REPORT OF THE STATE BOTANIST 1908

Dr John M. Clarke, Director of the State Museum:

The following report of work done in the botanical department of the State Museum for the year 1908 is respectfully submitted.

Since the date of my last report specimens of plants for the State herbarium have been collected in the counties of Albany, Dutchess, Erie, Niagara, Rensselaer, Rockland, Saratoga and Steuben. Specimens have been received from correspondents and others that were collected in the counties of Albany, Chenango, Clinton, Columbia, Dutchess, Erie, Franklin, Kings, Monroe, Niagara, Oneida, Onondaga, Orleans, Otsego, Rensselaer, Richmond, Rockland, Steuben, Suffolk, Sullivan, Tompkins, Ulster, Warren, Washington, Wayne, Wyoming.

The number of species of plants of which specimens have been added to the herbarium is 152. Of these, 88 were not before represented therein. A list of the added species is given under the caption "Species added to the herbarium." The number of those who have contributed specimens of plants, either as direct contributions or as specimens sent or brought to the office of the State Botanist for identification or other information, is 74. In the latter case the names of those persons only are included whose specimens were in such condition or of such value as to make them worthy of preservation. A list of the contributors and their respective contributions is given under the heading "Contributors and their contributions."

The number of species which have not before been reported and which may be considered as additions to our State flora is 63.

Of these, 10 are described as new species. These are all fungi. Their names and descriptions with localities, time of collecting, also the names of the other species added to the flora, with remarks, localities and other information may be found under the title "Species not before reported." Noticeable varieties or interesting forms of species already reported are sometimes found, singular variations in habitat or extensions of range observed or new hosts of parasitic fungi are discovered. Such and other similar facts are recorded under the title "Remarks and observations."

Among the specimens sent by correspondents for identification, it sometimes happens that no description can be found that will match some one or more of them. In such a case it becomes necessary to consider them the types of new species and to give them names and write descriptions of them. Eight species and one variety have been found among the specimens received the past season from places beyond our State limits. Names and descriptions of these may be found under the title "New extralimital species." According to the ruling of the International Botanical Congress held at Vienna in 1905 all new species of plants published in and after 1908 must be described in Latin in order to be recognized as valid species. In accordance with this rule Latin descriptions of the new species published in this report follow the English descriptions.

The custom of giving colored illustrations of natural size and, as far as practicable, nontechnical descriptions of such mushrooms as have, upon actual trial, been found to be edible, has been continued. Owing to the scarcity of mushrooms only four species have been added to our list of edible mushrooms the past year. This makes the number of New York edible mushrooms now known and figured 195. Descriptions of the four added species are given under the title "Edible fungi." Illustrations of these are given on plates 115 and 116. Two new species of New York mushrooms and two extralimital species are illustrated on plates U and V.

Specimens of plants sent or brought to the office of the State Botanist for identification or for other information are always welcome, for in this way not only is the desired information obtained by the person seeking it but also interesting and valuable plant specimens are sometimes added to the museum collections. The number of identifications made in such cases the past year is 1640. The number of persons for whom identifications have been made is 127.

Unfortunately, the information sought by means of these sendings and the value of the specimens sent are both lost by neglect of proper precautions in transmission. Soft, fleshy or fragile specimens of fungi are placed in a letter and mailed without any protection. Consequently they are generally crushed and spoiled beyond recognition. They are sometimes sent in a thin straw-board box or a mere paper wrapper and the result is the same. Such frail specimens should be wrapped in soft tissue paper (not in cotton) and packed closely enough to prevent jostling, in a firm cardboard box or a thin wooden box or other receptacle firm enough to protect them. It is well in sending fleshy perishable specimens of larger size to wrap each one separately before putting them in the mailing receptacle. Good sound specimens of both mature and immature age should be selected for sending. Specimens that have a sodden or water-soaked appearance or are visibly infested by insect larvae or are affected by incipient decay should never be sent, for they are almost sure to be completely spoiled before reaching their destination. Even in sending sound specimens long distances, it is well, as far as possible, to time the sending so that it will not be necessary for it to lie in the post office over Sunday. When the transmission would require more than three days it would be better to write full descriptive notes of the characters of the fresh plants, then dry the specimens and send both together. It is better not to cut, split or mutilate the specimens in any way before sending them.

Revised descriptions of the New York species of the genus *Lentinus* and of *Entoloma* have been prepared. They may be found under their respective headings, "New York species of *Lentinus*" and "New York species of *Entoloma*." Similar brief monographs of certain genera of mushrooms have previously been published and have been so well received by students of mycology and acknowledged by them to be such a valuable part of the reports that it is thought well to continue them. They furnish in compact and convenient form a ready means of obtaining a knowledge of the number and characters of our New York species and their generic relations. The descriptions are preceded in each genus by a "key" which is intended to facilitate the tracing of each species to its description.

