in multiple pea cultivars and provides a foundation for developing biocontrol strategies for managing pea root rot.

Text

Botrytis cinerea is a necrotrophic fungus causing grey rot (GR) with crucial economic losses in fruit crops but can also cause the desired noble rot (NR) in grape berries used to produce botrytized wines. In both states, *B. cinerea* is associated with several other fungi, but the functional role of these is still poorly understood. Metatranscriptomic data was generated from healthy (H), noble rot (NR) and grey rot (GR) grape berries and RNAseq reads were aligned to the most prevalent filamentous fungi namely *Alternaria alternata*, *B. cinerea*, *Epicoccum nigrum* and yeasts, *Aureobasidium pullulans* and *Rhodotorula graminis* based on previous

culture-based studies. Differential enrichment analyses and pathway enrichment analyses revealed that all fungi and yeasts are most active in NR, followed by GR and H berries. Beside *B. cinerea*, several functional genes of other fungi and yeasts were linked to the well-known physico-chemical changes such as the increase of aromatic precursors, organic acids and favoured metabolites associated with NR berries. In addition, antagonistic microbial- and plant interaction genes were identified highlighting the complex population dynamics in a successful NR development and that *B. cinerea* is the main causal agent responsible for the necrotrophism associated with GR.

IN VITRO CHARACTERIZATION OF PICHIA MEMBRANAEFACIENS FOR POSTHARVEST BIOCONTROL OF MONILINIA FRUCTICOLA.

LARCO TERÁN Elissa. (1), GODOY OLIVARES Liliana. (1)

(1) Pontifical Catholic University of Chile, Metropolitan Region, CHILE

Text

Yeast-based biological control agents are sustainable and promising alternatives to control postharvest fungal diseases, such as brown rot, caused by *Monilinia fructicola*. *Pichia spp* is a yeast genus with interesting *in vitro* biocontrol attributes. The present study evaluated the biocontrol capacity of two native wine yeast strains of *Pichia membranefaciens* YCPUC66 and YCPUC144. Antagonistic action was observed in both strains, where YCPUC66 strain inhibited 78% of mycelium growth, while YCPUC144 strain inhibited 28%. Additionally, the antagonistic capacity based on the production of volatile organic compounds was evaluated by double plate assay. It was observed that YCPUC66 strain reduced mycelium growth by 89%, while YCPUC144 strain 61%. Postharvest conditions could reduce the cell viability of yeasts with biocontrol capacity due to stressors present in the medium, such as reactive oxygen species. Consequently, the tolerance to oxidative stress of both strains was evaluated by exposure to H_2O_2 concentrations. The results indicated that YCPUC66 strain showed greater tolerance to H_2O_2, close to 3mM. Until now, YCPUC66 strain has shown to have a greater inhibitory effect on the growth of *M. fructicola* and a greater tolerance to oxidative stress, becoming a promising biocontrol agent.

Text

Grapes have many diseases caused by plant pathogens that reduce the quality of grapes, such as white stain symptoms, and anthracnose, and have been controlled mainly through

chemical control rather than biological control. In the case of beneficial microorganisms developed as biological control agents, due to their characteristics, much verification of grapefruit disease control has not been performed, and the control figures are insufficient. In this study, we selected the promising strain of Bacillus velezensis MWS28 which has induced systemic resistance and inhibitory effect on the plant pathogens such as White stain symptoms causing A. acutatum and T. roseum. Bacterial attachment increased as the concentration of alginate increased, and 0.3% alginate solution was most effective at gradient concentrations. As the attachment number increased, the biological control effect against grape white stain symptoms increased. At 3 weeks after MWS28 treatment, the grapefruits showed overweight, high sugar content, increased grapefruit size, and anthocyanin contents were significantly increased compared to the untreated control. These results showed that it can be used not only for grape disease control and yield increase during grape cultivation but also for eco-friendly pesticide-free cultivation.

Text

Mango and avocado are the main subtropical crops in southern Spain. These fruits are grown and processed in the same geographical area, and are transported to the rest of Europe. However, postharvest diseases during storage and transportation could damage the export market. In this work, symptoms of rot in mango fruits were detected, and analyzed in search of the causal agent. Parallely, asymptomatic avocado fruits were also analyzed. These two fruits share, on many occasions, farms, processing and even transport, and could act as cross inoculation source. The main fungal genera found, both in mango and avocado, were Alternaria sp. and Neofusicoccum sp. Of these two genera, only Neofusicoccum sp. was able to reproduce the symptoms of rot in mango similar to previously detected. Likewise, Neofusicoccum sp. isolates, but not Alternaria sp., could produce rot symptoms in avocado inoculated fruits.

To study the control of this disease through sustainable strategies, two microbial biological control agents were tested. Both are isolated antagonists against phytopathogenic fungi, and correspond to the bacterium Pseudomonas chlororaphis PCL1606. and Bacillus velezensis UMAF6639. The applications of both microorganisms on the fruit showed significant levels of protection, although only UMAF6639 showed greater persistence in the fruit during the preventive applications in the field.

THE RAPID DECLINE OF THE INVASIVE SPECIES AILANTHUS ALTISSIMA UNDER THE CHALLENGE OF VERTICILLIUM DAHLIAE: A PHYSIOCHEMICAL STUDY

PISUTTU Claudia. (1), **NALI Cristina. (1)**, COTROZZI Lorenzo. (1), LORENZINI Giacomo. (1)

(1) University of Pisa, Pisa, ITALY

Text

The decay of *Ailanthus altissima* due to *Verticillium* spp. (Fungi, Ascomycota) represents a relevant opportunity for the biocontrol of this invasive tree, which is not properly counteracted by traditional physical and chemical approaches. Verticillium wilt symptoms remember those of drought as they are caused by vessel occlusions, even if phytotoxins produced by the fungus are also involved in the pathogenic mechanism. Here, outcomes from an open air pot experiment aimed to investigate the physiochemical responses of *Ailanthus* trees stem inoculated with *V. dahliae* (VdGL16 strain, isolated from the same host in Tuscany) are reported. Inoculated plants showed foliar injuries starting from 2 weeks post inoculation (wpi), and a final severe defoliation. Already at 4 wpi, the infection induced a reduction in leaf water content (-14% compared with uninoculated plants), stomatal opening and net photosynthesis (-46 and -38%, respectively). Moreover, the disease altered the translocation of mineral elements and carbohydrates, that reached minimum values at 8 and 6 wpi, respectively (-84 and -14%). An accumulation of abscisic acid, proline and phenylalanine was also observed at 8 wpi (3-, 10- and 6-fold higher, respectively), suggesting a potential response mechanism. Despite this weak attempt to counteract the fungal colonization, plants were prematurely compromised and death inevitably occurred, confirming the great potential of using *Verticillium* to control *Ailanthus* invasion.

P1.1-065

BIOLOGICAL CONTROL OF ZYMOSEPTORIA TRITICI IN WHEAT

JØRGENSEN Hans Jørgen Lyngs. (1), JENSEN Birgit. (1), LATZ Meike Anna Christine. (1), COLLINGE David B.. (1)

(1) University of Copenhagen, Frederiksberg C, DENMARK

Text

The disease Septoria tritici blotch (STB), caused by *Zymoseptoria tritici*, is one of the most important and yield-reducing constraints in wheat production worldwide. Control relies heavily on fungicides, but there is an increasing desire to reduce fungicide use and the pathogen readily develops resistance against commonly used products. Biological control, using living microorganisms, is an upcoming trend within disease control, also for STB.
The mode of action of biocontrol agents is more complex than for traditional fungicides and therefore, the risk that they lose effect is considered much less than for chemical products. Potential biocontrol agents are often selected based on direct inhibitory effects *in vitro* and therefore, the mode of action is often not studied in detail. However, there is emerging evidence that one of the most important modes of action by biocontrol agents is induced resistance, which can only be discovered in assays using plants [1].
We use different fungi (e.g. endophytes and *Clonostachys rosea*) and bacteria to control STB and have found significant reductions of disease severity using spray applications of fungal

biocontrol agents under controlled and field conditions [e.g. 2]. Whereas *in vitro* studies showed limited inhibition of the pathogen, microscopy and transcriptomics implicated induced resistance as important mechanisms.

CAN WILD BRASSICACEAE DEFENSE COMPOUNDS ENHANCE THE ANTAGONISTIC EFFECT OF SEED-BORNE FUNGI AGAINST ALTERNARIA BRASSICICOLA ?

LERENARD Thomas. (1), ALIGON Sophie. (1), HAMON Bruno. (1), POUPARD Pascal. (1), LE CORFF Josiane. (1)

(1) Research Institute of Horticulture and Seeds (IRHS), Beaucouze, FRANCE

Text

Wild Brassicaceae plant species synthetize defense compounds that can have an impact on the interactions between seed-borne fungi, with contrasting effects depending on the identity of the compounds and of the fungal species. Some fungi can metabolize some glucosinolates while other fungi such as *Alternaria brassicicola*, the seed-borne causal agent of the black leaf spot disease on many Brassica crops, are inhibited by camalexin and isothiocyanates. To gain insights into the role of the host plant on the interactions between *A. brassicicola* and the potential seed-borne fungal antagonists, characterization of fungi associated with the seeds of wild Brassicaceae described as resistant to *A. brassicicola*, was conducted. Their antagonistic effect on *A. brassicicola* was tested in the presence of the main defense compounds encountered in their host plants. The impact of defense compounds identified in non-host Brassicaceae species was also measured. Through a series of confrontations conducted on solid media and on liquid media (by using nephelometry) enriched or not with glucosinolates and camalexin, the main goal of the study is to gain a better understanding of the mechanisms involved in the interactions between the host plant defenses and seed-borne fungal communities towards future design of biological control of *A. brassicicola*.

Text

ABSTRACT

Tomato is are regarded as one of the world's most economical crops that is only second to potato. They are important horticultural crop with significant contribution to world's food security as well as economic development from job creation. However, an invasive insect pest, Tuta absoluta, is a major threat to cultivation of tomato woldwide and is rapidly increasing its geographic presence. In a bid to develop an environmental-friendly control of this pest, next generation sequencing was used to unravel the microbiomes associated with the larvae of Tuta absoluta. DNA was extracted from larvae collected from different regions and sequenced using the illumina platform. Results of the sequencing showed that the dominant fungal phyla was Ascomycota, followed by Basidiomycota. Other fungal phyla present includes Mucoromycota, Glomeromycota, Mortiellomycota and Chrytridiomycota. Implications of these fungal occurrences in relation to biocontrol are discussed. There were also a large proportion of unidentified phyla, class, order, family, genus, and species.

Text

A study of the tomato endorhizosphere microbiome was performed in commercial greenhouse conditions. Results showed that keystone taxa were represented not only by bacteria with high relative abundance, such as Bacillus and Pseudomonas, but also by numerous and lesser-known genera. The systemic selection of cultivable bacteria enabled us to obtain representative isolates which, in vitro, showed diverse PGPR abilities and marked antagonistic activity. We selected ten bacterial isolates both from genera commonly used as bioinoculants, such as Bacillus and Pseudomonas, and also from unconventional genera like Arthrobacter, Paenarthrobacter, Acinetobacter, Glutamicibacter, and Enterobacter. Bacterial isolates were evaluated individually or in different combinations as consortia for their PGPR activity, induction of plant resistance and biocontrol potential against the soil-borne pathogen Fusarium oxysporum f. sp. radicis-lycopersici (Forl), causal agent of crown and root rot and the leaf pathogen Xanthomonas euvesicatoria pv. perforans (Xep), causal agent of bacterial spot. Most of the treatments significantly reduced the symptoms of both diseases although to a different extent. The efficacy against pathogens that infect different plant organs suggests a multifunctional potential that combines different modes of action. The genomes of the bacterial isolates were sequenced using Oxford Nanopore long read, and Illumina short read sequencing. Genome analysis is underway.

NEMATICIDAL ACTIVITY OF A BACTERIAL CONTROL AGENT AGAINST CLOVER CYST NEMATODE

KO Hyoung-Rai. (1), PARK Sekeun. (1), PARK Byeong-Yong. (1)

(1) National Institute of Agricultural Sciences, Rural Development Administration, Wanju, REPUBLIC OF KOREA

Text

Clover cyst nematode (CCN) is one of the important plant-parasitic nematodes worldwide, and mainly damage to Kimchi-cabbage production in Korea. Five chemical nematicides are available to control CCN in Kimchi-cabbage plant, but the nematicides are harmful to human and beneficial animals. Therefore, we need to develop the alternatives to control CCN. This study was performed to develop the bio-control agents (BCAs) using bacteria against CCN. Nematicidal activity of two bacteria (isolate BC1 and BC2) was assessed to CCN second-stage juveniles (J2s) using *in vitro* assay. As a result, culture solution of BC2 was highly toxicity to CCN J2s with 100% mortality. Culture filtrate of BC2 had also 74% of nematicidal activity to CCN J2s. To verify nematicidal activity of BC2 *in vivo*, pot experiment was conducted in a temperature-controlled room (25oC). The mean of fresh weight of Kimchi-cabbage in BC2 treatment were 1.4 and 2.2 times higher than that of the TSB (medium alone) and NemaO (nematode alone), respectively. The female reproduction on Kimchi-cabbage roots in BC2 treatment was inhibited by 77% (1st trial) and 73% (2nd trial) compared with control (NemaO), respectively. The BC2 treatments reduced the cyst size compared to NemaO treatment, but there was no significance. These results showed that the BC2 has nematicidal activity and potentials as BCAs against CCN.

Text

The microbiomes in rhizosphere, phyllosphere, and endosphere lived in symbiotic relationships with plants can influence plants to be holobiont by the phenotypic plasticity and extended phenotype. Last several decades, soil microbiota has taken notice as a source to identify specific species able to contorl resistance and tolerance to biotic and abiotic stresses. However, the mechanism of change about phenotype of plants by soil microbiota has yet to be fully understood. In this study, we aimed to identify soil microbiomes that could promote the growth and development of the tomato (cultivar Micro-Tom). Our results showed that the fruit maturity of the Micro-Tom grown with microbiomes from Gijang B soil was 22.8% higher on average compared to those produced in the mock-treated soil. Additionally, the growth of Micro-Tom treated with microbiomes from Gyeongju soil increased by 138% compared with those grown under mock-treated plants. To understand if the phenotypic changes of the Micro-Tom were due to epigenetic modifications by microbiome, we checked the transcript level of the representative genes related epigenetics in different tissues and conditions. Furthermore, we analyzed the similarities and differences among microbiomes used in this study. Our study will give new insight into how soil microbiome can regulate plant phenotype and suggest that soil microbiome has a role in shaping the epigenome of plants from an evolutionary perspective

RESISTANT KIWIFRUIT SPECIES OF HAYWARD CAN BENEFICIATION FLAVOBACTERIUM TO SUPPRESS BACTERIAL CANKER PATHOGENS

ZHENG Wei. (1), **HUANG Lili. (1)**

(1) Northwest A&F University, Yangling, CHINA

Text

Bacterial canker caused by *Pseudomonas syringae* pv. *actinidiae* (Psa) is the most destructive disease-causing great production loss to kiwifruit. Recent studies have shown that plant disease-resistant varieties can enrich beneficial microorganisms to inhibit the infection of pathogens. To investigate whether bacterial canker-resistant kiwifruit cultivars can enrich beneficial microorganisms, five common kiwifruit cultivars were identified for resistance by combining previous field surveys and laboratory resistance assays. Among them, the most resistant variety to Psa was *A. deliciosa* cv. Hayward, and the most susceptible was *A. chinensis* cv. HongYang. We researched the leaves, branches, root endospheric microbiome and rhizosphere soil microbiome of HongYang and Hayward by 16S rRNA gene amplicon sequencing in the field. The rhizosphere soil microbiome with the largest difference between the HongYang and Hayward, with more Flavobacterium in the resistant plants enriched. To identify whether Flavobacteria are involved in protecting plants against canker disease, we isolated and cultured 14 strains belonging to the high abundance of Flavobacteria OTU_1542, OTU_337, OTU_1542, OTU_6, OTU_193. It was proved that isolated Flavobacterium 55 and Flavobacterium B2 can reduce the occurrence of kiwifruit canker disease by inhibition zone methods and in the detached dormant experiments of leaves and branches.

Text

Sustainable agriculture is crucial to ensure food security for the expected 9 billion people in 2050. However, plant stress has led farmers to rely on chemical fertilizers and pesticides. This is also the case with managing the devastating tomato (*Solanum lycopersicum*) disease caused by *Fusarium oxysporum* f. sp. *lycopersici* (FOL). To address this issue, it is important to find an efficient, cost-effective, and eco-friendly solution. Beneficial microbes, which enhance nutrient availability and have anti-microbial properties, can serve as green alternatives to agrochemicals. This study aims to identify rhizobacteria with multiple plant

growth-promoting attributes and determine the key factors in stress mitigation. The bacterial strains were screened for various traits, such as solubilizing inorganic nutrients, tolerance to salt and drought, and production of indole acetic acid and siderophore. Strains were further assessed for *in vitro* inhibition on five economically significant phytopathogens, namely *F. oxysporum* f. sp. *niveum*, *Magnaporthe oryzae*, *Colletotrichum gloeosporioides*, and FOL. Thirteen potentially beneficial strains were obtained, and three of the best-performing strains were chosen for pot experiments in a greenhouse, which resulted in reducing disease severity of tomato infected by FOL. The use of these biocontrol agents is expected to regulate plant growth, defense-related genes, and chemical and physiological properties.

EVALUATION OF SEVERAL ARBUSCULAR MYCORRHIZAL FUNGI PRODUCTS ON GROWTH AND TOLERANCE OF OIL PALM SEEDLINGS AGAINST BASAL STEM ROT DISEASE CAUSED BY GANODERMA BONINENSE

NASARUDDIN Afnan Shazwan. (1), AHMAD RAFIE Meor Badli Shah. (1), AMIT Samsudin. (1)

(1) Sime Darby Plantation Research Sdn. Bhd., Banting, MALAYSIA

Text

Basal Stem Rot (BSR) disease caused by *Ganoderma boninense* has led to devastating yield losses in the oil palm industry and presently no effective solution to cure the disease spread has been discovered. Based on several product literatures, the use of Arbuscular Mycorrhizal Fungi (AMF) has been claimed to increase the oil palm tolerance against *Ganoderma* infection. AMF, being a beneficial microorganism, forms a symbiotic relationship with plant roots, which facilitates and increases the transfer of nutrients between the plant and the fungus. In Malaysia, several AMF products have been commercialised for use in oil palm. However, the effects of these products on oil palm growth and tolerance towards *Ganoderma* BSR disease have not been evaluated. Eight AMF products were selected in this study based on their contents. These products were applied during seed sowing, and their effects on oil palm growth were determined. Recorded growth parameters include oil palm seedling height and girth, as well as the number of fronds per seedling. After one year of inoculation with AMF, the oil palm seedlings were challenged with *Ganoderma boninense* PER 71 strain, using *Ganoderma* Rubberwood Block (RWB) to evaluate the AMF products' effectiveness against the BSR disease. Assessment based on the disease severity index was determined post-infection with the fungus.

RECOVERY OF METAGENOME-ASSEMBLED GENOMES FROM THE PHYLLOSPHERE OF 110 RICE GENOTYPES

LIU Yong. (1)

(1) State Key Laboratory of Hybrid Rice and Institute of Plant Protection, Hunan Academy of Agricultural Sciences, Changsha, CHINA

Text
The plant microbiota plays crucial roles in sustaining plant health and productivity. Advancing plant microbiome research and designing sustainable practices for agriculture requires in-depth assessments of microorganisms associated with different host plants; however, there is little information on functional aspects of many microorganisms of interest. Therefore, we enriched microorganisms from the phyllosphere of 110 rice genotypes and subjected them to shotgun metagenomic sequencing to reconstruct bacterial genomes from the obtained datasets. The approach yielded a total of 1.34 terabases of shotgun-sequenced metagenomic data. By separately recovering bacterial genomes from each of the 110 rice genotypes, we recovered 569 non-redundant metagenome-assembled genomes (MAGs) with a completeness higher than 50% and contaminations less than 10%. The MAGs were primarily assigned to *Alphaproteobacteria*, *Gammaproteobacteria*, and *Bacteroidia*. The presented data provides an extended basis for microbiome analyses of plant-associated microorganisms. It is complemented by detailed metadata to facilitate implementations in ecological studies, biotechnological mining approaches, and comparative assessments with genomes or MAGs from other studies.

P1.1-076

A BACTERIAL PROTEIN RHP-PSP MODULATES PLANT AUXIN PRODUCTION AND ALTERS LEAF METABOLITES COMPOSITION TO IMPLEMENT MUTUALISTIC INTERACTION WITH PLANT

SU Pin. (1)

(1) State Key Laboratory of Hybrid Rice and Institute of Plant Protection, Hunan Academy of Agricultural Sciences, Changsha, CHINA

Text
Mutualism is a dominant feature in a variety of host-bacteria interactions. Mutualistic bacteria confer plants with growth promotion and pathogen resistance, reciprocally, plants preferentially supply carbohydrates and a stable habitat to mutualistic bacteria to support their efficient colonization. However, whether these bilateral activities act independently or are interlinked via the shared molecular mechanism remains largely unexplored. In this study, the reactive intermediate deaminase A family protein Rhp-PSP secreted by phyllosphere bacterium *Rhodopseudomonas palustris* JSC-3b was required for both JSC-3b-generated plant health and efficient JSC-3b colonization. The growth of *Nicotiana benthamiana* seedlings was promoted as a result of Rhp-PSP-mediated plant auxin production. Constitutively, the expression of Rhp-PSP gene in *N. benthamiana* caused superior seedling growth, concomitantly, the altered leaf metabolite composition repressed the in-vitro and in-vivo proliferation of phytopathogens *Xanthomonas oryzae* and *Pseudomonas solanacearum*, but promoted that of JSC-3b. In addition, protein-protein interaction analysis revealed that Rhp-PSP interacted with plasma membrane-localized protein, which was responsible for the Rhp-PSP-mediated plant health and efficient colonization on leaves. Collectively, our study reveals a mode of mutualistic interaction between plants and bacteria, in which both partners benefit from the Rhp-PSP-mediated plant physiological alternations.

MICROBIOTA INTERACTIONS AND ASSEMBLY ON RICE LEAF

PENG Qianze. (1,2), ZHANG Deyong. (1,2)

(1) Hainan University, Haikou, CHINA; (2) State Key Laboratory of Hybrid Rice and Institute of Plant Protection, Hunan Academy of Agricultural Sciences, Changsha, CHINA

Text

Plant-associated microbiomes confer fitness advantages to the plant host, including growth promotion, nutrient uptake, stress tolerance and resistance to pathogens. While many studies have illustrated those key roles of the root microbiota, less is known about the role of the leaf microbiota and how it is maintained and assembled. Here, we applied shotgun metagenomic sequenced leaf microbiomes of 110 rice genotypes to characterize leaf microbiota grown in the field. We identified that *Rhodopseudomonas palustris*, *Pseudomonas fluorescens* and *Ralstonia solanacearum* are microbial hubs in the co-occurrence network of rice leaf microbiota. Furthermore, we found that amino acids and derivatives were the most possible metabolic exchanges in the leaf bacterial community. Using Genome-wide association studies (GWAS), We identified rice genetic loci connected with the abundance of *Pseudomonadales*, *Burkholderiales*, *Xanthomonadales* and *Enterobacterales*. Notably, those genes of rice genetic loci were enriched in metabolic pathway and biosynthesis of secondary metabolites pathway. Finally, we demonstrate that our results can be used to improve future studies of the microbe-microbe and microbe-host interaction.

Text

Calonectria leaf blight is a serious disease of *Eucalyptus* in India. In this study, the efficacy of five *Trichoderma* isolates was tested against two prominent *Eucalyptus* pathogens, *Calonectria cerciana* and *Ca. pseudoreteaudii*. All the *Trichoderma* isolates exhibited >80% mycelial growth inhibition of both the pathogens in inverted plate assays. Solvent extraction of Trichoderma liquid cultures with ethyl acetate followed by gas chromatography-mass spectrometry (GC-MS), revealed naphthalene, 2-methyl-5-formylfuran, ethenone, and other volatile organic compounds (VOCs). Additionally, GC-MS analysis also detected n-alkanes (n-C11 to n-C21), 1-tetradecene, quinoline, α-phellandrene, 1-propyldodecyl phenylacetate, phenol, 2,4-bis(1,1-dimethyl)-phosphite (3:1), benzaldehyde, 4-propyl, tetradecanoic acid, myristic acid, n-hexadecanoic acid, and 9(11)-dehydroergosterol tosylate. *Calonectria* fungal hyphae treated with *Trichoderma* VOCs subjected to electron microscopy revealed ultrastructural and morphological damage. To our knowledge, this is the first report implicating the ability of *Trichoderma* VOCs to suppress the growth of *Calonectria* fungi

known to infect *Eucalyptus* in India. These results suggest that *Trichoderma* antifungals may be an eco-friendly alternative to chemical fungicides for the management of Calonectria leaf blight in *Eucalyptus*.
Keywords: VOCs, *Trichoderma*, *Calonectria*, biocontrol, GC-MS, electron microscopy, *Eucalyptus,* disease management

INCREASED PRODUCTION AND USE OF INOSINE BY SPONTANEOUS VARIATION IN PAENIBACILLUS POLYMYXA E681

LEE Younmi. (1), JANG Rosa. (2), JEON Yongho. (2)

(1) Agricultural Science and Technology Research Institute, Andong National University, Andong, REPUBLIC OF KOREA; (2) Department of Plant medicals, Andong National University, Andong , Andong, REPUBLIC OF KOREA

Text
The variation in Paenibacillus polymyxa E681, a plant growth-promoting rhizobacterium (PGPR), occurs spontaneously, changing B-type (wild-typeical) to F-type (variant). To better understand the difference between the two types, a high-throughput analysis was performed using Biolog Phenotype MicroArray. Compared to the B-type, the F-type showed significantly different growth rates on 17 out of 960 substrates. There was no significant difference in substrates, such as osmolytes, pH, and sodium salicylate. The spectrum of substrates available for F-type was relatively wider than for B-type. In inosine, D-melezitose, and cytidine as single nutrients, the growth of F-type was significantly higher than that of B-type, and interestingly, a few endospores that F-type could not form were observed. To verify the phenotypic microarray result, each type was cultured in a flask containing a minimal medium, including inosine as a single carbon source, and similar results to those of the phenotypic microarray were obtained. A known inosine-related metabolism in E681 is de novo IMP biosynthesis, and all related genes including pur operon (purEKBCSQLFMNHD) were overexpressed in F-type as a result of RNA-Seq in our previous studies. In conclusion, F-type generated by a naturally occurring variation biosynthesized and utilized inosine better than B-type. The association between among inosine biosynthesis, endospore formation, and phenotypic variation needs to be further investigationed.

Text
Plant disease control generally uses chemical pesticides. This method is not effective because it can cause environmental damage. To realize sustainable agriculture, effective control is needed and does not pollute the environment. One way that can be used is the use of antagonistic agents such as Bacillus sp. Encapsulation methods involve covering and protecting the microorganisms. The bioencapsulation formulation can protect Bacillus sp. from environmental stress such as chemical residues, unstable temperature , unsuitable pH, and sunlight. So that bioencapsulation can increase the effectiveness of Bacillus sp. as a biological control agent. The main topics discussed are bioencapsulation technology, bioencapsulation as a biopesticide formulation, materials, and manufacturing processes. This review presents a thorough analysis of the advantages and disadvantages of bioencapsulation technology. As well as closing with views on the prospects for bioencapsulation as a biopesticide formulation.

IDENTIFICATION AND CHARACTERIZATION OF BREVIBACILLUS HALOTOLERANS B-4359: A POTENTIAL ANTAGONISTIC BACTERIUM AGAINST RED PEPPER ANTHRACNOSE IN KOREA

KIM Heejin. (1), LEE Younmi. (1), **JEON Yongho. (1)**

(1) Andong National University, Andong-Si, REPUBLIC OF KOREA

Text
This study aims to screen and identify potential biocontrol agents (BCAs) from Freshwater Bioresources Culture Collection (FBCC), Korea, against major phytopathogens under in vitro conditions. Of 856 strains, only nine strains exhibited antagonistic activity, from which only one representative isolate *Brevibacillus halotolerans* B-4359 has been selected based on in vitro antagonistic activity and enzyme production. Cell-free culture filtrate (CF) and volatile organic compounds (VOCs) of B-4359 have been shown to be effective against the mycelial growth *C. acutatum*. B-4359 showed an excellent biological control effect of anthracnose on red pepper fruits. Further, B-4359 has been found to show a growth promotion effect in red pepper seedlings. Based on in vitro results, B-4359 played a role to control anthracnose disease effectively in field conditions when compared to other treatments and a non-treated control. The genetic mechanism underpinning the biocontrol traits of B-4359 was characterized using the whole-genome sequence of B-4359, which was closely compared to related strains. In a whole-genome sequence, B-4359 consisted of a 5,761,776 bp length with a GC content of 41.0%, including 5,118 CDS, 117 tRNA, and 36 rRNA genes. The genomic analysis showed 23 putative biosynthetic secondary metabolite gene clusters. Therefore, our results provide a better understanding of the B-4359 strain as an effective biocontrol against red pepper anthracnose for sustainable agriculture.

Text

The improvement of crop management strategies is needed due to the demands of adaptation to climate change, the emergence of new and more aggressive phytopathogens and the deterioration of agricultural soil quality. Beneficial endophytes are non-pathogenic microbes that live within plant tissues and can provide sufficient protection of their hosts against biotic and abiotic stress. For potential use in agriculture, we isolated and characterized over 600 endophytic microbes from olive trees and crop wild relative halophytes. We investigated thoroughly 26 beneficial Bacillus isolates using a multi-disciplinary approach and under biotic and abiotic stress conditions. We sequenced full chromosomes and plasmids of selected 26 Bacillus isolates. Comparative genomics reveal high genetic/genomic dissimilarity, novel secondary metabolism gene clusters and the discovery of new species. Six isolates grow in-vitro in high salinity (>15%). 15 isolates inhibited the growth of important phytopathogens (eg, Ralstonia, Clavibacter, Fusarium, Botrytis, etc). Several isolates retain these characteristics in-planta. The inhibitions were intensified when testing eluents, obtained from Bacillus cultures using flash column chromatography. Our studies provide strong evidence that specific beneficial Bacillus endophytes demonstrate high metabolic and genetic diversity and are excellent candidates as Bioinoculants for the enhancement of growth and tolerance of crops under biotic and abiotic stress.

P1.1-084

BIOCONTROL POTENTIAL OF BJERKANDERA ADUSTA AND SISTOTREMA BRINKMANNII AGAINST HETEROBASIDION SPP. PRIMARY INFECTIONS

KLAVINA Darta. (1), STRIKE-VORSLAVA Zane. (1), LIONE Guglielmo . (2), PELLICCIARO Martina. (2), NIKOLAJEVA Vizma . (3), GAITNIEKS Talis . (1), GONTHIER Paolo . (2)

Text

One of the most efficient methods to control Heterobasidion root and butt rots is based on treatments of freshly cut coniferous stumps with biological or chemical products. Biological preparations based on the fungus Phlebiopsis gigantea are widely used in Europe as stump treatments against Heterobasidion spp., but these are more effective on pine stumps than on Norway spruce stumps. In the present study, we tested different Latvian isolates of

Bjerkandera adusta and Sistotrema brinkmanii for their antagonistic potential in vitro against both H. annosum sensu stricto and H. parviporum, using native isolates of P. gigantea and Finnish Rotstop® as controls. The best isolates were chosen using several features: growth rate on agar, antagonistic ability against Heterobasidion spp. and oidia production. Some of the B. adusta and S. brinkmanii isolates performed similarly to P. gigantea isolates. For those isolates the growth rate was measured in wood of Pinus sylvestris, Picea abies, Larix decidua and L. x eurolepis.
This study was funded by European Regional Development Fund project Nr. 1.1.1.1/20/A/095 “Biological control of Heterobasidion root rot using Latvian fungal strains”.

P1.1-085

IDENTIFICATION OF A STREPTOMYCES SPECIALIZED METABOLITE INVOLVED IN ANTIFUNGAL ACTIVITY, PLANT DEFENSE STIMULATION AND BACTERIA FITNESS IN THE RHIZOSPHERE

Text

Rhizospheric microbiota harbors bacterial strains participating in plant immunity and resistance to root diseases. Recently, we identified a *Streptomyces* strain AgN23 isolated from grapevine rhizosphere, which produce a broad spectrum of antifungal metabolites and activates hypersensitive responses (HR) in *A. thaliana*. A metabolomic approach lead to the identification of a candidate compound produced by AgN23 which may impair sphingolipid metabolism in plants. Sphingolipid metabolism of plants is involved in HR, thus we characterized the role of this metabolite through a reverse genetic approach, based on the construction of AgN23 knock-outs strains. These mutants showed a reduced antifungal activity and are unable to inhibit Inositol Phosphorylceramide Synthase activity, a crucial enzyme in plant sphingolipid pathway. The induction by AgN23 of markers associated with HR or immune responses was compromised in AgN23 knock-out strains: nuclear calcium influxes, necrotic lesions, defense gene expression, and production of camalexin. Finally, we explored the role of the candidate metabolite in the soil and found that it is involved in the rhizosphere colonization by AgN23. Thus, we identified a specialized metabolite produced by a *Streptomyces* strain which is involved in antifungal activity, plant defense stimulation and strain fitness in the plant environment. Further work will aim to investigate how this strain and its cognate metabolite structure the rhizospheric microbiota.

P1.1-086

BIOLOGICAL CONTROL EFFICACY OF CHINESE CABBAGE CLUBROOT CAUSED BY PLASMODIOPHORA BRASSICAE

NAM Joohee. (1), SHIM Changki. (2), SHIN Joungdu. (3)

(1) Gyeoungggi-Do Agricultural Research and Extension Services, Gwangju-Si, REPUBLIC OF KOREA; (2) Organic Agriculture Division, National Institute of Agricultural Sciences, Rural Development Administration, Jeonju-Si, REPUBLIC OF KOREA; (3) Bio-technology of Multidisplinary Sciences, Co, Jeonju-Si, REPUBLIC OF KOREA

Text

The club root of chinese cabbage can remain in the soi for a long period of 7 to 10 years, and after the dormant spores germinate, they break into the cabbage root hairs and multiply, forming root knots. Soil microbial community analysis and selection of useful microorganisms can be used as a basis for developing eco-friendly club root disease control technology from an agricultural point of view. Therefore, this study analyzed the microbial cluster difference between the outbreak and the undeveloped area of cabbage root knot disease for the development of the cabbage root knot disease eco-friendly control technology, and tested it to use as a basis for selecting eco-friendly biological control factors. The fungi soil microbiome examined the residual presence of club root pathogens in the soil to identify P. brassica in the site of the onset of club root disease, and not in the unendemic site. A comparison of the differences showed a 0.89-2.52% distribution difference in Trichoderma sp., Fusarium sp., and Purpureocillium sp.. The results of this study have provided a basis for the collection of root knot pathogen control microorganisms, especially, Trichoderma sp. is showed 47% club root disease inhibition effect in pot test. So it is believed that metagenomics data can be used as sufficient evidence when separating useful microorganisms for the development of eco-friendly club root disease control technology.

Key words : Chinese cabbage, clubroot, metagenomics, biocontrol

Text

Biocontrol agents are commonly used for disease management, however, biocontrol efficacy varies among plant genotypes, potentially because of genetic variation in plants for plant-biocontrol agent compatibility. This study aimed to explore the genetic variation in winter wheat for modulation of *Clonostachys rosea*-mediated biocontrol of septoria tritici blotch caused by *Zymoseptoria tritici*. In total, more than 200 wheat genotypes grown in the Scandinavian countries in the last 100 years were investigated under controlled greenhouse conditions. Foliar spray application of the pathogen and the biocontrol agent in two treatments, i.e. *Z. tritici* (Zt) alone and *Z. tritici* with *C. rosea* (ZtCr) was used to assess

disease progress over time and biocontrol efficacy. There was significant phenotypic variation among plant genotypes for disease progress in Zt and ZtCr treatments. Moreover, individual plant genotypes differed significantly between Zt and ZtCr treatments, indicating the plant genotype-dependent variation in biocontrol efficacy. Genome-wide association mapping using a 20K single-nucleotide polymorphism (SNP) marker array identified four SNP markers associated with *C. rosea* biocontrol efficacy and one distinct SNP marker associated with disease resistance. This work will serve as a foundation to further characterize the genetic basis of plant-biocontrol agent interactions, facilitating opportunities for concurrent breeding for disease resistance and biocontrol efficacy.

Text

The soil-borne pathogen *Ralstonia solanacearum* causes bacterial wilt and thereby crop losses in the Solanaceae plants including tomato, potato, pepper, and eggplant. Although the susceptibility to the wilt disease primarily depends on the plant genotype, the microbial community in the rhizosphere also contributes to the severity. A flavobacterium TRM1, isolated from the wilt-resistant tomato cultivar Hawaii 7996, suppresses *Ralstonia* wilt in a susceptible tomato cultivar. The antagonistic activity of TRM1 against *R. solanacearum* was also observed from co-cultivation of the two bacteria in mCPG medium. To infer the wilt-suppressing mechanism, a large-scale transcriptional characterization was conducted. The transcriptional changes of TRM1 and *R. solanacearum* under the co-cultivation condition were compared to those in mono-cultivation. The transcriptome data of TRM1, *R. solanacearum*, and tomato were also collected in the plant rhizosphere. Genes for several secretion systems in *R. solanacearum* were inferred to be associated with virulence, while genes encoding some membrane-bound proteins in TRM1 appeared to be associated with virulence suppression. Integrating the results of these transcriptional data helped us systematically understand the wilt-suppressing mechanisms between the plant pathogen, the disease-suppressing microbe, and the host plant.

P1.1-089

EVALUATING NEW ERWINIA PHAGES AS BIOCONTROL TOOLS AGAINST FIREBLIGHT DISEASE IN FRUIT TREES

Text

Fireblight disease is caused by the bacterium *Erwinia amylovora* and has catastrophic consequences for apple and pear trees. The development of an innovative strategy against it is a priority challenge for fruit production worldwide. A potentially successful biocontrol tool could be the use of bacteriophages (or phages), the viruses of bacteria. To achieve this goal, a collection of 16 *Erwinia* phages newly isolated in the south of France were phenotypically and genotypically studied. The genomic analysis revealed the presence of 5 phage genera, including a new one, and 7 different phage species, including 4 new ones. Phage lifestyle analysis determined that all phages are virulent (only lytic cycle) and none can perform a lysogenic cycle, as advised for applied purposes. Their host range on a panel of 46 *E. amylovora* international strains and 4 closely related species was quantitatively assessed. Three phages have a broad host range (100% of strains), 12 phages have a medium host range (≥ 20 strains), and one has a narrow host range (13 strains). One phage can target two non-amylovora strains but the rest are restrained to the *E. amylovora* species, proving their specificity. The capacity of some candidate phages to inhibit bacterial growth *in vitro* was confirmed, and we are currently optimizing phage cocktails by adjusting phage types and ratios. Overall, this project seeks to prove the potential of phages as an efficient biocontrol tools against fireblight disease.

P1.1-090

SPORULATION POTENTIAL, DISPERSAL GRADIENT AND MYCELIUM GROWTH IN CONIFEROUS WOOD OF THE BIOCONTROL AGENT PHLEBIOPSIS GIGANTEA

SILBAUMA Lauma . (1), LIONE Guglielmo. (2), KLAVINA Darta. (1), PELLICCIARO Martina. (2), **KRASTINA Keitlina . (1)**, GAITNIEKS Talis . (1), GONTHIER Paolo . (2)

Text

During the vegetation season, natural stump colonization by Phlebiopsis gigantea plays a role in controlling Heterobasidion on coniferous stumps but this process may differ in cooler climate conditions. The aim of the study was i) to analyse P. gigantea spore deposition at low temperatures and gradients using Petri dishes and coniferous wood discs, ii) to compare P. gigantea and Heterobasidion spp. colonization in Pinus sylvestris discs and coniferous logs. Results showed that viable spores of P. gigantea are released in November and December. When air temperature exceeds 0°C, one cm2 of P. gigantea hymenophore can discharge on average 330100 basidiospores per day. The number of P. gigantea spores decreases with increasing distance from fruitbodies. However, at a distance of 10 m, the number of spores can reach up to 120 000 per m2 per hour. P. gigantea better colonize pine wood compared to spruce. When the area occupied by P. gigantea exceeded 7% of the P. sylvestris disc surface area, Heterobasidion spore infection was not observed.
This research was funded by JSC Latvian State Forests project No. 5-5.9.1_007q_101_21_79, “Investigation of the impact of root rot and reducing risks caused by root rot”.

P1.1-091

EFFECT OF BIOACTIVE METABOLITES OF NATIVE STRAIN OF TRICHODERMA HARZIANUM FOR MANAGEMENT OF MAJOR FOLIAR DISEASES OF MAIZE IN MEGHALAYA, INDIA

MAHANTA Madhusmita. (1), DUTTA Pranab. (1)

(1) College of Post Graduate Studies in Agricultural Sciences, Central Agricultural University (Imphal), Umiam, Umiam, INDIA

Text

Trichoderma is a versatile ascomycetes fungus with lucrative biocontrol potential and plant growth promoting activity. To understand their biocontrol abilities, an isolate of *T. harzianum* (Th) native to Meghalaya, India was evaluated *in vitro* against three major pathogens of maize viz., *Rhizoctonia solani*, *Exserohilum turcicum* and *Sclerotium rolfsii* with significant inhibitory effect. The bioactive metabolite of Th was isolated, characterized and evaluated against the targeted pathogens, and found inhibitory effect. A field experiment was conducted for two seasons against Banded leaf and sheath blight, Exserohilum leaf blight and Sclerotium wilt of maize with eight treatment combinations of bioactive metabolite of Th. The results revealed a decrease in per cent disease incidence and severity with enhanced plant growth parameters and yield attributing parameters. A positive effect on total soil organic carbon percentage and total microbial populations as compared to the control was also observed during the experimentation. The results are indicative of the antifungal activities and PGP abilities of the bioactive metabolite of Th. The findings of the experiments may be useful as an effective way of managing the targeted diseases of maize.

MICROALGA-ANTIFUNGAL BACTERIA SYNERGISTIC EFFECT ON PLANT PATHOGENIC FUNGI AND KING'S STRAWBERRY QUALITY

MIN-JEONG Kim. (1), CHANG KI Shim. (1), JAE-HYEONG Lee. (1), YU-MI Han. (1)

(1) National Institute of Agricultural Sciences, Wanju, REPUBLIC OF KOREA

Text

King's strawberry is one of large-fruited strawberries and is highly preferred by consumers due to their large fruits, but it is necessary to develop eco-friendly management technologies that can improve the disadvantages of soft fruits and weak powdery mildew. The purpose of this study was to evaluate the effects of phytopathogenic fungi on mycelial growth and quality of Strawberries when King's strawberry was treated with microalgae and antifungal bacteria. 0.4% microalga, Chlorella fusca (CF) and antagonist bacteria, AFB2-2 were mixed and replaced with Botrytis cinerea (BC), Colletotrichum gloeosporioides (CG), Phytophthora capsici (PC) and Sclerotinia sclerotiorum (SS). It was found to inhibit all mycelial growth of five plant pathogenic fungi. Hardness of King's strawberry with 0.2% and 0.4% CF and AFB2-2 increased by 22.7% and 9.1%, respectively, compared to untreated. In addition, the hardness of Seolhyang Strawberry mixed with 0.2% and 0.4% CF and AFB2-2 increased by 49.4% and 34.5%, respectively, compared to untreated. Through the above results, it is revealed that the combined treatment of chlorella (CF) and antagonist bacteria (AFB2-2) can be used as a biological management technology that can increase the hardness and sugar

content of King's and Seolhyang strawberry as well as inhibit the mycelial growth of plant pathogens.

EXPERIMENTAL EVOLUTION TO STUDY THE ADAPTATION OF PLANT-BENEFICIAL PSEUDOMONADS TO INSECTS

ZWYSSIG Maria. (1), SPESCHA Anna. (1), SCHNEIDER Jana. (1), KEEL Christoph. (2), MAURHOFER Monika. (1)

(1) ETH Zurich, Zürich, SWITZERLAND; (2) University of Lausanne, Lausanne, SWITZERLAND

Text

Plant-beneficial pseudomonads are promising candidates for the biological control of plant diseases and insect pests. *Pseudomonas protegens* bacteria are efficient root and insect colonizer with antifungal as well as insecticidal activities. This versatility in lifestyles makes them highly interesting to study. Although many traits enabling root colonization and insect pathogenicity are already known, it is not clearly understood how these bacteria are adapted to a life in insects. We performed an experimental evolution with *P. protegens* CHA0 based on serial infection cycles of larvae of the crop pest *Plutella xylostella*. Although some evolved populations displayed altered insect killing speed compared to the original strain, bacterial virulence did not substantially change during the experimental evolution, indicating that *P. protegens* CHA0 is already well adapted to this insect species. *In vitro* screens of the evolved populations showed changes in growth rate and antimicrobial activities whereas genotyping revealed mutations in genes which are connected to the bacterial membrane structure. The adaptational phenotype of the identified genetic variations needs yet to be determined. Our experimental evolution provides new knowledge on the adaption of plant-beneficial pseudomonads to insects which is also important for their application in biological pest control.

Text

Pepper (*Capsicum annuum* L.) is an economically and nutritionally important vegetable within the family Solanaceae. Biotic stresses impact the quality and productivity of the crop. Wilting caused by soil-borne *Fusarium* species are among the most challenging diseases of peppers to control. Integrated disease management (IDM) is a sustainable approach to control diseases. Biocontrol is an important component of IDM approaches to manage soil-

borne pathogens. Plant microbiome analysis has allowed opportunities for identifying associated microbes with plant beneficial functions, including biocontrol. Samples of bulk soil, rhizosphere, roots, and stem of diseased pepper plants showing wilting symptoms and healthy pepper were collected from the experimental farm of the WorldVeg, Shanhua, Taiwan. Metagenomic sequencing and analysis of the 16S (V3-V4) and ITS (3-4) regions were compared among samples. Species composition showed an abundance of *F. oxysporum*, *F. proliferatum*, and *F. solani* associated with diseased peppers. The unique taxa directly associated with healthy peppers and distinct from the pepper-conserved microbial community were identified as potential biocontrol agents. Thus, analyzing plant-microbial communities can provide insights into key microbes for biocontrol against diseases and their interaction with host plants and pathogens.

Text

Atractylodes lancea is a perennial herb and an important medicinal plant with a long history of clinical application in China. With the massive market demand and the subsequent development of *A. lancea* farming, severe issues including root rot disease outbreaks resulted from the continuous cropping of perennial *A. lancea*. We performed extensive studies on the microbiota associated with *A. lancea* and the soil to seek solutions.
Via next-generation sequencing of the 16S and ITS amplicons of microbe communities in the root endosphere and rhizosphere of *A. lancea* samples of diverse origins. We identified a group of steadily co-existing microbes in the rhizome consisting of the bacterial genera Rhodococcus, Ralstonia, Burkholderia-Caballeronia-Paraburkholderia, Sphingomona, and Pseudomonas, and a fungal genus Ascomycota, which we believe comprised the specific core microbiome of this particular plant species. We managed to isolate 33 endophytic bacterial strains and 13 endophytic fungal strains from the rhizome of *A. lancea* and performed inoculation experiments to study their resistance against root rot pathogens and their individual inducing effects on the medicinal compound accumulation and growth of *A. lancea*. We screened for endophytes with biocontrol potentials via dual-culture with two strains of Fusarium spp., the major pathogenic fungi of A. lancea root rot disease. The microbe strains we acquired showed promising application potential in future A. lancea farming.

EFFICACY OF BCA'S AND PRI'S FOR THE CONTROL OF POTATO EARLY BLIGHT AND POTATO LATE BLIGHT

PÕLDMETS Marian. (1), PUIDET Britt. (1), LOIT Kaire. (1), KOPPEL Mati. (1)

(1) Estonian University of Life Sciences, Tartu, ESTONIA

Text
Early blight and late blight are both economically significant potato diseases worldwide. Control of potato early blight and late blight are currently heavily reliant on chemical fungicides. In the last decade, the use of biological control agents (BCA's) and plant resistant inducers (PRI's) for the suppression of plant pathogens has increased rapidly and has become a viable alternative for chemical pesticides. The aim of the present study was to assess the efficacy of different BCA's and PRI's for the control of both potato diseases in an artificially inoculated greenhouse studies. The influence of timing and dosage of BCA's and PRI's on disease development was evaluated on one moderately resistant and one susceptible potato cultivar. Efficacy of disease suppression was expressed through the area under the disease progress curve (AUDPC). Efficacies of biological products were compared with chemical fungicide Revus Top (mandipropamide, difenoconazole). There were significant differences in efficacies of used biological products. Results indicated that timing of application and product as well their interactions had marked effect on development of both diseases in both used varieties. The best products provided significant disease reduction, but none of them had the efficacy in the same level as used chemical fungicide. The experiment was carried out within the framework of the ECOSOL project.

Text
Plant elicitors (PE) have the ability to activate pattern triggered immunity (PTI), via there recognition by pattern recognition receptors (PRRs). PRRs contain extracellular domains and bind to PE in a receptor-ligand manner. For instance, PRRs containing leucine-rich repeats (LRRs) domains, are known to bind to peptides as bacterial flagellin, whereas PRRs containing lysine motifs (LysMs) are implicated in recognition of N-acetylglucosamines compounds as fungal chitin. PE perception results in the induction of a series of events such as reactive oxygen species (ROS) production, phytohormone signalling and defence molecules accumulation.

Here, we evaluated how the combination of two elicitors, perceived by different PRRs, affect A. thaliana PTI activation. Using an untargeted metabolomic approach, we found that

elicitors combination impacts a highest number of metabolites and deregulates specific metabolites pathway, when compared to the elicitors used alone. This highlights the interest to use a combination of elicitors in crop protection strategies. We then characterized a natural extract from Ulva algae from which we showed that plant eliciting activity was due to both ulvan polysaccharides and arabinogalactan-protein (AGP)-like compounds. We investigate defence response and metabolic changes induced by the Ulva extract treatment in A. thaliana and we studied how this type of complex extract is perceived by the plant.

Text

Nematodes have versatile lifestyles and provide a suitable lens to decipher the ecosystem conditions. Here, 18S rDNA metabarcoding was employed to study the effect on the nematode composition of arbuscular mycorrhizal fungi, bioeffector, and organic amendments in apple orchards, which were sampled during spring and autumn. Sampling time more than treatment had a significant effect on the nematode diversity and composition, and higher alpha-diversity indices were observed during spring as compared to autumn. Although treatments were able to reduce nematode richness and diversity, their effects varied. The composition of bacterivorous and herbivorous nematodes showed seasonal variations, and a higher number of bacterivorous- as compared to herbivorous- nematodes were seen during spring. The composition of nematode trophic guilds was driven by dominant families like Rhabditidae and Tylenchidae. Nematode-based indices like structure and enrichment indices revealed maturing and moderately disturbed soils for the two apple orchards; and maturity- and plant parasite- indices were generally low. This indicates potential soil nutrient enrichment in the two different orchards resulting in high primary productivity for the herbivorous nematodes. Our study provides insights into the effect of soil treatment on nematode, with implications for the development and modification of bioinoculants, as well as the potential to improve the soil ecosystem services.

IN VIVO AND IN VITRO ANTIFUNGAL ACTIVITY AND MOLECULAR MECHANISM OF DIMETHYL TRISULFIDE AGAINST COLLETOTRICHUM GLOEOSPORIOIDES FROM MANGO

TANG Lihua. (1,2), LI Qili. (1,2), CHEN Xiaolin. (1,2), HUANG Suiping. (1,2), GUO Tangxun. (1,2)

(1) Institute of Plant Protection, Nanning, CHINA; (2) The Key Lab for biology of Crop Diseases and Insect Pests of Guangxi, Nanning, CHINA

Text

Colletotrichum gloeosporioides can lead to huge economic losses during mango storage and transport, and dimethyl trisulfide (DMTS) was found in Streptomyces globisporus JK-1. The EC50 of DMTS to 66 representative strains of 13 mango Colletotrichum species in China was mainly from 0 to 20 μL/L, and the optimum treatment 80 μL/L for 6 h of DMTS to mango postharvest anthracnose could reach 66% control effect. A histological investigation demonstrated that DMTS exhibited strong inhibitory effects on the infection process of C. gloeosporioides in planta by inhibiting the germination of conidia and formation of appressoria, and contributing to deformation of appressoria prior to penetration. In vitro DMTS caused serious damage to the integrity of plasma membranes, which significantly reduced the survival rate of spores, and resulted in abnormal hyphal morphology. Moreover, DMTS caused deterioration of subcellular structures of conidia and mycelia, such as cell walls, plasma membranes, Golgi bodies, and mitochondria. In addition, to better understand the molecular antifungal mechanisms, the gene expression analysis showed DMTS significantly suppressed expression of ergosterol biosynthesis-related genes Cgerg6 and Cgerg11. The EC50 of ΔCgerg6 and ΔCgerg11 to DMTS was 3 folds and 1.9 folds of that of wild-type strain, respectively, and the wild-type phenotype was restored after the gene complements in situ, indicating that there was a close interaction between DMTS and the two genes.

EXPLORING SOYBEAN AND SUNFLOWER MICROBIOMES FOR BENEFICIAL BACTERIAL MICROORGANISMS.

HLONGWANE Neo. (1), SWART Wijnand. (1), ROTHMANN Lisa. (1), EDWARDS Alec. (1)

(1) University of the Free State, Bloemfontein, SOUTH AFRICA

Text

The control of Sclerotinia sclerotiorum in South Africa is limited to one registered fungicide for soybean and sunflower. There is an urgent need to identify biological control agents to combat white mold and promote plant health. In this study we isolate and identify beneficial microbes associated with soybean and sunflower to manage *S. sclerotiorum*. Soybean and sunflower phyllo- and rhizosphere samples from seedling to maturation were collected in Mpumalanga (South Africa). A total of forty bacterial strains were isolated and evaluated for plant growth-promoting properties, by determining phosphate solubilization, ammonium and indole acetic acid production. Sequencing of eleven bacterial isolates promoting plant growth and inhibiting four S. sclerotiorum isolates, varying in aggressiveness, was conducted using 16S-27F and 16S-1492R. Genera identified include *Bacillus*, *Lysinibacillus*, *Pantoea*, *Pseudomonas*, and *Sternophomonas spp*. In vivo root length, seedling vigor and biocontrol assays were conducted. *B. velezensis* significantly promoted root development and soybean vigor. Varying responses to *B. velezensis* was observed in *S. sclerotiorum* isolates with low and high oxalic acid production potential, ~50% and 67% inhibition, respectively. Aggressive pathogen strains must be considered when developing biological control strategies. Greenhouse and field experiments are underway to determine the reliability and efficiency of identified organisms against soybean stem rot.

P1.1-101

A CONSORTIUM OF BENEFICIAL MICROORGANISMS ALTERS THE RHIZOSPHERE MICROBIOME AND IMPACTS PLANT PERFORMANCE DIFFERENTLY IN CONTRASTING GROWING SEASONS

Text

Intensification of agricultural management for yield maximization is associated with detrimental side effects on soil and plant health. We hypothesize that extensive management with integrated use of beneficial microorganisms (BM) promote plant stress resilience. The aim of this study was to examine whether the use of a consortium with BM affects the rhizosphere microbiome and plant health of maize depending on farming practices over two growing seasons. A long-term field experiment allowed the comparison of two tillage practices (mould-board plough vs. cultivator tillage) and two nitrogen (N) fertilization intensities (intensive vs. reduced extensive N-fertilization). In both years, successful root and soil colonization of the BM was detected in all treatments, associated with changes in the rhizosphere microbiome. A significant increase in biomass and nutrient content of the inoculated plants could only be detected in the growing season of 2020, which was characterized by severe spring drought. This was associated with increased expression of physiological stress indicators involved in drought stress defense, such as osmotic adjustment and detoxification of reactive oxygen species (ROS), and accordingly reduced leaf concentrations of ROS. This multidisciplinary study provides insights into the influence of BM applications on plant-microbe interactions and plant performance inclusive the relevance of abiotic stress factors under field conditions.

P1.1-102

EVALUATION OF TRICHODERMA SPP. OIL PALM ENDOPHYTE ON THE IN VITRO GROWTH OF PHYTOPHTHORA PALMIVORA

CASTILLO Sandra. (1), ZÚÑIGA Franky. (1), LÓPEZ Juan Manuel. (1), SARRIA Greicy. (1)

(1) CENIPALMA, Bogota, COLOMBIA

Text

The Oomycete *Phytophthora palmivora* is the causal agent of Bud rot. This primary disease affects oil palm plantations in the Colombian North zone, which has reached high incidence and severity levels during the last five years. Endophytic microorganisms are of particular interest as biological control agents since they can colonize the internal tissue of plants

without causing apparent damage, compete for nutrients and space within the vascular system, and act as inhibitors of pathogenic microorganisms. Fungi of the genus *Trichoderma* comprise a group of filamentous fungi widely used in the biocontrol of plant pathogens. This study was carried out in six plantations in northern Colombia, where root samples were taken from 18 oil palms (*Elaeis guineensis*), which were processed in selective media for *Trichoderma*. Subsequently, 30 endophytic isolates of *Trichoderma* spp. were morphologically identified, and their antagonistic capacity against *P. palmivora* was evaluated with dual culture and mycoparasitism assays. The potential of 15 *Trichoderma* isolates for the control of this pathogen with PICR values >70% in the dual culture test and 100% parasitism, where mycelium coiling, sporangia and chlamydospore parasitism were observed. This study highlights the potential of using endophytic *Trichoderma* as biological control agents in the integrated management program of Bud rot in oil palm plantations in Colombia.

Text

Peanut rust caused by *Puccinia arachidis* is one of the most important peanut foliar diseases in the world. For sustainable peanut production, ecological disease management strategies are needed to limit the overuse of synthetic fungicides in the control of rust. Thus, the use of *Akanthomyces lecanii*, a hyperparasite of rust fungi, may be an alternative to control peanut rust. However, investigations of the mechanisms of action of *A. lecanii* are essential before its development as a biocontrol agent. To do so, peanut leaves bearing rust sori were detached, and each leaf was sprayed with 500 µl of a suspension of *A. lecanii* conidia (10^6 conidia/ml) at lower surface. Then, each leaf was incubated in a Petri dish on moist blotting paper at 20°C, under a 12:12 light/dark photoperiod. After 15 days' incubation, the inoculated and uninoculated rust sori were observed under photonic and electron microscopes. From our findings, pictures revealed that *A. lecanii* colonized the urediniospores of inoculated sori. Our results showed that the mechanisms of action of *A. lecanii* on *P. arachidis* could involve the following events: (i) attachment of the antagonist to urediniospores mediated by a mucilaginous extracellular matrix; (ii) penetration due to mechanical pressure and enzymes action on cell-wall; (iii) active growth of the antagonist inside of urediniospores and digestion of cell contents. From our study, the use of *A. lecanii* spores is promising tools for biocontrol of peanut rust.

Text

Forest trees frequently interact with a diverse range of microorganisms including ectomycorrhiza, bacteria, and fungal pathogens. Plant defense responses to individual pathogen have been widely studied, but very little is known on the effect of co-inoculation on host defenses. To study the impact of co-inoculation or tripartite interaction on plant growth and host defenses, Scots Pine (Pinus sylvestris) seedlings were inoculated with either Tricholoma sp or Streptomyces sp or both together with a root pathogen Heterobasidion annosum for three months. The inoculation with Streptomyces or Heterobasidion alone had negative effect on plant growth whereas co-inoculation of Tricholoma and Streptomyces sp in presence of the pathogen seems to promote plant growth (root length, number of lateral roots, seedling weight) of Scots pine over time. Based on the phenotypic examination, it was concluded that the ectomychorrhizal Tricholoma sp and Actinobacterial Streptomyces sp counteracts negative effect of H. annosum on plant growth. RNA-seq analysis of seedlings inoculated with Tricholoma sp, Streptomyces sp, infected with H. annosum will be analyzed for identification of differentially expressed genes (DEGs). The potential of pre-inoculation of seedlings to protect seedling roots before out-planting deserves to be further explored.

IN VITRO EVALUATION OF FUNGAL ENDOPHYTES OF ROSEMARY (ROSMARINUS OFFICINALIS) AGAINST DIPLODIA BULGARICA

DEMIRCAN Selale. (1), **EKEN Cafer. (1)**

(1) Aydin Adnan Menderes University, Aydin, TURKEY

Text

Endophytic fungi are a biodiversity-rich group of microorganisms that are widely present in internal plant tissues and often provide beneficial effects to their hosts. Rosemary (*Rosmarinus officinalis*) is an important medical and aromatic plant and has antimicrobial, antioxidant, antiviral, and immune system stimulatory properties. *Diplodia bulgarica* is one of the causal agents of canker and fruit rot in apples (*Malus domestica*). In this study, we isolated and identified endophytic fungi from healthy rosemary leaf, flower, and branch tissues collected in Aydin and Mugla provinces, Turkiye. An experiment on the in vitro screening of 452 endophytic fungi of rosemary against *D. bulgarica* CEE-273 indicated that four isolates showed more than 50% inhibition. Using the internal transcribed spacer (ITS) regions of rDNA, the isolates with biocontrol potential were identified as *Pyronema omphalodes* (Ro-321 and Ro-621), *Nigrospora gorlenkoana* (Ro-615), and *Sordaria fimicola* (Ro-611). This is the first report on the endophytic association of the above fungi with rosemary and the exploitation of their biocontrol potential against *D. bulgarica*.

This research was funded by Aydin Adnan Menderes University Scientific Research Projects Coordinator, grant number ZRF-21039.

Text

The plant microbiome can modulate plants' physiology and phenotype, such as development, growth, and responses to biotic and abiotic stresses. Previously, we demonstrated that a flavobacterial sp., isolated from the rhizosphere of a wilt-resistant tomato, suppresses the disease caused by *Ralstonia solanacearum*. Here, we defined bacterial species that are enriched in either resistant or susceptible tomatoes using 16S rRNA gene sequences and whole metagenome sequences. We established a collection of rhizosphere microbes, to constitute a synthetic microbial community for bacterial wilt resistance. We selected strains that belong to *Flavobacteriaceae*, *Rhizobiaeceae*, *Xanthomonadaceae*, *Rhodobacteriaceae,* and *Cyclobacteriaceae* as members of the synthetic community. An uncultured *Sphigomonadaceae* strain, which was abundant in the resistant tomato, was also successfully isolated by utilizing the metagenome-assembled genome information. The synthetic community and individual strains were subject to assays that assess their effects on bacterial wilt resistance and plant growth promotion. Our study on the rhizosphere microbiome for its involvement in disease resistance and plant health will shed light on understanding intricate relationships between plant, pathogen, and microbiome. Further, bacteria recovered in this work may serve as a useful resource to study microbe-host interactions and can be utilized as plant probiotics.

P1.1-107

BIOFORMULATION OF PHYLLOPLANE PSEUDOMONAS SPP. FOR MANAGEMENT OF SHEATH BLIGHT DISEASE OF RICE (ORYZA SATIVA)

AKTER Shamima. (1), JURAIMI Abdul Shukur. (2)

(1) Bangladesh Rice Research Institute, Gazipur, BANGLADESH; (2) Universiti Putra Malaysia, Selangor Darul Ehsan, MALAYSIA

Text

This study was conducted to formulate phylloplane Pseudomonas bacterial strain P. fluorescens and P. asplenii and to determine their efficacy on sheath blight suppression as well as on yield components of rice. Both strains were preserved in peat and talc as single

strains or in mixtures at 4°C and 28±°C. The peat formulation was found to be more suitable (at 4°C) than talc to retain longer shelf life of individuals and strain mixtures with sufficient viable cells. Evaluation of formulated strains for suppression of sheath blight revealed that the consortium and P. fluorescens alone significantly reduced the area under disease progress curve (AUDPC) compare to untreated control. Percent reduction of AUDPC was 32.79, 32.58 and 21.19 for consortium P. fluorescens and P. asplenii, respectively. Strain mixture also significantly reduced disease progress rate (0.011unit/day). In addition to disease suppression, strain mixture enhanced plant height, percent effective tiller and filled grain per plant. Effects of all the treatments on flag leaf area, total number of tiller and number of effective tillers were insignificant. However, the weight of 100-grain was significantly (1.65g) highest in strain mixture applied plants. This study suggested that indigenous Pseudomonas bacteria isolated from rice plant can be preserved in peat at 4°C until 6 months of storage and used as efficient biocontrol agents for management of sheath blight disease and increase grain yield as well.

P1.1-108

SCREENING OF VARIOUS MICROORGANISMS THAT INHIBIT THE GROWTH OF ERWINIA AMYLOVORA, THE CAUSATIVE AGENT OF FIRE BLIGHT OF FRUIT CROPS

SADANOV Amankeldy. (1), **ISMAILOVA Elvira. (1)**, ALIMZHANOVA Mereke. (1,2), SHEMSHURA Olga. (1), BAIMAKHANOVA Baiken. (1), BAIMAKHANOVA Gul. (1), MOLZHIGITOVA Assel. (1), TLEUBEKOVA Diana. (1), ELUBAEVA Akmeir . (1)

(2) Al-Farabi Kazakh National University, Almaty, KAZAKHSTAN

Text

The search for new approaches and solutions in the field of bacterial burn control is highly relevant. Microbial preparations based on microorganisms with antagonistic activity play an essential role. In this regard, the genera Bacillus, Pseudomonas, Lactobacillus and Saccharomyces, which are in the collection of the Scientific Production Center of Microbiology and Virology, have been screened and have inhibitory activity against Erwinia amylovora the causative agent of fire blight of fruit crops. It was established that in bacteria of the genus Bacillus only two strains suppressed the growth of the pathogen E. amylovora. B. amyloleguefaciens and Bacillus N2, the zone diameters of suppression were 30.0±0.6 mm and 14.0±1.0 mm, respectively. Among the bacteria of the genus Pseudomonas, no strains with inhibitory activity were found. Most strains of the genus Lactobacillus suppressed the growth of the pathogen. The maximum inhibition zone of E. amylovora was in strains L. paracasei 33-4 (39.6 ± 6.65 mm), L. plantarum M17 (35.6 ± 0.57 mm).
Among strains of the genus Saccharomyces, the largest growth inhibition zone (25.6 ± 2.08 mm) was found in S. cerevisiae (vini). It was found that the component composition of the culture fluid of B. amyloliquefaciens mainly contains acetoin and 2,3-butanedione. Strains of the genus Lactobacillus produce acetic acid and lactic acid to a greater extent. Strain S. cerevisiae forms phenylethyl alcohol, 1-butanol, 3-methyl.

P1.1-109

MYCOVIROIDS HAVE POTENTIAL TO CONTROL CROP FUNGAL DISEASES

DONG Kaili. (1), **XU Wenxing. (1)**

(1) Huazhong Agricultural University, Wuhan, CHINA

Text
Mycoviruses are the only acellular agents that have been extensively investigated and utilized to combat crop fungal diseases. Recently, a novel class of viroid-like RNAs naturally infecting a filamentous fungus Botryosphaeria dothidea were isolated from apple, and tentatively named Botryosphaeria dothidea circular RNAs (BdcRNAs) 1 to 3, which have been characterized and termed as mycoviroids referring to viroid-like RNAs naturally infecting fungi besides its original definition. BdcRNAs 1 to 3 in size of 450 to 221 nt display no detectable nucleotide identity to known RNA sequences, but share different identity levels with each other, replicate autonomously in the nucleus via a rolling-circle mechanism following a symmetric pathway. BdcRNAs significantly affect the biological traits of B. dothidea by regulating the gene expression and metabolic pathways related to important cellular processes of the fungal host. More importantly, BdcRNAs 1 and 2 can significantly attenuate or even erase the fungal virulence, while enhance the growth (for BdcRNA1) and increase the tolerance to some osmotic stress of the host fungus. These features provide an important alternative candidate to serve as a biocontrol tool for attenuation of fungal diseases similar to some mycoviruses that cause hypovirulence.

Text
Below-ground pests are difficult to control because either no effective control methods exist or suitable insecticides are or will soon be banned due to their negative effects on the environment. We evaluated the potential of disease-suppressing *Pseudomonas chlororaphis* bacteria with entomopathogenic activity for insect control. Moreover, we combined the pseudomonads with entomopathogenic nematodes (*Steinernema feltiae*) and fungi (*Metarhizium brunneum*) with the aim to increase reliability and efficacy of biocontrol measures.
In a series of experiments ranging from the greenhouse to the field, *P. chlororaphis* emerged to be highly efficient in controlling the cabbage maggot *Delia radicum*, an important pest of Brassicacean crops. Furthermore, the triple consortium of *P. chlororaphis* with *S. feltiae* and *M. brunneum* increased the number of marketable radishes by 50% in a field trial. In several experiments, we observed increased pest control when combining the pseudomonads with the nematodes or the fungi. These synergistic effects were verified when applying the combinations against two further pests. The triple consortium was the most lethal and fastest killing treatment against *Pieris brassicae* and *Diabrotica balteata* larvae. In the early stages

of the infection, all three agents established inside the larvae.
Our results show that entomopathogenic pseudomonads, nematodes and fungi are compatible and could potentially be used to control a variety of below-ground insect pests.

Text
In nature, bacterial pathogenicity is counteracted mainly by plant-derived antimicrobial defense molecules. In return, efflux pumps (EP) are part of the resistance mechanism employed by bacterial pathogens to promote their survival in a chemical hostile environment. We studied the effect of combinations of efflux pump inhibitors (EPIs) and plant-derived antimicrobial phenolic compounds on bacterial activity, using Pectobacteriun brasiliense 1692 (Pb 1692) as a model system. Specifically, we measured the minimal inhibitory concentration (MIC) of two phytochemicals, phloretin (Pht) and naringenin (Nar), and of one common antibiotic ciprofloxacin (Cip), either alone or in combinations with two known inhibitors of the AcrB EP of Escherichia coli, a close homolog of the AcrAB-TolC EP of Pb 1692. In addition, we also measured the expression of genes encoding for the EP, under similar conditions. Using the FICI equation, we observed synergism between the EPIs and the phytochemicals, but not between the EPIs and the antibiotic, suggesting that EP inhibition potentiated the antimicrobial activity of the plant-derived compounds, but not of Cip. Docking simulations were successfully used to rationalize these experimental results. Our findings suggest that AcrAB-TolC plays an important role in the survival and fitness of Pb1692 in the plant environment and that its inhibition is a viable strategy for controlling bacterial pathogenicity.

EXPLORING THE EFFICACY OF PLANT EXTRACTS IN VITRO AGAINST MANGO ANTHRACNOSE PATHOGEN: COLLETOTRICHUM GLOEOSPORIOIDES

ZOHAIB Latif. (1), MUHAMMAD Sajjad. (1), RASHIDA Atiq. (1)

(1) Department of Plant Pathology, Bahauddin Zakariya University, Multan, PAKISTAN

Text
Mango (Mangifera indica L.) is a delectable fruit grown in less than 90 tropical and sub-tropical countries in the world. Mango anthracnose, caused by Colletotrichum gloeosporioides, is a highly destructive disease. Chemical control is most frequently

practiced by the mango growers, which poses bad impacts on the environment and human health. Hence, alternate control strategies should be used for the management of disease and for increasing the potential yield of mango. The in vitro potential of neem, mint, and garlic for control of Colletotrichum gloeosporioides was investigated in the current study. The pathogen was isolated from diseased mango plant portions. Aqueous and methanolic extracts of neem, mint, and garlic were prepared and tested at different concentrations for their efficacy against fungal growth. All plant extracts significantly reduced the fungal growth in the poison food technique as compared to the control. The methanolic extract of neem was most effective in fungal growth suppression. Results of this study indicate that plant extracts can be used for the control of anthracnose disease in mango. It will be less expensive and safer, and it may be a viable alternative to synthetic fungicides.

Text

Biological control agents (BCA) play an important role in crop protection and can be used to reduce the usage of chemical plant protection products as desired by public policy. Differents *Bacillus* and *Trichoderma* are used in commercial BCA products. However, the BCA efficacy depends on a lot of environmental parameters such as pH, temperature, hygrometry or cultural practices. It is important to quantify the BCA dynamics in the environment to have a better understanding of their efficacy and the differences observed between controlled and fields conditions. This study aims to (i) develop specific qPCR and dPCR methods for *Trichoderma atroviride*, *Bacillus velezensis* species and *Bacillus amyloliquefaciens* operationnal group and (ii) monitor BCA populations dynamics in plants and soils. The different tools were validated for each organism under laboratory conditions (specificity, sensitivity, …) and have been tested on samples from field trials. We were able to monitor the dynamics of the BCA in the rhizosphere and in wheat according to the time after application. In our field conditions, the implantation of the BCA either in soils or in plants was variable, often weak and not durable over time which could explain the weak efficacy of the BCA observed against the targeted diseases. Thus, the generic tools developed will be useful to monitor different biocontrol agents that use *B. amyloliquefaciens* or *T. atroviride* whatever the crop and the strains.

Text

Cork oak decline is becoming a serious problem in Tunisian forests. This phenomenon is caused by a combination of biotic and abiotic factors mainly drought and several pathogenic fungi. Following a survey on the oak decline in Northwestern Tunisia, Biscogniauxia mediterranea, Diplodia corticola and Diplodia gallae were identified as the main causal agents of oak decline. Faced with the extent of this decline and the aggressiveness of these pathogens, control methods should be applied. For this purpose, the biocontrol potential of Trichoderma isolates towards these pathogens was investigated. Trichoderma strains, isolated from cork oak trees, were identified as T. harzianum, T. citrinoviride and T. saturnisporum through the sequencing of four DNA regions. Dual culture inhibition experiments were used to evaluate the antagonistic effect of Trichoderma isolates against B. mediterranea, D. corticola and D. gallae. The results showed the efficacy of T. harzianum in comparison with T. citrinoviride and T. saturnisporum by inhibiting totally the mycelial growth of pathogenic fungi. Microscopic observations showed a mycoparasitic relationship between T. harzianum and pathogens. These findings might prove the possibility of applying Trichoderma isolates in an eco- friendly way as biological agents against cork oak pathogens.

P1.1-116

INVESTIGATING CHANGES IN THE ROOT MICROBIOTA IN RESPONSE TO RICE'S CRY FOR HELP UNDER DIFFERENT FOLIAR PATHOGEN ATTACKS

JOBERT Léa. (1), MOULIN Lionel. (1), BENA Gilles. (1)

(1) IRD, Montpellier, FRANCE

Text

In response to biotic and abiotic stresses, plants have evolved various defence strategies, including the recruitment of health-promoting root-associated microorganisms via a “cry for help” mechanism. This selected community of microorganisms is known to help minimize the damages caused by the stress, for example by modulating plant nutrition or immunity. However, the rules of microbiome assembly following foliar pathogen infection and the mechanisms that govern its assembly and function in the diseased host are still poorly understood. In particular, it is not known whether different pathogens can induce different root microbiome changes. Using *Oryza sativa* subsp. *japonica* cv. Nipponbare, we analysed the modifications of the root-associated microbiome after host exposure to five different foliar pathogens, including two bacteria (*Xanthomonas oryzae* and *Xanthomonas oryzicola*), two fungi (*Pyricularia oryzae* and *Bipolaris oryzae*) and one virus (Rice Yellow Mottle Virus). Rice was grown in a greenhouse on rice field-sampled soil, and inoculated with the respective pathogens. One week after inoculation, we collected the rhizosphere and analysed the diversity of the microbiome using 16S/18S/gyrB amplicon sequencing approaches. Whether the pathogen has an effect on the root microbiome and whether each pathogen affects it differently, with common signatures specific to each group of pathogens, will be presented in this poster.

SECONDARY METABOLITES OF INSECT SYMBIONTS AND THEIR ANTIMICROBIAL ACTIVITY

YIN Caiping. (1), HUANG Zhong-Di . (1), JIANG Zhou . (1), WU Jun. (1), KONG Kun . (1), ZHANG Shu-Xiang . (1), **ZHANG Yinglao. (1)**

(1) Anhui Agricultural University , Hefei, CHINA

Text

The resistance of plant pathogenic fungi to fungicides is becoming more and more serious. It is of great significance to develop new agricultural fungicides. Insects are widely distributed in a variety of ecological niches, and their ability to live in unique habitats is often to promote symbiosis with their microbes, which were sources of new antibiotic metabolites. For example, the new metabolite isochromophilone XV from the symbiont of *Ectropis oblique* significantly inhibited *Colletotrichum graminicola* with IC_{50} value of 29.9 μg/mL. Insects are a group of organisms with the largest number of known species in the earth biosphere, and the special microorganisms symbiotic with insects are rich in diversity. However, compared with insect species, there is less research on insect symbionts and less research on their metabolites, so it is urgent to strengthen research.

P1.1-118

ASSESSING THE ANTAGONISTIC POTENTIAL AND BIOCONTROL EFFICACY OF RICE-ASSOCIATED BACTERIA AGAINST MAGNAPORTHE ORYZAE

SANGA Issouf. (1), **KASSANKOGNO Abalo Itolou. (1)**, KLONOWSKA Agnieszka. (2)

(1) National Center for Scientific and Technological Research (CNRST)/Institute of the Environment and Agricultural Research (INERA), Bobo Dioulasso, BURKINA FASO; (2) PHIM Plant Health Institute, Montpellier, FRANCE

Text

The fungal pathogen Magnaporthe oryzae causes one of the most important rice diseases: blast. It is found in rice-growing regions around the world and causes significant yield losses. Resistant cultivars and fungicides are the most widely used methods of control. However, the recent concept of the holobiont opens the way to promising sustainable alternatives for plant protection, based on plant-microbe interactions. In this context, we initiated a study of beneficial bacteria using two approaches: i) in vitro, to search for bacteria antagonistic to M. oryzae, through a bacterial/fungal confrontation test on two culture media, and ii) in planta, to search for bacteria with biocontrol activity, through the observation of blast symptoms on rice plants primed with the beneficial bacteria. The results allowed the selection of seven bacterial strains from the genera Azorhizobium, Bacillus, Burkholderia and Cupriavidus with the ability to reduce mycelial development by up to 57%, as well as four bacterial strains from the genera Azorhizobium, Bacillus and Burkholderia with the ability to reduce blast symptoms by up to 45%. Phylogenetic analysis based on 16S rDNA showed that the bacterial strains probably correspond to new species distinct from those already described. Two strains from

the genera Bacillus and Burkholderia had both abilities. The bacterial genomes were sequenced, which should help us to further investigate the mechanisms involved.

P1.1-119

WHAT MAKES A COMPOST SUPPRESSIVE TO SOILBORNE PATHOGENS?

LOGO Anja. (2,3,4), THÜRIG Barbara. (2), OBERHÄNSLI Thomas. (2), MAURHOFER Monika. (4), WIDMER Franco. (3), MAYERHOFER Johanna. (3), **FLURY Pascale. (1)**

Text

Composts have been shown to suppress soilborne pathogens in numerous greenhouse and field experiments. However, the effectiveness of disease suppression is highly variable between composts, and we currently lack reliable indicators to select composts for plant protection. We hypothesize that disease suppression is a complex interplay between abiotic and biotic compost properties. Investigating the microbial communities may help to develop tools for predicting suppressive properties and producing composts with strong biocontrol activity.

In the first part of the project, 17 composts were assessed for disease suppression in a cress–*Globisporangium ultimum* (syn. *Pythium ultimum*) system and assessed for their physico-chemical properties. Their microbial communities were analyzed using an Illumina metabarcoding approach, which identified bacterial taxa that are indicative for disease suppression. This data set has now been extended by 30 additional composts and a cucumber–*G. ultimum* and a cucumber–*Rhizoctonia solani* test system, which revealed differences in disease suppression between pathogens and plant species. The microbial communities are currently assessed by SMRT cell long-read sequencing with the goal to get a high taxonomic resolution to accurately relate the sequencing data with isolates obtained from the composts. Our comprehensive data set provides new insights into the contribution of different abiotic and biotic factors to disease-suppressive activity of composts.

ENVIRONMENTAL CONDITIONS AFFECT PUCCINIA PUNCTIFORMIS TELIOSPORE LONGEVITY

ASTETE FARFAN Almendra. (1), NORTON Andrew. (1), JAHN Courtney. (1)

(1) Colorado State University, Fort Collins, UNITED STATES

Text

The autoaecious rust-fungus *Puccinia punctiformis* is an obligate biotroph pathogen of *Cirsium arvense*; a cosmopolitan weed and one of the most harmful noxious weeds in

agricultural and forestry landscapes in North America and Europe. The pathogen completes its whole life cycle on *C. arvense*, occasionally causing a systemic infection characterized by the production of spore-bearing shoots that die before flowering or producing seeds, and a large reduction in above- and below-ground biomass. This high level of specificity and the severe damage caused by the systemic form of the rust disease makes *P. punctiformis* a promising biocontrol agent against *C. arvense*.
Although the pathogen has been found wherever its host is distributed and can persist in infected batches for years, it rarely reaches epidemic population levels. Since the viability of overwintering teliospores is crucial to forming basidiospores to establish systemic infection every new season, teliospore viability could be affected by field conditions of temperature and humidity through time. To test this hypothesis, teliospores collected in July-August 2022 were stored at -19°C, 6°C, or 23°C; and 5%, 22%, 62%, or 90% relative humidities (RH), to finally analyze their viability by measuring teliospore germination rate once each month later over 250 µl/L dodecyl-NSC in 1% agar. Germination results declined at 23°C under 90% and 62% RH suggesting that teliospore longevity decreases at high humidities and temperatures.

P1.1-121

DISEASE-INDUCED CHANGES IN SOYBEAN MYCOBIOME DETERMINE PLANT HEALTH

ZHAO Yao. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text
The plant microbiome is an essential part of the host and is gradually recognized as playing a critical role in plant growth and health. But still, the formation and functions of plant microbiomes during pathogen invasion are not fully understood. We investigated how the soybean plant attracts helpful microbes to suppress soil-borne diseases. We found that the soil mycobiome determined whether the plants survived or succumbed to infection. Surviving plant microbiomes were linked to unique taxa, pathogen-suppressing fungi, and fungi that induce plant immunity. Our findings imply that soil mycobiome composition and function might be recruited under pathogen attack, influencing the consequences of plant-pathogen interactions.

BIOCONTROL EFFECTS OF RHIZOBACTERIA PRODUCING VOLATILE-ORGANIC COMPOUNDS AND CYLCOLIPOPEPTIDES AGAINST THE MAJOR PATHOGEN FUNGI OF WHEAT

BALLOT Aline. (1), DORE Jeanne. (1), **PRIGENT-COMBARET Claire. (1)**

(1) University Claude Bernard Lyon 1, Villeurbanne, FRANCE

Text
The use of pesticides for managing crop pests and plant diseases had shown several

bottlenecks, stimulating research for developing alternative plant protection solutions. One of them relies on the use of biocontrol products to reduce pathogen populations and limit disease incidence. Plant Growth-Promoting Rhizobacteria (PGPR) could be considered as very good candidates.
In this work, we explore biocontrol potentials of a panel of PGPRs isolated from the wheat rhizosphere and belonging to several bacterial genera, against 2 major fungal wheat pathogens Fusarium graminearum and Zymoseptoria tritici. Characterization of bacterial volatiles and secreted secondary metabolites for their inhibition properties against mycelium and spore growth was made using in vitro antagonist confrontation tests on the two pathogens. It was followed by plant protection assays on wheat crown rot fusariosis under greenhouse conditions. This 2-step screening allowed us to identify strains with direct antagonist effects and others with indirect mechanisms related to plant defense stimulation. Combining genome mining and metabolomics approaches, we were able to identify some key molecular determinants for the inhibition of fungal pathogens in our PGPR library. Metabolic profiling and consecutive bio-guided fractionation of secondary metabolites secreted by antagonist strains reveal that lipopeptides and dimethylpolysulfide volatile organic compounds are among the main antifungal active biomolecules.

Text
A diverse group of microorganisms inhabiting plant seeds can colonize the host during growth and development. Previous studies have demonstrated the capacity of fungal and bacterial species recovered from wheat seeds to manage plant
disease. Trichoderma species are promising biocontrol agents. They are opportunistic, avirulent plant symbionts or endophytic fungi, and the molecular mechanisms employed by them to control fungal phytopathogens such as mycoparasitism and antibiosis have been previously described. Endophytic Trichoderma spp. have a broad host range with a remarkable ability to promote the host plant's performance. In the current study,
a Trichoderma sp. was isolated from seeds of wheat cv. Tiregan through surface disinfection. Our infection assay under greenhouse conditions revealed that spray application of Trichoderma sp. could reduce Septoria tritici blotch (STB) symptoms caused by the Z. tritici IPO323 on inoculated plants. The percentage leaf area covered in lesions (PLACL) and percentage leaf area covered in pycnidia (PLACP) were reduced by 70% and 18%, respectively, in wheat plants treated with applied Trichoderma sp. compared with control plants. Therefore, this endophytic Trichoderma sp. isolated from wheat seed can reduce symptoms caused by Z. tritici IPO323 under glasshouse conditions.

P1.1-125

EXPLOITING BIODIVERSITY IN PERENNIAL CROPS: EFFECT OF MYCORRHIZAL BASED PRODUCTS ON THE VINEYARD RHIZOSPHERE

ASINARI Florencia. (1), TAIBI Othmane. (1), ROSSI Vittorio. (1), **CAFFI Tito. (1)**

(1) Università Cattolica del Sacro Cuore, Piacenza, ITALY

Text

The massive use of chemical products not only affects the application effectiveness due to the risk of resistance, but also affects the environment. For this reason, the viticulture sector is facing a major challenge, which is an ecological transition. In recent years, the development of different vineyard management alternatives are trying to contribute to a sustainable viticulture model. Increasing biodiversity helps to reduce the use of pesticides and increase ecosystem services. The use of arbuscular mycorrhizal fungi improves the tolerance to abiotic stresses and protects the roots against pathogens. The main objective of this work was to analyze the effect on the biodiversity of vine rhizosphere under mycorrhizal products application. For a period of four years, the microbial rhizosphere biodiversity was manipulated in an experimental vineyard using seven different microbial products, with annual inoculations. Soil and root samples were taken annually for bacterial and fungal detection by the Illumina sequencing. For each treatment, the detected microorganisms and their respective number of reads was obtained. The microbial biodiversity was estimated by the indices: Shannon, Simpson, Pielou, species abundance and species richness. Preliminary results show that the products applied influence the rhizosphere biodiversity increasing the richness index and, in some cases, providing a promising induced resistance to downy mildew.

P1.1-126

OCCURRENCE OF NATURAL POPULATIONS OF ENTOMOPATHOGENIC NEMATODE STEINERNEMA FELTIAE IN CEREAL FIELDS OF SOUTHEAST IDAHO

ENSAFI Pooria. (1), RASHED Arash. (2), SMILEY Richard. (3), MARSHALL Juliet. (1)

(1) University of Idaho, Idaho Falls, UNITED STATES; (2) Virginia Tech Southern Piedmont Agricultural R&E Center, Blackstone, UNITED STATES; (3) Oregon State University, Pendelton, UNITED STATES

Text

Wireworms are very destructive in small grain production in the Pacific Northwest and difficult to control with insecticides. In a targeted survey to detect local populations of entomopathogenic nematodes (EPNs) in southern Idaho, USA, six populations of EPNs were isolated from the soils of cereal fields that were heavily infested with larval stage of click beetles (Coleoptera: Elateridae). Initial morphological characteristics placed the collected EPNs into the genus *Steinernema* (Travassos, 1927) which is a known biological control agent, with active nictation, cruiser locomotion, and infection dynamics that can be variable

at intraspecific level. Additional molecular analysis was required as morphological characteristics will not delineate the isolated samples to species level. The sequence analysis of partial ribosomal RNA gene complexes including internal transcribed spacers (ITS1 and ITS2) and D2D3 expansions of 28S large subunit confirmed the occurrence of *S. feltiae*. Phylogenetic relationships inferred from maximum likelihood (ML) analysis of ITS-rRNA sequences distinguished the isolated EPNs to the Feltiae clade. Cytochrome c oxidase I (*COI*) of mitochondrial DNA resolved the phylogenetic relationships to within *S. feltiae* subclade using ML analysis of *COI* mtDNA sequences. This study is the first report and characterization of *Steinernema feltiae* in southeast Idaho. Additional studies on the infection dynamics and bacterial symbiosis for these isolates is required.

P1.1-127

USE OF PSEUDOMONAS RHIZOBACTERIA AS BIOHEBICIDES FOR PROTECTING CROPS AGAINST BROOMRAPES

LURTHY Tristan. (1), VACHERON Jordan. (2), PRIGENT-COMBARET Claire. (1)

(1) University Claude Bernard Lyon 1, Villeurbanne, FRANCE; (2) Department of Fundamental Microbiology, University of Lausanne, Lausanne, SWITZERLAND

Text

Broomrapes (Orobanche and Phelipanche) are root parasitic plants that affect a wide range of economically important crops worldwide (rapeseed, sunflower, etc), thus posing tremendous threats as they can cause heavy yield losses. When broomrapes infest a field, farmers have to reduce their producing area using only non-infested plots. So far, crop protection against parasitic weeds is mostly based on the use of systemic chemical herbicides in combination with the use of crop genotypes that show tolerant behavior against broomrapes.

In conventional agriculture, large scale use of chemical plant protection products has led to the degradation of soil quality and has had a dramatic impact on natural flora and fauna. Living organisms able to protect plants against broomrapes, or any weed management strategies that are more environmentally friendly needs to be found.

We have identified and characterized several Pseudomonas rhizobacteria able to produce compound(s) that stop, under in vitro conditions, the germination of broomrape seeds, thus further affecting the growth of the parasitic plant under greenhouse conditions. One of this compound is a polyketide. It is efficient at concentrations below 25µM against P. ramosa and 50µM against O. cumana. Other Pseudomonas strains that do not produce this polyketide also shared an herbicide activity against these plant parasites, showing that a very wide diversity of novel secondary metabolites from Pseudomonas could be used as bioherbicides.

P1.1-128

USE OF NATURAL COMPOUNDS WITH LOW ENVIRONMENTAL IMPACT FOR THE PROTECTION OF SEED-BEARING ONION AGAINST FUNGAL DISEASES

PIANCATELLI Simone. (1), MOUMNI Marwa. (1), PEREZ ALVAREZ Eva Pilar. (2), DAVILLERD Yann. (3), CANTALAMSSA Gabriele. (1), TENTI Luca. (4), BENEDETTI

Text

Seed-bearing onion is an important crop in several area of production, and it can be affected by several fungal pathogens. Most of these infect the seed, which then become an efficient vehicle to disperse seedborne pathogens over long distances, resulting in potential severe crop losses. The need for high-quality seed and the increasingly stringent restrictions on the use of synthetic plant protection products imposed by the European Union fostered the search for alternative solutions to protect seedbearing vegetable crops from seedborne pathogens. Within the project “CleanSeed” promoted by PSR Marche, Central-Estern Italy, this work aimed to evaluate, on a company scale, the effectiveness of several innovative protection strategies based on the use of basic substances, biocontrol agents, plant extracts and low-risk active substances. Four strategies including chitosan, chito-oligosaccharides and oligo-galacturonides (COS-OGA), a mixture of terpenes, and Bacillus spp. were tested, and an assessment was carried out on the infections of the stem and flowers by Botrytis spp. Chitosan strategy reduced Botrytis spp. McKinney Index compared to untreated control on onion plant by 60%. The results obtained from this study open the way for new protection strategies based on the use of natural substances in the management of fungal diseases of seed-bearing vegetables.

P1.1-129

EVALUATION OF ESSENTIAL OILS OF LOCAL AROMATIC PLANTS AGAINST CHICKPEA BLIGHT IN PAKISTAN.

SAQIB Hafiz Muhammad. (1), CHOHAN Sobia. (1), **ABID Muhammad. (1)**

(1) Department of Plant Pathology, Faculty of Agricultural Sciences and Technology, Bahauddin Zakariya University, Multan 60800, Pakistan, Mutan, PAKISTAN

Text

The aim of this study was to evaluate the essential oils of Pakistan`s local aromatic plants as biological control of chickpea blight caused by *Ascochyta rabiei*. Another objective was to evaluate the impact of selected essential oils on plant health and growth. Out of 30 plants essential oils only 10 showed the antifungal activities against *A. rabiei*. Cumin (*Cuminum cyminum* L.) essential oil produced the highest fungal mycelial growth and spore germination inhibition and was selected for the further study on planta. The minimal inhibitory concentration was revealed as 0.5 ml/L and the minimal fungicidal concentration was found 1 ml/L. Microscopic examination of *C. cyminum* EO on hyphal morphology revealed that the essential oil caused degenerations, less branching, loss of septations, vesicles formation, shriveling and lysis of hyphae. Cumin essential oil improved the plant growth especially when the seeds were treated with essential oil (≥0.5ml/L) after inducing the priming with water. In greenhouse, cumin essential oil protective spray on chickpea reduced the disease severity was significantly reduced (upto 70%). The biochemical changes and expression of resitance genes in planta due to the treatment by cumin essential is in progress. It will help to understand the possible role of *C. cyminum* essential oil in resistance mechanism in chickpea plants. The results of field experiments and These studies will hopefully be completed and presented in the conference.

Text

Because they are sessile organisms, plants have developed different strategies to fight pathogen infections. Although the plant immune system has been mainly described for plant-pathogen interactions, commonalities between beneficial microorganism and pathogen infections have been established. Among beneficial interactions, the nitrogen fixing symbiosis of alders with the actinobacteria *Frankia* has been well studied. Establishment of this symbiosis leads to the formation of root nodules. In the other well-known nitrogen-fixing symbiosis between legumes-rhizobia, it is recognized that the plant immune system is modulated in early stages of symbiosis. Much less data is available on *Frankia-Alnus* model and it is still unclear how plant immune system reacts when root nodules are well established and how it impacts plant ability to face pathogen infections.
We hypothesised that the presence of *Frankia* in alder tissues activates the plant immune system and could play a role in the defence against *Phytophthora alni*.
Our objective is to understand whether the alder immune system is activated by the symbiosis with *Frankia* and whether this symbiosis can play a role in modulating the defences against the pathogen *Phytophthora alni*. For this purpose, we developed an experimental system of *Alnus*-*Frankia* interactions including the pathogen *Phytophthora alni*. We performed multi-omics analyses to compare plant defence reactions to face the pathogen when hosting or not its symbiont *Frankia*.

Text

Entomopathogenic fungi (EPF) offer potential biological solutions to manage plant sap-

feeding insect pests, such as aphids. The plant-colonization capability of notable endophytic EPF strains ensures their survival and confers plant protection and growth functions. This work is aimed to discover novel EPF candidates with the potential for effective management of Barley Yellow Dwarf Virus (BYDV) and the aphids that vector the virus in barley crops.
For this study nineteen endophytic fungal candidates were utilized, which were isolated from different plant niches-seed, stem, leaf and root tissues of cereal plants. These endophytic fungi candidates were associated with ten different taxonomic genera. For the screening experiment, the adult aphids were exposed to endophytic fungal spores for three hours and then transferred to the plants. The results under controlled conditions have shown a promising reduction in the aphid population across different time points. There were up to two-fold reductions in the number of adult aphids and nymphs elicited by four different fungal candidates. Interestingly, >30% of the endophytic fungal candidates screened demonstrated the potential to suppress aphids and nymph numbers.
The key findings suggest that diverse representations of these endophytic taxa could potentially offer multi-choice effective biological control agents. Ongoing work is focused on establishing a mechanistic understanding of aphid inhibition by potential endophytes.

P1.1-132

EVALUATION OF THE PATHOGENICITY OF ENTOMOPATHOGENIC NEMATODES ISOLATED IN TAIWAN AGAINST FALL ARMYWORM

PINI Emilia. (1), HUANG Shao-Chi. (1), GUO Hao-Yu . (1), YANG Jiue-In. (1)

(1) National Taiwan University, Taipei, TAIWAN

Text

The insect pest Fall armyworm *Spodoptera frugiperda* (FAW) invaded Taiwan in 2019. It is capable of causing severe damage to food crops. Entomopathogenic nematodes (EPNs) and thier symbiotic bacteria have the capacity to parasitize and kill their host. However, no local EPN products are currently available on the market in Taiwan. Therefore, this study aimed to obtain local EPN populations, identify and characterize the EPNs and their symbiotic bacteria, and further evaluate their parasitism efficacy and pathogenicity against FAW. Between 2019 and 2020, four EPN strains were isolated from a survey of 45 soils in Taiwan. The nematodes were identified as *Pristionchus pacificus* (strain 6) and *Oscheius myriophilus* (strains 16, G1A1, and G1B1). The bacteria *Serratia marcescens* and *Achromobacter insuavis* were isolated from *P. pacificus; Cupriavidus spp, Pseudomonas spp. Variovorax spp.* and *Stenotrophomonas spp.* were obtained from *O. myriophilus*. Among them, *C. malaysiensis* and *V. paradoxus* resulted in 41% and 30% mortality rates on FAW 3rd instar larvae, respectively. Moreover, *P. putida*, *C. alkaliphilus* and *C. malaysiensis* reduced the FAW pupae eclosion rate significantly. Further, three concentrations of EPN suspension were examined. As a result, the mortality rate of FAW was between 21-27 %, 21-23%, 18-20%, and 22-26% for the application of strains 6, 16, G1A1, and G1B1, respectively. The damage on leaves was 53-60%, 56-59%, 53-56%, and 53-56% for each EPN strain, respectively.

SYNERGISM OF TRICHODERMA GENOTYPES FOR MANAGEMENT OF FUSARIUM WILT IN TOMATO

HANNAN Abdul. (1), ALI Muhammad . (2), ATTA Sagheer . (1)

(1) Ghazi University D G Khan, D.g. Khan, PAKISTAN; (2) Government College University Lahore, Lahore , PAKISTAN

Text

Trichoderma genus has a good place in biological control market. Trichoderma spp are capable to recognize and attack on several soil borne plant pathogens but during current study, synergistic effects among four species were assessed against Fusarium wilt of tomato. Primarily, a comprehensive survey was conducted, and four dominating species of Trichoderma were identified and purified from different agro-ecological zones of Pakistan. These species were Trichoderma harzianum, T. viride, T. atroviride and T. virens. All these species were successfully cultivated in sets of two with different degree of success. In the present study an isolate of Fusarium oxysporum pv lycopersici was taken form First Fungal Culture Bank of Pakistan. After pathogenicity test, the pathogen was subjected to grow on PDA plates against all four Trichoderma species. In-vitro results showed that, T. harzianum and T. viride gave 92 and 84% reduction in colony growth over control whereas T. virens and atroviride gave 32 and 26% reduction respectively over control. Furthermore, sick plants were treated with all four strains of Trichoderma spp separately and in combinations of two with all possible blends. Statistical analyses revealed that, T. harzianum along with T. atroviride increased their antagonistic potential 3.6 fold where as T. atrovirude and T. viride gave 2.8 fold increase in protection value against Fusarium wilt of tomato with reference to single isolate application.

MANAGEMENT OF ADULT AND IMMATURE LARGE PINE WEEVIL (HYLOBIUS ABIETIS L.) USING NOVEL LOCAL-PROVENANCE ENTOMOPATHOGENIC FUNGI AND COMMERCIAL ENTOMOPATHOGENIC NEMATODES.

QUINZO-ORTEGA Luis. (1), RAE Robbie. (1), MOORE Roger. (2), WILLIAMS Christopher. (1)

(1) Liverpool John Moores University, Liverpool, UNITED KINGDOM; (2) Forest Research, Roslin, UNITED KINGDOM

Text

The large pine weevil (LPW) is a widespread forest pest in conifer clearfell restocking areas. Biological control agents are the best candidates to replace widely used synthetic chemicals with potential side effects on the environment and humans. Entomopathogenic nematodes (EPN) and fungi (EPF) are successful at controlling its immature stages and also present additive effects when applied together to tree stumps. We propose a new approach that also targets the adults that survived the control of immatures. Surviving emerging adults will be lured with volatiles like alpha-pinene to traps containing an EPF. A large-scale soil sampling campaign within various habitats has provided new locally sourced EPF to be used together with commercial EPN strains. High diversity of EPFs has been obtained from soil using a. The local strains of EPF are tested for pathogenicity on LPW to select the best entomopathogenic agent for adult traps and to study their additive/synergistic effects with commercial EPN. To test the efficacy of the approach in the field, mark-recapture

experiments will be conducted, which will inform the development of an efficient chemical-free method to control H. abietis on forest clearfell areas.

PRODUCTION AND ACTIVITY OF RHIZOBACTERIAL ANTIMICROBIAL-VOLATILES STRONGLY DEPEND ON CULTURE CONDITIONS

RAJER Faheem Uddin. (1), GAO Xuewen. (2)

(1) Sindh Agriculture University, Tandojam, PAKISTAN; (2) Key Laboratory of Integrated Management of Crop Diseases and Pests, Ministry of Education, Department of Plant Pathology, College of Plant Protection, Nanjing Agricultural University, Nanjing, CHINA

Text

Antimicrobial volatile activity of rhizobacteria has been achieved by growing them on rich media, raising a question of whether the production and activity of antimicrobial volatiles are limited to a few reported media types. Effect of inoculum amount and inoculation method of antagonist on production and activity of antimicrobial volatiles has not been reported. Therefore, antimicrobial activity of Bacillus cabrialesii FA26 against soilborne fungi was investigated under different culture conditions. Results showed that FA26 when grown on NA showed higher suppression against Fusarium oxysporum, Rhizoctonia solani, and Phytophthora capsici by 39.83, 63.57, and 43%, respectively under double-dish chamber. However, FA26 exhibited 56.38% better suppression against Sclerotinia sclerotiorum when grown on LB. Effect of inoculum amount and inoculation method on the production and activity of antimicrobial volatiles of FA26 showed a clear dose-dependent potential and was highly correlated with the increase in the amount of inoculum using either of the inoculation methods; however, spreading mode of inoculation was better than that of the drops. Headspace SPME/GC-MS analysis revealed 26 volatiles' production by FA26. Of these, 8 volatiles completely inhibited one of the four phytopathogens. The study suggests production and activity of rhizobacterial volatiles strongly depend on culture conditions. Furthermore, the results revealed a direct long-distance biocontrol mechanism of FA26.

P1.1-136

EFFICACY OF BOTANICALS AGAINST BROWN LEAF SPOT OF RICE CAUSED BY BIPOLARIS ORYZAE

SHAHEEN Hafiz Muhammad Usama. (1), RAJPUT Nasir Ahmed. (1), ATIQ Muhammad. (1), SAHI Shahbaz Talib. (1), KACHELO Ghalib Ayaz. (1), AHMAD Hadeed. (1), WAHAB Muhammad. (1), HASNAIN Abuzar. (1)

(1) University of Agriculture, Faisalabad, Pakistan, Faisalabad, PAKISTAN

Text

Rice (Oryzae sativa L) is suffering from several biotic and abiotic factors. Among biotic factors, brown leaf spot of rice (BLS) is potentially devastating disease of rice causing the severe yield losses up to 100%. The current study was designed to evaluate eco-friendly management strategy towards BLS to avoid environmental and human hazards. For this

purpose, thirty botanicals were screened out under in vitro conditions and five most effective extracts were further demonstrated against the targeted pathogen with three different concentrations (10, 20 and 30%) by using poisoned food technique. The results revealed that Ginger and Eucalyptus showed the strong inhibitory effect against B. oryzae at 30% concentration followed by Mint, Turmeric and Dhatura respectively. The promising extracts (Ginger and Eucalyptus) under lab conditions were further evaluated in vivo against BLS disease by using 3 types of applications i.e. Preventive, Curative and after symptoms appearance. Findings showed that, preventive application was found most effective as compared to other applications, furthermore combination of ginger and eucalyptus showed significant reduction in disease incidence percent as compared to solo applications. The reduction in disease incidence percent in all application methods suggested that these extracts could be used as alternative of synthetic fungicides against BLS of rice.

TRICHODERMA SPECIES INTERACTION WITH FUSARIUM OXYSPORUM PV LYCOPERSICI AND INDUCED RESISTANCE IN TOMATO

MUSA Muhammad. (1), AHMAD Mushtaq. (1)

(1) UNIVERSITY OF AGRICULTURE, FAISALABAD, PAKISTAN, Lahore, PAKISTAN

Text

Trichoderma are versatile beneficial fungi which can stimulate growth and plant resistance to biotic stress. Understanding the Trichoderma species for their diverse modes of action for management of Fusarium oxysporum, pv Lycopersici is a central goal of this research. In our ongoing studies most recently, we have tested the ability of T. harzianum to protect against salinity which adversely affects germination and growth of tomato seedlings. Trichoderma seed treatment improved plant tolerance. A model system for Trichoderma induced resistance to biotic stresses was provided by induction of a systemic response against fusarium wilt of tomato. Firstly 27 strains belonging to three species of Trichoderma were subjected to evaluate against F. oxysporum pv lycopersici through dual culture technique in-vitro. Statistical analysis revealed that eight species showed better antagonism against tested pathogen and were selected for field studies. These eight species were cultivated on sorghum based solid state fermentation on large scale and applied in field on artificially inoculated tomato seedlings. The results of current study showed that, the isolates of T. harzianum isolated from soil sample taken from tomato field expressed promising results and gave 94.6% reduction in disease over control whereas other isolates gave protection value under 62.0%. Therefore, the isolate which showed better performance under way to be characterized and its molecular identification.

BIOLOGICAL CONTROL OF AFLATOXINS USING NON-TOXIGENIC STRAINS OF ASPERGILLUS FLAVUS

VARVERI Maria. (1), KAMINIARIS Michail. (1), **TSITSIGIANNIS Dimitrios. (1)**

(1) Laboratory of Plant Pathology, Department of Crop Science, Agricultural University of Athens, Athens, GREECE

Text

Mycotoxins are one of the major threats to food and feed safety and quality worldwide. More specifically, aflatoxin AFB1 and its metabolite AFM1, have been classified by the International Agency for Research on Cancer (IARC) among the most carcinogenic compounds for humans. Due to the inability of chemical methods to control aflatoxin levels on maize and pistachios, the use of non-toxigenic strains of *Aspergillus flavus* has been characterized by numerous studies as the most effective control strategy. The purpose of the present study was to evaluate several non-toxigenic strains in terms of their ability to reduce aflatoxin production in situ, on artificially infected corn seeds with a highly toxigenic *A. flavus* strain from the collection of the Laboratory of Phytopathology, Agricultural University of Athens.Our experiments indicated the high effectiveness of these specific non-toxigenic isolates in inhibiting the biosynthesis of aflatoxins on pistachios, reaching reduction rates of aflatoxin levels between 80-90% both in laboratory experiments and in field experiments. In the context of biological management, the most effective of the non-toxigenic isolates in corn kernels were further applied to maize cultivation, under field conditions and their effectiveness was further confirmed at high percentages. Novel formulations of the application of the non-toxigenic strains in the field are also examined.

Text

In the context of reducing the use of synthetic pesticides, one of the solutions consists in using microorganisms. The strains belonging to the *Streptomyces* genus, known to produce a wide variety of antifungal metabolites, constitute a promising alternative to conventional products. To isolate new candidates a collection of 35 strains of *Streptomyces* was screened to detect antifungal and anti-oomycete activities using *Fusarium graminearum* and *Phytophthora capsici*. Five strains inhibited both fungal and oomycete growth among which a top candidate species was selected. This strain was further characterized for its ability to inhibit diverse plant pathogenic oomycete species belonging to *Phytophthora*, *Pythium* and *Aphanomyces* genus. To study protection of the strain against root disease, we performed soil inoculation or seed treatments on the legume model *Medicago truncatula* and on one of the major legume crops, pea, and evaluated the protection against *Aphanomyces euteiches*. To identify the mode of action of the strain, sequencing with PacBio CLR and Nanopore technologies of the genome was performed enabling us to annotate 34 specialized metabolite biosynthetic gene clusters. Untargeted metabolomics performed on culture medium confirmed the production of some candidate metabolites related to these gene clusters known to display as antifungal and anti-

oomycete. Our results suggest that this strain could be promising for the biocontrol of plant disease notably caused by oomycetes.

P1.1-140

EFFICACY OF TRICHODERMA SPP. AGAINST PHYTOPHTHORA CAPSICI, THE CAUSE OF ROOT ROT OF CHILLI

ALI Muhammad Usman. (1), RAJPUT Nasir Ahmed. (1), ATIQ Muhammad. (1)

(1) University of Agriculture, Faisalabad , Faisalabad, PAKISTAN

Text

Root rot caused by *Phytophthora capsici* is a devastating disease of chilli pepper in tropical and subtropical areas of the world causing huge economic losses. Now a days, management of *P. capsici* considered to be a great challenge due to its long-term survival in soil, resistance to fungicides and commercially available chilli varieties. New possibilities to manage phytophthora root rot in chili production are under demand due to emerging fungicide and plant resistance. Therefore, this study aimed to investigate the anti-oomycete activity of three different *Trichoderma* species (*T. viride, T. virens,* and *T. harzianum*) against *P. capsici* both *in-vitro* and *in-planta*. The lab trial, through dual culture plate method indicates that, each tested *Trichoderma* species were significantly inhibiting the mycelial growth of *P. capsici* as compared to control treatment. The mycoparsitic interaction was also observed between *P. capsici* and *Trichoderma* spp. during slide culture assay. On further, *in-planta* evaluation the combined application of *T. virens* and *T. harzianum* expressed the lowest disease incidence (22.56%) with highest control efficacy (72.82%) as compared to individual application of each tested *Trichoderma* spp. The observed disease reduction indicates that these *Trichoderma* spp. could have a significant role in biologically based plant disease management strategies for management of Phytophthora root rot of chili pepper.

P1.1-141

EVALUATING THE ANTAGONISTIC EFFICACY OF PLANT GROWTH-PROMOTING RHIZOBACTERIA AGAINST ALTERNARIA SOLANI-INDUCED EARLY BLIGHT DISEASE IN TOMATO PLANTS

GONDAL Amjad Shahzad. (1), HYDER Sajjad. (2)

(1) Department of Plant Pathology, Faculty of Agricultural Science and Technology, Bahauddin Zakariya University, Multan, PAKISTAN; (2) Department of Botany, G.C. Women University, Sialkot, PAKISTAN

Text

Present Study investigated the efficacy of PGPR as an alternative to chemical fungicides in controlling Alternaria blight, a severe fungal disease of tomato caused by Alternaria solani. At least 11 fungal isolates were recovered from symptomatic tomato plants and identified the most virulent one through virulence assay. A total of 17 bacterial strains belonging to two potential PGPR species; Bacillus and Pseudomonas were recovered from the rhizospheric soil of healthy tomato plants. Four rhizobacterial strains were selected based on their effectiveness in inhibiting the most virulent strain of A. solani in vitro. Two isolates belonging

to Azotobacter and Rhizobium spp. with proven plant growth promoting traits provided by AARI Faisalabad were tested in vitro for their efficacy against the same virulent strain. Among all the bacterial isolates, Pseudomonas isolates showed the highest mycelial growth inhibition of A. solani. In repeated pot trials, all tested bacterial strains alone and in combination significantly improved seed germination and plant growth and provided substantial protection against early blight disease. The PGPR-pretreated tomato plants also exhibited increased chlorophyll content, total phenol, free proline, total protein, and the activities of peroxidase and polyphenol oxidase. All treatments showed increased levels of indole acetic acid, abscisic acid, salicylic acid, and jasmonic acid compared to the levels in infected plants used as control.

Text

Microbial biocontrol agents are promising tools to reduce the use of chemical pesticides in agriculture. Due to their characteristics of living organisms, their deployment is more complex than applying chemicals, and result in the variability of their efficacy, which can hinder their adoption. Taking this complexity into account would make their use more reliable.
Thus, it is necessary to develop decision support systems (DSS) based on biological properties of biocontrol agents, those of plant pathogens, and the characteristics of cropping systems. To develop such a DSS, a database has been set up to integrate information collected from scientific and technical literature and synthesize them into easily accessible datasheet.
However, an analysis of the database reveals that the available data are not sufficient, and many information is lacking in particular on the real conditions of use of biocontrol agents and few factors can be apply in commercial situation.
To solve this issue, it seems both necessary and promising to supplement available data with feedbacks from users of biocontrol agents directly from the field. Therefore, an application is currently under development to collect these feedbacks on the use of biocontrol to enrich the database to allow better guideline when using biocontrol product.

P1.1-143

EFFECT OF BIOCONTROL AGENTS AS PRUNING WOUND PROTECTANTS AGAINST GRAPEVINE TRUNK DISEASES

BUSTAMANTE Marcelo. (1), ELFAR Karina. (1), BLUNDELL Robert. (2), ESKALEN Akif. (1)

(1) University of California, Davis, Davis, UNITED STATES; (2) Pro Farm Group Inc., Davis, UNITED STATES

Text

The world grape industry is seriously affected by grapevine trunk diseases (GTDs) and effective and sustainable management strategies are required. From 2019 to 2022, our laboratory evaluated biological and chemical fungicides as pruning wound protectants against GTD pathogens. In these trials, bacterial and fungal biocontrol agents (BCAs) obtained from healthy grapevine tissues were evaluated and compared to commercial chemical and biological fungicides. BCAs were prepared in liquid culture in the laboratory and applied on fresh pruning wounds of 10-years-old 'Cabernet Franc' vines. Commercial pruning wound protectants were applied at their label rate. After five days, treated pruning wounds were inoculated with spore suspensions (10,000 conidia) of *Neofusicoccum parvum*. After six months, pruning wounds were evaluated by performing isolations on potato dextrose agar. Results showed that fungal BCAs (*Aureobasidium pullulans* and *Trichoderma* spp.) exerted significant pruning wound protection when compared to synthetic chemicals and other biofungicides. In conclusion, fungal BCAs provided better pruning wound protection than bacterial BCAs in field conditions and constitute a suitable and sustainable management alternative for GTD management.

ITALIAN TRADITIONAL MAIZE LANDRACES AND THEIR MICROBIOME: NEW PERSPECTIVES FOR BIOLOGICAL CONTROL OF FUSARIUM VERTICILLIOIDES

FOLLADOR Alessia Regina Vera. (1), PASSERA Alessandro. (1), MIOTTI Niccolo'. (1), GHIDOLI Martina. (1), CONSONNI Gabriella. (1), BALCONI Carlotta. (2), PILU Salvatore Roberto. (1), CASATI Paola. (1)

(1) UNIVERSITA DEGLI STUDI DI MILANO, Milano, ITALY; (2) CREA-Centro di ricerca Cerealicoltura e Colture Industriali, Bergamo, ITALY

Text

Maize-associated microorganisms, established through the evolutionary mechanism of selection, change according to certain factors such as genotype, geographical location, and environmental variables. GEMMA project focuses on beneficial endophytic bacteria inhabiting the embryo of four traditional maize landraces (Nero Spinoso Valcamonica, Spinato Gandino, Rostrato Rosso Rovetta, Fiorine Clusone, preserved at CREA Bergamo Genebank) and an inbred line (B73). To highlight the effect of environmental selection and the influence of vertical microbiota inheritance, plants were grown for three years in four different locations (Landriano, Bergamo, Verderio, Carvico) under low-input farming systems. Since recent studies show how certain endophytes can fight pathogens, this study aims also to study the relationship between the isolated endophytes and the most common toxigenic maize fungal pathogen in Lombardy region: Fusarium verticillioides. In vitro and in vivo test antifungal assays show that, out of over 100 isolates, only 2 from Spinato Gandino significantly reduce fungal infection. Instead, field trial results from 2021 experimental fungal inoculations show that Spinato di Gandino is the most susceptible variety out of those

analysed.
Pathogen resistance traits from landraces and their associated microbiome can be of interest for future organic maize production and contribute to more sustainable biotic stress management and higher yields, even in the scenario of climate change.

P1.1-145

CAN PREDATORS MITIGATE SOILBORNE DISEASES?

SCHWELM Arne. (1,2), GEISEN Stefan. (2)

(1) Teagasc, Wexford, IRELAND; (2) Wageningen University & Research, Laboratory of Nematology, Wageningen, NETHERLANDS

Text
Soil predators are of central importance in regulating the interaction between plants, soil, and microbiota via a top-down control of microbes, including plant pathogens, and increased nutrient cycling. Infections by plant pathogens trigger defence, can alter the host metabolism and nutrient flow into the soil, leading to changes which feed-back to the soil microbiome. However, the links between soilborne pathogens, soil predators and the soil microbiome are only starting to be explored. We used the clubroot pathogen *Plasmodiophora brassicae* - a major obstacle for the cultivation of Brassica worldwide with no effective control options - to investigate disease induced changes of the soil microbiome and the role of soil predators in clubroot disease development. We aim to identify potentially disease suppressive and disease conducive predators and microbiome members, including bacteria, fungi and protist and other top-down controller. We combined soil physicochemical analyses with long-amplicon sequencing to decipher underlying drivers of taxonomic and functional changes in the microbiome to clubroot infections in field and greenhouse experiments. Additionally, feeding behaviour of soil predators on clubroot spores was investgated. We present insights of the potential of soil predators to control soilborne diseases such as clubroot that might lead to new biocontrol applications for soilborne pathogens in the future.

P1.1-146

HARNESSING THE SOIL MICROBIOME TO CONTROL ARMILLARIA ROOT ROT ON OLIVE.

ACI Meriem Miyassa. (1), AGOSTEO Giovanni Enrico. (1), MOSCA Saveria. (1), MALACRINÒ Antonino. (1), SCHENA Leonardo. (1)

(1) Mediterranea University of Reggio Calabria, Reggio Calabria, ITALY

Text

Armillaria root rot caused by *Armillaria mellea* represents a serious threat to several plant species, including olive trees. This fungus is highly pathogenic, and current control strategies are mainly based on the prevention of the disease since curative methods are generally ineffective and may have a significant impact on the environment. In this study we focused on

the use of the soil microbiome as a possible tool to control rots caused by *A. mellea*. Specifically, we mass-selected bacterial isolates with antagonistic activity against several soil-borne pathogens (*Rosellinia necatrix*, *Phytophtora sp*., and *Phytopythium sp*.) from soils with high microbial diversity, and we assessed their *in vitro* antagonism against *A. mellea* in dual-culture assays. The most effective isolates were then evaluated *in-vivo* using potted olive plantlets, testing the efficacy of both single microbial strains or their combinations to contrast A. mellea. Finally, we investigated the impact of selected combinations of strains on the plant and soil microbiomes, in presence or absence of *A. mellea*. Our results contribute to show that the fundamental understanding and the correct management of the soil microbiome can be one of the major tools shaping the future generation of plant protection strategies.

P1.1-147

TAR SPOT DISEASE SEVERITY INFLUENCES PHYLLOSPHERE-ASSOCIATED BACTERIAL AND FUNGAL MICROBIOMES

SINGH Raksha. (1), CRANE Charles. (1), SHIM Sujoung. (2), TELENKO Darcy. (2), **GOODWIN Stephen. (1)**

(1) USDA-Agricultural Research Service, West Lafayette, UNITED STATES; (2) Purdue University, West Lafayette, UNITED STATES

Text

Tar spot, caused by the obligate fungal pathogen *Phyllachora maydis*, is a foliar disease of corn that since 2015 has become a major concern in the USA. To test for interactions between other microbes and the tar spot pathogen, phyllosphere microbiomes were compared among corn inbreds with differential tar spot symptoms under natural infestation in the field. Leaf samples from sixteen inbred lines were assessed for tar spot symptoms, and bacterial and fungal microbiomes were characterized. Comparison of the phyllosphere microbiomes revealed distinct bacterial and fungal communities between resistant and susceptible lines. Bacterial and fungal species richness was significantly higher in resistant compared to susceptible inbred lines. In contrast, there were no clear differences in diversity when including evenness of bacterial communities between the resistant and susceptible lines. Diversity of fungal communities differed significantly, particularly between twelve of the fourteen susceptible versus resistant lines. Many of the bacterial and fungal species showed statistically significant correlations with *P. maydis* reads. Those that are positively associated could be mycoparasites that are more common with a more abundant food source. Species with significant negative correlations could be antagonistic with a potential for biocontrol. Further analyses of these distinct microbiota could lead to a better understanding of the potential role of foliar microbiomes on tar spot.

UNRAVELING THE MODE OF ACTION OF A FUNGICIDAL AND NEMATICIDAL DIPEPTIDE PRODUCED BY BACILLUS VELEZENSIS UMAF6639

VELA-CORCIA David. (1), HIERREZUELO Jesús. (1), PÉREZ-LORENTE Alicia. (1), DE VICENTE Antonio. (1), PÉREZ-GARCÍA Alejandro. (1), ROMERO Diego. (1)

(1) Instituto de Hortofruticultura Subtropical y Mediterránea “La Mayora”, Universidad de Málaga Consejo Superior de Investigaciones Científicas (IHSM-UMA-CSIC), Departamento de Microbiología, Universidad de Málaga, 29071, Málaga. , Malaga, SPAIN

Text

In the last decades, the use of beneficial bacteria has become a promising strategy to combat plant diseases. Previous studies have shown that the Bacillus velezensis UMAF6639 strain had an excellent biocontrol capacity against fungal and bacterial diseases of cucurbits. In addition, it had been observed that it could also be effective against plant parasitic nematodes.
Currently, the application of chemical agents remains the most common method for managing and controlling these pathogens. However, due to the increasing concern about environmental and public health safety issues, many highly toxic chemical compounds have been restricted in their use. Therefore, there is an urgent need to develop more environmentally friendly ecological alternatives for controlling these pathogens.
Therefore, in this study, the identification, characterization, and mode of action description of a molecule produced by Bacillus velezensis UMAF6639, a cyclic dipeptide, which was demonstrated to have nematicidal and fungicidal activity, was carried out. The results indicated that the activity of this molecule was based on a common mechanism capable of altering the physical characteristics of the pathogens plasma membrane, which is key to the physiology and homeostasis of these organisms. This discovery is important because it provides a basis for the development of new biological control agents that are effective against plant diseases caused by pathogens other than fungi and bacteria.

P1.1-149

UNLEASHING CRYPTIC CHEMISTRIES FROM THE BENEFICIAL MICROBE TRICHODERMA HAMATUM HEPA

EL-HASSAN Said. (1), SONG Lijiang. (1), GRANT Murray. (1)

(1) Warwick University, Coventry, UNITED KINGDOM

Text

Crop inoculation with the eco-friendly strain of *T. hamatum* or their secondary metabolites could induce active biologicals against soilborne pathogens and reduce the use of pesiticides and fertilizers in the agricultural and environmental systems. *Trichoderma* species have garnered interest for decades due to their plant growth promoting and antimicrobial properties. Mycoparasitism by *Trichoderma* was first observed in the 1930s, followed more recently by the identification of small molecules such as peptiabols, gliotoxin and 6-pentyl pyrone. Sequencing of *T. hamatum GD12* revealed that up to 38% of its genome is unique by comparison to other sequenced *Trichoderma* strains, and only 50% of the gene clusters identified by fungiSMASH have homology to clusters from other *Trichoderma* strains. These data combined imply that the genetic potential of *T. hamatum hepA* to produce novel specialised metabolites may be unprecedented within the *Trichoderma* genus. To access the biosynthetic potential of *T. hamatum hepA*, a mutant strain was constructed in which a gene encoding a heterochromatin protein – a global regulator of metabolism – was knocked out. This *hepA* mutant exhibits enhanced growth promotion in assays with lettuce, in addition to antifungal activity against *Sclerotinia sclerotiorum*. By a combination of comparative chromatography-mass spectrometry analyses and bioassays, we have begun to identify the cryptic metabolites responsible for the enhanced antimicrobial phenotype observed.

Text

Plants recruit soil microorganisms to provide various functions or protection against pathogens. Crop plants and their associated microbial communities are therefore increasingly studied together. However, the mechanisms that control the assembly of the root-associated microbiome remain difficult to disentangle, especially in rice ecosystems, which are poorly studied. Here, we compare the assembly of rice rootassociated microbiota sampled from 19 smallholder fields in the irrigated and rainfed lowlands of Burkina Faso. Using a 16S rRNA gene amplicon and ITS metabarcoding approach, we show that the rice production system is a major factor in the structure of the microbiome in addition to the expected structure by root compartments (root vs. rhizosphere) and geographic areas. In irrigated systems, we found greater diversity of rhizosphere prokaryotic communities and more complex co-occurrence networks, compared to rainfed lowlands, while fungal communities showed an opposite pattern. The main taxa were different between the two systems, and indicator species were identified: mostly within Bacillaceae in the rainfed lowlands, and within Burkholderiaceae and Moraxellaceae in the irrigated areas. Finally, a higher abundance in rainfed lowlands was found for mycorrhizal fungi. Our results highlight profound differences in the microbiome induced by contrasting rice production systems that should therefore be considered for microbial engineering applications.

P1.1-151

TOWARDS A MORE SUSTAINABLE CONTROL OF ALMOND WOOD DISEASES

ROMERO-CUADRADO Laura. (1), PICOS María Cinta. (2), CAPOTE Nieves. (1)

(1) Andalusian Institute of Agricultural and Fisheries Research and Training (IFAPA), Alcalá Del Río, Seville, SPAIN; (2) Universidad Pablo Olavide, Seville, SPAIN

Text

Almond is one the most important nut crops worldwide. The implementation of new management techniques such as high-density cultivation, prune intensification, drip irrigation and fertilization, mechanical harvest, use of more productive varieties, and the cultivation in agronomically and environmentally more favorable cropping areas, has increased the

productivity in last decades. However, this new scenario, together with the current climate change situation, have increased almond diseases such as those caused by fungi of the Botryosphaeriaceae family. Symptoms include cankers on the trunk, extensive gummosis, internal tissue necrosis, and occasional death of the plant. Control methods are based on cultural practices, fungicide application and the search for resistant varieties. In this work, two collections of bacteria, rhizospheric and endophytic, have been obtained and characterized as potential biological control agents (BCA) of almond wood diseases. The in vitro and in planta antagonistic effect of 22 bacterial strains against Botryosphaeria dothidea, Neofusicoccum parvum, Diplodia seriata and Macrophomina phaseolina has been evaluated. Strains of Bacillus velezensis, Pseudomonas aeruginosa, B. mobilis and B. safensis could inhibit the in vitro growth and reduce the length of the lesions caused by these fungi in almond trees. The production of hydrolytic enzymes could be related to the mechanism of action of these potential BCAs

EVALUATION OF VARIOUS FUNGICIDES AND BOTANICALS AGAINST POSTHARVEST BLUE MOLD OF ONION

WARIS Muhammad. (1,2)

(1) Balochistan agriculture college Quetta, Gandakha, PAKISTAN; (2) Sindh Agriculture university Tandojam , Tandojam , PAKISTAN

Text

Onion is important vegetable crops in Pakistan. It has special quality, adds taste to the flavor and is being consumed throughout the world. It has been affected by various post-harvest diseases on large scale that results in the reduction of shelf life of onion. Blue mold of onion is one of the detrimental disease in storage. The Experiment was conducted in Plant Pathology laboratory at Balochistan Agriculture College, Quetta to isolate and identify the pathogen and to check the efficiency of various fungicides viz., Acetic acid, Aerosol, Mancozeb and Puslan and three botanical extracts such as Coriander, Mint and Turmeric. These Fungicides were applied in vivo and in vitro conditions to find the most effective chemicals/ fungicide. Disease severity was checked from infected bulbs and data was statistically analyzed. On the basis of morphological characteristics Penicillium expansum was determined to cause blue mold of onion. It was revealed from research that Fungicides/Botanicals brought significant reduction in mycelial growth and spore germination of Penicillium expansum. Within tested fungicide aerosol gave effective result in controlling mycelial growth and spore germination followed by Puslan, Acetic acid and Mancozeb. Amongst Plant extract coriander gave significant result followed by mint and Turmeric.

Text

Olive knot disease caused by the Gram-negative bacterium *Pseudomonas savastanoi* pv. *savastanoi* is one of the most important diseases that affect olive trees (*Olea europaea* L.). The plant genotype has been recognized to be a key determinant of microbial community that is associated with plant health. We assessed the microbial community in phyllosphere and rhizosphere of olive varieties from the Olive Germplasm Collections. Varieties showed different susceptibility to olive knot disease. The trees showing the symptoms were compared with asymptomatic trees to elucidate the potential role of microbiome in protecting the host plants from the disease. DNA was extracted from root and leaf samples and whole metagenome shotgun sequencing of 16S rRNA gene was used to characterize microbiota in olive compartments. With regard to prokaryotic communities, both richness and diversity indices were compared. Bacterial communities were composed by dominant phyla *Proteobacteria*, *Bacteroidota* and *Actinobacteriota* in leaves and by *Proteobacteria*, *Actinobacteriota* and *Chloroflexi* in roots. The overall data suggest that genotype and pathogen infection may result in distinct microbial community structure. These results suggest that highly diverse microbiome may improve the plants ability to resist the effects of

pathogens potentially contributing to plant health.

C9.7-1

CHARTING THE INTERACTOME OF CAULIFLOWER MOSAIC VIRUS

SCHOELZ James. (1)

(1) University of Missouri, Columbia, UNITED STATES

Text

The ability of a virus to infect a plant is dependent on an intricate series of interactions between both the virus and the host. Viruses might appear to be handicapped by their genome size, as the genomes of many plant viruses have a coding capacity limited to less than ten proteins. However as new functions are described for individual virus proteins, the apparent simplicity of the virus genome has been shown to be an illusion that belies the true impact that plant viruses have on host physiology. In this presentation, we will discuss our evolving understanding of the interactome of cauliflower mosaic virus (CaMV), a process that was initiated over forty years ago with the publication of the genome sequence of CaMV. The initial nucleotide sequence revealed that the CaMV genome is composed of seven open reading frames (ORFs), and six proteins were subsequently matched up with their respective ORFs; the seventh putative protein has never been found in infected plants. Since the CaMV genomic sequence was finalized, numerous studies have been completed to determine the functions of the six CaMV proteins, as well as their subcellular localization, and new functions have been characterized for these proteins. In particular, interactome maps have illustrated how individual CaMV proteins interact with each other as well as with host proteins. Interactome maps coupled with subcellular localization studies can be used to reveal new insights into the CaMV disease cycle.

Kufa, IRAQ; (3) University of Leicester, Department of Genetics and Genome Biology, Leicester, UNITED KINGDOM; (4) Naturalis Biodiversity Center, Evolutionary Ecology Group, Leiden, NETHERLANDS

Text

Petunia is an ideal model system to study endogenous pararetroviruses (EPRVs), particularly Petunia vein clearing virus (PVCV). Bioinformatic analysis of available Petunia genome sequences and small (sm)RNA databases revealed two distinct variants of endogenous PVCV (ePVCV1 and -2) in both wild diploids as well as in today's garden Petunia, *Petunia hybrida*. ePVCV1 was present in all Petunia genomes studied, but ePVCV 2 existed only in *P. axillaris* and P. hybrida. Elements of ePVCV 1 showed 99% sequence identity with episomal PVCV (U95208.2) and homologous smRNAs mapped throughout the viral genome. Therefore, ePVCV 1 copies likely serve as a template for initiating episomal PVCV replication in *P. hybrida*. Sequences of ePVCV2 insertions possessed 74% similarity with PVCV and lacked several regulatory elements and homologous smRNAs. This suggests that ePVCV2 is replication incompetent. Chromosome 3 seems to be a hot spot for EPRV residence in permissive Petunia genomes like *P. axillaris* and *P. hybrida*. *P. parodii*, with no detectable ePVCV, was infected with an infectious PVCV-clone and grown in tissue culture followed by generative propagation via seeds. *De novo* integration of PVCV in the telomeric regions of single chromosomes was identified using FISH. Thus, the telomeric ePVCV localization additionally to the multiple pericentromeric insertions found in the *P. hybrida* line W138, may indicates a recent, transient activation of ePVCV1 resulting in a *de novo* integration.

DIAGNOSIS AND EPIDEMIOLOGICAL DYNAMICS OF CACAO SWOLLEN SHOOT BADNAVIRUSES IN WEST AFRICA: MAJOR ADVANCES AND GAPS IN KNOWLEDGE

AMEYAW George A.. (1), OWUSU Domfeh. (1), GYAMERA Ebenezer Appiah. (1)

(1) Cocoa Research Institute of Ghana, New Akim Tafo, GHANA

Text

Cacao swollen shoot disease (CSSD) badnaviruses, family Caulimoviridae, remains a major cacao production limitation in terms of yield loss and mortality of affected cacao plants in West Africa. This presentation highlight achievements from past research efforts such as; purification of viral particles, eradication as a control strategy, the use of tolerant cacao varieties, identification of mealybug vectors, mild strain cross protection, identification of alternative hosts, and shade effect on disease severity. Further research advances including; characterization of new species of the virus and their diversity across the cacao landscape diversity are also highlighted. Pertinent issues of epidemiological importance and diagnostics considered as knowledge gabs include the following; limited information on host-pathogen interactions and its effect on development of resistant planting materials, poor quantification of viral titre in host tissues, and poor primer detection efficiency with PCR based detection assays. Sustained investigations into these grey research areas would provide an updated knowledge on the epidemiological dynamics and diagnostics of the disease for improved molecular detection and characterization of the virus to support breeding of tolerant cacao planting materials, certification of virus-free cacao planting material for distribution to farmers, field surveillance and integrated management of the disease in West Africa.

(1) CIRAD, Montpellier , FRANCE; (2) IRD, Montpellier , FRANCE; (3) University of Reading, Reading, UNITED KINGDOM; (4) University of the West of England, Bristol, UNITED KINGDOM

Text

As part of an ongoing study to understand the diversity of the badnavirus complex, responsible for the cacao swollen shoot disease in West Africa, evidence was found recently of virus-like sequences in asymptomatic cacao plants. The present study exploited the wealth of genomic resources in this crop, and combined bioinformatic, molecular, and genetic approaches to report for the first time the presence of integrated badnaviral sequences in most of the cacao genetic groups. These sequences, which we propose to name eTcBV for endogenous Theobroma cacao bacilliform viruses, varied in type with each predominating in a specific cacao genetic group. Additionally to the viral insert of type VI first identified, we recently described, with the help of Oxford Nanopore technology, viral inserts of type I, II, III and V longer than 10kb. A diagnostic multiplex PCR method was developed to identify the homozygous or hemizygous condition of the specific insert of type VI, which was inherited as a single Mendelian trait.
These data suggest that these integration events occurred before or during the species diversification in Central and South America, and prior to its cultivation in other regions. Such evidence of integrated sequences is relevant to the management of cacao quarantine facilities, and may also aid novel methods to reduce the impact of such viruses in this crop.

Text

Rice tungro bacilliform virus (RTBV), family Caulimoviridae, genus Tungrovirus, is the causative agent for the devastating rice tungro disease (RTD), a potential threat to the regional food security in Asia. The viral dsDNA has a long 5’ untranslated region (5’ UTR) capable of folding into strong secondary structures, and four open reading frames (ORFs), ORF IV being the most variable. ORF III-encoded protein has domains resembling coat protein, aspartate protease (PRT) and reverse transcriptase-RNAseH. Infectious clones of RTBV have been developed, which give rise to mild RTD symptoms upon delivering through

agrobacterium into the crown region of young rice plants. This opens the way for precise mutations to be introduced in RTBV genes to study their effects on pathogenesis. ORF IV-encoded P4 functions as a suppressor of RNA silencing in an isolate from Philippines. Interestingly, the 5' UTR gives rise to a large populationof small RNAs,a potential decoy against RNA silencing. Emerging evidence indicates that PRT of an Indian isolate interacts with a component of RNA silencing machinery, revealing a surprising diversity of function. Rice plants show global changes in gene expression patterns, including hormonal pathways and membrane transport, among others. Using a transgenic approach, an ORF IV-derived ds RNA generating construct gives rise to tolerance against RTBV and reduces the viral levels 103-fold, simultaneously dampening the RTD symptoms.

Text

Endogenous viral elements (EVEs) of four distinct badnavirus species were previously partially characterized in the genome of African yam (*Dioscorea cayenensis* and *D. rotundata*), using molecular approaches. In order to fully elucidate the structure of badnaviral EVEs in African yams, the genomes of accessions 'Ti Guinée' (*D. cayenensis*) and 'Msg 5' (*D. rotundata*) were sequenced using HiFi PacBio high-throughput sequencing (HTS) and searched for badnavirus EVEs.

Large contigs of up to 50 Mbp were assembled and combined with optical maps produced by Saphyr system (Bionano), resulting in two high-quality reference sequences for *Dioscorea*. Twelve and six contigs originating from the genomes of 'Ti Guinée' and 'Mgs 5', respectively, contained badnaviral EVEs ranging in size between 124.4 and 17.7 kbp. All badnaviral EVEs were highly rearranged, especially those of *D. cayenensis*, which were also larger, and most contained interspersed sequences originating from distinct badnavirus species or from viruses in different *Caulimoviridae* genera. One EVE from accession 'Ti Guinée' contained badnaviral sequences surrounded by putative *Geminiviridae* sequences. Several EVEs from 'Ti Guinée' contained sequences of a yet unreported *Caulimoviridae* closely related to but distinct from Dioscorea nummularia-associated virus (DNUaV; *Dioscovirus*). Several EVEs originating from either species contained more-than-length copies of badnaviral genomes that may be replication competent and infectious.

Botryosphaeria dieback: which hosts are affected, what we know and how to fight

C8.1-1

BOTRYOSPHAERIACEAE ON CROPS: CURRENTS STATUS OF THE TAXONOMY OF GENERA AND SPECIES

ALVES Artur. (1)

(1) Universidade de Aveiro, Aveiro, PORTUGAL

Text

The Botryosphaeriaceae is the largest family in the Botryosphaeriales (Dothideomycetes) with 22 genera and over 200 species known from culture and for which DNA sequence data is available. Species in this family are widespread globally and include some important pathogens of woody plants. These pathogens are commonly associated with dieback, cankers and fruit rots that impact plant yield and lead to economic losses in several crops. Undeniably, grapevine is the most widely studied crop, with many species of Botryosphaeriaceae being associated with Botryosphaeria dieback. However, apple, avocado, blueberry, citrus, olive, pistachio, mango, and other crops are also affected by these fungi. Of the genera recognised in the Botryosphaeriaceae, Botryosphaeria, Diplodia, Lasiodiplodia and Neofusiccoccum are the most frequently associated with diseases in those crops. Some are also amongst the most species-rich genera in the family. Botryosphaeriaceae have been subjected to taxonomic revisions over time. The impact of DNA sequence data in resolving taxonomic issues is undeniable, but this DNA-based approach has its own set of problems and limitations. Arguably it has contributed to a proliferation of species names and to some taxonomic confusion. Thus, there are aspects that require attention. Some of the larger genera are clearly in need of revision. The fast growing of fungal genomics represents a potential tool to assist in the challenging task of delimiting genera and species.

C8.1-2

OCCURRENCE OF BOTRYOSPHAERIACEAE SPECIES PATHOGENS IN AGRICULTURE AND FOREST SYSTEMS IN CALIFORNIA

LYNCH Shannon C. . (2), BUSTAMANTE Marcelo I.. (1), ELFAR Karina. (1), ARREGUIN Molly. (1), ALARCON Karen. (1), CARACHURE Carlos. (1), **ESKALEN Akif. (1)**

Text
California produces nearly half of U.S.-grown fruit and nuts and contains 33 million acres of forested land. Pathogens in the Botryosphaeriaceae cause a wide range of diseases on crops and forest tree species in California, including “Bot” canker on woody plants and fruit stem-end and crown rots, resulting in significant ecological and economic losses across heterogeneous landscapes. Here, we review case studies of disease-causing pathogens in the Botryosphaeriaceae family in California. Since 2008, we identified over 30 species causing severe dieback on important agricultural and forest tree species in California (e.g., avocado, grapevine, citrus, tejocote, coast live oak, coast redwood, sycamore, willow, and strawberry). In addition, we recently identified a new pine ghost canker disease complex causing severe dieback on several pine species within a 40-ha urban forest in Southern California. Many Botryosphaeriaceae species are recognized as endophytes that become pathogenic following the onset of plant stress. The striking increase of observed diseases caused by these pathogens following prolonged drought in California highlights the impact of climate change on host-pathogen interactions.

Text
Diplodia sapinea is a pathogen of conifers that predominantly infects *Pinus* spp. It typically remains in a latent phase in infected trees until the onset of stress when disease symptoms such as shoot blight, stem cankers, root disease or die-back develop. Isolates of *D. sapinea* display varying degrees of aggressiveness, but little is known regarding the genetic basis for this variation. Using a combination of Nanopore and Illumina technologies we sequenced the genomes of three *D. sapinea* isolates. Comparing these genomes revealed the existence of two dispensable chromosomes (DCs) in two isolates, 0.46Mb and 0.64Mb in size, of which the former occurred in two isolates and the latter in a single isolate. Low coverage Illumina sequencing of seven additional isolates from various countries, of which six contained the 0.46Mb DC and one contained the 0.64Mb DC. These DCs were found to encode for 80 and 152 proteins, respectively, and had lower gene density and higher proportions of transposable elements compared to the core chromosomes. Sequence analysis indicated that genes on the DCs are rapidly evolving, probably owing to the low selection pressure. Gene ontology enrichment analysis showed that the DCs have enriched GO terms associated with transposable elements and pathogenicity. Pathogenicity trials conducted on *Pinus patula* seedlings, however, showed no obvious association between the DCs and isolate aggressiveness. The biological roles of the DC’s remain to be identified.

C8.1-4

BOTRYOSPHAERIACEAE CANKERS OF ALMOND IN CALIFORNIA: SPECIES DIVERSITY, MOLECULAR DETECTION AND BIOLOGICAL CONTROL

TROUILLAS Florent. (1), HOLLAND Leslie. (1), TRAVADON Renaud. (1), LAWRENCE Daniel . (1), NOURI Mohamed. (1), AVENOT Herve. (1), JAIME FRIAS Rosa. (1)

(1) University of California, Davis, Parlier, UNITED STATES

Text

Botryosphaeriaceae cankers represent some of the most common canker diseases affecting almond in California. To date at least 12 Botryosphaeriaceae spp. have been isolated from almond cankers, including *Neofusicoccum parvum*, *N. mediterraneum*, *Botryosphaeria dothidea* and *Neoscytalidium dimidiatum* as the most common species. Recently, our laboratory developed PCR-based assays for the specific detection of Botryosphaeriaceae pathogens directly from infected almond tissues. Eight species-specific primers were designed by exploiting sequence differences in the translation elongation factor or β-tubulin gene. We also investigated the efficacy of various biocontrol agents to protect almond pruning wounds from infection by these pathogens. Field assays indicated that *Trichoderma atroviride* SC1, *T. paratroviride* RTFT014, and *Clonostachys rosea* J1446 provided significant protection of pruning wounds from infection by *N. parvum*, with levels of disease control similar to those reached by the conventional chemical thiophanate-methyl. We also investigated the duration of pruning wound susceptibility to Botryosphaeriaceae infections according to the month of pruning, i.e. September, October, November, December and January. Pruning in January showed reduced wound susceptibility to Botryosphaeriaceae. Overall pruning wound susceptibility decreased sharply after one- and two-weeks following pruning.

C8.1-5

BOTRYOSPHAERIA PANICLE AND SHOOT BLIGHT OF PISTACHIO: FROM A DILEMMA OF THE CALIFORNIA PISTACHIO INDUSTRY TO A SUCCESS STORY

MICHAILIDES Themis. (1), MORGAN David. (1), GABRI Victor. (1)

(1) University of California Davis, Parlier, UNITED STATES

Text

Botryosphaeria panicle and shoot blight (BPSB) was first observed and reported in California pistachio in 1985. It was discovered in a few sprinkler-irrigated orchards in Butte County, CA, causing severe damage. Initially the pathogen was identified as *Botryosphaeria dothidea*. By 1990, erroneous opinions among industry representatives resulted in discontinuing any research on this disease, since the disease was considered very localized and of minor importance. As the acreage of pistachio has increased over the years and some years were really rainy in the spring, the disease became widespread, creating a major epidemic during 1997-1999 in our pistachios. The disease caused severe blighting and killing of clusters, shoots, leaves, and buds at a time when there was no known control, with the exception of an expensive sanitation by severely pruning and removing cankered branches, shoots, and infected rachises. Desperate growers started cutting down pistachio trees and planting

walnuts in the same locations, not knowing at that time that about 10 years later Botryosphaeria would become a major disease of walnut as well. The BPSB created a major dilemma among the pistachio growers, necessitating an urgent emergency action, which was an increase in research funding to quickly solve this major problem. Thus, this accelerated research from 1999 to 2005 helped determine the etiology, epidemiology, prediction, and successful disease management of BPSB of pistachio in California.

C8.1-6

NEOFUSICOCCUM PARVUM: A PLANT PATHOGEN OF GLOBAL SIGNIFICANCE

SLIPPERS Bernard. (1), POSTMA Alisa. (1), DUONG Tuan. (1), NAGEL Jan. (1), WINGFIELD Michael J.. (1)

(1) Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, SOUTH AFRICA

Text
Neofusicoccum parvum is an important pathogen with a global distribution and for which our knowledge has expanded rapidly in the past decade. We have synthesised research showing that it has a host range of more than 200 plant species residing in at least 64 families. These hosts include numerous important crops, urban and forest tree species. The most common disease symptoms caused by *N. parvum* are die-back and branch or stem cankers. *Neofusicoccum parvum* is also very commonly encountered as an endophyte in healthy plant tissues, and become pathogenic once the host is subjected to biotic or abiotic stress. Historical inaccurate taxonomic classifications, as well as difficulties in distinguishing it from a number of closely related species continue to be a problem. Our recent analyses of sequence data show that the global population of *N. parvum* is dominated by a few closely related haplotypes with little structure based on geography or host. These globally distributed populations have most likely arisen from inter-continental dispersal through the movement of infected plant material, which urgently requires characterization of common pathways. In addition, genomics and transcriptomics are beginning to provide insights into the molecular mechanisms that underpin *N. parvum* infections, their persistence as endophytes and disease development. A holistic perspective considering all these fields is needed to inform strategies to manage this pathogen of growing global importance.

Text

The European production of major crops such as pome and stone fruit, nut crops, berry fruit, citrus, grapevine, and olive is increasingly threatened by fungal trunk diseases (FTD). These diseases and the consequent production losses represent a relevant issue. Several fungi infect host wood mainly through wounds and subsequent colonization of tissues, causing symptoms such as cankers, gummosis, wood rotting, blight and dieback. Some of these fungal pathogens live as endophytes in hosts and their spread occurs through propagative plant material such as rootstock, seedlings and fruit. Abiotic factors are strongly involved in disease development. High planting densities combined with plant nutrient programmes, global warming and climate change favour stress to the cultivated plants. Wounds caused by pruning or mechanical shaking of trunks for fruit harvesting can promote the risk of infections through possible airborne pathogen entry points. The European working group presenting this work recently published an article to review literature on FTD, with a particular focus on the European situation of their causal agents, distribution and host associations, particularly relating to case studies on apple, citrus, grapevine, berry, nut and stone fruit, and olive trees. Moreover, epidemiology and hypotheses on the increase of FTD incidence were discussed. Future prospects and direction of FTD research are presented with the purpose of achieving sustainable disease management.

Text

Grapevine Trunk Diseases (GTDs), which affect 12% of French vineyards, have had no efficient treatment since Sodium Arsenite was banned in 2001. *Neofusicoccum parvum* is one of the most aggressive and prevalent fungi causing GTDs (namely Botryosphaeria dieback), but its infecting mechanisms are still not fully resolved. To control GTDs, understanding the virulence factors involved in grapevine-microbe interaction, and leading to wood degradation is crucial. This project aims to investigate the role of six secreted proteins of *N. parvum*, identified according to their affinity to arsenic, in the pathogenicity of two isolates causing differential symptom expression in detached wood cane assays. Kinetic observation of effectors expression was performed by RT-qPCR on grapevine cane, and the

impact on plant defense pathways was studied by agroinfiltration in *Nicotiana benthamiana* leaves. Notably, the two isolates have non-synonymous sequences for the genes coding for the six effectors. Preliminary results show that inoculation of grapevine wood by the fungi induces early expression of some effectors compared to damaged non-inoculated plants. Meanwhile, transient expression of at least one of these virulence factors in *N. benthamiana* leaves triggered cell death and modulated plant defense responses by targeting specific pathways. The effector's apoplastic localization seems particularly important to induce a complete necrotic response.

Text

Neofusicoccum parvum (Np) (Botryosphaeria parva) is a globally important fungal pathogen/endophyte of diverse native forest species and woody agricultural and ornamental hosts. Np was first identified as a pathogen of hemp (Cannabis sativa) in the U.S. in Arkansas in 2019. The molecular bases of endophytism and pathogenicity of Np, including its broad host range, are poorly understood. To address this gap, draft genome sequences were obtained and analyzed from two hemp reference isolates of Np (ON1 – MT093349 and MT141110; ON2 – MT093349). Genomes were sequenced at a predicted depth of ~80x coverage with DNBseq (BGI Americas) and assembled with CLC Genomics Workbench (Qiagen). The predicted genome sizes were 42.62 Mb and 42.69 Mb for ON1 and ON2, respectively, and similar to a previous report of 42.59 Mb for an isolate of Np from grape (UCD646So). Whole-genome alignments incorporating draft genomes from ON1 and ON2 (collected from two different years and two locations), indicated they are possibly clonal. Also, isolates of Np from diverse hosts and geographic origins revealed surprisingly high levels of genomic synteny and identity. The lack of molecular diversity among the disparate Np isolates examined suggests that some clonal lineages may predominate worldwide.

Text

Fungi of the Botryosphaeriaceae family are responsible for wood diseases worldwide, including the *Botryosphaeria* dieback associated with blight and cankers in grapevine and nut crops. Since 2013, new unseen symptoms, including branch dieback, fruit necrosis and blight, have appeared in French walnut orchards although widespread in Mediterranean-climate countries, such as California and Spain. To unravel the pathobiome associated with these symptoms, symptomatic husks and twigs were collected in 12 French orchards from the two main production areas and analyzed by culturing and metabarcoding. In addition to *B. dothidea* (Bd) and *Neofusicoccum parvum* (Np), the two main Botryosphaeriaceae, *Diaporthe eres*, *Colletotrichum fioriniae*, *C. godetiae* and *Fusarium juglandicola* were also predominant by both methods, suggesting that Bd and Np were part of a complex pathobiome. Simple Sequence Repeats (SSR) sequencing was then used to explore the diversity and structure of Bd (n=190) and Np (n=285) populations, including isolates from Californian walnut orchards (n=28) and French vineyards (n=62). First results revealed a low degree of genetic diversity of Np populations (28 markers, 100 haplotypes) which were not structured based on geographic origin or host, confirming an asexual reproduction mode. The level of genetic diversity between isolates from French symptomatic husks and twigs will be further compared, and Bd population structure (11 markers, 23 haplotypes) will also be analyzed.

EMERGING PECAN LEAF DIEBACK DISEASE CAUSED BY NEOFUSICOCCUM CARYIGENUM: RESEARCH UPDATE AND IMPLICATIONS FOR MANAGEMENT

JO Young-Ki. (1)

(1) Texas A&M University, College Station, UNITED STATES

Text

Pecan leaf dieback (PLD) is caused by the *Neofusicoccum caryigenum* pathogen and was first reported in 2021. PLD symptoms include darkening of leaves, dead leaves remaining on trees, and early defoliation, which can negatively affect tree health and productivity of pecan (*Carya Illinoinensis*). Research on the newly identified pathogen is needed to develop management strategies. Since 2021, Texas pecan orchards have been surveyed to determine the distribution of PLD. Over sixty *N. caryigenum* isolates were obtained, and greenhouse assays showed that *N. caryigenum* can cause disease on pecan seedlings effectively with petiole wounds. To better understand the genetic diversity of *N. caryigenum*, the whole genome of one isolate was sequenced, resulting in approximately 43 Mbp with a GC content of 56%. This sequencing data will be used to develop simple sequence repeat (SSR) markers for further pathogen population genetic diversity study. Understanding pathogen epidemiology and genetic diversity is crucial for developing effective management

strategies for PLD. This new information will provide a foundation for developing chemical and cultural management practices to prevent the spread of the disease and minimize its impact on pecan trees and the pecan industry. Further research is needed to combat this emerging disease and ensure the continued health and productivity of pecan trees.

Text

Mango tree (*Mangifera indica* L.) decline caused by Botryosphaeraceae fungi is an important threat to mangoes production worldwide. This study aimed to assess the incidence and severity of mango trees decline in Côte d'Ivoire, determine the impact of climate parameters and farmers' cultural practices on the disease, and identify its causal pathogen. Four surveys were conducted during two years in the dry and rainy seasons in 42 mango orchards distributed in four agroecological zones (AEZ) of Côte d'Ivoire and 2,100 mango trees were evaluated. Mango symptomatic organs were collected in each orchard and proceeded to the laboratory. Mango decline incidence varied from 30 to 100 % depending on AEZ and severity ranged from 25 to 80 % in orchards. However, disease severity evaluation could be affected by seasonal variations and pruning. Fungi isolated from diseased mango samples were identified using morphological characteristics and phylogenetic analyses based on the internal transcribed spacer (ITS) of rDNA and elongation translation factor 1-alpha (tef1-α) partial DNA sequences. Fungal isolates showed macro- and micro-morphological features of Lasiodiplodia spp. The phylogenetic analysis grouped mango isolates with *Lasiodiplodia theobromae*, *Lasiodiplodia euphorbicola* or *Lasiodiplodia brasiliense*. The pathogenicity tests revealed that all isolates were pathogenic to mango seedlings. These data will help for the control and prevention of mango trees decline in Côte d'Ivoire.

Text

Mango (Mangifera indica L.) is one of the most important fruit tree in tropical and subtropical regions of the world. Mango decline, caused by Lasiodiploadia spp., is a major disease of mango in Burkina Faso. The main objective of this study was to identify Lasiodiplodia species associated with the mango decline in the main mango-producing areas of the country. In addition, incidence and severity of mango decline was determined and climatic and edaphic factors affecting the geographic distribution of the disease were identified. The genetic diversity of 47 Lasiodiplodia isolates was studied on the basis of sequence data of the translation elongation factor 1-alpha gene (tef1-a) and the rDNA internal transcribed spacer region (ITS). Phylogeny analyses grouped the isolates with reference isolates of Lasiodiplodia brasiliensis, Lasiodiplodia caatingensis, Lasiodiplodia crassispora, Lasiodiplodia euphorbicola, Lasiodiplodia pseudotheobromae and Lasiodiplodia theobromae. Lasiodiplodia isolates tested on mango seedlings (cv. Amelie) induced the typical dieback symptoms, including necrotic bark lesions and wilting. The incidence and severity were strongly associated between each other and were generally higher in the eastern regions of the country, where the weather patterns are also drier and warmer than in the western regions. This study is of paramount importance for the establishment of strategies to control mango decline in Burkina Faso.

STATISTICAL IMAGE SEGMENTATION OF VINES' WOOD COLONIZED BY NEOFUSICOCCUM PARVUM IN FLUORESCENCE MICROSCOPY

OUALI Sonia. (2), COURBOT Jean-Baptiste. (2), **PIERRON Romain. (1)**, HAEBERLE Olivier. (2)

(1) UNIVERSITE DE HAUTE-ALSACE, Colmar, FRANCE; (2) UNIVERSITE DE HAUTE-ALSACE, Mulhouse, FRANCE

Text

Grapevine young decline associated with wood decays is a major threat for the grapevine industry. Understanding the fungal colonization is crucial to develop sustainable cures. Graftlings samples of vines inoculated with the esca-associated fungus *Neofusicoccum parvum* were observed under a wide field fluorescent microscope after a post staining treatment with WGA-fitc fluorescent marker. We aim at developing a tool to separate the pathogen from its auto fluorescent textured background and then quantify its colonization in woody tissues.
This classical task in image processing is hampered by the blur encountered in the images. Because the blur depends of the depth of the mycelium in images, the inverse problem is

twofold: estimate a mycelium map, as well as its depth. The blur is encoded in a point spread function that describes the degree of spreading of a point object, and measures imaging system quality. We introduce a dedicated statistical model encoding three elements: 1) the observation; 2) the “hidden” mycelium map to estimate and 3) the depth of the observation at each pixel. Assuming a pixelwise smoothness in the image (mycelium, and depth, do not vary rapidly from one pixel to its neighbors) this model belongs to the Triplet Markov Field family.
We propose an alternating Bayesian scheme to estimate jointly the hidden fields, and the model’s parameter (such as average fungi / wood colors) from the observation alone, i.e. without training database.

P8.1-009

BOTRYOSPHAERIA DIEBACK IN WALNUT ORCHARDS IN AUSTRALIA

ANTONY Stella. (1,2), BILLONES-BAAIJENS Regina. (2), STODART Benjamin. (1,2), STEEL Chris. (1,2), SAVOCCHIA Sandra. (1,2)

(1) School of Agricultural, Environmental and Veterinary Sciences, Charles Sturt University, Wagga Wagga, AUSTRALIA; (2) Gulbali Institute, Charles Sturt University, Wagga Wagga, AUSTRALIA

Text
An emerging challenge for the productivity of the Australian walnut industry is yield losses caused by dieback of branches and fruiting spurs. Species of Botryosphaeriaceae that have been implicated in dieback in many horticultural crops worldwide have been reported in walnut orchards in Australia, yet systematic studies on the species present and control strategies are incipient. This is the first systematic study to investigate the epidemiology and management of Botryosphaeria dieback in walnuts in Australia. DNA sequencing of fungi isolated from walnut tissues collected from major walnut growing regions of Australia confirmed the presence of five Botryosphaeriaceae species, namely Diplodia seriata, Dothiorella omnivora, Neofusicoccum parvum, N. macroclavatum and Spencermartinsia viticola. Of these, D. seriata and N. parvum were the most prevalent species. Pathogenicity studies using detached stems and potted plants in the glasshouse indicated that N. parvum was the most virulent, causing lesions that were three times greater than D. seriata. Pruning wounds were susceptible to N. parvum and D. seriata for up to four months and two months respectively, with the highest disease incidence occurring in the first week following pruning. The green shoots and younger tissues were more susceptible than the older stems to the isolates selected for pathogenicity studies. Further glasshouse experiments on disease progression and field trials on control strategies are in progress.

Investigaciones Agropecuarias Carillanca, Vilcún, CHILE; (3) Universidad de Talca, Talca, CHILE

Text

Hazelnut is one of the most important fruit crops in Chile (37.905 h) and is affected by trunk diseases. The objective was to determine their etiology, pathogenicity, epidemiology and susceptibility to pruning paintings. Wood samples (n=292) were collected from 46 orchards showing dieback and cankers, mostly from cvs. Giffoni, Barcelona, Lewis and Yamhill. Sections were cut, disinfected and plated on a quarter-strength acidified potato dextrose agar, incubated and purified on PDA. Fungal isolates (n=182) were morphologically identified. DNA was extracted and specific genes were amplified by PCR, identifying mostly Botryosphaeriaceae, Diaporthaceae, Nectriaceae and Basidiomycete. Mycelial plugs of representative isolates (n=25) were inoculated on injuries of healthy cuttings cv. Lewis and incubated for 72-d in flowing water at 22°C. The most virulent ones were inoculated on fresh pruning cuts of 3-y potted plants cv. Lewis and incubated for 112-d at shadehouse. For both tests, internal necrosis on inoculated twigs was measured, compared and fungi reisolated, finding that *Neofusicoccum*, *Diaporthe* and *Chondrostereum* were the most virulent. To study the epidemiology, a 9-y orchard cv. Lewis was weekly monitored for 12-m analysing the inoculum on glass spore traps by qPCR. Once the inoculum presence was confirmed, healthy plants were pruned and painted with commercial paintings (n=9) and control. After 10-m, internal necrosis varied from 6.5-17cm compared to the control (22,3cm).

Text

Neofusicoccum parvum is one of the most aggressive Botryosphaeriaceae species associated with grapevine trunk diseases. This species may secrete enzymes, such as cellulases, hemicellulases and oxidoreductases, capable of overcoming the plant cell wall barriers. Furthermore, N. parvum produces toxic secondary metabolites that may contribute to its virulence. To increase knowledge of the mechanisms underlying pathogenicity and virulence, we evaluated the N. parvum Bt-67 capacity in producing lignocellulolytic enzymes and secondary metabolites when grown in vitro on two biomasses: grapevine canes (GP) and wheat straw (WS). We performed a multiphasic study combining enzymology, transcriptomic and metabolomic analyses. Enzymatic activity assays showed higher xylanase, xylosidase, arabinosidase and glucosidase activities when the fungus was grown on WS in contrast with GP. Infrared spectroscopy confirmed the lignocellulosic biomass degradation caused by the secreted enzymes. Transcriptomics revealed up-regulation of 134 Carbohydrate Active Enzymes (CAZymes)-coding genes, where 94 were expressed in both biomass growth

conditions. Lytic polysaccharide monooxygenases, glucosidases and endoglucanases were the most represented CAZymes. The secondary metabolites diversity was variable depending on the carbon source. This diversity was higher when growth occurred with GP. Our results provide insight into the influence of lignocellulosic biomass on virulence factor expression.

Text

Botryosphaeria dieback (BD) is one of the big threat for global viticulture. Without effective sustainable treatments, biocontrol strategies are developed as alternatives to better cope with environmental concerns. A combination of biological control agents (BCAs) is tested as promising for managing BD through complementary ways of protection.
Indeed, Bacillus subtilis (Bs) PTA-271 and/or Trichoderma atroviride (Ta) SC1 efficiently protect Chardonnay and Tempranillo rootlings against Neofusicoccum parvum Bt67, an aggressive pathogen associated to BD. Indirect benefits offered by each BCA and their combination were then characterized in planta, as well as their direct benefits in vitro. Results provide evidence that the cultivar contributes to the beneficial effects of Bs and Ta against N. parvum, and that the in vitro BCA mutual antagonism switches to a strongest fungistatic effect toward NpBt67 in a three-way confrontation test. We also report for the first time the beneficial potential of a combination of BCA against NpBt67 especially in Tempranillo. Our findings highlight a common feature for both cultivars: salicylic acid (SA)-dependent defences were strongly decreased in plants protected by the BCA, in contrast with symptomatic ones. We thus suggest that the high basal expression of SA-dependent defences in Tempranillo explains its highest susceptibility to N. parvum, and that the cultivar-specific responses to the beneficial Bs and Ta remain to be further investigated.

Text
Fungal grapevine trunk diseases (GTDs) still represent a threat to viticulture, leading to important economic losses worldwide. In nurseries, grapevine planting material is very susceptible to infection by GTDs pathogens due to several cuts and wounds made during the different steps in the propagation process. Without effective chemical treatments, a combination of biological control agents (BCAs), could improve the plant material protection against GTDs pathogens in the nursery process. In this study, we evaluated the effect of single or combined treatments with Bacillus subtilis PTA-271 (Bs) and Trichoderma atroviride SC1 (Ta) to reduce infections caused by fungal pathogens belonging to the family Botryosphaeriaceae in grapevine planting material during the propagation process. Our results showed a reduction in Botryosphaeria dieback incidence and severity on grapevine propagation material treated with Ta and the combination Ta + Bs. Therefore, the Ta SC1 and Bs PTA-271 combination, showed the potential to reduce infections caused by these pathogens in the nursery propagation process. These biological treatments may be relevant components of an integrated approach, using complementary management strategies to limit infection by GTD pathogens. Further research is still needed to elucidate the effectiveness of Bs PTA-271 and the benefits of simultaneous application with Ta SC1 for the control of GTD pathogens in nurseries.

Controlling Globally Developing Disease Threats of Banana

C8.5-1

FUSARIUM WILT OF BANANA CAUSED BY TROPICAL RACE 4: PROBLEMS AND PROSPECTS

KEMA Gerrit Hj. (1)

(1) Wageningen University, Wageningen, NETHERLANDS

Text
Banana is the world's top fruit and one of the most important staple foods. Cavendish clones dominate total global banana production (> 50%) and export (>95%). Their importance goes back to the first epidemic of Fusarium wilt of banana (FWB), a soilborne disease that wiped out Gros Michel between the 1920s and 1950s. This epidemic, caused by the so-called Race 1, wreaked havoc on banana production in Central America and impacted millions of households. Cavendish clones boomed as they could be cultivated on heavily Race 1 - infested soils on which Gros Michel succumbed. However, FWB already re-emerged in Cavendish clones in the 1960s in Taiwan. The Fusarium strain that caused the disease was called Tropical Race 4 (TR4) and surged throughout Southeast Asia for decades, decimating Cavendish plantations and affecting manifold other banana varieties until its occurrence in Jordan in 2014. The rest is history. Since then, TR4 has disseminated to 14 new countries in all major banana-producing regions of the world with the latest incursion in Venezuela. What

next? Host resistance is the cornerstone of disease control and Cavendish's resistance to Race 1 - that still holds - is the ultimate benchmark of the required level of resistance to manage FWB caused by TR4, but foremost the crop needs to be diversified. Furthermore, all options for early warning, disease management, and innovation of cultivation systems need to align to sustainably secure this important crop.

Text

Around 20 years ago, we started the search for a banana gene that would provide resistance to Fusarium wilt (Panama Disease) tropical race 4 (TR4). At that time, TR4 had a limited distribution, confined primarily to south east Asia and northern Australia. It is now present and spreading in five continents and is considered the greatest threat to banana production worldwide. We identified a NBS-LRR gene in a TR4 resistant wild diploid banana that had characteristics consistent with a potential TR4 resistance gene. We transferred this gene to Cavendish bananas and regenerated several transgenic lines. These lines, together with controls, were transferred to a field with a history of high TR4 disease incidence. From the first small scale field trial, we identified four lines with varying levels of resistance and these were progressed into a large scale field trial. After three years and 5 crop cycles, one line, QCAV-4, was shown to be highly resistant to TR4 with only 2% of plants infected compared with 66% of the non-GM controls. Importantly, there was virtually no yield penalty for QCAV-4 compared with uninfected non-GM controls. We have now fully characterised this event and have submitted an application to the regulators in Australia towards commercial release of this line. Further, we have recorded the history of each plant of the four initial lines as well as non-GM controls and this is providing significant insights into the progression of the disease in a plantation.

C8.5-3

LIMITING FUNGICIDE USE IN THE MANAGEMENT OF BANANA LEAF SPOT DISEASES

CARLIER Jean. (1), ABADIE Catherine. (1,2), DE LAPEYRE DE BELLAIRE Luc. (1)

(1) CIRAD, Montpellier, FRANCE; (2) CATIE, Turrialba, COSTA RICA

Text

Three related fungi cause similar leaf diseases of banana and form the sigatoka leaf spot complex: Pseudocercospora fijiensis, P. musae et P. eumusae. The more aggressive species P. fijiensis has been recently spread throughout the world leading to a massive

systematic use of fungicides in most countries, especially in industrial export plantations. Research work has been conducted to limit the use of fungicides. The development of forecasting strategies and cultural practices (such as necrotic deleafing) first allowed to reduce significantly the number of applications. Other studies have been recently conducted at landscape or farm scale to quantify the effects on epidemics of hedgerows or association with other crops. In parallel, genetic improvement programs are being conducted to create new resistant varieties. However, as for fungicides, it has been shown that pathogen populations can adapt and breakdown or erode banana resistances after 5 years of monoculture. A more durable deployment strategy would be to combine resistances with antagonistic interactions in order to constrain and limit the adaptation of pathogen populations. Studies on populations pathogen adaptation and host-pathogen interactions are thus underway. Finally, a generic model has being adapted to P. fijiensis to test the efficiency and durability of various resistance deployment strategies. The last results obtained from all these studies will be presented.