In many parts of our State the season just passed has been strangely adverse to the mushroom crop. Rain was not lacking in the early part of the season, but the prevailing low temperature apparently prevented the development of mushrooms that other-

wise would doubtless have appeared. Later in the season when the prevailing temperature was more favorable, the necessary rain and moisture were lacking. This unfavorable condition continued so late in the season that those species which usually appear in August and September either failed entirely to appear or appeared much later in the season. Reports state that very large crops of the common mushroom, *Agaricus campestris* L. have appeared in a few localities in November. This is nearly or quite two months later than its usual time. The light fall rains, which were unusually late, gave the mycelium its first opportunity to develop. These rains were followed by exceptionally fine mild and sunny weather which was very favorable to the development and spread of the mycelium or "spawn." The result was a very abundant crop of mushrooms in those places where a rich soil aided the favorable weather conditions.

The new species and varieties of fungi described by the State Botanist are now so numerous and the periodicals, reports and bulletins containing these descriptions are so many and so scattered and the inquiries concerning the place where one and another of them can be found are so frequent that it has seemed quite desirable that a list of these species be given with the places of their publication. This has been prepared and will doubtless be of aid to all interested in mycology. The names are arranged alphabetically and the most obvious synonymy is given. This list may be found under the title "List of species and varieties of fungi described by C. H. Peck, State Botanist, with bibliographic locations cited and some of the most obvious synonyms given."

Mr S. H. Burnham has performed the necessary clerical duties of the office, disinfecting, mounting, labeling and arranging specimens, assisting in the identification of specimens, attending to the official correspondence of the office and giving information to callers during my absence in the field. He has also made contributions to the herbarium of specimens collected on Saturday half holidays.

CHARLES H. PECK

Albany, December 29, 1908

SPECIES NOT BEFORE REPORTED

Aecidium importatum Henn.

Living leaves of peltandra, *Peltandra virginica* (L.) Kunth. West Nyack, Rockland co. June 1907. E. P. Felt. June 1908. C. H. Peck. The species is peculiar in developing only on the midrib and on the basal part of the principal veins. It occurs chiefly on the lower surface, but sometimes sparingly on the upper surface also.

Amanita glabriceps n. sp.

PLATE U, FIG. I-4

Pileus thin, ovate or oval becoming broadly convex or centrally depressed, glabrous, rarely adorned when young with a few patches of the ruptured volva, viscid when moist, often finely striate on the margin, white or yellowish white, sometimes slightly brownish in the center, flesh white under the separable cuticle; lamellae thin, crowded, free, unequal, white; stem long, slender, stuffed, glabrous or floccose-squamulose, bulbous, white, the thin flabby annulus sometimes ruptured and partly adhering to the margin of the pileus, sometimes disappearing with age, the bulb margined by the remains of the definitely circumscissile volva; spores globose, .0003 of an inch in diameter.

Pileus 2-4 inches broad; stem 3-6 inches long, 3-6 lines thick.

Among fallen leaves in woods. Coopers Plains, Steuben co. August. C. H. Peck. Sand Lake, Rensselaer co. Miss E. A. Perine.

This species is closely related to *Amanita phalloides* Fr. from which it is separated by its more slender habit, its thinner pileus with the margin often striate, its longer slender stem with a webby pith and a more narrow bulb margined by the remains of the more definitely circumscissile volva. *Amanita phalloides striatula* Pk. [N. Y. State Mus. Bul. 54, p. 961] is a small variety of this species rather than of *A. phalloides*.

Pileus tenuis, ovatus vel ovalis, mox convexus vel centro depresso, glaber, juventate volvae ruptae fragmentis rare ornatus, viscidus, margine saepe striatus, albus flavidus-albusve, aliquando centro leviter fuscus, carne sub cute separabile alba; lamellae tenues, confertae, liberae, inaequales, albae; stipes gracilis, elongatus, farctus, glaber vel floccoso-squamulosus, bulbosus, albus, annulo tenui, aliquando rupto et partim adhaerente ad marginem pilei,

quandoque omnino evanescente, bulbo volvae reliquis persistentibus marginato; sporis globosis, 8 μ in diam.

Amanita porphyria Fr.

Woods. Sand Lake, Rensselaer co. and Menands, Albany co.

Aster vittatus Bu.

Rocky places. Near Corning. August.

Botrytis plebeja Fres.

Living leaves of the common red currant, *Ribes vulgare* Lam. Menands, Albany co. September. It develops on the lower surface of the leaves on large brown spots. Usually one or two spots occur on a leaf. They are on the margin.

Brassica japonica Sieb.

Introduced. Sometimes cultivated as a salad; but it seeds itself and persists in gardens. Coopers Plains, Steuben co. August. It is called pepper grass or California pepper grass.

Calicium alboatrum Floerk.

Decaying wood of red oak, *Quercus rubra* L. Catskill mountains. September.

Celtis crassifolia Lam.

Near Saugerties, Ulster co. May and October.

Cephalozia lunulaefolia Dumort.

Decaying wood. Near Little Moose lake, Herkimer co. September. Miss C. C. Haynes.

Cercospora rudbeckiae n. sp.

Spots irregular, unequal, sometimes confluent, brownish or greenish brown; hyphae hypophyllous, cespitose, .003-.004 of an inch long, .0002-.00024 broad, flexuous, sparingly septate; spores subcylindric or tapering upward .0008-.0036 of an inch long, .0002-.00024 broad, 1-3-septate, colored nearly like the hyphae.

Living leaves of the tall cone flower, *Rudbeckia laciniata* L. Near Painted Post, Steuben co. August.

Spots similar to those of *Ramularia rudbeckiae* Pk. but hyphae much longer, denser and colored.

Maculae irregulares, inaequales, subconfluentes, brunneae vel virido-brunneae; hyphae hypophyliae, caespitosae, $75-100 \times 5-6 \mu$, flexuosa, leviter septatae; sporis subcylindraceis vel sursum attenuatis, 1-3-septatis, $20-90 \times 5-6 \mu$.

Clitocybe comitialis Pers.

Under balsam fir trees. Fulton Chain, Herkimer co. October. This is related to *Clitocybe clavipes* Pers. from which it may be separated by its smaller size, thinner cap, closer and less decurrent gills. It is rare both in this country and in Europe.

Collybia hirticeps Pk.

Half buried decaying twigs or branches of hemlock, *Tsuga canadensis* (L.) Carr. Vaughns, Washington co. August. S. H. Burnham.

Cololejeunea biddlecomiae (Aust.) Evans

Decaying wood. First lake, Herkimer co. September. Miss C. C. Haynes.

Commelina communis L.

Waste places. Albany. August. J. Dearness. Introduced and perhaps escaped from cultivation.

Dacryomyces corticoides E. & E.

Decaying pine wood. Alcove, Albany co. October. C. L. Shear.

Diaporthe atropuncta n. sp.

Perithecia valloid, scattered or 3-6 in a cluster, nestling in the inner bark, minute, subglobose, black, surrounded by no black line; ostiola short, naked, black, surrounded by the slightly elevated ruptured epidermis; asci oblong or subcylindric, .004-.0044 of an inch long, .0004-.0005 broad, 8-spored; spores commonly distichous, hyaline, uniseptate, .001-.0014 of an inch long, .00028-.0003 broad.

Bark of basswood, *Tilia americana* L. Alcove, Albany co. April. C. L. Shear.

Related to *Diaporthe farinosa* Pk. but it has no farinose disk and its spores are much larger.

Perithecia subvalsea, 3-6 in caespitate vel sparsa, minuta, subglobosa, in cortice nidulantia, nigra, nulla linea nigra limitata; ostiola brevia, glabra, nigra, epidermide leviter elevata rupta cir-

cumdata; asci oblongi vel subcylindrici, 100-120 x 10-12 μ ; sporae subdistichiae, uniseptatae, hyalinae, 25-35 x 7-8 μ .

Diplodina robiniae n. sp.

Perithecia minute, sunk in the wood, scattered or clustered, erumpent, sometimes circumscribed by a black line, pallid becoming blackish; spores oblong fusiform, straight, uniseptate, hyaline, .0004-.0006 of an inch long, .00016-.0002 broad.

Dead branches of locust, *Robinia pseudacacia* L. Barrytown, Dutchess co. June.

Related to *Diplodina coronilla* Brun.

Perithecia minuta, in ligno insculpta, sparsa aggregata, erumpentia, aliquando linea nigra circumscripta, pallida vel nigricantia; sporae oblongo-fusiformes, rectae, uniseptatae, hyalinae, 10-12 x 4-5 μ .

Fusarium aurantiacum Cd.

Summer crookneck squash, *Cucurbita pepo* L. Menands, Albany co. September. A single fruit of this squash which had been laid aside for its seeds developed this fungus and four others on its surface. All were in sufficient quantity to make good herbarium specimens. The four other species are *Botrytis cinerea* Pers., *Sporodesmium pluriseptatum* (K. & H.) Pk., *Phoma lagenariae* (Thuem.) Sacc. and *Volutella cucurbitina* Pk. The last three species appear to develop most freely on the warts of the squash.

Geoglossum alveolatum Durand

Decayed wood. Fall creek near Ithaca. July. E. J. Durand.

Gloeosporium medicaginis E. & E.

Living and languishing leaves and stems of alfalfa, *Medicago sativa* L. Menands, Albany co. August.

Gonatobotrys lateritia n. sp.

Effused, forming thin brick-red patches; hyphae erect, .0003-.0004 of an inch thick, septate, with a few globose or oval nodules, the terminal one .0012-.0016 of an inch long, obscurely dentigerous; spores elliptic, .0003-.0005 of an inch long, .00024-.0003 broad.

On some decaying species of *Poria*. Star Lake, St Lawrence co. August.

Effusa lateritias maculas formans; hyphae erectae, crass. 8-10 μ , septatae, nodulis paucis globosis ovalibusve nodulo terminali obscure dentigero, long. 30-40 μ ; sporae ellipsoideae, 8-12 x 6-8 μ .

***Hygrophorus sphaerosporus* Pk.**

Utica. August. K. F. Symonds.

***Hymenula musae* Pat.**

Banana rind. Menands, Albany co. September.

***Hypoloma fragile* n. sp.**

PLATE V, FIG. 1-7

Pileus thin, fragile, conic or subcampanulate, becoming convex, obtuse or subumbonate, floccose squamulose when young, with the margin slightly appendiculate with fragments of the veil, glabrous when mature, yellowish, grayish or subochraceous, the center sometimes a little darker; lamellae thin, narrow, close, adnate, whitish or pallid becoming purplish brown; stem slender, stuffed or hollow, glabrous or minutely floccose, white; spores .0003-.0004 of an inch long, .00016-.0002 broad.

Pileus 6-12 lines broad; stem 1-2 inches long, 1-1.5 lines thick.