C8.5-4

EFFECT OF A PLANT-BASED BIOLOGICAL CONTROL OF FUSARIUM WILT ON THE SOIL MICROBIOME

TORRES BEDOYA Eliana. (1), BEBBER Daniel. (1), STUDHOLME David. (1)

(1) University of Exeter, Exeter, UNITED KINGDOM

Text

Plant root exudates exert strong influences on the soil microbiome, and rhizospheres are among the most diverse microbial communities. In agriculture, there is growing interest in the manipulation of the soil microbiome through root exudate management, for example for disease suppression. Fusarium Wilt is an important soil-borne pathogen of certain banana (Musa spp.) cultivars. Fusarium Wilt is difficult to eradicate from soils and currently there are no economically viable controls. Observations of apparent disease suppression in some Chinese banana plantations have resulted in the identification of a culinary understorey plant, Allium tuberosum (colloquially Chinese leek), as producing root exudates that kill Fusarium spores and inhibit disease development. However, the wider, non-target effects of Allium root exudates on soil microbes are unknown. Potentially, strong general antimicrobial activity could impact soil ecosystem function. Here, we investigate the influence of banana and Chinese leek roots on soil microbes in a pot trial. We compared the bulk soil and rhizosphere microbiome of Allium and bananas and evaluated the effect of their co-cultivation under greenhouse conditions. Our results indicate that Allium induces a significant shift in soil microbe community, however, this effect is outweighed by the presence of banana roots. Therefore, Allium is a potential plant-based biocontrol for Fusarium that does not significantly alter the soil microbiome in general.

C8.5-5

BANANA BUNCHY TOP VIRUS – MANAGING THIS EVER-EXPANDING THREAT

THOMAS John. (1)

(1) The University of Queensland, QAAFI, Brisbane, AUSTRALIA

Text

Banana bunchy top virus (BBTV) causes the most serious virus disease of banana (Musa sp.) worldwide. Though not yet present in the Americas, its distribution continues to spread in most other banana growing regions. Most of the production of this important crop (85%) is grown for domestic, often subsistence, consumption. No edible cultivars of banana are immune to BBTV, but differences in susceptibility and tolerance are found among the 1000 known cultivars. Combating this disease threat requires a multi-pronged approach. Exclusion through quarantine remains the best strategy for currently disease free-areas. In affected areas, eradication and the use of healthy planting material in low input situations can keep the disease at low, manageable levels. Growing less susceptible cultivars can reduce the rate of spread of epidemics. Apparent immunity has been uncovered in wild, seeded progenitor Musa sp. paving the way for introgression of resistance into conventional breeding lines or exploitation through genetic manipulation. Although several attempts have been made using an RNAi strategy to transform banana for BBTV resistance, adequate field resistance has not yet been demonstrated. However, RNAi strategies with the banana plant or the aphid vector and gene editing strategies still show promise for control of BBTV.

AN OPTIMISED SAMPLING AND DETECTION PROTOCOL FOR FUSARIUM OXYSPORUM F. SP. CUBENSE TROPICAL RACE 4 FROM ENVIRONMENTAL SOIL

MATTHEWS M.c. . (1), VAN DEVENTER M.. (1), BOTHMA S.. (1), VILJOEN A.. (1), **MOSTERT D.. (1)**

(1) Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text

The soilborne pathogen *Fusarium oxysporum* f. sp. *cubense* tropical race 4 (Foc TR4) is a major threat to banana production worldwide. Once introduced, Foc TR4 can persist in the soil as resistant chlamydospores for decades. Accurate and sensitive protocols are thus needed to detect and measure Foc TR4 inoculum levels in soil. This, however, is challenging due to the low concentration of pathogen DNA, the heterogenous distribution, and the presence of potentially inhibitory compounds that might prevent detection. In this study, a sampling and detection protocol was optimised to determine the presence and quantify of Foc TR4 inoculum in infested soil. Samples were collected between plants (bulk soil) and from the root rhizosphere at a commercial banana plantation in northern Mozambique. Higher levels of Foc TR4 inoculum were present in the root rhizosphere than in bulk soil, suggesting that bulk soil sampling needs a larger number of samples to be reliable. Concentrating spores with a soil washing protocol before extraction improved the limit of quantitative PCR detection of the pathogen, and pre-culturing soil on artificial media had an enriching effect and improved the number of positive samples detected. The optimised protocol can be used to determine the efficacy of integrated disease management strategies, or at least the spread of the pathogen in infested areas.

UNRAVELLING THE PLANT DEFENSE MECHANISMS OF DIFFERENT BANANA CULTIVARS AGAINST FUSARIUM WILT TR4, INCLUDING RESPONSES TO ELICITOR APPLICATION

ZHENG Sijun. (1)

(1) Yunnan Academy of Agricultural Sciences, Kunming , CHINA

Text

To determine the effect of elicitor isotianil on Fusarium wilt of banana TR4, a greenhouse experiment was showed that isotianil could significantly alleviate the symptoms of TR4, enhanced disease control on two cultivars with control effect 50.14% and 56.14%, respectively. The results showed that TR4 hyphae could rapidly penetrate the cortex into the root vascular bundle for colonization, and the colonization capacity in Brazilian was significantly higher than that in Yunjiao No.1.The accumulation of a large number of starch grains was observed in corms cells, and further analysis showed that the starch content in Yunjiao No. 1 as resistant cultivar was significantly higher than that in Brazilian as susceptible cultivar. Besides, a mass of tyloses were observed in the roots and corms and these tyloses increased after application with isotianil. Furthermore, the total starch and tyloses contents and the control effect in the corms of Yunjiao No.1 was higher than that in the Brazilian. These results suggest that there are significant differences between cultivars in response to TR4 invasion and plant reactions with respect to starch accumulation, tyloses formation and the expression of plant resistance induction and starch synthesis related genes. Isotianil application may contribute to disease control by inducing host plants to defend against TR4 infection and could be potentially used together with resistant cultivar as integrated approach to manage this destructive disease.

P8.5-002

MOLECULAR DIAGNOSIS AND VEGETATIVE COMPATIBILITY GROUP ANALYSIS OF FUSARIUM WILT OF BANANA IN NEPAL

ZHENG Sijun. (1)

(1) Yunnan Academy of Agricultural Sciences, Kunming , CHINA

Text

Fusarium wilt of banana (FWB) caused by Fusarium oxysporum f. sp. cubense (Foc) is the most important constraint of banana industry globally. In Nepal, epidemics resembling FWB have been increasingly observed on the cultivar Malbhog in the past several years. However, the disease has not been officially reported yet and consequently little is known about the pathogen present across the country. In this study, we characterized 13 fungal strains isolated from banana plants of the cultivar Malbhog (Silk, AAB) showing symptoms similar to FWB in banana plantations in Nepal. All the strains were typed as belonging to the F. oxysporum and caused FWB symptoms when inoculated in Malbhog and Cachaco (Bluggoe, ABB) cultivars. No symptoms were observed in the cultivar William (Cavendish, AAA). Vegetative compatibility group (VCG) analysis classified the strains as VCG0124 or

VCG0125. PCR analyses conducted with primers specific for Foc race 1 (Foc R1) or Foc tropical race 4 (TR4) revealed that all the strains reacted positively for Foc R1 and none for TR4. Altogether, our results demonstrated that the pathogen populations causing FWB of the cultivar Malbhog in Nepal are Foc R1. This work reports for the first time the occurrence of FWB in Nepal. Further studies with larger Foc populations are needed to better understand disease epidemiology to design sustainable disease management strategies.

Text

Consumption of bananas is crucial to the nutritional well-being of more than 400 million people around the world. There is, however, a continuing threat to global production caused by a soil-borne fungus known as Fusarium oxysporum f.sp. cubense, which causes wilting of bananas. Tropical Race 4 (FocTR4), a highly virulent strain of this fungus, has affected more than 20 countries, including Colombia, Peru, and Venezuela in South America. FocTR4 has now put Ecuador, the largest banana exporter, at increased risk. With no silver bullet in sight, producers are calling for a unified front to protect their farms-the backbone of the second most prosperous industry in the country, which has suffered millions of losses due to adverse climate, war conflicts, and other factors. This work will present the current efforts to secure the future of bananas in Ecuador, a significant contributor to the national economy and source of livelihoods and nutrition. Our presentation includes strategies for prevention, but also preparing for the worst-case scenario of an incursion. Some of the initiatives to be discussed include priming bananas with local microorganisms guided by exploratory microbiome studies, modulating soil changes using organic amendments to increase suppression, application of cloud-based technology to increase training, detection and biosecurity efforts, and first steps towards improving banana resistance using gene editing and nuclear energy.

Text

In order to combat the threat posed by the soil-borne fungal pathogen *Fusarium oxysporum* f. sp. *cubense* (*Foc*) tropical race-4 (TR4) to the economically important Cavendish banana cultivar, researchers are exploring various integrated pest management (IPM) strategies. These strategies include the use of biological control organisms (BCOs) that can exhibit direct antimicrobial activity or indirectly induce resistance in plants against pathogens. Our research focuses on investigating the direct and indirect activity of the BCO, *Trichoderma asperellum*, against *Foc* TR4 in Cavendish cultivars. Dual culture assays revealed that *T. asperellum* could directly inhibit the growth of the pathogen under *in vitro* conditions. *In planta* bioassays in the greenhouse with multiple applications of *T. asperellum* resulted in a significant decrease in Fusarium wilt disease symptoms. In a separate greenhouse experiment, we also evaluated the effect of *T. asperellum* on banana plant growth. Results revealed a significant increase in plant growth parameters such as banana pseudostem height and leaf surface area for the *T. asperellum* treated plants compared to the uninoculated control plants. In order to distinguish between the direct and indirect activity of the BCO against the pathogen, a split root assay is currently being performed.

Text

Indonesia is known as one of the centers of origin of banana (*Musa* spp.). Various banana cultivars with different genome types are grown across the country to meet domestic needs and for export purposes. Banana bunchy top disease (BBTD) is an important disease that has the potential to effect banana production in Indonesia. Field surveys conducted in recent years indicated that most of the banana cultivars are susceptible to BBTD. Several wild banana species native to Indonesia are moderately resistant to BBTD. One of the strategies to manage BBTD is to increase the resistance of banana cultivars to BBTD through the provision of priming agents. Two separate experiments were conducted to evaluate the effectiveness of the priming agents, i.e. (1) liquid smoke treatment on in vitro banana plantlets and (2) application of *Pseudomonas fluorescen*s and guano filtrate. The application of liquid smoke was given at several concentration levels and time during *in vitro* propagation. Liquid smoke treatment had a significant effect on the number of shoot multiplication and growth of banana plantlets; and it reduced disease incidence. *P. fluorescens* and guano filtrate was able to significantly reduce the intensity of the disease only when applied before BBTV infection occurred. Treatment of liquid smoke on banana tissue culture and the use of beneficial microbes can be recommended as part of BBTD control strategy.

Text

Bananas are major agricultural commodities in Cuba. One of the main constraints of banana production worldwide is Fusarium wilt of banana (FWB). Recent outbreaks in Colombia, Perú and Venezuela raised widespread concern in Latin America due the potential devastating impact on the sustainability of banana production, food security and livelihoods of millions of people in the region. Here, we phenotyped 18 important Cuban banana and plantain varieties with two *Fusarium* strains; Tropical Race 4 (TR4, aka *F. odoratissimum*) and Race 1 (R1, aka *F. oxysporum*) under greenhouse conditions. These varieties represent more than 70% of the total Cuban area planted to bananas and are also widely distributed in Latin America and Caribbean region. A broad range of disease responses from resistant to very susceptible was observed against Race 1. Contrary, not a single banana variety was resistant to TR4. These results underscore that TR4 potentially threatens nearly 56% of contemporary Cuban banana production area, which is planted with susceptible and very susceptible varieties, and call for a preemptive evaluation of new varieties obtained in the national breeding program and the strengthening of quarantine measures to prevent the introduction of TR4 into the country.

Text

Fusarium wilt of bananas caused by the soil-born pathogen, *Fusarium oxysporum* f. sp. *cubense* tropical race 4 (TR4), has been causing a severe problem in banana-producing countries. In most cases, the suffering field is abandoned once the disease occurs because of no control method.
To control the disease, we applied anaerobic soil disinfestation (ASD) using low-concentration EtOH in the Philippines. We prepared nit mutant of TR4 as a marker strain to

utilize selective detection and adjusted soil to 9 x 10^7 cfu/g. The soil was then packed inside mesh sachets and was buried under 15 and 30-cm depths (0.5 x 1 m/plot). One % and 0.5% EtOH were douched to the soil as a carbon source to activate microorganisms and covered with plastic sheets to make an anaerobic environment. Water and non-treated (dry) plots were prepared as controls. Three sachets were set at each depth in plots and repeated twice.
TR4 was not detected on selective media (MMCPA) from the 1.0 and 0.5% EtOH plots. While at the water plot, 1x10^2-4.3 x10^3 and 4 x10^2-2.6 x10^3 cfu/g of TR4 were detected at 15 and 30-cm depths, respectively. At the dry plots, 2 x 10^3-6.3 x 10^4 and 4 x 10^3-2.8 x 10^4 cfu/g of TR4 were detected at 15 and 30-cm depths, respectively. The oxidation-reduction potential at 10 cm depth at 1.0 and 0.5% EtOH plots, water, and dry plots decreased to -485, 11, 42, and, 137 mv, respectively. The results indicate that applying ASD using 1.0% and 0.5% EtOH effectively reduced TR4 in the soil.

Text
Fusarium musae is an agent of crown rot in banana fruits and was recently isolated as cause of keratitis and nail infection as well as cause of systemic infections in immunocompromised patients. It is a sister species to *F. verticillioides*. To confirm the hypothesis that *F. musae* is a cross kingdom pathogen, strains of *F. musae* (n=19), isolated worldwide from banana fruits and human patients were characterised in comparative analyses. Plant and human strains did not group according to their host origin by morphological, nuclear and mitochondrial molecular analyses. *In vitro* sensitivity to azoles widely used in agricultural and clinical settings showed that *F. musae* is less sensitive than its “sister species” *F. verticillioides*. No significant differences were observed between human and banana strains. *In vivo* infection on banana fruits and *Galleria mellonella* (as “human proxy”) demonstrated that both, banana and human strains, are able to invade both pathosystems causing comparable levels of infection. Complete genomes of 2 representative strains were assembled on chromosomal level, and these strains were used to generate fluorescent and luminescent *F. musae* reporter strains that will be used to study the interaction with both hosts. A survey from bananas sold on local market confirmed that *F. musae* can be isolated from fruit shipped from different producing countries. Our work proved that *F. musae* is a cross-kingdom pathogen likely originating in agricultural settings.

Text

The Philippines is the main exporter of banana from the Asian region. However, several plantations in Mindanao are affected by the problem of wilting disease, particularly in Davao, the largest banana producing region in the country. The epidemic predisposition of *Fusarium oxysporum* f. sp. *cubense* TR4 which causes Panama wilt in Cavendish banana cultivars has led this race to be widely studied particularly aimed at managing the disease. This idea delimits the banana wilting problem to be attributed solely to the race belonging to *F. oxysporum* species complex, which is a problem in the disease management. In this study, the taxonomic characteristics, phylogenetic position, and pathogenic traits of the *Fusarium* isolates collected from wilted Cavendish banana were analyzed. The isolates were collected from different production areas in Davao City, Davao De Oro, and Davao Del Norte. Phylogenetic analyses using trees based from the internal transcribed spacer 5.8S rRNA, translation elongation factor-1alpha, and the RNA polymerase II second largest subunit show that the *Fusarium* isolates fall into the *F. dimerum, F. incarnatum-equiseti, F. fujikuroi, F. oxysporum* and *F. solani* species complexes. The morphology of the isolates was further characterized and selected isolates from each species complex were tested for their pathogenicity to the Dwarf Cavendish banana cultivar following Koch's postulates.

Text

A severe outbreak of banana bunchy top virus (BBTV), responsible for the bunchy top disease of bananas, was reported in Tanzania and Uganda in 2021. BBTV spreads through infected planting material and by the aphid Pentalonia nigronervosa, which is widespread in all banana production areas. Uganda and Tanzania are leading producers and together contribute over 22% of all bananas grown in Africa. The first outbreak in Tanzania was noticed in the Kigoma region. Surveys in 2021-22 revealed that the virus had reached

several districts in Tanzania, including Dar es Salaam, Kilimanjaro, Mwanza, Pwani, and Rukwa. The virus was first reported in Uganda in Arua City, West Nile. Delimiting surveys conducted in October 2022 revealed widespread BBTV in the West Nile region and some other districts in Western Uganda. In many farms, virus infection led to a 90-100% production loss, a 100% to 150% increase in banana price, and a loss of jobs, income, and banana biodiversity. The drivers of BBTV spread include the lack of awareness that impeded early detection, lack of capacity for surveillance, diagnostics, eradication, and access to virus-free planting materials. This presentation will appraise the status of BBTV in East Africa and highlight steps taken to implement a response plan, including efforts to build a regional alliance to coordinate surveillance and early detection and implement actions to curb virus spread and recover banana production.

EVALUATION OF THE BIOCONTROL CAPACITY OF NATIVE MICROORGANISMS AGAINST FUSARIUM OXYSPORUM F. SP. CUBENSE

TRIGOSO Carla. (1), ARIE Tsutomu. (2), **ARAGON Liliana. (1)**

(1) UNALM, Lima, PERU; (2) TUAT, Tokyo, JAPAN

Text

Fusarium Wilt is an economically important disease of bananas caused by the fungus Fusarium oxysporum f. sp. cubense (Foc). It causes severe losses in the yield and quality of bananas and is extremely difficult to control conventionally using chemical fungicide. Biological control offers an eco-friendly alternative for sustainable plant disease management. In this context, the objective of this research is the determination of the biocontrol capacity of native microorganisms against Fusarium oxysporum f. sp. cubense. For the isolation of native rhizospheric microorganisms, samplings were carried out in the region of Perené and Satipo in the central jungle of Peru. Thirty rhizobacterial isolates were screened for antagonistic activity in dual culture, and isolate 27 showed the highest antagonistic activity (81,52% mycelial growth inhibition) against Foc. The metabolites of isolate 27 inhibited mycelial growth of Foc by 80%. Based on the morphological, physiological and phylogeny analysis with 16S rRNA sequence the isolate 27 was identified as Burkholderia sp. This is a preliminary study of the SATREPS project (Japan - Peru): "The Project on establishment of an alert system for Fusarium oxysporum f. sp. cubense the banana and plantain wilt pathogen, and biological mitigation strategy of the pathogen"

A POLYPHASIC APPROACH REVEALS NOVEL GENOTYPES AND UPDATES THE GENETIC STRUCTURE OF THE BANANA FUSARIUM WILT PATHOGEN

MOSTERT D.. (1), WICKER E.. (2), VILJOEN A.. (1)

(1) Stellenbosch University, Stellenbosch, SOUTH AFRICA; (2) CIRAD/UMR PHIM, Montpellier, FRANCE

Text

Fusarium oxysporum f. sp. *cubense* (Foc) is a soil-borne fungus that causes Fusarium wilt, a destructive plant disease that has resulted in devastating economic losses to banana production worldwide. The fungus has a complex evolutionary history and taxonomic repute and consists of three pathogenic races and at least 24 vegetative compatibility groups (VCGs). Surveys conducted in Asia, Africa, the Sultanate of Oman and Mauritius encountered isolates of *F. oxysporum* pathogenic to banana that were not compatible to any of the known Foc VCGs. Genetic relatedness between the undescribed and known Foc VCGs were determined using a multi-gene phylogeny and diversity array technology (DArT) sequencing. The presence of putative effector genes, the *secreted in xylem* (*SIX*) genes, were also determined. Fourteen novel Foc VCGs and 17 single-member VCGs were identified. The multi-gene tree was congruent with the DArT-seq phylogeny and divided the novel VCGs into three clades. Clustering analysis of the DArT-seq data supported the separation of Foc isolates into eight distinct clusters, with the suite of *SIX* genes mostly conserved within these clusters. Results from this study indicates that Foc is more diverse than hitherto assumed.

Text

Plant viruses have caused several devastating epidemics on annual and perennial crops in sub-Saharan Africa (SSA). All the effectively managed virus diseases in SSA relied on host-plant resistance. For viruses lacking durable host resistance, management relies on integrated methods (vector control, clean seed, habitat management, etc.) that are less effective, especially in preventing the transboundary spread of viruses due to weak phytosanitary capacity. This presentation discusses the case of emergence and spread of the banana bunchy top virus (BBTV) responsible for the devastating bunchy top disease for which durable host resistance is unavailable. First detected in the 1960s in the Democratic Republic of Congo, BBTV spread to 16 countries between 1990 and 2022. The virus transmitted by an aphid, *Pentalonia nigronervosa*, and vegetative propagation is increasingly becoming a serious threat due to the expansion into new regions, more recently to Tanzania and Uganda. BBTV management depends on preventing virus spread, eradicating infected plants, and replanting with virus-free planting materials. We will highlight the progress and status of the recent advances to control BBTV in SSA, including the search for host-plant resistance for BBTV and its vector, surveillance using remote sensing and machine learning methods, RPA-based rapid diagnostics, biocontrol for aphids, and ALLIANCE model for coordinated control of BBTV in the continent.

Text

Black sigatoka or black leaf streak (BLS) is the most important foliar disease of Musa production and is caused by Pseudocercospora fijiensis. The use of a diagrammatic scale helps people more effectively evaluate severity and improves disease measurement by evaluators. Our goal was to develop a new scale with colored pictures and seven disease levels 0 (0%), 1 (0.1 – 5.0%), 2 (5.01 – 13.0%), 3 (13.01 – 23.0 %), 4 (23.01 – 40.0%), 5 (40.01 – 65.0%) 6 (>65.0%) and then compare the severity results of BLS on banana leaves with those based on other scale. Three evaluations were performed by thirteen different evaluators and the evaluation was performed at seven-day intervals. The first assessment was performed without a scale. Raters performed four assessments with each of the two diagrammatic scales. We analyzed the statistics with linear regression and Lin's concordance correlation. The evaluators using the proposed scale improved the precision, accuracy and reproducibility of the evaluations and reduced residual distribution when compared to the evaluators who did not use the proposed diagrammatic scale or who used the other scale. Overall, the proposed diagrammatic scale is a tool that can assist users in producing a disease estimate close to the real value of BLS on banana leaves. Keywords: Banana, Pseudocercospora fijiensis, Diagrammatic Scale, Precision, Accuracy

CRISPR crops: plant Genome Editing Toward Disease Resistance

RESISTANCE TO VIRUSES BASED ON EIF4E: FROM NATURAL VARIATION TO EDITED GENES

GALLOIS Jean-Luc. (1)

(1) INRAE GAFL, Avignon, FRANCE

Text

eIF4E translation initiation factors have emerged as major susceptibility factors for RNA viruses. Natural eIF4E-based resistance alleles are found in many species and are mostly variants that maintain the translation function of the protein. eIF4E genes represent therefore targets for engineering viral resistance, and gene-editing technologies can be used to make up for the lack of natural resistance alleles in some crops. However, redundancy among eIF4E genes can restrict the efficient use of knockout alleles in breeding. Using Arabidopsis,

we previously showed how gene-editing technologies can be used to design de novo functional alleles, using knowledge about the natural evolution of eIF4E genes in different species, to drive resistance to viruses without affecting plant physiology. Here, we will also present how this knowledge can be applied to a crop, tomato, using CRISPR-Cas9 base editing. We will show that there is a trade-off to find between resistance and functionality, and discuss these results in the light of resistance durability.

Text

The discovery and application of genome editing introduce a new era of plant breeding, giving researchers efficient tools for the precise engineering of crop genomes1. Here, we demonstrate the power of genome editing for engineering broad-spectrum disease resistance in rice (Oryza sativa). We first isolated a lesion mimic mutant (LMM) from a mutagenized rice population, demonstrated that a 29-bp deletion in a gene we named RESISTANCE TO BLAST1 (RBL1) caused this phenotype and showed that this mutation caused a ca. 20-fold reduction in yield. RBL1 encodes a cytidine diphosphate diacylglycerol (CDP-DAG) synthase required for phospholipid biosynthesis2. Mutation of RBL1 results in reduced levels of phosphatidylinositol (PI) and its derivative PI(4,5)P2. Rice PI(4,5)P2 is enriched in cellular structures specifically associated with effector secretion and fungal infection, suggesting a role as a disease susceptibility factor3. Using targeted mutagenesis, we obtained an allele of RBL1, named RBL12, which confers broad-spectrum resistance but does not decrease yield in a model rice variety as assessed in small-scale field trials. Because RBL1 is conserved in plants, editing of RBL1 homologs is likely applicable to diverse crops.

Text

Gene editing via the CRISPR/Cas9 system is revolutionizing plant research and crop breeding. Here, we present an effective and streamlined pipeline for arrayed CRISPR library construction in plants. This pipeline introduces artificial PCR fragment-length markers for distinguishing guide RNAs (gRNAs) (named FLASH tags), and a group of 12 constructs harboring different FLASH tags are cotransformed into plants each time. Therefore, the identities of gRNAs in *Agrobacterium* mixtures and transgenic plants can be easily read out by detecting the FLASH tags, which only requires conventional PCR and gel electrophoresis rather than sequencing. We generated an arrayed CRISPR library targeting all 1,072 *receptor-like kinases* (*RLK*s) in rice using this pipeline, which resulted in a mutant population covering gRNAs targeting 955 RLKs. Our results indicate that the FLASH tags *bona fide* surrogate the gRNAs and tightly (92.1%) associate with frameshift mutations of intended target genes. Owing to their high editing efficiencies, these CRISPR lines enable fast identification of defense-related RLK genes. Additionally, we used *OsCPK18* (Calcium-dependent protein kinase) as an example that editing the phosphorylation motif can simultaneously improve rice disease resistance and yield. Together, we present a novel pipeline for arrayed CRISPR screening in plants and propose a gene editing strategy to improve rice disease resistance without yield tradeoff.

Text

Pathogens are the cause of devastating diseases and significant tomato crop losses worldwide. While resistance traits exist in wild tomato populations, transferal of this resistance to cultivated tomato has thus far had limited success. A well-known concept in the world of plant immunity is that of induced resistance (IR). We propose that tapping into plant immune priming by genetically manipulating plant immunity, generating constitutively immuno-activated plants, can result in increased pathogen resistance. Here we present two examples of constitutively primed plants that we obtained using CRISPR-Cas9 genome editing of defense receptors. In the first case, we knocked out an immune-decoy receptor, LeEIX1. LeEIX1 normally attenuates the plants' response to the Trichoderma elicitor EIX (Ethylene Inducing Xylanase). LeEix1 knockout plants have amplified systemic immunity, are more responsive to Trichoderma, and are more resistant to pathogens. In the second case, we constitutively activated an intra-cellular immunity-signaling hub by generating gain-of-function mutants in NRC family NLR receptors. NRC mutants also exhibited enhanced defense and biotic resistance. All our edited lines possess broad-spectrum resistance to plant pathogens without impairing fertility or agricultural traits, indicating this is a promising environmentally friendly approach for combating plant disease, which may be superior to priming, leading to better reproducibility and agricultural performance.

C9.1-5

GENOME EDITING OF AN AFRICAN ELITE RICE VARIETY CONFERS RESISTANCE AGAINST ENDEMIC AND EMERGING XANTHOMONAS ORYZAE PV. ORYZAE STRAINS

SZUREK Boris. (1)

(1) Plant Health Institute of Montpellier (PHIM), Université Montpellier, IRD, CIRAD, INRAE, Institut Agro, Montpellier, France, Montpellier, FRANCE

Text

Bacterial leaf blight (BB) of rice, caused by Xanthomonas oryzae pv. oryzae (Xoo), threatens global food security and the livelihood of small-scale rice producers. Analyses of Xoo collections from Asia, Africa and the Americas demonstrated complete continental segregation, despite robust global rice trade. Here, we report unprecedented BB outbreaks in Tanzania. The causative strains, unlike endemic African Xoo, carry Asian-type TAL effectors targeting the sucrose transporter SWEET11a and iTALes suppressing Xa1. Phylogenomics clustered these strains with Xoo from Southern-China. African rice varieties do not carry effective resistance. To protect African rice production against this emerging threat, we developed a hybrid CRISPR-Cas9/Cpf1 system to edit all known TALe-binding elements in three SWEET promoters of the East African elite variety Komboka. The edited lines show broad-spectrum resistance against Asian and African strains of Xoo, including strains recently discovered in Tanzania. The strategy could help to protect global rice crops from BB pandemics.

DISEASE RESISTANT GM AND GE CROPS: A REGULATORY TRIP AROUND THE WORLD

TURNBULL Crystal. (1), LILLEMO Morten. (1), HVOSLEF-EIDE Trine Ak. (1)

(1) Norwegian University of Life Sciences (NMBU), Ås, NORWAY

Text

Disease resistance has become one of the most important and desirable traits across all cultivated crops, for conventionally-bred, as well as transgenic (GM) and gene-edited (GE) crops. For over two decades, the largest cultivated transgenic crops focused on insect and herbicide resistance. Disease resistance presents a more complex task due to the sheer diversity of pathogens and infection mechanisms. Genome editing offers a precise, efficient, and affordable technique resulting in new GE crops entering regulatory schemes for commercialisation. We aver that the law is not static and must adjust to the *mores* of society, informed by the experiences of over 25 years of cultivation and regulation of GM crops. This work consolidates the global legislative landscape on GM crops, as well as specifically addressing how GE crops fit into the existing frameworks. Our presentation aims to highlight key regulatory developments that may impact the future of GE research and ultimately, GE products. To this end, countries leading in cultivating and exporting traditional GM crops are quickly adopting disease resistant GE products as non-GMO. This legislative development,

first implemented in Argentina, and soon followed by many, demonstrates considerable shifts in the landscape of agrobiotech products. We further illustrate the complex legal frameworks using specific examples of disease challenges such as potato late blight, and possible solutions.

CONTRIBUTION OF DISEASE RESISTANT CROPS DERIVED FROM GENE EDITING AND CISGENESIS TO EU SUSTAINABILITY OBJECTIVES

RODRIGUEZ-CEREZO Emilio. (1), BARREIRO-HURLE Jesus. (1), SCHNEIDER Kevin. (1)

(1) European Commission-Joint Research Centre (JRC), Sevilla, SPAIN

Text

The European Commission aims to reducing the use and risk of chemical pesticides by 50 percent and the use of more hazardous pesticides by 50 percent, by 2030. The use of varieties with improved biotic resistances or tolerances is a key tool to achieve these objectives. Work on a new proposal for legislation addressing crops obtained by targeted mutagenesis and cisgenesis is ongoing in the EU. Here, we present a market outlook for applications of targeted mutagenesis and cisgenesis on disease-resistant crops using a database compiled recently (1). The database comprises 113 entries of projects on disease resistances, mostly using targeted nucleases (67% CRISPR/Cas, 7% TALEN, 2.5% ZFN) . We also look in detail at 2 case studies and develop a methodology for estimating the farm level impacts (economic and pesticide use impacts) , the market impacts and the spatial environmental impacts of cultivating these varieties. The case studies selected are potato varieties with stacked resistance genes for late blight via cisgenesis and an apple variety with resistance to scab (2).

TARGETED AND UNTARGETED EPIGENETIC MODIFICATIONS TO CONTROL PLANT PATHOGENS

GÖTZ Monika. (1), **AMARI Khalid. (1)**

(1) Julius Kühn Institute, Quedlinburg , GERMANY

Text

Plants use epigenetics to regulate gene expression during development and environmental stress to achieve plasticity and rapid adaptation.
For a successful infection, pathogens must interact with host factors termed susceptibility factors, and these susceptibility factors are a valuable source of obtaining resistant plants.

We used epigenetics to silence susceptibility genes for different viruses and powdery mildew in Arabidopsis and tobacco plants, respectively. We used virus-induced gene silencing (VIGS) and the SunTag system coupled with the Nicotiana tabacum DRM methyltransferase catalytic domain [1] to stably methylate the promoter of selected host genes representing susceptibility factors. We investigated the mobilization of transposons as a source of phenotypic variation for pathogen resistance screening using epigenetics [2].
Our results show that epigenetics modifications can successfully downregulate the expression of the susceptibility factors providing resistance. Even in the absence of the transgene, the next generation of plants inherited the epigenetic effects.

Text
Fusarium wilt is a devastating fungal disease that continues to threaten the production of banana crops world-wide. *Fusarium oxysporum* f. sp. *cubense* subtropical race 4 (STR4) is a variant that infects banana plants predisposed to environmental stressors such as cool temperatures and drought. Many commercially and locally important cultivars in subtropical regions, including Lady finger, are susceptible to the pathogen, causing significant loss to farmers and industry. Management of Fusarium wilt relies on strict biosecurity regulations as no control measures are currently available. The discovery of plant-derived disease susceptibility genes has potentially created new opportunities for engineered plant disease management. Identification of fungal susceptibility genes in banana and development of gene-edited bananas with resistance to STR4 would future-proof this important crop against the pathogen. In this present study, we have identified four susceptibility gene targets in Lady finger through differential expression analysis and edited these in Lady finger bananas using CRISPR-Cas9. An average of four lines per gene target have been characterised for edits. An optimised STR4 bioassay will challenge edited lines to assess whether deletion of these susceptibility genes confers resistance to STR4.

Text

Resistance to potyviruses in plants have been largely provided by the selection of natural variant alleles of *eukaryotic translation initiation factors (eIF) 4E* in many crops. However, the sources of such variability for breeding can be limited for certain crop species, while new virus strains continue to emerge. Different methods of mutagenesis have been applied to inactivate the *eIF4E* genes to generate virus resistance, but with limited success due to the physiological importance of translation factors and their redundancy. Here, we employed genome editing approaches at the base level to induce nonsynonymous mutations in the *eIF4E1* gene and create genetic diversity in cherry tomato (*Solanum lycopersicum* var. *cerasiforme*). We sequentially edited the genomic sequences coding for two regions of eIF4E1, located around the cap-binding pocket and known to be important for susceptibility to potyviruses. We show that the editing of only one region, by gene knock-in and base-editing, respectively, is not sufficient to provide resistance. However, combining amino acid mutations in both regions resulted in resistance to multiple potyviruses without costing its functionality in translation initiation. Altogether, our work demonstrates that precision editing allows to design plant factors based on the knowledge on the evolutionarily selected alleles and enlarge the gene pool to potentially provide advantageous phenotypes such as pathogen resistance.

SALICYLIC ACID IS REQUIRED FOR BROAD-SPECTRUM DISEASE RESISTANCE IN RICE

LIANG Bingbing. (1), WANG Han. (1), QI Linlu. (1), CHEN Xujun. (1), **GUO Zejian. (1)**

(1) China Agricultural University, Beijing, CHINA

Text

Rice plants contain high basal levels of salicylic acid (SA), but some of its functions remain elusive. Here, we characterized four rice SA hydroxylase (OsSAH) genes and verified their roles in disease resistance. Knockout OsSAH (sahKO) genes conferred enhanced resistance to both hemibiotrophic and necrotrophic pathogens, whereas overexpression of each OsSAH gene increased susceptibility to the pathogens. sahKO mutants showed increased SA and jasmonate, and decreased indole-3-acetic acid levels compared to those of the wild-type and OsSAH-overexpressing plants. Analysis of OsSAH1 and OsSAH3 promoters indicated that the induction of these genes was mainly restricted around Magnaporthe oryzae infection sites. Recombinant OsSAH3 protein showed only SA 5-hydroxylase (SA5H) activity, which was remarkably higher than that of other OsSAHs that presented both SA3H and SA5H activities. Amino acid substitutions revealed that three amino acids in the binding pocket affected enzyme activity and/or specificity. Taken together, our findings indicate that SA plays a vital role in immune signaling. Moreover, fine-tuning SA homeostasis through suppression of SA metabolism provides an effective approach to study broad-spectrum

disease resistance in rice.

Text

Both the host organisms and the infecting viruses rely on the eukaryotic translation initiation factor 4E (eIF4E) for gene expression. Plants utilize the genes from the eIF4E family to develop antiviral resistance. The mechanisms of resistance previously studied are attributed to the lack of proper interactions of the resistant eIF4E protein with viral proteins, hindering the ability of targeted viruses to infect. Our research has demonstrated an alternative mode of eIF4E-mediated resistance. We used CRISPR/Cas9 to create tomato eIF4E1 alleles, including one with an in-frame 9-nucleotide deletion (9DEL) within the eIF4E1 coding sequence. Unlike a 1-nucleotide insertion knockout allele, we showed that the 9DEL deletion was associated with a significant reduction in susceptibility to cucumber mosaic virus (CMV). Here, we present new data shedding light on the molecular mechanism behind the 9DEL-mediated resistance to CMV. The 9DEL-encoded mutant eIF4E1 was found to bind to the CMV-encoded protein 2b through a strong affinity to the C-terminal of 2b. We have previously reported that 2b is a target of autophagy, a primary proteolytic pathway. Our results suggest that the 9DEL appears to enhance the 2b degradation. Consistently, the RNA silencing suppressor activity of 2b was weakened when co-expressed with 9DEL. Since 2b was essential for systemic CMV infection in tomato, we propose that the 9DEL mutation confers resistance to CMV on tomatoes by binding to and inhibiting 2b.

Text

Phytophthora infestans (*Pi*) is an Oomycyte pathogen known to cause blight in potato. Late blight is considered the most serious disease of potatoes because it can destroy the entire

crop in a span of days. Therefore, molecular studies might help pave the way for sustainable *Pi* resistance. miRNAs are known to actively regulate physiological processes as well as biotic and abiotic stress tolerance. The *miR396* gene in potato is known to promote the colonization of *Pi*. In addition, reduced invasiveness has been reported on tubers with downregulated polyphenol oxidase (PPO) genes when subjected to *Pi*, associating the defense to phenolic compounds.
Based on the strong literature evidence, we designed CRISPR/Cas targets to the *miR396* gene as well as for root- and tuber-specific *PPO* genes in potato and generated edited lines in the commercial cultivars 'Botond' for miR396, and 'Desirée' and 'Balatoni Rózsa' for *PPO* genes. The leaves of three *miR396* complete mutant lines along with the control are being evaluated for *Pi* resistance. Metabolomics analysis of the mutant PPO lines indicate higher levels of jasmonic acid and salicylic acid both in the leaves and roots compared to the control lines. This increase has been suggested to aid in conferring resistance.
The project has been supported by grants NKFIH K-132829 and ATK-MATE 0205K0036P.

Text
UDP-arabinopyranose mutases family is a key enzyme in arabinose biosynthesis and plays an important role in plant morphogenesis and response to stress. However, little work has been reported on UDP-arabinopyranose mutases in wheat. In the present, a full length cDNA of a UDP-arabinopyranose mutases gene (named TaUAM1) was isolated from wheat. The sequence analysis results showed that the full length of the open reading frame of TaUAM1 was 1107 bp encoding 368 amino acids. RNAi-based stable silencing of TaUAM1 resulted in decreased resistance to Pst. In addition, CRISPR-mediated genome editing (GE) of TaUAM1 enhanced susceptibility of wheat to Pst or compromised disease resistance accompanied by increased fungal growth and decreased H2O2 production in plant tissues. Moreover, the transcript levels of pathogenesis-related (PR) genes and ROS-generating genes were down-regulated in both the RNAi and CRISPR-edited plants, while the ROS-scavenging gene was up-regulated. Therefore, TaUAM1 positively regulates the resistance of wheat to Pst.

Text

Rice yellow mottle virus (RYMV) causes one of the most devastating rice diseases in Africa. Genetic resistance is the most effective control strategy. However most of the known resistance genes originate from the African cultivated rice *Oryza glaberrima* and their transfer to *O. sativa*, high yielding and world-grown, is hampered by interspecific sterility barriers. We tested wether CRISPR/Cas9 genome editing of the susceptibility genes *RYMV1* and *RYMV2*, encoding a translation initiation factor (OseIF(iso)4G.1) and a nucleoporine (OsCPR5.1) respectively, is effective in generating resistance alleles in the *O. sativa* Kitaake variety. We developed lines with knock-out mutations or in-frame deletions or substitutions in *RYMV1*, *RYMV2* and their paralogs and we analysed them for resistance, resistance durability and possible growth defect. Our results indicated that genome editing is a promising way to develop RYMV-resistant elite *O. sativa* lines and that some mutations may even increase resistance durability compared to the alleles found in the natural diversity. Besides, the comparison of the effect of the mutations obtained in the resistance genes and their paralogs will help understanding the specificity of the interactions between the virus and the host susceptibility factors.

Text

Bacterial leaf blight (BLB) of rice caused by Xanthomonas oryzae pv. oryzae (Xoo) is one of the major diseases affecting rice cultivation in Africa and Asia. BB causes substantial yield loss in rice. Xoo injects transcription activator-like effectors (TALes), which bind effector binding elements (EBE) in the promoters of the sucrose uniporter genes OsSWEET11a, OsSWEET13 and OsSWEET14, likely triggering sucrose efflux into the xylem sap. Six major SWEET-inducing TAL effectors have been identified: PthXo1 for OsSWEET11a, PthXo2 for OsSWEET13, PthXo3, AvrXa7, TalF and TalC for OsSWEET14. Elite lines with CRISPR-Cas9-induced EBE mutations in five EBEs were highly resistant to a wide range of Xoo strains. In countries with appropriate regulations, edited rice lines (SDN-1) that do not carry transgenes can possibly be introduced to protect from BLB. However, for countries without suitable regulations, an alternative approach is required. Here we introgressed a combination of six EBE mutations in the promoters of OsSWEET11a, OsSWEET13 and OsSWEET14 into FARO-44 and NERICA-4, and two major BLB resistance genes xa13 and Xa21 into Komboka, FARO-44 and NERICA-4 through marker assisted backcross breeding, respectively. Independent crosses were performed between donors and recipients to generate F1 generations. Derived F1 were confirmed by genotyping and sequencing.

Generation of stable homozygous BC2F4 and BC3F4 plants with broad spectrum resistance against BLB is under progress.

GENOME EDITING OF BANANA FOR RESISTANCE TO BACTERIAL WILT DISEASE

TRIPATHI Leena. (1), NTUI Valentine. (1), TRIPATHI Jaindra. (1)

(1) IITA, Nairobi, KENYA

Text

Banana is an important staple food crop and a source of income for resource-poor farmers in more than 136 tropical countries. Many diseases and pests severely constrain banana production, particularly where many pathogens co-exist. Banana Xanthomonas wilt (BXW) caused by *Xanthomonas campestris* pv. *musacearum* (Xcm) is among the most destructive banana diseases in East Africa. All the cultivated banana varieties are susceptible, and only the wild-type progenitor, *Musa balbisiana,* is resistant to BXW disease. Disease-resistant varieties are one of the most effective strategies for managing banana diseases. CRISPR/Cas9-based genome editing can accelerate the breeding of bananas for disease resistance traits. IITA is currently advancing the application of genome editing to control BXW disease by disrupting the function of disease-causing susceptibility ('S') genes, nutrient transporters, or negative regulators of plant defense. The target genes have been identified through literature or comparative transcriptomics of BXW-resistant wild progenitor banana 'Musa balbisiana' and BXW-susceptible banana cultivar during early infection with Xcm. Genome-edited crops can be released to the market without going through the same time-consuming regulatory process required for transgenic crops in several countries. This paper will present a synopsis of recent advancements in the application of genome editing to improve bananas for BXW disease resistance.

Text

The vast array of tools to generate or stimulate plant resistance to biotic stresses, such as bacteria, fungi, and viruses, is an important means for genetic improvement. However, using these tools in an open biogeocoenosis may brake the natural interconnections between consumer, producer and reducer organisms. Therefore, it is preferable to induce or enhance the defence mechanisms in the crop plants. Such measures may include the (increased)

expression or knockout of certain plant genes.
We selected as candidates members of the CML (calmodulin-like) gene family. These gene may act both as positive and negative regulators of plant defence. Knockouts of CML genes are predicted to reveal their specific physiological roles and may also lead to agronomically advantageous mutant phenotypes.
A literature review and bioinformatics analysis were performed to find target genes in potato for knockout by the CRISPR/Cas system. Two genes were found, the sequence of which was identified as potential targets. Two plasmid vectors were then constructd and transferred into the potato varieties 'Désirée'. At the present stage, mutant lines of potatoes were obtained, in which the knockout of the CML30 gene was proven. Currently, research is being conducted on the resistance of these plants to pathogen Phytophthora infestans.

Current and emerging forest pathology issues

A GLOBAL ACCOUNT OF THE DOTHISTROMA NEEDLE BLIGHT PATHOGENS AND RISKS POSED BY EMERGING NEW LINEAGES

BARNES Irene. (1), GRANADOS Ginna M. (1), MULLER Monique. (1), RODAS Carlos A. (1), VAN DER NEST Ariska. (1), WINGFIELD Michael J. (1)

(1) Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, SOUTH AFRICA

Text
Dothistroma needle blight (DNB) is caused by two pathogens; *D. septosporum* and *D. pini*. Questions regarding their origin, global distribution, evolutionary history, pathogenicity and their potential to hybridise are being elucidated through population genetics and genomic comparisons. The only areas where the two species are known to co-occur are Canada and some European countries. Whereas *D. septosporum* has a global distribution, *D. pini* is only present in certain Northern Hemisphere countries and distinct lineages are observed in populations of both species in North America compared to those found in Europe. Recently, genetic comparisons of strains collected from Central America, the area where *Dothistroma* is believed to be native, have revealed novel haplotypes of *D. septosporum* as well as lineages that may represent new *Dothistroma* species. The similarity of some of these strains with isolates collected from recent DNB outbreaks on Central American *Pinus* spp. in Colombia, suggests a possible route of movement out of their native area, similar to that of *Lecanosticta pharomachri*. The presence of these novel *D. septosporum* haplotypes on *P. patula* and *P. maximinoi*, that are both considered as species tolerant to infection, poses a risk to plantation forestry in countries utilising these pine species. Furthermore, this now emerges as an important global forest pathology issue given the fact that their impact on Northern Hemisphere *Pinus* species is unknown.

C5.3-2

IMPORTANCE OF HEALTHY CARRIERS IN ASH DIEBACK

MARÇAIS Benoit. (1), GIRAUDEL Arnaud. (2), HUSSON Claude. (2)

(1) INRAE, Champenoux, FRANCE; (2) Département de la Santé des Forêts, DGAL, Paris, FRANCE

Text

Ash dieback, induced by an invasive ascomycete, Hymenoscyphus fraxineus, has emerged in the late 1990s as a severe disease threatening ash populations in Europe. Future prospects for ash are improved by the existence of natural genetic resistance / tolerance to the disease and by limited disease impact in many environmental conditions where ash is common. Nevertheless, it was suggested that, even in those conditions, ash trees are infected and enable pathogen transmission. We studied the influence of the environment on the ability of H. fraxineus to infect, be transmitted and cause damage on its host. We showed that healthy carriers, i.e. individuals showing no dieback but carrying H. fraxineus, exist and play a significant role in ash dieback epidemiology. The environment parameters influencing H. fraxineus are different at different life cycle stage. The ability of H. fraxineus to establish on ash leaves and to reproduce on the leaf debris in the litter mainly depended on total precipitation in July-August and was not influenced by local tree cover. By contrast, damage to the host (shoot mortality) was strongly reduced by high summer temperature and by high autumn average temperature. Thus, ash trees are often infected and enable H. fraxineus transmission while showing very limited damage. We also observed a decreasing trend of severity (shoot mortality) with the time of disease presence in a plot that could be significant for the future of ash dieback.

Text

Phytophthora pathogens are serious threats to forest health around the world. Of the 38 species of Phytophthora currently noted as present in New Zealand, 16 have been found to be present in forests and natural ecosystems with variable impacts on forest health. One of the most devastating pathogens is Phytophthora agathidicida, which threatens Agathis australis (kauri), a foundational tree species of key northern forest systems. In addition to P. agathidicida, pathogens *P. cinnamomi* and *P. multivora* are also prevalent in these forest systems and are commonly associated with dying kauri. Similarly, in exotic pine plantations pathogens *P. pluvialis, P. kernoviae* and *P. aleotoria* all impact productivity either at

establishment or throughout the rotation and can co-occur within trees. Finally, the emergence of *P. podocarpi*, a species pathogenic to native t?tara (*Podocarpus totara*) is putatively associated with changes in climatic conditions. Given the increased intensity of weather events resulting from climate change, the resilience of forest systems to Phytophthora infection is of great concern. This talk will discuss the observed and projected impacts of a changing climate and extreme weather events and implications of Phytophthora on the health of forests and natural ecosystems.

C5.3-4

GENOMIC BIOSURVEILLANCE OF INVASIVE ALIEN TREE PATHOGENS CAN DETECT VARIANTS, HYBRIDS AND REVEAL SUPER-SPREADER EVENTS

HAMELIN Richard. (1), HEINZELMANN Renate . (2), BILODEAU Guillaume. (3), FEAU Nicolas. (4), BOYLE Brian. (5)

(1) UBC, Vancouver, CANADA; (2) Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Birmensdorf, SWITZERLAND; (3) Canadian Food Inspection Agency, Ottawa, CANADA; (4) Natural Resources Canada, Victoria, CANADA; (5) Université Laval, Quebec City, CANADA

Text

Invasive alien tree pathogens often have complex invasion histories. Understanding the source and pathways of invasion is crucial to improve prevention. Genomic biosurveillance can help untangle the invasion history. The BioSAFE project sequenced and analysed more than 500 genomes of a global collection of the pathogen responsible for the sudden oak death, the sudden larch death and Ramorum blight (*Phytophthora ramorum*). Variants within clonal lineages of *P. ramorum* were often geographically and/or chronologically restricted. We detected a shift in variants of the EU1 and NA2 lineages of *P. ramorum* in nurseries in British Columbia, Canada. One of the EU1 variants replaced all previous variants and spread to many nurseries, a signature of a potential super-spreader event. We also identified interlineage hybrids that are F1 progenies and produce viable sporangia and chlamydospores and are infectious to rhododendron, a common host. Comparison of variant composition in nurseries following treatment revealed both instances of eradication success and failure. For rapid and high-throughput biosurveillance, we have developed a tool, SODseq, that generates high-throughput sequence data for 355 informative amplicons that recapitulate the patterns obtained with whole genome sequencing. This tool can be used with DNA extracted from cultures or directly from environmental samples or infected host tissues and provide useful genomic data that can inform regulation and management.

C5.3-5

LATENT PATHOGENS TRIGGERED BY CLIMATE CHANGE ARE CAUSING LARGE-SCALE TREE DECLINE IN CALIFORNIA

GARBELOTTO Matteo. (1)

(1) University of California at Berkeley, Berkeley, UNITED STATES

Text
Large-scale tree mortality is thought to be caused by the emergence of invasive pathogens or by outbreaks of secondary organisms such as insects. Conversely, variability in resilience to climate-driven stressors may limit the scale of mortality driven exclusively by climate change. Until recently, disease caused by latent pathogens, i.e. pathogens that alternate between an endophytic , a pathogenic and a saprobic phase, has been thought to occur only in localized situations of acute stress. Since 2015, large-scale mortality of trees and shrubs, both native and exotic, has been occurring throughout Northern California. Isolations revealed that disease of each of eight tree/shrub species studied was associated with the widespread presence of latent pathogens in the genera *Botryosphaeria*, *Diplodia*, *Neofusicoccum*, *Dothiorella*, *Diaporthe* and *Pseudosysdowia*. Although most of the fungi identified are generalists, different pathogen species were dominant and widespread on different tree species. For unreported pathogen x host combinations, inoculation studies confirmed these fungi can cause disease, although at different rates, and showed that lack of water and increasing temperatures, can lead to higher disease severity. Together, our field and lab data suggest that physiological stress caused by changing climate is triggering true outbreaks of latent pathogens, regarded now as an additional class of agents causing large scale mortality in tree populations at the regional scale.

EXOGENOUS APPLICATION OF DOUBLE-STRANDED RNA TO CONTROL FUSARIUM CIRCINATUM IN PINES

BOCOS-ASENJO Irene T.. (1,2), AMIN Huma. (1,2), MOSQUERA Sandra. (1,2), GINÉSY Mireille. (1,2), DIEZ Julio J.. (1,2), NIÑO-SÁNCHEZ Jonatan. (1,2)

(1) Universidad de Valladolid, Palencia, SPAIN; (2) Instituto Universitario de Investigación en Gestión Forestal Sostenible - iuFOR, Palencia, SPAIN

Text
Fusarium circinatum is an invasive fungal pathogen that affects coniferous species, resulting in significant socio-economic impact. This fungus can affect all stages of tree development, causing seedling mortality in nurseries and cankers and dieback in adult trees. So far, there is no effective way to control this pathogen and phytosanitary products cannot be applied in forests. SIGS (Spray-Induced Gene Silencing) could be used as an environmentally friendly method to control *F. circinatum*. This strategy is based on RNA interference (RNAi), a conserved eukaryotic gene-silencing mechanism naturally occurring in cells. It is initiated by double-stranded RNA (dsRNA), which triggers the degradation of homologous mRNAs. By applying exogenous dsRNA, the pathogenic fungus uptake the molecules and trigger RNAi. In this study, we show that *F. circinatum* is able to uptake dsRNA and we designed dsRNA molecules targeting essential genes of the pathogen, successfully blocking important pathways for its survival. The application of dsRNAs to pine seedlings resulted in the inhibition of fungal growth and delayed symptoms. Furthermore, the efficacy of the dsRNAs has been tested on the wheat pathogen *Fusarium graminearum*, successfully reducing the infection. Although this strategy is being developed intensively for mainly agricultural pathogens, it has been less investigated in forestry. These results suggest that SIGS could be a sustainable method for disease management in forests.

CANDIDATE EFFECTOR PROTEINS CONSERVED ACROSS FUNGAL AND OOMYCETE FOLIAR PINE PATHOGENS

TARALLO Mariana. (1), MCDOUGAL Rebecca L.. (3), MESARICH Carl H.. (2), BRADSHAW Rosie E.. (1)

(1) Bioprotection Aotearoa, School of Natural Sciences, Massey University, Palmerston North, NEW ZEALAND; (2) Bioprotection Aotearoa, School of Agriculture and Environment, Massey University, Palmerston North, NEW ZEALAND; (3) Scion, Rotorua, NEW ZEALAND

Text

Dothistroma needle blight, Cyclaneusma needle cast and red needle cast are devastating *Pinus radiata* diseases, caused by the fungi *Dothistroma septosporum*, *Cyclaneusma minus* and oomycete *Phytophthora pluvialis*, respectively. These pathogens colonize the apoplastic host environment, secreting effector proteins to promote disease. If these effectors are recognized by corresponding host resistance proteins, they activate the plant immune system to stop pathogen growth. Two *D. septosporum* candidate effectors, Ds69335 and Ds131885, were identified with orthologues in both *C. minus* and *P. pluvialis*. Their protein structures were analysed using AlphaFold2 and the corresponding genes disrupted through CRISPR/Cas9 to study their function during pine infection. Ds69335 is structurally similar to proteins with known roles in fungal virulence and *Ds69335*-disrupted strains showed decreased fungal biomass *in planta* compared to wild-type (WT). Ds131885, a cell death elicitor in *Nicotiana* species and *P. radiata*, showed structural similarity to a cross-kingdom PAMP that was recognized by a *Nicotiana benthamiana* immune receptor, triggering defence responses. Disruption of *Ds131885* did not convincingly alter fungal biomass. Unexpectedly, none of the complementation strains restored WT fungal biomass. Despite these ambiguous results, these candidate cross-kingdom effectors deserve further exploration as they might ultimately hold the key to selection for broad spectrum resistance in pines.

P5.3-001

LAUREL WILT DISEASE MANAGEMENT: CURRENT STRATEGIES AND ONGOING LINES OF RESEARCH

GAZIS Romina. (1), NAVIA-URRUTIA Monica. (1), SENDOYA Carlos. (1), CRANE Jonathan. (1)

(1) University of Florida, Homestead, UNITED STATES

Text

Laurel wilt (LW), caused by Harringtonia lauricola, is a deadly vascular disease affecting numerous hosts in the Lauraceae, including ecological important forest species and avocado trees. The fungal pathogen is spread by beetle-vectors, through root grafts, and human-mediated transport of infested wood. LW is present in 12 U.S. states and continues to move towards major avocado-producing areas. The destructive nature of this disease, in combination with its multiple hosts and potential vectors, makes it an eminent threat to avocado production worldwide. The potential loss could be devastating, as LW has led to the

destruction of at least 300,000 fruit bearing trees in Florida alone. In forested ecosystems, LW has decimated entire populations of dominant and ecologically important tree species likely changing ecosystem functioning and compromising important reservoirs of biodiversity. Current management strategies are limited and rely on the implementation of cultural practices, such as sanitation and pruning (light management). The prophylactic injection of Tilt® was once recommended; however, our recent work has proven it only delays the death of the tree while remaining a source of inoculum. This presentation will provide evidence for the need of active ingredients with lower fungicidal thresholds, longer half-life, and higher xylem mobility. We will also present the progress our group has made on the screening of avocado germplasm for traits associated to LW tolerance.

P5.3-002

EXTENT OF DALBERGIA SISSOO (SHISHAM) DECLINE IN DIFFERENT AGRO-ECOLOGICAL ZONES AND ITS INTEGRATED MANAGEMENT

MUSA Muhammad. (1), AHMAD Mushtaq. (1)

(1) UNIVERSITY OF AGRICULTURE, FAISALABAD, PAKISTAN, Lahore, PAKISTAN

Text

Shisham (Dalbergia sissoo) has been attacked by various pathogens responsible for 80% mortality in Pakistan. Hence a study was designed to identify a better approach to manage shisham decline caused by Fusarium solani, Botryodiplodia theobromae, Curvularia lunata and Ganoderma lucidum. Primarily, efficacy of 8 fungicides were evaluated by the poisoned agar technique against colony growth of all 4 pathogens in-vitro. Among tested chemicals four (Score 250SC, Topsin-M 70%WP, Avito 480SC and Carbendazim 50%WP) were significantly inhibited pathogen growth. Simultaneously, four isolates of Trichoderma harzianum were also evaluated through dual culture technique against all pathogens and one isolate was selected for further study. Subsequently, four fungicides and an isolate of T. harzianum were appraised on mature fully effected diseased plants. During January 2022, five regions were selected from different agro-ecological zones and were classified as healthy, partially and fully affected. All four chemicals with different doses (50, 100, 200, 400PPM) and a biocontrol isolate were applied together on fully affected diseased trees in all regions. The mean results of field trials indicated that Topsin-M 70%WP gave 98.4%, while Carbendazim 50%WP, Score 250SC and Avito 480SC showed 72.8, 64.0 and 48.4% protection value respectively in the field with integration of T. harzianum after 6 months. Topsin-M 70%WP was most effective when integrated with T. harzianum at all doses.

P5.3-003

OCCURRENCE OF CYPRESS CANKER PATHOGENS ON CUPRESSACEAE IN SOUTH AFRICA

AYLWARD Janneke. (1,2), WINGFIELD Brenda. (1), ROETS Francois. (2), WINGFIELD Michael. (1)

(1) Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, SOUTH AFRICA; (2) Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text

Trees and shrubs in the Cupressaceae are widely planted in gardens and public spaces globally. Several Cupressaceae, particularly planted varieties of *Cupressus*, are highly susceptible to infection by various *Seiridium* species, causing a disease collectively known as cypress canker. The global distribution of these plants has led to many examples of pathogenic *Seiridium* species being introduced into new environments. These include well-documented examples of the pathogens undergoing host-jumps to native Cupressaceae. Most recently, cypress canker caused by *S. neocupressi* has been reported on native *Widdringtonia nodiflora* cedars in South Africa. This prompted a study to consider the distribution of *Seiridium* species in South Africa and the possible source of *S. neocupressi*. A large collection was assembled by isolating *Seiridium* from cankers on *Cupressus* and including isolates available in our culture collection. Isolates were identified by sequencing the *RPB2* gene and performing phylogenetic analyses. At least five different *Seiridium* species were present on Cupressaceae in South Africa. Of these, the well-known *S. cardinale* was most abundant. Importantly, *S. neocupressi,* that has evidently invaded native *W. nodiflora* forest, was rarely found on non-native *Cupressus* species, but had a wide distribution. This study emphasizes the fact that the global movement of *Seiridium* species, strongly linked to the nursery trade, is a growing threat to native Cupressaceae globally.

P5.3-004

OCCURRENCE OF SOME EMERGING POWDERY MILDEWS ON ORNAMENTAL AND FOREST TREES IN ALGERIA: A THREAT TO PARKS, AVENUES AND PUBLIC RECREATION AREAS.

BOUZNAD Zouaoui. (1), GHIAT Naouel. (1), KEDDAD Abdelaziz. (1), PASTIRCARKOVA Katarina. (2), TAOUTAOU Abdelmoumen. (1)

(1) Laboratoire de Phytopathologie et biologie moléculaire, Ecole Nationale Supérieure Agronomique Algiers, Algiers, ALGERIA; (2) Branch for Woody Plant Biology, Institute of Forest Ecology, Slovak Academy of Sciences, Nitra, SLOVAKIA

Text

During the last two decades, outbreaks of powdery mildew have been emerging on ornamental and forest trees in different regions of Algeria, thus constituting a threat to parks and recreation areas. On plane trees, the symptoms appear in early spring on both sides of the leaves, whereas on mulberry and ash they occur later on only the lower side of the leaves. Attacks on the three species of mulberry, Morus alba, M. nigra and M. platanifolia, are severe on the first two species while the last one seems immune. Microscopic observations of samples collected from several sites in Algiers showed the presence of both types of fungal fruiting bodies: solitary spindle-shaped conidia and chasmothecia with characteristic appendages. The morphology of these fruiting bodies enabled us to identify three species: Erysiphe platani on plane trees, Phyllactinia moricola on mulberry trees, and P. fraxini on ash trees. Due to the high morphological similarities of the fungal fruiting bodies of the pathogen on mulberry and ash trees and the proximity of sampling on these two host plants, the use of specific molecular markers (ITS sequencing) to confirm the identity of these two species was needed, to discriminate the species. These observations constitute a first signalisation of these species in Algeria where, so far, only ash powdery mildew was reported by Patouillard (1901). An evaluation of the frequency and incidence of these

pathogens is necessary to take measures to control them.

CLIMATIC DRIVERS OF PHYTOPHTHORA PLUVIALIS INFECTION AND SPORULATION ON PINUS RADIATA

MCLAY Emily. (1), LANE David. (1), SOMCHIT Chanatda . (2), BANHAM Catherine. (1), FRASER Stuart. (1)

(1) Scion, Rotorua, NEW ZEALAND; (2) AgReasearch, Hamilton, NEW ZEALAND

Text

Red needle cast (RNC), primarily caused by *Phytophthora pluvialis*, is a foliar disease of radiata pine. Outbreaks of RNC in New Zealand typically occur in winter and have been associated with cooler temperatures and higher rainfall. To quantify the impact of these climatic factors, we completed controlled studies on the effect of temperature and needle wetness on infection of detached radiata pine needles by *P. pluvialis*, as well as sporulation. Infection, as detected by qPCR, was highest in needles inoculated between 5 and 25ºC and when needles remained wet for 12 or more hours. Sporulation occurred at temperatures between 5 and 23ºC. Latent period was shortest at 20ºC, however, the greatest production of sporangia within 14 days occurred at 15ºC. Incubation at 23ºC resulted in the production of abnormal sporangia in vitro and no sporangia in planta. Incubation at 25ºC also restricted sporangia production, however, only when infected needle remained at 25ºC for more than 4 hours per day. Pilot studies suggest that needle wetness is required for sporulation. Infected needles expressed symptoms typical of RNC when incubated in wet or dry conditions, but sporangia were only observed under wet conditions. These findings improve our understanding of key processes in the RNC disease cycle and their relationship with temperature and wetness. These results advance our ability to predict RNC outbreaks, with plans to integrate temperature response curves into an infection risk tool.

P5.3-006

BEECH LEAF DISEASE: A EMERGING ISSUE OF INTERNATIONAL CONCERN

BONELLO Pierluigi. (1)

(1) The Ohio State University, Columbus, Oh, UNITED STATES

Text

Beech leaf disease (BLD) was first noted as an unknown ailment of American beech, Fagus grandifolia, near Cleveland, Ohio, U.S.A. in 2012. The disease is characterized by very uncommon symptoms for a forest tree disease. It is now accepted that a foliar nematode, Lytilenchus crenatae mccannii, is a necessary, if not sufficient, condition to cause BLD, making it the first case worldwide of a major forest disease associated with a foliar nematode. Due to the explosive nature and specific dynamics of the North American epidemic, it is hypothesized that the nematode is a non-native pathogen. The disease

eventually leads to abortion of new buds and subsequent failure to produce new leaves, leading to progressive decline and death over several years, especially of younger understory trees. The disease has now spread throughout the Northeastern U.S.A. and threatens the entire distribution range of this iconic and ecologically significant tree species, from the Great Lakes to Georgia, and East of the Mississippi to New England. Furthermore, it has been demonstrated that European beech, F. sylvatica, is also susceptible, which has put Europe on edge as they are dealing with several concurrent forest disease epidemics of major significance. In this talk I will provide an excursus of the discovery and spread of the disease, significant research development in the last 10 years, and an informed opinion on where we are heading with this emerging forest epidemic.

IMPACTS OF ENHANCED CO2 ON OAK DEFENCES AGAINST POWDERY MILDEW

RAW Mark. (1), **SANCHEZ-LUCAS Rosa. (1)**, PLATT Emma. (1), HAWKINS Katie. (1), PASTOR Victoria. (2), LUNA Estrella. (1)

(1) University of Birmingham, Birmingham, UNITED KINGDOM; (2) Universitat jaume I, Castellon, SPAIN

Text

Rising levels of atmospheric Carbon Dioxide (CO2), have been demonstrated as harmful for environment and human health. Different strategies are in place to mitigate it such as reducing deforestation and increasing forested areas. In the UK, planting strategies include oak species. However, young oak are highly susceptible to *Erysiphe alphitoides*, the causal agent of oak powdery mildew (PM), which is considered a limiting factor in oak woodland regeneration. Previous work in our group has shown that elevated CO2 (eCO2) causes seedlings to become more susceptible to the infection, which could have devastating future impacts. However, mature oaks are able to tolerate annual powdery mildew infection. We aim to understand how eCO2 impacts mature oaks. For this, monthly leaf samples from the canopy were collected from May-September. Leaf-metabolites were subjected to LC-MS/MS. Spectra were filtered using the XCMS R script and MarVis was employed to putatively identify metabolites and pathways. Mature trees showed low differentially expressed metabolites amounts within the same month, however changes occurred gradually over the months also demonstrating highly different patterns of expression between the months where the PM is present from those without. Comparisons between mature oak trees and an earlier experiment on oak seedlings were performed. Seedling profiles showed unique expression patterns but many of these compound groups are shared between young and mature trees.

ERYSIPHE LONICERIGENA SP. NOV., A POWDERY MILDEW SPECIES FOUND ON LONICERA HARAE

CHOI Inyoung. (1), YUN Seonhee. (1), ABASOVA Lamiya. (1), CHOI Joonho. (1), KIM Mihee. (1), SHIN Hyeondong. (1)

(1) Jeonbuk National University, Jeonju, REPUBLIC OF KOREA

Text
A powdery mildew (Erysiphaceae) has been continuously collected on the leaves of Loncera harae from the southern part of the Korean Peninsula, where this shrub is indigenous. Microscopic examination of asexual morphs revealed that the current isolate is differentiated from the all known Erysiphe-Lonicera associations by its longer conidiophores and longer conidia. Although the morphology of the chasmothecia is reminiscent of Erysiphe ehrenbergii and E. lonicerae, but the isolate is differentiated from them by having smaller ascospores. A phylogenetic tree generated from a combined dataset of the internal transcribed spacer region and 28S rDNA gene sequences demonstrates that sequences obtained from three powdery mildew collections on L. harae clustered together as an independent clade with high bootstrap values and placed distinctly from other Lonicera-Erysiphe combinations, representing a species of its own. Based on morphological differences and molecular-phylogenetic results, the powdery mildew on L. harae was proposed as a new species, Erysiphe lonicerigena, and the holomorph of the fungus was described and illustrated in this study.

EARLY DETECTION METHODS TO PREVENT THE SPREAD OF FOREST PATHOGENS

LUCHI Nicola. (1), PECORI Francesco. (1), PEPORI Alessia Lucia. (1), **SANTINI Alberto. (1)**

(1) National Research Council - Institute for Sustainable Plant Protection (CNR-IPSP), Sesto Fiorentino, ITALY

Text
Plant diseases caused by pathogenic microorganisms represent a serious threat to plant productivity and natural ecosystems. Early warning and a rapid response are crucial for a successful eradication or mitigation of the impacts and of the possible further spread of the invasive organism. For these reasons, early detection tools play an important role in monitoring plant health, surveillance, and quantitative pathogen risk assessment, thus improving best practices to mitigate and prevent plant pathogens threats.
Recent advances in nucleic acid-based methods, to detect plant pathogens, offer increased specificity and sensitivity over traditional microbiological approaches. The potential benefit of nucleic acid-based methods is reduced time to diagnosis, high throughput, and accurate and reliable results.
Considering prevention to be the best strategy to protect plants from diseases, this contribution focuses on fast and reliable molecular methods to detect forest pathogens by using both in field laboratory techniques, even at early stage of disease development before symptoms occur in the host.
Here we present a series of examples of tools, protocols and assays that shown to be or that, if used, could be useful early detection tools for a successful prevention, eradication or control of threatening both emerging and non-native pathogens.

RNA VIRUSES IN DECLINING MEDITERRANEAN FORESTS

DIEZ-HERMANO Sergio. (1), NIÑO-SANCHEZ Jonatan. (1), DE LA PEÑA Marcos. (2), **DIEZ Julio Javier. (1)**

(1) Sustainable Forest Management Research Institute (iuFOR), University of Valladolid, Palencia, SPAIN; (2) Institute for Plant Molecular and Cellular Biology (CSIC-UPV), Valencia, SPAIN

Text

Global change alters forestry habitats and facilitates the entry of new pathogens that don't share a co-evolution history with the forest. Due to urban massification, the human population is particularly exposed to new infectious diseases, such as the coronavirus pandemic. For this reason, the study of RNA viruses is essential to understand how viral flow across different hosts might occur, and to prevent possible outbreaks of human diseases in the future. In this work the viral diversity found in trees, insects and fungi from Spanish Mediterranean forests is described. To this extent, three habitats (Quercus ilex, Castanea sativa and Pinus radiata) were sampled and RNAseq was performed on tree tissues, insects and fungi. 161 viral sequences were detected by searching for matches to conserved motifs of the RNA-dependent RNA polymerase (RdRP) using Palmscan. Up to 15 viral families were identified, with Botourmiaviridae (25%) and Partitiviridae (6%) being the most abundant. Viruses belonging to families with cross-kingdom capabilities such as Hypoviridae (1), Mitoviridae (7) and Narnaviridae (5) were also found. Distribution of viruses across ecosystem was: Q.ilex (57%), P.radiata (27%) and C.sativa (16%). Interestingly, 40% of RdRP sequences had no matches in available viral databases, thus constituting a starting point to search for novel viruses that might be participating in unknown infectious pathways within forests and potentially posing a threat to the human being.

Text

Ailanthus altissima (Mill.) is a highly invasive tree established worldwide, included into the European Union list of invasive alien species. *Verticillium dahliae* Kleb. and *V. nonalfalfae* Inderb. *et al*. (formerly *V.albo-atrum* Reinke & Berthold) have been reported as the causal agents of Verticillium wilt and mortality of *Ailanthus*. In the last decade, ailanthus trees showing Verticillium wilt disease symptoms have been observed in forests in Catalonia (Spain). Aimed at establishing the disease aetiology and its impact in the ailanthus trees in Girona area, the disease progress was monitored yearly since 2018. Morphological, molecular and pathogenic characterization was performed on about 100 isolates recovered from symptomatic samples.

Based on morphology, 77% of the isolates were identified as *V.dahliae* and 23% as *V.albo-atrum/V.nonalfalfae*. BLASTn study based on ITS sequences showed high identity to *V.dahliae, V.albo-atrum* and *V.nonalfalfae* type strains, depending on isolates. Regarding to pathogenicity, 100% of the tested isolates caused chlorosis, wilting or dying on ailanthus inoculated plants, whereas control plants remained healthy. As far as we know, this is the first report of *V.dahliae* and *V.albo-atrum* as causal agents of Verticillium wilt of *Ailanthus* in Spain.

This research was funded by Diputació de Girona (grants 2017/8719-2019/3091-2020/7565-2021/1468-2022/3571) and Carol, J. was recipient of a fellowship from AGAUR, Generalitat de Catalunya (2021FISDUR00102).

BLAST FROM THE PAST: A STUDY OF DECADES-OLD FUNGAL CULTURES RESOLVES A LONG-STANDING TREE DISEASE MYSTERY

WINGFIELD Michael. (1), PHAM Nam. (1), MARINCOWITZ Seonju. (1), DUONG Tuan. (1), WINGFIELD Brenda. (1), WILSON Andi. (1)

(1) FABI, University of Pretoria, Pretoria, SOUTH AFRICA

Text

A root disease in plantations of *Pinus radiata* and *Pinus pinaster,* where trees died in distinct patches, was present in the Western Cape province of South Africa during the 1970s and 1980s. The disease was originally believed to be caused by *Phytophthora cinnamomi*, but was later attributed to *Leptographium serpens* (Ophiostomatales), an insect-associated fungus. However, doubt regarding *L. serpens* as the causal agent was raised because most *Leptographium* spp., particularly those, like *L. serpens*, which colonise ray parenchyma tissues, are not typically primary pathogens. In the present study, we revived cultures collected from dying trees almost 40 years ago and identified them using DNA sequencing methods, which were not available when the disease was first studied. These cultures were identified as the pyrophillic pathogen *Rhizina undulata*, well-known to cause patch death of conifers in South Africa and elsewhere in the world. Unfortunately, the patches of dying trees no longer exist and thus cannot be further investigated, however it is most likely that *R. undulata* was the primary cause of the patch death observed in the *Pinus* plantations. The study provides a vivid example of the value of preserving cultures of fungi for later study and the power of modern techniques to identify fungal pathogens.

P5.3-013

THE OPHIOSTOMATOID FUNGI IN KOREA

SEO Sang-Tae. (1), KIM Yong-Ho. (1), HEO A-Yeong. (1), LEE Dong-Hyeon. (1)

(1) National Institute of Forest Science, Seoul, REPUBLIC OF KOREA

Text

The ophiostomatoid fungi includes important fungal pathogens, some of which cause serious diseases on agricultural and forestry crops worldwide. Of those, *Raffaelea quercus-*

mongolicae is one of the ophiostomatoid fungi occurring in Korea, which is believed to be associated with oak mortality in the country. Despite the fact that the oak mortality has continued to spread across the country since its first discovery of the disease in 2004 and the significant impact that the pathogen has on forest ecosystem in the country, little is known regarding its biology of the fungus. In addition, wound-associated fungi that belongs to Ophiostomatales and Microascales were first found occurring on Korean native trees via a survey to assess the diversity of the ophiostomatoid fungi, especially including Dutch Elm Disease. These results clearly emphasize the general lack of information on fungal diversity, especially for species of Ceratocystidaceae or other insect related fungi such as the Ophiostomatales in Korea, requiring more surveys on this group being conducted.

P5.3-014

PHYTOPHTHORA SPECIES ASSEMBLAGES IN KAURI FORESTS: COMPARING ISOLATION THROUGH BAITING AND METABARCODING

HUNTER Shannon. (1,2), WILLIAMS Nari. (4), WAIPARA Nick. (1), SCOTT Peter. (3), BURNS Bruce. (2)

(1) New Zealand Institute for Plant and Food Research, Auckland, NEW ZEALAND; (2) School of Biological Sciences, University of Auckland, Auckland, NEW ZEALAND; (3) Western Australia Department of Primary Industries and Regional Development, Perth, AUSTRALIA; (4) The New Zealand Institute for Plant and Food Research Limited, Havelock North, NEW ZEALAND

Text

Phytophthora species are serious pathogens of many foundation and keystone forest tree species globally. In New Zealand, *Agathis australis* (kauri), a threatened foundation tree species, is under attack by *Phytophthora agathidicida.* This root-rot pathogen causes canopy dieback, creates massive basal lesions and eventually leads to tree death. During routine surveillance programmes, several other *Phytophthora* species have been detected from kauri trees, although their role in kauri dieback is unknown. Our research aimed to characterise the *Phytophthora* species assemblages from randomly selected kauri in the Waitakere Ranges, Auckland. Seven species were detected with metabarcoding and confirmed through both baiting isolation and qPCR analysis of the soils. This is the first time metabarcoding has been used to detect *Phytophthora* in kauri forests. A qPCR assay was developed to validate the metabarcoding results and confirmed that the enrichment approach used for the metabarcoding was useful for giving a qualitative description of the *Phytophthora* species within environmental soil samples. *P. cinnamomi* was the most abundant species, found in 59.2% of all samples, followed by *P. agathidicida* in 10.9% of samples. There were 5 and 51 samples that were positive with sequencing only for *P. agathidicida* and *P. cinnamomi*, respectively. We recommend using both traditional isolation methods and high-throughput sequencing to detect *Phytophthora* populations.

P5.3-015

LOW GENETIC DIVERSITY IN COLOMBIA FUSARIUM CIRCINATUM POPULATION

CERIANI Callin . (1), VAN WYK Stephanie. (1), STEENKAMP Emma. (1), RODAS Carlos. (1), WINGFIELD Michael. (1), FRU Felix. (1), **WINGFIELD Brenda. (1)**

(1) University of Pretoria, Pretoria, SOUTH AFRICA

Text

The pitch canker fungus, *Fusarium circinatum* is one of the most important pathogens of *Pinus* species globally. It now occurs in plantations and production nurseries in most regions where non-native Pinus species are propagated commercially. In Colombia, *F. circinatum* was first reported in 2005, both from nursery seedlings with root disease and established plantation trees displaying pitch canker symptoms. Since then, disease associated with this pathogen has gradually increased, but information regarding its population biology remains lacking. The aim of this study was to consider the mode of reproduction, population diversity and structure of *F. circinatum* isolates in Colombia. This was achieved using 10 microsatellite markers to analyse a collection of 94 isolates obtained from multiple geographic regions, collected at different time points and from different *Pinus* species. The population in Colombia was found to be predominantly clonal, with no evidence of sexual recombination (P = 0.0001) occurring and all isolates were of the MAT 1-1 mating type. Generally, this limited diversity was structured based on date of collection and *Pinus* host from which isolates were recovered. The findings support the view that following an initial introduction of *F. circinatum* into Colombia, its genetic diversity has not changed greatly over time. Its spread and the increasing incidence of disease is largely due to forestry operations such as movement of infected planting material.

P5.3-016

MULTIVARIATE ANALYSIS AND MODELLING OF SCOTS PINE BLISTER RUST DISTRIBUTION IN CENTRAL AND NORTHERN SWEDEN

ZHANG Ke. (1), SVENNERSTAM Henrik. (2)

(1) Department of Forest Mycology and Plant Pathology, Swedish University of Agricultural Sciences, Uppsala, SWEDEN; (2) The Forestry Research Institute of Sweden (Skogforsk), Uppsala, SWEDEN

Text

Scots pine (*Pinus sylvestris* L.) is one of the most common tree species in Sweden, it formed 33% of the total volume of the Swedish forest. Scots pine blister rust/resin top disease is caused by the rust pathogen *Cronartium pini*. Severe *C. pini* infection can girdle the stem and cause the death of the top or the entire pine tree. This pathogen is native to Fennoscandia, but its recent epidemics in the central and northern Swedish forests, especially young Scots pine forest stands, caused significant economic and ecological losses in forestry. To understand the distribution of *C. pini* in the Swedish forest and the biotic and abiotic factors associated with Scots pine blister rust, forest surveys were executed in 2021 and 2022. The Surveys covered 3373 plots from 421 forest stands in Norrbotten, Västerbotten, Jämtland and Västernorrland County (62° N to 67° N). Topographical, vegetation, and climate data, and the binary data of *C. pini* occurrence were analyzed in multiple logistic regression with generalized linear mixed (GLMM) models. Results showed *C. pini* has aggregated geographical distribution in Northern Sweden, and it is associated with the distribution of the alternate host (*Melampyrum* spp.), and warmer and more humid weather from May to July. At last, we used the GLMM model to predict the current C. pini occurrence in central and

northern Sweden, and discussed the change of *C. pini* distribution under future climate scenarios.

A STUDY OF TREE DISEASE ON ST HELENA

WEBSTER Amy. (1), RABIEY Mojgan. (1), MCDONALD Megan. (1), MACZEY Norbert. (2), CAIRNS-WICKS Rebecca. (3), TAYLOR Philip. (2), REEDER Robert. (2), JACKSON Robert. (1)

(1) University of Birmingham, Birmingham, UNITED KINGDOM; (2) CABI, Egham, UNITED KINGDOM; (3) St Helena research institute , St Helena, SAINT HELENA

Text

Situated in the South Atlantic Ocean, St Helena is an island home to an abundance of endemic flora and fauna. The cloud forest established at the high peaks of the central ridge support a complex ecosystem for biodiversity to thrive. However, human activity, animal introduction and deforestation have reduced naturally occurring vegetation, and fragmented communities of ecological importance. In conjunction with changes to the climate, the introduction of invasive plants and an increased risk of pests and diseases endanger this unique ecosystem. One of the keystone species to the forest, the black cabbage tree (Melanodendron integrifolium) as well as the other endemic trees, are now threatened by sudden dieback due to an unknown disease causing agent. Other symptoms such as leaf wilt, yellowing, spotting and root rot are also seen across the islands plant nurseries and field gene banks. To identify a causal agent of this disease(s) the microbiota associated with these plants have been surveyed and several candidates for disease have been identified. Pathogenicity testing will be carried out to identify the host range of the candidates and genomic analysis of the candidates will be done to develop a diagnostics tool which will build local capacity to monitor disease on the island. These findings may help prevent the spread of disease and inform management decisions by characterisation of the causal agent(s) and through communication with locals, tourists and land owners.

P5.3-018

INVESTIGATING THE VARIATION IN VIRULENCE OF HYMENOSCYPHUS FRAXINEUS, THE CAUSAL AGENT OF ASH DIEBACK

RIDLEY Maia. (1), ENDERLE Rasmus. (1)

(1) Julius Kuehn-Institute, Federal Research Centre for Cultivated Plants, Braunschweig, GERMANY

Text

The causal agent of ash dieback, *Hymenoscyphus fraxineus* [synonym: *H. pseudoalbidus*], is an introduced species in Europe that causes damage on European ash (*Fraxinus excelsior*).

The necrotic lesions and shoot dieback reduce vitality, timber quality, and can cause tree mortality. Consequently, the pathogen is associated with significant economic and ecological damages, and continues to threaten the survival of ash populations in Europe.

As part of the FraxForFuture project, we are analysing pathogen virulence using infection trials and microsatellite analysis. Initially, we investigated *H. fraxineus* virulence using amended culture media and host reintroductions. We also tested the impact of different inoculation protocols on disease development *in-planta*. We hypothesised isolation, storage and inoculation protocols could influence disease development, and subsequent determination of strain virulence and host resistance. We then established an infection trial to assess virulence for newly isolated *H. fraxineus* strains from across Germany. We hypothesised virulence may vary with the geographical origin and/ or starting substrate (leaves, shoots, stem base) of strains. We are also examining the population structures of these strains using microsatellite analysis. Overall, these results will provide important insights into pathogen evolution and disease development, which we expect will facilitate the development of improved strategies for forest health and disease management.

P5.3-019

INSIGHTS INTO THE BIOLOGY, HOST RANGE AND POTENTIAL PATHWAYS OF PHYTOPHTHORA PLUVIALIS IN BRITAIN

PEREZ SIERRA Ana Maria. (1), CRAMPTON Michael. (1), EACOCK Amy. (1), JONES Ben. (2), BIDDLE Mick. (1), WYLDER Barnaby. (2), OLIVIERI Leone. (1), KRZYWINSKA Elzelzbieta . (1), CHITTY Ruth. (1), GORTON Caroline. (1), LEWIS Alex. (1), HARRIS Anna. (1), WEBBER Joan. (1)

(1) Forest Research, Farnham, England, UNITED KINGDOM; (2) Forestry Commission, Bristol, UNITED KINGDOM

Text

Phytophthora pluvialis was detected in England in 2021 on Tsuga heterophylla. This was a new UK record for the pathogen, and symptoms of resinous bleeding cankers on T. heterophylla were a first worldwide. Initially described in 2013, P. pluvialis was previously only known from the USA and New Zealand, mainly causing a needle disease on Pseudotsuga menziesii and Pinus radiata, with some records on Notholithocarpus densiflorus and occasionally other pine species. A risk assessment was conducted in the UK, and P. pluvialis was classified as a quarantine pest for regulatory purposes. Official surveys, monitoring programs and research were carried out to establish the symptomatology, distribution, dispersal, hosts, association with timber and potential pathways of P. pluvialis. Between 2021 to early 2023, over 2000 forest tree samples were tested for the pathogen, with findings in England, Scotland and Wales on both T. heterophylla and Ps. menziesii. A symptom guide was created to aid surveillance activities and staff training. Over 15 different hosts were exposed under or near infected trees and all tested negative. Rainwater traps and stream baiting were used as a monitoring system on a bi-weekly basis for one year at several locations which identified optimal times for pathogen detection and a range of successful baiting hosts. All the results will be presented and a life cycle for the pathogen will be proposed

P5.3-020

CHEMOTYPING EUROPEAN AND ASIAN FRAXINUS: UNDERSTANDING HOST DEFENCE MECHANISMS ASSOCIATED WITH RESISTANCE AGAINST THE ASH DIEBACK PATHOGEN HYMENOSCYPHUS FRAXINEUS.

TOLIO Beatrice. (1,2), SHERWOOD Patrick . (1), MARCIULYNIENE Diana. (1), LIZINIEWICZ Mateusz. (2), CLEARY Michelle. (1)

(1) Swedish University of Agricultural Sciences, Alnarp, SWEDEN; (2) Skogforsk - Forestry Research Institute of Sweden, Svalöv, SWEDEN

Text

European ash (*Fraxinus excelsior*) has suffered large-scale decline and mortality due to the invasive fungal pathogen *Hymenoscyphus fraxineus*. The fungus is native to East Asia where it is non-pathogenic on native ash in its natural distribution range. As with most introduced pests and pathogens where the host plant lacks a history of co-evolution, the damage is devastating.
Breeding for resistance is the most preferred method to ensure European ash survival. There is evidence that a small proportion of ash genotypes show tolerance to the disease. Studies conducted around Europe show that low susceptibility to the disease is strongly genotypically controlled, inheritable, polygenic, and stable over time. However, traditional breeding practices are time-consuming and highly costly.
Research shows that chemical fingerprints have been uniquely associated with resistant phenotypes and can be useful as markers for selection and breeding. Studies on defence phytochemicals and their role in non-native ash species, particularly Asian species of *Fraxinus* that have co-evolved with the fungus can be valuable to understand mechanisms of resistance to *H. fraxineus*. In this study, we aimed to i) characterize the metabolite-basis of host defence in congeneric species of *Fraxinus* that differ in their evolutionary history and susceptibility to the fungus *H. fraxineus*, and ii) identify chemical biomarkers associated with disease resistance.

Text

Fig (*Ficus carica*) and plane (*Platanus* sp.) are two important tree species in the Mediterranean basin. Members of *Ceratocystis* affect both plant species, causing lethal canker-wilt diseases. *C. platani* invaded Europe during World War II, causing important losses in *Platanus* sp.; in Greece, it was first reported in 2003 and spread quickly in mainland natural riparian ecosystems of *Platanus orientalis*, having caused an ecological disaster. Since 2018, *C.*

ficicola has been reported affecting fig orchards in Greece. Both fungal pathogens are soil-born and mostly spread by human activity. Due to the fact of co-existence of two different invading *Ceratocystis* species in Greece, a new collection of isolates and molecular studies took place in the affected areas of the country. Differentiation in molecular level was found to rise in both species based on sequence variation in ITS and FG1093, MS204 and RPB2 genes. Furthermore, in 2019, another pathogenic species of *Ceratocystis* was isolated from fig orchards on Euboea Island, Greece. Based on conducted molecular, morphological and pathogenicity studies, this isolate could not be included in a previously known species. In 2022, *C. ficicola* has entered into EPPO Alert List, and it is crucial to prevent it from generally spreading in fig orchards. Preliminary studies in Greece have demonstrated that different varieties of *F. carica* show different susceptibility when artificially inoculated with *C. ficicola.*

THE TRAVAILS OF TROUBLESOME TRAVELERS: DISTRIBUTION OF THOUSAND CANKERS DISEASE COMPLEX MEMBERS INTO EXPANDED RANGES ALTERS THE GENETIC SIGNATURES OF THEIR POPULATIONS

HADZIABDIC Denita. (1), GAZIS Romina. (2), ONY Meher. (1), KLINGEMAN William. (1), GRAVES Andrew. (3)

(1) University of Tennessee, Knoxville, UNITED STATES; (2) University of Florida, Homestead, UNITED STATES; (3) US Forest Service, New Mexico, UNITED STATES

Text

The Thousand Cankers Disease (TCD) disease complex includes the fungal pathogen, Geosmithia morbida, walnut twig beetle (WTB; Pityophthorus juglandis) as a principal insect vector, and Juglans spp. or Pterocarya spp. host plants. TCD has been spread from the western to the eastern USA and into Italy, where it affects several walnut species, including J. nigra (Eastern black walnut) and J. regia (English walnut). Previous work has elucidated pathogen and vector genetic diversity, yet understanding about potential spread, spatial distribution, dispersal pathways, and host-parasite co-adaptation is largely unknown. This study evaluates knowledge gaps in diversity patterns and possible pathways of range expansion from the hypothesized western USA center-of-origin. Using microsatellite loci, we evaluated 807 G. morbida and 1,714 WTB individuals that were genotyped across subpopulations in the western USA. To reduce dataset over-representation of California (CA)-sourced samples for G. morbida (n=501/807) and WTB (n=1188/1714), data were analyzed with four approaches: CA group versus southwestern USA group (that included fewer CA samples) for each of beetle and pathogen datasets. Our results indicate generally high genetic diversity, weak but significant overall linkage disequilibrium, and the presence of population structure in all but the CA WTB dataset. Our data support prior hypothesis that the pathogen and vector are long-standing associates with southwestern USA host plants.

BRAZILIAN RESEARCH ABOUT SANITY IN FOREST SEEDS

FERREIRA Thiago Costa. (1)

(1) UNIVERSIDADE ESTADUAL DA PAIRAIBA, Lagoa Seca, BRAZIL

Text
The sanity of Brazilian forest seed is a theme few explored in the literature. The forest planted is growing in Brazil and seed sanity is more important to this establishment. Then, this research has the aim of resuming information about the sanity of forest seed from Brazilian Research. For this research, on Web of Science platform were inscribed the keywords: seeds, forest, pathogen, and Brazil. As a result, only eighteen papers were found about this theme. The prevalent area was Plant pathology, and Dr. Alvaro F. dos Santos (Brazilian Agricultural Research Corporation) and Dr. Acelino C. Alfenas (Viçosa Federal University) were the most important authors. The most relevant plant species analyzed were Cedrela fissilis, Anadenanthera macrocarpa, Aspidosperma polyneuron, Enterolobium contortisiliquum, Jacaranda spp., Pinus spp., Cacao spp., and others. The themes from these papers are the Blotter test seed analysis method for fungi identification, parasitism of pathogens in commercial forest seeds, and methods to sanity in Brazilian forest seeds. The research about Brazilian forest seed pathology diagnosis is an important and few-studied theme, more research can be made to better the seed sanity in Brazil.

Text
Ganoderma Root Rot (GRR) caused by *Ganoderma* spp. is a common disease occurring sporadically in native tree species around the world. In the past few years, mortality caused by GRR has emerged in Indonesian *Eucalyptus* plantations. Disease symptoms are mostly detected on the roots and root collar regions. Infected roots are characterized by the presence of reddish rhizomorphs on the bark surface and yellowish-white mycelium under the bark. Affected trees display yellowing canopies after which they wilt and die. Aerial surveys followed by field evaluation have revealed that GRR occurs in patches and spreads from tree to tree, mostly within the planting lines via root contacts between diseased and healthy trees. Plant mortality occurs on a variety of sites and at different tree ages beginning at six months and progressing up to rotation age. Preliminary data reveal approximately 12.5% mortality in a susceptible clone up to 4-years-old. Fungus fruiting bodies are rarely seen on dead trees and stumps from previous rotation, but the pathogen can easily be isolated from freshly infected roots. Based on morphological and DNA sequence analyses, the causal agent has been identified as *Ganoderma philippii*. As a soil-borne pathogen, disease management is challenging and losses can be important. For this reason, GRR

management strategies including a robust survey system to quantify the impact and sylvicultural activities to reduce losses will be increasingly important in the future.

P5.3-025

POPULATION STUDIES SUGGEST MULTIPLE INTRODUCTORY EVENTS OF DOTHISTROMA PINI INTO FRANCE

MULLER Monique. (1), VAN DER NEST Ariska. (1), MARÇAIS Benoit. (2), FABRE Bénédicte. (2), WINGFIELD Michael J. (1), **BARNES Irene. (1)**

(1) FABI, University of Pretoria, Pretoria, SOUTH AFRICA; (2) Université de Lorraine - Inrae, UMR Interactions Arbres/Microorganismes, Nancy, FRANCE

Text

Dothistroma needle blight (DNB) is an important disease of *Pinus* spp. in many parts of the world. Although a single disease, it can be caused by two different pathogens, *Dothistroma septosporum* and *D. pini*. The earliest occurrence of DNB in France was recorded in 1860 in the central part of the country. Although both species of Dothistroma occur in France, more recent DNB outbreaks in central France have been attributed to *D. pini*. Previous population genetic studies of *D. pini* strains from central France revealed an established population with high genetic diversity. Outbreaks of DNB have also occurred in southern France, but these populations have not been investigated. The aim of this study was to investigate the genetic relatedness of the *D. pini* populations from central- and southern France using microsatellite markers. Significantly higher levels of diversity were found in central France compared to southern France where populations were clonal and structured. There were no shared haplotypes between central- and southern France and there was little support for geneflow occurring between these regions. The results suggest that there have been multiple introductions of the pathogen into southern France but not originating from central France. One possibility is that *D. pini* has been introduced to southern France from neighbouring Spain, where DNB is also known to occur.

Text
Understanding the role of climate on the distribution of plant pathogens is paramount owing to the upraising effects of climate change. While this has been studied for other plant-associated microbes, such as bacteria and mycorrhizal and endophytic fungi, the effect of climate on oomycetes has been rarely studied from a community ecology perspective. Oomycetes include the genus Phytophthora which comprises some of the most damaging plant pathogens of agricultural, forestry and natural ecosystems. We explored the role of climate in the assembly of Phytophthora species at >250 river sites across two gradients, a latitudinal gradient spanning from Mediterranean to Arctic conditions, and an altitudinal gradient including the Spanish Pyrenees. Phytophthora communities were obtained by metabarcoding river filtrates. Climate and not host distribution determined Phytophthora biogeography. Two key processes determined species assembly. In southern latitudes, dry climate posed an environmental filter for Phytophthora communities resulting in a lower functional diversity due to communities dominated by drought-tolerant species with thick oospores and high optimum growth temperatures. In northern regions, species diversity decreased and communities were dominated by few species adapted to cold and with the ability to form enduring survival structures.

NEW INSIGHTS INTO DATE PALM INFLORESCENCE ROT BIOLOGY AND CONTROL IN MOROCCO

BOUHLALI Eimad Dine Tariq. (1), ESSARIOUI Adil. (1)

(1) National Institut of Agricultural Research, Errachidia, MOROCCO

Text
Date palm inflorescence rot (DPIR) is a significant fungal disease in Moroccan date producing areas. However, research into determining disease prevalence and management measures has received little attention. We conducted a three-year study (2019-2022) to assess the occurrence of DPIR across 9 locations, find out factors associated with its spread, and develop an effective chemical management method. Disease incidence varied among years and locations (5.64 – 27.51%). Intercropping and high planting density combined with frequent irrigations created ideal conditions for disease development, especially in young date palms. Farmers' cultural practices and lack of exclusion methods, specifically the use of diseased male inflorescence in pollination, contribute significantly to pathogen spread. Four pathogenic fungus were isolated from symptomatic inflorescences among which Mauginiella scaettae was the dominant species. In vitro assay and field experiments showed that out of five fungicides two pulverizations of copper oxychloride (400 g/ha) at the beginning of December and January decrease incidence by 96.8%. Overall, our findings shed light on the biology of DPIR and pave the road for future studies on management methods of this disease.

P5.3-028

IN VITRO ACTIVITY OF BLAD AGAINST CORK OAK PATHOGENS AND ECTOMYCORRHIZAL FUNGI SPECIES

TRINDADE Manuel. (1), FERREIRA Ricardo Boavida. (1), MACHADO Helena. (1)

(1) ISA/UL - INIAV, IP, Lisboa - Oeiras, PORTUGAL

Text
BLAD is a polypeptide isolated during the growth of *Lupinus* seedlings and is a breakdown product of β-conglutin catabolism. Among its properties, BLAD showed anti-fungal, anti-oomycete, and biostimulant activity and is already commercially available as a fungicide targeting over twenty diseases of several agricultural crops.
We performed a set of *in vitro* assays testing the effect of BLAD in cork oak decline-related pathogens such as *Biscogniauxia mediterranea*, *Diplodia corticola*, and the root rot agent, *Phytophthora cinnamomi*.
A particular emphasis was given to *P. cinnamomi* comparing five isolates and studying several parameters: mycelium growth rate, sporangia, chlamydospores, and zoospores production.
Four species of ectomycorrhizal fungi (*Amanita citrina*, *Amanita pantherina*, *Suillus bovinus* and *Tricholoma sulphureum*) were also submitted to BLAD action.
These tests clearly illustrated a disturbance in all tested species vs BLAD concentrations, namely in the pathogens, reaching, in some cases, an almost complete growth inhibition with higher BLAD concentrations (15-20 gL-1).
Ectomycorrhizal fungi species exhibited a higher resistance to BLAD activity in the mycelium growth rate parameter, except the *Suillus bovinus* case with a similar reaction to those of the pathogens.

Development of Molecular Diagnostic Tools for Plant Pathogens in a Globalizing World

Text
In the last decade, next generation sequencing has accelerated the identification of new species of plant pathogens. Dealing with species newly described is a plant health challenge for both risk assessment and risk management. In commodity risk assessment and in horizon scanning, hundreds of new species of plant pathogens are identified when screening

scientific reports, albeit only for a few information is sufficient to complete the assessment. New plant pests identified as potential threats for the European Union territory, by the commodity risk assessment as well as by the horizon scanning processes, are then further assessed by conducting pest categorisations or, when needed, quantitative probabilistic pest risk assessments. Even in these further steps, knowledge gaps may impede conclusions or cause high uncertainties. This presentation will summarise the challenges encountered when dealing with plant pathogens newly identified by next generation sequencing, for both the plant health risk assessment processes (commodity risk assessment, horizon scanning, pest categorisation, quantitative pest risk assessment) and the phytosanitary legislation.

Text

Wheat yellow rust, caused by the fungus *Puccinia striiformis f. sp. tritici* (*Pst*), is a constant threat to wheat production in Nepal, leading to significant loss of wheat yields each year. However, in recent years the number of new pathotypes of *Pst* being detected each year has significantly increased, with these new emerging races having broad virulence profiles, being more aggressive and tolerant to warmer temperatures. This has led to rapid failure of established and newly released wheat varieties in Nepal. To track the rapid changes in *Pst* strains in this region, we have begun to implement real-time genotyping using the Mobile And Real-time PLant disEase diagnostics methodology, based on nanopore sequencing technology. This approach has helped to gain a better understanding of the Nepalese *Pst* population diversity. For instance, revealing a recent incursion of unique genotypes of *Pst* in Pyuthan and Kailali districts of Nepal in 2021. The phylogenetic analysis indicates these isolates are close to *Pst*6 reported from Pakistan and also East Africa. Our results also revealed the *Pst* population in Nepal is quite diverse and most strains analyzed are close to races that were previously found in Central Asia. These results indicate the Himalayan foothill could be a center of diversity for *Pst* and that more in-depth studies are essential to decipher the mechanism of new race evolution in Nepal.

C4.2-3

A PANGENOME APPROACH TO STUDY DIVERSITY AND FUNCTIONAL MARKERS AND ITS APPLICATIONS TO ENHANCE DIAGNOSTICS.

VANDERLEE Theo. (1), JONKHEER Eef. (1), PARDESHI Lakhansing . (1), YANG Meixin. (1), BRANKOVICS Balazs. (1), DE RIDDER Dick. (1), BONANTS Peter. (1), SMIT Sandra. (1)

(1) Wageningen Plant Research, Wageningen, NETHERLANDS

Text
Advances in next-generation sequencing technologies (NGS) made the reconstruction of genomes easier and more accessible over the years. The diversity that was found among strains of the same species resulted in the concept of a pangenome, which reflects a species more accurately than any single member can. The pangenome is an abstract representation of the genomes of all the strains that are present in the population, species or genus. The graphical pangenomic data analysis platform, PanTools [1], has a hierarchical data structure, integrating sequence data (represented as a localized, compressed De Bruijn graph), structural/functional annotations, and crosslinks between DNA and protein sequences and annotations. Recently this platform was extended with modules to study phylogeny and to include and use phenotypic data [2]. Incorporating these allows assessment of functional diversity and population genomic analysis of plant pathogens. This facilitates the selection of target regions or SNP's that are diagnostic for subpopulations that originate from a particular geographical location or that show specific phenotypes such as specificity to a particular host or disease expression. These regions/SNP's can then be used to design efficient and very specific diagnostic methods for different plant pathogens.

[1] PanTools is implemented in Java 8 https://git.wur.nl/bioinformatics/pantools.

IMPROVING AND DEVELOPING DIAGNOSTICS FOR HIGH THROUGHPUT IDENTIFICATION OF VIRUSES, WITH A FOCUS ON BEGOMOVIURSES.

FILARDO Fiona. (1), VUKOVIC Peter. (1), SHARMAN Murray. (1), CAMPBELL Paul. (1)

(1) QLD Department of Agriculture and Fisheries, Brisbane, AUSTRALIA

Text
Begomoviruses are a large group of over 400 plant viruses that infect many dicot vegetables and crops throughout the subtropical and temperate regions of the world. Australia currently has only five known begomovirus species. Thus, the biosecurity threat posed by potential incursions is significant. To date, detection of the different species and strains relies on several different generic PCR's. To simplify begomovirus detection, we set out to develop assays with the capacity for in-field diagnostics. We developed a novel tissue blot hybridization chain reaction (TB-HCR). In this assay, plant stems are blotted onto nitrocellulose membrane tissue blots and then probed with specific probes designed to bind to either a family or group of viruses or specific viruses. During the assay one probe or several different probes can be used for screening at the same time. After the probe binds to the virus, labelled RNA hairpins (HP) are added and bind to the probe initiating a hybridization chain reaction. We have also developed a generic begomovirus Recombinase Polymerase Amplification (RPA) lateral-flow assay which to date, has successfully detected eleven different begomoviruses from Australia, Timor-Leste and PNG. We have also tested specific LAMP assays for agriculturally important begomoviruses in Australia. Our results

with begomoviruses and other virus species, and the advantages and disadvantages of these novel assays will be discussed.

C4.2-5

ADVANCEMENT IN PLANT PATHOGEN DIAGNOSTICS IN HIGH THROUGHPUT SEQUENCING ERA

ARIF Mohammad. (1), STACK James P.. (2)

(1) University of Hawaii at Manoa, Honolulu, UNITED STATES; (2) Kansas State University, Manhattan, UNITED STATES

Text

New strains/species of plant pathogens are emerging and threatening economically important crops worldwide. Accurate detection and identification of a pathogen is the key to successful and timely disease management and prevention of further incursion of exotic pathogens. Therefore, advanced tools capable of accurately detecting and differentiating plant pathogens is a critical need. PCR or isothermal technologies mostly target single species and cannot detect, identify, or differentiate emerging species/strains. Use of High Throughput Sequencing (HTS), along with ELISA and PCR, has become one of the most significant advances in molecular diagnostics. The HTS-based methods are not simply for pathogen detection but, can also be used to understand the strain's phylogeny, global dissemination, and evolutionary heritage. The HTS-based pipelines are available, including EDNA, Nanopore EP2ME WIMP, and PhytoPipe but, most of them use public databases. In our lab, we have developed a new pipeline "BacPath" that can rapidly and accurately detect pathogens in infected samples using our highly curated complete genome database. The pipeline is compatible with both long- and short-reads. The processing cost per sample can substantially be reduced by barcoding multiple samples in a single run. The HTS-based pipelines and high-quality genome database with accurate metadata will enhance our capabilities in diagnostics and national and international crop biosecurity.

C4.2-6

CRISPR-CAS DETECTION COUPLED WITH ISOTHERMAL AMPLIFICATION OF BURSAPHELENCHUS XYLOPHILUS

WU Jin. (1), TANG Chen. (1), CHEN Qi. (1), WANG Yonglin. (1)

(1) Beijing Foresty University, Beijing, CHINA

Text

Pine wilt disease (PWD) caused by the nematode *Bursaphelenchus xylophilus* is the most destructive threat to pine forests worldwide, particularly in China, Korea, and Japan. Ultrasensitive diagnosis of *B. xylophilus* at an early stage is therefore imperative for effectively monitoring PWD in pine forests. Herein, we established two isothermal diagnostics methods based on clustered regularly interspaced short palindromic repeats (CRISPR)-based platforms (CRISPR/Cas12a and CRISPR/Cas13a) for *B. xylophilus*–specific detection. The guide RNA

(gRNA) and CRISPR RNA (crRNA) were designed to target the 5S rDNA intergenic spacer sequences (IGS) region of *B. xylophilus*. Recombinase-aided amplification (RAA) was used for pre-amplification whose reaction condition was 37°C for 15 min. The sensitivity of CRISPR/Cas12a could reach 2.33 copies/μl of purified genomic DNA (gDNA) within 45 min at 37°C, while the sensitivity of CRISPR/Cas13a was 100 times higher than that of CRISPR/Cas12a at the minimum reaction time of 4 min via fluorescence measurement. The CRISPR/Cas12a assay enabled the detection of 0.01 PWNs/100 mg of pine wood, 10 times higher than that of the CRISPR/Cas13a assay. At the same time, CRISPR/Cas13a direct test was able to realize the detection of single-headed live nematodes. Therefore, this work could eventually facilitate the protection of healthy pines from *B. xylophilus* infection and enable accurate diagnosis of quarantine nematode species in the pine wood trade.

Text

Leaf blotch and defoliations have been observed for some years in apple orchards of France. These symptoms have raised serious concerns for both the French plant health authorities and apple growers, as it could be caused by the *Alternaria* 'apple pathotype', a fungus that was until recently considered as a quarantine pest in the European Union. This pathogen has the particularity to produce toxins involved in host specificity (AMT toxins). The apple pathotype had so far only been reported twice in Europe: in the Balkans and in Italy. However, recent studies have shown that similar symptoms can also be caused by *Alternaria* that not produce these toxins. As *Alternaria* is a genus with a complex taxonomy, the identification of isolates requires the study of several genes. Our project had four objectives: I. To identify strains isolated from France, II. To track the presence of the apple pathotype in France, III. To assess the pathogenicity of the strains *in vitro*, and IV. To identify, by comparative genomics, candidate regions for the development of specific tests able to detect the *Alternaria* involved in this disease. Our results showed that the apple pathotype is not present in France and that two genetically related taxa are responsible of leaf blotch and defoliations: *A. alternata* and *A. arborescens*. Finally, the analysis of the complete genomes allowed the identification of candidate loci allowing a precise identification of *Alternaria* taxa involved in apple defoliation.

Text

Pepper (*Capsicum annuum*) is an important crop due to its massive consumption as a seasoning vegetable in Korea and many other countries. Anthracnose disease in chili pepper has caused serious damage to plant growth and reduced yield with apparent symptoms and signs on the fruits. In this study, we report a deep learning-enabled detection model for chili anthracnose among chili pepper disease based on a computer-vision algorithm. The model was developed based on a deep learning architecture based on a Convolutional Neural Network (CNN) that specializes in extracting features from image datasets. Large datasets of expert pre-screened pepper disease images were collected from 'AI Hub', a platform of AI infrastructure. We examined the effectiveness of image preprocessing and data augmentation to create a balanced dataset. The implemented model achieves higher than 90% classification accuracy compared with training and validation dataset. Our results showed that CNN could be the deployable method for digital disease detection. This meaningful success makes the model a useful disease detection tool, and this research could be further extended to develop a mobile application to help millions of farmers directly in the fields. Further results for the detection of chili pepper disease will be discussed.

COMPARISON OF MOLECULAR DIAGNOSTIC TOOLS FOR FUNGAL PATHOGEN DETECTION IN SOIL

JAYAWEERA Dasuni. (1), DICKINSON Matthew. (1), **RAY Rumiana. (1)**

(1) University of Nottingham, Sutton Bonington, UNITED KINGDOM

Text

Soil-borne plant pathogens can cause significant economic losses due to reduction in plant establishment and seedling death. Diagnosis of these pathogens in the soil is therefore important for effective disease control in the form of cultural and chemical methods to protect seedling health. In this study a series of soil DNA extraction methods and diagnostic techniques were compared to identify the easiest to use and most effective method for the detection of Fusarium graminearum, Microdochium nivale, M. majus, Rhizoctonia solani and Pythium spp. in soils sampled from UK and Europe. Diagnostic methods used for comparison included DNA quantification using real-time qPCR, LAMP and MinION oxford nanopore technology. Results showed that soil sample size affects the efficiency of extraction for pathogen DNA detection. The LAMP assay showed potential trade-offs between sensitivity and specificity but was identified as the most easily deployed method for commercial testing for pathogen detection and semi-quantification. LAMP and Nanopore sequencing analyses were comparable to qPCR analysis for F. graminearum, R. solani and Pythium spp. Nanopore sequencing provided further information on the wider network of pathogens present in the soil. The findings from these studies can be utilised for further development of field-based rapid diagnostics for key soil-borne pathogens.

P4.2-001

FUSARIUM SPECIES ON IMPORTED VEGETABLES IN THE UK

AIGBE Sylvester. (1,2), WOODWARD Stephen. (2)

(1) Ambrose Alli University, Ekpoma, NIGERIA; (2) University of Aberdeen, Aberdeen, UNITED KINGDOM

Text

Three Fusarium species: Fusarium graminearum, Fusarium chlamydosporum and Fusarium oxysporum were tentatively identified among fungi isolated from green beans (Phaseolus vulgaris) and okra (Abelmoschus esculentus), imported into the UK from Kenya and Thailand, respectively. Isolates were identified using a combination of morphological characters on potato dextrose agar and ITS sequencing. Fusarium chlamydosporum was isolated from 35 and 50% of the green beans and okra, respectively, where as F. graminearum and Fusarium oxysporum were isolated only from green beans at 75 and 50%, respectively. These Fusarium species are well-known pathogens of many important crops plants. The presence of these potentially damaging pathogens on imported crops demonstrates the threat posed to local agriculture and horticulture enterprises by international trade pathway in plants and plant products.

P4.2-002

ABUNDANCE, DIVERSITY, AND PHYLOGENETIC STUDY OF THE FABA BEAN FOOT AND ROOT ROT DISEASE COMPLEX IN THE UNITED KINGDOM

ATTAR Basem. (1), BOONHAM Neil . (1), KITSON James. (1)

(1) Newcastle University, Newcastle Upon Tyne, UNITED KINGDOM

Text

The root rot disease complex comprises a group of organisms (Fungi, Bacteria, viruses and oomycetes) that affect a very broad spectrum of crops worldwide.
The United Kingdom is one of the most important faba bean producers after Ethiopia and Australia. Foot and root rot of faba bean is an important disease that is reported as a limiting factor for faba bean production in many areas, including the UK. The causal agents are not fully characterised, and progress on control measures such as identifying resistant germplasm through to predictive diagnostics for land management are hampered as a result. Infected plant samples and soil samples will be collected from faba bean growing areas in the United Kingdom. Putative pathogens will be isolated, and pathogenicity will be tested for the isolates obtained. DNA barcoding using ITS and TEF1α will be used to identify the pathogenic organisms and species-specific qPCR assays will be developed to detect the essential and dominant fungal species in the UK. qPCR will be used to perform a larger survey of faba bean growing areas. In addition, the qPCR will form an essential component of a soil risk prediction tool to enable growers to understand the risk of disease on new land in production.

P4.2-003

THE POWER OF ELECTROCHEMICAL BIOSENSORS FOR BOTRYTIS SSP. DIAGNOSTICS AND APPLICATION IN IDM PRACTICES

FORD Rebecca. (1), BILKISS Marzia. (1), SAMBASIVAM Prabhakaran. (1), LINDBECK Kurt. (2), BAR Ido. (1), SHIDDIKY Muhammad. (1)

(1) Griffith University, Brisbane, AUSTRALIA; (2) NSW Department of Primary Industries, Wagga Wagga, AUSTRALIA

Text

Botrytis cinerea is a necrotrophic fungus that causes botrytis grey mould (BGM), a widespread and destructive disease affecting many broadacre and horticultural species. The pathogen travels particularly quickly through mature and close-canopy crops during conducive cool and wet growing seasons, leading to multiple fungicide applications and frequent crop loss. Therefore, early, fast and accurate diagnosis of B. cinerea in the field is essential for best informed disease management practices, to avoid wrongly timed and costly under or over-spraying. To aid in decision-making on optimal spray timing, an electrochemical molecular biosensor device for detecting, quantifying and discriminating B. cinerea, and to discriminate it from the co-occurring B. fabae pathogen was developed. The device detected the target Botrytis ssp. down to picogram levels in three field locations in southern Australia. This has significant advantages over Loop-mediated isothermal amplification (LAMP) and other portable diagnostics devices, since no amplification is required, and a quantitative result is realised within minutes at extremely low application and resource cost. In summary, this new device represents a powerful tool for future on-farm informed disease management scenarios with potential for broad application.

Text

RNA-binding proteins (RBPs) play essential roles in regulating gene expression. However, the RNA ligands of RBPs are poorly understood in plants, not least due to the lack of efficient tools for genome-wide identification of RBP-bound RNAs. An RBP-fused ADAR (adenosine

deaminase acting on RNA) can edit RBP-bound RNAs, which allows efficient identification of RNA ligands of RBPs in vivo. Here, we report the RNA editing activities of ADARdd (ADAR deaminase domain) in plants and then engineered ADARdd to identify the RNA ligands of rice Double-stranded RNA Binding Protein 1 (OsDRB1), which is closely related to the rice responses to multiple (a)biotic stress. Protoplast experiments indicated that RBP-ADARdd fusions efficiently edit adenosines within 41 nt of their binding sites. Overexpressing the OsDRB1-ADARdd fusion protein in rice introduced thousands of A-to-G and T-to-C RNA-DNA variants (RDVs). We developed a stringent bioinformatic approach to identify A-to-I RNA edits from RDVs, which removed 99.7%-100% of background single nucleotide variants in RNA-seq data. Small RNA sequencing also identified 191 A-to-I RNA edits in miRNAs and other sRNAs, confirming that OsDRB1 is involved in sRNA biogenesis and/or function. Our study presents a valuable tool for genome-wide profiling of RNA ligands of RBPs in plants and provides a global view of OsDRB1-binding RNAs, offering a novel insights into RBPs in rice immunity against pathogens and other stresses.

P4.2-005

CHARACTERIZATION AND DIVERSITY OF PECTOBACTERIUM AND DICKEYA SPECIES IN THE NETHERLANDS

PEL Michiel. (1), VAN DE BILT Jeroen. (1), VOLKERS Rita. (1), LANDMAN Marco. (1), GORKINK-SMITS Peggy. (1), RAAYMAKERS Tom. (1), BERGSMA-VLAMI Maria. (1)

(1) Netherlands Institute for Vectors Invasive plants and Plant health (NIVIP), Wageningen, NETHERLANDS

Text

Many members of the genera *Pectobacterium* and *Dickeya* cause important plant diseases on a large range of host plants. Accurate taxonomic determination is necessary to perform epidemiological studies and to take the right measures to restrict pathogen spread. Surveys performed in the last two decades on various host plants in the Netherlands resulted in a high number of representatives of these genera. Their accurate identification in the past was rather complicated due to lack of specific tests. This, in combination with recent taxonomic changes made it hard to get insight in the epidemiology of these soft rot pathogens. This study focusses on the characterization of 70 of these isolates. Using Illumina sequencing, whole genome sequences were generated and the assembled genomes were compared with the genomes of the type strains that were available at NCBI or were generated as part of this project. This analyses revealed that many *Pectobacterium* and *Dickeya* species do occur in the Netherlands and that for some species high intra-species variation exists. Although none of these isolates originated from potato, several of them belong to species that are known potato pathogens. Based on their phylogenetic relationship, isolates have been selected and tested for their virulence on potato. Additionally, the use of MALDI-TOF MS for the reliable identification of isolates belonging to *Pectobacterium* and *Dickeya* species has been investigated. Preliminary results will be discussed.

P4.2-006

EARLY DETECTION OF PHYLLACTINIA GUTTATA, THE CAUSAL AGENT OF POWDERY MILDEW, THROUGH THE USE OF SPORE HUNTING AND PCR SPECIFIC PRIMERS IN EUROPEAN HAZELNUT (CORYLUS AVELLANA L.) ORCHARDS

Text

European hazelnut occupies an approximate area of 30.000 ha between the Maule and La Araucanía Regions in Chile. In recent seasons there has been a greater recurrence of powdery mildew, caused by the fungus *Phyllactinia guttata*, an obligate parasite that reduces the photosynthetic rate of the tree and influences the aging of the plants. Currently, there are no registered control alternatives for this disease in European hazelnut in Chile, then developing integrated and sustainable management strategies to management powdery mildew is required. Specific PCR primer sets were validated for early detection of the fungus in the field. Through the comparison of 5 sets of primers, the specificity was validated in the DNA of 13 recurrent species of powdery mildew present in the mentioned area. DNA was extracted from spore-hunting equipment tapes obtained weekly during spring to validate the ability of specific primers to detect the presence of *P. guttata* in three hazelnut orchards. Results showed that the PG 2 (f/r) primer set, with an amplification of 375 bp, is capable of specifically detecting *P. guttata* when extracting samples from spore hunting tapes, without detecting the presence of other powdery mildew species. This early detection allowed to start control treatment programs two weeks before to detect sign of the pathogen and improving the control of the disease.

P4.2-007

THERMAL TOLERANCES AND MOLECULAR PHYLOGENY OF THIELAVIOPSIS PARADOXA ISOLATES.

Text

Many diseases of forest trees and agricultural crops have been linked to the ascomycete fungal pathogen *Thielaviopsis paradoxa*. This study compared the growth rate of 41 isolates

of *T. paradoxa* from different hosts and two countries (Nigeria and Papua New Guinea (PNG)) under six temperature levels (22°C, 25°C, 30°C, 32°C, 34°C and 35°C). Phylogenetic relationships were obtained from the analysis of their rDNA- internal transcribed sequence (ITS) data. All the PNG isolates and few from Nigeria grew optimally between 22°C and 32°C, the majority had their highest growth rate (2.9 cmd-1) between 25°C and 32°C. Growth performances were generally low between 34°C and 35°C; no sugar cane isolate grew at these high temperatures. The oil palm isolate DA029 was the most resilient with the highest growth rate (0.97cmd-1) at 35°C. Phylogenetic analysis delineated 3 clusters: a very large clade with the majority (31 Nigerian and 4 PNG oil palm isolates), a four-member and the smallest clade with two members. To a large extent, the clustering pattern failed to address the temperature-isolate growth relationship. However, only the smallest clade has members with perfectly matching temperature tolerances. A wider analyses with more diverse isolates and genetic markers could provide better insight on thermal resilience of *T. paradoxa*. The information provided will help in formulating effective management and control strategies against the pathogen especially in this era of climate change.

Text

Fusarium oxysporum f. sp. *lactucae* (Fol), the cause of wilting and vascular browning in lettuce, has spread rapidly in Western Europe in recent years. In Belgium, two races have been identified: race 1 and race 4. Race 4 has been especially problematic, causing significant losses for the soil-grown lettuce industry. Race-specific and sensitive real-time PCR assays were developed for Fol race 1 and race 4. Based on Genotyping-by-sequencing, unique DNA loci in both races were identified and used to develop primers and hydrolysis probes. To ensure sensitive detection in soil and swabs from surfaces, we included an enrichment step based on incubation of the sample in a semi-selective Fusarium medium. By controlling the incubation conditions, it was possible to relate the real-time PCR signal to the number of spore equivalents in the original sample. The enrichment step results in the detection of exclusively living fungal propagules, allowing evaluation of control measures. Using this method, the epidemiology of Fol race 1 and race 4 was studied at lettuce farms and nurseries by sampling soil, irrigation water, surfaces of farming equipment, plant boxes, etc... The pathogen was found on several surfaces of farming equipment, indicating that hygienic measures remain important in stopping the spread. No detection occurred at plant nurseries, implying that these are currently not contributing in the spread of Fol. The novel assays are currently applied to assess potential control measures.

METAFLORE 2.0: AN INNOVATIVE APPROACH TO DETECT PATHOGENIC FUNGAL AND BACTERIAL MICROORGANISMS IN SEEDS USING MINION SEQUENCING

ADAM Kévin. (1), GASTON Mégane. (1), DEGRANDI PEZZI Laura. (1), BUENDIA Luis. (1)

(1) BIOVA FRANCE, Ramonville-Saint-Agne, FRANCE

Text

Fungal, oomycete, and bacterial pathogens cause substantial losses in agriculture and forestry, but rapid and accurate identification can reduce disease impact and biocide costs. The Plant Health Laboratory (LSV) developed analysis methods based on detection and morphological characterization through conventional cultivation for determining the sanitary quality of seeds. However, these methods are time-consuming, prone to false negatives, only detects cultivable phytopathogens and therefore, they do not guarantee the detection of many others.

The Metaflore 2.0 project aims to revolutionize the field of seed health analysis by leveraging the power of the Oxford Nanopore MinION third-generation sequencer to detect pathogenic microorganisms in seeds. The project seeks to implement new and more efficient protocols, close to the metagenomic methods, for diagnosing plant pathogens. These analyzes make it possible to reduce the analysis time while being more exhaustive on pathogen detection.

By sequencing long DNA fragments from the hypervariable regions (16S/18S rDNA, Internal Transcribed Spacer (ITS)) of the microorganisms genome, the MinION sequencer provides easier identification and differentiation of species that are genetically very close, streamlining the diagnostic process and turning decision-making faster and more efficient.

EVALUATION OF MOLECULAR TESTS FOR THE DETECTION 'CANDIDATUS LIBERIBACTER' SPECIES ASSOCIATED WITH HUANGLONGBING DISEASE IN CITRUS: RESULTS FROM AN INTERNATIONAL TEST PERFORMANCE STUDY AND A PROFICIENCY TEST

RAAYMAKERS Tom. (1), WARBROEK Tim. (1), VAN DOORN Bo. (1), VOLKERS Rita. (1), BLOM Nathalie. (1), VLAMI-BERGSMA Maria. (1)

(1) Netherlands Institute for Vectors, Invasive plants and Plant health (NIVIP), Wageningen, NETHERLANDS

Text

Huanglongbing (HLB), also known as Citrus greening disease, is a lethal disease of *Citrus* caused by three obligate biotrophic bacteria: '*Candidatus* Liberibacter africanus', '*Candidatus* Liberibacter americanus', and '*Candidatus* Liberibacter asiaticus'. These quarantine pests are considered priority pests by the European Union due to their potential economic, environmental, or social impact. Various tests have been developed for the detection of HLB-associated bacteria in host tissues. An international test performance study (TPS) organized by the Netherlands Institute for Vectors, Invasive plants and Plant health (NIVIP) in its role as

EU Reference Laboratory for pests of plants on bacteria (EURL) in 2020 evaluated three promising molecular tests for the detection of '*Candidatus* Liberibacter' species. These tests can be considered fit for purpose and are recommended for routine testing of survey samples of *Citrus* leaves for the detection of '*Candidatus* Liberibacter' species causing HLB.

A Proficiency Test (PT) on the molecular detection of HLB was organized in 2021 by NIVIP to assess the diagnostic competence of EU national reference laboratories (NRLs) to detect this bacterium in *Citrus*. Results revealed a high level of accuracy among participating laboratories. No false negatives were reported and only in a few cases HLB was confused with a sample containing '*Candidatus* Liberibacter' solanacearum, the zebra chip disease of potato.

P4.2-011

FUNGI SPECIES ASSOCIATED WITH POTATO APHIDS IN BAMENDA, NORTHWEST REGION OF CAMEROON.

KAIN Chia Genevieve. (1), KATAMSSADAN Tofel Haman. (1), KINGE Tonjock Rosemary. (1)

(1) THE UNIVERSITY OF BAMENDA, Bamenda, CAMEROON

Text

Potato (Solanum tuberosum L.) is one of the world's most important cultivated tuber crop. There has been inaccurate cultural identification of fungi species associated with potato aphids. The aim of the study was to identify fungi associated with aphids of potato using a combined cultural and molecular method. Insect cadavers were periodically collected in the field (100 samples) and taken to the laboratory where they were cultured on potato dextrose agar. After a period of 7 days, they were subculture to obtain pure cultures. Cultural characters were measured and noted, and the mycelia of the pure cultures were harvested and stored in 10% glycerol. Molecular identification was done for the ITS and TEF regions. The species identity of the sequences was Identified using BLAST. Results of cultural identification gave three different groups of fungi, identified as Fusarium species, different species of Aspergillus including A. flavus, A. niger and A. fumigatus and Penicilium species. After performing the BLAST, 19 fungal species were identified belonging to Fusarium, Chaetomium, Trichoderma, Aspergillus, Cladosporium, Periconia, Claviceps, Curvularia, Microascus and Penicillium. These results portray a diverse group of fungi associated with potato aphids. There is great possibility that some of them may be entomopathogenic and hence, further research is ongoing to use them as biocontrol against potato aphids as a component of integrated pest management.

P4.2-012

A NEW DIAGNOSTIC TOOL FOR THE IDENTIFICATION OF FOUR BEET YELLOWS VIRUSES BY MULTIPLEX RT-QPCR

RUH Mylène. (1), BALDWIN Thomas. (1), LEVEQUE Thomas. (1), HOUDAULT Sandrine. (1), PERROT Sophie. (1), MIRGUET Céline. (1), CADOT Valérie. (1), MARMONIER Aurélie.

(2), BRAULT Véronique. (2)

(1) GEVES, Beaucouzé, FRANCE; (2) INRAE Grand Est-Colmar, Colmar, FRANCE

Text
Virus yellows disease (VY) of sugar beet is caused in Europe by a complex of four aphid-transmissible virus species present as mono- or co-infections: beet yellows virus (BYV), beet chlorosis virus (BChV), beet mild yellowing virus (BMYV) and beet mosaic virus (BtMV). VY can impact yields by up to 50%. The losses were limited with neonicotinoids (NNI), that are now banned in UE.
To find alternatives to NNI, the National Plan of Research and Innovation has financed the Yellows Resistbeet project led by GEVES and involved in the evaluation of varietal resistance. As the ELISA method does not distinguish BChV from BMYV detection, BioGEVES with INRAE Colmar developed primer and probe pairs to detect and identify the four viruses simultaneously in a same sample.
To ensure viral diagnosis, GEVES validated a multiplex RT-qPCR method by evaluating performance criteria. Our first results showed that all primers and probes are specific to the four targeted viruses with 100% inclusivity and exclusivity and that RT-qPCR multiplex is 100 to 10,000 times more sensitive than ELISA.
Our new diagnostic tool is used for varietal resistance testing to control inocula and to provide in one step the viral composition as well as semi-quantitative data on the viral load in sugar beets tested. This detection method at a lower cost has been validated and offered as a service by GEVES. Later, it can be used in epidemiological surveillance to monitor the evolution of VY in the field depending on the year.

P4.2-013

MALDI-TOF MS AS AN ACCREDITED METHOD FOR RAPID AND ACCURATE IDENTIFICATION OF REGULATED PLANT PATHOGENIC BACTERIA

VAN DE BILT Jeroen. (1), VOLKERS Rita. (1), PEL Chiel. (1), LANDMAN Marco. (1), GORKINK-SMITS Peggy. (1), BERGSMA-VLAMI Maria. (1)

(1) Netherlands Institute for Vectors, Invasive plants and Plant health (NIVIP), Wageningen, NETHERLANDS

Text
MALDI-TOF MS is an accurate technique for identification of bacteria on species level. Until recently, the technique was poorly implemented in phytobacteriology but it has shown recently it’s potential, even at a subspecies level. The lack of reference spectra for most plant pathogens in commercially available databases was solved relatively easy by creating the missing reference spectra in-house. Sets of reference spectra for regulated bacteria were validated according to international standards. Several performance characteristics were evaluated of which the analytical specifity is the most important as it reflects the accuracy of the technique. Experiments on inclusion (lack of false negatives) and exclusion (lack of false positives) were carried out, using strains of the target bacteria, close relatives and bacteria known to occur on relevant hosts of the target. Results confirm the accuracy on species level for the regulated bacteria Ralstonia solanacearum, R. syzygii, Clavibacter sepedonicus, C. michiganensis subsp. michiganensis, Curtobacterium flaccumfaciens, Pantoea stewartii, Erwinia amylovora and Acidovorax citrulli. For Ralstonia pseudosolanacearum the technique discriminates even below the species level, in phylotypes. Although the technique shows

poor seperation of pathovars or subspecies within a species, it still serves as a complementary technique for identification purposes, which is currently recommended in international diagnostic protocols.

P4.2-014

PRACTICAL APPLICATIONS IN PATHOGEN DETECTION: STRATEGIES AND PROGRESS OF A SENSITIVE SURVEILLANCE TOOL FOR DETECTING THE LAUREL WILT PATHOGEN

GAZIS Romina. (1), NAVIA-URRUTIA Monica. (1), SENDOYA Carlos. (1), ONY Meher. (2), KLINGEMAN William. (2), HADZIABDIC-GUERRY Denita. (2)

(1) University of Florida, Homestead, UNITED STATES; (2) University of Tennessee, Knoxville, UNITED STATES

Text
Laurel wilt (LW), caused by the ambrosia fungus *Harringtonia lauricola*, is a lethal vascular disease affecting numerous hosts in the Lauraceae, including important forest species and avocado trees. The disease has caused the death of 300,000 avocado trees and as many as half-a-billion native trees. Laurel wilt has experienced a rapid geographic expansion through host and vector jumping, which in turn generated a critical need for the development of early detection and monitoring tools. Monitoring *H. lauricola* is challenging due to the lack of selective media, the low titer of the pathogen often carried by alternative vectors, the abundance of secondary or transient fungal associates, and the recalcitrant nature of the target samples. Recent advances in molecular techniques and the development of specific markers have facilitated the detection of the pathogen directly from host and insect's DNA extracts. Screening susceptible hosts and potential alternative vectors for the presence of the LW pathogen represents a critical tool to prevent the spread and monitor the arrival and establishment of this devastating disease into larger avocado production areas. This presentation shares current molecular protocols available for the direct detection of the LW causal agent, and updates on progress in optimizing detection accuracy and sensitivity. These technologies are directly adoptable for use in the high-throughput screening of beetle trap samples from regional surveillance programs.

P4.2-015

DEVELOPMENT OF RAPID DNA-BASED DETECTION ASSAYS FOR COLLETOTRICHUM SPECIES CAUSING APPLE BITTER ROT IN THE MID-ATLANTIC U.S.A.

MCHENRY Diana J. . (1), **ACIMOVIC Srdjan G.. (1)**

(1) Virginia Tech , Winchester, Va, UNITED STATES

Text
Bitter rot of apple is caused by many *Colletotrichum* species in the Mid-Atlantic U.S.A., and this can confound management strategies due to differences in life cycle, ecology and

pathogenicity among *Colletotrichum* species, in addition to differences in susceptibility of apple cultivars. A fast, inexpensive method for identifying *Colletotrichum* spp. would facilitate earlier classification of the causal species of bitter rot and future epidemiological studies. Alignments of 1,344 GenBank accessions were surveyed visually for areas of high DNA polymorphism in 12 gene regions in order to develop species-specific hydrolysis-probe qPCRs for the key players in the Mid-Atlantic USA: *C. fioriniae* and *C. nymphaeae* in the *Colletotrichum acutatum* species complex, and *C. chrysophilum, C. fructicola, C. gloeosporioides* s.s., *C. henanense, C. noveboracense, C. siamense,* and *C. theobromicola* in the *Colletotrichum gloeosporioides* species complex. Preliminary results indicate that the newly designed primer-probe sets for *C. fioriniae* (CAL), *C. gloeosporioides* s.s. (GAPDH), *C. henanense* (APN2), and *C. theobromicola* (TUB2) were highly species-specific. Further optimization is ongoing and will be necessary for other species but early tests were encouraging.

Text

Annual ryegrass toxicity (ARGT) is an often-fatal poisoning of livestock that consume annual ryegrass infected by the bacterium Rathayibacter toxicus. This bacterium is carried into the ryegrass by a nematode, Anguina funesta, and produces toxins within seed galls. The actual mechanism of production of this toxin remains unclear and no clear-cut information is available on what type of volatile organic compounds accumulate in the infected galls. Therefore, to fill this research gap, the study was designed to analyze the chemical differences among nematode galls, bacterial galls and healthy seeds of annual ryegrass by using direct immersion solid-phase microextraction (DI-SPME) coupled with GC-MS. Overall, 48 compounds were identified in all three groups. Five volatile organic compounds are the most frequent indicators of bacterial infection, whereas the presence of 15-methylnonacosane, 13-methylheptacosane, ethyl hexacosyl ether, heptacosyl acetate and heptacosyl trifluoroacetate indicates nematode infestation. Metabolites occurring in both bacterial and nematode galls included batilol (stearyl monoglyceride) and 9-octadecenoic acid (Z)-, tetradecyl ester. This study demonstrated that DI-SPME is a valid technique to study differentially expressed metabolites in infected and healthy ryegrass seed and it may help to understand the biochemical interactions between plant and pathogen to aid in management of ARGT.

Text

Plant pathogens that cause plant diseases can harm our agricultural ecosystems and have devastating impacts on our livelihoods. Researchers in agriculture and phytopathology routine testing labs play a key role in monitoring and managing plant diseases.
The key to managing the spread of plant pathogens is rapid and accurate detection. Molecular techniques can be very efficient in detecting plant viruses, viroids, bacteria, fungi and yeast, provided that robust nucleic acid extraction methods and amplification reagents are available.
In this poster, we describe optimized protocols for the molecular detection of bacterial and viral plant pathogens, respectively *Xylella fastidiosa* (Xf) and Rose Rosette Virus (RRV). Xf causes olive trees death within 1 or 2 years after infection. With no existing cure and a worldwide spread, it causes immense destruction to our environment and dramatically affects economy of olive oil industry. RRV is an RNA virus infecting rose and eventually causing death. Widely spread in North America, surveillance is currently reinforced in Europe to avoid outbreak.
We have developed automated extraction techniques based on paramagnetic beads allowing isolation of high-quality pathogenic DNA or RNA from different plant parts with minimal hands-on. We will also discuss the use of optimized amplification master mixes, to overcome potential inhibition, frequently observed with plant samples.

Text

Phyllosticta citricarpa is quarantine fungus in the European Union. If introduced in the EU, it would jeopardize the citrus growing sector. Strict controls are regularly performed to verify its absence in fruit imports. Its sister species *P. paracitricarpa* was described in 2017, and was only distinguished from *P. citricarpa* by the occurrence of few SNP over the sequences of two housekeeping genes. In Europe, this new taxon has been reported in Greece, on lemon leaf litter, but has not being found as a pathogen on fruits. Its presence was later confirmed in China, after re-examination of *P. citricarpa* strains, but it is still uncertain if this new species deserves consideration as a quarantine pathogen. After a request from the European Commission, we re-examined the taxonomy of these two species and aimed at the development of a specific detection assay targeting *P. citricarpa*. Genomes of representative strains of *P. citricarpa*, *P. paracitricarpa* and other *Phyllosticta* species were sequenced. Based on 64 genes we assessed the phylogeny of these pathogens. We showed that the *P. citricarpa* and *P. paracitricarpa* clustered in two different clades, supporting the description of *P. paracitricarpa* as a new species. This genomic dataset was used to select a *P. citricarpa* species-specific marker and new real-time PCR assay was developed. These results demonstrate the power of genomics to solve taxonomic issues, with great consequences in terms of phytosanitary regulations.

P4.2-019

DEVELOPMENT OF DETECTION TECHNOLOGY FOR TOMATO PITH NECROSIS CAUSED BY PSEUDOMONAS MEDITERRANEA

TSAI Chia Hsin. (1), HWANG Shu Ling. (1), LIN Mei Ju. (1)

(1) Taiwan Agricultural Research Institute, Taichung, TAIWAN

Text

The phytopathogenic bacterium Pseudomonas mediterranea mainly infects Solanaceae crops and can be transmitted through soil. In recent years, the pathogen has caused pith necrosis and wilt symptoms on tomato plants in Taiwan. For rapid diagnosis of the disease, the bacteria-specific primers were designed to be both used in polymerase chain reaction (PCR) and recombinase polymerase amplification (RPA) detection of pathogen. The specific PCR products were amplified for the pathogen in electrophoresis analysis. The commercial strips were used to test RPA products. The positive reaction was seen in diseased tomato DNA extracts and negative in healthy tomato DNA extracts. The technology can support farmers in diagnosing crop diseases, seedling propagators to control product quality independently, and biotechnology companies to detect plant pathogens to improve the health and quality of crops and seedlings.

P4.2-020

FIRST REPORT OF WATERMELON CRINKLE LEAF-ASSOCIATED VIRUS 1 AND 2 (WCLAV-1 AND -2) INFECTING STRAIGHTNECK SQUASH IN THE UNITED STATES

KADER JAILANI Abdul. (1), **IRIARTE Fanny. (1)**, PARET Mathews. (1)

(1) University of Florida IFAS North Florida Research and Education Center (NFREC), Quincy, Fl, UNITED STATES

Text
In fall 2022, straightneck squash showing mild leaf crinkling, as well as leaf and fruit mosaic symptoms were observed in scattered areas of a ~15-ha field in Jackson County, Florida. Seventeen plants were sampled randomly for testing. Plants tested negative for zucchini yellow mosaic virus (ZYMV), cucumber mosaic virus (CMV) and squash mosaic virus (SqMV), using ImmunoStrips (Agdia, USA, Cat No: 77700, 44501, 26400 respectively). A conventional one-step RT-PCR (NEB, USA) was used to test all plants for cucurbit chlorotic yellows virus (CCYV) (Jailani et al. 2021), and watermelon crinkle leaf-associated virus WCLaV-1 and WCLaV-2 (Hernandez et.al. 2021). All plants tested negative for CCYV, and 12 out of 17 plants tested positive for WCLaV-1 and WCLaV-2 using primers targeting RNA dependent RNA polymerase (RdRP), and movement protein (MP) genes of both viruses (Hernandez et al., 2021). The partial RdRP sequences for WCLaV-1 (OP389252) and WCLaV-2 (OP389254) shared 99% and 98% nt identity with isolates KY781184 and KY781187 from China; the partial MP sequences for WCLaV-1 (OP389253) and WCLaV-2 (OP389255) shared 98% and 95% nt identity with isolate from Brazil (LC636069) and China (MW751425). Previously, both viruses were first reported in Texas, (Hernandez et al., 2021), Florida (Hendricks et al., 2021), Oklahoma (Gilford and Ali., 2022), and Georgia (Adeleke et al., 2022) in watermelon. This is the first report of WCLaV-1 and WCLaV-2 in straightneck squash in the USA.

P4.2-021

DIAGNOSIS OF FUSARIUM OXYSPORUM F. SP. CICERIS CAUSING FUSARIUM WILT OF CHICKPEA USING LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) AND CONVENTIONAL END-POINT PCR

ACHARI Saidi. (1), MANN Ross. (1), SHARMA Mamta. (3), EDWARDS Jacqueline. (1,2)

(1) AgriBio, Agriculture Victoria, Bundoora, AUSTRALIA; (2) School of Applied Systems Biology, La Trobe University, Bundoora, AUSTRALIA; (3) International Crop Research Institute for the Semi-Arid Tropics (ICRISAT), Hyderabad, INDIA

Text
Fusarium oxysporum (Fo) is ubiquitous in soil and forms a species complex of pathogenic and putatively non-pathogenic strains. Pathogenic strains cause disease in over 150 plant species. Fusarium oxysporum f. sp. ciceris (Foc) is a major fungal pathogen causing Fusarium wilt in chickpeas (Cicer arietinum). In some countries such as Australia, Foc is a high-priority pest of biosecurity concern. Specific, sensitive, robust and rapid diagnostic assays serve as an effective biosecurity control measure and are essential for effective disease management on the farm. We developed and validated a novel and highly specific PCR and a LAMP assay for detecting the Indian Foc race 1 based on a putative effector gene uniquely present in its genome. These assays were assessed against 39 Fo formae speciales and found to be specific, only amplifying the target species, in a portable real-time fluorometer (Genie III) and qPCR machine in under 13 minutes with an anneal derivative temperature ranging from 87.7 – 88.3°C. The LAMP assay is sensitive to low levels of target DNA (>0.009 ng/µl). The expected PCR product size is 143 bp. The LAMP assay developed

in this study was simple, fast, sensitive and specific and could be explored for other Foc races due to the uniqueness of this marker to the Foc genome.

P4.2-022

DEVELOPMENT OF MOLECULAR DIAGNOSTIC METHODS FOR AGROBACTERIM SP. CAUSING ROOT MAT DISEASES

HAN Inyoung. (1), KANG Dongwan. (1), CHIN Young-Don. (1), LEE Seok Min . (1), CHOI Jaehyeok . (1)

(1) Geongsangnam-do Agricultural Research & Extension services, Jinju, REPUBLIC OF KOREA

Text

In June 2019, root mat disease was observed in hydroponically cultivated tomatoes in Jinju, South Korea, which occurred in at least 30% of the plants in the greenhouse. To isolate the causal bacteria, 10 g of infested tomato root mat sample was ground with 50 ml of sterile water. A 100-µl aliquot of the homogenate was serially diluted and spread on mannitol-glutamate medium amended with 0.1% yeast extract (MGY) and incubated at 28°C for 48 h. To confirm the identity, four housekeeping genes of GNIY2 were sequenced (16S rRNA, trpE, rpoB, and recA). Multilocus sequence analysis performed as previously showed that GNIY2 strain was grouped in *Agrobacterium* genomospecies 4. This is the first report on mat root disease caused by *Agrobacterium* biovar 1 in hydroponic tomatoes in South Korea. And then, we developed detection kits using diverse molecular biological methods based on genome sequences for *Agrobacterium* sp. The detection kit we developed enables diagnosis based on the differences in gene sequences between pathogenic strains and non-pathogenic strains. We wil study supplement the detection kit that enables more precise diagnosis through sequencing of pathogenic strains and non-pathogenic strains.

P4.2-023

DIVERSITY OF COLLETOTRICHUM SPECIES COMPLEXES ASSOCIATED WITH FRUIT ANTHRACNOSE IN SOUTH KOREA AND THEIR SENSITIVITY TO DIFFERENT FUNGICIDES

CHANG Taehyun. (1)

(1) Kyungpook National University, Sangju, REPUBLIC OF KOREA

Text

Several Colletotrichum species responsible for the anthracnose of apple, persimmon, plum, peach, and grape were identified by the present study based on molecular analysis, six genes and morphological characteristics, as well as pathogenicity test. The in-vitro sensitivity of identified Colletotrichum species to the common fungicides using for the control of anthracnose in South Korea was also evaluated. Seven Colletotrichum species including C. gloeosporioides, C. siamense, C. fructicola, C. vinifera, C. aenigma from the C.

gloeosporioides species complex, and C. fioriniae, and C. nymphaeae from the C. acutatum species complex were identified as the causal agent of anthracnose of these common fruits. The result also indicated that several Colletotrichum species are associated with a single host. C. siamense, C. fructicola and C. nymphaeae were isolated from apple, peach plum and persimmon and C. gloeosporioides and C. fioriniae were from apple and plum. In jujube, C. gloeosporioides and C. nymphaeae were identified.The anthracnose of grape caused by C. siamense, C. fructicola and C. vinifera. There were significant differences among the virulence of these Colletotrichum species to the same host in the development of anthracnose. Fungicides sensitivity test showed that the EC50 value of specific Colletotrichum species varied greatly among the fungicides. Same Colletotrichum species isolated from different host showed different sensitivity against same fungicide

P4.2-024

DEVELOPMENT OF A REAL-TIME PCR FOR THE DETECTION OF BLUEBERRY RUST (THEKOPSORA MINIMA) AND ITS PERFORMANCE DURING A UK OUTBREAK.

ELLIOTT Ashleigh . (1), SCHIRMACHER Alexandra . (1), FIELD Christopher . (1), BEATON Heather. (1), BARNES Ann. (1)

(1) Fera Science Ltd., York , UNITED KINGDOM

Text

Thekopsora minima (syn. *Pucciniastrum minimum*) is a rust species which infects the economically important host highbush blueberry (*Vaccinium corymbosum*). It was added to the EPPO A2 list in 2017 as it had spread from North America and Japan to numerous European countries. On blueberry, *T. minima* causes small, yellow necrotic spots on the upper surface of leaves which as they enlarge and coalesce can lead to extensive defoliation. The entry risk of *T. minima* into a new country is high and most likely to occur through global trade of *Vaccinium* plants for planting. Therefore, it is essential that effective phytosanitary control measures are in place to test imports. The morphological appearance of *T. minima* is similar to native rusts on blueberries, such as *Naohidemyces vaccinii*. Therefore, we developed a molecular test to facilitate fast and reliable detection of *T. minima* on symptomatic blueberry leaves. The test was specific to *T. minima* when tested against a range of non-target pathogens found on blueberry and the test also proved highly sensitive, with a limit of detection of 10 spores on a sample for DNA extraction. In September 2021 *T. minima* was detected in the UK in a nursery in Perthshire, Scotland. This initiated a survey of other sites in the UK with samples being sent to Fera diagnostic laboratories for analysis. This new test was shown to be an effective tool in the diagnostic process for the rapid and sensitive detection of *T. minima* on blueberry plants.

P4.2-025

A MULTIPLEX REAL-TIME PCR ASSAY FOR THE UNIVERSAL DETECTION OF ORCHID FLECK VIRUS AND DIFFERENTIATION AMONG ITS FOUR STRAINS INFECTING MULTIPLE HOSTS

ROY Avijit. (1,2), PADMANABHAN Chellappan. (2), OTERO-COLINA Gabriel. (3), RIVERA Yazmin. (2), MAVRODIEVA Vessela. (2), NAKHLA Mark. (2)

Text

In the regulatory environment, the one-tube reverse transcription quantitative polymerase chain reaction (RT-qPCR) is mostly used for RNA-virus detection due to its rapidity, sensitivity, reproducibility, and to reduce risk of carry-over contamination. Recent findings of Orchid fleck virus (OFV) in citrus in South Africa and Hawaii, highlighted the need for a sensitive and specific RT-qPCR method for OFV detection. There are two orchid and two citrus strains of OFV. To know the presence of OFV and its strain in citrus, orchid and ornamentals, a panel of duplex and multiplex TaqMan RT-qPCR assays were optimized using total RNA of all four OFV strains. For developing generic and strain-specific primers and probes of OFV, conserved region of L-gene and variable regions of P- and G -genes were targeted along with the plant internal control Nad5 gene. Comparison between the Ct value of duplex and multiplex RT-qPCR assays of each strain indicates that there is no significant interference on assay sensitivities caused by multiplexing. The limit of detection (LOD) range between ~10-3 to 10-4 dilution. Specificity test on 90 citrus leprosis samples, 40 orchid and ornamental host target samples and 20 non-target samples revealed that both duplex and multiplex RT-qPCR panel are 100% specific, and there is no cross amplification observed. Results of RT-qPCR were also verified with high throughput sequencing followed by electronic (e) probe detection method.

P4.2-026

DEVELOPMENT OF DIAGNOSTIC METHODS FOR HOP VIROIDS

GUCEK Tanja. (1), JAKSE Jernej. (1), RADISEK Sebastjan. (1)

(1) Slovenian Institute of Hop Research and Brewing, ŽAlec, SLOVENIA

Text

Intensive monoculture production, climate change, global trade, and the evolutionary ability of pathogens to adapt rapidly are the main causes of current epidemics in man-made agroecosystems that have become more susceptible to pathogens. Incurable plant diseases caused by viroids can limit crop production and quality and result in significant losses. One such example is the destruction of nearly 500 ha of Slovenian hop yards by the outbreak of the citrus bark cracking viroid (CBCVd). An important factor in preventing its spread is the use of rapid and reliable diagnostic tools. Due to the nature of viroids, which are non-coding naked RNAs, limits their detection only to RNA level. We developed and validated a methodology for reliable and sensitive RT-qPCR assays for individual and combined detection of CBCVd, hop latent viroid (HLVd), and hop stunt viroid (HSVd). The developed assays were found to be specific, reliable and suitable for rapid screening of hop viroids on a large-scale to prevent further spread of disease. In addition, we are developing CRISPR/Cas-RT-RPA assay that has the advantage of being applicable in field-based scenarios, as the tests require minimal sample preparation and are performed at constant temperature without the use of sophisticated equipment. The method will be used for rapid

detection of new outbreaks, evaluation of cultivar resistance, and epidemiological studies. This will limit further spread of the disease and the economic damage to hops.

CURTOBACTERIUM FLACCUMFACIENS PV. FLACCUMFACIENS, A CHOICE OF DETECTION TARGETS

KNIGHT Noel. (1), SAAD Ahmed. (1), VAGHEFI Niloofar. (1,2)

(1) University of Southern Queensland, Toowoomba, AUSTRALIA; (2) The University of Melbourne, Melborune, AUSTRALIA

Text

Detection of a target pathogen is ideally based on a unique genetic region, likely a phylogenetically informative gene or a pathogenicity gene. PCR of such targets can be used to detect and quantify the pathogen in host tissues or environmental samples, and report on relative susceptibility or pathogen sources. For *Curtobacterium flaccumfaciens* pv. *flaccumfaciens* (*Cff*), the cause of tan spot in beans, the target for detection is not necessarily a singular choice. Recently, the most used target for detecting *Cff* was reported to be a gene on a plasmid, with the presence of the plasmid linked to virulence on mung beans in Australia. Strains missing the plasmid were also described, suggesting the potential to miss detecting portions of the *Cff* population in mixed samples. To improve detection, a PCR assay was designed targeting a conserved region of the *gyrB* gene on the main chromosome of *Cff*. Assays for both regions were combined in a droplet digital PCR assay to confirm detection of both targets in the pathogen DNA. Interestingly, based on *gyrB* being a single copy gene, the plasmid target was detected as twice as many copies in at least six strains. Investigations of more strains are ongoing to determine if there is copy number variation among *Cff* strains, and what effect that may have on virulence. These relatively simple tools will enable more informed investigations of *Cff* populations and their dynamics within plant tissues, between different strains and in the environment.

COMPARISON BETWEEN FLUORESCENCE IMAGING TECHNIQUES AND LAMP FOR EARLY DETECTION OF SEVERAL PLANT PATHOGENS

ALJAFER Naofel. (1)

(1) University of Plymouth, Plymouth, UNITED KINGDOM

Text

Chlorophyll Fluorescence (Chl F) Imaging: An extremely important technique for the non-invasive study of photosynthesis dynamics in intact plants, algae, and in cyanobacteria is the measurement of Chl F kinetics. Light is absorbed by plants to be used in photosynthesis, but not all energy from this light is used. Some of the energy is emitted as fluorescent light. It is this emitted light that we collect and use to diagnose the plant health, unhealthy plants are

less efficient at using absorbed light in photosynthesis and so will emit more as fluorescence. Herbicides can reduce the photosynthetic capacity to zero, as can a strong pulse of light that transiently congests the photosynthetic electron transport pathway. so, these techniques are very useful for crop monitoring in alleviating stress at an early stage and thus substantially reducing yield losses. To confirm the imaging result, molecular method should be followed, thus, Loop-mediated isothermal amplification (LAMP) technique has been widely used due to its high efficiency, specificity, simplicity and quickness. LAMP has three great advances, 1- it can be carried out at a constant temperature with a short reaction time, which makes LAMP ideal for point-of-care detection of pathogens in open fields. 2- LAMP is relatively cost effective, as it requires simple equipment. 3- It has very high amplification efficiency and sensitivity as it generates large amounts of PCR products with low amounts of DNA.

PREDICTING SOILBORNE DISEASE RISK OF PULSE CROPS IN MONTANA, UNITED STATES

MURPHY Carmen. (1), BRELSFORD Monica. (1), BURROWS Mary. (1)

(1) Montana State University, Bozeman, UNITED STATES

Text

Soilborne diseases have been a constraint on performance and sustainability of pulse crops worldwide. The pathogens associated with disease can be difficult to manage due to long-lived survival structures, limited fungicide options, and large host ranges. When environmental conditions such as moisture and temperature are conducive to pathogen growth, root rot pathogens can lead to yield loss and crop failure. In Montana pulse fields, numerous pulse crop pathogens have been identified through surveys, including *Aphanomyces euteiches*, *Fusarium* spp., *Pythium* spp., *Phytophthora* spp., and more. To monitor soilborne pathogen presence and severity, 25 fields with a history of pulse crops were soil sampled in Northeast Montana. Selected fields had grown dry pea, lentil, or chickpea in 2022, the year of sampling. Soil was included in a greenhouse bioassay with chickpea, dry pea, and lentil seed planted. DNA was extracted from plant roots and soil, for analysis of samples using qPCR. Testing is ongoing; however, preliminary bioassay and morphology results show root browning and root lesions caused by a variety of pathogens in multiple field samples. Dry pea and lentil were particularly susceptible to diseases in the bioassay, compared to chickpea roots which were generally healthier. Results from this work will assist with development of detection protocols, assist growers with management strategies, and benefit breeding efforts for plant disease resistance.

A SENSITIVE IMMUNO-DOT BLOT ASSAY FOR THE EARLY DETECTION OF CHONDROSTEREUM PURPUREUM USING ANTIBODY-CONJUGATED GOLD NANOPARTICLES

HERMOSILLA Edward. (2), MOORE Francisca. (1), GRINBERGS Daina. (1), CHILLIAN Javier. (1), **MEJIAS Jaime. (1)**

(1) Instituto de Investigaciones Agropecuarias INIA-Chile, Temuco, CHILE; (2) Universidad de la Frontera, Temuco, CHILE

Text

Chondrostereum purpureum is the causal agent of Silverleaf, a serious fungal trunk disease on fruit crops, that decreases fruit yield and orchard's longevity. Fungal spores infect wood injuries and mycelia colonize the xylem, producing necrosis and foliar silvering due to the accumulation of the endopolygalacturonase1 (endoPG1) enzyme. The disease doesn't have an efficient control method yet, so preventive measures, like an early diagnosis, are essential. A diagnostic kit with the potential to detect low concentrations of endoPG1, when foliar symptoms are not visible yet, was developed using a Dot-blot method. The endoPG1 was targeted by polyclonal antibodies conjugated to colloidal gold nanoparticles (GNPs) of 35,88 nm size. The pH 9 and 90 ug/mL of antibody were found the optimal conditions for conjugating GNPs (OD:5) achieved through salt-induced nanoparticle aggregation. The immune-dot blot method was assembled using nitrocellulose membranes, which were spotted with 2 µL of endoPG1 concentrations ranging from 0.039 to 0.49 ug, blocked for not specific binding with 10% skim milk. The membranes were revealed using conjugated GNPs dispersions. A goodness of fit of R2 >0.95 was achieved between spotted endoPG1 concentrations and dot intensities. A detection limit of 0.1 ug endoPG1 was observed. The results demonstrate the effectiveness of the dot-blot method, making it a promising tool for the rapid diagnosis of Silverleaf disease.

Text

Assessment of plant disease severity has been so far dependent on a visual rating, pathogen growth assay, and quantification stress-responsive gene expression. Despite widespread adoption in numerous studies, these methods have been limited to a small set of samples due to labor-intensive and costly processes. Digital plant phenotyping is emerging as an alternative approach. Image-based analysis enables the measurement of plant size and color in a fast and non-destructive manner, allowing high-throughput evaluation of disease symptom development. In this study, we developed an image analysis tool, the Arabidopsis Disease Quantification (AraDQ), for examination of diseased rosette-type seedlings grown on agar plates. Its deep learning pipeline automatically calculates 10 different color and morphological parameters with a high accuracy of object detection and seedling segmentation in the given image. It provides a user-friendly graphical interface without any requirements for hardware/computing platforms or programming languages, and thus is easily accessible to all researchers. We demonstrated that through two case studies characterizing bacterial and plant mutants, AraDQ can be effectively used for the detection of subtle differences in plant disease severity between samples not distinguishable by naked

eyes. AraDQ has the potential to expand our understanding of plant-microbe interactions by providing a highly reliable and robust phenotyping methods for diseased plants.

IMPROVED REVERSE TRANSCRIPTION–LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (RT-LAMP) TEST FOR RAPID AND SENSITIVE DETECTION OF YAM MOSAIC VIRUS IN SEED YAM SYSTEMS

FESTUS Ruth. (1), SILVA Goncalo. (1), PREMPEH Ruth. (2), QUAIN Marian. (2), SEAL Susan. (1)

(1) University of Greenwich, Kent, UNITED KINGDOM; (2) Crops Research Institute- Council for Scientific and Industrial Research, Kumasi, UNITED KINGDOM

Text

Yam (Dioscorea spp.) productivity is constrained significantly by a lack of a formal seed system. Propagation through tuber setts and seed yams encourages the recycling of infected planting materials, contributing to high virus incidence and yield losses. Efforts are ongoing to increase the production of high-quality seed yams in a formal seed system to reduce virus-induced yield losses and enhance the crop's productivity and food security. Therefore, virus detection using sensitive diagnostic tests is imperative to prevent the multiplication of infected materials.

This research aimed to evaluate and optimise existing diagnostic tests for detecting Yam mosaic virus (YMV), the most destructive yam virus in West Africa. Five diagnostic tests, comprising DAS-ELISA, IC-RT-PCR, RT-PCR, RT-LAMP, and qRT-PCR, were evaluated for specificity and sensitivity in YMV detection.

An improved RT-LAMP assay was developed for the detection of YMV. Compared to other tests, it offers a rapid, sensitive and cost-effective approach for virus detection in the seed yam systems.

LISIANTHUS DISEASES ASSOCIATED WITH FUSARIUM OXYSPORUM AND ITS POPULATION DYNAMICS IN FIELDS

WU Cheng-Chun. (1), CHUNG Wen-Hsin. (1,2,3)

(1) Department of Plant Pathology, National Chung Hsing University, Taichung, TAIWAN; (2) Master Program for Plant Medicine and Good Agricultural Practice, National Chung Hsing University, Taichung, TAIWAN; (3) Innovation and Development Center of Sustainable Agriculture (IDCSA), Taichung, TAIWAN

Text

Lisianthus is one of the most important cut-flowers in Taiwan for export to Japan. In 2020, lisianthus plants showed root rot, stem rot, and wilting symptoms in Changhua County, Taiwan. Based on morphological characteristics, pathogenic assay, and phylogenetic

analyses, the causal agent was identified as *F. oxysporum* f. sp. *eustomae* (*Foe*) with two groups (I and II) reported by Bertoldo et al. (2014). It is the first report that *Foe* causing lisianthus diseases in Taiwan. Wounds were necessary for *Foe* to infect lisianthus, and group I and II have diverse virulence. Furthermore, optimum temperatures for group I and II growth are 24 and 24-28 ºC, respectively. Because *F. oxysporum* has been considered as species complex (FOSC), the multi-locus genes (*cmdA*, *rpb2*, *tef1*, and *tub2*) were used to identify the FOSC isolates from lisianthus to species. The result indicated that Taiwanese *Foe* group I was classified into *F. nirenbergiae*; however, *Foe* group II was distinguished from other species in FOSC. For studying the population dynamics of *Foe* group I and II in the greenhouse, two specific primer pairs, *SIX6*-220628-F/R for group I and *SIX1*-220813-F/R for group II, were designed from *Secreted in Xylem* genes. Multiplex and touchdown PCR with the specific primer pairs could successfully detect *Foe* group I and group II. The PCR test demonstrated that *Foe* group I was the dominant pathogen to cause lisianthus diseases, which started from winter and kept appearing until the crop harvest.

Text

African yam bean (AYB; Sphenostylis stenocarp) is an underutilized tuberous legume indigenous to Africa. It is a security crop with lofty nutraceutical benefits but the low grain yield caused by fungal diseases deters farmers from large-scale cultivation. The causal agents of pod and tip dieback diseases associated with AYB are largely uncharacterized. To investigate major AYB fungal diseases leading to low grain yield in this crop, a survey was conducted in 2018 in major AYB-growing areas in Nigeria. Morphological and molecular assays were conducted to identify causal agents of these diseases. Fungi from four genera were isolated from AYB leaves and pods showing disease symptoms. However, Koch's postulates were satisfied for C. truncatum and C. gleosporiodes (Cg) complex. The other three genera produced no disease symptoms in healthy AYB tissues. The morphological characteristics of the isolates in the Cg complex were similar and difficult to delineate to the species level. Therefore, a representative panel of isolates was characterized by sequencing the ITS, glyceraldehyde-3-phosphate dehydrogenase, calmodulin, and Apmat loci. A combined phylogenetic analysis revealed four Colletotrichum species: C. jasmini-sambac, C. theobromicola, C. fructicola, and C. truncatum. The results from this study provide information useful for developing integrated management strategies that may stimulate greater cultivation of AYB, which in turn can contribute to diet diversification.

HIGH-RESOLUTION MELTING CURVE ANALYSIS TO DETECT SEVERAL CERATOCYSTIS SPECIES IN THE LATIN AMERICAN CLADE

LYNN Kira. (1), WINGFIELD Michael. (1), HAMMERBACHER Almuth. (2), BARNES Irene. (1)

(1) Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Research Institute (FABI), University of Pretoria, Pretoria, SOUTH AFRICA; (2) Department of Zoology and Entomology, Forestry and Agricultural Biotechnology Institute (FABI), Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, SOUTH AFRICA

Text

The Latin American Clade (LAC) of the genus *Ceratocystis* encompasses 16 species, many of which are aggressive tree pathogens. Due to the rising importance of these pathogens, the need for a rapid and cost-effective screening protocol to detect these fungi has arisen. The aim of this study was to develop a high-resolution melting curve analysis (HRMA) based on the cerato-platanin (CP) gene region, to detect and differentiate *Ceratocystis* spp. in the LAC, and bypass the need for laborious isolation and post-PCR procedures. Primers targeting a 172bp region of the CP gene were designed to amplify all species in the LAC. The accuracy of HRMA to detect and differentiate LAC species using these CP primers, was assessed on DNA from 12 cultured LAC representatives. The 12 LAC representatives resolved into seven HRMA clusters. Cluster one contained *C. curvata*, *C. mangivora*, *C. manginecans* (Type 2), *C. fimbriatomima*, *C. platani* and *C. adelpha*. Cluster two grouped *C. manginecans* (Type 1) and *C. eucalypticola* together. The remaining clusters represented single LAC species, including *C. fimbriata*. The efficacy of the CP-based HRMA analyses was also tested and validated on DNA extracted directly from *Ceratocystis* infected wood samples obtained in field. Combined with regional historic data, this HRMA diagnostic method allows for rapid screening and semi-specific identification of *Ceratocystis* pathogens in the LAC.

DEVELOPMENT OF RECOMBINASE POLYMERASE AMPLIFICATION ASSAYS FOR SPECIFIC DETECTION OF XANTHOMONAS ORYZAE PV. ORYZAE AND XANTHOMONAS ORYZAE PV. ORYZICOLA

DOBHAL Shefali. (1), ARIF Mohamamad. (1)

(1) UNIVERSITY OF HAWAII AT MANOA, Hawaii, UNITED STATES

Text

Xanthomonas oryzae pv. *oryzae* (*Xoo*) and *Xanthomononas oryzae* pv. *oryzicola* (*Xoc*) are serious pathogens of rice and listed as Select Agents in the United States. Both are widely distributed in Asia, Africa and Australia but have not been detected in the United States. A field-deployable sensitive, and robust tool is required for monitoring, eradication, and surveillance of these high consequence pathogens. Unique genomic regions were identified for *Xoo* and *Xoc* through comparative genomics, and specific primers and probes were designed—in silico analyses showed 100% similarity with target pathogens. An RPA assay targeting the rice genome was also developed and used as an internal control. The specificity of each assay was confirmed with 114 bacterial strains (n=45 *Xoo*, n=10 *Xoc*) representing different geographical locations and time period, closely related Xanthomonads

and other related species, endophytes, healthy rice, soil and wheat. No false positives or negatives were observed. Limit of detection (LOD) of *Xoo*-specific RPA with 10-fold serially diluted pure genomic DNA and spiked (rice sap was added in each dilution) assays were 1 pg and 10 pg, respectively. The LOD for *Xoc*-specific RPA was 1 pg for both pure genomic DNA and spiked assays. Both RPA assays have capabilities to detect and discriminate the target pathogens in the presence of rice matrix. These assays have potential applications in routine diagnostics, disease management, and agricultural biosecurity.

Text

Global seed trade is subjected to various national, regional and international regulations to prevent the spread of harmful seed-borne and seed-transmitted pathogens including requirements for freedom of pest certification of seed lots. When trade partners use different detection protocols, different test results may be produced requiring additional testing that can result in trade delays. Establishing comparability of the protocols used by trade partners can harmonize test results, thus benefiting trade. NAPPO conducted a pilot project on harmonizing diagnostic protocols for a seed-transmitted virus, Tomato Brown Rugose Fruit Virus (ToBRFV), an emerging pathogen that has hampered tomato and pepper world seed production and trade. The project partnered academia, industry, trade organizations and regulatory plant health agencies from North America. Five RT-PCR protocols (three endpoint and two real-time) were selected for comparability studies via a ring test consisting of analytical, diagnostic and calibrator samples. Nine laboratories from the three countries participated in the ring test, generating 3,680 data points. Four out of five methods were found transferrable between the laboratories, and three of those demonstrated optimal performance for accurate, reproducible and user-friendly detection.

Text

Fraxinus excelsior, European ash, is a commercially and ecologically important tree species in the UK, that is host for a devastating fungal pathogen as well as an endemic bacterial disease. Developing knowledge of tree responses to pathogens is helpful for understanding how plants can resist pathogens as well as develop biomarkers for disease surveillance. The quantification of secondary metabolites could prove particularly useful in understanding the processes of disease progression. We used an untargeted metabolomics approach to do this and examined different protocols that are least biased towards one group of compounds. A fully factorial experiment was conducted, using healthy tree samples, to test the best metabolite extraction method using the following variables: three different temperatures (4, 20 and 50°C), number of extraction cycles (1 and 3), and three different solvents (10% and 80% methanol, and methanol:chloroform(MCH)). All variables had significant effects of on the overall variation of the metabolites extracted, with the solvent being the most important, explaining ~70% of the total variation. The more non-polar the solvent, and the higher the temperature, resulted in the largest amount of metabolite diversity in extracts, while the number of extraction cycles significantly affected the amount of yield. The best protocol to use for ash is 50°C, 80% methanol or MCH and 3 cycles.