Decaying wood or among fallen leaves. Star Lake, St Lawrence co. and near Painted Post, Steuben co. August.

Pileus tenuis, fragilis, conicus vel subcampanulatus, in maturitate convexus, obtusus vel subumbonatus, primus floccoso-squamulosus et margine leviter appendiculatus vel fragmentis, denum glaber, flavescens, griseus vel subochraceus, aliquando centro coloratior; lamellae tenues, angustatae, confertae, adnatae, albidae pallidaeve denum purpureo-brunneae; stipes gracilis, farctus, cavusve, glaber vel minute floccosus, albus; sporae 8-10 x 4-5 μ .

***Lactarius peckii* Burl.**

Damp ground near Smithtown, Suffolk co. August.

***Lecanora fuscata* (Schrad.) Th. Fr.**

Rocks. Haverstraw, Rockland co. C. F. Austin.

***Leptosphaeria inquinans* n. sp.**

Perithecia densely gregarious, subcarbonaceous, nestling in the bark, covered by the epidermis which is pierced by the minute black ostiolum, globose, $\frac{3}{4}$ mm broad, black; asci cylindraceous or sub-

clavate; spores distichous or crowded, cylindric, obtuse, generally curved, 3-septate, colored, the terminal cells subhyaline, .0006-.00006 of an inch long, .00016-.00024 broad, often oozing out and forming black spots on the matrix.

Bark of sugar maple, *Acer saccharum* L. Vaughns, Washington co. April. S. H. Burnham.

Before the exudation of the spores the bark is minutely dotted by the black ostiola. The spores are similar to those of *Hendersonia brunneoidiana* S. & R.

Perithecia dense gregaria, subcarbonacea, epidermide ostiolis nigris perforata tecta, globosa, $\frac{3}{4}$ mm lat., nigra; asci cylindraceo-clavulati; sporae distichae vel confertae, cylindraceae, obtusae, plerumque curvae, 3-septatae, coloratae, loculis extimis subhyalinis, 16-24 x 4-6 μ .

Leucolejeunea clypeata (Schw.) Evans
Rocks. Dresden, Washington co. August.

Lophocolea macounii Aust.

Decaying wood in a cedar swamp. Jordanville, Herkimer co. C. F. Austin.

Lophocolea minor Nees
Ground. Kenwood, Albany co. November. S. H. Burnham.

Massariovalsa sudans (B. & C.) Sacc.

Bark of red maple, *Acer rubrum* L. Shushan, Washington co. May. S. H. Burnham and F. Dobbin.

Our specimens agree much better with the figure of the species given in North American Pyrenomycetes, plate 30, than with the published descriptions of it.

Melanconis modonia Tul.

Bark of chestnut, *Castanea dentata* (Marsh.) Borkh. Alcove, Albany co. November. C. L. Shear.

Mnium orthorrhynchum B. & S.

Eagle Rock gorge near Chilson lake, Essex co. June. Mrs C. W. Harris.

Monilia angustior (Sacc.) Reade

This fungus which attacks the immature fruit of chokecherry, *Prunus virginiana* L., was reported under the name

Monilia peckiana var. *angustior* Sacc. in the 39th Report of the New York State Museum, page 49, but it has recently been raised to specific rank of which it certainly seems worthy. Professor Reade finds that the fungus attacks also the stems, petioles and principal veins of the leaves of the chokecherry.

Myxosporium castaneum n. sp.

Acervuli gregarious, orbicular, $\frac{1}{3}$ - $\frac{2}{3}$ mm broad, nestling in the bark, surrounded by the ruptured epidermis, pallid or grayish; spores oblong or elliptic, hyaline, .00024-.0004 of an inch long, .00012-.00016 broad, sporophores filiform, equal to or longer than the spores.

Dead branches of chestnut, *Castanea dentata* (Marsh.) Borkh. Queens co. March. J. Mickleborough.

This fungus is sometimes associated with the conidial form of *Diaporthe parasitica* Murr. from which it may be distinguished by the paler color of the acervuli and the larger size of the spores.

Acervuli gregarii, orbiculares, lat. $\frac{1}{3}$ - $\frac{2}{3}$ mm in cortice nidulantes, epidermide rupta circumscripti, pallidi vel subgrisei; sporae oblongae vel ellipsoideae, hyalinae, 6-10 x 3-4 μ , basidia filiformia; sporis aequalia vel longiora.

Nardia crenuliformis (Aust.) Lindb.

Rocks in rivulets. Rockland co. November. C. F. Austin.

Nectria sambuci E. & E.

Dead stems of sweet elder, *Sambucus canadensis* L. Wells, Hamilton co. September.

Neottiella polytrichi (Schum.) Mass.

On hair cap mosses. Glenmont, Albany co. November. S. H. Burnham.

Pellia endiviaefolia (Dicks.) Dumort.

Banks of ditches near Syracuse. October. L. M. Underwood.

Phoma corni Fckl.

Dead twigs of round leaved cornel, *Cornus circinata* L'Her. Rensselaer lake, Albany co. April. S. H. Burnham.

Phoma lagenariae (Thuem.) Sacc.

Rind of summer crookneck squash, *Cucurbita pepo* L. Menands, Albany co. September. The perithecia in our specimens become black with age; the spores exude and form whitish masses.