MOLECULAR DIAGNOSTICS OF ALLORHIZOBIUM VITIS, THE MAIN CAUSATIVE AGENT OF GRAPEVINE CROWN GALL IN CALIFORNIA NURSERIES

TODD Colin. (1), GARCIA Jadran. (2), CANTU Dario. (2), ROLSHAUSEN Philippe. (1)

(1) University of California Riverside, Riverside, UNITED STATES; (2) University of California Davis, Davis, UNITED STATES

Text

Grapevine crown gall is a devastating disease, particularly in regions with a cooler climate. Its causative agent *Allorhizobium vitis* (syn. *Agrobacterium vitis*) is not part of the California grapevine registration and certification program ensuring that nursery plant materials are free of this pathogen. A molecular diagnostic TaqMan assay was developed targeting the VirA gene on the *A. vitis* tumor-inducing (Ti) plasmid and the chromosomal gene pehA which differentiates *A. vitis* from *Agrobacterium tumefaciens*, because *A. tumefaciens* is found at low abundance in grapevine galls and harbors the Ti plasmid. The assay was deployed on Chardonnay and Cabernet Sauvignon clones grafted on 1103P rootstocks collected across several nurseries at different steps of the propagation pipeline (mother field, callusing, green vines, dormant vines) for two consecutive years. For each vine, samples were taken from three trunk compartments comprising the root-rootstock, below the graft union, and above the graft union. Initial results from the VirA target show drastic differences in incidence both between different nurseries, at different stage of the propagation pipeline as well as within the same nurseries in different years. Our results highlight the dynamic nature of *A. vitis* epidemiology, potentially being explained by differences in infection incidence of the nursery

mother vines and/or environmental substrata in which cuttings are being immersed during propagation.

USE OF METABOLOMICS TO DIAGNOSE PLANT DISEASES AND TO EVALUATE POTENTIAL THERAPEUTICS OR PREVENTIONS: A CITRUS HLB CASE STUDY

MCCARTNEY Mitchell. (1), EZE Michael. (1), BORRAS Eva. (1), DAVIS Cristina. (1)

(1) University of California Davis, Davis, UNITED STATES

Text

Metabolomics affords superior plant disease detection when gold standard diagnostics fall short, and can be used to evaluate potential therapeutics or preventions. We demonstrate these capabilities with Citrus greening disease, or Huanglongbing (HLB), which has spread globally and caused severe crop destruction. The causal bacterium, Candidatus Liberibacter asiaticus, does not spread evenly in the tree canopy and moves seasonally between branches and roots, causing a high frequency of false negative readings per gold standard qPCR. With metabolomics, we measure the plant host response to infection and identify a HLB signature from citrus metabolites in leaf tissue, diagnosing HLB without the need for CLas to be present in the sample. In this presentation, we compare six metabolomics assays and determine a liquid chromatography-mass spectrometry (LC-MS) method as most accurate. Multivariate models were further optimized to identify HLB from hundreds of orchard-grown orange and grapefruit trees in Florida and Texas, which resulted in a sensitivity and specificity of >99%. Finally, we apply our HLB model to trees receiving one of several treatments that attempt to prevent or cure HLB infection in a field trial. We showcase the capabilities of metabolomics to accurately diagnose a plant pathogen, to screen therapeutics for the efficacy against disease, and to reveal biochemical pathways impacted by disease and by applied treatments.

Text

Purple seed stain disease of soybean, which occurs in Korea, is one of the diseases that appear in the late stage of soybean growth stages and after harvest. As a result of an analysis of the disease generation ratio with 48 varieties cultivated by the National Institute of Crop Science in 2021, 3 varieties including Nuriol had more than 10% and 10 varieties including Cham-ol had less than 10%. The results of the analysis of the seed germination ratio between infected seed and ordinary seed, infected seeds reduced germination rate of 0

to 8% depending on the variety. More than 200 PSS pathogen candidates were isolated from soybean seeds collected from different regions and it was analyzed phenotype. And, to select representative pathogens from all isolates, it was analyzed cercosporin toxin contents related to virulence. Also, it was sequenced of ITS, TEF, HIS, and ACT genes and analyzed phylogenetic tree. As a result, 12 strains out of 18 analyzed individuals showed the closest genetic relationship with *C. flagellalis*, and 6 other strains showed the closest genetic relationship with *C. sigesbeckiae*. To confirm the virulence of *Cercospora* spp on the soybean in the natural condition, 5 different soybean cultivars were inoculated with *Cercospora* spp complexes. After harvest, Jangol(31.5%) and Nuriol(61.9%) showed a high infection ratio. This report is the first report to reveal the occurrence of purple seed stain disease caused by *C. flagellalis* and *C. sigesbeckiae* in Korea.

(1) Commonwealth Scientific and Industrial Research Organisation, Canberra, AUSTRALIA

Text

Ascochyta Blight (AB) disease, caused by the fungal pathogen Ascochyta rabiei, is a serious disease in many chickpea-growing regions globally, leading to significant reductions in grain yield and seed quality. Currently, host genetic resistance offers limited AB control. Increases in the pathogenicity of A. rabiei, even in clonal populations such as those in Australia, can further limit the efficacy of resistance sources. The rapid detection and quantification of A. rabiei are vital to screen chickpea germplasm for resistance selection, characterisation of A. rabiei pathogenicity and timely management interventions in the field. At present, this relies on the visual assessment by an expert pathologist. We developed a specific, sensitive, single-copy marker for the detection and quantification of A. rabiei using a digital droplet PCR (ddPCR) assay. Comparisons of this marker and ddPCR assay with conventional PCR, quantitative PCR and plant-based techniques confirmed it is highly specific for the detection and quantification of A. rabiei. The sensitivity of detection and quantification is ≤5×10-2 pg DNA from field samples. Therefore, we propose that this method has the potential for early diagnosis and precise quantification of AB in chickpeas with application to breeding, pathogen studies and integrated disease management strategies to support the increased production of plant-based protein.

ONSITE DETECTION OF CUCUMBER MOSAIC VIRUS BY LATERAL FLOW STRIP-BASED REVERSE TRANSCRIPTION RECOMBINASE POLYMERASE AMPLIFICATION IN PEPPER

KIM Min Jeong. (1), LEE Woo-Il. (1), LEE Kui-Jae. (1), JU Ho-Jong. (1), YOON Ju-Yeon. (1)

(1) Jeonbuk National University, Jeonju, REPUBLIC OF KOREA

Text

Cucumber mosaic virus (CMV) is a prevalent virus affecting the great loss of quality and yield of pepper in Korea. In this study, a reverse transcription recombinase polymerase amplification (RT-RPA) assay combined with a lateral flow (LF) strip assay was developed for the detection of CMV in pepper plants. A pair of primers that amplifies highly specifically a part of the coat protein gene of CMV was determined for RT-RPA assay. The RT-RPA assay involved incubation at an isothermal temperature of 32-42 degrees and could be performed rapidly within 30 min. In addition, CMV was detected in 1 pg of total RNA using RT-RPA combined LF strip (LF-RT-RPA) assay, and no cross-reactivity was observed to occur with five viruses caused in pepper crops. We demonstrated that LF-RT-RPA assay is the simple and accurate method for CMV detection since the assay did not require any equipment, comparing results with those of conventional RT-PCR. Furthermore, on-site application of LF-RT-RPA assay for CMV detection was validated in field-collected pepper. The additional results and further analysis will be discussed.

DEVELOPMENT OF LATERAL FLOW RECOMBINASE POLYMERASE AMPLIFICATION ASSAY FOR THE SIMULTANEOUS DETECTION OF SOYBEAN MOSAIC VIRUS AND SOYBEAN YELLOW MOTTLE MOSAIC VIRUS

OH Bong Geun. (1), YOON Ju-Yeon. (1), JU Ho-Jong. (1)

(1) Jeonbuk National University, Jeonju, REPUBLIC OF KOREA

Text

Soybean (*Glycine max* L.) is one of the world's most widely planted and used legumes for food, animal feed products, and industrial production. More than 14 viruses have been found in the soybean grown in the fields of Korea. Among them, soybean mosaic virus (SMV) and soybean yellow mottle mosaic virus (SYMMV) are the most prevalent viruses infecting soybean. This study aimed to develop duplex reverse transcription-recombinase polymerase amplification (RT-RPA) technique applied to rapid, sensitive, and simultaneous detection of SMV and SYMMV. A pair of specific primer sets for detecting SMV and SYMMV, respectively, were selected from over 10 designed primers and RT-RPA conditions were optimized to amplify a part of the coat protein gene of SMV and SYMMV. The optimized reaction temperature for duplex RT-RPA reaction was at 38 degrees for 20 min with two primer sets specific to SMV and SYMMV, but it could be detected at a temperature of 34-42 degrees within a minimum reaction time of 10 minutes. The duplex RT-RPA assay has no cross-reactivity with other soybean-infecting viruses. The limit of detection and reproducibility for detection were evaluated in the soybean seeds. Our result shows that the duplex RT-RPA assay could feasibly be used for rapid and reliable on-site detection of both SMV and SYMMV.

Text

Orchid, one of the most prominent families of flowering plants, is commercially important cultivated in the world. Among 41 orchid-infecting viruses that occurred in Korea, cymbidium mosaic virus (CymMV) and odontoglossum ringspot virus (ORSV) are the most prevalent and economically important. Previously, we developed reverse transcription-recombinase polymerase amplification (RT-RPA) to detect CymMV on *Phalaenopsis* and *Cymbidium* sp. Here, we report that duplex one-step RT-RPA assays were developed to detect CymMV and ORSV simultaneously, and a three-segment lateral flow strip (LFS) has been established. Amplification of duplex RT-RPA assay was optimized with a specific primer set corresponding to CymMV and ORSV, respectively. The duplex RT-RPA reaction could be detected at a temperature of 34-42 degrees within a minimum reaction time of 10 minutes without cross-reactivity with other viruses. Further sensitivity and specificity analysis of duplex RT-RPA assay will be discussed. Taken together, a duplex RT-RPA assay for the simultaneous detection of CymMV and ORSV was established, and this RPA assay can be offered as a valuable tool for routine diagnosis and epidemiological studies of these viruses, as well as the production of virus-free orchids.

GRAPEVINE RED BLOTCH DISEASE DIAGNOSIS: OPPORTUNITIES AND CHALLENGES

KC Achala. (1), DESHIELDS Joseph. (1)

(1) Oregon State University, Central Point, UNITED STATES

Text

Grapevine red blotch disease (GRBD) diagnosis is often challenging due to the nature of symptoms in grapevines. We compared four GRBD diagnosis methods using samples collected from a commercial vineyard in southern Oregon. Tissue samples were collected at fruit set, veraison, harvest, and dormancy from basal, middle, and apical canopy of twenty GRBV-positive and negative vines. GRBD symptoms on grapevines were recorded at the time of collection, and leaf samples were tested for GRBV using LAMP, endpoint PCR, and qPCR. The detectability of GRBV-positive vines by the assays differed significantly among node positions depending on phenology. At fruit set and veraison, the sensitivity of qPCR and endpoint PCR assays was 98%, whereas the sensitivity of LAMP was 49% and 78%, respectively, from basal leaf samples. At harvest and dormancy, the sensitivity of all assays was 100% in basal and middle samples. None of the GRBV-positive grapevine samples expressed symptoms at fruit set and 31% of the basal canopy samples expressed symptoms at veraison. At harvest, 90% of these vines expressed symptoms which was not significantly different than other methods. At fruit set, the specificity of LAMP was less than 75%, whereas at veraison and harvest it increased to 100%. The result of this study shows that PCR-based

assays are the most accurate option if early diagnosis is needed, and less expensive methods such as LAMP and basal canopy symptoms are reliable at later phenological stages.

CRISPR-BASED APPROACHES FOR RAPID AND SENSITIVE DETECTION OF POSPIVIROIDS

ZHAI Ying. (1), AGINDOTAN Bright. (2), RIVERA Yazmin. (2), **PAPPU Hanumantha. (1)**

(1) Washington State University, Pullman, UNITED STATES; (2) USDA APHIS PPQ, Science and Technology, Laurel, UNITED STATES

Text
Pospiviroids continue to be a major concern as a production constraint as well as for quarantine purposes, including new germplasm arriving at the United States. USDA APHIS issued a federal order requiring all imported tomato and pepper seed be certified free of six pospiviroids of quarantine significance or produce in a country where these are not known to occur. The pospiviroids of interest are Potato spindle tuber viroid, Tomato chlorotic dwarf viroid, Tomato planta macho viroid, Pepper chat fruit viroid, Columnea latent viroid, and Tomato apical stunt viroid. The current detection of these six pospiviroids are based on RT-qPCR tests and requires a real-time PCR machine. Specific High-sensitivity Enzymatic Reporter unLOCKing (SHERLOCK), is a CRSPR-based detection method highly specific and sensitive with the potential to detect and differentiate closely related pathogens and does not require expensive equipment and can be used for on-site detection. Here, we report a rapid and highly sensitive SHERLOCK platform via recombinase polymerase amplification (RPA) with CRISPR and CRISPR-associated (CRISPR-Cas) RNA-guided endoribonuclease, Cas13 for pospiviroids detection. Specific RPA primers and crRNAs were designed based on the pospiviroids sequences. This method is portable and quantitative, in which fluorescence can be detected by handheld fluorometers or a fluorescence plate reader and can be done in half hour.

TESTING COMPOST AND CASING SOILS FOR VARIOUS MUSHROOM PATHOGENS

VAN DER WOLF Jean Martin. (1), VERBEEK Martin. (1), VAN DIEPENINGEN Anne D.. (1), MENDES Odette. (1), HENDRIKS Marc. (1), KRIJGER Marjon. (1)

(1) Wageningen University & Research, Wageningen, NETHERLANDS

Text
The Dutch production of the white button mushroom (*Agaricus bisporus*) is one of the biggest in the world. Mushroom diseases can cause substantial losses, and the presence of pathogens associated with substrates (compost and casing soil) used for mushroom cultivation therefore pose a serious threat to this sector. Especially since chemicals permitted to control these pathogens become limited. There is a need for methods to test (bulk)

substrates and their constituents before being used, but sampling methods are lacking while for various mushroom pathogens also suitable molecular diagnostic methods are not available.
We developed sensitive and specific detection methods based on enrichment TaqMan assays for detection of the causative agent of ginger blotch (*Pseudomonas gingeri*) in casing soil and for *Trichoderma aggressivum*, causative agent of green mold. For detection of *Agaricus bisporus* virus 16 (AbV16, former name Brown cap mushroom virus (BCMV)) and AbV6, two viruses from the so-called Mushroom virus X-complex, reverse transcriptase TaqMan assays were developed and successfully applied to diagnose recent outbreaks.
This work was financially supported by the Foundation TKI Horticulture and Starting Materials (grant nr. TU18025), Kekkilä BVB, CNC, Legro, Sterckx, Amycel, Walkro, Lambert Spawn and Sylvan.

APPLICATION OF RAPID NUCLEIC ACID EXTRACTION METHOD TO SIMPLIFY MOLECULAR DETECTION OF PLANT PATHOGENS

LIN Chu Ping. (1), **CHEN Chin Chih. (1)**, CHENG Ying Huey. (2), LIN Mei Ju. (1)

(1) Taiwan Agriculture Reaserch Institute, Taichung City, TAIWAN; (2) Fengshan Tropical Horticultural Experiment Branch, Taiwan Agricultural Research Institute, Kaohsiung, TAIWAN

Text
Simplifying the extraction method of plant nucleic acid is one of the strategies to achieve the goal of simple and rapid detection of plant pathogen. Purification of the plant total RNA or DNA can be done with commercial nucleic acid extraction kits, but the required materials and operating time still needs a certain amount of cost when used in large sample numbers. A nucleic acid extraction solution (named CF fast extraction solution) was developed in this study, which can be used to extract nucleic acids quickly from plants and fungi for detection purposes. Plant species that have been tested including passion fruit, orchid, tomato, papaya, cabbage, cucurbit, Solanaceae seeds, potato, dragon fruit branches, quinoa and tobacco; plant pathogens including Phytophthora sp., Neoscytalidium dimidiatum and viruses, among those viruses can be effectively detected include cucumber mosaic virus CMV), tobacco mosaic virus (TMV), Cymbidium mosaic virus (CymMV), Odontoglossum ringspot virus (ORSV), Euphorbia leaf curl virus (EuLV) and Papaya leaf curl Guangdong virus (PaLCuGDV). For extraction of nucleic acids takes about 20-25 minutes by our technology, which can reduce the extraction time for rapid and large-scale sample detection. In addition to detection accuracy, this technology has the advantages of simplifying the processing flow, eliminating the need for organic solvents, saving detection consumables, and shortening operating time.

PILOT INITIATIVE FOR SHARING OF POST ENTRY PLANT QUARANTINE AND DIAGNOSTIC SERVICES BETWEEN AUSTRALIA AND NEW ZEALAND.

YAN Juncong. (2), ELLIOTT Candace. (1), DELMIGLIO Catia. (2), THOMPSON Jeremy. (2), **PATTEMORE Julie. (1)**

(1) Australian Government, Canberra, AUSTRALIA; (2) New Zealand Government, Auckland, NEW ZEALAND

Text

Australia and New Zealand each have unique ecosystems and strong reliance on primary industries, thus both countries deploy stringent biosecurity policies and measures to afford protection from high impact pests and pathogens. Both countries have strict quarantine measures for the importation of new plant germplasm, with an overlap of regulated pests and diseases, and requirements for plants to undergo post entry quarantine in high containment facilities. Given each country has complementary strengths, a pilot initiative was carried out to test the concept of a shared PEQ arrangement, whereby plants undergo quarantine in one facility and are subsequently released to both countries simultaneously at the end of testing and the quarantine period. This paper details the harmonization of biosecurity outcomes, import and export regulations, diagnostic testing protocols and target lists, and the logistics of successfully releasing a consignment of strawberry (Fragaria x ananassa) to both countries in November 2022.

P4.2-056

EARLY DETECTION AS A TOOL TO STOP THE SPREAD OF DISEASES: THE CASE OF CERATOCYSTIS PLATANI IN EUROPE

SANTINI Alberto. (1), PECORI Francesco. (1), LUCHI Nicola. (1)

(1) National Research Council - Institute for Sustainable Plant Protection, Sesto Fiorentino, ITALY

Text

In Europe, both Oriental plane and London plane trees are seriously threatened by the invasive fungal pathogen *Ceratocystis platani*, the causal agent of the canker stain disease (CSD) of plane trees, a lethal disease able to kill a mature tree in one-two years. The fungus is considered to be indigenous to North America and was unintentionally introduced into Europe during World War II. So far, the disease is reported in Italy, France, Switzerland, mostly in urban or peri-urban environments and in Greece, Albania and Turkey in both anthropized and natural environments. The impact of CSD in Europe can be compared with notorious tree diseases such as Dutch elm disease, chestnut blight, and, more recently, ash dieback, which have all caused devastating losses to natural woody ecosystems and ornamental trees. Once the disease is introduced, if not promptly detected, it is hard to be eradicated, since it is highly infective and easily transported by occasional vectors, although humans, through the use of infected pruning tools and terracing machinery, are the main agents of spread.
To prevent further eastward or northward spread and to study the biology of the pathogen, several early and sensitive detection tools, both biochemical and molecular based, have been developed and validated. Here we describe the different tools and their possible use to prevent the further spread of such a destructive disease.

P4.2-057

DNA-BASED SOIL ANALYSIS OF APHANOMYCES EUTEICHES INCREASES SUSTAINABLE PRODUCTION OF LEGUME-BASED FOODS

OMER Zahra . (1), DUBUSC Sofia Eivor. (5), EDIN Eva. (3), WALLENHAMMAR Ann-Charlotte. (2), JONSSON Anders. (4), KARLSSON Magnus. (5)

(1) Rural Economy and Agricultural Society/HS Konsult AB, Sweden, Uppsala, SWEDEN; (2) Rural Economy and Agricultural Society/HS Konsult AB, Sweden, Örebro, SWEDEN; (3) Rural Economy and Agricultural Society/HS Konsult AB, Sweden, Västerås, SWEDEN; (4) Swedish University of Agricultural Sciences, Skara, SWEDEN; (5) Department of Forest Mycology and Plant Pathology, Swedish University of Agricultural Sciences, Uppsala, SWEDEN

Text

Swedish peas are among the most climate-smart legumes we can eat. Pea root rot, caused by the plant pathogenic oomycete Aphanomyces euteiches, is the major problem in pea cultivation in Sweden. Since the dormant oospores survive for up to 20 years in the soil, it is important for the grower to cultivate peas in fields with healthy soil. The aim of this study is to provide growers with a sensitive DNA-based method for analysing A. euteiches in soil. Soil samples were collected from different fields with suspected occurrence of pea root rot and they were tested in a bioassay with a susceptible pea cultivar “Linnea”. After three weeks the plants were uprooted, carefully washed and assigned a disease severity index (DSI). The shoots were dried at 60°C over night and then weighed. DNA was extracted from the roots and analysed by PCR and gel electrophoresis. DNA was also extracted from soil to assess the occurrence of A. euteiches. The DSI varied across the different samples and the correlation between the DSI and shoot dry weight was significant (R2=0.66). DNA of A. euteiches was detected in the roots of some of the plants. Even though the roots of other pea plants were heavily discoloured the occurrence of A. euteiches DNA could not be confirmed. This indicates either lower amount of DNA or that the symptoms were caused by other plant pathogens. Soil analysis by PCR-methods is under progress.

P4.2-058

IDENTIFICATION OF BLACKLEG PATHOGENS IN SWEDISH WINTER OIL SEED RAPE

OMER Zahra . (1), WALLENHAMMAR Ann-Charlotte. (2)

(1) Rural Economy and Agricultural Society/HS Konsult AB, Sweden, Uppsala, SWEDEN; (2) Rural Economy and Agricultural Society/HS Konsult AB, Sweden, Örebro, SWEDEN

Text

Blackleg is a serious disease of Brassica napus var. oleifera and is caused mainly by the fungus Leptosphaeria maculans (Lm), but also to some extent by the species L. biglobosa (Lb). The disease is of major economic importance worldwide and causes severe yield losses, especially in winter oil seed rape (OSR). It is, however, not fully investigated which Leptosphaeria species that causes the symptoms in Swedish OSR. The aim of this study was to investigate the occurrence of these fungi using the previously developed Loop-mediated Isothermal Amplification (LAMP) assays. Plant samples were collected from winter OSR fields in three regions in Sweden during 2019-2021. Pooled leaf samples with visual

spots were collected in autumn and infected stems were collected from the same fields in the following summer. DNA was extracted with a commercial kit and real-time LAMP was performed with Genie® II platform. The results showed that both Lm and Lb were prevalent in the sampled fields. The most prevalent species on the leaves was Lm, whereas Lb was prevalent in the stems during summer. Both species occurred in the stem base and upper part of the stem. There were both regional and seasonal differences. DNA of Lm and Lb identified in 93 % and 87 % of leaf samples collected in 2019, respectively. In autumn 2020, 86 % of the samples were Lm positive whereas 67 % of samples were Lb positive. In general, the occurrence of both species was low in autumn 2021 compared to 2019 and 2020.

P4.2-059

DNA BARCODE IDENTIFICATION BEYOND SIMILARITY INDICES: INFORMATIVE NUCLEOTIDES OF XANTHOMONAS BACTERIA ON COMMON BEAN (PHASEOLUS VULGARIS)

GRUJIC Vladimir. (1), PIRC Manca. (1), DREO Tanja. (1)

(1) NIB FITO, Ljubljana, SLOVENIA

Text

Xanthomonas phaseoli pv. phaseoli and Xanthomonas citri pv. fuscans (Xpp-Xcf) cause common bacterial blight (CBB) on bean (Phaseolus vulgaris). Their detection in seeds relies on isolation on semi-selective media and subsequent identification of purified colonies. For many laboratories, the DNA barcoding is a method of choice for identification relying on sequence similarity between the isolates and the reference sequences in EPPO-Q-Bank. In this study, we have identified informative nucleotides in partial gyrB and avrBs2 barcodes through analysis of reference EPPO-Q-bank sequences. Differentiation of Xpp-Xcf from other Xanthomonas spp. relies on a single nucleotide difference and 6 nucleotides/684 (< 1 %) in partial gyrB and avrsBs2 sequences, respectively. Unequivocal differentiation of Xpp and Xcf is not possible for all reference isolates possibly reflecting their pathological convergence. The approach was validated on 45 target and non-target isolates with Xanthomonas-like morphology from 17 seed samples. Of these, 29 were identified as Xpp and 11 as Xpp-Xcf. Non-target bacteria (5) could be clearly differentiated from Xpp-Xcf. Overall, the analysis approach taking into account informative nucleotides improves the reliability of typing, enables its automation and a more high-throughput approach. Further analysis is underway to identify other informative nucleotides/sequences, which would allow differentiation between the Xpp and Xcf.

P4.2-060

DEVELOPMENT OF A NEW LATERAL FLOW IMMUNOASSAY FOR DETECTION OF BANANA BUNCHY TOP VIRUS

VANCE Megan. (1), THOMAS John. (1)

(1) University of Queensland, Brisbane, AUSTRALIA

Text
Enzyme-linked immunosorbent assay (ELISA) has previously been a valued method for detection of banana bunchy top virus (BBTV) in many countries due to its reliability and use of simple laboratory equipment. However, detection of plant pathogens using ELISA can be time-consuming. We used newly developed BBTV antibodies to produce a lateral flow immunoassay that can be used for rapid detection of BBTV in the field. Lateral flow test strips were constructed with capture antibodies as test and control lines on a nitrocellulose membrane. Two monoclonal antibodies specific to BBTV were conjugated to gold nanoparticles and loaded onto a conjugate release matrix. Functional testing of the lateral flow assay has shown that BBTV can be detected in crude leaf extracts from infected banana plants diluted up to 1:320 and in as little as 10 minutes. Optimisation of the lateral flow assay has produced a rapid test that is more sensitive than ELISA and is a simple method for detection of BBTV directly in the field.

PATHOTRACER: A TOOL FOR MONITORING RICE PATHOGENS AND RESISTANCE GENES IN ASIA

NGUYEN Hanna. (1), QUIBOD Ian. (1), GRANDE Genelou. (1), BALAHADIA Paolo. (1), PINILI Dale. (1), OLIVA Ricardo. (2), **SCHEPLER-LUU Van. (1)**

(1) International Rice Research Institute , Los Banos, PHILIPPINES; (2) World Vegetable Center, Shanhua, TAIWAN

Text
In South and Southeast Asia, bacterial blight and leaf blast are two major rice diseases caused by Xanthomonas oryzae pv. oryzae and Magnapother oryzae, respectively. Climate change affects the distribution and severity of these diseases, making it essential to monitor the diversity and distribution of the pathogens to predict outbreaks. While more than 47 BLB and 100 blast-resistance genes have been discovered, their effectiveness varies depending on pathogen variants. Thus, having information on their effectiveness is crucial to deploy resistance genes effectively in a given region.

To monitor the bacterial blight pathogen population, a network of 18 institutions across 10 countries in Southeast Asia and South Asia was established for pathogen surveillance and monitoring. Using 40 SNP markers, the Xoo populations were monitored and their distribution was mapped. This information is available on PathoTracer, a GIS-based platform that provides detailed information on the genetic diversity of rice pathogens and the effectiveness of resistance genes and released rice cultivars in a given region or country. Plant pathologists can use this information to develop targeted and effective disease management strategies. PathoTracer provides a better understanding of the diversity and distribution of rice pathogens, which is crucial for developing sustainable and effective approaches to control these diseases.

P4.2-062

DETECTION AND STABILITY OF CITRUS BARK CRACKING VIROID (CBCVD) IN WATER

DOBRAJC Maja. (1), JAKŠE Jernej. (1), **RADIŠEK Sebastjan. (1)**

(1) Slovenian Institute of Hop Research and Brewing, ŽAlec, SLOVENIA

Text

Citrus bark cracking viroid (CBCVd) is un-encapsidated, circular, single-stranded plant pathogenic RNA ranged 282–286 nucleotides that was discovered in 1988 from grapefruit and causes aggressive symptoms on hop. CBCVd spreads mainly by mechanical means such as residues of plant sap of infected plants on tools and plant residues on hop fields. There are no data available on viroid CBCVd survival in aqueous environments. Plant pathogens occur in water at low concentrations, so identification is based on successful extraction from sample. The purpose of the research was to develop detection method for CBCVd extraction from water samples and to study stability of CBCVd in water. We optimized detection of CBCVd in spiked water samples by using different RNA isolation commercial kits and with real time RT-PCR. For stability study we weekly sampled and tested artificially contaminated water which was stored in a growth chamber. Infectivity of samples was performed on hop plants by using mechanical inoculation. Our results showed that CBCVd could be detected with QIAamp Viral RNA Mini kit up to dilution 10-3 and with RNeasy Power Water kit up to dilution 10-1, whereas successful artificial infections were obtained up to dilution 10-2. In stability study we confirmed presence of CBCVd till 56th day, but infectivity of samples was confirmed up to three weeks. In our further work we will investigate the transmission of viroid CBCVd with water in hydroponic systems.

COMPARISON OF RELIABLE AND EFFECTIVE PCR-BASED DETECTION METHODS FOR PCN IN POTATO FIELDS

WUIJSTER Bart. (1), DEKKER-NOOREN Toos. (1), VAN DUIVENBODE Inge. (1), LOMBARD Lorenzo. (1)

(1) Dutch General Inspection Service for agricultural seeds and seed potatoes, Emmeloord, NETHERLANDS

Text

The potato cyst nematodes (PCN) Globodera pallida and G. rostochiensis are a major constraint to the potato industry in the Netherlands and even worldwide. These pests can negatively impact yield and lead to economic losses due to limitations of cultivation on infested fields. Since PCN can survive for a very long time without a host, effective control and eradication measures have been implemented. Therefore, it is important to have a reliable, robust and efficient assay for the detection of (viable) PCN. In recent years, several new PCR methods have been developed for the detection of PCN. In this study, multiple PCR-based detection assays were compared that are included in the EPPO standard PM 7/40. This includes both TaqMan and conventional PCR tests targeting either DNA or RNA regions. Comparisons of the assays using the same samples revealed each of the assays applied have their own discrepancies that warrant further investigations. Therefore, care should be taken prior to selecting a reliable and effective PCR based assay for the detection on PCN.

P4.2-064

A MULTI-PRONGED AND GENOME-INFORMED REAL-TIME PCR DETECTION OF XYLOPHILUS AMPELINUS, A CAUSATIVE AGENT OF BACTERIAL BLIGHT OF GRAPEVINE

BENCIC Aleksander. (1,2), DREO Tanja. (1)

(1) National Institute of Biology, Ljubljana, SLOVENIA; (2) Jožef Stefan International Postgraduate School (IPS), Ljubljana, SLOVENIA

Text

Xylophilus ampelinus (Xamp) is a plant pathogenic bacterium that causes bacterial blight of grapevine, previously reported from the European Mediterranean, South Africa, Japan and Russia. It is regulated in many countries and can restrict international trade with planting material. Because of its fastidious growth its detection relies on molecular methods. The real-time PCR for its detection in symptomatic plant material (Dreo et al., 2007) is one of the first real-time PCR tests included in the EPPO guidelines (PM7/96(1)). Recently, conflicting results of various detection tests were reported when testing grapevine cuttings for latent infections with Xamp. With the aim to improve reliability of detection for novel type of samples we have developed a multi-pronged detection approach consisting of a number of real-time PCR tests targeting genome-informed specific regions of Xamp core genome identified with RUCS (Thomsen et al., 2017). In total, 26 novel qPCR tests were designed with Primer Express 2 (Applied Biosystems) employing TaqMan and MGB probes. Their amplification efficiency ranged from 0.62 to 1.00 and none amplified DNA from a closely related *X. rhododendri* (KACC 21265). Further validation of the sensitivity and specificity of the newly developed approach for detection of Xamp in latent samples is underway. The preliminary results show high potential of the multi-pronged detection to facilitate international trade.

P4.2-065

PREVALANCE AND DISTRIBUTION OF AREOLATE MILDEW IN MISSISSIPPI COTTON

JIMENEZ MADRID Alejandra. (1), ALLEN Tom. (2), WILKERSON Tessie. (2)

(1) University of Georgia, Tifton, UNITED STATES; (2) Mississippi State University, Stoneville, UNITED STATES

Text

Areolate mildew is a fungal disease of cotton caused by *Ramulariopsis* spp. The disease is characterized by white, powdery fungal growth on the underside of the leaf. Although it was first reported in the United States in Alabama in 1890, the disease was not commonly observed in the southeastern U.S., until recently. In 2022, the disease was observed in 19 counties in Mississippi, between 08/15 and 10/03. Disease severity ranged from low (n=10), moderate (n=8) and high (n=1). Symptomatic leaves were collected from infected fields and were transported to the lab for microscopy observation, pathogen isolation and molecular identification. The pathogen was isolated on V8 medium amended with antibiotics. Conidia arising in short chains, fusiform, 0 to 3 septate, mostly 20–30 × 4 µm were observed from the symptomatic leaves. Surface raised, lumpy, pale grey, with margins undulate, and fimbriate colonies developed after 14 days incubation at 25°C. DNA was extracted from 11 isolates

and PCR was conducted using ITS universal primers. In addition, a preliminary screening of the cytochrome *b* gene (*cytb*) was conducted using Sanger sequencing. ITS sequences confirmed all isolates as *Ramulariopsis* spp. However, additional molecular testing is needed to confirm the species. No common substitutions (F129L, G137R or G143A) were observed in the *cytb* region. Screening of additional isolates is critical to monitor for QoI fungicide resistance development within the pathogen population.

P4.2-066

SUCCESSFUL ISOLATION OF XYLELLA FASTIDIOSA SUBSP. MULTIPLEX PORTUGUESE STRAIN, IN AXENIC CULTURE, FROM LAVANDULA DENTATA

PIRC Manca. (1), SÁ PEREIRA Paula. (2), DREO Tanja. (1)

(1) National Institute of Biology, Ljubljana, SLOVENIA; (2) Instituto Nacional de Investigação Agrária e Veterinária, I.P., Oeiras, PORTUGAL

Text
Xylella fastidiosa (Xf) is one of the top 20 regulated quarantine pests in the European Union. The species is divided into several subspecies. The subspecies differ in their host range and determine the phytosanitary measures taken. All Xf are fastidious, slow growing and difficult to isolate in pure culture, even from highly contaminated plants. In this study we have attempted to isolate Xf in axenic culture from three samples of symptomatic *Lavandula dentata* plants, from Portugal (NLR-INIAV). Sub-samples of these plants were previously tested for Xf, in INIAV, confirming the infection. For the isolation procedure, extracts from each sample were prepared from: (i) individual leaves and (ii) two bulk samples of veins (approximately 1 g) as described in EPPO PM 7/24(4) with some modifications. Bulk samples were macerated and some additionally sonicated. Extracts were plated on PWG and BCYE medium. Additionally, DNA was extracted using the QuickPick™ Plant DNA Kit (BioNobile) and the presence of Xf was determined by real-time PCR (Harper *et al.*, 2010, erratum 2013). As expected, the isolation of Xf proved to be challenging. Preliminary results show that isolation was successful from one out of three samples and from a single leaf. No correlation was observed between Cq values obtained by molecular methods and isolation on media. The isolate was identified as subsp. multiplex, following Hodgetts *et al.* (2020), confirmed previously finding based on MLST on plant extract.

P4.2-067

NEPODETECT - DIRECT DETECTION OF PLANT VIRUSES FROM VECTOR NEMATODES

ORLANDO Valeria. (1), ADAMS Ian. (1), PRIOR Thomas. (1)

(1) Fera Science Ltd, York, UNITED KINGDOM

Text
The Longidoridae and Trichodoridae are two families within the phylum Nematoda, of which

some species are classified as plant virus vectors. They can cause economic damage to agricultural and horticultural crops by feeding directly on the roots, and by transmitting viruses such as nepoviruses and tobraviruses into host plants, generating wilting diseases. Non-European populations of *Xiphinema americanum* group are quarantine regulated for Europe as certain species have been proven to transmit nepoviruses such as Tobacco ringspot virus (TRSV) and Tomato ringspot virus (ToRSV). Virus detection inside the nematode offers a good strategy to directly identify the possible presence of such plant viruses and determine if phytosanitary measures are necessary for nematode populations intercepted in trade. The aim of this project was to investigate the main molecular methods already available for identification of viruses vectored by nematodes, and to develop a new diagnostic approach for rapid detection and identification using HTS technology. Virulent nematodes were collected from different locations and RNA extraction directly from nematodes was performed using MagMAX™ Plant RNA Isolation kit for KingFisher method. Viruses such as Grapevine fanleaf virus (GFLV), ToRSV and TRSV were successfully detected by TaqMan real-time PCR. Efficacy of Illumina MySeq System will also be investigated, although considering the limitation of low RNA concentrations, this may pose a challenge.

CRISPR/CAS-BASED BIOSENSING TOOL FOR POINT-OF-CARE DETECTION OF ERWINIA AMYLOVORA

CHO Ye Ram . (1), LEE Boyoung. (1), SONG Ju Yeon. (1), KIM Jihyun. (1)

(1) Department of Systems Biology, Division of Life Sciences, Institute for Life Science and Biotechnology, and Microbiome Initiative, Yonsei University, Seoul, REPUBLIC OF KOREA

Text

Fire blight is a destructive disease of apples and pears that threatens agricultural production. Caused by *Erwinia amylovora*, it is classified as a quarantine disease due to its aggressiveness, contagiousness, and difficulty in containment. Despite efforts to prevent its transmission, fire blight is still spreading across borders and causing severe outbreaks. Moreover, controlling the disease is challenging as symptoms are difficult to distinguish from those caused by other pathogens such as *Erwinia pyrifoliae*. Here, we attempt to detect *E. amylovora* using a sequence-specific system originating from bacterial and archaeal immune systems involving clustered regularly interspaced short palindromic repeats (CRISPR) and the Cas protein. The system is highlighted as a valuable tool in genome editing and disease diagnosis. The *trans*-cleavage activity of the Cas protein can be coupled with a fluorescent readout by employing a reporter, thus producing a fluorescent signal only in the presence of the target nucleotide sequence. Specific sequences for *E. amylovora* were derived by comparative analyses of the genomes of *E. amylovora* and those of its close relatives. Cas and the crRNA complementary to the target sequences successfully detected *E. amylovora* strains including those responsible for the Korean outbreak. Our work provides a useful resource for developing a rapid as well as highly specific and sensitive tool via the CRISPR/Cas system for point-of-care diagnosis of fire blight.

Text

The genus Rahnella contains widely distributed, facultative, Gram negative, anaerobic bacteria in the Yersiniaceae. Rahnella species have been isolated from water, human wounds, oak trees, beetle guts and, recently, symptomatic onion bulbs and foliage. There can be significant losses in onion crops from pre- and/or post-harvest diseases caused by bacterial pathogens. To develop management strategies, it is important to understand the diversity and pathogenicity of Rahnella species on onions. In 2020-2021, Rahnella was isolated from diseased onion bulbs in the USA and South Africa. The 60 isolates formed cream, round, convex colonies on nutrient agar, and were identified as Rahnella based on 16S rRNA sequences. A multilocus sequence analysis (MLSA) with atpD, gyrB, infB, and rpoB was used to define Rahnella strains to species. Pathogenicity trials were completed with onion bulb, foliage, and a red scale necrosis (RSN) assays. A concatenated maximum likelihood phylogenetic tree of the four genes revealed multiple Rahnella species, with large clusters of R. perminowiae, R. aceris, and R. aquatilis. Other species from the USA included R. varrigena and R. victoriana. Among South African isolates, R. perminowiae, R. aceris, and R. aquatilis were dominant. Mild to moderate internal bulb decay was observed with all the species but no isolates were pathogenic with the RSN and foliar assays. The mechanisms by which Rahnella species cause onion bulb rot should be investigated.

Text

Fungal pathogens are a major threat to plants, whether they are cultivated for food or for recreational areas. Pyricularia oryzae is a fungal pathogen infecting more than 50 grasses and is particularly known on major food species such as rice and wheat. This fungus is also known on turf grass as the causal agent of gray leaf spot. As of 2016, in France, the disease is present on the lawns of professional Football stadiums. Gray leaf spot is a cyclic disease, difficult to eradicate once establish on the field. Indeed, phytosanitary treatments are often

ineffective if the application is too late. To manage efficiently the gray leaf spot disease on their sport fields, turf managers require an early and quick diagnostic during the first cycle of the disease. The objective of the Diapason project (partnership UMR PHIM / IAGE company) is thus to develop an early diagnostic method based on digital PCR. The diagnostic was first validated in vitro on pure strains of fungal pathogens and in vivo on samples produced under controlled conditions by artificial inoculations. The application of the diagnostic on sport fields was then done on grass clippings, sampled on a Football stadium presenting symptoms of the disease. An improvement of the diagnostic is under progress (i) to discriminate the P. oryzae lineage affecting turfgrass, rice and wheat and (ii) to extend the diagnostic to other turfgrass diseases identified in stadium, golf courses, and race courses.

P4.2-071

FROM ORCHARD TO STORAGE: DIAGNOSE YOUR APPLES.

GRUET Cécile. (1), DI MATTIA Jérémy. (1), CRETE Xavier. (2), DUCOUSSO Marie. (1), COUILLEROT Olivier. (1)

(1) IAGE , Montpellier, FRANCE; (2) Sudexpe, Marsillargues, FRANCE

Text

Apple diseases can cause heavy losses, difficult to control for the farmers. Many of them develop during storage. Currently, phytosanitary products are used on the harvested apples to control these diseases. To limit such treatments and to assist farmers in reducing their economic losses, four main diseases must be considered: the emerging ramularia disease (caused by Ramularia mali/eucalypti), the already established and problematic Bitter Rot (caused by different species of Colletotrichum), or gleosporium rot (caused by the plant pathogen Neofabrae vagabunda), as well as the mildew (caused by phytophthora syringae/cactorum), a disease transmissible from apple to apple once harvested. Sampling is a key step to ensure a reliable diagnosis of the whole orchad because each one occurs at a different time. However, they are all detectable on apples a few days before harvesting the fruits.

IAGE guides the farmers on apples' sampling in the orchard and then uses an innovative diagnosis based on digital PCR to simultaneously target the pathogens causing the four diseases of interest. Then, IAGE's expertise allows advice to be given to the farmers about the apple's storage. The bottom line of this diagnosis is to help reducing the use of phytosanitary products from the orchard to the storage.

Unit, Merelbeke, BELGIUM; (2) The Netherlands Institute for Vectors, Invasive plants and Plant health (NIVIP), Wageningen, NETHERLANDS

Text

Curtobacterium flaccumfaciens pv. *poinsettiae* (Cfp) is known to cause prominent symptoms on Christmas star or poinsettia (*Euphorbia pulcherrima*), ranging from leaf spots and stem cankers to blight, defoliation and vascular discolouration. The disease was first reported in 1942 in New Jersey, USA[1] and still occurs in American horticulture. Trade of (latently) infected plant material is the main pathway to disseminate Cfp. Latent infections are common and disease often appears on plants close to finishing, making it easy to overlook. Intermittent records in Germany since 2014 have alerted the EPPO region of the insidious threat Cfp poses to glasshouse poinsettia production. To elucidate the pathogen's phytosanitary status on EPPO territory, a survey was done in poinsettia production and wholesale/retail in Flanders (Belgium) and the Netherlands. Yellowish-pigmented *Curtobacterium*-like colonies were isolated from symptomatic plants from over half of the sampled sites. Majority of these were identified as *C. flaccumfaciens* based on MALDI-TOF MS profiles and partial *gyrB/recA* gene sequences. Pathogenicity tests confirmed the isolates as pv. *poinsettiae*. Comparative genomics clustered the 'yellowish-coloured European strains' into three closely related groups, clearly separated from the pink strains isolated from poinsettias in the 1950s in the USA. Early and specific detection in cuttings and mother plants by LAMP is explored.

KRISP: A COMPUTATIONAL PIPELINE FOR RAPID DEVELOPMENT OF CRISPR-BASED MOLECULAR DIAGNOSTICS FROM RAW READS

FOSTER Zachary. (1), TUPPER Andrew. (1), PRESS Caroline. (1), CHANG Jeff. (2), GRÜNWALD Niklaus. (1)

(1) United States Department of Agriculture, Corvallis, UNITED STATES; (2) Oregon State University, Corvallis, UNITED STATES

Text

CRISPR-based molecular diagnostic assays like SHERLOCK and DETECTR are affordable, field-deployable, and easy to use. However, these require specialized primers and guide-RNAs that must be inferred from sequence data and tested in the lab. Designing such assays from genomic data is time consuming, potentially delaying effective pathogen monitoring and mitigation. We are developing a framework for rapid development of CRISPR-based diagnostic tests from raw reads using a computational pipeline called KRISP. KRISP outputs primer and guide RNA sequences needed to uniquely distinguish any number of user-defined groups of organisms. Both human-readable HTML reports and files optimized for downstream analysis are created. KRISP leverages many existing open source tools and introduces others that can be used independently, such as the KRISP python package that finds diagnostic sites from assembled genomes or variants stored in VCF files. A pipeline orchestration language called Nextflow allows for seamless use on personal computers, high performance computing clusters, and commercial cloud services. Results are fully reproducible due to the use of docker containers for all tools. Using KRISP we were able to find a crRNA locus that can differentiate Phytophthora ramorum from other Phytophthora species and validated it in the lab. We hope that this will allow for rapid development of diagnostics essential to track and manage emerging plant pathogens.

P4.2-074

RISK ASSESSMENT FOR TRUNK DISEASES IN SWEET CHERRY ORCHARDS BY USING SPORE TRAPS AND QPCR

CHILIAN Javier. (1)

(1) Instituto de Investigaciones Agropecuarias, Chillan, CHILE

Text

Trunk diseases affect the longevity and productivity of sweet cherry trees in Chile. They are caused by numerous species of fungi that infect and damage the wood, causing chronic infections. The most frequent fungal canker pathogens are Calosphaeria pulchella, Chondrostereum purpureum, Cytospora leucostoma and Eutypa lata. There are not eradicative methods yet available for their control, hence,
to predict the risk of primary infections by these pathogens and subsequent outbreaks of canker, it is crucial to understand their occurrence in cherry orchards. The aim of this study was to analyze the occurrence of Calosphaeria, Chondrostereum, Cytospora and Eutypa airborne inoculum in cherry orchards in relation to weather conditions. For this purpose, three commercial orchards were monitored weekly during two years using microscope slide traps, and pathogens were detected and quantified by qPCR and specific pathogen-primers. The qPCR method was efficient to identify the DNA of each pathogen in spore traps, in both years and with a marked seasonal distribution, from mid-fall (mid-May) throughout winter and early spring (June–October). Spore dispersal patterns were correlated with rainfall events, with maximum detection levels of 5, 4.5-4 and 3.8 fg of DNA for Eutypa, Calosphaeria, Cytospora and Chondrostereum, respectively. The qPCR method demonstrated to be rapid and sensitive in detecting fungal inoculum and may contribute to the implementation of management strategies.

Text

Xylella taiwanensis (Xt) is a nutritionally fastidious bacterial pathogen causing pear leaf scorch disease (PLSD) in Taiwan. Xt detection plays a key role in PLSD management. Multiple PCR systems based on single- or two-copy genes have been developed for Xt

diagnosis. Xt detection could be further improved utilizing multi-copy genes. A total of 32 Xt whole genome sequences are now available in the GenBank, providing a sound resource for the development of robust PCR detection systems. By self-aligning the genome sequences of Xt Type strain PLS229, seven 714-bp sequences with similarity > 97% each other were identified. The sequences were annotated as part of the hemagglutinin-like protein gene. Based on this sequence, two primer sets, Xt7cp-378-F/R and Xt7cp-573-F/R, were designed. In silico experiment using GenBank database showed the high Xf-specificity of the two primer sets. SYBR green qPCR experiments using pure culture DNA from strains of Xt, X. fastidiosa and Xanthomonas campestris and PLSD plant DNA samples collected in Taiwan further confirmed the Xt-specificity. To evaluate PCR detection sensitivity, five previously developed Xt-specific primer sets, two from single-copy locus and three from two-copy locus, were simultaneously compared with Xt7cp-378-F/R and Xt7cp-573-F/R against the same set of PLSD samples. A reduction of 1-3 Ct values from the two 7-copy gene-based PCR systems were observed. Further evaluation of the two PCR systems is underway.

P4.2-076

DIAGNOSIS OF TAR SPOT OF CORN CAUSED BY PHYLLACHORA MAYDIS USING LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) AND CONVENTIONAL PCR

SIC Wily. (1), GOMEZ Sandra. (1), GOODWIN Stephen. (1), CRUZ Christian. (1)

(1) Purdue University , West Lafayette, UNITED STATES

Text

The diagnosis of tar spot of corn currently relies on visual assessment. PCR is used for plant pathogen detection but requires specialized equipment and is not suitable for field applications. The loop-mediated isothermal amplification (LAMP) assay is a new method that is emerging as a simple and sensitive diagnostic tool. Here conventional PCR and LAMP tests for diagnosis of Phyllachora maydis in diseased corn leaves are described. The calmodulin gene of P. maydis was used as a target to design PCR and LAMP primers in the Open Reading Frame (ORF) and in a region extended 1 kb on both ends of the ORF to identify a unique region of the gene. Six primer pairs for PCR and five primer sets for LAMP were designed and synthesized. We tested the PCR primers on 13 P. maydis samples from the United States, five P. maydis samples from Ecuador, and 43 isolates from other corn pathogens. One PCR primer pair was specific for all P. maydis isolates. The LAMP assay is performed at 65 °C for 40 min and the amplification is observed by the addition of SYBR Green to the reaction. A green color reaction, that is visible to the naked eye, indicates amplification in the presence of P. maydis DNA, otherwise, the reaction turns orange. The LAMP assay is a promising technique for the rapid detection of P. maydis in diseased corn leaves in contrast with conventional PCR which requires a well-equipped laboratory.

P4.2-077

IMPLEMENTATION OF REAL-TIME PCR FOR QUANTITATIVE DIAGNOSIS OF CASSAVA COMMON MOSAIC VIRUS IN CASSAVA GERMPLASM (MANIHOT ESCULENTA CRANTZ)

NIÑO-JIMENEZ Diana Patricia. (1), LOPEZ LOPEZ Karina. (2), CUERVO Maritza. (1)

(1) Alliance Bioversity Int. and CIAT, Cali, COLOMBIA; (2) Universidad Nacional de Colombia, Palmira, COLOMBIA

Text

Cassava is considered the sixth most important crop, with a production of more than 300 million tons with an annual yield of 11.03 tons/ha, with economic and main importance for food security. Currently, the Bioversity International Alliance and CIAT have a cassava germplasm bank made up of 5,965 accessions under in vitro conditions, which require the indexing of quarantine pathogens. To carry out continuous improvement in diagnostic processes, the objective was to establish a quantitative protocol based on real-time PCR (qPCR) for the detection of *Cassava common mosaic virus* (CsCMV). The establishment of the methodology required the design of primers and a probe, the standardization of concentrations, reaction volume, and amplification time. In addition to this, the sensitivity and specificity of the reaction were determined, and a comparison of methodologies was made between DAS-ELISA, PCR, and qPCR, using 140 accessions from the cassava bonsai collection to evaluate the level of sensitivity and specificity of each technique. The established qPCR protocol allowed the detection and quantification of the CsCMV virus up to 77.97 copies/µL, demonstrating a sensitivity 10 times greater than PCR. The optimization of the qPCR for the diagnosis of CsCMV, allowed us to obtain a sensitive, fast, and specific protocol for the diagnosis, contributing to the sanitary certification of the cassava materials for safe distribution.

Text

The quarantine pathogen *Phytophthora ramorum* has at least 75 hosts and over 100 associated hosts. Outbreaks have been linked to the introduction and movement of ornamental landscape plants near susceptible forests. Uniform and reliable detection of *P. ramorum* from a diverse host range is complex. Traditional ELISA techniques are not specific enough to confidently identify pathogen presence and TaqMan assays require rigorous measures to handle the expansive host range. An RPA assay was developed and optimized for *P. ramorum* to improve diagnostic specificity and provide confirmatory molecular diagnostics for end users. The developed assay shows sensitive and specific detection of *P. ramorum* detecting down to 1 fg/µl of DNA from each lineage while not cross reacting to over 100 different oomycetes in at least 30 hosts. The RPA assay was put through three tiers of

validation. The first validation, a single lab multi-operator validation, produced diagnostic specificity and sensitivity scores of 100% and 92% respectively with 100% reproducibility and repeatability among operators. Tier two validation resulted in 100% diagnostic specificity and sensitivity on a blind sample set performed at two independent labs. The capstone validation is a blind conglomerate test performance study involving five independent labs representing academia, government, and industry. The developed RPA assay provides a rapid and simplified approach for molecular detection and identification of *P. ramorum*.

Text

Fungal diseases of wheat are among the most damaging plant pathogens, causing significant losses of total grain yield if left untreated. Parastagonospora nodorum (Pn) and Pyrenophora tritici-repentis (Ptr) cause septoria nodorum blotch (SNB) and tan spot (TS) of wheat, respectively. Pn and Ptr can co-exist in the same lesion of infected wheat and are non trivial to distinguish from one another based on physical disease symptoms. Digital droplet PCR (ddPCR) is a high throughput and highly sensitive polymerase-based assay that allows for the quantification of SNP-level specific DNA sequences. We have developed a fluorescent probe-based assay capable of single well, reference-free simultaneous quantification of SNB and TS during host infection. The assay shows no off-target effects across a wide range of closely related cereal necrotrophs and can resolve pathogen titre at up to 5pg/µl of purified fungal gDNA, or 1ng/µl of infected plant tissue. Based on a hypervariable region within the highly conserved α-tubulin gene, the assay can be easily adapted for studying other cryptic plant pathosystems, and will provide another tool for dissecting the relationship between pathogens as well as with their hosts. We have also exploited ddPCR to examine competition between pathogen isolates of the same species during infection on wheat. The implications of this study will be discussed.

MULTILOCUS SEQUENCE TYPING (MLST) AND PHYLOGENETIC STUDY REVEAL SPECIES DELIMITATION OF COLLETOTRICHUM SPP. ASSOCIATED WITH THE DIEBACK OF GUAVA

IQRA .. (1), HAQ Imran Ul. (1), IJAZ Siddra. (1)

(1) University of Agriculture Faisalabad, Faisalabad, PAKISTAN

Text

Colletotrichum species complex is an important group of fungal pathogens infecting many host plants worldwide. We investigated the population structure, genetic variation, and species delimitation in the *Colletotrichum* community associated with dieback-affected guava plants using integrative phylogenomics analyses. Five housekeeping genes, actin (*act*), calmodulin (*cal*), Glyceraldehyde 3-phosphate dehydrogenase (*gapdh*), tubulin (tub_2), and internal transcribed spacer region of rDNA (*ITS*), were used in this study. The isolate genotyping was based on allelic profiles. The typing efficiency of the GAPDH locus was shown higher in MLST analysis, which suggests it is a potential DNA barcode marker to delimit species boundaries for distinguishing *Colletotrichum* species in phylogenetic studies. A multilocus phylogenetic tree was generated for species delimitation through Bayesian inference analysis congruent with the coalescent theory-based species tree. The phylogenetic tree resolved these isolates as independent evolutionary lineages of the *Colletotrichum siamense* species complex. The Coalescent theory-based species tree also supported these lineages as independent *Colletotrichum siamense* species of its complex. Hence, based on morpho-genetics analyses, we reported two new *Colletotrichum* species (*C. parkukiae* and *C. psidium*) associated with guava dieback.

P4.2-081

TWO NEW QPCR ASSAYS FOR DETECTION AND QUANTIFICATION OF ASPERGILLUS FLAVUS CLADE AND ASPERGILLUS PARASITICUS CLADE IN MAIZE KERNELS

LEHARANGER Alexandre. (1), PAUMIER Delphine. (1), ORLANDO Béatrice. (1), **VALADE Romain. (1)**

(1) ARVALIS-Institut du végétal, Boigneville, FRANCE

Text

Aspergillus section *Flavi* mainly produce carcinogenic mycotoxins known as aflatoxins (AFs) divided into two types, B and G types (AFB and AFG). They are highly hazardous for human and animal health, so AFs are extremely regulated in food production with low accepted limits. In France, global warming has led to some AFs detection in maize harvests since 2015. Thanks to mycoflora analysis, the species *A. flavus* (AFB producer) and *A. parasiticus* (both AFB and AFG producer) were identified as responsible of AFs contaminations. However, mycoflora analysis is a time-consuming method which limits the characterization of many samples. Thus, we propose here a clade specific and functional TaqMan® qPCR method based on the calmodulin gene to discriminate the *flavus* clade (FC) and the *parasiticus* clade (PC). We applied these methods on more than 1100 maize samples, collected over seven different years (2016 to 2022). About 20% of all the samples were detected positive for FC, which is three times higher than PC. We found, as expected, significant positive correlations between AFB and FC DNA (R^2 = 0.665), and between AFG and PC DNA (R^2 = 0.844). Our methods will be useful to characterize maize grains contamination by *Aspergillus* section *Flavi* quickly, easily, and cheaply. Thus, these methods will be used to study the relationship between agroclimatic conditions, AFs content and species prevalence in order to anticipate AFs risks in France with global warming.

Text

The EURL for Bacteria in plants activity is focused on the organisms listed in the EU Regulation 2019/2017 as union quarantine pests, among which *Pantoea stewarti*i subsp. *stewartii* (Pss). Pss is the causal agent of Stewart's vascular wilt of maize, responsible for serious crop losses, indigenous of North America and it spreads through maize seeds. For commercial seed certification and official analysis, several molecular and serological tests were developed to detect Pss but some of them cannot distinguish Pss from *P. stewartii* subsp. *indologenes* (Psi) non-pathogenic on maize. Italian isolates recovered in 2015 and 2018 were characterized (molecular, biochemical, pathogenicity and sequencing) and genomes were assembled through MinION and Illumina. Exploiting these results, a new primer combination was defined to specifically detect Pss by real-time PCR up to 10^3 CFU/mL in spiked maize seeds. Critical reagents were also assessed by a TPS involving Italian official laboratories to verify the possible influence on the robustness of the test. Another approach is ongoing to properly detect and identify Pss in maize seeds. It is based on the implementation of barcoding procedure described on Brady et al., 2008 and developing an amplicon sequencing approach by Nanopore. This study addresses the critical issue related to the import of maize seeds from regions where the disease is endemic and, in general, can prove to be a reliable tool in detecting different seed-borne pathogens.

Text

Phytoplasmas are uncultured pathogenic bacteria that colonise the phloem and are transmitted by sap-sucking insects. In Papua New Guinea, the centre of origin of banana plants, banana wilt associated phytoplasmas (BWAP) are causing devastating losses in banana and coconut, whose associated disease is called Bogia Coconut Syndrome (BCS).

BCS is localised to PNG's Madang Province, while BWAP on banana has spread within PNG and to Solomon Islands. Identification of infected plants and follow-up containment and eradication campaigns are reliant on accurate diagnostics. Detection tests are also crucial to prevent new disease incursions via worldwide movement of banana germplasm for genetic improvement. This is especially relevant as the ongoing global spread of Fusarium wilt TR4 increases the need for novel resistant banana varieties.
Although published methods to identify phytoplasmas are available, related bacteria are often detected in banana and lead to false positives. We developed a rigorous approach to validate novel and published nested PCR and real time PCR based diagnostic assays for phytoplasmas on a range of DNA samples from phytoplasma-infected plants and from plants that contain phytoplasma-related endophytic bacteria. We designed novel molecular assays using BWAP draft genomes and identified the most reliable method to detect phytoplasmas in banana. Our results enable a scientifically informed assay choice for phytoplasma indexing of banana germplasm worldwide.

Text
Pantoea stewartii subsp. *stewartii* (*Ps*) is a plant pathogen causing wilting in corn (*Zea mays*). It is native to the Americas where the disease is spread mainly via its beetle vector (*Chaetocnema pulicaria*). It is a quarantine pathogen in the European Union where it has been detected with some regularity despite the presumed absence of the vector. In recent years it has been reported mainly from Italy and Slovenia. From 2018 to 2022, the official survey for *Ps* in Slovenia confirmed its presence in 11 samples of corn in the Mediterranean region bordering on Italy. The infected plants exhibited leaf wilting in the summer and autumn and were of different varieties. The status of *Ps* in Slovenia following official phytosanitary measures is 'transient'; it remains under eradication and under surveillance. With the aim to identify the origin of infections whole genome sequencing of the *Ps* isolates was done with Illumina and Nanopore technologies. Following hybrid genome assembly, the ANI analysis confirmed the Slovenian corn isolates as *Ps*. However, phylogeny-inferring analysis grouped these isolates somewhat distant to the American *Ps*. At this stage, it is not clear whether this positioning is caused by the lack of more recent genomic data on *Ps* from the Americas or a historical divergence of the European *Ps* strains. Additional comparative genomics analysis is ongoing to shed more light on the origin of the findings in Europe.

Text

The aim of the INDICANTS project is to develop innovative diagnostics for four banana wilt pathogens, including *Fusarium oxysporum* f. sp. *cubense* (Foc) TR4 (Fusarium wilt), *Ralstonia solanacearum* (Moko disease), R. *syzygii* subsp. *celebesensis* (Blood disease), and *Xanthomonas vasicola* pv. *musacearum* (Xanthomonas wilt). The main objectives are to: (I) develop low-cost LAMP (loop-mediated isothermal amplification) assays (II) compare simplified DNA extraction methods for field application; (III) validate the LAMP protocols via inter-laboratory and field tests. LAMP primer sets were designed for the bacterial pathogens, using *in silico* comparative genomic analysis of target and non-target genomes, and showed 100% specificity when tested with a wide range of target and non-target strains. A limit of detection of 10^4 CFU/ml was obtained for the LAMP assays. A simplified DNA extraction method from banana tissue was developed and successfully validated in a banana plantation infested with Foc TR4, using several candidate LAMP primer sets. Ready-to-use diagnostic kits, based on these protocols, are currently being developed by a private company. These point-of-care diagnostic tools will allow rapid identification of the different pathogens in the field for disease management.

P4.2-088

CURRENT STATUS OF PRUNUS NECROTIC RING SPOT VIRUS IN MONTENEGRO

(1) University of Montenegro, Biotechnical Faculty, Podgorica, MONTENEGRO; (2) University of Ljubljana, Biotechnical Faculty, Ljubljana, SLOVENIA; (3) University of Zagreb, Faculty of Science, Zagreb, CROATIA

Text

Prunus necrotic ring spot virus (PNRSV) is one of the most economically important viruses of stone fruit trees. It is distributed on peach and nectarine in Podgorica district but information about its incidence and genetic diversity on other Prunus sp. in other parts of the country is

limited. We determined the incidence of PNRSV in 11 municipal districts of Montenegro and studied its genetic diversity from different Prunus sp. Out of 65 samples analysed by RT-PCR, 12.3% were infected with PNRSV from 2 out of 11 districts. CP gene (675 bp) sequences from one peach, two nectarine and two cherry samples showed that Montenegrin isolates 139/21 (peach) and 55/22 (cherry) had 98.4% identity with a Spanish nectarine isolate (AJ133208), while isolate 46/22 (cherry) was 98.4% identical with an Italian peach isolate (AJ133205). Two nectarine isolates 137/21 and 138/21 showed 99.3% identity with previously described Montenegrin peach isolate (JX569826). The phylogeny reconstruction (minimum-evolution method) allowed clustering of Montenegrin isolates in two groups. Three isolates (139/21, 46/22 and 55/22) clustered within PV-96 group, while two isolates (137/21 and 138/21) clustered within PE-5 group. Five PE-5 specific amino acid residues (K59, N121, R139, N142 and I181) were also identified in two Montenegrin isolates. This study highlights the need for strict phytosanitary measures implementation and the production of certified propagative material in the country.

DISPERSAL PATTERNS OF PETRI DISEASE ASSOCIATED PATHOGENS IN ROOTSTOCK MOTHER VINES AND IMPACT OF PATHOGENS ERADICATION IN THE PRODUCTION OF HEALTHY PROPAGATION MATERIAL

TSOUKAS Christos. (1), BAKASIETAS Konstantinos. (2), TZIMA Aliki. (1), PAPLOMATAS Epaminondas. (1)

(1) Agricultural University of Athens, Athens, GREECE; (2) Vine Nurseries Bakasietas, Korinthos, GREECE

Text

Petri disease caused by *Phaeomoniella chlamydospora* and *Phaeoacremonium minimum* included in the complex of grapevine trunk diseases (GTDs), is a major threat to grapevine cultivation. The pathogens' presence in grapevine nurseries has been widely reported, affecting the produced propagation material, and leading to huge losses. The aim of this study was to investigate the pathogens distribution along canes of nine different clonal rootstocks and the effect of diseased mother vine eradication in pathogens inoculum dispersal in a three-year survey. Detection of the pathogens was carried out by using a Nested PCR approach. PCR reactions showed that the detection percentage followed a sequential decrease during the three growing seasons, where in some cases the pathogens were not detected. Due to the low concentration levels of the pathogens, quantification of the prevailing fungus *Pa. chlamydospora*, was carried out by utilizing a newly developed Nested qPCR methodology based on pre-amplification of the regions flanking the dual-labeled probe that was subsequently used in the qPCR assays. Quantification experiments revealed the pathogens biomass was decreasing up to 95% in the basal end of the canes not exceeding the levels of fg/ng of plant DNA. The data presented indicate that uprooting of mother vines showing typical GTD symptoms, could be an effective control measure to reduce pathogens inoculum in the field, and to produce pathogen-free grafted vines with added value.

SNP4ORPHANSPECIES: A BIOINFORMATICS PIPELINE TO ISOLATE MOLECULAR MARKERS FOR STUDYING GENETIC DIVERSITY OF ORPHAN SPECIES

PENAUD Benjamin. (1), LAURENT Benoît. (1), MILHES Marine. (2), NOÜS Camille. (3), EHRENMANN François. (1), **DUTECH Cyril. (1)**

(1) INRAE UMR Biogeco, Cestas, FRANCE; (2) INRAE Genotoul, , Castanet-Tolosan, FRANCE; (3) Laboratoire Cogitamus, Bordeaux, FRANCE

Text

For several decades, an increase in disease or pest emergences due to anthropogenic introduction or environmental changes has been recorded. Many of these events involve species with poor or no genomic resources (called here "orphan species"). This lack of resources is a serious limitation to our understanding of the origin of emergent populations, their ability to adapt to new environments and to predict future consequences to biodiversity. We developed a generic bioinformatics pipeline to rapidly isolate such markers with the goal to be applied in studies of invasive taxa from different taxonomic groups, with a special focus on forest fungal pathogens and insect pests. This pipeline is based on: 1) an automated de novo genome assembly obtained from shotgun whole genome sequencing using paired-end Illumina technology; 2) the isolation of single-copy genes conserved in species related to the studied emergent organisms; 3) primer development for multiplexed short sequences obtained from these conserved genes. The pipeline's functionality was evaluated with sequenced genomes of five invasive or expanding pathogen and pest species in Europe (Armillaria ostoyae, Bursaphelenchus xylophilus, Sphaeropsis sapinea, Erysiphe alphitoides, Thaumetopoea pityocampa). We successfully isolated several pools of one hundred short gene regions for each assembled genome, which can be amplified in multiplex. The bioinformatics pipeline is user-friendly and requires little computational resources.

P4.2-093

SPECIES-SPECIFIC PCR REVEALS THE OCCURRENCE OF THE ALIEN FUNGUS ERYSIPHE CORYLACEARUM INFECTING HAZEL IN HUNGARY

KALMÁR Klementina. (1), ÁGOSTON János. (2), MOLNÁR Orsolya. (3), PREININGER Éva. (1), **NÉMETH Z. Márk. (3)**

Text

The market demand for common hazel (*Corylus avellana*) fruit is steadily increasing. The powdery mildew (PM) on hazel in Hungary, and also in whole Europe, was caused earlier by *Phyllactinia guttata*. However, since 2017, an other fungus of Asian origin, *Erysiphe corylacearum*, has been infecting hazels in Europe. The aim of the study was to assess the presence of the alien fungus in Hungary. We collected ~40 samples from across Hungary in 2022. Morphology of the PM fungi was observed, and the internal transcribed spacer (ITS) of

the ribosomal DNA was sequenced. To aid differentiation of *P. guttata* and *E. corylacearum*, a species-specific PCR was developed. In approx. half of the samples, *E. corylacearum* was present; on the other half, both fungi could be found, and only few samples carried solely *P. guttata*. Mostly, but not exclusively, *P. guttata* was found on the lower, while *E. corylacearum* on the upper side of the leaves. *E. corylacearum* also infected nuts, and it was found not only on *C. avellana*, but also on *C. colurna* (Turkish hazel). As *E. corylacearum* spreads rapidly, it can be considered as an invasive pathogen. Its practical importance lies in its ability to infect nuts, potentially causing economic losses. Our species-specific PCR method supports the correct identification of the fungus, which is a prerequisite for successful plant protection.

Text

Identification of plant pathogens and inoculum quantification in soil samples using conventional methods is rather labor-intensive and time-consuming. Therefore, the development of rapid, and simple to perform PCR-based identification methods that use pathogen-specific primers is necessary. Herein, a real-time quantitative PCR approach coupled with high-resolution melting (HRM) analysis was developed with one primer set to identify and distinguish several fungal species associated with grapevine trunk and black-foot diseases. In detail, the developed method targeted several Cylindrocarpon-like asexual morphs belonging to the genera *Ilyonectria* or *Dactylonectria* and the fungal species *Phaeomoniella chlamydospora*, *Phaeoacremonium aleophilum* and *Diplodia seriata*. The technique's reliability was first assessed on DNA extracted from pure cultures. The melting curve analysis of the amplicons allowed for the distinction of all target species with confidence levels >99%. For each targeted genera/species HRM curve profiles were generated. The identification of the target pathogenic species in the fortified soil samples was achieved in a range confidence between 60-75%. The quantification of the detected pathogen DNA in the soil material was assessed with quantitative PCR and the sensitivity was evaluated using standard curve. This study provides the development of a new molecular tool to detect and quantify several GTD or Black foot pathogens in soil samples of grapevine nurseries.

Text

The causal organism of bacterial leaf spot of *Hydrangea*, *Xanthomonas hydrangeae*, was the subject of a disease report and a new bacterial species description in 2021. These publications, including the developed *X. hydrangeae*-specific isothermal diagnostics assay, the raising of awareness about this pathogen thereof, and the favorable wet weather conditions during the summer of 2021 in Europe uncovered a wider historical and contemporary prevalence of this disease. In 2022, the pathogen was also reported for the first time on hydrangea plants in Tuscany, Italy. Global trade of plants appears to play an important role in the dissemination of this pathogen. Furthermore, scouring the literature revealed multiple instances, mainly in the USA, of bacterial leaf spot of *Hydrangea*, attributed to various *Xanthomonas* species (e.g., *Xanthomonas campestris*, *Xanthomonas hortorum*). The first known mention of bacterial leaf spot of *Hydrangea* dates to 1996 in Georgia, USA. However, those 1996 isolates were not available and thus their identity as *X. hydrangeae* cannot be confirmed. This work outlines the challenges encountered when studying *X. hydrangeae*, as related to 1) the development of a diagnostics assay targeting *X. hydrangeae*, especially given its phylogenetic similarity to *X. hortorum* and 2) the information discontinuity regarding the historical and contemporary occurrence of bacterial leaf spot of *Hydrangea*.

DEVELOPMENT OF RAPID AND AFFORDABLE VIRUS-MIMICKING ARTIFICIAL POSITIVE CONTROLS AND THEIR APPLICATION IN DIAGNOSTICS

SINGH Shivani. (1), STAINTON Daisy. (1), **TZANETAKIS Ioannis. (1)**

(1) University of Arkansas System Division of Agriculture, Fayetteville, UNITED STATES

Text

Existence of positive controls is the tailback in the development of detection assays. Failure to acquire positive controls, majority of diagnostics labs use an in-vitro synthesis approach e.g. the target sequence integrated into a plasmid. Even though plasmids yield positive results, they have disadvantages as it takes time between design and delivery, they are costly and increase the chances of contamination which risk the integrity of the assays. The high concentration of DNA in plasmids does not represent the natural titer of a pathogen in plants nor their tropism in tissues. Here, we present a new approach that is cheaper than the present alternatives i.e., plasmids, RNA transcripts or synthetic oligonucleotides and are ready to use within a week including the time for designing, ordering and detection. It is feasible to work with both DNA and RNA viruses and provides an actual representation of virus titer and tropism. They can be used in routine diagnostics as well as in outbreaks, where an immediate response is of utmost importance.

DETECTION OF LATENT INFECTIONS OF APPLES CAUSED BY NEOFABRAEA SPP AND MONILINIA SPP FUNGI USING LAMP METHOD

MICHALECKA Monika. (1), PONIATOWSKA Anna. (1), PU?AWSKA Joanna. (1)

(1) The National Institute of Horticultural Research, Skierniewice, POLAND

Text

Bull's eye rot of apple (BER; caused by fungi of the genus Neofabraea: N. vagabunda, N. kienholzii, N. perennans and N. malicorticis) is considered the most important storage disease of apples, due to significant yield losses. Brown rot of apples (caused by fungi from the genus Monilinia: M. fructicola, M, fructigena and M polystroma) also occurs on stored apples, however, less frequently. It is considered that the fungi present at the time of harvesting hidden in apple lenticels and arrested in grow, are mainly responsible for the BER development on stored fruits. On the other hand, the causal agents of brown rot infect the apple not only via lenticels but also via microcracks in the cuticle and mechanical damage. In terms of risk assessment and prediction of the severity of mentioned diseases, it is important to assess fruit health status prior to placing them in cold storage and during storage, which is enabled by fast, sensitive, and thorough diagnostic tests based on LAMP technique.
The study aimed to develop the detection methods of the fungi causing BER and brown rot on apples in infected but yet-asymptomatic apple fruits. Presented here diagnostic protocols, based on the LAMP technique, enabled sensitive and specific detection of fungal pathogens responsible for the development of bull's eye rot as well as brown rot in apples at an early stage of disease development. The performance of the whole diagnostic protocol: from the step of preparation of the apple peel to the step of final fungal DNA detection in mixed plant-fungal material lasted two days. At the same time the LAMP reaction itself allows for the detection in a time of 35 minutes. The whole proposed procedure allowed for the evaluation of the health status of the fruit before the disease symptoms development. The sensitivity of LAMP detection in reaction with DNA from axenic Neofabraea cultures was about 4 pg/µl, while with DNA from axenic Monilinia cultures was 10 pg/µl. The sensitivity of detection of fungal DNA in the mixture with apple DNA ranged from 1,5 to 10 pg/µl for Neofabraea – specific primers sets, while 2 pg/µl for Monilinia – specific primer set. In general, preamplification followed by LAMP increased the sensitivity of target detection about 10 times. The specificity of the tested protocol in the detection of DNA of three targeted Neofabraea or Monilinia species among the DNA of various fungi occurring on apple peel was confirmed.

Text
Xanthomonas arboricola pv. corylina (formerly *Xanthomonas campestris* pv. corylina; Vauterin *et al*. 1995) is the causal agent of the bacterial blight of hazelnuts, a devastating disease of trees in plant nurseries and young orchards. Currently, there are no PCR assays to distinguish *X. arboricola* pv. corylina from all other pathovars of *X. arboricola*. A comparative genomics approach with publicly available genomes of *X. arboricola* pv. corylina was used to identify unique sequences, conserved across the genomes of the pathogen. We identified a 2,440 bp genomic region that was unique to *X. arboricola* pv. corylina and designed identification and detection systems with conventional PCR, qPCR (SYBR Green and TaqMan), and loop-mediated isothermal amplification (LAMP). All PCR assays performed on genomic DNA isolated from all eight *X. arboricola* pathovars and closely-related bacterial species confirmed the specificity of selected primers. Moreover, these assays enabled accurate and sensitive detection of *X. arboricola* pv. corylina in pure cultures and plant tissues. These new multi-platform molecular diagnostic tools may be used by plant clinics and researchers to rapidly and accurately detect and identify *X. arboricola* pv. corylina in pure cultures and in hazelnut tissues.

Text
Fungal taxonomy is in constant flux and the advent of reliable DNA barcodes has allowed to improve the accuracy of identification of cryptic species. In California, Aspergillus Vine Canker (AVC) and Sour Rot (SR) are two diseases that affect the wood and the fruit of grapevines, respectively, and their causal agents have been previously studied using morphological characters. During the last decade, the taxonomy of *Aspergillus* section *Nigri* has been revised and modified. In this study, we aimed to reassess the etiology of AVC and SR using a combination of morphological and phylogenetic analyses. Thirty-two isolates were selected based on morphological characters from 266 isolates grown on malt extract agar. Upon DNA extraction, a fragment of the calmodulin (*CaM*) gene was amplified through PCR and sequenced using the primer pair CL1/CL2A. Results revealed that isolates associated with AVC recovered from recent detections correspond to *A. tubingensis*,

whereas isolates from previous studies that were initially identified as *A. niger* and *A. carbonarius* were re-identified as *A. welwitschiae* and *A. carbonarius*. The isolates from table grapes with SR corresponded to *A. tubingensis*, *A. welwitschiae*, and *A. carbonarius*. Overall, our results indicate that *A. tubingensis* was the dominant species causing both AVC and SR, and representative isolates were able to cause disease in both wood and fruits of Red Globe grapevines.

P4.2-100

MAJOR CASSAVA DISEASES IN THE TROPICS: THREATHS TO FOOD SECURITY AND LIVELIHOODS FROM ASIA AND THE AMERICAS

CUELLAR Wilmer. (1)

(1) International Center for Tropical Agriculture, Palmira, COLOMBIA

Text

Cassava in the tropics is recognized as a prominent food security crop for poor and vulnerable communities. But its efficient growth under harsh environmental conditions is limited by re-emerging diseases occurring in distinct geographies. Cassava witches broom disease (CWBD) is spreading again in Southeast Asia (SEA), where it now has to coexist with the geminivirus Sri Lankan cassava mosaic virus (SLCMV), a recently introduction to the region. In the Americas, the center of origin of this crop, Cassava Frogskin Disease (CFSD) remains as a major constrain to cassava production in Colombia and neighbouring countries. Recent field and laboratory experiments, including high throughput DNA and siRNA sequencing, show that CFSD is associated with a unique virome, while CWBD is associated with a fungal infection, and not with phytoplasma as previously suspected. None of these diseases has been reported in Africa, where major efforts are focused on managing Cassava Brown Streak Disease caused by ipomoviruses, and Cassava Mosaic Disease, caused by a different set of geminiviruses. Neither CWBD nor CFSD re-emergence is completely unexpected, they are known to occur for over 15 and 30 years, respectively. However there is still limited knowledge on its biology which affects its local management and increase the risk of its distribution to new areas. Strenghtening existing regional research networks to tackle re-emerging disease threats is needed to implement pre-emptive responses

PREVENTING A WORLD WITHOUT ROSES: RT-LAMP TARGETING GENE-FRAGMENTS OF ROSE ROSETTE VIRUS

SALAZAR Andrea. (1), GOMES RUSCHEL Rafaela. (1), **OCHOA-CORONA Francisco. (1)**, OLSON Jennifer. (1), BABU Binoy. (2), PARET Matthews. (2)

(1) Oklahoma State University, Stillwater, UNITED STATES; (2) University of Florida, Quincy, UNITED STATES

Text

Rose rosette virus (RRV) is a negative-sense, ss-RNA virus in the genus *Emaravirus* (*Fimoviridae*) and the causal agent of rose rosette disease (RRD). RRV is

windborne and transmitted by two mite species. RRD devastated rose gardens in the USA, is reported in Canada and India, and threatens rose industries worldwide. Loop-mediated isothermal amplification (LAMP) for RRV can be implemented in quarantine labs and nurseries. Although symptoms are characteristics, early diagnosis is misleading and may appear like herbicide damage. RRD takes a long incubation time for symptoms visualization. RRV gene sequences P3 and P4 were analyzed and two sets of four LAMP primers were designed. Direct virus-capture into polypropylene-PCR tubes was used to circumvent kit-based RNA extraction. RT-LAMPs take 1 hour at 64°C (RRV-P3) and 66.5ºC (RRV-P4) using either a thermocycler or portable dry bath. A synthetic artificial positive control (APC) conceived de novo concatenating sense and anti-sense primers created a plasmid positive control for use with most RRV and eriophyid mites reported primers. RRV was detected in symptomatic and non-symptomatic RRD tissue from Oklahoma. The limit of detection (LoD) was 1pg/µL and 1 fg/µL using Bst 2.0 LAMP and GspSSD LD qLAMP. The LoD was 10 pg/µL and 0.1 pg/µL using hydroxy naphthol blue (120 µM) and SYBR green I (1:10 dilution), respectively. No cross-reactivity was detected in the RT-LAMP reactions.

P4.2-102

DEVELOPMENT OF A REAL-TIME PCR FOR THE DETECTION AND QUANTIFICATION OF FUSARIUM EQUISETI INOCULUM IN SOIL FROM LETTUCE FIELDS

TZIROS George T.. (1), SAMARAS Anastasios. (1), KARAOGLANIDIS George S.. (1)

(1) Aristotle University of Thessaloniki, Thessaloniki, GREECE

Text
In this study, an emerging foliar disease observed in commercial lettuce farms has been associated to the pathogen *Fusarium equiseti*, a member of the *Fusarium incarnatum-equiseti* species complex (FIESC). Thirty *F. equiseti* isolates obtained from symptomatic lettuce plants were identified based on morphology and evaluated for their pathogenicity. The isolates were further characterized using amplification and sequence analysis of the internal transcribed region (ITS-rDNA), and of the translation elongation factor 1-alpha (*TEF1-a*), calmodulin (*CAM*), beta-tubulin (*Bt*), and small subunit (*SSU*) genes. Moreover, a novel RT-qPCR assay was developed, designing a primer pair and a probe based on the *TEF1-a* sequences. This assay showed high specificity, amplifying *F. equiseti* DNA samples, while no amplification product was observed from samples of other common soilborne fungi. The generated RT-qPCR assay could be a useful tool for the detection and quantification of *F. equiseti* in soil samples deriving from fields cultivated with lettuce and other leafy vegetables, hosts of this specific pathogen. The emergence of the specific fungus on new plant hosts could be associated with environmental changes. In addition, *F. equiseti* could be transmitted by seeds of several leafy vegetable hosts, such as wild rocket. This epidemiological aspect along with the climate change scenario, could constitute a potential cause for the outbreak of *F. equiseti* on leafy vegetables.

P4.2-103

A TAQMAN-BASED MULTIPLEX REAL-TIME RT-QPCR FOR THE SIMULTANEOUS DETECTION OF BOTRYOSPHAERIACEAE SPECIES IN WOODY CROPS

ROMERO-CUADRADO Laura. (1), FERNÁNDEZ Ana. (2), **CAPOTE Nieves. (1)**

(1) Andalusian Institute of Agricultural and Fisheries Research and Training (IFAPA), Alcalá Del Río, Seville, SPAIN; (2) Universidad Pablo Olavide, Seville, SPAIN

Text

Botryosphaeria dieback is a fungal disease that is increasingly threatening woody crops worldwide. To develop a simple, rapid, accurate, and high-throughput detection method for diagnosis and quantification of Botryosphaeriaceae species, specific primers and probes were designed based on the translation elongation factor 1 alpha (tef) and B tubulin (tub2) genes. A TaqMan-probe-based multiplex real-time RT-qPCR assay was developed, optimized and validated to simultaneously detect Neofusicoccum parvum, Botryosphaeria dothidea and any species of the Botryosphaeriaceae family. Performance of multiplex and singleplex qPCR were compared. The results showed that the limit of detection can reach as low as 10 fg of genomic fungal DNA in simplex and multiplex real-time RT-qPCR assay, with high correlation coefficients (R2) and amplification efficiencies between 90 and 120%. This multiplex real-time RT-qPCR assay demonstrated high sensitivity, specificity, and repeatability and provides a rapid, accurate and easy-to-use tool for detection and quantification of Botryosphaeriaceae fungi. The high sensitivity of this qPCR assay allows the detection of Botryosphaeriaceae fungi in plant material even before the appearance of symptoms. Therefore, this powerful diagnostic tool could be applied for the preventive detection of Botryosphaeriaceae fungi in nursery plant material or recently planted young trees, avoiding he introduction and dispersion of these pathogens in production fields

Emerging Phytophthora's: Tackling Global Outbreaks that Impact Food security

C8.2-1

PREDICTING FUTURE PHYTOPHTHORA OUTBREAKS: NEW TOOLS TO IDENTIFY EMERGING LINEAGES AND TRACK SPREAD

RISTAINO Jean. (1)

(1) NC State University, Raleigh, UNITED STATES

Text

The risk of introduction of pathogens into the US with trade requires continued surveillance and improved diagnostic capabilities at our borders. *Phytophthora infestans*, the causal agent of potato late blight was responsible for the Irish potato famine and is still a threat to

food security globally. A disease surveillance and mapping system called USAblight.org has been operative since 2011 to report disease and alert stakeholders; SSR genotyping and sequence based approaches have been used to track spread of modern and historic lineages (FAM-1) of the pathogen and now targeted amplicon sequencing is under development to monitor emergence of new lineages. We have also developed LAMP assays deployed on smart phones and a phone APP for rapid in field detection of emerging species and lineages of *Phytophthora*. A a tree based complete phylogeny of *Phytophthora* has been released as a community tool for identification and phylogenetic tracking of SSR lineages of *P. infestans* and emergent new *Phytophthora* species. All these tools will help us respond to and mitigate outbreaks, improve deployment of host resistance and inform policy.

Text

Biosecurity protocols are based on listed threats to plant health but monitoring is increasing our awareness of a potential reservoir of novel undescribed *Phytophthora* taxa. We need to understand the range and spread of known and unknown *Phytophthora* taxa to protect both food production and plant health in natural ecosystems. We have combined in situ filtration, a generic rDNA ITS1-based PCR test and high-throughput sequencing technology to explore the diversity of plant pathogenic oomycetes in environmental DNA (eDNA) samples. We discuss current applications of this metabarcoding to the study of *Phytophthora* and downy mildew diversity in natural and plant production systems. The method is proving valuable but technical challenges and questions remain. Validation of the downstream computational biology pipeline to process the data while accessing a robust database of contemporary reference sequences is critical. We also report on the crucial role that internal synthetic sequence controls play in the interpretation of metabarcode data and explore the options for other barcodes to improve those based on rDNA ITS.

MULTIVARIATE BAYESIAN ANALYSIS TO PREDICT INVASIVENESS OF PHYTOPHTHORA PATHOGENS

BURGESS Treena. (1), SCOTT Peter. (1,2), MARCOT Bruce. (3)

(1) Murdoch University, Perth, AUSTRALIA; (2) Department of Primary Industries and Regional Development, Perth, AUSTRALIA; (3) USDA Forest Service, Pacific Northwest Research Station, Portland, UNITED STATES

Text
Global concerns are many for the invasive impacts of Phytophthora pathogens on native vegetation, agriculture, nurseries and urban parks and gardens. We compiled a database of 32 traits on 204 species of Phytophthora including data on each species' taxonomy (clade and subclade), historical knowledge (years since first described), impacted ecosystems, micro-environments inhabited, dispersal mode, physiology, and morphology. Drawing from approximately 11 394 unique host, pathogen, and country plant disease records from Genbank and other sources, we calculated potential invasiveness of 103 better-studied species from cluster relationships. We used the species data to create a Bayesian network model predicting the degree and probability of invasiveness of individual Phytophthora species. Model calibration testing resulted in <1% error rate in classifying invasiveness categories of well-known species. We applied the model to predicting potential invasiveness of 101 other species with unknown invasiveness dynamics. The model can also be used to predict the invasive risk of other poorly-studied and newly-identified Phytophthora species, and the general modeling approach can be used for other pests and pathogens, to advise land and resource managers to thwart potential invasions before they occur or intensify.

C8.2-4

IMPLICATIONS OF HOST RANGE AND THERMAL RESPONSE EVOLUTION FOR EMERGENCE OF PLANT PATHOGENIC PHYTOPHTHORA SPECIES

BEBBER Daniel. (1), CHALONER Thomas. (1), GURR Sarah. (1)

(1) University of Exeter, Exeter, UNITED KINGDOM

Text
We investigated the evolution of temperature response and host range in the genus Phytophthora to determine which, if either, niche axis is under stronger phylogenetic constraint and thus more likely to control geographical distributions. We found a small but statistically significant phylogenetic signal in temperature relations for Phytophthora species. While closely related Phytophthora species had more similar thermal physiology than random pairs, in all but one case differences were greater than that expected under a Brownian motion evolutionary model. Apparent latitudinal range shifts of plant pathogens in response to global warming suggest niche conservatism rather than adaptation to new climates in situ. Our analysis suggests limited phylogenetic constraint in temperature niche evolution in Phytophthora. Host jumps (to a host phylogenetically distant host) and transitions from specialist to generalist or vice versa are known in plant pathogens, suggesting that host range could be more evolutionarily labile than temperature physiology. We found a small but statistically significant co-phylogenetic association between the topologies of three Phytophthora phylogenies and the phylogeny of their plant hosts using Procrustean super-imposition. Taken together, our results show that both the thermal niche and host ranges are evolutionarily labile within genus Phytophthora, but retain weak phylogenetic signal.

Text

Plant diseases emerge ever more frequently as global trade connections diversify and climate and land-use changes alter the environmental context for plant-pathogen interactions. Phytophthora are oomycete pathogens impacting diverse hosts in ornamental, agricultural and forestry sectors and threatening urban and natural, highly valued, ecosystems. We examine the use of biological traits and phylogeny to inform global horizon-scanning for future threats from Phytophthora. We use a species-level trait database and phylogeny for 203 Phytophthora species to develop risk frameworks for pathogens' successful transport, presence in nurseries, establishment in the wider environment and interactions with hosts to promote targeted surveillance of higher risk pathogens, hosts and locations. Phytophthoras with a broader thermal tolerance range are more likely to be introduced globally. Species with multiple dormant survival structures, (potentially facilitating asymptomatic infections) may also spread more easily through global trade networks. Species with similar traits and/or phylogenetic proximity to known high-impact species may be expected to behave similarly. These risk frameworks are currently limited by incomplete and biased recording globally, but fostering international and cross-sectoral collaborations has significant potential to capture more complete data on the host ranges and niche breadths of pathogens and improve the transferability of predictions to novel pathogens.

C8.2-6

INVESTIGATING THE RISK FROM PHYTOPHTHORA IN PLANT NURSERY GREEN WASTE

SCHIFFER-FORSYTH Kadiatou. (1,2), FREDERICKSON-MATIKA Debbie. (1), GREEN Sarah. (1)

(1) Forest Research, Roslin, UNITED KINGDOM; (2) The University of Edinburgh, Edinburgh, UNITED KINGDOM

Text

Phytophthora is a genus of destructive plant pathogens. Novel introduced species are increasingly causing damage to native ecosystems, forestry and horticulture sectors. There is evidence that some species have arrived in the UK through the trade in live plants. Central nodes of the plant trade are horticultural nurseries and it was hypothesised that green waste and spent growing media disposal sites in nurseries could act as a reservoir and conduit facilitating *Phytophthora* spread into nursery stock as well as the wider environment. This

project identified *Phytophthora* species associated with waste disposal sites at three Scottish plant nurseries by sampling waste piles, water run-off from waste piles and roots from discarded plants. *Phytophthora* species were identified using a traditional baiting method where the organism is baited into live culture, as well as metabarcode sequencing of sample DNA. Eighteen *Phytophthora* species were found, including the highly damaging species *P. ramorum* and *P. austrocedri*. Plant nursery green waste was shown to harbour highly diverse and varied *Phytophthora* species assemblages, and differences between the three nursery sites appeared linked to their different approaches to biosecurity. Results suggest that the improved management of waste from the horticultural sector, for example through effective on-site composting, is essential to reduce the risk of *Phytophthora* pathogens spreading from nurseries into the wider environment.

IMPACT OF CLIMATIC FACTORS ON GROWTH AND DEVELOPMENT OF PHYTOPHTHORA INFESTANS CAUSING POTATO LATE BLIGHT IN MAURITIUS

TAKOOREE Sandhya Devi. (1), NEETOO Hudaa. (1), RANGHOO-SANMUKHIYA Vijayanti Mala . (1), HOSENALLY Muzzammil. (1)

(1) University of Mauritius, Moka, MAURITIUS

Text

Potatoes are considered as one of the most economically important non-sugar food crops in Mauritius but they are affected by many pathogens; Late Blight (LB) being a greater threat. The aim was to study the prevalence of LB based on weather factors and to identify the causative agent of LB. A disease surveillance of potato plantations was conducted in potato fields over a two-year study period. Disease Incidence (DI) of LB, was estimated in different potato fields. Infected leaf samples with LB symptoms were identified by microscopy, culturing and molecular methods. Equally, a predictive model was developed using multi-stepwise regression analysis based on DI of LB and weather data. To characterize the growth kinetics, the isolates were grown on Pea Sucrose Agar plates, incubated at five different temperatures and relative humidity conditions up to 10 days in climate-controlled chambers. Results revealed mean DI for LB was 26.95% and the causative agent was confirmed to be *Phytophthora infestans*. LB was significantly influenced by weather factors temperature, rainfall, wind speed and relative humidity ($R2 = 0.27$, $P < 0.05$). Controlled chamber studies indicated that a temperature of 20ºC (*Gr* = [6.30 ± 0.498] mm/day) and a relative humidity of 86% (*Gr* = [8.42 ± 1.770] mm/day) were most favorable for the growth of *P. infestans*. We can infer that LB incidence was strongly dependent on weather conditions in Mauritius that can compromise the yield of this important commodity.

Text

The active management of *Phytophthora* (Oomycetes) in commercial nurseries represents a priority for the biosecurity of traded plants. Furthermore, the constant monitoring of the incidence of this important plant pathogen is a crucial prerequisite to prevent its spread in the nearby environment.
For this purpose, potted plants showing Phytophthora spp. symptoms were selected and sampled, together with irrigation and runoff water from one commercial nursery in Tuscany during autumn and spring season. The samples were processed to detect *Phytophthora* species using baiting technique and molecular identification of the isolated colonies.
The results showed a very high presence of the pathogen during the spring season, with eleven different *Phytophthora* species isolated from both potted plants and water, and where singular symptomatic ornamental potted plants were found to have up to four Phytophthora highly pathogenic species. The sample type ‘run-off water from the drainage canals’ showed the highest number of Phytophthora species, followed by ‘flow-through potted plants irrigation water’ and ‘puddles’ water’.
This study provided considerable evidence of the high incidence of Phytophthora in the ornamental nursery sector; highlighted how a substantial taxonomic variety of the pathogen could potentially spread in the urban environment; as well as the high likelihood of a hybridization event between two previously geographically isolated species.

P8.2-004

EVIDENCE FOR INCREASED SEXUAL REPRODUCTION OF PHYTOPHTHORA INFESTANS UNDER GLOBAL WARMING

WAHEED Abdul . (1), SHEN Lin-Lin. (1), ANDERSSON Björn . (2), ZHAN Jiasui. (2), **YANG Li-Na. (1)**

Text

The reproductive system of eukaryotic pathogens plays an important role in disease epidemiology, but how global warming may affect the reproductive system of plant pathogens is poorly understood. In our study, we analyzed oospore production of five *Phytophthora infestans* populations sampled from the same potato variety grown at different altitudes (1976-2677 m) along a single hill under five temperature regimes. We found that both the altitude, a proxy for adaptation of the pathogen to historical temperature, and the experimental temperatures affected the capacity of the pathogen to produce oospores, with the experimental temperature playing a more important role than the historical temperature. In addition, the sexual reproduction potential of *P. infestans* was positively associated with the estimated temperature breadth of the pathogen and reached the maximum at the experimental temperature of 21 ?, which is higher than the annual average temperature in many potato producing areas and the optimum temperature of asexual reproduction of the pathogen. These results suggest that sexual reproduction of *P. infestans* may occur

throughout the potato and tomato growing seasons, and that increased air temperatures associated with global warming may enhance sexual reproduction of the pathogen, which could result in an increased threat to agricultural production and highlights the need to implement new epidemiological strategies to ensure future food security.

ENDOPHYTISM, AN EVOLUTIONARY GATE TO SYMBIOSES

SELOSSE Marc-André. (1), BOURCERET Amelia. (1), MINASIEWICZ Julita. (1)

(1) Muséum national d'Histoire naturelle, Paris, FRANCE

Text

An accumulating number of studies report fungi of ‘known’ ecological niche in bizarre, unexpected situations, especially thanks to molecular barcoding. This occurs in fungi forming mycorrhizal symbioses with the roots of Ericaceae, orchids or forest trees: they also colonize various other plant species that are not their mycorrhizal hosts as endophytes. (Endophytism is a symptomless, loose colonization without morphological differentiation nor tight dependence on the plant side). Based on our research, we provide direct and indirect evidence, both morphological and functional, for root endophytic abilities in fungi mycorrhizal on trees, including Tuber spp., but also Sebacinales or Russulales. Similarly, fungi that are characterized as plant parasites from symptomless endophytism in non-host species.
We propose here an evolutionary interpretation of such dual niche: the evolution of tight interactions with plant (symbiosis, parasitism) through a pathway called the ‘waiting room hypothesis’. Root endophytism may act as a symbiotic ‘waiting room’, where loose biotrophic coexistence predisposes evolution towards tighter interactions, with more complex morphologies and host adaptations. Some fungal taxa, now mycorrhizal or parasitic, also retain their ancestral endophytic habit. We will illustrate this on the evolution of the orchid mycorrhizal symbioses.
To conclude, fungal ecological niches are largely postulated by mycologist, and as such, not reliably realistic.

Text
Endophytes can affect the composition and function of the plant apoplast, for example, by triggering apoplastic immunity. The role of the plant immune system in detecting and controlling pathogens is well described; however, its effect on plant-associated endophytes is still poorly understood. Z. tritici is a fungal pathogen that colonized the apoplastic space of wheat plants. Wheat resistance and susceptibility can be mediated via gene-specific between wheat and Z. tritici. Here, we validated the apoplastic fluids as a proxy to understand the warfare between plants and microbes. Using proteomic analysis, we show that Z. tritici diminishes the photosynthetic functionality in the susceptible cultivar, while the resistant is significantly enriched in defense response-related proteins. This difference in plant immune response affects the apoplastic microbial composition. Next, we determined the tolerance of apoplastic microbes to plant-produced immune-related antimicrobial compounds. We also found several bacterial isolates showing susceptibility to antimicrobial compounds and negatively affecting the growth of Z. tritici. Finally, we analyzed the genome of antagonistic bacterial strains and found that a biosynthetic gene cluster associated with fungal growth inhibition is under positive selection. Our findings highlight the potential of a multi-omics approach targeting the outcomes of complex plant defense compounds and microbial-microbial interactions in apoplastic fluids.

RELATIONSHIP BETWEEN FUNGAL ENDOPHYTES AND PLANT DISEASE

JENSEN Birgit. (1), COLLINGE David Brian. (1), JØRGENSEN Hans Jørgen Lyngs. (1)

(1) University of Copenhagen, Frederiksberg C, DENMARK

Text
The endophytic community of plants includes diverse fungi ranging from true endophytes (not causing disease in a specific host species) to latent pathogens. In fact, a fungus can be pathogen in one species and endophyte in another species. Both endophytes and pathogens have developed ways to circumvent recognition to the extent that the plant immune system does not hinder colonisation. However, why some organisms turn pathogenic while others develop a mutualistic or commensal endophytic relationship is poorly understood.
We have studied endophytic fungal communities in tomato and wheat using amplicon sequencing and isolation of fungi primarily for functional characterisation of their interaction with plants. Communities in symptomless plants harboured high frequencies of known pathogens. Lifestyle testing of isolated fungi confirmed the presence of both beneficial endophytes and latent pathogens, suggesting complex interactions within the microbiome, which is in equilibrium with the plant, preventing pathogens from causing disease. Inoculating plants with endophytes revealed induction of plant defence-related genes and changes in specialised metabolite composition both locally and systemically. This may be key for keeping pathogenic organisms in check.

FROM FIELD TO MICROBIAL LANDSCAPES: IMPACT OF SUSTAINABLE PRACTICES IN MICROBIAL COMMUNITY IN A CORN-SOYBEAN ROTATION SYSTEM

ROA Jenniffer. (1), FAN Qiurong. (1), SPURLOCK Terry. (2), ROBERTS Trenton. (1), **ROJAS Alejandro. (1)**

(1) University of Arkansas - Division of Agriculture, Fayetteville, UNITED STATES; (2) University of Arkansas System – Cooperative Extension System, Litlle Rock, UNITED STATES

Text
Cover crop rotation is a sustainable practice to improve soil fertility and enhance soil health. Cover crops are associated with increasing the diversity of microbial communities, providing a range of symbiotic relationships with the plant host. We hypothesize that beneficial microbes will prevail in the soil and be recruited by crops to enhance plant growth and mediate interactions reducing disease. To investigate this, a long-term study focused on a corn-soybean cropping system in combination with a cover crop rotation was used to determine the influence of rotations on soil health, the severity of soilborne diseases, and plant health. Five cover crop treatments: fallow, cereal, legumes, soil health recommendation (60% cereal and 40% legume), and alternation between winter cereal (before soybean) and legume (before corn). Aerial images were used to establish NDVI and one “healthy” and one “unhealthy” point were located within each strip. A combination of amplicon-based approaches characterizing fungal and bacterial communities and bioassays have been used to understand the community composition and statistically classify communities that could drive plant health toward a tolerant host. There are standing questions on the complexity of the communities and the actual mechanisms by which cover crops enhance soil health promoting plant health. Using a three-pronged approach would provide a framework to understand the role of rhizospheric/endophytic microbes on plant health.

C9.3-6

PATHOGENICITY OF ENDOPHYTIC FUSARIUM SPECIES FROM CORN PLANTS (ZEA MAYS) IN PENINSULAR MALAYSIA

Text
Endophytes are widely known as microbes that infect internal tissues of host plants for all or part of their life cycles, without causing any visible symptoms of disease. The present study was carried out to identify and investigate the pathogenicity of endophytic *Fusarium* spp.

resident of corn plants, grown on different fields in Peninsular Malaysia. Endophytic *Fusarium* spp. were identified using a combination of morphological characterization, and molecular analysis of β-tubulin and TEF-1α sequences. Endophytic *Fusarium* spp. isolated from corn plants were identified as *F. pseudocircinatum, F. verticillioides, F. andiyazi, F. sacchari, F. mangiferae, F. fujikuroi, F. proliferatum,* and *F. incarnatum.* Pathogenicity test showed that all tested endophytic fungi produced varying levels of disease symptoms on healthy corn plants. *Fusarium verticillioides* was the most pathogenic, followed by *F. fujikuroi, F. andiyazi, F. sacchari, F. proliferatum, F. mangiferae, F. pseudocircinatum* and *F. incarnatum*. The study revealed that endophytic *Fusarium* spp. in corn plants grown in Peninsular Malaysia, are able to cause serious effects on the host plants. Measures targeted at controlling corn infection by latent pathogens masking as symptomless endophytes, are required to improve plant health and preserve yield of corn plants in Malaysia and other corn-growing regions.

Text

Soil-borne oomycete and fungal pathogens, mainly Pythium, Fusarium and Monosporascus are a limiting factor to vegetable production in different countries. They have been reported to result in high mortality and yield reduction in diffrenet crops, especially cucurbits and tomatoes. Deserts of the Arabian Peninsula are characterized by their dry conditions and high temperatures that can reach 50oC. A three year study reveled the isolation of more than 250 fungal endophytes from desert plants in Oman, in the southern part of the Arabian Peninsula. A number of fungal species belonging to Talaromyces, Aspergillus, Cladosporium and Trichoderma, some of which are novel species, were found to have high efficacy in inhibiting soil-borne pathogen growth in culture. Scanning electron microscopic studies indicated the effect of the antagonists on hyphae morphology and spore production and morphology. Culture filtrates from the antagonistic fungi induced electrolyte leakage from the mycelium of the pathogenic fungi and oomycetes. GC-MS analysis of metabolites showed the presence of different antimicrobial, antifungal and plant growth promoting volatile compounds such as fatty acids, alcohols, alkenes, ketones and triterpenes. The antagonists also suppressed damping-off and vine decline diseases and imporved growth and yield of cucurbits and tomatoes. The study shows that endophytic fungi from desert plants can act as biocontrol agents against fungal and oomycete pathogens.

FUNGI ASSOCIATED WITH MACADAMIA PLANTS AT DIFFERENT GROWTH STAGES

KHAN Jahangir. (1), DRENTH André. (1), AKINSANMI Olufemi A.. (1)

(1) The University of Queensland, Brisbane, AUSTRALIA

Text
Macadamia is an Australian native tree that is grown for its edible kernel in tropical and subtropical regions worldwide. Young plants infected by fungi causing stem and leaf pathogens in the nursery may cause disease problems in commercial macadamia orchards. To investigate, we used a culture dependent approach to examine the structure and diversity of the fungal community in macadamia nursery plants at four different growth stages. Fungi isolated from roots, stems, and leaves of germinated seeds,1-3 month-old seedlings, 12-month-old non-grafted plants and 18-month-old grafted plant stages were characterised. Twenty-two fungal genera, mostly in the phylum Ascomycota were identified from the various macadamia tissues. The fungal community structure was significantly ($P < 0.05$) influenced by the growth stages and plant organs. Grafted plants had the richest fungal composition and diversity (21 fungal genera). Neopestalotiopsis, Alternaria, Collectotrichum and Neofusicoccum populations were more frequent in leaf tissues than other organs. In contrast, Diaporthe, Lasiodiplodia and Pestalotiopsis populations were dominant in stem tissue. This study revealed that fungal community richness and diversity in macadamia plants are dependent on the growth stage. Ongoing investigations would determine the pathogenicity of these fungal species in mature macadamia plantations.
Keywords: Fungal diversity, Endophyte, Ascomycota, Tree nut.

BIO-FUMIGANT PROPERTIES OF VOLATILE METABOLITES FROM ENDOPHYTES IN POST-HARVEST DISEASE MANAGEMENT

SANTRA Hiran Kanti. (1), BANERJEE Debdulal. (1)

(1) Vidyasagar University, Midnapore, INDIA

Text
Volatiles from plant-beneficial endophytic fungi is considered promising alternatives to be used in the biological control of dreadful phytopathogens, as a sustainable approach in an agroecosystem. Here, a volatile emitting endophytic fungus Diaporthe sp. CEL3 with bio-fumigation activity was isolated from leaves of the ethnomedicinal plant Chloranthus elatior Sw., collected from North-East India. Camphor odor volatiles of CEL3 inhibited eight phytopathogens in-vitro and minimised the infections of Monilinia fructicola and Penicillium digitatum, causal agents of fruit rot of cherry and orange, in VOC-exposed fruits. Rhizoctonia solani, Botrytis cinerea, Pythium ultimum, M. fructicola, and P. digitatum were maximally inhibited upto 51.5%, 55.8%, 61.9%, 87.9%, and 78.5% respectively in comparison to control by the volatiles. Another isolate CEL7 identified as Curvularia sp. synthesised antifungal metabolites (mainly phenol and imidazole derivatives) in its cell-free extracts with a MIC of 250-2000 µg mL-1. Optimum VOC emitted in a modified PDA media with wheat husk (20 g L-1). CEL3 emitted different volatiles- Trans-verbenol (32.25%), Geraniol (30.32%), Trans-ocimenol (12.90%), Mentha-4,8-diene (5.16%). They cause lethal leakage of protein and necessary intracellular molecules from fungal pathogens. Thus, CEL3 could potentially be used as a bio-fumigant to control post-harvest infections and paves opportunities for the discovery of novel antifungals.

HOW PLANT IMMUNITY SHAPES THE COEXISTENCE OF PATHOGENIC AND COMMENSAL STRAINS DURING EARLY LEAF INFECTION

LUNEAU Julien. (1), MOTTES Francesco. (1), MITRI Sara. (1), DAL CO Alma. (1)

(1) University of Lausanne, Lausanne, SWITZERLAND

Text

Crop pathogens significantly reduce agricultural production. Yet, pathogen ecology during the infection remains elusive. In particular, the determinants underlying the pathogen-microbiota-immunity interactions during early infection steps, which are critical to determine if disease will occur, are not well understood. To successfully establish infection, bacterial pathogens use the type III secretion system to repress plant immune defenses, which in turn can facilitate the growth of co-localizing non-pathogenic strains in plant tissues. However, which properties of the commensal strains or the plant tissue influence the co-existence between pathogenic and non-pathogenic strains is unclear. Here, we use single-cell time-lapse microscopy in microfluidic chambers using the Xanthomonas campestris pv. campestris phytopathogen and combine it with an individual-based model to explore the conditions leading to pathogen establishment or exclusion. We consider a simple case where a bacterial mutant lacking the type III secretion system co-infects the plant along with a pathogenic wild-type strain and ask how different fractions of pathogen-to-mutant cells, growth rates and plant tissue constraints, affect pathogen establishment. While the work is still in progress, our project will help to better understand strategies of plant pathogens in their natural ecological context.

Text

Soybean is known for being an important source of protein and for a wide range of agricultural, food, and industrial applications. However, soybeans are being affected by *Xanthomonas axonopodis* pv. *glycines* cause bacterial pustule, which results in a reduction in crop yield and quality. According to the importance of soybean, research is more essential to increase yield under biotic stresses. As part of the study, it is known that the diverse microbial communities of plants are involved in various plant stresses. We designed to study the microbial community differential depending on the infection of *X. axonopodis* pv. *glycines* and the non-infected soybean. When microbial community abundance, diversity, and similarity analysis was

performed that showed a difference between infected and non-infected soybean. In analysis except for *X. axonopodis* pv. *glycines*, it turned out that an increase in Pseudomonadaceae was observed in the infected group. Additionally, *Streptomyces bacillaris* S8, an endophyte microbiota member, was nominated as a key microbe in the healthy soybeans. It will be composited for core microbiota and applied to soybeans for verification to control *X. axonopodis* pv. *glycines*. Composition research of the soybean-associated microbiota will serve as information on the core microbes in soybeans and enable biological control against *X. axonopodis* pv. *glycines*.

Text

Fire blight has caused significant economic harm in over 50 countries since the 1870s. In response, many countries have used chemical control, such as copper-based bactericides, to manage the disease. However, these methods can lead to phytotoxicity and the development of pathogen resistance. Alternative methods, such as biological control, have been attempted, but the microbial structure analysis of the plant-microbe interactions in the ecological metabolites of apples is not well understood. In this study, we compared the bacterial community structure between healthy and unhealthy apples, identified the core taxa in healthy conditions, and analyzed twigs and leaves endosphere in healthy orchards in 9 regions in the Republic of Korea. Our findings indicate that orchards in different regions share many common taxa and functions that suppress *Erwinia amylovora*. Specifically, we observed high relative abundances of *Pseudomonas* and *Methylobacterium* in healthy orchard. Additionally, the analysis of microbiota community metabolites pathways showed 11 common pathways in healthy orchards, including fatty acid and lipid biosynthesis and amino acid biosynthesis. These results highlight the importance of understanding the ecology of pathogens for gaining a better understanding of the dissemination route of pathogens in the environment. In conclusion, metagenomics is a revolutionary field in microbial ecology that provides techniques for analysis without the need for culturing methods.

METAGENOME ANALYSIS OF BACTERIA PRESENT IN STORAGE ONION BULBS IN THE USA

IBANEZ Verushka. (1), LIAKOS Christopher. (1), DERIE Mike. (2), DU TOIT Lindsey. (2), DUTTA Bhabesh. (3), KVITKO Brian. (3), VAN DER WAALS Jacquie. (1), **COUTINHO Teresa. (1)**, LEBRE Pedro. (1)

(1) University of Pretoria, Pretoria, SOUTH AFRICA; (2) Washington State University, Mount Vernon, UNITED STATES; (3) Georgia State University, Athens, UNITED STATES

Text

Storage diseases of onions have the potential to cause serious losses. Bacterial rot is caused by a number of genera and species, with many infections involving a cohort of co-occurring pathogens rather than a single agent. Aim of this study was to undertake a functional analysis to determine their potential role in bulb rot using a metagenomics approach. The bacterial communities present in asymptomatic and symptomatic mature bulbs harvested in Georgia and Washington States were determined. DNA extracted was sequenced using Illumina MiSeq and assembled into metagenomes, from which metagenome-assembled genomes (MAGs), were identified and analysed. Seven MAGs [*Burkholderia gladioli* pv. *gladioli, Enterobacter ludwigii, Gluconacetobacter diazotrophicus, Pantoea agglomerans* (2 MAGs) and *Pseudomonas simiae* (2)] were assembled from the Washington State symptomatic bulb dataset. In the dataset collected from the symptomatic bulbs in Georgia, *Acetobacter* (2), *B. gladioli* pv. *gladioli* (3), *B. cepacia (*2) and *Rahnella* sp. (1) were assembled. With the exception of *Acetobacter*, *G. diazotrophicus* and *P. simiae*, the assembled MAGs belonged to bacteria known to cause bulb rot. Functional analysis of both the metagenomic and MAG data revealed the presence of several genes involved in thiol and oxidative stresses, T3SS and T6SS, and other pathogenicity factors. The results suggest that bacterial rot of bulbs can be caused by a diverse microbial cohort of primary and opportunistic pathogens.

Text

The study aimed to evaluate the antagonism of endophytic bacteria to the phytopathogenic fungi Claviceps purpurea and Fusarium oxysporum and the effect of bacteria associated with silica nanoparticles (SiNPs) on Paspalum notatum. For the in vitro antagonistic tests, Alcaligenes sp., Pseudomonas sp., Enterobacter sp., and Serratia sp. were plated with C. purpurea and F. oxysporum in a BDA medium. In the in vivo tests, seeds of P. notatum and Poa annua were inoculated with treatments composed of bacteria and bacteria plus F. oxysporum. Seeds submitted to the same treatments were plated in Petri dishes with 0.7% agarose, and the seedling roots were 3,3'-diaminobenzidine stained for visualization. In a different experiment, 85 nm SiNPs at 0.05 and 0.1 mg/mL concentrations were added to the bacteria culture media. Treatments were inoculated in seeds of P. notatum and subjected to the same conditions. Serratia sp. and Enterobacter sp. inhibited C. pupurea growth on the plates. In the soil experiment, Serratia sp. promoted P. notatum growth. F. oxysporum with Enterobacter sp. promoted the greatest plant growth. Seedlings inoculated with F.

oxysporum exhibited thin and fragile roots and shoots. Pseudomonas sp. promoted significant growth of P. annua. The three isolates promoted the growth of P. notatum. The highest germination and shoot dry weight were obtained with 0.1 SiNPs plus Serratia sp. and Enterobacter sp. SiNPs associated with the three bacteria increased root.

P9.3-008

CHARACTERIZATION OF ENDOPHYTIC FUNGI ON BANANA PLANTS GROWN IN SOIL FROM THE RHIZOSPHERE OF PLANTS WITH AND WITHOUT SYMPTOMS OF PANAMÁ DISEASE.

CORREA-DELGADO Raquel. (1), PEREZ PARRADO Patricia. (1), BRITO LOPEZ Patricia. (1), JAIZME VEGA Maria Del Carmen. (1), LAICH Federico. (1)

(1) INSTITUTO CANARIO DE INVESTIGACIONES AGRARIAS, San Cristóbal De La Laguna, SPAIN

Text
Endophytic fungi are microorganisms that inhabit the living internal tissues of host plants without causing any immediate and overt negative effects. Endophyte-host plant relationships have important implications for fungal biodiversity and plant health. In Canary Islands, banana crops are affected by *Fusarium oxysporum* f. sp. *cubense* (*Foc*-STR4). Therefore, knowing the diversity of endophytic fungi that share a niche with the pathogen can provide information on the microbiome of a diseased plant. The aim was to characterise the endophytic *Trichoderma* and *Fusarium* species in banana plants. Soil rhizosphere of banana plants with and without symptoms of *Foc*-STR4 were collected in different zones of Tenerife. These soil samples were used to cultivate banana seedlings (in 3 l pots) during six months under controlled conditions. After that, plant tissues (rhizome and pseudostem) were sampled. Samples surface were sterilised and cultured on PDA medium. Isolates were identified by phylogenetic analysis of tef1 gene. It was obtained 119 isolates: 75 of *Fusarium* and 44 of *Trichoderma*. Eleven endophytic *Fusarium* species were identified: *F. veterinarium, F. languescens, F. gossypinum, F. tardicrescens, F. solani, F. phialophorum, F. nirenbergiae, F. inflexum, F. contaminatum, F. foetens* and *F. annulatum*. In relation to *Trichoderma* endophyte, eight species were identified: *T. harzianum, T. virens, T. hamatum, T. gamsii, T. atrobrunneum, T. koningii, T. atroviride* and *T. cf. harzianum.*

FIGHTING FUNGI WITH FUNGI: THE BIOCONTROL POTENTIAL OF TRICHODERMA AGAINST ARMILLARIA ROOT ROT

MILLEN Morgan. (1,2), DRAKULIC Jassy. (2), CROMEY M. (2), FOSTER Gd. (1), BAILEY Am. (1)

(1) University of Bristol, Bristol, UNITED KINGDOM; (2) Royal Horticultural Society, Wisley, UNITED KINGDOM

Text
Armillaria root rot (ARR) is a major fungal plant pathogen which spreads through soil and

attacks the roots of plants. There are currently no chemical controls available and the possibility of utilizing biocontrol agents against ARR is lacking in the scientific literature. *Trichoderma* are commonly considered for the biocontrol of plant pathogens, as many species are endophytic, produce an array of lytic enzymes, and directly attack other fungi. We previously isolated a collection of 42 root endophytic *Trichoderma* isolates across 12 species and these have been tested in plate-based studies and evaluated for protective potential against ARR *in planta*. Two isolates of *Trichoderma atrobrunneum* have shown strong potential to prevent disease in strawberry and privet plants. My current work investigates how *Trichoderma* is able provide control against ARR through the production of extracellular enzymes and volatiles. This presentation will highlight how *Trichoderma* is altering the rhizosphere to the detriment of *Armillaria*, whether effective control of *Armillaria* is feasible, and further characterisation of the promising *T. atrobrunneum* isolates.

P9.3-010

DIVERSITY OF ENDOPHYTIC FUNGI ASSOCIATED WITH CITRUS SPECIES IN INDIA AND THEIR BIOCONTROL POTENTIAL AGAINST PHYTOPHTHORA ROOT ROT DISEASE

DAS Ashis Kumar. (1)

(1) ICAR- Central Citrus Research Institute, Nagpur, INDIA

Text

Endophytic fungi were isolated from tissues of various commercial citrus cultivars grown in India. A total of 152 endophytic fungal isolates were obtained from 527 segments (262 root, 159 bark and 106 leaf tissue segments). Based on their morphological characteristics, the isolates were preliminarily grouped to 60 morphotypes and finally identified by ITS sequence analysis into 52 species belonging to 14 orders of Ascomycota (Hypocreales, Microscales, Sordariales, Glomerellales, Diaportheales, Trichosphaeriales, Xylariales, Botryosphaeriales, Saccharomycetales, Pleosporales, Eurotiales, Capnodiales, Patillariales and Bezeromycetales) and 2 orders of Basidiomycota (Cantharellales and Agaricales). The species composition was highly diversified with Simpson's diversity index figuring 0.932. Phylogenetic analyses confirmed their species identity and evolutionary processes. The most frequent species found associated were belonging to the genera *Fusarium, Colletotrichum, Daldinia* and *Hypoxylon*. The fungal endophytes were tested for anti-oomycete activity against *Phytophthora nicotianae* by in vitro dual culture assay and in vivo pot experiments. Isolates CFE 109 (*Chaetomium globosum*) and CFE-142 (*Aspergillus terreus*) were found very effective. Overall these results suggest that *Citrus* spp. in India harbors diversified endophytic fungi, which could be exploited as sources of potential biocontrol agents against *P. nicotianae* causing root rot and decline of citrus plantation.

Text

Different diseases affect the banana crop in the subtropical areas, among which Panamá disease stands out for its severity. In Canary Islands (Spain) the subtropical race 4 (*Foc*-STR4) has been described, however, this information is not known in detail in Madeira. For this reason, a preliminary sampling was carried out in banana plantations affected by the disease. The aims of this work were to determine the *Foc* race that causes Panamá disease and to characterize the community of cultivable *Fusarium* endophytes. In each farm, pseudostem and rhizome samples were collected from symptomatic and healthy plants. Each sample was processed in two ways: a) DNA extraction from plant material, and b) PDA culture to isolate the fungal colonies with *Fusarium* morphology. From the plant tissue DNA extractions, we performed: a) conventional PCR using race-specific primers based on the secreted in xylem gene effectors, and b) real-time PCR based on the intergenic spacer. The results showed that all the plants with symptoms (15) were positive for the subtropical race 4 of *Foc* (STR4) and negative for the tropical race 4 (TR4), while the pathogen was not detected in healthy plants. Culture on PDA confirmed these results, since the predominant species in all symptomatic plants was identified as *F. phialophorum* (*Foc*-STR4) by sequencing the *tef1* gene. Likewise, five other endophytic *Fusarium* species were detected in the plants with symptoms, while no *Fusarium* was isolated from the healthy ones.

Text

Microalgae are well-known biofertilizers to various crops, known to contain high contents of fatty acids, protein, steroids, carotenoids, and other nutrients. Despite the observed plant growth-promoting activity of microalgae in crops, research on the mechanisms of this efficacy remains scarce. This study aimed to investigate the plant growth-promoting activity of microalgae from a microbiota level using *Chlorella fusca* CHK0059 to strawberry as a model strain. This type of microalgae is known to promote plant growth and exhibit resistance to *Fusarium oxysporum* f. sp. *fragariae*. This study results showed that Chlorella treatment led to increased leaves and shoot weights compared to untreated samples. Although the beta diversity was not significantly different between treated and untreated samples, the richness

of the treated root endosphere was decreased. In the rhizosphere, specific bacteria seemed to be correlated with Chlorella that had phosphate solubilizing activity to promote plant growth. The study also showed that the concentration of plant-available P (phosphate) in the strawberry pulp was higher in the Chlorella-treated samples. Overall, this study suggests that microalgae have the ability to change alpha diversity and stimulate specific microorganisms in the rhizosphere to promote plant growth.

Text

In viticulture and oenology, the *terroir* concept is widely used to explain differences among wines. The concept itself partly is based on spatial differences in edaphic and mesoclimatic factors. These environmental differences likely affect plant-associated microbes also, with implications for plant health. In this study, we compared the compositional dynamics of plant pathogenic fungi in three different microhabitats: soil, woody tissue, and bark of grapevine cv. *Furmint*, sampled in late winter and summer of 2020 and 2021 in three different *terroirs* in the Tokaj wine region. Sequence data of the ITS2 region of the ribosomal DNA repeat were generated by Illumina NovaSeq. Of the 123 plant pathogenic genera found, *Diplodia*, *Phaeomoniella*, and *Fusarium* showed the highest richness in bark, wood, and soil, respectively. Both richness and abundance differed significantly among microhabitats, with plant pathogenic fungi known to cause grapevine trunk diseases (GTDs) showing highest richness and abundance in wood and bark samples, and non-GTD pathogens dominating soil. We found significant compositional differences among *terroirs*, season, and vintage, with *terroir* explaining 14.5-24.7%, season 1.8-2.98%, and vintage 3.7-6.4% of the variance in community composition. Some of the observed differences likely are caused by environmental filtering both at microhabitat and *terroir* levels, while weather and fungicide applications may explain the observed temporal dynamics of fungi.

Text

Plant health is highly dependent on plant-associated microbes and despite recent advances, we still lack a systematic overview of how the fungal grapevine microbiome is influenced by cultivation methods. In this study, we compared the diversity and composition of plant pathogenic fungal communities in grapevine leaves under organic and conventional management. We hypothesized that the differences in fungicides used in conventional and organic vineyards would have a significant impact on the diversity and composition of the leaf-associated fungal community. We generated DNA metabarcoding data of the cultivar *Bianca* collected throughout the growing season at the experimental vineyard of the Eszterházy Károly Catholic University, Hungary. The rarefied dataset contained 911 amplicon sequence variants (ASVs) of plant pathogenic fungi, representing 88 genera. *Phaemoniella* showed the highest richness, followed by *Alternaria*, *Epicoccum* and *Diplodia*. Differences in richness and composition did not differ significantly between organic and conventionally managed grapevines, but significant changes were apparent among months, explaining the greatest compositional variation. We found that this strong temporal turnover likely is caused partly by the application dates of different fungicides and possible differences in sensitivity among fungal species, particularly in mid-summer, and partly by seasonality, i.e. leaf maturation and the gradual onset of senescence by September.

P9.3-015

EXPLORING THE MICROBIAL CONNECTIONS BETWEEN GRAPEVINE AND NEARBY WILD AND CULTIVATED WOODY ROSACEAE SPECIES IN EGER WINE REGION IN HUNGARY

Text

Grapevine (Vitis vinifera) is one of the major fruit crops worldwide and is naturally colonized by commensal, beneficial or pathogenic microorganisms that influence grapevine health. However, the composition of the microbial community in leaves and trunk parts has been less studied than in soil and roots. In addition, relationships between the microbiomes of different cultivated plant species and environmental microbial reservoirs in nearby vegetation are scarcely known.

In this study, we focus on shared endophytic fungi between grapevine and nearby cultivated or naturally occurring woody Rosaceae species at a landscape level. We generated and analyzed DNA metabarcoding data to assess the compositional overlap of leaf- and wood-associated fungi associated with grapevine, apricot (Prunus armeniaca), pear (Pyrus communis), dogrose (Rosa canina) and blackthorn (Prunus spinosus).

We found that both sampling source (leaf vs. wood) and host identity had strong influence on fungal community composition, explaining ca. 20% and 26.6% of compositional variance, respectively. The observed compositional overlap among grapevine and wild and cultivated Rosaceae fruit species living near vineyards suggests that a landscape-level approach is

needed to better understand the microbiomes of grapevine and fruit trees, with implications for integrated crop protection.

Text

Improving our knowledge on biotic and abiotic factors that influence the composition of the grapevine mycobiome is of great agricultural significance, due to potential effects on plant health, productivity, and wine characteristics. We assessed the influence of scion cultivar on the mycobiome diversity and composition in berries and leaves by generating DNA metabarcoding data from three different cultivars and explore correlation with chemical and physiological parameters of the leaves sampled. Fungal communities in leaves and berries show contrasting patterns among cultivars. Richness and relative abundance of fungal functional groups statistically differed among berry and leaf samples, but less so among cultivars. Community composition of the dominant functional groups of fungi, i.e., plant pathogens in leaves and saprotrophs in berries, differed significantly among cultivars. We also detected cultivar-level differences in the macro- and microelement content of the leaves, and in acidity and sugar concentration of berries. We found significant correlation between mycobiome composition and measured differences in chemical composition and physiological traits of leaves which merits further research to explore causality. Our findings suggest that a relatively diverse set of fungi make up the grapevine mycobiome, spanning several cultivars at the sampled terroir, and that both berry and leaf mycobiomes are influenced by the chemical characteristics of berries and leaves.

RELATIONSHIP BETWEEN FUNGAL ENDOPHYTES AND PLANT DISEASE?

JENSEN Birgit. (1), COLLINGE David Brian. (1), JØRGENSEN Hans Jørgen Lyngs. (1)

(1) University of Copenhagen, Frederiksberg C, DENMARK

Text
The endophytic community of plants includes diverse fungi ranging from true endophytes (not causing disease in a specific host species) to latent pathogens. In fact, a fungus can be pathogen in one species and endophyte in another species. Both endophytes and pathogens have developed ways to circumvent recognition to the extent that the plant immune system does not hinder colonisation. However, why some organisms turn pathogenic while others develop a mutualistic or commensal endophytic relationship is poorly understood. We have studied endophytic fungal communities in tomato and wheat using amplicon sequencing and isolation of fungi primarily for functional characterisation of their interaction with plants. Communities in symptomless plants harboured high frequencies of known pathogens. Lifestyle testing of isolated fungi confirmed the presence of both beneficial endophytes and latent pathogens, suggesting complex interactions within the microbiome, which is in equilibrium with the plant, preventing pathogens from causing disease. Inoculating plants with endophytes revealed induction of plant defence-related genes and changes in specialised metabolite composition both locally and systemically. This may be key for keeping pathogenic organisms in check.

Text
Grapevine is an important plant cultivated in more than 80 countries worldwide. Our knowledge on to what extent environmental factors influence grapevine microbiome and how the microbiome of „healthy" (asymptomatic) and diseased plants differ is scarcely known. In this study, we characterized the mycobiome of grapevines affected by the Esca type of grapevine trunk disease (GTD) and that of asymptomatic individuals. We tested the influence of cultivar, season, vintage and microhabitats (isolation sources) on the mycobiome. DNA metabarcoding data were generated from bark, soil and wood from four different cultivars collected in four sampling times, February and August of 2020 and 2021 each. The strongest driver of mycobiome was microhabitat, explaining 4,2% of the variaton in community composition. Wood decomposers and plant pathogenic genera associated with GTDs mainly occurred in bark and wood, mycoparasites were mostly found in bark, while non-GTD pathogens, soil and litter saprotrophs dominated soil. Abundance and richness values differed across microhabitats but not among health states. Season and cultivar did not affect the mycobiome significantly. Richness values of 2021 were lower in case of plant pathogens, wood saprotrophs and mycoparasites, probably due to the drier vintage. This suggest that

environmental factors could be particularly important shaping the mycobiome of grapevine, and studies are needed to investigate the effect of abiotic conditions on mycobiome.

Text

Botryosphaeriaceae (Bot) fungi include pathogens of woody plants, that can cause cankers, diebacks and postharvest diseases, but they are also endophytes or latent pathogens. The diseases caused by fungi of this family are common to avocados in Canary Islands, where their production has reached relevance. The aims of this study were the isolation and identification of endophytes from seedlings in nurseries and from adult plants in orchards (symptomatic and asymptomatic plants), and to assess the role that they would play in the epidemiology of the diseases. Samples from 166 seedlings from nine nurseries and 18 plants from two diseased orchards were superficially disinfected and two isolation methods were use: small internal fragments plated on PDAS for fungi and extracts of internal tissue streaked on YPGA for bacteria. The ITS1-2 region and 16S gene were sequenced for the identification of fungi and bacteria, respectively. Endophytic isolates were obtained from 37.3% of the nursery plants (146 fungi and 41 bacteria) and from 50% of the field plants (125 fungi and 36 bacteria). Also tef1, tub2 and rpb2 genes were used for the molecular characterization of Bot fungi, that were isolated in 8.0% of the seedlings and 16.7% of the adult plants and identified as *Neofusicoccum cryptoaustrale*/*stellenboschiana*, *N. parvum* or *N. luteum*. Other pathogenic species of fungi and bacteria were also isolated as well as potential antagonist of the Bot pathogens of avocado plants.

Text
Persea americana a super fruit and a worldwide commercial crop is mostly affected by diseases incited by plant parasitic fungi that commonly cause important reductions in yield and quality of its fruit. Fungal pathogens are a major cause of pre-harvest infections that cause both pre- and post-harvest diseases resulting in significant crop losses. Agrochemicals have been used to manage most avocado plant diseases. However, they are being lost to the avocado industry due to EU MRL levels being reduced in many countries, including those of the EU, a major market for South African fruit exports. Therefore, there is an urgent need to find alternative that will comply with the regulations in the management of the fungal pathogens. This study was initiated to successfully isolate endophytic strains of Trichoderma spp, and evaluate in-vitro and in-vivo their abilities of controlling key fungal pathogens. Result of isolation revealed successful isolation of both fungal pathogens and strains of Trichoderma spp. The screening test indicated their endophytic properties which were tested in-vitro and in-vivo using various techniques for their pathogenicity capabilities. Some of the Trichoderma isolates were able to control the fungal pathogens during in-vitro screening (at levels of between 70 and 100%). The best strains tested for in-vivo activity on avocado fruit confirmed the potential of endophytic strains of Trichoderma spp. to control key pre-harvest infections of avocado fruit.

Text
Fusarium graminearum is one of the main pathogen of *Triticum aestivum* causing Fusarium head blight (FHB) and Fusarium crown rot (FCR), contaminating grains with mycotoxins. *Streptomyces sp*. DEF39 was previously described to be able to colonize systemically wheat plants after seed treatment and to reduce disease and deoxynivalenol contamination in grains, during field trials. Under drought stress, DEF39 induced a shortening of the life cycle in seed inoculated plants, without affecting the grain production. This work aims to study the bacteria-plant-fungus crosstalk during their tripartite interaction, deciphering the mechanism of action of the DEF39 strain. An in-vitro system was developed to assess the interactions, comparing the wheat root proteome of plants exposed to 4 treatments both in normal and drought conditions: the control plant, the DEF39 seed inoculated plant, the *F. graminearum* infected plant and the DEF39 seed inoculated infected by the fungus. The 1D GeLC-MS/MS approach allowed to quantify more than 300 proteins, of which about 90% belongs to wheat. The root proteome changed in response both to the fungus, DEF39, their interaction and water availability. The major effect was induced by the fungal infection, involving primary and redox metabolism, transport, and defence. Interestingly, the plant responses were also influenced by the seed inoculation, suggesting that Streptomyces sp. DEF39 has an effect on the plant defence mechanisms against different stress.

Text

Species in the *Botryosphaeriaceae* establish asymptomatic infections that persist for extended periods in their plant hosts. Under certain conditions, typically when the hosts are subjected to stress, these fungi cause dieback and cankers, amongst other symptoms. A number of recent genome and transcriptome studies have provided unprecedented insights into this infection and disease development process. Here we reflect on the insights from comparative genomic analyses on the genetic basis of the interactions of these fungi with their plant hosts. Our studies have shown that *Botryosphaeriaceae* genomes are enriched in carbohydrate-active enzymes (CAZymes), proteases, lipases and secondary metabolic biosynthetic gene clusters (BGCs). Some genomes in *Botryosphaeriaceae* genera, such as *Botryosphaeria*, *Macrophomina*, *Lasiodiplodia* and *Neofusicoccum*, are notably expanded for elements of the secretome such as CAZymes involved in plant cell wall degradation. The composition of the genomes with respect to secreted hydrolytic enzymes and secondary metabolite BGCs in species of the *Botryosphaeriaceae* are similar to those in necrotrophic plant pathogens and some other endophytes of woody plants. The results of these studies provide useful hypotheses to explore the mechanisms underlying *Botryosphaeriaceae* host-plant interactions.

Text

Among biotic adversities of hazelnut (*Corylus avellana* L.) bacterial canker and bacterial blight, respectively incited by *Pseudomonas avellanae* and *Xanthomonas arboricola* pv. *corylina*, represent a major threat for hazelnut farmers affecting crop yield in several production areas worldwide. Nowadays, their control is mainly based on the use of copper-based products, which have been announced to be phased out in the European Union because of undesired side effects on the environment. In the need of finding alternative

control measures following the paradigm of sustainable agriculture, the possible employment of plant-associated microorganisms is to be particularly considered. Endophytic fungi are renowned for their involvement in defensive mutualism with plants, and they are regarded as a possible tool to be exploited for disease management in semi-extensive crops. However, data so far collected with reference to their occurrence and ecological role in hazelnut are scanty. In the context of an accurate investigation concerning the endophytic mycobiome associated to both healthy and diseased hazelnut plants currently in progress in the major Italian cropping areas, the antibiotic properties of endophytic fungi isolated from secondary branches were assessed against the two bacterial species in vitro. A series of strains were selected to be further analyzed for their capacity to synthesize bioactive products, and ultimately perform an antagonistic role in planta.

Text

Xylella fastidiosa subsp. *pauca* ST53 (Xfp) is the causal agent of Olive Quick Decline Syndrome (OQDS), which has resulted in a devastating impact in Apulia (Southern Italy). Recently, several reports from Greece, Spain, and South Africa suggested a direct pathogenic activity on olive of different *Pseudophaeomoniella* spp. Considering that olive resistant genotypes appear as the most promising management strategy of OQDS, the role of these wood inhabiting fungi, and their possible correlation with OQDS severity need to be further investigated. Wood fragments were collected from susceptible and symptomatic olive trees showing a different OQDS severity, from both Xfp-infected and uninfected areas. Isolations, performed on potato dextrose agar amended with streptomycin sulfate, showed that 72% of fungal strains from discoloured wood belonged to *Pseudophaeomoniella* and 28% to other genera. Representative isolates of *Pseudophaemoniella* (n=35) and other endophytes (n=13) were molecularly identified. The multilocus phylogenetic analyses performed on *Pseudophaemoniella* isolates using ITS, LSU, TEF and ACTIN genes showed that most strains belonged to *P. oleae* (40%) and *P. oleicola* (37%), and 23% formed a separate clade not defined yet. The other fungal endophytic strains belonged to *Pleurostomophora richardsiae* and *Paraconiothyrium brasiliense* species. Pathogenicity tests on susceptible and resistant cultivars are ongoing to determine the role of each species in the etiology of OQDS.

P9.3-026

ENDOPHYTIC BACTERIA FROM OLIVE DRUPES AS PLANT DEFENCE INDUCERS AGAINST COLLETOTRICHUM ACUTATUM IN OLIVE TREE

PAPAGEORGIOU Anastasia. (1), VARVERI Maria. (1), **TSITSIGIANNIS Dimitrios. (1)**

(1) Laboratory of Plant Pathology, Department of Crop Science, Agricultural University of Athens, Athens, GREECE

Text
Olive anthracnose is one of the most important diseases affecting olives worldwide and is caused by fungi belonging to the genus *Colletotrichum*. The predominant strains are associated with *C. acutatum* and *C. gloeosporioides* species complexes. Due to the withdrawal of several fungicides and the risk of pathogen resistance, finding more sustainable control measures of the disease, such as using biological control agents and plant-resistance inducers is considered essential. Some biological agents can act as inducers of plant defense mechanisms, while they can also combine more than one mode of action, which makes them more suitable for their use in agriculture. This study aimed to evaluate antagonistic endophytic bacteria from olive drupes against *C. acutatum* for their ability to induce plant defense mechanisms. The experiments were conducted on olive trees treated with the bacterial antagonists and the pathogen. The expression of ten defense genes was evaluated by RT-qPCR. All four tested bacterial strains showed increased expression of genes associated with Pathogenesis-related proteins (*PR10, Mpol*) compared to controls, while the application of bacteria K13 (*Bacillus methylotrophicus*), B1 (*B. amyloliquefaciens*) and Π8 (*Serratia* sp.) caused increased expression of genes related to biosynthetic pathways of phenylpropanoids and salicylic acid. Finally, strain B1 also induced increased expression of the lipoxygenase (*LOX*) gene involved in the jasmonic acid biosynthetic pathway.

Text
Apple production in California reaches 5,665 ha, being the fifth largest apple-producing state in the United States. During a routine survey in 2021, branch dieback and wood cankers symptoms were observed in several apple (‘Fuji’, ‘Gala’, ‘Granny Smith’, ‘Newtown’, ‘Red Delicious’) orchards in Lodi, San Joaquin, and Santa Cruz counties in California. Symptomatic plant samples from dying twigs, and cankered branches were collected from nine commercial orchards. The most common symptoms in cross-section were light brown to brown, irregular, and hard wood necrosis. Isolations from the symptomatic tissues revealed the occurrence of *Eutypa lata* as the most prevalent species, followed by *Diplodia* spp. (*D. seriata*, *D. mutuila*), *Diaporthe* spp. (*Di. australafricana*, *Di. eres*, *Di. chamaeropis*, *Di. foeniculina*) *Cytospora parasitica*, *Kalmusia variispora*, and *Phaeocremonium* sp. Isolates were identified by morphological characters and multi-locus phylogenetic analyses using the internal transcribed spacer (ITS) region of rDNA, partial sequences of beta-tubulin and translation elongation factor 1-alpha gene regions. Pathogenicity of all isolated species was demonstrated by successfully fulfilling Koch’s postulates on wounded 2-years-old branches of 12-years-old ‘Fuji’ trees at UC Davis field station. In conclusion, *E. lata*, *Diplodia* spp., and

Diaporthe spp., were the most prevalent fungal species causing branch dieback and canker of apples in California.

SELECTION OF BACILLUS STRAINS AS POTENTIAL CANDIDATE AGAINST PATHOGENIC FUSARIUM

MASIELLO Mario. (1), TOUATI Rim. (1), SOMMA Stefania. (1), MORETTI Antonio. (1), DE BELLIS Palmira. (1)

(1) Research National Council of italy, Bari, ITALY

Text
Fusarium species are important fungal pathogens of many crops of food interest, able to synthetize harmful mycotoxins and cause worldwide Fusarium Head Blight (FHB), the most devastating disease of cereals. The disease is caused by co-occurrence of several Fusarium species, mainly F. graminearum and F. culmorum. Also the ubiquitous, toxigenic F. proliferatum has been largely isolated from cereals. Nowadays, the increasing interest to reduce chemicals in agriculture, prompts researchers to select new eco-friendly strategies. The aim of this study was the identification of antagonistic bacteria potentially suitable as bio-control agent against Fusarium species. Thirty-eight Bacillus strains, isolated from wheat and maize kernels, and belonging to Bacillus velezensis, B. amiloliquefaciens, B. subtilis, B. licheniformis, B. mojavensis, B. simplex, B. megaterium, B. oleronius, B. pumilus and B. safensis were considered. The antagonistic activity against F. graminearum, F. culmorum and F. proliferatum species, by co-colture assay, and the antimicrobial effect of bacteria filtrates were evaluated. Thirty-seven strains, including all B. velezensis and B. amyloliquefaciens strains, showed a good antagonistic activity. Deeper investigations will elucidate the molecular mechanisms involved in the synthesis of bioactive molecules of the potential candidates for biological control

Food Security for Sustainable Food Systems

CONNECTED: A COMMUNITY NETWORK FOR AFRICAN VECTOR-BORNE PLANT VIRUSES

OCKENDON-POWELL Nina. (2), BAILEY Andy. (2), HIRD Diane. (2), FOSTER Gary. (2), BOONHAM Neil. (1)

(1) Newcastle University, Newcastle Upon Tyne, UNITED KINGDOM; (2) University of Bristol, Bristol, UNITED KINGDOM

Text
The CONNECTED Network (Community Network for African Vector-Borne Plant Viruses) builds multidisciplinary research capacity to tackle crop diseases spread by insects in Sub-Saharan Africa, contributing to food security and reducing poverty. The Network brings together plant pathology and entomology research communities to tackle the complex problems of vector-borne crop diseases. The CONNECTED Network comprises 1500 members across 84 countries, this community represents a valuable resource of technical expertise and knowledge, and is a pool of potential international collaborators. CONNECTED has partnered with a range of international partners (including IITA in Nigeria and BecA-ILRI Hub in Kenya) to fund international research, provide innovative training, and run networking events primarily for early career researchers. The CONNECTED Network has funded a portfolio of 20 innovative international projects involving 14 countries, 11 different crops, and collaborations of 55 researchers in 34 institutions, each representing a new productive collaboration between UK and African institutions. The Network has delivered over 100 training opportunities awarded for multidisciplinary courses or educational visits for delegates from 18 different countries. The Network is free to join and members can access a programme of conferences, workshops, seminars and online resources, including training manuals and other educational materials.

C2.7-2

A QUANTITATIVE AND QUALITATIVE ANALYSIS OF RHIZOSPHERE MICROBIAL POPULATIONS OF MAIZE AND SOYBEAN AS INFLUENCED BY SOIL AND PLANT GENOTYPE

VENTER Karen. (1), SWART Wijnand. (1), VISSER Botma. (1), **ROTHMANN Lisa. (1)**

(1) University of the Free State, Bloemfontein, SOUTH AFRICA

Text
The importance of soil health in modern agriculture is gaining increased attention as more emphasis is placed on holistic, sustainable, and regenerative agricultural practices. The use of glyphosate tolerant (GT) crops in modern cropping systems has made a significant impact on yields and food security in modern agriculture, but the impact that these crops might have in terms of biosafety has become very concerning. The effect of GT maize and soybean on rhizosphere microbial populations was compared in soil having a high clay content (HCC) and low clay content (LCC), assessed across non-isogenic and conventional cultivars. Microbial activity in rhizosphere soil was determined by means of five biochemical techniques (active carbon, community level physiological profiling, ergosterol quantification and fluorescein diacetate hydrolysis) as well as molecular techniques (DGGE and tRFLP). No effect of the CP4-EPSPS (5-enolpyruvylshikimate-3-phosphate synthase) gene on rhizosphere microbes, either qualitatively or quantitatively, was observed. Higher microbial activity was evident in HCC than in LCC soil. Results could not confirm GT maize and soybean as a potential biosafety hazard to rhizosphere microbial activity.

Keywords: DGGE, tRFLP, Rhizobiome, Glyphosate-tolerant soybean, Glyphosate-tolerant maize, clay content sl.

C2.7-3

UNDERSTANDING THE BENEFITS OF BREEDING MAJOR FOOD CROPS FOR DURABLE RESISTANCE: A CONCEPTUAL REVIEW AND META-ANALYSIS OF EMPIRICAL EVIDENCE

GEFFERSA Abebayehu. (1), BARRETT Luke. (1), **SPRAGUE Susie. (1)**

(1) CSIRO, Canberra, AUSTRALIA

Text

A critical challenge for food security is to protect crops from damage caused by microbial pathogens. Breeding crops for disease resistance is a sustainable approach to meeting this challenge. However, pathogen adaptation, leading to the breakdown of resistance, is common and can cause damaging outbreaks of disease. While the importance of genetic, evolutionary and epidemiological factors to managing resistance breakdown are reasonably well understood, there has been little effort to understand the parallel socio-economic dimension. Consequently, incentives for individual decision-makers to invest in managing pathogen evolution are often difficult to articulate or support with solid evidence. We will present research investigating how socio-economic factors influence the management of genetic resistance and pathogen evolution. We first develop a conceptual framework that illustrates the socio-economic challenges to proactively managing resistance ineffectiveness. We extend our conceptual model with a meta-analysis of the agronomic and economic impacts of the adoption of disease-resistant crops worldwide to consolidate empirical evidence. Our assessment highlights that resistance delivers considerable economic and agronomic benefits. However, such benefits will only be fully realized if a significant effort is put into the identification of effective incentives for the adoption and uptake of resistance deployment strategies to increase resistance durability.

C2.7-5

PEARL MILLET-FUTURE FOOD FOR ASIA AND AFRICA: THE IMPORTANCE, BIOTIC CONSTRAINTS AND THEIR MANAGEMENT

NAYAKA Chandra. (1)

(1) UNIVERSITY OF MYSORE, Mysore, INDIA

Text

Millets are grown in 131 countries, and 60 million people in Asia and Africa consume millets as a traditional diet. Pearl millet (Pennisetum glaucum (L.) R. Br.) is one of the most widely grown millet and an important crop in India and Africa, extensively cultivated in arid and semi-arid regions after rice, wheat, Maize and sorghum. In terms of both production and area, India is the leading producer of pearl millet. The crop grows best in locations with poor soil fertility, droughts, extreme heat, low pH, or high salinity. The crop replaces other important cereals that are otherwise impractical to cultivate, which is crucial for the food and energy security of rural populations, especially in rain fed areas. The major biotic constraints are downy mildew and blast diseases. These diseases are one of the key challenges to boosting the grain yield potential of improved pearl millet cultivars in India and Africa. New aggressive strains of downy mildew and blast pathogens have emerged as a result of the commercialization of new hybrids in India over the past decades. For the first time, we report a de novo complete genome assembly and analysis of S.graminicola and M.grisea, one of the most virulent pathotypes from India. This research potentially contribute in deciphering

pathogen evolution and elucidating effector evolution in order to develop effective durable resistance breeding techniques in pearl millet.

C2.7-6

CHICKPEA SEED ENDOPHYTIC (BACILLUS SUBTILIS) AS EFFECTIVE PLANT GROWTH PROMOTING MICROBES TO IMPROVE CHICKPEA PRODUCTIVITY AND NUTRITIONAL QUALITY UNDER SUSTAINABLE AGRICULTURE

MUKHERJEE Arpan. (1), VERMA Jay Prakash. (1)

(1) Banaras Hindu University, Varanasi, INDIA

Text
Chickpea used as a rich source of protein and energy both in human and livestock's diets. Moreover, the chickpea foliage can serve as an alternative fodder. Our present study evaluates the effect of chickpea seed endophytes inoculation on the nutritional values in the edible parts of chickpea and productivity. The competent chickpea seed endophyte Bacillus subtilis BHUJPCS-12 was selected on the basis of plant growth promoting biochemical properties and antagonistic against soil borne phytopathogen Fusarium sp. Pot experiment was conducted with the chickpea seed to check the plant growth and development. Chickpea seeds treated with the seed endophytes showed significant increase in plant growth (20%), biomass (19.76%) and nutrients quality in chickpea seed and plant. Additionally, nutritional quantity like total protein (5%, 7%), carbohydrate (14%, 10.90%), flavonoid (33.3%, 25%), micro and macro nutrient were also found significant enhancement in seed and foliage of the endophyte treated chickpea plants as compared to the control plant. Therefore, this potential seed endophyte strains Bacillus subtilis can be used as potential plant growth promoting inoculants for enhancing plant growth, nutritional quantity and productivity of chickpea crops under sustainable agriculture. This PGPM can be further used for field demonstration for chickpea productivity. This should be cost effective, economically viable and environment friendly.

IMPROVED SHIITAKE MUSHROOM CULTIVATION IN THE NATURAL GROWING CONDITIONS FOR THE FOOD AND NUTRITIONAL SECURITY OF TRIBAL FARMERS OF INDIA

PERIASAMY Raja. (1), HITESH Doley . (2), M Mathiyazhagan. (2)

(1) COLLEGE OF HORTICULTURE AND FORESTRY, PASIGHAT, Pasighat, INDIA; (2) Silapathar Science College, Dhemaji, Assam-787059, , Dhemaji,, INDIA

Text
The shiitake mushroom is a source of protein and vitamin D for villagers and is collected in the jungle from December to April. It is consumed fresh, dried, and stored. The

collected Lentinus edodes cap varied from 3.65 to 4.87 cm, and the stalk was measured from 2.20 to 3.75 cm. We have cultured the shiitake mushroom on PDA, paddy extract, and wood extract media. The fastest growth of mycelium is seen on a wood extract of Meliosma simplicifolia. The highest mycelium growth was noticed in the Meliosma simplicifolia medium extract (30 mm), followed by Terminalia arjuna (28 mm), paddy extract medium (20 mm), and PDA medium (19 mm) in 28 days. We have produced the spawn on the paddy grain; it took 10 to 15 days for full growth. To standardize the natural and improved way of cultivation, we have used different species of logs measuring 60–90 x 5–15 cm (150–200 cubic feet) and inoculated the spawn artificially by trilling and plugging with cotton. The highest yield of shiitake mushrooms was recorded in Meliosma simplicifolia (1 kg/cm3). We have obtained the second-highest yield of 0.56 kg in Terminalia arjuna logs. The lowest yield was noticed in Terminalia bellerica, at 0.30 kg. The selling price is INR 800 per kilogram, which will provide a stable income to poor farmers and provide economic security worth $1000 per year

P2.7-002

INTEGRATED MANAGEMENT OF FINGER MILLET PRODUCTION SYSTEM IN NORTHEAST INDIA FOR FOOD SECURITY AND SUSTAINABILITY

NIROULA CHHETRY Gopal Kumar. (1,2), DHIREN Khundrakpam. (1,2)

(1) MANIPUR UNIVERSITY, Imphal(Canchipur), INDIA; (2) Manipur university, Imphal(Canchipur), INDIA

Text

Northeast India comprises of eight states accounts 7.9% of total geographical area in India,has a predominantly humid-subtropical climate that favours the cultivation of varieties of crops including finger millet but millet is grown only in certain pockets of the region.Although finger millet is largely resistant to plant diseases and pests, its yield is low, variable and unpredictable often because of damage caused by emerging fungal diseases (blast,banded blight,brown leaf spot,etc.) which were minor in the past, becoming major ones in the face of changing climatic conditions.As the crop is grown in marginal organic soil,farmers mitigate further spread of the fungal diseases using a range of traditional control options including habitat management.Finger millet is grown by subsistence farmers in the region and highly valued by traditional communities as it is nutritious in terms of micronutrients,drought tolerant,short duration and requires low input.Integrated management of the crop using trasitional knowledge system offers an efficient cost effective to increase small holder production,serve market needs and significantly improve food and nutritional security across marginal rural communities of the region.Considering the importance of millet,expansion of production system under various land use systems such as Jhum fallow land,terraced land, dry land,etc has been suggested to espoused vulnerable farmers increase food security and sustainability across northeast India.

P2.7-003

ASSESSMENT OF COMBINING MICROBIAL AGENTS AND SILICON DIOXIDE TO CONTROL STEM ROT AND SOUTHERN BLIGHT DISEASE ON KIDNEY BEAN IN TAIWAN

LIANG Ying-Ru. (1), SUNG Meng-Chen. (1), LIAO Fang-Chin. (1)

(1) Agricultural Chemicals and Toxic Substances Research Institute, Council of Agriculture, Executive Yuan, Wufong, TAIWAN

Text
Si is the second most abundant element in the earth and has not been regarded as an essential growth nutrient. It shows the effectiveness of improving crop resistance and pest control. The possible mechanism of silicon dioxide to disease resistance and stress tolerance is reported through the formation of silicon complexes in cell walls to increase the rigidity of plant tissues. The rhizosphere microorganisms improve plant disease resistance through plant growth promotion and production of antagonistic substances. The feasibility of combining SiO2 and rhizosphere microorganisms for controlling the soil-borne diseases of kidney beans was conducted. Our preliminary results showed that the disease severities caused by Pythium myriotylum after applying conventional chemicals and Bacillus siamensis CB36 + SiO2 on kidney beans were 32.0% and 4.0%, respectively; while the disease severities caused by Sclerotium rolfsii after applying conventional chemicals and B. siamensis CB36 + SiO2 on kidney beans were 83.0% and 6.0%, respectively. Otherwise, the soil microbiomes were analyzed and the results showed that applying B. siamensis CB36 + SiO2 were different from other treatments. It is obviously that B. siamensis CB36 + SiO2 treatment showed the best control effects against both stem rot and southern blight of kindey bean. Therefore, the management strategy of combination of B. siamensis CB36 + SiO2 is a potential combination for controlling soil-borne diseases of kidney bean.

Forest pathogenic fungi interacting with insect pests: research fronts and perspectives

C9.5-1

A PHYLOGENETIC EPIDEMIOLOGY APPROACH TO PREDICTING THE ESTABLISHMENT OF A MULTIHOST PEST-PATHOGEN COMPLEX

LYNCH Shannon. (1), ESKALEN Akif. (2), GILBERT Gregory. (3)

(1) State University of New York College of Environmental Science and Forestry, Syracuse, UNITED STATES; (2) University of California Davis, Davis, UNITED STATES; (3) University of California Santa Cruz, Santa Cruz, UNITED STATES

Text
Decision-makers require robust and broadly applicable analytical tools to manage emergent microbial and insect pests that attack multiple host species, but current approaches built on assumptions of narrow host ranges do not address their complexity. Here, we take an evolutionary ecology approach and develop and test a new approach to modeling the establishment and spread of Fusarium dieback-invasive shot hole borers (FD-ISHB), an emergent multihost beetle-pathogen complex introduced from Southeast Asia to Southern

California, where it now affects trees in urban-wildland forests and avocado groves. To determine which locations are most vulnerable to pest establishment and impacts, we established a network of 260 0.25-ha permanent monitoring plots across a range of host communities and environmental conditions in California. We estimated the probability of an infested site based on the interaction between phylogenetic structure and host density of a local plant community (community favorability) and microclimate. Site susceptibility was strongly associated with the interaction between community favorability and microclimate-unfavorable host communities were still susceptible where microclimate supported beetle development. Microclimate had a smaller influence on site susceptibility in locations with a highly favorable host community, but sites with unfavorable host communities could be susceptible where microclimate favored beetle development.

C9.5-2

A NEW AND UNUSUALLY WIDESPREAD INFESTATION OF THE PREVIOUSLY RARE STROMA-FORMING FUNGUS CURREYA PITYOPHILA IN ASSOCIATION WITH THE ADELGID SPECIES PINEUS PINI AFFECTING PINUS SYLVESTRIS ACROSS SCOTLAND

GREEN Sarah. (1), STANISZ-MIGAL Maria. (1), TAYLOR Joanne. (2), HENDRY Steven. (1), A'HARA Stuart. (1), LESTER Katherine. (1), DAVIDSON Molly. (1), ROEHRIG Laura. (1), PURSER Ewan. (3)

(1) Forest Research, Roslin, UNITED KINGDOM; (2) Royal Botanic Gardens Edinburgh, Edinburgh, UNITED KINGDOM; (3) Scottish Forestry, Edinburgh, UNITED KINGDOM

Text
In late 2022, reports were received of canker and dieback symptoms on Scots pine (Pinus sylvestris) at various locations across Scotland. Investigations are still at an early stage, but a common factor observed at all sites is the presence of a previously rare stroma-forming fungus Curreya pityophila (syn.Cucurbidothis pityophila) infesting shoots and branches of Scots pine in an apparently symbiotic association with the adelgid species, Pineus pini. The fungus colonises the outer bark of Scots pine, frequently encircling young branches at shoot junctions but appears itself to remain superficial. Encased beneath the fungal stroma are colonies of P. pini nymphs which feed on the phloem causing necrosis of host tissues, in some cases to the cambium. Affected Scots pine also exhibits lower crown dieback and abundant older, blackened shoot and branch cankers from which the fungal pathogen Crumenulopsis sororia and various endophyte species have been isolated. The primary cause of these cankers may be P. pini in association with C. pityophila, with feeding sites subsequently colonised by canker-causing pathogens. Curreya pityophila and its association with adelgids has been described occasionally from the UK, continental Europe and north America on various conifer species since the 1800s, yet it remains obscure in the literature. We will present the results of our early research findings and discuss the possible reasons for this current, widespread outbreak in Scotland.

C9.5-3

XYLOSANDRUS SP. AND ASSOCIATED FUNGI: A HIGH-RISK SYMBIOSIS FOR NATURAL ENVIRONMENTS

MORALES-RODRIGUEZ Carmen. (1), VANNINI Andrea. (1)

(1) Tuscia University, Viterbo, ITALY

Text

Insects, like many other organisms, live in association with many fungal symbionts, which impact their host's fitness. Symbiotic fungi associated with Ambrosia beetles contribute to insect damage to the impact on invaded environments. Also providing food for the insect development stages, some of the Ambrosia beetle symbiotic fungi are severe pathogens of plant hosts. Moreover, like many insects, ambrosia beetles may carry commensalist fungi on their body. Thus, monitoring of fungi introduced through specific pathways (mostly trading of living plants), their identification and determination of pathogenicity behavior is essential to design and apply prevention and mitigation quarantine measures.
The EU LIFE project SAMFIX was launched having among the objectives to monitor the fungal population associated to three species of Xylosandrus (*X. compactus*, *X. crassiusculus* and *X. germanus*) after the invasion of the Mediterranean basin in natural areas and nurseries. The present work aims to describe and analyze the total fungal community associated and to determine their functional guild, ecology, and taxonomic position; to analyze 'new' and already recorded associations using taxonomy and lifestyle as references; finally to discuss the possible risk for an insurgence of invasive insect-fungus interactions.

C9.5-4

OPHIOSTOMATOID FUNGAL SPECIES ASSOCIATED WITH MEDITERRANEAN BARK BEETLE ORTHOTOMICUS EROSUS IN CROATIA

KOVAC Marta. (1), PERNEK Milan. (1)

(1) Croatian Forest Research Institute, Jastrebarsko, CROATIA

Text

Trees in the urbanized landscape are highly influenced by the presence of harmful insects and diseases due to anthropogenic conditions and recent climate changes which, in some cases, can change the habitat of native pests that can become therefore more aggressive. Mediterranean bark beetle *O. erosus* is native to Croatia and so far it has been considered only as a minor pest but a surprising outbreak that occurred in Forest Park Marjan, Split in 2017 had serious consequences on this important forest in the following years. *O. erosus* is associated with ophiostomatoid species that can show increased virulence and it is assumed that they help their vectors, bark beetles, to break the defensive mechanisms of the host plant. The aim of this research was the identification of ophiostomatoid fungi transmitted by *O. erosus* in different locations of the Mediterranean part of Croatia, as well as investigating possible hosts other than Aleppo pine. Isolates were obtained from *O. erosus* adults and their blue-stained galleries and sapwood and identified according to the morphological characteristics and DNA sequencing. A total of six ophiostomatoid fungi (*Ophiostoma ips*, *O. piceae*, *O. rectangulosporium*, *O. floccosum*, *Sporothrix pseudoabietina,* and *Ceratocystiopsis minuta*) were identified in the study. This is the first research of ophiostomatoid fungi associated with *O. erosus* in Croatia that gave new insight into this bark beetle-fungal symbiotic relationship and opened up a new research area.

C9.5-5

EFFECTS OF LYMANTRIA MONACHA OUTBREAKS ON FOLIAR FUNGAL COMMUNITIES AND NON-TARGET INSECTS

CESNA Vytautas. (1), LYNIKIENE Jurate. (1), MARCIULYNAS Adas. (1), GEDMINAS Arturas. (1), MARCIULYNIENE Diana. (1)

(1) Institute of Forestry, Lithuanian Research Centre for Agriculture and Forestry, Liepu Str. 1, Girionys, Kaunas Distr., LITHUANIA

Text

Pinus sylvestris L. is comparably resistant to defoliation, caused by phytophagous insects. However, abiotic factors are expected to increase the frequency of many insect pests in the future due to climate change. Historically, *Lymantria monacha* L. has been one of the major forest pests in temperate Europe, regularly reaching outbreak levels, with increasing incidence in the last decade. This study was aiming to investigate complex changes in fungal communities and actively moving insects in the outbreaks of *L. monacha* in Scots pine forests. We hypothesized that pest outbreaks cause a significant effect on the composition of fungal communities and non-target insects. To determine this, we sequenced libraries of PCR products, using fungal-specific primers on a PacBio high-throughput sequencing platform, meanwhile, insect counts were analyzed using a binocular microscope and identification keys. A comparison was made between an outbreak and a stand treated with the biological insecticide Foray76B (before damage). Preliminary results show significant structural changes in fungal communities and non-target insect species that may disrupt the normal functioning of pine forests. It is expected that detailed data analysis will provide valuable information on species changes that may significantly influence the resilience of stands in the future and will improve the selection of *L. monacha* outbreak management measures.

C9.5-6

ELMS, BEETLES, OPHIOSTOMA NOVO-ULMI AND GEOSMITHIA SPP.: A COMPLEX INTERACTION BETWEEN MAIN PLAYERS OF DUTCH ELM DISEASE

PEPORI Alessia Lucia. (1), LUCHI Nicola. (1), **PECORI Francesco. (1)**, FACCOLI Massimo. (2), SANTINI Alberto. (1)

(1) National Research Council - Institute for Sustainable Plant Protection, Sesto Fiorentino, ITALY; (2) Department of Agronomy, Food, Natural resources, Animals and Environment, University of Padua, Padova, ITALY

Text

Bark beetles of the genus Scolytus Geoffroy are the main vectors of the fungus *Ophiostoma novo-ulmi*, the pathogenic agent of Dutch elm disease (DED), a tracheomycosis that has devastated elm populations throughout Europe, North America and part of Asia. Recently it has been shown that in the DED pathosystem is also present *Geosmithia* spp., an anamorphic ascomycete genus mainly associated to phloem-feeding bark beetles. *O. novo-*

ulmi and *Geosmithia* spp., more than just occupying the same habitat and having the same vectors, are connected in a complicate association: it seems that *Geosmithia* acts as a mycoparasite towards *O. novo-ulmi.*
We used a specially developed duplex qPCR to specifically identify and quantify the presence of *O. novo-ulmi* and *Geosmithia* spp. on the insects' bodies. The beetles were collected with funnel traps, baited with a pheromone lure, at locations characterized by different stages of the DED epidemic, where Ulmus minor trees were naturally present.
The work allowed to determine the real quantity of both fungi DNA on male and female insect bodies all season round; and the ratio between the two fungi in different periods.
The results strengthen our knowledge on disease spread and the role of insect vectors, providing essential information on the life cycle of *Geosmithia* within the DED pathosystem, and provides relevant data to support the use of *Geosmithia* as a natural biocontrol agent of *O. novo-ulmi*.

P9.5-001

THE ROLE OF MICROHABITAT CONDITIONS AND SUBSTRATE QUALITY ON DIVERSITY AND COMPOSITION OF INVERTEBRATES INHABITING HETEROBASIDION SPP. FRUITBODIES ON DECAYED WOOD OF PICEA ABIES

LEGZDINA Liva. (1,2), MENKIS Audrius. (4), SPUNGIS Voldemars. (2), KAGAINIS Ugis. (2,3), GAITNIEKS Talis. (1)

Text
Pathogenic fungi from the genus Heterobasidion cause root rot in conifers of temperate and boreal forests, particularly in Norway spruce (Picea abies). Heterobasidion produces conspicuous fruitbodies on infected P. abies wood, which may represent a habitat for a range of different organisms, including invertebrates. The aim of this study was to determine the invertebrate diversity and factors affecting their composition in Heterobasidion spp. fruitbodies on decayed P. abies wood. Sampling was carried out in the autumn of 2018 in three P. abies stands in Latvia. A total of 247 Heterobasidion fruitbodies and 247 decayed P. abies wood samples were collected from logging residuals of different dimensions and stages of decomposition. The collected samples of Heterobasidion fruitbodies were of different successional stages, thickness, and age. By placing these samples in Tullgren funnel traps, a total of 7198 invertebrate individuals were collected representing 13 orders. The results showed that the environmental factors significantly affecting the number of trapped invertebrates were wood diameter, fruitbody thickness, fruitbody wet weight, relative humidity. The number of trapped invertebrates increased with the increase of wood diameter, fruitbody thickness, fruitbody wet weight. Further studies are needed on interactions between invertebrates and Heterobasidion, including the study assessing the possible role of insects as vectors for Heterobasidion spores.

P9.5-003

FOREST PATHOGEN SPORES CARRIED BY INSECTS VERSUS AIRBORNE SPORES

BERUBE Jean. (1), LAROUCHE Louis-Olivier. (2), BERNIER Louis. (2), ALLISON Jeremy. (3), SWEENEY Jon. (4)

(1) Canadian Forest Service, Quebec City, CANADA; (2) Université Laval, Quebec City, CANADA; (3) Canadian Forest Service, Sault Ste Marie, CANADA; (4) Canadian Forest Service, Fredericton, CANADA

Text

Forest pathogens are infecting trees via airborne spores or carried by insect vectors, but the contribution of both pathways is not well studied. We deployed 240 black Lindgren 12-funnel traps baited with four semiochemical lures known to increase captures of several species of bark and wood boring beetles in the families Cerambycidae and Curculionidae (subfamily Scolytinae) to study spore dispersal in a forest environment. At each site, we deployed 60 baited and 60 unbaited traps (unbaited traps were also covered with a screen to block insect from entering). Total DNA was extracted from the preservative fluids collected in each collection cup, PCR amplified for fungal ITS gene and COI insect gene and sent for Illumina paired-end MyseQ sequencing. Insect traps are excellent aerial spore collectors, allowing identification of both airborne fungi and insects captured by analysis of collection cup preservative fluids. Analyses for the comparison of fungi in the preservative fluids from baited traps and screen protected traps are ongoing but will be completed and presented to determine the contribution of insect carried spores versus airborne spores.

P9.5-004

FUNGI ASSOCIATED WITH THE PINE TORTOISE SCALE TOUMEYELLA PARVICORNIS

RUSSO Elia. (2), BECCHIMANZI Andrea. (2), GARONNA Antonio Pietro. (2), ABATE Gaspare. (2), **NICOLETTI Rosario. (1,2)**

(1) Council for Agricultural Research and Economics, Caserta, ITALY; (2) Department of Agricultural Sciences, University of Naples 'Federico ii', Portici, ITALY

Text

The non-native pine tortoise scale, *Toumeyella parvicornis* (Cockerell) (Hemiptera: Coccidae), has emerged as a severe threat to pine trees in pinewoods and urban areas in Italy. Traditional chemical control measures have proven difficult due to the large size of the trees and the urban environment. Therefore, alternative management practices must be explored, with a focus on the ecological factors that influence pest population dynamics, such as manipulation of antagonistic and mutualistic microbial partners. Fungi have been found to impact the population dynamics of scale insects and other hemipterans in multiple ways. Entomopathogens may be responsible for epidemics in colonies of these insects, even if they are generally unable to stop outbreaks. Plant pathogenic fungi may weaken hosts, compromising their ability to react to pest attacks. Alternatively, scale insects may act as vehicles of pathogenic fungi or facilitate the conversion of endophytic associates into pathogens, promoting opportunistic host infection through damaged tissues. Moreover, recent studies have highlighted the potential role of fungi belonging to the Ophiocordycipitaceae as scale mutualists, stimulating further consideration about their true

impact and possible benefits of disrupting this association. In this study, we investigated *Toumeyella*-associated fungi in urban contexts of Campania and Lazio, Italy, based on both isolation on agar media and direct identification through DNA-marker sequencing.

AN AMBROSIA BEETLE RECENTLY INTRODUCED IN EUROPE SHOWS SPECIFIC ASSOCIATION WITH A YEAST FUNGUS

ROBIN Cécile. (1), FERNANDEZ-CONRADI Pilar. (3), CHANCEREL Emilie. (1), PENAUD Benjamin. (1), AUGER-ROZENBERG Marie-Anne. (2), ROQUES Alain. (2)

(1) INRAE, UMR BIOGECO, Bordeaux, FRANCE; (2) INRAE, URZF, Orléans, FRANCE; (3) INRAE, URFM, Avignon, FRANCE

Text

Ambrosia beetles are wood boring insects which can become tree killers. They are also characterized by a high invasion success rate and by symbiotic and phoretic relationships with different fungi. Together, insects and their fungal communities cause important damages to forest and agricultural ecosystems worldwide. A better preparedness to this threat requires to identify the fungal communities associated with any newly introduced ambrosia beetle and a better knowledge of tree killing mechanisms operating in such complex associations.
We aimed to determine whether the fungi associated with the insects intercepted during a monitoring program were sufficiently stable to be characterized with a culture-independent method. The insect species used for this study was *Amasa* sp. near *truncata* (Erichson). Beetles were captured by using interception traps in 2018 and 2021 in different locations France. DNA extraction was performed from the 53 *Amasa* individuals. Fungal ITS1 and ITS2 regions were amplified and library pool was sequenced on the Illumina MiSeq platform. In all Amasa samples, fungal communities showed a low richness and diversity compared. In all samples, OTUs assigned to a *Millerozyma* sp. were dominant. *Millerozyma* species belong to a yeast family frequently associated with wood-boring insects but never reported as phytopathogens. The type of relationships between this fungus and Amasa sp. near truncata needs to be investigated.

Text

A collection of isolates of the plant pathogenic fungi *Leptosphaeria maculans* and *L. biglobosa*, agents of disease on *Brassica napus* (canola) and other *Brassicaceae* species, were assembled to represent the global diversity of these pathogens and to establish an international research resource. The collection consists of 226 isolates, 205 *L. maculans* and 21 *L. biglobosa*, representing eleven countries. All 205 *L. maculans* isolates had their genomes sequenced and were characterized for the distribution of avirulence gene alleles using this information and phenotypically for reactions on *Brassica napus* lines with specific resistance genes. Analysis of the SNP diversity within the *L. maculans* isolates revealed geographical separation of the populations. This ‘open access’ resource provides a standardized set of isolates that can be used to define the basis for how these fungi cause disease, and as a tool for the discovery of new resistance traits in *Brassica* species.

Text

Blackleg disease caused by the hemibiotrophic pathogen *Leptosphaeria maculans* is a major constraint to rapeseed (canola, *Brassica napus*) production worldwide. Host genetic resistance underpins blackleg control. Both major gene (complete) and quantitative (partial) resistance effectively limits yield losses but the large genetic diversity and evolutionary potential of *L. maculans* can rapidly render major genes ineffective. Thus, quantitative resistance (QR) is considered a more sustainable approach but breeding efforts are restricted by the absence of a biologically relevant screening method for this complex pathogen due partly to the lack of fundamental knowledge. We conducted experiments in controlled environment and field conditions quantifying blackleg disease using standard visual assessments and highly accurate digital droplet PCR. Contrary to the current understanding, we found that QR is expressed at the seedling and adult plant stages but there is no relationship between the presence of QR in cotyledons at the seedling stage and QR in mature plants for crown canker, and QR does not provide partial resistance to all isolates but instead reacts with individual isolates differently. QR expression was strongly influenced by the environment and potentially also by the major gene resistance. This research advances our understanding of QR expression in rapeseed, improving efforts to identify QTL's and the development of a rapid and reliable phenotyping method.

Text

The main strategy to control the fungus *Leptosphaeria maculans*, the causal agent of stem canker in *Brassica napus*, is genetic control by plant varieties carrying resistance (R) proteins. However, the massive deployment of a single source of resistance in the fields exerts strong selection pressures towards pathogen populations, leading to the rapid breakdown of the resistance. Recently, advances in effector repertoire prediction, in effector protein heterologous production and structural prediction algorithms have resulted in the identification of several effector families in L*. maculans*, these families being also present in other plant pathogenic fungi, mainly from the Dotheomycetes and Sordariomycetes. Furthermore, some of the structural analogues identified both in *L. maculans* and other plant pathogenic fungi share conserved functions during plant infection, suggesting an interesting evolutionary model. In addition, using transcriptomic data collected along the *L. maculans* life-cycle highlighted expression waves of distinct structural families, suggesting a striking coordination of them during the infection process. Here, we will review the recent advances in structural prediction / structure determination among *L. maculans* secretome and their implication to gain insight into the putative functions of candidate effectors. We will also propose possible strategies to improve resistance management or increase R proteins recognition spectrum using structural effector families.

Text

Leptosphaeria maculans is a pathogen of oilseed rape, mainly controlled by major resistance genes (Rlm) in varieties. Such genes may be rapidly overwhelmed due to the selection of virulent isolates displaying inactivation, deletion, or mutations in the corresponding avirulence genes (AvrLm). It is thus important to monitor the presence of virulent isolates in populations. First, we analysed the AvrLm gene diversity in 89 French isolates. We found a highly variable level of polymorphism, depending on the gene, ranging from one to 14 alleles per gene, with the occurrence, or not, of deletions or inactivating mutations. We developed a tool using multiplex PCR and Illumina sequencing to rapidly characterize allelic variants for eight avirulence genes in field populations.
We tested the multiplex PCR on DNA of pooled samples of 32 L. maculans leaf spots. After paired-end sequencing with Miseq technology, reads were mapped on an in-house AvrLm sequence database. The data were filtered using thresholds defined from specific control samples included in each run. Proportions of each allelic variant, including proportions of deletion events, were then calculated in each sample. The method was found to be highly reproducible and accurate. Finally, around 1400 symptoms from nine experimental fields were analyzed in a single run. The proportion of virulent isolates estimated by sequencing the pooled leaf spots perfectly matched their known proportions in local L. maculans populations.

Text

Race-specific disease resistance (R) genes have been widely applied in canola/rapeseed (Brassica napus) breeding for resistance to blackleg disease, caused by the fungus Leptosphaeria maculans (Lm). Technological advances in genomics have led to the cloning of five race-specific resistance genes (Rlm or LepR) belonging to two classes of cell surface receptors, receptor-like proteins (RLP) and wall-associated kinase-like (WAKL) proteins. Cloning of the five Rlm and LepR genes, along with their corresponding Lm effectors has promoted the Brassica-Leptosphaeria interaction to a model pathosystem to study the function of cell surface receptors, especially WAKLs for which there are very few functional examples reported to date. Here we present our current knowledge of the molecular function

of the WAKL gene cluster on B. napus chromosome A07 (Rlm3-4-7-9), gained through allele sequence comparison and functional studies.

SUCCESS IN R-GENE LABELING, MULTI GENES, KASP MARKERS AND QR: A GAME CHANGER IN THE CANOLA BLACKLEG PLAYBOOK IN CANADA

FERNANDO Dilantha. (1)

(1) University of Manitoba, Winnipeg, CANADA

Text
Blackleg caused by Leptosphaeria maculans is the most important disease in canola in Canada. Blackleg became a major issue since 2010 with an increase in prevalence, incidence, and severity in Canada. Studies identified that Rlm3 was the predominant gene in most Canadian canola cultivars. Rlm3 breakdown with the advent of avrLm3 was reported, and the increase in the disease was attributed to it. A systematic approach was undertaken to mitigate this occurrence with the seed industry, researchers, and government participating. R-genes in commercial cultivars were identified, and some of the seed companies decided to label their commercial cultivars with the known R-genes. Stacking of R-genes occurred. KASP markers were developed to identify the pathogen avirulent and virulent alleles in grower fields, so growers can select the right R-gene package for the following season. An R-gene rotation was introduced in 2018. Since then, we have monitored the nature of the disease in canola in a country that grows 22 million acres of canola each year to understand the nature of the disease and monitor the pathogen through profiling. The use of stacked R-genes and their performance including the nature of quantitative resistance in disease mitigation has been studied in grower fields. Disease mitigation through a combination of certain R-genes has been identified. The proposed talk will give the success behind these approaches, the challenges faced and what needs to be done in the future.

Text
Plenodomus lingam (*Leptosphaeria maculans*, LM) and *P. biglobosus* (*L. biglobosa*, LB)

cause phoma leaf spotting and stem canker of oilseed rape (*Brassica napus*). Extracellular polymeric substances (EPSs) play a key role in shaping the interactions within microbiome and between the microbiota and plants; enable adaptation to changing environmental conditions, affect the colonization of rhizosphere, rhizoplane and endosphere of plants, and provide a competitive advantage in the environment. EPSs were obtained from liquid cultures of 3 LM and 3 LB isolates grown on Czapek-Dox medium. The highest concentration of EPSs produced by LB were obtained on the 8th day and in LM on the 12th day of incubation. The average EPS concentration on the highest production day was 0.47±0.15 for LB and 1.3-fold higher (0.62±0.13) for LM. Strains belonging to both species secreted very strong complexing compounds capable of taking iron ions from the ternary Fe complex with HDTMA and CAS in the Schwyn and Neilands blue medium. There was a very clear difference in the efficiency and rate of siderophore production between species; the rate on the blue medium for LB averaged 28.5±3.61 and was twice as high as for LM (15.5±1.0). LB strains produced siderophores after 24 hours of incubation at 20oC and LM strains after 120-144h. The results indicate that EPSs and siderophores produced by *Plenodomus*/*Leptosphaeria* species differ in their effects on plants and other microorganisms.

Text

The complex species *Leptosphaeria maculans* Desm. Ces and de Not. (*L. maculans*)-*Leptosphaeria biglobosa* (*L. biglobosa*) represent one of the most damaging phytopathogenic fungi threatening oilseed rape (*B. napus*) growing regions worldwide (Wang et al., 2020). Since their first occurrence in Tunisian oilseed rape production in 2018 (Maghrebi et al., 2023), the Phoma stem canker disease has been affecting mainly 7 regions and increasing in prevalence over the past few years.

Given the rapid expansion of oilseed rape cultivation in Tunisia, studying the *L. maculans* – *B.napus* pathosystem and research into these newly emergent disease has become of crucial importance. From 2018 to 2020, researches have specially focused on the pathogen's biology, race structure, epidemiology and genetic diversity. Lately, other studies have touched to some degree the disease management control. In this work, we state the principal results of research conducted to date on blackleg disease in Tunisia and outline the scope of the current progress made in the fight against this disease.

The outcomes provide essential information for the development of disease management strategies in the Tunisian and Mediterranean context.

P8.6-003

CHARACTERISATION AND MANAGEMENT OF LEPTOSPHAERIA SPP. CAUSING BLACKLEG OF CANOLA IN SOUTH AFRICA

SCHREUDER H. M. . (1), VAN COLLER G. J. . (2), **MOSTERT D.. (1)**

(1) Stellenbosch University, Stellenbosch, SOUTH AFRICA; (2) Western Cape Department of Agriculture, Stellenbosch, SOUTH AFRICA

Text

Blackleg is a major constraint in global and local canola production. As part of a larger project on managing blackleg in the Western Cape, the prevalence, and species identity of *Leptosphaeria* species associated with canola in the Western Cape were investigated. Cultivar trials were also established at two locations in 2021 and four locations in 2022, across the two canola productions regions (Swartland and Overberg) in South Africa. All commercially available cultivars were included, with 12 cultivars planted in 2021 and 17 cultivars in 2022. *L. maculans* was predominantly isolated from canola in the Western Cape. In both years disease severity was significantly higher in the Swartland region. Significant differences in disease severity were found between cultivars at all locations, with cultivars performing similar within regions. Hyola 559TT were most susceptible at all locations in 2021, while Diamond and CHYB3688TT were most susceptible at all location in 2022. In both years, 45Y95 and 45Y93 performed best across all locations. Both cultivars have the resistance gene Rlm3, suggesting that there is pressure on the pathogen population to shift away from the corresponding avirulence gene (*AvrLm3*), since most locally planted cultivars lack the Rlm3 resistance gene. Determining the vulnerability of commercially available cultivars to blackleg in different locations will assist farmers in choosing the cultivars best suited for their region to prevent losses due to blackleg.

Text

Global warming also brings new problems in terms of plant resistance to pathogens and pests. In addition to the emergence of new pathogens, which have so far mainly occurred in warm regions, plants have to face other abiotic stress factors. Besides high temperature stress, plants can also be damaged by more frequent temperature fluctuations. In this context, cold stress is becoming increasingly important. In our study, we investigated how chilling stress can modulate plant susceptibility or resistance to subsequent infection by a fungal pathogen. Winter (cv. Columbus) and spring (cv. Westar) cultivars of oilseed rape

(*Brassica napus*) were inoculated with *Plenodomus lingam* and both the extent of symptoms and the underlying mechanisms were investigated. Both cultivars were significantly more susceptible to *P. lingam* when inoculated immediately after short-term cold stress. However, the winter cultivar Columbus showed a higher degree of resistance when inoculated after a few days of recovery at normal temperatures. The mechanisms underlying these results were determined by studying the transcription of defence genes and genes involved in cold stress, and by proteome, metabolome, and hormonome analyses.

Genome evolution in filamentous plant pathogens

WALTZ WITH PLANTS: GENOME EVOLUTION IN FILAMENTOUS PATHOGENS

KAMOUN Sophien. (1)

(1) The Sainsbury Laboratory, Norwich, UNITED KINGDOM

Text

Fungi and oomycetes include deep and diverse lineages of eukaryotic plant pathogens. Fundamental concepts have emerged from the sequencing of the genomes of a multitude of species of these filamentous plant pathogens. Filamentous plant pathogen genomes tend to harbor large repertoires of genes encoding virulence effectors that modulate host plant processes. Effector genes are not randomly distributed across the genomes but tend to be associated with compartments enriched in repetitive sequences and transposable elements. This particular distribution of effector genes is the result of coevolutionary dynamics with host plants. Here, I will discuss how plant pathogens are great model systems to study evolutionary adaptations at multiple time scales. I will also discuss how genome evolution can be applied to the study of pandemic plant pathogen lineages.

Text

Macrophomina phaseolina has a broad host range, but individual isolates may be pathogenic to a limited number of hosts. Previous work demonstrated: 1) strawberry is not susceptible to all isolates of the fungus, and 2) host specialization may have occurred among highly aggressive, strawberry-pathogenic isolates. A survey of the genus was conducted to identify host-genotype associations, pangenomic structure and mechanisms of genetic exchange. Short-read sequence data were obtained for 422 *Macrophomina* spp. isolates collected from 94 host plant species in 27 countries (113 from strawberry, 54 from soybean, 255 from other hosts). High-quality short-reads were assembled and mapped to reference genomes. *M. phaseolina* was grouped into ten partially recombinant clades, with high admixture in some isolates suggesting on-going recombination. Three of the identified clades clustered with respect to isolate's host of origin (78% of strawberry-derived isolates were in a single clade, whereas 74% of soybean isolates resolved into two clades). This pattern suggests that host specialization may be occurring among isolates in specific clades. Furthermore, pathogenicity tests of select isolates representing each clade suggest strawberry is only highly susceptible to isolates from the "strawberry clade". *Macrophomina* appears to have a one-speed genome. This work provides insight into host specialization and evolutionary mechanisms within this economically important pathogen genus.

Text

Plant pathogens secrete proteins called effectors that target host cellular processes to promote disease. Recently, structure-based clustering has identified several families of fungal effectors that share a conserved three-dimensional structure despite remarkably

variable amino-acid sequences and surface properties.
To explore the selective forces that underlie the sequence variability of structurally-analogous effectors, we focused on MAX effectors, a structural family of effectors that are major determinants of virulence in the rice blast fungus Pyricularia oryzae. Using structure-informed gene annotation, we identified 58 to 78 MAX effector genes per genome in a set of 120 isolates representing seven host-associated lineages. The expression of MAX effector genes was primarily restricted to the early biotrophic phase of infection and strongly influenced by the host plant. Pangenome analyses of MAX effectors demonstrated extensive presence/absence polymorphism and identified several candidate gene loss events possibly involved in host range adaptation. MAX effectors displayed high levels of standing variation and high rates of non-synonymous substitutions, pointing to widespread positive selection shaping their molecular diversity.
Our work demonstrates that MAX effectors represent a highly dynamic compartment of the genome of P. oryzae, and suggests that MAX effectors are key players in molecular coevolutionary interactions with plant hosts.

Text
Leptographium wageneri is an ascomycete fungal pathogen that causes black stain root disease (BSRD) of conifers. As a primary pathogen that has evolved from closely related saprotrophic species, *L. wageneri* offers an opportunity to identify the possible determinants of pathogenicity. We sequenced the genomes of the three varieties of *L. wageneri* and the closely related non-pathogenic *L. douglasii* and performed comparative genomics between the pathogens and closely related non-pathogenic species. The three varieties of *L. wageneri* were found to have larger genomes, higher gene numbers and a higher content of transposable elements. A putative laccase gene was present only in the three varieties of *L. wageneri* and *L. douglasii*. This laccase gene was horizontally acquired by the common ancestor of *L. wageneri* and *L. douglasii* and encodes for a secreted laccase. Infection of *P. patula* seedlings followed by qRT-PCR analysis indicated that this laccase gene was upregulated in-planta, suggesting its role in pathogenicity. Subsequently, laccase knockout mutants were generated using CRISPR-Cas9 and used in a pathogenicity test. The results showed that the laccase-deleted mutants failed to cause typical symptoms of infection by *L. wageneri*. Collectively, this study illustrates patterns of genome evolution in *L. wageneri* from a non-pathogenic relative. The results also provide some evidence that a horizontally acquired laccase is a key virulence factor in this tree pathogen.

Text

Many fungi including plant pathogens and ecologically important symbionts are dikaryotic, meaning they carry two separate and different haploid nuclei per cell. Rust fungi are dikaryotic and critical pathogens of many crops, especially wheat and other cereals. Due to the absence of the alternate host required for sexual reproduction and recombination in most parts of the world, rust fungi are restricted to clonal reproduction which should severely limit the generation of genetic diversity. Nevertheless, new races emerge frequently and non-sexual processes such as somatic nuclear exchange have been postulated to play a role, but have been difficult to detect due the lack of genome resolution between the two haploid nuclei. We have recently taken advantage of Hi-C chromatin contact information to develop tools to accurately phase the dikaryotic genomes of rust fungi to their nuclei of origin. This has allowed the detection of numerous instances of somatic nuclear exchange between clonal lineages of cereal rusts. These data suggest that repeated exchange events have shuffled haploid nuclei between clonal lineages leading to global populations consisting of different combinations of a limited number of haploid genome types. Thus, nuclear exchange seems to be the predominant mechanism generating diversity and the emergence of new strain lineages in these otherwise clonal pathogens.

Text

The genomes of many fungal
pathogens are compartmentalized into core regions and accessory regions, which are enriched in transposable elements (TEs). TEs are widely regarded as drivers of adaptive evolution, but direct experimental evidence remains limited. Here we used an evolve and re-

sequence approach to follow environmental adaptation in *Fusarium oxysporum*, a devastating fungal pathogen that attacks more than 150 crops and causes deadly infections in immunocompromised humans. Serial passaging of a clonal isolate through tomato plants or axenic media plates resulted in rapid adaptation and increased fitness under the selection condition. Plate-passaged populations displayed recurrent evolutionary trajectories of sequential loss-of-function mutations that lead to increased proliferation at the cost of reduced virulence. TE insertions accounted for more than half of the variants detected and localized preferentially to sites of histone H3 lysine 27 trimethylation, a hallmark of accessory regions. Our findings reveal that TEs act as the main drivers of adaptation in F. oxysporum and reveal fitness trade-offs between developmental programs stimulating proliferation versus invasion.

F4.3-1

ADAPTIVE GENOME EVOLUTION OF THE CEREAL POWDERY MILDEW FUNGI

KUSCH Stefan. (1), QIAN Jiangzhao. (1), PANSTRUGA Ralph. (1)

(1) RWTH Aachen University, Aachen, GERMANY

Text
The cereal powdery mildews (Blumeria spp. of the family *Erysiphaceae*) are globally occurring fungal pathogens of grasses and cereals and pose a constant threat for agriculture. *Blumeria* species infect grasses and cereals in a host-specific manner. Ubiquitously distributed transposable elements make up >75% of the genomes of the cereal powdery mildews, which can be a source of genetic variation and genome instability. We study if and how *Blumeria* regulates and repurposes transposable elements to rapidly overcome host resistance. We found transcriptional activity of transposable elements in the barley powdery mildew pathogen *B. hordei* at specific stages of infection, particularly during early host cell penetration and haustoria establishment. Epigenetic profiling in conidia revealed increased 5mC methylated DNA levels in retrotransposons, while small RNA sequencing of isolated mycelia and haustoria indicated accumulation of phasiRNAs in >1,500 retrotransposon loci, suggesting dynamic control of transposon expression through epigenetic mechanisms and RNA interference. We further discovered long spliced antisense RNAs (antisense lncRNAs) at loci of transposon replication genes. These transposon antisense lncRNAs exhibit time point-dependent expression patterns as well as distinct co-expression patterns with transposons, indicative of both positive and negative regulation of transposons by antisense lncRNAs.

THE MAIZE LATE WILT FUNGUS MAGNAPORTHIOPSIS MAYDIS IN ISRAEL CONSISTS OF AGGRESSIVE STRAINS THAT CAN SPECIALIZE IN DISRUPTING GROWTH OR PLANT HEALTH

DEGANI Ofir. (1,2), SHOFMAN Galia. (1,2), BAHOUTH Marlen. (2)

(1) Migal - Galilee Research Institute, Kiryat-Shmona, ISRAEL; (2) Tel-Hai College, Tel-Hai, ISRAEL

Text

Maize late wilt disease caused by the fungus *Magnaporthiopsis maydis* significantly damages crops in Israel and in other countries. Resistant maize cultivars are the preferred method for disease restraining. However, the pathogen populations of Spain and Egypt have varying aggressiveness, and virulent strains can overcome host resistance. In 2001 and from 2016 to -2019, 17 *M. maydis* strains were isolated from infected maize fields in Israel. The isolates' effects on seed germination, plant development, and disease symptoms severity were evaluated. The isolates from Israel display a diverse degree of aggressiveness that is not linked to their geographic distribution. The virulent strains are found in mixed populations, whereas less virulent *M. maydis* isolates exist. Aggressive strains harmed the development of plants and ears and caused severe wilting and death. In contrast, plants inoculated with less virulent strains exhibited only mild dehydration signs, and crop yield was similar to that of the non-infected control. Interestingly, different host cultivars can evoke specific virulence of *M. maydis* strains. Moreover, some pathogen strains significantly repress plant development, while the impact of other strains was evidenced by wilting symptoms. The current research further increases our understanding of the pathogen and our ability to control it.

GENOME SEQUENCING AND COMPARISON OF SEVEN STRAINS OF TILLETIA HORRIDA, CAUSAL AGENT OF KERNEL SMUT OF RICE

KHANAL Sabin. (1,2), ZHOU Xin-Gen. (2), ANTONY-BABU Sanjay. (1)

(1) Texas A&M University, College Station, UNITED STATES; (2) Texas AgriLife Research Center, Beaumont, UNITED STATES

Text

Kernel smut of rice, caused by Tilletia horrida, is characterized by the replacement of rice grains with black sooty masses of teliospores. Kernel smut occurs to varying degrees in six continents and 29 countries around the world. In the US, kernel smut has increased its occurrence and severity in the last decade and is currently one of a major disease, threatening the US rice industry. In this study, we sequenced and assembled seven phylogenetically distinct strains of T. horrida. Four (TX1, TX2, TX3, and TX4) of the isolates were assembled to 26 mb in length and the remaining three (TX5, TX6, and TX7) to 20 mb in length. The assembly sizes of the strains in the latter group were similar to previously reported strain QB-1 from China. The genome-based phylogeny analyses confirmed our previous multi-locus analysis results that strains TX1, TX2, TX3, and TX4 were genetically distinct from the strains TX5, TX6, and TX7, along with strain QB-1. Gene prediction and secondary metabolic gene clusters of the seven T. horrida strains ranged from 6, 975 to 8, 108 and 10- to13. These genome resources lay the foundation for future studies on the population genomics of T. horrida and the host-pathogen interactions.

REOCCURRING WILT, A NEW DISEASE OF COTTON IN AUSTRALIA CAUSED BY NOVEL EUTYPELLA SPECIES

SMITH Linda. (1), GREENFIELD Paul. (2), KAFLE Dinesh. (1), SCHEIKOWSKI Linda. (3), VADAKATTU Gupta. (4)

(1) Department of Agriculture and Fisheries, Brisbane, AUSTRALIA; (2) Commonwealth Scientific and Industrial Research Organisation, Lindfield, AUSTRALIA; (3) Department of Agriculture and Fisheries, Toowoomba, AUSTRALIA; (4) Commonwealth Scientific and Industrial Research Organisation, Urrbrae, AUSTRALIA

Text

Reoccurring wilt is a new disease of cotton in Australia which was first detected in the 2017/18 season as a single small patch of wilting and dying cotton plants in a field in Central Queensland. The disease reoccurred in the same location in subsequent cotton plantings, increasing to approximately 1 ha in 2020. Fungal isolations from diseased field grown plants were consistently dominated by one fungus based on culture morphology. Identification was established on sequences of the internal transcribed spacer region of ribosomal DNA and showed that all the isolates had high homology to *Eutypella scoparia*. Further analyses revealed that there were two distinct *Eutypella* species present. Pathogenicity tests showed that a *Eutypella* isolate when inoculated into the stem of healthy cotton caused cankerous growth and necrosis of vascular tissue, typical of trunk disease. The fungus caused a red-brown streaking of the vascular tissue like that observed in diseased field plants. Community profiling of diseased root samples showed that two operational taxonomic units related to *E. scoparia* were the most abundant fungi accounting for 45 to 99% of all sequences. This study shows that the fungal isolates, which form a distinct group within the *Euypella*, are associated with the root and stem of dying cotton and were the dominant fungi of diseased roots. This is the first known case of *Eutypella* affecting cotton worldwide and is considered an expansion of this genus' host range.

GENOME COMPARISONS BETWEEN EUCALYPTUS LEAF- AND STEM-INFECTING TERATOSPHAERIA SPECIES REVEAL GENE FAMILY EXPANSION IN THE ABSENCE OF REPEAT GAIN

AYLWARD Janneke. (1), WINGFIELD Michael. (1), ROETS Francois. (2), WINGFIELD Brenda. (1)

(1) Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, SOUTH AFRICA; (2) Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text

Several species of the fungal genus *Teratosphaeria* (Dothideomycetes: Mycosphaerellales) are pathogens of *Eucalyptus* trees in plantations globally. While most of these fungi cause leaf and shoot blight, two species are unusual in causing resinous stem cankers. We have sequenced the genomes of all the economically important *Teratosphaeria* species occurring on *Eucalyptus*, providing an opportunity to compare the stem and leaf pathogen lineages at a genomic level. The *Teratosphaeria* genomes were annotated and compared with regards to genome assembly statistics as well as gene content and function. To confidently identify genes unique to *Teratosphaeria* pathogens, the genomes of seven other Teratosphaeriaceae

species were included as outgroups. The stem pathogens were found to have repeat-sparse genomes, yet their gene expansion was at least three times greater compared to the leaf pathogen lineage. Unique functional categories identified in both leaf and stem pathogens included genes that code for CAZymes, proteases, secondary metabolites, and transcription factors. Overall, the results highlight candidate genes that may play an important role in leaf and stem pathogenicity. Furthermore, they suggest that gene expansion has partly driven the evolution of the *Teratosphaeria* stem pathogens from their leaf-associated ancestors.

Text
The fungus *Fusarium oxysporum* is infamous for its devastating effects on economically important crops worldwide. *F. oxysporum* isolates are grouped into formae speciales based on their ability to cause disease on different hosts. Assigning *F. oxysporum* strains to formae speciales using non-experimental procedures has proven to be challenging due to their genetic heterogeneity and polyphyletic nature. However, genetically diverse isolates of the same forma specialis encode similar repertoires of effectors, proteins that are secreted by the fungus and contribute to the establishment of compatibility with the host. Based on this observation, we previously designed the *F. oxysporum* Effector Clustering (FoEC) pipeline which is able to classify *F. oxysporum* strains by forma specialis based on hierarchical clustering of the presence of predicted putative effector sequences, solely using genome assemblies as input. Here we present the updated FoEC2 pipeline which is more user friendly, customizable and, due to multithreading, has improved scalability. It is designed as a Snakemake pipeline and incorporates a new interactive visualization app. We showcase FoEC2 by clustering 537 publicly available *F. oxysporum* genomes and further analysis of putative effector families as multiple sequence alignments. We confirm classification of isolates into formae speciales and are able to further identify their subtypes.

Soil Sciences, Forestry and Agricultural Biotechnology Institute (FABI), Faculty of Natural and Agricultural Sciences, University of Pretoria, Hatfield Campus Pretoria, 0083, SOUTH AFRICA

Text

Sclerotinia is a genus in the *Sclerotiniaceae,* a fungal family that includes many important plant pathogens. In filamentous Ascomycetes such as *Sclerotinia,* sexual reproduction is controlled by the mating-type (*MAT*) genes located at the mating-type locus (*MAT1*). This study aimed to characterize the *MAT1* locus of seven previously unstudied *Sclerotinia* species. To achieve this, the locus was annotated from draft genome sequences generated during the study. The *MAT1* locus differed in gene content and arrangement between the different species. The *S. pseudotubarosa MAT1* locus contained the *MAT1-1-1, MAT1-1-5, MAT1-2-1,* and *MAT1-2-10* genes, indicative of homothallism. For *S. spermophila* and *S. sulcata*, the *MAT1-1-5* gene was absent although *MAT1-1-1, MAT1-2-1*, and *MAT1-2-10* were present. *S. sativa* and *S. matthiolae* had all four *MAT* genes, although the presence of inverted repeat sequences suggests an inversion event might occur during meiosis. Such an inversion would truncate *MAT1-1-1*, while inverting the orientation of *MAT1-2-10* and *MAT1-2-1.* The *MAT1* locus of *S. bulborum* and *S. asari* also had four *MAT* genes, although the presence of direct repeats could delete the *MAT1-2* genes through unidirectional mating-type switching. This process would convert a self-fertile isolate to self-sterility. This study produced draft genomes for seven Sclerotinia species, while also shedding light on the evolution of sexual reproduction and the *MAT1* locus in this economically important group.

P4.3-007

FOLDING FEATURES AND DYNAMICS OF 3D GENOME ARCHITECTURE IN PLANT FUNGAL PATHOGENS

XIA Chongjing. (1,2), HUANG Liang. (1), CHEN Xianming. (3), LIU Taiguo. (1), CHEN Wanquan. (1)

(1) Chinese Academy of Agricultural Sciences, Beijing, CHINA; (2) Southwest University of Science and Technology, Mianyang, CHINA; (3) Washington State University, Pullman, UNITED STATES

Text

Folding and dynamics of three-dimensional (3D) genome organization are fundamental for eukaryotes executing genome functions but have largely unexplored in non-model fungi. Using the Hi-C data, we generated two chromosome-level assemblies for *Puccinia striiformis* f. sp. *tritici* (*Pst*), a fungus causing stripe rust disease on wheat, for studying 3D genome architectures of plant pathogenic fungi. The chromatin organization of the fungus followed a combination of the fractal globule model and the equilibrium globule model. Surprisedly, chromosome compartmentalization was not detected. Dynamics of 3D genome organization during two developmental stages of Pst indicated that regulation of gene activities might be independent of the changes of genome organization. In addition, chromatin conformation conservation was found to be independent of genome sequence synteny conservation among different fungi. These results highlighted the distinct folding principles of fungal 3D genomes. Our findings should make an important step towards a holistic understanding of the principles and functions of genome architecture across different eukaryotic kingdoms.

Text

Barley grass (*Hordeum leporinum*), which often occurs in proximity to commercial barley (*Hordeum vulgare*), is an alternative host to *Pyrenophora teres*, an economically important pathogen causing net blotch in barley. Population and pathogenicity studies of *P. teres* isolates obtained from barley and barley grass have reported that the two populations are genetically distinct and host specific, suggesting that isolates collected from barley or barley grass are two different species. The first successful in vitro sexual recombination event between *P. teres* from barley and barley grass was confirmed by our group using a neighbour-net network and haploblocks based on whole genome sequencing of seven progeny isolates. Pathogenicity assays revealed that *P. teres* isolates from barley grass are not host specific but could infect both barley and barley grass and that the progeny isolates are virulent on commercially grown barley cultivars. Despite the genetic divergence of *P. teres* isolates from barley and barley grass revealed through our phylogenomic, evolutionary and haploblock analyses, there seems to be no complete host or reproductive separation between these populations. Thus, there is a potential for the generation of novel pathotypes through sexual recombination between *P. teres* isolates associated with barley and barley grass, with a risk of increased impacts on commercial barley cultivars that do not carry resistance to these potentially emerging pathotypes.

DIVERSITY AND PATHOGENICITY OF COLLETOTRICHUM SPECIES CAUSING PASSION FRUIT ANTHRACNOSE IN TAIWAN

TSAI Jyh Nong. (1), TSAI H L. (1), HUANG C C. (1), LIN C P. (1), ANN Pao Jen. (1)

(1) Taiwan Agricultural Research Institute, Taichung, TAIWAN

Text

Anthracnose caused by *Colletotrichum* spp. poses a serious threat to the yield and quality of passion fruit, an economically valuable fruit crop of Taiwan. In order to effectively control passion fruit anthracnose, this study aims to identify isolated fungal species, analyze their pathogenicity, and screen for effective disease control materials. In total, 56 fungal isolates were collected from diseased leaves and fruits of passion fruit during 2018 to 2022 from main passion fruit producing areas of Puli Town and Dapingding, with 17 of them further characterized in terms of morphology, pathogenicity, and multi-gene phylogeny. The fungal species identified include *C. brasillense* (11%), *C. fructicola* (18%), *C. karstii* (30%), *C. plurivorum* (23%), and *C. theobromicola* (18%), which belong to *Colletotrichum gloeosporioides* species complex, *C. boninense* species complex, and *C. orchidarium* species complex, respectively. Of note, a severe outbreak of passion fruit anthracnose

occurred at Puli Town in July 2022 and *C. theobromicola* was found to be the main causal agent. Evaluation of candidate fungicides found that both azoxystrobin plus Difenoconazole and cyprodinil plus fludioxonil showed better curative effect for passion fruit anthracnose. Moreover, 4-4 Bordeaux mixture and two cinnamon oil-based non-pesticide agents were able to inhibit the growth of mycelia, thus showing the potential as therapeutic agents. These results will help effective management of passion fruit anthracnose.

COMPARATIVE SECRETOME ANALYSIS OF ZYMOSEPTORIA TRITICI ISOLATES AND DOTHIDEOMYCETE SPECIES TO IDENTIFY CONSERVED SECRETED EFFECTOR PROTEINS

GOMEZ Sandra. (1), GRIBSKOV Michael. (1), GOODWIN Stephen. (2)

(1) Purdue University, West Lafayette, UNITED STATES; (2) Crop Production and Pest Control Research Unit, USDA–Agricultural Research Service, West Lafayette, UNITED STATES

Text
Zymoseptoria tritici (Zt) is the cause of Septoria tritici blotch in wheat. Pathogens secrete effectors that modulate innate immunity of the plant and can overcome pattern-triggered immunity mechanisms to facilitate infection. Effector molecules from fungal pathogens are small, secreted proteins (SSPs). They typically are fewer than 300 amino acids in length, are cysteine-rich, contain signal peptides at the N-terminus, and lack transmembrane domains. Proteins of five *Zt* isolates and seven Dothideomycete species were retrieved from JGI Mycocosm and NCBI databases. Functional domain annotations were conducted using BLAST+ 2.12.0., Pfam v.35.0, dbCAN, and the MEROPs database. Secreted proteins were identified by the presence of signal peptides and the absence of transmembrane domains detected by Phobius v1.01, Target P v.2.0. and SignalP v4.1. EffectorP v.3.0, ApoplastP and LOCALIZER were applied to identify effector features and predict the localization of the effectors within the plant cell. The four European isolates of *Zt* showed the highest number of SSPs among all the organisms. The IPO323 strain has similar numbers of SSPs and predicted effectors as *Cladosporium fulvum* and *Parastagonospora nodorum*. A clustering analysis on the predicted effectors revealed two clusters that contain effectors with significant sequence similarity among all the species. We identified shared effectors in 11 species including non-pathogens *Baudoinea compniacensis* and *Cryomyces antarcticus.*

P4.3-011

MATING PHEROMONE AND RECEPTOR GENES ARE GENERALLY CONSERVED IN THE CERATOCYSTIDACEAE, A GROUP INCLUDING IMPORTANT PLANT PATHOGENS WITH DIVERSE MATING STRATEGIES

LANE Frances A. (1), WINGFIELD Brenda D. (1), WINGFIELD Mike J. (1), WILKEN P Markus. (1)

(1) Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria, SOUTH AFRICA

Text

The pheromone-receptor system allows fungi to communicate during mating. Heterothallic fungi require opposite partners for sexual reproduction to occur, with compatible mating partners each producing a different pheromone to attract each other and communicate. In contrast, homothallic fungi are able to reproduce without a mating partner. Homothallic fungi also rely on these pheromones and receptors as they have roles other than mate recognition. We identified the a- and α-pheromone genes and their respective receptor genes from the genome assemblies of 34 species in the *Ceratocystidaceae* (*Ascomycota*), which includes many important plant pathogens, and where many are homothallic. Both receptor genes were identified in all species investigated, although the α-pheromone receptor appears non-functional in *Ambrosiella* species as they lack the essential transmembrane domains. The α-pheromone gene was present in all species apart from *Ambrosiella*. In *Berkeleyomyces* species, the α-pheromone gene was duplicated. It was not possible to identify the a-pheromone gene in any of the genome assemblies, likely because of the lack of sequence and locus conservation commonly seen in pheromone genes. The results show that the pheromone-receptor system remains conserved in most members of the *Ceratocystidaceae*, regardless of their sexual strategy.

P4.3-012

MAT1-1-2 GENE KNOCKOUT REDUCES THE FREQUENCY OF UNIDIRECTIONAL MATING-TYPE SWITCHING IN CERATOCYSTIS ALBIFUNDUS

LANE Frances. (1), WINGFIELD Brenda D. (1), WINGFIELD Mike J. (1), WILKEN P Markus. (1)

(1) Department of Biochemistry, Genetics and Microbiology, Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, SOUTH AFRICA

Text

The African tree pathogen *Ceratocystis albifundus*, exhibits the unusual form of sexual reproduction known as unidirectional mating-type switching. The switching process produces two progeny types that differ in their sexual phenotypes and the gene content at the mating-type (*MAT1*) locus. Self-fertile progeny can complete the sexual cycle in isolation, producing both self-fertile isolates having four mating-type (*MAT*) genes and self-sterile isolates with only two genes. Self-sterile progeny result from mating-type switching, and these isolates require a mating partner for sexual reproduction. While two direct repeats within the *MAT1* locus likely facilitate the deletion of the target region, the role of the *MAT* genes in unidirectional mating-type switching has not been considered. In this study, a CRISPR/Cas9 system was used to delete the *MAT1-1-2* gene from the *MAT1* locus of *C. albifundus*. The deletion resulted in self-sterility while also drastically reducing the ability of the fungus to switch mating-types. Cultures of the transformant have few copies of the switched *MAT1* locus when compared to the wild-type. This likely prevents self-fertilisation from occurring, indicating a role for the MAT1-1-2 protein in *MAT* gene deletion during switching. The gene knockout also resulted in pleiotropic effects in the transformant such as reduced growth rate and lower levels of conidiation, suggesting a role for this gene is the overall fitness of the pathogen.

P4.3-013

BLAZING A TRAIL: UNCOVERING THE MECHANISMS THAT UNDERLIE THERMOTOLERANCE IN THE POST-FIRE FUNGUS RHIZINA UNDULATA

WILSON Andi. (1), SUZUKI Hiroyuki. (1), DUONG Tuan. (1), MARINCOWITZ Seonju. (1), WINGFIELD Michael. (1), WINGFIELD Brenda. (1)

(1) FABI, University of Pretoria, Pretoria, SOUTH AFRICA

Text

Rhizina undulata is the causal agent of Rhizina root rot of *Pinus* species in South Africa, and parts of Europe and Asia. The fungus is also known as the “coffee fire fungus” because its ascospores, which rely on heat shock for germination, are activated by camp fires used to prepare coffee along forestry trails. In this study, we aimed to elucidate the genetic mechanisms that underlie thermotolerance in *R. undulata*. This was achieved by sequencing the genome of this pathogen and comparing it to other species within the Pezizales. The *R. undulata* genome harboured 16 heat shock protein 20 (HSP20) genes and 10 glutathione S-transferase (GST) genes. The remaining Pezizales species possessed, on average, four HSP20 genes and five GST genes, suggesting significant expansions of these two protein families in the genome of *R. undulata*. Both HSPs and GSTs have been associated with heat shock defence in other fungi, supporting the hypothesis that the expansion of these protein families may be responsible for the thermotolerance exhibited by *R. undulata*. Given that this fungus requires heat shock for ascospore germination and subsequent host infection, these genes may influence other biological processes of this serious pine pathogen, warranting further investigation and functional characterisation.

P4.3-014

FUSARIUM OXYSPORUM F. SP. FRAGARIAE RACE 2 IN CALIFORNIA DID NOT EVOLVE THROUGH A SINGLE MUTATION IN THE AVRFW1 AVIRULENCE GENE

HENRY Peter. (1), DILLA-ERMITA Jade. (2), PENNERMAN Kayla. (1)

(1) United States Department of Agriculture, Salinas, UNITED STATES; (2) University of California, Davis, Davis, UNITED STATES

Text

In the fall of 2022, *Fusarium oxysporum* f. sp. *fragariae* (*Fof*) race 2 was discovered for the first time in California. This new race was comprised of a single strain that caused severe Fusarium wilt of strawberry and was present in multiple fields at the time of its discovery. The resistance gene it overcame, called *FW1*, was fortuitously present in commercially available strawberry cultivars at the time of *Fof* race 1’s discovery in 2006 and was a critical tool for managing disease caused by *Fof* race 1. This presentation will review what is known about the emergence of this new pathogen, gene-for-gene interactions between *Fof* and *FW1*-resistant strawberry cultivars, and new insights about the evolutionary mechanisms that led to the emergence of *Fof* race 2 in California. Knocking out a single avirulence gene

from *Fof* race 1 confers pathogenicity on *FW1*-resistant varieties, but *FW1*-resistant varieties retain quantitative resistance to the *Fof* race 2 strains generated by single-gene knockouts. By contrast, wild *Fof* race 2 isolates collected from diseased strawberry plants in Japan and California are equally virulent on *FW1*-resistant and *fw1*-susceptible cultivars. These wild *Fof* race 2 isolates share several potentially important pathogenicity factors that are absent in other *Fof* race 1 strains. These data suggest that a fully virulent race 2 phenotype cannot be gained by a single mutation in an avirulence gene; acquisition of other virulence factors is also necessary.

P4.3-015

IDENTIFICATION OF GANODERMA SPECIES ON DIFFERENT HOST IN THE NORTHWEST REGION OF CAMEROON

NDEH Bih Joan. (1), KINGE Tonjock Rosemary . (1), NDAM Tacham Walter . (1)

(1) THE UNIVERSITY OF BAMENDA, Bamenda, CAMEROON

Text

Ganoderma is a well-known plant pathogen causing root and stem rots and mortality of a wide range of economically important trees and perennial crops. It is difficult to identify Ganoderma species based on morphology alone due to the resemblance of its macroscopic character, the use of cultural and molecular methods is imperative. This research is aimed at identifying Ganoderma species with its host tree. Ganoderma species were collected using opportunistic sampling. Morphological and cultural identification was done. DNA was extracted and molecular analysis was done using ITS and TEF gene regions. Phylogenetic analyses was done using MEGA. Macromorphological characters of 68 species were described. Species distribution map was produced using ArC GIS 9.3. The colony colour of the different Ganoderma species varied from cream white, green, orange to black. Eight trees namely: Persea americana, Elaeis gineensis, Mangifera indica, Maesopsis eminii, Cola acuminata, Ficus sp., Albizia adianthifolia, and Canarium sweinfurthii were identified as hosts. Twelve species of Ganoderma (G. angustisporum, G. australe, G. orbiforme, G. eickeri, G. multiplicatum, G. weberianum, G. multipileum, G. applanatum, G. brownii, G. cupreum, G. gibbosum and G. lucidum) were identified after nucleotide blast in NCBI. There exists a monophyletic relationship between the species identified. The use of modern taxonomic methods to identify Ganoderma species compliments traditional identification methods.

P4.3-016

RETICULATED EVOLUTION, HYBRIDIZATION EVENTS AND GENE TREE INCONGRUENCE REVEALED IN THE TRICHODERMA HARZIANUM COMPLEX

PINEDA Rence Marrion. (1,2), NOZAWA Shunsuke. (1), TAKATA Yoshiki. (1), SETO Yosuke. (1,3), WATANABE Kyoko. (1)

(1) Tamagawa University, Tokyo, JAPAN; (2) Central Luzon State University, Science City Of Muñoz, PHILIPPINES; (3) Japanese Foundation for Cancer Research, Tokyo, JAPAN

Text

Trichoderma harzianum species are infamous biocontrol agents, mycoparasites, and pathogens. Phylogenetic analyses based on ITS, RPB2, and TEF1α have presented T. harzianum as a species complex of cryptic species. We hypothesized that reticulation events and/or poorly delineated reference trees have caused cryptic speciation, due to incomplete lineage boundaries. To answer the problem, we inferred the range of reticulated lineage using ASTRAL-III and Species Network applying Quartets (SNaQ). To evaluate the use of the traditional phylogenetic analysis in inferring evolutionary histories, we compared the three-loci maximum likelihood (RAxML) tree to genome-wide concatenation-based (RAxML) and coalescence-based trees (ASTRAL-III). Phylogenomic relationships of 21 Trichoderma strains were inferred using 4176 orthologous genes. ASTRAL-III and SNAQ revealed reticulated lineages and robust branches. Concatenation-based tree supported the robust branches inferred in the coalescence-based tree. The three-loci ML tree had high incongruence to the phylogenomic trees, including genome-wide inferred robust branches. Detected hybridization events and reticulated evolution among several species offered evidence of gene flow, indicating that the complex consists of only few species, not several. High incongruence of the three-loci ML tree means poor depiction of the genome-wide data for delineation, crucial to predict the evolution of biocontrol, mycoparasitism, and pathogenicity traits.

P4.3-017

CLASSIFICATION AND CHARACTERIZATION OF COLLETOTRICHUM SPECIES ASSOCIATED WITH APPLE BITTER ROT IN KOREA

KIM Jungyeon. (1), LEE Younmi. (1), **JEON Yongho. (1)**

(1) Andong National University, Andong-Si, REPUBLIC OF KOREA

Text

Apple is one of the important fruit crops with economic value in Korea. Apple bitter rot caused by *Colletotrichum* spp. is one of the most severe diseases in worldwide. *Colletotrichum* spp. affects the fruits preharvest in the field and postharvest in storage, resulting in considerable economic losses. To analyze the diversity of pathogens causing Apple bitter rot in Korea, a survey was conducted in 2020, and *Colletotrichum* species were identified through analysis of glyceraldehyde 3-phosphate dehydrogenase (GAPDH) and internal transcribed spacer (ITS) 2 genes. Among 314 isolates collected from 39 orchards in 22 regions in Korea, new species, such as *C. conoides* (2 of 314) and *C. aenigma* (2 of 314) have been identified. Predominant species of *C. siamense* (183 of 314) and *C. fructicola* (120 of 314) have been isolated. Additionally, 3 species of *C. gloeosporioides* (3 of 314), *C. fioriniae* (2 or 314) and *C. nymphaeae* (2 or 314) have been isolated. All these species caused lesions on apples. A fungicidal sensitivity test was conducted for isolates that have been identified. Understanding these research findings emphasizes the importance of identification and characterization of Colletotrichum spp. within each species complex, which will help in disease management.

A MULTIPURPOSE TOOLKIT OFFERED PRACTICAL ASSISTANCE TO ADVANCED FUNCTIONAL ANALYSIS OF PHYTOPHTHORA SOJAE GENES

TAN Xinwei. (1), HE Zheng. (1), **WANG Qunqing. (1)**

(1) Shandong Agricultural University, Taian, CHINA

Text

Oomycetes, represented by *Phytophthora*, have a threat of serious injury to natural and farm ecosystems due to complex pathogenic mechanism. Recently, CRISPR/Cas9-based gene-editing strategy has been established in *Phytophthora sojae*, becoming a powerful tool for oomycete functional gene research. However, an integrated gene research system needs functional complementation and reintroduction of target gene(s). Currently, lacking efficient selection marker for complementation becomes the short board of gene function research. Here, we report that the gene *NAT1* (GenBank: CAA51674.1), which encodes Nourseothricin acetyltransferase and confers resistance to antibiotic Nourseothricin, can be used as a selection marker for *Phytophthora* transformation. Therefore, a new genetic manipulation toolkit is developed based on vectors containing *NAT1* or *NPT II*, offered practical assistance to advanced functional analysis of *P. sojae* avirulence genes. In this study, we demonstrated that the *NAT1* gene can be used as a screening marker and constructed a complete functional genetic research system in *P. sojae*. This report will greatly accelerate the functional genomics of oomycetes.

P4.3-019

COMPARATIVE GENOMICS OF CERATOBASIDIUM THEOBROMAE STRAINS ASSOCIATED WITH VASCULAR STREAK DIEBACK OF CACAO IN ASIA AND RED MAPLE IN NORTH AMERICA.

MCVAY John. (1), BONKOWSKI John. (2), URBINA-YANEZ Hector. (1)

(1) Florida Department of Agriculture and Consumer Services, Gainesville, UNITED STATES; (2) Plant and Pest Diagnostic Laboratory, Purdue University, West Lafayette, In, UNITED STATES

Text

Since 1960, vascular streak dieback (VSD) of cacao, associated with Ceratobasidium theobromae (Ceratobasidiaceae, Basidiomycota), has contributed to major yield loss in cacao in SE Asia and Oceania. In the mid 2010's, ornamental trees in nurseries in Eastern North America began to present symptoms of dieback with streaking in xylem and an associated fungus was isolated. Morphology, disease symptoms and a nearly identical ITS DNA sequence led to the diagnosis of C. theobromae. In Summer 2022, symptoms consistent with this disease were reported in red maple (Acer rubrum) in a nursery in Florida. Subsequent analysis at Purdue University, Indiana, USA and Florida Department of Agriculture and Consumer Services confirmed the presence of the same North American strain. Based on ITS, this strain appeared to be more closely related to a strain reported from China in Lonicera japonica, also a widespread invasive plant in Eastern North America, than to cacao strains. We performed whole genome sequencing on the Florida strain (37M 150bp

paired end Illumina reads) and mapped high-quality reads to two previously published genome assemblies from cacao strains from Borneo and Sulawesi. Similarity between Asian and Florida strains was lower (~95%) than among Asian strains (>99%) and numerous putative effector genes present in Asian strains appear to be incomplete or absent in the Florida strain, prompting a more robust evaluation of the latter's functional properties and taxonomic status.

EXPLORING THE SURPRISING DIFFERENCES IN EFFECTOR COMPLEMENTS OF THE CLOSELY RELATED APPLE AND STRAWBERRY POWDERY MILDEW PATHOGENS

HEAVEN Thomas. (1), COCKERTON Helen. (2), GODDARD Matthew. (3), XU Xiangming. (1), ARMITAGE Andrew. (4)

(1) NIAB EMR, West Malling, UNITED KINGDOM; (2) University of Kent, Canterbury, UNITED KINGDOM; (3) University of Lincoln, Lincoln, UNITED KINGDOM; (4) Natural Resources Institute, Chatham, UNITED KINGDOM

Text

Podosphaera aphanis is an obligate biotroph and the causal agent of strawberry powdery mildew and is considered the most important aerial disease affecting strawberry cultivation. Similarly, *Podosphaera leucotricha* is an economically damaging pathogen and the causal agent of apple powdery mildew. We have assembled pan-genomes from three *P. leucotricha* and three *P. aphanis* field samples. *In silico* methods have been used to predict genes within these assemblies, particularly candidate 'effector' proteins. The genomes share features with other powdery mildew lineages. Proliferation of similar transposable elements to those in endoparasitic powdery mildew species was found, along with numerous *RALPH* gene orthologues (RNAse like proteins associated with haustoria). Comparable expansion of the *RALPH* gene family has not previously been reported outside of monocot powdery mildews. Enlarged powdery mildew effectorome size has previously been associated with narrow host range and the *Blumeria* lineage. Despite being closely related species, with comparably restricted host ranges, our results reveal a *P. leucotricha* effectorome that is more than four times larger than that of *P. aphanis.* An isolate's effector complement determines its host range. Identifying candidate effector genes in *P. leucotricha* and *P. aphanis* will facilitate investigation into the evolution of these species as well as aiding breeding and diagnostic efforts to combat these economically important pathogens.

MINI-CHROMOSOMES DRIVE LARGE-SCALE GENOME REARRANGEMENTS AND HORIZONTAL GENE TRANSFER IN THE BLAST FUNGUS MAGNAPORTHE ORYZAE.

BARRAGAN A. Cristina. (1), MALMGREN Angus. (1), HARANT Adeline. (1), LATORRE Sergio M.. (2), WIN Joe. (1), BURBANO Hernan A.. (2), LAMOUR Kurt. (3), KAMOUN Sophien. (1), **LANGNER Thorsten. (1)**

(1) The Sainsbury Laboratory, Norwich, UNITED KINGDOM; (2) Centre for Life's Origins and Evolution, Department of Genetics, Evolution and Environment, University College London, London, UNITED KINGDOM; (3) Department of Entomology and Plant Pathology, University of Tennessee, Knoxville, UNITED STATES

Text

Blast disease epidemics caused by the fungus Magnaporthe (syn. Pyricularia) oryzae are often dominated by clonal pathogen lineages. In absence of sexual recombination, a major driver of genomic diversity and purging of deleterious mutations, these lineages manage to continuously adapt to their host plants. Contrary to their very low genetic diversity in core genomic regions, we observed vast chromosome diversity in clonal blast fungus populations. We found that variable mini-chromosomes (mChr) contribute to megabase-scale genome rearrangements, chromosome duplications, and horizontal transfer of mChr between diverse host-specialized lineages. These transfer events include mChr-encoded virulence effector candidates. We hypothesize that mChr rearrangements and inter-lineage transfer contribute to blast fungus genome diversity and to the adaptive potential of the blast fungus.

NOVEL PIPELINES FOR ASSEMBLING AND ANNOTATION OF GENOMES FOR PLANT PATHOGENIC FUNGI. APPLICATION ON TWO MAJOR BANANA PATHOGENS.

RAVEL Sebastien. (1), BACHE Simon. (1), DURAND Theo. (1), MOSTERT Diane. (2), VILJOEN Altus. (2), CARLIER Jean. (1), **WICKER Emmanuel. (1)**

(1) CIRAD, Montpellier, FRANCE; (2) Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text

An understanding of the evolutionary dynamics that allow plant pathogens to break down host resistance and develop fungicide resistance, is needed to develop durable and efficient control methods. To address the plasticity of fungal genomes, long-read genome sequences and adequate bioinformatic support is required to generate high-quality chromosome-level assemblies. In this study, the variability in the structural genomes of two important banana pathogens, *Pseudocercospora fijiensis* (causing the black Streak) and *Fusarium oxysporum* f.sp. *cubense* TR4 (causing the Fusarium wilt), were investigated. We first developed the workflow « Podium ASM » to assess the quality of long-read genome assemblies, based on contig numbers, genome completeness, and the presence of telomeric sequences. A second workflow, named « EffiCAZ », was then used to improve functional annotation of pathogenicity-related effectors and CAZymes. Chromosome-level genome assemblies were obtained from four Nanopore sequences of each species, and compartmentalised into a core and an accessory part, with contrasting gene densities and effector distribution. A much higher proportion of transposable elements was observed in *P. fijiensis* than in *F. oxysporum* f.sp. *cubense* TR4. These new pipelines pave the way for the comprehensive characterization of the pangenomes of the two banana pathogens.

P4.3-025

MAJOR PROLIFERATION OF TRANSPOSABLE ELEMENTS IN THE LAST 10 MILLION YEARS HAS SHAPED THE GENOME OF THE SOYBEAN RUST PATHOGEN PHAKOPSORA PACHYRHIZI

DUPLESSIS Sebastien. (1)

(1) INRAE, Champenoux, FRANCE

Text
The soybean rust disease caused by *Phakopsora pachyrhizi* is a major constraint for soybean production. It can lead to yield losses of up to 80% and it is one of the most economically damaging agricultural disease. This rust fungus is only known to reproduce through clonal propagation of dikaryotic urediniospores on legume species. The dramatically large and highly repeated nature of the genome of *P. pachyrhizi* prevented the production of an accurate assembly, and sequencing attempts in the dawn of fungal genomics have proven unsuccessful. In the frame of a combined effort from ***the international soybean rust genome consortium***, we independently sequenced three *P. pachyrhizi* genomes uncovering a genome size of up to 1.25 Gbp comprising two haplotypes with a transposable element (TE) content of ~93%. We performed a detailed annotation of TEs and showed the rapid genome expansion through the recent proliferation of long terminal repeat (LTR) TEs in the *P. pachyrhizi* genome. We studied the incursion and dominant impact of these TEs on the genome and show how they have a key impact on various processes such as host range adaptation, stress responses and genetic plasticity. The high-quality *P. pachyrhizi* genomes represent a key community resource for developing novel control methods and understanding the molecular mechanisms of *P. pachyrhizi*-soybean interactions.

P4.3-026

HOTSPOT GENOMES SHED LIGHT ON P. ORYZAE EVOLUTION IN SUB-SAHARAN AFRICA

ONAGA Geoffrey. (1), OLIVA Ricardo. (2), TELLA Euridice. (1)

(1) AfricaRice, Bouake, COTE D IVOIRE; (2) IRRI, Los Banos, PHILIPPINES

Text
The rice blast fungus, Pyricularia oryzae, is responsible for the widespread economic losses on rice in several rice producing countries when environmental conditions are favorable. Since its initial outbreak in Uganda in the 1920s, P. oryzae has been a major threat to the SSA rice sector and continues to impede rice cultivation in various countries across the region. We used genomic analysis to demonstrate that P. oryzae in SSA originated from a number of different genotypes that were brought over from Asia. The phylogeny of 42 SSA isolates collected from 13 rice growing countries and 139 global genomes retrieved from sequence archives showed that the blast population had two primary clades, one of which formed three sub clades, all of which at least contained isolates from SSA, although group 1 and 2 are less represented in SSA. Genome analysis strongly supports the notion that East Africa was the initial point of introduction in SSA. Using Bayesian stochastic search variable selection (BSSVS), the relative transition rates between different countries showed that the majority of P. oryzae population found in the world originate from China. Madagascar appears to have the fewest connections of all the samples analyzed. To a significant extent, Burundi acts as a sink for isolates coming from China, the Philippines, and West Africa.

Because multiple genotypes have already been introduced in SSA, preventing any more introductions is crucial.

Germplasm seed movement and global plant health

C3.7-1

REGULATORY FRAMEWORK FOR SEED HEALTH

MILLER Nathan. (1), PODLECKIS Edward. (1), BRUNS Tracy. (1), OSTERBAUER Nancy. (1), **BALCI Yilmaz. (1)**

(1) United States Department of Agriculture (USDA), Riverdale, Maryland, UNITED STATES

Text
Seed production and movement is an increasingly global business where seed lots may move through five or ten countries before they are planted. Phytosanitary certification for international trade of seed specific pests of concern, and each seed lot can be tested or inspected for multiple pests. As an outcome, seed exporters must meet the phytosanitary requirements set by the importing National Plant Protection Organization (NPPO) for each country they enter. To create an alternative phytosanitary mechanism in seed trade, in 2022, USDA-APHIS published a Regulatory Framework for Seed Health (ReFreSH) accreditation standard and supplemental participant manual. The program will accredit a systems approach for managing phytosanitary risk in the seed supply system. A systems approach under ReFreSH would leverage current seed industry best management practices. This allows for flexibility in pest management if entities can provide equivalence in efficacy. The new regulatory framework will allow for an audit-based accreditation for managing seed health as an alternative to consignment-by-consignment inspection or testing for phytosanitary certification. Currently, pilot projects are being established to determine if a systems approach will provide phytosanitary equivalence and an appropriate level of protection against pests of concern. The pilot will also give information about the extent of NPPO resources that are required to implement this program.

Batan, MEXICO; (3) CIP, Lima, PERU; (4) Alliance Bioversity-CIAT, Cali, COLOMBIA; (5) Alliance Bioversity-CIAT, Gembloux, BELGIUM; (6) ICARDA, Terbol, LEBANON; (7) ILRI, Addis , ETHIOPIA; (8) IRRI, Los Banos, PHILIPPINES; (9) AfricaRice, Bouake , COTE D IVOIRE

Text

Germplasm seed exchange from CGIAR genebanks and breeding is important to global agricultural research and development programs. Seed as a pathway for pest spread is an inherent risk for international seed exchanges. Phytosanitary controls have been established in accordance with the International Plant Protection Convention (IPPC) to protect global plant health from transboundary pest invasion. This presentation summarizes pest risks to international germplasm distribution; CGIAR Germplasm Health Units (GHUs) procedures to ensure the production and distribution of pest-free germplasm; bottlenecks to germplasm distribution, including the inadequacy of phytosanitary regulations guided by the International Standards for Phytosanitary Measures (ISPMs) of IPPC; and consequences of delayed germplasm access on crop improvement programs. It also presents the 'CGIAR Greenpass Phytosanitary Protocol (CGPP)' concept as a comprehensive phytosanitary compliance assurance procedure. Based on a systems approach of pest risk identification and pest risk mitigation in the germplasm seed production pipeline and the rigorous implementation of phytosanitary controls in collaboration with national plant protection organizations, the CGPP is expected to fast-track pest-free germplasm distribution to the global community.

C3.7-3

IMPACT NETWORK ANALYSIS (INA) FOR NATIONAL MITIGATION STRATEGIES FOR EMERGING SEED-BORNE PATHOGENS

GARRETT Karen. (1)

(1) University of Florida, Gainesville, UNITED STATES

Text

National programs tackling emerging seed-borne pathogens need efficient approaches to make the most of often limited resources. Impact network analysis (INA) is a tool for scenario analysis to understand the likely outcomes of the regional management strategies that are being considered (Garrett 2021). INA evaluates the network of pathogen movement through seed trade and/or the movement of vectors or propagules (examples for potato, sweetpotato, and banana: Buddenhagen et al 2017; Andersen et al 2019; Andersen Onofre et al 2021; Nduwimana et al 2022). It can also incorporate the network of communication among stakeholders, which influences decisions about management (example for avocado: Etherton et al 2023). The scenario analyses in INA can be used to evaluate the most important locations for surveillance and mitigation, and the likely outcomes from specific policies that could be implemented to support disease management. INA can also be used to evaluate whether seed systems are providing benefits, such as improved varieties and protection against disease, to all the stakeholders in the system. This presentation will introduce a new user interface for INA, along with new examples of scenario analyses for a range of crops and diseases.

C3.7-4

PHYTOSANITARY TESTING AND SANITATION FOR SAFE TRANS-NATIONAL MOVEMENT OF CLONALLY PROPAGATED CROPS: HISTORY AND FUTURE

MÜLLER Giovanna. (1), KREUZE Jan . (1), FUENTES Segundo. (1)

(1) International Potato Center, Lima, PERU

Text

Crops that are propagated through vegetative tissues such as stem cuttings, tubers or roots tend to accumulate virus infections over growing seasons because in contrast to seed crops that can reduce virus infections every generation as most viruses are not, or relatively poorly transmitted through seeds. Other pest and pathogens can also easily be transmitted through vegetatively propagated materials and so material is usually shipped as sterile explants in test tubes, thus eliminating most pests, except those that replicate intracellularly, such as viruses. Virus testing procedures have evolved over the years, starting from evaluating symptoms directly or after transmission to biological indicator plants, evolving to electron microscopy, ELISA, PCR, nucleic acid hybridization and more recently high throughput sequencing (HTS) approaches. We will present the evolution of methods and strategies for virus diagnostics as they occurred at the International Potato Center culminating in the current move to HTS as the novel standard for virus indexing for safe movement of clonal crops.

C3.7-5

PUBLIC-PRIVATE PARTNERSHIP MODEL TO ENHANCE SAFE INTERNATIONAL SEED TRADE IN THE GLOBAL SOUTH: A CASE STUDY IN SOUTH AND SOUTHEAST ASIA

KHETARPAL Ravi. (1)

(1) Asia- Pacific Association of Agricultural Research Institutions (APAARI), Bangkok, THAILAND

Text

The importance of public-private partnerships for seed trade cannot be overstated as the bulk of seed production is carried out by the private sector while the public sector is are responsible for vetting and approving to ensure the safe import or export of seed lots. APAARI with the support from STDF/WTO and in active partnership of private seed sector agencies. viz., Asia-Pacific Seed Alliance (APSA), International Seed Federation (ISF), CropLife Asia (CLA) and American Seed Trade Association (ASTA), a project has been launched recently on Strengthening phytosanitary compliances and public private partnership for boosting seed trade for the Asia Pacific region. The pilot countries are Bangladesh, Cambodia, Laos, Nepal, Philippines, Thailand and Vietnam along with engaging New Zealand and Australia as mentoring countries. The initiative is addressing the NPPOs' regulated pest lists, the capacity to adopt and implement ePhyto, and scope for accreditation of private sector seed health testing laboratories, and strengthening of public–private coordination platform for seed trade through capacity building and policy dialogues.

C3.7-6

QUARANTINE OF GERMPLASM FOR PLANT BIOSECURITY AGAINST TRANSBOUNDARY VIRUSES: IMPORTANCE OF DIAGNOSTICS AND PHYTOSANITARY REGULATIONS

VASIMALLA Celia Chalam. (1), KUMARI Pooja. (1), KALAIMUGHILAN Kalaiponmani. (1), YADAV Priya. (1), MAURYA Ashok Kumar. (1)

(1) ICAR-National Bureau of Plant Genetic Resources, Delhi, INDIA

Text

The global movement of germplasm has the potential to introduce new viruses which may pose potential risk to the agriculture of importing country. In India, ICAR-National Bureau of Plant Genetic Resources has been empowered for quarantine processing of imported germplasm including transgenics meant for research purposes. As per the Plant Quarantine (Regulation of Import into India) Order, 2003, 1261 pests including 264 viruses are regulated pests which are of quarantine significance for India. Early, sensitive and accurate diagnosis is necessary for detection of viruses in quarantine. The challenges in virus detection include availability of antisera, virus genome sequences in GenBank, detecting an unknown/exotic virus etc. Adopting a strategy of post-entry quarantine growing/inspection followed by use of combination of physical, serological and molecular detection techniques, 45 viruses of great economic and quarantine importance were intercepted in imported germplasm including transgenics in the last two decades. The interceptions include 19 viruses not yet reported from India and several viruses not known to occur on particular host(s) in India. India should put in place a “National Plant Pests Diagnostic Network” to enhance preparedness. Adopting reliable virus detection techniques and implementing quarantine regulations strictly would go a long way in ensuring plant biosecurity against transboundary viruses through quarantine and exchange of virus-free germplasm.

F3.7-1

SEED PATHWAY FOR PEST DISSEMINATION: THE ISTA REFERENCE PEST LIST, A BIBLIOGRAPHIC RESOURCE IN NON-VEGETABLE PLANT SPECIES.

DENANCE Nicolas. (1)

(1) GEVES, Beaucouzé, FRANCE

Text

Food safety is intimately linked to plant health. It is threatened by pests whose impact varies greatly depending on the crop, agricultural practices, and regions of the world. In a global trade context, the transport of infested plant materials is an important factor in the spread of organisms to new territories, which can cause emerging diseases. It is critical to deploy strategies to limit this from happening. Identifying pests and their vectors is a first step towards risk analysis. International initiatives are bringing together research results on the role of seeds as vectors of pests. The International Seed Testing Association Reference Pest List (ISTA-RPL) focuses on seed-borne pathogenic organisms in about 50 plant species (field crops, legumes, fruit and forest trees, aromatic plants). The aim is to determine, based on scientific results, if these organisms can (or cannot) be transmitted vertically or transferred

in the environment under natural conditions, making seeds a vector of dissemination. The ISTA-RPL currently inventories 333 pests, of which 146 are transmitted or transferred via seeds in 23 host species (v9.0; July 2022). It is a living tool, and an additional set of hosts is under investigation. This literature resource may be a valuable source for risk assessors and policymakers. It also opens avenues of R&D work by seed companies, academic laboratories or industry to develop diagnostics, detection methods, or treatments

P3.7-001

SEED TRANSMISSION OF SPINACH DOWNY MILDEW

CLARK Kelley. (1), KANDEL Shyam. (1,2), MOU Beiquan. (1), CORRELL James. (3), KLOSTERMAN Steven. (1)

(1) USDA-ARS, Crop Improvement and Protection Research Unit, Salinas, UNITED STATES; (2) USDA-ARS, Edward T. Schafer Agricultural Research Center, Fargo, UNITED STATES; (3) University of Arkansas, Fayetteville, UNITED STATES

Text
Spinach downy mildew, caused by the oomycete pathogen *Peronospora effusa*, remains a constraint on spinach production. New races of *P. effusa* continue to appear and can overcome cultivar resistance. Spread of the pathogen via airborne sporangia is well established. However, the role of oospores from seed and infected crop debris has been long debated and remained uncertain. We have found oospores to be present in around 19% of evaluated spinach seed lots. To evaluate seedborne downy mildew transmission, we used isolated glass chambers to grow out oospore-infested spinach seeds, and seeds mixed with oospore-infested crop debris in two independent trials. Downy mildew diseased spinach plants were found 37 days after planting in the first trial, and 34 days after planting in the second trial, in glass chambers that contained one of two oospore-infested seed lots or seeds coated with oospore-infested leaves. Spinach plants in glass chambers initiated from seeds without oospores did not show downy mildew symptoms. These findings provide evidence of seed transmission of downy mildew to spinach plants via oospores and suggest management practices such as seed treatments to reduce the primary inoculum of the pathogen are needed.

P3.7-002

DEVELOPMENT AND APPLICATION OF REVERSE TRANSCRIPTION DROPLET DIGITAL PCR ASSAYS FOR DETECTION AND QUANTIFICATION OF MAJOR APPLE VIRUSES FROM IN VITRO MICROPROPAGATED APPLE PLANTLETS

LEE Hyo-Jeong. (1), KIM Sung-Woong. (1), JEONG Rae-Dong. (1)

(1) Chonnam National University, Gwangju, REPUBLIC OF KOREA

Text
Most apple cultivars reproduce mainly through asexual propagation, and their replicas have been distributed as vegetative cuttings around the worldwide. The fruit trees, including

apples, are propagated in tissue vegetative and become grafted on root stock. These reproduction methods result in the infection of numerous plant viruses with some of them causes several diseases, fruit crop losses and reducing. Apple stem groove virus (ASGV) and apple stem pitting virus (ASPV) are major viral pathogens of pome fruit crops, such as apple, pear, and causes significant losses to fruit production in many countries. To reduce these economic losses, it is important to develop effective methods to acquire virus-free propagation material and prevent the spread of virus. Accordingly, in order to produce in vitro micropropagated plantlets without viruses, accurate and sensitive detection methods are urgently required. This study purposes a sensitive and accurate method for detection and quantification of ASGV and ASPV from in vitro micropropagated apple plantlets using a reverse transcription droplet digital polymerase chain reaction (RT-ddPCR) assay. Recently, several studies have reported the successful detection and quantification of plant RNA viruses using ddPCR in plants. The RT-ddPCR assay represents a promising alternative for accurate quantitative detection and diagnosis of ASGV and ASPV infection in virus-free certification programs.

P3.7-003

RECOVERY OF BLS-ASSOCIATED PATHOGEN FROM SEED, SEEDLINGS, AND LEAF SAMPLES IN SOUTH DAKOTA

KAUR Jaswinder. (1), SEHGAL Sunish. (1), GLOVER Karl. (1), SHIRES Madalyn. (1), **ALI Shaukat. (1)**

(1) South Dakota State University, Broonings, UNITED STATES

Text

Bacterial leaf streak (BLS) caused by Xanthomonas translucence pv. (translucens/undulosa), is a significant disease threatening wheat production in South Dakota and its surrounding regions. The pathogen can survive on crop residue and seed, making it a persistent source of infection for future crops. In this study, we analyzed 28 seed samples, 12 leaf samples collected from the field, and 18 seedlings of HRSW, raised from Xanthomonas translucens-infected seed, to check the presence of the Xanthomonas translucence pv. Translucens(Xtt) and Xanthomonas translucencepv. Undulosa (Xtu) . All grain, leaf, and seedlings samples were plated on KB medium for four days. The phenotypic data on the colonies obtained from the 20 seed, 12 leaves, and 10 seedlings suspected presence of Xtt/Xtu. Further, these suspected Xanthomonas translucens - colonies from seed, leaves, and seedlings were genotyped using Xtt and Xtu specific primers. Of 42 samples genotyped 23 samples (13 seeds, 7 leaves, 3 seedlings) were positive with either Xtt or Xtu. The results reveal that seed could be a significant source of inoculum for BLS development in South Dakota. Also, both Xtt and Xtu could be responsible for disease development. In addition, more grain samples and leaf samples collected from various locations and cultivars are under investigation to obtain a broad picture of the pathogen's pathovars and their survival on seed.

P3.7-004

EMERGENCE OF NEW DISEASES IN IMPORTED GERMPLASM OF APPLE

RAJ Harender. (1), VERMA Shalini. (1)

(1) Dr Y. S. Parmar University of Horticulture and Forestry, Solan, INDIA

Text
Transboundary movement of germplasm carries an inadvertent risk of introduction of new diseases and pests into new areas. India is Asia's major apple importer and accessing apple from 29 destinations across the globe. In India, 8 fungal and 13 viral pathogens of quarantine importance have been intercepted during 2015-20 in general. Himachal Pradesh is dominantly an apple State in India with 0.14 million ha area. Apple cultivation is going in a big transformation in the State to replace the more than 50 years of old plantation. In this State, more than 3.0 million plants of apple have been imported for the replacements and also for high density plantation. The State has history of serious threats of diseases like apple scab (*Venturia inaequalis*) and pre-mature leaf fall (*Marssonina coronaria*) causing epidemics resulting in serious losses and their severity is also attributed to the inter-state movement of planting material. In the orchards and nurseries raised out of the imported planting material, many new fungal, viral, and phytoplasma pathogens have been recorded causing leaf spots and blight (*Curvularia* spp.), white thread blight (*Ceratobasidium stevensaii*), root rot (Fusarium solani), fruit rots (*Curvularia lunata*, *C. spicifera*, *Trichoderma gamsii*), flat limb (phytoplasma) and other viral diseases. Incidence of some already prevalent pathogens like pink canker (*Corticium salmonicolor*) and stem brown canker (*Botryosphaeria obtusa* and *B. dotheidea*) has also increased.

Text
The relationship between insect pests and seeds is an increasing issue. Insect damage in the field and/or during storage can have a significant impact. Indeed, seeds can be a major vector for the spread of insects across territories. Moreover, the restrictions imposed by countries on the import of seed lots are increasingly stringent.
Currently, ISTA rules do not provide methods to meet the increasing demands of seed testing laboratories for insect detection. For this reason, an ISTA-funded project was developed with the objective of testing and comparing the effectiveness of different methods with potential for detecting insects in all their forms in seed lots.
Based on the results of a survey on the needs of laboratories, several seed/insect combinations were selected with a priority for insects concerned by phytosanitary certificates. Literature searches were conducted to identify existing and potential methods to be tested. The methods to be explored were defined for each combination according to the type of insects and seeds.
The combinations Bruchus sp./Lentils; Acanthoscelides obtectus/Common bean; Zabrotes

subfasciatus/Common bean and Sitophilus granarius/Wheat were tested with different methods: Berlese funnel, sieving, morphological inspection, 2D X-rays, oxygen consumption and multispectral imaging. The results will be presented and compared

P3.7-006

ALFALFA SEED VIROME

NEMCHINOV Lev. (1), IRISH Brian. (2), GRINSTEAD Sam. (1), SHAO Jonathan. (4), POSTNIKOVA Olga. (1,3)

(1) USDA/ARS/Beltsville Agricultural Research Center, Molecular Plant Pathology Laboratory, Beltsville, UNITED STATES; (2) USDA/ARS, Plant Germplasm Introduction and Testing Research, Prosser, UNITED STATES; (3) School of Plant and Environmental Sciences, Virginia Tech, Blacksburg, UNITED STATES; (4) USDA/ARS/ OFFICE OF THE AREA DIRECTOR, Beltsville, UNITED STATES

Text
Seed transmission of plant viruses is important due to the role it might play in their dissemination to new areas and subsequent epidemics. Seed transmission largely relies on the replication capacity of a virus in reproductive tissues and its survival during a seed maturation process. It occurs mainly through the infected embryo, although contaminated seed coats can be a source of infection by mechanical means. Alfalfa (*Medicago sativa* L.) is an important legume forage crop worldwide, and except a few individual seedborne viruses infecting the crop, its seed virome is poorly known. The goal of this work was to perform initial seed screenings of alfalfa germplasm accessions maintained as part of the USDA ARS National Plant Germplasm System to identify pathogenic viruses and understand their potential for dissemination. For detection of viruses, we used high throughput sequencing combined with bioinformatic tools. Prior to the experiment, the seeds were scarified with concentrated sulfuric acid and sterilized with 70% ethanol to eliminate surface contamination. Our results suggest that in addition to common viruses, alfalfa seeds are infected by other potentially pathogenic viral species that could be vertically transmitted to offspring. The information gathered will be used to make decisions on whether germplasm distributions need to be restricted based on viral presence. The data will be uploaded to the Germplasm Resources Information Network (GRIN)-Global database.

P3.7-008

SEED POTATO CERTIFICATION ROLE IN DISEASE MANAGEMENT IN AUSTRALIA

CRUMP Nigel. (1)

(1) Australian Seed Potato Industry Certification Authority (AuSPICA), Toolangi, AUSTRALIA

Text
Seed potato certification provides high plant health planting material to the Australian industry to produce commercial potatoes for processing and table stock markets. Phytosanitary data is collected on each seed crop including the incidence and severity of

endemic diseases in addition to the absence of exotic and/or quarantine diseases. This data is important to the production of high health seed potatoes but also is a valuable data set in relation to domestic and international trade of seed potatoes and this data can be used for support pest area freedom.
Seed certification has relied on the visual assessment of seed potato crops for symptoms of disease. For many years, this approach was successful in mitigating Potato Virus Y, however increased occurrence of PVY often without visual disease symptoms, required a different approach of routine leaf testing of seed potato stocks. Initially, a higher rejection of crops occurred but after several years of continued testing the levels of PVY were reduced and seed quality improved.
Potato Spindle Tuber Viroid (PSTVd) is not reported to occur in Australian potato production.. Targeted surveillance for PSTVd in potato crops submitted for certification from 2016 to 2022 was conducted. . Samples of potato leaves were collected from 10% of all seed crops. Leaf samples were analyzed using RT-PCR. PSTVd was not detected during the 7-year surveillance period.

P3.7-009

EVALUATION OF IN SITU AND EX SITU FORAGE GERMPLASM COLLECTIONS REVEALED THE FIRST OCCURRENCE AND SEED-TRANSMISSION OF ALFALFA MOSAIC VIRUS AND SOUTHERN BEAN MOSAIC VIRUS INFECTING BRACHIARIA SPP.

BEDANE Woubit. (1), MULATU Fikerte . (1), ESHETE Yesuf. (1), NEGAWO Alemayehu. (1), ALICE Muchugi. (1)

(1) International Livestock Research Institute (ILRI), Addis Ababa, ETHIOPIA

Text
Brachiaria spp (syn. Urochloa spp) is one of the most important tropical forages grasses of African origin. It is adapted to drought and low fertility soils, and known for palatability and high-quality biomass production, and thus improves livestock productivity. The International Livestock Research Institute (ILRI) forage Genebank maintains 671 accessions of Brachiaria grass, belonging to 28 species, of which 261(39%) accessions are Urochloa brizantha. The susceptibility of Brachiaria grass to diseases and insect pests is a key challenge to the sustainable production of the grass in Africa. In this study, using dot blot assay and RT-PCR methods, we report for the first time the detection of Alfalfa Mosaic Virus (AMV) and Southern Bean Mosaic Virus (SBMV) on 88 % of the tested accessions conserved in situ and ex situ at ILRI forage genebank. In addition, the virus transmission from seed to plant and legume to grass and vice versal was confirmed through bioassay test. The detection of these two viruses on Brachiaria spp. will present a new challenge to germplasm conservation, distribution, and its sustainable production in the regions and demands an immediate attention towards developing an effective virus cleaning method of the conserved germplasm. Furthermore, there is also an urgent need to assess the economic importance of the diseases on the grass and selection of germplasm that has a better resistance to the diseases.

P3.7-010

TAXONOMIC DIVERSITY OF RICE SEED ASSOCIATED BACTERIA IN REPRESENTATIVE SEED IMPORTS FROM VARIOUS COUNTRIES INTO AFRICARICE GHU

BACHABI Fatimata. (1), ONAGA Geoffrey. (1)

(1) AfricaRice, Bouaké, COTE D IVOIRE

Text

In recent years, seeds have become the primary pathogen inoculum carrier worldwide. Due to the rise in seed-borne diseases, taxonomic charactrization and detection of seed-borne pathogens has become increasingly important. This study isolated and identified culturable bacteria from rice seeds exchanged with AfricaRice over two years, starting in 2021. Metagenomic whole genome shotgun (mWGS) sequencing was used to identify dominant colonies in 1177 seed samples from eight countries: Senegal (139), Tanzania (64), Mali (124), Madagascar (19), Kenya (31), Nigeria (440), Guinea (340), and Philippines (20). Pantoea, Bacillus, and Pseudomonas were the three most prevalent genera in seed samples, with Pantoea being the most common in samples from the Philippines, Mali, Nigeria, Senegal, and Madagascar, and Pseudomonas being equivalent to Bacillus in samples from Tanzania and Guinea. Fifty percent of Kenyan bacterial isolates were Sphingomonas. This study also detected non-pathogenic taxa such Kosakonia, Enterobacter, Microbacterium, Sporosarcina, and Stenotrophomonas. Overall, we found considerable taxonomic diversity among the culturable bacterial isolates from imported rice seeds, as has been reported for many seed exchange microbial analyses. Further analysis of the dorminant species will be conducted to develop techniques for routine identification in countries exchanging seeds with AfricaRice Germplasm Health Unit, to limit the spread of seed borne pathogens.

P3.7-011

SWEETPOTATO VIRUS INCIDENCE AND ELIMINATION IN THE GLOBAL GERMPLASM COLLECTION MAINTAINED AT THE INTERNATIONAL POTATO CENTER (CIP)

ROMAN Maria. (1), MARIO Ruiz. (1), ANDREA Carrion. (1), REYNALDO Solis. (1), MÜLLER Giovanna. (1), KREUZE Jan . (1), **MELLO Alexandre. (1)**, AZEVEDO Vania. (1)

(1) INTERNATIONAL POTATO CENTER, Lima, PERU

Text

The CIP’s Genebank has the goal of conserving and distributing sweetpotato genetic resources. This implies on the permanent receival of new accessions to sustain the global genotypic diversity of the collection. The introduction of external accessions implies on the permanent development of detection procedures and elimination of plant pathogens prior to the introduction of these genotypes in the *in vitro* collection. The current procedure applied on imported accessions consists of a post entry quarantine, plant indexing, followed by NCM-ELISA and PCR. Serological and molecular tests assess the presence of 10 different virus species and the genus Begomovirus. Samples that are positive to the presence of a pathogen are subjected to thermotherapy and meristem isolation. Data from 175 samples

showed that 76% of the samples were virus infected. Begomoviruses in single or mixed infections were the most prevalent viruses, occurring in 53% of the positive samples evaluated. SPCFV, SPCV, SPFMV were also detected in mixed and single infections representing an overall of 31% of the infected plants. The remaining positive samples were due to the presence of SPMMV, SPVCV and SPVG in single infections or symptoms on the indicator plant with nonidentified causal agent. A single thermotherapy and meristem isolation removed 62% of viruses. However, in some specific virus mixtures up to six meristems were required to be evaluated until a virus free accession line was identified.

P3.7-012

PHYTOSANITARY EVALUATION OF THE IN VITRO CASSAVA COLLECTION (MANIHOT ESCULENTA CRANTZ): COLLECTION HISTORY AND PHYTOSANITARY EVALUATION

CUERVO Maritza. (1), NIÑO-JIMENEZ Diana Patricia. (1), ARANZALES Ericson. (1), VELEZ Monica. (1), MARTINEZ Angelica. (1), GIL Alejandra. (1)

(1) Alliance Bioversity Int. and CIAT, Cali, COLOMBIA

Text

Cassava is an important crop for more than a billion people around the world. Currently, more than 300 million hectares are produced yearly, supporting industrial consumption, and impacting food security. For this reason, the conservation of cassava crop diversity in genebanks is important for crop improvement. The Genetic Resources Program of the Alliance Bioversity and CIAT, conserves and facilitates access to the globally largest collection of cassava (5965 accessions). The collection of cassava was initially established in 1969 under field conditions in Palmira, Colombia. However, the emergence of quarantine diseases, such as Cassava frogskin disease, triggered the establishment of the collection under in vitro conditions. Later, in 1983, the Germplasm Health Unit (GHU) was created to ensure safe distribution of germplasm. The GHU has worked on diagnosing quarantine diseases, using traditional methods (graft-test), serological methods, and molecular techniques. Considering the emergence of new pathogens, the GHU continues working on implementing protocols with more sensitivity, specificity, and faster. As a result of this effort, and with a phytosanitary certification process underway, recognized by the Colombian Plant Protection Organization, the GHU was carried out the evaluation of the 100% of the cassava accessions, for at least one pathogen. This work allowed genebank users to have access to 92% of the germplasm, free of quarantined pathogens for safe distribution.

P3.7-013

IDENTIFICATION, CONSERVATION AND FORMATION OF A BANK OF STRAINS OF QUARANTINE FUNGI ISOLATED FROM BEAN SEEDS AND TROPICAL FORAGES, FROM THE GERMPLASM BANK “FUTURE SEEDS”.

RAMIREZ Julio Cesar. (1), NIÑO-JIMENEZ Diana Patricia. (1), GIL Alejandra. (1), DORADO Edwin Fabian. (1), MUNOZ Christian David. (1), CUERVO IBANEZ Maritza. (1)

(1) Alliance Bioversity Int. and CIAT, Cali, COLOMBIA

Text
Reference strains are an important resource that allows guaranteeing the quality of the results used mainly in phytosanitary diagnostic laboratories. Acquiring this biological material is difficult and its transboundary movement is highly restricted, due to the risks of introducing pathogens into disease-free geographic areas. The Germplasm Health Unit (GHU) of the International Bioversity Alliance and CIAT is responsible for evaluating the presence of quarantine-type fungi in the bean and tropical forages collections of the Germplasm Bank "Future Seeds". Having this type of reference material is of vital importance to carry out quality controls in accordance with the ISO 17025 standard. The GHU has built a collection of fungal strains isolated from seeds, as well as plant material collected from phytosanitary monitoring in the regeneration fields. The strains isolated were taxonomically characterized up to the species level, developing a DNA extraction protocol and amplifying the ITS (Internal Transcribed Spacer) region. Several isolates were sequenced using Oxford Nanopore Sequencing Technology. The sequenced genomes will allow the implementation of complementary molecular tests (PCR and/or qPCR) in routine diagnosis, strengthening the evaluation of quarantine-type fungi through phenotypic and genotypic characterization, guaranteeing the quality of the results obtained, which translates in an increase in the availability of the materials evaluated.

P3.7-014

DETECTION AND CHARACTERIZATION OF SEED-BORNE BACTERIAL LEAF BLIGHT IN WHEAT

KUMARI Safaa G.. (1), **MOUKAHEL Abdul Rahman. (1)**, ABO BAKR Abdo. (2), KASSEM Mohammad. (3)

(1) The International Center for Agricultural Research in the Dry Areas (ICARDA), Zahle, LEBANON; (2) General Commission for Scientific Agricultural Research (GCSAR), Aleppo, SYRIAN ARAB REPUBLIC; (3) Faculty of Agriculture, University of Aleppo, Aleppo, SYRIAN ARAB REPUBLIC

Text
Wheat is one of the most important crops which contributes toward global food security and represents a main source of food and income for millions of smallholder farmers worldwide. *Pseudomonas syringae* pv. *syringae* (*Pss*) is the causal agent of bacterial leaf blight wheat disease which can cause up to 50% yield loss or more depending on the time of infection and region. In addition, *Pss* is transmitted by wheat seeds, which can play a role in long-distance spread. Therefore, developing and implementing effective management strategies for bacterial diseases is very important to reduce yield and quality loss. However, rapid and accurate detection of diseases is the first essential step for effective management strategies for control of this disease. Even though molecular tools for *Pss* precise detection and characterization has been developed, the most practical approach for rapid diagnosis is the use of serological assays using specific antibodies. A polyclonal antiserum against a Syrian isolate of *Pss* was produced and its quality was evaluated by Dot-blot Immunoassay using homologous and heterologous antigens. Results revealed that the produced antiserum was able to detect *Pss* up to 1×10^3 CFU/ml dilution using raw antiserum at a dilution of 1/160 with no cross reactivity with other bacterial species (e.g. *Xanthomonas*).

Text

Seed-bearing crops represent a sector with considerable economic and strategic importance worldwide. The resurgence of fungal diseases, need for high quality seeds and increasing restriction on the use of synthetic pesticides, have spurred the search for alternative solutions to protect seedbearing vegetable crops from seedborne pathogens. This work aimed to evaluate the main fungal pathogens on seedbearing cabbage and to control them under farming conditions applying four innovative active substances in different protection strategies: chitosan, chito-oligosaccharides and oligo-galacturonides (COS-OGA), mixture of terpenes and *Bacillus amyloliquefaciens*. The field-trials were carried out involving two companies located in the Marche region, Central-Eastern Italy. According to the laboratory investigations on different symptoms observed in the experimental field, it was isolated several pathogens from different leaves symptoms. The main fungi detected were: *Alternaria alternata*, *Alternaria brassicicola*, and *Stemphylium* spp. In both cabbage fields, all innovative management strategies provided a good protection against leaf necrosis due to fungal infections, better than conventional application with the standard management strategies.

GERMPLASM SEED MOVEMENT AND GLOBAL PLANT HEALTH

PULLIKANTI Lava Kumar. (1), KUMARI Safaa. (2)

(1) International Institute of Tropical Agriculture (IITA), Ibadan, NIGERIA; (2) ICARDA, Terbol, LEBANON

Text

Global seed transfers through trade, and collection and distribution of genetic resources by genebanks are important pathways for the transboundary spread of seed-borne pests, especially viruses that the insect vectors can further transmit upon introduction. Various phytosanitary procedures, including the IPPC International Standard Phytosanitary Measures, have been established to minimize the risk of seed transmission and provide access to quality seeds crucial for food production and biodiversity conservation. This session will summarize the current state of efforts in minimizing the seed-transmission risk and measures to overcome bottlenecks to comply with phytosanitary standards. Presentations will cover pest risk to seed pathways and implications to global plant health,

strategies for minimizing seed-transmission risk, advances in diagnostic techniques for characterization and sensitive detection of seed-borne pests, and efforts to enhance phytosanitary capacity, especially in low- and middle-income countries to enable safe seed exchanges. The session will also highlight policy and regulatory limitations/bottlenecks necessary to improve safe exchange of germplasm and boost seed trade.

P3.7-017

PHYTOSANITARY PROCEDURES FOR THE CONSERVATION AND USE OF PLANT GENETIC RESOURCES CONSERVED IN THE IITA'S INTERNATIONAL GENEBANK

PULLIKANTI Lava Kumar. (1), OGUNTADE Oluwole. (1), AJAMU Deborah. (1), OLUDATE Aderonke. (1), ABBERTON Michael. (1)

(1) International Institute of Tropical Agriculture (IITA), Ibadan, NIGERIA

Text

Phytosanitary procedures are essential for the sustainable conservation of plant genetic resources and their safe international distribution. This presentation summarizes the methods used at the International Institute of Tropical Agriculture (IITA) to support the collection, conservation, and distribution of genetic resources of some of sub-Saharan Africa's most important food and nutritional security crops. It includes seed crops such as cowpea, soybean, maize, and several indigenous wild Vigna species and vegetatively propagated crops such as cassava, banana/plantain, and yam. These collections comprising over 33,000 accessions acquired over 50 years from over 100 countries, have been conserved as seed, in vitro plants, on the farm, and in third-party genebanks as part of the safety duplication. Procedures used include bioassays, ELISA and PCR-based methods, high-throughput sequencing (HTS) to assess the seed health status, and physical or chemical treatments to eliminate/inactivate pests or regenerate healthy propagation materials in-vitro and inspect for pests and diseases before germplasm can be exchanged. We will also discuss the challenges posed by the integrated viruses and cryptic viruses identified by the HTS to germplasm distribution and the development of a decision framework to evaluate the pest risk and decisions on distribution, regulatory challenges to international germplasm distribution, and the future prospects.

High throughput sequencing approaches for the detection of pathogens

C6.2-1

TO TRUST OR NOT TO TRUST ? THAT IS THE QUESTION WHEN DETECTING A PATHOGEN WITH HIGH THROUGHPUT SEQUENCING : CONSIDERATIONS FOR IMPROVING THE RELIABILITY OF DETECTION

MASSART Sebastien. (1)

(1) Liege University, Gembloux, BELGIUM

Text

High-throughput sequencing (HTS) technologies and the bioinformatics analysis of the generated data have brought tremendous improvements in the ability to detect plant pathogens. As any promising technology becoming widespread, there is a key question that needs to be addressed by the scientific community: how reliable are the generated results? Indeed, bias can occur at any step of the analysis.
The presentation will review nearly a decade of collaborative efforts to improve the reliability of HTS protocols for detecting plant pathogens: viroids, viruses, bacteria, fungi, oomycete…. Starting by demonstrating the huge impact of bioinformatics analysis on virus detection, the presentation will go through publications that focused on performance criteria evaluation for viruses (based on shotgun sequencing) and fungi (based on amplicon sequencing) detection by HTS.
In addition, the recent publication of international guidelines for reliable plant pathogen detection, published by more than 50 plant pathologists during Valitest project, has been a cornerstone in our collective path toward improved reliability. These guidelines will be summarized with a strong focus on the identified bias and on the controls to be used with HTS test. In addition, the usefulness of an alien control, a new external control to monitor the contamination burden between samples and to determine an adaptative threshold of detection, will be shown as well as the doubts that can arise in its absence.

C6.2-2

HIGH THROUGHPUT SEQUENCING: RESEARCH TO REALITY – THE AUSTRALIAN POST ENTRY QUARANTINE JOURNEY.

PATTEMORE Julie. (1), DINSDALE Adrian. (1), WHATTAM Mark. (1), ELLIOTT Candace. (1), GAUTHIER Marie-Emilie. (2), LELWALA Ruvini. (2), BARRERO Roberto. (2)

(1) Australian Government, Canberra, AUSTRALIA; (2) Queensland University of Technology, Brisbane, AUSTRALIA

Text

The ability to detect all viruses and viroids present in plants undergoing post-entry quarantine is the ‘holy grail’ for both plant health scientists and regulators alike. For the Australian Government Post Entry Quarantine (PEQ) facility, the aspiration has become a reality after a near-decade long journey from proof-of-concept and validation through to operationalisation. In December 2022, small RNA sequencing and VirReport bioinformatics were deployed as

the primary screening tool for virus and viroid detection in imported Prunus, Rubus, Fragaria and clonal grass species at PEQ. The outcomes from this deployment include the potential to reduce quarantine lag times, thousands fewer PCR tests per year, reduced use of biological indexing, and increased capacity for higher volumes of plant imports as a result of increased availability of glasshouse bench space. We anticipate that adopting high throughput sequencing (HTS) will enable plant industries to remain competitive and access more rapidly emerging high-value market opportunities.

C6.2-3

VALIDATING SMALL RNA SEQUENCING AND ASSEMBLY AS A GENERIC METHOD FOR VIRUS INDEXING IN POTATO AND SWEETPOTATO GERMPLASM.

KREUZE Jan. (1), MULLER Giovanna. (1), AMAO Melody. (1), VILLACORTA Jorge. (1), FUENTES Segundo. (1)

(1) International Potato Center, Lima, PERU

Text

Metagenomic sequencing has been used extensively for identification of viral infections by known and novel viruses in plants since over a decade. Different nucleic acids can be targeted in metagenomic approaches each with their benefits and draw-backs. Small RNA sequencing and assembly (sRSA) has shown to be a sensitive and relatively rapid method for detection of any viral infections in plants, fungi and insects, but includes some technical challenges related to the use of short sequences and quality and detection thresholds to implement in routine testing. Virus testing for international movement of potato and sweetpotato germplasm has traditionally been performed by a combination of technologies, including expensive and time-consuming host range testing that has been a bottleneck to rapid availability for international distribution. The International Potato Center has developed procedures, software and analysis approaches for sRSA and performed several years of validation experiments representing several hundred sweetpotato and potato accessions. Results indicate that using the developed procedures, sRSA generated essentially equivalent results to current routine indexing procedures and can be adopted to replace them at a similar cost, but significant reduction in time to result.

C6.2-4

ROSE VIRUSES: UNDERSTANDING THE CURRENT STATUS AND PROTECTING THE FUTURE OF THE UNITED KINGDOM ROSE SECTOR

VAZQUEZ IGLESIAS Ines. (1), CLOVER Gerard. (3), ROBINSON Rebekah. (4), BOONHAM Neil. (2), FOX Adrian. (1)

(1) Fera Science Ltd., York, UNITED KINGDOM; (2) Newcastle University, Newcastle Upon

Tyne, UNITED KINGDOM; (3) Forest Research, Farnham, UNITED KINGDOM; (4) Royal Horticultural Society, Wisley, UNITED KINGDOM

Text

Rosa spp. is the national flower of England and one of the most valued ornamental flowering shrubs grown around the globe. Despite the spread of rose viruses, they have not been studied in detail in the United Kingdom (UK) since the 1980s. Molecular methods have evolved since then, and as a result they have rarely been deployed to study these viruses. In the UK many viruses have been reported previously infecting roses such as arabis mosaic virus (genus *Nepovirus*). However, numerous viruses have been identified infecting roses in recent years, especially with the application of high-throughput sequencing (HTS). Diagnosis is fundamental to facilitate the management of plant diseases, and early detection is essential for successful biosecurity campaigns, for example against rose rosette virus (RRV; genus *Emaravirus*). In this project, different molecular and serological methods have been used to understand the baseline of viruses present in roses in the UK. Detailed experiments were performed to compare various targeted and non-targeted methods, including two different pipelines for HTS data analysis. The performance of this study has allowed the estimation of the prevalence of some previously reported viruses in the UK but also the identification of *Rosa* spp. as a new host for viruses that are widespread in the country. This work resulted in three first virus records in the UK, and the discovery of a new virus species.

C6.2-5

HIGH THROUGHPUT SEQUENCING APPROACHES FOR FASTIDIOUS BACTERIAL DETECTION AND IDENTIFICATION

CONSTABLE Fiona. (1), BROHIER Natasha. (1), RODRIGUES JARDIM Bianca. (1), KANT Pragya. (1), MANN Rachel. (1), RODONI Brendan. (1)

(1) Agriculture Victoria, Bundoora, AUSTRALIA

Text

Detection and identification of some fastidious bacteria, such as phytoplasmas, can be achieved by metagenomic sequencing. Metagenomic sequencing is highly valuable as it can produce high quality draft genomes for diagnostic and surveillance purposes as well as informing taxonomy, biology and epidemiology. However, this approach is not always effective for diagnostics due to the overwhelming presence of host genomic DNA, especially when the fastidious bacteria are present in the host in low titre. Additionally, depending on the application, full genome assembly of a bacteria is not always required. In this presentation an overview will be given about the use of metagenomic sequencing and alternative approaches, from pre-sequencing enrichment of the target to targeted high throughput sequencing (HTS) methods, to improve detection and identification of fastidious and other bacteria using HTS. These methods show potential in reducing limitations of HTS detection and identification of fastidious bacterial pathogens.

C6.2-6

METAGENOMIC SEQUENCING FOR TOMATO AND PEPPER BACTERIAL SPOT DIAGNOSTICS

Text

The first step in combatting plant diseases is accurate, swift disease diagnosis. Metagenomic sequencing (MGS) has the capability to provide diagnostic results to describe the entire phytobiome in the context of disease. Although a common research tool, MGS has not yet been regularly adopted for diagnostic purposes in clinics. We are working towards establishing MGS-based disease diagnostics by using bacterial spot of fresh market tomato and pepper as a model pathosystem. Bacterial spot caused by Xanthomonas spp. is one of the most significant and yield-reducing diseases of tomato and pepper worldwide, and management options are limited as bacterial populations have acquired copper bactericide resistance. To advance MGS for plant diagnostics, we conducted a survey of bacterial spot in Ohio fresh market tomato and pepper production systems and elucidated the current distribution of bacterial species, new potential variants, virulence factors, and copper resistance statewide. We assessed growers' perceptions of MGS based diagnostics before and after interacting with MGS diagnostic information from their farms. Our data show that MGS can successfully identify the disease-causing agent in both tomato and pepper bacterial leaf spot samples in two days and we can recover near complete pathogen genomes from MGS data. MGS has the capability to transform plant disease diagnostics, and we are laying the groundwork for MGS-based diagnostics for any pathosystem.

F6.2-1

PLASMIDS PLAGUE PELARGONIUMS: A TALE OF BACTERIAL BLIGHT AND CONVERGENT EVOLUTION

Text

The way in which we diagnose and respond to bacterial disease outbreaks has transformed over the past several decades. Serological and molecular methods were once the gold standard for diagnostics; however, these methods are labor-intensive and can make it difficult to identify and characterize pathogens. To combat these challenges, we used in-house, low-cost whole genome sequencing (WGS) to rapidly define and track an outbreak in real-time of Xanthomonas hortorum pv. pelargonii (Xhp) on US geraniums (Pelargonium x hortorum) that occurred in the spring and summer of 2022. We used short- and long-read sequencing to assemble 31 Xhp isolate genomes from the 2022 outbreak, and five Xhp genomes from previous decades. We compared the content and size of the core and plasmid

genomes in order to investigate the evolution of virulence. The outbreak strains (Xhp2022) clustered in a new lineage and showed plasmid expansion when compared to older Xhp isolates. The new, larger plasmid acquired genes via horizontal gene transfer and cointegration of other plasmids, leading to expansion. These additional genes may have led to enhanced virulence and fitness, such as heavy metal resistance, and we speculate these factors led to the outbreak of 2022. WGS gave us insight within 2-3 weeks of receiving samples and allowed us to quickly characterize the outbreak, leading us to conclude that rapid sequencing can be used as a model for the surveillance and tracking of other pathogens.

F6.2-2

FINDING A NEEDLE IN A HAYSTACK USING NGS AND ASSOCIATED BIOINFORMATICS TOOLKIT

LI Xiang (Sean). (1), CHUAN Jiacheng. (1,2)

(1) Canadian Food Inspection Agency, Charlottetown, CANADA; (2) Department of Biology, University of Prince Edward Island, Charlottetown, CANADA

Text

Emerging and re-emerging plant diseases pose an enormous threat to agricultural production and global food security. Early detection and identification of outbreaks using advanced high-throughput sequencing (HTS) technology and bioinformatics tools are playing increasingly important roles. At CFIA, the PolyChrome (PC) system and the Clasnip platform (www.clasnip.com) are developed for the early detection and identification of bacterial ring rot, zebra chip and soft rot of potato, as well as potato wart disease. The PolyChrome system, is comprisied of two command-line pipelines (PCC and PCD), an integrated state-of-the-art bioinformatics software and a high-quality genomic reference database. The analysis system allows for timely and accurate detection and identification of high-risk pathogens at the species/subspecies levels. The Clasnip platform is a web-based platform to quickly classify pathogens and their closely-relatives based on SNPs and/or whole-genome sequences. It was developed to allow users with minimum bioinformatics background to compare SNPs with curated, high-quality reference databases. Clasnip can accurately identify CLso haplotypes based on specific genetic signatures in seconds, and is also available for identifying bacterial ring rot pathogen from its close relatives of Clavibacter spp, differentiating different species of soft rot and blackleg bacteria, and different phylogroups of Potato Virus Y (PVY).

AUTOMATED PIPELINE FOR GENOMIC EPIDEMIOLOGICAL DIAGNOSES OF PHYTOPATHOGENIC BACTERIA

IRUEGAS BOCARDO Fernanda. (1), **FOSTER Zachary. (1)**, PHAN Hung. (1), WEISBERG Alexandra J.. (1), PUTNAM Melodie L.. (1), GRÜNWALD Niklaus J.. (1), CHANG Jeffrey H.. (1)

(1) Oregon State University, Corvallis, Or, UNITED STATES

Text
The emergence of new and re-emergence of extant plant pathogens can lead to severe disease outbreaks in situations such as nurseries. Rapid responses to limit pathogen spread require quick and robust detection methods coupled to timely and appropriate management strategies. Whole-genome based diagnoses allow for fine-scale resolution and transmission-chain tracking, with potential to dramatically reduce the response time to an outbreak. However, the availability of infrastructure, tools, and expertise have delayed adoption in many diagnostic settings. To address this gap, we are developing an automated pipeline that processes raw whole genome sequencing reads, performs genome assembly and annotation, calls variants, generates a core genome phylogeny, and mines genomes for features of interest such as those implicated in virulence, antibiotic resistance, and management. We are using the Nextflow platform to develop this automated and reproducible bioinformatic pipeline. As a proof-of-concept, we applied the pipeline to analyze strains of the geranium pathogen *Xanthomonas hortorum* pv. *pelargonii* reportedly implicated in a common source outbreak that spread US wide within the nursery industry in 2022. This new bioinformatic pipeline is expected to support surveillance efforts and improve early detection as well as reduce response times to accelerate deployment of adequate management strategies against plant pathogens that afflict agriculturally important crops.

Text
The development of several molecular diagnostic tools for pathogens has a remarkable increase over the past few decades. Diagnostic methods commonly used to detect plant viruses have limitations in that prior knowledge of the pathogen is required and the ability to simultaneously detect multiple viruses is limited. Therefore, in this study, we used MinION, a portable sequencing device based on Oxford Nanopore Technologies (ONT), was used to rapidly detect plant viruses in various horticultural crops; lily (Lilium spp.), spearmint (Mentha spicata), moth orchid (Phalaenopsis), Prunus mume and Malva verticillate. Plant virus populations for each crop were identified with the What's In My Pot workflow and BLASTn. Three plant viruses (lily mottle virus, lily symptomless virus and plantago asiatica mosaic virus) in lily, cucumber mosaic virus in spearmint, three viruses (odontoglossum ringspot virus, cymbidium mosaic virus and nerine latent virus) in moth orchid, five viruses (mume virus A, cycas necrotic stunt virus and asian prunus virus 1, 2, 3) in Prunus mume and three viruses (turnip mosaic virus, clover yellow vein virus and lettuce mosaic virus) in Malva verticillate were identified by nanopore sequencing. The ONT platform can be used as an effective strategy for efficient monitoring of plant pathogens, including fast run times, portability, low cost, and possibility to be used in any laboratory and field conditions.

Text

Cowpea is an important crop for small-scale farmers in poor areas but is also being developed for commercial agriculture as a possible substitute for commercial legumes. Endophytic fungi are omnipresent and play crucial but diverse roles in plants. This study characterized the endophyte component of the cowpea mycobiome from leaves, main and crown stems and roots using Illumina MiSeq of the ITS2 region of the ribosomal operon.Ascomycetes exhibited the highest diversity, with Molecular Operational Taxonomic Units (MOTUs) assigned as Macrophomina, Cladosporium, Phoma, Fusarium and Cryptococcus, among the most dominant genera. Certain MOTUS showed preferential colonization patterns for above or below ground tissues. Several MOTU generic groups known to include phytopathogenic species were found, with relative abundances ranging from high to very low. Phylogenetic analyses of reads for some MOTUs showed that a level of identification could be obtained to species level. It also confirmed the absences of other species, including phytopathogens. This is the first study that adopted a holistic metagenomic typing approach to study the fungal endophytes of cowpea from a single location, a crop that is so integral for low-income households of the world.

(1) Department of Energy, Environment and Climate Action, Bundoora, AUSTRALIA; (2) La Trobe University , Bundoora, AUSTRALIA; (3) Royal Botanic Gardens, Melbourne, AUSTRALIA

Text

The use of molecular techniques to investigate herbarium specimens has increased over the last decade. However, fungal obligate biotrophic plant pathogens such as powdery mildews present a massive knowledge gap in next-generation sequencing from reference collections. This study analysed powdery mildew reference collection specimens over a 117-year period to better understand how powdery mildew DNA decays. We examined DNA base substitution, fragmentation and investigated the microbial community present on the powdery mildew specimens. We found that powdery mildew DNA degraded at a similar rate to plant

herbarium DNA regarding nucleotide misincorporations at DNA break points and excess cytosine to thymine substitutions. The microbiome profiling revealed the dominant fungal families were *Erysiphaceae*, *Aspergillaceae* and *Saccotheciaceae* and the dominant bacterial families were *Microbacteriaceae*, *Pseudomonadaceae* and *Sphingomonadaceae*. Abundance plots showed *Saccotheciaceae* and *Pseudomonadaceae* were more abundant in recent herbarium samples and *Aspergillaceae* being more abundant in ancient herbarium samples. These findings will provide baseline knowledge for future diagnosticians and researchers how to extract and amplify obligate biotrophic plant pathogen DNA from reference collections.

P6.2-004

TOBACCO RINGSPOT VIRUS: A NEW EMERGING VIRUS INFECTING COTTON (GOSSYPIUM HIRSUTUM L.) IN THE UNITED STATES

ALI Akhtar. (1), CONNOR Ferguso. (1)

(1) Tulsa University, Tulsa, UNITED STATES

Text
Cotton (Gossypium spp.) is an economically important crop in the United States (U.S.) More than >11.5 million acres of cotton is cultivated in the southwestern states of the U.S. Among them Oklahoma cotton's acreage exceeds 490,000 acres during 2021 growing season. However, various virus diseases are recently emerging in the U.S. cotton which could pose a potential threat to the productivity and yield of cotton. Recently, cotton leaf roll dwarf virus (CLRDV) was first reported from Alabama in 2017 and subsequently the infection was recorded in >12 states. The purpose of this study was to monitor virus-like disease in the cotton fields of Oklahoma. During 2021 growing season, symptomatic cotton leaf samples were collected and tested by RT-PCR against CLRDV. A few symptomatic samples were negative to CLRDV by RT-PCR and two of them were subjected to high-throughput sequencing (HTS). A total of 17,542,322 and 22,572,118 trimmed pair-ends reads for both samples were assembled using CLC Genomics Workbench and subjected to BLASTn analysis. Blast results showed 91-100% nucleotide identities with different genes of Tobacco ringspot virus (TRSV) RNA1 of isolates WA-AM1 (MW495243.1), and IA-1-2017 (MT563078.1). Further confirmation of TRSV was achieved by specific RT-PCR. Our results showed the first natural infection of cotton by TRSV which could pose a new threat to cotton crops in Oklahoma, and the U.S in the coming growing seasons.

(1) Tecnologico de Monterrey, Santiago De Querétaro, MEXICO; (2) University of California-Davis, Davis, UNITED STATES

Text

Although the grapevine industry is relatively small in Mexico, some of the oldest vineyards in the American continent are situated in the country. Here, the first search for grapevine viruses via high throughput sequencing (HTS) was conducted in Mexico. In 2021, 48 plants displaying virus-like symptoms were sampled in an important grapevine-producing area of Mexico, and later analyzed for the presence of viruses using HTS. Virus screening was verified by real-time RT-PCR following the grapevine disease testing protocol 2010, a certification scheme developed at University of California-Davis. As a result, fourteen different viruses were identified, including grapevine Pinot gris virus (GPGV), grapevine rupestris stem pitting-associated virus (GRSPaV), grapevine Syrah virus-1 (GSyV-1), grapevine rupestris vein feathering virus (GRVFV), grapevine fanleaf virus (GFLV), grapevine fleck virus (GFkV), grapevine virus B (GVB), grapevine asteroid mosaic-associated virus (GAMaV), grapevine red globe virus (GRGV), grapevine Cabernet Sauvignon reovirus (GCSV) and grapevine leafroll-associated viruses 1, 2, 3, 4 (GLRaV-1, 2, 3, 4). In addition, divergent variants of GLRaV-4 and GFkV, and a novel Enamovirus-like virus were discovered. This is the first report of GPGV, GLRaV-4, GRVFV, GSyV-1, GRGV, GAMaV and GCSV infecting grapevines in Mexico. Virus infection in Mexican vineyards represent a concern due to the potential for economic losses and management strategies should be implemented.

P6.2-006

COMPLETE GENOME OF AN ITALIAN TOMATO BROWN RUGOSE FRUIT VIRUS ISOLATE FOLLOWING A NEW TARGET-SPECIFIC NANOPORE SEQUENCING APPROACH.

ABOU KUBAA Raied. (1), **AMOIA Serafina Serena. (1)**, ALTAMURA Giuseppe. (2), MINAFRA Angelantonio. (1), CHIUMENTI Michela. (1), CILLO Fabrizio. (1)

(1) National Research Council, Bari, ITALY; (2) Research, Experimentation and Education Centre in Agriculture “Basile Caramia” (CRSFA), Locorotondo, ITALY

Text

Tomato brown rugose fruit virus (ToBRFV) is an emerging and rapidly spreading RNA virus that infects tomato and pepper causing severe crop losses and threatening their production worldwide. ToBRFV is transmitted mainly via contaminated seeds and mechanical contact. A ToBRFV infection was discovered in a commercial tomato and pepper greenhouse in southern Italy and confirmed by RT-PCR and qPCR. RNA extracted from infected samples was processed for high-throughput sequencing with a nanopore MinION device. In order to reconstruct the full ToBRFV genome, two libraries were synthesized by using six specific primer, custom-designed along the whole sequence, during the reverse transcription phase. This original target-specific protocol resulted in an enrichment of reads mapping to the viral genome (30% of total reads) and consequently, in the obtainment of the complete ToBRFV genome (Acc No. OK624678). This new isolate shared a high nucleotide sequence identity (99.82%) with the ToBRFV-Israeli isolate, while maximum-likelihood phylogenetic analysis showed the closest relationship to a Swiss and a British isolates. Moreover, the complete genome of pepino mosaic virus (PepMV;Acc. No. OL362110) was also obtained from the same libraries suggesting that this technology could have enough sensitivity even towards non-target sequences. Our study discloses that a low number of off-target reads can provide clear evidence on unforeseen mixed virus infections.

Text

Cyst nematodes form a major taxon of plant-parasitic nematodes causing a significant economic impact globally. They are characterised by the female's ability to retain hundreds of eggs in its body after the completion of its life cycle. They are notorious agricultural pests, classified into eight genera of which *Heterodera* and *Globodera* are two of the most economically important. Traditionally, detection of cyst nematodes is reliant upon morphological identification. However, this is time consuming and requires expertise, so, there has been an increase in the use of molecular diagnostic strategies. Whole genome sequencing (WGS) provides information to identify unique molecular barcodes to distinguish species as well as underlying mechanisms of host invasion. However, WGS of cyst nematodes is difficult since it is very challenging to extract DNA from an individual juvenile. Therefore, millions of juveniles are pooled together to generate enough data to obtain a high-quality sequence. To date, only six draft genomes have been sequenced which have given an insight into the diverse biological processes associated with cyst nematodes. Our study aims to sequence, assemble and annotate draft genomes of cyst nematodes that are endemic to Australia. The goal of this genome sequencing effort is to expand on the existing genomic resources and provide usable data of sufficient quality to the nematology community and develop diagnostic assays for species identification and management.

Text

Through the recent advances of modern high-throughput sequencing technologies, "one microbe - one disease" concept is being gradually replaced with the principle of "pathobiome". A pathobiome is a diverse community of pathogenic microbes associated with reduced host fitness. This consortium may affect the viability of the plant collectively, through complex interactions between different pathogens and the host, leading to increased disease incidence and severity. To date, a concept of pathobiome as one of the major players in limiting the productivity of alfalfa (*Medicago sativa* L), the most frequently grown forage

legume, is non-existent. We approached this task by characterizing the biodiversity of the alfalfa pathobiome using high throughput sequencing technologies. Our metagenomic study revealed a remarkable abundance of different pathogenic communities associated with alfalfa in field production settings. Plant viruses constituted a significant proportion of the alfalfa pathobiome, representing a ubiquitous background for all other host–pathogen interactions. In many cases, alfalfa samples analyzed in this study also carried bacterial and fungal coinfections, many of which are known plant pathogens of agricultural importance. This initial research on characterizing the alfalfa pathobiome is a starting point in addressing the complexity of plant microbial interactions, their impact on crop health, and insights into the development and evolution of plant pathogenesis.

HIGH-THROUGHPUT SEQUENCING FOR PATHOGEN INDEXING TO SAFEGUARD THE INTERNATIONAL MOVEMENT OF CLONAL CROPS

WINTER Stephan. (1), MARGARIA Paolo. (1)

(1) Leibniz Institute - DSMZ Deutsche Sammlung von Mikroorganismen und Zellkulturen, Braunschweig, GERMANY

Text
The exchange of genetic resources is vital to the improvement of crops, the diversification of food supply, the adaptation to climate challenges and threats from biotic agents. The international transfer of clonal crops carries the inherent risk of spreading diseases along with vegetative propagules hence stringent testing is required to assure that germplasm is free of pests and diseases prior to movement. The risk associated with movement of tissue culture (TC) materials of clonal crops is that pathogens at low concentrations may be present that escape testing and are thus passaged with TC. Growing-on tests during transit or post entry quarantine are therefore prescribed to assess the plants during active growth by inspection and testing. This results in a lengthy and cumbersome process that is further accompanied by uncertainties associated with latent or unknown viruses. We therefore included high-throughput sequencing to screen cassava germplasm from South America for presence of pathogen sequences and compared the results with the commonly used growing-on indexing. We found several new viruses and highly diverse sequences of known viruses that did not result in pronounced symptoms in cassava and thus would probably be overseen. HTS of total RNA pools prepared from TC proved sensitive and robust to detect RNA as well as DNA viruses in a straightforward and robust workflow. The use of HTS in transit quarantine testing of clonal crops will be discussed.

P6.2-011

METAVIROMICS REVEALS THE PRESENCE OF NOVEL VIRAL DIVERSITY ASSOCIATED WITH CULTIVATED OLIVES IN SOUTH AFRICA

READ David. (1), SLIPPERS Bernard. (1), STEENKAMP Emma. (1)

(1) Forestry and Agricultural Biotechnology Institute, Pretoria, SOUTH AFRICA

Text
Woody Mediterranean crops appear disproportionately affected by viral pathogens. Few virological studies have been carried out on olive (*Olea europaea*) when compared with their *Vitis* and *Citrus* counterparts, with concomitantly fewer known viruses. South Africa has a small but growing olive industry (~3000 ha) producing both table olives and oil. During 2021 and 2022, leaf samples were collected from orchards in the Stellenbosch area. Virus-like symptoms included leaf yellowing, leaf mosaic and decline were observed. RNAtag-seq was used to generate metaviromes and the genomes for five viruses were identified among the *de novo* assembled contigs. These are considered novel based on shared amino acid identities with related viruses and currently accepted species demarcation thresholds. Four of these are putative members of the *Closteroviridae* family and one from the *Solemoviridae* family. Their presence was confirmed with reverse-transcription PCR. The closteroviruses are tentatively named olive virus A (OlVA) (*Amplelovirus*, 21,087 nt), olive virus O (*Olivavirus*, 16,514 nt), olive virus P (*Olivavirus*, 16,589 nt) and olive virus V (*Velarivirus*, 17,050 nt). Based on current demarcation thresholds, the solemovirus (4,226 nt) may represent a new viral genus. While no specific symptoms could be ascribed to these viruses, many closteroviruses are yield limiting pathogens. The OlVA genome represents the longest, non-segmented RNA genome of any plant virus reported thus far.

NOVEL VIRAL DIVERSITY ASSOCIATED WITH HELIANTHUS ANNUUS L. IN SOUTH AFRICA

READ David. (1), SLIPPERS Bernard. (1), STEENKAMP Emma. (1)

(1) Forestry and Agricultural Biotechnology Institute, Pretoria, SOUTH AFRICA

Text
Helianthus annuus L. (sunflower) is one of the world's most important oilseed crops. Diverse viruses from the *Potyvirus*, *Begomovirus* and *Umbravirus* genera are known to infect sunflower, however little to no data is available regarding the sunflower-associated viral diversity in South Africa. During the 2021 and 2022 growing seasons, sunflowers showing symptoms of either severe leaf mottle, mosaic, or ringspots, were collected from major sunflower production areas. Total RNA from each sample was used to generate RNAtag-seq libraries. *De novo* assembly of trimmed reads was performed using metaSPAdes and blast analyses of the resulting contigs, showed that samples were infected with either bidens mottle virus (BiMoV) (*Potyvirus*), pepper ringspot virus (PepRSV) (*Tobravirus*), or a novel member of the *Umbravirus* genus. RT-PCR assays were performed to confirm the presence of the respective viruses. This is the first time that BiMoV is being reported in South Africa and is represented by diverse variants. This is also the first report of PepRSV outside of Brazil and on sunflower. The novel umbravirus has been tentatively named sunflower chlorotic mottle virus. Phylogenetic analyses suggest the virus is most closely related to Ixeridium yellow mottle virus 2. Although all three viruses have been associated with characteristic foliar symptoms, further research is required to determine their capacity to cause yield limiting disease.

Text

Shotgun high-throughput sequencing approaches enable virome analyses of a wide array of sample types, spanning from host tissues to environmental samples. To obtain an extended insight into the virome of selected agroecosystems linked with tomato farms, we analysed viromes of tomatoes, wild and volunteer plants growing in the vicinity of tomatoes, and irrigation water sources used for irrigation of crops on the analysed sites. Over a span of two years, we collected more than 400 plant samples and 24 water samples. We isolated total RNA from the samples and prepared each sample type appropriately for shotgun sequencing using Illumina platform. After in-depth bioinformatics analysis of the obtained data, we detected many known, and even higher number of novel viruses in different sample types. Most of the previously unknown viruses were detected in wild plants, nevertheless, several were also discovered in tomatoes and water samples. Some stable plant viruses (e.g., tobamoviruses) were detected in across diverse sample types. Supplementing the information obtained from analysis of plants with analysis of water samples, provided markedly extended information about the prevalence of some newly discovered viruses in the analysed ecosystems. This multiple sample type virome study brings rare insights into the epidemiological links between plants and environmental waters, and helps to better understand possible future emergences of viral diseases in tomato and other crops.

Text

Olive (*Olea europaea* L.) or its wild relatives have been a part of the Mediterranean diet and trading routes since antiquity. The shallow Pupak off the island of Palagruža was on the ancient trans-Adriatic waterway and is the site of the shipwreck where a large number of olive stones and well-preserved fruits were found in two amphorae. The biological material was carbon- dated and confirmed to be 2200 years old. Total nucleic acids were extracted

from olive embryos found in some of the stones after opening, and DNase treated. Preamplification was performed for these low-biomass samples prior to shotgun high-throughput sequencing (HTS). In-house developed bioinformatic pipeline was used for the detection of viruses. Near-complete genomic sequence of a putative alphacarmovirus was obtained from the data. Based on the comparison of sequence identities, the RNA-dependent RNA polymerase sequence of the new virus is most similar to that of Cichorium alphacarmovirus 1 (62 % identity) and honeysuckle ringspot virus (61 % identity). Phylogenetic analysis confirmed that the new virus belongs to the genus *Alphacarmovirus*, family *Tombusviridae*. RT-PCR primers were constructed and amplicons were obtained from different samples to validate the HTS data. Further tests are planned to ascertain the ancient origin of viral RNA. If confirmed, this finding represents unprecedented insight into the sanitary status of olives in antiquity and possible olive viruses over the span of two millennia.

P6.2-015

APPLICATION OF MINION SEQUENCING FOR THE DETECTION OF VIRUSES IN SEED YAM SYSTEMS

FESTUS Ruth. (1), SILVA Goncalo. (1), PREMPEH Ruth. (2), MCGREIG Sam. (3), ADAMS Ian. (3), QUAIN Marian. (2), SEAL Susan. (1)

(1) University of Greenwich, Kent, UNITED KINGDOM; (2) Crops Research Institute- Council for Scientific and Industrial Research, Kumasi, GHANA; (3) FERA Science Ltd., York, UNITED KINGDOM

Text

The use of virus-free planting materials is the most effective method to control the spread of yam viruses, including Yam mosaic virus, able to cause up to ~50% yield losses. Sensitive nucleic acid-based tests have been developed to detect a large range of yam viruses. Yet, there is the potential for new viruses or emerging variants to escape detection because existing methods target only known viruses and sequence diversity. This would result in the dissemination of infected materials with potential threats to crop production and food security.

High throughput sequencing (HTS) technologies can detect known and unknown viruses in any plant sample, overcoming the limitations of standard tests. This research aimed to develop an HTS workflow to detect and characterise viruses in yams (Dioscorea spp.). MinION, a portable high-throughput sequencer from Oxford Nanopore Technologies, offers a potential adoption of this technology in low-resource laboratories where other HTS platforms are impractical or too expensive. This will improve molecular diagnostic testing capability and support the production and sustainable supply of high-quality seed yams in Sub-Saharan Africa.

RNA preparation methods and MinION sequencing protocols were compared and optimised to develop a sequencing workflow adaptable for virus indexing in yam seed systems in Ghana. The study established MinION sequencing workflows that can be used to detect and accurately sequence up to full-length genomes of yam viruses.

Text

Viral diseases represent a major threat to food production, worldwide. Treating virus-infected plants is impractical, unlike bacterial or fungal diseases. Therefore, reducing the impacts of viruses on crop production relies on our capacity to monitor and anticipate, outbreaks. Early detection is a critical step in defining upstream mitigation strategies to facilitate viral disease management. Because viruses lack shared conserved regions for identification at the species level, virion-associated nucleic acid (VANA) and metagenomic sequencing are commonly used instead to harness the virome. VANA sequencing systematically favors DNA and enveloped RNA viruses, while metagenomic sequencing is influenced by large-genome organisms and their prevalence. We have improved double-stranded RNA (dsRNA) extraction methods by optimizing the existing cellulose-based method and developing new methods employing dsRNA-binding proteins. These methods were used to sequence dsRNA using the Illumina MiSeq and Nanopore MinION platforms. The results demonstrate that dsRNA sequencing is a powerful universal tool for the detection and genomic characterization of viruses regardless of the genome type, size or the genomic heterogeneity. In the One health context, which requires the monitoring of known and unknown viruses throughout the virosphere (plants, animals, insects and soil), dsRNA sequencing provides a unique opportunity to increase our capacity for monitoring and anticipating, viral outbreaks

EVIDANSES: A QUALITY MANAGEMENT-FRIENDLY BIOINFORMATICS PIPELINE FOR VIRUS DETECTION IN PLANTS

REMENANT Benoit. (1), TIAN Sixing. (1), BAHUT Muriel. (2), PORCHER Laetitia. (1), ROLLAND Mathieu. (1)

(1) Anses - Plant Health Laboratory, Angers, FRANCE; (2) Univ Angers - SFR QUASAV, Angers, FRANCE

Text

High throughput sequencing is now used in routine for many applications, and the diagnostic of plant pathogens is not an exception. It enables the detection of poorly characterized pathogens even in co-infected samples composed of multiple organisms. However, the analyses after sequencing remain a black box for labs without bioinformatics competences. To ensure that each step is in line with quality management requirements, we chose to develop a complete analysis workflow from the wet lab, including library preparations and sequencing, to the bioinformatics.
The eVIDanses bioinformatics pipeline was written to analyze automatically raw reads from single end or paired ends sequencing, throught different stages: quality trimming, de-novo

assembly, contigs identification, mapping on reference genome, and metagenomics analysis, via Krona. The script allows the creation of a pdf report that includes the main results of the analysis and the traceability (versioning of the script, software, virus database, etc.).
This bioinformatics pipeline was tested successfully on Ion torrents Proton and Illumina sequencings. Next steps will be to include specific analyses for MinION sequencing, and to include the complete workflow in a quality management system.

Text

Vegetable food products can be contaminated with human and plant pathogens from production to consumption. Such contaminations can have serious effects on plant health or human food safety. The aim of this collaborative work was to develop a method based on high throughput sequencing, using MinION sequencer, to identify all pathogens (virus, bacteria and fungi) in contaminated vegetable food products. The efficiency of the method was tested on mock DNA communities and on vegetable food products artificially contaminated with relevant human and plant pathogens. Metabarcoding analyses allowed the detection of some plant pathogen genera and of human pathogens (*Listeria monocytogenes* and *Salmonella enterica*) at very low concentration, close to infectious doses while metagenomic analyses were demanding on high quality DNA extracts. Concerning RNA and virus detection, the method was very efficient on phytovirus, but not on human virus even inoculated at high doses. The phytosanitary risk of 15 plant pathogens of tomato absent from France was also evaluated: one bacteria and four viruses showed high potential of introduction. In conclusion, this method is very interesting compared to targeted methods as it can give information on pathobiome without *a priori* and identify potential emergence, although it needs optimizations on DNA extraction for metagenomic analyses and gene selection for metabarcoding analyses.

(1) Flanders Research Institute for Agricultures, Fisheries and Food, Melle, BELGIUM

Text
At ILVO, one of our key missions is to ensure healthy crops for a sustainable agricultural production. In this context it is important to monitor the biodiversity of the environment in the vicinity of the plants, for both harmful and beneficial (micro-)organisms. Here, we highlight some high-throughput-sequencing (HTS) applications related to biodiversity monitoring. In a first application, we study the genetic diversity within or between species by means of genotyping-by-sequencing (GBS), allowing the investigation of genetic relationships between individuals or pools of individuals using thousands of genetic markers. In a second application, we study the taxonomic composition of communities using metabarcoding. This can be done to monitor soil health, for example by investigating the microbial community composition (fungi and/or bacteria) and bio-indicator organisms such as nematodes, or to detect plant pests and their natural enemies in pitfall traps or on sticky plates. In a third application, we use an untargeted approach (RNA-seq) to study biodiversity by taxonomically classifying all sequences present in a plant, insect or environmental sample. This can be used to find the biological cause of certain disease symptoms and is particularly interesting for large-scale virus and viroid scanning. In conclusion, HTS-based methods have greatly expanded our toolbox to investigate the biodiversity of the plant's environment, its microbiome, and its pathogens and pests.

Text
Andean root and tuber crops (ARTCs) are a group of diverse crops belonging to a variety of families, that originate from the Andean. FroIn Europe, these plants often enter the country for planting via internet trade, which is may be a phytosanitary risk. The CIP Genebank has identified developing tools for phytosanitary diagnostics of ARTCs as priority area.
This study follows on from a High Throughput Sequencing (HTS) paper on (Ullucus tuberosus) plants grown in the UK. Work so far has been focused on determining the virome of ARTCs imported through internet trade and determine the potential risk of this commodity to UK plant health. This project used HTS to study the viruses present in oca (Oxalis tuberosa) plants purchased from two mainland European countries via eBay. Using an Illumina MiSeq two bulks of these plants were sequenced, uncovering six novel virus candidates from different genera. Following in silico molecular characterisation based on genome sequence, RT-PCR and qRT-PCR assays were designed to these viruses. Additionally, biological characterisation of new findings is lacking. A review of 78 papers reporting on fruit tree viruses examined the biological data included with virus discovery. Only 8% included transmission studies, a vital part of biological characterisation. This talk will discuss the virome findings so far, as well as consider challenges of modern diagnostic

biological characterisation when applied to HTS novel findings as shown by this project.

P6.2-022

RNA-FULL THE PIPELINE FOR FULL LENGTH GENOME SEQUENCING OF PLANT RNA VIRUSES

GOLYAEV Victor. (1), HERVÉ Vanderschuren. (1)

(1) KU Leuven, Heverlee, BELGIUM

Text

Accurate pathogen characterization in infected plants is critical for agriculture production that could prevent economic losses and spread of viral diseases. Over the recent years the Illumina sequencing platform has become an important standard in HTS of plant viruses and has led to the identification and characterization of many previously unknown viruses. In the meantime, the platform is based on the use of relatively short read sequencing (up to-300 base pair read lengths) and subsequent assembly of these reads into so-called consensus sequences that could prevent in-depth profiling of full-length virus genomes. Viruses are often present in complex populations of highly similar sequences and accurate assembly of virus genomes of several kilo-bases in length using only ~100 base pair reads is challenging. To address this constrain we have developed a protocol for full-length genome sequencing of RNA viruses (RNA-full) that is based on recently emerged MinION technology. Furthermore, RNA-full was used for identification and accurate profiling of dsRNA viral intermediates that are produced during virus replication.

Text

High-throughput sequencing (HTS), more specifically RNA-seq of plant tissue, has become an indispensable tool for plant virologists to detect and identify plant viruses. During the data analysis step, plant virologists typically compare the obtained sequences to reference virus databases only, which lead to our hypothesis that they might be missing possible traces of other pathogens in the data. In this study, we set up a community effort to re-analyze existing RNA-seq datasets used for virus detection to check for the potential presence of non-viral pathogens or pests. In total 101 datasets from 15 participants derived from 51 different plant species were re-analyzed, of which 37 were selected for subsequent in-depth analyses. In 29 of the 37 selected samples (78%), we found convincing traces of non-viral plant pathogens or pests (>100 reads per million). The most observed organism categories were fungi (15/37 datasets), insects (13/37) and mites (9/37). Nematodes were not observed and only a few samples showed the presence of plant pathogenic phytoplasmas (1/37), bacteria (3/37) and oomycetes (4/37). In conclusion, we were able to show that it is possible to detect non-viral pathogens or pests in these metatranscriptomics datasets, in this case primarily fungi, insects and mites. With this study, we hope to raise awareness among plant virologists that their data might be useful for fellow plant pathologists in other disciplines (bacteriology, mycology, entomology) as well.

PLANT VIRUSES DIAGNOSTIC FROM HIGH-THROUGHPUT SEQUENCING (HTS) DATA USING VIROSCOPE: A FIELD-SCALE PILOT STUDY TO IMPLEMENT HTS FOR FAST-TRACK QUARANTINES.

MORGANTE Verónica. (1), JIMÉNEZ Juan Cristóbal . (1), URRUTIA Cristóbal. (1), PONCE Claudio. (1), VERA Fernanda. (1), FARÍAS Camila. (1), **POLLAK Bernardo. (1)**

(1) Multiplex SPA, Santiago, CHILE

Text

Plant trade and food consumer demand has greatly increased the global movement of plants. Current post-entry quarantines programmes facilitate testing the imported plants for virus pathogens but are highly extensive, cost demanding and viruses diagnostics are subject to conventional PCR bias. Although the HTS-based virus diagnostics is considered as the gold standard in molecular diagnostics, challenges related to both the data analysis and at the regulatory level implementation are still discussed.
In this work, we performed a robust study (n=200) using the Viroscope.io web-service to provide viral diagnosis from HTS data for phytosanitary purposes of fast-track quarantines. The leaves samples of *Prunus sp.*, *Malus sp.*, *Fragaria sp.* and *Citrus sp.* were provided by the SAG (Servicio Agrícola Ganadero), and sequenced using Illumina®. The samples were processed *in-house* (total RNA extraction; ribodepletion RNA; library construction). Simultaneously, the samples were processed at the SAG laboratory for virus detection by using its own RT-PCR protocols.
Here we report the side-by-side comparison with conventional techniques currently used for phytosanitary post-entry quarantines. Further, functional annotation provided by Viroscope provides enhanced biological insight for diagnostic certainty in cases of low abundance.

P6.2-025

CHARACTERIZATION OF THE SOIL, RHIZOSPHERE AND ROOT MICROBIOME ASSOCIATED TO KIWIFRUIT VINE DECLINE SYNDROME IN ITALY

GUASCHINO Micol. (1), GARELLO Marco. (1), NARI Luca. (2), **SPADARO Davide. (1)**

(1) University of Torino, Grugliasco, ITALY; (2) Fondazione Agrion, Manta, ITALY

Text
Kiwifruit vine decline syndrome (KVDS) has been threatening kiwifruit cultivation in Italy for the last decade. Symptoms lead to severe root decay and plants usually die within a few weeks. Aboveground symptoms include leaf curl, necrosis, and twig wilting, which appear long after root impairment. KVDS is commonly identified as a multifactorial disease, caused both by abiotic and biotic factors. The copresence of different stresses impacts plant growth and yield, leading to rapid decline. Pathogens associated to disease development are soilborne oomycetes. This work focused on defining the microbial communities characterizing soil, rhizosphere, and root population present both in affected and healthy fields in North-West Italy, by analyzing the whole pathobiome, as bacteria, fungi, and oomycetes, through metabarcoding. Bacteria and fungi showed a wide diversity, even when grouped by sampling location. Focusing on oomycetes, Phytopythium spp. was the main genus across all infected matrices. Phytopythium spp. was present in significantly higher abundances in diseased orchards, compared to healthy ones, showing a statistically significant correlation with the occurrence of the syndrome. From the same sites, isolation was performed through the years revealing the presence of Phytopythium spp. mainly associated to symptomatic roots. Bacteria, fungi, and oomycetes were considered together for the first time, reinforcing the role of Phytopythium spp. in KVDS.

Text
The whitefly *Bemisia tabaci* is an important crop pest and causes over a billion euro of damage per year worldwide. It is well-known to transmit plant viruses and more than a hundred plant virus species are known to be vectored by *B. tabaci*. In the EU, 'non-European' populations of *B. tabaci* - those found in plant commodities imported from non-European countries - are considered as quarantine pests (EU directive 2019/2072). According to EPPO, *B. tabaci* is present in Belgium but its current distribution is unknown. In addition, it is unknown whether the Belgian and non-European populations carry whitefly-transmitted viruses that could pose a phytosanitary risk to Belgian greenhouse crops. In 2022, the Flanders Research Institute for Agriculture, Fisheries and Food and the Vegetable Research Centre joined forces in a FPS Public Health funded project, called VIRTAB, to fill this knowledge gap. During the second half of 2022, more than 20 non-European *B. tabaci* populations were intercepted at ports of entry, while two Belgian *B. tabaci* populations could be collected from local greenhouses. Both classical molecular techniques and high-throughput sequencing were used to identify and characterize the whitefly itself, as well as the viral load they carry. The identification of these viruses will allow to assess the potential impact of *B. tabaci* on Belgian greenhouse crops and the possible measures that have to be taken.

TRACKING BUNT AND SNOW MOLD PATHOGENS IN SWITZERLAND USING SOIL MONITORING

SULLAM Karen. (1), PANZETTI Cecilia. (1), WIDMER Franco. (1), GSCHWEND Florian. (1)

(1) Agroscope, Zürich, SWITZERLAND

Text
Long-term environmental monitoring projects are essential to understanding human-driven effects on ecosystems and detecting threats such as pollution, erosion, and biodiversity loss. High throughput sequencing (HTS) has revolutionized biological soil monitoring, enabling expansive data collection on soil biodiversity, including pathogenic fungi. In this study, we tracked the occurrence of seed-borne cereal pathogens that can also spread through contaminated soils using the Swiss Soil Monitoring Network. The network's sampling for microbial biodiversity was conducted in 30 sites composed of an equal number of forest, grass- and arable land sites during five consecutive years. We focused on the taxa of snow mold (*Microdochium nivale* and *M. majus*) and bunt pathogens (*Tilletia* spp.). These fungi are regularly evaluated in cereal seed health testing, but their presence in soil can contribute to disease occurrence. The *Microdochium* spp. were found in all sites, though most abundant in grass- and arable lands. Reads matching *Tilletia controversa*/*caries* were limited to 2 arable land sites, while other *Tilletia* spp. were found at 13 grass- and arable land sites. The pathogens' distributions may have implications for disease avoidance, and future work should compare fluctuations of pathogen abundance in the soil with disease occurrence.

These pathogens serve as a case study for adapting biological soil monitoring networks to survey plant diseases.

Text

Phytopathogens & Invasive Alien Species pose an increased risk to plant health & food security, threaten biodiversity and exacerbate phytosanitary issues. Their effects are amplified by climate change led by more permissive conditions for their establishment in previously inhospitable areas. More restrictive international trade regulations are among the repercussions of the establishment of adventive species. High-Throughput Sequencing is a powerful approach to pre-screen phytopathogens and locate hotspots. We use metabarcoding (fungi, oomycetes) & Whole-Genome Shotgun sequencing (WGS; bacteria) to develop surveillance tools, increase plant health and enhance agriculture sustainability (beneficial endophytes). First, preliminary results from a metabarcoding workflow for analyzing spore and suction trap samples collected biweekly will be introduced (abundance, diversity, incidence & distribution forecasting models). Then, results from the metabarcoding of endophytic community in barley seeds will be shared. Next, results obtained by WGS bacterial profiling of canola seed washes will be shown. Taxa detected by culture-independent methods were compared with culture-dependent communities. This study could provide a baseline of Canadian microbes in crops/seed washes which may be instrumental in international plant trade disputes and crop improvement (endophytes). Combined results will help understand pest incidence in space & time and improve risk readiness & response measures.

TILED AMPLICON PCR AS A VIROLOGY DIAGNOSTIC TOOL FOR POST-ENTRY QUARANTINE TESTING IN NEW ZEALAND

NUNES LEITE Luciano. (1), LIEFTING Lia. (1), WAITE David. (1), KHAN Subuhi. (1), DELMIGLIO Catia. (1), THOMPSON Jeremy R.. (1)

(1) New Zealand Ministry for Primary Industries (MPI), Auckland, NEW ZEALAND

Text

Post-entry quarantine is one of the most valuable tools for protecting New Zealand from

unwanted plant diseases. High-throughput sequencing technologies allows the testing of imported plant germplasm for pathogens present in a sample with high sensitivity comparable to Polymerase Chain Reaction (PCR) based diagnostics. It also offers strain-specific detection not offered by PCR-based assays. Tiled Amplicon PCR (TA-PCR) has been tested as an enrichment technique to amplify partial or complete genomes of viruses present in low titres. We developed a series of primer panels targeting three viruses of Fragaria: strawberry chlorotic fleck-associated virus (SCFaV), strawberry mottle virus (SMoV) and strawberry vein banding virus (SVBV). These represent two positive single stranded RNA viruses (SCFaV and SMoV) with different replication strategies, and a double stranded DNA virus (SVBV). The primer panels for each virus can be combined as a multiplex assay to detect all three viruses from samples with low viral titres around the limit of detection for quantitative PCR. Illumina and Oxford Nanopore platforms were successfully used for sequencing of the tile amplicons, covering up to 100% of the reference genomes for each virus. TA-PCR allows for targeted strain-specific regulation of unwanted organisms. The limit of detection of TA-PCR is comparable to that of quantitative PCR assays, the current gold standard for diagnostic of plant pathogenic viruses.

COMPARING SHORT- AND LONG-READ HIGH-THROUGHPUT SEQUENCING METHODS WITH TRADITIONAL PLATING FOR THE CHARACTERIZATION OF TREE SEED MYCOBIOMES

MITTELSTRASS Jana. (1), HEINZELMANN Renate. (1), ESCHEN René. (2), HARTMANN Martin. (3), KUPPER Quirin. (1), PROSPERO Simone. (1), SCHNEIDER Salome. (1), **FRANIC Iva. (4)**

(1) Swiss Federal Institute for Forest, Snow and Landscape Research WSL, Zurich, SWITZERLAND; (2) CABI, Delemont, SWITZERLAND; (3) ETH Zürich, Zurich, SWITZERLAND; (4) Swedish University of Agricultural Sciences, Alnarp, SWEDEN

Text

Tree-associated mycobiomes have traditionally been analyzed by isolating fungi on agar media from plant host material. A shortcoming of this approach is that not all fungal species, in particular obligate biotrophs, can be grown in culture. Nowadays, fungal microbiome analyses are increasingly conducted with high-throughput amplicon sequencing using Illumina platforms, which allows the identification of fungal species without culturing them. However, with the short-read sequencing using Illumina platforms, usually only a small fraction of reads can be assigned to fungal species. A better assignment might be obtained with long-read sequencing using Oxford Nanopore Technologies. However, few studies exist in which the same biological samples were compared using these three different approaches. Here, we compared the diversity and community composition of tree seed mycobiomes captured by traditional culturing, with diversity and composition captured by both Illumina and Nanopore amplicon sequencing. Seeds from 13 tree species native to Europe, North America, or Asia were analyzed. Preliminary results show that a main proportion of the dominant fungal taxa obtained by Illumina sequencing comprised of culturable fungal species. Further analyses will reveal potential differences across methods, and determine the most appropriate method for identifying potentially pathogenic fungal species in tree seeds, which will improve the safety of tree seed movement.

FAST HIGH-RESOLUTION PLANT PATHOGEN IDENTIFICATION THROUGH MULTIPLEXED PCR AND HTS

BRECKELL Georgia. (1), **TAYLOR Rob. (1)**, BASKARATHEVAN Jeyseelan. (1), TOOME Merje. (1), HO Wellcome. (1), RIGANO Luciano. (1)

(1) Ministry for Primary Industries, Auckland, NEW ZEALAND

Text

The Ministry for Primary Industries' Plant Health and Environment Laboratory is responsible for the identification of all suspected exotic, new, and emerging pests and pathogens affecting plants and the environment in New Zealand.

Current identification of bacteria and fungi isolated from diagnostic samples is performed by a 2-round Sanger sequencing workflow: First, a general phylogenetic marker is sequenced to allow identification to the genus level. Typically, these general markers do not provide enough resolution to determine species but allow to select taxon-specific markers for the second round of sequencing to generate data for species level identification. This sequential identification process is time consuming and challenging when results are urgently required.

To facilitate faster sample processing, we are developing multiplex PCR assays and HTS workflows to enable rapid identification of fungal and bacterial plant pathogens from cultured isolates in a single HTS step. We developed two sets of degenerate primers which amplify diagnostically informative genes across a broad range of bacterial and fungal genera. We combined these into a single multiplexed reaction for bacteria or fungi, amplifying up to six taxonomically relevant markers. To enable flexibility, sequencing workflows were developed for both Illumina and ONT platforms. This new workflow will reduce turnaround time, costs, and provide greater taxonomic resolution for isolate identification.

Text

General plant health can be improved by the use of virus-tested starting material for vegetative propagation. HTS-based untargeted detection replacing specific molecular methods, or even biological indexing, is extremely promising for this purpose. Illumina sequencing has already proven to be a reliable and sensitive method for virus detection, yet

also the ONT MinION has gained interest as a promising tool over the last years. ONT sequencing generates long reads, can be performed in every lab and decreases the costs. For MinION sequencing a protocol based on Liefting et al. (2021) and similar to our standardized Illumina sequencing protocol, was used. In short, total RNA extraction was followed by rRNA depletion and random primed double stranded cDNA synthesis. Barcodes and adapters were added, samples were pooled and sequenced for 72 hours on a MinION Flow Cell. Reads were classified by comparing against the Genbank non-redundant Nucleotide database with Kraken2 and mapped to virus reference genomes with Minimap2. Five plant samples, previously screened for viruses with Illumina sequencing, were selected for this study. Overall, most of the viruses could be detected and were identified correctly with this MinION sequencing protocol. Viruses detected below 50 rpm with Illumina sequencing could only be detected with poor genome coverage or failed to be detected. It can be concluded that correct virus detection and identification is possible but sensitivity is still lower.

MULTILOCUS GENES AND WHOLE GENOME SEQUENCING TO IDENTIFY AGROBACTERIUM ARSENIJEVICII, CAUSAL AGENT OF CROWN GALL DISEASE IN RASPBERRY PLANTS

GODÍNEZ-ALEMAN José Eduardo. (1), SILVA-ROJAS Hilda Victoria. (1), REBOLLAR-ALVITER Angel. (2)

(1) Colegio de Postgraduados, Texcoco, MEXICO; (2) Universidad Autónoma Chapingo, Morelia, MEXICO

Text

Raspberry is a widely cultivated fruit species with increasing demand in national and international markets. However, its production can be severely impacted by crown gall disease, which is commonly attributed to the soil-borne bacterium Agrobacterium radiobacter, causing stunted growth and reduced yields. It spreads through infected nursery propagative material and is maintained by the use of contaminated soil. However, the symptoms are not always indicative of A. radiobacter, making it challenging to identify the bacterium responsible for the disease. In this study, multilocus genes atpD, gyrB, glnA, rpoB, and recA were used to identify the actual causal agent of crown gall disease in raspberry plants from plantations in the states of Michoacán and Jalisco, Mexico. The results indicated A. arsenijevicii as the causal agent. Furthermore, the whole genome sequencing of sample CPO J19 revealed a genome size of approximately 5.7 Mb, with a G+C content of 58.45 %. The assembly produced 46 contigs, with N50 of 305 kb. Annotation analysis identified a total of 5578 protein-coding genes. A comparative genomic analysis showed a high degree of similarity with the A. arsenijevicii type strain KFB 330, confirming the identity of the causal agent responsible for crown gall disease in raspberry plants. The identification of the causal agent is critical to improve disease management strategies. The use of certified nursery propagative material can help prevent the spread of the disease.

Immune receptors: activation, signaling & evolution

CONNECTING THE DOTS OF PRR-MEDIATED IMMUNE SIGNALING

ZIPFEL Cyril. (1,2)

(1) UNIVERSITY OF ZURICH, Zurich, SWITZERLAND; (2) THE SAINSBURY LABORATORY, Norwich, UNITED KINGDOM

Text
Plant immunity relies on both cell-surface and intracellular immune receptors. Recent studies showed that signaling triggered upon activation of these receptors is more connected than previously thought, and that both types of immune receptors can induce congruent cellular immune signaling outputs. Yet, the exact molecular mechanisms and components involved in the generation and regulation of such outputs are not fully understood. I will present our recent efforts to gain a better understanding of the molecular basis of early immune signaling, particularly that mediated by cell-surface receptor kinases acting as pattern-recognition receptors (PRRs).

Text
TIR (Toll, interleukin- receptor, resistance protein) domains feature in a subset of plant NLRs (nucleotide-binding – leucine-rich repeat receptors - TNLs) that respond to plant pathogen effectors and trigger effector-triggered immunity (ETI). Following the demonstration that the TIR domains from the human protein SARM1 have enzymatic activity - cleavage of NAD+ (nicotinamide dinucleotide), such activity was also demonstrated for a number of plant TIR domains (1). We have studied the molecular and structural bases of these enzyme reactions and the role of the corresponding enzymatic products in signalling. In particular, we have defined the chemical structures of two cyclic ADP ribose isomers produced by NAD+ hydrolysis, 2′cADPR and 3′cADPR, which are cyclized by O-glycosidic bond formation between the ribose moieties (2). While 2′cADPR appears to be associated with ETI signalling, 3′cADPR appears to be associated with suppression of plant immunity. Our work

has provided new information about how TIR domains work, how they produce signalling molecules and how these products signal, but much future work is needed to fill the gaps.

Text
The plant immune system heavily relies on intracellular NLR immune receptors, which recognise pathogen secreted effectors to trigger a robust immune response. In barley, resistance to powdery mildew conferred by *Mildew locus a* (*Mla*) is mediated by an NLR that exists as an allelic series wherein each allele recognises its cognate sequence-unrelated mildew effector. Recent findings have shown that different *Mla* alleles confer resistance to divergent fungal pathogens in addition to barley powdery mildew. We established that the *Mla3* allele confers resistance to *Magnaporthe oryzae* by recognising *PWL2*, an effector that conditions host-specificity towards weeping lovegrass. We aimed to dissect the molecular basis of Pwl2 recognition by Mla3. We established that Pwl2 associates with Mla3 in planta, and that the last 83 amino acids of Mla3 are sufficient for this interaction to occur. Association in yeast-two-hybrid and co-purification from *E. coli* of Pwl2 with this C-terminal region of Mla3 strongly suggest that Mla3 directly recognises Pwl2. Pwl2 targets an HMA-containing plant protein as virulence target. The predicted structure of Pwl2 bound to the C-terminal region of Mla3 shows that the binding interface with Mla3 resembles the actual interface of Pwl2 bound to the HMA target. This prediction was validated by mutagenesis experiments, suggesting that a singleton NLR recognising multiple pathogens evolved to mimic the binding interface of an effector target to confer resistance.

Text

Plants rely on population level diversity of the innate immune receptors to recognize rapidly evolving pathogen-derived molecules. The Nucleotide Binding Leucine Rich Repeat-containing plant immune receptors (NLRs) can recognize pathogens through either direct binding of pathogen-derived effectors, indirect guarding of plant proteins or integration of additional protein domains that act as effector baits. Availability of high-quality plant pan-genomes allowed us to identify subsets of highly variable NLRs (hvNLRs) and to predict their ligand binding sites. hvNLRs show a strong overlap with hybrid incompatibility loci, suggesting that generation of new immune specificities comes at the cost of autoimmunity. We have now extended these analyses to pangenomes of maize, soybean as well as to other gene families, uncovering other highly variable receptors, such as Receptor like kinases and receptor like proteins, and protein families. In our current work, we investigated genomic features that differentiate highly variable NLRs from their conserved paralogs. Using whole genome bisulfite and RNAseq extracted for the same leaf in Arabidopsis, we found that highly variable NLRs are more expressed, less methylated, and closer to TEs than non-highly variable NLRs. This provides a strong foundation for understanding the diversity generation mechanisms in these rapidly evolving genes.

Text

Cell-surface receptors form the first layer of the plant innate immune system. Receptor-like cytoplasmic kinases (RLCKs) bridge activated receptor complexes with their downstream signaling components. Arabidopsis thaliana RLCK class VII subfamilies 4, 5, 6, 7 and 8 are generally involved in immunity, among which is the accumulation of ROS. It is largely unknown what the role is of the different RLCK-VII subfamily members downstream of the tomato RLP Cf-4. Cf-4 is the receptor of Avr4, an apoplastic effector secreted by Cladosporium fulvum. Cf-4 is functional in Nicotiana benthamiana and by studies involving rlck knockouts in N. benthamiana, we show that RLCK-VII subfamilies 6, 7 and 8 are required for the Avr4/Cf-4-triggered ROS production. Typically, the Avr4 protein triggers a biphasic ROS burst in the leaves of N. benthamiana:Cf-4. Interestingly, the first ROS burst is strongly reduced, whereas the second ROS burst is completely abolished in rlck-vii-6

knockouts. In addition, ROS production is overall strongly compromised in rlck-vii-7 knockouts. Furthermore, both the first and second phases of the Avr4/Cf-4-triggered ROS burst are highly impaired in rlck-vii-8 knockouts, with the first burst also being delayed. These observations indicate that there are different ROS regulatory mechanisms in N. benthamiana. Further studies show that RLCK-VII-6, 7 and 8 are also essential for ROS production triggered by flg22, chitin, nlp20/RLP23, and pg13/RLP42 in N. benthamiana.

THE BASAL EXPRESSION OF IMMUNE RECEPTORS DEPENDS ON SALICYLIC ACID LEVELS REGULATED BY THE DMR6 FAMILY OF HYDROXYLASES

VAN BUTSELAAR Tijmen. (1), SILVA Savani. (1), BAÑALES BELAUNDE Iñigo. (1), **LAPIN Dmitry. (1)**, VAN DEN ACKERVEKEN Guido. (1)

(1) Utrecht University, Utrecht, NETHERLANDS

Text
Immune receptors alarm the host plant about the presence of invading pathogens. Despite advances in understanding how receptor proteins are activated by non-self molecules, little is known about the regulation of their expression at the transcript level. Broad-spectrum disease resistance in Arabidopsis and crops can be conferred by mutations in the susceptibility genes *DOWNY MILDEW RESISTANT 6* (*DMR6*) and its close paralog *DMR6-LIKE OXIDOREDUCTASE 1* (*DLO1*). The DMR6 and DLO1 proteins are salicylic acid (SA) hydroxylases that act as negative regulators of immunity. RNAseq profiling of the transcriptomes of Arabidopsis *DMR6*/*DLO1*mutant and overexpression lines revealed a role of basal SA levels in the regulation of the expression of immune receptor genes. These *DMR6*/*DLO1*-affected and SA-dependent genes belong to specific groups of surface and intracellular immune receptors. We will present further experimental evidence for the importance of the expression control by SA through *DMR6*/*DLO1* for early immune signaling. We propose that immunity in the *dmr6* and *dlo1* mutants involves enhanced basal expression of immune receptor genes that boosts the plant recognition potential.

Text

Plant secreted signaling peptides known as phytocytokines regulate immunity via cell-surface receptors. Recently, a handful of phytocytokines have been shown to display also antimicrobial activities against pathogens, suggesting that such peptides may function as multifunctional molecules reminiscent to host-defense peptides in animals. RISPs (RUST INDUCED SECRETED PEPTIDEs) constitute a family of small secreted cationic peptides from poplar trees. *RISP* genes systematically cluster with receptor-like protein (RLP)-encoding genes in poplar genomes, that we termed RISP-ASSOCIATED RECEPTOR-LIKE PROTEINs (RALRs). We show that RISPs display anti-fungal activity towards Pucciniales (rust fungi) *in vitro* and *in planta*. In addition, RISPs trigger stomata closure in poplar. Notably, while the Solanaceae plant species *Nicotiana benthamiana* is insensitive to RISPs, expression of RALRs is sufficient to confer RISP-responsiveness, suggesting RALRs are RISP receptors in poplar. We will also discuss the convergent evolution of eukaryotic defense peptides as multifunctional molecules.

Text

Fusarium spp. cause severe economic damage in many species of cultivated plants exemplified by Fusarium Head Blight or Panama Disease. Microbe-associated molecular patterns (MAMPs) can be perceived by plants supporting disease resistance via the activation of pattern-triggered immunity (PTI). However, knowledge of MAMPs or corresponding plant immunity components is largely lacking for Fusarium spp.. We identified a new peptide elicitor fraction present in Fusarium and related fungal species, which elicits PTI responses in monocots and dicots. We then mapped the causal mutation in an elicitor-insensitive Arabidopsis mutant (fere1) to a leucine-rich receptor-like kinase (MIK2). PTI loss-of-function in fere1 was fully complemented with the full-length FERE1/MIK2 protein. The strength of the phenotype in fere1 and independent mik2 mutants supports that MIK2 is a new key component in sensing Fusarium. MIK2 also contributes towards basal resistance to Fusarium wilt. We now widened MIK2 functions to the perception of comparable elicitors from a broader spectrum of fungal species. Genetic interaction of MIK2 with PTI signalling components, new data on elicitor-interaction and biochemistry further establish MIK2 as a potential pattern-recognition receptor. Because MIK2 was also described as a receptor for endogenous SCOOP peptides that act as phytocytokines, MIK2 may represent an integrator of endogenous and exogenous danger peptides for an optimal immune response under fungal attack.

Text

Harnessing plant genetic resistance to disease contributes to sustainable improvement of crop production. Plant defense responses to pathogens are initiated by two large families of immune receptors that function in an integrated network. Immune receptors directly or indirectly monitor the presence of specific pathogen-derived molecules. Genomic approaches have revealed the extent of the nucleotide-binding leucine-rich repeat receptors (NLRs) repertoires in diverse plant species but the identification of receptor genes involved in recognition of the devastating bacterial wilt disease agent, *Ralstonia pseudosolanacearum* (*Rps*), remains a challenging task. Here, we have characterized several type III secreted effectors present in Korean *Rps* isolates that trigger robust defense responses in the model Solanaceae *Nicotiana benthamiana*. Using the combinatorial silencing of ~ 300 NLRs genes in *N. benthamiana*, we were able to rapidly identify and clone NLRs activating effector-triggered immunity. Further genetic and biochemical characterization of these receptors are ongoing. Altogether, our findings expand the pool of resource to improve bacterial wilt disease resistance in Solanaceae crops.

Text

Musa acuminata cv. Cavendish is the most important export banana cultivar worldwide. It is, however, susceptible to a variety of diseases, which can lead to losses in yield and fruit quality. Although resistant banana germplasm has been identified for some important diseases, little is known about the molecular basis underlying that resistance. The most predominant type of resistance (R) genes contain nucleotide binding site and leucine rich repeat (NBS-LRR) domains. The identification and characterisation of R genes in Cavendish bananas would enhance the knowledge needed for its genetic improvement and possibly uncover the basis of its resistance to Fusarium oxysporum f.sp. cubense (Foc) race 1. We have generated a high coverage genome sequence of Cavendish and this is a valuable resource for analysing the genomic organisation of R genes in this important cultivar group. In this study, we identified 361 NLR genes in the Cavendish genome and characterised their

protein motifs, gene structures and phylogenetic relationships. Our study establishes a haplotype-resolved NLRome for Cavendish banana which is an important resource for the identification of functional R genes against various pathogens. This is a stepping-stone for improving this cultivar and may aid the development of gene-edited Cavendish resistant to Foc Tropical race 4 in the future.

Text
Phytophthora infestans causes late blight, a highly destructive potato disease which has challenged global agriculture for centuries. Genes involved in resistance to *P. infestans* (*Rpi* genes) have been discovered in wild potato species (*Solanum* spp.), and some of these *Rpi* genes have been introduced into potato cultivars. However, we do not know which *Rpi* genes are present in the many different potato genotypes. The goal of our work is to investigate the incidence of 11 *Rpi* genes and to analyse their diversity in potato cultivars grown in Poland and Norway using an Amplicon Sequencing (AmpSeq) approach. The 183 potato cultivars were selected based on resistance to late blight and acreage of cultivation. In addition, 98 breeding lines and 54 genotypes of wild potato species were included.
Plant material was initially screened for the presence of *Rpi* genes using PCR targeting short fragments of *Rpi* genes (1-3 primer pairs per gene). Subsequently, the entire coding sequences of the genes in 316 of 335 potato genotypes were amplified. So far, 243 amplicons of *R1*, *R2*, *R3a*, *R3b*, *Rpi-phu1*, *Rpi-blb1* and *Rpi-ber1* were sequenced using PacBio high fidelity long read technology. The first batch of *Rpi* gene sequencing resulted in more than 4 million reads with an average length of 4,086 bp. The AmpSeq strategy proved to be reliable and efficient, and will allow us to obtain data on the nucleotide diversity of genes crucial for the potato defence against *P. infestans*.

Text

Bean common mosaic virus (BCMV) and Bean common mosaic necrosis virus (BCMNV) cause severe economic losses in common bean (Phaseolus vulgaris), which is one of the most important grain legumes for human consumption worldwide. The dominant resistance gene *I* confers hypersensitive-type resistance to BCMV and BCMNV and has been introduced by breeders in many bean cultivars. The *I* gene is located at a complex multiparasitic cluster with dramatic structural variation in the number of TNL genes, ranging from one to 34, depending on the genotypes. Because of its agronomic importance, many teams have tried unsuccessfully to clone the *I* gene, due to suppression of recombination and/or repeated sequences at this resistance cluster. Our team identified the TNL gene encoding *I* through two independent BAT93 mutants: a tilling mutant and a natural mutant, linked to the insertion of a transposable element (TE). The *I* gene encodes a TNL presenting a C-JID domain in C-terminal. The TE belongs to the LTR/Gypsy/Retand family and is inserted in the *I* gene near repetitive and palindromic sequences. This TE is not present in the same TNL gene in other BAT93 genomic resources and LTR of the TE are 100% identical. This suggests a recent TE insertion event in certain BAT93 seed batches in our laboratory. Since another spontaneous mutant of the *I* gene has been reported in the literature, we suspect that the *I* gene could be a hot spot of mutation.