They are .0003-.0006 of an inch long, .00016-.0002 broad (8-16 x 4-5 μ).

Phyllosticta orbicula E. & E.

Living or languishing leaves of horse-radish, *Radicula armoracia* (L.) Robins. Menands, Albany co. October.

Pleurotus applicatus (Batsch) Fr.

Decaying wood and bark. Old Forge, Herkimer co. C. H. Peck. On beech bark. Vaughns, Washington co. S. H. Burnham. Alcove, Albany co. C. L. Shear.

Specimens of *Pleurotus atropellitus* Pk. were erroneously referred to *Agaricus applicatus* Batsch in the 22d Report of the New York State Cabinet, page 78.

Pleurotus griseus Pk.

In the 44th Report of the New York State Museum, page 35 this mushroom was described under the name *Pleurotus atrocaeruleus griseus*. Having observed it for many years and having received specimens of it from correspondents who collected it in widely separated localities, and finding it constant in its characters, I am persuaded that it is worthy of specific distinction. I have never seen specimens of it showing any blue color nor even bluish tints.

Polyporus arcularius (Batsch) Fr.

Decaying wood. Lyndonyville, Orleans co. C. E. Fairman.

Polyporus delectans Pk.

Decaying wood. Vaughns, Washington co. October. S. H. Burnham.

Polyporus trabeus Rostk.

Decaying wood of poplar. Gansevoort, Saratoga co. October. Our specimens were found growing with *Polyporus caesius* Fr. on the same prostrate trunk and in close proximity to it. They are nearly the same size, but more glabrous and with no bluish tints.

Puccinia agrostidis Plow.

Stems of white bent grass, *Agrostis alba* L. Wells, Hamilton co. September. Both the uredo and the telial forms were growing on the stems.

Puccinia albiperidia Arth.

Leaves and culms of *Carex crinita* Lam. Wells, Hamilton co. September. The aecial form inhabits living leaves of gooseberry, *Ribes cynosbati* L.

Puccinia campanulae Carm.

Living radical leaves of harebell, *Campanula rotundifolia* L. Near Ithaca. March. Edna Porter.

Puccinia cyani (Schleich.) Pass.

Living leaves and stems of bluebottle, *Centaurea cyanus* L. Menands, Albany co. C. H. Peck. Shelter island, Suffolk co. W. G. Farlow. This species was formerly considered a variety of *Puccinia suaveolens* (Pers.) Rostk. but is now raised to specific rank.

Puccinia phlei-pratensis E. & H.

Culms and sheaths of timothy, *Phleum pratensis* L. Wells, Hamilton co. September.

Pucciniastrum potentillae Kom.

Living leaves of three-toothed cinquefoil, *Potentilla tridentata* Ait. Berlin mountain, Rensselaer co. September. W. G. Farlow.

Rhinotrichum curtisii Berk.

Decaying wood of poplar. Gansevoort, Saratoga co. August. This species is closely related to *R. ramosissimum* B. & C. from which it differs in color. Its spores are very variable, being subglobose, ellipsoid or obovate.

Solanum rostratum Dunal

Afton, Chenango co. September. H. S. Sizer. Probably introduced from the west.

Sorosporium saponariae Rud.

In flowers and flower buds of field chickweed, *Cerastium arvense* L. Helderberg mountains. June. S. H. Burnham. So far as known this is its first discovery in this country.

Sphenolobus hellerianus (Nees) Steph.

Decaying wood. Altamont, Albany co. May.

Sporodesmium pluriseptatum (K. & H.) Pk.

Rind of summer crookneck squash, *Cucurbita pepo* L. Menands, Albany co. September.

This is *Sporodesmium mucosum* var. *pluriseptatum* Karst. & Har. but it differs so decidedly from *S. mucosum* that it is far more satisfactory to give it specific rank than varietal. The spores in our specimens exceed in size and in the number of septa the spores of the typical variety even and therefore intensify the difference between it and *S. mucosum*. In our specimens they are 40-80 μ long and 3-8-septate with usually more than two longitudinal septa. The fungus forms black velvety patches $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter.

Tricholoma subcinereum n. sp.

Pileus thin, plane or centrally depressed, subglabrous, whitish pale cinereous or grayish brown, the center sometimes a little darker and with a slight pruinose appearance, flesh white, odor strong, taste slightly and tardily acrid; lamellae thin, close, slightly sinuate, white; stem central or eccentric, equal or slightly thickened toward the base, solid, silky-fibrillose, whitish or brown externally, brownish within; spores broadly elliptic, .0003-.00036 of an inch long, .00024-.00028 broad.

Pileus 1.5-2.5 inches broad; stem 1.5-3 inches long, 3-7 lines thick.

Ground or buried wood in a cellar. Pittsford, Monroe co. June. F. S. Boughton.

A singular species suggestive in some of its characters of *Tricholoma humile*, *T. schumacheri* and *T. subpulverulentum*. The forms with whitish pileus sometimes become grayish brown in drying.