RESISTANCE TO FUSARIUM WILT IN HEIRLOOM CULTIVAR “EARLIGLOW” IS CONFERRED BY UNLINKED RESISTANCE GENES ON CHROMOSOME 2B IN STRAWBERRY

VACHEV Mishi V.. (1), PINCOT Dominique D. A.. (1), BJORNSON Marta. (1), FELDMANN Mitchell J.. (1), COAKER Gitta L.. (1), KNAPP Steven J.. (1)

(1) University of California, Davis, Davis, UNITED STATES

Text

Fusarium wilt, a soil-borne disease caused by the fungal pathogen *Fusarium oxysporum* f. sp. *fragariae* (Fof), has become an increasingly important cause of strawberry plant death and yield losses in many other parts of the world. The pathogen colonizes vascular tissue, causing wilt, collapse, and death in susceptible accessions. Several sources of resistance to Fof have been identified through genome-wide association studies of genetically diverse cultivars and ecotypes. However, no resistance gene has been characterized in strawberry. To date, five resistance loci are known to confer innate immunity to Fof and are hypothesized to encode well-known resistance (*R*) proteins. The cultivar “Earliglow” was previously shown

to be resistant to California race 1 and Japanese race 2 isolates of the pathogen. An Earliglow F2 population was screened for resistance to a race 1 isolate, and a 15 resistant to 1 susceptible phenotypic segregation ratio was observed. QTL-mapping revealed that “Earliglow” harbors a dominant *R*-locus (*FW6*) in a near-telomeric cluster of *R*-loci on chromosome 2B and a second dominant *R*-locus (*FW7*) approximately 20 Mb downstream of *FW6*. The proteins encoded by *FW6* and *FW7* are currently unknown; thus, we plan to utilize HiFi long-read sequencing and transcriptomics to identify candidate genes and uncover the *FW6* and *FW7* genes. These epistatically interacting *R*-genes expand the arsenal of *R*-genes available for developing strawberry cultivars resistant to race 1.

Text

Potato virus Y (PVY) is among the top ten economically important plant viruses. It causes potato tuber necrotic ringspot disease, leading to decreased yield and tuber quality. Wild relatives of potato are valuable sources of genes involved in resistance to many pathogens that attack potatoes, including PVY. The gene Ry_{sto} derived from *Solanum stoloniferum* confers extreme resistance to PVY. The aim of this work is to screen Ry_{sto} homologues and to analyze their diversity in wild relatives of potato (298 genotypes representing 29 accessions of 26 wild potato species, IHAR-PIB’s collection) using PacBio Circular Consensus Sequencing (CCS) technology. Using PCR primers targeting part of the Ry_{sto} gene, fragments of the Ry_{sto} homologues were detected in 102 out of the 298 wild potato genotypes. Subsequently, the full coding sequences of the Ry_{sto} gene from 88 amplicons representing 72 genotypes (12 accessions, 10 wild potato species) were obtained by CCS. More than 1.7 M HiFi reads with an average length of 4741 bp were generated, representing 56 unique amplicon sequence variants (ASVs) and 41 different protein sequences with 76.4 – 99.9 % (54 ASVs) and 100% (2 ASVs) identity to the reference Ry_{sto} protein (QEL52752.1). Among them, 17 ASVs were detected in PVY-resistant wild potato genotypes, 20 in susceptible ones and 5 in both. Knowledge on PVY resistance and resistance gene contents in analyzed accessions will enable their exploitation in potato breeding programs.

THE SOYBEAN (GLYCINE MAX) LYSM RECEPTOR KINASES GMNFR5A AND GMCERK1 MEDIATE CHITOOLIGOSACCHARIDES-TRIGGERED IMMUNITY

SUN Guangzheng. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text
Chitin is a major component of fungal cell walls and serves as a molecular pattern for the recognition of potential pathogens in the innate immune systems of plants. Previous research suggested that chitin has different immune signaling pathways in Arabidopsis and rice, including extracellular receptor recognition and intracellular signal transduction. The mechanism of induced resistance of chitin oligosaccharide (COSNAC) and its deacetylated product chitosan oligosaccharide (COS), collectively referred to as chitooligosaccharides, is not clear in soybean. Herein, we report that chitooligosaccharides trigger immune responses and plant disease resistance in soybean. GmNRF5a and GmCERK1 are required for chitooligosaccharides recognition in soybean. Unexpectedly, COSNAC is directly recognized by GmNFR5a and GmCERK1, whereas COS only binds GmNFR5a. In addition, we confirmed that GmCERK1 and GmRLCK5 transduce intracellular signals of chitooligosaccharides through proteins interaction and phosphorylation. Taken together, our results suggest GmNFR5a and GmCERK1 play a key role in the perception of chitooligosaccharides elicitors, and the existence of a complete phospho-signaling transduction pathway from GmNFR5a and GmCERK1 mediated chitooligosaccharides recognition to GmRLCK5 activation in soybean.

A NOVEL SOYBEAN APOPLASTIC PROTEIN TRIGGERS RESISTANCE TO PHAKOPSORA PACHYRHIZI

WU Jinbin. (1), WANG Yan. (1), WANG Yuanchao. (1)

(1) NANJING AGRICULTURAL UNIVERSITY, Nanjing, CHINA

Text
Soybean (*Glycine max*) is a worldwide economic oilseed crop and could be infected by various pathogens at different growth stages. Soybean rust caused by obligate, biotrophic fungus *Phakopsora pachyrhizi* leads to severe yield losses and raises the strategy to protect soybean production via plant immunity. Plants have a two-tier immune system mediated by plasma membrane-localized pattern recognition receptors and intracellular receptors, which recognize apoplastic effectors as well as damage-associated molecular patterns (DAMPs) and intracellular effectors, respectively. However, DAMPs and their cognate receptors in soybean are barely known. This study aims to identify *P. pachyrhizi*-triggered soybean DAMPs (PTSDs). With the combined strategy of mass spectrometry, RNA-seq, bioinformatic prediction and *Agrobacterium*-mediated transformation in *Nicotiana benthamiana*, 2 out of 7 candidates were able to trigger hypersensitive response and PTSD1 was further analyzed. Infection of *P. pachyrhizi* triggers PTSD1 expression and plant immunity activation enhances PTSD1 protein abundance in the apoplast. In addition, PTSD1 activates soybean immune responses and triggers resistance to *P. pachyrhizi*. Moreover, PTSD1 could also be recognized by *Solanum* species and relies on yet unknown leucine-rich repeat receptor-like proteins to trigger immune responses. Collectively, this study identifies that PTSD1 acts as a DAMP and triggers immunity against *P. pachyrhizi*.

Text

Plant pathogens have a major impact in both natural and agricultural ecosystems, inducing widespread disease, reduced fitness, and mortality. Genes encoding nucleotide-binding leucine-rich repeat (NLR) proteins are the major class of disease resistance (R) genes in plants, and encode receptors that directly or indirectly detect the molecular signals of pathogens and activate defense response. NLR genes are among the most variable in plant genomes, exhibiting tremendous diversity in sequence and structure. This structural diversity makes NLRs difficult to study but with long read sequencing we can directly sequence complex gene clusters. Here, we assembled the genomes of 18 diverse lines of Arabidopsis thaliana using the PacBio HIFI sequencing technology. We performed comprehensive genome annotation integrating full-length transcript data generated with Iso-Seq, pan-TEome (transposable elements) annotation, CG-methylation, segmental duplications, and recombination to investigate the processes that lead to the birth, death and maintenance of NLR diversity across the species. We found that TEs play a major role in generating structural diversity and that pseudogenization is a major force in moderating the genomic load of active NLRs. We also unravel hidden NLR diversity generated through isoform variation. Our findings give a better understanding of the different strategies used by plants to compete in the defensive arms race against pathogens.

Text

The Tandem Kinase Protein (TKP) family, discovered by our lab, emerged as new regulators of plant immunity.

Plant pathogens can modulate plant metabolism and immune responses to their benefit by secreting effector proteins into plant cells. In turn, plants have numerous intracellular nucleotide-binding leucine-rich repeat (NLRs) receptors that are powerful components of effector-triggered immunity. Most functionally characterized plant disease resistance genes encode NLRs specific to certain pathogen races, which rapidly evolving pathogens may overcome.
The discovery of the wheat stripe rust resistance gene *Yr15* and barley stem rust resistance gene *Rpg1* encoding a rather nontypical resistance protein with a combination of two kinase domains prompted a new chapter in plant immunology. To date, numerous TKPs from cereal crops have been discovered. However, both their evolutionary history and mechanism of action remain poorly understood.
The creation of the TKPs' Atlas shall play a pivotal role in the future discoveries of TKP evolution and molecular function. Defining TKPs as protein sequences with two or more protein kinase domains, we scanned the genomes of 105 plant species and discovered TKPs across all Plant kingdoms. We found that over half of the discovered TPKs have kinase domains lacking critical catalytically important residues (thus, representing pseudokinases) likely serving as decoys for the effector recognition in TKP-related immune responses.

Text
Wild emmer wheat (WEW), the progenitor of common wheat, is a valuable genetic source for resistance breeding. However, gene cloning in repeat-rich polyploid genomes remains challenging. Previously, we used the "Durum as a bridge" approach for map-based cloning of WEW genes, such as the yellow rust resistance genes *Yr36*, and *Yr15*. The cloning of *Yr15* have shed light on the novel plant tandem kinase-protein family, which is a new player in plant immunity. Here we describe a new strategy for overcoming the major bottlenecks encountered during the cloning of the WEW powdery mildew (Pm) resistance gene *Pm69*. Conventional positional cloning approach encountered structural variations that suppressed recombination, while chromosome sorting was compromised by insufficient purity. A *Pm69* physical map, constructed by assembling Oxford Nanopore Technology long-read genome sequences, revealed a rapidly evolving nucleotide-binding leucine-rich repeat (NLR) gene cluster. Transcriptome sequencing of susceptible mutants revealed a candidate NLR that contains Rx_N with RanGAP interaction sites, NB-ARC, and LRR domains. The candidate

gene, located within a rapidly evolving R-gene cluster was validated by the virus-induced gene silencing approach. *Pm69* is a very rare allele found only in one location across the distribution range of WEW natural populations. We introgressed *Pm69* into common wheat lines currently available for wheat resistance breeding.

THE TOOTHPICK PROJECT: THE IMPACTS OF A COMMERCIALIZED BIOHERBICIDE INNOVATION

BAKER Claire. (1), SANDS David. (1)

(1) Toothpick Company Ltd., Kakamega, KENYA

Text
The International Congress of Plant Pathology One Health venn diagram displays environmental health, human health, and animal health, all overlapping in a unified One Health strategy to promote interdisciplinary collaborations and communications. We see the United Nations codify human, environmental, and animal health through the Sustainable Development Goals, with seventeen impact goals defined with measurable indicators. Are these impact indicators linked to the One Health research strategy we are seeing and vice versa? With the opportunity to talk about the real-life impact and exactly how the Venn diagram could look, a commercialized bioherbicide development in Africa stands as a successful example of multi-layered and intersecting impact stemming from plant pathology research. Using a fungal pathogen to target a parasitic weed that reduces staple crop yield by 20-100%, the bioherbicide clearly addresses human health by preventing crop loss. In deeper evaluation and intentionality during the design and strategic development process, the innovation also addresses poverty alleviation with particular attention to women; biodiversity and nutritional diversity; access to technical training; ensuring women's participation; reducing chemical pollution; promotion of local economic growth; reduce the production of greenhouse gas emissions associated with pesticide production and use; fostering collaboration, partnerships, and innovation.

THE PLANT DISEASE PYRAMID: PLANT DISEASE AND EPIDEMIC MANAGEMENT REQUIRES A HOLISTIC APPROACH

SLIPPERS Bernard. (1), STUCKENBROCK Eva H. . (2)

(1) Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria,

SOUTH AFRICA; (2) Environmental Genomics, Christian-Albrechts University of Kiel and Max Planck Institute for Evolutionary Biology, Kiel And Plön, GERMANY

Text

The plant disease triangle is a central tenet of plant pathology. The field has undergone transformative changes since this simple but powerful concept was originally proposed in the 1960's. Six decades of accumulated knowledge and powerful current tools now provide deep insight into plant-pathogen interactions at very fine physical and molecular scales, as well as how abiotic factors affect these interactions across time and space. This rich knowledge base is, however, also leading to changing perspectives on the disease triangle. Recently, for example, researchers have argued that the model is incomplete without a fourth dimension that consider the influence of biotic factors such as the microbiome on disease development. We argue that another dimension is needed in this model, namely the critical role that socio-economic systems play in the emergence, evolution and severity of disease and epidemic developments. The influence of all these elements of the system needs to be considered if successful interventions are to be developed in the context of interrelated local, regional and global systems. We argue that such a holistic approach is urgently needed in the context of the increasing pressure on food security and environmental health.

Text

Scientific advances continue to be made by plant pathologists on topics in plant health, environmental protection, and food security. It is important for the scientific community to evaluate the impact of these advances given the global challenges of the 21st century. Impact will depend on recognition of the multidimensional nature of these challenges and the ability to transcend discipline-based research, integrating studies from the molecular to the ecological in a systems level approach. The adoption of high throughput sequencing for diagnosis and detection will make little impact unless providing the agricultural and ecological context and combined with improved surveillance. Deployment of novel resistances to specific pathogens needs to be aligned with a greater appreciation of genetic diversity and the complementary contribution made by tolerance of plant disease. Epidemiological understanding of the temporal and spatial spread of plant diseases can be enhanced by population dynamic and genetic approaches for established, invasive, and emerging plant pathogens. Recent emphasis on holobiont research can invigorate soil microbial studies especially for disease complexes and declines. The challenge of climate change cannot be

met with single crop disease studies but requires these to be placed in the context of shifting populations of new crops, wild plants, and soil microbes. Advances in informetric analysis illustrate the global impacts of plant disease introductions.

SYSTEMATIC MAPS FOR IDENTIFICATION OF SCIENTIFIC EVIDENCE FOR DISEASE CONTROL METHODS IN OATS, OILSEED RAPE AND POTATO

VILVERT Elisa. (1), ANDERSSON Björn. (1), WALLENHAMMAR Ann-Charlotte. (2), STRIDH Linnea. (3,4), ALDÉN Louise. (5), OLSON Åke. (1), **BERLIN Anna. (1)**

(1) Swedish univeristy of agricultural sciences, Uppsala, SWEDEN; (2) HS Konslut AB, Örebro, SWEDEN; (3) Swedish univeristy of agricultural sciences, Alnarp, SWEDEN; (4) Sveriges Stärkelseproducenter, förening u.p.a, Kristianstad, SWEDEN; (5) Swedish Board of Agriculture, Landskrona, SWEDEN

Text
Systematic maps are a tool for compiling available and relevant research results in a structured way. We have produced systematic maps for disease control methods in oats, oilseed rape and potato. The aim was to identify scientific literature to support crop protection strategies for the crops. For oats 58 articles, for oilseed rape 118 and for potato close to 1,000 articles were identified. At the same time there are common trends within the crops studied, as there is a clear increase in the number of publications over the last decade, which can be linked to the general increased volume in scientific publishing. The extent of the research is largely based on which crop(s)/diseases that attracts funding. This is reflected in the fact that the most serious crop diseases are also the most studied, for oilseed rape black leg (*Leptosphaeria* spp.) and Sclerotinia stem rot (*Sclerotinia sclerotiorum*) for oats Fusarium head blight (*Fusarium* spp.) and crown rust (*Puccinia coronata*) and for potato late blight (*Phytophthora infestans*). Overall, the two most common control methods against plant diseases are the use of pesticides and resistant varieties. Biological control is included in only a few studies for oats, while several products were tested in oilseed rape and potato. Various cultivation and tillage methods were also identified in all three maps. We show that systematic maps can be used to identify both knowledge and knowledge gaps relevant in plant protection of different crops

C4.7-5

DATA-DRIVEN DECISION MAKING TO REDUCE GLOBAL CROP LOSSES

SZYNISZEWSKA Anna. (1), **TAYLOR bryony. (1)**

(1) CABI, Wallingford, UNITED KINGDOM

Text
According to the IPCC, activities related to agriculture amount to 8.5% of all greenhouse gas (GhG) emissions with a further 14.5% attributed to land use change (mainly deforestation

and clearing land for food production). GhG emissions from agriculture are predicted to increase 30-40% by 2050, as food systems are under constant pressure of producing more food to meet growing demand of rapidly increasing population number. At the same time, farmers face challenges due to climate change and associated weather shocks and increasing pest pressures. An estimated 20-40% of crops are lost due to pests before they're even harvested – so the potential for closing this gap is enormous. The Global Burden of Crop Loss (GBCL) initiative identified the need for rigorous crop health metrics and methodology to assess annual losses of the world's most important crops. The goals of the initiative are to provide actionable baseline estimates of crop losses to inform multi-scale decision making towards assessing agricultural resilience to climate change and the introduction of mitigation strategies. Our ambition is to build a comprehensive database of reported pest and abiotic impacts on crops, including their evolution due to climate change, to underpin our assessment.

C4.7-6

NOVEL PLANT GROWTH PROMOTING RHIZOBACTERIAS (PGPRS) AS POTENTIAL INDICATOR OF SUSTAINABLE AGRICULTURE DEVELOPMENT

HUSSAIN Touseef. (1), DABAWALA Mohsin. (1), DHOLIA Akil. (1)

(1) Mati Mate Agromart Pvt Ltd. , Bhavnagar, INDIA

Text

Biostimulants can be used as a tool to complement the use of chemical inputs, by involving living-based products, containing beneficial rhizosphere bacteria, such as plant growth-promoting rhizobacteria. Increase in soil fertility, plant growth promotion, and suppression of phytopathogens are the targets of the bioformulation industry that leads to the development of eco-friendly environment. To scope this cope, we investigated the potentiality of PGPRs (Plant Growth Promoting Rhziobacterias) from different hot agroclimatic states of India, characterized and correlate them with the potential effects on seed germination under unfavourable stress. Results indicate that *Bacillus safensis FO-36b* MMAPL-W, *Dyella jiangningensis* MMAPL-Fa and *Agrobacterium tumefaciens* MMAPL-Q strains exhibited high levels of qualitative and quantitative assays for biological Nitrogen fixation, Phosphorus (solubilisation index =7.8; 8.7; 6.9) and Potassium solubilizing bacteria (solubilisation index =2.85; 3.30;2.89), Siderophore production activities along with Biofilm characters. These strains render multifaceted benefits and presence of peculiar traits to the plants by several mechanisms. The inoculation of wheat, chickpea and moong seeds with culture filtrate directly during germination as well after two weeks of growth, were the most efficient methods of protecting seeds from growth inhibition. These PGPR strains can make it potential liquid biofertilizer candidates.

REMOTE SENSING IN THE CONTRIBUTION TO THE STUDY OF FOLIAR DISEASES OF CEREALS "APPROACH TO THE EPIDEMIOLOGICAL STUDY AND IDENTIFICATION OF BARLEY DWARF YELLOWS" IN ALGERIA

ZEGRAR Ahmed. (1), SMAHI Zakaria. (2)

(1) Centre of Spatial Techniques, Arzew, ALGERIA; (2) university USTO, Oran, ALGERIA

Text

Cereals continue to be at the center of the concerns of governments, regional and international institutions, constitute the staple food, of populations throughout the world and of constantly growing needs.
Thus, the investigations carried out over the last ten years in certain potential cereal-growing regions of eastern Algeria (Constantine, Mila, Guelma, Annaba, etc.) indicate the risks of epidemic development of certain cryptogamic diseases (yellow rust, Helminthosporioses, Septorias , etc.), a large number of cereal samples from the surveyed regions and its severity is linked to its epidemiology correlated with a high activity of aphid vectors such as: Rhopalosiphum padi, Rhopalosiphum maidis, etc. Remote sensing is efficient technique for acquiring and analyzing the spectral properties of plants and the earth's surface at different distances. This modern technology shows promise in agricultural production, including crop protection. The variability of plant reflectance spectra resulting from the occurrence of diseases and pests, allows their identification using remote sensing data. Various techniques such as infrared, multiband, multispectral imaging and hyper-spectral imaging, have been studied for the detection of plant diseases. In this work we use data from the satellites ALSAT, LANDSAT and SENTINEL sensor for the diagnosis of wheat disease and thus make agriculture more sustainable and safer, avoid the costly use of pesticides in crop protection.

BIOLOGICAL AND MOLECULAR CHARACTERISATION OF CITRUS VIROID VII

CHAMBERS Grant. (1,2), DONOVAN Nerida. (2), HOLFORD Paul. (3), VIDALAKIS Georgios. (4), BOGEMA Daniel. (2), GEERING Andrew. (1)

(1) University of Queensland, QAAFI, St Lucia, AUSTRALIA; (2) NSW Department of Primary Industries, EMAI, Menangle, AUSTRALIA; (3) Western Sydney University, Penrith, AUSTRALIA; (4) University of California - Riverside, Riverside, UNITED STATES

Text

Citrus is notable for being susceptible to a broad range of viroids, including citrus exocortis viroid, hop stunt viroid and the recently discovered citrus viroid VII (CVd-VII). CVd-VII was first detected in Australia in ‘Lisbon’ lemon plants held at a citrus germplasm field collection in south-western New South Wales by RT-PCR using universal primers designed against members of the genus apscaviroid. The viroid is enigmatic, as it has not been found beyond these original trees, either in Australia or overseas, raising questions regarding its origin. Host range studies suggest that CVd-VII can experimentally infect many types of citrus but not plant species outside the *Rutaceae*. Most infections appear to be asymptomatic, but in ‘Etrog’ citron, downward leaf curling and plant stunting occurs. Field and pot trials have been established to determine the long-term effect of CVd-VII on yield, and to investigate potential synergistic interactions with other viroid species. miRNA expression studies are investigating how CVd-VII may disrupt normal plant metabolism to induce symptoms in 'Etrog' plants. Finally, the regions of the viroid genome that are prone to mutation are being identified to guide design of PCR primers for diagnosis.

FOXES IN CHARGE OF HENHOUSES: COMBATTING SUGARCANE RATOON STUNTING DISEASE (RSD) AND ITS DEFENDERS IN AUSTRALIA

YOUNG Anthony. (1)

(1) The University of Queensland, Gatton, AUSTRALIA

Text

Management of sugarcane ratoon stunting disease (RSD) in Australia continues to falter, despite significant diagnostic advances. This failure has far-reaching deleterious impacts on sugarcane production and the environment. The inadequacies of current management are in part due to the symptomless presentation of RSD that baffles farmers, but also on long-standing but untested perceptions within the industry that the disease is under control. The development of the leaf-sheath biopsy (LSB) qPCR diagnostic has cast RSD through a new lens as it is quicker, samples more stalks in a field, and is more sensitive than previous methods. This has led to changes in the diagnostic platform offered in Australia, in turn revealing that far from being under control, RSD is rampant in most regions. This presentation discusses the consequences of the problematic nature of RSD on the profitability and sustainability of sugarcane production in Australia, and its impacts on sensitive river catchments and the Great Barrier Reef.

EVALUATING THE OILSEED RAPE GROWTH-STATUS USING NDVI AND NDYI OBTAINED FROM UAV-BASED RGB IMAGERY

ZAMANI-NOOR Nazanin. (1), BERGER Beatrice. (1)

(1) Julius-Kuehn-Institute, Braunschweig, GERMANY

Text

The study aimed to evaluate the potential of the normalized difference vegetation index and the normalized difference yellowness index derived from RGB-imaging to monitor the growth status of oilseed rape. Subsequently, collected values were used to evaluate their correlations with the yield. Field trials with different seed densities and nitrogen rates were conducted for two years. The images were taken by an unmanned aerial vehicle carrying a multi-spectral camera. The NDVI and NDYI values for each plot were calculated from the reflectance at RGB and NIR bands' wavelengths pictured in a re-constructed and segmented orthomosaic. During both seasons, the NDVI increased significantly from the seedling stage to the beginning of the winter season, then decreased slightly after winter, again increased to reach the first pick before crop flowering, then significantly decreased during flowering stages. The NDVI approached the highest pick at the full pod development stage and then reduced strongly until maturity. In contrast, the NDYI accessed saturation around flowering time, decreased during pod development stages, shortly increased at the end of pod development, and then decreased until plant maturity. The strongest correlations were found between the final yield and NDVI of full leaf development before winter and the final yield

with NDVI of full pod development stages. A significant correlation was observed between NDYI at the full flowering stage with the final yield.

Text

Insects' olfactory systems guide important behaviours throughout their life, such as host preference and mate choice. The chemosensory superfamily is the largest gene family in genomes and has been seen as an ideal model for understanding evolutionary divergence and speciation. It has been hypothesised that ecological adaptation, such as changing host species and range, may correlate with the 'birth-and-death' evolution of olfactory genes. Beetles are the most diverse order of insects, providing an ideal model for comparative evolutionary studies. This study focuses on flea beetles (*Alticinae*), some of which are agricultural pests, such as the cabbage stem flea beetle *Psylliodes chrysocephala* L. From a feeding preference perspective, *Phyllotreta vittula* R. is of special interest since it represents one of the closest polyphagous relatives of the monophagous *chrysocephala*. With a whole-genome assembly of *vittula*, we hope to better understand their host interaction for developing better pest control methods.

Aims (1) Sequence and assemble the genome of the polyphagous flea beetle *Ph. vittula*. (2) Test the hypothesis that host adaptation drives chemosensory gene evolution using a comparative genomic approach.

We will compare the olfactory gene families of the polyphagous with the newly acquired genome of *Ps. chrysocephala* and other closely related beetle species to identify key olfactory genes involving host selection and pave the way for our further knock-out verification.

INVESTIGATING GRAPE SOUR ROT DEVELOPMENT IN A COMMERCIAL VINEYARD IN MARYLAND, USA

JUMBAM Blaise. (1), **HU Mengjun. (1)**

(1) University of Maryland, College Park, UNITED STATES

Text

Grape sour rot (GSR) is a disease complex involving fungi and bacteria that can cause significant yield losses of susceptible cultivars. It is widely spread in eastern U.S. and other grape-growing regions globally. Previous studies suggest that damaged fruit skin and feeding

insects like *Drosophila* spp. are required for the disease to occur. Synthetic insecticides and fungicides are recommended for GSR management, but the specific insects and microbes involved in GSR development are not well understood. We aimed to (i) determine the bacterial and fungal species associated with GSR development using culture-based and high throughput sequencing techniques and (ii) conduct in vitro assays to investigate the pathogenicity of the core communities. So far, we have isolated about 700 bacteria and fungi combined from healthy and infected grape berries of three cultivars collected at multiple time points from a commercial vineyard. We found five bacterial species in the genera *Pantoea* and *Curtobacteria* associated with GSR as opposed to *Gluconobacter* and *Acetobacter* species frequently reported in literature. Among the core fungi involved in GSR were many undescribed yeast species including *Pichia*, *Hanseniaspora*, *Rhodotorula*, *Starmerella*, and *Sporobolomyces* species. Filamentous fungi like *Cladosporium*, *Pestalotiopsis*, and *Neopestalotiopsis* were also isolated from GSR-infected berries. These results will form a basis for downstream analyses to elucidate the mechanism of GSR development.

TAKING A TOUR INSIDE THE KIWIFRUIT MICROBIOME: A STUDY ON THE ETIOLOGY OF KIWIFRUIT VINE DISEASE SYNDROME (KVDS)

CARDACINO Antonella. (1), TURCO Silvia. (1), BALESTRA Giorgio Mariano. (1)

(1) University of Tuscia , Viterbo, ITALY

Text

Since 2012, Italian kiwifruit orchards and overall production have been particularly threatened by a new complex disease known as Kiwifruit Vine Decline Syndrome (KVDS). The main symptoms associated with this syndrome are the reduction and browning of roots, xylem necrosis, progressive loss of capillitium, hypertrophy, and separation of the cortical layer. These symptoms can quickly spread systemically, inducing the collapse and death of plants within the same season. The etiology of KVDS is not yet understood and, to date, no causative agents have been significantly associated to it. Thus, a field trial has been carried out in an experimental kiwifruit orchard in Lazio region. Soil and root samples from plants showing KVDS symptoms have been collected at different time-points, from vegetative renewal to flowering, and compared to healthy-looking samples. To deeply investigate the causative agents related to this syndrome, total DNA extracted from both healthy and symptomatic samples was sequenced using an Illumina platform for downstream metagenomics analysis. The results gave the first insights into the different microbiome composition and how it is influenced by the different experimental conditions. In future, a transcriptomic and a metabolomic analysis will shed light on the plant defense mechanism against KVDS, narrowing down the circle of possible causative agents and helping to design more specific control strategies.

P4.7-008

IDENTIFICATION AND FUNCTIONAL CHARACTERIZATION OF THE IMMUNE ACTIVATION-BOOSTING DOMAIN OF LILIUM DEFENSE-PRIMING PROTEIN LSGRP1

LIN Chia-Hua. (1), CHIANG Min-Jui . (1), **CHEN Chao-Ying. (1)**

(1) National Taiwan University, Taipei, TAIWAN

Text
Defense priming of induced resistance is a form of plant immunological memory[K1] to certain biotic or abiotic stimulations, which leads to faster and stronger immune activation upon subsequent pathogen challenges without causing growth retardation. Herein, the resources capable of triggering defense priming are considered potential disease control agents to reduce chemical pesticide usage. Lilium LsGRP1 is a defense-priming protein involved in both growth promotion and immune activation, crucial for fighting off Botrytis elliptica. LsGRP1-transgenic Arabidopsis driven by constitutive promoter shows better growth and confers resistance to various pathogens accompanied with enhanced defense responses triggered by pathogen-associated molecular patterns (PAMPs) and effectors, revealing this system could help to identify the functional region of LsGRP1 for immune activation. Through comparing the levels of Pseudomonas infection, PAMP flg22-triggered callose deposition and FRK1 expression, and effector AvrRpm1-triggered hypersensitive response among Arabidopsis transformants of wild-type and different region-deleted mutants of LsGRP1, the essential region for LsGRP1 boosting immune activation was located. Besides, the synthetic peptide of this region was proven to enhance B. elliptica secretion-triggered callose deposition in Lilium leaves that this peptide alone did not cause, revealing the potential of this immune activation-boosting domain of LsGRP1 in plant health management.

P4.7-009

OCCURRENCE STATUS OF NATIONAL MANAGEMENT VIRUS IN CHUNGCHEONGBUK-DO PROVINCE, KOREA FROM 2020 TO 2022

YEON Eunsol. (1), PARK Young-Uk. (1), HAN Jong-Woo. (1), PARK Areum. (1), LEE Seongkyun. (1), JEON Jong Ock. (1), KIM Ju Hyoung. (1)

(1) Chungcheongbuk-do Agricultural Research and Extension Services, Chengju, REPUBLIC OF KOREA

Text
In this study, high-risk viruses and quarantine viruses, which are national-managed viruses, were investigated. The investigation was conducted for 3 years from 2020 to 2022, and 7 types of viruses were investigated in the Chungcheongbuk-do Province of Korea. The types of viruses are BRRV(Blueberry red ringspot virus), INSV(Impatiens necrotic spot virus), CNSV(Chrysanthemum stem necrosis virus), TSWV(Tomato spotted wilt virus), TYLCV(Tomato yellow leaf curl virus), CABYV(Cucurbit aphid borne yellow virus), CCYV(Cucurbit chlorotic yellows virus). As a result, TSWV was detected in red pepper, TYLCV in tomato, CCYV, and CABYV in melon, cucumber, and watermelon. The most frequently occurring virus was CABYV in melon, with an incidence rate of 81.8 to 100% over 3 years. CABYV was found in watermelons, cucumbers and melons. CCYV was also found in watermelons, cucumbers, and melons, and the incidence rate over 3 years was highest in melons, ranging from 9.7 to 25%. TYLCV had an incidence of 0-20% for 3 years in tomato, and TSWV had an incidence of 14.3-22.2% for 3 years in pepper. Three types of viruses, BBRV, CSNV, and INSV, did not occur.

P4.7-011

CHLOROPHYLL FLUORESCENCE TECHNIQUE FOR SCREENING THE COLD HARDINESS OF OLIVE (OLEA EUROPAEA L.) CULTIVARS

GARCÍA LÓPEZ María Teresa. (1), MIHO Hristofor. (1), MUÑOZ DÍEZ Concepción. (1), MORAL Juan. (1)

(1) University of Cordoba, Córdoba, SPAIN

Text

The olive is an evergreen tree with low and cultivar-dependent frost tolerance. In winter, air temperatures below 0ºC can cause damage during dormancy. Also, the olive cold hardiness is affected by the plant's age, sanitary and nutritional stages or tissue. Indeed, olive leaves are considered more sensitive than shoots. Here, we evaluated the cold-hardiness of 12 olives (*Olea europaea* L.) cultivars ('Arbequina' 'Arbosana' 'Arroniz' 'Cornicabra' 'Empeltre' 'Frantoio' 'Hojiblanca' 'Koroneiki' 'Manzanilla Cacereña' 'Manzanilla de Sevilla' 'Picual' and 'Sikitita') using the electrolyte leakage method as standard, and a chlorophyll fluorometer. We collected fully expanded, uniformly sized leaves from 1-year-old shoots from 10-year-old trees in the dormant period (winter pause) and exposed them to low temperatures at 0, -3, -6, -9, -12, and -18ºC for one hour each. We assessed the leaf frost damage by measuring the electrical conductivity of the cell electrolytes released into an aqueous medium and the frost impact on the leaf fluorometry. Both evaluation methods correlated for classifying the cultivar's cold hardiness. The optimum temperature to classify varieties was -6ºC. This year, a freezing event during January-February (2 weeks with -2 to 0ºC) in the Olive Germplasm Bank of the University of Cordoba permitted evaluate most varieties (300 approx) by fluorometry. This information is essential for selecting olive cultivars for regions with elevated frost risk.

Text

Synthesis of the international scientific literature available from the 30 last years regarding impacts of Plant Protection products (PPP) on biodiversity and ecosystem functions was conducted on behalf of the French Ministries in charge of the Environment, Agriculture and Research through a collective scientific assessment. We present the main highlights regarding the impacts of PPP on primary producers, from cyanobacteria, microalgae to terrestrial plants, in various environments such as agroecosystems, freshwater, estuarine, marine ecosystems. Our literature review evidenced a general lack of knowledge at the community level, whatever the type of organism or environment, particularly for estuarine,

marine waters and soil photosynthetic microorganisms.
Unintended effects of PPP on field edge plant communities are still insufficiently known to allow a robust assessment of the nature and extent of risks posed by herbicides.
Toxicity of herbicides on marine phototrophs is still poorly documented, especially in overseas territories.
Most toxic compounds to aquatic primary producers were photosynthesis inhibitors, terrestrial plants were mostly affected by acetolactate synthase inhibitors. Copper was also highlighted as potentially toxic to photosynthetic microorganisms at environmentally realistic concentrations. Only a few studies actually address the impacts of PPP on a few ecosystem functions of primary producers, the main one being the function of organic matter production.

Text
Soybean (*Glycine max*) is one of the most important crops worldwide. Since 2020, Brazil has been the largest producer of soybeans in the world, producing 114.2 million tons in the 2019/2020 growing season. Several diseases affect soybean production, and viruses cause major problems, with at least 46 viruses identified infecting soybean worldwide. This study reports an isolate of Passiflora virus Y PaVY naturally infecting soybean plants growing near a commercial passion fruit crop. The nearly complete genome sequence is 9679 nt long and shares 84.4% nt sequence identity with a previously reported PaVY isolate from Passiflora sp. The putative ORF of PaVY starts at an AUG codon at nucleotide positions 170–173 and ends with an UGA codon at nt 9419–9422, encoding a polyprotein of 3083 amino acids (aa) with a molecular weight of 352.16 kDa. PaVY-Br induced chlorotic spots and systemic mosaic on soybean and chlorotic local lesions on yellow passion fruit (*Passiflora edulis*) and sesame (*Sesamum indicum*). The virus was successfully transmitted by *Myzus persicae*, indicating that this aphid vector can contribute to the spread of PaYV from passion fruit to soybean plants. It is worth mentioning that PaYV had never been reported in Brazil, even infecting passion fruit. The presence of PaYV was reported to the Brazilian Ministry of Agriculture, Livestock and Food Supply (MAPA) as required by federal law. Its distribution in soybean production areas in Brazil needs to be studied further.

Text

Viruses transmitted by *Brevipalpus* mites belong to the genera *Cilevirus*, fam. *Kitaviridae* [ss(+)RNA] and *Dichorhavirus*, fam. *Rhabdoviridae* [ss(-)RNA]. They produce non-systemic infections in crops and ornamental plants, and some of them cause citrus leprosis, a serious disease of citrus in the Americas. We analyzed the virome of large periwinkle (*Vinca major*) plants collected in Chile in 2019, exhibiting chlorotic and ring spots; and sweet orange (*Citrus sinensis*) trees collected in Brazil from 1933 (herbarium samples) to 2022, with symptoms of zonate chlorosis. Plant RNA extracts were sequenced using HTS technology. In periwinkle, the genome of two bi-segmented viruses with genomic organizations of cileviruses and dichorhaviruses were identified. Sequence analyses indicated that both viruses represent new species in their respective genera. In citrus plants, the genome of a tri-segmented virus with >98% nucleotide sequence identity with the kitavirus hibiscus green spot virus 2 (HGSV2, genus *Higrevirus*) was identified. Sixty mites collected in periwinkle plants were anatomically and molecularly identified as *B. chilensis*, while in citrus, *B. yothersi* and *B. papayensis* were detected. HGSV2 was transmitted to healthy Arabidopsis plants using specimens of both species. Here we report, for the first time: the presence of BTVs in Chile, *B. chilensis* as a potential viral vector, transmission of a higrevirus by *Brevipalpus*, and HGSV2 as the causal agent of citrus zonate chlorosis.

P4.7-015

NUTRIENTS' EFFECT PREDICTION ON WHEAT PHYSIOLOGY BY USING MACHINE LEARNING

MAHAPATRA Chitaranjan. (1), PRADHAN Ashish Kumar. (2)

(1) Indian Institute of Technology Bombay, Mumbai, INDIA; (2) Indian Institute of Sciences, Bangalore, INDIA

Text

Nutrient management involving wheat has been a matter of interest for a long time owing to the unique production environment of wheat. Machine learning is increasingly being used in agriculture to classify plants, identify pests, predict the weather, and track yield. Here, a machine learning-based prediction model was developed to understand the role of individual nutrients (N, P, K, Zn, and S) on different plant parameters (plant height, tiller number, dry matter production, leaf area index, grain yield, and straw yield) of wheat. A feed-forward

neural network with back-propagation training was developed using the neural network toolbox. For the training of the model, data obtained from two consecutive crop seasons over two years (four crops of wheat) were used. In the present study, an attempt was made to understand the role of individual nutrients in achieving crop growth and yield using an artificial neural network-based prediction model. The model predicts that growth parameters such as plant height, tiller number, and leaf area index often achieve their maximum performance at below the maximum applied dose, while the maximum yield in most cases is achieved at 100% N, P, K, Zn, and S dose. In addition, the present study attempted to understand the impact of individual nutrients on both plant growth and yield in order to optimize nutrient recommendation and nutrient management, minimizing environmental pollution and the wastage of nutrients.

PHENOTYPING FOR QUANTITATIVE RESISTANCE TO LEPTOSPHAERIA MACULANS IN BRASSICA NAPUS (RAPESEED): A FRAMEWORK USING MACHINE LEARNING AND ARTIFICIAL INTELLIGENCE (MLAI)

RABAB Saba. (1), BARRETT Luke. (1), SCHNIPPENKOETTER Wendelin . (1), MAHER Rebecca . (1), SPRAGUE Susie . (1)

(1) CSIRO, Canberra, AUSTRALIA

Text

Phenotyping of plant diseases has not kept pace with the rapid progress in genetic and genomic characterisation and is a bottleneck for breeding. Blackleg crown canker (caused by L. maculans) of B. napus causes large economic losses but breeding for quantitative resistance is challenging due to the large number of genes involved and the lack of an economically viable non-subjective phenotyping method deployable at the scale required for in-field screening in a breeding context. To overcome this issue, we developed machine learning and artificial intelligence (MLAI) techniques for automated assessment of crown canker severity in cross-sections of canola stems at plant maturity using RGB images. The MLAI algorithm was trained on a data set of 4000 images to extract the region of interest (ROI), resulting in an overall accuracy of 88%. Moreover, the disease was quantified based on the pixel values extracted from the images. To ensure the accuracy of our approach, we validated the results by comparing them with standard visual assessments. Overall, the MLAI framework provides an automated disease assessment approach which could form the basis to identify the genes underlying QR and help growers to have resistant varieties of canola to reduce Blackleg related yield loss.

CAL POLY STRAWBERRY CENTER IS A MODEL FOR INDUSTRY-UNIVERSITY PARTNERSHIPS

HOLMES Gerald. (1)

(1) Cal Poly San Luis Obispo, San Luis Obispo, UNITED STATES

Text
In 2014, the California Strawberry Commission (CSC) and Cal Poly State University entered a partnership to increase the sustainability of the California strawberry industry through applied research and workforce training that is aligned with industry needs. The campus is centrally located to California's 16,823 ha of strawberries and 47 km from Santa Maria, where 42% of the state's strawberries are grown. The Center's laboratories and fields are located within walking distance from campus, facilitating student participation. The Center has grown to 6 Ph.D. scientists and 8 support staff who work in three research areas: plant pathology, entomology, and automation. An industry advisory council composed of industry leaders, meets biannually to provide feedback on the Center's programs and outcomes. Over 125 students have received hands-on work experience in the field and lab and 20 students received master's degrees in plant pathology or entomology. The Center leverages financial support from the CSC to compete for grant funding and has obtained $3.7 million USD, resulting in 16 peer-reviewed publications and 35 published product efficacy trials. More importantly, direct improvements to pest and disease management and labor efficiency have been made to the industry. The Strawberry Center is poised to have greater impact in the future through an expansion of lab and field facilities and national and international research collaborations.

Text

Improving the sustainability of agriculture and, at the same time, reducing the adverse effects of synthetic pesticides on human health requires effective alternatives that improve the productivity while maintaining the food quality and safety. Basic substances are relatively novel compounds that can be used in plant protection without neurotoxic or immune-toxic effects and are still poorly known by phytosanitary consultants, researchers, growers, consumers, and decision makers. The BasicS project takes together the experience of 30 Research Units from 19 Countries representing all continents, to test and validate the use of 24 basic substances currently approved in the EU and further potential basic substances. Most of these substances have a fungicidal activity (calcium hydroxide, chitosan, chitosan hydrochloride, *Equisetum arvense* L., hydrogen peroxide, lecithins, cow milk, mustard seed powder, *Salix* spp., sunflower oil, sodium chloride, sodium hydrogen carbonate, *Urtica* spp., vinegar, and whey). Considering the increasing requests from consumers of fruits and vegetables with no or a reduced amount of pesticide residues, basic substances can complement and, at times, replace the application of synthetic pesticides with benefits for users and for consumers. Large-scale trials are important to design the best dosage and strategies for the application of basic substances against pathogens and pests in different growing environments and contexts.

(1) Marche Polytechnic University, Ancona, ITALY; (2) Moncaro, Montecarotto (An), ITALY; (3) Belisario, Matelica (Mc), ITALY

Text

The implementation of the sustainable practices in viticulture has become an important issue for the wine industry. In organic grapevines, copper-based treatments are widely used to control grapevine downy mildew (GDM) and this can affect the quality of wine due to the presence of residues on the grapes. This study was conducted in three commercial vineyards and years (2019-2021) to evaluate the effectiveness of chitosan against GDM. Strategies were based on application of chitosan alone, chitosan alternated with copper, and chitosan combined with copper at half rate each were tested, using copper sprayed alone and untreated plants as controls. Our results showed that all the strategies applied were able to reduce GDM McKinney Index on bunches compared to untreated control. Chitosan alone provided a good protection against GDM, and when alternated with copper have the same effectiveness of copper. Chitosan combined with copper at half rate provided a protection by GDM better than copper alone. All innovative strategies based on chitosan were able to reduce copper amount on harvested bunches. These investigations demonstrated that

chitosan can be a good alternative to complement and even replace copper in GDM management strategies. Further investigations are needed to test the effectiveness of the different chitosan formulations available on the market and the effects on the quality of the wine.

This work was conducted within the framework of the PSR Marche Vitinnova Project

(1) The Federal State Institution “Federal Research Centre “Fundamentals of Biotechnology” of the Russian Academy of Sciences, Moscow, RUSSIAN FEDERATION

Text

Grapevine germplasm collections are unique repositories of grape cultivars; therefore, it is necessary to minimize their infection with pathogens, including viruses, and develop various programs to maintain them in a virus-free state. In our study, we examined the virome of the largest Russian grapevine germplasm collections using high-throughput sequencing of total RNAs. As a result of bioinformatics analysis and validation of its results by reverse transcription PCR and quantitative RT-PCR, we identified 28 viruses and 4 viroids in 120 libraries. All samples were infected with 1 to 12 viruses and viroids, including those that cause economically significant diseases: leafroll, fleck, and rugose wood complex. Two new grapevine viruses were discovered in these germplasm collections. One of them is member of the genus Umbravirus with the provisional name Grapevine umbra-like virus. The second virus is pararetrovirus from the genus Caulimovirus, which was tentatively named Grapevine pararetrovirus.

The research was made possible with support from the Ministry of Science and Higher Education of the Russian Federation in accordance with agreement ? 075-15-2022-318 date 20 April 2022 on providing a grant in the form of subsidies from the Federal budget of Russian Federation. The grant was provided for state support for the creation and development of a World-class Scientific Center “Agrotechnologies for the Future”.

EFFECT OF SILICON ON PLANT GROWTH AND REDUCING DISEASE IN BLACK PEPPER (PIPER NIGRUM L.)

MOHAMED SIDIQUE Siti Nordahliawate. (1), NUR AINU FARHAH Rabae. (1), JIN Xiaolei. (2)

(1) Research Interest Group (RIG) Biointeractions and Crop Health, Laboratory for Pest, Disease and Microbial Biotechnology (LAPDiM), Faculty of Fisheries and Food Science, Universiti Malaysia Terengganu, Kuala Nerus, MALAYSIA; (2) Department of Biological Sciences, National Sun Yat-Sen University, Kaohsiung, TAIWAN

Text

Silicon in bio-available form (silicic acid) application effectively suppressed diseases caused by fungi in a variety of plant species. Various fungicides had been used to control Phytophthora foot rot diseases and Fusarium wilt of black pepper (Piper nigrum L.) but ineffective for a better sustainable agriculture. Thus, this study to confirm the silicon (Si) uptake ability and other nutrients accumulation in leaves and to determine the passive defense pathways (cuticles thickness and wax of the leaf surface). Silicon had been applied once a week on pepper plants variety Kuching at different concentration; T1 [0.5% Si (v/v)], T2 [1.5% Si (v/v)] and T3 [2.0% Si (v/v)] for six months. Although P. nigrum L. is known as Si intermediate accumulators, results proven that it could uptake Si and enhance plant growth. Plants showed the greatest plant height, diameter and chlorophyll content compared to control (without Si). Moreover, disease severity was reduced with increasing tissues concentration of Si whereas nutrients such as K, P, Ca, Mg, Mn and B accumulated more in leaves. The passive defense pathways had mechanically deterred hyphae invasion of the pathogen by strengthening the leaf cell walls. Undoubtedly, Si can be included in disease management plans as an important component of the integrated disease management.

Impact of war and conflicts in plant pathology research and food safety of countries

RESEARCH AND EDUCATION IN PLANT VIROLOGY IN UKRAINE: THE PRESENT IS FOGGY, THE FUTURE IS BRIGHT?

BUDZANIVSKA Irena. (1), SHEVCHENKO Tetiana. (1), SHEVCHENKO Oleksiy . (1)

(1) Taras Shevchenko National University of Kyiv, Kyiv, UKRAINE

Text

Ukraine has been at war for a year now. Writing these lines in February 2023, we really hope that when we report back in summer, this absurdity will be over.

The war has greatly affected research and education in general, including that in plant virology, especially in the affected areas of the country. Research and collaboration ties have been disrupted, making it difficult for Ukrainian scientists to share their expertise.

A brain drain of Ukrainian scientists remains an important issue, as many were forced to leave the country in search of safer options and better opportunities. This led to a loss of experience and knowledge in the field of plant virology in Ukraine. Dozens of universities have been relocated to other regions of the country, and many students preferred to pursue academic mobility programs abroad.

The war also led to the destruction of some of the country's security systems related to plant pest control, where it became difficult or impossible for Ukrainian authorities to monitor and control the spread of plant diseases.

Despite these challenges, some Ukrainian scientists continue to work in plant virology research and education, especially in regions of the country not directly affected by the conflict or abroad. International cooperation and support have played an important role in maintaining our capacities in plant virus research and nurturing future generations of plant virologists. Here we discuss these challenges and how these are mitigated.

Text

Ukraine is one of the 5 largest exporters of grain, supplying more than 45 million tons of grain to the world market every year. Plant viruses are an important economic factor. Our research showed that the isolates of WSMV, BYDV, WDV are circulating in Ukraine and have high epidemic potential, because they lead to a decrease in wheat yield (by 30-50%) and significant deterioration in the products` quality. Our research has shown that species composition of wheat viruses is influenced by climate changes. In recent years, winter wheat in Ukraine suffers from significant temperature drops in phases of emergence into tube and beginning of earing, which leads to significant economic losses. Due to climate change, it is often difficult to distinguish viral infections symptoms from other abiotic factors.
In addition to decrease in crop yield and quality due to damage by plant pathogens and climate changes, the following problems arised in today's realities of the war waged by russia against Ukraine:i) reduction of sown areas due to active warfare, occupied territories, mined fields (by 45 % compared to 2021);ii) mined fields cannot be cultivated, so they are source of virus-carrying insects and plants. The forecast for the gross production of winter wheat in 2023 is decrease of 15-20%, without occupied territories by 30%.Thus, the main goal of plant pathologists, geneticists and breeders in Ukraine should be creatiion of wheat varieties resistant to viruses, fungi and abiotic factors

Text

Agriculture is one of the sectors that has suffered the greatest losses during the full-scale war of russian federation against Ukraine. The direct and indirect damages to the industry resulting from the nine months of hostilities are estimated to exceed $40 billion. Due to military actions, productive plantations and farms' facilities for growing fruits and berries were damaged or destroyed, when the machinery was either destroyed or stolen. In 2022, the production of certified planting material saw sharp decrease over 40%, paralleled by respective reduction in the number of registered nurseries. At least two horticultural germplasm collections with over 900 varieties and forms remain inaccessible and in an uncertain condition. The loss of production potential and stock plants will create a shortage of healthy planting material in the future. Lack of plant protection products leads to the impossibility of proper phytopathogens' control in orchards and non-adherence to recommended treatment regimens. Funding for institutions responsible for phytosanitary supervision and monitoring of phytopathogens has substantially decreased. In current situation, the support of the Ukrainian government and international organizations is important for specialized enterprises and research institutions since it will contribute to mitigating risks to the food security and preserving the production potential, which is important for the post-war reconstruction of Ukrainian horticulture.

Text

The Ukraine crisis has caused major disruptions in the availability of wheat flour in Africa. Many African bakers have turned to banana, cassava, potato, and sweetpotato flours. This shift will likely increase pressure on the seed systems of these crops in the coming years. Since these crops are vegetatively propagated, the accumulation of pests and pathogens is a serious concern. The risk of epidemics in seed systems can be affected by the geographic distribution of crops and climate. Here we evaluated cropland connectivity of these crops in the Lake Kivu region of Rwanda and Burundi. The analysis of cropland connectivity allowed us to develop a risk map of locations that are candidate priorities for disease/pest surveillance in the Lake Kivu region. We surveyed 292, 50, 194 and 211 fields for banana, cassava, potato, and sweetpotato, respectively. We evaluated the severity and community structure of major pathogens and pests of these crops as a function of altitude, climate

variables, and the geographic structure of croplands. There was high variability in pests and pathogens severity, but effects of altitude, climate and cropland structure were observed. We used several machine learning algorithms, including support vector machines and random forests, to predict severity. Climate variables and the geographic structure of croplands can be used to predict severity. Models to guide surveillance and mitigation can improve responses to new epidemics and global change.

C1.7-5

PHYTOSANITARY MANAGEMENT OF ICARDA'S GERMPLASM SEED COLLECTIONS FOR BETTER FUTURE USE

KUMARI Safaa. (1), MOUKAHEL Abdelrahman. (1), EL-MIZIANI Inaam . (2)

(1) International Center for Agricultural Research in the Dry Areas (ICARDA), Terbol Station, Zahle, LEBANON; (2) International Center for Agricultural Research in the Dry Areas (ICARDA), Rabat, MOROCCO

Text

Recent years have witnessed an increasing global concern about the loss of plant genetic resources, as a result of conflicts, epidemics, earthquakes, etc., which led to disrupting access to some germplasm and undermining social protection systems, and thus an increase in global awareness to preserve germplasm for their current and future use. This led genebanks all over the world to create disaster risk reduction policies to organize activities in the safekeeping, conservation, and dissemination of germplasm resources. Safety duplication of base collection at different geographic sites, such as Svalbard Global Seed Vault, is one of the essential measures. Any procedure must comply with phytosanitary regulations to enable direct and rapid response for safe germplasm exchange and retrieval. In order to make sure that germplasm is viable to combat challenges, ICARDA's Germplasm Health Unit (GHU) exercises maximum effort to maintain the health status of germplasm collections, ensure compliance with phytosanitary regulations in international germplasm distributions, and develop methods to detect and manage seed-borne pathogens to guarantee minimum loss of genetic resources. In addition, maintaining plant health during germplasm regeneration is essential to reducing the risk of seed-borne pathogen spread via future germplasm distributions. The role of ICARDA's GHU in preserving germplasm through conservation, seed regeneration, exchange, and retrieval will be presented.

C1.7-6

EMERGING AND (RE)EMERGING VIRAL THREATS FOR COMMERCIAL PLANTS IN UKRAINE: WAR AND OTHER PROBLEMS

SHEVCHENKO Oleksiy. (1), SNIHUR Halyna. (1), SHEVCHENKO Tetiana. (1), BUDZANIVSKA Irena. (1)

(1) Virology Department, ESC 'Institute of Biology and Medicine', Taras Shevchenko National University, Kyiv , UKRAINE

Text
Here we review different risk factors which are or may be important for emergence and establishment of plant virus infections in a new environment/host(s), as well as their subsequent spread and reoccurrence with a focus on Ukraine. In this context, virus properties, transmission routes including vector- or seed-born spread, host range, availability of wild-growing reservoir plants, and effect of some anthropogenic factors (i.e., heavy metals, radioactivity and war activities) are covered.
To showcase this, we analyzed particular plant pathogens which are of specific importance to Ukraine, and suggested major issues possibly contributing to the emergence or further successful persistence of viral diseases of important crops. Additionally, we also show that abiotic stressors (heavy metals and radionuclides) may be essential drivers of virus abundance in the ecosystems, as well as of higher incidence rate of plant infection. Main risk factors favouring the appearance and spread of viruses in Ukraine are summarized.

Latest advancements in knowledge and management of Ralstonia species

C8.3-1

DESCRIBING THE KNOWN GLOBAL DISTRIBUTION, HOST RANGE, AND GENOMIC DIVERSITY OF THE RALSTONIA SPECIES COMPLEX THROUGH COHORT-BASED UNDERGRADUATE RESEARCH

LOWE-POWER Tiffany. (1)

(1) UC Davis, Davis, UNITED STATES

Text
The Ralstonia species complex is a genetically diverse group of plant wilt pathogens with a wide distribution around the world. Collectively, the global plant pathology community has carried out hundreds of population surveys for Ralstonia. However, this rich biological data is fragmented into tables of hundreds of papers. To unify this information, we created a cohort undergraduate research experience (CURE) where we train junior scientists to consolidate data on the reported global distribution and host range of Ralstonia clades. We have cataloged information from almost 8,000 strains isolated from almost 400 plant species in 105 geographic regions. The Global Ralstonia Diversity Database is currently available as a BioRxiv preprint with the strain metadata organized into an Excel spreadsheet. The aggregated data shows that the pandemic brown rot lineage (IIB-1 and IIB-2) is the most widely dispersed lineage. Phylotype I and IIB-4 lineages are also widely distributed and these lineages have the broadest natural host range. Recently, we have created a parallel CURE where junior scientists generate whole-genome resources of Ralstonia isolates. We are regularly submitting new Ralstonia genome sequences to public databases. Moreover, to improve the accessibility of carrying out RSSC phylogenomic studies, we have also created an open graphical user interface (a KBase narrative) where colleagues can identify phylogenetic relationships of new strains with 250 public RSSC genomes.

Text

R. solanacearum phylotype IIB-1 strains, also known as R3bv2, cause destructive potato brown rot and tomato bacterial wilt in cool zones. But are all cool virulent strains R3bv2? To improve regulation of threatening Ralstonia strains, we built a robust phylogenetic tree using genomes of >275 Ralstonia strains. Measuring virulence and colonization of diverse strains on tomato and potato at 22°C and 28° revealed cool virulence is a quantitative trait not limited to R3bv2. Still, epidemiological data indicate that a clonal lineage of S. American origin causes the rapidly spreading brown rot pandemic. This brown rot pandemic lineage (BRPL) can be identified by whole genome sequencing and has a unique LINbase identifier. Host resistance is the best control for bacterial wilt, but mechanisms of the widely used Hawaii7996 tomato breeding line are unknown. We found H7996 resistance is overcome by BRPL strain UW551. Unlike other Ralstonia strains, UW551 grew well in ex vivo xylem sap from Ralstonia-infected H7996 plants. Further, other Ralstoniastrains could grow in sap from H7996 plants previously infected by UW551, which detoxifies inhibitors in H7996 xylem sap. Metabolomics suggested the inhibitors in sap are phenolic compounds. Culturing UW551 in this sap reduced total phenolic levels, indicating that the resistance-breaking BRPL Ralstonia strain degrades these chemical defenses. Thus, H7996 tomato wilt resistance depends in part on inducible phenolic compounds in xylem sap.

Text

We have used live monitoring together with grafting of susceptible and resistant varieties to investigate the spatio-temporal *R. solanacearum* colonization dynamics in tomato1. Our work reveals four different restrictions to the bacterium in resistant tomato and that structural constraints are key for resistance to bacterial wilt both in root and shoot tissues. We have investigated the physico-chemical nature of the induced plant barriers as ligno-suberin coatings and tyramine-derived hydroxycinnamic acid amines. In agreement with these findings, overexpression of the ligno-suberin pathway in a susceptible tomato enhanced resistance by restricting R. solanacearum movement inside the plant and delaying disease

progression2,3.
In parallel, we have studied tomato apoplastic proteases activated in response to R. solanacearum infection. We described important papain-like cysteine proteases, hidrolases and especially the P69 clade of serine proteases as strongly activated upon pathogen challenge. We will present the biochemical characterisation of the P69 family and their role in resistance to bacterial wilt.
Our findings open new avenues to engineer resistance against vascular wilt pathogens.

Text
In a given geographic area, a shift in climatic conditions may result in major effects on plant pathogens. Ralstonia pseudosolanacearum (phy I) populations mainly originate from Asia. It is thought that this group of bacteria is not pathogenic at low temperatures although they occur frequently as latent infections in the plant. Given the high recombination frequency and the high virulence plasticity of these strains, adaptation to various new host plants and diversification to cope with different environmental conditions in many geographic areas worldwide could easily be achieved. Over the past decade new plant species, including many ornamentals, have been reported as hosts, particularly in North and South America and Asia. In 2015 an I-seq 33 population was detected in roses in the Netherlands showing typical bacterial wilt symptoms; this population was highly virulent to many plant species, including roses and potato. Recently R. pseudosolanacearum (phy I) has been found in aquatic environments in temperate climates in Europe. These findings, in combination with the pattern of dissemination of this pathogen through irrigation water, crop debris, common agricultural practices and increased trade in plant products, pose a serious threat to agricultural production in the temperate climates and could result in major outbreaks of this disease on known and new host plants. The results obtained from our work on Ralstonia pseudosolanacearum (phy I) will be discussed.

C8.3-5

BACTERIAL WILT OF POTATO: A THREAT TO FOOD SECURITY IN SUB-SAHARAN AFRICA

SHARMA Kalpana. (1)

(1) International Potato Center, Nairobi, KENYA

Text
Potato is an important food security crop and source of household income for many rural smallholder farmers in sub-Saharan Africa (SSA). Despite the importance of potato, potato productivity remains at 4-9 t ha-1, largely due to bacterial wilt caused by Ralstonia solanacearum species complex (RSSC). Latently infected propagation material such as potato seed tubers are known to be a source of long distance spread of the pathogen and pose a threat to crop production and contribute to pathogen dispersal. The potato seed system in SSA is largely informal, and unrestricted in regional and cross-border movement of seed potato. The unregulated seed movement poses a great threat in disseminating RSSC strains to uninfected areas and have been introducing new strains from abroad as well. Here, we will give insight into the potato seed system in sub-Saharan Africa; distribution, pathogenic diversity, epidemiology of RSSC strains, and the state of the art for management of bacterial wilt under small holder farmers' prospective. Components of the bacterial wilt management strategies examined include diagnostics and surveillance, prevention and control of infection using phytosanitation and use of bacterial wilt free seed, and management of disease through the breeding and promotion of varieties, and cultural practices. We highlight key research areas that need prioritization and conclude by examining the future outlook for bacterial wilt disease management in potato from SSA prospective.

ELUCIDATION OF INFECTION MECHANISM OF RALSTONIA SOLANACEARUM ON GINGER USING ASEPTICALLY REGENERATED PLANTS

HASAN Mehbub. (2), KIBA Akinori. (1), HIKICHI Yasufumi. (1), TSUZUKI Masayuki. (1), **OHNISHI Kouhei. (1)**

(1) Kochi University, Nankoku, JAPAN; (2) Ehime University, Matsuyama, JAPAN

Text
Ginger (Zingiber officinale) is an important spice crop vegetatively propagated through rhizomes. *Ralstonia solanacearum* hampers ginger production. It is laborious and time-consuming to prepare enough numbers of ginger plants for the pathogenicity test. We developed a new pathogenicity test of *R. solanacearum* using aseptically regenerated ginger plants. Ginger plants were regenerated in vitro using 6-benzyl adenine and 1-naphthalene acid (NAA) in Murashige-Skoog (MS) agar media from shoot tips. The regenerated plants were cultured in liquid MS media with NAA and used to evaluate the pathogenicity by root dipping inoculation. When a wild-type strain MAFF 211479 was inoculated, wilt symptoms such as yellowing of leaves were observed within 15 days of post-inoculation (dpi), and ginger plants died at 28 dpi. MAFF 301069, a non-virulent strain of ginger, did not show symptoms on ginger plants. These results demonstrated that new method using the regenerated ginger plants in vitro is suitable for the virulence assessment of *R. solanacearum*. We constructed MAFF 211479 mutants defective in type III secretion system. All the mutants lost pathogenicity in the regenerated ginger plants as well as in the eggplants. The mutant cells proliferated less efficiently than the wild type in the inoculated ginger plants. Based on these results, we conclude that the aseptically regenerated ginger

plants could be used to elucidate the infection mechanism of R. solanacearum in ginger.

P8.3-001

CONTRIBUTION OF THE QUORUM SENSING OF RALSTONIA PSEUDOSOLANACEARUM STRAIN OE1-1 TO ITS INFECTION IN TOMATO ROOTS AND VIRULENCE

HIKICHI Yasufumi. (1), INOUE Kanako. (2), KIBA Akinori. (1), OHNISHI Kohhei. (1), KAI Kenji. (3), TSUZUKI Masayuki. (1)

(1) Kochi University, Nankoku, JAPAN; (2) Osaka University, Irbaragi, JAPAN; (3) Osaka Metropolitan University, Sakai, JAPAN

Text
The soil-borne Gram-negative β-proteobacterium *Ralstonia pseudosolanacearum* strain OE1-1 secretes methyl 3-hydroxymyristate (3-OH MAME) as a quorum sensing (QS) signal. In the active state of QS, the LysR family transcriptional regulator PhcA regulates virulence-related genes. Our omics analysis of the strain OE1-1 showed that QS consists of the 3-OH MAME-dependent cascade for the PhcA activation and the 3-OH MAME-independent cascade for the PhcA production. To elucidate how QS contributes to the infection process of strain OE1-1 in tomato roots, we developed an in vitro pathosystem using 4 days after sowing-tomato seedlings. The microscopic observation showed attachment of the strain OE1-1 to surfaces of the meristematic and elongation zones in tomato roots and a detached epidermis. The strain OE1-1 colonized intercellular spaces between the epidermis and cortex, then infected cell wall-degrading cortical cells adjacent to the epidermis, followed by forming mushroom-shaped biofilms. The strain OE1-1 next progressed through intercellular spaces of the cortex and endodermis, infecting pericycle cells and xylem vessels. The *phcA*-deletion mutant lost its infectivity in cortical cells and the following infection in xylem vessels to lose its virulence. Taking results together, infection of the strain OE1-1, which attaches to surfaces of the meristematic and elongation zones, in cortical cells dependently on QS leads to its subsequent infection in xylem vessels and virulence.

P8.3-002

PLANT SIGNALS THAT INDUCE THE HRP REGULON IN RALSTONIA SOLANACEARUM AND THE COGNATE R. SOLANACEARUM RECEPTORS

CAO Yuzhu. (1), MASAYUKI Tsuzuki. (2), AKINORI Kiba. (2), YASUFUMI Hikichi. (2), **KOUHEI Ohnishi. (2)**

(1) Ehime University, Ehime, JAPAN; (2) Kochi University, Kochi, JAPAN

Text
Genes encoding a type III secretion system in *Ralstonia solanacearum* are regulated by HrpB as a *hrp* regulon, which is induced only in the plant. This study aims to identify plant

signals inducing the *hrp* regulon and confirm the recognition mechanism of signals.
Signal molecules inducing the *hrpB* expression were screened with an assay system using resting cells of the *hrpB-lacZ* reporter strain. The soluble and insoluble fractions were prepared from tobacco seedlings. Only the soluble fraction induced the *hrpB* expression. The heated soluble fraction retained the *hrpB*-inducing activity, indicating that active compounds were not proteins. When the soluble fraction was fractionated into acidic, neutral, and basic components, the acidic and neutral fractions induced the *hrpB* expression. Among organic acids in the acidic fractions and sugars in the neutral fractions, malic acid and sucrose mainly induced the *hrpB* expression.
The sucrose-induced *hrpB* expression was significantly reduced in a *prhA* mutant, suggesting that sucrose might be perceived with the outer membrane protein PrhA. This result agrees that the *hrpB* expression is controlled by a signal cascade, PrhA-PrhI/R-PrhJ-HrpG. We constructed a mutant library of histidine kinase genes in the two-component system. The malic acid-induced *hrpB* expression was reduced in the mutant of one of the histidine kinase genes, *rsc1598*. Rsc1598 could perceive malic acid, and the signal might be transferred to a response regulator HrpG.

P8.3-003

COEXPRESSION NETWORK ANALYSIS TO UNDERSTAND THE QUORUM SENSING-DEPENDENT GENE REGULATION MECHANISM IN RALSTONIA PSEUDOSOLANACEARUM STRAIN OE1-1

TSUZUKI Masayuki. (1), KIBA Akinori. (1), OHNISHI Kouhei. (1), KAI Kenji. (2), HIKICHI Yasufumi. (1)

(1) Kochi University, Kochi, JAPAN; (2) Osaka Metropolitan University, Osaka, JAPAN

Text
Soil-borne Gram-negative bacteria, *Ralstonia solanacearum* species complex (RSSC), cause wilt diseases in a wide-range of crop plant species. For infection of a phylotype I strain of RSSC, *Ralstonia pseudosolanacearum* strain OE1-1, cell density-dependent gene regulation system, quorum sensing (QS), has an important role. Although it is known that QS affects the gene expression of OE1-1 cells as well as their behaviors, its gene regulatory manner is largely unknown. To understand the gene regulatory manner by QS, we performed gene coexpression network analysis using a series of transcriptome data. Coexpression network analysis successfully provided multiple coexpression modules with distinct gene expression patterns. Gene Ontology enrichment analysis was applied to the gene set in each module and the terms indicating specific functions were identified. The expression of the multiple modules was significantly affected by QS in both positive and negative ways, suggesting that QS has a large effect on global transcriptome change in OE1-1 cells. Also, we found that the presence of iron significantly affects the expression level of the specific modules including QS-dependent ones. These data suggest that OE1-1 cells change their behaviors during host plant infection by changing the gene expression patterns through QS-dependent gene regulation dependently on environmental conditions including iron acquisition from environments.

Text

The plant intercellular place or apoplast is the main battlefield between plants and pathogens.We carried out a proteomic analysis of the tomato apoplast andidentified the serine proteases of the P69 family as specifically activated upon Ralstonia solanacearum infection in the resistant cultivar Hawaii7996.
We present the characterisation of tomato P69s in tomato defence to bacterial wilt. Transient expression of 6 P69 paralogs was performed in Nicotiana benthamiana , showing that overexpression of P69B, D and G limited multiplication of R. solanacearum, while P69C caused cell death in tomato. Heterologous production and purification of P69s showed low cleavage specificity in vitro. The P69D prodomain removal occurred in an autocatalytic and intramolecular reaction in residue(s) other than that immediately preceding the TTHT motif. Finally, generation of a P69D CRISPR loss-of function mutant in resistant tomato Hawaii 7996 rendered the plant more susceptible to R. solanacearum but not to other vascular pathogens like Fusarium oxysporum.
Our results demonstrate for the first time a key role for the P69 clade of serine proteases in plant defence.

P8.3-005

FERRIC UPTAKE REGULATORS, FUR1 AND FUR2, AFFECT THE EXPRESSION OF QUORUM SENSING-REGULATED GENES IN THE CONDITIONS WITH AND WITHOUT FERROUS IRON IN RALSTONIA PSEUDOSOLANACEARUM STRAIN OE1-1

(1) Kochi University, Kochi, JAPAN

Text
The LysR-type transcription regulator PhcA is activated by the bacterial density-dependent quorum sensing (QS) and regulates QS-dependent genes containing virulence-related genes in the soil-borne Gram-negative β-proteobacterium *Ralstonia pseudosolanacearum* strain OE1-1. We previously identified an involvement of ferrous iron in QS-dependent phenotypes of the strain OE1-1. Furthermore, two Ferric uptake regulator sequences, Fur1 and Fur2, were found in the genome of the strain OE1-1. To elucidate the mechanisms of Fur1 and Fur2 on QS-dependent gene regulation in the conditions with and without ferrous iron, we first performed the RNA-seq to identify the transcriptome of *R. pseudosolanacearum* strains. In the condition with ferrous iron, *fur1*-deletion led to a significantly reduced expression of 267 QS-dependent genes. Among these genes, expression of 115 genes including virulence-related genes involved in production of ralfuranone, major extracellular polysaccharide EPSI and plant cell wall degradation enzymes was significantly enhanced by the *fur2*-deletion in the condition without ferrous iron. Furthermore, *fur2* expression in the condition without ferrous iron was significantly enhanced compared to that with ferrous iron. Taking results together, Fur1 and Fur2 positively and negatively regulate some QS-dependent genes in the condition with and without ferrous iron, respectively.

SELECTIVE ISOLATION OF RALSTONIA SOLANACEARUM ON MSMSA IN A SAPROPHYTIC CONTEXT

BLOM Nathalie. (1), VAN DE BILT Jeroen. (1), VOLKERS Rita. (1), GORKINK-SMITS Peggy. (1), TEUNISSEN Manon. (1), LANDMAN Marco. (1), **BERGSMA-VLAMI Maria. (1)**

(1) Netherlands Institute for Vectors, Invasive plants and Plant health (NIVIP), Wageningen, NETHERLANDS

Text
For the official testing of Ralstonia solanacearum (R. sol) a high level of standardization among diagnostic laboratories already exists. Isolation of R. sol on the modified semi-selective medium from South Africa (mSMSA) is part of the official testing. Although this isolation results in highly consistent results even at low bacterial densities, it often requires more training of laboratory staff than the more common molecular techniques. The reason is that secondary bacterial infections or saprophytic bacteria on isolation plates will interfere with the development of R. sol colonies, resulting in atypical colony morphology or inhibition. Additionally, there are several physical and chemical parameters that will influence the performance of mSMSA, such as pH, brand of agar and antibiotics, quality control issues during the in-house preparation, quality control elements during the storage and expiration date, etc. Recently, a practical training on the R. sol isolation on mSMSA was organized at the Netherlands Institute for Vectors, Invasive plants and Plant health (NIVIP) in Wageningen, in the framework of the European Reference Laboratory (EURL) for Bacteria. Well-defined samples containing R. sol cells or spiked plant extracts have been used to assess the growth of R. sol (colony numbers and colony morphology) and the suppression of saprophytes, respectively on mSMSA plates prepared by the EU National Reference Laboratories (NRLs). Results will be discussed.

Text

Potato (*Solanum tuberosum*) is one of the most important widespread hosts of *Ralstonia solanacearum*, the causal agent of bacterial wilt. In Uruguay, germplasm with resistance to *R. solanacearum* has been identified and advanced clones with different responses to *R. solanacearum* infection were selected and characterized. Previous results showed that plant resistance was correlated with differential bacterial colonization patterns and induced defense responses after infection. The aim of this work is to study the correlation between plant resistance and rhizosphere microbiome in selected genotypes with different responses to bacterial wilt. Plants were grown in a macrotunnel greenhouse with soil collected from a potato field. Pathogen colonization effects on rhizosphere microbiota were evaluated in healthy and infected plants. Disease progression was recorded and pathogen was quantified in rhizosphere samples. A resistant genotype showed delay in pathogen colonization and high final pathogen concentration in the rhizosphere, comparable to the susceptible genotype. These results suggest that the resistant genotype restricts rhizosphere pathogen colonization, preventing root and stem infection. Bacterial community composition is being analyzed in 76 samples comparing the sequence of V3-V4 region of 16S rARN. It is expected to identify potentially beneficial microbial groups related with resistant plants, contributing to an integrated disease control.

P8.3-008

APPLICATION OF RECOMBINANT INTERNAL CONTROL FOR INCREASING QPCR RELIABILITY IN THE QUANTITATIVE DETECTION OF RALSTONIA SOLANACEARUM SPECIES COMPLEX (RSSC) IN SOIL SAMPLES

CHEN Wei. (1), ZHANG Jun-Wei. (1), LI Shan-Kui. (1), JIANG Wen-Jun. (1), XIA Zhen-Yuan. (2), LU Can-Hua. (2), **ZHANG Li-Qun. (1)**

Text

Quantitative PCR (qPCR) was frequently used to detect soil-borne pathogens, but the

accurate quantification is compromised by poor DNA extraction and the presence of PCR inhibitors. Here, we developed a new qPCR system and an Internal Sample Process Control (ISPC) strain, RsPC, for the detection of the bacterial wilt pathogen RSSC, including *R. solanacearum*, *R. pseudosolanacearum*, and *R. syzygii*. Specific primers and TaqMan MGB probes were designed based on the analyses of 16S rDNA sequences from 603 *Ralstonia* genomes, and the RsPC was constructed by chromosome insertion of an artificial ISPC fragment in a closely related non-pathogenic strain, *R. pickettii* JCM 5969. The qPCR target sequences of RSSC and RsPC shared primers in PCR amplification, but distinguished from each another by different TaqMan probes. We tested 10 different soil samples with artificially co-spiked RsPC and *R. pseudosolanacearum* LMG 9673 at different concentrations, and found comparable recovery efficiencies (REs) of two strains in most samples, and the RE values of LMG 9673 after correction by RsPC were much closer to theoretical values. The most obvious improvement was observed in a heavy clay soil sample, in which the RE of LMG 9673 was increased by 3.0-fold. The qPCR system and ISPC strain developed in this study could be applied for the accurate detection of RSSC in soil, and similar ISPCs can be developed in future for risk analysis of soil-borne animal and plant pathogens.

FIRST REPORT OF RALSTONIA PSEUDOSOLANACEARUM ON BOESENBERGIA ROTUNDA FROM THAILAND

CARROLL Sarah. (1), MCGREIG Sam. (1), BRYNING Adam. (1), VICENTE Joana. (1), **ASPIN Andrew. (1)**

(1) Fera Science Ltd., Sand Hutton, UNITED KINGDOM

Text

Ralstonia pseudosolanacearum is part of the *Ralstonia solanacearum species complex* (RSSC). This group of bacteria has a very wide host range including many economically important crops, such as potato and tomato, and can cause large scale crop losses. The members of the RSSC are all quarantine organisms in the UK. Routine testing is carried out at Fera Science Ltd. to screen for the presence of R. solanacearum in latent potato tubers and river water; additionally, symptomatic samples intercepted by the UK Plant Health and Seed inspectorate are tested for the RSSC.
In October 2021 a sample of *Boesenbergia rotunda* (Chinese ginger, fingerroot) from Thailand was received at Fera showing symptoms of vascular discolouration and a milky ooze. The sample tested positive for *R. pseudosolanacearum*; the first finding on this host. Two distinct colony morphologies were observed when grown on semi-selective media and were treated as two isolates. The isolates were whole genome sequenced, and a novel *Ralstonia* phage was found to be associated with one isolate only. Host testing was carried out to assess pathogenicity, showing that the isolate with the associated phage was less virulent on eggplant and tomato. The interception of quarantine pests at the borders is vital for maintaining good biosecurity practices to prevent the entry of pathogens into countries where they are currently absent, and it is important to investigate novel methods of controlling this pathogen.

P8.3-010

VARIETY OF PATHOGENICITY OF RALSTONIA SOLANACEARUM STRAINS.

Text

Brown rot of potato caused by Ralstonia solanacearum (Rs) (Smith) Yabuuchi et al., is one of the most important quarantine diseases of the plant. Its presence is usually associated with significant economic losses to the potato industry where the disease exists.
One of the most crucial factors responsible for the uncontrolled spread of the pathogen in the environment and during the production process is its pathogenicity.
Of the four phylotypes of the Ralstonia species listed in EPPO diagnostic protocol No. PM 7/21, each consisting of many different phylogenetic and pathogenic variants, one of the most virulent genotypes is phylotype IIB 1 (formerly known as race 3 biovar 2). This phylotype is particularly harmful because it has a relatively low growth temperature (approximately 27 °C) and often causes latent (asymptomatic) infections. It can relatively easily adapt to colder climates and is favored by the wetness of the soil. Also, the presence of the pathogen in low concentrations in potato tissue is very dangerous and allow to contributes to its rapid spread of it in the environment.
In all the above cases, it is essential to determine the virulence of pathogenicity of the pathogen, which was the purpose of the research. The obtained results allowed for the determination of the influence of the examined Ralstonia solanacearum strains, on the level of expression symptoms on the tested plants and for comparison with the obtained result of the molecular test.

Mind the Gap: Innovation and Opportunities in Seed Health testing

C1.6-1

IMPACT ON GLOBAL FOOD SECURITY AND BIOLOGICAL RELEVANCE

SOUZA-RICHARDS Rose. (1)

(1) International Seed Federation, Nyon, SWITZERLAND

Text

Seed is a globally traded agricultural product. Predictable international movement of seed is critical to ensure food security. Seed companies produce and trial seed in different countries all over the world to mitigate the risk of crop failures due to several different reasons,

including adverse weather conditions or pests. The supply of healthy seeds is essential to help assure growers of a healthy crop.
Routine seed health assays may use several different types of technology. There are basic methods such as a grow out or seed plating, in which seeds are germinated under favourable environmental conditions to encourage disease development should the seed be contaminated with a pathogen. This type of assay is considered a direct method, that is, it permits the pathogen to be observed, recovered, and confirmed as such via Koch's postulates. Given the amount of time and resources associated with direct assays, many researchers are pursuing the development and implementation of indirect assays such as ELISA and PCR.
Indirect methods provide an indication of pathogen presence as these assays detect specific proteins or nucleic acids. Indirect methods may give a positive result even when no viable pests are present. Consequently, when testing seeds with these methods, results should be interpreted carefully. Confirmatory tests based on a different biological principle may be required to confirm the presence of a viable pest in a sample and to determine associated disease risk.

C1.6-2

IDENTIFICATION AND PREVALENCE OF SEEDBORNE FUNGAL PATHOGENS ASSOCIATED WITH SOYBEAN

HLONGWANE Neo. (1), JACKSON Mariette. (1), MINNAAR-ONTONG Adre. (1), **ROTHMANN Lisa. (1)**

(1) University of the Free State, Bloemfontein, SOUTH AFRICA

Text
Seed health is critical to ensuring a healthy yield and mitigating risks associated with pathogen introduction and spread. The study identified and determined prevalent fungal pathogens associated with South African soybean seed to inform management decisions. Approximately 650 kg seed from the first season (2020) was manually separated into twenty-one symptom categories. Seed germination and fungal enumerations were conducted. Genera identified through morphology and sequencing include *Alternaria, Chaetomium, Cladosporium, Epiccocum, Fusarium, Mucor, Nigrospora, Phoma, Rhizoctonia, Sclerotinia, Stagonosporopsis* and *Trichoderma*. Prevalence was determined by fungal enumerations and germination testing from 415 and 402 seed harvested in season two (2021) and three (2022), respectively. Seedborne fungi significantly reduced seed germination in season three (3.5%) compared to season two (35.4%), suggesting weather conditions were more conducive for disease development. *S. sclerotiorum* and *Fusarium* spp. were detected in the highest frequencies across the seasons. The significant prevalence of seedborne *S. sclerotiorum* is cause for concern as seed is retained by producers for subsequent seasons, as only one fungicide is registered to control soybean stem rot in South Africa. Koch's postulates and a diversity study of 24 *Fusarium* isolates is ongoing to determine whether causal organisms of sudden death syndrome are present and differ in aggressiveness.

STREAMLINING DIAGNOSTICS FOR SEEDS IMPORTED INTO AUSTRALIA

CONSTABLE Fiona. (1), BARRERO Roberto. (2), CAMPBELL Paul. (3), WRIGHT Dominie. (4), RODONI Brendan. (1)

(1) Agriculture Victoria, Bundoora, AUSTRALIA; (2) Queensland University of Technology, Brisbane, AUSTRALIA; (3) Department of Agriculture and Fisheries, Brisbane, AUSTRALIA; (4) Department of Primary Industries and Regional Development, Brisbane, AUSTRALIA

Text

Seed is a pathway for the global spread of some pathogens that can be seedborne, and that impact crop production. The Australian Department of Agriculture, Fisheries and Forestry requires testing for specified pathogens to mitigate the risk of regulated and exotic seed borne pathogens of grains, pulses, and selected vegetable species entering Australia. While seed testing reduces the risk of introduction, seed testing can impose a significant economic impact on seed companies, associated with the cost of the high volume of seed required for testing. A flow-on effect is increased cost of seed for Australian producers. Importantly, it results in reduced availability of new genetics that improve quality and production for Australian growers and enable them to remain competitive globally, because seed companies import less into Australia. There is a need to find a balance between testing to support the biosecurity of the Australian agricultural industries and the requirement of an affordable seed supply for producers and access to new varieties. In this presentation, an overview of the regulatory seed testing required for Australia will be presented along with an overview of new research that will evaluate the application of novel metagenomic and targeted high throughput sequencing approaches to improve the efficiency, sensitivity, and cost-effectiveness of seed testing to meet the needs of Australia's biosecurity and minimise the economic impact of seed importation to industry.

C1.6-4

IDENTIFICATION, DETECTION AND MANAGEMENT OF SEEDBORNE SQUASH PATHOGENS

MOUMNI Marwa. (1), MUROLO Sergio. (1), LANDI Lucia. (1), ALLAGUI Mohamed Bechir. (2), ROMANAZZI Gianfranco. (1)

(1) Marche Polytechnic University, Ancona, ITALY; (2) Institut National de la Recherche Agronomique de Tunisie (INRAT), Tunis, TUNISIA

Text

Squash is one of the most important vegetable crops, and it can be affected by several fungal seedborne pathogens. Samples of asymptomatic and symptomatic squash fruits (Cucurbita maxima, Cucurbita moschata) were collected from Tunisia and Italy. Following the blotter test, seedborne fungi were identified in seeds extracted from fruit samples. The most frequent fungi in Tunisia seed samples were Alternaria alternata, followed by Stagonosporopsis cucurbitacearum. For the fruits from Italy, the most frequently identified fungal species in seed samples were A. alternata, followed by Stemphylium vesicarium. Seedborne fungi were identified in all fruit samples tested, including asymptomatic fruit. Considering that S. cucurbitacearum can cause medium-high economic losses in the field, even with low seed infection, our research focused on setting up a rapid and sensitive

protocol, based droplet digital polymerase chain reaction (ddPCR). Blotter and ddPCR tests showed a high degree of correlation (R2 = 0.986, p ≤ 0.01). Our ddPCR protocol provided rapid detection and absolute quantification of S. cucurbitacearum, offering a useful support to the standard procedure. To control these fungi, the antifungal activity of seven essential oils have been studied by tests performed in vitro and in vivo conditions. Both assays showed that Cymbopogon citratus essential oil was the most effective to reduce seedborne fungi and to control transmission of S. cucurbitacearum from seeds to plantlets.

Text

Tobamoviruses are a serious challenge for the production of tomato and pepper. Tobamovirus contaminated seeds are a pathway for dissemination, and several complementary methods are used to determine whether tobamoviruses are present in seeds and if this poses a risk for disease establishment. ELISA is widely used to detect tobamoviruses on seeds but this method cannot distinguish between infectious and non-infectious viruses. Only bioassays can differentiate infectious tobamovirus particles, and the efficacy of disinfection treatments is evaluated with a bioassay. Seed extract (SE) TaqMan RT-PCR assays were introduced more recently to detect ToBRFV and ToMMV. However, these assays do not discriminate between infectious and non-infectious viruses, but are very sensitive and highly specific. Naturally contaminated seed lots with tobamoviruses have been collected at Naktuinbouw since 1993. A high throughput sequencing (HTS) project using almost 100 tomato and pepper seed lots from this collection was started. The objective was to determine the presence, abundance and genetic variability of tobamoviruses. Illumina HTS was performed with purified RNA from the seed lots. In addition, a SE PCR assay and a bioassay were carried out to further characterise infection in these seed lots. In pepper and tomato seed lots, several tobamoviruses were detected using HTS, with a highly variable virus load. Pros and cons of HTS and the currently applied detection methods will be presented.

Text

Agricultural policies aim to reduce synthetic plant protection products (PPPs), including prophylactic seed treatments. A broader use of untreated seed would help limit synthetic PPP applications. Currently, seed is certified through the visual detection of seed-borne diseases, including loose smut (*Ustilago nuda*) of barley (*Hordeum vulgare*). *U. nuda* infection is asymptomatic in seeds and plants until its teliospores develop at barley heading. PCR-based molecular detection of *U. nuda* can help streamline the certification process for untreated seed and improve its accuracy and precision. We developed a multiplex qPCR protocol that targets *U. nuda* and *H. vulgare* DNA. The new molecular assay and a visual detection method using extracted embryos were performed to analyze seed samples with varying rates of infection. The resulting disease levels were then evaluated in field. Based on the 2022 data, *U. nuda* field infections show a stronger positive correlation with the qPCR results than those from the visual analysis of embryos. The experimental results enable us to propose a threshold value of *U. nuda*/*H. vulgare* DNA to delineate healthy and diseased seeds. Future research with additional samples from practice is needed to validate the proposed threshold under diverse environmental conditions. Molecular methods in seed health testing could aid in the wider adoption of sowing untreated seed and reduce synthetic PPP application.

TESTING AND TRENDS IN SEED-TRANSMITTED DISEASES OF PULSE CROPS IN MONTANA, USA

GUNNINK TROTH Erin. (1), PARIKH Lipi. (1), NYAMESORTO Bernard. (1), AGINDOTAN Bright. (2), BURROWS Mary. (1)

(1) Montana State University, Bozeman, UNITED STATES; (2) U.S. Department of Agriculture - Agricultural Research Service, Beltsville, UNITED STATES

Text

The Regional Pulse Crop Diagnostic lab (RPCDL), founded at Montana State University (USA) in 2014, conducts disease testing of pulse crops (dry peas, chickpeas, and lentils) for management of seed-transmitted diseases and to protect international trade. Testing samples through the RPCDL facilitates tracking of disease incidence and severity over time. The primary seed-transmitted disease of interest is typically Ascochyta blight (*Didymella*, *Peyronellaea* spp). Disease tracking allows the lab to do further testing for concerns such as fungicide insensitivity. For example, Ascochyta blight pathogen isolates were collected from the 2013 crop year and tested for fungicide insensitivity. Of 145 isolates, 4 chickpea (*Didymella rabiei*) and 1 dry pea (*Didymella pisi*) isolate were insensitive to pyraclostrobin; 1 chickpea isolate was insensitive to fluxapyroxad and boscalid. These seed lots were eliminated from re-planting. No insensitivity was detected in 2014, and 1 chickpea seed lot with pyraclostrobin insensitivity was identified and eliminated from re-planting in 2015. No insensitivity was detected in 2016. Persistent regional drought reduced disease levels in 2017 through 2022 and thereby negated demand for fungicide insensitivity testing. However, chickpea seed lots infested with Botrytis were noted despite dry conditions. Fungicide insensitivity testing has resumed in 2023 as high-infestation seed lots have been received.

P1.6-002

VALIDATION OF A ASCOCHYTA RABIEI DETECTION METHOD ON CHICKPEA SEEDS.

SERANDAT Isabelle. (1), LE DARE Lorine. (1), LE GUISQUET Céline. (1), PENANT Agathe. (2), LAMBERT Quentin. (2), GRIMAULT Valérie. (2)

(1) GEVES, Beaucouzé, FRANCE; (2) Terres Inovia, Ardon, FRANCE

Text

Blight of chickpea caused by Ascochyta rabiei is a not well-known disease with a significant impact on yields in both organic and conventional farming.
The AsCoLup project, funded under the CASDAR IP 2019, bringing together 15 partners aims to provide producers with knowledge on Ascochyta rabiei as well as an adapted technical itinerary in order to improve disease management, both in seeds and food production.
Pathogen detection is an important part of the technical itinerary. It contributes to the guarantee of production of healthy seeds and to the evaluation of the risk in the field.
The international validation of a seed detection method is essential for disease management.
A quantitative method on media has been chosen and the performance criteria (analytical sensitivity, analytical specificity, accuracy, repeatability and reproducibility) are studied to validate the method. A pathogenicity test is also developed to verify the pathogenicity of isolates.
The validation of this method will lead to a proposal of an ISTA method on a new pathogen/host combination.

P1.6-003

BRAZILIAN PCR TESTING IN CROP SEEDS

FERREIRA Thiago Costa. (1)

(1) UNIVERSIDADE ESTADUAL DA PAIRAIBA, Lagoa Seca, BRAZIL

Text

The PCR is an essential tool for the identification of seed pathogens from crops around the world. In Brazilian research, this theme is growing for the modernization of disease diagnostics. Then, this research has the aim of resuming information about the PCR methods from Brazilian Seed Pathology Research. For this research, on Web of Science platform were inscribed the keywords: seeds, PCR, pathogen, and Brazil. As a result, just fifty-seven papers were found about this theme. The prevalent area was Crop production (30% of the total), Dr. José da Cruz Machado (Lavras Federal University) was the most important author (6 publications). The most important pathosystems analyzed were Corynespora cassiicola, Sclerotinia sclerotium, Colletotrichum truncatum, and Phomopsis spp. (Glycine max); Stenocarpella spp. and Fusarium spp. (Zea mays), Xanthomonas spp. (Brassica spp.). Primer design and PCR methods were the important theme in this bibliometric research. The use of Pcr methods for seed pathology diagnosis is an important and few-studied theme, more research can be made to better the seed sanity in Brazil.

Text

Seedborne pathogens represent an overly critical issue for successful agricultural production worldwide. Seed treatment with plant protection products constitutes one of the first options useful to reduce seed infection or contamination and prevent disease spread. Basic substances are active, non-toxic substances already approved and sold in the EU for other purposes, e.g., as a foodstuff or a cosmetic, but that can also have a significant role in plant protection as ecofriendly, safe, and ecological alternatives to synthetic pesticides. They are regulated in EU according to criteria presented in Article 23 of Regulation (EC) No 1107/2009. In recent years, various potential uses of already approved and potential seed treatment products were investigated for their proven activity against fungal, bacterial and viral seed-borne pathogens. The aim of this research, run within Euphresco BasicS project, is to is to collect the information on application of basic substances and potential basic substances for seed treatment and to make this large amount of published research results more manageable for consultation and use. The latest advanced research in finding the best application methods to coat seeds are also described.

This work was conducted within the framework of the Euphresco BasicS Project

Modeling and analysis to better understand and predict epidemics

C5.1-1

BAYESIAN SPATIAL EPIDEMIOLOGICAL MODELS TO ASSIST IN OUTBREAK RESPONSE. THE CASE OF XYLELLA FASTIDIOSA

CENDOYA Martina. (1), VICENT Antonio. (1)

(1) Valencian Institute for Agricultural Research (IVIA), Valencia, SPAIN

Text
Epidemiological models can assist in extracting information from disease outbreak data and improve response programs. Climatic and spatial effects on the distribution of *Xylella fastidiosa* (*Xf*) were studied in two outbreaks with different epidemiological settings (Lecce, Italy, and Alicante, Spain) using spatial Bayesian models. The climatic covariates were not related with the *Xf* distribution in the study areas, indicating that climate is unlikely to stop disease spread to adjacent areas. The probability of *Xf* presence increased with the proximity to the infested area, illustrating the strong influence of the spatial component. Though, spatial dependence in epidemiological models is often assumed directionally invariant and uniform across the study area (i.e., isotropic and stationary). These assumptions do not hold when there are elements limiting disease spread, such as geographical barriers or control measures. Hence, the effects of dispersal barriers in the *Xf* outbreak in Alicante were analyzed. A Bayesian stationary model, without barriers, was compared with non-stationary models including a continuous or discontinuous cordon sanitaire as containment barriers. The cordon sanitaire resulted in a reduced probability of *Xf* presence outside the infested area, except in the discontinuities of the cordon sanitaire with low sampling intensity. The spatial range of the stationary model provided a reference value to define the size of the buffer zone.

C5.1-2

A COMPARTMENTAL MATHEMATICAL MODEL BASED ON APHID FEEDING BEHAVIOURS ALLOWS MORE REALISTIC MODELLING OF NON-PERSISTENTLY TRANSMITTED PLANT VIRUSES

FALLA Elin. (1), CUNNIFFE Nik. (1)

(1) University of Cambridge, Cambridge, UNITED KINGDOM

Text
Plant viruses threaten global food security and are often transmitted by arthropod vectors. Non-persistently transmitted (NPT) plant viruses are characterised by a very short virus retention time in the vector and are transmitted almost exclusively by aphids. Compartmental models using ordinary differential equations to capture the course of an epidemic have been used in plant virus epidemiology for decades. However, the underlying model structure, in which the infective period of vectors is fixed, omits a key feature of non-persistent transmission: probing or feeding on a plant is often what causes an aphid to lose its infectivity. A recent model by Donnelly et al. (2019) captures this behaviour via a Markov chain that tracks the behaviour of individual aphids. We introduce a new compartmental model which replicates this model, while allowing the easy extensibility characteristic of compartmental models. It is comprised of linked Susceptible-Infected models for the plants and aphids, where loss of aphid infectivity is conditioned upon aphid probing and feeding behaviour, rather than occurring at a fixed rate. This additional biological realism means our model behaves differently to previous compartmental models of NPT viruses, therefore allowing us to more accurately investigate virus transmission dynamics for all NPT systems. We focus on the case of viral manipulation of host plant phenotype, which changes aphid landing and feeding behaviour to enhance virus spread.

C5.1-3

EXPLOITING SIMILARITIES WITHIN PHYLOGENETIC CLADES OF COLLETOTRICHUM SPP. TO DEVELOP A MECHANISTIC, WEATHER-DRIVEN MODEL FOR ANTHRACNOSE DISEASES

SALOTTI Irene. (1), LIANG Yu-Jie. (1,2), JI Tao. (1), ROSSI Vittorio. (1)

(1) Università Cattolica del Sacro Cuore, Piacenza, ITALY; (2) Universitat Politècnica de València, Valencia, SPAIN

Text

Fungi of the genus Colletotrichum cause serious pre- and post-harvest losses to several agricultural crops worldwide. A systematic literature review was conducted to retrieve the metadata on the influence of temperature on four biological processes: (mycelial growth, conidial germination, infection by conidia, and sporulation) for seven Colletotrichum clades (acutatum, graminicola, destructivum, dematium, gloeosporioides, and orbiculare) and the singleton species, C. coccodes. The metadata was first analyzed to define inter- and intra-clades similarities and differences, and then used to develop temperature-dependent equations representing the effect of temperature on the biological processes for the different clades. This clade-based approach was used to develop a mechanistic, weather-driven model for Colletotrichum anthracnose diseases, able to predict anthracnose progress during the growing season on the aerial organs of different herbaceous and fruit tree crops. The model was evaluated against the disease progress of fungi belonging to five clades on six different hosts by using data from epidemics occurred in Italy, the USA, Canada, and Japan. Results showed high concordance between model predictions and field data, with overall concordance correlation coefficient of 0.928. After further validation, the model could be used to support decision-making for crop protection in a wide range of cropping systems.

C5.1-4

EFFECTS OF PATHOGEN SEXUAL REPRODUCTION ON THE EVOLUTIONARY AND EPIDEMIOLOGICAL CONTROL PROVIDED BY DEPLOYMENT STRATEGIES FOR TWO MAJOR RESISTANCE GENES IN AGRICULTURAL LANDSCAPES

ZAFFARONI Marta. (1,2), RIMBAUD Loup. (3), REY Jean-François. (2), FABRE Frédéric. (1), PAPAÏX Julien. (2)

(1) INRAE, Bordeaux Science Agro, SAVE, Villenave-D'ornon, FRANCE; (2) INRAE, BioSP, Avignon, FRANCE; (3) INRAE, Pathologie Végétale, Montfavet, FRANCE

Text

Resistant cultivars are of value for protecting crops from disease, but can be rapidly overcome by pathogens. Several strategies have been proposed to delay pathogen adaptation (evolutionary control), while maintaining effective protection (epidemiological control). Resistance genes can be *i*) combined in the same cultivar (pyramiding), *ii)* deployed in different cultivars sown in the same field (mixtures) or in different fields (mosaics), or *iii*) alternated over time (rotations). The outcomes of these strategies have been investigated principally in pathogens displaying pure clonal reproduction, but many pathogens have at least one sexual event in their annual life cycles. Sexual reproduction may promote the emergence of superpathogens adapted to all the resistance genes deployed. Here we improved the spatially explicit stochastic model *landsepi* to include pathogen sexual

reproduction, and then investigated the effect of sexual reproduction on evolutionary and epidemiological outcomes across deployment strategies for two major resistance genes. Sexual reproduction favours the establishment of a superpathogen when single mutant pathogens are present together at a sufficiently high frequency, as in mosaic and mixture strategies. However, sexual reproduction did not affect the optimal strategy recommendations for a wide range of mutation probabilities, associated fitness costs, and landscape organisations.

C5.1-5

A SPATIALLY EXPLICIT NETWORK MODEL TO ASSESS THE EFFECTIVENESS OF WITHIN- AND BETWEEN-SITE TREATMENT ON EPIDEMIC SPREAD ACROSS A LANDSCAPE

OJIAMBO Peter. (1), CUNNIFFE Nik. (2), XU Xiangming. (3)

(1) North Carolina State University, Raleigh, UNITED STATES; (2) University of Cambridge, Cambridge, UNITED KINGDOM; (3) NIAB East Malling Research, East Malling, UNITED KINGDOM

Text

The relevance of networks for improved understanding and control of plant disease epidemics has gained prominence in plant pathology in the last two decades. Disease spread between nodes in a network has been a central topic and limited attention has been given to within-node dynamics. We develop a spatially explicitly network model to establish relative effectiveness of implementing within-node treatment (protectant or curative fungicide and roguing) and between-node treatment (quarantine, trade) on epidemic spread of an aerially dispersed pathogen. The dynamic component of the model is captured by the number of host units that are either Susceptible (S), Protected (P), Exposed (E), Infected (I), Treated (T) or Removed. Within-node dynamics modeled using rates at which, I infect others, E becomes infectious, I loses infectivity, and fungicide effectiveness parameters. Spread between nodes is modeled using a power-law dispersal kernel and the rate of trade between nodes. Surveillance time is drawn from a uniform random number and when disease is detected, a node is treated as described above. Simulations are run with the model, representing experiments with three network structures [small-world, random, and scale-free] of 200 nodes with varying sizes with three different levels of connectivity for network sizes of 200, 400 and 800. Results of the simulations will be discussed and we plan to avail the model in an open-source environment for use by interested researchers.

C5.1-6

MODELING THE AIRBORNE INOCULUM OF POLYSTIGMA AMYGDALINUM FOR IMPROVING THE CONTROL OF ALMOND RED LEAF BLOTCH

PONS-SOLÉ Gemma. (3), TORGUET Laura. (2), MARIMON Neus. (2), MIARNAU Xavier. (2), **LÁZARO Elena . (1)**, VICENT Antonio. (1), LUQUE Jordi. (3)

(1) Centre de Protecció Vegetal i Biotecnologia, Institut Valencià d'Investigacions Agràries

Text

Red leaf blotch (RLB) of almond, caused by *Polystigma amygdalinum*, is one of the most important foliar diseases affecting this crop in the Mediterranean Basin and Middle East regions. The pathogen overwinters in the leaf litter, where ascospores mature in the perithecia and are released in spring, infecting new leaves. The main control strategy is the application of fungicides on a calendar basis. Thus, predicting pathogen inoculum availability is important to determine the protection period and to optimize RLB fungicide programs. A Bayesian beta-regression mixed modeling framework was assessed to model the dynamics of airborne *P. amygdalinum* ascospores considering different meteorological variables. The model with the best predictive performance included the variables ADD (accumulated degree days) and ADDwet (ADD considering precipitation and vapour pressure deficit), together with a random factor. This selected model was used to define action thresholds to delimitate the start and the end of the protection period. The performance of a fungicide program based on the proposed prediction model was commercially evaluated in comparison to the standard calendar-based program and an untreated control in terms of RLB incidence and number of fungicide sprays per season. The fungicide program based on the model was similarly effective as the calendar-based, resulting only in a 2.6% higher RLB incidence but with fewer sprays (three to four, compared with seven in the calendar).

A COMBINED AEROBIOLOGICAL APPROACH ALLOWS DIFFERENTIATING THE BIOLOGY AND ENVIRONMENTAL DRIVERS OF SPORULATION OF TWO MAJOR FUNGAL PATHOGENS OF CHESTNUT

LIONE Guglielmo. (1), GONTHIER Paolo. (1)

(1) Department of Agricultural, Forest and Food Sciences (DISAFA), University of Torino, Grugliasco, ITALY

Text

Investigating sporulation patterns is pivotal in plant disease epidemiology because it may shed light on relevant biological features of pathogens and on the environmental factors driving the release of infectious propagules. The ascomycetes *Cryphonectria parasitica* and *Gnomoniopsis castaneae* are major pathogens of chestnut (*Castanea* spp.) characterized by having both teleomorphic and anamorphic stages. In this study, we assessed and compared spatial and temporal spore deposition patterns of the two pathogens by using an aerobiological approach combining passive spore trapping, taxon-specific qPCR assays, and statistical modelling based on a novel index called Standardized Deposition Rate. Approximately 1300 samples collected at regular intervals over two years in three chestnut orchards in northern Italy were analyzed. Results showed that both species sporulate all year long, but while for *C. parasitica* peaks are seasonal and propagule loads are driven by the number of weekly rainfalls, spore deposition of *G. castaneae* increases with raising temperatures and wind gusts. Differences in the geospatial patterns of spore deposition

between the two pathogens are discussed. Our results may contribute predicting the risk of infection of these two fungal plant pathogens.

AEROBIOTA COMMUNITY ASSEMBLY IN VEGETABLE PRODUCTION: ADAPTING METACOMMUNITY THEORY TO NANOPORE METABARCODING.

VAN DER HEYDEN Herve. (1), BLANCHET Guillaume F.. (1), CARISSE Odile. (1)

(1) McGill, Ste-Anne-De-Bellevue, CANADA

Text

The intensification of agriculture has served to meet the ever-increasing food demand. However, it is also responsible for the loss of biodiversity. Among the alternatives to intensive agriculture, agroecology stands out. Its aim is to develop production systems based on the ecological performance of agrosystems, which depends in part on the assembly of the ecological communities (group of species that occurs together in space and time) and metacommunities (group of communities linked together through dispersal) that structure them. Aerobiota metacommunities represent a model system for testing metacommunity theory, as they include a variety of phylogenetically distantly related groups of organisms with different life cycles and dispersal potentials. In 2021 and 2022, aerial samples from onion fields in Québec, Canada, were sampled three times a week in six onion fields from June 1 to August 15. Targeted sequencing of the ITS region was performed on the MinION, while weekly scouting was conducted in each field to monitor plant growth and disease intensity. Using these data, the community structure of the aerobia was investigated from a temporal perspective to model how Natural (weather) and anthropogenic (pesticide treatments) perturbations impacted community composition. This research aims to develop a conceptual framework to test the hypothesis that the type and duration of a disturbance influence both the structure of the metacommunity and post-disturbance recovery.

GENETIC VARIATIONS AMONG COMMERCIAL VARIETIES AND LANDRACES OF WHEAT FROM PAKISTAN

IFTIKHAR Shazia. (1), BATOOL Syeda Qamer. (1)

(1) Fatima Jinnah Women University, Rawalpindi, Pakistan, Rawalpindi, PAKISTAN

Text

Karnal bunt caused by Tilletia indica is one of the most important disease for the international wheat trade market. In this study, epidemiological surveys were conducted in the six districts of lower Punjab, Pakistan. The causal pathogen of karnal bunt were isolated for pathogenicity trials. Wheat germplasms (199) were planted and at the 2nd leaf stage, the crop was thinned and samples were bagged, labeled, and stored for DNA isolation. At the booting stage, five boots per line were infected with spore suspension, and provided a favorable environment for disease infection. At the ripening stage, infected and non-infected

spikes were harvested separately and disease incidence was recorded. The disease incidence was found higher in commercial varieties as compared to landraces. The DNA was studied for genetic variations and trait association studies Illumina iSelect 90K wheat SNP chip was applied on the panel of 199 wheat germplasms. Based on 31,000 SNP markers, 199 wheat germplasm were grouped into two different clusters showing significant genetic variations among them. Six significant markers were identified that were associated with karnal bunt disease. Thirty-two candidate genes were also identified as resistant resources coded on six significant markers. F-box family and kinase like protein family are the genes which has also been reported previously while few novel genes linked with Karnal bunt resistance were also identified in this study.

P5.1-002

CROSS INFECTION OF BOTRYOSPHAERIA SPP. CAUSING DIEBACK IN FRUIT TREES IN CHILE

DIAZ Gonzalo. (1), SUMONTE Constanza. (1), HERNÁNDEZ Yadira. (1), LOLAS Mauricio. (1)

(1) UNIVERSIDAD DE TALCA, Talca, CHILE

Text

Epidemiological studies have focused on the inoculum sources that come from the same host fruit tree. Recently, Neofusicoccum australe and N. stellenboschiana have been described as causing dieback on four different fruit trees in South Africa. However, in Chile, no study has shown infection by Botryosphaeriaceae spp. obtained from different fruit tree species (hosts) induce canker and dieback symptoms in apples, blueberries, grapevines, and walnuts. Therefore, this work aims to determine the virulence of 12 isolates, including Diplodia seriata, D. mutila, Dothiorella sarmentorum, Lasiodiplodia theobromae, N. arbuti and N. parvum collected from different fruit trees with symptoms of canker and dieback. The study was carried out under greenhouse and field conditions, inoculating lignified tissues of grapevine, apple, blueberry, and walnut in central Chile. The results indicate that all the Botryosphaeriaceae species developed lesions in fruit hosts vary in severity, but the most virulent in apple, blueberry, grapevine, and walnut were N. arbuti (apple origin), N. parvum (vine, blueberry, and walnut origin) and D. mutila (walnut origin). An intermediate virulence was obtained by D. seriata (grapevine and apple origin). In contrast, L. theobromae (apple origin) had low virulence in four fruit tree hosts. This study demonstrates the cross-infection capacity of Botryosphaeriaceae obtained from different fruit tree species causing canker and dieback in several hosts.

P5.1-003

ROLE OF SEED TRANSMISSION OF MAGNAPORTHE ORYZAE PATHOTYPE TRITICUM (MOT) FOR THE EPIDEMIOLOGY OF WHEAT BLAST

SUROVY Musrat Zahan. (1,2), ISLAM Tofazzal. (2), VON TIEDEMANN Andreas. (1)

(1) University of Goettingen, Goettingen, GERMANY; (2) Bangabandhu Sheikh Mujibur Rahman Agricultural University, Gazipur, BANGLADESH

Text

Magnaporthe oryzae pathotype *Triticum* (MoT) is a dangerous fungal pathogen causing wheat blast (WB). The limited knowledge on life cycle, epidemiology and pathogenicity of MoT hamper effective disease control. The study aimed to investigate MoT infection, invasion routes, and colonization on wheat ears and seeds to assess the potential of long and short-distance seed transmission of WB. MoT was spray inoculated on susceptible Sumai 3 and resistant Milan. Incidence of MoT on Sumai 3 seeds was 100% and 20-25% on Milan. MoT sporulation rate on Sumai 3 contaminated seeds was 15 times higher than on Milan. The colonization of MoT within seed tissues was monitored by CLSM. Invasion of MoT in seeds was observed predominantly in the caryopsis germ region but also in other seed parts. In the greenhouse, no spread of MoT from infected seeds to seedlings later than GS 21 or to ears was detected, neither in Milan nor in Sumai 3. Initial blast symptoms, only found on seedlings of Sumai 3, resulted in the formation of new conidia, which may serve as inoculum source for plant-to-plant dissemination by airborne infection of plant stands in the field. Ultimately the inoculum formed on young plants may infect ears in the field and contaminate next-generation seeds. We conclude that seed transmission with MoT may disseminate the pathogen long-distance by seed trade and short-distance in the field, strengthening the importance of seed health in strategies to control any further spread of WB.

P5.1-004

POPULATION GENETICS OF GANODERMA BONINENSE, THE CAUSAL AGENT OF BASAL STEM ROT OF OIL PALM IN MALAYSIA AND INDONESIA

TUNG Hun Jiat. (1), CHOO Hui Yuen. (1), GOH You Keng. (2), WONG Wei Chee. (1)

(1) Advanced Agriecological Research S/B, Semenyih, MALAYSIA; (2) Applied Agricultural Resources S/B, Petaling Jaya, MALAYSIA

Text

African oil palm (Elaeis guineensis Jacq.) is a perennial oil crop cultivated commercially in Southeast Asia since 1917. Oil palm basal stem rot (BSR) disease, which causes decay of the root bole and palm trunk and eventual death, is the most economically important disease affecting palm losses in oil palm plantations in Indonesia, Malaysia, and Papua New Guinea. SSR genotyping of G. boninense isolates collected from Malaysia and Sumatra (Indonesia) showed constant high genetic diversity and gene flow among populations. This is evidenced by the existence of three genetic clusters and different admixed populations of G. boninense across regions. Low spatial genetic differentiation of G. boninense (FST = 0.05) indicated non-restricted geographical gene dispersal, but a sign of isolation by distance was evident. Furthermore, evidence of population bottlenecks was found in the oldest oil palm plantations in Peninsular Malaysia and Sumatra isolates. The impact of the evolutionary processes on G. boninense population structure and possibly pathogenicity that differs across geographical regions will probably negate the effectiveness of the present generalised approaches to manage infected oil palms in many instances. This may seriously imperil the plantations in the future. Therefore, it is vital to develop BSR disease control taking into consideration

pathogen adaptation and environmental tolerance conferred by pathogen variability in current plantings and future replants.

P5.1-006

EPIDEMIOLOGICAL CHARACTERIZATION OF MULBERRY RUST IN BRAZIL

GONÇALVES Manoel. (1), SIMÕES Ana. (1), **AMORIM Lilian. (1)**

(1) UNIVERSITY OF SAO PAULO, Piracicaba, BRAZIL

Text

Mulberry rust, caused by *Cerotelium fici*, was recently detected on *Morus nigra* in Brazil. The host is an important crop for silk industry. In order to evaluate the monocyclic components of this disease, we have performed experiments under controlled conditions. Inoculum of *C. fici* (5×10^4 urediniospores mL^{-1}) was sprayed on potted mulberry plants. As a control, mulberry plants were sprayed with distilled water. Inoculated and mock-inoculated plants were kept in a dark moist chamber at 23 °C for 24 h. After this period, plants were moved to a greenhouse (25 ± 5 °C). The experimental design was completely randomized with five replicates. Pre-penetration process of *C. fici* on mulberry leaves was analyzed using a scanning electron microscope and the monocyclic components of rust were quantified over time. Twenty-four hours post-inoculation, appressoria were observed on ordinary epidermal cells, indicating direct cuticular penetration of *C. fici.* Rust latent period was 13 d, when small sporulating lesions appeared on the abaxial surface of fully expanded leaves. Mean values for lesion density, lesion size, and rust severity by the end of the experiment were 16 lesions cm^{-2}, 0.9 mm^2, and 13% leaf area diseased, respectively. The infectious period of rust was 52 d. The cumulative production of spores was, on average, 1,585 urediniospores $lesion^{-1}$. Inoculum production showed a gradual increase up to 44 days post-inoculation when 486 urediniospores were produced by a single lesion.

P5.1-007

TEMPORAL AND SPATIAL PROGRESS OF RASPBERRY LATE RUST IN TWO CROPPING SYSTEMS IN BRAZIL

AZEVEDO Daiana. (1), LEITE Gabriel . (1), LOURENÇO Silvia. (1), AMORIM Lilian. (1)

(1) Escola Superior de Agricultura Luiz de Queiroz, University of São Paulo, Piracicaba - Sp, BRAZIL

Text

Due to the increasing global demand for raspberries, its cultivation is expanding to non-traditional areas, including subtropical regions in Brazil. However, a bottleneck to production of this fruit in the country is the occurrence of late rust caused by *Aculeastrum americanum*. In order to understand whether the cropping system using plastic cover impacts on the rust behavior, the temporal and spatial progress of disease was assessed in a commercial orchard located in the municipality of Piracicaba, Brazil. The experiment was carried out in plots planted with raspberries cv. Heritage with and without plastic cover. Disease monitoring

was performed weekly between April and July 2022. The number and position of symptomatic plants as well the disease severity in the leaves were recorded throughout the evaluations. To understand the temporal dynamics of airborne *A. americanum* urediniospores, passive impactor spore traps were installed in the plots. The incidence of the disease has reached 100% of plants in both covered and uncovered plots. Disease severity and the number of urediniospores captured by traps were significantly lower in the covered plot. The dispersion index used to characterize the spatial pattern of symptomatic plants revealed that disease distribution was random in the covered plot and aggregated in uncovered plots. The results suggested that plastic covering delay the progress of late raspberries rust by reducing the dispersal of *A. americanum*.

WITCHES' BROOM DISEASE OF ACID LIME (CITRUS AURANTIFOLIA L.): RESEARCH FINDINGS AND FUTURE PROSPECTS

AL-SADI Abdullah. (1), AL-SUBHI Ali. (1), AL-YAHYAI Rashid. (1), AL-ABRI Ibtisam. (1)

(1) Sultan Qaboos University, Seeb, OMAN

Text

Acid lime is a major and historical crop in Oman. Several biotic stresses affect acid lime, including witches' broom disease of lime (WBDL), which killed approximately one million lime trees since its first report in the beggining of the 1970s. The disease has also been reported in the United Arab Emirates and Iran. WBDL results in dense branching and the production of small and large number of light green to yellow leaves, and the affected trees usually collapse within 4 to 6 years of first symptom appearance. Studies have shown that 'Candidatus Phytoplasma aurantifolia' is associated with WBDL. Phylogenetic analysis of phytoplasma strains from Oman, the UAE and Iran has shown that all strains are similar. Hishimonus phycitis leafhoppers and Diaphorina citri psyllids were found to transmit phytoplasma, with lefhoppers been more efficient in transmission. The developmeht of yellow leaves was suggested to attract more H. phycitis leafhoppers, which increases the spread of phytoplasma. WBDL phytoplasma indirectly suppresses several defense genes in acid limes. The symptomatic acid lime leaves accumulate some minerals beyond the recommended levels, which was suggested to trigger the decline of lime trees. Typical WBDL symptoms were found to be suppressed under certain environmental conditions. The findings suggest that WBDL can be managed by controlling vectors, removing the symptomatic branches and growing limes in areas less conducive for disease development.

MONITORING OF VENTURIA PARALIAS, A FUNGAL BIOCONTROL AGENT FOR THE INVASIVE COASTAL WEED SEA SPURGE (EUPHORBIA PARALIAS), REVEALS PATTERNS OF DISEASE ESTABLISHMENT AND SPREAD IN AUSTRALIA

HUNTER Gavin. (1), DELAISSE Caroline. (1), MARSDEN-SMEDLEY Jon. (2), MORIN Louise. (1), GOODEN Ben. (1)

(1) Commonwealth Scientific and Industrial Research Organisation (CSIRO), Canberra, AUSTRALIA; (2) Sea Spurge Remote Area Teams (SPRATS), Hobart, AUSTRALIA

Text

Sea spurge (*Euphorbia paralias*) is a significant environmental weed of coastal ecosystems along Australia's southern coastline. Sea spurge forms dense infestations that outcompete native flora, restricts nesting habits of shorebirds and exudes a toxic latex when damaged. Host-specificity testing of *Venturia paralias*, a candidate fungal biological control agent, demonstrated that it is specific to sea spurge and that severe necrotic leaf and stem lesions are the dominant disease symptoms. The agent was approved for release in Australia to help control sea spurge in 2020. Subsequent community-led releases of the agent in parallel with releases at nine monitoring sites along the Victorian and Tasmanian coastlines have provided information on the establishment and epidemiology of the fungus. As of December 2021, community-led releases of the agent have occurred at 70 sites along the coastline, with the agent confirmed as present at more than 40% of these sites. Detailed assessments made at the nine monitoring sites at 6-12 months of the release indicated that the agent had established at all sites and begun to naturally spread to other sea spurge infestations in the vicinity (up to 250 metres). In the field, stem lesions caused by the fungus were initially observed on sea spurge and leaf lesions appeared later, which is the opposite to that observed in laboratory studies. Further spread and impact on sea spurge in relation to environmental conditions will also be presented.

FACTORS INFLUENCING HULL ROT OF ALMONDS IN AUSTRALIA

WIECHEL Tonya. (1), KREIDL Simone. (1), FAULKNER Peta. (2), GIRI Khageswor. (1), EDWARDS Jacky. (1)

(1) Agriculture Victoria, Bundoora, AUSTRALIA; (2) Agriculture Victoria, Irymple, AUSTRALIA

Text

Hull rot of almond is a complex disease that causes direct loss of yield due to infected rotten nuts and downgrading of in-shell nuts, as well as reducing future yield due to twig dieback and spur death caused by toxic fungal metabolites. Hull rot is commercially important in all production regions of Australia except Western Australia. Hull rot occurrence begins in January during early hull split which is the most susceptible stage for infection. Our research is focused on understanding this disease, with particular emphasis on factors that influence disease development under field conditions. Extensive surveying over two seasons found significant relationships between agronomic practices, climatic factors and disease incidence. Hull rot symptoms were significantly influenced by both irrigation and rainfall, cultivar and rootstock and fungicide used. Hull rot incidence was reduced with applications of Fluopyram/Trifloxystrobin, and Pyraclostrobin/Fluxapyroxad. Future research is continuing management strategies for hull rot. This research was part of a national project AL16005 funded by Hort Innovation using the almond research and development levy and funds from the Australian Government and in-kind contributions by Agriculture Victoria.

Text

Biological resource centers are repository were scientists can deposit their resources and make them available for future research. These often proved to be invaluable for plant health.

For instance, when the outburst of bacterial canker of kiwifruit hit New Zealand in 2010, the presence of the type strain of Pseudomonas syringae pv syringae in collection did insure a fast identification and a rapid response. Or, when an epidemic of Dickeya on pineappple broke in Australia in 2016, the analysis of strains isolated in 1956 on ginger in the same region permitted to avoid unnecessary biosecurity responses. The complete barcoding of the Pectobacterium strains held in CIRM-CFBP permitted to uncover a not-yet described species and to shed a new light on the ecology of the whole genus, thanks to the diversity of the strains available and the quality of the associated data.

The collections are the memory of our past and key for future research. However, many gaps still exist and we observe a decrease in the deposits over time. A gap in the records may hamper identification and response to a pathogen and can have important consequences for disease management or trade.

Deposit resources in a collection have a lot of personal and community benefits, resulting in sharing the necessary efforts, facilities, competences and expertise, permitting to enhance the overall quality of the preservation and to invest for the future.

Text

Basal rot is a widespread onion disease caused by fungi belonging to *Fusarium* genus. The disease is known to incur onion yield loss worldwide. This study aims to identify and determine the pathogenicity of *Fusarium* species associated with basal rot of onions in Burkina Faso. Thirteen *Fusarium* isolates from seven regions of Burkina Faso were identified based on morphological observations and molecular diagnosis and their pathogenicity was assessed in laboratory and Greenhouse. Onion seeds, bulbs and seedlings were used for

the pathogenicity test. For seedling test in greenhouse, a Factorial Block design with two factors (inoculated varieties and species) with five replicates was set up using pots. Results showed that, the 13 isolates belonged to *Fusarium falciforme*, *Fusarium acutatum* and *Fusarium oxysporum* species. *Fusarium. falciforme*, *F. acutatum* and *F. oxysporum* were pathogenic on onion seeds, seedlings and bulbs. *F. falciforme* caused lower seedling damping-off rate compared to that caused by *F. acutatum* and *F. oxysporum*. All these species of *Fusarium* genus induced onion bulbs rots. The results of this study confirmed the presence of these species in Burkina Faso and that they are pathogenic on onion. Therefore, it would be useful to suggest an implement sustainable management approach of these pathogens.

Text

Aflatoxins are potent carcinogens produced by *Aspergillus* sp. that occasionally contaminate pistachio nuts. The international markets impose restrictive limits, thus affecting producers' economies. The spread of the biological control strain AF36 (a non-toxigenic *A. flavus* strain) stands out for limiting aflatoxin contamination. Since 2017, the product AF36 Prevail®, sorghum grains coated with AF36 propagules, has been commercially used in pistachio in California, but its sporulation occasionally fails. We studied the effect of soil moisture on the % AF36-sporulated sorghum grains (S.G.) and the number of spores per grain using a sporulation index (S.I.). Under controlled conditions, S.G. was higher than 85% when soil moisture was ≥ 13%, and the S.I. was maximum at field capacity. In the field, the best AF36 sporulation occurred near the micro-sprinklers but where non-impacted by the water drops. The AF36 Prevail® loss was more pronounced in the non-tilled ground due to quick predation by arthropods. Also, the density of spores decreased markedly with the height and distance from the inoculum source, fitting well with diffusion equations. Even so, the spores of AF36 reached the canopies of the pistachios located 10 m from the inoculum source. This work has contributed to optimizing the biocontrol AF36 Prevail® application approach in tree-nut-producing areas of California in terms of retaining more inoculum in the field and treatment-cost savings.

UNDERSTANDING THE EPIDEMIOLOGY AND ECOLOGY OF CARROT VIRUSES IN THE UNITED KINGDOM

MYNETT Mary. (1), JUKES Andrew. (2), FOWKES Aimee. (1), CHISNALL Kiera. (1), COLLIER Rosemary. (2), VAZQUEZ IGLESIAS Ines. (1), FOX Adrian. (1,3)

(1) Fera, York, UNITED KINGDOM; (2) University of Warwick, Coventry, UNITED KINGDOM; (3) Newcastle University, Newcastle Upon Tyne, UNITED KINGDOM

Text

In the UK, viruses severely impact carrot production causing reduction in yield, growth defects and necrosis. The main viruses of concern are carrot yellow leaf virus (CYLV) and the carrot motley dwarf complex (CMD) – the key virus of which is carrot red leaf virus (CtRLV). The main vector of these viruses is thought to be Cavariella aegopodii (willow carrot aphid), however, the peach-potato aphid, Myzus persicae, may also play a role in the transmission of these viruses. Two years of trials were carried out to determine the importance of different vector species focusing on the timing of transmission of these key viruses into carrots. Results suggest that a focus on early season vector control strategies may be a better approach to manage the transmission of viruses in UK carrot crops by comparison to prolonged full-season treatment. However, the sources of these viruses and their epidemiology remain unclear.

To better understand the sources of these viruses in UK carrots, baseline surveillance has been conducted focused on crops and associated weeds using ecological sampling approaches supported by high throughput sequencing. This has revealed previously known viruses of Apiaceae spp.. Some of these viruses, such as CtRLV, appear to form phylogroups associated with either crop or non-crop hosts. The factors influencing these host associations, such as vector influence and agronomy, will be discussed.

STUDY OF CHILLI ANTHRACNOSE DISEASE; A POTENTIAL THREAT TO CHILLI CROP IN MAJOR CHILLI PRODUCING AREAS OF PUNJAB, PAKISTAN

SATTAR Abdul. (2), RIAZ Abid. (2), **MEHMOOD Nasir. (1)**, YASIN Yasin. (2)

(1) Rawalpindi Women University, Rawalpindi, PAKISTAN; (2) PMAS-Arid Agriculture University Rawalpindi, Rawalpindi, PAKISTAN

Text

Chilli anthracnose is a widely distributed and economically important disease which affects the crop at pre and post-harvest crop stages. The disease is caused by *Colletotrichum capsici* and *C. gloeosporoides* which produce small, circular black spots with concentric rings of acervuli on fruit skin which turn the fruit black. The field survey was conducted in five major chilli-growing districts of Punjab province viz., Rawalpindi, Kasur, Vehari, Okara, Multan and Bahawal Nagar to access the disease incidence and severity. The study revealed variations in mean disease incidence and severity levels in the five visited districts. The mean disease incidence was highest in the Kasur district (35.1%) followed by 24.8% in the Vehari district. Of the five districts, the minimum mean disease incidence was observed in the Rawalpindi district (09%). The maximum disease severity (24.6%), was measured in terms of fruit area infected from the Kasur district followed by 17.3% from the Vehari district and minimum severity was observed at 12% in the Rawalpindi district. It reveals the predominance presence of anthracnose disease as a major constraint to chilli cultivation in

Punjab, Pakistan. The disease is also been reported in other chilli-producing countries of the world and required joint efforts towards the formulation and adaptation of joint research for devising the effective management strategies to reduce the losses.

POPULATION GENETIC RELATIONSHIPS OF WHEAT PUCCINIA TRITICINA BETWEEN YUNNAN-GUIZHOU AND NORTHWEST, CENTRAL AND EASTERN CHINA

CHEN Wanquan. (1), ZHANG Qinqin. (1), LIU Taiguo. (1)

(1) Chinese Academy of Agricultural Sciences, Beijing, CHINA

Text

Wheat leaf rust caused by *Puccinia triticina* (*Pt*) is an important fungal disease of cereals in the world, which frequently occurs in the southwest China as well as in the Huang-Huai-Hai wheat regions, and gradually becoming serious in the northwest China in recent years. Leaf rust in Guizhou is increasing every year due to its unique geography, but there have been few studies on the population structure of leaf rust in Guizhou in the past. Leaf rust in Yunnan is easily endemic and has an early onset. However, little research has been done in the past on population genetic relationships between Yunnan and most other regions. In this study, 246 *Puccinia triticina* isolates were collected from eight provinces including Yunnan, Guizhou, Xinjiang, Shaanxi, Gansu, Hubei, Henan, and Shandong in 2021. The population genetic structure and genetic diversity as well as the relationship between ecological factors and genetic diversity were analyzed by SSR molecular markers to infer the mycological relationships and exchanges of the *Pt* populations between different regions and Guizhou and Yunnan. Our study found that wheat *Pt* in Yunnan and Guizhou had the ability to spread to central (Hubei) and eastern (Shandong) China. Similarly, *Pt* in Shaanxi and Gansu tended to spread to central (Hubei) and eastern (Shandong) China. Lastly, *Pt* in Xinjiang showed moderate genetic divergence from other populations.

MONITORING SPORE DISPERSAL AND EARLY INFECTIONS OF DIPLOCARPON CORONARIAE CAUSING APPLE BLOTCH USING SPORE TRAPS AND A NEW QPCR METHOD

BOUTRY Clémence. (1), BOHR Anne. (2), BUCHLEITHER Sascha. (2), LUDWIG Mathias. (1), OBERHÄNSLI Thomas. (1), TAMM Lucius. (1), SCHÄRER Hans-Jakob. (1), FLURY Pascale. (3)

(1) Research Institute of Organic Agriculture (FiBL), Frick, SWITZERLAND; (2) Competence Center for Fruit Crops at the Lake of Constance (KOB), Ravensburg, GERMANY; (3) University of Basel, Basel, SWITZERLAND

Text

Apple blotch (AB) is a major disease of apple in Asia and recently emerged in Europe and

the USA. It is caused by the fungus Diplocarpon coronariae (Dc) (formerly: Marssonina coronaria; teleomorph: Diplocarpon mali) and leads to severe defoliation of apple trees in late summer resulting in reduced yield and fruit quality. To develop effective disease management strategies, a sound knowledge of the pathogen's biology is crucial. Data on the early phase of disease development is scarce: no data on spore dispersal in Europe is available. We developed a highly sensitive TaqMan qPCR method to quantify Dc conidia in spore trap samples. We monitored temporal and spatial dispersal of conidia of Dc, and progress of AB in spring and early summer in an extensively managed apple orchard in Switzerland in 2019 and 2020. Our results show that Dc overwinters in leaf litter and spore dispersal and primary infections occur in late April and early May. We provide the first results describing early-season dispersal of conidia of Dc, which, combined with the observed disease progress, helps to understand the disease dynamics and will be a basis for improved disease forecast models. Using the new qPCR method, we detected Dc in buds, on bark, and on fruit mummies, suggesting that several apple tissues may serve as overwintering habitats for the fungus, in addition to fallen leaves.

MORPHOLOGICAL AND PATHOGENIC VARIABILITY OF AUSTROPUCCINIA PSIDII FROM GUAVA AND ROSE APPLE

MORALES João V. P.. (1), **BOUFLEUR Thaís R.. (1)**, GONÇALVES Manoel P.. (1), MASSOLA Nelson S.. (1), AMORIM Lilian . (1)

(1) Luiz de Queiroz College of Agriculture, University of São Paulo (ESALQ/USP), Piracicaba, BRAZIL

Text

Myrtle rust caused by *Austropuccinia psidii* has been the subject of several recent studies due to its unusual polyphagous lifestyle. The high pathogenic and genetic variability of the pathogen was already reported, indicating that the complexity of the species is higher than currently known. We aimed to evaluate morphological and epidemiological aspects of *A. psidii* specificity to guava (*Psidium guajava*) and rose apple (*Syzygium jambos*). Suspensions of isolates GM1 (from *P. guajava*) and JM1 (from *S. jambos*) (2×10^4 urediniospores mL^{-1}) were sprayed on *S. jambos* leaves. The density of the lesions (number of lesions per cm2) was quantified, and the germination of urediniospores and the formation of appressoria of both isolates was evaluated in a scanning electron microscope. The percentage of germination on leaves was 97%, with 93% of appressoria for JM1 and 93% with 55% of appressoria for GM1. A higher density of sporulating lesions was observed for *S. jambos* plants inoculated with JM1 when compared with GM1, which caused small necrotic areas without sporulation. The mean densities of lesions were 38.7 and 11.6 lesion per cm2 for JM1 and GM1 isolates, respectively. These results indicate that there is pathogenic specialization within *A. psidii* isolates, which will be used in further studies regarding the genetic complexity of this fungus.

CURRENT EPIDEMIOLOGICAL SITUATION OF MEALYBUG WILT OF PINEAPPLE DISEASE IN ECUADOR

CORNEJO Juan. (1), OLMEDO Alejandro. (3), QUITO Diego. (2)

(1) Centro de Investigaciones Biotecnológicas del Ecuador, CIBE, Escuela Superior Politécnica del Litoral, Guayaquil, ECUADOR; (2) Facultad de Ciencias de la Vida, FCV, Escuela Superior Politécnica del Litoral, Guayaquil, ECUADOR; (3) CALS - SIPS - Plant Path & Plant-Microbe Bio Section END, Cornell University, New York, UNITED STATES

Text

In this study, we analyze the current epidemiological situation of mealybug wilt of pineapple (MWP) disease in Ecuador. Ninety symptomatic and asymptomatic leaves samples from MD2 hybrid and cultivar “Criolla” were collected for viral detection in a pineapple plantation located in Santo Domingo of the Tsachilas, the largest pineapple producing province in the country. MD2 hybrid showed several tip dieback stages, while cultivar “Criolla” did not show typical MWP symptoms. To determine virus prevalence, total RNA extraction was carried out followed by reverse transcription - polymerase chain reaction (RT-PCR). Samples were tested for eleven viruses, including the ampeloviruses pineapple mealybug wilt-associated virus 1 (PMWaV-1), PMWaV-2, PMWaV-3, PMWaV-5 and PMWaV-6; the sadwaviruses pineapple secovirus A (PSV-A), PSV-B, PSV-C and PSV-D; and two badnaviruses, pineapple bacilliform CO virus (PBCOV) and PBERV. The virus identity was confirmed by cloning, Sanger sequencing and blast. The presence of mealybugs (Dysmicoccus spp.) was observed in all the symptomatic pineapple plants sampled in this study. The RT-PCR results revealed the presence of PMWaV-1, PMWaV-2, PMWaV-3, PSV-A, PSV-B and PBCOV in MD2 hybrid. These viruses, except PMWaV-2, were also detected in asymptomatic “Criolla” samples, suggesting that plant genotype is related with virus-induced symptom expression in pinneaple. These findings coincide with those previously reported in Hawaii and Australia.

IMPACT OF CULTIVAR RESISTANCE ON CERCOSPORA BETICOLA EPIDEMIOLOGY ON SUGAR BEET

YANG Yixuan. (1), VARRELMANN Mark. (1), LIEBE Sebastian. (1)

(1) Institute of Sugar Beet Research (Institut für Zuckerrübenforschung), Göttingen, GERMANY

Text

Cercospora leaf spot (CLS) is the most destructive foliar disease on sugar beet caused by the fungal pathogen Cercospora beticola. The emergence of fungicide-resistant populations highlights the importance of developing and cultivating resistant cultivars. Understanding the interactions between the cultivar resistance and C.beticola is essential in CLS management. A field trials were designed in 2022 and 2023 to investigate the interactions from an epidemiological aspect. We aimed to describe the relationship between the cultivar resistance and the spore flight of C.beticola. The trials were conducted in two geographical locations as a completely randomized block design with four cultivars containing different resistant properties in triplicate. In the trial in 2022, spore flight during the vegetation period was examined by a pre-developed method using spore traps and TaqMan real-time PCR assay. Disease development on each cultivar was also monitored during the same period. We observed a delayed disease incidence and decreased disease severity in highly resistant cultivars. Results of the real-time PCR shows a similar tendency of reduced spore quantity sampled from the highly resistant cultivars.The results indicate that the highly resistant

cultivars produce fewer secondary aerial spores, which further decreased the disease development. The trial will be repeated in 2023 to gain further insight into the interaction between cultivar resistance and CLS epidemiology.

PARTIAL RESISTANCE TO MYRTLE RUST ON GUAVA CV. SUPREMA EXPRESSED BY REDUCTION OF UREDINIOSPORE PRODUCTION OF AUSTROPUCCINIA PSIDII

SALES Lucas. (1), GONÇALVES Manoel. (1), APPEZZATO-DA-GLÓRIA Beatriz. (1), AMORIM Lilian. (1)

(1) Universidade de São Paulo, Escola Superior de Agricultura , Piracicaba , BRAZIL

Text

Myrtle rust (*Austropuccinia psidii*) is the most important fungal disease on guavas in Brazil and cultivars with partial resistance to the disease should be used as an alternative to the consolidated cv. 'Paluma', which is susceptible to the disease. While infection and colonization of guava leaves by *A. psidii* are well characterized in cv. 'Suprema', components of partial resistance related to inoculum production have not yet been evaluated. The objective of this study was to evaluate the infectious period and the urediniospore production of *A. psidii* in Paluma and Suprema. Young leaves of potted Paluma and Suprema plants were inoculated with an *A. psidii* suspension (2.5×10^4 urediniospores mL^{-1}). From one week after symptoms appeared, the inoculum produced on leaves was weekly collected using a glass nozzle and a suction pump. The *A. psidii* urediniospore concentration was determined using a Neubauer chamber. The disease infectious period was approximately 35 days in both cultivars. The *A. psidii* urediniospores weekly production was 2.5 to 14 times higher in Paluma than in Suprema. Considering the complete infectious period, each rust lesion in Paluma produced between 2,294 and 10,273 urediniospores, while in Suprema only 580 to 1,517 urediniospores were produced per lesion. The lower inoculum production in Suprema may act by reducing the rate of disease increase (*r*) and slowing down the epidemic in the field. Histopathological analyses of diseased leaves are underway.

Text

Candidatus Liberibacter solanacearum (Lso) is a non-culturable, phloem-limited and vector-borne phytobacterium transmitted by species belonging to the superfamily Psylloidea (Hemiptera). Five haplotypes of Lso have thus far been described that are known to cause widespread losses across the globe in commercially important Solanceae and Apiaceae crops. In apiaceae crops damaging outbreaks are regularly occurring across the Middle East and mainland European countries. Lso and some of its vectors have also been recorded in the UK in association with arable areas utilised for important apiaceous crops (carrots and parsnips); however, there have not yet been reports of disease on the UK apiaceous crops production. Lso is an obligate pathogen so studies on its complex epidemiology and population dynamics rely on molecular testing of plants and vectors from the field. In this study we completed a large-scale ecological survey to describe the epidemiology and potential management of Lso in the UK with the aims: a) to investigate the incidence and distribution of Lso in carrot and parsnip fields, b) to determine the UK-wide diversity and potential distribution of Lso vector species, and c) to investigate the potential role played by wild non-crop Apiaceae (wild hosts) that are present in and around apiaceous crops in the UK.

Text

Peanut is a major oil-seed crop in the world. It contributes to food security and generates income for farmers in Africa. Unfortunately, this crops is subject to numerous leaf diseases which have been reported in West Africa. In recent years, there is a resurgence of leaf diseases on peanut crops in Burkina Faso. They induce specific symptoms often associated with plant stunting and yield losses. Preliminary data indicated the occurrence of fungi and a complex of virus species. However, these data remained old and not up to date. The epidemiology of these diseases remains poorly understood, which hampers the design of appropriate control measures to reduce yield losses. The research planned in the thesis aims to inventory peanut leaf diseases and identify the main epidemiological parameters of diseases caused by virus in Burkina Faso. More than a thousand peanut leaf samples were collected in several regions of Burkina Faso during year 2022. During the surveys, the common diseases were rosette, peanut stripe, peanut clump, peanut stunt, peanut yellow spot diseases. The same diseases were reported by farmers when interviewed. Base on molecular diagnosis, the next step of this study will contribute to generate information on virus species and hosts. Lastly, available peanut germplasm will be screened to identify tolerant or resistant accessions to be included in integrated disease management strategies.

Keywords: Arachis hypogaea, diseases, epidemiology, virus, Burkina Faso.

DAMAGE TO GUAVA PLANTS CAUSED BY MULTIPLE INFECTIONS OF AUSTROPUCCINIA PSIDII

SIMÕES Ana Laura. (1), GONÇALVES Manoel. (1), AMORIM Lilian. (1)

(1) ESALQ-USP, Piracicaba, BRAZIL

Text

Rusts are polycyclic diseases which can cause polyetic damage to perennial plants. This type of damage has not yet been quantified for myrtle rust, caused by Austropuccinia psidii. Therefore, this work aimed to simulate, in a greenhouse, the polycyclic process that occurs in the field and to assess its impact on the development of 'Paluma' guava plants. For this purpose, guava plants were inoculated with 2 x 104 urediniospores.mL-1 suspensions of A. psidii for three times, 14-days apart. Humid chambers were provided for 24 h after each inoculation. As control treatment, guava plants were sprinkled with water. The inoculations were performed on the three youngest pair of leaves. Disease severity, leaf area, the length of the main stem and internodes and the total number of leaves were assessed weekly. The dry mass of leaves, shoots and roots was quantified by the end of the experiment. Inoculated plants showed reduced leaf area and stem length (p<0.05) in relation to healthy plants. The shoot growth of inoculated plants was reduced by 30% as compared to healthy plants. Disease severity reached 40% of the leaf area and symptoms of leaf curling and leaf wrinkling were observed before leaf drop. A severe defoliation occurred only in inoculated plants. There was a significant reduction (p<0.05) in the dry mass of plants submitted to successive inoculations with A. psidii. The successive inoculations of A. psidii cause intense reduction on the development of ‘Paluma’ guava plants.

RESEARCH ON METEOROLOGICAL FACTORS RELATED TO THE INCIDENCE OF RICE FALSE SMUT

RYU Hyunjoo. (1), HONG Sung Kee . (1), CHOI Hyo-Won. (1)

(1) Crop Protection Division, National Institute of Agricultural Sciences, Wanju-Gun, REPUBLIC OF KOREA

Text

Rice false smut caused by *Ustilaginoidea virens* is the most crucial grain disease in rice production worldwide. The disease has been considered a minor disease that occurs scatteringly in certain regions under certain climate conditions. However, rice false smut could significantly reduce the quantity and quality of rice grains. To make a disease forecasting system for the disease, we aimed to find out the factors contributing to the disease by understanding the relationship between its incidence and weather factors. The primary inoculum (ascospores) invades rice flowers at the booting stage. Therefore, we analyzed the correlations during the booting, flowering, and both stages. First, in the booting stage, the average relative humidity had a statistically significant positive correlation (Pearson’s r = 0.705, p < 0.05). The disease incidence decreased as average sunshine hours increased, although this correlation was non-significant. Second, no significant correlations were found between all factors and the disease incidence in the flowering stage. Lastly, from the booting to flowering stages, the average relative humidity had a significant positive correlation (Pearson’s r = 0.644, p < 0.05). These results suggest that the influence

of weather factors in the booting stage may be critical. For successful and accurate predictions, we keep conducting additional annual investigations on the host, pathogen, and environment.

Text

Stripe rust on wheat and barley caused by *P. striiformis* f. sp. *tritici* (*Pst*) and P. striiformis f. sp. *hordei* (*Psh*), respectively. Whereas, *Pst* can attacked barley. To understand relationship between both rusts, 260 isolates were collected from wheat (120) and barley (140) from 2018-2020, identified on wheat and barley genotypes, and genotyped by 26 KASP-SNP markers. A cross between *Pst* and *Psh* was made to determine sexual recombination. As a result, massive multi-locus genotypes (MLGs), high virulence diversity was detected in wheat, barley, mixed (virulent to barley and wheat) populations. Common MLGs were detected between or among populations. Highly genotypic diversity was detected in the three populations, and low linkage disequilibrium were found in the most sampling sites of both crops, indicating that two stripe rust populations were sexual. Phenotype and the population structure support the wheat and barley forms were separate. However, clustering and common MLGs exhibited a similar lineage in the mixed population and other both populations, displaying gene drifts among these populations. Many isolates in mixed population originated from sampling sites where sexual reproduction occurred. A F_2 progeny were established from a cross between a *Psh* isolate and a *Pst* isolate on *B. aggregata* seedlings, showing avirulence / virulence segregation to 8 *Yr* loci. The results make an insight into evolution of *Pst* and *Psh* in mixed wheat and barley growing regions.

ASCOSPORE RELEASE BY NEONECTRIA DITISSIMA IN NORWAY.

HARTEVELD Dalphy. (1), BØRVE Jorunn. (1), STENSVAND Arne. (1)

(1) Norwegian Institute of Bioeconomy Research, Ås, NORWAY

Text

European canker, caused by the ascomycete *Neonectria ditissima*, is a significant threat to the Norwegian apple industry. A major part of ascospores of *N. ditissima* are dispersed in air following rain and moist periods, while conidia, and occasionally also ascospores, are splash dispersed during rain. Relative importance and timing of ascospore release may differ between geographical locations. It has not been clear when ascospores are released in

Norway, thus limiting the understanding of the pathogen biology and disease development, and the potential deployment of management options. Timing of ascospore release in two Norwegian apple production regions and its associations with weather parameters were studied for three years. Burkard volumetric spore traps were used to capture ascospores, and weather stations provided hourly data of temperature, rainfall, and other factors. Ascospores were captured year-round. Peak periods of ascospore production occurred in late spring (May-June) and to a lesser extent in the autumn (Sept.-Oct.). The highest numbers of ascospores per day were captured when temperatures were between 5°C and 15°C and rainfall <10 mm. Ascospores were captured after up to 30 days without rainfall. The importance of the fact that ascospores potentially are available year-round in apple orchards will be discussed in relation to management options.

GROUNDWATER AS A RESERVOIR FOR PLANT PATHOGENIC BACTERIA: THE CASE OF THE PSEUDOMONAS SYRINGAE COMPLEX IN THE ALLUVIAL AQUIFER OF AVIGNON

BERGE Odile. (1), NOFAL Salah. (2), ROUSSET Ludivine. (1), COGNARD-PLANCQ Anne-Laure. (2), GUILBAUD Caroline. (1), MORRIS Cindy E.. (1)

(1) INRAE, Avignon, FRANCE; (2) INRAE-AU Avignon University, Avignon, FRANCE

Text

During the last decades, the use of groundwater for irrigation has increased following agriculture intensification and climate change, especially in southern Europe. However, there is a significant lack of information on the presence of plant pathogens in aquifers the current knowledge being to consider the risk negligible.
In this work, we report evidence for the presence of bacteria from the Pseudomonas syringae (Ps) complex an archetypical phytopathogenic bacterium, at various places and dates in the groundwater of the Avignon region, an intensively irrigated area in the southeast of France. The concentration of Ps was variable and inversely correlated with water conductivity explaining 27% of the variability. The mean abundance of Ps was 100 times lower than in the River Durance connected with the aquifer but surprisingly, their genetic structure was more homogeneous than in the river. Moreover, most strains (98%) from groundwater were potentially pathogenic on plants according to lab tests, while in the river only 66% were pathogenic. Determinants of this low diversity and prominence of pathogenic strains in groundwater remain to be identified.
We conclude that aquifers are potential reservoirs of plant pathogens. More surveys are needed, notably to understand the real impact on crops during irrigation. These results could be included in prediction models and new approaches to disease forecasting and surveillance and could lead to the adaptation of agricultural practices.

P5.1-029

EPIDEMIOLOGY AND GENETICS OF THE WHEAT YELLOW RUST FUNGUS

LIVBJERG My. (1)

(1) Aarhus University, Slagelse, DENMARK

Text

Yellow rust (stripe rust) caused by the biotrophic fungal pathogen Puccinia striiformis f. sp. tritici is one of the most important and destructive wheat diseases globally. A recent study at Aarhus University, Denmark, discovered that several wheat varieties acquired significant resistance to yellow rust after a prolonged cold treatment. The aim of this study is to investigate the genetics of virulence in yellow rust and the durability of cold-induced resistance in wheat when challenged with yellow rust races of different origin.
Unique sexually derived progeny isolates from three dominant genetic groups in Europe are being both genotyped using 19 SSR markers and virulence phenotyped on a differential set of wheat lines carrying well-characterized yellow rust R-genes. Progeny isolates will be selected to further investigate the durability of cold-induced resistance in wheat by conducting virulence phenotyping on newly bred wheat cultivars with cold-induced resistance. Subsequently, histological analysis of plant-pathogen interactions will be carried out to determine plant defence responses and pathogen development. The results of these studies will provide improved knowledge on how yellow rust virulence is inherited and enable assessment of the potential of cold-induced resistance in wheat against yellow rust. This will contribute to the development of optimized breeding programs for resistant wheat varieties and a better understanding of plant-pathogen interactions.

Text

Yellow rust (YR, *Puccinia striiformis* f. sp. *tritici*) and late wilt (LW, *Magnaporthiopsis maydis*) are damaging diseases on winter wheat and summer maize, respectively, in Egypt. Assessing impacts of climate change on these diseases is necessary for developing adaptation measures and food security. YR severity was recorded in late February/early March on six wheat cultivars in 2013-2020 in seven governorates, while LW incidence was recorded in 2005-2019 in 13 governorates. Climate change scenarios were created with two climate models under RCP4.5 and RCP8.5 in four future periods. Best regression models were determined by step-wise regression on monthly rainfall and average monthly minimal, maximal and mean temperatures in December to February for YR for a very susceptible cv. Gemmeiza-11 and a moderately susceptible cv. Misr-1, and in June to August for maize LW. For YR, there was little disease before 2016 but severity started to increase since then. For LW, incidence was greater in Lower than in Upper Egypt (5-20% versus 3 to 15%). Initial

results in Al-Behera governorate showed that YR severity was predicted at 100% for cv. Gemmeiza-11 under all climate change scenarios but it will increase from 30 to >60% for cv. Misr-1 in future climatic conditions. However, a small increase in LW incidence was predicted (<3%). This suggests a greater impact of climate change on winter diseases and thus Egypt should develop control strategies for this wheat disease.

DETECTION OF PHYTOPHTHORA PALMIVORA CAUSATIVE AGENT OF THE DISEASE BUD ROT IN SOIL AND IRRIGATION WATER IN AN OIL PALM PLANTATION IN COLOMBIA

ZUÑIGA Leon Franky. (1), CASTILLO Sandra Yulieth. (1), LÓPEZ Juan Manuel. (1), SARRIA Greicy Andrea. (1)

(1) Colombian Oil Palm Research Center—Cenipalma, Bogotá D. C, COLOMBIA

Text

Oil palm Bud Rot (BR) caused by *Phytophthora palmivora* is the most important disease in Colombia due to the more than 70.000 hectares affected in the Central and Southwestern zone and the almost 15.000 hectares that are currently being affected in the Northern zone of the country,. Understanding the frequency of appearance of the pathogen in areas where the disease is advancing is valuable information for producers to take the most appropriate measures to help mitigate the impact of this pathology. In order to verify the presence of the pathogen, a sampling was carried out that involved water sources such as rivers and soil from plots with a low incidence of the disease. To capture the pathogen, leaflets from healthy palms and fruits were used as bait traps. For the latter, three points of the river were monitored at three different depths of 10, 50, and 100 cm. In soil, a total of 528 samples from 54 sites were analyzed, where 80% of the samples analyzed were positive for *Phytophthora*, a comparison of the river monitoring points, where it was only possible to verify the presence of the pathogen between 20 and 33.3% of the bait traps analyzed. The presence of the microorganism in this samples taken indicates a constant source of inoculum and possibly an increase in new cases of BR from plantations that use river water in their irrigation systems.

EFFECT OF THE TRUNK SHAKER HARVESTING ON THE DISPERSION OF VENTURIA OLEAGINEA SPORES, THE CAUSAL AGENT OF OLIVE SCAB

CAMPOS Rafael. (1), GUERRERO Fº Abel. (1), CASTRO Sergio. (1), ALCAZAR Purificacion. (1), SANCHEZ-HERNANDEZ Esperanza. (1), **MORAL Juan. (1)**

(1) UNIVERSITY OF CORDOBA, Cordoba, SPAIN

Text

Traditional olive oil orchards are usually harvested by trunk shakers, which can cause the

dispersion of *Venturia oleaginea* spores, the causal agent of olive Scab, but it has not been studied. Six olives of the susceptible cv. Picual and six trees of the resistant cv. Frantoio were used for evaluating the latter hypothesis. Thus, we established eight spore trapping points per tree in two opposite lines: under the tree canopy, at 1, 3, and 6 m from the trunk. At each point, three slides, impregnated with a silicone-3%cyclohexane solution, and two Petri dishes with selective media. The olives were then vibrated for 10-12 s with a trunk shaker (AgromelcaTM) adapted to a John Deer tractor. Tree vibration energy was determined using accelerometers. Two non-shaked olives were used as control. The density of captured spore was maximum (38 spores×cm²) under the tree canopy and decreased exponentially with distance (at 6 m, it was 6 spores×cm²). Nineteen percent of the *V. oleaginea* spores were trapped attached to their conidiophore. Also, more than 20 epiphytic fungal species were isolated, with the genera *Alternaria*, *Aspergillus*, and *Penicillium* being the most frequent. It should be noted that pathogen some spores (0.1 spore×cm²) were also caught on non-shaked trees. The data reveal that trunk shakers cause extraordinary dispersion of pathogen spores. We are currently conducting new trials under controlled and field conditions to investigate this pathogen's spore dynamics further.

Text

Several pathogens can co-occur in arable fields or co-infect the same plant. To be efficient, control strategies need to consider the multiple pathogens that can affect a given crop. The design of such strategies require a better understanding of how local management (e.g. crop variety), landscape characteristics (e.g. amount of the same crop around) and their interactive effects affect the incidence and severity of multiple diseases in a field. Spatiotemporal field surveys considering multiple diseases simultaneously remain however rare, limiting the development of agroecological solutions.

Taking wheat diseases as a case study, we selected 56 landscape units of 1-km radius distributed along gradients of amount of wheat (from 11% to 48%) and of organic farming (from 0.1% to 76%) in the long-term research platform "Zone Atelier Plaine & Val de Sèvre" (South-West of France) in 2021 and 2022. In each central wheat field within a landscape unit, we carried out symptom observations in a 4 × 6 grid by recording the incidence and severity of wheat leaf, ear, and stem base diseases at three growth stages during the growing season.

We found that: (i) a large diversity of pathogens co-occur in a given wheat field (pathogen-specific facilitative, neutral, suppressive effects); (ii) both a low amount of wheat and a high amount of organic farming in the surrounding landscape increase the number of diseases that are present but decrease the severity of plant disease epidemics.

Text

Cacao mild mosaic virus (CaMMV) is considered an emerging pathogen of *Theobroma cacao* that reduces yield and causes branch dieback, posing a risk to the $12 billion global cacao harvest and to the millions of small holder farmers that depend on the crop for their livelihoods. In the past few years, CaMMV has been detected in the USA, Brazil, England, and Indonesia. Two widely known transmission routes are mealybugs and the use of infected material during grafting. Research has shown that the virus can be transmitted even when symptoms are absent. More recently, we discovered up to 68% of seedlings grown from seeds of infected mother trees were also infected, thus adding an additional transmission route. This is significant because although the importance of screening budwood for viruses is understood, trees whose seeds are propagated for rootstock are not routinely screened. It also means that the movement of whole pods can introduce the pathogen to new locations. Current research is also looking for alternative hosts of the pathogen that could serve as inoculum reservoirs. Relatives of *T. cacao*, such as *Ceiba* spp. and *Ochroma* spp. are present in regions where the crop is grown commercially and could serve as CaMMV reservoirs. Infected plants cannot be cured, so preventing transmission and removing inoculum reservoirs are the most effective ways to combat it. CaMMV epidemiology and its implication on germplasm conservation and commercial production will also be discussed.

ANALYSIS OF LITERATURE DATA MAY INCREASE THE EPIDEMIOLOGICAL KNOWLEDGE ON GRAPEVINE TRUNK DISEASES

SALOTTI Irene. (1), ROSACE Maria Chiara. (1), JI Tao. (1), ROSSI Vittorio. (1)

(1) Università Cattolica del Sacro Cuore, Piacenza, ITALY

Text

Grapevine trunk diseases (GTDs) are serious threats in all viticultural areas of the world, and their management is complex and frequently inadequate. Wounds are considered the entry points for fungi causing GTDs, and particularly pruning wounds. Quantitative analyses of published information were performed (i) to determine the effects of temperature on mycelial growth and the effects of temperature and moisture duration on spore germination, and (ii) to identify the factors that most affect the length of pruning wound susceptibility. The mycelial growth of the fungi causing Botryosphaeria dieback (BD) and the Esca complex (EC) responded similarly to temperature, and preferred higher temperatures than those causing Eutypa dieback (ED) (with optimal temperature of 25.3, 26.5°C, and 23.3°C, 27 respectively).

At any temperature, the minimal duration of the moist period required for 50% spore germination was shorter for BD (3.0 h) than for EC (17.2 h) or ED (15.5 h). Concerning infection through pruning wounds, infection incidence was higher for fungi associated with BD than those associated with ED or EC, and wound susceptibility decreased faster for ED than for other GTD agents. Grapevine variety and pruning season also affected the wound susceptibility period, with Sauvignon Blanc showing longer susceptibility than other varieties. These results increase our understanding of GTD epidemiology and should help growers to control infections.

Text

The severity of citrus black spot (CBS), caused by *Phyllosticta citricarpa*, depends on several factors including the age of the fruit at the time of infection. Fruit have been reported to become resistant to CBS infection with maturity, but recent research indicate that fruit is susceptible to infection for longer periods than previously assumed. To conclusively demonstrate ontogenic resistance development of citrus fruit to *P. citricarpa* infection, fruit in commercial Valencia, Nova and Empress orchards were inoculated on a monthly basis with different concentrations (10^1, 10^3 and 10^5 conidia/mL) of *P. citricarpa* suspensions or exposed to natural pathogen infection at different times through a staggered fungicide spray program. Significant increases in CBS incidence and severity were observed between November and January on inoculated Valencia oranges and Nova mandarins. Although orange fruit were still susceptible after January, CBS incidence and severity were very low and comparable to the un-inoculated control in the inoculation trials. These observations of ontogenic resistance were supported in the 2017-2018 staggered spray trials: leaving orange trees unprotected after January did not significantly increase the incidence and severity of CBS. Findings from the mandarin spray trials were inconclusive due to low disease pressure in both seasons.

P5.1-037

SYMPTOMS IN IMMATURE AND RIPE APPLE FRUIT CAUSED BY COLLETOTRICHUM SPECIES ISOLATED FROM GLOMERELLA LEAF SPOT

CASTELLAR Camilla. (1), PETTERMANN Débora. (1), **MAY DE MIO Louise Larissa. (1)**

(1) UNIVERSIDADE FEDERAL DO PARANÁ, Curitiba, BRAZIL

Text
Colletotrichum isolates from Glomerella leaf spot (GLS) symptoms can also cause bitter rot (BR) and small lesions spot, called here as Colletotrichum fruit spot (CFS). We investigate 5 *Colletotrichum* species, obtained from GLS symptoms on leaves, on causing diseases in immature and ripe apple unwounded fruit, assessing symptoms development. *C. chrysophilum, C. nymphaeae, C. paranaense, C. melonis* and *C. siamense* were inoculated in immature 'Gala' (Ø = 5.5 cm) and 'Eva' (Ø = 4.8 cm) fruit in the field (2016/17 season). Subsequently, *C. chrysophilum* and *C. nymphaeae* were inoculated in different fruit sizes (Ø = 2.4–6.3 cm) in the laboratory and in the field (2017/18 and 2021/22 seasons). Gala and Eva cultivars differed regarding their susceptibility to Colletotrichum fruit spot (CFS). The CFS lesions of inoculated fruits did not evolve to BR after harvest, even under optimal environmental conditions for the pathogen up to the sixth week of incubation. Gala was susceptible to *C. chrysophilum, C. nymphaeae, C. paranaense, C. melonis* and *C. siamense*, showing symptoms of CFS in immature fruit inoculated in the field, and for 'Eva', the incidence varied between species. Only CFS symptoms were observed in both cultivars inoculated in the field, at harvest. CFS incidence in 'Gala' reached 50% for all species and fruit sizes. For 'Eva', *C. melonis* caused CSF in the 2016/17 season (Ø = 4.8 cm) and, C. chrysophilum and *C. nymphaeae* in the 2021/22 (smallest fruit sizes only).

Text
Citrus black spot (CBS), caused by *Phyllosticta citricarpa*, was reported for the first time in Tunisia in 2019. Previous studies indicated that this pathogen was unable to develop the disease in Mediterranean climates, while others suggested the contrary. In this study, a generic model was used to evaluate the suitability of the climates in the Mediterranean Basin for CBS development by simulating potential infections by ascospores and pycnidiospores of *P. citricarpa*. The model was implemented for the citrus-growing regions in the Mediterranean Basin and locations where CBS is present worldwide, using hourly climatic data at high spatial resolution (~9 km) retrieved from the ERA5-Land dataset. Two simulation scenarios were considered, in the first one the model parameters were set with values from literature and in the second estimated by a Bayesian inferential process. The results indicated that ascospore and pycnidiospore infections would be mainly concentrated in autumn, and also in spring for pycnidiospores. In contrast to previous studies, the model consistently estimated that the percentage of favourable hours for pycnidiospore infections was higher than for ascospores. The values simulated for Tunisia and several CBS-affected locations in South Africa were similar to those in citrus-growing regions in Europe and Northern Africa, where the disease has not been reported. These results confirm the climatic suitability of the Mediterranean Basin for CBS development.

Text

Yam (*Dioscorea* spp.) production in West Africa is constrained by the yam mosaic virus (YMV). YMV-resistant yams are unavailable, but the recent introduction of rapid clean seed propagation technologies promises to control the yield losses. However, rapid YMV reinfection to clean yam seedlings in the field undermines the effectiveness of new technologies. This study between 2016 and 2020 determined the factors contributing to the spread of YMV in field trials conducted in Ibadan, Nigeria. Yellow water traps were set to monitor aphid diversity and movement. Seedlings were assessed monthly for YMV infection. The study revealed no significant difference ($P>0.05$) in the number of aphids trapped at different positions within trials. The overall distribution of aphids demonstrated a biphasic pattern marked by an initial increase in the aphid population followed by a rapid decline. Eight aphid species were trapped, of which *Aphis spiraecola* and *Pentalonia* spp., were dominant. YMV incidence was highest in 2019 (46.4±3.3%) and lowest in 2016/17 (7.9±4.5%), and we found evidence showing clustering of YMV-infected seedlings at the edge of trial fields. Results demonstrated the role of non-yam colonizing aphids in YMV spread, the correlation between symptom severity, tuber yield, and seedling establishment, and the importance of integrated management, especially positive control, to manage YMV reinfection to clean plants in Nigeria. We will present the findings in this presentation.

Text

Wheat, a major crop for global food security, is threatened by diverse pathogen species. Some wheat pathogens such as rust fungi have been the focus of extensive studies to optimize mitigation. Here we evaluate more general strategies for surveillance and mitigation of a range of wheat pathogens. Effective management of an increasing burden of diseases requires geographic prioritization to guide epidemic risk-reducing efforts by global and

national stakeholders. Our first objective is to provide candidate priority locations for epidemic surveillance based on global risk analysis of wheat cropland and trade networks. For example, locations with high cropland connectivity in Kansas, Nebraska and North Dakota in the USA, and in each wheat production region, are identified as likely important for pathogen spread. Pathogen introduction risk via wheat trade networks, if there is inadequate phytosanitary testing, is higher in countries such as the United Arab Emirates, the Netherlands, and the USA. Our second objective is to provide a global biogeographic analysis of 100 economically important wheat pathogens based on their reported geographic distribution. Although pathogen richness peaks in countries with high wheat cropland extent, early epidemic emergence events have been more frequent in the native range of wheat than elsewhere. These findings provide starting points for building global epidemic surveillance and mitigation systems to support sustainable wheat production.

Text

Bacterial canker of cherry, caused by *Pseudomonas syringae* pathovars, is a major constraint to cherry growing in New Zealand and particularly in Central Otago, the primary growing area for cherries. To gain a better understanding of the disease's epidemiology, *Pseudomonas* spp. isolates were collected from symptomatic and asymptomatic cherry tissue from 23 commercial Central Otago cherry orchards in 2015. Isolates were classified into different taxonomic groups using phylogeny based on the *gltA* gene sequence for all strains (250) and Multi Locus Sequence Analysis (MLSA) of four housekeeping genes for 35 strains. The two main taxonomic groups were *P. syringae* pv. *syringae* (Pss) and *P. syringae* pv. *morsprunorum* race 1 (Psm1), in Phylogroup 2 (PG2) and Phylogroup 3 (PG3), respectively. The third group comprised non-pathogenic strains classified as *Pseudomonas* spp. Strains of Psm1 formed a monophyletic group, representing an almost clonal population. There was more variation detected within strains of Pss, although they were restricted to group PG2b. Non-pathogenic P. spp. and pathogenic Pss and Psm1 strains coexisted in the same orchard. It was concluded that Pss is the predominant pathovar in Central Otago. This is the first detailed study of the *P. syringae* species complex in cherry orchards in New Zealand and provides the basis for future epidemiology studies.

COMPLEMENTARY APPROACHES TO QUANTIFY AND CHARACTERIZE INOCULA DYNAMICS AND LEAF INFECTION AT PLOT LEVEL: CASE OF BLACK LEAF STREAK DISEASE

SEIDEL Marine. (1), AVELINO Jacques. (3), CHILIN-CHARLES Yolande. (1), ABADIE Catherine. (2)

(1) Cirad, UMR PHIM, Capesterre-Belle-Eau, GUADELOUPE; (2) Cirad, UMR PHIM, Turrialba, COSTA RICA; (3) Cirad, UMR PHIM, Montpellier, FRANCE

Text

Black Leaf Streak Disease is a major leaf disease of banana caused by the airborne ascomycete Pseudocercospora fijiensis. A better understanding of the disease epidemiology would help to find alternatives to fungicides. According to empirical knowledge, plant infection is mainly due to the inoculum from outside the plot (external inoculum, supposedly ascospores) whereas the inoculum within the plot (internal inoculum, supposedly mainly conidia) plays a minor role. We propose to implement two complementary and original experimental approaches to (i) characterize and quantify the external and internal inocula of a plot, and (ii) to identify which leaves are infected by each inoculum. The study is carried out in Guadeloupe, on two experimental plots planted either with a susceptible or a partially resistant cultivar to reduce ascospore production. For the first aim, we install six Burkard multi-vial cyclone samplers above and under canopy to catch respectively the external and internal inocula. Then, we quantify conidia by microscopy and ascospores with quantitative PCR. For the second aim, we describe the leaf infection due to the external and internal inocula by comparing with image analysis the number of lesions produced on leaves, protected or not from the inocula with spore proof nets. The inocula and infection dynamics will be related to the cultivar and the microclimate. This study is the first contribution to understand the role of each inoculum in the leaves' infection.

GRAPEVINE TRUNK DISEASE PATHOGENS IN ROOTSTOCK MOTHER VINES: A POTENTIAL THREAT TO THE SOUTH AFRICAN GRAPEVINE INDUSTRY

VAN JAARSVELD Wynand. (2), MOSTERT Lizel. (2), HAVENGA Minette. (1), **HALLEEN Francois. (1,2)**

(1) Agricultural Research Council (ARC) - ARC Infruitec-Nietvoorbij, Stellenbosch, SOUTH AFRICA; (2) University of Stellenbosch, Stellenbosch, SOUTH AFRICA

Text

Rootstock mother vines are known as sources of grapevine trunk disease (GTD) pathogen inoculum. Vines become infected through pruning wounds and spread to canes which are used as propagation material. The risks associated with ageing mother plants are unknown as most of these infected canes appear visually healthy. The aim of the study was to characterize GTD pathogens from mother vines and one-year-old canes harvested from these vines. Fungal isolations were made from 1900 mother vines of different ages and 2050 one-year-old canes. Isolates were identified based on morphology, species-specific PCRs and amplifying and sequencing relevant gene regions of representative isolates. From mother vines, *Phaeomoniella chlamydospora* occurred at the highest incidence (25.9%), followed by Botryosphaeriaceae spp. (18.6%; predominantly D*iplodia seriata*), Basidiomycetes (12.4%; predominantly *Fomitiporia* sp.) and *Phaeoacremonium* (5.9%; predominantly *P. minimum*). All major GTD pathogens occurred in mother vines as young as 4-years-old, including wood rotting Basidiomycetes. This is of great concern since wood rotting fungi could drastically reduce the productive lifespan of mother vines. A total of 4.0%

of one-year-old canes harboured GTD pathogens of which Botryosphaeriaceae species were predominant (3.4%), followed by *Diaporthe* species (0.3%) and *Phaeomoniella chlamydospora* (0.2%). The productive lifespan of rootstock mother plants must be re-evaluated and not merely be based on age.

Text

Downy mildew represents a real threat for grapevines in all vine-growing areas of the world, leading to significant yield losses and massive recourse of fungicides. Over the past years, breeders have been engaged in breeding programs for resistance to grapevine downy mildew, resulting in the creation of several resistant varieties. At present, growers can plant monogenic (with mainly the resistance factors Rpv1, Rpv3 but also Rpv10 and Rpv12) or pyramided cultivars (mainly cumulating Rpv1 and Rpv3). Currently, the resistance factors Rpv1 and Rpv3 start to be deployed in France. These two resistance factors can be deployed in: (i) monogenic cultivars sown in the same field (mixture strategy), (ii) monogenic cultivars sown in different fields (mosaic strategy), (iii) pyramided cultivars (pyramid strategy) and (iv) in hybrid strategies that combine the three previous basic strategies. Here, we used the spatially explicit stochastic model *landsepi* to investigate the epidemiological, evolutionary and economic outcomes associated to these deployment strategies. Our results particularly highlight the risks for resistance durability associated to the coexistence of monogenic and pyramided cultivars in the same landscape. Finally, we discuss how the model *landsepi* has been used to design deployment scenarios and discuss their outcomes with the staff of a cooperative cellar growing nearly 2000 ha of grapevine in South-western France.

Text

Anthracnose disease in olive orchards has acquired pandemic characteristics worldwide with significant yield losses and olive oil deterioration. In the present study, the population structure of Colletotrichum species of two orchards in Preveza, Greece was investigated during the period 2021 - 2023. Additionally, the effect of the intensity of olive fruit infestation by Colletotrichum species complex on quality and organoleptic characteristics in extracted oil was evaluated. Olive droops were collected from the olive groves based on symptom incidence, common harvesting practices and disease management. Preliminary sequencing analysis of the ITS (internal transcribed spacer) region of fungi isolated from olive fruits collected in 2021 indicated the presence of C. godetiae and other Colletotrichum spp. in the same groove. Olive oil extracted from these olive fruits by cold pressing was of lower category and quality. They exhibited higher acidity and peroxide value, and lower levels of phenolics, antioxidant activity and organoleptic quality. A further epidemiological study is under way in 2022- 2023, with additional isolation of Colletotrichum spp., their evaluation of sensitivity to fungicides, but also quantification of the pathogen biomass in olive fruit, petioles, stems and alternative hosts. Correlation of results with olive oil quality and local climatic conditions will lead to the development of an integrated protocol for disease management.

P5.1-047

TRACKING ASIAN SOYBEAN RUST IN BRAZIL

GODOY Claudia. (1)

(1) Embrapa, Londrina, BRAZIL

Text

Asian soybean rust (ASR), caused by *Phakopsora pachyrhizi*, is one of the most severe diseases of soybean. The fungus survives year-round in Brazil and regulatory measures were adopted to reduce the inoculum between crop seasons (soybean-free period). In 2004, a website (consorcioantiferrugem.net) was developed to track the disease. After 2010, the information added to the website focused on the first reports of ASR during the crop season, to warn farmers of the fungus´s presence. The information is available in an App that releases warning messages. From 2010 to 2023, average reports before R5 stage (beginning seed) in commercial areas were 23%, and after R5, 77%. Reports on the website show a later onset of the disease, with less damage potential. Since 2005, the soybean cultivars cycle has been reduced in Brazil, and early soybean sowing allowed a significant increase in the sowing of successive crops (e.g., soybean-corn, soybean-cotton). Soybean is sown in Brazil after September and the first ASR reports on the website start in November (2%) and December (11%). Harvest starts in January, showing that areas sowed earlier

escape the disease. The reports increase in January (38%) when the first areas are harvested. Soybean rust in Brazil is a threat to areas sowed late in the season. Data from the website gathered from 2010 to 2023 shows a predominance of SBR first occurrence after R5 and the first reports from November and December, with a significant increase in January.

P5.1-048

ECONOMIC INEFFICIENCIES IN PRIVATE MANAGEMENT OF EPIDEMICS SPREADING BETWEEN FARMS

MARTINEZ César. (1), COURTOIS Pierre. (1), **THÉBAUD Gaël. (1)**, TIDBALL Mabel. (1)

(1) INRAE, Montpellier, FRANCE

Text

Most plant disease epidemics spread both within and between farms. However, in the absence of collective action, each farmer generally takes disease control decisions based on personal costs and benefits. It is important to identify under which conditions the combination of such private control decisions can have synergistic or antagonistic effects, and can lead to collective economic inefficiencies. We used the game theory framework to investigate these questions, considering a simplified two-period game where two farmers decide whether or not to control an epidemic on their farm. Taking the example of sharka epidemics, caused by plum pox virus in Prunus orchards, we characterized the game and its outcomes according to initial epidemic conditions and focused on those likely to produce economic inefficiencies. Our results show that depending on the initial infection levels, a broad range of games may arise, some of which involving synergistic or antagonistic control decisions. This means that the nature of strategic interactions between famers may change depending on the state of the epidemic. After a thorough characterization of the epidemic conditions for which private management produces collective economic inefficiencies, we investigated the expected effect or different public policy incentives aiming to reduce such inefficiencies.

P5.1-049

MODEL-BASED CHARACTERIZATION OF INTERACTIONS BETWEEN PLUM POX VIRUS STRAINS FROM A FIELD SURVEY

Text

Multiple pathogen strains often co-circulate within the same host population and may lead to multiply infected individuals. However, the characterization of the interactions between strains and of their epidemiological impact is still a burgeoning research field. Here we show how modeling multi-strain epidemiological dynamics provides a more reliable assessment of strain interactions in the field than statistical tests of independence. The constructed model, which accounts for orchard age and all possible strain combinations, was applied to test for

interactions between three virus strains under the assumption of endemicity. The Serbian survey data used for the inference showed that sharka, caused by the plum pox virus (PPV), is widespread in the 91 sampled plum orchards and that three strains (M, D, and Rec) are present even as double and triple infections in the field. The observed co-infection frequencies were compared with their predicted frequency under the neutral/null hypothesis that there is no direct or indirect interaction between strains. We showed that D+Rec co-infections were less frequent than expected in the neutral case but also, in contrast with model predictions, that D+Rec coinfection frequency decreased with the orchard age. Our results raise biological and epidemiological questions on the Rec strain of PPV and emphasizes the importance of coupling models and data to understand and predict dynamics in complex epidemiological systems.

P5.1-050

GLOMERELLA LEAF SPOT IN APPLE ORCHARDS OF SOUTH TYROL (ITALY) AND THE DEVELOPMENT OF CONTROL STRATEGIES

DELTEDESCO Evi. (1), PRIMISSER Stefanie Maria. (1), **OETTL Sabine. (1)**

(1) Laimburg Research Centre, Auer/ora, ITALY

Text

Glomerella leaf spot (GLS), caused by several *Colletotrichum* species, is an emerging disease of apple worldwide. So far, GLS was restricted to apple growing areas with humid, subtropical climate, and was not reported from Europe. But, extreme weather conditions, including heavy rainfall and warm temperatures in summer 2020, led to an unknown symptomatology in South Tyrolean (Italy) apple orchards: necrotic lesions and chlorosis developed on leaves, premature leaf dropping was observed. Within a few days, circular, brownish spots appeared on above 90 % of apples in affected orchards. Fungal isolates were obtained from symptomatic leaves and fruit spots, morphological analysis was performed as well as multi-locus sequence analysis based on the eight gene loci: the ITS region; actin (ACT), DNA-lyase (APN2), calmodulin (CAL), glyceraldehyde-3-phosphate dehydrogenase (GAPDH), glutamine synthetase (GS), beta-tubulin (TUB2), and partial mating type gene (Mat1-2). *Colletotrichum chrysophilum* was identified as causal agent of GLS in South Tyrol. Pathogenicity assays on fruit and apple seedlings were established, and Koch’s postulates were confirmed. These results constitute the foundation for the development of in vitro and in vivo screenings of biologicals as well as of active substances. Together with agronomical measurements, these findings shall contribute to targeted plant protection and containment strategies for the largest contiguous apple growing area in Europe.

Molecular aspects of plant-fungal interactions Part 1: Effectors

C3.1-1

TOWARDS UNDERSTANDING HOW MAGNAPORTHE ORYZAE CO-OPTS PLANT ENDOCYTOSIS FOR TRANSLOCATION OF CYTOPLASMIC EFFECTORS

OLIVEIRA-GARCIA Ely. (1), VU An Hong. (1), TALBOT Nicholas J.. (2), VALENT Barbara. (3)

(1) Department of Plant Pathology and Crop Physiology, Louisiana State University Agricultural Center, LA 70803, Baton Rouge, USA; (2) The Sainsbury Laboratory, University of East Anglia, Norwich Research Park, Norwich, UK; (3) Department of Plant Pathology, Kansas State University, Manhattan, USA

Text

Fungal and oomycete pathogens deliver effector proteins directly into plant cells to suppress the plant immune system, reprogram cellular processes and enable pathogens to rapidly invade and proliferate within plant tissue. To date, little is known about the mechanism by which these pathogens translocate effector proteins across the plasma membrane into the plant cytoplasm. The M. oryzae-rice pathosystem possesses advantages for the study of effector cell biology due to the specific localization of cytoplasmic effectors within the specialized biotrophic interfacial complex (BIC) before translocation. We have shown that cytoplasmic effectors within BICs are packaged into dynamic, vesicle-like membranous effector compartments (MECs) that are occasionally observed in the host cell cytoplasm. Live cell imaging with fluorescently labeled proteins in rice revealed that these MECs colocalize with the plant plasma membrane and with CLATHRIN LIGHT CHAIN 1, a component of clathrin-mediated endocytosis (CME). By contrast, early- and late-endosome markers Ara6 and Ara7 did not colocalize with MECs in BICs. Inhibiting CME using virus-induced gene silencing and chemical treatments resulted in cytoplasmic effectors in swollen BICs lacking MECs. We also identified the first plant plasma membrane-associated effector, Bas83, that appears to play a role in recruiting plant membrane for the endocytic machinery at the BIC. Silencing of the BAS83 gene suggests a potential role of this effector in fungal virulence. Colocalization assays between fluorescently-labeled effectors and rice LifeAct showed accumulation of plant actin at BICs, suggesting possible short-distance transport of MECs. Since endosomes normally deliver cargos to other compartments and not to the cytoplasm, and MECs do not colocalize with early-and late endosome markers, it is unclear if effectors enter through the normal endosome system. A major question remains about how cytoplasmic effectors are released from MECs into rice cell cytoplasm. One possible route is lipid degradation in the MEC via fungal lipases. In fact, we identified a BIC and MEC localized lipase-like effector that may be associated with effector content release from MECs into rice cell cytoplasm. Taken together, this study provides evidence that cytoplasmic effector translocation is mediated by CME in BICs and suggests a role for M. oryzae effectors in coopting plant endocytosis.

C3.1-2

EVOLUTION OF STRUCTURALLY CONSERVED EFFECTOR FAMILIES IN ASCOMYCETE FUNGI

RAFFAELE Sylvain. (1), DERBYSHIRE Mark. (2)

(1) INRAE, Castanet Tolosan, FRANCE; (2) Centre for Crop and Disease Management, School of Molecular and Life Sciences, Curtin University, Perth, AUSTRALIA

Text
The range of hosts that parasites can infect is a key determinant of the emergence and spread of disease. In fungal pathogens, host range varies from a single host genotype (specialists) to hundreds of unrelated species (generalists). Pathogen small-secreted protein effectors play a major role in manipulating plants to facilitate disease. Studies of host adaptation in plant pathogen specialists revealed strong diversifying selection in effector genes, associated with tradeoffs on effector activity in diverse plant species. Tradeoffs on effector activity may easily account for evolution by host switching but not for host range expansion and the evolution of generalists. To search for candidate effectors associated with a generalist lifestyle, we analyzed the predicted structure of small-secreted proteins lacking functional annotation (orphans) across twenty Ascomycete genomes. I will present evidence for the existence of a limited repertoire of conserved general-purpose effectors. Insights into their macroevolution will be discussed. These findings point towards molecular mechanisms and evolutionary patterns favoring parasitism on multiple hosts.

C3.1-3

ENTERING VIA THE FRONT DOOR: CYTOPLASMIC EFFECTORS TAKEN INTO HOST CELLS VIA ENDOCYTOSIS

Text
Phytophthora plant pathogens threaten food security, forestry and ecosystems. The delivery of effectors into host plant cells to modulate plant defence is essential for infection success. The RxLR class is the best characterised group of cytoplasmic effectors. How they are translocated is still being unravelled and a key question is: how do they enter host plant cells after secretion?
Tagged forms of key endocytosis components, clathrin and Ara6, expressed in infected plant cells, associate with vesicles around P. infestans haustoria. Silencing expression of clathrin or Ara6 in Nicotiana benthamiana reduced P. infestans infection and reduced translocation of tagged RxLR effectors into infected cells. In contrast, silencing PP1c isoforms, susceptibility factors that are not required for endocytosis, reduced infection but did not attenuate RxLR effector uptake.
After endosome enrichment tagged RxLR effector Pi04314-RFP co-localised in sucrose gradients with clathrin-labelled vesicles. Immunoprecipitation of clathrin- or Ara6-associated vesicles co-immunoprecipitated RxLR effectors Pi04314-RFP and Avrblb1-RFP but not the apoplastic effector PiSCR74-RFP from infections with transgenic P. infestans lines secreting these fusions. Proteomic analyses of proteins detected in immunoprecipitated Ara6-labelled endosomes from infection revealed enrichment of multiple RxLR, but no apoplastic effectors. Our data show that uptake of P. infestans RxLR effectors into plant cells occurs via CME.

C3.1-4

PARASTAGONOSPORA NODORUM USES DIVERSE EFFECTOR FUNCTIONS TO FACILITATE THE COLONIZATION OF WHEAT

FRIESEN Tim. (1,2), KARIYAWASAM Gayan. (2), NELSON Ashley. (2), FARIS Justin. (1)

(1) USDA-ARS Edward T. Schafer Agricultural Research Center, Fargo, UNITED STATES;
(2) Department of Plant Pathology, North Dakota State University, Fargo, UNITED STATES

Text
To facilitate the completion of its pathogenic life cycle on wheat, *Parastagonospora nodorum* secretes multiple necrotrophic effectors (NEs), which are defined as effectors that trigger programmed cell death (PCD). To induce PCD, NEs target wheat susceptibility genes resulting in the initiation of a defense response (DR), including PCD. Typically, initiation of DR pathways would result in resistance, however, *P. nodorum* uses the triggering of the DR to its advantage. Five NEs have been functionally validated and characterized, and at least eight host targets have been validated, with some NEs having multiple host sensitivity genes. In addition to NE activity, two of the five NEs have secondary effector functions, including chitin binding/chitinase protection (SnTox1) and inhibition of PR1 protein activity (SnTox3). We used confocal microscopy to show that in addition to its NE function, SnTox5 also showed hallmarks of an additional effector function where it facilitated the colonization of the mesophyll, even in the absence of its PCD-inducing target *Snn5*. Subsequent RNA-Seq analysis comparing a *P. nodorum* wild type and an *SnTox5*-disrupted strain showed that SnTox5 is involved in the regulation of wheat DR genes as well as several transcription factors previously shown to regulate DR pathways in other plant-pathogen interactions. This result shows that in addition to its NE activity, SnTox5 is likely modulating the DR to facilitate the colonization of wheat.

LESSONS TO LEARN FROM A GALL-INDUCING FUNGUS

DJAMEI Amin. (1)

(1) University of Bonn, Bonn, GERMANY

Text
Smut fungi form a large group among the basidiomycetes and are biotrophic specialists in infecting a diverse set of mainly grasses, among them important crops like sorghum, millet, barley and maize. The maize smut fungus Ustilago maydis serves as an important model for smuts fungi and induces prominent galls on all aerial parts of its host, reflecting a metabolic and developmental reprogramming of the plant. This massive manipulation of the host is achieved with the help of fungal secreted molecules, so called effectors. In a systematic approach we screened in the past decade hundreds of putative effector proteins to identify their specific place of action and their functions on the plant side. Here I will present our current molecular understanding of the fungal effectome and the biotrophic interaction between the fungus and its host plant maize.

C3.1-6

PLANT PATHOGENS MANIPULATE HOST MICROBIOTA TO PROMOTE DISEASE DEVELOPMENT

THOMMA Bart. (1)

(1) University of Cologne, Cologne, GERMANY

Text

Beneficial plant-associated microbes are found in and on all organs of the plant and help to mitigate (a)biotic stresses. Moreover, plants are able to shape their microbiota and specifically attract beneficial microbes to suppress pathogen attack. Hence, the plant's microbiome can be considered an inherent, exogenous layer that complements its endogenous innate immune system. Microbes typically secrete a plethora of molecules into their environment to promote niche colonization. Especially soil-dwelling microbes are well-known producers of antimicrobials that are exploited to outcompete microbial co-inhabitants in the soil. Plant pathogenic microbes similarly secrete a diversity of molecules into their environment for niche establishment. Upon plant colonization, microbial pathogens secrete so-called effector proteins that promote disease development. While such effectors are typically considered to exclusively act through direct host manipulation, for instance through the suppression of host immune responses, increasing evidence demonstrates that pathogenic fungi exploit effector proteins with selective antimicrobial properties to promote host colonization through the manipulation of beneficial host microbiota. Given that effector-mediated microbiota manipulation may have evolved in fungal ancestors that encountered microbial competition before symbiosis with land plants evolved, we propose that effector-mediated microbiota manipulation is fundamental to fungal biology.

Text

Plant pathogenic effector is secreted into the host and modulates the host immune system. Nuclear effectors translocated in the host nuclei and interact with proteins and DNA to regulate various defense mechanisms. Nuclear localization sequence (NLS) is the most well-known factor for nuclear transportation. However, the molecular mechanism of NLS-associated vehicles and the roles of NLS in transcriptional reprogramming still need to be understood. We previously reported that MoHTR1, a nuclear effector of the rice blast fungus, *Magnaporthe oryzae*, is translocated to rice nuclei but not to fungal nuclei. MoHTR1 was

localized in the plant nucleus by interacting with rice importin alpha. We found one NLS (PGRSKKE) and further identified that RxKK residues were necessary for the nuclear localization of MoHTR1. MoHTR1 NLS altered the localization of cytoplasmic effectors of *M. oryzae* in the host. Furthermore, nuclear effector candidates which have RxKK sequence also localized in rice nuclei. SUMOylation, post-translational modification, was involved in the secretion and translocation of MoHTR1 to biotrophic interfacial complexes and host nuclei. In addition, MoHTR1 NLS was essential for the pathogenicity of *M. oryzae* by reprograming defense-related genes and host target gene candidates. Our findings will provide unprecedented details on the roles of plant-specific NLS on nuclear effector in pathogen-host interactions.

Text
Apple scab caused by the pathogenic fungi *Venturia inaequalis* is the most common disease in apple orchards. Resistance genes such as *Rvi6* have been introduced in apple varieties to reduce the use of fungicides in the management strategies of this disease. However, in the 90's, we observed a breakdown of *Rvi6* resistance and the emergence of *V. inaequalis* virulent stains on trees carrying *Rvi6*. Using genomic analysis, we identified *AvrRvi6*, the first fungal avirulent gene responsible for a gene-for-gene interaction in the Apple-*V. inaequalis* pathosystem. *AvrRvi6* codes for a small secreted protein with structure similar to the MAX effector family. On the plant side, Rvi6 is a receptor-like protein (RLP), similar to RXEG1 and predicted to localize at the plasma membrane. We observed that fungal virulent strains have mutations in the coding or regulatory sequences of AvrRvi6 which we hypothesize are responsible for the escape of Rvi6 immunity. Using transient expression in *Nicotiana benthamiana* we were able to replicate the recognition of AvrRvi6 by Rvi6 resulting in a strong cell death phenotype. This *N. benthamiana* assay allowed us to test the AvrRvi6 alleles and identify essential residues for Rvi6 recognition. We also investigated the protein-protein interactions between AvrRvi6 and Rvi6 and the subcellular localization of this allele-specific immune recognition.

Text
A collection of Botrytis cinerea ATMT-strains revealed that random mutants exhibiting total loss of virulence toward different host plants share a common profile including impaired secretion of hydrolytic enzymes and severe deficiency in mature infection cushion (IC). IC is a multicompound appressorium differentiated by an epiphytic mycelium to penetrate a plant host. Transcriptomic and proteomic analysis of the mature IC highlighted high secretion of ROS and proteins involved in virulence such as plant cell-death inducing proteins. These results support a role for the IC in stimulating plant immunity and inducing necrotrophy of the pathogen. But surprisingly, effectors suppressing the plant chitin-triggered immunity were also induced in the IC. Chitin deacetylases genes (cda) are up-regulated and the conversion of chitin into chitosan was confirmed by differential staining of the IC cell wall. Cda mutants show a reduced pathogenicity compared to the wild-type strain and stimulate plant immunity. A LysM effector accumulated by the IC can bind the chitin in the fungus cell wall and protects hyphae against degradation by external chitinases. It is also able to sequester chitooligosaccharides and to prevent them from inducing ROS production in A. thaliana. Deletion strains of the LysM gene show a delay in infection initiation. It is hypothesized that the infection cushion must hide from the plant during the asymptomatic phase and then induces necrotrophy.

Text
Iron is an important nutrient that plays a prominent role in diverse biological functions in all organisms, including fungi. Due to its poor solubility, iron is a limiting factor in growth and development. On the other hand, an excess of iron leads to toxicity through the formation of hydroxyl radicals. In the maize anthracnose fungus *Colletotrichum graminicola*,the non-ribosomal peptide synthetase Nps2 is responsible for the synthesis of the intracellular siderophore ferricrocin and thus indispensable for iron scavenging and for prevention of iron toxicity. Also, in Magnaporthe oryzae and Alternari alternata Nps2 is required for the biosynthesis of ferricrocin as an intracellular storage siderophore. Since the exact role of Nps2 in C. graminicola is yet unknown, we generated *NPS2* deletion and green fluorescent protein (GFP) promoter fusions strains to elucidate the role of NPS2 in intracellular siderophores biosynthesis and control of intracellular iron homeostasis under iron deficiency and iron surplus conditions. Our findings to date show that expression of *NPS2* occurs at each stage of pathogenesis. Although the differences in growth and development between WT and *Δnps2* strains appear to be marginal under standard conditions, the deletion mutants show higher susceptibility to oxidative stress. In addition, infection experiments on maize leaves, qPCR analyses, and quantification of infection structures revealed that NPS2 is

required for full virulence of *C. graminicola*.

VIRULENCE PROFILE OF COLLETOTRICHUM FALCATUM WENT ISOLATES PREVAILING IN PAKISTAN

ARSHAD Waqas. (1), HASSAN Nadeem. (2), AFGHAN Shahid. (3)

(1) University of Agriculture Faisalabad, Faisalabad, PAKISTAN; (2) COMSATS University , Islamabad, PAKISTAN; (3) Sugarcane Research and Development Board, Faisalabad, PAKISTAN

Text

Sugarcane grows well in the tropical and subtropical climates of Pakistan. Diseases, particularly, red rot caused by Colletotrichum falcatum, is the major factor for country's low sugarcane yields of only 60.31 tons/ha. Losses estimated at 10-77% in cane yield and 4-74% in sugar recovery have been reported. C. falcatum is highly variable pathogenically making it extremely difficult to obtain stable resistant varieties. Hence, detail studies were initiated to identify the number of strains present in Pakistan. The pure cultures (n=12) were prepared from naturally infected sugarcane stalks, surveyed on 09 commercially grown varieties from 28 different localities during 2020-21 cropping season. The cultures were identified as C. falcatum based on spore morphology and were divided into under three distinct molecular groups as Group I, II, and III. Among the isolates, 5 proved to be virulent with light colored and abundant sporulating mycelium, 2 were moderately virulent with light colored and moderate sporulating type and 5 were least virulent with dark colored and least sporulating mycelium. The isolates showing variable virulence were characterized at molecular level by 18S rRNA/ITS gene analysis. The PCR conditions were optimized for the amplification of 600-700 bp 18SrRNA/ITS genes. The genes were sent to commercial organization for sequencing and analysis at NCBI/gene bank using the blast n homology tool to identify the isolates at molecular level.

Text

The Plant immune system is made up of a complex response network that involves several lines of defense to fight invading pathogens. In this study interaction between Ascochyta pisi fungus and pea genotypes was explored to investigate the progression of ascochyta blight (AB) in pea. Here we developed genetics transformation system for A. pisi by constructing a new binary vector, pBIF-DsRed and pBIF-EGFP, for the constitutive expression of the red fluorescent protein (DsRed) and green fluorescent protein (EGFP) used as a highly efficient vital marker to study the developmental changes in A. pisi during AB disease progression. The initial infection stages were similar in both the resistant and susceptible accessions where A. pisi uses infection structures such as germ tubes and appressoria to gain entry into the host while the host uses defense mechanisms to prevent pathogen entry. The pathogen attempted to penetrate and colonize in radly enter in resistant, but further fungal advancement appeared to be halted, and A. pisi did not enter the mesophyll. But successful entry and colonization in susceptible, coincided with structural changes in A. Pisi. Pycnidia-bearing spores appeared 3-14 days post-inoculation. The use of fluorescent proteins in plant pathogenic fungi together with confocal laser scanning microscopy, provide a valuable tool to study the intracellular dynamics, colonization strategy, and infection mechanisms during plant-pathogen interaction.

IDENTIFYING EFFECTORS FROM THE FUNGAL PATHOGEN ZYMOSEPTORIA TRITICI THAT CAN OVERCOME RESISTANCE IN COMMERCIAL WHEAT CULTIVARS

MIRZADI GOHARI Amir. (1,2), BURKE Jimmy. (1,3), FEECHAN Angela . (1,4)

(1) University College Dublin, Dublin, IRELAND; (2) University of Tehran, Karaj, IRAN (ISLAMIC REPUBLIC OF); (3) Origin Enterprises PLC, Dublin, IRELAND; (4) Institute for Life and Earth Sciences, Edinburgh, UNITED KINGDOM

Text

Zymoseptoria tritici causes the major fungal wheat disease Septoria tritici blotch (STB), which is the most economically destructive disease of wheat worldwide threatening global food security. Disease management is obtained through fungicide application and breeding for resistance. Control of STB by applying fungicides has resulted in the frequent development of fungicide-resistant strains over the last decades. Therefore, crop protection to STB is more and more dependent on resistant cultivars. To deploy these cultivars effectively, we require knowledge on the molecular mechanisms employed by Z. tritici to overcome host resistance in wheat. Hence, identification of isolates that can overcome resistance and identification of the virulence genes (effectors) responsible is a crucial factor in designing new effective approaches for STB management. We aim to (1) identify Z. tritici virulence factors, contributing to the aggressiveness of Z. tritici on commercial wheat cultivars and (2) perform functional characterization of the (a)-virulence factor(s) that are key elements in the Z. tritici-wheat interaction. To accomplish these goals, we are employing, a Genome-Wide Association Study followed by functional genomics. This will allow the future informed deployment of resistant wheat cultivars and the ability to monitor for virulent Z. tritici isolates in the field.

ANALYSIS OF FACTORS INVOLVED IN GROWTH INHIBITION AND BLACKENING OF RICE ROOTS INFECTED WITH PYRICULARIA GRISEA

XIANG Zikai. (1), TSURUSHIMA Tetsu. (2), NAKAYASHIKI Hitoshi. (1), IKEDA Kenichi. (1)

(1) Kobe university, Kobe, JAPAN; (2) Hannan University, Matsubara, JAPAN

Text

Pyricularia spp. are pathogenic filamentous fungi that cause blast disease mainly in various monocotyledonous plants. *Pyricularia* isolates consist of pathotypes that show strict host specificity at the plant genus level in above-ground parts such as leaves. However, we reported that the host specificity of *Pyricularia* fungi was less strict in the underground parts. We found that *P. grisea* isolated from *Digitaria*, Dig4-1, caused strong growth inhibition and blackening lesion on rice roots. It was known that Dig4-1 secreted a phytotoxin, Pyrichalasin H belonging to cytochalasans. We constructed a mutant lacking the PyiB gene involved in Pyrichalasin H biosynthesis. The resultant mutant ?pyiB showed a reduction in root growth inhibition, suggesting that Pyrichalasin H is one of the factors inhibiting root growth. While most *Pyricularia* isolates showed a browning lesion on rice roots, Dig4-1 induced a blackening lesion. Cytological observation of blackening lesions revealed that infection hyphae were intensively localized at the outer layer of the root tissue. In addition, infected root cells were filled with hyphae. ROS generation was relatively lower at blackening lesions than browning lesions. RNA-seq analysis revealed that expression levels of defense-related genes were low at blackening lesions than browning lesions. These results suggest that the Digitaria pathotype is more virulent on rice roots than other *Pyricularia* pathotypes.

MELALEUCA QUINQUENERVIA; TOWARDS A MODEL FOR MYRTLE RUST RESEARCH

MARTINO Alyssa. (1), PARK Robert . (1), TOBIAS Peri. (1)

(1) The University of Sydney, Sydney , AUSTRALIA

Text

Myrtle rust caused by the biotrophic fungal pathogen *Austropuccinia psidii* infects hundreds of species in the family Myrtaceae, with variability in response to the pathogen identified both within and between species. As a result, studies investigating resistance to *A. psidii* have been conducted in a range of Myrtaceae species. While important to understand the extent of species susceptible to the disease, no model has been established for the study of *A. psidii*. *Melaleuca quinquenervia* is a keystone paperbark species broadly distributed across the east coast of Australia and displays a variable response to *A. psidii*. It can be propagated from cuttings, seed can be collected year-round, seedlings establish rapidly, a high-quality genome has been generated, and transcriptomic analysis conducted. These qualities provide the opportunity to utilise this species as a model system for the study of resistance to *A. psidii*. Using our chromosome-level phased genome, we have annotated genes encoding the Nucleotide-binding Leucine-rich Repeat (NLR) domain intracellular receptors within a resistant *M. quinquenervia*, an important family of plant resistance genes. Transcriptomic analysis of the progeny from this tree sheds light on the mechanisms and pathways for resistance to *A. psidii*. Importantly, these analyses provide a framework for identification of

resistance genes and pathways in other *Melaleuca* species and a proof of concept for this species as a model.

THE PERFECT DAWN: THE ROLE OF EARLY MORNING LIGHTING ON IMMUNITY

VONG Gina. (1), DENBY Katherine. (1), EZER Daphne. (1)

(1) University of York, York, UNITED KINGDOM

Text
Botrytis cinerea (grey mould) is estimated to cost up to a global $10 billion per year in crop losses and management. Many of its hosts are greenhouse crops (e.g. tomato, lettuce, strawberry, grape). These controlled greenhouse environments provide the warmth and humidity required for rapid fungal disease spread. Moreover, many indoor farms use supplementary artificial lighting, or are fully dependent on artificial lights.

Recent work has identified a light-dependent Dawn Burst Transcriptional Network in *Arabidopsis thaliana*, which is independent of the circadian clock (1). We have found that the Dawn Burst hub genes (HY5, HYH, BBX31) influence resistance to *B. cinerea* in a time-dependent manner. This suggests that modifying early morning lighting (i.e. dawn) may enhance disease resistance in an indoor farm setting.

However, these experiments were carried out under unnatural lighting conditions and so may not necessarily be commercially applicable. Here, we simulate more realistic dawns to investigate the effect of dynamic morning light on lettuce (*Lactuca sativa*) and Arabidopsis, and their response to *B. cinerea* infection. This enables us to gain a more nuanced understanding of the role of the Dawn Burst Network on immunity, as well as potentially developing commercially applicable lighting regimes.

FOREST TREE MYCOBIOME: IMPACT ON HETEROBASIDION PATHOGENESIS AND PLANT HEALTH

ASIEGBU Fred. (1), WEN Zilan. (1), WANG Kai. (1), KOVALCHUK Andriy. (1)

(1) University of Helsinki, Helsinki, Finland, Helsinki, FINLAND

Text
Microorganisms constitute an integral component of all terrestrial ecosystems and plays an important role in maintaining the host fitness. In fact, all macroorganisms live in close association with a diverse range of microbial symbionts. Despite a significant progress in our understanding of the plant microbiome, very little is known about their effect on host genetics

as well as on other tree microbiomes. In this study, we analysed the mycobiome of asymptomatic and symptomatic Norway spruce trees naturally infected by Heterobasidion spp. Our results demonstrate that the structure of fungal communities residing in the wood differed significantly among symptomatic and asymptomatic Heterobasidion infected trees. The result also showed that under in vitro conditions, one of the trees associated mycobiome, a dark septate endophyte (Phialocephala sphaeroides, DSE) promoted the root growth of Norway spruce seedlings. The DSE significantly reduced H. parviporum transcripts (by 92%) during co-infection. A specific transcriptional response to P. sphaeroides inoculation was the increased transcripts of genes involved in jasmonic acid biosynthesis and plant hormone signal transduction. The P. sphaeroides experienced a shift from cell growth to anti-stress, while it repressed H. parviporum carbohydrate/polysaccharide-degrading enzyme machinery. We conclude that H. parviporum triggered reprogramming of host metabolism whereas the endophyte counteracted the negative effects of pathogen.

Text

Quantitative disease resistance in necrotrophic pathosystems involves various mechanisms, including chemical warfare. *Alternaria dauci*, a necrotrophic fungus, synthesizes toxins conferring pathogenicity to carrots. Aldaulactone, a phytotoxic benzenediol lactone from *A. dauci*, has been shown to be central in both the pathogenicity of *A. dauci* and carrot partial resistance toward the fungus. Secondary metabolite biosynthesis is thus of prime importance in this interaction. Our study provides the first comparative examination of the SM genetic basis in *Alternaria*. Using transcriptome data, we assembled the *A. dauci* genome data set and identified 19 putative SM clusters. Comparison of these genomic data with the already published genomes of other *Alternaria* species predicted 55 putative families of SM core genes in the *Alternaria* genus. Exploitation of phylogeny allowed us to pinpoint cluster 8 as a candidate for aldaulactone biosynthesis. This cluster harbors *AdPKS7* and *AdPKS8*, homologs of genes encoding a reducing and a non-reducing polyketide synthase necessary to produce benzenediol lactones. The expression patterns of *AdPKS7* and *AdPKS8* correlated with aldaulactone production. We also produced KO-mutant *A. dauci* strains for both PKS genes. Aldaulactone production in the transformed strains was abolished as determined by HPLC analysis. Our results provide strong evidence that *A. dauci* PKS cluster 8 harboring *AdPKS7* and *AdPKS8* is responsible for aldaulactone biosynthesis.

Text

An extensive yield-oriented breeding approach, climate change and a faster rate of adaptation of pathogens have rendered cultivated mustard (Brassica juncea) susceptible to many diseases including Alternaria blight caused by Alternaria brassicae. Past research has established that the disease resistance mechanism in plants is regulated by SA and JA-mediated pathways. However, recently the studies on the involvement of ABA in SA-JA cross-talk have gained momentum because of the diverse role of ABA in disease resistance. Depending on the phyto-patho system ABA can be a positive or a negative regulator. In terms of the A. brassicae-brassica system, the role of ABA as a regulator has not been established assertively. This study aims at understanding the existing variation concerning phytohormone signalling in susceptible B. juncea and its resistant wild relatives and to decipher the effect of the pathogen on variable SA-JA-ABA cross-talk. Our study revealed a significant difference in the initial trigger of phytohormone signalling with 3hrs of inoculation in susceptible and tolerant genotypes. Also, the involvement of ABA in SA-JA cross-talk differs considerably in susceptible and resistant genotypes. Our studies revealed ABA as the key modulator of resistant/susceptible response in Brassica-A. brassicae phyto-pathosystem by regulating the SA-JA biosynthesis pathways in the early hours of the inoculation.

Text

Unlike, R gene-mediated resistance, quantitative disease resistance (QDR) can provide

crops with durable control against pathogens. QDR is a desirable trait for crop improvement, but little is known about causative genes, which makes incorporation into breeding programmes difficult. Light leaf spot, caused by Pyrenopeziza brassicae, is an important disease problem of oilseed rape (Brassica napus) in the U.K. and Europe. To identify new QDR gene loci, we have used a high-throughput screening pathosystem with P. brassicae on 195 lines of B. napus in combination with an association transcriptomics platform. We have demonstrated that all resistance against P. brassicae was associated with QDR and not R genes. We have used genome-wide association mapping with an improved B. napus population structure to reveal four loci significantly associated with QDR in regions showing linkage disequilibrium. In addition, eight gene expression markers (GEMs) were associated with QDR against P. brassicae. For seven of these, expression was positively correlated with resistance whereas for one, an HXXXD-type acyl-transferase negative correlation indicated a potential susceptibility gene. Pathogen-induced gene expression was detected in resistant B. napus lines for five out of seven GEMs tested. The acyl transferase was only induced in susceptible B. napus lines. A TILLING mutant with a D167N substitution was more resistant against P. brassicae than the cv. Cabriolet background.

Text

Southern blight of common bean caused by *Sclerotium rolfsii* Sacc. is an economically important disease commonly occurring in the tropics, sub tropics and warm temperate regions. Yield losses of up to 64% have been reported due to the disease. Use of host plant resistance is the most suitable option for management of the disease. Southern blight is currently the most important root rot disease of common bean in Uganda. The National Legumes Research Programme of the National Crops Resources Research Institute has initiated research activities that will lead to the development and release of Southern blight resistant varieties in Uganda. Accordingly, 200 isolates of *S. rolfsii* obtained from within Uganda have been observed to be culturally, morphologically and phenotypically diverse. We are currently undertaking molecular characterization to determine genetic diversity of the isolates. In our efforts to identify sources of resistance to Southern blight disease, we have a collection of 582 diverse Common bean germplasm from disease nurseries, interspecific lines, advanced breeding lines, etc. Preliminary findings have shown significant differences in the reaction of the germplasm lines to *S. rolfsi*i infection. With further evaluations, we hope to identify reliable sources of resistance that can be used 1) to map Southern blight resistance and develop markers to accelerate breeding in Common bean and 2) as parents in Southern blight resistance breeding programmes.

Text

Fungal pathogens often secrete virulence proteins into plant cells during the infection process to modulate host immune responses. Recent genomic and transcriptomic studies of Phyllachora maydis which causes tar spot disease in maize, revealed 163 putative effector proteins, eighteen of which are abundantly expressed during disease development. Here, we used heterologous expression in N. benthamiana to elucidate whether any of these eighteen candidate effector proteins have effector-like functions. Live-cell imaging of N. benthamiana epidermal cells revealed that a majority of the putative effectors localized to the nucleus and cytosol. We also show that though all candidate effectors expressed detectable protein, none were able to suppress cell death triggered by BAX or INF1 when transiently expressed in N. benthamiana, indicating that these putative effectors likely do not function as general cell death suppressors. Importantly, some candidate effectors consistently suppressed cell surface-triggered immune responses including chitin-induced reactive oxygen species production and MAP kinase activity, revealing these putative effectors contribute to inhibition of immune responses. These results provide valuable insights into the putative functions of candidate effectors from P. maydis and will stimulate new research aimed at elucidating the molecular mechanisms potentially manipulated by this fungal pathogen.

Text

Fusarium oxysporum species complex is a cosmopolitan, soil-borne, plant pathogenic fungus with a wide host range spanning over 120 species. In *F. oxysporum*, a pathogenicity chromosome (necessary for pathogenicity toward its host but not for vegetative growth) has been reported. However, the presence of a pathogenicity chromosome has not been verified in *F. oxysporum* f. sp *cepae* (*Foc*), which causes Fusarium basal rot disease on onions.

Therefore, the aim of this study was to determine whether a pathogenicity chromosome is present in *Foc*. We initially screened for effector candidates in the Japanese strain *Foc*_TA using genomic sequence data. Twenty-one effector candidates were identified, of which five were expressed during infection. Interestingly, four of the expressed effector candidates were located on the 4-Mb chromosome in *Foc*_TA. To elucidate the relationship between pathogenicity and the 4-Mb chromosome in *Foc*_TA, nine putative 4-Mb chromosome loss strains were generated by benomyl (a mitosis inhibitor drug) treatment. Pathogenicity testing with these putative 4-Mb chromosome loss strains revealed impaired pathogenicity toward onion. Moreover, genome analysis of the putative 4-Mb chromosome loss strains demonstrated that the 4-Mb chromosome functioned as a pathogenicity chromosome in *Foc*_TA, and a 2.7-Mb region within the 4-Mb chromosome is necessary for full pathogenicity toward onion.

P3.1-016

A TRANSCRIPTOMIC ANALYSES OF THE ROLE OF OTHER FUNGI IN BOTRYTIS CINEREA CAUSED NOBLE ROT OF GRAPEVINE

HEGYI Ádám István. (1), OTTO Margot. (1), HEGYI-KALÓ Júlia. (1), GEML József. (1), GOMBA-TÓTH Adrienn. (1), GEIGER Adrienn. (1), GOLEN Richárd. (1), SZABADI Kriszta Lilla. (1), CELS Thomas. (1), VÁCZY Kálmán Zoltán. (1)

Text

Botrytis cinerea is one of the key fungi of grape production, which can lead the formation of noble rot under certain environmental conditions. Noble rot results unique metabolic profile, changes the physical texture and chemical composition. The functional genes during the process have been poorly characterized. We generated metatranscriptomic data from *Botrytis cinerea* infected grape berries representing the four phases of noble rot, from the healthy to the fully dried out berry. The genes were significantly enriched characterizing the carbohydrate and protein metabolism of the fungi involved in the breakdown of the berry skin structure. In addition, we identified genes expressed by the most abundant filamentus fungi and yeast during the noble rot process belonging to enriched pathways that can be crucious in grapevine cultivation. These fungi have been found to compete with *Botrytis* and to play an important role in the chemical composition of grapes

P3.1-017

METATRANSCRIPTOMIC ANALYSIS OF POSSIBLE CHANGES IN OENOLOGICALLY RELEVANT COMPONENTS OF GRAPE BERRIES DURING NOBLE ROT

Text

Noble rot of grapevine (*Vitis Vinifera*) berries caused by Botrytis cinerea together with other filamentus fungi and yeasts. This development causes a unique aromatic profile of botrytized wines. To have more insight into this process we generated metatranscriptomic data representing the four NR stages (I-IV) from the Tokaj wine region of Hungary over three months. The most abundant filamentous fungi and yeast include Alternaria alternata, Botrytis cinerea, Epicoccum nigrum, Aureobasidium pullulans and Rhodotorula graminis, RNAseq reads were aligned to the latter species. Gene module clusters generated by WGCNA clustering, enriched pathways involved in the synthesis of aromatic compounds such as amino acid-, carbohydrate- and lipid metabolism co-jointly expressed by all filamentous fungi and yeast were identified within the turquoise module. It was found that the enzymes involved in the synthesis of aromatic compounds are expressed and up-regulated during the later stages (III-IV) of the NR process. This study has indicated that beside the *B. cinerea* other microbes are playing important role in aromatic development of grape berries during the noble rot process.

P3.1-018

COMPARATIVE TRANSCRIPTOMIC ANALYSIS OF MAPK-MEDIATED REGULATION OF PATHOGENICITY, STRESS RESPONSES AND DEVELOPMENT IN CYTOSPORA CHRYSOSPERMA

YU Lu. (1), **XIONG Dianguang. (1)**

(1) Beijing Forestry University, Beijing, CHINA

Text

MAPK cascades are highly conserved signal transduction pathways that mediate cellular responses to various biotic and abiotic signals in plant pathogenic fungi. Our previous studies have shown that CcPmk1 is a core regulator of fungal pathogenicity in Cytospora chrysosperma, the causal agent of canker disease in a wide range of woody plants. Here, we identified and functionally characterized the other two MAPK genes (CcHog1 and CcSlt2), and then compared the transcriptional differences among these three MAPKs in C. chrysosperma. We found that the MAPKs shared convergent and distinct roles in fungal development, stress responses and virulence. For example, CcHog1, CcSlt2 and CcPmk1 were all involved in conidiation and response to stresses, including hyperosmotic pressure, cell wall inhibition agents and H2O2, but only CcPmk1 and CcSlt2 were required for hyphal growth and fungal pathogenicity. Transcriptomic analysis showed that numerous hyperosmosis and cell wall related genes significantly reduced their expression levels in ΔCcHog1 and ΔCcSlt2, respectively. Moreover, two secondary metabolite gene clusters were significantly down-regulated in ΔCcPmk1, ΔCcSlt2 and/or ΔCcHog1. Importantly, some virulence-associated genes were significantly down-regulated in ΔCcPmk1 and/or ΔCcSlt2, such as candidate effector genes. Collectively, these results provide a better understanding of the regulation network of MAPKs in C. chrysosperma.

Text

Oilseed rape (*Brassica napus* and its related species), the second largest oilseed crop in the world, is particularly susceptible to fungal pathogens. The most significant of these are blackleg caused by *Leptosphaeria maculans* and *L. biglobosa*, followed by Sclerotinia stem rot caused by *S. sclerotiorum*, and Alternaria blight caused by *Alternaria brassicae* and *A. brassicicola*. It has been reported that the Class III acyl-CoA-binding proteins (ACBPs) from dicots (Arabidopsis and grapevine) protect against biotrophic pathogens. Also, the overexpression of the monocot *Oryza sativa* (rice) OsACBP5 in transgenic Arabidopsis and rice has been demonstrated to enhance broad-spectrum disease resistance against selected phytopathogens. In this study, transgenic rapid-cycling *Brassica napus* (*B. napus*-RC) and canola cv. Westar OsACBP5-OEs were generated and tested against Alternaria blight, blackleg and Sclerotinia stem rot diseases. Alternaria blight and blackleg pathogen assays were based on infecting young cotyledons, while detached true leaf assay was used to test the tolerance of *B. napus* plants toward *S. sclerotiorum*. OsACBP5-OE plants exhibited resistance 5 days after inoculation with *Alternaria brassicae*, 12 days after inoculation with *Leptosphaeria maculans*, and 24 h after inoculation with *Sclerotinia sclerotiorum*. This study provides an insight into the usefulness of OsACBP5 in enhancing resistance to necrotrophic phytopathogens.

P3.1-020

IDENTIFICATION AND USE OF A CONSERVED LOCUS FOR STANDARDISED TARGET SITE INTEGRATION IN FUSARIUM GRAMINEARUM

DARINO Martin. (1), URBAN Martin. (1), HAMMOND-KOSACK Kim. (1)

(1) Rothamsted Research, Harpenden, UNITED KINGDOM

Text

Fusarium graminearum (*Fg*) is a destructive fungal pathogen of wheat, barley, maize and other crop species. Infections cause the production of different mycotoxins that contaminate grains making them unsafe for human and animal consumption. Transformation protocols have been developed for *Fg* allowing gene/protein function studies in different ways such as overexpression and/or fusions to fluorescence tags. These protocols exploit fungal recombination to insert an expression cassette randomly into the Fg genome. However, this may result in variable gene expression of off-target genes. To address this problem, we identified a 3.2 kb intergenic region contained within a conserved *Fg* locus on chromosome 1 suitable for standardised target site integration (STSI). We created an efficient cloning vector

system based on the Golden Gate method and show evidence that the expression cassette integration into this locus does not affect fungal virulence or fungal growth under different stress conditions. In addition, the activities of a metabolism-dependent promoter and an effector promoter were not altered by STSI. Finally, we established a protocol to study protein secretion in wheat coleoptiles using confocal microscopy and STSI for stable expression of different gene fusions.

Text
Zymoseptoria tritici causes Septoria tritici blotch on wheat. The biotrophic lifestyle of *Z. tritici* makes this fungal pathogen an attractive model to investigate infection phase-specific gene expression. Differential gene expression, Gene Ontology and KEEG enrichment were determined in comparisons among *Z. tritici* during a compatible interaction with the susceptible cultivar Taichung29, two incompatible interactions with the resistant cultivars Veranopolis and Israel493, and one non-host interaction with barley, at 1, 3, 6, 10, 17 and 23 days after inoculation (DAI). We found 978 up-regulated genes at 1 DAI and 2,317 up-regulated genes at 3 DAI in the compatible compared to the non-host interaction. *Z. tritici* activates 1,300 genes at 10 DAI in the compatible compared to the incompatible interactions which correlates with the initiation of the necrotrophic lifestyle. Of the *Z. tritici* genes that are significantly up-regulated at 1 DAI in the compatible interaction, 31 are predicted to be effectors. Examination of the protein sequences of several of the candidate effectors revealed that they likely target specific subcellular organelles, including the nucleus, chloroplasts, and mitochondria. We are currently investigating the subcellular localization patterns of super yellow fluorescent protein (sYFP)-tagged *Z. tritici* effectors using a *Nicotiana benthamiana*-based heterologous expression system.

P3.1-022

RESISTANCE TO SCLEROTINIA SCLEROTIORUM BY OVER-EXPRESSING EXECUTER1, DEFENSIN, SYNTAXIN OF PLANTS (SYP121) OR LECRK A4.3 IN TRANSGENIC BRASSICA NAPUS

BUCHWALDT Lone. (1), FU Fuyou. (1), DAVIES Alan. (1), DURKIN Jonathan. (1), LUI Helen. (1)

(1) Agriculture and Agri-Food Canada, Saskatoon, CANADA

Text
Brassica napus genes conferring resistance to *Sclerotinia sclerotiorum* were identified in a genome wide association study. Selected genes were cloned from resistant lines and together with promoter CaMV35S, transformed into a susceptible control. Homozygous single gene-insert lines were obtained after 3-6 generations. Stems were inoculated with mycelium at full flower to simulate yield loss. To ascertain resistance was long lasting, symptoms were rated 21 days after inoculation (dai). The following four gene products were constitutively expressed in stem tissue, upregulated 1-14 dai, and provided sclerotinia resistance. Importantly Executer1, which causes programmed cell death (PCD) when exposed to $^1O_2$ in photosynthesis, also triggered PCD during the initial oxidative burst caused by infection. Defensin accumulates in vacuoles and has antifungal activity. Syntaxin of plants (*SYP121*) regulates fusion of bilayer lipid membranes vital for secretion of vacuolar contents into the apoplast. Lectin receptor kinase A4.3 in the cell membrane is activated by pathogen-associated molecular patterns that induces defense cascades. Amino acid differences were insignificant between the inserted gene and homolog genes in the control. Resistance was therefore due to the gene promoter which ensured the protein was present before infection and expressed at higher levels than the native protein. Consequently, the above results could not have been obtained using gene modification such as CRISPR.

P3.1-023

GENETIC CHARACTERIZATION AND PATHOGENICITY SCREENING OF FUSARIUM SPP. ISOLATES CAUSING POST FLOWERING STALK ROT IN MAIZE

JAMBHULKAR Prashant. (1), BAJPAI Ruchira. (1), REDDY Harish. (1)

(1) Rani Lakshmi Bai Central Agricultural University, Jhansi, INDIA

Text
Post Flowering Stalk Rot (PFSR) of maize caused by the Fusarium species complex. Seventy-one isolates were collected from 40 sites in five agro-climatic zones of India to assess the diversity of Fusarium spp. associated with maize crops showing symptoms of PFSR in the field. In-vitro, Kharif, and Rabi seasons were utilized to investigate the pathogenicity of Fusarium spp.-causing PFSR. The isolates were judged to be virulent based on their ability to decrease seedling vigour in in-vitro situations and high disease severity in field experiments. Pathogenicity test in Kharif season showed 12 isolates with virulent reactions causing mean severity ranging between 50 to 67% whereas in Rabi season, only five isolates were considered virulent, and the mean severity ranged between 51.9% and 66.7%. Molecular identification of the ten most virulent isolates was from the partial sequence of the Tef-1 α. Based on the examination of pathogenicity in in-vitro, Kharif, and Rabi field trials, ten strains, namely, Fusarium acutatum (FUR11, F10), Fusarium verticillioides (Syn. Fusarium fujikuroi) (Davanagere, Raichur, FUG9, FUR15, F21, F13, and F59), Fusarium andiyazi (F18), (FUR15), recorded the highest diseases index. Morphological characterization, molecular identification, and information on the geographical distribution of virulent Fusarium isolates will be helpful for the efficient management of PFSR, including screening for resistance in maize-inbred lines.

Text

Across kingdoms, exosomes are produced by pathogenic organisms that are associated with signalling for host recognition and invasion, including by fungi and when in contact with their plant hosts. However, very little is known about plant pathogenic fungal exosomes, with data limited to a few early studies. Meanwhile, *Ascochyta rabiei* is an widespread necrotrophic ascomycete fungus that causes significant impact on chickpea production. Very few *A. rabiei* avirulence (avr) factors have been proposed and none have been functionally assessed for how they are delivered to the chickpea plant. Therefore, the current study focuses on determining if *A. rabiei* exosomes are the carrier mechanism for the avr sequences involved in the initial recognition and establishment on chickpea. To determine their presence, exosomes were initially isolated from *A. rabiei* broth cultures through optimised ultrafiltration methods, and morphologically characterized under TEM. This revealed typical cup-shaped structures with double membranes of 30-150 nm in size. Subsequently, ribonucleic acid was extracted from the exosome-concentrated fractions. Methods to remove non-exosome material from the exosome fraction were then optimised and the purified exosome fraction was sent for full transcriptome sequencing with and without exposure to chickpea host material. Differentially expressed transcripts were investigated for those potentially functionally associated with host recognition and early invasion.

OXALIC ACID METABOLISM CONTRIBUTES TO FULL VIRULENCE AND PYCNIDIAL DEVELOPMENT IN THE POPLAR CANKER FUNGUS CYTOSPORA CHRYSOSPERMA

WANG Yuanyuan. (1), WANG Yonglin. (1)

(1) Beijing Key Laboratory for Forest Pest Control, Beijing, CHINA

Text

Poplar Cytospora canker, which is mainly caused by *Cytospora chrysosperma*, is one of the most destructive and widespread tree diseases worldwide. Although oxalic acid (OA) is demonstrated as an important virulence determinant in several necrotrophic fungi, specific functions of OA during pathogenesis remain controversial. Here, we identified three genes (*CcOah*, *CcOdc1*, and *CcOdc2*) directly involved in OA biosynthesis and catabolism in *C.*

chrysosperma. We demonstrated that *CcOah* is required for OA biogenesis. All three genes were found to be highly upregulated during early infection stages of the poplar stem. The deletion of any of the three genes led to an obvious reduction of pycnidial production but no abnormality of hyphal growth and morphology. Furthermore, the individual deletion strain exhibited significantly limited lesion sizes on poplar twigs and leaves. Exogenous application of OA or citric acid can complement the virulence defects of Δ*CcOah* and Δ*CcOdc1* strains. We further found that the Δ*CcOah* strain strongly promoted reactive oxygen species burst of poplar leaves during infection. Finally, induced secretion of OA was observed by monitoring color change of the plates after poplar stem extracts were added in the cultures; however, we failed to quantify OA concentration by high-performance liquid chromatography. Taken together, the present results provide insights into the function of OA acting as an important virulence factor of *C. chrysosperma*.

VDTPS2 MODULATES PLANT SYMPTOM DEVELOPMENT AND STRESS RESPONSES IN VERTICILLIUM DAHLIAE

TANG Chen. (1), XIAO Luyao. (1), KLOSTERMAN Steven J.. (2), WANG Yonglin. (1)

(1) Beijing Forestry University, Beijing, CHINA; (2) United States Department of Agriculture, Salinas, UNITED STATES

Text

Trehalose is critical for protection against several environmental stresses and virulence in plant and human pathogens. Trehalose phosphate synthase/trehalose phosphate phosphatase (TPS/TPP) are widely conserved components of trehalose biosynthesis in fungi. Although the TPS complex has been studied in many fungi, seldom of them have been functionally characterized in the vascular phytopathogenic fungi *Verticillium dahliae*. In this study, we identified the TPS complex including VdTps1, VdTps2, and VdTps3 in *V. dahliae* and found that VdTps1 and VdTps3 appeared dispensable for fungal development, trehalose biosynthesis, and virulence. However, the deletion of *VdTps2* severely restrained growth which is likely caused by abnormal hyphal tip swelling. The Δ*VdTps2* strain showed promoted microsclerotia formation and melanin biosynthesis and is more resistant to cell wall perturbation, reactive oxygen species (ROS) stress, and high-temperature stress. Virulence assays showed that VdTps2 regulates disease symptom development by regulating the spread of V. dahliae in the host above the crown. However, the deletion of *VdTps2* promoted plant colonization by increasing penetration peg formation under ROS stress. Additionally, our results also revealed the role of VdTps2 as a regulator of autophagy. Together, these results indicate that VdTps2 modulates disease development, radial growth, melanized microsclerotia formation, stress response, and autophagy in *V. dahliae*.

P3.1-028

SEPTINS REGULATE VIRULENCE IN VERTICILLIUM DAHLIAE AND DIFFERENTIALLY CONTRIBUTE TO MICROSCLEROTIAL FORMATION AND STRESS RESPONSES

WANG Haifeng. (1), TANG Chen. (1), DENG Chenglin. (1), LI Wenwen. (1), KLOSTERMAN Steven J.. (2), **WANG Yonglin. (1)**

(1) Beijing Forestry University, Beijing, CHINA; (2) United States Department of Agriculture, Salinas, UNITED STATES

Text

Verticillium dahliae is a notorious root-infecting pathogen causing vascular wilt diseases on many woody plant species worldwide. Its infection requires VdSep5 to form a specialized fungus-host interface for effector delivery. However, the roles of other septins are unclear and the different functions of VdSep5 also need to be investigated further in *V. dahliae.* Herein, we characterized and studied the functions of septin-coding genes (*VdSep3*, *VdSep4*, *VdSep5*, and *VdSep6*) in microsclerotia formation and various stress responses. Lossing, any of four septins led to weakened hyphal expansion into plant cells and attenuated virulence. All the septin gene deletion mutants showed an abnormality in chitin distribution but varied in their responses to several stresses examined. VdSep4 and VdSep6 regulated melanized microsclerotia formation positively while VdSep3 and VdSep5 are dispensable for it. Deletion of *VdSep3* or *VdSep4* increased sensitivity to reactive oxygen species (ROS) and reactive nitrogen species (RNS) stress, whereas VdSep6 played a role in RNS stress response but not in ROS stress response. Deletion of *VdSep4* or *VdSep5*, but not *VdSep3*, resulted in hypersensitivity to high-temperature stress. VdSep3 and VdSep4 played a contrary role in response to benomyl. Taken together, our results indicate that four septins play diverse roles in regulating melanized microsclerotia development and stress responses, while they are all required for full virulence in *V. dahliae*.

P3.1-029

TRANSCRIPTOME VARIATIONS IN VERTICILLIUM DAHLIAE IN RESPONSE TO TWO DIFFERENT INORGANIC NITROGEN SOURCES

TANG Chen. (1), **LI Wenwen. (1)**, KLOSTERMAN Steven J.. (2), WANG Yonglin. (1)

(1) Beijing Forestry University, Beijing, CHINA; (2) United States Department of Agriculture, Salinas, Ca, UNITED STATES

Text

Verticillium dahliae causes vascular wilt in hundreds of plant species. Research into the control of this fungus has focused on infection processes such as penetration and effector secretion, but the ability of the fungus to acquire and utilise nutrients is often overlooked and may offer additional potential for formulating new disease control approaches.The molecular mechanisms of nitrogen acquisition and uptake in *V. dahliae* are poorly understood. This study used RNA sequencing and gene expression analysis to investigate differentially expressed genes in response to nitrate and ammonium in *V. dahliae*.In response to nitrate and ammonium treatments, a total of 3244 and 2528 differentially expressed genes, respectively, were identified. The data suggest that nitrate metabolism requires additional energy expenditure, whereas ammonium metabolism reduces certain cellular processes. Furthermore, we showed that mutants of three differentially expressed transcription factors (VdMcm1, VdHapX, and VDAG_08640) exhibited abnormal phenotypes under nitrate and ammonium treatment compared to wild-type. This suggests that nitrogen assimilation requires regulation of the bZIP transcription factor family and involves the cell cycle.Overall, our results reveal convergent and distinct regulatory mechanisms between

preferred (ammonium) and alternative (nitrate) nitrogen metabolism at the transcriptome level, leading to a better understanding of inorganic nitrogen metabolism in *V. dahliae.*

CHARACTERIZATION OF THE PROMOTER OF THE AVIRULENCE GENE AVRPI9 IN THE RICE BLAST FUNGUS MAGNAPORTHE ORYZAE

JANTASURIYARAT Chatchawan. (1), DAMCHUAY Katanyutita. (1), HEMSART Siwaporn. (1), LONGYA Apinya. (1), LEETANASAKSAKUL Kantinan. (2), KIM Ki-Tae. (3), CHUNG Hyunjung. (3), LIM You Jin. (3), YOON Yoon-Ju. (3), LEE Yong-Hwan. (3)

(1) Kasetsart University, Bangkok, THAILAND; (2) National Center for Genetic Engineering and Biotechnology (BIOTEC), Pathumthani, THAILAND; (3) Seoul National University, Seoul, REPUBLIC OF KOREA

Text

Rice Blast disease, caused by the fungus Magnaporthe oryzae, poses a significant threat to global food security. During the interaction between rice and the blast fungus, the fungus's effector proteins encoded by avirulence (Avr) genes are secreted into the plant tissue. This process decreases the plant's defense signals and supports the growth of fungus. In Thailand's rice blast population, AvrPi9 gene is predominantly found, but there is a lack of knowledge on the specific regulatory elements for this gene. In this study, the minimum AvrPi9 promoter was identified and the 200 bp located between -900 to -700 upstream of the promoter was investigated. A protein-DNA pull-down assay was used to identify MoHOX6, which contains a Homeobox domain, as a potential transcription factor for AvrPi9. It was observed that the expression of AvrPi9 was induced 24 and 48 hours after inoculation but was delayed in ΔMoHOX6 mutant. The results suggest that MoHOX6 plays a role in accelerating the expression of AvrPi9. Furthermore, the AvrPi9 promoter was able to direct the expression of the luciferase reporter gene in transfected rice protoplasts. Additionally, co-transfection of the AvrPi9 promoter fused with the luciferase gene and expression of MoHOX6 resulted in a significantly increased luciferase signal. This is the first glimpse into the regulation of the AvrPi9 promoter of M. oryzae and has the potential to advance our understanding of fungal infection mechanisms in the future.

Text
Occurrence and parasitic specialization of large-spored Alternaria species associated with early blight of potato and tomato in Algeria

Ayad D. 1,2,3, Aribi D. 1, Kedad A.1, Simoneau P. 2 and Z .Bouznad1

1 ENSA-El Harrach, Laboratoire de Phytopathologie et Biologie Moléculaire. Algiers, Algeria
2 UMR 1345 IRHS, Université d'Angers-INRA-Agrocampus Ouest, SFR QUASAV, 42 Rue G. Morel, F-49071 Beaucouzé - France
3 ISEN Yncrea Ouest, L@BISEN, 20 rue Cuirassé Bretagne, 29200 Brest - France

Potatoes and tomatoes are two important solanaceous crops in Algeria. The two crops are often grown in succession in many coastal regions. Symptoms of early blight and morphological characteristics of the isolates do not allow a clear distinction between the different species of Alternaria large spored. Using specific primers, PCR/RFLP by double enzymatic digestion of a portion of calmodulin gene and sequence analysis with calmodulin and RPB2 genes, allowed us to identify four distinct species: Alternaria solani, A. linariae, A. grandis and A. protenta. To our knowledge, this is the first report of A. linariae on potato in the world, and the first occurrence of A. protenta as pathogen on potato in Algeria. Pathogenicity tests for the four species, confirmed that all were pathogenic to potato and tomato, with varying virulence. These results suggest that parasitic specialization of these Alternaria species should be reconsidered, and good agricultural practices for the control early blight diseases.

THE RICE BLAST FUNGUS SR PROTEIN 1 REGULATES ALTERNATIVE SPLICING WITH UNIQUE MECHANISMS

SHI Wei. (1), **YANG Jun. (1)**, CHEN Deng. (1), YIN Changfa. (1), ZHANG Huixia. (1), PENG Youliang. (1)

(1) China Agricultural University, Beijing, CHINA

Text
Serine/arginine-rich (SR) proteins are well known as splicing factors in humans, model animals and plants. However, they are largely unknown in regulating pre-mRNA splicing of filamentous fungi. Here we report that the SR protein MoSrp1 enhances and suppresses alternative splicing in a model fungal plant pathogen *Magnaporthe oryzae*. Deletion of *MoSRP1* caused multiple defects, including reduced virulence and thousands of aberrant alternative splicing events in mycelia, most of which were suppressed or enhanced intron splicing. A GUAG consensus bound by MoSrp1 was identified in >94% of the intron or/and proximate exons having the aberrant splicing. The dual functions of regulating alternative splicing of MoSrp1 were exemplified in enhancing and suppressing the consensus-mediated efficient splicing of the introns in *MoATF1* and *MoMTP1*, respectively, which both were important for development and virulence. Interestingly, MoSrp1 had a conserved sumoylation site that was essential to nuclear localization and enhancing GUAG binding. Further, we showed that MoSrp1 interacted with a splicing factor and two components of the exon-joining complex via its N-terminal RNA recognition domain, which was required to regulate mycelial growth, development and virulence. In addition, only orthologues from Pezizomycotina

species could completely rescue defects of the deletion mutants. This study reveals that the fungal conserved SR protein Srp1 regulates alternative splicing in a unique manner.

P3.1-033

BIOLOGICAL CHARACTERISTICS CONTRIBUTING TO VIRULENCE ENHANCEMENT IN FUSARIUM OXYSPORUM F. SP. CUCUMERINUM AFTER THE SELECTIVE PRESSURE OF RESISTANT CUCUMBER

UDDIN Md Jamal. (1), HUANG Xiaoqing. (1), LU Xiaohong. (1), **LI Shidong. (1)**

(1) Institute of Plant Protection, Chinese Academy of Agricultural Sciences, Beijing, CHINA

Text
Cucumber is commonly suffering from Fusarium wilt disease, caused by *Fusarium oxysporum* f. sp. *cucumerinum* (*Foc*). Although resistant cultivars play certain role in Fusarium wilt disease control, the enhancement of virulence of *Foc* has been found after monoculture of wilt-resistance cultivar. To investigate biological characteristics of which contribute to the virulence evolution of Foc, a wild type strain foc-3b (WT) and its virulence-enhanced variant Ra-4 (InVir) were compared in growth characteristics, stress tolerance, and infection process. The InVir strain showed similar culture characteristics on PDA media as the WT strain, but exhibited less pigment accumulation than the WT. The InVir strain produced significantly more conidia with distinctly higher germination rate than the WT strain. In addition, the InVir WT strain produced visible more macroconidia than microconodia, inversely, the WT produced more microconidia than macroconidia. Colony diameter of the InVir strain increased faster than the WT strain on PDA plates, however, mycelia dry weight of the InVir was significantly less than that of the WT harvesting from PDB. The InVir strain exhibited significantly increased tolerance to osmolality. The InVir strain infected and propagated in the cucumber vascular faster than the WT strain. These results would provide insight into the virulence evolution, and help to understand the mechanisms underlying the evolutionary biology of *F. oxysporum*.

Text
During plant-phytopathogen interactions, fungi secrete effector proteins in the host cells to subvert the immune system or alter host metabolism for successful infection. Despite the functions of many effector genes have been elucidated so far, there are only limited information on the mechanisms of regulating *in planta* expression of effector genes. To understand the *in planta* specific expression of effector genes, we characterized the promotor of a nuclear effector gene of *Magnaporthe oryzae*, *MoHTR1*. To identify the cis-elements regulating transcription of *MoHTR1*, we performed a truncation analysis in the promoter region of *MoHTR1* with *sGFP* tagging. By evaluating the fluorescence intensity to determine the promoter activity, we found the 8 bp of cis-element (TATTTCGT). Transversion substitution mutation of these 8-bp sequences led to reduced virulence of the fungal pathogen similar to the deletion of *MoHTR1*. We further unveiled that in planta specific expression of *Slp1* is also regulated by the same *cis*-element of *MoHTR1*. Through promoter switching, we verified that *MoHTR1*'s promoter can induce expression of other genes, which are not expressed during infection, in the biotrophy stage. We are now identifying transcriptional factor(s) binding to this *cis*-element of *MoHTR1* using pull-down assay and yeast one hybrid. This study will provide comprehensive insights into the regulatory mechanisms of *in planta* specific expression of fungal effector genes.

Text
Programmed cell death (PCD) plays an important role in plant immunity against pathogens. SPL11 cell-death suppressor 2 (SDS2), a receptor-like protein kinase, positively regulates PCD by phosphorylating the U-box E3 ligase SPL11, OsRLCK118 and OsRLCK176 that leads to OsRbohB-mediated ROS production and defense activation. However, how SDS2 is activated and how the activation triggers downstream signaling are still unknown. In this study, we performed RNA-seq and identified many up-regulated genes in the SDS2 overexpression line. Among them, the leucine-rich repeat (LRR)-containing gene OsBDG1 was highly induced in the SDS2 overexpression line, and the protein interacted with SDS2 in different interaction assays. The subcellular localization assay showed that OsBDG1 was localized on the cell membrane and in the nucleus. The luciferase and GUS assays indicated that co-expression of SDS2 and OsBDG1 in rice protoplasts led to decreased luciferase and GUS activities compared to the expression of single genes. DAB staining after co-expression of SDS2 and OsBDG1 in N. benthamiana caused ROS accumulation and cell death. Additionally, luciferase complementation imaging assays revealed that OsBDG1 also interacted with OsRbohB, OsRLCK118 and OsRLCK176. Furthermore, we identified an E3 ligase that may regulate the protein level of OsBDG1. These results demonstrate that OsBDG1 might be an important component in the SDS2-mediated cell death and defense pathway in rice.

Text

Fusarium oxysporum f. sp. *cepae* (FOC) is a causal agent of Fusarium basal rot disease of onions, contributing to substantial economic losses worldwide. The FOC genome contains the effector genes *SIX3* and *SIX5*, the functions of which have yet to be determined. In this study, we sought to establish the functions and host cell localizations of SIX3 and SIX5. A *SIX3*-disrupted mutant was found to be characterized by reduced pathogenicity on onion plants susceptible to FOC, whereas a *SIX5*-disrupted strain showed high virulence against FOC-resistant shallot plants. These findings indicate that SIX3 functions as a virulence factor that contributes to determining pathogenicity against onions, whereas SIX5 serves as an avirulence factor against shallots. Immunostaining using anti-SIX3 and anti-SIX5 antibodies was performed to clarify cell localization in the basal plate. In susceptible onion plants, SIX3 and SIX5 proteins were broadly localized in the xylem vessels and apoplastic spaces in basal plates, and FOC spores and mycelia were observed at 21 dpi. Contrastingly, in resistant shallots, we detected comparatively few SIX3 and SIX5 signals, and observed no FOC spores or mycelia. Moreover, yeast two-hybrid assays revealed that SIX3 interacts directly with SIX5. Collectively, our findings indicate that the SIX3 and SIX5 effectors jointly contribute to determining the virulence of FOC against onions by localizing in the xylem and apoplast of the basal plate.

Text

Magnaporthe oryzae snodprot1 homologous protein (MSP1) has been shown to act as a pathogen-associated molecular pattern (PAMPs) and trigger PAMP-triggered immunity (PTI) response including programmed cell death and expression of various defense-related genes in rice. The involvement of several post-translational modifications (PTMs) in the regulation of plant immune response, especially PTI, during pathogen infection is well established, however, the information on the regulatory roles of these PTMs in response to MSP1-induced signaling in rice is currently elusive. Here, we report the phosphoproteome,

ubiquitinome, and acetylproteome to investigate the MSP1-induced PTMs alterations in MSP1 overexpressed rice. Our analysis identified a total of 4,666 PTMs-modified sites in rice leaves including 4,292 phosphosites, 189 ubiquitin sites, and 185 acetylation sites. Among these, the PTM status of 437 phosphorylated, 53 ubiquitinated, and 68 acetylated peptides was significantly changed by MSP1. Functional annotation of MSP1 modulated peptides by MapMan analysis revealed that these were majorly associated with cellular immune responses such as signaling, transcription factors, DNA and RNA regulation, and protein metabolism, among others. Taken together, this study uncovers the MSP1-induced PTM changes in rice proteins and identified several novel components of rice-MSP1 interaction.

Text

In pears, blue mold decay caused by *Penicillium expansum* is a destructive postharvest disease around the world, which leads to stasis of the pear industry and creates substantial economic losses. Transcription factors play a crucial role in the defense of pears against infection, and some of their functions are witnessed. Despite this, the roles of many TFs have not been explored in the defense of pear against *P. expansum*. Therefore, this study used ATAC-seq analysis to screen the TFs of postharvest pear. According to GO enrichment and KEGG pathway to analyze the peak-related genes which were expressed differentially. In our results, the up-regulated genes involved in MAPK signaling pathway-plant, plant hormone signal transduction pathway, plant-pathogen interaction pathway, glutathione metabolism pathway, phenylpropanoid biosynthesis, flavonoid biosynthesis pathway and carotenoid biosynthesis pathway were identified. Especially the transcription factors TGA, gene *SAUR* and *CYCD3* in plant hormone signal transduction pathway and *NCED*, *CYP707A* in carotenoid biosynthesis pathway were differentially regulated. The accuracy of ATAC-Seq analysis of *P. expansum*-infected pear was confirmed by RT-qPCR analysis on twelve randomly selected differentially expressed peak-related genes. In this study, TFs of pears against *P. expansum* were screened by using ATAC-seq, thereby understanding the chromatin-mediated gene regulation in the defense of pear against infection.

CCEG1, A GLYCOSIDE HYDROLASE 12 PROTEIN FROM CYTOSPORA CHRYSOSPERMA, CAN TRIGGER PLANT IMMUNITY BUT IS NOT REQUIRED FOR FUNGAL VIRULENCE

ZHIYE Xu. (1,2)

(1) Universidad de Málaga, Málaga, SPAIN; (2) beijing forestry university, Beijing, CHINA

Text

Phytopathogens secrete numerous effectors to host cells which can facilitate their infection and colonization. However, little is known about the pathogenic mechanism of effectors in the *Cytospora chrysosperma*, the causal agent of canker disease of many woody plants. In this study, we identified five glycoside hydrolase family 12 (GH12) effectors in *C. chrysosperma* genome, which were all significantly upregulated during the infection stage. Among them, *CcEG1*, containing an additional carbohydrate-binding module family 1 domain (CBM1) at the C-terminal, was selected for further analysis. Transient expression found that *CcEG1* was localized to the apoplast region of *Nicotiana benthamiana* and acted as a pathogen-associated molecular pattern (PAMP) to induce cell death, which could also activate the expression of downstream immune signaling pathway. Furthermore, the GH12 domain was sufficient for cell death-inducing activity without the CBM1 domain. Additionally, both the leucine-rich repeat (LRR) receptor-like kinases *NbBAK1* and *NbSOBIR1* were required for *CcEG1* to induce plant defense responses. Intriguingly, *CcEG1* mutant did not affect fungal growth, pathogenicity, and response to cell wall stress factor, but it is required for cellulase degradation. Collectively, our results suggest that cellulase *CcEG1* can be recognized by conserved receptors *NbBAK1* and *NbSOBIR1* to activate plant immune responses.

Text

Botryosphaeria dothidea infects hundreds of woody plants, causing a severe economic loss in apple production through fruit rot and warts, rough skins, and cankers on stems. We described the characterization of proteins containing the LysM domain and BdLM1 containing one LysM domain from B. dothidea. BdLM1 suppressed programmed cell death (PCD) caused by the mouse protein BAX (BT-PCD) through Agrobacterium-mediated transient expression in N. benthamiana and increased the lesion size of Phytophthora nicotianae with the accumulation of H2O2. The expression of BdLM1 was dramatically induced at 6 h in wounded apple fruit, and strongly induced at 7 dpi, peaked at 20 dpi on intact shoots. The knockout mutants of BdLM1 had a significant decrease in disease severity on intact apple shoots (20%), in lesion length on wounded apple shoots (40%), and in lesion size on wounded apple fruit (40%). Moreover, BdLM1 binds chitin and is able to protect fungal hyphae against degradation by plant hydrolytic enzymes. Results here indicated that the LysM effector BdLM1 is required for full virulence of B. dothidea and plays different roles during the colonization of fruit and branches. Furthermore, BdLM1 mediates plant immunity probably via dual functions including the perturbation of the activation of chitin-triggered host immunity and protecting hyphae against chitinases.

Text

One of the main limitations of the cucurbit crops production is the powdery mildew disease, caused by the biotrophic fungus *Podosphaera xanthii*. An integrated management, using several strategies, is carried to control the disease but the application of fungicides is the most effective one. The problem is that *P. xanthii* has been classified by the Fungicide Resistance Action Committee (FRAC) as a pathogen with a high risk of resistance developing, in addition of the strong restrictions on the use of phytosanitary products at a European level. For this reason, new phytosanitary tools are necessary to allow a sustainable control of this devastating disease such as the use of the RNA interference (RNAi) technology. In this work, dsRNA targeting a *P. xanthii* gene, which encodes a protein that appears to be essential for the correct assembly of the fungal cell wall, was evaluated. Preliminary gene silencing results have shown a significant reduction of fungal development on melon plants suggesting that this gene may be a promising target for the control of powdery mildew of cucurbits.

This work has been funded by AEI (PID2019-107464RB-C21).

Text

The rice blast fungus is a devastating fungal disease in rice-cultivated areas worldwide. In 2021, rice leaf and stem blast occurred severely in the northern area (Yeoncheon, Gyeonggi province) of Korea. In order to determine the cause of the outbreak, we investigated the genetic diversity of the rice blast fungus using the genetic variation of the avirulence gene. A total of 165 isolates were collected and subjected to select representatives using repetitive element-based polymerase chain reaction (rep-PCR). Approximately all of the 58 isolates were separated among isolates in over 83% similarity, showing genetically identical of the collected isolates. Based on this result, we selected five representative isolates and then

examined the presence of avirulence genes through pathogenicity test using over 25 near-isogenic lines. Further analysis will be displayed. [This work was supported by a grant from the Rural Development Administration (PJ0152782023).]

Text

Eugenol, widely distributed in various plants including cloves, is a well-known powerful antifungal and antibiotic molecule that is concentrated in hybrid grapevines, notably in the cultivar Baco blanc (*Vitis vinifera x Vitis riparia x Vitis labrusca*) created by F. Baco in the 19th century. Under biotest conditions, by assessing fruit rot incidence and severity, we confirmed that this variety is highly resistant to *Botrytis cinerea* by comparing with two Vitis vinifera cultivars, also of prime importance in the Armagnac region: Folle Blanche and Ugni Blanc. The marked varietal resistance was also confirmed in the vineyards and may arise from differential chemical feature of the berry skin. The Baco blanc berry skin was highly concentrated in eugenol, notably at veraison (1118 to 1478 µg/kg), contrarily to the two other cultivars (e.g. Ugni Blanc 22 to 28 µg/kg). Furthermore, significant intra-varietal differences in *B. cinerea* resistance among six Baco blanc clones were shown in terms of incidence and severity of fruit rot and/or sporulation. These differences in resistance were related to different fruit chemical composition, including the berry skin eugenol content. Finally, a significant negative correlation was highlighted between the fruit technological maturity and the skin eugenol content, allowing us to propose eugenol as a key fruit skin biomarker of the ontogenic resistance of the hybrid cultivar, Baco blanc, to such a major necrotrophic pathogen in grapevine.

Text
Global potato production is plagued by multiple pathogens, among which the Verticillium. dahliae and Fusarium oxysporium is the casual agents of Potato verticillium wilt and potato fusarium wilt respectively. In present study, Agrobacterial mediated transformation system was used to generate transformants of both V. dahliae and F. oxysporum, which were isolated from a single potato diseased sample. A green fluorescent protein (GFP) and a red fluorescent protein (mCherry) tagged isolates of V. dahliae (V.dG9) and F. oxysporum (F.oM4) were used to study the co-infection progression in potato. The results showed that the conidia of two inoculated strains could germinate and the mycelia expanded alone the cortical cells and catheter of the root tip, suggesting that the root tip of potato was the earliest infection site. V.dG9 colonized the vascular bundles much faster than F.oM4 ; however, the mycelium proliferation rate of F.oM4 was significantly faster than that of V.dG9 inside the potato root vascular system. The expansion speed of V.dG9 was much faster than that of F.oM4 above ground tissues. Both V.dG9 and F.oM4 were able to colonize inside the vascular bundles of potato stolons after 35 days of post co-inoculation. However, only the GFP or mCherry signal could be detected separately inside the vascular bundles of the tuber. This is the first study on characterizing co-infection of both V. dahliae and F. oxysporum on potato systematically.

Text
Thousand cankers disease is caused by the fungus *Geosmithia morbida* and threatens *Juglans nigra* trees. Host-pathogen interactions at a molecular level have not been well characterized. Furthermore, the effects of potential disease management strategies on these interactions are unknown. To address this knowledge gap, we used transcriptomic approaches to identify gene expression changes in both host and pathogen following treatment with chemical (PHOSPHO-jet) and biological (RootShield) management strategies. These treatments were compared to water-only controls using 24 trees per treatment (N=72). One week following treatment, 36 trees (12 per treatment) were inoculated with *G. morbida*, and potato dextrose agar (PDA) was used as a negative control. At 14-, 28-, and 56-days post-treatment application (PTA), RNA was extracted and sequenced from canker-bordering phloem tissues. For *J. nigra*, the number of differentially expressed genes (DEGs) between *G. morbida* and control trees declined over time with 4,386 DEGs at day 14 to 148 DEGs at day 56 PTA. Furthermore, *G. morbida* gene expression changed with time, with the greatest number of DEGs (1560) occurring between days 14 and 56 PTA. Additionally, *G. morbida* gene expression in PHOSPHO-jet trees differed from control trees at each sampling date. This study will provide a deeper understanding of mechanisms related to *G. morbida* pathogenicity and identify how management strategies influence pathogen virulence at a molecular level.

Text

Botrytis cinerea is one of the most important pathogens in the tomato industry. The indiscriminate use of chemicals to control *Botrytis* has generated more resistant pathogens and a growing interest in safer alternatives. The study of plant transcriptomic response to infection has traditionally provided a better understanding of crop defense mechanisms. Multiple papers have compared *S. lycopersicum* to more resistant *Solanum* species. However, little research compares the transcriptomic response of contrasting commercial varieties. In this work, we compare the defense response to *Botrytis* of a highly susceptible and traditional Chilean variety (Rosado) with a resistant variety (Marmande). Results show that 4406 genes are downregulated, and 309 genes are upregulated during infection in Marmande compared to Rosado. When the main gene ontology differentially expressed was analyzed both varieties have upregulated processes related to lipid, jasmonic acid, and fatty acid response. However, processes related to hormone and ethylene stimulus were only upregulated in Marmande samples, meanwhile, Rosado samples have upregulated processes related to the salicylic acid pathway, response to oxidative burst, and senescence. Besides, most of the gene ontology categories downregulated are shared in both varieties, including photosynthesis and carbohydrate metabolism. These results are the base to develop new tools to defeat *B. cinerea* infections in commercial and traditional Chilean varieties.

Text
F. graminearum is an important fungal pathogen of cereal crops, responsible for Fusarium head blight disease and the accumulation of harmful mycotoxins in grain products. The cell wall integrity (CWI) pathway of fungi is important for normal fungal growth and reproduction, and plays a role in plant-pathogen interactions. The mitogen-activated protein kinases (MAPKs) cascade, FgBck1-FgMkk1-FgMgv1, is thought to regulate the CWI pathway in F. graminearum, and disruption of any of these 3 genes results in slow growth phenotypes and an apparent loss of virulence. To further characterize this pathway, a series of knockout and overexpression (OX) strains targeting the CWI MAPK cascade are being investigated. OX of FgMgv1 had no effect on growth or virulence. Meanwhile, OX of FgMkk1, either as the wild-type gene or as a presumed 'hyperactive' variant, resulted in slow growth on potato dextrose agar compared with the wildtype strain, similar to observations made of hyperactive mutants of the yeast orthologue. Surprisingly, neither set of FgMKK1 OX strains seem to activate FgMgv1, which is thought to be turned on by FgMkk1. Furthermore, it appears that FgMkk1 is a negative regulator of chemotropic growth towards wheat exudate or horse radish peroxidase, whereas FgMgv1 was previously shown to be necessary for chemotropism. Additional experiments are underway to understand the implications of these results.

Text
Botrytis cinerea is an important pathogen to the tomato industry. The current strategy for *B. cinerea* control is the use of chemical fungicides. However, the indiscriminate use of these chemicals has generated more resistant pathogens and a growing interest in safer alternatives. The recent discovery of bidirectional small RNA transfer between *Solanum lycopersicum* and *B. cinerea* represents a new level of transcriptional regulation with great biotechnological potential. Therefore, in this work we sought to study and identify small RNAs transferred from tomato to the fungus in response to infection and explore new ways to combat the disease. For this purpose, a susceptibility study of twelve commercial tomato varieties to *B. cinerea* was conducted. Marmande and Rosado varieties were the most resistant and susceptible cultivars, respectively. Money Maker showed an intermediate susceptibility. Subsequently, sRNAseq libraries were generated from set of tomato leaves control and inoculated with *B. cinerea* B05.10 and a list of small RNAs differentially expressed in response to the fungus was obtained and their putative mRNAs target in *B. cinerea* were identified. Those sRNA targeting fungi genes involved in virulence and growth were selected. These results will allow us to identify sRNA candidates that are potentially transferred by the plant to the pathogen and that may affect the virulence of the fungus, thus allowing us to explore new alternatives for *B. cinerea* control.

Text

Early blight, caused by Alternaria solani is an economically important disease affecting potato tuber yield worldwide. Chemical plant protection agents mainly control the disease and over-using these chemicals can lead to the evolution of resistant strains. For sustainable early blight management, identifying genetic disease resistance factors is crucial. Therefore, we performed transcriptome sequencing of Magnum Bonum, Désirée, and Kuras potato cultivars with varying levels of early blight resistance at 18 and 36 hours post-infection (hpi) to identify key host genes and pathways in a cultivar-specific manner. The number of differentially expressed genes (DEGs) increased with susceptibility and infection time. Interestingly, the up-regulated DEGs were twice in number as compared to down-regulated ones in all cultivars and time points, except Kuras at 36 hpi. Many transcription factor families were enriched, of which a significant number were up-regulated. Key transcripts involved in the jasmonic acid, ethylene biosynthesis, mevalonate pathway, and terpene biosynthesis were up-regulated across the potato cultivars and time points. Compared to Magnum Bonum and Désirée, multiple components of the photosynthesis machinery, starch biosynthesis and degradation pathways were down-regulated in the most susceptible potato cultivar, Kuras. The results provide important insights into the molecular events at the early stages of disease development and help to shorten the knowledge gap.

Text

Verticillium longisporum is a soil-born fungal species causing sever disease on mainly Brassicaceae family across the world. The fungus secretes diverse small proteins, known as effectors, to evade plant immunity. However, little information is available about the mechanisms of pathogenicity of this species. Genome analysis of the V. longisporum stain VL1, showed that it contains more than 60 candidate effector genes. Transcriptome analyses of 14 candidate genes in this study revealed that the effector genes VIsPLA2 phospholipase, and an endolysin-like gene were highly expressed during the infection on its host. The functional characterization of candidate effectors indicated that overexpression of the VlPLA2

increased virulence of the fungus. Protein expression in E. coli cells, showed that it is an active A2 phospholipase. Transient expression in *Nicotiana benthamiana* plants also confirmed that PLA2 associated with vesicle associated membrane proteins (VAMPs), to be transferred to the nuclear envelope, facilitating the entry to the nucleoplasm, and altering the expression of genes involved in plant defense. Overall, our data indicated that VlPLA2 is a fungal virulence factor targeting host nuclei and suppressing basal plant immunity responses. The results from the current study give us deep knowledge towards understanding the precise role of these lytic enzymes in fungal infection biology.

TRANSCRIPTOMIC RESPONSES CONTROLLING AGGRESSIVENESS OF ASCOCHYTA RABIEI DURING ASCOCHYTA BLIGHT INFECTION IN CHICKPEA

MONSUR Mahmuda Binte. (1), BAR Ido. (1), CHRISTIE Melody. (1), FORD Rebecca. (1)

(1) Griffith University, 170 Kessels Rd, Nathan Qld 4111, AUSTRALIA

Text

Ascochyta blight of chickpea, caused by *Ascochyta rabiei*, is one of the most important foliar diseases in chickpea, with substantial worldwide economic impact on production quality and yield. Foundational research on plant-pathogen molecular interactions have provided clues to the molecular mechanisms underlying *A. rabiei* infection in early stage of chickpea seedlings. These studies identified several signaling molecules (effectors) and transcription factors that have suggested to play key roles in the infection and establishment of the disease. To reveal the underlying molecular mechanisms that contribute to the aggressiveness of *A. rabiei*, a dual RNA-Sequencing approach was chosen to compare the transcriptomic responses of both the plant and the pathogen between highly aggressive and mildly aggressive isolates while infecting vegetative and reproductive parts of chickpea plant. The identified differentially and co-expressed genes have been functionally annotated using homology and domain searches and cross-referenced to a database of *A. rabiei* predicted effector proteins. The results of this study will help to identify the key genes contributing to *A. rabiei* aggressiveness and unravel the pathogen's strategy to overcome the chickpea defense responses. This knowledge will be useful for developing targeted disease management strategies and breeding for resistance chickpea varieties.

Text

In this study, we investigated the global diversity and evolution of two major virulence genes, ToxA and ToxB, in the tan spot pathogen Pyrenophora tritici-repentis. A total of 427 isolates collected from regions across the Americas, Europe, North Africa, the Fertile Crescent, and Asia were analysed. Over the past 30 years, only one haplotype of the necrosis-inducing effector gene ToxA had been reported in tan spot. However, in our study, we identified additional five haplotypes from Argentina, Japan, Canada, and North Africa, all of which induced necrosis on susceptible wheat. We also identified twenty haplotypes in the chlorosis-inducing effector gene ToxB, but only three of these were associated with the ability to induce chlorosis. ToxB upstream sequences revealed the presence of short sequence repeats of 25 nucleotides, present in tandem repeats, that may have an impact on gene expression. We identified ToxB-like proteins in species associated with plant hosts, either as pathogens or endophytes, in the Dothidiomycetes and Sordariomycetes, as well as for the first time in the Leotiomycetes class. All of these ToxB-like proteins exhibited a conserved structure. Most of the mutations in the ToxA and ToxB genes were non-synonymous, indicating that they likely evolved under positive selection pressure. A direct correlation between selection pressure and effector isoform may highlight the importance of exploring the variation in effector-encoding genes at a global scale.

MAIZE ANTIFUNGAL PROTEIN AFP1 ELEVATES FUNGAL CHITIN LEVELS BY TARGETING CHITIN DEACETYLASES AND OTHER GLYCOPROTEINS

MA Lay-Sun. (1), TSAI Wei-Lun . (1), DAMEI Florensia . (1), KALUNKE Raviraj . (1), XU Meng-Yun . (1), LIN Yu-Han. (1)

(1) Academia Sinica, Taiwan, Taipei, TAIWAN

Text

Pathogenic fungi convert chitin to chitosan to evade plant perception and disarm chitin-triggered immune responses. Whether plants have evolved factors to counteract this evasion mechanism remains obscure. Here, we decipher the mechanism underlying the antifungal activity of maize secretory mannose-binding cysteine-rich receptor-like secreted protein (CRRSP), Anti-Fungal Protein 1 (AFP1). AFP1 binds to multiple sites on the surface of sporidial cells, filaments, and germinated spores of the biotrophic fungus *Ustilago maydis*. It inhibits cell growth and budding, as well as spore germination. AFP1 promiscuously interacts with most chitin deacetylases (CDAs) by recognizing the conserved NodB domain to interfere with the enzyme activity. Deletion of O-mannosyltransferase 4 reduces the protein mannosylation, which correlates with reduced AFP1 binding and antifungal activity, suggesting that AFP1 interacts with mannosylated proteins to exhibit an inhibitory effect. AFP1 also has extended inhibitory activity against *Saccharomyces cerevisiae*; however, AFP1 did not reduce binding to the double *Sccda*1,2 mutant, indicating that the targets of AFP1 have expanded to other cell-surface glycoproteins, probably facilitated by its mannose-binding property. Increasing chitin levels by modulating the activity of cell-surface glycoproteins is a universal feature of AFP1 interacting with a broad spectrum of fungi to inhibit their growth.

COLLAPSE OF AERIAL HYPHAE AS A POTENTIAL SIGNAL TO INDUCE PERITHECIUM FORMATION IN THE CEREAL PATHOGEN FUSARIUM GRAMINEARUM

CHOI Yun-Seon. (1), KIM Da-Woon. (1), YUN Sung-Hwan. (1)

(1) Soonchunhyang University, Asan, REPUBLIC OF KOREA

Text

Fusarium graminearum, the causal agent of Fusarium Head Blight in cereal crops, produces a sexual fruiting body (perithecium) on plant debris as an overwintering and dissemination strategy. In an artificial condition (e.g. carrot agar medium), a *F. graminearum* Z3643 strain was able to produce perithecia mostly at the central region of fungal culture where aerial hyphae were naturally collapsed. To explore the molecular mechanism underlying hyphae collapse-mediated sexual development in this fungus, we focused on a total of 699 genes differentially expressed at the collapsed region, among which only 13.9% were overlapped with those controlled at the transcriptional level by the *MAT* loci, master regulators of sexual development in *F. graminearum*. For further functional analysis, we generated transgenic strains of Z3643, which carried single deletions of the selected 26 genes. Most strains exhibited no dramatic changes in hyphal growth and sexual development, but those deleted for 5 genes significantly differed from Z3643 in pattern of hyphae collapse, and/or perithecium formation. Particularly, the deletion strain of FGSG_09210, which was highly induced during hyphal collapse but not regulated by *MAT*, showed no clear hyphal collapse, and produced no perithecia on carrot agar. Taken all together, it is possible that aerial hyphae collapse, if occurred on plant debris, would act as a physical signal leading to sexual development in *F. graminearum* in a natural condition.

Text

Plant cell wall is a dynamic barrier to pathogen infection. Successful pathogens secrete cell wall degrading enzymes (CWDEs) to support their virulence. However, fungal CWDEs could be inhibited by plant inhibitors, such as TAXI-I which inhibits the activity of xylanases from Botrytis cinerea and Aspergillus niger. Whether fungal pathogens have overcome this inhibitory action is less explored. Here, we report that Ustilago maydis effector ALE1 is

upregulated and secreted to the maize apoplast during biotrophic stages to promote fungal virulence. ALE1 is N-glycosylated and has a conserved virulence function among smut fungi in a glycosylation-dependent manner. ALE1 confers its virulence function by interacting with maize TAXI-I, presumably negating its inhibition on U. maydis xylanase Xyn11A. However, glycosylation of ALE1 is not required for the interaction of ALE1 with TAXI-I, suggesting that glycosylation of ALE1 may involve an as-yet-undetermined function. Indeed, a maize hypothetical protein preferentially interacts with un-glycosylated ALE1. This indicates a possibility that glycosylation of ALE1 help in escaping the interference by the hypothetical protein. Our study attempts to reveal the strategy of U. maydis in counteracting maize's sophisticated defense mechanisms at the apoplastic interface between fungus and plant.
Keywords: Ustilago maydis, TAXI, N-Glycosylated ALE1

PATHOGENIC EFFECTOR VMUSP1 CONTRIBUTES TO THE FULL VIRULENCE OF VALSA MALI AND INTERACTS WITH APPLE HEAT SHOCK PROTEIN 70 AS A POTENTIAL TARGET

WANG Chengli. (1), **HUANG Lili. (1)**

(1) Northwest A&F University, Yangling, CHINA

Text
Apple Valsa canker caused by *Valsa mali* results in a huge economic loss each year. Pathogens manipulate host immunity to achieve colonization and infection by secreting effector proteins, which are typically identified based on the presence of signal peptides. Similar to other pathogens, effector proteins are important pathogenic weapons for *V. mali*. Here, we show that an effector protein VmUSP1, not only inhibits BAX-induced cell necrosis but also contributes to the complete virulence of *V. mali*. The pathogenicity of the *VmUSP1* gene knockout mutant was significantly reduced to that of the wild type, and overexpression of *VmUSP1* in apple promoted host susceptibility to V*. mali*. Interestingly, VmUSP1 lacks a typical signal peptide but exhibits characteristics of unconventional secretion. In assays of yeast two-hybrid system, bimolecular fluorescence and, coimmunoprecipitation, it's confirmed that VmUSP1 targets apple (*Malus domestica*) heat shock protein 70 (MdHSP70). MdHSP70 participated in the immune response of apple to *V. mali* and induced the accumulation of callose and reactive oxygen species. In addition, overexpression of *MdHSP70* enhanced the resistance of apple to *V. mali*. However, VmUSP1 greatly compromised the MdHSP70-mediated resistance of apple to *V. mali*. Taken together, our results revealed a mechanism by which a *V. mali* effector protein VmUSP1 promotes the infection of *V. mali* by interfering with MdHSP70-mediated plant immunity.

Text

Development of cereal crop varieties with resistance to Fusarium head blight (FHB) is a main breeding goal worldwide. Currently, AAC Tenacious is the only spring wheat cultivar in Canada to receive a resistant (R) rating to FHB and its resistance is unparalleled. We are integrating genetics, genomics, and host-pathogen responses to elucidate the genetic and physiological mechanisms of resistance in AAC Tenacious. We have performed transcriptomic and histological analyses of AAC Tenacious after inoculation with Fusarium graminearum. In addition, from a cross between AAC Tenacious and Roblin, we evaluated FHB response in a doubled haploid (DH) population grown under inoculated field conditions. A linkage map of 8951 SNP markers (Infinium iSelect 90k SNP wheat array) was generated and QTLs associated with resistance to FHB were identified. In a current project, we have used gamma irradiation mutagenesis of seeds to develop a TILLING population of AAC Tenacious. Through preliminary field evaluations, we have observed that this treatment has induced susceptibility, suggesting some of these mutations have “knocked-out” resistance genes such that they no longer function, resulting in TILLING lines that have become susceptible. By sequencing the genome of AAC Tenacious and comparing that to the DNA sequence of the susceptible TILLING mutants, we can point the exact mutations resulted in the susceptible phenotype.

A VALSA MALI VIRULENCE EFFECTOR VMPR1C REPRESSES APPLE RESISTANCE TO VALSA CANKER BY COMPROMISING MDVQ29-MEDIATED IMMUNITY

HAN Pengliang. (1), WANG Chengli. (1), **HUANG Lili. (1)**

(1) Northwest A&F University, Yangling, CHINA

Text

The pathogenic fungus *Valsa mali* (*Vm*) is the major causal agent of apple Valsa canker (AVC) that causes great economic loss. Effector proteins secreted by the phytopathogens play important roles in virulence to manipulate host immunity. qRT-PCR analysis showed that the effector protein VmPR1c of *Vm* was significantly up-regulated during the early stages of infection, and the virulence of the Δ*VmPR1c* was significantly reduced compared with that of the wild-type strain, indicating that VmPR1c was an important virulence effector of *Vm*. However, the molecular mechanism of its virulence function remains largely unknown. Here, we reported that VmPR1c interacted with a VQ-motif containing protein MdVQ29 and overexpression of *MdVQ29* enhanced apple resistance to AVC. In addition, MdVQ29 interacted with MdWRKY23, which was further shown to bind the promoter of *MdCOI1* and activated its expression. Overexpression of *MdWRKY23* and *MdCOI1* enhanced apple resistance, whereas silencing them attenuated resistance to AVC. Importantly, *MdVQ29*

promoted the transcriptional activity of MdWRKY23, however, *VmPR1c* compromised *MdVQ29*-mediated resistance. Taken together, our findings revealed that the *Vm* effector protein VmPR1c subverts host immunity by targeting disease-resistant related factor MdVQ29 to facilitate infection.

Text
Diversification of effector function, driven by a co-evolutionary arms race, enables pathogens to establish compatible interactions with their hosts. Structurally conserved plant pathogenesis-related PR-1 and PR-1-like (PR-1L) proteins are involved in plant defense and fungal virulence, respectively. However, how fungal PR-1L counteracts plant defense to promote fungal virulence has not been elucidated. Here, we demonstrate that *Ustilago maydis Um*PR-1La and *Saccharomyces cerevisiae Sc*PRY1 localize to the fungal cell surface mediated by their serine/threonine-rich domains to protect against plant phenolics. Despite it, *Um*PR-1La has gained additional specialized activity in eliciting hyphal-like formation upon phenolic perception, suggesting that *U. maydis* deploys *Um*PR-1La to sense environmental signals and direct their growth within the plant host. *U. maydis* also hijacks maize Cathepsin B-like 3 (CatB3) to release a functional CAPE-like peptide upon cleavage of the conserved CNYD motif of *Um*PR-1La to subvert plant immunity and promote fungal virulence. However, it is unclear how CatB3 selectively avoids cleaving plant PR-1s to release CAPE peptides, despite the presence of the same conserved CNYD motif. Our work highlights that *Um*PR-1La has acquired additional functional roles to suppress plant defense and sustain the infection process of fungal pathogens.

Text
Rice blast, caused by the fungal pathogen Magnaporthe oryzae, is one of the most serious rice diseases. The ubiquitin-proteasome system (UPS) is one of the most important protein

turnover mechanisms. Among the three main UPS enzymes, E3 ubiquitin ligases (E3s) are highly flexible and diverse. The regulation mechanism of E3s in the rice-M. oryzae interaction is still unclear. We found the RING-type E3 APIP10 promotes the degradation of two rice transcription factors OsVOZ1 and OsVOZ2, while silencing of OsVOZ1/2 decreases the NLR protein Piz-t accumulation and mediated resistance, indicating that the UPS is essential for the NLR-mediated immunity. Moreover, we found that the U-box-type E3 OsPUB73 positively regulates rice resistance against M. oryzae by promoting the degradation of OsVQ25. Knockout mutants of OsVQ25 exhibit enhanced resistance to the pathogen without a growth penalty, revealed that the E3 fines tune plant immunity and growth. To rapidly identify the cognate E3s of ubiquitinated proteins, we generated a complete ubiquitin E3 library containing 98.94% of the 1515 E3 genes in the rice genome. Using this library, we identified the hub F-box-type E3 OsFBK16 that promoted the degradation of phenylalanine ammonia lyase family (OsPALs). Loss-of-function of OsFBK16 displayed enhanced blast resistance, indicating that OsFBK16 negatively regulates rice immunity. Taken together, these results indicate that E3s play important roles in rice immunity against M. oryzae.

IMPACTS OF MYRTLE RUST DISEASE ON THE SOIL MICROBIAL COMMUNITY ASSOCIATED WITH THE NAÏVE HOST LOPHOMYRTUS BULLATA

PADAMSEE Mahajabeen. (1), DOPHEIDE Andrew. (1), MCCARTHY James. (1), GRELET Gwen. (1), PARK Duckchul. (1), DAVIS Carina. (1)

(1) Manaaki Whenua Landcare Research, Auckland, NEW ZEALAND

Text

Lophomyrtus bullata (ramarama; Myrtaceae) is endemic to New Zealand and although widespread, is now considered threatened due to the ongoing spread of *Austropuccinia psidii,* the causal agent of myrtle rust. *Lophomyrtus bullata* is a shrub or mid-storey tree, which is widespread but uncommon in coastal and lowland forests especially on riparian margins. This species is often present in lowland podocarp riparian forest and is extremely susceptible to myrtle rust. Since it's relatively uncommon, *L. bullata* had not been the focus of many studies until the 2017 myrtle rust incursion into New Zealand. We investigated the associated soil microbial diversity, focussing on fungi and bacteria, in the vicinity of myrtle rust symptomatic and asymptomatic *L. bullata* to assess the impact of the disease on the surrounding soil community. The study site included three 60 metre long transects containing twenty-four 5 × 5 metre subplots; three soil samples were taken from subplots containing at least one tagged *L. bullata* plant. A comprehensive disease assessment of 146 *L. bullata* plants within the transects was conducted simultaneously; over 37500 leaves were assessed for presence of *A. psidii* urediniospores. Five loci were targeted for metabarcoding analyses to cover the microbial diversity present along the disease gradient. We specifically wanted to investigate what, if any, impact this devastating disease has on soil microbial networks.

Molecular aspects of plant-fungal interactions Part 2: Mechanisms of infection

C7.1-1

FUNCTIONAL ANALYSIS OF THE MEP EFFECTOR GENE REPERTOIRE OF THE BLAST FUNGUS MAGNAPORTHE ORYZAE

TALBOT Nicholas. (1)

(1) The Sainsbury Laboratory, Norwich, UNITED KINGDOM

Text

Magnaporthe oryzae is the causal agent of rice blast disease, one of the most serious diseases affecting rice cultivation around the world. During plant infection, M. oryzae forms a specialised infection structure called an appressorium, which uses mechanical force to breach the rice cuticle and utilises a second infection structure, the transpressorium, to move between rice cells. During invasive growth, the blast fungus deploys a large repertoire of at least 546 Mep (Magnaporthe effector protein) effectors, which are expressed in a co-ordinated manner during plant infection. These include structurally conserved ADP-ribosyl transferase and MAX effectors, which are temporally co-regulated. We are investigating the function of the Mep effectors by identifying their host targets based on the generation of transgenic rice and barley lines expressing them and co-immuno-precipitation experiments. In parallel we are analyzing targeted effector mutants and the localisation and delivery of Mep effectors. Using these approaches, we have identified a sub-set of effector proteins that can target host chloroplasts and interact with photosystem II components to suppress chloroplast immunity responses, and a second group associated with transpressorium function. We have also characterized the contribution of effectors to pathogen fitness based on competition assays and identified regulatory proteins necessary for transcriptional regulation of MEP effectors. Progress in the functional characterization of the effector repertoire of M. oryzae will be presented.

C7.1-2

REGULATION OF EFFECTOR GENE EXPRESSION AS CONCERTED WAVES IN LEPTOSPHAERIA MACULANS: A TWO-PLAYERS GAME INVOLVING A CHROMATIN REMODELER AND A SPECIFIC TRANSCRIPTION FACTOR

CLAIRET Colin. (1), GAY Elise J.. (1), PORQUIER Antoine. (1), BLAISE Françoise. (1), MARAIS Claire-Line. (1), BALESDENT Marie-Hélène. (1), ROUXEL Thierry. (1), SOYER Jessica. (1), **FUDAL Isabelle. (1)**

Text
Leptosphaeria maculans is a phytopathogenic fungus responsible for oilseed rape stem canker that displays a particularly complex lifecycle. Different sets of effector-genes are expressed at each stage of oilseed rape infection. Repeat-rich regions of L. maculans genome are enriched in effector-genes specifically expressed during biotrophic stages of infection. These regions show a repressed chromatin state during mycelial growth in vitro. We showed the importance of chromatin remodeling in the control of effector-genes expression. As such, the repressive histone modification H3K9me3 deposited by the methyltransferase KMT1, is involved in the regulation of these genes not expressed in vitro but highly expressed during infection. However, inactivation of KMT1 did not de-repress the expression of effector-genes in vitro at the same level as observed during infection, suggesting additional actors involved, such as transcription factor(s) (TF). We investigated the involvement of Pf2, a fungal specific Zn2Cys6 TF, in the control of effector-gene expression. Deletion of LmPf2 lead to a non-pathogenic mutant. Its over-expression was not sufficient to express effector-genes in vitro. In contrast, its over-expression in a Kmt1 mutant background induced the expression of effector-genes in vitro to the same level as during plant infection. These results demonstrated for the first time a dual control of effector-gene expression involving a chromatin remodeler and an infection specific TF.

Text
The plant cell wall is a major defence barrier against pathogens and a major source of nutrients for colonizing microorganisms. Pathogenic fungi hydrolyse cell wall polymers with a diverse set of secreted cell wall degrading enzymes (CWDEs). Here, we demonstrated that the cellulase ZtCel45A from the wheat pathogen *Zymoseptoria tritici* hydrolyses wheat cell wall cellulose and mixed-linked glucans (MLGs). We showed that *ZtCel45A* is tightly regulated and only expressed at the necrotrophic infection stage. Early misexpression of *ZtCel45A* impairs fungal virulence and enhances the production of cello-oligomers and MLG-oligomers. Exogenous treatment of wheat seedlings with MLG43 and cello-triose enhances resistance to Z. tritici. These results demonstrate that the balance between cell wall degradation and release of resistance-inducers, such as wall damage-associated molecular patterns (DAMPs), by fungal CWDEs governs the outcome of host invasion. We suggest that this balance drives the evolution of fungal CWDE expression regulation to favour plant colonization.

Text

Botrytis cinerea is a wide host range necrotroph. During invasion, it quickly kills host cells and colonizes dead tissue, supported by secretion of CWDE, cell death inducing proteins (CDIPs) and metabolites, and tissue acidification. However, it is still unclear how the fungus induces host cell death. Based on a highly efficient CRISPR/Cas9 protocol, we have constructed a series of up to 22-fold *B. cinerea* mutants, lacking all currently known CDIPs. The mutants showed normal growth, but decreased virulence with increasing numbers of deleted CDIPs. The 22x mutant caused strongly reduced lesion formation on leaves and almost no infection of fruits of different species. High resolution secretome analysis of the mutants confirmed the loss of the deleted CDIPs. The search for remaining CDIPs is ongoing, to generate finally a non-necrotrophic *B. cinerea* mutant. This is one of the first systematic approaches to address functional redundancy of fungal virulence factors. B. cinerea triggers the plant hypersensitive response (HR) as an infection strategy. We assume that CDIPs contribute to HR by activating plant pattern-triggered immunity (PTI). Infection of mutants or silenced tissues of Arabidopsis or tobacco lacking the coreceptors of pattern recognition receptors (PRRs), BAK1 and SOBIR1, did not reveal differences to WT plants in susceptibility against *B. cinerea*. More mutants are tested to identify cell death pathways that are activated by isolated CDIPs and the invading fungus.

Text

Fungal cell walls undergo continual remodeling during hyphal growth, development, infection and adaptation to environmental stress. The cell wall remodeling generates β-1,3-glucan fragments by diverse endo-glycosyl hydrolases (GH), which are well-known pathogen-associated molecular patterns (PAMPs). How fungal pathogens evade the plant immunity triggered by β-1,3-glucan fragments and associated GH proteins is not known. Here, we

report a novel mechanism of immune evasion underlying the suppression of ?-1,3-glucan-triggered plant immunity by the blast fungus Magnaporthe oryzae. An exo-β-1,3-glucanase of the GH17 family, named Ebg1, is found important for fungal cell wall integrity and virulence of M. oryzae. Ebg1 can hydrolyze β-1,3-glucan and laminarin into glucose to prevent β-1,3-glucan-triggered plant immunity, but also acts as a PAMP, independent of its hydrolase activity. Surprisingly, M. oryzae engages an elongation factor 1alpha protein (EF1α) to interact and co-localize with Ebg1 in the apoplast to suppress Ebg1-triggered immunity. Further, both Ebg1 and EF1α are widely distributed in fungi, and their orthologues from Fusarium graminearum were revealed to interact with each other and rescued the phenotype defects in EBG1 and EF1α deletion mutants in M. oryzae. Together, our results suggest that the interaction between Ebg1 and EF1α may be a conserved mechanism whereby fungal pathogens evade plant immunity and safeguard cell wall remodeling during infection.

Text

Ustilago maydis is a biotrophic fungus causing common smut in maize, which is characterized by plant tumors localized to the infected organs. In leaves, U. maydis infection results in two types of tumor cells: hypertrophic cells that develop from mesophyll, and hyperplasic cells which result from de novo cell division of bundle sheath1. Multiple studies have shown that U. maydis virulence depends on the activity of secreted effector proteins2. However, little is known about the mechanistic basis of fungal effectors to orchestrate tumorigenesis. A cross-species transcriptome analysis between U. maydis and the closely related maize pathogenSporisorium reilianum, which does not induce tumors, identified effectors being differentially regulated in both pathogens and likely evolved diversified virulence functions3.

Here, we show that such effectors trigger the formation of plant tumors by modulating host gene transcription. One example is Sts2, which induces the formation of hyperplasic tumor cells. Sts2 acts as a transcriptional activator in the host nucleus, where it activates maize key regulators of leaf meristem development. Besides Sts2, we found at least one additional U. maydis effector that actively modulates maize gene expression to trigger tumor growth and executes a distinct molecular mechanism. Together, our findings show that a fungal pathogen evolved a highly sophisticated molecular toolbox to directly reprogram plant developmental processes to trigger disease.

Text

Pathogen attacks elicit dynamic and widespread molecular responses in plants. While our understanding of plant responses has advanced considerably, little is known of the responses in the asymptomatic “green” regions (AGR) adjoining lesions. Here, we explore spatiotemporal transcriptome data and elemental maps to report the changes in the AGR of two wheat cultivars infected with a necrotrophic fungal pathogen, Pyrenophora tritici-repentis. We show, for the first time, that calcium oscillations are modified in the susceptible cultivar, resulting in possible “frozen” host defence signals at the mature disease stage, and silencing of the host’s recognition and defence mechanisms which would otherwise protect it from further attacks. In contrast, Ca accumulation and heightened defence response was observed in the moderately resistant cultivar. Other findings include the inability of the AGR of the susceptible wheat to recover post disease disruption and expression of eight predicted pathogen proteinaceous effectors. The targeted tissue sampling for gene expression analysis resulted in a unique dataset which creates capability to study plant-pathogen interactions at a higher resolution compared to classic bulk leaf tissue analysis. Collectively, our results highlight the benefits of spatially resolved molecular analysis in providing high-resolution spatiotemporal snapshots of host-pathogen interactions, paving the way for detangling complex disease interactions in crop plants.

Text

Plant diseases risk global food security and significantly limit wheat production. Stripe rust is one of the most wheat-devastating diseases caused by the fungus *Puccinia striiformis* f. sp. *tritici* (*Pst*). The most cost-effective and sustainable solution is the development of disease-resistant food crops carrying resistance genes. *Yr15* encodes a protein with a tandem kinase-pseudokinase architecture designated wheat tandem kinase 1 (WTK1) that confers broad-spectrum resistance to *Pst*. To investigate the transcriptional changes activated by WTK1 in response to infection with *Pst*, we conducted transcriptional time-course analyses of a resistant durum wheat genotype transformed with WTK1 under its native promoter and compared with its susceptible sister line (near-isogenic lines, NILs) after inoculation with *Pst*. Data sets from 80 samples were processed and analyzed using the R package Moanin for

time-course gene expression analysis. Using spline clustering, we identified 10 differentially expressed gene clusters that exhibit various patterns of regulation. Six clusters were upregulated in the resistant line and were enriched in genes involved in pathogen recognition, signal transduction, phytohormone production, and hypersensitive cell death. To conclude, whole transcriptome analysis of wheat NILs revealed that WTK1 activates defense-associated transcriptional reprogramming upon pathogen infection leading to disease resistance.

Text

Brown root rot is a common tree disease affecting a wide variety of fruit trees and woody horticultural trees in tropical and subtropical regions. The pathogen *Phellinus noxius* often causes root rot, making the trees susceptible to falling and resulting in economic losses or safety hazards. Little is known about the pathogenesis of *P. noxius* and how it can infect a wide range of hosts. We found that following inoculation with *P. noxius*, rapid cortical collapse can be observed prior to the appearance of symptoms. To determine whether effectors are involved in the pathogenesis, we analyzed the genome and transcriptome data. We used the ab initio gene prediction method to predict 9,684 coding sequences of *P. noxius*. 472 potential secreted proteins without transmembrane regions were predicted using SignalP6.0 and TMHMM2.0. The small secreted proteins were predicted by EffectorP3.0, and a total of 129 candidate effectors were selected. As a preliminary screening, a set of candidate effector genes from the cDNA of a highly virulent *P. noxius* strain FBS71 infecting *Populus trichocarpa* will be expressed in the *Nicotiana benthamiana* leaves by agroinfiltration method to analyze their function in inducing plant cell death. For the cell death-inducing candidate effector genes, *Agrobacterium*-mediated transformation of the *P. trichocarpa* roots will subsequently be conducted to observe their effects on root tissues and analyze the activation or suppression of plant defense-related genes.

Text

Brown root rot disease, caused by the white rot fungus *Phellinus noxius*, can infect more than 200 hardwood and softwood tree species. However, the pathogenic mechanisms of *P. noxius* remain to be elucidated. In this study, we compared the transcriptomes of high- and low-virulence isolates inoculated on *Populus trichocarpa* and the grain inoculum at 2-day post-incubation. A total of 1305 genes were differentially expressed. Of these, 123 carbohydrate-active enzymes were up-regulated, and 61 of them were *glycoside hydrolase* (*GH*) family proteins. These enzymes might be involved in the degradation of plant tissues, and some of them were known to be virulence factors in other pathogens. In addition, a phytotoxin gene *cerato-platanin* was induced during the infection of *P. noxius*, and a significantly higher level of expression was observed in the high-virulence isolate. On the other hand, the transcriptome data indicated that the pathogenesis-related (PR) genes *PR1*, *glucan endo-1,3-ß-glucosidases* (*PR2*), *chitinases* (*PR4*), *germin-like proteins* (*PR16*), and the cell wall reinforcement genes *extensins*, *pectinesterases*, and *lignin-forming anionic peroxidases* might contribute to the early defence in poplar. These results provide new insights into the early interaction between *P. noxius* and the host, and candidate virulence genes of *P. noxius* will be verified by double-stranded RNA-induced gene silencing.

Text

Stripe rust, caused by *Puccinia striiformis* f. sp. *tritici* (*Pst*), gives great threats to wheat production. Therefore, it is very important to uncover molecular mechanisms of important and conversed *Pst* effectors regulating wheat immunity for sustainable control of stripe rust. We have identified an important glycine-serine-rich effector family PstGSREs and found that PsGSRE1 and PstGSER4 are important pathogenicity factors of Pst. PstGSRE1 and its glycine-serine-rich motif PstGSRE1-m9 could disrupt nuclear localization of TaLOL2 and suppressed ROS-mediated cell death induced by TaLOL2, thus compromising wheat immunity. Interestingly, unlike the PstGSRE1, the PstGSRE4 does not contain m9 motif and does not interact with TaLOL2. Furthermore, we found that PstGSRE4 can interact with TaCZSOD2 and reduce the enzyme activity of TaCZSOD2, indicating that PstGSRE4 can reduce H2O2 accumulation by inhibiting the enzyme activity of TaCZSOD2, thereby promoting Pst infection. Further study revealed that TaGAPDH2 interacts with PstGSRE4 and hijacked by the PstGSRE4 as a plant immunity negative regulator to promote *Pst* infection. Taken together, we systematically analyzed the function of PstGSREs during wheat-*Pst* interactions. Our studies expanded the understanding of the biological functions of rust fungal effectors, and laid a foundation for the development of a lasting and effective

strategy for the prevention and control of wheat stripe rust.

Text
The phytopathogenic genus *Venturia* is composed different pseudo-biotrophic species highly specialized. Among them are *V. oleaginea*, causal agent of olive leaf scab, and *V. inaequalis*, which cause the apple scab. One of the most important control methods for apple scab is the use of resistant varieties, but genetic resistant has been poorly studied in the case of olive scab. In apple, which may be considered here a model pathosysthem for olive, 20 major *V. inaequalis* resistance genes (Rvi) have been identified. In this study, we performed a search for homologs to Rvi in olive by studying both their structural and functional organization. Using the reference sequence of the apple genome (ASM211411v1), we mapped the QTL (Rvi1, Rvi3, Rvi5, and Rvi12) to the corresponding genomic regions in the olive genome assembly (CNAG: Oe9) through BLAST searches. Further analysis based on functional annotation using gene ontology terms (GO) narrowed eventually the list to 28 annotated genes. Specific primers for quantitative real-time PCR have been designed and qPCR assays and transcriptome profiles analysis on contrasting plant material are ongoing.

MTA1-MEDIATED RNA M6A MODIFICATION REGULATES AUTOPHAGY AND IS REQUIRED FOR INFECTION OF THE RICE BLAST FUNGUS

XIAOLIN Chen. (1)

(1) Huazhong Agricultural University, Wuhan, CHINA

Text
In eukaryotes, N6-methyladenosine (m6A) is abundant on mRNA, which plays key roles in the regulation of RNA function. However, the roles and regulatory mechanisms of m6A in phytopathogenic fungi are still largely unknown. Combing with biochemical analysis, MeRIP-seq and RNAseq methods, as well as biological analysis, we showed Magnaporthe oryzae *MTA1* gene is an ortholog of human *METTL4*, which is involved in m6A modification and plays a critical role in autophagy for fungal infection. The Δ*mta1* mutant showed reduced virulence due to blockage of appressorial penetration and invasive growth. Moreover, the autophagy process was severely disordered in the mutant. MeRIP-seq identified 659 hypomethylated m6A peaks covering 595 mRNAs in Δ*mta1* appressorium, 114 m6A peaks was negatively related to mRNA abundance, including several ATG gene's transcripts.

Typically, the mRNA abundance of *MoATG8* was also increased in the single m6A site mutant ?*atg8/MoATG8*^{A982C}, leading to an autophagy disorder. Our findings reveal the functional importance of the m6A methylation in infection of M. oryzae and provide novel insight into regulatory mechanism of plant pathogenic fungi.

Text
Pathogen development in plant tissues can be facilitated by the expression of specific host genes known as susceptibility genes. By targeting these genes, small secreted proteins called effectors act as a key determinants of disease development. Recent works on Fusarium graminearum have described the nature and dynamics of effectors upon early stages of the infection progress, especially by innovative dual-omics approaches of infected and non-infected wheat varieties.
Starting from this relevant effector set, we selected 31 core-effectors shared by different strains and propose their functional validation. A structural characterization of their sequence demonstrated canonical sequences of either chloroplast or nuclear localization signals but failed to define common protein motifs/domains. In order to define the localization of the effectors in the host cell, we designed GFP-fused effector proteins and screened their expression patterns in transient expression in tobacco. Most effectors localized to the plant nucleus with some enrichment in the nucleolus or at the envelope.
Merging all information allowed the selection of a reduced numbers of candidate effectors to determine whether they can physically interact with wheat proteins by using Yeast two-hybrid system along with a specific wheat spike cDNA library. This work will allow connecting effectors to their supposed targets in wheat and will contribute to the identification of new and unpredictable susceptibility genes.

Text
Puccinia striiformis f. sp. *tritici* (Pst), the causal agent of wheat stripe rust, is of massive destructiveness to wheat production worldwide. New variants overcome the resistance of

wheat cultivars due to pathogenic variation. Identification and cloning of an avirulence gene provide an insight into understanding mechanism of virulence variation of Pst in molecular level. We developed a sexual population by crossing CYR32, avirulent to *Yr10* and *Yr26*, and CYR34, virulent to *Yr10* and *Yr26* on Berberis aggregata seedlings. All of F_1 progeny showed resistance at both *Yr10* and *Yr26* loci. A F_2 population consisting of 221 progeny was developed by selfing a F_1 progeny on B. aggregata seedlings, showing identical phenotypes with a avirulence and virulence segregation ratio of 167:54 (≈3:1, $\chi 2 = 0.01$, $P = 0.92$) at either of both loci. These results indicated that avirulence of Pst against *Yr10* and *Yr26* was controlled by an dominant gene with independent effect, respectively. Two DNA bulks of both parental races, together with genome avirulent and virulent DNA bulks were constructed for bulked segregation analysis (BSA). Totally, 210,260 SNPs were obtained, 22,322 of which caused non-synonymous mutations. While InDel detection obtained 34,931 Small InDel. Using the ED and SNP index for association analysis, one candidate region with a genetic interval of 0.02 Mb on Chr14 with 3 candidate genes were obtained, which will facilitate the fine mapping and cloning of both avirulence genes.

Text

Fusarium head blight (FHB) is one of the most harmful diseases affecting cereal crops. Polyphenols provide a protective effect against biotic and abiotic stresses. It is therefore interesting to focus on genotypes with a high concentration of these compounds in the aleurone and pericarp. This research examines the interaction between five different pigmented wheat cultivars (Purendo, Skorpion, Rosso, Vanilnoir and Indigo) and the fungal pathogen Fusarium graminearum. Data obtained from phytopathological experiments and AUDPC calculation, demonstrate that blue aleurone genotypes are highly sensitive to FHB while genotypes with purple pericarp are less sensitive. Notably, Vanilnoir demonstrated a disease incidence identical to the resistant control Sumai3 (less than 10% after 21 days of infection). FDK evaluation and the total phenolic content showed no differences between genotypes. Furthermore, the quantification of the fungal genome by RT-qPCR showed that the pathogen had a lower diffusion in the Vanilnoir cultivar (compared to the more vulnerable varieties such as Skorpion), suggesting the involvement of a type II resistance mechanism. As a further level of investigation, a transcriptomic (mRNAseq) experiment was performed on the Vanilnoir and Rosso cultivars with the aim of identifying genes involved in the mechanisms of SAR induction at 2 days after infection.

Text

Pine needle blights are serious fungal diseases affecting European forests. Brown-spot needle blight disease (BSNB), caused by the phytopathogenic ascomycete *Lecanosticta acicola* (von Thümen) Sydow, is responsible for crown transparency and severe productivity losses. Genetic variation for disease resistance exists among pine species, where *P. radiata* is considered susceptible and *P. pinea* is relative resistant.

The main objective of our work was to explore how *L. acicola* modulates proteome and secretome in the presence of these pines with different degrees of susceptibility to BSNB. *Lecanosticta acicola* was grown in liquid medium (control) and media amendment with *P. radiata* or *P. pinea* needles. The secretome and the cellular proteome were analysed by LC-MS/MS.

The total number of proteins was higher when *L. acicola* faced pine needles. As expected, proteome presented higher number of proteins when compared to secretome.

A differential modulation of *L. acicola* protein profile was observed depending on the pine species. Secretome analysis - which is the host-fungi interface, showed that *L. acicola* expresses proteins able to overcome the first physical plant barrier, the cell wall. Cell wall degrading proteins were particularly overexpressed when *L. acicola* faced *P. pinea*.

This work demonstratesthat the fungus is able to distinguish between hosts and modulate its protein profile set to succeed during the infection process.

Text

Pathogen-associated molecular patterns (PAMPs) play a key role in triggering PAMPs triggered immunity (PTI) in rice. Recently, *Magnaporthe oryzae* snodprot1 homolog (MSP1) has been identified that functions as pathogen-associated molecular pattern (PAMP) and triggering PTI in rice and tobacco. However, potential receptor responsible for recognition of

MSP1 during PTI was elusive until recently. In this study, we successfully identified a putative MSP1 binding receptor (MBR) protein using transcriptomic analysis and showed up-regulation during infection of *M. oryzae*, Cochliobolus miyabeanus, and Xanthomonas oryzae in rice leaves. Moreover, to determine the interaction between MSP1 and MBR proteins, co-immunoprecipitation (Co-IP) assay was performed and it revealed that MSP1 binds with high affinity to the extracellular domain of MBR. Besides, we further confirmed that overexpression of MBR in rice showed enhanced resistance to rice blast disease. However, it still requires further investigation of MBR-MSP1 interaction-mediated downstream signaling during rice-M. oryzae interaction.

Text

Upon perception of biotic stress, some endogenous peptides known as phytocytokines, such as the peptide hormone systemin, are released to the apoplast functioning as endogenous regulators of plant immune responses. When a plant perceives mechanic damage or is attacked by a necrotrophic pathogen or a herbivore, systemin is released from its precursor prosystemin and perceived by specific membrane receptors (SYR1/2) triggering a signalling cascade that induces jasmonic acid-dependent responses. It is possible to enhance plant resistance by using beneficial microorganisms such as Arbuscular Mycorrhiza Fungi. This process is known as Mycorrhiza Induced Resistance (MIR). Previous studies showed that mycorrhizal tomato plants perceive faster *Botrytis cinerea* infection through JA-dependent responses. In this study, to understand why mycorrhizal tomato plants are more sensitive to *B. cinerea* infection, we studied the perception of systemin in tomato mycorrhizal plants, since both, systemin and MIR, involve JA responses. Mycorrhizal plants displayed higher basal levels of systemin compared to control plants. We also observed a priming profile in SYR1/2 gene expression. Finally, SYR1/2-silenced mycorrhizal plants displayed higher disease symptoms, indicating that MIR is mediated by systemin.

Text

Wheat blast caused by the *Triticum* pathotype of *Pyricularia oryzae* is now spreading from South America to Asia and Africa. To control this devastating disease, it is crucial to identify resistance genes, their corresponding avirulence (AVR) genes, and monitor their dynamics. We focused on oat (*Avena sativa*) as a potential source of wheat blast resistance genes. The avirulence of *Triticum* isolate Br48 on oat is controlled by a single gene designated as *PAT1*. Br48ΔPAT1, a *PAT1* disruptant, showed virulence on most of oat cultivars. However, two oat cultivars, Red Algeria (Ot-5) and Winter Culberson (Ot-22), were still resistant to Br48ΔPAT1. These resistant cultivars were crossed with susceptible cultivars, PI173579 (Ot-25) and Byzantina 11 (Ot-28), respectively. Infection assays of these F_2 seedlings with Br48ΔPAT1 suggested that each resistant cultivar carries a single resistance (R) gene. To identify AVR genes corresponding to these R genes, we screened F_1 progeny derived from Br48ΔPAT1 x Br58 (*Avena* isolate) on Ot-5 and Ot-22. Although both Br48ΔPAT1 and Br58 were avirulent on Ot-5, one fourth of the F_1 hybrids showed virulence, suggesting that each parent carry an AVR gene against Ot-5 at different loci. Similar results were obtained on Ot-22. In addition, F_1 hybrids avirulent on both, avirulent on Ot-5 alone, avirulent on Ot-22 alone, and virulent on both segregated in a 9:3:3:1 ratio, suggesting that the AVR genes against Ot-5 and Ot-22 are inherited independently.

Text

The Esca complex of diseases (ECD) is a widespread threat to viticultural panorama worldwide, with varying degrees of severity depending on location. Despite its economic importance, there is still a lack of understanding of the connection between the presence of fungal pathogens in the trunk and the development of typical leaf symptoms. The associated ascomycetes *Phaeomoniella chlamydospora* and *Phaeoacremonium minimum* are found worldwide, while the wood rot basidiomycete species vary according to geographical location. The degradation ability of the European white rot agent *Fomitiporia mediterranea* (Fmed) has been well studied, and recent research has shown that Fmed can trigger both enzymatic and non-enzymatic mechanisms to degrade lignocellulose. However, the phenotypical characteristics and degradation abilities of other grapevines white-rot agents besides Fmed are largely unknown. To fill this gap of knowledge, this study aimed to: i) a phenotypical characterization of the different species, and ii) screen all the major steps of the non-enzymatic radical-generating pathway among the *Vitis*-white rot agents (namely, the ability to acidify the microenvironment, produce Fe^{3+}-reducing compounds, ultimately leading to hydroxy radicals production through redox cycling). The preliminary results indicate

differences both in growth and wood degradation abilities among ECD basidiomycetes, encouraging further research in this direction.

ATTENUATED ISOLATE GIBELLULOPSIS NIGRESCENS VN-1 ENHANCES RESISTANCE AGAINST VERTICILLIUM DAHLIAE IN POTATO

HAO Jianxiu. (1), WANG Dong. (1), MENG Huanwen. (1), ZHOU Hongyou. (1)

(1) Inner Mongolia Agricultural University, Hohhot, CHINA

Text

Abstract: *Verticillium* wilt in potatoes caused by *Verticillium dahliae* is a devastating disease that is difficult to control. To identify potential avenues for disease control, the pathogenicity of 72 *V. dahliae* isolates was tested here. We also tested the resistance to the most virulent isolate (Vd-36) induced by the attenuated isolate *Gibellulopsis nigrescens* Vn-1. Induction of *Verticillium* wilt resistance was strongest when using attenuated isolate Vn-1 to inoculate potatoes with a spore suspension concentration of 1×10^6 conidia mL^{-1}, followed by infection with isolate Vd-36 at 5 d intervals. And reactive oxygen species (ROS) and hydrogen peroxide (H_2O_2) were produced and accumulated in potato leaves 12 h post-inoculation. The changes in respective defense enzymes, except phenylalanine ammonia-lyase, were consistent with the changes in ROS and H_2O_2 levels. Furthermore, the content of salicylic acid (SA) in inoculated plants was higher than the control, and biosynthesis-related genes StNPR1, StPR1b, StPR2, StPR5 were activated. However, there was no significant difference in the jasmonic acid and ethylene (JA/ET) content between the treatment and control groups. These results demonstrated that the attenuated isolate Vn-1 enhanced resistance to *Verticillium* wilt by inducing the SA signalling pathway and weakly activating the JA/ET signalling pathways in potatoes.

Text

Protein crops, like faba beans, are an inexpensive, readily available source of protein, complex carbohydrates, vitamins and minerals, making them a valuable food and feed

commodity. Furthermore, faba bean is an excellent break crop in rotations, and like other legumes, has the potential to reduce N-requirements in the following cereal crop. However, yield instability, associated with abiotic and biotic stresses, has reduced the crops' acceptance by farmers and the production area in Europe remains small.
Chocolate spot (CS) is one of the major diseases compromising yield stability. This work aimed to develop rapid screening methods to identify genetic sources of CS resistance within a diversity panel of 220 faba bean lines (ProFaba), which have been yield-tested in European field conditions.
We successfully established a rapid screening assay for CS using detached leaf assays. Plant material grown in controlled conditions (4-6 weeks) was infected with an Irish isolate of *Botrytis fabae*, using a multiple droplet technique. Lesion development was recorded every 24h, for a period of five days post inoculation, with a digital camera. Lesion area was estimated using image analysis software APS Assess, generating a quantitative phenotype dataset, which was then used in GWAS analysis. This methodology allowed early stage selection of highly susceptible lines as well as tolerant lines. Scoring of intermediate resistance levels required whole plant screening in glasshouse conditions.

Text
Populations of American elm (*Ulmus americana*) were greatly impacted by successive pandemics of Dutch elm disease (DED) caused by *Ophiostoma ulmi* and *O. novo-ulmi*. In order to unravel *Ulmus*-*Ophiostoma* interactions, we inoculated *U. americana* saplings with strains representing the moderately virulent *O. ulmi*, three genetic lineages of the highly virulent *O. novo-ulmi*, the related pathogen *O. himal-ulmi*, and the saprobe *O. quercus*, and analyzed plant and fungal transcriptomes at days 3 and 10 post infection. Differential expression analyses of 8640 *Ophiostoma* genes and over 23000 *U. americana* genes showed that gene expression in both organisms differed depending on the strain inoculated and the length of infection. Genes overexpressed in the more virulent strains of *Ophiostoma* included genes that encode hydrolases that may act synergistically, as well as genes for putative cytoplasmic effectors. Elms genes overexpressed in response to the most virulent strains of *Ophiostoma* were linked to the synthesis of secondary metabolites and to the degradation of xenobiotics. Based on the results of fungal transcripts analysis *in planta*, we produced a first set of CRISPR-*Cas9* targeted deletion mutants for 23 *Ophiostoma* candidate pathogenicity genes and are currently phenotyping *O. ulmi* and *O. novo-ulmi* mutants *in vitro* and *in planta*. Mutants analyzed so far include weakly virulent, virulent, and hypervirulent individuals which will help improve our understanding of DED.

CHROMOSOME-LEVEL GENOME RESOURCE FOR CACAO IDENTIFIES THE GENETIC BASIS FOR RESISTANCE TO VASCULAR STREAK DIEBACK

TOBIAS Peri. (1), DOWNS Jacob. (1), SINGH Gurpreet. (1), PARK Robert. (1), **GUEST David. (1)**

(1) The University of Sydney, Camperdown, AUSTRALIA

Text

Vascular Streak Dieback (VSD) of cacao is caused by the fungal pathogen Ceratobasidium theobromae. The pathogen is an obligate parasite that causes significant crop losses in Southeast Asia and the Pacific and presents a serious biosecurity threat to cacao farming in West Africa and Latin America. VSD resistance has been shown to be highly heritable and durable, with evidence for both qualitative and quantitative resistance. QTLs associated with resistance have been mapped and confirmed on chromosomes 8 and 9 using a population derived from a cross between the cacao genotypes S1 (VSD resistant) and CCN51 (VSD susceptible). Interestingly, one of these QTLs co-localized with a chromosomal region identified for Phytophthora Pod Rot (PPR) and for Frosty Pod Rot (FP) resistance. We built new genome resources for a susceptible progeny and conducted fine scale investigation of these genomic regions to determine the resistance gene complements inherited from both parents. Our investigations provide insights into resistance to VSD and potentially other serious diseases of cacao.

Wheat stripe rust, caused by the Puccinia striiformis f. sp. tritici (*Pst*), is a widespread disease that poses a significant threat to wheat production. Xiaoyan 6, a wheat cultivar conferring high-temperature seedling plant (HTSP) resistance, which is non-race-specific and durable, has maintained consistently resistant to *Pst* for more than 40 years in China, making it the promising candidate for elucidating the genetic basis of the resistance. In our study, we conducted transcriptome sequencing on the *Pst*-infected Xiaoyan 6 seedlings under different temperature conditions and identified 1395 differentially expressed genes (DEGs). Among these DEGs, receptor-like kinase (RLK) genes, *TaXa21*, *TaCRK10*, *TaSERK1* and *TaRIPK*, were identified to serve as the sensors for *Pst* infection and high temperature, which activate a series of defense responses through phosphorylation. In additional to the RLKs,

transcriptional factors *TaWRKY70*, *TaWRKY62* and *TaWRKY45* were involved in defense responses, which might receive the signal from phosphorylated RLKs to regulate the expression of related resistance genes. The resistance genes *TaRPS2* and *TaRPM1* were also found to positively associated with HTSP resistance, as evidenced by accumulation of reactive oxygen species and number of necrotic cells when exposing to *Pst* under high temperature. The insights gained from these results could advance our understanding of the HTSP mechanism, and potentially assist in enhancing and utilizing the resistance.

Text

Pyricularia oryzae is composed of host genus-specific subgroups such as *Oryza* pathotype (PoO), *Setaria* pathotype (PoS), *Eleusine* pathotype (PoE), *Lolium* pathotype (PoL), *Avena* pathotype (PoA) and *Triticum* pathotype (PoT), which are exclusively pathogenic to rice, foxtail millet, finger millet, perennial ryegrass, oat, and wheat, respectively. This host specificity at the genus level is conditioned by gene-for-gene interactions. We previously cloned *PWT3* and *PWT4* conditioning avirulence of Br58 (a PoA isolate) on common wheat and *PWT6* conditioning avirulence of MZ5-1-6 (a PoE isolate) on common wheat. In the present study, we cloned an avirulence gene from Br58 through the map-based method and designated it as *PWT7*. *PWT7* homologs were widely distributed in PoE and PoL isolates and infrequently in PoS, but completely absent in PoT isolates. The *PWT7* homolog found in PoE was one of the five genes involved in its avirulence on wheat. Phylogenetic relationships and distribution of *PWT7*, *PWT6*, and *PWT3* in *P. oryzae* suggested that, in the course of parasitic specialization toward PoT, a common ancestor of PoE, PoA, PoL, and PoT first lost *PWT6*, secondly *PWT7*, and finally the function of *PWT3* through recombination events. *PWT7* or its homologs were located on core chromosomes in PoS and PoE isolates but on supernumerary chromosomes in PoA and PoL isolates. This is an example of inter-chromosomal translocations of effector genes between core and supernumerary chromosomes.

Text
Wheat blast, caused by *Pyricularia oryzae* pathotype *Triticum* (PoT), first emerged in Brazil in 1985 and has recently spread to Asia and Africa. Previously, we identified a resistance gene in common wheat cultivar S-615, and designated it as *Rmg8*. We also identified and cloned its corresponding avirulence gene, *AVR-Rmg8*. Subsequently, we screened 520 worldwide local landraces of common wheat with Br48 (a PoT isolate), and found 18 resistant lines carrying *Rmg8*. In the present study, we screened *Aegilops* spp., ancestral wild species of wheat, and found that 27 out of 201 accessions of *Ae. umbellulata* were resistant to Br48. Interestingly, all resistant accessions were susceptible to Br48ΔA8, an *AVR-Rmg8* disruptant of Br48, but resistant to Br48ΔA8+eI, a transformant of Br48ΔA8 carrying the eI type of *AVR-Rmg8*. This indicated that all resistant accessions of *Ae. umbellulata* recognize *AVR-Rmg8*. In F_2 populations derived from their crosses with susceptible accessions, resistant and susceptible individuals segregated in 3:1 ratios, suggesting that a single major gene is involved in the resistance. On the other hand, crosses among resistant accessions yielded no susceptible individuals, suggesting that all resistant accessions tested share the same resistance gene. This gene should be *Rmg8* (or its homolog) because it recognizes *AVR-Rmg8*. These results suggest that *Rmg8* originated in Triticeae tribe before the differentiation of *Triticum* and *Aegilops*.

TERPENOIDS ARE INVOLVED IN EXPRESSION OF SYSTEMIC INDUCED RESISTANCE IN AUSTRIAN PINE

GHOSH Soumya. (1), ISHANGULYYEVA Guncha. (2), ERBILGIN Nadir. (2), **BONELLO Pierluigi. (1)**

(1) The Ohio State University, Columbus, Oh, UNITED STATES; (2) University of Alberta, Edmonton, CANADA

Text
Phenolics are known to play a critical role in systemic induced resistance (SIR) of Austrian pine to the tip blight and canker pathogen Diplodia pinea. Here, we explored the role of terpenoids in this phenomenon at a very early stage in the interaction. We induced Austrian pine saplings by either wounding or inoculating the lower stems with D. pinea. The seedlings were then challenged after 12 h, 72 h, or 10 d with D. pinea 15 cm above the induction. Lesion lengths and terpenoids were quantified at both induction and challenge locations. Key terpenoids were assayed for antifungal activity in in vitro bioassays. SIR increased over time and was correlated with inducibility of several compounds. α-Pinene and a cluster of b-pinene, limonene, benzaldehyde, dodecanol, and n-dodecyl acrylate were positively correlated with SIR and were fungistatic in vitro, while other compounds were negatively correlated SIR and served as a carbon source for D. pinea. This study shows that, overall, terpenoids are involved in SIR in this system, but their role is nuanced, depending on the type of induction and time of incubation. We hypothesize that some, such as a-pinene, could serve in SIR signaling.

UNCOVERING FUNGAL MICROBIOME ASSOCIATED WITH WINTER PEA NODULES

YURGEL Svetlana. (2), PIERRE-PIERRE Nickisha. (2), MCGEE Rebecca. (2)

(1) USDA ARS, Prosser, UNITED STATES; (2) Grain Legume Genetics and Physiology Research Unit, Prosser, UNITED STATES

Text

Rhizobia are not the only inhabitants in legume nodules. Other nodule-occupying bacteria are known to originate from the soil and interact with the nodule microbiome to affect N fixation and fitness of the host plant. However, little is known about the composition of the nodule-occupying fungal community and its role in establishment and maintenance of effective rhizobium-legume symbiosis. In this study we assessed the composition of the fungal root and nodule microbiome associated with 4 winter pea (Pisum sativum L.) cultivars across several fields in Washington state. Our data indicated that field location was the strongest factor affecting community structure (R2=0.15). Additionally, tissue type and cultivar were also significant factors affecting fungal microbiome. When the community from individual fields were analyzed separately, ~16% and ˜15% of fungal community variation was explained by tissue type and cultivar, respectively. Several fungal genera, including Didymella andFunneliformisI, were differentially represented between the root and nodule microbiomes or between cultivars. The nodule microbiome exhibited less Shannon diversity than the root microbiome. This data indicate that a fungal community is part of the complex interaction between a N-fixing legume-host and the soil microbiome and its role in establishment of effective symbiosis should be further investigated. The cultivar genotype should be also considered as a factor affecting legume-fungi interaction.

Text

Leaf mould is a serious disease of tomato plants and is caused by the fungus *F. fulva*. Resistant tomato varieties can recognize specific *F. fulva* effectors by means of receptors called Cf proteins, resulting in a hypersensitive response. *Cf-9*, which recognizes F. fulva effector *Avr9*, is currently the most widely deployed resistance gene against *F. fulva* and is part of a locus harbouring five homologous genes, of which two are known to contribute to resistance. *Cf-9* itself confers resistance in all stages of growth, whilst its close homolog *Cf-9B* confers resistance to adult plants only. In the last decade, *F. fulva* strains have emerged that break the resistance conferred by both *Cf-9* and *Cf-9B*. It was previously determined that *Avr9* is deleted in these strains, however the identity of *Avr9B* had remained elusive so far. In this study, we identified two major candidates for *Avr9B* by means of a comparative genomics approach, and by means of transient expression and gene complementation assays we identified one of these to be the true *Avr9B* gene. Next, we assessed the allelic variation of *Avr9B* in a large selection of *F. fulva* isolates and found a striking correlation between deleterious mutations in this gene, and the ability to overcome *Cf-9B*-mediated resistance. This work is exemplary for the way in which plant pathogens can evolve to sequentially break down the resistance conferred by an introgressed resistance locus carrying multiple functional resistance genes.

Text

Fusarium head blight (FHB) is one of the most devastating diseases of barley. FHB is caused by a species complex of Fusaria, of which Fusarium graminearum Schwabe is the species responsible for most FHB epidemics. Field surveys show that two or more Fusarium species often co-exist within the same field and F. poae is as another dominant species in barley. This study investigated the effect of the interactions between F. graminearum and F. poae on FHB and mycotoxin accumulation. Two susceptible barley genotypes were spray-inoculated with Fusarium conidiospore suspensions and the disease severity and fungal accumulation was evaluated based on symptom and genomic DNA. There was a significant difference in FHB severity between F. graminearum and F. poae infections, where F. graminearum produced severe FHB disease symptoms while F. poae did not cause FHB. When heads were co-inoculated with both Fusarium species, the resulting FHB severity was unchanged relative to heads inoculated with F. graminearum which was reflected in the DNA quantification of the species. The mycotoxin profile of the co-inoculated treatment appeared to be most influenced by F. graminearum-related metabolites with a minor influence by F. poae-related metabolites. Forty-six features were annotated with metabolite study and which shows F. graminearum appears to outcompete F. poae in its ability to establish infection in barley and as a result contributes the majority of mycotoxin contamination within this crop.

Text

With the increasing availability of high-quality fungal genomes, effectors conserved among species and genera have been uncovered. Two avirulence effectors, AvrLm10A and AvrLm10B, of Leptosphaeria maculans, responsible for stem canker of oilseed rape, are members of such a large family of conserved effectors. AvrLm10A and AvrLm10B are neighboring genes in divergent transcriptional orientation. Sequence searches within the L. maculans genome showed that AvrLm10A/AvrLm10B belong to a multigene family comprising five pairs of genes with similar tail-to-tail organization, specifically expressed during biotrophic stages of infection. Two of the corresponding protein pairs, including AvrLm10A and AvrLm10B, have the ability to physically interact. AvrLm10A homologues were identified in more than 30 Dothideomycete and Sordariomycete plant-pathogenic fungi. One of them, SIX5, is an effector from Fusarium oxysporum f.sp. lycopersici (Fol) physically interacting with the avirulence effector Avr2 and required for the movement of Avr2 from cell-to-cell through plasmodesmata. We demonstrated that members of the AvrLm10A family in L. maculans can complement SIX5 function in plant cell-to-cell mobility assays and Fol virulence. We found that AvrLm10A/SIX5 homologues were associated with at least eight distinct effector families, suggesting an ability to cooperate with different effectors. These results point to a general role of the AvrLm10A/SIX5 proteins as “cooperator proteins”.

VOLATILE ORGANIC COMPOUNDS AS BIOMARKER TO ASSESS THE PHENOTYPE OF SUSCEPTIBLE AND RESISTANT APPLE CULTIVARS

PRATIBHA Pratibha. (1), SIRCAR Debabrata. (1)

(1) IIT ROORKEE, Haridwar, INDIA

Text

Plants of varying genotypes, species, and taxa exhibit unique patterns of volatile organic compound (VOC) emissions, either constitutive or induced. However, the functional correlation between genotypes and phenotypes is not well understood, especially in plant-environment interaction studies. This research aimed to investigate the correlation between genotypes and VOC emissions in apple cultivars to identify potential pheno(chemo)typic

markers for differentiation between origins and provenances. The study analyzed ten different apple cultivars for their VOC emissions using thermal desorption-GC-MS and assessed their potential role in disease resistance. Results showed that resistant cultivars (Florina, Firdous, liberty) emitted more sesquiterpenes than susceptible cultivars and contained distinct markers such as 3-hexanoic acid and benzoic acid-methyl ester. Further investigation revealed that 3-Hexenoic acid exhibited potent antifungal activity against *Venturia inaequalis*, a common apple pathogen, and could serve as a promising alternative to traditional fungicides. The use of 3-Hexenoic acid as a biomarker may help distinguish between susceptible and resistant cultivars, allowing for more targeted and efficient breeding programs. These findings highlight the potential of VOC analysis as a valuable tool for identifying plant genotypes that exhibit desirable traits in terms of pathogen resistance and other key factors.

SIGNIFICANCE OF WHEAT RESISTANCE GENE(S) LOCATED ON CHROMOSOME 1DS AS A HOST BARRIER TO NON-ADAPTED PATHOTYPES OF PYRICULARIA ORYZAE

TSUCHIYA Reina. (1), KANO Hiroyasu. (1), IWAKAWA Mizuki. (1), ASUKE Soichiro. (1), TOSA Yukio. (1)

(1) Kobe University, Kobe, JAPAN

Text

Pyricularia oryzae, a causal agent of blast disease on various gramineous plants, is composed of pathotypes with host specificity at the plant genus level. The avirulence of an *Eleusine* pathotype (specific to finger millet) on common wheat is controlled by at least five genes. Here we report map-based cloning of the fourth avirulence gene, *PWT8*, and identification of its corresponding resistance gene, *Rwt8*. An F_1 culture derived from MZ5-1-6 (*Eleusine* isolate) x Br48 (*Triticum* isolate) was backcrossed with Br48 twice. When resulting BC_2F_1 cultures were sprayed onto wheat cultivar Norin 4 (N4), avirulent and virulent cultures segregated in a 1:1 ratio, suggesting that a single gene condition the avirulence on it. Fosmid clones and their subclones were introduced into Br48. Complementation tests revealed that one predicted ORF on chromosome 4 of MZ5-1-6 conditions avirulence on N4. We designated this gene as *PWT8*. Segregation analyses of F_2 seedlings with Br48+PWT8 (a transformant of Br48 carrying *PWT8*) indicated that N4 carries a single resistance gene corresponding to *PWT8*. This gene was designated as *Rwt8*. Interestingly, a result of molecular mapping with 93 F_3 lines derived from N4×Hope showed that *Rwt8* was closely linked to *Rwt3* and *Rwt6*, previously reported genes involved in the incompatibility between common wheat and MZ5-1-6. There is a possibility that one resistance gene involved in the pathotype- genus specificity corresponds to three different avirulence genes.

Text

As a well-known traditional herbal medicine, ginseng has various pharmacological effects. Ginsenoside, which belongs to the group of triterpenoid saponin, is one of the bioactive compounds of ginseng. Endophytes exist inside of plant tissues and they have harmonious symbiotic relationships with their host plants. Various Trichoderma species have been discovered as one of many endophytic fungi that could increase host plants resistance, and promote plant growth and secondary metabolites of their host plants through various modes of action. Our preliminary study shows that formulated Trichoderma isolates are successfully used as biological control agents, bio-fertilizers, and bio-stimulants (elicitors). We also observe various changes in molecular and metabolic processes after treatment of the fungal endophyte, Trichoderma, isolated from mountain-simulated ginseng. One of our goals is to investigate the role of total metabolite produced by Trichoderma as an elicitor for ginsenoside production. To achieve the objective, it is required to assess the optimal growth condition of the fungal endophyte (carbon / nitrogen sources, temperature, and shaking condition). The extracted total metabolite will be formulated and the effect of ginsenoside induction will be analyzed after treatment into the mountain-simulated ginseng.

Text

Ability to constrict hyphae is essential for go through complex structures in the soil, fungal development, and pathogenesis. The hemi-biotrophic rice pathogen, Magnaporthe oryzae is one of the most socio-economically important crop diseases in the world. During host infection, successful colonization is dependent on the ability of the fungus to move to the adjacent cells through pit field by undergoing severe hyphal constriction up to ~ 0.5 μm. We developed a method to evaluate hyphal constriction ability and investigated its genetic basis in the rice blast fungus. We demonstrated nitrocellulose membranes can be used to test hyphal constriction by monitoring whether the fungus pass through the membrane and form a colony on the underlying medium. Electron microscopy confirmed the passage of M. oryzae is not due to degradation of the membrane but the constriction of hyphae. Assays using mutant lines showed MAP kinase pmk1 mutant, which was shown in previous study to be required for cell-to-cell movement, cannot pass through the membrane. Furthermore, we found M. oryzae sirtuin, MoSir2 is required for the efficient passage of hyphae through the

membrane. Sheath assay for Mosir2 mutant confirmed that cell-to-cell movement of the mutant was not as efficient as that of the wild type. RNA-seq experiments using our assay gives insight into the genomic basis of hyphal constriction. We anticipate that our work would provide a model for studying genetic mechanisms and the evolution of hyphal constriction.

STUDY OF NUCLEOLAR DYNAMICS USING A NUCLEOLAR MARKER MONOP1 IN THE RICE BLAST FUNGUS, MAGNAPORTHE ORYZAE

CHO Eunbyeol. (1), LEE Songhee. (1), KIM Minji. (1), JEON Junhyun. (1)

(1) Yeungnam University, Gyeongsan, REPUBLIC OF KOREA

Text

The nucleolus has emerged as a central hub for nuclear functions in eukaryotic cells. Recent studies in mammals and the model yeast Saccharomyces cerevisiae showed that the nucleolus is essential for nuclear functions including but not limited to ribosome biogenesis. It has been well established that nucleolar functions such as rDNA transcription and subsequent ribosome assembly positively correlate with the size of the nucleolus. However, little is known about the nucleolus of filamentous fungi. Here, we investigated in the plant pathogenic filamentous fungus, Magnaporthe oryzae, changes of nucleoli in response to nutrient availability and infection-related development by monitoring localization of the nucleolar marker protein, MoNOP1 tagged with red fluorescent protein (RFP). This showed that nucleoli of M. oryzae remain constant in size, while nuclei shrank under low nutrient availability. Our observations were further supported by 1) no significant difference in steady-state level of rRNA between nutrient-rich and -poor media and 2) down-regulation of key genes involved in nuclear membrane synthesis. Nucleoli in conidia monitored by the signal of RFP were not very active but became active during appressorium differentiation and maturation. We propose that such distinctive nucleolar dynamics may reflect the strategy of filamentous fungi under low nutrient availability to forage for food resources as well as roles of the nucleolus during fungal development.

JMJD2 GENE ENCODING A HISTONE DEMETHYLASE IS REQUIRED FOR FUNGAL DEVELOPMENT AND PATHOGENICITY THROUGH TRANSCRIPTIONAL REGULATION OF RIBOSOMAL DNA AND NUCLEAR GENES IN THE RICE BLAST FUNGUS

LEE Song Hee. (1,2), KIM Taehyeon. (1), CHO Eunbyeol. (1), JEON Junhyun. (1,2)

(1) Department of Biotechnology, College of Life and Applied Sciences, Yeungnam

University, Gyeongsan, REPUBLIC OF KOREA; (2) Plant Immunity Research Center, Seoul National University, Seoul, REPUBLIC OF KOREA

Text

Histone demethylases play crucial roles in transcription regulation and genome integrity by regulating histone methylation status via interplay with histone methyltransferase. Histone lysine demethylases have been classified into two families, which are JmjC (Jumonji C) and LSD (Lysine Specific Demethylase). Here we report that a JmjC domain-containing histone demethylase, MoJMJD2 regulates transcription of both rDNA loci in nucleolus and a set of nuclear genes, which are development and pathogenesis related genes, via H3K9 and H3K36 demethylation in *Magnaporthe oryzae*. We showed that alternative splicing in *MoJMJD2*, which appears to be generated in an environment-dependent manner generates a protein isoform lacking a putative nucleolar localization sequence. Deletion of *MoJMJD2* led to defects in vegetative growth, asexual reproduction, pigmentation, penetration, invasive growth and cell wall synthesis, and re-introduction of wild-type copy of gene into the mutant was able to complement all these defects. Moreover, rDNA and some of the key conidiogenesis, melanin synthesis and cell wall synthesis genes were directly regulated by MoJMJD2-mediated histone demethylation. Taken together, we propose that MoJMJD2 coordinates transcriptional regulation of rDNA in nucleolus and nuclear genes via histone demethylase activity and alternative splicing, linking ribosome biogenesis to transcription of nuclear genes in response to environmental cues.

INVESTIGATING THE CELL BIOLOGY OF PLANT INFECTION BY THE RICE BLAST FUNGUS MAGNAPORTHE ORYZAE

QUIME Berlaine. (1), YAN Xia. (1), WERE Vincent. (1), RYDER Lauren. (1), TALBOT Nicholas. (1)

(1) The Sainsbury Laboratory, Norwich, UNITED KINGDOM

Text

Rice blast disease, caused by the filamentous, ascomycete fungus, *Magnaporthe oryzae*. is one of the most important limiting factors in rice production. Infection starts when a conidium lands on the leaf surface, carried by wind or splash dispersal. To enter the rice leaf, the fungus forms a dome-shaped infection structure called an appressorium. The melanized appressorium develops a penetration peg, which differentiates into a narrow primary invasive hypha (IH) and subsequently into bulbous invasive hyphae that colonize the first host cell. Previous live-cell imaging studies have demonstrated that IH are surrounded by the extra-invasive hyphal membrane (EIHM), an invagination of the host plasma membrane, which bounds IH as they proliferate in epidermal rice cells. We have generated a series of rice (cv Kitaake) transgenic lines expressing green fluorescent protein (GFP)-labelled subcellular components, including the plasma membrane, endoplasmic reticulum (ER), Golgi, nuclei, F-actin, microtubules, early and late endosomes. Using these transgenic lines, we aim to characterize the temporal development of blast disease and create a spatial atlas of the major cellular changes associated with blast infection, in both compatible and incompatible interactions. We have classified major changes in plasma membrane and F-actin organization and integrity during invasive growth. We will report the major plant cellular changes that accompany host tissue colonization by *M. oryzae*.

Text

Phytopathogens produce a large number of host intracellular effectors to suppress host immune responses by targeting diverse cell organelles, such as nucleus. And nucleus are vital during the growth and immunity of plants. Here, we identified that Hasp170, an early-induced nucleus-targeting effector secreted from the wheat stripe rust pathogen, Puccinia striiformis f. sp. tritici (Pst), could suppress plant immunity. As a virulence factor of Pst, silencing of Hasp170 markedly reduced Pst growth and development. Hasp170 interacted with a novel wheat liquid-liquid phase-separated protein TaMad1. The intrinsically disordered region 1 (IDR1), which was required for driving phase separation of TaMad1, played a crucial role in TaMad1-mediated wheat resistance to Pst. Hasp170 could bind IDR1 domain to disturb the phase-separated bodies formation of TaMad1 in the nucleus and interference the host immunity. Therefore, our data demonstrate that the nucleus-targeting effector Hasp170 suppresses host immunity by disturbing the liquid-liquid phase separation of TaMad1, thereby enhancing the pathogenicity of Pst to wheat.

THREE AVRPM60D CANDIDATE GENES HAVE BEEN ACHIEVED FROM THE HIGH-DENSITY LINKAGE MAPPING METHOD

WENQI Shi. (1), LIJUN Yang. (1)

(1) Institute of Plant Protection and Soil Science, Hubei Academy of Agricultural Sciences, Wuhan, CHINA

Text

Wheat powdery mildew, caused by Blumeria graminis f.sp. tritici (Bgt), poses a serious threat to wheat production worldwide. Monitoring the virulence and diversity of Bgt population can guide the spatio-temporal deployment of R genes in the field. The genetic mapping and cloning of avirulence gene (Avr gene) is the prerequisite and foundation of monitoring Bgt population, and is critical for understanding pathogenesis of Bgt as well as interaction between Bgt and wheat. In this study, Isolates E21 and HB-24 was virulent and avirulent respectively on differentials carrying Pm60d. A cross was performed between the two strains, and a suitable mapping population of 128 progenies was produced. Using denovo sequenceing Bgt isolate 96224 from Switzerland as the reference genome, We performed whole genome re-sequencing of these 128 progenies and generated 20766 SNPs markers to construct the high-density linkage map in 11 chromosomes. Combined with the gene annotation results from reference genome 96224?we identified three candidate genes for AvrPm60d. The construction of high-density linkage map provides a useful platform for genetic mapping of all other Avr genes of Bgt if the parent isolates E21 and HB-24 have

significance difference in the differentials carrying corresponding powdery mildew resistance genes, and it will help us to clone these Avr genes.

NOVEL TRICHODERMA ASPERELLOIDES-NT33 ALLEVIATE WATER DEFICIT STRESS IN SUSCEPTIBLE TOMATO GENOTYPES

RAWAL Ranjana. (1), BENITEZ Maria-Soledad. (2), SCHEERENS Joseph. (2)

(1) Nepal Agricultural Research Council, Lalitpur, NEPAL; (2) The Ohio State University, Wooster, UNITED STATES

Text

Water deficit stress (WDS) is the most destructive abiotic stress limiting global crop productivity. The application of growth-promoting fungi Trichoderma has been established as a sustainable tool to mitigate the negative impact of WDS. However, the mechanism by which Trichoderma inoculation impacts WDS in tomatoes remains unknown. In addition, plant genotype also influences fungal colonization and stress-mitigating potential. This work evaluates the ability of 43 novel isolates from several species of Trichoderma, primarily native to Nepal, to improve growth in different tomato genotypes. The results demonstrate differences in the ability of Trichoderma isolates to confer tolerance to WDS. Trichoderma asperelloides-NT33, isolated from a dry region, delivered consistent performance advantages in tomato partners. NT33 inoculation improves the physiological, and biochemical parameters in drought susceptible tomato genotype ‘Jaune Flamme’ and ameliorates the negative impact of WDS. Further, transcriptomic analysis was conducted to elucidate the key molecular mechanisms involved in WDS response. The study showed that the metabolic pathways involved in secondary metabolite production and antioxidative defense are the key mechanisms adopted by NT33 inoculated plants for the maintenance of homeostasis balance under WDS. This research delivers insights into mechanisms adopted by novel Trichoderma isolates to increase plant growth and induce defense responses in inoculated plants.

Text
Crop wild and domesticated relatives are valuable sources of new resistance gene specificities against fungal plant pathogens. The durability of such resistance gene introgressions is highly variable, a phenomenon that remains poorly understood mainly because the corresponding avirulence effectors are unknown. Until their breakdown, the resistance genes *Pm8* and *Pm17*, located on independent rye to wheat translocations, conferred resistance against the wheat powdery mildew disease caused by *Blumeria graminis* f.sp. *tritici*. We used genome-wide association studies (GWAS) and quantitative trait loci (QTL) mapping in mildew to identify the corresponding *AvrPm8* and *AvrPm17* effectors both encoding small, secreted proteins that are highly expressed during the early stages of infection. Diversity analysis in powdery mildew collections from major wheat growing areas as well as related powdery mildew lineages revealed that several gain-of-virulence variants of *AvrPm17* and one variant of *AvrPm8* are likely ancient and predate the introgressions of *Pm17* and *Pm8* from rye to wheat. We concluded that standing genetic variation can underlie rapid resistance breakdown of introgressed resistance genes. Our studies demonstrate the relevance of pathogen-based genetic approaches to understand resistance gene durability. We, therefore, argue that the effort to identify durable resistance genes cannot be dissociated from studies of pathogen avirulence genes.

THE ECTOMYCORRHIZA FUNGUS PROMOTES GROWTH OF SCOTS PINE SEEDLINGS AND MITIGATES NEGATIVE EFFECTS OF CONIFER ROOT PATHOGEN

WEN Zilan. (1), MANNINEN Minna. (1), ASIEGBU Fred. (1)

(1) University of Helsinki, Helsinki, FINLAND

Text
Mycorrhizal fungi always associate with the roots of plants including forest trees, which can improve the nutrient status of their host plants, influencing disease resistance and growth. In this study, it was hypothesized that mycorrhizal fungal inoculation could improve the growth and disease resistance of Scots pine (Pinus sylvestris L.) against Heterobasidion. annosum. Scots pine seedlings were inoculated with ectomycorrhizal fungus (Suillus luteus) prior to H. annosum infection. The result showed that Scots pines with ectomycorrhizal inoculation grew much better than the seedlings without ectomycorrhizal inoculation. Ectomycorrhizal inoculation was able to promote the growth of the primary roots. Transcriptomic changes due to mycorrhiza or pathogen challenge were monitored. The results will be presented and discussed.

Text
Z. tritici is a hemibiotrophic pathogen, which has an extended latent growth phase through the wheat leaf (approximately two weeks) before inducing necrotic lesion symptoms. The molecular interactions that occur during Z. tritici infection are poorly understood, and so we are examining effectors with the ability to suppress host-immune responses. Among these, we have identified a secreted leucine-rich repeat (Zt-sLRR) that is highly expressed during the biotrophic phase of infection. We have found that the Zt-sLRR is able to suppress pathogen triggered immunity (PTI) when transiently expressed in Nicotiana benthamiana. Structural prediction shows that the Zt-sLRR is predicted to be a structural homologue of extracellular plant immune receptors. We have also identified various plant plasmid membrane-associated proteins that are known to interact with these plant receptors as also being interaction partners of the Zt-sLRR effector. We believe that the effector is functioning as a mimic for plant leucine-rich proteins and inhibits functionality of the BAK1/FERONIA signaling complex and interacting protein partners.

Text
With the drastic change in climate, wheat is affected by multiple biotic stresses that decreases its production. Among others, diseases caused by *Puccinia striiformis f. sp. tritici* pathogen affect wheat production annually. Hence, the development of varieties that confer durable resistance/tolerance to rust infections is a sustainable strategy to control the diseases in wheat. Herein, an RNA-seq approach was utilized to profile differentially expressed genes (DEGs) in response to rust infection in a putative stripe rust resistant Senqu variety that is well grown in South Africa. A total of 713 and 417 significant genes were differentially expressed at 14 and 21 days post infection. Gene annotations revealed upregulation of genes associated with defence response, including the disease resistance proteins, LRR domain proteins and transcription factors, among others. Furthermore, gene ontology analysis showed enrichment of upregulated genes under the molecular function

categories. The expression patterns of these genes have also been associated with both environmental stress responses in various crops including Arabidopsis and rice. Based on our results, the variety used in this study may be considered tolerant to stripe rust. However, more analysis should be done to understand the mechanisms underlying the DEGs profiled in response to stripe rust infection in this variety. Overall, our findings will also assist in paving a way for wheat breeding regimes in SA.