Pileus tenuis, planus vel centro depresso, subglaber, albidus pallido-cinereus vel griseo-brunneus, aliquando in centro magis coloreus et leviter pruinosis, carne alba, odore pungente, flavore

leve tardeque acre; lamellae tenues, confertae, leviter sinuatae, albae; stipes centralis eccentricus aequalis vel basi leviter in-crassatus, solidus, sericeo-fibrillosus, albidus vel extus brunneus, intus brunnescens; sporae late ellipsoideae, $8-9 \times 6-7 \mu$.

Trichothecium candidum Wallr.

On a drying specimen of *Polyporus hispidus* (Bull.) Fr. Albany. September.

Uromyces caricinus E. & E.

Leaves and culms of *Carex scoparia* Schk. Alcove, Albany co. July. C. L. Shear.

Uromyces scirpi (Cast.) Burr.

Leaves of river bulrush, *Scirpus fluviatilis* (Torr.) Gray. Clayton, Jefferson co. September. The aelial form occurs on leaves of poison hemlock, *Cicuta maculata* L.

Volutella cucurbitina n. sp.

Sporodochia orbicular, crowded in orbicular patches which are sometimes confluent, purplish brown becoming brown with age or in drying, adorned with slender subulate blackish setae, .0024-.0048 of an inch long, .00012-.00015 broad; spores oblong, obtuse, hyaline, .0004-.0009 of an inch long, .00016-.0002 broad, sporophores very short or obsolete.

Rind of summer crookneck squash, *Cucurbita pepo* L. Menands, Albany co. September.

Sporodochia orbicularia, in maculis orbicularibus dense conferta, interdum confluentia, oculo inermi brunneo-purpurea, in aetate brunnescentia, setis gracilibus subulatis nigris, 60-120 x 3-4 μ , ornata; sporae oblongae, obtusis, hyalinis, 10-22 x 4-5 μ , sporophoris brevissimis obsoletisve.

REMARKS AND OBSERVATIONS

Brachysporium obovatum (Berk.) Sacc.

Park of hop hornbeam, *Ostrya virginiana* (Mill.) K. Koch. Lyndonville, Orleans co. March. C. E. Fairman. A form not fully agreeing with the description of the type. It grows in tufts instead of velvety patches and the spores are often oblong instead of obovate and the septa vary from one to three.

Castanea dentata (Marsh.) Borkh.

This valuable tree has been attacked by a destructive fungus, *Diaporthe parasitica* Murr. In the parks of Brooklyn and New York city and in the country around these cities many trees have been injured or killed by it and many have been cut in consequence of the attack and its destructive effects. Numerous articles have been published concerning this disease and various experiments tried, designed to check or overcome the ravages of the fungus, but none of them has been successful or satisfactory. The fungus attacks the tree in wounds or abrasions of the bark and by killing the inner vital part of the bark in which it lives and spreads, it kills the tree in two or three years. It apparently does not otherwise affect the wood which may still be utilized after the death of the tree. The disease has been reported to have extended as far north as Dutchess county and a special trip was made to that region for its investigation, but no signs of its presence were found. Nor was it found in Albany, Rensselaer and Steuben counties in which it has been sought. On the other hand wherever the chestnut trees in these and other counties have been observed by myself the past season, they have generally appeared to be in good health and vigor and unusually full of fruit. A correspondent who is interested in the study and observance of the disease reports that he did not find it in the Catskill mountain region. It is therefore improbable that it has spread far in our State, if at all, either north or west of the limits assigned to it last year. It is more likely that the pessimistic views concerning its rapid spread and destructive consequences, entertained by some writers, will scarcely be realized. Unusually destructive outbreaks of parasitic fungi are apt to be dependent on unusual climatic conditions and therefore to be of short duration.

Cephalanthus occidentalis L.

Most of our botanies describe the leaves of this shrub as opposite or in whorls of three. A form occurs near Saugerties, Ulster co. in which there are four leaves in a whorl.

Epicoccum neglectum Desm.

On fruit of cucumber, *Cucumis sativa* L. Menands, Albany co. October. The patches or areas of this fungus at first appear to be pale brown but with age they become very black.

Eupatorium sessilifolium L.

Near Saugerties, Ulster co. September. This species is rare in the eastern and northeastern parts of the State.

Hydrangea arborescens L.

Near Coopers Plains and abundant near Lindley, Steuben co. G. D. Cornell. Also near Painted Post. C. H. Peck. Fruiting specimens were collected in August.

Hypoderma desmazieri Duby

On leaves of pitch pine, *Pinus rigida* Mill. Menands, Albany co. August. In these specimens the infested leaves were still on the tree and in some cases they were still green at the base, appearing as if the fungus was the cause of the partial death of the leaves.

Lycopodium inundatum L.

Rensselaer lake, Albany co. S. H. Burnham. September. This species is common in the cold bogs and marshes in the northern and eastern parts of the State, but would scarcely be expected to grow so near Albany. *Xyris caroliniana* Walt. was found growing in company with it.

Microsphaera alni (Wallr.) Salm.

Leaves of cream vetchling, *Lathyrus ochroleucus* Hook. Very abundant on hillsides south of Corning. August.

Panax quinquefolia L.

Woods. Rensselaer co. June. Fruit ripe the last week in August.