Text

Distribution of wheat blast resistance genes in tetraploid wheat
Yoshino Takahashi, Kohei Morita, Soichiro Asuke, and Yukio Tosa
Graduate School of Agricultural Science, Kobe University, Japan
Wheat blast, caused by *Pyricularia oryzae* pathotype *Triticum* (PoT), is a new threat to the global wheat production. Wheat blast was first reported in Brazil and has recently spread to Bangladesh and Zambia. Previously, we identified two resistance genes in tetraploid wheat cultivar St24 and common wheat cultivar S-615 and designated them as *Rmg7* and *Rmg8*. However, *Rmg8* and *Rmg7* recognize the same avirulence gene, *AVR-Rmg8*, suggesting that these two genes are equivalent to a single gene from the viewpoint of resistance breeding. In the present study, we screened 133 tetraploid wheat accessions (*Triticum turgidum* ssp. *durum* and *T*. *turgidum* ssp. *dicoccoides*) and found that 47 out of 133 accessions were resistant to Br48 (a PoT isolate) at the seedling stage. In the resistant accessions, 38 were susceptible to Br48Δ*A8* (an *AVR-Rmg8* disruptant of Br48), but resistant to Br48Δ*A8*+eI (a transformant of Br48Δ*A8* carrying the eI type of *AVR-Rmg8*), indicating that the majority of the resistant accessions recognized *AVR-Rmg8*. They were inferred to be *Rmg7* carriers. These results suggest that *Rmg7* is widely distributed in tetraploid populations. Alternatively, 9 accessions were resistant to all of the three strains, suggesting that these accessions may carry novel resistance genes to wheat blast.

Text
In reverse genetic, one issue when studying essential or lethal genes is the difficulty to characterize them unless their expression is finely regulated. The Tetracycline-regulated expression system (widely used in eukaryotes) has the potential to circumvent this difficulty. By using tetracycline (or an analog), it is possible to down-regulate (with the Tet-off system) or to up-regulate (with the Tet-on system) the expression of a gene of interest in a concentration-dependent manner. In this study, we focus on the development of the Tet-on and Tet-off systems for inducible gene expression in the phytopathogenic fungus *Botrytis cinerea*. Using classical molecular approaches, coupled with fluorescence microscopy, we are assessing the Tetracycline system in various biological contexts such as axenic cultures and during plant infection. Altogether, this study will bring a molecular tool that will facilitate the functional characterization of essential and lethal genes involved in the development and pathogenicity of the phytopathogenic fungus.

Text
Sweet basil (Ocimum basilicum L.) is a medicinal and aromatic plant with low tolerance to salinity. This conditions its performance to face biotic stresses. Fusarium wilt is a common disease and the causal agent of the production constraint, because of without any symptoms during the growth. However, no effective biological treatment is available to control the disease. In this study, basil plants were submitted to the infection by Fusarium in the presence or absence of treatment of Trichoderma atroviride AT10, under saline stress or mock condition. The phenotypic changes were recorded using non-destructive methods based on digital imaging. The physiological changes were complemented by metabolomic analysis of the leaf using UHPLC-IM-qTOF. Results highlighted that under saline conditions carboxylic acids, and especially amino acids were depleted in basil. These plants reacted upregulating salicylic acid pathway. Moreover, defense compounds like eugenol were detected in non-saline conditions but diminished after salt treatment. Infected plants in contact with Trichoderma AT10 strain increased the synthesis of tetrapyrroles preventing the loss of photosynthetic pigments. Surprisingly, the addition of Trichoderma AT10 strain to the infected plants showed the increase of salicylic acid and ethyl salicylate in a greater way. Overall, these studies provide technical insight of phenotyping into metabolic level and promise to develop microbial solution to control fungal disease.

Text

Magnaporthe oryzae, causes the most serious disease of cultivated rice . The ability of Magnaporthe isolates to infect weeping lovegrass (Eragrostis curvula) was reported to be controlled by a single gene, PWL2. Our data shows that PWL2 belongs to a gene family and unlike other members in the family, PWL2 is present in all limited host forms and outside M. oryzae species. PWL2 occurs as multiple copies in the rice blast genomes and we use CRISPR/Cas9 to generate Dpwl2 mutants in a M. oryzae strain, which has three copies, resulting in gain of virulence towards weeping lovegrass. Additionally, constitutively expressing PWL2 in transgenic rice and barley lead to suppressed reactive oxygen species (ROS) burst suggesting it is involved in modulating PAMP-triggered immunity. We have also performed co-IP/Mass spectrometry from stable transgenic barley plants expressing Pwl2-YFP to reveal a total of 46 proteins in the Hordeum vulgare (barley) proteome database that associated with Pwl2. One of the putative interactors was identified as an isoprenylated heavy metal binding domain containing protein called Hv-HIPP2. We have generated transgenic barley lines expressing Hv-HIPP2 and shown that they are attenuated in response to PTI like transgenic lines expressing Pwl2. Our study provides evidence that Pwl2 belongs to the MAX-fold group of conserved M. oryzae effectors and plays an important role during the biotrophic phase of infection by suppressing ROS burst.

Text

Horizontal gene transfer (HGT) is a tool that many organisms use to rapidly adapt to novel hosts or environments. One well-known example of HGT is the movement of the necrotrophic effector ToxA between three fungal wheat pathogens, *Parastagonospora nodorum, Pyrenophora tritici-repentis* and *Bipolaris sorokiniana*. Defining the extent of horizontally transferred DNA is important because it can define the mechanisms that facilitate

HGT. Our previous analysis of *ToxA* and its surrounding 14 kb showed that this region was a class II DNA transposon we named ToxhAT due to the hAT-like transposase gene near to ToxA. Importantly, there was some evidence that this transposon may remain active and mobile in *B. sorokiniana*. Long-read genome sequencing of eight ToxhAT carrying *B. sorokiniana i*solates confirmed that ToxhAT is an active transposon with a two base-pair "TA" target site duplication. This feature suggests that it should be re-classified as a member of the Tc1/Mariner transposon superfamily. In addition to confirming ToxhAT is an active transposon, these assemblies revealed that ToxhAT was a passenger within a giant transposon (~200kb). This transposon, *Sanctuary I*, has been classified as a giant *Starship* transposon a new transposon family found in fungi. In parallel, the region carrying ToxhAT in *Pyrenophora tritici-repentis* has also been shown to be a mobile Starship, named "Horizon". This indicates two independent captures of the smaller ToxhAT by these large transposons.

Text

Verticillium dahliae is a soil-borne pathogen and the causal agent of Verticillium wilt on a broad range of plants, including tomato. To dissect host resistance, we created bi-grafted plants with scions from near-isogenic lines (NILs) of tomato exhibiting (R, Ve1) or lacking (S, ve1) resistance to race 1 of V. dahliae grafted onto rootstocks of both genotypes. Ten days after inoculation (DAI), scion and rootstock tissues were subjected to differential gene expression and co-expression network analyses. Symptoms only developed in susceptible scions regardless of the rootstock. Although relatively few transcripts mapped to V. dahliae, susceptible rootstocks contained more V. dahliae transcripts than resistant tissues. Signal peptides were common in highly expressed genes. The infection resulted in a dramatic alteration of tomato gene expression in resistant and to a greater extent in susceptible tissues, including pathogen receptor, signaling pathway, PR protein, and cell wall modification genes. Differences in gene expression patterns were observed between scions and rootstocks, primarily related to differences in physiological processes in these tissues. A few genes were associated with the Ve1 genotype, which was independent of infection or tissue type. This research provides a fundamental comprehensive insight into tomato responses to V. dahliae infection and helps further elucidate the tissues and mechanisms associated with resistance to this destructive pathogen.

Text

Clubroot of crucifers, caused by *Plasmodiophora brassicae*, has been detected in more than 80 countries and results in severe yield losses. In Canada, the widespread cultivation of clubroot-resistant canola (*Brassica napus*) cultivars has exerted significant selection pressure on *P. brassicae* populations, leading to the emergence of novel resistance-breaking pathotypes. Transcriptome analysis of the effector repertoire of the resistance-breaking pathotype 3A was conducted at 7, 14, and 21 days after inoculation of resistant and susceptible *B. napus* cultivars. Two highly expressed putative effectors, SPR01261.1 and SPQ99289.1, were chosen for characterization. Each effector's signal peptide was confirmed using a yeast signal sequence trap assay. Both effectors localized to the nucleus and cytoplasm in *Nicotiana benthamiana* when monitored via fluorescent protein tagging. The function of SPR01261.1 and SPQ99289.1 will be assessed using protease and kinase assays, respectively. Experiments are underway to evaluate various heterologous protein expression systems, as *P. brassicae* cannot be cultured axenically since it is an obligate biotroph. The expression, solubility, and activity of each protein will indicate which system is most suitable for expressing *P. brassicae* proteins. Characterization of effectors deployed by the resistance-breaking pathotypes of *P. brassicae* will provide an improved understanding of the molecular interactions between this pathogen and its *B. napus* host.

Text

The plant cell wall (CW), a rigid yet dynamic polysaccharide-protein matrix, is an essential player in plant responses to external stimuli acting as the first physical barrier to outside invaders or stresses and as a source of signals to trigger downstream responses upon perception of incoming threats. CW alteration directly influences stress response pathways, especially during plant reaction to microbes that mainly live in the apoplast, like the vascular pathogenic strains of *Fusarium oxysporum* species complex (*FOSC*) that cause severe disease in more than 100 plant hosts. However, these essential plant CW modification

processes remain largely unknown. The results of the present study showed that the disruption of the gene encoding the *β*-amylase 3 protein (BAM3), the major BAM isoform that degrades starch to maltose, led to increased resistance to *F. oxysporum* f. sp. *raphani* (*For*), since the *bam3* mutant showed the lowest disease incidence and severity and contained smaller amount of fungal DNA in its vascular tissues compared to the wild type (wt) plants. Additionally, our study provides significant insights into the role of the remodeling of cell wall pectin in the regulation of Arabidopsis *bam3* defense against *For*.

NEW QUANTITATIVE TRAIT LOCI (QTL) FOR RESISTANCE TO TAR SPOT IN MAIZE

SINGH Raksha. (1), CRANE Charles. (1), SHIM Sujoung. (2), TELENKO Darcy. (2), GOODWIN Stephen. (1)

(1) USDA-ARS, Crop production and Pest Control Research Unit, Westlafayette, UNITED STATES; (2) Department of Botany and Plant Pathology, Purdue University, West Lafayette, UNITED STATES

Text

Tar spot is a destructive disease of maize that was first discovered in Central and South America but has spread to the USA and Canada since 2015. During the past several years it has become the most important disease in the Corn Belt of the USA. A major quantitative trait locus (QTL) for resistance to tar spot was identified previously in tropical maize germplasm on chromosome 8 with minor QTL on other chromosomes, but a great need for additional resistance remains. To address this deficiency, progeny from the Nested Association Mapping (NAM) population of maize were selected for phenotypic analysis after a difference was identified between the resistant parent CML52 and the susceptible B73. Phenotyping of 197 recombinant-inbred lines of the CML52 by B73 plus the parents during the 2020 and 2021 growing seasons and analysis with existing molecular markers identified a major QTL on chromosome 9, a moderately strong QTL on chromosome 2 and minor QTL on chromosome 1, 4, 5, 7 and 8. The major QTL on chromosome 9 and many of the minor QTL appear to be novel and potentially provide a new source of resistance against the disease. Additional molecular markers in the region containing the QTL on chromosome 9 are being developed and the region is being screened to identify potential candidate genes. Several other NAM parental lines showed strong resistance to tar spot during field trials in North America and could provide a rich source of materials for future breeding programs.

Text

The *Fusarium oxysporum* species complex (*FOSC*) includes soilborne plant pathogens that cause destructive vascular wilt diseases in a wide range of economically important crops leading to high economic losses. Different strategies and means are currently being employed in agriculture to combat Fusarium wilts, with resistant host plant varieties being a key, effective, sustainable, economic and environmentally friendly component of an integrated management program. In the present study, an *Arabidopsis thaliana* mutant with disruption of the gene encoding the *β*-amylase 3 protein (BAM3) showed significantly lower susceptibility to *F. oxysporum* f. sp. *raphani* (*For*) compared with the wild type (wt) plants. To understand the molecular networks of interactions in the above pathosystem, transcriptomic and metabolomic analyses were conducted using DNA microarrays and gas chromatography-mass spectrometry (GC-MS). Alterations in starch degradation, carbohydrate and auxin metabolism were found to be components of Arabidopsis *bam*3 defense against *For*. These findings provide an essential source for the development of Fusarium-tolerant germplasm and cultivars.

IDENTIFICATION AND CHARACTERIZATION OF NOVEL EFFECTOR PROTEINS REGULATED BY THE MAP KINASE PMK1 DURING CELL-TO-CELL MOVEMENT OF THE RICE BLAST FUNGUS MAGNAPORTHE ORYZAE

BAUTISTA Mark Jave. (1), CRUZ-MIRELES Neftaly. (1), YAN Xia. (1), WERE Vincent. (1), MENKE Frank. (1), TALBOT Nick. (1)

(1) THE SAINSBURY LABORATORY, Norwich, UNITED KINGDOM

Text

Rice blast pathogen *Magnaporthe oryzae* secretes a large battery of effectors to inhibit host defence mechanisms. Although effectors are associated to pathogen invasive growth, little is known about their role during cell-to-cell movement. Interestingly, the MAP kinase Pmk1 has been recently shown to regulate effectors when the fungus is moving to the neighbouring cells. In this study, using a comparative proteomics approach, we identified three putative Pmk1-regulated effectors (PREs). PREs are specifically expressed and phosphorylated during transpressorium-mediated cell-to-cell movement. Subcellular localisation of GFP-tagged PRE strains inoculated on rice leaf sheath showed effector expression *in planta* at 26-48 hpi. PRE1 localized at the Biotrophic Interfacial Complex (BIC), while PRE2 and PRE3 were found at the hyphal tip. Preliminary infection assay showed reduced virulence in *pre2* mutant strain compared to the wild-type strain. To identify the host protein targets, barley transgenic lines expressing PREs were generated and subjected to immunoprecipitation-mass spectrometry (IP-MS). Preliminary results of PREs interactomes identified potential host targets related to disease resistance and susceptibility. Furthermore, AlphaFold prediction revealed distinct structures for PREs, with no structural similarities to any known effectors. Overall, this work paves the way for further studies dissecting the functions of cell-to-cell movement effectors during rice blast disease.

Text

Rice blast, caused by Magnaporthe oryzae, is among the most devastating fungal diseases affecting agriculture worldwide. The blast fungus enters plant cells using a specialised dome-shaped structure called an appressorium, which requires the Pmk1 MAP kinase for its morphogenesis. Although the Pmk1 pathway controls phosphorylation changes in the appressorium, little is known about the phosphorylation events on the fungal proteins. Here, we report the phosphorylation landscape of early appressorium morphogenesis in the blast fungus. Using MS1 analysis from a time series study of appressorium samples, we mapped 5,737 phosphosites corresponding to 2,101 proteins. This approach reveals a dramatic rewiring of phosphorylation during early appressorium development. Furthermore, using quantitative phosphoproteomic analysis, we identified 33 putative direct downstream targets of the Pmk1 MAPK during plant infection. One of the targets, named Vts1, is phosphorylated by Pmk1 at two proline-directed sites. Targeted mutation showed that Vts1 is necessary for mycelium growth, sporulation, appressorium development and pathogenicity. Additionally, Vts1 phosphomimetic and phosphodead mutants demonstrated the importance of its phosphorylation. Taken together, our results show how quantitative phosphoproteomics can identify novel regulators, such as Vts1 which are essential for rice blast disease.

MOLECULAR ASPECTS: plant-nematode interactions

C6.3-1

CELLULAR AND MOLECULAR MECHANISMS INVOLVED IN GPA2-MEDIATED EFFECTOR-TRIGGERED IMMUNITY AGAINST POTATO CYST NEMATODES

ZHENG Qi. (1), PUTKER Vera. (1), SLOOTWEG Erik . (1), BERTRAN André. (1), OVERMARS Hein. (1), VAN SCHAIK Casper. (1), VAN DE RUITENBEEK Stefan. (1), SMANT Geert. (1), STERKEN Mark G.. (1), **GOVERSE Aska. (1)**

(1) Laboratory of Nematology, Department of Plant Science, Wageningen University, Wageningen, NETHERLANDS

Text
Cyst nematodes are considered a dominant threat to yield for a wide range of major food crops. Current control strategies of cyst nematodes mainly dependent on crop rotation and the use of resistant crop cultivars. Various crops exhibit single dominant resistance (R) genes able to activate effective host-specific resistance to certain cyst nematode species and/or populations. An example is the potato R gene Gpa2, which confers resistance against the potato cyst nematode Globodera pallida. Gpa2 encodes an intracellular nucleotide binding-leucine-rich repeat (NB-LRR) immune receptor, which is able to specifically recognize the effector GpRBP-1. However, knowledge about the cellular and molecular mechanisms underlying effector detection and the activation of plant immune responses is still largely unknown. Here, we show that effector detection by Gpa2 occurs in the cytoplasm and that both the nuclear and cytoplasmic pools of Gpa2 contribute to effector-triggered immunity in cell death assays and nematode infection tests on transgenic potato roots. Moreover, a comparative transcriptome study was conducted to uncover differential gene expression patterns upon infection of Gpa2 resistant potato roots using virulent and avirulent nematode populations. This revealed specific DEGs involved in the activation of plant defence pathways linked to calcium binding and metabolic activity, systemic acquired resistance, salicylic acid biosynthesis and immune responses.

GENOMIC VARIATIONS ASSOCIATED TO MI-1 RESISTANCE BREAKING DOWN BY MELOIDOGYNE INCOGNITA

ZOTTA MOTA Ana . (1,2), MULTARI Maxime. (1,2), GOULAMHOUSSEN Rahim Hassanaly . (1), DA ROCHA Martine. (1), ZURLETTO Laetitia Perfus-Barbeoch. (1), BOTTINI Silvia. (2), ABAD Pierre. (1), DANCHIN Etienne. (1)

(1) INRAE, Biot, FRANCE; (2) Université Cote d'Azur, Nice, FRANCE

Text
Plants possess resistance genes to a variety of pathogens, allowing them to avoid deleterious effects of infection. Some pathogens were able to overcome these barriers during the course of evolution. One known example is the *Mi-1.2* gene from the tomato *Solanum lycopersicum* conferring resistance to the root-knot nematode *Meloidogyne incognita*. Previous studies in our lab have tested the durability of *Mi-1.2* resistance against *M. incognita*. Tomato plants carrying the resistance gene *Mi-1.2* were inoculated with a load of avirulent nematodes. Collecting the initial few offspring and reinoculating on tomato plants bearing Mi-1.2, allowed the establishment of a resistance-breaking subpopulation after 5 to 10 generations. This same experience was carried out with two initially avirulent populations, from Mexico and Russia, both yielding virulent subpopulations in the lab. We sequenced both populations from Mexico and Russia, and both avirulent and virulent phenotypes, to study whether genomic variations accompany resistance breaking down. Using long-read sequencing, we were able to identify not only single-nucleotide polymorphisms, but also structural variants (> 50 bp) exclusively present in the two virulent subpopulations (Mexico and Russia). We also studied the genome expression profiles of these populations, and whether the different genomic variations could influence the expression of candidate virulence / avirulence genes.

C6.3-3

BEECH LEAF DISEASE: AN EMERGENT THREAT TO BEECH FOREST ECOSYSTEMS

VIEIRA Paulo. (1)

(1) ARS-USDA, Beltsville, UNITED STATES

Text

The beech leaf disease nematode, *Litylenchus crenatae mccannii*, is recognized as a new emergent species that causes beech leaf disease (BLD) in beech trees (*Fagus* spp.) in North America. Since the first report of BLD on *F. grandifolia* in Ohio in 2012, the disease has rapidly spread to other states, such as PA, NY, CT, MA, ME, MI, RI, NJ, WV, and VA, as well as Ontario. Leaf symptoms include swelling and darkening of interveinal tissues as well as chlorosis, while tissue necrosis and leaf curling occur at later stages of the disease. As a result, mortality of nematode infected understory beech trees has been reported after several years of infection in the US. To advance our understanding into this new host-nematode system, we investigated the cellular aspects of this interaction using bright-field and scanning electron microscopy. Our data reveal that these nematodes can induce dramatic morphological changes in both leaf and bud tissues. These cellular changes provide the necessary nutrients for completion of the nematode life cycle, while dramatically affecting bud and leaf morphology. In addition, we used Illumina mRNAseq to obtain insight into the transcriptome of this nematode. Spatial expression of transcripts within the esophageal glands of *L. crenatae mccannii* validated a list of novel effector genes to the Nematoda phylum. These analyses provide additional data for the understanding the mode of parasitism of this new emergent plant-parasitic nematode.

Text

Plant-parasitic cyst nematodes have evolved unique and intimate relationships with their host plants. At the core of these interactions are effectors, proteins that enable nematodes to successfully parasitise their host plant. Effector production is restricted to specialised tissues, primarily two sets of gland cells, in the nematode. Investigation of this spatial confinement allowed us to discover the first regulatory mechanism that unifies effector production in the nematode, and in so doing exposes a potentially attractive target for nematode control.

We used RNA interference to identify a transcriptional regulator of effector production in cyst nematodes: the Subventral Gland Regulator (SUGR). SUGR controls the expression of 261 genes, with 45% of these genes encoding for secreted proteins, including 16 of the known 39 cell wall degrading enzymes. Furthermore, SUGR, in conjunction with the transcription factors that it also activates, directly binds the promoters of effector genes in a partially overlapping manner. Together, this reveals a regulatory network underpinning effector production.

Interestingly, at the top of this network, transcription of *SUGR* itself is activated by a plant-derived small molecule found inside roots of hosts. These data allow us to build a working model for effector regulation that ultimately describes a careful balancing of resource-sparing when you must, and promoting parasitism when it counts.

C6.3-5

DETECTION OF ROOT-KNOT NEMATODES: TRADITIONAL VS. NOVEL APPROACH WITH HYPERSPECTRAL IMAGING

GERIC STARE Barbara. (1)

(1) Agricultural Institute of Slovenia / Kmetijski inštitut Slovenije, Ljubljana, SLOVENIA

Text

Traditional detection of root-knot nematodes (RKN, Meloidogyne spp.) is based on the visual observation of non-specific symptoms such as stunning and wilting and specific symptoms on the roots, i.e. root knots or galls. The next step is sampling, usually followed by extraction of nematodes. Identification can be based on morphological characteristics, analysis of isoenzymes or molecular methods such as PCR. There is increasing evidence of the usefulness of remote sensing for detecting nematode infestations. Remote sensing with analysis of hyperspectral images enables the detection of RKN-infected plants. We have shown that analysis of hyperspectral images of the above-ground parts of potato and tomato plants, as well as images of potato tubers, can enable accurate detection of RKN-infected plants. Detection of nematode infestation by remote sensing has several advantages: Detection without having to uproot the plants (non-invasive approach); Monitoring of large production areas with cameras on tractors, drones or aircraft; Detection in the early stages of infestation in the field (finding small patches of infected plants in the field); Detection in the early stages of plant infection before the plant develops visible symptoms (pre-symptomatic detection); Distinguishing non-specific symptoms on the above-ground plant parts from very similar symptoms of drought. The detection and differentiation of closely related RKN species using hyperspectral analysis will be also discussed.

C6.3-6

SHOOT! WHERE'S MY FEEDING SITE? DEFINING A TISSUE-INDEPENDENT RESPONSE TO NEMATODE PARASITISM.

KRANSE Olaf. (1), WEI Siyuan . (1), SENATORI Beatrice . (1), ZHOU Jie. (2), ZHOU Ji. (2,3), EVES - VAN DEN AKKER Sebastian. (1)

Text

Root-parasitic cyst nematodes establish a unique feeding organ via the re-regulation of endogenous plant genes. A specific combination of gene expression defines the feeding site, some of which will be the ‘core’ to parasitism (i.e. susceptibility genes). Understanding the biology of susceptibility genes has intuitive routes to application in agriculture. In Arabidopsis

thaliana, ~ 5,500 genes are differentially regulated over the course of infection by the beet cyst nematode Heterodera schachtii. To screen mutants in all these genes for susceptibility, using the current state-of-the-art nematode infection assay, would take at least 7 years. In this work, we exploit for utility the underappreciated fact that these nematodes can also induce feeding site formation in aerial parts of the plant. By cross-referencing RNA-seq data from infected roots and infected shoots, we define a tissue-independent parasitism response, substantially reducing the number of putative susceptibility genes. To accelerate screening further, we developed a novel phenotyping platform combining low-cost and open-source 3D printed hardware with computer vision and deep-learning software. We use this novel capacity to conduct an exhaustive screen of mutants in genes that are differentially regulated by the parasite, independent of tissue. Susceptibility genes identified in this way represent attractive targets to engineer resistance using genome editing.

Text

Root-knot nematodes (*Meloidogyne* spp.) have evolved infection mechanisms that involve the secretion of effector proteins into host plants to suppress immune responses and facilitate parasitism in a wide range of land plants. Effector genes are, therefore, attractive targets for the genetic improvement of plant resistance to *M. incognita*. In this study, RNAi-mediated gene silencing of the *Minc03328* and *Minc16803* parasitism genes was used to generate transgenic Arabidopsis plants. We designed a T-DNA construct with the full-length regulatory region of the soybean E2 ubiquitin-conjugation promoter that modulates hairpin-type dsRNA expression in the nuclear genome of *Arabidopsis thaliana*. Data showed that transgenic Arabidopsis expressing the dsRNA-targeting *Minc03328* and *Minc16803* exhibited significantly increased resistance to nematode infection. Gall numbers and egg masses were reduced by up to 81% and 93%, respectively, in the dsRNA-*Minc03328* transgenic lines, whereas the dsRNA-targeting *Minc16803* showed 76% and 87% reduction in the same parameters. Interestingly, histopathological analyses of *M. incognita*-induced galls strongly suggest that both genes may play an important role during the early parasitism stages, encompassing amorphous giant cells with lower cytoplasmic content in the transgenic lines, besides a hallmarked effect on the nematode cuticle, reinforcing their potential as a promising specific target for application in modern crop protection development.

THE LNCRNA6155-MIR169F-HAP2C MODULE REGULATES RICE IMMUNITY AGAINST THE ROOT-KNOT NEMATODE (RKN), MELOIDOGYNE GRAMINICOLA (MG)

XU Xing. (1), KYNDT Tina. (1), NKENGEH Fabrice Ajonglefac. (1)

(1) ugent, Gent, BELGIUM

Text

Non-coding RNAs (ncRNAs) are involved in the regulation of diverse plant biological stresses, but it is unclear if they play a role in rice immunity against *Meloidogyne graminicola* (Mg). In previous transcriptome analyses, rice miR169f and its predicted target genes NF-YAs were differentially expressed after inoculation with Mg. Based on sequence comparisons, we found a lncRNA (lncRNA6155) that contains miR169 endogenous target mimics. It suggests that lncRNA6155 may act as the competitive endogenous RNA of miR169. In this study, we confirmed that the expression level of miR169f was significantly downregulated in rice upon Mg infection. In contrast with miR169f, the levels of lncRNA6155 and of predicted target gene *OsHAP2C* were significantly increased. Transient expression in *N.benthamiana* showed that the expression of *OSHAP2C* and lncRNA6155 was silenced by the overexpression of miR169f. However, the expression of *OSHAP2C* was strongly increased when lncRNA6155 was transiently overexpressed like that of overexpression of a target mimicry (STTM169f) that acts as a sponge to trap miR169f. Exogenous miR169f treatment reduced the expression of lncRNA6155 and *OSHAP2C* and this was associated with decreased root gall formation. Currently, transgenic over-expression lines of lncRNA1655, miR169f, and *OsHAP2C* are being generated. Our results indicate that the lncRNA6155-miR169f-HAP2C module regulates rice resistance to Mg, but more detailed mechanisms should be further investigated.

P6.3-004

UNDERSTANDING THE HYPERVARIABILITY OF HYP EFFECTORS IN POTATO CYST NEMATODES

SONAWALA Unnati. (1), THORPE Peter. (2), JONES John. (3), EVES-VAN DEN AKKER Sebastian. (1)

(1) Crop Science Centre, University of Cambridge, Cambridge, UNITED KINGDOM; (2) School Of Medicine, University Of St Andrews, St Andrews, UNITED KINGDOM; (3) School Of Biology, University Of St Andrews, St Andrews, UNITED KINGDOM

Text

Plant-parasitic nematodes have evolved a large repertoire of effectors. Like many effectors, HYPs are secreted into the host and are necessary for infection. HYP genes consist of a ‘hyper-variable’ domain characterized by variable number, organization, and subfamily-specific repeats. The hyper-variable domain is flanked by 410 and 94 nucleotides that have remained 95% identical for ~30 million years of evolution. The objective of this research is to understand how it is possible for the genome of an animal to permit such variability in a single domain of a gene family, while maintaining the stability of the genome in general, and HYPs in particular. In order to capture the entire HYP gene in a single read we sequenced the genomes of *Globodera pallida* and *Globodera rostochiensis* using long-read sequencing technologies.

Strikingly, we found that the dominant majority of HYP variation is allelic. To unravel the extent of such unprecedented diversity in an allelic series of a single gene, we have performed Cas9-based targeted Nanopore sequencing to enrich for HYP gene containing locus. Additionally, we have performed amplicon sequencing of multiple individuals across the lifecycle using Pacbio HiFi sequencing to understand when and how HYP variation is introduced. Latest results from these efforts at understanding the extent and nature of HYP diversity, and potentially yet unknown biology underlying HYP variation will be presented.

A SMALL CYSTEINE-RICH MELOIDOGYNE JAVANICA EFFECTOR (MJCRSP) MODULATES PLANT IMMUNITY TO PROMOTE NEMATODE PARASITISM

MACHARIA Teresia. (1,2), MOLELEKI Lucy. (1,2)

(1) University of Pretoria, Pretoria, SOUTH AFRICA; (2) Forestry, Agriculture and Biotechnology Institute, Pretoria, SOUTH AFRICA

Text
Root-knot nematodes (RKNs), *Meloidogyne* spp., are among the most important nematodes that evolved towards plant parasitism. The host-nematode interface is mediated by a plethora of effectors, which facilitate intricate parasitic mechanisms. A vast array of potential effector proteins was previously identified from the *M. javanica* genome sequence. However, it is unknown how these effectors contribute to successful nematode infection processes. Here, we characterize a *M. javanica* core effector conserved within important RKN species. This effector encodes a small cysteine-rich secretory protein denoted as MjCRSP. Fluorescence *in situ* hybridization showed that MjCRSP is localized within amphidial glands of pre-parasitic second stage juvenile (J2s) nematodes. *Agrobacterium* transient expression analysis showed that MjCRSP does not induce a hypersensitive response (HR) but rather, suppresses infestin 1 (INF1) triggered cell death (ICD). MjCRSP also subdues defense responses triggered by Flg22. MjCRSP is localized in the nucleus and cytoplasm of *Nicotiana benthamiana* leaves when expressed transiently. Our results provide functional evidence that MjCRSP is a bona fide effector secreted from this nematode's secretory glands into host tissues to interfere with plant immunity and enhance nematode parasitism.

Text
The burrowing nematode (*Radophoulus similis*) is a major pest that causes significant

economic damage in banana cultivation field in Australia, Central and South America, Africa, the Pacific, and the Caribbean, and is therefore managed as a key nematode. It has been designated as a prohibited disease and insect pest in Korea since 1996 and import restrictions on host plants from around the world are being implemented. Recently, there have been concerns about its domestic occurrence, as it has been detected in host plants from Laos and Hungary, leading to urgent restriction measures. Accordingly, we attempted to develop a root-rot nematode classification and diagnostic technology that can quickly identify domestic occurrences using artificially synthesized nucleic acid samples based on the genome information of the burrowing nematode. In this study, real-time PCR was performed using PNA probes, and the results showed that *R.similis* could be distinguished from two closely related species, *R.arabocoffease* and *R.daklakensis*, at a copy level of 10^2. If suspected cases of burrowing nematode occurrence are found in domestic foliage plants, we expect that the results of this study could be helpful for infection monitoring and diffusion information analysis through rapid species diagnosis.

GENETIC DIVERSITY ANALYSIS OF FOUR CYST NEMATODES ISOLATED IN KOREA USING MIG-SEQ ANALYSIS

SONG Seon-Kyeong. (1), KO Hyoung-Rai . (2), YUN Chan-Do. (1), NAM Moon. (1)

(1) genomicbase, Namyangju, REPUBLIC OF KOREA; (2) RDA, Wanju, REPUBLIC OF KOREA

Text

The cyst nematode is agriculturally important pest that cause a lot of damage to domestic cabbage, soybeans, and other crops every year. Since the first outbreak of sugar beet cyst nematode (HS) in 2011 in Taebaek, Gangwon-do, it has continued to spread to nearby cabbage fields, and three species of nematodes, sugar beet cyst nematode (HS), clover cyst nematode (HT), and soybean cyst nematode (HG), are mainly found in domestic cabbage fields. In this study, we performed a relationship analysis of four closely related cyst nematodes collected in Korea through MIG-seq analysis and investigated the genetic differences among the four nematodes. MIG-seq analysis can select thousands of genome-wide SNP markers using the multiplex ISSR genotyping method, and it is very effective for genome-based relationship analysis targeting small samples of nematodes because it can construct NGS libraries using low-quality DNA. The four species of cyst nematodes were subjected to MIG-seq analysis, and the genome-wide SNP markers was selected through various filtering steps and then subjected to phylogenetic tree, PCA, and genetic structure analysis. We were able to identify genetic differences in each of the four species of nematodes and the genetic relationships were also confirmed. The analysis of the genetic diversity of the nematode population using MIG-seq method will provide very important information for the study of genetic differences and relationships among domestic strains.

CHANGES IN THE RHIZOSPHERE MICROBIOME OF WINTER WHEAT LINES WITH VARYING RESPONSE TO ROOT LESION NEMATODE INFECTIONS

CONSOLI Erika. (1), DYER Alan. (1), EBERLY Jed. (2)

(1) Montana State University, Bozeman, UNITED STATES; (2) Montana State University, Central Ag Research Center , Moccasin, Mt, UNITED STATES

Text

Exploiting the rhizosphere microbiome to suppress root diseases is important for advancing sustainable agricultural production. This may be achieved through the deployment of plant phenotypes that favor pathogen suppressive microbial communities. The root lesion nematode, Pratylenchus neglectus (RLN, Pn) represents a major constraint of wheat production worldwide. Toward Pn control, we have bred winter wheat phenotypes displaying significant resistance to Pn in greenhouse trials. Currently, these lines, their susceptible sister lines, and commercial winter wheat varieties are being evaluated in Pn infested fields across Montana. Our aim is to release our first Pn resistant winter wheat cultivar in Montana and to examine the interactions among plant phenotype, nematode induced disease, and the surrounding microbiome. We hypothesize that nematode resistant phenotypes significantly affect the composition and services rendered by the rhizosphere microbiome. The work presented examines differences in nematode and microbial communities as affected by wheat lines with common genetic backgrounds but differing in susceptibilities to Pn. In future work, comparative rhizosphere metagenomic analysis of Pn resistant and susceptible winter wheat lines will be performed to better understand the role of these microbial communities in suppressing RLN.

Text

Plant-parasitic nematodes are a major, and in some cases dominant, threat to food security. The major barrier to identifying new sources of resistance is phenotyping. To address this constraint, we designed and built a bespoke high-throughput, low-cost, and semi-automated phenotyping system that combines custom 3D-printed hardware and deep-learning-powered trait recognition.

Using this unprecedented capability, we screened the Arabidopsis Multiparent Advanced Generation Inter-Cross (MAGIC) population for susceptibility to the beet cyst nematode Heterodera schachtii. All 527 recombinant inbred lines, each with 20 biological replicates (approx. 10,000 plants), were phenotyped 45 times over the following 90-days (some ~400,000 phenotyping events, including tens of millions of nematodes).

This exemplifies a truly holistic (i.e. whole plants) and dynamic (i.e. the whole life cycle) phenotyping approach that sets a precedent in pathology in general. Using these extensive data, we explored novel aspects of strategic and academic merit. Firstly, we used genome

wide association studies to map the plant-loci that contribute to nematode phenotypes (i.e. novel susceptibility and resistance loci). Secondly, we define, with high confidence, new fundamental features of the nature of parasitism.
Taken together, we demonstrate the power of AI to deliver a step change in our understanding of, and ability to control, plant-parasitic nematodes.

Text
The soybean cyst nematode, (SCN; *Heterodera glycines*), is one of the most important of plant parasitic nematodes in soybean fields, which has distributed widely in the world. Most important management procedure of SCN is integrated management by applying the resistant cultivars, cultivation of non-host crops and proper rotation. In this study, 21 soybean cultivars and lines were evaluated to SCN in infested field. Katool resistance cultivar and Williams susceptible cultivar are used as controls. In field experiment, a plot with infestation history were selected in a soybean field in Mazandaran province and after preparation the plot, each line was planted in 3 meters lines. A randomized complete block design was followed for implementing the experiment containing three replications for each line. After the end of growing season, the population density of female and cyst were determined in roots and soil samples. The female index was calculated based on the average of number of female (cyst) found on each cultivar relative to the susceptible control. Soy-98-6 had resistance response (FI<10%), Saland had moderate resistance response (FI=10-30%), Saba, Sahar, SOY-98-17 and SOY-98-18 had moderate susceptible (FI=30-60%), and other cultivars had susceptible response (FI>60%). All data were subjected to analysis by GLM (Generalized Linear Model) using statistical software SPSS that indicated significant differences at among the soybean cultivars and lines for resistance to HG 0.

Text

Idaho is a key state for wheat and barley production in the United States. The continuous planting of susceptible cultivars in Southeast Idaho has allowed populations of the cereal cyst nematode pathogen to increase to economically damaging levels. During the 2018 project on identification and pathotyping of *Heterodera avenae*, cysts from an infested spring wheat field were extracted for morphological and molecular identification. Initial amplification of ribosomal RNA sequence for ITS1, 5.8S, and ITS2 regions, and partial mitochondrial cytochrome oxidase I gene (*CTC*-1) produced significant alignment with *H. filipjevi*. Further analysis on the extracted soil sample revealed mixed populations of *H. filipjevi* and *H. avenae*. Sequence analysis using a species-specific primer confirmed the presence of *H. filipjevi* in the soil samples. A PCR-RFLP protocol using seven endonucleases *Taq*I, *Hinf*I, *Pst*I, *Hae*III, *Rsa*I, *Alu*I and *Cfo*I (Yan and Smiley 2010) is in progress to distinguish individuals of any possible CCN species co-occurring in soils of Southeast Idaho. The complete results including the morphological characteristics of local populations will be included in our presentation at ICPP2023.

Text

Root-knot nematodes (RKNs) stand out negatively on agriculture worldwide, with emphasis to Meloidogyne spp. Infection by RKNs alters the root system morphology, reducing plant vigor, and product quality. The use of botanical extracts is a sustainable method for the control of phytonematodes. However, synthetic nematicidal remains very explored, even presenting an imminent risk to human and environmental health. The Solanaceae botanical family represents an abundant source of metabolites for the control of plant pathogens. The present study aimed to evaluate the nematotoxic potential of the aqueous crude extracts (ACEs) of four different Solanaceae plant accessions. The seed ACEs from the accessions 48, 52 and 78 are nematicidal, killing more than 90% of J2 M. incognita, and that activity is thermostable. The accessions 48 and 52 had the resistance reaction confirmed, and 48, 52 and 78 presented low cytotoxicity to blood cells and insects cells. The cellular viability of human keratocytes treated with these ACEs was superior to 50%, and these extracts were not phytotoxic to soybean (Glycine max) seed germination. In addition, these ACEs did not inhibit the growth and development of the beneficial soil organisms (fungi, bacteria and yeast). The accession 48 presented 100% nematicidal activity. This ACE was fractionated via HPLC-ME, and the fraction 6 that demonstrated the highest nematicidal activity, was further purified by HPLC-RP, and the molecular mass measured by MALDI-TOF

Text

Papaya (*Carica papaya* L.) may be subject to attacks by plant-parasitic nematodes causing production losses. This study aims to identify the nematode species associated with papaya in the main producing regions in Burkina Faso and to determine their life cycle in papaya. Nematodes extracted from 138 soil and root samples were identified based on morphology and molecular characterization using specific PCR primers. Nine genera of nematodes were identified, with *Rotylenchulus*, *Helicotylenchus* and *Meloidogyne* genera frequently associated with papaya. Total DNA from 120 complex soil or root samples could be obtained, 52 tested positive for *Meloidogyne javanica*, 23 tested positive for MIG primers, and *Rotylenchulus reniformis* was detected in 60 samples. *M. javanica* larval development in Solo 8 papaya roots was recorded by microscopy during 5 weeks after inoculation and staining with acid fuchin. In parallel, histological sections of roots stained with toluidine blue, FASGA and Schiff-Naphthol Blue Black were prepared. Feeding sites formed in the root central cylinder and 6 to 8 multinucleated giant cells (GCs) on average rounded the nematode body. The GC cytoplasm appeared highly enriched in proteins, becoming denser from 26 to 35 days, when adult females developed. Females laying eggs in the cortex were observed at 35 days. Characterization of nematodes species and their life cycle are important data for selecting nematode-resistant papaya to control populations in Burkina Faso.

Text

In Kenya, Potatoes are an important staple food as well as cash crops. In this case, they play an important role when it comes to national food security, income generation and poverty alleviation in the country. The Potato Cyst Nematode (PCN) was initially detected in Kenya in 2015. Since then, the pest has been identified as one of the major threats to the production of potatoes in the country. Resistance is a key strategy for managing pests and diseases, including PCN. In this research, we conducted both a phenotypic and genotypic screening on

64 germplasm acquired from The International Potato Centre (CIP) to assess for resistance. Five known sources of resistance were assessed using molecular means and compared with phenotypic resistance, following inoculation PCN.19 lines showed the presence of one or more Rgenes: H1, Gro 1, Gro 6, and Gpa 2. 0 lines were selected for a repeat experiment following a comparative analysis of both phenotypic and genotypic results. Separately, a high throughput method of phenotypic resistance screening was developed using genotypes identified as resistant and susceptible from the prior screening. An assessment period of 14-days post inoculation was determined as a suitable, short duration screening time for establishing resistance, based on the non-development of PCN juveniles once entering the root tissue, compared with susceptible lines in which juveniles developed into adults.

Text

Plant-parasitic nematode (PPN) species infect every crop. Of these, root knot and cyst nematodes pose the biggest threat. These species are sedentary endoparasites which form long-term, biotrophic relationships with the host by secreting hundred of effectors into plant cells. The vast majority of PPN effectors are produced by pharyngeal gland cells, but the PPN "effectome" remains undefined due to the technical intractability of these glands.

To address this, we take advantage of recent techniques for isolating gland cells. Here we define a stringent annotation of effectors using gland-cell-specific transcriptomics of the beet cyst nematode Heterodera schachtii at three life stages. We identify 682 effectors (317 known, 365 high-confidence candidates), in 321 families, with extremely skewed membership. The five largest families contain a quarter of effectors, and yet two fifths of effectors are the only member of their family. To understand the evolutionary origins of effectors, these data were cross-references with proteomes of 60 nematodes. This revealed the effector repertoire to be shaped by: neofunctionalization of highly-conserved genes (20 %); expansion of families present in the last common biotrophic ancestor of H. schachtii (64 %); and recent addition of orphans (7 %). These data represent the most comprehensive view of cyst nematode effectors to-date and further our understanding of an important pathogen. Ultimately, they provide the basis for crop improvement.

Text

The success of plant infection in phytonematodes relies on a precise control of gene expression dedicated to parasitism. The animal produces in its secretory glands an arsenal of parasitism proteins "effectors" ultimately delivered into host cells. These effectors module and counteract important host cellular processes necessary to invade the plant. The effector gene expression is timely orchestrated in response to nematode lifecycle and plant physiology. If effectors are crucial weapons, a critical next step is to shift the focus away from effectors to “high-level” processes: how parasitism genes are regulated?

Several research groups actively work on effector biology in phytonematodes, leading to the discovery of promoter motifs unifying effector gene expression levels and consequently helping the identification of potential proteins related to parasitism regulation.

In the Mel-DOG project, I focus on the non-coding signatures in effector promoters of the root-knot Meloidogyne incognita involved at pre- and late parasitic stages. M. incognita is not transformable so far. Here, I combine two technologies to plant-nematode research - an engineered chromatin immunoprecipitation (ChIP)-CRISPR and Yeast One-Hybrid (Y1H) library assay – allowing the identification of regulatory candidates and then functionally validate their parasitism role by RNA interference.
I will discuss about their potential role in molecular mechanisms governing effector gene expression in M. incognita.

Text

Gossypium hirsutum L. is the leading cotton species of economic importance for agribusiness. The main challenge to cotton productivity is the constant attack of several pests. Therefore, the aim of this study was to identify and characterize new promoters that can be applied as a biotechnological asset to drive the transcription of genes encoding molecules more efficiently than the viral-constitutive Cauliflower Mosaic Virus (pCaMV35S) promoter in vegetative and reproductive cotton tissues attacked by insects and phytonematodes. In this study, two cotton promoters were characterized: pGhERF105 and pGhNc-HARBI1. Interestingly, a comparative

analysis of these cotton promoters and pCaMV35S by quantitative real-time PCR showed that the two cotton promoters encompassed a significantly higher GUS transcription activity in plant vegetative and reproductive tissues than pCaMV35S. Additionally, the transgenic plants were subjected to bioassays with the major pests that attack cotton plants. The data indicated that the promoters were induced in at least one of the tested time-points when in the presence of RKN infestation. Finally, leaves of pGhERF105, pGhNc-HARBI1 and pCaMV35S transgenic plants were infested with 3rd instar larvae of insects. The analysis for GUS expression confirmed the induction of these promoters by pest. Overall, the present study provides new insights into a set of cotton promoters suitable for biotechnological applications in GM plants for pest resistance.

Text

Necrosis- and ethylene-inducing 1-like proteins (NLPs) are important virulence factors of plant-associated microorganisms. NLPs exhibit cytotoxic activity towards plant cells and therefore promote infections and toxic effects in a variety of crops. They damage lipid membranes through a multi-step mechanism involving binding to lipid membranes by the plant-related sphingolipids glycosyl inositol phosphoceramides (GIPC). They then oligomerise at the plant membrane level and eventually disrupt the membrane by forming small, transient pores. We are investigating this process using structural biology, biophysical and biochemical approaches to gain unique insights. Pore formation by NLPs is distinct from other families of pore-forming toxins and is adapted to plant target membranes. Understanding pore formation at the molecular level will also enable the development of strategies to inhibit NLP activity.

Text
The movement of effector proteins and RNAs from pathogen into host cells during infection is known to occur. However, the exact mechanisms facilitating this movement are still being widely studied. One possible delivery route involves the secretion and uptake of extracellular vesicles (EVs) between organisms.
In this study we isolated EVs from the oomycete Phytophthora infestans, cause of potato late blight, with the aim of identifying oomycete-associated EV markers and investigating the cargo of these bodies. This is being achieved by a proteomics approach to identify both secreted and vesicular proteins during in vitro growth. We have identified some known EV proteins found widely in EV proteomes, supporting our methodology and approach. Additionally, we have identified some oomycete-specific proteins that have as yet unknown functions but appear to be transmembrane proteins, including TMP1 (Trans-Membrane Protein 1). TMP1 accumulates in the same density fraction in sucrose gradients as the RXLR effector protein, PITG_04314, during EV isolation implying they could be associated with the same EV. The overall aim of this work is to find markers of EVs that we can use to determine how these EVs are secreted and taken up into the plant cell and whether this is a mode of transport for pathogenicity factors such as RXLR effectors.

C5.2-3

KINETICS OF ZOOSPORES APPROACHING A ROOT USING A MICROFLUIDIC DEVICE

Text
Zoospores are flagellated spores, asexual and motile cells, produced by different organisms including oomycetes. Oomycetes of the genus Phytophthora are plant pathogens (e.g. potato blight). The zoospores of oomycetes are biflagellates and are able to swim in aqueous environments by using chemotaxis.
We focus on the plant-pathogen interactions, in the first events of infection: attraction of the pathogen toward the host, adhesion, aggregation. We use a simple microfluidic device including a living root to study the movement of zoospores swimming towards a root. We investigate the telluric species P. parasitica, a polyphagous pathogen attacking a wide range of hosts, swimming towards a root of Arabidopsis thaliana.
Processing of image acquisitions around and away from the root allows to reconstruct the trajectories of zoospores and to precisely analyze their kinetics as a function of their distance from the root.

Text

The pathogenic oomycete Phytophthora infestans poses a significant threat to global food production and agriculture. It is the causative agent of late blight in many important crop plants including potato and tomato plants, and is well known as the trigger of the Irish potato famine during the 19th century. To this day, control of the pathogen globally is estimated to cost up to $10 billion per annum due to crop loss and fungicide use. The long-term use of fungicides to combat the spread of this pathogen has resulted in the emergence of resistant strains. Ca2+ plays a key role in regulating oomycete biology. Understanding Ca2+ signalling mechanisms in oomycetes may play a key role in developing new, more targeted, ways of controlling infection. In the current study we used commercially available small molecules that interfere with the Ca2+ signalling proteins in P. infestans. The chemicals were incorporated into Rye A agar plates at different concentrations (10μM, 20μM, and 50μM), to monitor hyphal growth of P. infestans. Complete inhibition of hyphal growth was observed using 4-chloro-3-methylphenol (4-C3-MP) at the 50μM concentration. Different structural and halogenated variants of 4-C3-MP were also tested, but only the 4-C3-MP gave a total inhibition at 50μM. 4-C3-MP has been reported to be produced by some endophytic Bacillus species of tomato, exhibiting antifungal properties, thus could be a promising anti-blight fungicide in tackling P. infestans outbreaks.

Lab-on-a-Chip (LOC) is a term that is used to describe microfluidic devices that have the capability of integrating one or more laboratory functions. The devices allow high-through-put analyses, are typically small and compact, quick and easy to produce, and can be replicated accurately and cheaply. While their initial design and fabrication can be technically demanding, their many advantages mean that they have found widespread use in biological and medical research, and in the clinic, where they offer cheap and rapid point-of-care testing. In an attempt to better understand the interactions between pathogenic oomycetes and their hosts, at various stages of the pathogen life cycle, we have designed a number of LOC devices, which I will describe. The first device replicates the chemical and electrical environment around plant roots and allows the observation of the swimming patterns and encystment of motile *Phytophthora* zoospores. The second device incorporates pneumatic microvalves that allow the trapping and compartmentalisation of individual zoospores, their germination and the measurement of μN forces exerted by emerging germ tube tips. The third allows the measurement of forces exerted by invasive hyphae with concurrent cytoskeletal imaging. The fourth allows the generation of O_2 gradients facilitating the study of

aerotropic growth of hyphae. I will also describe devices that replicate the leaf topography of rust fungi hosts that allow study of plant/rust interactions.

Text

Avocado is an important crop plant in many countries worldwide. Phytophthora root rot caused by the hemibiotrophic oomycete, *Phytophthora cinnamomi*, remains one of the most destructive pathogens within the avocado industry since there are a limited number of effective control methods available to control disease. One such method includes the use of partially resistant avocado rootstocks, which demonstrates stronger immune responses during infection. Plant Nucleotide binding-Leucine rich repeat (NLR) proteins play a significant role during the activation of Effector triggered immune responses, however, a genome-wide set of avocado *NLR* genes have only recently been identified. During this study, RNA-sequencing data showed significant differences in *NLR* expression levels when compared between a partially resistant and susceptible rootstock, following *P. cinnamomi* inoculation. The partially resistant rootstock showed increased and prolonged *NLR* expression when compared to the susceptible rootstock. Genome comparisons revealed little differences between the partially resistant and susceptible rootstock *NLR* promoter sequences, however, differing transcription factor expression patterns may explain *NLR* expression differences between the two rootstocks. Understanding the role of NLR proteins during *P. cinnamomi* infection, and how the expression of *NLRs* are regulated, is critical to unravelling the molecular mechanisms underpinning rootstock resistance towards *P. cinnamomi* infection.

Text

Phytophthora cinnamomi poses a serious threat to biodiversity, especially in Australia, with a host range of almost 5000 species. Elicitins, a group of highly conserved sterol-binding proteins are produced by *Phytophthora* species, one function of which is to support their auxotrophic lifestyle, among other putative, yet elusive, functions. Multi-omics approaches along with gene editing have expanded opportunities for functional genomics. However, success with CRISPR/Cas gene editing of these coenocytic and multinucleated oomycetes has been limited. To address these challenges, we have optimized the critical steps for transformation of *P. cinnamomi* via the use of PEG/$CaCl_2$, optimally viable starting material, nucleated protoplasts, proper guide RNA construction and suitable selection markers. The polyploid genome of *Phytophthora* presents a challenge in the selection of homokaryotic transformants. To overcome this constraint, we have compared approaches for detection of non-homologous end joining-mediated gene editing which includes T7 endonuclease assays, restriction enzyme digestion and high-resolution melt curve analysis. To test the virulence of transformants and utilise omics technologies to understand their interaction with plants, we established a soil-free growth system for the model host *Nicotiana benthamiana*. These combined approaches are enabling our studies of elicitins and will assist in expanding the strategies to reduce *Phytophthora* diseases.

Text

Clubroot disease, caused by the soilborne protist pathogen-*Plasmodiophora brassicae*, is a devastating disease to cruciferous crops worldwide and leads to a huge economic loss annually. As an intracellular obligate biotrophic phytopathogen, the life cycle of *P. brassicae* was complicated and not fully understood. Combined the fluorescent probe-based confocal microscopy and the transmission electron microscopy, we systematically investigated the infection process of *P. brassicae* and proposed a refined model of *P. brassicae* life cycle. In this model, we have made four major improvements: 1) *P. brassicae* also initiates the primary infection in root epidermal cells; 2) documented and characterized almost all the life forms; 3) firstly captured the sexual behaviours of secondary zoospores; 4) indicated the diploid nature of the secondary plasmodia. Based on above results, we compared the infection process of *P. brassicae* in susceptible hosts, immune hosts and nonhosts. We found that *P. brassicae* could initiate the primary infection in both immune hosts and nonhosts. However, host resistance blocked the secondary infection phase at the stage of uninucleate secondary plasmodium and nonhost resistance blocked the primary infection phase at the stage of uninucleate primary plasmodium. Our study provided new insights into understanding of the complex life cycle of P. brassicae and the cellular and molecular mechanisms underlying clubroot host and nonhost resistance.

(1) Department of Biochemistry, Genetics and Microbiology, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, SOUTH AFRICA; (2) Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, SOUTH AFRICA

Text

Phytophthora cinnamomi is a globally important oomycete pathogen and the causal agent of Phytophthora root rot in *Persea americana* (avocado). Our understanding of the mechanisms *P. cinnamomi* utilises to infect and successfully colonise avocado is currently lacking, especially pertaining to how the pathogen can maintain its biotrophic and necrotrophic lifestyles respectively during infection. Crinkling and necrosis effectors (CRNs) are a class of cytoplasmic effectors in oomycetes known to manipulate plant cell death during infection. The current study aimed to identify the full repertoire of *P. cinnamomi CRNs* genes and subsequently classify them as either putative cell death inducers or suppressors based on their expression profile during avocado infection. A total of 25 full-length and 1 partial/CRN-like sequences were identified, of which seven are suspected to either induce or suppress cell death. Interestingly, *CRN53* and *CRN95* were shown to have two different alleles. This was confirmed in two separate *P. cinnamomi* isolates. The proteins encoded by these alleles are hypothesised to have contradictory functions during infection. Functional characterisation studies need to be performed to confirm the roles these effectors play in manipulating cell death during infection. This work has enhanced our understanding of how *P. cinnamomi* is able to maintain the different stages of its hemi-biotrophic lifestyle to successfully ensure colonisation of the host plant.

Text

Abstract

Marine oomycetes of the genus Olpidiopsis (sensu lato) are one of the main disease-causing agents affecting Neoporphyra (commonly known as Nori) sea farms. Mechanisms of host resistance remain largely unknown. A recent study described a Scottish variety in the Scottish water Olpidiopsis porphyrae var. scotiae. We studied the resistance of 11 red algae (‘Bangia’) strains against this new described variety by using brightfield and fluorescence microscopy and RTqPCR assay. Results from microscopy inspection showed a significant effect for ‘Bangia’ strain identity on incubation period (days from inoculation until observation of the first symptom) and the percentage of infection (the number of infected cells as percentage). qPCR assay showed also significant effect for the ‘Bangia’ strain identity

suggesting different levels of resistance for different 'Bangia' strains. These results open up novel possibilities to investigate underlying mechanisms of resistance in the model.

P5.2-004

PHYTOPHTHORA PARASITICA "CORE" RXLR EFFECTOR PROTEINS INDUCE HOST DEFENCES

NXUMALO Celiwe. (1), MOLELEKI Lucy. (1), CHEPSERGON Jane. (1), SALASISNI Brenda. (1)

(1) University of Pretoria, Pretoria, SOUTH AFRICA

Text

Phytophthora species are eukaryotic pathogens that are harmful to a wide variety of plants, many of which are important in agriculture and forestry. During the infection process, *Phytophthora* spp. secrete hundreds of RxLR effector proteins (including the conserved RxLR effectors (CRE)) into the cytoplasmic region, as putative virulence factors. The goal of this study was to determine the functions of CRE in *P. parasitica*. Towards this end, *in silico* analyses revealed that *P. parasitica* INRA 310 secretes 71 RxLR effectors that are conserved across 14 *Phytophthora* spp. Twenty-six CRE were found to be shared by more than five different *Phytophthora* spp. Two of these, PpRxLR1 and PpRxLR6 were selected from among the 26 CRE for further functional characterization. Quantitative reverse transcription-polymerase chain reaction (RT-PCR) analyses of the inoculated leaves showed that *P. parasitica* PpRxLR1 and PpRxLR6 are expressed during the biotrophic phase, suggesting their importance in virulence. *Agrobacterium tumefaciens*-mediated transient expression of PpRxLR1 and PpRxLR6 in *Nicotiana benthamiana* revealed potential mechanisms of *P. parasitica* PpRxLR1 and PpRxLR6 in promoting disease development. This includes inducing reactive oxygen species as well as callose deposition. Additionally, PpRxLR1 and PpRxLR6 induce phytohormones (SA, ET, and JA) and MAPKs (MPK3 and MPK6). These data indicate that both PpRxLR1 and PpRxLR6 are important virulence factors of *P. parasitica*.

Text

Membrane-associated NAC transcription factors have important functions in plant biotic and abiotic stress adaptation. These transcription factors require cleavage from the membrane before they can translocate to the nucleus, where they regulate gene expression. Data show that the translocation mechanism is a prominent target of effector proteins from a variety of

pathogens. Here we focus on oomycete RxLR effector proteins and their respective host targets, the Arabidopsis NAC13 cluster, which also contains lettuce LsNAC069 and potato NTL1/2. This particular cluster is known to be involved in retrograde signalling associated to cellular reactive oxygen species, linking a multitude of abiotic and biotic stresses. We have shown that effectors and NAC targets co-localize at the endoplasmic reticulum; CoIP and Y2H experiments confirmed interaction of the proteins. Interestingly, co-expressed effectors hinder nuclear translocation of NACs induced by osmotic stress and pathogen associated molecular patterns. In a similar manner Ser/Cys-protease inhibitor TPCK reduced their translocation significantly. Utilizing targeted point mutations, structural biology and computational modelling we identified regulatory elements important for the translocation mechanisms of this NAC cluster. Our results indicate conservation of the NAC13 cluster translocation mechanism, which associates to their role in immunity, water acquisition, as well as to effector targeting by oomycetes.

Text

Phytophthora pluvialis, the causative agent of Red Needle Cast, is a destructive foliar disease of pine. Like other oomycetes, it utilises host-translocated effector proteins to promote successful infection. An RNA sequencing approach was chosen to elucidate differential expression effector genes in mycelium and pine needles of susceptible and resistant pine lines infected with P. pluvialis at two different time points (3- and 5-days post infection). Overall, 311 effector genes were identified to be differentially expressed (136 were Crinklers, 115 RxLRs, and 60 Elicitins). Further down-stream analysis focused on RxLR effectors expressed during the early stage of infection. First we employed a computational approach to acquire understanding on protein sequence and structural conservation. As expected, conservation on sequence level was limited. Interestingly, structural modelling showed that more than 90% of the early expressed RxLR effectors contained at least one WY-motif. Transient expression in *N. benthamiana* for nine selected candidates showed diverse localisation in planta. Successful protein expression was confirmed by Western blotting. Three WY-motif containing effectors candidates, PpR03, PpR06, PpR07 were expressed in *E. coli*, purified and characterised in detail. Infiltration assays with purified proteins in pine confirmed that PpR03 is not recognised, whereas PpR06 and PpR07 infiltrated samples showed browning of needles, indicating induced cell death.

Text

Potato and tomato are important crops in Algeria. Every year, late blight caused by the oomycete Phytophthora infestans, is responsible for important losses on these two crops. A total of 208 isolates were collected from the main production regions during (2010 to 2016). This collection included 77 isolates collected from tomato and 131 isolates were collected from potato samples and 92 DNA fingerprints were captured on FTA cards. Isolates were phenotypically characterised for mating type, metalaxyl resistance, aggressiveness and host adaptation on potato and tomato. Genotypic diversity was analysed with 17 microsatellite loci. Results showed that both A1 and A2 mating type were found on potato isolates, but A1 mating type was only found on tomato isolates. All potato isolates were resistant to metalaxyl, except one. However, all isolates collected from tomato were susceptible. SSR markers revealed the prevalence of EU_13_A2 lineage on EU_2_A1 and EU_23_A1 in potato isolates, but in tomato, EU_23_A1 was the most important lineage which was mainly found in late season crops. This investigation showed that although tomato and potato are grown in the same production areas, the difference in population structure is clearly observed between the two hosts. The Knowledge of this pathogen diversity will contribute to the development of a sustainable control strategy for late blight of potato and tomato through a sustainable rotation of these crops.

Text

Successful infection by pathogenic microbes requires the effective acquisition of nutrients from their hosts. Root and stem rot (RSR) caused by Phytophthora sojae is one of the most important diseases of soybean (Glycine max). However, the specific form and regulatory mechanisms of carbon acquired by P. sojae during infection remain unknown. Here, we show that P. sojae boosts trehalose biosynthesis in soybean through the virulence activity of an effector PsAvh413. PsAvh413 interacts with soybean trehalose-6-phosphate synthase 6 (GmTPS6) and increases its enzymatic activity to promote trehalose accumulation. P. sojae

directly acquires trehalose from the host and exploits it as a carbon source to support primary infection and development in plant tissue. Importantly, GmTPS6 overexpression promoted P. sojae infection, whereas its knockdown inhibited the disease, suggesting that trehalose biosynthesis is a susceptibility factor that can be engineered to manage RSR in soybean.

Text

Capsidiol is a bicyclic sesquiterpenoid phytoalexin synthesized by pepper and tobacco in species-specific manner. A significant decrease in capsidiol accumulation by virus-induced gene silencing compromises nonhost resistance in pepper against *Phytophthora infestans*, the Irish potato famine pathogen. However, adapted *Phytophthora capsici* causes severe disease on pepper. We have investigated the mechanism of *P. capsici* to overcome capsidiol activity different to non-adapted *P. infestans*. Different to *P. capsici*, mycelial growth of *P. infestans* on the media containing 5 μM capsidiol was inhibited and then the mycelia of both pathogens were harvested for transcriptome analysis. We found 2,113 differentially expressed genes (DEGs) in capsidiol-treated *P. capsici*, including 652 up-regulated and 1,461 down-regulated DEGs. KEGG pathway results showed that up-regulated DEGs were significantly enriched in membrane transport related to ABC transporters. Various ortholog groups of ABC transporters were identified in both *P. capsici* and *P. infestans* using Orthofinder. In particular, the ortholog group of OG0000284 existed in both genomes of two pathogens. Only *P. capsici* DEGs in the ortholog group was up-regulated, while those of *P. infestans* was down-regulated. Host-induced gene silencing of *P. capsici* ABC transporter gene displayed a significant symptom reduction by *P. capsici*. This study provides an insight to understand chemical defense in host and nonhost resistance.

Text

Plant innate immunity is characterized by the proper placement of immune components at the appropriate time and location. A cascade of transport regulators works together to achieve this by directing vesicular defense cargoes to the infection site. The emerging paradigm holds that *Phytophthora* species use effectors as a key virulence tactic to rewire host vesicle transport networks. Despite recent developments, little is understood about how vesicle trafficking is regulated in plant immunity. Here, we identified a novel strategy used by oomycete pathogens to subvert host vesicle trafficking. A host GTPase-activating protein (RabGAP) is targeted as a susceptibility factor by a conserved RXLR effector secreted by *Phytophthora infestans* and *P. palmivora* to subvert defense-related trafficking. Our proteomics screen, followed by biochemical and cell biology assays, suggests a model in which a RabGAP negatively regulates immunity by inactivating a host Rab GTPase that mediates defense-related vesicle transport towards the pathogen interface. Intriguingly, the RabGAP is guarded against effector manipulation by an NLR immune receptor. However, one of the *P. infestans* effector variants can evade and suppress activation of that NLR receptor. Our results shed light on the mechanism of defense-related secretion in plants by uncovering a negative regulatory mechanism controlled by the RabGAP-Rab association, that is guarded by host immune receptors against pathogen manipulation.

PLACING THE SPOTLIGHT ON THE NPR1-DEPENDENT DEFENCE RESPONSE IN PERSEA AMERICANA (MILL.): INSIGHTS FROM A TIME COURSE DUAL RNA-SEQUENCING STUDY OF BOTH A SUSCEPTIBLE AND PARTIALLY RESISTANT ROOTSTOCK INOCULATED WITH PHYTOPHTHORA CINNAMOMI

BACKER Robert. (1,2,3), ENGELBRECHT Juanita. (1,2,3), VAN DEN BERG Noëlani. (1,2,3)

(1) Department of Biochemistry, Genetics and Microbiology, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, SOUTH AFRICA; (2) Forestry and Agricultural Biotechnology Institute, University of Pretoria, Pretoria, SOUTH AFRICA; (3) Hans Merensky Chair in Avocado Research, University of Pretoria, Pretoria, SOUTH AFRICA

Text

In plants, the salicylic acid (SA)-signalling pathway is essential for defence responses that are effective against biotrophic and hemibiotrophic pathogens. Here, the nonexpressor of pathogenesis-related genes 1 (NPR1) is necessary for the majority of SA-related defence gene expression and the subsequent development of systemic acquired resistance (SAR). Therefore, to better understand pathogen defence, it is vital to understand the NPR1 pathway. *Phytophthora cinnamomi*, the causal agent of Phytophthora root rot (PRR) in avocado (*Persea americana*), is especially significant to the avocado industry which experiences significant financial losses each year as a result. It is reasonable to suggest that, given the hemibiotrophic lifestyle of *P. cinnamomi*, that the SA-signalling pathway and by extension the NPR1 pathway, could be vital to avocado's initial defensive response. Using

the *P. americana* West-Indian pure accession rootstock genome (Avocado Genome Consortium) we identified 88 NPR1 pathway-associated orthologs. Dual RNA-sequencing data was then used to investigate their expression following *P. cinnamomi* inoculation, in both a susceptible (R0.12) and partially resistant rootstock (Dusa®) at 6, 12, 24 and 120 hours post-inoculation. To date, this research is the most thorough analysis of the SA-induced, NPR1-dependent pathway in avocado, offering a fresh perspective on the potential mechanisms influencing *P. cinnamomi* resistance.

Text
The apoplast constitutes a major interaction niche in plant-microbe interactions. During infection, microbial pathogens secrete a large repertoire of effectors that act in the apoplast to modulate host conditions for infection. Plants respond to microbial attack via perception of conserved molecular patterns or apoplastic effectors using cell surface immune receptors to mount defense. The apoplastic effector XEG1 is a glycoside hydrolase 12 protein secreted by the soybean root rot pathogen *Phytophthora sojae*. XEG1 displays hydrolase activity toward xyloglucans and essential for *Phytophthora* infection. As a countermeasure, soybean secretes the inhibitor GmGIP1, which binds directly to XEG1 and inhibits its hydrolase activity, to increase soybean resistance. *P. sojae* secretes a paralogous XEG1-like protein, XLP1, with no enzyme activity. XLP1 binds GmGIP1 more tightly than XEG1, and acts as a decoy protecting XEG1 from the inhibitor GmGIP1. XEG1 is degraded by host aspartic protease GmAP5 in the apoplast. However, XEG1 undergoes N-glycosylation, which protects XEG1 from GmAP5 degradation. In addition, XEG1 can be recognized by a plant membrane-localized receptor-like protein RXEG1 to mount defense. Structural analyses revealed that RXEG1 inhibits the hydrolase activity of XEG1 and plays a dual immunogenic role in plant defense. Together, these studies revealed that co-evolutionary arms race tailored the multi-layered defense and counter-defense in plant-microbe interactions.

Text

Upon pathogen infection, plant-activated defense systems undergo dramatic transcriptome reprogramming. In eukaryotes, conserved mediator complex bridges transcription factors and RNA polymerase II to regulate the transcription of specific genes. Mediator complex affects almost all stages of transcription and plays an essential role in the transition from normal development to immune response. However, pathogens may manipulate host transcription by delivering effectors into plant cells. Here, we report that the nucleus-localized RxLR effector PsAvh109 of *Phytophthora sojae* regulates plant immunity by interacting with the soybean (*Glycine max*) mediator subunit 21 (GmMED21). We further showed that GmMED21 is a positive regulator of plant resistance to pathogen. Silencing of *MED21* in *Nicotiana benthamiana* suppresses the expression of salicylic acid (SA) signaling pathway genes, leading to increased pathogen infestation. Consistent with this, over-expression of *PsAvh109* in soybean also suppressed the genes response to SA signaling pathway and significantly enhanced the invasion by *P. sojae*. In addition, we found that the nuclear localization of the effector PsAvh109 is crucial for its action. The further research reveals Avh109 blocks the function of host core Mediator. As a result, our study identifies a regulatory mechanism by which pathogen effectors target the mediator complex to regulate the transcription of plant defense genes.

Text

Plant pathogens have evolved a wide range of strategies enabling surface colonization and invasion of host despite the plant defense mechanisms. Current knowledge of small spatio-temporal scales on mechanisms allowing attraction toward hosts and progression across each first plant cell layer remains sparse. To characterize which host signals and plant cell functions regulate zoospore attraction and penetration, we developed a multidisciplinary study of the rhizospheric dialogue between the telluric oomycete, *Phytophthora parasitica* and Arabidopsis. On the one hand, we generated new phenotyping tools dedicated to the short time-scale quantification of both zoospores behavior swimming in the presence of ionic signals and aggregation on the root surface. On the other hand, we defined the transcriptome of roots and zoospores during attraction of *P. parasitica* and the translatome of each root cell layer during the penetration of zoospores. Thus, we showed that (1) the zoospores aggregated on root in the first minute after inoculation, (2) both roots and zoospores stimulated transcriptomic changes during attraction, and (3) when *P. parasitica* penetrated the rhizodermis, the translatomes were also modulated beyond in the cortex, the endodermis and the stele while these cell layers are not yet colonized. The implication of these results in understanding the early stages of infection, at short spatio-temporal scales, and their use for disease control will be discussed.

Text

Late blight, caused by the oomycete pathogen *Phytophthora infestans*, is one of the most damaging diseases of potato worldwide. During infection, *P. infestans* secretes effector

proteins that manipulate host cell function and enable infection by hampering basal resistance of the plant. The pathogen reproduces both asexually and sexually, resulting in constant development of new clonal lineages with varying aggressiveness. The lineages are routinely defined by analysis of simple sequence repeat markers and mating types. Twelve *P. infestans* isolates, representing three recently emerged clonal linages (genotypes) in Europe, EU13_A2, EU37_A2 and EU41_A2, were tested for aggressiveness by inoculating the three potato cultivars Craigs Royal, Irys and Tarpan that are susceptible to *P. infestans.* Aggressiveness was measured using three values: latent period, lesion diameter and sporulation. To find out whether the different genotypes were similar in functional genes, the conserved effector gene *Avr-vnt1* was sequenced for all isolates. One isolate of the EU13_A2 had all three alleles (V1, V2, V3) of the *Avr-vnt1* effector gene while three isolates had the V1 and V3 alleles. All isolates of the EU37_A2 had the V1 and V2 alleles, and all isolates of the EU41_A2 genotype had all three alleles. The EU41_A2 genotype was least aggressive as it showed significantly lower sporulation and smaller lesion diameter compared to the other genotypes according to ANOVA followed by Tukey's test.

ADAPTING TO SURVIVE: THE KEY TO THE SUCCESS OF THE BIOTROPHIC PATHOGEN PLASMOPARA VITICOLA

MADDALENA Giuliana. (1), BIANCO Piero Attilio. (1), TOFFOLATTI Silvia Laura. (1)

(1) University of Milan, Milan, ITALY

Text

Biotrophic pathogens have an absolute dependence on their hosts. Adaptation is an imperative for their success since it also allows to endure changing conditions, as in the case of *Plasmopara viticola*, the grapevine downy mildew agent. It originates from North America, where it adapted to climate and autochthone host species, thus resulting in a complex pattern of coevolved traits. Several QTLs (*Rpv*) have been found in resistant American grapevines. Despite the high susceptibility of the host (*Vitis vinifera* L.), when first introduced in Italy *P. viticola* caused limited damages, due to its appearance in autumn. Soon, *P. viticola* adapted to climate causing serious losses, for the overlap with the susceptible stages of the grape, suggesting that adaptation also includes a temporal component. Adaptation to the host resistance and phenology have been investigated with a multidisciplinary approach. Transcriptomic analysis revealed unique genes encoding effectors modulated by *P. viticola* to evade resistance to *Rpv3-1*, the major QTL used for introgressing resistance traits in *V. vinifera*. The analysis of oospore maturation and germination dynamics showed a great adaptation of the oospore, that are able to modulate their behavior in correlation with plant phenology to maximize the infection possibilities. The results provide new insight into host-pathogen interaction that could improve the development of durable disease control by preventing the selection of adapted strains.

Text

In the soil, early infection events of *Phytophthora* species are mediated by sensory and propulsion capabilities of biflagellate unicellular zoospores, orchestrated by rhizospheric guidance factors. Lack of detailed information on zoospores plasma membrane proteins prevents a comprehensive understanding of how they contribute to the perception of rhizospheric environment, particularly during migration toward host plant. A bio-physical approach was developed to identify the molecular key-players mediating host-driven taxis. At first, the membrane protein repertoire of *Phytophthora parasitica* zoospores was investigated through LC-MS/MS approach, resulting in a distinct peptide signature between zoospores cell body and flagella plasma membranes. Then, using a microfluidic set-up, functional biomechanics analyses were developed to quantify both zoospore motion (velocity, trajectory and cell rotation) and flagella beating (frequencies and oscillation amplitude) in response to distinct rhizospheric stimuli. The set-up further enabled to discriminate zoospores specific stimuli response among other rhizospheric microbial species. Altogether, the obtained results contribute to elucidate the mechanism of protein-mediated sensing and motion response of *Phytophthora* zoospores and improve the understanding of the complex rhizospheric interaction network driving oomycete dispersal.

PHASE-SPECIFIC TRANSCRIPTIONAL PATTERNS OF THE OOMYCETE PATHOGEN PHYTOPHTHORA SOJAE UNRAVEL GENES ESSENTIAL FOR ASEXUAL DEVELOPMENT AND PATHOGENIC PROCESSES

QIU Min. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Oomycetes are filamentous microorganisms easily mistaken as fungi but differ in physiology, biochemistry, and genetics. These differences are also reflected in the large variations in functional genes targeted by conventional fungicides. Thus, identifying novel functional genes for precisely controlling oomycete diseases is necessary. Therefore, this study reboots the analysis from available transcriptome data in a model oomycete pathogen, Phytophthora sojae, to excavate more functional genes. A set of expression matrix of 10,953 genes across ten stages were applied to recognize the transcriptional changes underlying critical stages for disease spreading. Based on hierarchical clustering, specification, and diversification analyses, we focused on the developmental stages due to their more remarkable transcriptional plasticity than the infection stages, and eventually these genes were resolved into six modules with their expression distinctness. Detailed analysis of these six modules identified candidate genes with stage-specific expression, including a serine/threonine phosphatase expressed in mycelial and sporangium stages, a histidine kinase expressed in zoospore and cyst stages, and a bZIP transcription factor exclusive to cyst germination.

Finally, diversiform gene editing tools were applied to obtain mutants of these three genes, and they were functionally verified with multiple phenotypes covering phase-specific developmental and infection stages.

THE NON-CANONICAL AND OOMYCETE-SPECIFIC BAG IS ESSENTIAL FOR THE MAINTENANCE OF PROTEOSTASIS IN PHYTOPHTHORA SOJAE CYST GERMINATION

JING Maofeng. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text
The maintenance of protein homeostasis is vital for the survival of all living organisms, and this process is carried out by molecular chaperones. The Bcl-2-associated athanogene (BAG) family is a conserved group of co-chaperones that helps maintain proteostasis in animals, plants, and fungi. This family functions by binding to heat shock protein 70 (HSP70) through its C-terminal BAG domain (BD). In this study, researchers discovered an unconventional subfamily of BAGs in oomycetes, which contain an N-terminal BD with a short, species-specific α1 helix and a unique C-terminal small heat shock protein (sHSP) domain. These BAGs are crucial for the germination of cysts and the pathogenicity of the oomycete pathogen Phytophthora sojae. Moreover, researchers found that PsBAGs play a role in the unfolded protein response, assisting in the degradation of misfolded proteins through the 26S proteasome. Both the BD and sHSP domains are necessary for the proper function of Phytophthora sojae, and these proteins form a homodimer through the unique α1 helix instead of the classical BAG-HSP70 complex. This study highlights a new mechanism for the protective role of oomycete BAGs, providing a potential target for disease control.

Text
Successful pathogens can rapidly overcome host resistance through epigenetic silencing, but the underlying mechanisms of epigenetic variation are largely elusive. Based on genome-wide association study, we identified a natural allele of an Argonaute protein in *Phytophthora sojae* that confers adaptability to resistance soybean cultivar. Knockout of *PsAGO2* impaired avirulence gene *Avr1b* silencing and the *psago2* mutants were recognized by soybean cultivar carrying *Rps1b*. Further data revealed that PsAGO2 can bind 24-26 nt sRNAs and recruit the histone methyltransferase complex PRC2 to establish H3K27me3 at *Avr1b* loci. Our finding supports a model in which H3K27me3 formation is mediated by sRNA in

oomycete, highlighting the role of a new function of AGO protein in epigenetic gene silencing in a plant pathogen.

Text

The relationship between microbial pathogens and their host plants is epitomized by an endless arms race in the battle for survival. Successful plant pathogens, including *Phytophthora* spp. are known to secrete specific effector proteins to manipulate host immune responses. Examples of such effectors are the RxLR effector proteins, named after conserved Arg?any amino acid?Leu?Arg (RxLR) motif at the N-terminus. Our understanding of specific functions of RxLR effectors is limited by lack of knowledge concerning the motifs that facilitate functioning of these effectors at the cellular and molecular level. In this study, a highly conserved PpRxLR1 effector from *P. parasitica* was shown to encode a six aa long short linear motif (SLiM). We established that the SLiM mediates cell death inducing activity of PpRxLR1 effector that promotes the infection of P. parasitica. Similarly, the SLiM was shown to facilitate the interaction between PpRxLR1 effector and its host target protein. However, it was shown to be dispensable for effector subcellular targeting into the host cell. Together, our findings indicate that PpRxLR1 could be an important virulence RxLR effector of *P. parasitica,* promoting the pathogen's infection with the help of its SLiM. Uncovering the mechanisms of effector interference with targeted host functions is a critical step towards understanding host-pathogen interactions. Ultimately, this can be harnessed to breed for durable resistance in plants.

PECTIN METHYLESTERASES INHIBITOR MODULATE PLANT HOMOGALACTURONAN STATUS IN DEFENSES AGAINST THE PHYTOPHTHORA SOJAE

XIA Yeqiang. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Pectin Methylesterases Inhibitor Modulate Plant Homogalacturonan Status in Defenses against the *Phytophthora sojae*

Yeiqiang Xia et al., Yan Wang, Yuanchao Wang*

Hosts and pathogens are engaged in a continuous struggle for physiological dominance that drives the evolution and specialization of key defense and virulence proteins. A major site on the struggle is the plant cell wall. Here, we show the involvement of the dynamic remodeling pectin methylesterification of cell wall in the co-evolutionary struggle between host and microbe. Pathogen-secreted apoplastic pectin methylesterases, PsPME1, that loosening the plant cell wall and synergizing the activity of pathogen secreted endo-polygalacturonases by decreased the degree of pectin methylesterification. However, GmPMEI, a soybean produced pectin methylesterases inhibitor protein, expression controlled by PME-related damage-associated molecular patterns that binds to both soybean and *P. sojae* pectin methylesterases and inhibits them enzyme activity to remodeling the pectin to high methylesterification status for protecting themselves from enzymatic degradation. Totally, our work highlights that plants exploit induced defense mechanisms based on biochemical modification on the cell wall in shaping the balance of the arms race in the co-evolutionary conflict between host and microbe.

(1) University of Dundee, Dundee, UNITED KINGDOM; (2) James Hutton Institute, Dundee, UNITED KINGDOM

Text

Plant pathogens secrete many effector proteins which are translocated inside plant cells and act to suppress host defences and promote pathogen colonisation. The RxLR effector Pi06099 from potato late blight pathogen *Phytophthora infestans* interacts with the plant red light receptor Phytochrome B (PhyB). Red light promotes plant immunity by accelerating cell death in response to the *P. infestans* MAMP INF1. Silencing the *Pi06099* effector using Host Induced Gene Silencing (HIGS) and stable RNAi transgenic lines demonstrated that it contributes to the virulence of *P. infestans* on Potato and *Nicotiana benthamiana*. Furthermore, domain swapping and mutagenesis of Pi06099 has been used to investigate the disruption of the interaction with PhyB and phenotypes associated with effector virulence.

Text

Plants and pathogens constantly adapt to each other. In turn, the adaptation pressures impose on pathogens shape their variations and the fitness towards corresponding hosts. Our study shows that the XEG1/XLP1 gene pair originated from Phytophthora, and they had functioned differently through the evolution of Phytophthora, which is caused by the dependence of Phytophthora on its virulence function. Based on the distribution, phylogeny, collinearity, and gene arrangement, it appears that the XEG1/XLP1 gene pair originated with the Phytophthora. As well, Different Phytophthora XEG1/XLP1 paralogs exhibit different abilities to induce cell death, induce the expression of defense genes, and produce reducing sugars. Actually, XEG1/XLP1 ancestor genes produced reducing sugars less efficiently and induced immunity less effectively. A further analysis revealed that XEG1/XLP1 displayed different selection pressures, and these pressure sites were crucial to its ability to produce reducing sugars and induce immune. Meanwhile, the replacement experiments with ancestral genes indicate XEG1/XLP1 virulence is closely related to its ability to produce reducing sugar, and as virulence increases, immune activation increases as well. Overall, the results show that XEG1 and its decoy partner XLP1 continuously adapted to their hosts through functional divergence during Phytophthora evolution.

SCREENING OF ALFALFA VARIETIES RESISTANT TO PHYTOPHTHORA CACTORUM AND RELATED RESISTANCE MECHANISM

YANG Bo. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Alfalfa is one of the most important legume forages in the world. Root rot caused by soil-borne pathogens severely restricts the production of alfalfa. The knowledge of the interaction between alfalfa and root rot-pathogens is still lacking in China. Phytophthora cactorum was isolated from symptomatic seedlings of an alfalfa field in Nanjing with high levels of damping-off. We observed the different infection stages of P. cactorum on alfalfa, and found that the purified P. cactorum strain was aggressive in causing alfalfa seed and root rot. By evaluating the resistance of 37 alfalfa cultivars from different countries to P. cactorum, we found Weston is a resistant variety, while Longdong is a susceptible variety. We further compared the activities of various enzymes in the plant antioxidant enzyme system between Weston and Longdong during P. cactorum infection, as well as gene expression associated with plant hormone biosynthesis and response pathways. The results showed that the disease-resistant variety Weston has stronger antioxidant enzyme activity and high levels of SA-responsive PR genes, when compared to the susceptible variety Longdong. These findings highlighted the process of interaction between P. cactorum and alfalfa, as well as the mechanism of alfalfa resistance to P. cactorum, which provides an important foundation for breeding resistant alfalfa varieties, as well as managing Phytophthora-caused alfalfa root rot.

Text

Late blight, caused by an oomycete; Phytophthora infestans continues to be the primary disease of concern for potato farmers. The pathogen virulence is attributed to the presence of effectors (pathogenicity factors), which if recognised by plant resistance (R) genes, triggers the immune response. Not surprisingly P. infestans has evolved accordingly, which has driven effector diversity in P. infestans populations. Yet, our understanding of this adaptive evolution remains poor. Therefore, tracking effector diversity in light of disease resistance gene deployment is critically important if robust IPM strategies are to be developed in support of Farm to Fork (F2F) goals.

Enrichment sequencing techniques enable cost effective, high-confidence identification of functional R genes and effectors. Although merits of enrichment sequencing over WGS has been previously demonstrated, but its comparison with gene expression remains elusive. In this regard, P. infestans infected potato plants were subjected to RNAseq, PenSeq and RenSeq at different time points. The analysis reveals the presence of some unknown effectors (PITG_08949, PITG_14932, PITG_02900, etc.) with 100% gene coverage at very early stages of infection which was otherwise not possible with RNAseq.

This information combined with R gene expression during infection have potential to widen our current knowledge of potato-P. infestans interactions, and can be used as a platform for introducing informed phase of potato breeding.

Text

Phytophthora cactorum causes crown rot, a devastating disease of strawberry plants, by attacking its roots and rhizome. Many commercial octoploid strawberry cultivars are susceptible, while many accessions of the wild diploid species *Fragaria vesca* are resistant to *P. cactorum*. To gain insights into the strawberry defence mechanisms and virulence mechanisms of *P. cactorum*, comparative transcriptome profiles of two resistant and one susceptible genotype of *F. vesca* were analysed by RNA-sequencing after inoculation with *P. cactorum*.

Differential gene expression analysis identified thirty-one putative disease resistance genes in *F. vesca* that were highly expressed in the resistant genotypes relative to the susceptible genotype after inoculation with *P. cactorum*. These included genes encoding receptor-like

proteins, receptor-like kinases, and leucine-rich repeat proteins with nucleotide binding sites. Furthermore, approx. 4600 *P. cactorum* genes were detected, of which 544 were predicted to encode secreted proteins that are potential effectors of importance to the pathogen's virulence.
Selected differentially expressed *F. vesca* genes and effector genes from *P. cactorum* were studied by transient expression in the model plant *Nicotiana benthamiana*. Some of these induced cell death or hypersensitive response, including accumulation of reactive oxygen species and callose deposition in the plant cell wall, indicating functional relevance in the plant-pathogen interaction.

PUNCHING TRANSIENT SMALL HOLES INTO PLANT PLASMA MEMBRANE: THE UNIQUE CASE OF AN OOMYCETE NLP CYTOLYSIN

SNOJ Tina. (1), ANDERLUH Gregor. (1)

(1) National institute of Chemistry, Slovenia, Ljubljana, SLOVENIA

Text
Necrosis and ethylene-inducing peptide 1-like proteins (NLPs) are produced by a variety of phytopathogens. Many NLPs cause cell death and tissue necrosis by disrupting the plant plasma membrane. Glycosylinositol phosphorylceramides (GIPC), the most abundant class of plant sphingolipids, are targets for NLP binding to membranes. Just recently, it was shown that this lipid recognition is electrostatic-driven and leads to shallow membrane binding, protein aggregation, and transient pore formation.
We are exploiting various model lipid systems, composed of plant-isolated GIPC, e.g. cell-sized vesicles, which are conveniently followed with confocal microscopy. Visual information after NLPPya – membrane interaction about localized toxin binding, changes in the morphology of the vesicles, and differential leakage of different-sized probes allows making predictions about membrane-damaging mechanisms. Furthermore, molecular dynamics simulations revealed that the C-terminal α-helix of NLPPya undergoes conformational rearrangements during membrane interactions. We are tackling this clue by designing mutants of NLPPya, among which cysteine ones are of special interest. Introduced cysteines are labeled with IANBD to monitor the insertion of these residues into the lipid bilayer by changes in its fluorescence.
Our study will contribute specific molecular insights into the toxic NLPs- plant membrane interaction which is crucial for the development of better strategies for crop protection.

RENSEQ AS A ROBUST TOOL TO IDENTIFY NOVEL DISEASE RESISTANCE GENES IN WILD AND CULTIVATED POTATOES

VIKRANT Sharma. (1,2), KUMAR Anil. (2), HEIN Ingo. (1,3)

(1) JAMES HUTTON INSTITUTE, Dundee, UNITED KINGDOM; (2) Thapar Institute of

Engineering & Technology, Patiala, INDIA; (3) University of Dundee, Dundee, UNITED KINGDOM

Text
Late Blight (caused by Phytophthora infestans), leads to an annual loss of ~€6 bn across the globe. Successful introgression of disease resistance (R) genes, mostly belonging to the nucleotide-binding, leucine-rich-repeat (NLRs) gene family, from wild species into commercial potato varieties provide a means to protect crops from the emerging virulent P. infestans isolates. NLRs account for only 0.25% of the entire genome, thus WGS for functional NLRs identification is a costly process. Resistance gene enrichment and sequencing (RenSeq), if used in a diagnostic mode (dRenSeq) can be utilised as a cost-effective, robust R gene identification tool. It led to the discovery and annotation of about 755 NLRs from Solanum tuberosum group Phureja clone DM.
The present study was focused on identifying broad-spectrum novel R genes from important potato species. The resistant accessions found through detach leaf assay were subjected to dRenSeq to gain insight into NLR profile. Our analysis revealed that although the cultivar Athlete is highly resistant to P. infestans, the source of resistance remains unknown. Therefore, two F1 progenies of Athlete X Gemson and Athlete X Ivory Russet were subjected to bulk segregant analyses in combination with enrichment sequencing to identify and map underlying novel resistances. The identified R gene(s) can be further deployed in potato cultivars through breeding programmes to reduce crop loss and thereby contribute towards sustainable food security.

Text
Xanthomonas campestris pv *campestris* (*Xcc*) is a phytopathogenic bacterium which causes black rot disease on cultivated and wild Brassicaceae. During its disease cycle, *Xcc* experiences changing environments from the leaf surface to distinct endophytic compartments (hydathode, xylem and mesophyll), seeds and plants residues. So far, genetic screens have only identified major determinants important for pathogenicity. Mechanisms of pathogen entry, vascular immunity suppression, metabolic adaptation and microbial fitness in the distinct plant environments, are essentially unknown. In order to identify bacterial determinants of plant adaptation we have performed high-throughput RB-TnSeq screens during colonization of different plant compartments. The results of these screens yields important insights into the physiological state of the bacterium during the infection process and to the identification and characterization of virulence determinants.

Text
Synaptotagmin A (SYTA) is a protein responsible, together with NET3C and VAP27, for the formation of ER-PM membrane contact sites (MCSs). MCSs are regions in which two membranes come into close contact without fusing. MCSs are characterized as sites for membrane trafficking and Ca^{2+} fluxes, being Ca^{2+} dependent, and resealing membranes after damage. Besides its role in the MCSs formation, SYTA plays a role in the movement and replication of plant viruses, and plants with downregulated SYTA showed enhanced resistance to the pathogens. Here we studied the role of SYTA during *Candidatus* Liberibacter asiaticus (*C*Las) infection, an unculturable gram-negative bacterium that inhabits the sieve elements of Citrus *spp*. In Arabidopsis, SYTA::RFP co-localized with SUC2::GFP in the phloem. Moreover, in *syta-1* mutants, the cisterna shape of the sieve element reticulum (SER) was abnormal and detached from the PM. In Citrus, the downregulation of phloem SYTA with citrus tristeza virus (CTV) VIGS delayed the onset and severity of the symptoms in CTV-syta plants. Phloem plugging genes were downregulated, and the total area of callose deposits was lower. We suggest that the disruption of the SER could play a pivotal role in delaying the infection: this could affect the attachment of the pathogen to the SER and, therefore, disturb the trophic host-pathogen interaction.

Text

Bacteria have evolved a large array of signaling pathways that allow them to reprogram behavior in response to environmental conditions. One such pathway is the carbon catabolite repression (CCR) pathway, in which the presence of glucose results in the inhibition of specific genes. In this regard we found that when *Paenibacillus* spp. bacteria are grown on glucose their motility is inhibited, thereby restricting them to a favorable environment. However, when these colonies are grown in proximity to other bacterial species, such as the plant pathogens *Xanthomonas perforans* or *Acidovorax citrulli*, the CCR pathway is overridden and the *Paenibacillus* cells start migrating towards their neighbors. Notably, a directional swarming induction of *Paenibacillus* cells by neighboring colonies was observed even when the colonies were inoculated on media without glucose. We further show that, when inoculated on plants, the interaction of *Paenibacillus* swarms with these phytopathogens could have two opposing effects on plant health. The outcome could either be harmful or helpful to the plant, depending on the characteristics of the *Paenibacillus* species in the swarm. Our results suggest that in mixed populations, interspecies interactions can affect the community's spatial organization and significantly impact disease outcomes in plants.

Text

CRISPR-based genome editing technology is revolutionizing prokaryotic research, but it has been rarely studied in bacterial plant pathogens. Here, we have developed a targeted genome editing method with no requirement of donor templates for convenient and efficient gene knockout in *Xanthomonas oryzae* pv. *oryzae* (*Xoo*), one of the most important bacterial pathogens on rice, by employing the heterologous CRISPR/Cas12a from *Francisella novicida* and NHEJ proteins from *Mycobacterium tuberculosis*. FnCas12a nuclease generated both small and large DNA deletions at the target sites as well as it enabled multiplex genome editing, gene cluster deletion, and plasmid curing in the *Xoo* PXO99^{A} strain. Accordingly, a non-TAL effector-free polymutant strain PXO99^{A}D25E, which lacks all 25 xop genes involved in *Xoo* pathogenesis, has been engineered through iterative genome editing. Whole-genome sequencing analysis indicated that FnCas12a did not have a noticeable off-target effect. In addition, we revealed that these strategies are also suitable for targeted genome editing in another bacterial plant pathogen *Pseudomonas syringae* pv. *tomato* (*Pst*). We believe that our bacterial genome editing method will greatly expand the CRISPR study on microorganisms and advance our understanding of the physiology and pathogenesis of *Xoo.*

Text

Protein homeostasis is epitomized by a tight equilibrium of protein biosynthesis and degradation; the 'life and death' of proteins. Approximately one-third of newly synthesized proteins are degraded. As such, regulated protein turnover is required to maintain cellular integrity and survival. Autophagy and the ubiquitin-proteasome system (UPS) are the two principal intracellular degradation pathways in eukaryotes. Both degradation pathways orchestrate many cellular processes during plant development and upon environmental stimuli. As such, both pathways play a major role during plant-microbe interactions. We have recently identified that autophagy and the proteasome system are exploited by bacterial pathogens to reprogram host cellular pathways. By studying this intimate interplay, we can utilize plant pathogenic bacteria as tools to understand host cellular degradation machineries and to decipher novel components and functions. In my presentation, I will not only cover our recent work on the role of autophagy and the proteasome in plant-microbe interactions but will report on our attempts to identify new autophagy regulators and new functions of known UPS components. I will highlight different examples and discuss our recent advances.

Text

The *Xanthomonas* genus includes several plant pathogens responsible for significant crop losses worldwide. Most of the functional studies of virulence in this genus have been carried out by directed mutagenesis through homologous recombination. However, this strategy is

cumbersome for the study of gene families. CRISPR interference (CRISPRi) allows precise silencing of target genes by using a catalytically dead Cas9 (dCas9) which interferes with gene expression. Because of its RNA-directed nature, this technology can be used for silencing several genes in a single experiment in bacteria and other organisms. We implemented a CRISPRi strategy to silence several members of the Transcriptional activator-like effectors (TALE) gene family at once in four different species of *Xanthomonas*. Our results underscore the importance of the activation of the *SWEET* gene family in cassava upon infection by *Xanthomonas phaseoli* pv. *manihotis*. Remarkably, we report the importance of this gene family in the infection of this host by the non-vascular pathogen X. cassavae. In addition, we successfully silenced several TALE genes in a total of five species, including *X. oryzae* pv. *oryzae*, *X. citri* pv. *citri* and *X. campestris* pv. *campestris* using CRISPRi, confirming the importance of this gene family in these pathosystems. The CRISPRi tool can be further modulated to silence sets of genes within a gene family for functional studies in *Xanthomonas* and other plant pathogenic bacteria.

Text

Plant small RNAs (sRNAs) can trigger non-cell autonomous RNA interference (RNAi) in interacting eukaryotic pathogens or parasites possessing canonical RNAi factors. However, it is currently unknown whether a similar process could operate against a phytopathogic bacterium, which lacks a eukaryotic-like RNAi machinery. We recently demonstrated that Arabidopsis-encoded artificial sRNAs can trigger the sequence-specific silencing of a virulence factor from *Pseudomonas syringae* pv. *tomato* strain DC3000 (*Pto* DC3000). However, the sRNA species that are implicated in this phenomenon remain elusive. In the present study, we identified and characterized two populations of apoplastic sRNAs that orchestrate antibacterial gene silencing. The first one involves sRNAs that are associated with extracellular vesicles (EVs), and presumably incorporated in ribonucleoprotein complexes. Intriguingly, the second one involves sRNA duplexes that are in a free form, and thus referred to here as extracellular free small RNAs or efsRNAs. Here, I will present the experimental data supporting these findings. I will also discuss the relevance of these findings in the understanding of how plants regulate transcriptome, community composition and genome evolution of associated bacteria.

F2.1-2

SA-INDEPENDENT MECHANISM IN THE TOMATO DIAGEOTROPICA (DGT) MUTANT ENHANCE ROOT-MEDIATED RESISTANCE TO RALSTONIA SOLANACEARUM K60

RIVERA-ZULUAGA Katherine. (1), CHOUDARY Pratibha. (1), ÁVILA-ORJUELA Harryson G. (1), TREJOS-RAMIREZ Stefani. (1), GHASTE Manoj. (1), WIDHALM Joshua. (1), IYER-PASCUZZI Anjali. (1)

Text

Bacterial Wilt is among the most devastating plant diseases in the world. This disease is caused by the soilborne *Ralstonia solanacearum* (*Rs*) and affects more than 200 species of plants. In tomato, resistance to *Rs* is quantitative and the result of many genes and no resistance genes to the US *Rs* strain K60 have been identified in tomato. Transcriptomic analysis of resistant tomato roots showed that at 48 hours post inoculation with *Rs*K60, genes involved in auxin transport and signaling pathways are downregulated. A tomato mutant defective in auxin transport and signaling, known as *diageotropica* (*dgt*) has enhanced resistance to *Rs*K60. Auxin acts antagonistically with the plant hormone Salicylic Acid (SA), and we found that *dgt* roots have endogenously higher levels of SA and a strain of *Rs* that can degrade SA is partially virulent on *dgt*. However, after inoculation with *Rs*K60, the expression of SA-dependent response genes is not activated and the SA-deficient double mutant *dgtxNahG* is still resistant to *Rs*K60. Inoculation with *Pseudomonas syringae* pv *tomato* showed that *dgt* is susceptible to this foliar pathogen. Our research suggests that the resistant response of the *dgt* mutant to *Rs*K60 may be due a SA-independent mechanism in roots and that the *DGT* gene and proper auxin transport and signaling are important for susceptibility to *Rs*K60 in tomato roots. Understanding the role of DGT and auxin in defense responses to *Rs* in tomato is important for Solanaceae crop improvement.

Text

Bacterial Leaf Blight of rice (BLB) caused by Xanthomonas oryzae pv. oryzae (Xoo) is a major threat for food security in many rice growing countries including Burkina Faso where the disease was reported first in the 1980's. In line with the intensification of rice cultivation in West-Africa, BLB has been on the rise along the last 15 years. West-African strains of Xoo differ from their Asian counterparts as they (i) are genetically distant, (ii) belong to new races and, (iii) contain reduced repertoires of Transcription Activator Like (TAL) effector genes. In order to investigate the evolutionary dynamics of Xoo populations in Burkina Faso, 177 strains were collected from 2003 to 2018 in three regions where BLB is occurring. Multilocus VNTR Analysis (MLVA-14) targeting 10 polymorphic loci enabled to discriminate 24

haplotypes and showed that Xoo populations were structured according to their geographical localization and year of collection. Considering their major role in Xoo pathogenicity, we next surveyed the TAL effector repertoires of the 177 strains upon RFLP-based profiling. Surprisingly an important diversity was revealed with up to eight different RFLP patterns. Finally, comparing neutral vs. TAL effector gene diversity allowed to suggest scenarios underlying the evolutionary dynamics of Xoo populations in Burkina Faso, which could be helpful to guide the deployment of BLB resistant varieties in the country.

P2.1-001

INCREASING THE RESILIENCE OF PLANT IMMUNITY TO A WARMING CLIMATE

HE Sheng-Yang. (1)

(1) Duke University, Durham, UNITED STATES

Text

Extreme weather conditions associated with climate change affect many aspects of plant life, including the response to infectious diseases. Production of salicylic acid (SA), a central plant defense hormone, is particularly vulnerable to suppression by short periods of hot weather above the normal plant growth temperature range. We recently found that suppression of SA production in Arabidopsis thaliana at 28 °C is independent of PHYTOCHROME B (phyB) and EARLY FLOWERING 3 (ELF3), which regulate thermo-responsive plant growth and development. Instead, we found that formation of GUANYLATE BINDING PROTEIN-LIKE 3 (GBPL3) defense-activated biomolecular condensates (GDACs) was reduced at the higher growth temperature. The altered GDAC formation in vivo is associated with impaired recruitment of GBPL3 and SA-associated Mediator subunits to the promoters of CBP60g and SARD1, which encode master immune transcription factors. Unlike many other SA signaling components, including the SA receptor and biosynthetic genes, optimized CBP60g and SARD1 expression was sufficient to broadly restore SA production, basal immunity and NLR-mediated immunity at the elevated growth temperature without significant growth trade-offs. CBP60g family transcription factors are widely conserved in plants. These results have implications for understanding the concept of the “plant–pathogen–environment” disease triangle and the emergence of new disease epidemics in a warming climate.

Text

The plant defense responses to microbial infection are tightly regulated and integrated with the developmental program for optimal resource allocation. Several types of association between disease susceptibility or resistance and the floral transition have been reported. The functional characterization of pathogen virulence factors, termed effectors, provides molecular insights into plant disease susceptibility. Ralstonia pseudosolanacearum injects tens of effectors in the host cells that collectively promote bacterial proliferation inside the vascular tissues and cause bacterial wilt in many solanaceous crops. Here, we characterized the function of the broadly conserved effector RipL, through heterologous expression in Arabidopsis thaliana. RipL-expressing transgenic lines presented delayed flowering which correlated with a low expression of flowering regulator genes. In parallel, RipL promoted plant susceptibility to virulent strains of Pseudomonas syringae in the effector-expressing lines or when delivered by the type III secretion system. Although the SA-dependent immune signaling was not significantly affected by RipL expression, RNA-seq analysis of infected RipL-expressing lines revealed that the overall amplitude of the transcriptional response was dampened compared to the control line. Together, our results indicate that RipL could contribute to the pathogen virulence in an SA-independent manner.

P2.1-003

SSTF, A NOVEL SULFORAPHANE SENSING TRANSCRIPTION FACTOR OF XANTHOMONAS CAMPESTRIS, IS REQUIRED FOR SULFORAPHANE TOLERANCE AND VIRULENCE

WANG Bo. (1), XU Zhizhou. (1,2), GUO Baodian. (1), ZHAO Yancun. (1), **LIU Fengquan. (1)**

(1) Jiangsu Academy of Agricultural Sciences, Nanjing, CHINA; (2) Nanjing Agricultural University, Nanjing, CHINA

Text

Avoiding the host defence system is necessary for the survival of pathogens. However, the mechanism by which pathogenic bacteria sense and resist host defence signals is still unknown. Sulforaphane (SFN) is a secondary metabolite of crucifers. It not only plays an important role in maintaining the local defence response but also directly inhibits the growth of some pathogens. In this study, we identified a key SFN tolerance-related gene, *saxF*, in *Xanthomonas campestris* (*Xcc*), the causal agent of black rot of crucifers. More interestingly, we found that the transcription of *saxF* was regulated by the novel transcription factor SFN sensing transcription factor (SstF). As a LysR family transcription factor, SstF can sense SFN and regulate the expression of *saxF* cluster genes to increase SFN resistance by directly binding the promoter of *saxF*. In addition, we found that SstF and *saxF* also play an important role in positively regulating the virulence of *Xcc*. Collectively, our results illustrate a previously unknown mechanism by which *Xcc* senses the host defence signal SFN and activates the expression of SFN tolerance-related genes to increase virulence. Therefore, this study provides a remarkable result, that is, during pathogen-plant coevolution, new functions of existing scaffolds are activated, thus improving the proficiency of the pathogenic mechanism.

P2.1-004

IDENTIFICATION OF GENES REQUIRED FOR PTR1-MEDIATED IMMUNITY IN NICOTIANA BENTHAMIANA

MAZO MOLINA Diana Carolina. (1,2), MARTIN Gregory. (1,2)

(1) Cornell University, Ithaca, UNITED STATES; (2) Boyce Thompson Insttitute, Ithaca, UNITED STATES

Text

The *Ptr1* (*Pseudomonas tomato race 1*) gene confers resistance to race 1 strains of *Pseudomonas syringae pv. tomato* and to *Ralstonia pseudosolanacearum* by recognizing the type III effector AvrRpt2 or RipBN, respectively. To identify host proteins that play a role in Ptr1-mediated immunity, we performed virus-Induced gene silencing (VIGS) on *Nicotiana benthamiana* plants, which naturally expresses Ptr1, to knock down the expression of various immunity-associated proteins and protein kinases. Cell death assays using *Agrobacterium* carrying AvrRpt2 revealed that plants silenced for the *RAR1*, *SIPK*, *SIPKK*, *MKK1*, and *Epk1* genes showed less or no Ptr1-associated cell death in response to AvrRpt2, indicating their involvement in the Ptr1 response. Interestingly, the *Nrc2/3* genes, which are required for the function of the Pto/Prf complex, showed no involvement in the Ptr1 response to AvrRpt2. The *SIPK*, *MKK1*, and *Epk1* genes play a role in both the Ptr1 and the Pto/Prf responses, whereas the *RAR1* and *SIPKK* genes only appear to play a role in the Ptr1 response. These results provide the foundation for investigating the role of different well-studied signaling kinases and immunity-associated proteins and their function in the Ptr1 pathway in response to AvrRpt2.

P2.1-005

A NOVEL PSEUDOMONAS CYCLIC LIPOPEPTIDE INDUCES PLANT IMMUNITY THROUGH CELL WALL PERCEPTION AND CYTOPLASTIC SIGNALING

GU Yi-Lin. (1), LI Jun-Zhou. (1), **WEI Hailei. (1)**

(1) Chinese Academy of Agricultural Sciences, Beijing, CHINA

Text

Cyclic lipopeptides (CLPs) are multifunctional secondary metabolites produced by a large variety of bacteria and have emerged as an important category of plant immunity elicitors. Pseudomonas-CLPs (Ps-CLPs) are extremely diverse in structure and biological activity. However, current understanding of CLP-plant structure–function interactions remain elusive. Here, we identified medpeptin, a novel CLP from P. mediterranea, which consists of 22 amino acids and is synthesized by a non-ribosomal peptide synthase gene cluster and regulated by a quorum-sensing system. Further research indicates that medpeptin does not exhibit antimicrobial activity but instead induces plant cell death immunity and confers resistance to bacterial infection. Comparative transcriptome analysis and virus-induced gene silencing revealed a set of immune signaling candidates involved in medpeptin perception. Silencing of a cell wall leucine-rich repeat extensin protein (NbLRX3) or a receptor-like protein kinase (NbRLK25), but not BAK1 or SGT1, compromises medpeptin-triggered cell death and resistance to pathogen infection in Nicotiana benthamiana. Our findings point to a non-canonical mechanism of CLP sensing and suggest perspectives for the development of plant disease resistance.

A UBIQUITIN FAMILY PROTEIN PLAYS A ROLE IN THE PATHOGENICITY OF ACIDOVORAX CITRULLI

OTHMAN Maram. (1), **TAMIR-ARIEL Dafna. (2)**, SHOTLAN Yoram. (1), BURDMAN Saul. (2)

(1) Shamoon College of Engineering, Beer Sheva, ISRAEL; (2) Hebrew University of Jerusalem, Rehovot, ISRAEL

Text

Acidovorax citrulli is a plant pathogenic bacterium that causes bacterial fruit blotch (BFB) disease of cucurbits. Symptoms of BFB include seedling blight, necrotic spots in cotyledon and leaves, and blotch on the fruit that can result in significant yield losses. In this study, bioinformatic analysis was applied to rank genes according to their potential contribution to pathogenicity of plant-pathogenic Acidovorax species. BlastP analysis of one of the selected genes suggested it encodes a ubiquitin family protein. Signal peptide prediction tools indicated an N-terminal fused signal peptidase I (SPI) signal sequence, suggesting its secretion to the extracellular environment. We applied a marker-free mutagenesis approach to delete the entire ORF of this gene and found the mutant to be severely compromised in virulence on melon plants in a seed-to-seedling transmission assay. Furthermore, in-vitro growth curves indicated that the mutant differed from the wild type during the late-lag phase of growth and during the stationary phase, where it persisted for much longer than the wild type before the population declined. This is in line with much larger colonies formed by the mutant, with greater number of cells per colony and significantly longer cells than the wild type. We are currently investigating how this protein influences bacterial growth and virulence.

Text

Chili pepper (*Capsicum annum*) is a globally important crop, but its production is impacted by Bacterial Leaf Spot (BLS), caused by *Xanthomonas euvesicatoria* pv. *euvesicatoria*. The

fine-scale interaction between the pathogen and host remains unknown. Utilizing stranded total RNA sequencing and the Illumina NovaSeq6000, high-depth Dual RNA-Sequencing was undertaken to investigate the host and pathogen gene expression profiles for a resistant and a susceptible cultivar over a time course of 0, 7, and 14 days after infection. A customized host-pathogen tailored ribosomal RNA (rRNA) depletion step removed >95% rRNA in all samples. The remaining sequences were mapped into the host (65-85%) and pathogen (0.01-8.9%) genomes. Differentially expressed genes (DEGs) were identified using fold change in expression and Manhattan distance of each treatment, compared to controls. The up-and-down-regulated genes among the resistant and susceptible chili pepper cultivars were identified, and gene ontology (GO) functional classes and the Kyoto Encyclopedia of Genes and Genomes (KEGG) were assigned. Obtained KEGG pathways suggest that resistant and susceptible cultivars showed different responses against *X. euvesicatoria* pv. *euvesicatoria* infection. This study provides a comprehensive representation of the genes involved in disease progression from both the host and pathogen which presents as a model for the exploration of genetic factors in other plant-microbe interactions.

P2.1-008

NICOTIANA BENTHAMIANA AS A SURROGATE HOST OF TWO PLANT-PATHOGENIC CLAVIBACTER SPECIES

HWANG In Sun. (1), PARK In Woong . (2), OH Eom-Ji . (3), OH Chang-Sik . (1,2,4)

Text

Clavibacter michiganensis and *C. capsici* are Gram-positive bacterial pathogens that cause bacterial canker in tomato and pepper, respectively, as host plants. In terms of detail symptoms, both bacterial pathogens cause canker in stems, blisters in leaves, and bird's eyes in fruits, and *C. michiganensis* additionally cause wilting in whole plants. Here we show that *Nicotiana benthamiana*, a commonly used model plant for studying molecular plant–pathogen interactions, is a surrogate host of *C. michiganensis* and *C. capsici*. When *C. michiganensis* and *C. capsici* were infiltrated into leaves of *N. benthamiana* with low concentration ($5x10^4$ cfu/ml), blister-like lesions were observed on the infiltrated sites, and their growth was dramatically increased about 10^4-fold like natural pathogens. Blister-like lesions were closely associated with cell death and the generation of reactive oxygen species. Infiltration with a high concentration (10^8 cfu/ml) of two *Clavibacter* species caused strong necrosis in leaves. When both pathogens were injected into *N. bethamiana* stems, they caused typical canker like in tomato and pepper, and *C. michiganensis* eventually caused wilting. These results suggest that both *Clavibacter* bacteria can cause all symptoms in *N. benthamiana* similar to those developed in tomato and pepper. We propose that *N. benthamiana* is a surrogate host of these *Clavibacter* pathogens and it can be used for identifying novel virulence factors.

Text

The Vfm quorum sensing (QS) system is preponderant for the virulence of different species of the phytopathogenic bacteria of the genus *Dickeya*. In the model strain *D. dadantii* 3937, the Vfm QS system was shown to be responsible for the control of the production of plant cell wall degrading enzymes (PCWDEs). The transduction of the Vfm QS signal results into the activation of the promoter of the gene *vfmE* encoding a transcriptional regulator of the AraC family which itself activates the promoter of PCWDE genes. The *vfm* gene cluster includes 26 genes involved in the biosynthesis, sensing or transduction of the QS signal. It encodes several nonribosomal peptide synthetases (NRPS), indicating that the Vfm QS signal is a complex short peptide. To date, the Vfm QS signal has escaped detection by analytical chemistry methods. Using a strain-specific polymorphism in the NRPS genes *vfmO* and *vfmP* was shown to determine the production of different analogs of the Vfm QS signal. By analogy with the Agr QS system of *Staphylococcus aureus*, the production of different analogs of the signal is expected to be related to variations in the signal transduction activity of the Vfm QS system, resulting in variations in the level of activation of the promoter of the regulator gene *vfmE*. To explore this hypothesis, we used a reporter gene fused to the promoter of the gene *vfmE* to compare the activity of the *vfmE* promoter among strains of *Dickeya* producing different analogs of the Vfm QS signal.

Text

Bacterial fruit blotch, caused by *Acidovorax citrulli*, severely damages watermelon, melon, and other cucurbit crops worldwide. Although many virulence determinants have been identified in *A. citrulli*, including swimming motility, twitching motility, biofilm formation, and the type III secretion system (T3SS), research on their regulation is lacking. To study virulence regulation mechanisms, we found a putative histidine kinase $BarA_{Ac}$ that may

be related to the T3SS regulator HrpG in *A. citrulli*. We deleted and characterized $barA_{Ac}$ in *A. citrulli* Aac5 strain. Compared to the wild-type Aac5, virulence and early proliferation of $barA_{Ac}$ mutant in host watermelon cotyledons were significantly increased, and induction of hypersensitive response in non-host tobacco was accelerated, while biofilm formation and swimming motility were significantly reduced. In addition, the transcriptomic analysis revealed that the expression of many T3SS-related genes was upregulated in the Δ$barA_{Ac}$ deletion mutant when cultured in KB medium. Meanwhile, the Δ$barA_{Ac}$ deletion mutant showed increased accumulation of the T3SS regulator HrpG in KB medium, which may account for the increased deployment of T3SS. This suggests that the putative histidine kinase $BarA_{Ac}$ is able to repress the T3SS expression by inhibiting HrpG in the KB medium, which appears to be important for rational energy allocation. In summary, our research provides further understanding of the regulatory network of *A. citrulli* virulence.

P2.1-011

DDI1 – A NOVEL REGULATOR OF THE 26S PROTEASOME AND IMMUNITY IN PLANTS

RAFFEINER Margot. (1,2), LANGIN Gautier. (1,2), HUANG Tan. (2), FRANZ-WACHTEL Mirita. (3), MACEK Boris. (3), LOZANO-DURÁN Rosa. (2), ÜSTÜN Suayb. (1,2)

Text

The yeast DNA-damage inducible protein 1 (Ddi1, mammalian DDI1/DDI2) has been previously shown to be a ubiquitin-dependent protease, acting synergistically with the 26S proteasome protein degradation machinery. One of the characterized targets of DDI2 in mammals is NRF1, a transcription factor that is translocated to the nucleus and activates transcription of proteasome subunit genes upon proteotoxic stress. Here, we identify DDI1 as a potential important regulator of the plant 26S proteasome, as well as plant immune responses. Proteomics analysis revealed DDI1 as a putative interactor of the NRF1 functional Arabidopsis analogs NAC53 and NAC78, suggesting a similar role of DDI1 in plants. Its role as a novel regulator of proteasome-dependent processes is further validated by additional proteomics and TurboID proximity labeling experiments with DDI1. Moreover, virus-induced gene silencing (VIGS) of *DDI1* in *N. benthamiana* enhances proteasome activity upon infection with the plant pathogen *Pseudomonas syringae pv. tomato* (*Pst*), further supporting a synergistic function between DDI1 and the 26S proteasome in plants. VIGS of *DDI1* also leads to a higher susceptibility of *N. benthamiana* towards *Pst*, revealing that DDI1 has a positive regulatory role during plant immune responses. As such, DDI1 might be a novel component at the nexus of proteolytic degradation and plant immunity. We will discuss different approaches to unravel the mode of action of DDI1 regulating both processes.

Text

Compartmentalization of transcripts in membraneless aggregates allows rapid and cost-efficient responses to stimuli. Processing bodies (PBs) are dynamic ribonucleoprotein aggregates formed by phase separation in the cytosol. PBs are involved in translational arrest and mRNA decay and regulate several developmental processes and responses to stresses, including plant-pathogen interactions. Basal plant defense responses trigger a quick disassembly of PBs, possibly deregulating the expression of immunity genes. Here, we show that upon *Pseudomonas syringae* (*Pst*) infection, PB assembly is enhanced in an effector-dependent manner. Moreover, a PB-defective mutant is more tolerant to bacterial infection. Counterintuitively, this mutant is not affected in canonical defense responses such as salicylic acid or ROS production, suggesting alternative mechanisms contributing to susceptibility currently being studied through transcriptomic approaches. We identified two *Pst* effectors that associate with PB components and induce their formation. Interactomic studies allowed us to identify new PB-associated components upon infection. Among these, we found translational regulators, proteasomal subunits and ubiquitin-binding proteins, connecting RNA metabolism with protein homeostasis in the context of compatible plant-pathogen interactions. Altogether, this work reveals PBs as novel negative regulators of plant immunity directly targeted by bacterial effectors to promote infection.

Text

Pseudomonas syringae pv. *actinidiae* (Psa) is a causative agent of bacterial canker of kiwifruit (*Actinidia chinensis*) and its pandemic lineage has caused considerable damage in kiwifruit orchards worldwide. While there is growing understanding of how pathogens evolve in agricultural environments subsequent to their emergence, far less is understood about how pathogens and wild crop relatives coevolve prior to pathogen spillover to crops. To better understand how plants and pathogens coevolve in the wild, we collected samples from nearly 200 wild kiwifruit relatives across South Korea for dual pathogen virulence and host immunity enrichment sequencing (PenSeq + RenSeq). A complementary analysis of the genus-wide diversity of nucleotide-binding leucine-rich repeat proteins in 43 previously sequenced *Actinidia* genomes was performed, for comparison with a detailed examination of

Psa effector dynamics and evolution. This work enables us to uncover the coevolutionary dynamics of effectors and immunity genes circulating in wild populations.

P2.1-014

EVALUATION OF DEFENSE INDUCTION IN GRAPEVINE PLANTS (VITIS VINIFERA L.) BY PSEUDOMONAS PROTEGENS, THROUGH QPCR.

RUIZ Braulio. (1), MOYA-ELIZONDO Ernesto. (1)

(1) University of Concepcion, Chillán, CHILE

Text

In Chile, the production of wine grapes has annual growth rates of 7.4%. However, there is a great threat to this growth associated with the development of vineyard diseases that can lead to low yields and loss of competitiveness in the market. Disease control is based on the application of chemical fungicides and bactericides that affect the environment and limit the target markets. Induction of resistance in plants through biological inducers appears as an alternative to be include in integrated disease management programs. The objective of this study was to evaluate the induction of resistance genes in grapevines plants cultivar Chardonnay by applying two inducers based on Pseudomonas protegens (Taniri® WP; 1 g L^{-1}, MaxGrowth 0,1 mL L^{-1}), by qPCR, through the ΔΔCt method. The expression of the genes coding for the PR1 (Pathogenesis-related protein 1), PR2 (Beta-1,3-glucanase), PR10 (Pathogenesis-related protein 10), PAL (Phenylalanine ammonia-lyase), SUB (Protease-Subtilisin), and LOX (Lipoxygenase) proteins was studied at 24 hours, 7 days, and 14 days after application of the bioinductors. Bacterial formulation induced the expression of this genes at a level equal to or greater than a chemical inducer (Acibenzolar-S-metil), evidencing their effectiveness in inducing resistance in grapevines plants.

Text

Pseudomonas amygdali pv. *lachrymans* (*Pal*) causes two different diseases on cucumber: bacterial stem wilt and bacterial angular leaf spot. Under field conditions, bacterial stem wilt of cucumber infects leaf veins and stems, while bacterial angular leaf spot of cucumber does

not infect leaf veins and occasionally infects stems. The aim of this study was to characterize the colonization ability of *Pal* strains of the two cucumber diseases. Representative *Pal* strains were labeled with an ultraviolet green fluorescent protein (GFPuv) for the bacterial stem wilt pathogen (A2-GFPuv) and the angular leaf spot pathogen (psl8-GFPuv). Cucumber tissues (leaf, stem, and fruit) were inoculated with strains A2-GFPuv and psl8-GFPuv, and observed under ultraviolet light and by a fluorescent microscope. The results showed that *Pal* strain A2-GFPuv infected leaf veins in the seedling spray-inoculation assay, and colonized up to the true leaves and down to the roots in the stem inoculation assay. However, *Pal* strain psl8-GFPuv could not infect leaf veins, and the stems showed relatively mild symptoms near the inoculation point at 7 days post inoculation. On cucumber fruit tissues, the water-soaked spots were larger and more obvious for fruits inoculated with A2-GFPuv compared with those of psl8-GFPuv. Overall, the ability of bacterial stem wilt pathogen *Pal* A2-GFPuv to infect cucumber leaves, stems, and fruits was more aggressive than that of bacterial angular leaf spot pathogen *Pal* psl8-GFPuv.

Text

Pseudomonas syringae pv *syringae* (Pss) has a reduced type III effector repertoire, but often produces syringomycin, syringopeptin, and syringolin A toxins. Comparative genomics was used to categorize the effector abundance in Prunus-infecting Pss strains. In addition to the conserved effector locus (CEL) identified in most *P. syringae* (Ps) pathogens (*hopAA1*, *hopM1*, and *avrE1*), a Core of effectors was found to be common in Ps phylogroup 2 (*hopAG1*, *hopAH1*, *hopAI1*, and *hopI1*). A set of Prunus-specific effectors is associated with cherry pathogenicity (*hopAR1*, *hopH1*, *hopA2*, *hopAE1*, and *avrRpm1*) and a Flexible set (*hopAF1*, *hopAZ1*, and *hopBE1*) varies among isolates. RNA-seq of Pss9644 validated effector gene expression in Hrp-Inducing Minimal Media. Effectors were then deleted group-by-group using the Flexible, Prunus, Core, CEL, and toxin gene sets. The pathogenicity of the mutants was tested on wood, leaves, and fruits of sweet cherry (*Prunus avium* L.). Toxins were found to play a key role in disease development in wood and fruit. The effectorless mutant had a zero-pathogenicity phenotype in leaves and CEL played an important role in the early stages. *HopAF1* in an otherwise effectorless background was found to be required for virulence in wood, despite deletion having no phenotype when more conserved effectors were present. Our results highlight the niche-specific differential roles of toxins in cherry tissues and the complexity of effector redundancy in cherry pathogens.

P2.1-017

CHEMOTAXIS AND AEROTAXIS ARE REQUIRED FOR PLANT INFECTION OF PSEUDOMONAS SYRINGAE PV. TABACI 6605

WATANABE Yuta. (1), TUMEWU Stephany. (1), MATSUI Hidenori. (1), YAMAMOTO Mikihiro. (1), NOUTOSHI Yoshiteru. (1), TOYODA Kazuhiro. (1), **ICHINOSE Yuki. (1)**

Text

Pseudomonas syringae pv. *tabaci* 6605 (*Pta*6605) is a causal agent of wildfire disease in host tobacco plants. Although chemotaxis has been shown to be necessary for *Pta*6605 for tobacco infection, the chemoattractants at the site of infection are unclear. *Pta*6605 was attracted to the apoplastic fluid from host tobacco leaves, which contain abundant amino acids, including γ-aminobutyric acid (GABA). *Pta*6605 has 54 potential chemoreceptor genes. Among them, we investigated 5 dCache_1 type chemoreceptor genes and identified a GABA chemoreceptor gene, *mcpG*, and three amino acids chemoreceptor genes, *pscA*, *pscB*, and *pscC2*. Although, the deletion of *mcpG* retained surface motility and chemotaxis ability to amino acids, the mutant abolished chemotaxis to GABA and reduced the ability to cause disease. The *pscA*, *pscB*, and *pscC2* mutant strains reduced chemotaxis to most amino acids. A mutant of another dCachs_1 type chemoreceptor, *pscC1* lost motility. Among these mutant strains, *pscB*, *pscC1*, and *pscC2* remarkably reduced surface motility and virulence. *Pta*6605 also shows positive aerotaxis ability. We found at least two aerotaxis receptor genes, *aerA* and *aerB*. Although *aerA* and *aerB* mutant strains showed wild-type levels of surface motility and chemotaxis ability to yeast extract, these mutant strains showed less colonization in the early stage of plant infection. These results indicate chemotaxis and aerotaxis contribute to the successful plant infection of *Pta*6605.

P2.1-019

CONTACT DEPENDENT INHIBITION IN RALSTONIA PSEUDOSOLANACEARUM

GOPALAN NAIR Rekha. (1), EVSEEVA Daria. (1), MCCANN Honour. (1)

(1) Max Planck Institute for Biology, Tübingen, GERMANY

Text

Ralstonia pseudosolanacearum is a deadly bacterial plant pathogen known to infect many plant species. Comparative genomics of a South Korean population of R. pseudosolanacearum revealed that recombination frequently targets secreted gene products including type III secreted effectors and CdiA proteins, similar to hemagglutinin. CdiA proteins vary in the presence of a C-terminal toxin domain that inhibits the growth of adjacent cells lacking cognate immunity protein CdiI, a phenomenon called contact-dependent growth inhibition (CDI). CDI mediates both antagonistic and cooperative contact-dependent interactions, contributing to the formation of populations sharing identical CDI loci. R. pseudosolanacearum carries an expanded set of CDI loci compared to Burkholderia spp., where their function is better characterized. My work examines whether these loci mediate contact-dependent interactions and contribute to phenotypes associated with virulence and cooperative behavior in R. pseudosolanacearum.

Text

Durable resistance to Xanthomonas oryzae pathovars oryzae and oryzicola is highly sought after in rice due to the pathogens' ability to impact crop yield. Regions of the rice genome known as quantitative trait loci (QTL) were previously identified using a multi-parent advanced generation intercross (MAGIC) rice population. These QTL are associated with decreased lesion lengths by X. oryzae on rice. What remains unknown is the molecular basis for induction of rice genes within QTL during pathogen infection. Upon infection, X. oryzae injects the host with transcription activator-like effector (TALE) proteins. These effectors bind to plant promoters to induce gene transcription. We hypothesize that differential binding of TALE to promoters of rice genes under QTL leads to the varied phenotypes exhibited across varieties. We designed a pipeline that predicts TALE-regulated candidate genes involved in quantitative resistance. This pipeline identifies genes under QTL that have binding sites for X. oryzae TALEs in their promoter and a strong correlation between binding site presence and disease phenotype. We used this pipeline with data for the eight MAGIC founders to identify candidate genes involved in resistance against seven X. oryzae strains. We then analyzed transcriptomes of plants inoculated with X. oryzae to validate candidate genes. Here, we propose a method that could streamline the identification of genes involved in quantitative resistance to TALE-harboring Xanthomonas.

FLAVONOIDS AND FATTY ACIDS, KEY METABOLITES IN PSEUDOMONAS SYRINGAE DEVELOPMENT ON CHERRY SHOOTS

VINCHIRA-VILLARRAGA Diana. (1), RABIEY Mojgan. (1), JACKSON Robert. (1)

(1) University of Birmingham, Birmingham, UNITED KINGDOM

Text

Pseudomonas syringae pv. *syringae* (*Pss*) and pv. *morsprunorum* (*Psm*) are the causal agent of the bacterial canker of cherry trees. Both pathogens infect woody tissues but exhibit different pathogenicity towards their host, which may be related to their adaptation to this environment. In this study, we aimed to characterize (*in vitro*) the changes in *Pss/Psm* metabolism in the presence of their host using mass-spectrometry-based untargeted metabolomics. After five days of inoculation on sterile cherry shoots, *Pss* and *Psm* caused the accumulation of several flavonones, such as naringenin, suggesting the degradation of their respective glycosylated forms. This hypothesis was supported by the reduction in the abundance of several o-glycosylated flavonoids (e.g. Naringenin-7-O-glucoside), which

remained stable on the control shoots. Additionally, a significant decrease of epicatechin was observed in *Pss*, and *Psm* inoculated shoots. *Pss* seemed to be more efficient at degrading cherry flavonoids than Psm, which could explain why this bacterium grows better while using cherry as the sole source of nutrients. Interestingly, only *Psm* accumulated Rhamnolipid-related backbone fatty acid chains while growing on cherry shoots. Despite its role in the infection process remains unclear; a relationship with *Psm* motility is suggested. Further research will be done to understand the differences between *Pss* and *Psm* interaction with cherry and to confirm the observed results under in vivo conditions.

CHARACTERIZING ENVIRONMENTAL SENSING MECHANISMS IN DICKEYA DADANTII

GONZALEZ-TOBON Juliana. (1), STODGHILL Paul. (1,2), FILIATRAULT Melanie. (1,2)

(1) Cornell University, Ithaca, UNITED STATES; (2) USDA-ARS, Ithaca, UNITED STATES

Text

Bacteria sense their surrounding environment and move accordingly via chemoreceptor proteins in a process known as chemotaxis. These proteins play essential roles during the disease cycle. Members of the *Dickeya* genus, that cause disease on numerous crops and ornamental plants, present notoriously more methyl-accepting chemoreceptors (MCPs) than other closely related bacteria. However, the functions and signals of many of these MCPs remain unknown. Interestingly, long untranslated regions exist upstream of the coding regions of MCPs in *Dickeya*. We hypothesized these regions harbor small non-coding RNAs. Transcription start sites were identified using Cappable-seq and found to align well with the areas being transcribed, which were detected via RNAseq and validated via qRT-PCR, *in vitro* and *in planta*. Using biocomputational methods we identified potential promoters, putative regulatory sequences, and terminators in these regions. Together these results showed that such intergenic regions and MCP genes are actively transcribed *in planta*. Mutants lacking these regions, as well as lacking the MCP genes, showed differences in their ability to swim and swarm, compared to wild-type. Opposite patterns of motility were noticed among some MCP mutants and their corresponding upstream deletion mutants. Some mutants displayed altered symptoms in potato stems. Our results provide new insight into the sensing and signaling mechanisms used by *Dickeya* and provide targets for disease control.

Text

Bacterial blight caused by Xanthomonas oryzae pv. oryzae (Xoo) severely affects rice yield. Transcription activator-like (TAL) effectors and non-TAL effectors play key roles in Xoo pathogenicity. The TAL effectors were reported to regulate gene expression by combining with host target gene promoters. However, the study on non-TAL effectors virulence mechanism is very limited. Here, we report a new non-TAL effector NUDX4 of Xoo that contains a Nudix hydrolase motif. The NUDX4 knockout mutant displays lower virulence in rice than wild-type Xoo. Ectopic expression of NUDX4 suppressed reactive oxygen species (ROS) burst and pathogenesis-related genes expression in transgenic rice plants, which are more susceptible to Xoo infection. The biochemical assays showed that NUDX4 possesses NADH/ ADP-ribose pyrophosphorylase activity. Mutation of key residue in Nudix hydrolase motif significantly impaired NUDX4 catalytic activity and virulence function. Upon further investigation, we found NUDX4 is a dimer in vitro and in vivo. We then built the homodimer model of NUDX4 through the three-dimensional structure predicted by AlphaFold 2. Based on structure-guided mutagenesis, we demonstrated that homodimerization of NUDX4 is essential for catalytic activity and virulence function. Taken together, our results indicate that Xanthomonas could produce Nudix hydrolase effector to manipulate host immunity.

Text

Onion bacterial diseases are caused by diverse pathogens belonging to Pantoea, Pseudomonas, Burkholderia, Rouxiella, Rahnella, and Enterobacter. Interestingly, virulence factors employed by these bacteria to infect onion are diverse. For example, Pantoea ananatis and some onion-adapted strains of P. stewartii subsp. indologenes utilize distinct phosphonate biosynthetic gene clusters, “HiVir” and “Halophos”, respectively, to infect onion. The thiosulfinate tolerance cluster “alt” in Pantoea spp. aids in colonization of the thiosulfinate-rich environment in onion bulbs. Two closely related Pseudomonas species, P. viridiflava and P. alliivorans are also associated with onion. While an “alt” gene cluster is present in both, alt makes greater contributions to symptom development in P. viridiflava than in P. alliivorans. Onion pathogenic strains of Rouxiella badensis utilize a lipopeptide gene cluster, the “rot” cluster, to infect onion. Management of these bacterial pathogens is based primarily on applications of copper-based bactericides at susceptible crop growth stages. Cultural practices, e.g., use of a chain digger for mechanical harvest, also reduced internal bacterial bulb rot in field trials. Clipping onion necks at least 5 cm above the bulb reduced bacterial rot in storage compared to shorter necks. Together, advances in onion-pathogen interactions and applied aspects of onion production are aiding long-term sustainable strategies to reduce losses to bacterial rots.

(1) Institute for Molecular Physiology, Heinrich Heine University, Düsseldorf, GERMANY; (2) Institute for transformative Biomolecules, Nagoya University, Nagoya, JAPAN

Text
The plant pathogen *Xanthomonas oryzae pathovar oryzae* (*Xoo*) is responsible for the so-called bacterial leaf blight in *Oryza sativa*. Infestation of rice plants by *Xoo* not only causes monetary losses of several billion U.S. dollars annually, but also threatens global food security, as rice is considered a staple food in Africa and Asia. *Xoo* is mainly spread during the typhoon season. The storms ensure that the rice leaves are wounded, offering a potential entry point into the plant. However, even without wounding, *Xoo* can invade the plant through natural openings. After invasion of the hydathodes or the wound, *Xoo* colonizes into the xylem, where it spreads rapidly throughout the plant. Controversial here is the direction of the colonization from the leaf tip toward the stem, while the flow in the infested xylem is the opposite direction from the root through the stem to the leaf tip.

Text
The type VI secretion system (T6SS) is deployed by many proteobacteria for interbacterial competition or pathogenesis against the host. Agrobacteria, a group of soil-borne phytopathogen causing crown gall disease, use the T6SS to attack closely- and distantly-related bacteria *in vitro* or *in planta*. Current evidence suggests that the agrobacterial T6SS is not essential for pathogenesis, but its influence on natural disease incidence and gall-associated microbiota (i.e., gallobiome) is unknown. Here, we established a soil inoculation method for wounded tomato seedlings that mimics natural infections, and optimized a blocker-mediated enrichment method for bacterial 16S rRNA gene amplicon sequencing to address these questions. By comparing the *Agrobacterium* wild-type strain C58 with two T6SS mutants, we demonstrated that the T6SS promoted disease occurrence and influenced on gallobiome composition. Also, the season of inoculation played a more important role than

the T6SS in shaping the gallobiome. The influence of T6SS was evident in summer, in which two Sphingomonadaceae species and the family Burkhoderiaceae were enriched in the gallobiome induced by the mutants. In vitro competition and plant colonization assay showed T6SS-mediated antagonism to Sphingomonas sp. R1 strain isolated from tomato rhizosphere. In conclusion, this work demonstrates that the Agrobacterium T6SS promotes tumorigenesis in infection process and provides competitive advantages in gallobiome.

P2.1-027

GENE EXPRESSION PROFILING IN SOILS OF DICKEYA DADANTII, A CAUSAL PATHOGEN OF QUICK DECLINE DISEASE OF FRUIT TREES

FUJIKAWA Takashi. (1)

(1) National Agriculture and Food Research Organization, Tsukuba, JAPAN

Text

The plant pathogen *Dickeya dadantii* is known as a soft-rot disease pathogen of various plants. Many economic crops and vegetables are affected by production losses due to this pathogen. In Japan, *D. dadantii* has been known to exist on farmlands throughout the country. Additionally, it has been reported that the diseases caused by this pathogen occur not only in annual crops but also in some fruit trees such as peach, Japanese apricot, apple, and Japanese pear. These diseases of fruit trees have been reported as “the quick decline”.

Typical symptoms of “the quick decline” are the sudden leakage of reddish-brown sap from the trunks and branches, and are that the trees decline rapidly. In addition, *D. dadantii* seems to invade the roots and grafting parts of rootstocks from the soil and proliferate inside the trees.

To elucidate the pathogenicity of *D. dadantii* to fruit trees, especially the virulence factors working during soil-to-fruit tree invasion, our group analyzed gene expression in orchard-like soils.

The analysis by RNA-seq and qRT-PCR revealed that *D. dadantii* in soils expressed *hrpN* gene more strongly than pectinase genes, and expressed the related genes to iron ion chelation. These results will help to clarify the ecology of *D. dadantii* in soils and understand the pathogenicity to fruit trees.

This work was supported partly by MAFF Commissioned project study on “Development of stable cultivation technology in young stage of fruit trees” Grant number JPJ008720.

GERMANY; (3) University of Tübingen, Tübingen, GERMANY; (4) Leibniz Institute of Plant Biochemistry, Halle (Saale), GERMANY

Text

Apple Proliferation is an economically important and widespread disease in apple growing regions in Europe. It is caused by an infection with the plant pathogen 'Candidatus Phytoplasma mali' (P. mali). The infection leads to the production of low-quality fruits and disease outbreaks cause high economic losses in affected regions. Phytoplasma release different types of effector proteins which are involved in changing the plant host metabolism and play a pivotal role in symptom development. Thus, unravelling their function is an important step towards a better understanding of the disease and an indispensable prerequisite for developing specific control strategies against Apple Proliferation disease. PME10 is a novel, potential P. mali effector. It is expressed during infection and binds different Malus × domestica proteins, such as RuBisCo- Activase (RCA) and E3 ligases. RCA plays an important role during photosynthesis by activating RuBisCo. E3 ligases are a class of enzymes that are involved in the regulation of proteasomal protein degradation. A direct interaction between the PME10-interacting RCA and E3 ligases could not be demonstrated. It is hypothesized that PME10 acts as an adaptor that mediates an interaction between E3 ligases and RCA and thus drives the proteasomal degradation of the latter one. The aim of this project is to elucidate the role of the PME10 on photosynthesis during infection and disease development.

TYPE III EFFECTORS OF PSEUDOMONAS SYRINGAE REGULATE THE NLR TRANSCRIPTS' STABILITY BY TRIGGERING UPF3 DEGRADATION IN ARABIDOPSIS

LEE Eunji. (1), JUNG Ho Won. (1)

(1) Dong-A University, Busan, REPUBLIC OF KOREA

Text

Plants have evolved two layers of immunity: the first layer is pattern-triggered immunity (PTI) triggered by the recognition of microbe-associated molecular patterns via pattern recognition receptors, and the second layer is effector-triggered immunity (ETI) activated through interaction between pathogen-derived effectors and nucleotide-binding oligomerization domain (NOD)-like receptors (NLRs). Nonsense-mediated mRNA decay (NMD), a conserved eukaryotic mRNA surveillance mechanism that degrades aberrant RNAs, has been shown to play a role in the plasticity between PTI and ETI. Recently, our group reported that NMD controls the expression of a subset of NLR genes. However, the role of bacterial effectors in manipulating NMD activity during infection remains unclear. Infection of *Pseudomonas syringae* pv. *tomato* DC3000 (*Pst*DC3000) dramatically impacted on accumulation of UP-FRAMESHIFT 3 (UPF3) protein, while degradation of UPF3 was minimized in leaves infected with effector-depleted derivatives of *Pst*DC3000. The transcripts of NLRs carrying NMD-sensitive features were more stable in infected plants with *Pst*DC3000 than those with mutated *Pst*DC3000. Further analysis of the total RNAome revealed transcriptional changes under NMD-defective conditions, such as pathogen-infected conditions and mutant plants. These results propose a possibility that plants may use the NMD machinery, especially UPF3 protein, as a decoy-like thing to enhance the level of NLR transcripts during infection.

THE SECRETED SERINE PROTEASE CHPG OF CLAVIBACTER MICHIGANENSIS ACTS AS A HOST SPECIFICITY DETERMINANT THAT RESTRICTS IT FROM EGGPLANTS

VERMA Raj Kumar. (1), **TEPER Doron. (1)**

(1) Agricultural Research Organization (ARO) - Volcani Institute, Rishon Lezion, ISRAEL

Text
Clavibacter michiganensis (Cm) is the causal agent of bacterial canker of tomato. Data regarding the host range of Cm outside of tomato is not well established. We found that eggplant is resistant to Cm strain 382. A screen of a Cm mutant library for HR elicitation found that a marker exchange mutant of the secreted serine protease chpG failed to elicit HR in eggplant. In addition, the chpG mutant was able to cause disease in eggplant and the mutant bacterial populations in eggplant were 1000-fold higher than Cm 382, indicating that chpG acts as an avirulence gene. Complementation analysis conducted with wild-type and catalytically inactive chpG variants showed that immune recognition of ChpG is dependent on its catalytic activity. To examine whether chpG acts as a host specificity determinant within Cm populations, we screened 50 Cm isolates for virulence and HR elicitation in eggplant. We identified that only two isolates, C47 and C48, were pathogenic on eggplant, and both failed to elicit HR. We sequenced chpG regions of Cm isolates and found that eggplant-pathogenic clones harbor a unique allelic variant of chpG. Introduction of the chpG variant of C48 into the 382 chpG mutant failed to complement it while the introduction of the chpG variant of 382 into C48 abolished its virulence in eggplant. Our data shows that chpG is an avirulence gene of Cm in eggplant, and that natural allelic variations in chpG act as a host range determining factor in different Cm isolates.

PHENOTYPIC TESTING OF CANDIDATE VIRULENCE GENES IN PSEUDOMONAS SYRINGAE PV. AESCULI ASSOCIATED WITH ADAPTATION AND INFECTION IN HORSE CHESTNUT

DHAOUADI Sabrine. (1), RABIEY Mojgan . (1), JACKSON Robert W. (1)

(1) University of Birmingham, School of Biosciences, Birmingham, UNITED KINGDOM

Text
The bleeding canker of European horse chestnut is a recently emerged disease caused by *Pseudomonas syringae* pathovar *aesculi* (*Pae*). The major virulence mechanisms driven by this pathogen to infect woody hosts are scarcely investigated. However, genome comparison of the *Pseudomonas syringae* complex revealed conserved regions only present in *Pae* which are implicated in the metabolism of aromatic and phenolic compounds, in sucrose uptake and utilization and in fatty acid biosynthesis. The *hopAB1* effector and HrpL regulon are essential for suppressing and/or triggering defences in different plant species and for symptom development, respectively. However, their contribution to the virulence of *Pae* is also important to analyse.
Our goal was to investigate the main components contributing to *Pae* virulence on horse chestnut. Therefore, we conducted functional analyses through mutagenesis and

complementation experiments to evaluate the genetic adaptations to infection of the woody parts of the tree. Our study revealed the important role of *hopAB1* and hrpL in suppressing the plant immune response and causing disease in tobacco plants and horse chestnut. The deletion of the genes encoding for the catabolism of anthranilate and catechol reduced virulence in horse chestnut as well as those encoded within sucrose and fatty acid clusters. Our results highlight the role of the enzymatic activities encoded within *Pae* and their implication on its evolution and adaptation to woody hosts.

IMPROVED METHOD FOR ISOLATION OF CLAVIBACTER SEPEDONICUS FROM POTATO EXTRACTS USING SOLANUM MELONGENA

NAS Mathijs. (1), VREEBURG Robert. (1)

(1) NAK, Emmeloord, NETHERLANDS

Text
Clavibacter sepedonicus is the causal agent of bacterial ring rot characterized by wilting of potato plants and rotting of tubers and is known from Europe, North-America and Asia leading to substantial economic losses. Isolation of C. sepedonicus from material with a low level of infection is required for confirmation of a positive diagnostic test. Limited information is available on the minimum inoculum concentrations needed to confirm Koch's Postulates. Inoculation of Solanum melongena is used for isolation of low concentrations of C. sepedonicus from potato extracts. Here we present an improvement of this method by adding sodium pyruvate and/or D-mannitol to the inoculation solution. C. sepedonicus suspensions were mixed with potato extracts to obtain concentrations ranging from 1,6x102 – 1,4x104 cfu ml-1 and injected into the axil of the first grown leaves. The inoculation solutions were supplemented with sodium pyruvate or D-mannitol. After 2 wks the inoculated stem parts were harvested, processed and plated on MTNA+Natamycine agar plates. Plates were evaluated for the presence of C. sepedonicus after 6d of incubation at 22 °C. Isolation of C. sepedonicus with sodium pyruvate or D-mannitol was 10-100 times more sensitive compared with isolation without the additives. Concentrations of C. sepedonicus as low as 1,6x102 cfu ml-1 in potato extract have been successfully isolated with the improved method.

P2.1-033

INTERACTIONS AND GENOME BIOLOGY OF DICKEYA FANGZHONGDAI: A POTENTIAL THREAT TO POTATO INDUSTRY

DOBHAL Shefali. (1), ARIZALA Dario . (1), BOLUK Gamze. (1), ARIF Mohammad. (1)

(1) UNIVERSITY OF HAWAII AT MANOA, Hawaii, UNITED STATES

Text
Soft Rot *Pectobacteriaceae* (SRP) incurred significant losses globally to vegetable, ornamental and fruit industries. *Dickeya fangzhongdai* strain PL145 was isolated from

infected taro corm (Hawaii, USA), and found highly pathogenic to potato. The strain (peritrichous; confirmed using TEM) was identified using qPCR and MLSA, and phenotypically characterized using Biolog GEN III microplate and in vitro assays. High-quality hybrid assembly (5.26 Mb; 56.4% GC) was prepared using Oxford Nanopore MinION and Illumina NovaSeq data. The ANI and dDDH values were 97.1 and 73.3% with DSM10197^T *D. fangzhongdai*, respectively. The genome showed high heterogeneity—the presence of CWDE, Out-type T2SS, Type III secretion system, flagellar type secretion system (except Pilus cluster I) were similar to DSM10197^T. *vir* gene Type IV secretion system was present in PL145 but not in DSM10197^T. Sixty-four genomic islands, prophage, and CRISPR-Cas 1E and 1F were present in PL145. Significant differences (p=0.05) were observed in motility, and found significantly (P=0.05) aggressive, macerating entire taro corm but produced no symptoms on aerial parts of the plants. On potato, a typical severe black leg symptoms leading to death of the plants were observed. The Tn7 generated mScarlet-I mutant of PL145 rapidly colonized the potato plants, while no symptoms were observed with DSM10197^T, demonstrating differences in virulence and potential threat to the vegetable industry.

Text

Bacterial canker of kiwifruit caused by *Pseudomonas syringae* pv. *actinidiae* biovar 3 (Psa3) is a serious threat to kiwifruit production worldwide. To investigate the molecular mechanism of Psa3 infection, we developed a rapid and reliable high-throughput flood-inoculation method using kiwifruit seedlings. Using this inoculation method, we screened 3000 Psa3 transposon insertion mutants and identified 91 reduced virulence mutants and characterized the transposon insertion sites in these mutants. We identified seven type III secretion system mutants, and four type III secretion effectors mutants including *hopR1*. Mature kiwifruit leaves spray-inoculated with the *hopR1* mutant showed significantly reduced virulence compared to Psa3 wild-type, indicating that HopR1 has a critical role in Psa3 virulence. Deletion mutants of *hopR1* in Psa1, Psa3, Psa5, and Psa6 revealed that the type III secretion effector HopR1 is a major virulence factor in these biovars. Moreover, *hopR1* mutants of Psa3 failed to reopen stomata on kiwifruit leaves, suggesting that HopR1 facilitates Psa entry through stomata into plants. Furthermore, defense related genes were highly expressed in kiwifruit plants inoculated with *hopR1* mutant compared to Psa wild-type, indicating that HopR1 suppresses defense-related genes of kiwifruit. These results suggest that HopR1 universally contributes to virulence in all Psa biovars by overcoming not only stomatal-based defense, but also apoplastic defense.

RECENT XANTHOMONAS TRANSLUCENS PV. UNDULOSA ISOLATES ARE MORE VIRULENT AND POSSESS A DISTINCT TAL EFFECTOR REPERTOIRE COMPARED TO OLDER ISOLATES

GUTIERREZ CASTILLO Diego. (1), ROBERTS Robyn. (1)

(1) Colorado State University, Fort Collins, UNITED STATES

Text

Xanthomonas translucens, the bacterial pathogen that causes leaf streak disease in cereals, has become increasingly destructive around the world. While climate change and other challenges likely contribute to increased disease incidence and severity, many isolates collected within the past decade appear to be more virulent, and we hypothesize that genetic variation may be contributing to the increased aggressiveness in recent years. We characterized the virulence phenotypes of two isolates collected in 2018 from Colorado in the US and found that both caused more disease than older isolates from our collection. One isolate was collected from barley (CO236) and the other from wheat (CO237). We then sequenced the whole genomes of these isolates using ONT long-read sequencing and compared these to previously sequenced genomes in GenBank. While we did not observe any major genomic rearrangements between genomes, the analysis grouped CO236 and CO237 with all other translucens and undulosa pathovar genomes, respectively. We then analyzed the Type III Effectors of the pathovar undulosa and found that while the putative effectors were highly conserved, there were differences between isolates in their encoded Transcription Activator-Like (TAL) effectors, suggesting that more aggressive isolates had a similar TALE repertoire, distinct from less aggressive ones. We are currently conducting mutagenesis studies to determine the contribution of these TALE classes to the pathogen virulence.

Text

Clavibacter michiganensis (*Cm*) is a Gram-positive, xylem-colonizing bacterial pathogen of tomato. Worldwide, *Cm* is one of the most important tomato bacterial pathogens, causing bacterial canker. *Cm* is known to secrete serine protease effectors that contribute to bacterial virulence. Recently, two *Cm*-secreted protease effectors, Pat-1 and ChpG, were found to elicit host-specific immune responses in *Nicotiana tabaccum* (tobacco) and *Solanum melongena* (eggplant), respectively. Using comparative genomics, serine protease effectors of the chp family including Pat-1 and ChpG were found to be highly conserved in Clavibacter species causing disease on Solanaceous hosts, indicative of candidates mediating host range. The purified Pat-1 effector elicits cell death in *N. tabacum* varieties and one of two tobacco progenitors, but not in *N. benthamiana*. The ChpG effector elicits cell death in 15 cultivated S. melongena varieties, but not in the eggplant progenitor *Solanum incanum*. Because Cm lacks machinery to secrete proteins into host cells, we

hypothesize surface-localized immune receptors may recognize Pat-1 and ChpG. We seek to discover these receptors and will report progress on our screen of receptor candidates. If immune receptor candidates can be identified, their transfer into tomatoes would mark an important first step in breeding for *Cm* resistance.

SERRATIA FONTICOLA, A PUTATIVE BACTERIA ASSOCIATED WITH ABNORMAL VERTICAL GROWTH SYNDROME IN MACADAMIA

ZAKEEL Mohamed Cassim Mohamed. (1), GEERING Andrew. (1), **AKINSANMI Olufemi. (1)**

(1) Centre for Horticultural Science, Queensland Alliance for Agriculture and Food Innovation, The University of Queensland, Brisbane, Queensland, AUSTRALIA

Text

Abnormal vertical growth is a disease syndrome that affects macadamia, an evergreen tree nut crop. The syndrome is expressed as physiological and morphological aberrations causing significant yield losses to farmers. Based on the symptoms including abnormal elongation and reduced lateral branching and flowering, this study hypothesised that a vascular-limited pathogen, which modulates plant hormone production, is likely the cause of the syndrome. Two approaches were used to profile the assemblage of bacteria in macadamia trees with or without the symptoms. Conventional media culturing techniques revealed that regardless of the host phenology, Bacillus species were the most abundant, followed by Serratia and Paenibacillus. Serratia fonticola was exclusively isolated from the roots of all symptomatic trees sampled. DNA metabarcoding revealed 15 bacterial taxa only occurred on symptomatic trees, but only S. fonticola was consistently identified from the roots of affected trees. Based on the fact that S. fonticola strains are known to alter the hormone balance in plants, we suggest it is a likely candidate responsible for abnormal vertical growth syndrome in macadamia.

GENOMIC DIVERSITY AND PATHOGENICITY OF AUSTRALIAN AGROBACTERIUM SPECIES IN HORTICULTURE CROPS

ROACH Rebecca. (1), MANNERS Andrew. (1), CAMPBELL Paul. (1)

(1) Department of Agriculture and Fisheries, Brisbane, AUSTRALIA

Text

Agrobacterium is a genus of bacteria that interact with and alter the growth of host plants that may be beneficial or pathogenic in nature. Where this interaction is pathogenic, the presence of Agrobacterium species with tumour-inducing plasmids causes uncontrolled growths in plant tissue that may affect growth and yield in commercial crops. Detection and isolation of pathogenic Agrobacterium species in a diagnostic context is complicated by the limited distribution of the bacteria in the host plant and the potential diversity of these populations.

While detection of the Ti (tumour-inducing) plasmid is often used as an indicator of the presence of pathogenic Agrobacterium, the presence and content of these plasmids in Australian Agrobacterium populations requires more work to elucidate. The implications of Agrobacterium plasmid number and content and how this affects pathogenicity will allow for a more in-depth understanding of these interactions and their impact on Australian crops. This work utilised genomic analyses of genome and plasmid content in conjunction with pathogenicity assays to investigate the diversity of pathogenic Agrobacterium in Australia.

Text

Bacterial extracellular vesicles (BEV) are lipidic shuttles allowing the export of cellular material at a great distance from the cell. Mostly studied in animal-bacteria interactions, BEV were shown to play a role in virulence, inter-species competition and induction of the host immune response. Little is yet known about phytobacterial BEV. Recently, biotic factors have been shown to regulate BEV production such as in Pseudomonas putida where lignin derivatives influence BEV size and cargo (1). Hydroxycinnamic acids like ferulic acid, are largely released in plant environment, where they can modulate the ecology of numerous phytobacteria (2 ,3) . We hypothesized that ferulic acid would influence the production of BEV in the phytopathogen *Agrobacterium fabrum* C58 and the phytobeneficial *Azospirillum* sp. B510. Conversely, we also hypothesized that BEV from bacteria would have an influence on the host plant metabolites. In both *A. fabrum* and *Azospirillum* sp., we assessed the effect of ferulic acid on the BEV production and their cargos using microscopy and LC-MSn analyses respectively. Finally, after an exposure to BEV, we compared the specialized metabolite of plants using UHPLC-MS/QTOF. Our first results support the view that the plant environment influences the production of BEV in plant-associated bacteria and provide insight on their potential ecological role in plant-bacteria interactions.

Text

Xanthomonas campestris pv. *campestris* (*Xcc*) is a vascular pathogen of Brassicaceae naturally infecting leaf hydathodes to initiate black rot disease. Hydathodes are plant organs located at leaf margin and mediate guttation, ie. release of fluid derived from xylem sap. We conducted two parallel genetic screens on the Arabidopsis HEM (Homozygous EMS mutants) mutant collection searching for changes in hydathode numbers per leaf and bacterial multiplication in plant tissues upon hydathode infection conditions. Surprisingly, mutants with increased number of hydathodes did not sustain higher *Xcc* titers while plants with less hydathodes showed significantly more *Xcc* multiplication. Infection of Arabidopsis mutants with lower hydathode densities or infection of leaves with sealed hydathodes confirmed this phenotype. These conditions that promote watersoaking of leaf mesophyll link a developmental phenotype with an immune defect and suggest that water availability inside leaf tissues is critical for pathogen fitness and plant immunity.

BIOINFORMATICS APPROACH FOR IDENTIFYING POSSIBLE PHYTOPLASMA EFFECTOR PROTEINS

DERECIK Kayhan. (1), TULUM Isil. (1)

(1) ISTANBUL UNIVERSITY, Istanbul, TURKEY

Text

Phytoplasmas, which are plant pathogens belonging to the class Mollicutes, are transmitted by insects feeding on plant phloem. These pathogens manipulate host cell functions through the effector proteins they secreted and cause various anomalies in the plants. Our current aims to identify effector proteins, which cause damage to various agricultural crops.

In order to determine candidate effector proteins, N-terminal signal peptides containing candidate effector proteins were identified by using SignalP 4.1, TMHMM v2.0 and Phobius tools. The results were compared with the the signal peptides and genes organization of previously reported effectors. To examine the relationship of the orthologs and to predict the function, Conserved Domain Database (CDD), PSI-BLAST, and HMMER tools used. Second step, candidate protein structures were predicted for structure/function analysis with the AlphaFold 2 tool, then investigated in Protein Data Bank (PDB) and AlphaFold Protein Structure Database by DALI server tool.

Our results showed that one of the most potential effector candidates was SAP55 which has a metalloendopeptidase-like structure and contains the peptidase family M41 like domain. Interestingly, SAP55 does not have ATPase domain, but rather an additional α-helix at its C-terminus. As a result of our *in silico* study, an effector showing possible protease activity was discovered for the first time in Phytoplasmas.

Text

Agrobacterium tumefaciens is a tool for genetic engineering based on its ability of transferring a specific segment of DNA on its tumor-inducing plasmid (pTi) to the host genome. Although *A. tumefaciens* strains are genetically diverse and can be classified into > 10 genomospecies, the disarmed strains used in *Agrobacterium*-mediated transformation are mostly derived from one genomospecies 8 strain, C58. In our characterization of wild-type *A. tumefaciens* strains from different genomospecies, we found that one genomospecies 1 (G1) strain, 1D1108, has strong virulence while another G1 strain, Ach5, has weak virulence against several Fabaceae hosts. To further characterize agrobacterial virulence, we expanded the sampling to allow for comparisons of diverse G1 strains. A total of 30 G1 strains are selected for phenotyping and comparative genomics. Our result indicates that virulence, as measured by transient transformation efficiency in *Nicotiana benthamiana*, has no obvious link to overall gene content or the pTi type. We also found that 1D1108 has the highest transient transformation efficiency among all tested strains. Transcriptomic analysis of 1D1108 identified ~400 genes exhibiting differential expression in planta. Further investigations of these candidates are required to confirm their roles and to understand the mechanisms. The knowledge may be used for future synthetic biology work to improve *Agrobacterium*-mediated transformation.

Text

Citrus stubborn disease (CSD) is one of the most important vector-borne diseases in most citrus growing regions worldwide. *Spiroplasma citri*, the causal agent of CSD, is a phloem-limited, wall-less bacterium, belonging to reduced genome, high A-T content bacteria group, Class Mollicutes.

In the present study, *S. citri* was detected and characterized from naturally infected citrus trees and *in vitro* cultures obtained from periwinkle, sesame, turnip and cicadellids by PCR-based detection techniques focusing on spiralin , P58 putative adhesin-like multigene, and P89 putative adhesin genes of *S. citri*. The detection rate of *S. citri* was consistently higher in the fruit columella than in the leaf midribs for naturally infected field samples. For cultured samples,P89 were more sensitive in recognizing *S. citri* in field samples than those based on the spiralin gene and P58 gene. Furthermore, the obtained isolates showed 99.75% identity with *S. citri* GII3-3X strain which was originally isolated from the leafhopper *Circulifer haematoceps*, collected in Morocco (1980) and 99.25 % identity with

BLH-MB strain which was originally isolated from a Navel orange tree in Riverside, California (1972). In terms of the current situation of *S. citri*, this study presents an overview of the disease's spread in the citrus-growing regions and compare the genomic features of *S. citri* in culture and naturally infected citrus.

Text

Xanthomonas bacteria cause many diseases affecting commercially important crops. Most *Xanthomonas* species translocate Transcription Activator-Like Effectors (TALEs) into plant cells via their type III secretion system. TALEs are a unique class of bacterial effector acting as eukaryotic transcription factors to upregulate the expression of specific plant genes called susceptibility genes (S genes) for the bacteria benefit. According to recent studies, *Xanthomonas* species-specific disease management techniques can be developed by manipulating the host S genes.

SWEET genes are S genes targeted by *Xanthomonas* species, which encode for sugar transporters that are key to susceptibility in rice, cassava and citrus. Upregulation of these transporters in response to TALEs is speculated to accelerate disease development by increasing the amount of nutrients supplied to pathogens and/or by contributing to sugar signaling for disease resistance.

We identified the repertoire of *Xanthomonas* tal genes from *Xanthomonas campestris* pv. *campestris* (*Xcc*), the causal agent of blackrot disease in *Brassicaceae*. To determine the transcriptome modifications induced by the *Xcc* TALEs, we did RNAseq experiments in cauliflower (*Brassica oleracea*). Interestingly, we demonstrated that Tal12a contributes to *Xcc* virulence on cauliflower, possibly by inducing the expression of *BoSWEET* sugar transporters.

We will present our latest results on the contribution of *SWEET* genes to susceptibility in cauliflower.

Text
cynT (PSPTO_5255) encodes a carbonic anhydrase whose expression is induced by calcium in *Pseudomonas syringae* pv. *tomato* DC3000. Previously we showed *cynT* contributes to growth of DC3000 and symptom development in tomato plants. To understand the mechanism of how *cynT* impacts the virulence of DC3000, global transcriptome analysis (RNA-Seq) was performed for the *cynT* mutant and wild-type (WT). The expression of many virulence-related genes was impacted when *cynT* was deleted. On rich media (nutrient broth agar) supplemented with calcium, 73 genes were upregulated, and 56 genes were downregulated in the Δ*cynT* strain compared to the WT. On minimal media (mannitol-glutamate agar) supplemented with calcium, 495 genes were upregulated, and 253 genes were downregulated in the Δ*cynT* strain compared to the WT. Comparing the datasets, we found that the regulation of 31 genes by *cynT* was independent of the growth condition, however many of these genes showed opposite patterns of expression, including PSPTO_2870 and PSPTO_2871. PSPTO_2870 and PSPTO_2871 are predicted orthologs of putative virulence genes, *srfA*, and *srfB* respectively in *P. syringae* pv. *syringae* B728. Little is known about the functions of these genes in DC3000. Knockout mutants of srfABC operon were constructed in DC3000 and currently being characterized. The results indicate that the carbonic anhydrase, CynT is a key regulator for bacterial factors related to virulence.

(1) U.S. Department of Agriculture - Agricultural Research Service, Fargo, UNITED STATES;
(2) North Dakota State University, Fargo, UNITED STATES

Text
Several significant plant diseases are caused by members of the genus *Xanthomonas*, including bacterial leaf streak on small grains and forage grasses caused by *X. translucens*. Despite the importance of these diseases, genetic tools to understand the molecular basis of disease and host-pathogen interactions remain limited. Implementation of high-throughput sequencing, including comparative genomics, has facilitated discovery of many genes associated with virulence that are candidates for further molecular characterization. Functional characterization of candidate genes is currently limited by challenges to reverse genetics in this genus. In our work, we have created a series of broad-host-range plasmids that allow for inducible expression of phage lambda red-recombinase genes, which have been successfully used for recombineering in various bacterial genera, such as *Escherichia*, and *Pseudomonas*. Using these plasmids, we have developed protocols for an implementation of recombinase-based mutagenesis in *X. translucens*. We have successfully replaced target DNA sequences in the chromosome with an antibiotic cassette, creating gene knockouts for various proof-of-concept genes. Our approach allows use of PCR products directly for gene replacement without need of cloning. We anticipate that these tools and approaches will be broadly applicable to the genus of *Xanthomonas* and will facilitate molecular studies in the genetic and physiological basis of host-pathogen interactions.

Text

Chemoreceptors are essential proteins able to detect environmental changes for bacterial adaptation to the environment. The genes encoding these proteins are found individually in the genome or forming clusters with other genes related to chemotaxis. In plant-pathogenic bacteria, about 82 thousand chemosensory sequences have been described. In the *Pseudomonas syringae* complex, important groups of plant-pathogenic bacteria, four chemotaxis-related clusters have been described. However, cluster II is absent in some bacteria of this complex infecting woody hosts of the *Apocinaceae* family. Therefore, the aim of this work focuses on the functional characterization of cluster II, not only in bacteria isolated from woody hosts, but also in strains infecting herbaceous plants.

First, we constructed knockout mutants of genes encoded in cluster II, i.e. *cheA*, *cheB*, *cheD, cheY* and two genes coding for chemoreceptors in Psn23 strain and in *P. syringae* pv. tomato DC3000. Motility and virulence assays performed in oleander, dipladenia and tomato plants revealed that cluster II is involved in both phenotypes. In addition, bioinformatic analysis of the ligand-binding domain (LBD) of the two chemoreceptors encoded in cluster II showed that only one of them has an LBD domain. To characterise this chemoreceptor in strain Psn23, capillarity chemotaxis assays are being performed, and its LBD domain has been purified. The purified domain will be used in protein-ligand interaction assays.

GENOME BIOLOGY AND EVOLUTION OF CLAVIBACTER MICHIGANENSIS

ARIF Mohammad. (1), ARIZALA Dario. (1), LARREA-SARMIENTO Adriana. (1), DOBHAL Shefali. (1)

(1) University of Hawaii at Manoa, Honolulu, UNITED STATES

Text

Gram-positive bacterium Clavibacter michiganensis (Cm) is a high consequence pathogen and causal agent of tomato canker. The electronic microscopic and genomic studies were conducted to understand the pathogenicity determinants and evolution of this seed-borne pathogen. Total 17 genomes were sequenced using either Pacbio or Illumina and Oxford Nanopore (hybrid assembly); genomes were also retrieved from the NCBI GenBank. Non-

pathogenic strains showed either no or truncated clusters of pathogenicity islands (tomA and chp), and no colonization inside the tomato plant (absence of chpG). The Scanning Electron Microscopy (SEM) and qPCR analyses suggested that pathogenic EPS-producing strain moved and colonized faster than EPS non-producing strain. In evolutionary studies, phylogeny and recombination events were identified using ClonalFrameML—4,080 recombination sites were predicted with the largest recombination fragment size of 1.7kb. The genome analyses indicated 1,801 core genes, 4,44 soft core genes, 1,305 shell genes and 3,120 cloud genes. The fastGear was used to detect recent (1,494) and ancestral (169) recombination events—strains from lineage VI were predicted as major donor. The recombination events indicated that C. michiganensis is continuously adapting and evolving.

Text

Pseudomonas syringae pv. *tomato* DC3000 (*Pto* DC3000) is a plant pathogenic bacterium that infects tomato and *Arabidopsis.* During infection bacteria produce a number of proteins, including those of the Type III secretion system (T3SS) to suppress the host defense response and promote disease. Previously we found that deletion of a *Pto* DC3000 carbonic anhydrase, *cynT*, reduced disease symptoms and bacterial population in tomato and resulted in a delay in a hypersensitive response (HR) in *Nicotiana benthamiana*. To further investigate the role of the *cynT* in *Pto* DC3000, we performed a global transcriptome analysis for the Δ*cynT* and wild-type (WT) strains in different media. The analysis revealed opposite patterns of expression for some T3SS genes in the *cynT* mutant compared to the WT when calcium was present. The RNA-Seq data also showed that many genes that encode proteins involved in motility were down regulated in the *cynT* mutant compared to WT. To investigate regulatory mechanisms involved in expression of *cynT*, we evaluated expression of *cynT* in multiple mutant backgrounds. T3SS-related genes such as *hrpS*, *hrpL*, *hrpJ*, and *hrpP*, were found to impact expression of the *cynT* gene, suggesting that CynT is a key regulator for interaction with host plants. More research is being conducted to determine how CynT affects the pathogenesis.

Text

Although not well comprehended and recognized, phytoplasmas (genus '*Candidatus* Phytoplasma') are bacteria that infect many plant species causing substantial losses in agriculture. These uncultivable endocellular wall-less pathogens have a specific life-style including colonization of plant phloem and insects. Their genomes are small and diverse (0,53-1,35 Mbp), but often repetitive, prone to rearrangements and characterized by the presence of putative transposon-like elements named potential mobile units (PMUs). So far, there are only a few that are fully sequenced and assembled. Within this study we sequenced two '*Ca*. P. solani' strains (ST19 and STOL) from infected periwinkle on Illumina MiSeq and Nanopore platforms. *De novo* assemblies generated 2 draft genomes with total size of 707,036 bp (ST19) and 656,141 bp (STOL) in 28 and 19 contigs, respectively. Detailed genome analyses revealed the presence of PMU-like regions and elements (14 in ST19 and 6 in STOL strain) of a different composition and size, up to 12 kbp. In STOL strain some of the PMUs were more complete and resembled those already described in '*Ca.* P. solani' and '*Ca*. P. asteris', while in ST19 more diversification in PMU-like elements was revealed. In both, effector and putative secreted protein genes were frequently found within PMU-like regions. Molecular phylogeny of selected PMU genes demonstrated different origin and horizontal gene transfer suggesting their role in host adaptation and pathogenicity.

Text

The *P. syringae* species complex has a very important economic impact, causing diseases on many plant species. Considerable research effort is being invested to understand how effector repertoires could determine the host-range of a given strain. Recently, we showed that the incapacity of *P. syringae* pv. *actinidiae* to induce the hypersensitive response (HR) in *A. thaliana* is due to its inability to inject effectors rather than the absence of a recognized effector. In this context, we compared several *P. syringae* strains carrying the same plasmid-borne avirulence gene for their ability to induce an HR in *A. thaliana* Col-0, at different temperatures. *Pto* DC3000 and *Pma* M6 consistently triggered a strong HR while other strains induced it at different intensities significantly depending on temperature. Moreover, the strains were also compared for their growth dynamics at different temperatures in about ten plant species from various botanical families. Although temperature influenced bacterial growth dynamics *in planta*, the differences observed among the strains were partially correlated to their ability to activate their type-three secretion system. Together, these results

indicate that (i) *Pto* DC3000 is a reliable model strain but not representative of the *P. syringae* complex, (ii) temperature plays a crucial role in bacterial fitness, and (iii) deployment of molecular virulence factors may be influential but not sufficient to predict the outcome of plant-bacteria interactions.

Text

Walnut bacterial blight (WBB) is one of the important bacterial disease in Türkiye. Walnut immature fruit drops caused by Brown Apical Necrosis (BAN) also threatened walnut production in Aegean and Marmara Region. *Xanthomonas arboricola* pv. *juglandis* (*Xaj*) is the causal agent of WBB and BAN. Alternaria/Fusarium are secondary agents of BAN. The purpose of this study was to determine the prevelance and causal agents of WBB and BAN in Manisa, Bal?kesir, Çanakkale. 31 isolates were identified as *X.arboricola* based on classical diagnosis. For WBB, in pathogencity tests on immature walnuts only 11 of 31 *Xaj* isolates evaluated as negative. Otherwise, 4 bacterial x fungal isolates caused BAN symptoms. Furthermore, molecular identification of *Xaj* strains was performed using 16S rRNA sequence and showed the highest homology to *Xaj* (%99.83-100). rep-PCR and MLSA using 7 housekkeping genes showed genetic diversity between *Xaj* strains. According to MLSA, *Xaj* grouped in 3 different clades. *Xaj* strains obtained from WBB symptoms in Bal?kesir were grouped in same clade. Although *Xaj* strains from BAN symptoms in Manisa and Çanakkale were grouped in same clade but different grouped with WBB strains. Variability between groups resulted different pathogenicty and virulence that are still being adressed. This is the first study of genetic diversity for *Xaj* strains in Türkiye which provides evidence for genotypic variability and provide a better understanding of WBB and BAN epidemiology.

P2.1-054

MOLECULE POLYMORPHISM OF G-X-Y INTERRUPTIONS IN COLLAGEN TRIPLE HELIX PROTEIN OF CANDIDATUS LIBERIBACTER ASIATICUS

LIN Shengjie. (1), ZHOU Jiale. (1), XU Guoliang. (1), WANG Guoping. (1), HONG Ni. (1), HARTUNG John S.. (2), **DING Fang. (1)**

(1) Huazhong Agricultural University, Wuhan, CHINA; (2) USDA ARS MPPL, Beltsville, UNITED STATES

Text
Candidatus Liberibacter asiaticus, currently an unculturable phloem-limited bacterium, is associated with the most devastating disease of citrus Huanglongbing worldwide. Collagen-like proteins involved in a key aspect of pathogenicity, are an important source of genetic diversity in pathogenic bacteria. In the present study, 358 samples collected from different areas and hosts in China and 52 samples from USA were analyzed. Full length amplicon of 1652 bp were got only from USA isolates. Sequences ranging from 941 bp to 1588bp were got both from Chinese and USA isolates. A typical 63-amino-acid terminal domain with a potential transmembrane helix domain, a central collagen-like region containing Gly-Xaa-Yaa (G-X-Y) repeats, and a 7-amino-acid carboxy-terminal domain were found. Both the N' and C'-terminals of CthP were always conserved among different isolates. Yet hypervariable (Gly-X-Y) n repeats were identified. Phylogenetic analysis indicated most of USA isolates were grouped into one independent clade indicating a complex origination. The rest were grouped with gene-variants from Jiangxi, Yunnan and Fujian. Yunnan isolates contains most gene-variants and differ greatly from all the others. There's no correlation between symptoms and gene-variants. Based on our results, it can be concluded that the population of CLas contains different gene-variants which resulted in a complex citrus pathosystem for the study of interactions of phenotype and virulence.

P2.1-055

COLONIZATION OF THE LEAF VASCULATURE BY XANTHOMONAS CAMPESTRIS PV. CAMPESTRIS

PAAUW Misha. (1), VAN DEN BURG Harrold. (1)

(1) University of Amsterdam, Amsterdam, NETHERLANDS

Text
Xanthomonas campestris pv. campestris (Xcc) causes systemic infection of the leaf vasculature after initial colonization of hydathodes, water pores at the margin of leaves. By contrast, the closely related pathovar Xc pv. raphani (Xcr) colonizes the leaf mesophyll by entering stomata. The genetic basis of this striking difference in virulence strategy is not well understood. Here, we report about the genome sequence of 96 Xanthomonas campestris isolates and use comparative genomics to determine which genes exclusively occur in Xcc, while being absent in Xcr. This Xcc-specific set of genes contains four plant cell wall degrading enzymes (CWDEs), which are likely to be secreted by the type 2 secretion system. We show experimentally that this secretion system is required for colonization of the leaf vasculature after colonization of hydathodes, whereas it is dispensable for initial hydathode colonization, vascular mobility or multiplication in the leaf apoplast. Single CWDE knockouts show a similar loss of vascular colonization. Taken together, these results demonstrate that a hydathode-specialized pathovar uses an adapted repertoire of cell wall degrading enzymes to colonize the vasculature of its host plant.

Text

'*Candidatus* Liberibacter asiaticus' (Las) is one of the causal agents of huanglongbing (HLB), the most devastating disease of citrus worldwide. Due to the intracellular lifestyle and significant genome reduction of Las, it is extremely challenging to culture Las *in vitro*. In this study, we developed semi-selective media with the optimized growth conditions Las *in vitro,* and methods for re-inocuation of the cultured Las back to citrus. Under the optimized conditions we were able to culture Las to a growth peak in 2-3 weeks in the liquid medium, which was estimated as 10^6-10^7 cells per/ml with approximate 500-fold increase. The cultured Las bacteria remained in a dynamic growth for over 24 months and displayed limited growth in subcultures. We further confirmed the presence and growth of the Las bacterial cells using fluorescence *in situ* hybridization, gene expression profiling and metagenomic sequencing. It is worth noting that Las growth in the medium relied on the presence of a helper bacterium that co-exists both in citrus and psyllid hosts. Cultured Las was inoculated back to citrus sedlings via psyllid feeding. Although only a relatively low percentage of the fed psyllids and inoculated plants became positive, this is the first demonstration of significant growth of Las *in vitro* and successful inoculation of cultured Las back to psyllids and citrus plants. Factors that affect Las growth *in vitro* and the completion of "Koch's postulates" for Las are discussed.

REVEALING BARELY SUSCEPTIBILITY GENES RESPONDING TO BACTERIAL LEAF STREAK

LIU Zhaohui. (1), SHI Gongjun. (1), SCHACHTERLE Jeffrey. (2), BALDWIN Thomas . (1)

(1) North Dakota State University, Fargo, UNITED STATES; (2) USDA-ARS Edward T. Schafer Agricultural Research Center, Cereal Research Unit, , Fargo, UNITED STATES

Text

Bacterial leaf streak (BLS), caused by *Xanthomonas translucens* pv. *translucens* (Xtt), is a major disease of barley in the world. Our understanding of the barley-Xtt interaction is very limited, making it difficult to develop resistant cultivars for disease control. Xanthomonads are known to utilize transcriptional activator like (TAL) effectors to cause disease by upregulating specific host susceptibility genes, such as *SWEET* genes. In this work, we conducted a genome wide transcriptomic analysis to reveal barley susceptibility genes in response to Xtt infection. The barley cultivar Morex was inoculated with a local strain or buffer using infiltration and clipping methods. Leaf samples were taken at different time points with each having three biological replicates. Transcriptional analysis revealed slightly over half of barley genes expressed during infection for both inoculation methods. A total of 1037 and 23 differentially expressed genes (DEG) were identified between bacterial and mock inoculation

for infiltration and clipping method, respectively, and among them only one gene was shared by both methods. Most *SWEET*-like genes in barley had either low level of expression or no significant difference in expression between treated and mock samples for all time points. Using TAL effector RVD sequences, we identified five highly upregulated DEGs that could be targeted by Xtt TAL effectors. Those genes can be edited to investigate their role in disease susceptibility to BLS.

Text

Dickeya zeae causes soft rot of *Colocasia esculenta* and bacterial heart rot of *Ananas comosus. Dickeya zeae* is responsible for a wide range of diseases and significantly reduces crop production. In this study, we used Pacific Biosciences SMRT sequencing to sequence two high-quality complete genomes of *D. zeae*: PL65 (4.74997 MB) and A5410 (4.779) isolated from taro and pineapple, respectively. Additional complete genomes of D. zeae representing three additional hosts (philodendron, rice and banana) were included in the comparative analyses. The truncated T3SS and T4SS were observed in taro strain, which only harbors 1 and 2 genes of T3SS and T4SS, respectively, and showed high heterogeneity in T4SS. Unlike strain EC1, which was isolated from rice and recently reclassified as *D. oryzae*, neither the PL65 nor the A5410 genome harbors the zeamine biosynthesis gene cluster, which plays a key role in virulence of other Dickeya species. In this study, we compared major virulence factors produced by *D. zeae* strains and evaluated virulence on taro corms and pineapple leaves. Both strains produced proteases, pectate lyases and cellulases but no significant quantitative differences were observed among the strains. All the strains produced symptoms on taro corms and pineapple leaves, but strain PL65 produced symptoms more rapidly than the others.

Text

Dickeya dadantii is a bacterium causing soft rot disease in a wide range of plant species. During the infection process, *D. dadantii* undergoes environmental stresses: acidic stress during penetration in the apoplast, oxidative stress due to the plant immune response, and osmotic and oxidative stresses during plant maceration and disease generalization. Interestingly, these stresses affect DNA supercoiling (SC): acid and oxidative stresses lead to DNA relaxation and osmotic stress induces an increase in SC level. Deciphering the mechanisms of SC-related transcriptional regulation in that species is thus crucial for our understanding of the mechanisms of virulence. As far as we know, the SC level is mainly regulated by topoisomerase I and DNA gyrase. Inhibiting either of these enzymes with antibiotics leads to global SC modifications and subsequent changes in global gene expression. We analyzed the first transcriptomic response of a Gram-negative bacterium to topoisomerase I inhibition by an antibiotic. We detected distinct patterns of expression level and spatial organization along the chromosome. Particularly, we found that all SC variations affect the expression of two major virulence genes, encoding pectate lyases (destroyer of the cell wall, causing the soft rot symptom), *pelE* and *pelD*.

Text

Xanthomonas campestris pv. *campestris* (*Xcc*) is the causal agent of black rot disease, which is the most important and destructive bacterial disease of Brassica crops. Most *Xanthomonas* species translocate Transcription Activator-Like Effectors (TALEs) proteins inside plant cells using their type III secretion machinery. TALEs are a unique type of bacterial effector proteins that help the pathogen to exploit and modify the plant environment by directly altering the expression of plant genes to the benefit of the bacteria. TALEs play an essential role in many plant diseases caused by *Xanthomonas* spp. but the contribution of TALEs to virulence of *Xcc* has not been characterized. We identified a rich repertoire of *tal* genes (TALome) in *Xcc* and studied its functional role in disease development. First, we successfully silenced the *tal* genes in two *Xcc* strains using CRISPRi technology, demonstrating the role of TALEs for *Xcc* pathogenicity. In addition, the contribution of individual *Xcc* TALEs to bacteria virulence was tested by gain and loss-of-function experiments. Our data provide a platform to explore the roles of TALEs in black rot disease. We will present our latest results on the mechanisms of TALE-mediated susceptibility in Brassicaceae.

Text

Sugars Will Eventually be Exported Transporters (*SWEETs*) genes are key susceptibility factors in several *Xanthomonas*-plant pathosystems. *Xanthomonas phaseoli* pv. *manihotis* (*Xpm*), the causal agent of Cassava Bacterial Blight (CBB), transcriptionally activates the susceptibility (*S*) gene *MeSWEET10a* via the highly conserved Transcription Activator-Like Effector (TALE) TAL20. Until this study, *MeSWEET10a* was the only *S* gene described for CBB, and its transcriptional activation was shown to be necessary to develop watersoaked symptoms and to enhance *Xpm* growth. In this study, exploration of *Xpm* genomes and TALomes across a world-wide collection of strains revealed an alternative virulence-promoting mechanism based on activation of the gene *MeSWEET10e*, which encodes another clade-III SWEET sugar transporter. Here we validated the role of *MeSWEET10e* as a new cassava *S* gene and provided evidence that its transcriptional activation is TALE-independent, indirectly induced upon the action of a so far unknown host transcription factor. Our study provides the first report of a TALE-independent *SWEET* activation in the *Xanthomonas* genus, implying that non-TAL effectors may also determine *SWEET*-based host susceptibility.

Text

Transcription-activator-like effectors (TALEs) are a well-known class of effectors from plant-

pathogenic *Xanthomonas* bacteria but are also present in *Ralstonia solanacearum*, the causal agent of bacterial wilt disease in many crop plants. Within the genetically diverse *R. solanacearum* species complex (Rssc) TALE-like proteins (RipTALs) are found in all four phylotypes of the pathogen. Typically, TALEs are injected into plant cells by the bacterial type-III-secretion system and translocated into the plant nucleus where they specifically bind to host promoters in order to activate target genes that either promote disease or trigger plant resistance. In *Xanthomonas*, TALEs show a remarkably amount of diverse plant target genes and mechanisms of disease promotion or resistance. However, here we report that despite of significant genetic variation within the Rssc, RipTALs from different *Ralstonia* phylotypes all target *arginine decarboxylase* (*ADC*) genes in their host plants. While clear bacterial benefits from *ADC*-activation remain mostly elusive, this constraint on the part of *Ralstonia* enabled us to engineer transgenic tobacco plants with resistance to bacterial wilt in a RipTAL-dependent manner, showing that the conservation of RipTAL target specificity can be used as a hook for enhanced bacterial wilt control in crop plants.

COMPLETE GENOME SEQUENCES AND CHARACTERIZATION OF XANTHOMONAS ARBORICOLA, THE NOVEL CAUSAL AGENT OF BACTERIAL LEAF BLIGHT OF BLUEBERRY

KALUZNA Monika. (1), POTHIER Joël F.. (2)

(1) The National Institute of Horticultural Research , Skierniewice, POLAND; (2) Environmental Genomics and Systems Biology Research Group, Institute for Natural Resource Sciences, Zurich University of Applied Sciences (ZHAW), Wädenswil, SWITZERLAND

Text
The cultivation of blueberry (Vaccinium corymbosum L.) is becoming increasingly important. For many years this plant species remained rarely infected by bacterial pathogens. Hitherto described, were tumorigenic Agrobacterium spp., Burkholderia andropogonis, Xylella fastidiosa and Pseudomonas spp. Recently, new pathogenic bacteria – the subject of this study] – were discovered. In 2013, on the blueberry cv. Toro and Duke growing in a nursery located in Central Poland russet brown, irregular spots on leaves were observed. From these leaf spots, fluorescent and yellow bacteria were isolated. Two yellow isolates, named 1311a and 1314c, were positive in a PCR assay using primers X1 and X2 specific for bacteria belonging to the genus Xanthomonas. Based on partial sequences analysis of gyrB, fuyA and rpoD, the strains were placed within the strains of Xanthomonas arboricola. Their complete genomes were determined. The genomes size of the strains 1311a and 1314c are 4,889,189 bp and 4,891,143 bp, respectively. Whole genome-based taxonomic analysis using the Type (Strain) Genome Server confirmed the affinity of these two strains to X. arboricola. It is the first report on the occurrence of bacterial leaf blight on blueberries caused by a Xanthomonas species.

Text

Gram-negative bacterial pathogens inject variable repertoires of effectors into host cells to interfere with defense responses. Among those, the Yersinia outer protein J (YopJ) effector family of acetyltransferases, produced by diverse animal and plant bacterial pathogens, promote pathogen virulence by acetylating specific host components. However, the range of host processes that YopJ effectors can interfere with remains elusive. Thus, we developed a proximity-dependent protein labeling involving the Turbo biotin ligase for identifying the interactomes of two well-characterized YopJ members: the *Ralstonia pseudosolanacearum* PopP2 and its close homolog, XopJ6 from *Xanthomonas campestris*. Both of them are recognized by the Arabidopsis RRS1/RPS4 pair through manipulation of an integrated WRKY domain that mimics effector primary targets, the WRKY transcription factors. Interestingly, a single residue substitution in a XopJ6 natural variant disrupts physical interaction with WRKY proteins, enabling XopJ6 to avoid host recognition while retaining XopJ6 virulence functions, likely through interference with components other than WRKYs. The different PopP2 and XopJ6 variants fused with Turbo will be expressed in both *N. benthamina* and *Arabidopsis*. Alternatively, we developed an approach consisting in *Pseudomomas fluorescens*-mediated delivery of the Turbo fusion proteins to remain as close as possible to the level of effectors injected in plant cells by pathogenic bacteria.

Text

Yeast two-hybrid (Y2H) protein interaction screening has proven instrumental to identify countless plant-pathogen interactions (1). However, interaction map completeness has been limited using full-length proteins and C-terminal polypeptide fragments which result in significant false negative rates.

To circumvent these limitations, we used a domain-based strategy to build 35 random-primed cDNA libraries from 21 plant species: from model plants and crops, but also from exotic plants (*G. barbadense, K. laxiflora*, Morning glory, Cacao Tree…), fruit-giving plants

(Melon, oranges…), root vegetables (sugar beets, manioc…) or numerous plant pests. Each library has a complexity of 10 million independent fragments, with an average 1000bp fragment size.
Using an optimized mating procedure, these libraries are screened to saturation, allowing to test on average 83 million interactions per screen. Therefore, multiple independent fragments are isolated for each interactant, enabling to delineate the minimal interacting domains and to compute confidence scores (2).
These libraries have been integrated into our ULTImate Y2H high-throughput platform and are available for screening on a fee-for-service basis. **We will introduce how the platform recently supported the discovery of a mechanism by which *R. Solanacearum* bacteria hikacks plant immunity** (3).

Text
During infection, Gram-negative plant-pathogenic bacteria use a Type III secretion system (T3SS) to deliver effector proteins into the host cells. Type III-secreted effectors (T3E) modulate a variety of host biological processes, including immunity, physiology, or gene expression, promoting host-susceptibility, and causing disease. For most pathosystems, studies have extensively focused on effector functions but the spatiotemporal dynamics of T3E activity during infection remain poorly understood. Here, we developed a method to visualize T3E activity of Xanthomonas translucens during live infection of barley. We engineered transgenic barley that only expresses green fluorescent protein (GFP) when a Type III-secreted artificial transcriptional activator-like effector (TALE), designated as dTALE-GFP, binds and activates the GFP promoter. X. translucens harboring dTALE-GFP also constitutively express a red fluorescent protein enabling simultaneous detection of bacteria and dTALE-induced GFP via confocal microscopy. With this system, we demonstrated that

stomatal guard cells and mesophyll cells, but not epidermal cells, are targeted by X. translucens T3Es during the internal leaf infection stage. This system provides new insights into the spatiotemporal dynamics of plant-bacteria interactions during infection.?

Text
The necrotrophic plant pathogenic bacterium *Dickeya solani* emerged in the potato agrosystem in Europe. All isolated strains of *D. solani* contain several large polyketide synthase/non-ribosomal peptide synthetase gene clusters. Analogy with genes described innother bacteria suggests that the clusters *ooc* and *zms* are involved in the production of secondary metabolites of the oocydin and zeamine families, respectively. A third cluster that we named ssm for solani secondary metabolite had an unknown function. In this study, we constructed mutants impaired in each of the three secondary metabolite clusters *ssm*, *ooc*, and *zms* to compare first the phenotype of the *D. solani* wild-type strain D s0432-1 with its associated mutants. We demonstrated the antimicrobial functions of these three PKS/NRPS clusters against bacteria, yeasts or fungi. The secondary metabolite cluster ssm, conserved in several other *Dickeya* species, produces a secondary metabolite inhibiting yeasts. Phenotyping and comparative genomics of different *D. solani* wild-type isolates revealed that the small regulatory RNA ArcZ plays a major role in the control of the clusters *ssm* and *zms*. A single-point mutation, conserved in some *Dickeya* wild-type strains, including the type strain IPO 2222, impairs the ArcZ function by affecting its processing into an active form.

Text

To increase virulence, plant pathogenic effectors disturb the ubiquitin-proteasome system and autophagy proteolytic pathways by interfering with host cellular functions. We studied the bacterial pathogen *Xanthomonas campestris pv. vesicatoria* (*Xcv*), a significant agricultural pest. We demonstrated that the *Xcv* type-III effector, XopL, inhibits host autophagy. XopL interacts with and ubiquitinates a component of the host autophagic machinery, SH3P2. This causes SH3P2 to be degraded by the proteasome, perturbing host autophagy and enhancing *Xcv* bacterial growth. In turn, the plant uses NBR1, a defense-related selective autophagy receptor, to defend itself triggering XopL degradation through a process termed “effectorphagy”. However, we discovered that this connection is driven by both ubiquitin-dependent and -independent interaction. This suggests another layer, apart from “effectorphagy”, in NBR1-mediated immunity. To unravel the tight regulation of this component, we aim to understand the dynamic of Ubiquitin-dependent and -independent NBR1 interactome in an infection context. In response to *Xcv* infection, we identified multiple post translational modifications as well as novel interactors involved in protein degradation, plant immunity, trafficking and cytoskeleton regulation. This supports the role of selective autophagy as a central plant immune mechanism and will permit to decipher its precise regulation in response to phytopathogenic bacteria.

Text

Plant and pathogen are in eternal arms race. Longer the plant-pathogen get in touch and more sophisticated are the mechanisms that regulate the resistance and the virulence. Alien pathogens cannot be perceived by the host by co-evolved molecular patterns such as the zig-zag model. Early reactions to an alien pathogen include the production of free fatty acids (FFA) and oxylipins. Xylella fastidiosa (Xf) evolved into several hosts in the Americas and it is relatively new in Europe where can be considered as “alien”. Global trade shipped it in Italy causing in less than 10 years death of hundreds of thousands olive trees. In our study FFA and oxylipins signature characterise the plant reaction to Xf subsp. pauca (Xfp). Nicotiana benthamiana, Arabidopsis thaliana, Olea europea develop a specific lipid signature in response to Xfp infection: increase of monoenoic fatty acids (14:1; 16: 1; 18:1) and of linoleic and linolenic acid derived oxylipins (9/13-HpOD/TrE). These lipids are more abundant in symptomatic plants and less in positive-Xfp plants, symptomless or with a low rate of symptoms (i.e. olives treated with zinc-copper-citric acid biocomplex, resilient olive trees,

plant deleted in lipoxygenases). The modulation of FFA and oxylipin-forming enzymes may allow the plant-pathogen to co-exist and turn-down the “Xylella” emergency in Europe.

Text

Plants and bacteria release extracellular vesicles (EVs) that carry various molecules, nucleic acids, proteins, and lipids. Plant EVs contain defence-related proteins that may reduce the virulence of pathogens. Bacterial EVs contain effectors that participate in pathogenicity and modulate plant immunity. This study analysed the EVs produced during the interaction between *Pectobacterium* and *Arabidopsis*. The MALDI-TOF/TOF-MS analysis was conducted to identify the cargo of EVs.

Using electron microscopy, we showed that *Pectobacterium* and *Arabidopsis* secreted small amounts of EVs when cultivated separately in a liquid MS medium. The inoculation of *Arabidopsis* with bacteria resulted in increased production of EVs.

Proteomics analysis of EVs content showed that three times more proteins were secreted when plants were cultivated in the presence of bacteria than alone. Among 394 proteins identified in EVs isolated from plants inoculated with bacteria, 126 were also recognised for the monoculture of *Arabidopsis*. Only 36 proteins were unique for the non-inoculated plants. Among the plant proteins, the most abundant were those related to the stress response, protein synthesis and various transporters. In the case of bacterial proteins, virulence factors were detected. Our results indicate that EVs mediate the interaction between plants and bacteria, and their cargo consists of proteins that play a role in virulence and nutrient acquisition.

'Candidatus Liberibacter solanacearum' (Lso) is a phloem restricted bacterium infecting

potato and other Solanaceae in the USA, and carrots and other apiaceous crops in Europe and the Mediterranean basin. Liberibacter pathogens do not encode a Type III or Type IV secretion system therefore, effectors sec-dependent and non-traditionally secreted protein. Candidate effectors were selected from analysis of Lso proteins using Signal P and secretome. Our strategy for effector validation includes validation of the signal peptide and secretion in a surrogate system, followed by transient expression to evaluate if the candidates induce and reduce HRs, followed by identification of proteins targets using yeast-two hybrid, bimolecular fluorescent complementation, and co-immunoprecipitation. Using this strategy, we characterized five effectors, which suppressed the hypersensitive response induced by PrfD1416V. Lso-HPE1 interacts with Solanum lycopersicum RAD23c, d and e but not RAD23a. We also identified CKC_5770 which interact with APX-6. Both of these effectors have homologous gene in Ca. L. asiaticus (CLas, the pathogen responsible for citrus greening) which interact with the corresponding citrus proteins. This finding demonstrate that the Lso-tomato interaction can be used as a model for CLas – citrus system. Three other effectors specific of Lso are under investigation.

Mycotoxin producing fungi and their management: a serious challenge to attain the One Health goals

Text

Climate change (CC) has a significant impact on agricultural systems and threatens safety and security of food and feed. Increased temperature and CO2, along with uncertainties related to extreme weather events, such as heat waves, droughts, and heavy rains, are driving variables for fungi and mycotoxin occurrence. Europe has experienced unexpected outbreaks of aflatoxin contamination in maize since the early 2000s, particularly during extremely warm and dry seasons. Fungi showed a shift towards higher latitudes, and significant differences in mycotoxin contamination were noticed depending on the growing year. Fungi and mycotoxin co-occurrence were underlined in different crops, enhanced by extreme weather events, with relevant variation also in small geographic scales. CC has already impacted the cropping systems and the geographical distribution of crops. As a result, we can expect increased variability and new scenarios, therefore accurate predictions will be crucial for ensuring sustainable food systems. Big data, machine learning (ML), and decision support systems are rapidly advancing in agriculture, offering a new approach to farm management. ML can effectively combine qualitative data input, like cropping system information, with meteorological data, thereby improving the accuracy of predictions. To

address the adverse effects of CC, research needs to embrace predictive data-driven solutions for a more sustainable future.

Text

Fusarium proliferatum, is a polyphagous plant pathogen of a wide range of agriculturally important plant hosts and produces a relevant number of mycotoxins, mainly the carcinogenic fumonisins B (FBs). Many studies on F. proliferatum mycotoxin profile according to the crop of origin and its genetic variability have been carried out, aimed to understand the capability of this fungus to perfectly adapt in a wide array of different ecological niches and express its pathogenicity. A wide amount of studies have shown that F. proliferatum is a major FB producing species worldwide. However, strains isolated from a number of crop plants worldwide (date palm, fig, sugarcane, wheat) lack capacity to produce FBs, although the data on gene occurrence, orientation and genome location of the FB gene cluster between producing and non-producing strains revealed no significant differences. Phylogenetic analyses for identifying possible clades within the species provided only slight differences. Therefore, genomic and metabolomics investigations were carried out and underpinned that a poly-omic approach is a powerful tool for unraveling the genetic and mycotoxin profile variability of F. proliferatum from different plants. The capability of F. proliferatum to adapt to such a wide number of ecological niches allows us to acknowledge it as a perfect example of fungal biodiversity. Studies performed in cooperation with several reasearch groups worldwide will be presented

Text

The risk of exposure to mycotoxins in countries in sub-Saharan Africa is high. The Sahel

region is particularly affected due to its adverse climatic conditions exacerbated by climate change impacts. Consequently, maize, groundnut, and sorghum grown in Burkina Faso, Mali, Niger, and Togo are frequently contaminated with aflatoxins biosynthesized by *Aspergillus* spp. Exposure assessments conducted in Burkina Faso, Mali and Niger revealed elevated aflatoxin levels in crops with estimated liver cancer cases up to 126 cancer cases/100,000 persons/year in some regions. About a decade ago, an aflatoxin biocontrol product named Aflasafe BF01 containing four atoxigenic isolates of A. flavus, widely distributed across Burkina Faso, was developed. The efficacy of the product in Burkina Faso (70 to 100% less aflatoxins in treated compared to untreated crops) paved the way for its registration with the Sahelian Pesticide Committee (CSP) of the Permanent Interstate Committee for Drought Control in the Sahel (CILSS) which currently has 13 member states. Similar efficacies were demonstrated in Mali, Niger, and Togo. Consequently, use of this nature-based solution is proving an effective pre-harvest management solution against aflatoxins. The technology can expand potential market outreach and provide a true area-wide strategy for sustainable solution to One Health and trade challenges posed by crop aflatoxin contamination in the region.

Text

Mycotoxin contamination of fruits and their derived products is a problem of great concern. Patulin, a secondary metabolite mainly produced by Penicillium expansum, is the most potent mycotoxin in fruits, especially apples and apple-based products. Traditional physical and chemical methods are currently limited because of chemical hazards and affecting nutritional quality of the products. Biological detoxification methods using microorganisms or enzymes represent fewer health and environmental risks and are emerging as promising alternatives. Recently, we identified a short-chain dehydrogenase/reductase CgSDR from a patulin biodegrading strain Candida guilliermondii. CgSDR could transform patulin into E-ascladiol with NADPH as a coenzyme. A molecular docking analysis and site-directed mutagenesis indicated that VAL188 and THR190 were the key active binding sites for patulin biodegradation. Further, we covalently linked CgSDR to magnetic nano-Fe_3O_4 particles to prepare an immobilized enzyme. The immobilized CgSDR combined the advantages of both the magnetic nanoparticles and the degrading enzyme, could completely remove 1 μg/mL patulin in phosphate-buffered saline within 4 h. It also exhibited a high detoxification rate in apple juice and did not cause adverse effects on juice quality. Immobilized CgSDR had characteristics of high efficiency, stability, safety, and easy separation, showing a good application prospect in controlling patulin contamination.

C1.4-5

EFFICACY OF THE ASPERGILLUS FLAVUS ATOXIGENIC STRAIN TECHNOLOGY TO REDUCE RISKS OF AFLATOXIN CONTAMINATION IN COMMERCIAL TREE NUT ORCHARDS IN CALIFORNIA

JAIME Ramon. (1), LAKE John S. (1), SINGH Pummi. (1), PUCKETT Ryan D.. (1), DOSTER Mark A.. (1), GABRI Victor M.. (1), **MICHAILIDES Themis J.. (1)**

(1) University of California Davis, Parlier, UNITED STATES

Text

Aflatoxins are the most toxic mycotoxins, which are highly regulated worldwide. They are produced by fungi in the *Aspergillus* section *Flavi*, including *A*. *flavus* and *A*. *parasiticus* commonly found in California. Aflatoxins pose a highly economical threat to the tree nut (pistachio and almond) industries due to product rejection from markets. The *A*. *flavus* atoxigenic strain technology effectively reduces aflatoxins in crops by increasing the proportion of atoxigenic isolates and reducing the aflatoxin production potential of the population. The efficacy of *A*. *flavus* AF36 to reduce aflatoxins in commercial tree nut orchards has been evaluated for over a decade in California, including the effects of product rates, time of application, and irrigation method on both aflatoxin content, and displacement of toxigenic isolates by the biocontrol AF36. Aflatoxin content in 200-500 samples annually was determined by HPLC and displacement was determined from soil samples taken after harvest each year. Results indicate that the biocontrol AF36 reduces aflatoxin contamination by increasing the proportion of the atoxigenic strain AF36 in commercial orchards. However, the efficacy of the biocontrol applications in tree nuts in California has not reached its full potential with only an average 40% aflatoxin reduction compared to untreated controls, and 70% displacement of toxigenic isolates in both pistachio and almond orchards. The effect of treatments to improve efficacy will be discussed

C1.4-6

PREPARING THE OAT INDUSTRY FOR HT2 AND T2 MYCOTOXIN LEGISLATION

EDWARDS Simon. (1)

(1) Harper Adams University, Newport, UNITED KINGDOM

Text

HT-2 and T-2 are related fusarium mycotoxins produced by several *Fusarium* species but are predominantly produced by *Fusarium langsethiae* on European cereals, with oats being particularly susceptible. European legislative limits for HT-2 and T-2 are currently in draft and expect to be introduced in 2024. Based on previous surveys of UK commercial oat crops, the proportion of samples exceeding the draft limit for unprocessed oats (1250 µg/kg combined HT2+T2 concentration) varied between 0 and 25% each year, with a mean of 13%.

Analysis of the impact of agronomic factors on the HT-2 and T-2 concentration of oat crops within the surveys identified significant differences between HT2+T2 concentration across production systems (organic v conventional), rotations and oat varieties. Field experiments have confirmed differences between varieties but have failed to show any differences

associated with conventional production (fertilisers, plant growth regulators and fungicides). When HT-2 and T-2 legislation is set then growers will need to minimise the risk of exceeding limits. Based on the known impact of agronomy on the HT2+T2 content of oats there are few economically viable options to reduce these mycotoxins. The most readily available option for growers to reduce the risk of exceeding HT2+T2 legislations is a change to more resistant oat varieties.

F1.4-1

EVALUATION OF WINTER WHEAT FOR FUSARIUM HEAD BLIGHT RESISTANCE AND DEOXYNIVALENOL LEVEL IN ONTARIO, CANADA

TAMBURIC-ILINCIC Ljiljana. (1), SPARRY Ellen. (2)

(1) University of Guelph, Ridgetown, CANADA; (2) C&M Seeds, Palmerston, CANADA

Text

Development of wheat resistant to Fusarium head blight (FHB), while improving yield and maintaining quality requirements is important in Ontario, Canada. FHB is a serious disease of wheat and deoxynivalenol (DON) is the most common mycotoxin produced by Fusarium graminearum (FG). All wheat commercially grown in Ontario is entered in the Performance Trials, and tested for agronomy traits and FHB resistance, in nurseries spray inoculated with FG isolates, at anthesis. FHB symptoms are recorded as incidence (percent of heads infected) and severity (percent of spikelets infected). FHB index is calculated as severity x incidence, divided by 100. DON level is estimated using ELISA method. Wheat cultivars and checks are grouped, based on FHB visual symptoms and DON level, using historical and the most recent data (www.gocereals.ca). The categories are: moderately resistant (MR), moderately susceptible (S), susceptible (S) and highly susceptible (HS). Some cultivars have different category for FHB index and DON level. Phenotyping, genotyping and development of new cultivars, with increased level of FHB resistance and higher yield is in progress, in breeding program from University of Guelph, Ridgetown Campus. Correlation among morphological traits (plant height, heading date, awns presence), FHB related traits (severity, incidence, index, and DON level) and yield, will be presented. DON level of winter wheat populations, with different sources of FHB resistance, will be compared.

CASE STUDIES OF MYCOTOXIN CONTAMINATION IN ORGANIC MAIZE STORED AND MILLED BY SMALLHOLDER FARMERS IN SOUTHWEST FRANCE

SAVOIE Jean-Michel. (1), FOUILLET-VINDRAS Camille. (2)

(1) INRAE, Villenave D'ornon, FRANCE; (2) ITAB, Saint Marcel Les Valence, FRANCE

Text

In Europe, there is a trend toward increased production of small grain cereals and maize by small-scale organic farmers storing and processing their production on-farm. This responds to consumer demand for local, healthy food. In this context, knowing what happens to

mycotoxins throughout the grain production chain, from the field to the final product, is a challenge for food safety and the resilience of this production system.
With the contribution of 12 organic farmers growing population varieties of maize for human consumption, we collected samples of grains at harvest and after storage for several months at the farms and the resulting flour and meal after milling, for two successive years. The samples were analysed for mycotoxin content. (Trichothecenes B and A, Zearalenone, Fumonisins, Aflatoxins) and contamination by different Fusarium species. The results of the analyses were interpreted in the light of the farmers' technical practices regarding cultivation, storage and processing.
Alarming levels of contamination have been measured in some samples and levers for action have been identified. Convincing farmers to adapt some of their practices that they associate with the typicality of their product is a new challenge.

Text
Essential oils (EOs) having antifungal activity and mycotoxins reduction ability are candidates to develop bioactive alternatives and environment friendly treatment against *Fusarium* species affecting cereals and other crops. However, their practical use is facing limitations such as high volatility, UV sensitivity, and oxidation. Nanoencapsulation techniques are supposed to provide protection to the EOs and control their release into the environment. We selected *Ammoides pusilla* essential oil (AP-EO) as an efficient inhibitor of *Fusarium avenaceum* growth and its Enniatins (ENNs) production. AP-EO was encapsulated, into mesoporous silica nanoparticles (MSNPs) with narrow slit pores (3.1 nm). In contact assays in an agar medium, the antifungal activity of AP-EO at 0.1 µL mL-1 was improved three times when encapsulated into MSNPs and the ENNs production was significantly inhibited. Controls of MSNPs also inhibited the ENNs production without affecting the mycelial growth. In fumigation experiments assessing the activity of the EO volatile compounds, encapsulation into MSNPs improved significantly both the antifungal activity and the ENNs inhibition. Encapsulation of an EO into MSNPs improving its antifungal and antimycotoxins properties is promising for the formulation of a natural fungicide to protect plant or food products from the contamination by *Fusarium spp*. and their potential mycotoxins, after risk assessment of the use of silica nanoparticles in agriculture.

P1.4-003

INVESTIGATION OF THE EFFECTIVE INHIBITION OF DON PRODUCTION BY BOTANICAL COMPOUNDS LA AND MEJA AND THEIR INHIBITION MECHANISM

GAO Jing. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

Deoxynivalenol (DON) is one of the mycotoxins produced by Fusarium head blight, which not only seriously threatens human and animal health, but also is an important pathogenic factor. However, the number of DON-inhibiting fungicides is small, and there are problems with chemical fungicides such as resistance and environmental pollution. Here, botanical compounds that are environmentally friendly and difficult to develop resistance are screened to address DON contamination. Among dozens of botanical compounds, lauric acid (LA) and methyl jasmonate (MeJA) with the best DON-inhibiting effect were screened. The inhibition rates of LA (2.65 mM) and MeJA (1 mM) were about 65% and 75%, respectively. In terms of application potential, LA had protective activity against wheat coleoptile and exhibited synergistic effects when used in combination with metconazole. As for the mechanism of DON inhibition, LA was able to destroy the toxisome. Interestingly, LA also affected DON synthesis by influencing pathogen metabolism, as deletion mutants of the LA metabolism gene were inconsistent in DON production compared to wild-type. In contrast, MeJA did not affect toxisome, but was effective in reducing DON content in the seeds in field trials and reducing the pathogenicity of coleoptile by inhibiting DON. Collectively, all results suggest that LA and MeJA have a high potential to be developed as DON-inhibiting fungicides. This study provides new insights into the prevention and control of DON.

P1.4-004

POPULATION GENETIC STRUCTURE OF PATHOGENS CAUSING FUSARIUM CROWN ROT AND ITS MYCOTOXIN CONTAMINATION OF WHEAT IN CHINA

ZHANG Hao. (1)

(1) Institute of Plant Protection, Chinese Academy of Agricultural Sciences, Beijing, CHINA

Text

Fusarium crown rot (FCR) caused by *Fusarium* spp. has been prevalent in China in recent years, posing a serious threat to wheat production. In this study, a large investigation of the species composition of FCR pathogen in 375 sites of 13 provinces was conduct, covering all the main wheat growing areas in China. A total of 23 Fusarium species were isolated and identified. *F. pseudograminearum* and *F. graminearum* were predominant species in Winter Wheat Region in North China and Northeast Spring Wheat Region, respectively. *F. asiaticum* was the dominant species in the Middle-Lower Yangtze Valleys Winter Wheat Region. The *F. pseudograminearum* population had increased in North China in the recent years. The proportion of *F. graminearum* had also raised in the Middle-Lower Yangtze Valleys Winter Wheat Region. Simple sequence repeats analysis showed that the population diversity of *F. pseudograminearum* was low and asexual reproduction was dominant in all regions. Mycotoxin was mainly observed in lower internodes of infected wheat plants and a low amount

was detected in the upper parts above the 4th internode in artificial inoculation. However, under field conditions, high levels of trichothecene accumulation were detected in the upper segments. Trace amounts of mycotoxin appeared to be translocated to grains, indicating that FCR infection in natural fields poses a relatively small threat to contamination of grains, but a larger amount to plant parts that may be used as animal feed.

P1.4-005

ENDOPLASMIC RETICULUM-MITOCHONDRIA ENCOUNTER STRUCTURES (ERMES) REGULATE ENERGY METABOLISM: A NEW DRUG TARGET FOR PATHOGENIC FUNGI?

SONG Jichang. (1)

(1) Nanjing Agricultural University, Nanjing, CHINA

Text

In fungal cells, the information exchange between mitochondria and endoplasmic reticulum (ER) is realized through the contact sites of organelle—ER-mitochondria encounter structure (ERMES) complex. ERMES complex consists of four subunits MMM1, MDM10, MDM12, MDM34. Our study found that ERMES complex plays a regulatory role in energy synthesis and secondary metabolism in *Fusarium graminearum*. In the ERMES mutants, the mitochondrial morphology significantly changed from normal filamentous to functional defect spherical, and ATP content decreased. This suggests that it may be involved in regulating mitochondrial morphology and function. Our further study that MDM10 interacts with the mitochondrial fission protein DNM1 confirms this result. DON produced by *F. graminearum* is a secondary metabolic product and a vital virulence factor. Our research shows that the generation of ERMES mutants leads to the decrease of DON and morphological structural disruption of Tri1-labeled toxisome, and all subunits of the ERMES complex were partially co-located with Tri1-labeled toxisome under confocal microscopy. These data indicates that the ERMES also plays a regulatory role in DON production and toxisome formation in *F. graminearum*. Although SDHIs fungicides can obviously reduce the transcription and protein expression of ERMES, whether SDHIs can reduce DON is related to ERMES remains unclear. ERMES was found only in fungal cells, making it a potential target for pathogen fungal control.

EFFORTS TO DEVELOP MANAGEMENT STRATEGIES FOR THE AFLATOXIN CONTAMINATION OF HAZELNUT IN AZERBAIJAN

AGHAYEV Fagan. (2), **ORTEGA-BELTRAN Alejandro. (1)**, BANDYOPADHYAY Ranajit. (1)

(1) International Institute of Tropical Agriculture, Ibadan, NIGERIA; (2) UN Food and Agriculture Organization, Baku, AZERBAIJAN

Text

Hazelnut is of great cultural and economic importance in Azerbaijan. Apart from domestic consumption, a large portion of the production is exported. However, hazelnut trade has been recently affected by aflatoxin contamination by *Aspergillus* spp. FAO and various

partners are implementing a project to improve productivity and safety of hazelnut. However, in Azerbaijan, little is known about factors contributing to aflatoxin contamination of hazelnut. FAO and IITA met with farmers, partners, and key institutions affected by aflatoxin in hazelnut. Aflatoxin was determined in samples collected in farmers' stores in three regions using an *in-situ* quantification protocol. The processing and quantification were conducted in farmers homes/warehouses. Aflatoxin was found in all 33 examined samples (range = 1.1 to 7.2 ppb). Most farmers stored hazelnut sub optimally. Chances of increased aflatoxin throughout storage are thus high. Despite several challenges, there is a strong desire and political will of various stakeholders to reduce aflatoxin and improve trade in hazelnuts. Opportunities to reduce aflatoxin relatively rapidly in Azerbaijani hazelnut exist. There is a need to converge efforts of different stakeholders and continue to create awareness about aflatoxin and its repercussions. Challenges and opportunities for effective aflatoxin mitigation strategies to reduce contamination, reduce rejection of hazelnut from Azerbaijan, and increase trade in the region will be discussed.

P1.4-007

THE OCCURRENCE AND CONTROL OF OCHRATOXIN A FROM POSTHARVEST DISEASES

XING Fuguo. (1), WANG Gang. (1)

(1) Institute of Food Science and Technology, Chinese Academy of Agricultural Sciences, Beijing, CHINA

Text

Ochratoxin A (OTA) contamination and the associated issues of food security, food safety and economic loss are widespread throughout the world. The occurrence of OTA depends on ochratoxigenic fungi, foodstuffs and their environment. In this report, natural occurrence and control strategy of OTA, with a focus on the impact of environmental factors, are summarized. First, this report introduces potentially contaminated foodstuffs, including the emerging ones which are not regulated in international legislation. Secondly, we gives an update of native producers based on foodstuffs and OTA biosynthesis. Thirdly, complicated environmental regulation is disassembled into individual factors in the research, such as pH and substrates, in order to clarify their regulatory effect and mechanism. Finally, we developed some strategies to control OTA, including biocontrol and effective detoxification.

Text

Cassiicolin (Cas), a toxin produced by *Corynespora cassiicola*, is responsible for Corynespora leaf fall disease in susceptible rubber trees. Currently, the molecular mechanisms of the cytotoxicity of Cas and its host selectivity have not been fully elucidated. Here, we analyzed the binding of Cas1 and Cas2 to membranes consisting of different plant lipids and their membrane disruption activities. Using high-speed atomic force microscopy and confocal microscopy, we reveal that the binding and disruption activities of Cas1 and Cas2 on lipid membranes are strongly dependent on the specific plant lipids. The negative phospholipids, glycerolipids, and sterols are more sensitive to membrane damage caused by Cas1 and Cas2 than neutral phospholipids and betaine lipids. Mature Cas1 and Cas2 play an essential role in causing membrane disruption. Cytotoxicity tests on rubber leaves of Rubber Research Institute of Vietnam (RRIV) 1, RRIV 4, and Prang Besar (PB) 255 clones suggest that the toxins cause necrosis of rubber leaves, except for the strong resistance of PB 255 against Cas2. Cryogenic scanning electron microscopy analyses of necrotic leaf tissues treated with Cas1 confirm that cytoplasmic membranes are vulnerable to the toxin. Thus, the host selectivity of Cas toxin is attained by the lipid-dependent binding activity of Cas to the membrane, and the cytotoxicity of Cas arises from its ability to form biofilm-like structures and to disrupt specific membranes

POST-HARVEST SUSTAINABLE STRATEGIES TO REDUCE MYCOTOXINS CONTAMINATION AND PEST INFESTATION IN CHICKPEA (CICER ARIETINUM L.) STORED SEEDS

RISOLI Samuele. (1), PISUTTU Claudia. (1), NALI Cristina. (1), PELLEGRINI Elisa. (1), SARROCCO Sabrina. (1)

(1) University of Pisa, Pisa, ITALY

Text

Mycotoxigenic fungi and pests represent a pivotal threat for global food safety, with crucial implications for human and animal health. Controlled atmosphere and oxidising agents (i.e., nitrogen, N_2; ozone, O_3) represent a sustainable strategy for the reduction of mycotoxin content and the growth of deleterious organisms in foodstuffs. In our work, O_3 treatment (500 ppb; 30, 60 or 90 min) and high N_2 concentration (98.5%; 21 days) were tested in the post-harvest storage of four batches of *Cicer arietinum* L. seeds to reduce the presence of mycotoxigenic fungi (i.e. *Penicillium* spp.) and their mycotoxins (i.e. aflatoxins and patulin), as well as pest (i.e., *Callosobruchus maculatus*) infestation. Ozone exposure critically decrease the presence of *Penicillium* spp. (−50% on average, independently to the time of exposure) and the patulin and aflatoxins amount after just 30 min from the beginning of the exposure (−85 and −100%, respectively). High N_2 concentrations remarkably reduced mycotoxins contamination (−94% on average) and induced *C. maculatus* mortality (100% after 5 days of exposure). These results confirm the promising potential of controlled atmosphere and oxidizing agents in post-harvest storage to drastically reduce the risk of

mycotoxin contamination and pests infestation. Further investigations are needed to extend these technologies on a large scale and to elucidate the effects of these treatments on the qualitative traits of seeds.

P1.4-011

QUEST FOR FUSARIUM: A SAMPLING STRATEGY TO PREDICT THE RISK OF CONTAMINATION IN IRISH CEREAL CROPS

BUCUR Diana. (1), KILDEA Steven. (1), BLACK Lisa. (3), DOOHAN Fiona. (2)

(1) Teagasc, Carlow, IRELAND; (2) University College Dublin, Dublin, IRELAND; (3) Agri-Food and Biosciences Institute, Belfast, UNITED KINGDOM

Text

Fusarium spp. are pathogenic fungi producing toxic secondary metabolites called mycotoxins; the most common mycotoxins in cereals are deoxynivalenol, zearalenone, T-2 and HT-2. As there is a concern regarding the health impact of emergent, modified and combination of mycotoxins present in cereals, the EU is considering imposing new limits for the mycotoxins commonly found in oats. In oats, mycotoxin contamination can occur in the absence of visual symptoms of fungal contamination, making it more difficult to assess. Mycotox-I aims to minimise the mycotoxin contamination in Irish cereals, focusing on oats. As the production of the mycotoxin starts in the field and continues during storage, the project will develop and standardise the technologies for predicting the mycotoxin potential in crops and mycotoxin content in cereal products.
To identify the spectrum of Fusarium species and mycotoxins in cereals, the level of infection is assessed based on field scale surveys developed to cover different production systems and key factors that might contribute to fungal infection. Further, the Fusarium species are isolated, identified and characterised. The impact of cropping systems on mycotoxin contamination of Irish grains will be also evaluated by conducting field scale trials.

P1.4-012

RESISTANCE TO FUSARIUM HEAD BLIGHT IN WHEAT: INFLUENCE OF THE FUNGAL MYCOTOXIN PROFILE

MNGOMEZULU Diana. (1), HERSELMAN Liezel. (1), MARÉ Ansori. (1), ROTHMANN Lisa-Ann. (1), STEYN Chrisna. (1), MINNAAR-ONTONG Adré. (1)

(1) University of the Free State, Bloemfontein, SOUTH AFRICA

Text

Fusarium head blight (FHB) is a destructive wheat disease which reduces yield and grain quality, and the associated mycotoxins threaten food safety. Host resistance especially resistance to tricothecenes (deoxynivalenol) is considered an important management strategy. The study aims to determine the correlation between FHB resistance and the FHB causal pathogen mycotoxin profile. Species-specific primers validated morphological results of 39 isolates from eight localities, identified as *F. graminearum* (*sensu lato*). TRI13 sequences were used for the genotypic characterisation of trichothecene gene clusters. All

isolates were deoxynivalenol (DON) producers. In cooler regions of South Africa, temperature < 35°C, a high frequency and concentration of 3-ADON was recorded. In contrast, warmer regions, temperature > 35°C, had a high frequency and concentration of 15-ADON isolates. PCR assays confirmed the presence of FHB resistance QTLs and genes in the evaluated wheat lines. Under inoculated conditions with three isolates, wheat lines with type I resistance had a lower incidence than those with type II resistance. A high disease incidence (~39%) in wheat spikes and low disease severity (~4%) was observed. Suggesting little need to breed for type III (resistance to DON accumulation) as type I and II (resistance to disease initiation and spread) can manage disease in South African wheat.

P1.4-013

EFFICACY OF THE ASPERGILLUS FLAVUS ATOXIGENIC STRAIN TECHNOLOGY TO REDUCE RISKS OF AFLATOXIN CONTAMINATION IN COMMERCIAL TREE NUT ORCHARDS IN CALIFORNIA

JAIME Ramon. (1), LAKE John S. (1), SINGH Pummi. (1), PUCKETT Ryan D.. (1), DOSTER Mark A.. (1), GABRI Victor M.. (1), MICHAILIDES Themis J.. (1)

Text

Aflatoxins are the most toxic mycotoxins, which are highly regulated worldwide. They are produced by fungi in the *Aspergillus* section *Flavi*, including *A. flavus* and *A. parasiticus* commonly found in California. Aflatoxins pose a highly economical threat to the tree nut (pistachio and almond) industries due to product rejection from markets. The *A. flavus* atoxigenic strain technology effectively reduces aflatoxins in crops by increasing the proportion of atoxigenic isolates and reducing the aflatoxin production potential of the population. The efficacy of *A. flavus* AF36 to reduce aflatoxins in commercial tree nut orchards has been evaluated for over a decade in California, including the effects of product rates, time of application, and irrigation method on both aflatoxin content, and displacement of toxigenic isolates by the biocontrol AF36. Aflatoxin content in 200-500 samples annually was determined by HPLC and displacement was determined from soil samples taken after harvest each year. Results indicate that the biocontrol AF36 reduces aflatoxin contamination by increasing the proportion of the atoxigenic strain AF36 in commercial orchards. However, the efficacy of the biocontrol applications in tree nuts in California has not reached its full potential with only an average 40% aflatoxin reduction compared to untreated controls, and 70% displacement of toxigenic isolates in both pistachio and almond orchards. The effect of treatments to improve efficacy will be discussed

P1.4-014

DISPLACEMENT OF AFLATOXIN PRODUCING FUNGI BY AN ASPERGILLUS FLAVUS ATOXIGENIC BIOCONTROL IN COMMERCIAL ALMOND ORCHARDS IN SEVERAL AREAS OF CALIFORNIA

JAIME Ramon. (1), LAKE John S. (1), SINGH Pummi. (1), RUIZ-POSSE Agustina. (1), PAPANGELIS Apostolis. (1), GABRI Victor M.. (1), FIORE Giuseppe. (1), MICHAILIDES Themis J.. (1)

(1) University of California Davis, Parlier, UNITED STATES

Text
Aflatoxins are toxic secondary metabolites produced by fungi in *Aspergillus* section *Flavi* and pose a highly economical threat to the tree nut industries, including almond, due to risks of product rejection from markets by government regulations. Avoiding insect damage, mainly by navel orangeworm (*Amyelois transitella*), does not completely prevent contamination. The *A. flavus* atoxigenic strain biocontrol technology effectively reduces aflatoxins in susceptible crops. The goal of this technology is to reduce the aflatoxin production potential of the fungal population by increasing the proportion of atoxigenic isolates. The efficacy of atoxigenic *A. flavus* AF36 applications to reduce the risk of aflatoxin contamination in almonds was evaluated in seven areas with a total of 5,000 treated acres in California. Soil samples were taken before application of the biocontrol and after harvest. Fungal isolates were recovered from the soil samples and characterized as *A. flavus* AF36, toxigenic strains and other non-toxigenic strains. Five of the 7 areas had 70% or higher of the biocontrol AF36. In two areas, although there was an increase of AF36, it was <50%. Results indicate that application of the *A. flavus* AF36 biocontrol in commercial almonds is effective to change the population structure of the aflatoxigenic fungi by displacing the toxigenic strains with atoxigenic strains, which will reduce the aflatoxin production potential and the risk of aflatoxin contamination in almonds.

Text
During postharvest storage, contamination of cereals, such as wheat and maize, by mycotoxigenic fungi affects the quality and produces toxic substances rendering the grains unsafe for consumption. *Aspergillus flavus*, and *Fusarium proliferatum* are considered major contaminants of stored grains that are usually controlled by chemicals applied by fumigation. There is an urgent need for sustainable and ecologically safe approaches to manage mycotoxigenic fungi. In this work, we focused on isolation of endophytic microorganisms and testing their antagonistic activity against both mycotoxin-producing fungi. Results showed that among the isolated endophytic microorganisms, bacterial strains belonging to Bacillus spp. were found effective in inhibiting the growth of *A. flavus* and F. *proliferatum*, both in vitro and on grains. The fungal DNA was reduced by 70.5% and 89.7% for the wheat grains that were inoculated with *A. flavus* and pretreated with *B. subtilis* or *B. amyloliquefaciens*, respectively, as compared to control. The fungal DNA was decreased by 41.6% and 62.7%, for the wheat grains inoculated with *F. proliferatum* and pretreated with *B. subtilis* or *B. amyloliquefaciens*, respectively, as compared to control. In addition, their secondary metabolites exhibited antifungal activity against *A. flavus* and *F. proliferatum* in a disc diffusion assay. Further, isolate VB24 significantly decreased the production of Aflatoxin B1 in liquid culture by *A. flavus* as compared to the control.

Text

Mycotoxin producing fungi are causing new challenges for safe and sustainable food systems due to climate change. Apples and their derived products are largely consumed by the European population. Patulin is the only regulated mycotoxin in apple derived products, but recently aflatoxin B1 and fumonisins were signaled in apple puree. Therefore, the aim of this study was to monitor mycotoxin producing fungi and mycotoxin in the apple chain. Apple fruits, cv Golden delicious and Imperatore, were collected in three orchards placed across three different production zones located in north Italy during harvesting. Stored fruits, same varieties, were sampled before processing together with the corresponding puree. Fruits were mashed using a portable blender before analysis. Alternaria spp and Penicillium spp were almost always isolated from field samples and the related toxins, patulin and Alternaria toxins too. In addition, aflatoxins were detected, even with differences between cultivars and growing areas. The same fungi and mycotoxins were detected in stored apples, with in addition the sporadic occurrence of Aspergillus section Flavi and Fusarium spp. In the puree, no fungi were isolated, due to the thermal treatment, but all the mentioned toxins occurred, with the addition of fumonisins. This study confirmed the co-occurrence of mycotoxins in apples fruits and puree at non neglectable levels, but further research is requested to contribute to a safer sustainable apple system.

P1.4-018

POTENTIAL FOR AFLATOXIN B1 AND B2 PRODUCTION BY ASPERGILLUS FLAVUS STRAINS ISOLATED FROM BAMBARA GROUNDNUT (VIGNA SUBTERRANEA (L.) VERDCOURT) SEEDS PRODUCED IN BURKINA FASO

OUILI S. Amidou. (1), MAIGA Ynoussa. (1), OUEDRAOGO Mahama. (2), OUATTARA Aboubakar Sidiki. (1)

(1) Université Joseph KI-ZERBO/Laboratoire de Microbiologie et de Biotechnologies Microbiennes (LAMBM), Ouagadougou, BURKINA FASO; (2) Laboratoire de Génétique et de Biotechnologies Végétales, Institut de l'Environnement et de Recherches Agricoles (INERA), Ouagadougou, BURKINA FASO

Text

In Burkina Faso, Bambara groundnut is the second most important food legume after cowpea, especially in rural areas. However, this crop, due to certain conditions of production,

storage or preservation is susceptible to be contaminated by potential mycotoxin producing fungi. The aim of this study was to evaluate the aflatoxinogenic capacity of Aspergillus flavus strains isolated from Bambara groundnut seeds produced in Burkina Faso. Thus, 198 strains of fungi belonging to section Flavi were isolated from 99 samples of Bambara groundnut seeds collected in the three agro-ecological zones of Burkina Faso. According to molecular identification, from the 198 isolates, 28 were identified as Aspergillus flavus. Then, we investigated their potential for aflatoxin B1 (AFB1) and B2 (AFB2) production by growing them on rice at 25°C for 7 days. AFB1 and AFB2 were extracted and quantified by liquid chromatography–mass spectrometry (LC-MS/MS). All of the strains (28) produced AFB1 at concentrations ranging from 46.987 µg kg–1 to 1080.320 µg kg–1. However, AFB2 was produced by 26 strains with concentrations ranging from 47.200 µg kg–1 to 1760.240 µg kg–1. Globally, most of the tested strains produced higher levels of AFB1 than AFB2. The results obtained point out the risk associated with post-harvest fungi and the need for the development of storage technics to control them, for food security.

P1.4-019

IDENTIFYING SORGHUM GRAIN FUNGAL COLONISERS, QUANTIFICATION OF MYCOTOXINS AND DEVELOPMENT OF WEATHER-BASED PREDICTIVE MODELS FOR FUSARIUM GRAMINEARUM

MASISI Thabiso. (1), ROTHMANN Lisa. (1), JACKSON Mariette. (1)

(1) University of the Free State, Bloemfontein, SOUTH AFRICA

Text

Sorghum grain mold negatively affects crop yield and quality across the globe, and associated mycotoxin contamination poses a risk to livestock and human health. In the study mycotoxigenic fungi in sorghum grain were identified, concomitant mycotoxins quantified and conducive weather to initiate disease during anthesis was explored. Grain harvested from field trials in KwaZulu Natal and Limpopo (South Africa) were used, from 2009-2013 and 2017-2019, respectively. Thirty-six fungi were morphologically and molecularly identified. Mycotoxin quantification was conducted on representative grain samples. Nine of the 24 representative samples contained deoxynivalenol (DON) and zearalenone (ZEA). One sample contained a ZEA concentration of 1250 µg/kg, exceeding the maximum legislative limit. All DON detected in samples was lower than 1000 µg/kg. Nonlinear regression analyses determined five conducive days of air temperature between 20 and 28°C (R2 = 0.81), 3 to 8 days of rainfall greater than 1 mm (R2 = 62) and six days of 70% relative humidity (R2 = 0.98) as critical for disease initiation. A significant positive correlation between FgSC DNA and DON (R = 0.63) and nivalenol (NIV; R = 0.82) were detected. Suggesting a greater risk of DON and NIV with greater FgSC DNA concentrations. Defining conducive periods associated with infection provides a platform to explore future risk indicators for disease intervention and mycotoxin mitigation.

OCCURRENCE OF FUSARIUM SPP. IN GERMAN OAT FIELDS – RESULTS FROM A THREE YEAR MONITORING

RODEMANN Charlotte. (1), ALHUSSEIN Mohammad. (2), VON TIEDEMANN Andreas. (1)

(1) Plant Pathology and Crop Protection, Georg - August University Göttingen, Göttingen, GERMANY; (2) Molecular Phytopathology and Mycotoxin Research, Georg - August University Göttingen, Göttingen, GERMANY

Text

In recent years the cultivation of oats in Germany as well as the interest in oat-based products has increased continuously. In particular, the nutritional excellence, as well as the position of oats as a "health crop" in cropping systems have increased the agronomic value of oats. In general, oats are considered a comparatively healthy crop regarding susceptibility to fungal pathogens. Nonetheless, elevated levels of mycotoxins in the harvested material have become an issue of concern in recent years. Such contamination is caused by the infestation with various Fusarium species. The present study was conducted in order to investigate the risk of Fusarium infection in German oat cultivation, to identify the involved Fusarium species and to analyze the range of associated mycotoxins. To this end, a monitoring was performed in the years 2020 to 2022. Samples from fungicide untreated plots were collected, and examined. In addition, agronomic and meteorological field data were recorded. Fusarium spp. were isolated from surface-sterilized oat grains on a nutrient medium. The obtained strains were identified both morphologically and by sequence analysis. Mycotoxins were determined by HPLC-MS/MS. The strains identified from 2020 to 2022 included the following species: F. poae, F. tricinctum, F. avenaceum, F. culmorum, F. equiseti, F. graminearum, F. langsethiae, F. cerealis. Major mycotoxins analyzed in grain samples were nivalenol, deoxynivalenol, T-2 and HT-2, and enniatins.

Text

Plants represent the nutritional basis of all life on earth and are essential for feeding an increasing human population while facing new challenges posed by climate change and plant pathogens.
While the genomes and transcriptomes of crops are increasingly elucidated, little is known about crop proteomes. To address this knowledge gap, we have launched a new initiative

with enormous socio-economic relevance at TUM with the Elitenetzwerk Bayern-funded International Doctoral Program “The Proteomes that Feed the World” at its core. One of the program’s overarching aims is to map the proteomes of all major tissues and organs of the 100 crop plants most important for human nutrition, thereby creating a Crop Proteome Atlas of extremely high value to academia as well as the agricultural industry. On top of the creation of the Crop Proteome Atlas, several sub-projects are investigating detailed aspects of plant proteomes in response to biotic stress. For instance, we aim to better understand the mode of action of the Fusarium mycotoxin deoxynivalenol (DON) and its protein biosynthesis inhibitor function in barley.
In preparation for the Crop Proteome Atlas project, a robust and reproducible protocol for the processing and analysis of a variety of plant tissues by liquid chromatography tandem mass-spectrometry (LC-MS/MS) was devised. This protocol constitutes a central component of the Crop Proteome Engine. All data will be made available on PRIDE and ProteomicsDB.

Text
This study assessed the impact of Conservation Agricultural (CA) practices and planting soil fertility enhancing trees on toxigenic Aspergillus spp., peanut aflatoxin levels, and aflatoxin exposure risks in Zambia. Soil and peanut samples (270) were collected at farmgate of CA (peanuts grown in basins), AGF (peanuts grown in basins in farms containing Gliricidia sepium agroforestry trees), and NCA (peanuts grown on ridges). Aspergillus population density and aflatoxin level were quantified using the direct plate count and quantitative Neogen Lateral Flow techniques, respectively. Dietary exposure risk was computed using the aflatoxin dataset. Aspergillus spp. concentration [colony forming units (CFU)/g)] ranged from 10 to 7400 CFU/g. NCA supported higher propagules than CA or AGF. The S-morphotype (55%) was the most predominat Aspergillus species followed by A. parasiticus (34%), and A. flavus L strains (11%). Aflatoxin prevalence in peanuts averaged 64% but didn’t differ across farming techniques. Mean total aflatoxins were 110.4, 87.0 and 99.0 µg/kg for AGF, CA and NCA, respectively. Probable daily aflatoxin intake ranged from 12.7 to 767.1 ng/kg bw/d. The estimated liver cancer risk due to consumption of raw peanuts (0.334 - 20.128) was highest among children below 5 years. Therefore, CA has minimal impact on kernel aflatoxin level. Children are at higher risk of developing aflatoxin-related illnesses; thus, their exposure through diets should be controlled.

MYCOTOXIN PRODUCING FUSARIUM SPECIES IN ESTONIAN GRASSLANDS AND SILAGE

PUIDET Britt. (1), KÕIV Meelis. (1), SOONVALD Liina. (1), LOIT Kaire. (1)

(1) Estonian University of Life Sciences, Tartu, ESTONIA

Text

Grass silage is an important part of animal feed in many European countries. Recent studies have shown mycotoxin contamination in silage, which can have a negative impact on animal health. The aim of this study was to identify mycotoxin producing *Fusarium* species from Estonian grasslands and to analyze the effect of fungicide applications on their presence. Two experiment plots were treated with two different commercially available fungicide products and one plot remained untreated as a negative control. The experiment was repeated on two consecutive years on different grassland plots. Samples were collected before and after fungicide applications and analyzed using species-specific PCR primers. The findings presented in this study did not confirm the effect of fungicides on *Fusarium* species on grassland plants. Evidence for potentially mycotoxin producing fungi was found. Three *Fusarium* species, *F. culmorum, F. cerealis and F. poae* were identified.

FUSARIUM CULMORUM PRODUCES NX-2 TOXIN SIMULTANEOUSLY WITH DEOXYNIVALENOL AND 3-ACETYL-DEOXYNIVALENOL OR NIVALENOL

SCHIWEK Simon. (1), ALHUSSEIN Mohammad. (2), RODEMANN Charlotte. (3), BUDRAGCHAA Tuvshinjargal . (4), BEULE Lukas. (5), VON TIEDEMANN Andreas. (3), KARLOVSKY Petr. (2)

(1) Institute for Plant Protection in Field Crops and Grassland, Julius Kuehn-Institute, Brunswick, GERMANY; (2) Molecular Phytopathology and Mycotoxin Research, University of Goettingen, Göttingen, GERMANY; (3) Plant Phytopathology and Crop Protection, University of Goettingen, Göttingen, GERMANY; (4) Department of Bioorganic Chemistry, Leibniz Institute for Plant Biochemistry, Halle, GERMANY; (5) Plant Analysis and Stored Product Protection, Institute for Ecological Chemistry, Julius Kuehn-Institute, Berlin, GERMANY

Text

Fusarium culmorum is a major pathogen of grain crops. Infected plants accumulate deoxynivalenol (DON), 3-acetyl-deoxynivalenol (3-ADON), or nivalenol (NIV), which are mycotoxins of the trichothecene B group. These toxins are also produced by the F. graminearum species complex. New trichothecenes structurally similar to trichothecenes B but lacking the carbonyl group on C-8, designated NX toxins, were recently discovered in atypical isolates of F. graminearum from North America. Only these isolates and a few strains of a yet to be characterized Fusarium species from South Africa are known to produce NX-2 and other NX toxins.

In this study, we report that among 20 F. culmorum strains isolated from maize, wheat, and oat in Europe and Asia over a period of 70 years, 18 strains produced NX-2 simultaneously with 3-ADON and DON or NIV. Rice cultures of strains producing 3-ADON accumulated NX-2 in amounts corresponding to 2–8% of 3-ADON (1.2–36 mg/kg). A strain producing NIV accumulated NX-2 and NIV at comparable amounts (13.6 and 10.3 mg/kg, respectively). In

F. graminearum, producers of NX-2 possess a special variant of cytochrome P450 monooxygenase encoded by TRI1 that is unable to oxidize C-8. In F. culmorum, producers and nonproducers of NX-2 possess identical TRI1; the reason for the production of NX-2 is unknown. Our results indicate that the production of NX-2 simultaneously with trichothecenes B is a common feature of F. culmorum.

SEASONAL PREVALENCE OF AFLATOXIN AND STRATEGIES FOR MITIGATION IN THE GROUNDNUT, MAIZE AND SORGHUM VALUE CHAINS IN UGANDA

MAHUKU George. (1), NAKATO Valentine. (1), ASEA Godfrey. (2), BOMET KWEMOI Daniel . (2), BANDYOPADHYAY Ranajit. (3), ORTEGA-BELTRAN Alejandro. (3)

(1) International Institute of Tropical Agriculture (IITA), Kampala, UGANDA; (2) NaCRRI, Kampala, UGANDA; (3) IITA, Ibadan, NIGERIA

Text

Aflatoxin contamination in food crops is a major public and policy concern in Uganda. However, there is limited consistent seasonal monitoring data on aflatoxin occurrence. Aflatoxin was monitored for three seasons in Northern, Eastern, Western, and Central regions of Uganda. Samples (993 maize, 169 groundnut, 92 sorghum) were randomly collected from farmer fields at crop physiological maturity. In groundnut, the mean aflatoxin level in 2021A and 2022A seasons was 12.1 ppb and 30.6 ppb, respectively. The Northern and Eastern regions had the highest aflatoxin level in 2021A (28.6 ppb) and 2022A (52.5 ppb), respectively. A similar trend was observed for maize, where average levels were 8.6 ppb in 2021A, 18.7 ppb in 2021B, and 46.7 ppb in the 2022A season. In 2021A only maize from Northern Uganda (18.0 ppb) had aflatoxin levels above 10 ppb, the EAC tolerance threshold. In 2021B, maize from the Northern region had the highest avg. aflatoxin levels (46.6 ppb) followed by Eastern (11.9 ppb). In 2022A all regions had aflatoxin levels above 10 ppb, and the Northern region had the highest (101.5 ppb), and Western region had the lowest (26.9 ppb). Aflatoxin levels in sorghum were below 10 ppb in all regions and seasons. The seasonal variations allude to the need to constantly monitor aflatoxin content in staple crops. This presentation highlights efforts to manage aflatoxin and points to gaps required to address the aflatoxin menace in staple crops in Uganda.

MYCOTOXIN EXPOSURE IN FOODS EATING BY VEGANS AND VEGETARIANS: EVALUATING THE CURRENT RISK ASSESSMENT

RUBIO-LOPEZ Fernando. (1), GARCIA-CELA Esther. (1), LAWSON Rita. (1), **HALL Avice. (1)**

(1) University of Hertfordshire, Hatfield, UNITED KINGDOM

Text
Mycotoxins are secondary metabolites produced by filamentous fungi along the food chain. Despite the maximum legal limits legislated for in most countries, consumers are still exposed to these contaminants through their diets. Exposure to Ochratoxin A (OTA) is associated with liver failure and renal cancer and it is commonly detected in cereals, spices, nuts, dried fruit and beverages as coffee. A recent publication showed that serum OTA levels were two-fold higher in vegans than in omnivores. Another report calculated that the substitution of meat products with soy-based could lead to potential risk of renal cancer due to an increased intake of OTA, leading up to 1,208 extra cancer cases. Most of the publications assessed the contamination in raw material, but there is a lack of knowledge on role of organic plant-based products commonly consumed by vegans and vegetarians. Therefore, the main goal of this study was to quantify the OTA occurrence in plant-based milk and cereal processed foods. Samples were purchased in conventional supermarkets and OTA was quantified by ELISA kit. The results of this project will help to understand the OTA exposure through highly processed organic foods and provide foundations for a Risk Assessment based on a cross case analysis of the food chain, from farm to fork.

MODELLING THE EFFECT OF WEATHER ON DEOXYNIVALENOL CONTAMINATION IN SWEDISH SPRING CEREALS USING MACHINE LEARNING ALGORITHMS

MARZEC-SCHMIDT Katarzyna. (1), BÖRJESSON Thomas. (2), PERSSON Kristin. (1)

(1) SLU, Skara, SWEDEN; (2) Agroväst, Skara, SWEDEN

Text
Fusarium head blight (FHB) is one of the most serious diseases of small-grain cereals, resulting in yield reduction and an accumulation of deoxynivalenol (DON) in grain. Weather conditions are known to have a significant effect on the production of toxins by fusaria. Since 2011, when about half of all oats grown in Sweden had a DON content too high for human consumption, almost all oats produced are tested for DON, generating a high cost to farmers and the grain industry. In this study, data from Swedish field trials on oats, spring barley, and spring wheat were analysed to identify the most crucial weather variables for DON contamination. Relationships between weather and DON content at harvest were analysed using Spearman's rank correlation coefficient. Based on the weather variables and the trial location, Machine Learning-based models were developed to classify the risk of grain DON contamination exceeding 200 µg/kg. Models based on Support Vector Machine performed overall best in predicting the risk of DON contamination with an accuracy between 70% and 81%. High relative humidity and precipitation around flowering, during grain development and ripening, were correlated with high DON levels. High temperatures during grain development and senescence reduced the risk of DON accumulation. In future studies, it might be of interest to determine whether the inclusion of pre-crop, agronomic factors, and crop resistance to FHB could further improve the performance of the models.

P1.4-028

ALTERNARIA SPECIES: A "FROM FARM TO FORK" PHYTOPATHOLOGICAL AND TOXICOLOGICAL GLOBAL CONCERN IN MEDITERRANEAN AREA

MASIELLO Mario. (1), SOMMA Stefania. (1), MORETTI Antonio. (1)

(1) Research National Council of italy, Bari, ITALY

Text
The fungal genus Alternaria represents a serious problem for agri-food crops, from tfield to post-harvest, for both ability to be pathogenic and produce several toxic metabolites. In particular, Alternaria species produce more than 70 metabolites, including alternariol, alternariol monomethyl ether, tenuazonic acid, altenuen mycotoxins. We report here, our last years studies on the occurrence of Alternaria species on different crops, in the Mediterranean area, their mycotoxin profile, and phylogeny. About 700 strains isolated from wheat, tomato, date palm, and the European sea-rocket, collected in Italy, Lebanon, and Tunisia, were studied. Phylogenetic analyses revealed that the most frequent species occurring on wheat kernels belonged to Alternaria and Infectoriae Sections and the majority of strains isolated from the other hosts belonged only to Alternaria Section. Few strains grouped in Ulocladiodes, Chalastospora and Pseudoalternaria Sections. More than 90% of strains included in Alternaria Section produced multiple mycotoxins, with variable amount. Our in-depth investigations demonstrate that geographical origin and host plants did not influence Alternaria species distribution and genetic diversity. Finally, the plasticity of this genus represents a great pathological and toxicological risk, not only in the Mediterranean Area, but also at worldwide level.

Necrotrophic plant pathogens

C9.2-1

MECHANISMS OF HOST SPECIFICITY IN THE GENUS BOTRYTIS

VAN KAN Jan. (1)

(1) Wageningen University, Wageningen, NETHERLANDS

Text
Fungi of the genus *Botrytis* are necrotrophic pathogens and *B. cinerea* is the best studied among them. With exception of *B. cinerea* and *B. pseudocinerea*, all other *Botrytis* species are considered to be restricted to a single host species or a group of closely related hosts. The genomes of 16 *Botrytis* species were sequenced, but features that provide clues about factors determining host specificity could not (easily) be identified from genome comparisons. In an effort to unravel mechanisms underlying host specificity, we focused on *B. elliptica*, a specialised pathogen of lily. Previous studies showed that quantitative differences in virulence of *B. elliptica* isolates are correlated with the cell death-inducing capacity of secreted proteins in liquid culture filtrates. We studied the proteins secreted by *B. elliptica* that induce cell death specifically on its host plant, and analysed the protein composition by mass spectrometry. Among the secreted proteins, one of the most striking was an enzyme

with chorismate mutase activity and a sequence motif that would target the protein to plant chloroplasts. I will discuss how this effector participates in virulence of *B. elliptica* on lily. I will also discuss features of minichromosomes (<300 kbp) that were detected in the genomes of several (but not all) *B. elliptica* isolates, and their occurrence in other *Botrytis* species.

Text

Necrosis- and ethylene-inducing 1-like proteins (NLPs) constitute a superfamily of proteins found in diverse phyla of plant-associated microorganisms. Numerous NLPs are cytotoxic and facilitate infections in a wide range of crops. The evidence of NLPs being toxic to both monocot and dicot plants is inconclusive. The target for interaction with the plant plasma membrane is a sphingolipid glycosyl inositol phosphoceramide (GIPC). Studies of NLP_{Pya} from *P. aphanidermatum* highlighted critical residues for interaction with the terminal hexose unit of GIPC and a unique mode of membrane damage was observed. Upon binding, the protein oligomerizes on the membrane, followed by the formation of transient heterogeneous pores that are permeable to small molecules. So far, other NLPs have not been studied for their plant plasma membrane binding and mechanism of damage and respective pore formation. We study the ability of MpNEP2 from *Moniliophthora perniciosa* to induce damage to the plant plasma membrane of mono- and dicot plants. We utilize the microfluidic system to study the binding and pore-forming activity of MpNEP2 to GIPC-containing vesicles. As shown previously in NLP_{Pya}, MpNEP2 also binds and exhibits pore-forming activity on GIPC-containing vesicles from dicots. In addition, the same action is observed in vesicles containing monocot GIPC. This is the first study of MpNEP2 to show GIPC as a receptor and explore putative pore-forming activity.

C9.2-3

PECTOBACTERIUM BRASILIENSE: WHAT HAVE WE LEARNED IN NEARLY TWO DECADES OF RESEARCH?

MOLELEKI Lucy. (1)

(1) University of Pretoria, Pretoria, SOUTH AFRICA

Text

Pectobacterium brasiliense (Pbr) is a member of the Soft Rot Pectobacteriaceae (SRP) best known for causing blackleg and soft rot of potatoes. This species of Pectobacterium was first

reported nearly 20 years ago in Brazil. Since then, several Pbr isolates have been identified and shown to cause significant problems in different crop production systems globally. In addition, since the first report, a large body of research has been published leading to better understanding of the biology of the species. In our research, we use a combination of comparative and functional genomics, transcriptomic and metabolomic profiling to identify key virulence factors required for Pbr1692 colonisation of their main host, potato tubers. We found that there is a plethora of antibacterial systems upregulated in Pbr1692 during host colonisation. These include the type 6 secretion system (T6SS), pyocin and carbapenem. An interesting finding is the role of outer membrane vesicles (OMV) in ferrying some of these factors. We show that most of these factors are recruited to confer competitive advantage and enhance adaptation to different host niches rather than virulence. Finally, we show that there is a complex regulatory network of virulence factors and antibacterial agents by the different Pbr1692 transcription factors.

C9.2-4

IDENTIFICATION OF PTTNLS1 – A PUTATIVE PYRENOPHORA TERES F. TERES EFFECTOR INVOLVED WITH BARLEY RPT5-MEDIATED RESISTANCE

EFFERTZ Karl. (1), BRUEGGEMAN Robert. (1)

(1) Washington State University, Pullman, UNITED STATES

Text

Net form net blotch of barley is a destructive foliar disease caused by the necrotrophic fungal pathogen *Pyrenophora teres* f. *teres* (*Ptt*). The strongest resistance to this pathogen is conferred by the resistance gene *Rpt5*, specifically the allele from Ethiopian landrace CI5791, although this resistance has recently been overcome by *Ptt* populations in Canada and Morocco. We have identified and began to characterize a putative effector protein that interacts with the CI5791 Rpt5 receptor-like protein and is broadly conserved across *P. teres* isolates. This protein, PttNLS1, is encoded by a gene underlying a virulence QTL on chromosome 8 that was found to be contributed by *Ptt* isolate 0-1 in a bi-parental mapping population between isolates 0-1 and Mor40-3. Interestingly, Mor40-3 is the only known isolate to possess a mutated copy of the gene encoding PttNLS1, resulting in a predicted truncation of the protein, possibly contributing to the increased virulence this isolate has on CI5791. Infiltration studies with the 0-1 isoform of PttNLS1 reveal a strong suppression of the induction of two pathogenesis-related (PR) genes, *PR-1b* and *PR4*. We propose that *PttNLS1* evolved to suppress host PTI and that the Rpt5 resistance receptor evolved to recognize this PttNLS1 and trigger early effector triggered immunity, providing the strong resistance observed in CI5791.

C9.2-5

SMALL MOLECULES, BIG IMPACT: MULTILEVEL REGULATION OF C-DI-GMP AND ITS EFFECTORS ON VIRULENCE FACTORS OF DICKEYA DADANTII

YANG Ching-Hong. (1), GHASEMIMIANAEI Alaleh. (1), YUAN Xiaochen. (1)

(1) University of Wisconsin, Milwaukee, Milwaukee, UNITED STATES

Text
A small bacterial molecule, bis-(3?-5?)-cyclic dimeric guanosine monophosphate (c-di-GMP), acts as a second messenger that regulates various cellular processes in different bacterial species. The diguanylate cyclases (DGCs) synthesize c-di-GMP from two molecules of GTP, whereas the phosphodiesterases (PDEs) break down c-di-GMP to 5′-phosphoguanylyl-(3′-5′)-guanosine (pGpG) or guanosine monophosphate (GMP), together are responsible for controlling the intracellular levels of c-di-GMP. c-di-GMP effectors bind to c-di-GMP and are allosterically governed by this small molecule, further exerting diverse influences in the cell. Dickeya dadantii is an Enterobacterium that causes soft-rot disease in many economically important crops. In this study, we examined the molecular interactions between two PDEs, EGcpB and EcpC, and c-di-GMP effectors, BcsA and YcgR, in the regulation of the type III secretion system (T3SS) in D. dadantii. Furthermore, we explored the co-regulation between a novel putative transcriptional regulator, CdeR, and a DGC, GcpD, in regulating the T3SS and pectate lyase (Pel). We found that CdeR regulates the above two virulence factors of D. dadantii in a c-di-GMP-dependent manner. A multi-tiered regulatory mechanism that links the DGC, PDE, and c-di-GMP effector to the bacterial virulence factors was proposed.

C9.2-6

A COUNTER STAINING TECHNIQUE ELIMINATES THE NEED FOR TRANSFORMATION AND RESULTS IN MORE ACCURATE QUANTIFICATION IN MULTIPLE FUNGAL-PLANT INTERACTIONS

NELSON Ashley. (1), KARIYAWASAM Gayan. (1), WYATT Nathan. (1,3), LI Jinling. (1), BOROWICZ Pawel. (2), FRIESEN Timothy. (1,3)

(2) Department of Animal Sciences, North Dakota State University, Fargo, UNITED STATES;
(3) Edward T. Schafer Agricultural Research Center, USDA-ARS, Fargo, UNITED STATES

Text
3D imaging using confocal microscopy is invaluable for visualizing plant-fungal interactions and the use of fluorescent proteins has been common, requiring transformation. We introduce a counter staining technique that uses propidium iodide and wheat germ agglutinin labeled with fluorescein isothiocyanate (WGA-FITC) to look at fungal colonization of plants. This method relies on the use of KOH to remove the cutin layer of the leaf, creating permeability of the staining solution, allowing the visualization of colonization. Subsequently, a quantitative volume analysis and program cell death (PCD) assessment was done. Volume analysis (fungal biomass) was performed using machine learning through pixel quantification to differentiate between fungal growth and plant cells using Imaris software. Because an early hallmark of PCD is the breakdown of organelles including the nucleus, PCD was quantified using Manders' overlap coefficient to assess the separation/overlap of red (plant DNA) and blue (plant autofluorescence) where color overlap indicates PCD. This technique worked effectively on both monocots and dicots, including the wheat-Parastagonospora nodorum, barley-Pyrenophora teres f. teres, and the sugarbeet-Cercospora beticola interactions. Since transformation is not required for this technique, it can be applied to any interaction, offering a higher quality cellular visualization, resulting in more accurate quantification of pathogen biomass and the analysis of PCD induction.

Text

Blackleg causes high economic losses for the seed potato industry worldwide. The disease is caused by bacteria belonging to the genera Pectobacterium or Dickeya. Recent developments in sequencing technology led to refine their taxonomy. Since 2016, the number of described species has increased from 12 to 33, highlighting their great genetic diversity. To date, few data are available about their specific behavior on potato host.
In order to compare the aggressiveness of 5 different Pectobacterium and 2 Dickeya species, we inoculated the pathogens on tubers just before plantation in trial fields. Each inoculum consisted in a mix of 5 strains belonging to a same species. Then, different parameters reflecting the aggressiveness and fitness of the inoculated strains were observed, as blackleg expression or vertical transmission in harvested tubers.
The results showed differences between species for all the parameters studied, highlighting different colonization strategies on potato host. Moreover, the qPCR analysis of blackleg symptoms obtained after inoculation with a mix of strains belonging to two different species can reveal a possible antagonistic relation between pectinolytic bacteria species association. Finally, a metabarcoding sequencing approach performed to monitor each inoculated strain revealed the predominance of one strain in each analyzed symptom, not always the same, highlighting a pioneer effect during the symptom development.

Text

Bacteria are ubiquitous and occupy a very wide range of ecological niches where oxygen can be rapidly limited. In this case, bacteria develop flexible metabolic respiration. Therefore, demonstrating the possibility of using carbon sources as alternative terminal electron

acceptors (TEAs) and elucidating the underlying genetic pathways has great potential to help understand bacterial strategies to adapt and persist in the environment. This question is more relevant in the case of phytopathogenic bacteria which face many specific challenges to infect plants. It is the case for Dickeya, an emergent pathogen, found in various ecological niches, such as plant apoplast, and responsible for soft rot disease in a wide variety of plants. Understanding anaerobic respiratory pathways involved in Dickeya persistence and colonization will allow us to better understand its pathogenicity, and thus better counter it. In this study, we demonstrated that D. dadantii is able to use malate and asparagine as TEA. By constructing metabolic model of D. dadantii, we predicted pathways involved in anaerobic growth using asparagine and malate. Mutants affected in asparagine pathway were constructed and we evidenced the role of asparagine respiration in D. dadantii virulence. We also tested whether asparagine pathway is conserved among Dickeya and Pectobacterium genus.This study demonstrated that anaerobic respiration is an important trait involved in D. dadantii virulence.

F9.2-3

SMALL SECRETORY PROTEINS IN THE PATHOGENESIS OF SCLEROTINIA SCLEROTIORUM

CHENG Jiasen. (1), FU Yanping. (1), XIE Jiatao. (1), JIANG Daohong. (1)

(1) Huazhong Agricultural University, Wuhan, CHINA

Text
Sclerotinia sclerotiorum is a typical necrotrophic fungal pathogen and has a wide host range including rape and soybean. Previous studies have shown that the cell wall degrading enzymes and oxalic acid play major roles in the pathogenesis of *S. sclerotiorum*. We found that small secretory proteins, such as SsSSVP1, SsCP1 and SsITL, also are important virulence factors of *S. sclerotiorum*. SsSSVP1 interacts with a plant mitochondrial protein QCR8 and hijacks it into cytoplasm, thereby disable its biological functions and induce cell death. SsCP1 interacts with PR1 in the apoplast and then maybe inhibiting the potential antifungal activity of PR1. SsITL interacts with a chloroplast-localized calcium-sensing receptor (CAS) in chloroplasts, and thereby reduces salicylic acid accumulation during the early stage of infection. These secretory proteins tend to attack the conserved proteins widely existing in host plants, which is consistent with the wide host range of *S. sclerotiorum*. Recently, we found that some new secretory proteins that induce host cell necrosis, such as SsNIP1 and SsNIP2, play important roles in the pathogenesis of *S. sclerotiorum*, and the mechanism of these proteins is still under further study. Together, our findings revealed a new mechanism of the pathogenesis of *S. sclerotiorum*, and could also help us to understand the pathogenic mechanism of necrotrophic fungal plant pathogen from a new perspective.

P9.2-001

INCIDENCE, DIVERSITY AND PATHOGENICITY OF DIAPORTHE SPECIES ASSOCIATED WITH SOYBEAN SEEDS IN SOUTH AFRICA

MAKHATHINI MKHWANAZI Gugulethu Joy. (1,2), SPIES Chris. (1), MCLEOD Adele. (2), LAMPRECHT Sandra. (1)

(1) Agricultural Research Council – Plant Health and Protection, Stellenbosch, SOUTH AFRICA; (2) Stellenbosch University, Stellenbosch, SOUTH AFRICA

Text

Seedborne Diaporthe species on soybean can cause seed decay, stem canker, and pod and stem blight, leading to economic losses. Despite their importance as soybean pathogens, information on Diaporthe spp. on soybean in South Africa (SA) is scarce. This study investigated the occurrence, diversity and pathogenicity of Diaporthe associated with soybean seed in SA. One hundred and sixty-two seed lots representing 11 cultivars were collected from 11 sites in SA from 2014 to 2015. Diaporthe isolates were recovered both years from all locations. Although the overall incidence was low (3.6% of seed infected), individual seed lots had up to 71% infected seeds. A subset of Diaporthe isolates were selected for species-level identification which was conducted through phylogenetic analyses of the ITS, EF1-α and TUB regions. Ten species were identified, of which D. ueckerae comprised the most isolates. Other species included some known soybean pathogens. Pathogenicity assays showed that D. longicolla contained the most virulent isolates, causing more than 88% damping-off, followed by D. ueckerae causing up to 70%. The D. ueckerae isolates caused a notable symptom which was confirmed to be associated with secondary metabolites experimentally in cell-free culture filtrate. This study showed that Diaporthe species pathogenic to soybean may be of major concern at specific sites in SA. This is the first report of D. foeniculina and D. ueckerae on soybean in South Africa.

P9.2-002

CHARACTERISTICS AND FUNGICIDES SENSITIVITY OF FUSARIUM INCARNATUM-EQUISETI SPECIES COMPLEX (FIESC) CAUSING MUSKMELON FRUIT ROT DISEASE IN TAIWAN

WANG Chao-Jen. (1), HUANG Yu-Fang . (1), HSU Wei-Che . (2), CHUNG Wen-Hsin . (2)

(1) Taichung District Agricultural Research and Extention Station, Changhua, TAIWAN; (2) National Chung Hsing University, Taichung, TAIWAN

Text

A newly emerging fruit rot disease of muskmelon caused by *Fusarium incarnatum-equiseti* species complex (FIESC) was reported in Taiwan in 2022. However, the species of FIESC causing melon fruit rot have been confirmed as pathogens during post-harvest. The aim of this study was to identify the FIESC species causing fruit rot in muskmelon in Taiwan and evaluate the sensitivity to fungicides. Fifteen FIESC isolates were collected from the diseased fruits located in different orchards, and the species were identified through phylogenetic analysis based on ITS rDNA, *tef1* and *rpb2* genes. Results indicated that three FIESC species were identified, including *F. irregular* (one isolate), *F. pernambucanum* (eight isolates), and *F. sulawesiense* (six isolates). The pathogenicity test confirmed that all the species could infect muskmelon (cultivar : Tainan No.13) and develop fruit rot symptoms. For fungicides test, the major species *F. pernambucanum* and *F. sulawesiense* were used to examine the reaction to carbendazim, chlorothalonil, fluopyram, fluxapyroxad, and trifloxystrobin. The results showed that carbendazim, chlorothalonil and trifloxystrobin have efficacy to inhibit mycelial growth and spore germination of most of *F. pernambucanum*, except FE02 isolate. In this study, *F. sulawesiense* were low sensitivity to five fungicides.

These results demonstrated that the sensitivities of two FIESC species to fungicides have high variation in Taiwan.

MOLECULAR AND PHYSIOLOGICAL CHARACTERIZATION OF FUSARIUM OXYSPORUM CICERI ISOLATES FROM DIFFERENT CHICKPEA AREAS IN IKR, IRAQ

AL-MAAROOF Emad. (1), RAHIM Kazhal. (1)

(1) University of Sulaimani, Sulaimani, IRAQ

Text
Thirty-two different F. oxysporum ciceri isolates were isolated from 54 chickpea fields in Sulaimani and Halabja governorates in 2021. Fourteen of the isolates were pathogenic and displayed various morphological traits. The ideal temperature range for Foc was 25-30°C. PDA was the best media for the fungal growth. The isolates showed a variety of growth patterns, including appressed, flat/velvet, fluffy to partial fluffy, and cottony. However, Foc-28 isolate in contrast to the others, displays mycelium growth that resemble nerves on PDA at 25ºC, making it stand out morphologically from the others. Microconidia (6.1-8.7x2.9-4.98µm), macroconidia (10.0-20.1x2.7-5.2µm), chlamydospores (7.2-15.0x 6.8-10.7µm), and colony diameter on PDA were all significantly differed between isolates. Significant differences in the pathogenicity and virulence of 14 Foc isolates were detected on 10 differentials. The isolates were classified in to two groups and nine physiological races accordingly. Each isolate's genomic DNA was amplified by the ITS primers to a maximum size of 400bp, producing a single band for each accession. The ITS sequences classified all the races into six clusters, which were all registered at NCBI Gen Bank under different accession numbers. Significant genetic diversity within populations and low genetic diversity between groups were discovered. The basic local alignment search tool (BLAST) analysis displayed a similarity to Foc genomic sequences of 95.1-100%.

P9.2-004

ROS IS ESSENTIAL FOR THE NORMAL MYCELIA GROWTH IN FUSARIUM GRAMINEARUM

LI Taiying. (1), LEE Seunghyun. (1), KIM Haeun. (1), SONG Seonghwa. (1), LEE Jungkwan. (1)

(1) DONG-A university, Busan, REPUBLIC OF KOREA

Text
Reactive oxygen species (ROS) have been proven to play an important role in cell differentiation and elongation. Studies on ROS have also been conducted in *Fusarium graminearum*, a filamentous fungus whose life cycle involves asexual sporulation and conidial germination. Here, we knocked out a transcription factor gene associated with conidial germination in *F. graminearum* and found that mutant exhibited simplified life cycle, in which the conidia that germinate directly generate further conidia without forming mycelia.

By detecting intracellular ROS, it was found that the intracellular ROS of mutant was significantly decreased compared with that of wild type. Moreover, when detected *NoxA* and *NoxB*, two genes related to ROS production, it was found that the gene expression in mutant was significantly down-regulated. In addition, the life cycle of the wild type was also simplified when Nox inhibitors was applied. Moreover, ROS was stained during conidial germination, it was found that ROS accumulated on the top of mycelia. However, under sporulation, ROS accumulated only in conidia and did not at the top of mycelium. Notably, in this study, we also found that induce intracellular ROS accumulation in mutant could restore normal conidial germination, but in wild type, the ROS accumulation induced sporulation.
Thus, since ROS accumulation leads to different results for wild type and mutant, we will further study how ROS regulate *F. graminearum* conidial germination and sporulation.

P9.2-005

DECIPHERING HOST-PATHOGEN AND FUNGAL-FUNGAL INTERACTIONS WITHIN THE LATENT FRUIT ROT OF WINTERBERRY PATHOSYSTEM: FROM THE FIELD TO THE BIOCHEMISTRY

EMANUEL Isabel B.. (1), LIN Shan. (1), LAIRD Aleacia E.. (1), COOPERSTONE Jessica L.. (1), **HAND Francesca. (1)**

(1) The Ohio State University, Columbus, UNITED STATES

Text
Ilex verticillata (common winterberry) is a deciduous species of holly bearing colorful, persistent fruit, commonly used in landscape design and as woody cuts for winter seasonal decoration. *Diaporthe ilicicola* is a recently described fungal species that establishes latent infections in winterberry flowers at bloom, leading to necrosis when the fruit is fully mature. The formation of *D. ilicicola* pycnidia within the fruit epicarp was observed to create micro-wounds in the fruit cuticle facilitating co-infection by opportunistic necrotrophic fungi and leading to fast-progressing rot. *D. ilicicola* pycnidia formation was induced by increased intensity of white light *in vitro*, and by exposure to fruit ethanolic extracts *ex vivo*. Additionally, drops in field temperature were significantly correlated with disease incidence, suggesting that *D. ilicicola* infection may weaken the fruit cuticle and increase susceptibility to cold damage. Commercially available cultivars were screened for susceptibility to the disease and a quantitatively resistant phenotype was identified. Metabolomic analysis showed that the fruit of less susceptible cultivars display distinctly different profiles compared to more susceptible cultivars, with 89 unique metabolite features putatively associated with resistance. Future work will determine whether *D. ilicicola* asymptomatic infection can alter fruit cuticle integrity and identify compounds with bioactivity toward *D. ilicicola* or *I. verticillata* fruit.

P9.2-006

IN DICKEYA DADANTI, THE TYPE II SECRETION SYSTEM (T2SS) IS COVALENTLY ATTACHED TO THE BACTERIAL CELL WALL.

NICOLAI Xavier. (1), SHEVCHIK Vladimir. (1)

(1) MAP UMR 5240 CNRS, MTSB team, Villeurbanne-Lyon, FRANCE

Text

Dickeya dadantii is a broad-spectrum phytopathogenic γ-proteobacterium that provokes soft rot disease in various plants. *D. dadantii* pathogenicity is caused by an arsenal of plant cell-wall degrading enzymes secreted by the Type II Secretion System (T2SS) named Out. The Out system is a multiprotein complex spanning the cell envelope. Recently, we showed that OutB, an inner membrane T2SS component plays an important scaffolding role and that deletion of outB causes a striking reduction of pectinase secretion and virulence of *D. dadantii*. Here, we show that in *D. dadantii*, OutB is covalently attached to the PG. We investigated the molecular mechanisms of OutB attachment to peptidoglycan (PG) and the possible implication of this phenomenon in the virulence of *D. dadantii*. First, the covalent attachment of OutB was demonstrated after extraction, purification and analysis of the PG of *D. dadantii* by Western blot. Second, we characterized the enzymes implicated and identified the region and residues of OutB important for covalent attachment to PG: the two C-terminal lysines of OutB are involved in its attachment to PG and two L,D-transpeptidases, Ldt03 and Ldt84, catalyze this process. These results suggest that the covalent attachment of OutB to PG allows a better stabilization of the T2SS in the bacterial cell envelope. Moreover, it shows that the phenomenon of covalent attachment of proteins to PG in proteobacteria could be more widespread and remains largely unexplored.

INTERACTIONS OF THE SPECIES OF THE ASCOCHYTA BLIGHT DISEASE COMPLEX AND HOST RESISTANCE

ANNAN Emmanuel. (1), HUANG Li. (1)

(1) Montana State University, Bozeman, UNITED STATES

Text

Ascochyta blight (AB) is an important seed-borne and foliar disease of field peas and is widely recognized as a major productivity barrier. The disease is caused by necrotrophic fungal pathogens, Ascochyta pisi Lib. (Didymella pisi sp. nov), Peyronellaea pinodes (Berk & A. Bloxam) Aveskamp, Gruyter & Verkley 2010 (Mycosphaerella pinodes (Berk & A. Bloxam) Vestergr. 1912, Pe. pinodella (Phoma medicaginis var. pinodella L.K Jones (Morgan-Jones & K.B. Burch), and Phoma koolunga. These pathogens can exist independently or together (known as the Ascochyta blight disease complex) within a pea field and even on single plants. We set up a study to monitor the three species of A. pisi, Pe. pinodes and Pe. pinodella in single-pea plants to reveal their interactions during pathogenesis with or without a biocontrol agent in a resistant or susceptible host. The results revealed dynamic changes in the complex over time with antagonistic/mutualistic interactions between species and host response. These findings are valuable to assist AB-resistance breeding and disease management with a biocontrol agent.

GLOBAL DIVERSITY AND DISTRIBUTION OF NECROTROPHIC EFFECTORS IN A GLOBAL COLLECTION OF PYRENOPHORA TRITICI REPENTIS, CAUSAL AGENT OF TAN SPOT OF WHEAT

KAUR Jaswinder. (1), **ALI Shaukat. (1)**, AMEEN Gazala. (1), GONZALEZ Jose. (1), SOLANKI Shyam. (1)

(1) South Dakota State University, Broonings, UNITED STATES

Text

Pyrenophora tritici-repentis (Ptr), is a necrotrophic fungal pathogen that causes tan spot, a foliar disease of wheat. The effector repertoire of Ptr includes distinctive necrotrophic effectors ToxA, ToxB, and ToxC associated with disease development. The unexplained correlation between Ptr's geographical origin and its ability to produce distinct effector combinations suggests a divergent evolution of Ptr and Tox effectors. This study analyzed 52 Ptr isolates from diverse regions to determine Ptr's race structure, host range, and Tox gene diversity. Genomic DNA of these isolates was extracted and a subset of 25 isolates were sequenced using Illumina Mi-Seq platform. Sequencing data analysis reveals the presence of several SNP variations in Tox coding genes, and we predicted that these isolates would have differential response on wheat. PCR with ToxA, ToxB, and ToxC primers on additional isolates was performed to expand our ongoing Tox diversity analysis.Disease phenotyping of these isolates on wheat differentials characterize these isolates as race1, but races 2, 3, 4, and 5 were also observed, thus confirming our hypothesis of diversity in studied pool. These results, along with available functional genomic tools, will help breeders and pathologists to efficiently breed for tan spot-resistant wheat varieties, increasing revenue for wheat growers.

DIVERSITY AND PATHOGENICITY OF GLOBISPORANGIUM AND PYTHIUM SPP. ASSOCIATED WITH PYRETHRUM IN AUSTRALIA

LIU Yuzhu. (1), VAGHEFI Niloofar. (1), ADES Peter. (1), IDNURM Alexander. (1), AHMED Aabroo. (2), TAYLOR Paul. (1)

(1) The University of Melbourne, Parkville, Melbourne, AUSTRALIA; (2) University of Saskatchewan, Saskatchewan, CANADA

Text

Pyrethrum (*Tanacetum cinerariifolium*) cultivation in Australia suffers from a persistent yield decline which in part is caused by a complex of soilborne pathogens. There has been no research on the relationship between oomycetes and pyrethrum yield decline. During surveys between 2018 to 2021, ten known *Globisporangium* species, two new *Globisporangium* species and three *Pythium* species were recovered from crown and root tissues of infected pyrethrum plants and from soils from 16 sites in Tasmania and Victoria, Australia. Identification of *Globisporangium* and *Pythium* spp. was based on morphological characters and multigene phylogenetic analyses using ITS, *Cox1* and *Cox2* sequences. *Globisporangium ultimum* var. *ultimum* was the most abundant in soils, while *G. sylvaticum* and *G. commune* sp. nov. were most abundant in pyrethrum plants. Seven *Globisporangium* species were pathogenic on both pyrethrum seeds (*in vitro* assays) and seedlings (glasshouse bioassays) causing pyrethrum seed rot, seedling damping-off and significant plant biomass reduction, while two *Globisporangium* species and three *Pythium* species only

caused significant symptoms on pyrethrum seeds. The results suggest that *Globisporangium* and *Pythium* species could be contributing to yield decline in pyrethrum in Australia. This is the first report of *Globisporangium* and *Pythium* species as pathogens of pyrethrum globally.

NOVEL HARZIA IXTARENSIS FUNGUS ON ANNONA CHERIMOLA FRUIT IN MEXICO

VILLANUEVA-ARCE Ramón . (2), **YÁÑEZ-MORALES María De Jesús. (1)**, ALANIS-MARTÍNEZ Iobana. (1), SILVA-ROJAS Hilda V. . (1), VALDEZ-CARRASCO Jorge M.. (1)

(1) Colegio de Postgraduados-Campus Montecillo, Fitosanidad-Fitopatología (Plant Diseases), Seeds and Entomology Depts., Montecillo-Texcoco, MEXICO; (2) Instituto Politécnico Nacional. Unidad Profesional Interdisciplinaria de Biotecnología-Laboratorio de Biotecnología Alimentaria., Ciudad De México, MEXICO

Text
Since 2005 in Íxtaro, Michoacán, symptoms of *Harzia* infection have been observed on immature *Annona cherimola* fruit with *Colletotrichum fragariae*-induced anthracnose lesions and mummified fruit. This study aimed to identify the *Harzia* sp. Four isolates were obtained from fruit exhibiting symptoms, cultured in four types of agar under various conditions, and characterized based on concatenated internal transcribed spacer ITS + large subunit and ITS + small subunit sequences. Additionally, the isolates were compared with two CBS species (two-type strains and two isolates) of *Harzia patula* and *H*. *tenella* under the same conditions as the *Harzia* isolates, and all known *Harzia* spp. in culture were included in two phylogenetic analyses. *H. ixtarensis* **sp. nov.** was proposed. Compared with *H. patula* CBS isolate 121524, which was the most closely phylogenetically related species, *H. ixtarensis* was characterized by slower colony growth (white to salmonish-beige), different percentages of two forms of conidia (elongated and globose; unicellular and hyaline to subhyaline), and smaller conidia. The conidia mainly germinated with two hyaline tubes without an appressorium. This study proposes the existence of a novel species, *H. ixtarensis*. It contributes to the evidence of the biodiversity of the genus *Harzia*, and its host range. Pathogenecity behavior is showed in a second abstract.

P9.2-011

ASSESSMENT OF APPLE AND PEAR CULTIVAR TOLERANCE AND AGGRESSIVENESS OF FUNGI ISOLATED FROM CANKERS AND FRUIT ROTS ON TREES

DREVINSKA Kristine. (1), **MOROCKO-BICEVSKA Inga. (1)**

(1) Insitute of Horticulture, Dobele, LATVIA

Text
Several pathogenic fungi cause fruit rots and damage in the orchards and storages (e.g. *Neofabraea* spp., *Monilinia* spp., *Venturia* spp.) or both - cankers on trees and fruit rots in the orchards and storages (e.g. *Neofabraea* spp., *Monilinia* spp.). This study aimed to

assess apple and pear cultivar tolerance and aggressiveness of fungi isolated from fruit rots and cankers of apple and pear on trees. Four apple and four pear cultivars were used for the studies. In addition, apple rootstock B396 and pear seedling rootstock of local landrace 'Kazraušu pear' were included in the tests. The aggressiveness of nine fungal isolates belonging to *Neofabraea* and *Fusarium* was characterised by inoculating potted trees in the greenhouse. The differences in the aggressiveness among *Neofabraea* species and strains within species were found. *Fusarium* sp. strain isolated from apple canker was capable of causing cankers on both hosts. Several *Neofabraea* strains isolated from cankers were more aggressive than those obtained from fruits. The isolates from apples were also causing disease on pears and vice versa. Noticeable preference among the strains in the host species was noted in tree inoculation tests with rootstocks B396 and 'Kazraušu pear' seedlings. Further would be necessary to investigate the mechanisms determining the disease development for each pathogen and host on fruits (fruit rot) and trees (canker), and evaluate the role of rootstock in the host tolerance to canker.

PR1-LIKE PROTEINS FROM CYTOSPORA CHRYSOPERMA SHARE COMMON AND DISTINCT ROLES IN FUNGAL VIRULENCE AND PLANT SUSCEPTIBILITY

HAN Zhu. (1,2), SCHNEITER Roger. (2), XIONG Dianguang. (1), TIAN Chengming. (1)

(1) Beijing Forestry University, Beijing, CHINA; (2) University of Fribourg, Fribourg, SWITZERLAND

Text

Canker diseases caused by necrotrophic fungus Cytospora chrysosperma damages up to 80 species of woody plants. Accumulating evidences show that necrotrophy has evolved clever means to compromise host recognition and establish disease?possibly by employing the pathogenic PR1-like proteins which are emerging virulence-related immune suppressors. Here we identified three PR1-like proteins, CcCAP1-3. CcCAP1 and CcCAP2 were required for fungal virulence and their overexpression in Nicotiana benthamiana promoted Botrytis cinerea colonization. In addition, CcCAP1 inhibited plant immune responses, which was dependent on its PR1-like domain and nuclear localization; Yeast two-hybrid analysis identified plant RNA polymerase II subunit 11 (RPB11), eukaryotic initiation factor 3 (eIF3), splicing factor 3A subunit 2 (SF3A2) and plastocyanin (PCN) as CcCAP1-interactors. Overexpression of poplar RPB11 promoted fungal infection. While CcCAP2 but not CcCAP3 interacted with eIF3 and PCN. CcCAP1 and CcCAP2 were also involved in the regulation of genes associated with carbohydrate metabolism and candidate effector proteins, and CcCAP1 affected the expression of pathogenesis-related secondary metabolic gene clusters. Intriguingly they exhibited sterol- export and binding activity. Taken together, this study identified three PR1-like proteins from C. chrysosperma and characterized their roles in pathogen-plant interactions from the perspective of phytopathogen.

PROTEOMIC ANALYSIS OF PENICILLIUM EXPANSUM INFECTING POSTHARVEST APPLES BASED ON LABEL-FREE AND PARALLEL REACTION MONITORING (PRM) TECHNIQUES

WANG Kaili. (1), ZHANG Hongyin. (1), YANG Qiya. (1), ZHAO Lina. (1), XU Meng. (1)

(1) Jiangsu University, Zhenjiang, CHINA

Text

Blue mold caused by *Penicillium expansum* is the leading cause of apple decay during postharvest storage. It is of great significance to study the molecular mechanism of *P. expansum* infecting apples. In this study, label-free technology was used to study the proteomic changes of *P. expansum* infecting the apples at crucial time points, and the results were verified by PRM technology. The expression of target proteins measured by PRM was consistent with the expression trend of the proteomics results, indicating that the results were stable and reliable. Through bioinformatics analysis of the proteomics results, 267 differentially expressed proteins (DEPs) were screened, 136 up-regulated, and 131 down-regulated. Bioinformatics analysis of all DEPs showed that the DEPs at the early stage of *P. expansum* infection were associated with growth promotion and spore development, which improved the pathogenicity. Up-regulated expression of MAGE protein, heat shock protein, FKS2 and other pathogenic-related proteins positively regulated the infection. During the early infection, activation of metabolic pathways related to oxidative stress eliminated reactive oxygen species through catalase and cytochrome P450.These findings may help to further study the molecular mechanism of *P. expansum* infecting apple.

Text

Botrytis cinerea is one of the most destructive phytopathogens. B. cinerea is difficult to control because of its strong stress resistance and flexible infection modes. The pathogenic mechanisms of B. cinerea have been studied at multiple levels, but little is known at epigenetic level. In this study, we focused on the function of DNA methyltransferases (MTases) in regulating the development and pathogenicity of B. cinerea. The expressions of the cytosine MTase genes were significantly inhibited during the infection process of B. cinerea. Treating B. cinerea conidia with the DNA methylation inhibitor 5-azacytidine led to compromised virulence. These results implied that DNA methylation is involved in the pathogenesis of B. cinerea. Among the four conserved DNA MTases, BcDIM2 and BcRID2 showed a strong synergistic effect. Double knockout mutant ?Bcdim2rid2 showed slower growth, attenuated oxidative tolerance, and complete non-pathogenicity, which is related to the reduced expression of virulence-related genes in ?Bcdim2rid2 and the induced resistance of the host. Although B. cinerea has multiple DNA MTases, the global methylation level is very low, and few 5mC sites can be detected through whole genome bisulfite sequencing. We speculate that DNA MTases may be mainly involved in the repeat-induced

point mutation (RIP) of B. cinerea, in which cytosine methylation is an intermediate state that is difficult to monitor.

Text

Pectinolytic bacteria from the *Pectobacteriaceae* family have been detected in waterways globally, including Europe, Asia, Northen America and Australia. Due to the ongoing climate change, it is anticipated that the number of crops subjected globally to irrigation during the vegetation period will constantly rise. Therefore the aim of this project was to describe the biodiversity and potential pathogenicity of *Pectobacteriacea*e isolates originating from Polish waterways.

During long-term monitoring of the presence of pectinolytic bacteria in natural water reservoirs in Poland, 57 isolates were detected and identified with the use of multiplex PCR and/or species-specific PCR as Dickeya or Pectobacterium spp. Based on the species-specific PCR, genotypic profiling (ERIC- and BOX-PCR) and phylogenetic analysis of recA and dnaX genes sequence, the presence of the strains from species: *D. chrysanthemi, D. aquatica, D. zeae, P. versatile* and *P. quasiaquaticum* was confirmed. Analysis of the ability to macerate potato tuber tissue and activities of pectinolytic, cellulolytic and proteolytic enzymes indicated that *D. chrysanthemi* isolates are the most homogeneous and have the highest level of pathogenicity in comparison to other analyzed species.

Preseted data indicated that the use of natural water reservoirs in Poland for irrigation of agricultural fields can lead to the spread of the soft rot *Pectobacteriaceae* in farmlands and as a results cause crops losses.

P9.2-016

IDENTIFICATION AND CHARACTERIZATION OF ALTERNARIA SPP. ASSOCIATED WITH CHERRY FRUIT BLACK ROT DURING PREHARVEST IN THE MAULE REGION, CHILE

CANCINO Sebastian. (1), GALDOZ Liszoe. (1), LOBOS Gustavo. (1), CABEZA Ricardo. (1), LOLAS Mauricio. (1), **DIAZ Gonzalo. (1)**

(1) UNIVERSIDAD DE TALCA, Talca, CHILE

Text

In Chile, cherry trees are considered an important fruit crop, with an area of 48,960 ha

planted under Mediterranean conditions in the Maule Region, Central Chile. In the last five years, the occurrence of black rot during preharvest has increased in commercial orchards in the Maule Region. The goal of this work was to identify the causal agent associated with the black rot of cherries during pre-harvest in the Maule Region, and to evaluate the nutrients´ distribution in cherry fruits infected with black rot using X-ray microfluorescence spectroscopy (u-XRF). For this purpose, pre-harvest fruits with black rot were collected, and Alternaria spp. were isolated using Agar-Potato-Dextrose (APD, 2%) medium incubated for seven days at 20°C. From pure colonies, isolates of Alternaria sp. were identified at level species by morphology and phylogenetic analysis using the RPB2, ATPase, and calmodulin genes. Conidial suspensions of four Alternaria spp. were used for pathogenicity tests on ripe fruit. Based on the morphological and genetic characteristics, the species Alternaria alternata and A. arborescens were identified. The distribution of nutrients revealed a high concentration of potassium in the infected region. Otherwise, calcium was observed in the periphery of the symptomatic region, coinciding with the area of progress of the infection

Text

Cucumber Fusarium wilt disease caused by *Fusarium oxysporum* f. sp. *cucumerinum* (*Foc*) seriously threatens the yield and quality of cucumber. During infection, *Foc* delivers a large number of different secreted proteins into host plant tissues. So far, only a few proteins secreted by this fungus have been proved to be toxic effectors. We found a gene *FoCubl* was extremely up-regulated in the wild type (WT) during the early stage of infection and would be a virulence effector. The *FoCubl* has a single copy in the genome with a full length of 696 bp, containing an intron and a CDS length of 645bp, and encodes a 214-amino-acid protein. FoCubl has an N-terminal secretory signal peptide and a Cu_bind_like domain. *FoCubl* knockout mutants significantly reduced the aggressiveness, indicating its essential role in the full virulence on cucumber. Compared with the WT, the knockout mutants produced significantly less conidia, but did not exhibit differences in germination, suggesting an important role for FoCubl in conidiation. The deletion mutants did not show distinct changes in mycelial growth on PDA, however, accumulated significantly more mycelia in PDB. In addition, the deletion mutants were more sensitive to osmotic stress such as 1 M glycerol, glucose, NaCl, and KCl, respectively. In summary, these results suggest that FoCubl is a novel virulence effector of *F. oxysporum*. To our knowledge, this is first time to report an effector with a Cu_bind_like domain in *Fusarium* species.

P9.2-018

CHARACTERIZATION OF FUSARIUM SPP. ASSOCIATED WITH STRAWBERRY ROOT ROT IN CHINA

WU Xuehong. (1)

(1) China Agricultural University, Beijing, CHINA

Text

Strawberry is a popular and economically valuable fruit planted worldwide. Strawberry root rot can be caused by Fusarium, resulting in root death and reduced plant vigor and productivity. However, there is no detailed report on the identification of Fusarium spp. associated with strawberry root rot in China. In this study, strawberry roots with symptoms of root rot were collected from twenty-four provinces, autonomous regions, or municipalities across China. 159 isolates of Fusarium were isolated from these diseased roots. Based on morphological traits of fungal colonies on potato dextrose agar and carnation leaf agar, colony growth rate, morphological characteristics and size of conidium, conidiophore and chlamydospore and sequence analyses of internal transcribed spacer region of ribosomal DNA and translation elongation factor 1-α gene region, these isolates were identified as eight species of Fusarium, namely Fusarium oxysporum, F. acuminatum, F. incarnatum, F. equiseti, F. fujikuroi, F. asiaticum, F. solani, and F. falciforme, with F. oxysporum being predominate. The eight Fusarium species were all pathogenic on strawberry, and average disease incidence and average disease index of strawberry caused by F. oxysporum were 98.68% and 79.97, respectively, which were higher than those of strawberry incited by the other seven species of Fusarium. This is the first report that F. incarnatum, F. fujikuroi, F. asiaticum, and F. falciforme cause root rot on strawberry in China.

Département Ecologie, Rennes, FRANCE; (4) Consiglio per la ricerca in agricoltura e lo studio dell'economia agraria, Rome, ITALY

Text

Food and fodder *Fabaceae* are of great importance in agricultural systems. In Algeria, they are used as a major protein supply for human and animal nutrition, also in crop rotation with cereals for enriching the soil with nitrogen. These *Fabaceae* are susceptible to many diseases, mainly caused by fungal pathogens. Surveys conducted during 2015-2019 have shown the presence of different types of symptoms on pea, chickpea, faba bean, alfalfa and berseem crops. These symptoms presented as necrotic brown spots, bordered by a clear margin on the different organs (leaves, stems, roots and pods), often with the presence of pycnidia. With the combination of morphological identification and molecular characterisation by sequencing the genes ITS, LSU, *tub2*, several species, belonging to 3 genera, were identified: *Phoma* (*P. herbarum*), *Ascochyta* (*A. rabiei*, *A. medicaginicola*, *A. nigripycnidia*), *Didymella* (*D. pisi*, *D. fabae*, *D. pinodes*, *D. pinodella*). Among these species *A. nigripycnidia* is reported for the first

time on berseem (*Trifolium alexandrinum*). The host specificity test showed that the host range is wider for forage pathogens than food ones, with varying degrees of speciation to their host of origin. However, the host range is wider for forage pathogens than for pathogens of food legumes species. These results will be used to establish a control strategy through a sustainable rotation of these crops.

P9.2-020

COLLETOTRICHUM SPP. IN HUNGARY: SIGNIFICANCE OF NEW SPECIES AND NEW HOSTS

SZENDREI Lilla. (1), PETRÓCZY Marietta. (1), AGOSTON János. (2), PALKOVICS László. (2,3), TÓTH Annamária. (1)

Text
Colletotrichum species are significant pre- and postharvest pathogens worldwide. Symptoms of anthracnose occur not only on fruits (e.g. sour cherry, strawberry, avocado, mango, blueberry, fig, banana) but also on ornamentals. The aim of the study was to identify the *Colletotrchium* species causing anthracnose on numerous hosts. For morphological studies, pathogens were isolated from infected tissues on potato dextrose agar (PDA) medium. The general characteristics of the colonies and the size and shape of the conidia (n=50) were examined. Reliable identification of *Colletotrichum* species on the basis of morphological features is not possible, especially within a given species complex. To identify the pathogen at the species level total DNA was extracted, and partial sequences of the internal transcribed spacer (ITS) region and calmodulin (CAL), histone3 (HIS3) genes were amplified by polymerase chain reaction and sequenced. Pathogenicity of the isolates was verified on their original host species. We identified several species within the *C. gloeosporioides* complex: *C. fructicola, C. musae, C. kahawae, C. siamense, C. asianum. C. godetiae, and C. fioriniae* from the *C. acutatum* species complex. To our knowledge, this is the first report of *C. fructicola, C. kahawae, C. asianum* species in Hungary.

ALTERNARIA SPECIES ASSOCIATED WITH LEAF SPOT DISEASE OF DRACAENA SPP. IN OMAN

KARUNASINGHE Thamodini . (1), VELAZHAHAN Rethinasamy. (1), AL SADI Abdullah M.. (1)

(1) Sultan Qaboos University , Muscat, OMAN

Text
Desert plant restoration programs in Oman are hindered by emerging diseases at Oman

Botanic Garden (OBG), which is planned to be one of the largest botanic gardens in the world. A study was conducted to characterize disease incidence, severity and causal agents of leaf spot diseases affecting two Draceana species, Draceana serrulata (endemic) and D. hanningtonii. A survey of more than 150 plants of D. serrulata and D. hanningtonii grown at OBG showed that the disease incidence is 100% in both plants. Disease severity, which was assessed based on the percentage of leaf coverage with spots indicated an average severity of 2.8 % for D. serrulata and 2.2 % for D. hanningtonii. Isolation of fungi from 10 randomly selected samples of each Dracaena species yielded 21 morphologically different fungi for D. serrulata and 34 fungal isolates for D. hanningtonii. Pathogenicity tests showed that two fungal isolates from D. serrulata, (DS18, DS20) and three isolates from D. hanningtonii (DH3, DH4 and DH6) were pathogenic on their respective host pants. Molecular identification of the pathogenic fungal isolates based on internal transcribed spacer (ITS- ITS5/4) region indicated that the leaf spot disease in both Dracaena spp is caused by Altenaria spp. This appears to be the first report of Alternaria leaf spot disease among D. serrulata and D. hanningtonii.

ROLE OF NON-PROGRAMMED CELL DEATH INDUCING EFFECTORS OF PARASTAGONOSPORA NODORUM IN INFECTION PROCESS

KARIYAWASAM Gayan. (1), WYATT Nathan. (2), LIU Zhaohui. (1), FARIS Justin. (2), FRIESEN Timothy. (1,2)

(1) Department of Plant Pathology, North Dakota State University, Fargo, Nd , UNITED STATES; (2) Edward T. Schafer Agricultural Research Center, USDA-ARS, Fargo, Nd, UNITED STATES

Text

Effectors are small, secreted proteins that play an important role in virulence of plant pathogenic fungi. Parastagonospora nodorum, which causes septoria nodorum blotch of wheat, secrets multiple necrotrophic effectors that induce programmed cell death (PCD) in susceptible wheat genotypes. To date, five necrotrophic effectors including SnToxA, SnTox1,SnTox267,SnTox3 and SnTox5 have been characterized. However, less is known about effectors that are involved in the necrotrophic lifestyle that do not induce PCD. Therefore, in this study we screened the proteome of P. nodorum strain Sn2000 using effectorP v3.0 and identified 556 predicted effectors. RNA-Seq data generated for samples collected at 0, 4, 12, 24, 48, 72, and 96 hours post inoculation of Sn2000 on the wheat line LP29 supported the in planta expression of 332/556 effectors. Differential expression analysis of effector genes expressed in time points relative to the expression at 0 hpi revealed that 77 effectors were differentially expressed. In addition, we identified 69 non-differentially expressed effector genes that consisted of at least 100 reads to be used in further analysis. InterProScan screening of these effectors revealed, 23 cell wall degrading enzymes, six chitin binding proteins, five proteases, four ROS-protection proteins, and eleven nutrient break-down enzymes, suggesting these non-PCD inducing effectors play a critical role in adhesion, penetration, and colonization stages of the infection process.

EXPLORING A NOVEL PUTATIVE FUNGAL RIBOSOMALLY SYNTHESISED AND POST-TRANSLATIONALLY MODIFIED PEPTIDE FROM THE WHEAT PATHOGEN ZYMOSEPTORIA TRITICI.

FORD Rosie. (1), FOSTER Gary. (1), BAILEY Andy. (1)

(1) University of Bristol, Bristol, UNITED KINGDOM

Text

When we consider the compounds produced by fungi, our first thoughts take us to their medical uses, while their more sinister employment in plant pathology and as mycotoxins often comes second. Intriguingly, a family of peptides exists which spans both areas, known as ribosomally synthesised and post-translationally modified peptides (RiPPs). RiPPs from bacteria and animals have anthropogenically useful functions; nisin as an antibiotic and ziconotide as a painkiller. However, the more recently identified fungal RiPPs, of those with known functions, are all to some extent cytotoxic varying in specificity regarding the organisms to which the toxins are targeted. Pertinently, the dikaritin group of RiPPs includes the known mycotoxins phomopsin and ustiloxin, with genome mining identifying a putative novel dikaritin RiPP cluster within the genome of the wheat pathogen *Zymoseptoria tritici*. The IPO323 strain of the fungus has 9 copies of a repeated YVIPVD sequence within its RiPP precursor peptide. YVIPVD copy number varies from 6 to 11 repeats between different *Z. tritici* strains indicating some level of selection on the peptide, the direction of which is currently unknown. Ongoing studies aim to discover the structure of this RiPP and its full biosynthetic pathway by utilising knockout strains of genes within the cluster. The role of the peptide in this important wheat pathogenic fungus has been assessed in terms of pathogenicity and resource competition but remains elusive.

VIRULENCE REGULATORY NETWORK OF DICKEYA DADANTII: WHAT IS THE ROLE OF POST-TRANSCRIPTIONAL REGULATION?

MOUTACHARRIF Sara. (1), VILLARD Camille. (1), RATAFIKA Krystal. (1), NASSER William. (1), REVERCHON Sylvie. (1), HAICHAR Feth El Zahar. (1), HOMMAIS Florence. (1)

(1) Université de Lyon, INSA Lyon, Université Claude Bernard Lyon 1, CNRS, UMR 5240 MAP, Microbiologie, Adaptation, Pathogénie, Villeurbanne, FRANCE

Text

The genus *Dickeya* are enterobacterial plant pathogens responsible for soft rot disease in a wide range of plant species, including economically important crops e.g. potato and rice. The infection process is divided into two main phases: the asymptomatic phase where *Dickeya spp.* produce early virulence factors to colonize the apoplastic spaces between plant cells; and the symptomatic phase, which is associated with the secretion of late virulence factors, i.e. plant cell wall degrading enzymes that macerate the plant tissue. Therefore, the spatial and temporal production of the virulence factors must be precisely controlled to ensure the efficient colonization and degradation of the host. While many transcriptional regulators are involved in controlling *Dickeya*'s virulence factors, knowledge of post-transcriptional regulation is still in infancy. Our first results on *Dickeya dadantii* RNA chaperons suggest a post-transcriptional regulation of virulence. Additionally, the obtention of *D. dadantii* transcriptional landscape

allowed us to identify RNAs predicted to interact with the mRNAs of virulence factors regulators that play a role in response to oxidative stress and changing metabolic content in the apoplast. Ongoing work aims to establish a link between regulatory RNAs, virulence factors, and environmental changes encountered by bacteria during infection, which will lead to a better comprehension of the complex virulence regulatory network of *D. dadantii*.

Text
Spot-form net blotch (SFNB) of barley is a devastating foliar disease caused by the fungal pathogen *Pyrenophora teres* f. *maculata*. To deepen our understanding of the barley/*P. teres* f. *maculata* interaction, we screened a host population consisting of a cross between the resistant barley line PI 67381 and the susceptible line Hockett with a diverse set of *P. teres* f. *maculata* isolates, resulting in the identification of two major quantitative trait loci (QTL) associated with resistance/susceptibility on barley chromosomes 2H and 7H. We then screened a *P. teres* f. *maculata* pathogen population on PI 67381 and Hockett as well as other barley lines currently used in breeding programs and identified two major pathogen loci associated with virulence/avirulence on *P. teres* chromosomes 1 and 2. By screening the host population as well as host F_2 lines with pathogen progeny harboring the virulent allele at only one of the two identified loci (i.e. Chr1 or Chr2), we were able to determine that individual dominant susceptibility genes in the host were being targeted by individual virulence genes in the pathogen to facilitate colonization, providing evidence for an inverse gene-for-gene interaction, a hallmark of necrotrophic host-pathogen interactions. Finally, the genomic regions underlying the pathogen QTL were screened for candidate effector genes, which were then systematically evaluated in terms of effector function by performing CRISPR-Cas9 mediated gene disruptions.

THE VIABILITY OF SCLEROTINIA SCLEROTIORUM SCLEROTIA EXPOSED TO DRY HEAT TEMPERATURES AND THE RUMEN OF CATTLE.

MEIRING Marlese. (1), MCLAREN Neal. (1), **ROTHMANN Lisa. (1)**

(1) University of the Free State, Plant Sciences, Plant Pathology, Bloemfontein, SOUTH AFRICA

Text
Sclerotinia sclerotiorum sclerotia can survive in soil and plant residues for several years thus, reducing inoculum prevalence and persistence is critical to disease management. We address two producer-posed questions regarding sclerotia viability within production systems. The first aim simulated crop stubble burning by assessing the effect of dry heat temperatures on sclerotia viability. The germination ability of sclerotia, collected from fields affected by soybean stem rot, grouped into four weight classes and exposed to temperatures between 125 and 200 °C for 5-, 10- or 15-min durations either buried at 5 cm in soil or on the surface (n = 384) was conducted. Larger sclerotia survived increasing temperatures and durations more readily than smaller structures, and temperatures exceeding 185 °C yielded all sclerotia non-viable. Sclerotia on the soil surface were less sensitive to increasing temperatures than buried sclerotia, likely due to rapid heat dissipation. Although viable sclerotia were reduced by dry heat temperatures, the elucidation of narrow windrow burning is required. The second aim determined the ability of sclerotia to survive in the rumen of cattle. Faecal samples of cattle which grazed on white mold-infected sunflowers were collected and enumerated (n = 104). Less than 4% of sclerotia in cattle manure germinated, suggesting cattle grazing on infested stubble poses a reduced risk of unintentional pathogen introductions to disease-free fields.

SEARCHING FOR PUTATIVE VIRULENCE FACTORS IN THE PYRENOPHORA TERES F. TERES GENOME

MARTIN Anke. (1), DAHANAYAKA Buddhika. (1)

(1) University of Southern Queensland, Centre for Crop Health, Toowoomba, AUSTRALIA

Text
Net form net blotch (NFNB) of barley, caused by the fungus Pyrenophora teres f. teres (Ptt) is an economically important foliar pathogen in many barley growing regions of the world, including Australia. This fungus is a heterothallic ascomycete where sexual recombination can lead to changes in disease expression in the host. Knowledge of the genetic architecture and genes involved in virulence is vital to increase the durability of NFNB resistance in barley cultivars. Through bi-parental and genome-wide association mapping we have identified and confirmed genomic regions associated with virulence in Ptt, the most significant of which were located on Ptt chromosomes 3 and 5. We have further defined fungal genomic regions by fine mapping and proteomics analysis using single QTL isolates to facilitate virulence gene identification and isolation and are correspondingly co-locating their interactions within the genomic regions in the barley host.

P9.2-028

HIGH HUMIDITY OR ABA COMPENSATES FOR T3SS AND DSPE MUTATIONS IN PECTOBACTERIUM CAROTOVORUM.

JOSHI Janak. (1), **CHARKOWSKI Amy. (1)**

(1) Colorado State University, Fort Collins, UNITED STATES

Text
Pectobacterium carotovorum is a gram-negative phytopathogenic bacterium that causes soft rot on diverse plant species. It encodes and secretes a single type III secretion system (T3SS) effector protein, DspE. This effector is required for plant cell death when the pathogen is infiltrated into tobacco leaves, which is surprising since *P. carotovorum* also encodes multiple plant cell wall degrading enzymes (PCWDEs). The PCWDEs are up-regulated by AHL and secreted through the type II secretion system (T2SS). The AHL synthase, *expI*, was down-regulated in a *dspE*-mutant when the mutant was infiltrated into plant leaves, but not when the mutant was grown in culture medium. In addition, tobacco genes associated with abscisic acid (ABA) synthesis were up-regulated when wild type *P. carotovorum* was infiltrated into leaves, compared to infiltration of the *dspE* mutant. Co-infiltration of the *dspE* mutant and ABA resulted in plant cell death. The *dspE* mutant also caused plant cell death when tobacco plants were infiltrated with the *dspE* mutant and covered with plastic or when the infiltrated leaves were detached and placed in a moist chamber. When the plants were covered with plastic bags, expression of plant genes required for ABA synthesis was similar in leaves infiltrated with wild type *P. carotovorum* or the *dspE* mutant. These observations suggest that DspE function in plant cells indirectly upregulates AHL production and that DspE function can be compensated for by adding ABA.

THE INFECTION PROCESS OF PHELLINUS NOXIUS IN WOODY PLANTS

KO Yi-Chun. (1), WU Zong-Chi. (1), TSAI Isheng Jason. (2), TSAI Jyh-Nong. (3), CHUNG Chia-Lin. (1)

(1) National Taiwan University, Taipei, TAIWAN; (2) Biodiversity Research Center, Academia Sinica, Taipei, TAIWAN; (3) Plant Pathology Division, Taiwan Agricultural Research Institute, Council of Agriculture, Taichung, TAIWAN

Text
While most wood decay fungi are saprophytic, a few are highly pathogenic to living trees. Brown root rot, caused by *Phellinus noxius*, mainly infects the stem base and roots of trees, causing root rot and wilting of the entire plant. Previous studies have only investigated the colonization of *P. noxius* on wood blocks, but how *P. noxius* infects living woody plants remains unknown. In this study, the infection process of *P. noxius* in woody plants was observed in artificially inoculated seedlings using improved microscopy techniques. To observe the initial stage of infection, stem inoculation was conducted on the seedlings of *Populus trichocarpa*, *Ficus benjamina*, and *Eriobotrya japonica*. *P. noxius* hyphae penetrated the epidermis through the opening or wounds and rapidly destroyed parenchyma cells, causing a cavity. The hyphae then extended through the ray parenchyma cells into the vessel and the pith of the xylem. To understand the late stage of infection, naturally infected root tissues were collected from the field. Numerous *P. noxius* hyphae were found in the cortex, and the hyphae in the xylem were only observed near bundles of reticulated mycelial cords or in the vessel. Understanding the pathogenesis of brown root rot has provided the basis for developing effective control strategies.

Text

Septoria nodorum blotch (SNB) is an economically important disease of wheat caused by a fungal necrotrophic pathogen, Parastagonospora nodorum (P. nodorum). The majority components of SNB can be explained by interactions between effectors secreted by the pathogen and their matching susceptibility genes in the host. The necrotrophic interactions were found to induce programmed cell death (PCD) to promote the pathogen's proliferation leading to disease. In this study, we cloned and functionally validated SnTox8 and characterised its role in pathogenesis of this pathosystem.

SnTox8 has the typical characters of an effector including being a small Cysteine rich protein, having signal peptide and is light and heat sensitive. Based on protein modelling, SnTox8 is structurally dissimilar to most known fungal effectors. Quantitative trait loci (QTL) mapping identified the effector is targeting Snn8 located on wheat 2A chromosome to produce PCD. Ninety-nine percent of Australian P. nodorum isolates and eighty-four percent of commercial wheat cultivars carry SnTox8 and Snn8, respectively, making this interaction an important target for SNB resistance breeding program in Australia. In this talk, I will present the finding and its significant role in SNB as well as suggest a strategy to improve SNB resistance breeding.

Text
Lipases, which catalyze the hydrolysis of long-chain tri-, di-, and monoglycerides into free fatty acids and glycerol, participate in various biological pathways in fungi. In this study, we examined the biological function and regulatory mechanisms of fungal lipases via two approaches. First, we performed a systemic functional characterization of 86 putative lipase-encoding genes in the plant pathogenic fungus Fusarium graminearum. The phenotypes were assayed for vegetative growth, asexual and sexual reproduction, stress responses, pathogenicity, mycotoxin production, and lipase activity. Most mutants were normal in the assessed phenotypes, implying overlapping roles for lipases in *F. graminearum*. In particular, Lip1 and Fgl1 were revealed as core extracellular lipases in *F. graminearum*. Second, we examined the lipase activity of previously constructed transcription factor (TF) mutants of *F. graminearum* and identified three TFs and one histone acetyltransferase that significantly affect lipase activity. The relative transcript levels of *LIP1* and *FGL1* were markedly reduced or enhanced in these TF mutants. Among them, Gzzc258 was identified as a key lipase regulator which is also involved in the induction of lipase activity during sexual reproduction. To our knowledge, this study is the first comprehensive functional analysis of fungal lipases and provides significant insights into the genetic and regulatory mechanisms underlying lipases in fungi.

Text
Plants have evolved to cope with environmental threats. Some beneficial microorganisms (BM) can improve plant defensive responses and helping the plant to survive. Among these BM, endophytic bacteria (EB) and arbuscular mycorrhiza fungi (AMF) are of the highest interest. By one side, some EB are known to have a protective effect in plant response against pathogens. They can penetrate the plant from the rhizosphere and colonize different tissues without producing any damage, also they help plants to adapt to stress. On the other side, mycorrhiza plants through mycorrhiza-induced resistance (MIR) mechanisms, which has been largely proved to be efficient for biocontrol. In our group, the *Bacillus mycoides*, isolate O2, was identified by sequencing the 16S rRNA gene. We showed that this isolate O2 in bioassays, can protect tomato plants and prime callose against *B. cinerea*, as the AMF *Rhizophagus irregularis* does. In nature, plants are in contact with different BM at the same time, thus we wonder how the consortium EB+AMF works against the pathogen. To study the protecting effect in plants of the consortium AMF + EB, preliminary phenotypic studies have been performed to see whether AMF and *B. mycoides*, isolate O2 synergize to protect the plant against a fungal infection. It has been shown that there is a clear protection exerted by the consortium AMF+EB in tomato plants Moneymaker variety, against *B. cinerea*. The

mechanisms underpinning this phenotype are going to be studied.

Text

Potato soft rot leads to considerable damage in the fields and warehouses all over the world. Although it is well-known that bacteria from the genera Pectobacterium and Dickeya are the main causative agents of this disease, several recent studies indicated an involvement of pectinolytic Bacillus pumilus in the soft rot disease outbreaks in diverse geographical regions. In this view, the aim of this work was to identify bacteria responsible for soft rot disease in high potato production areas of Tunisia.
1001 samples of the affected potato tubers were collected in the growing seasons of 2018, 2019 and 2020 from eight governates of Tunisia. From this material 270 bacterial isolates were acquired. 20 of isolated bacterial strains indicted pectinolytic activity by forming deep cavities on Crystal Violet Pectate medium. All pectinolytic isolates were able to macerate potato tuber tissue under laboratory conditions. Phenotypic characterization showed that these isolates were Gram-positive bacilli, exhibiting pectinolytic, cellulolytic, proteolytic and amylolytic activities. Majority of the isolates indicated swimming and swarming motility. Application of MALDI-TOF MS, sequencing of 16S rDNA and API commercial tests allowed for assignment of 19 of the tested isolates to the species B. pumilus and 1 to the species Paenibacillus amylolyticus.
To the best of our knowledge, this is the first report of soft rot on potato caused by pectinolytic Bacillus and Paenibacillus spp. in Tunisia.

HISTOPATHOLOGY OF RHIZOCTONIA ROOT AND CROWN ROT OF SUGAR BEET

MINIER Douglas H. . (1), HANSON Linda E. . (1,2)

(1) Michigan State University, East Lansing, UNITED STATES; (2) USDA-ARS, East Lansing, UNITED STATES

Text
Rhizoctonia root and crown rot (RRCR), caused by *Rhizoctonia solani* AG 2-2, is one of the most important soil-borne diseases of sugar beet (*Beta vulgaris*) throughout the world. Necrosis usually takes the form of dark, shallow lesions that often develop in a ladder-like pattern and spread laterally. While infection cushions on the root surface are commonly reported as the primary route of infection, our observations indicate that lesions associated with lateral roots may involve an alternate route of entry. In the current study, we utilized advanced microscopy to examine the physiological traits of sugar beet roots associated with the development of RRCR symptoms. Hyphae that entered through infection cushions on smooth root tissue were largely restricted to the outermost cortical layer between the outer cambium and the periderm. However, in areas where the outer cambium was discontinuous, hyphae were observed to penetrate deeper into the root tissue, suggesting the outer cambium acts as a barrier to fungal penetration. In contrast, no infection cushions were observed in tissue of the lateral roots and it appears the hyphae were able to invade relatively unimpeded due to the lack of secondary cambium in this area. A region of autoflurescence caused by an unknown factor was observed in advance of the hyphae. Our observations provide an updated histological study of RRCR and offers some physiological explanations for the characteristic symptoms associated with this disease.

THE ROLE OF OXALIC ACID IN CLARIREEDIA JACKSONII PATHOGENESIS ON AMENITY TURFGRASS

HUO Daowen. (1), WESTRICK Nate. (1), KOCH Paul. (1), KABBAGE Mehdi. (1)

(1) University of Wisconsin Madison, Madison, UNITED STATES

Text
Dollar spot is a destructive foliar disease of amenity turfgrass caused by the fungus *Clarireedia jacksonii*. Oxalic acid (OA) is an important pathogenicity factor in related fungal plant pathogens such as *Sclerotinia sclerotiorum*, however, direct evidence supporting the role of OA in the pathogenic development of *C. jacksonii* is lacking due to its recalcitrance to genetic manipulation. Herein, we developed a CRISPR/Cas9-mediated homologous recombination approach to overcome recalcitrant transformation and delete an oxaloacetate acetylhydrolase (Oah) gene that is required for OA's biosynthesis. We hypothesize that OA is an important pathogenicity factor for *C. jacksonii* and oah-deficient *C. jacksonii* mutants will result in reduced dollar spot disease. Two independent CRISPR-Cas9 mutants *ΔCjoah-1* and *ΔCjoah-2* were generated. The mutants, WT, and a *C. jacksonii* positive control strain (LWC) were inoculated on potted creeping bentgrass in a controlled environment chamber to measure dollar spot symptom development. Results showed that after 12 days, bentgrass inoculated with *ΔCjoah-1* and *ΔCjoah-2* exhibited 59.41% lower dollar spot severity than WT and LWC isolates. Moreover, OA production was significantly reduced by 71.51% at pH 5 and 78.07% at pH 8 in *ΔCjoah-1* and *ΔCjoah-2* compared to the WT and LWC. These results clearly demonstrate that OA plays a significant role in *C. jacksonii* pathogenesis on creeping bentgrass, and may offer novel directions for dollar spot suppression.

(1) MAP - UMR5240, Villeurbanne, FRANCE; (2) BF2I - MUR 0203, Villeurbanne, FRANCE; (3) iMean, Toulouse, FRANCE

Text

A.M. and C.B. contribute equally

Plant pathogenic bacteria face many specific challenges colonizing and/or infecting plants. Thus, for the bacterium Dickeya dadantii capable of colonizing different plants and living in anoxic environments of the rhizosphere and in plant tissues, the ability to grow in anoxic conditions represents an adaptive trait favouring its development and dissemination. We hypothesise that the capacity to anaerobically respire carbon compounds (C) constitutes a physiological advantage for phytopathogenic bacteria. Our objective is to highlight the ability of D.dadantii to anaerobically breathe C compounds, present in the apoplast. Apoplast's C compounds able to be used as terminal electron acceptors by D.dadantii were identified, and the conservation of their metabolic pathways in Dickeya and Pectobacterium genera is studied. The mutants of the identified metabolic pathways' genes are being built.

FIRST REPORT OF CHERELLE WILT CAUSED BY NEW SPECIES OF COLLETOTRICHUM IN THE PHILIPPINES

TAKATA Yoshiki. (1), MALONZO Mike Andre. (2), NOZAWA Shunsuke. (1), REYES Renato. (2), WATANABE Kyoko. (1)

(1) Tamagawa University, Tokyo, JAPAN; (2) Central Luzon State University, Science City Of Munoz, PHILIPPINES

Text

Cherelle wilt (CW) and Cacao pod rot (CPR) have been causing a decline in cacao production (*Theobroma cacao*) in the cultivation. Several fungal species are reported as causal agents of both CW and CPR, however, there is not enough information indicating whether all of those pathogens are related. Thus, it is not clear if the causal agent of CW is also responsible for the occurrence of CPR. In this study, we collected a cherelle which turned black and covered with slightly white mycelia in June 2022 in the Philippines, and isolated a novel *Colletotrichum* species from the symptomatic CW. The pathogenicity test using the monoculture strain showed that the isolate is pathogenic to young cacao pods (with/without wound) but not to mature pods and leaves. This may indicate that the isolate is only the causal pathogen of CW and not of CPR and anthracnose of leaves. In molecular phylogenic tree based on ITS, *GAPDH*, *CHS1*, *ACT*, and *TUB2*, the isolate is an independent which belongs to the *Colletotrichum gigasporum* species complex (CGSC) consisting of nine known species. The size and number of septa of the ascospores were different from those of *C. gigasporum* and *C. taiwanense*. Moreover, all of the characteristic features of the appressoria, conidia and the colony do not much with any CGSC species.

Based on the aforementioned results, it is therefore concluded that the isolate is a new species of *Colletotrichum* and is being proposed to be added as a causal pathogen of CW.

DEFENCE OF BRASSICA NAPUS TO RHIZOCTONIA SOLANI AG2-1 AND HOST-PATHOGEN INTERACTIONS IN THE SOIL ENVIRONMENT

RAY Rumiana. (1), SIMS Isabelle. (1), JAYAWEERA Dasuni. (1), STURROCK Craig. (1)

(1) University of Nottingham, Sutton Bonington, UNITED KINGDOM

Text

Rhizoctonia solani Anastomosis Group (AG) 2-1 causes damping-off and root/hypocotyl rot of Brassica napus(Oilseed Rape; OSR) resulting in significant crop losses in field. Resistance variation and the regulation of defence of OSR to AG2-1 or the effects of the soil environment on host-pathogen interactions have not yet been fully elucidated. Presently, cultural practices and/or seed treatment remain as the main methods of disease control. We carried out a series of experiments to determine the varietal responses of B. napus to AG2-1 and used confocal microscopy and computed micro-tomography to visualise infection and to quantify the temporal effects of soil type, moisture and seed treatment on pathogen growth and development. Molecular approaches and functional analysis with Arabidopsis thaliana mutants were employed to define the defence response to AG2-1. Auxin, abscisic acid, and the MYC2 branch of jasmonate signalling contributed to plant susceptibility, whilst induced systemic resistance was enhanced by NAPDH RBOHD, ethylene signalling and the ERF/PDF branch of jasmonate signalling. AG2-1 development and infection were favoured by low soil moisture irrespective of soil type, with excessive moisture causing preferential pathogen growth on the soil surface in the absence of seed treatment. The findings from these studies identify defence pathways, sources of resistance and soil environmental factors that can lead to improved OSR management of soil-borne R. solani.

P9.2-039

COLLETOTRICHUM SPECIES ASSOCIATED WITH PRE-HARVEST CITRUS ANTHRACNOSE IN SOUTH AFRICA

STOLTZ Danae. (1), MOSTERT Lizel. (1), HAVENGA Minette. (2), VAN NIEKERK Jan. (3), **HALLEEN Francois. (2)**

(1) University of Stellenbosch, Stellenbosch, SOUTH AFRICA; (2) Agricultural Research Council (ARC) - ARC Infruitec-Nietvoorbij, Stellenbosch, SOUTH AFRICA; (3) Citrus Research International, Mbombela, SOUTH AFRICA

Text

Colletotrichum is the causal agent of pre- and post-harvest anthracnose on many important crops such as citrus. Although *C. gloeosporioides* is known to occur on South African citrus, a European survey identified *C. karsti* from imported fruit from South Africa for the first time in 2017. The aim of this study was therefore to determine which *Colletotrichum* species are associated with pre-harvest citrus anthracnose symptoms in different regions in South Africa.

This was done by sampling different plant parts, namely leaves, twigs, green and mature fruit, fruit stems and flowers, in 20 citrus-growing areas in four provinces in South Africa. A total of 1141 *Colletotrichum* isolates were obtained. Representative isolates were identified by amplifying and sequencing GAPDH, TUB2 and ITS gene regions. The main *Colletotrichum* species associated with citrus in all the growing regions were *C. gloeosporioides* and *C. karstii*. The two species were identified in an even ratio from all citrus varieties surveyed and were isolated from all plant parts sampled. Navel oranges had the highest incidence. *Colletotrichum gloeosporioides* was obtained from more fruit than *C. karstii* and more *C. karstii* isolates were obtained from leaves. This is the first large-scale study to investigate the distribution of *Colletotrichum* species associated with anthracnose symptoms, in South African citrus orchards.

P9.2-040

THE ETIOLOGY OF ALTERNARIA BROWN SPOT AND ALTERNARIA CORE ROT OF CITRUS IN SOUTH AFRICA

KEET Marcelle. (2), MOSTERT Lizel. (2), HAVENGA Minette. (1), VAN NIEKERK Jan. (3), **HALLEEN Francois. (1)**

(1) Agricultural Research Council (ARC) - ARC Infruitec-Nietvoorbij, Stellenbosch, SOUTH AFRICA; (2) University of Stellenbosch, Stellenbosch, SOUTH AFRICA; (3) Citrus Research International, Mbombela, SOUTH AFRICA

Text

Many small-spored *Alternaria* species cause serious damage to fruit, such as Alternaria brown spot and Alternaria core rot in citrus orchards worldwide. The aim of this study was to clarify which small-spored *Alternaria* species are associated with these diseases in South African citrus orchards. Fungal isolations were made from leaves, twigs, young and mature fruit, fruit stems and flowers from 33 citrus cultivars in four main citrus production areas in South Africa. *Alternaria* isolates were identified by amplifying and sequencing the rpb2, endoPG and OPA10-2 gene regions and by fungal morphology. Most of the isolates were identified as *A. alternata* and divided into two clades. *Alternaria alternata* was mostly isolated from soft citrus types, and specifically from fruit. *Alternaria alternata* was furthermore associated with brown spot and core rot fruit lesions. This study showed that small-spored *Alternaria* species were found from different plant parts including leaves, twigs, young and mature fruit, fruit stems and flowers. Results of this will lay the foundation for decision making in future disease management strategies of Alternaria brown spot and Alternaria core rot of citrus.

DEVELOPMENT OF MICROSATELLITE MARKERS FOR POPULATION STUDIES OF ROSELLINIA NECATRIX.

MIYAMBO Tsakani. (1,2,3,4), ENGELBRECHT Juanita. (1,3,4), VAN DEN BERG Noelani. (1,2,3,4)

(1) University of Pretoria, Pretoria, SOUTH AFRICA; (2) Department of Biochemistry,

Genetics & Microbiology, Pretoria, SOUTH AFRICA; (3) Forestry and Agricultural Biotechnology Institute, Pretoria, SOUTH AFRICA; (4) Hans Merensky Chair in Avocado Research, Pretoria, SOUTH AFRICA

Text

Rosellinia necatrix is a soil-borne pathogen, the causal agent of white root rot (WRR), affecting several economically important ornamental plants and fruit trees. This fungus was first reported in South Africa in 1974, on apple and pear trees, and grapevines in the Western Cape. In 2016, it was reported on avocado orchards in Limpopo for the first time. Since then, WRR has also been detected in KwaZulu-Natal and Mpumalanga. Despite these reports, limited knowledge is available on the origin, spread and population biology of this fungus. Therefore, the aim of this study was to develop a set of polymorphic microsatellite markers to study the genetic diversity and population structure of *R. necatrix* in South Africa. Using genome sequences of three isolates from *R. necatrix*, 29 primer pairs were designed to amplify microsatellite regions consisting of tri-, tetra-, penta- and hexa-nucleotide repeats. Polymorphism at each microsatellite locus was determined through the amplification of six isolates from Israel, Spain and South Africa. Thirty isolates from Limpopo were used to plot a genotype accumulation curve. The efficacy of the microsatellite markers for population genetic analyses studies was demonstrated on two populations of *R. necatrix* from South Africa. The markers developed in this study are a useful tool to study the population structure and genetic diversity of *R. necatrix* populations in countries where it is an important pathogen.

EFFICIENT ISOLATION AND TRANSFORMATION PROTOCOL OF ZYMOSEPTORIA TRITICI PROTOPLAST FROM THE GLOBAL REFERENCE STRAIN IPO323

CHOI Michael. (1), MCDONALD Megan. (1)

(1) University of Birmingham, Institute of Microbiology and Infection, School of Biosciences, Edgbaston, Birmingham, UNITED KINGDOM

Text

Zymoseptoria tritici is a devastating filamentous fungus and the causal agent of Septoria tritici blotch (STB) in wheat. It has been documented STB could cause up to 50% yield loss in severe conditions while it is also responsible for up to 70% of the total fungicide usage on wheat in Europe. *Z. tritici* has one of the most expansive genome resources for any plant pathogen, with over 1000 publicly available genomes along with over 20 high-quality long-read assemblies. However, our ability to take full advantage of this rich dataset is limited by the lack of a high-throughput method for genetic manipulation of this species.

This is especially more complicated in *Z. tritici* as the novel global reference strain IPO323 has anecdotally been reported to be difficult to protoplast. Adding to this difficulty was the only published enzyme (glucanex, Sigma) used to generate *Z. tritici* protoplasts has now been discontinued. Here we developed a protocol for protoplast isolation and transformation of the *Z. tritici* reference IPO323 and other modern *Z. tritici* isolates using the cheap and commercially available winemaking enzyme ‘extralyse’ (Laffort). We will present an overview of our

optimised protoplast isolation method, and transformation efficiency of IPO323 using PEG-mediated transformation.

Text

The bacterial order *Enterobacterales* is currently divided into eight recognized families: *Budviciaceae*, *Enterobacteriaceae*, *Erwiniaceae*, *Hafniaceae*, *Morganellaceae*, *Pectobacteriaceae*, *Thorselliaceae*, *Yersiniaceae*, and the not yet recognized genus *Bruguierivoracaceae*. The *Pectobacteriaceae* family comprises plant pathogens able to provoke diverse diseases, including plant maceration due to the production of pectinases disrupting the plant cell wall. To better understand their natural diversity, a survey of pectinolytic bacteria was performed in lakes of the French region La Camargue near the Mediterranean Sea. Sixteen atypical pectinolytic isolates were obtained from brackish water of three lakes. In phylogenetic trees, the novel strains formed a new clade of *Pectobacteriaceae*, separate from the previously described genera of this family: *Affinibrenneria*, *Brenneria*, *Dickeya*, *Lonsdalea*, *Musicola*, *Pectobacterium*, and *Samsonia*. Phylogenomic study of representative members of the order *Enterobacterales* clearly indicated that *Acerihabitans* does not belong to *Pectobacteriaceae* and should be reclassified in the *Bruguierivoracaceae* family. In contrast, the relative position of *Symbiopectobacterium* in the *Enterobacterales* tree supports its appurtenance to *Pectobacteriaceae*. Finaly, based on phenotypic, genomic and phylogenetic characteristics, we propose the creation of a new genus including the sixteen pectinolytic isolates from Camargue brackish lakes

Text

Botrytis cinerea is known as a necrotrophic phytopathogenic fungus: the pathogen kills the

plant cells before feeding on them. However, an asymptomatic growth is also reported in *B. cinerea* that could last over several weeks under certain conditions. Our group started a study with the assumption that various biotic and abiotic parameters might favor the switching of *B. cinerea* from the asymptomatic growth to the necrotrophic lifestyle. Another highlight is the ability of the model plant *Arabidopsis thaliana* to secrete exosomes in response to *B. cinerea*. The plant exosomes internalize the fungal cell and deliver signaling molecules that downregulate the fungal virulence. Our working hypothesis is that plant exosome trafficking contributes to lower the fungal virulence and maintain the asymptomatic phase of the fungus during its infection. Using a combination of fluorescent reporter systems in *Arabidopsis* transgenic lines, various developmental and physiological stages in addition to the way of inoculation of *B. cinerea* were assessed to (1) determine the best conditions necessary to analyze the asymptomatic phase ; (2) observe by fluorescence microscopy the exosome trafficking between the host and its pathogen. In an integrative biology perspective, this study will contribute to better understand the complex molecular dialogue between *B. cinerea* and its host; and at term the behavior of this pathogen in the field.

Text

Tan spot caused by Pyrenophora tritici-repentis (Ptr), a necrotrophic fungal pathogen, is one of the most prevalent diseases of spring wheat (Triticum aestivum L.) in Nordics and especially in Finland. Three Ptr necrotrophic effectors (NEs) are currently known; ToxA and ToxB, which are proteins, and ToxC, a small polar molecule. Here we tested the sensitivity of 181 spring wheat genotypes, mostly Nordic cultivars and breeding lines, to purified ToxA and ToxB effector proteins to examine the importance of these virulence factors behind tan spot epidemics in Nordics. Both ToxA and ToxB sensitivities were present in the tested wheat material, ToxA sensitivity being more common than sensitivity to ToxB. We compared the sensitivity data with observations from artificially inoculated field experiment in Finland in 2022 and found that both ToxA and ToxB sensitivity explained only little of phenotypic variation in tan spot susceptibility. ToxA and ToxB have previously been described as important facilitators of tan spot susceptibility in NE-sensitive lines, but our results indicate other factors being more important in Nordic wheat production area. We will continue the study by collecting second year of field data to better capture year-by-year variance. We will also explore the genetic diversity of Ptr populations in Finland to better understand the factors driving the epidemic development from the fungus perspective.

Text

The development and morphology of filamentous fungi rely on the polar delivery of secretory vesicles to growing hyphal apexes. Those vesicles bring lipids required for the extension of the plasma membrane and parietal enzymes involved in the synthesis of the cell wall. While extensively studied in plant pollen tubes that also exhibit polar growth, the temporal dynamic of vesicles at fungal apexes has been understudied. Here, the chitin synthase CHSIIIa of the phytopathogenic fungus *Botrytis cinerea*, known to be transported by secretory vesicles, has been fused with eGFP. Confocal microscopy has been used to study the temporal dynamics of labelled vesicles. First, pulses of vesicles were observed in actively growing hyphae that were neither observed in non-growing hyphae nor in differentiated penetrative structures. Second, the kinetic measurement and analysis of the fluorescence signals collected from growing hyphae highlighted a rhythmic behaviour characterized by a bi-sinusoidal pattern. This pattern has been characterized using sinusoidal regression and Discrete Fourier Transform. To our knowledge, this is the first description of a bi-sinusoidal dynamic of vesicle secretion in filamentous fungi. Together, these results shed new light on the current models of fungal cell elongation.

Text

The stalk rot disease of sugarcane, caused by *Phaeocytostroma sacchari*, is considered a secondary disease. However, it is frequency and importance have increased in Brazil. The objective of this work was to evaluate the in vitro conditions for the germination of *P. sacchari* conidia. The colonies were grown in PDA medium for 30 days, under photoperiod 12/12 h at 25ºC. Suspension of 10^5 conidia mL^{-1} was obtained through serial dilution and counting in a hemocytometer. For the evaluation of germination, 20 µL of conidial suspension was deposited in water agar (WA) culture medium, on a microscope slide. Different methodologies were tested, being added to the WA medium, in the ration 0,5:1 (extract:suspension): (i) extract of stalk bark, (ii) extract of midrib, (iii) sugarcane juice, and (iv) sterile water, as control. Each treatment was constituted by three repetitions. Incubation took place in BOD at temperatures of 22ºC, 25ºC and 28ºC. The germination rate was evaluated 12, 18 and 24 hours after

incubation. To interrupt germination, a drop of lactophenol blue was deposited. A conidium whose germ tube was longer than it is width in it is median region was considered germinated. The beginning of conidial germination was observed 12 hours after incubation for treatments containing extracts. Germination rates greater than 50% were observed 24 hours after incubation at 28ºC, for treatments containing sugarcane extracts. No conidium germinated in the control treatments.

Text

In the last decades, the main diseases associated with the crop have been well managed through the use of varietal resistance. However, lately there has been a resurgence of diseases previously considered of secondary importance, and others, still little known. Such diseases occur separately, or sometimes simultaneously, apparently originating from infections and co-infections caused by necrotrophic pathogens. The objective of this work is to highlight the presence of a disease associated with a complex of symptoms, which summarize stem rot, concomitantly due to fermentation and characteristic odor, and the presence of coincident wilted stems, which lead to a large reduction in production. Symptoms are observed from the beginning of maturation, with gradual evolution in subsequent phases. Such symptoms have been observed in several varieties, and in different bioecological conditions. The damage resulting from such diseases are very high, with losses of up to 32% of stalks with symptoms of the disease. Reductions in productivity of the order of 22.9 tons of stalks per hectare were also reported. Phaeocytostroma sacchari, Colletotrichum falcatum and Fusarium spp., the most frequent fungi, have often been isolated from diseased stalks. Associated with the absence of spatial and space-time discontinuity, it is speculated that the high frequency and population of such pathogens is associated with a high source of inoculum resulting from the absence of cycle break of these fungi.

New Developments in Fungicide Resistance

Text

Barley spot form net blotch and net form net blotch diseases are caused by *Pyrenophora teres* f. *maculata* (Ptm) and *P. teres* f. *teres* (Ptt), respectively. Ptt and Ptm show high genetic diversity in the field due to intraspecific sexual recombination and interspecific hybridisation of the two species, although the latter is considered rare. Here we describe the detection of Ptt × Ptm hybrids with demethylase inhibitor (DMI) fungicide resistance (HR Ptm) and discuss the implications for barley disease management. The genomes of one putative hybrid, three Ptm and ten Ptt isolates were sequenced, and recombination analyses performed at the intergenic and whole genome levels. Of the 12 chromosomes, 11 showed significant recombination events in the intergenic regions while variable recombination rate showed significant recombination across all the chromosomes. Further genotyping of fourteen Ptt, fifteen Ptm, 48 HR Ptm, and two P. teres isolates from barley grass, showed that all HR Ptm isolates were clonal and not clustered with Ptt or Ptm. Locus specific analyses of the DMI target *Cyp51A* gene showed four recombination breakpoints, including the F489L point mutation that is correlated with DMI resistance. These results confirm the occurrence of natural recombination between Ptt and Ptm and indicates that the HR Ptm likely acquired DMI fungicide resistance through interspecific recombination, followed by clonal expansion of this genotype in barley-growing areas of Western Australia.

STATUS OF RESISTANCE EVOLUTION OF BARLEY DISEASES AND CURRENT CONTROL STRATEGIES IN EUROPE

HOFFMEISTER Mascha. (1), STROBEL Dieter. (1), HUF Anna. (1), STAMMLER Gerd. (1)

(1) BASF SE, Limburgerhof, GERMANY

Text

Barley is affected by different diseases, whereas Ramularia leaf spot (Ramularia collo-cygni), scald (Rhynchosporium secalis) and net blotch (Pyrenophora teres) are of high importance in most European barley growing regions. These diseases have been efficiently controlled for many years by various modes of action especially by QoIs, DMIs and SDHIs. For R. collo-cygni, QoI resistance mediated by the G143A mutation in the cyt b, is widespread and SDHIs and DMIs are also affected by mutations in their respective target genes. However, both modes of action, especially the DMIs, still contribute to effective Ramularia control. R. secalis is efficiently controlled by QoIs and SDHIs, there are only single reports on adapted isolates, which have no practical relevance so far. For P. teres, SDHI resistance affects SDHI field efficacy with regional differences and is mediated by various mutations in the SDH subunits B, C and D. QoI adaptation in P. teres is conferred by the mutation F129L in the cyt b and widespread in various European regions, however some QoIs such as pyraclostrobin show high field efficacy on F129L-adapted populations. A single detection of a G143A-mutated isolate of P. teres from Denmark in 2019 was intensively investigated and studies showed that this event was based on a partial cyt b gene transfer by P. tritici-repentis. In last seasons

monitoring studies, based on sensitivity assays and molecular analysis, such isolates have not shown up again.

Text

The first cases of Asian Soybean Rust (ASR) in Brazil were reported in season 2001, causing high level of defoliation and yield reduction in brazilian's soybean fields. The use of fungicides to control this disease has been essential among the years. Initially this disease was controlled with triazoles solo, but in 2005 the first reports were of reduced performance of this fungicide group was observed in the field, being later detected some mutations in the fungus associated with resistance to triazoles. After this event, to control this disease was adopted the strategy of fungicides mixes. The combination of strobilurins and triazoles began to be applied and keep good level of performance until season 2012/2013 when was identified the mutation F129L that impact partially the performance of strobilurins in all regions in Brazil. In 2014 was introduced into the market the carboxamides fungicides group to control ASR. Considering the area cultivated and disease pressure level in different years in 2017 was reported first case of mutation that effect carboxamides (I86F). This last mutation associated to mutations for triazoles and strobilurins generates a new challenge for fungicides to control ASR. The strategy adopted to reduce the impact of this mutation in control of ASR was associated to use multi-site fungicides in tank mixtures, select short cycle cultivars, anticipated the planting time to avoid or reduce the better weather condition for disease evolution.