The demand for the root of this plant has been so great and the price so remunerative in recent years that the plant has been

nearly exterminated in our State. It is therefore very gratifying to know that there is even a limited station only a few miles from Albany. This place is so well fitted for its growth that most of the plants are very vigorous and bear four leaves at the top of the stem instead of three, the usual number. The roots also are of unusual size and bear two to four branches, each of which is as large as the unbranched root of ordinary plants. Only enough specimens have been taken to properly represent this interesting form in the State herbarium. It is very desirable that the plant may continue to occupy this favorable locality for many years.

Phyllosticta labruscae Thuem.

Living leaves of Boston ivy, *Ampelopsis tricuspidata* S. & Z. Menands, Albany co. July and August. A new host plant for this parasitic fungus, which usually attacks leaves of grapevines.

Phycomyces nitens (Ag.) Kunze

Decaying specimens of the oak loving collybia, *Collybia dryophila* (Bull.) Fr. Star Lake, St Lawrence co. August. This is a form having spores .0016 of an inch (40μ) or more in length.

Psathyrella graciloides Pk.

Split Rock, Onondaga co. September. G. E. Morris. This is a rare species found in our State but once before.

Uromyces hyperici (Schw.) Curt.

Leaves of northern St Johnswort, *Hypericum boreale* (Britton) Bickn. Griffin, Hamilton co. September.

Urnula geaster Pk.

This species was described from mature specimens collected near Austin, Tex. Fresh specimens, recently received from the same locality and sent by Mr F. D. Heald, show that the character "urceolate or cupulate" in the original description [N. Y. State Mus. Rep't 46, p. 39. 1893. Bot. ed.] is erroneous. The recent specimens show both the mature and the immature condition. The unopened plant has a closed receptacle, ellipsoidal, hollow, tapering downward into a solid fleshy tough stem and furnished at the apex with a slight blunt umbo. The plants grow in clusters about the base of old stumps. They take their origin several inches below the surface. The whole exterior is of a uniform brown color and covered with a minute velvety tomentum, but the flesh within is white both in the stem and in the receptacle.

The whole plant is 2-5 inches long and 1-2 inches broad in its widest part. The stem is .25-2 inches long and 3-5 lines thick.

In opening, the receptacle splits longitudinally into 4-6 rays which curve gracefully outward revealing the whitish or subochraceous hymenium. The chinks first appear at or near the middle of the receptacle and extend each way; downward to or nearly to the stem and upward to and through the umbo. The spores sometimes contain a single large nucleus, sometimes several small ones of unequal size. The paraphyses are moniliform, at least in the upper part.

This species has been made the type of a new genus, *Choriactis*, chiefly because the cells of the receptacle are wholly parenchymatous instead of being mostly prosenchymatous, as in the receptacle of *Urnula craterium*, the type species of the genus *Urnula*. To ignore all the plainly perceptible and easily ascertainable generic characters of a plant as large as this and give more weight to a slight difference in the cellular structure of the receptacle than to them, certainly does not seem scientific or reasonable. And the absurdity of it is emphasized when, as in this case, this slight difference is made the chief reason not only for the establishment of a new genus but for removing that genus with its one species to the family Pezizaceae with which it has little else in common. If such a course is to be followed it would be necessary to examine with a compound microscope all similar plants before it would be possible to refer them to their proper genera and families.

In the species under consideration all the generic characters ascribed by Fries to the genus *Urnula* are shown except one, namely "ore rotundo rimose dehiscens," (splitting open in a rounded mouth). In Sylloge, this part of the Friesian generic description was modified or extended by adding after "rotundo," "vel laciniato" (or lacinate). There is also added under the description of *Urnula craterium* (Schw.) Fr. the remark, "Passim lacinatum dehiscit." From this it appears that even the type species of the genus *Urnula* sometimes splits longitudinally. The gross difference then between the generic character assigned by Fries to the genus *Urnula* and the species described as *Urnula geaster* comes so near the vanishing point that it seems superfluous to separate the two plants generically.

Verpa digitaliformis Pers.

At the base of sand banks. Karner, Albany co. May. D. B. Young. A rare species in our State and remarkable in this case for growing in sandy soil.

NEW EXTRALIMITAL SPECIES OF FUNGI

Agaricus approximans

PLATE V; FIG. 8-14

Pileus thin, conic or campanulate, often obtusely umbonate, squamulose except the umbo, often radiately rimose, whitish, with brownish squamules and blackish brown or fuscous umbo, flesh white, unchangeable, taste sweet, agreeable; lamellae thin, close, free, white becoming brown or blackish brown; stem equal or tapering upward, stuffed or hollow, whitish, sometimes brownish below the white annulus; spores .0002-.00024 of an inch long, .00014-.00016 broad.

Pileus 1-2 inches broad; stem 1-1.5 inches long, 2-3 lines thick.

Gregarious or sometimes two united at the base. On manure. Near Trenton, N. J. September. E. B. Sterling.

Growing with *Agaricus placomyces* Pk. from which it differs in its smaller size, campanulate pileus and brown umbo. It is one of the few species in which the color of the lamellae changes from white to brown without any intervening pink color. From similar species of *Lepiota* it may be distinguished by its brown spores and brown mature lamellae.

Pileus tenuis, conicus vel campanulatus, saepe obtuse umbonatus, squamulosus praeter umbonem, saepe radiate rimosus, albidus, squamulis brunnescentibus et umbone brunneo-nigro fuscove, carne alba, immutabile, sapore dulce, grata; lamellae tenues, confertae, liberae, albae deinde brunneae vel nigrescentes; stipes aequalis vel sursum attenuatus, farctus cavusve, albidus, annulo albo; sporae 5-6 x 3.5-4 μ .

Pileus 2.5-5 cm latus; stipes 2.5-4 cm longus, 4-6 mm crassus.

Amanita elongata

Pileus thin, conic or ovate becoming broadly convex, glabrous, even or striate on the margin, yellow or orange, sometimes more deeply colored in the center, flesh white; lamellae close, free, white; stem long, slender, flexuous, white or whitish at the top, pallid below, slightly thickened at the base, slightly radicating; the annulus pale yellow; spores broadly elliptic, .0003-.0004 of an inch long, .00024-.0003 broad.

Pileus 1-2 inches broad; stem 3-6 inches long, 2-4 lines thick. Damp grassy ground in the borders of woods. Pennsylvania. July. E. B. Sterling.

Pileus tenuis, conicus ovatusve, deinde late convexus, glaber, in margine levis striatusve, luteus aurantiacusve, saepe in centro coloratior, carne alba; lamellae confertae, liberae, albae; stipes elongatus, gracilis, flexuosus, apice albus albidusve, deorsum pallidus, basi leviter incrassatus, subradicatus, annulo flavidus; sporae 8-10 x 6-8 μ .

Pileus 2.5-5 cm latus; stipes 7.5-15 cm longus, 4-8 mm crassus.

Boletinus glandulosus

Pileus fleshy, convex becoming nearly plane; viscid, subumbonate, chestnut or brown, flesh pallid; tubes medium size, angular, adnate or slightly decurrent, brown becoming blackish brown, the dissepiments everywhere dotted with minute compact tufts of elongated slightly irregular blackish cells, .0008-.0016 of an inch long, .00016-.0002 broad; stem subequal, viscid, solid, annulate, yellowish brown; spores oblong, .0004-.0005 of an inch long, .00016-.0002 broad.

Pileus 1.5-3 inches broad; stem 1-2 inches long, 4-6 lines thick. New Brunswick. G. U. Hay.

The dense blackish dots on the tube walls appear at first sight like glands and suggest the specific name. They furnish a singular character which belongs to no other known species of the genus and serves as a ready mark of distinction for this species.

Pileus carneus, convexus deinde subplanus, viscidus, subumbonatus, subcastaneus brunneusve, carne pallida; tubuli angulares, adnati vel leviter decurrentes, brunnei deinde nigro-brunnei; dissepimentis ubique punctatis cum caespitibus minutis loculorum elongatorum, leviter irregularum, nigrescentium, 20-40 x 4-5 μ ; stipes subaequalis, viscidus, solidus, annulatus, flavo-brunneus; sporae oblongae, 10-12 x 4-5 μ .

Pileus 3.5-7.5 cm latus; stipes 2.5-5 cm longus, 8-12 mm crassus.

Clavaria pallescens

Club simple, loosely cespitose or sometimes gregarious, about 1 inch tall, clavate, obtuse, generally terete, soft, fragile, stuffed or hollow, pale buff fading to whitish, more persistent lemon-yellow within; stem distinct, short, glabrous, 1-2 lines long, pale yellow;

spores white, oblong or ellipsoid, .00035-.0005 of an inch long, .00024-.0003 broad.

Dry gravelly soil near clumps of lamb kill, *Kalmia angustifolia* L. South Acton, Mass. October. S. Davis and G. E. Morris.

Allied to *Clavaria ligula* Fr. from which it may be separated by its smaller size, pallescent color externally and lemon-yellow color within, glabrous pale yellow stem and its broader spores. It is apparently a rare species.

Clava simplex, laxe caespitosa vel aliquando gregaria, in altitudine uncialis, clavata, obtusa, plerumque teres, mollis, fragilis, farcta cavaye, ochroleuca, pallescens, intus citrina; stipes distinctus, brevis (2-4 mm) citrinus; sporae albae, oblongae vel ellipsoideae, 6-8 x 9-12 μ .

Galera besseyi

PLATE V, FIG. 15-20

Pileus thin, ovate or oval, rarely subglobose, obtuse, glabrous, never expanding, isabelline or pale dingy ochraceous, the margin abruptly contracted and closely embracing the stem; lamellae thin, close, ascending, adnate, ferruginous brown; stem slender, slightly flexuous, hollow, glabrous, even or slightly striate, colored like the pileus; spores broadly ellipsoid, .00055-.00065 of an inch long, .0004-.0005 broad.

Pileus 2.5-6 lines long, 2-5 lines broad; stem 1-2 inches long, .5-1 line thick.

Sandy soil. Garden of the Gods, El Paso co., Col. August 1908. C. E. Bessey and E. A. Bessey.

This is a well marked and readily recognized species, having two very peculiar and interesting characters. The permanently closed pileus and the abruptly contracted amplexicaul margin are features not found in any other known species. The persistently clasping margin, surrounding the top of the stem like a sheath, strongly emphasizes the generic character, "margin at first straight, appressed to the stem." Being an inhabitant of an arid region we may suppose the persistently closed pileus to be a character designed to promote the conservation of moisture in the pileus till the spores can be fully developed. That it is not due in this instance to an unusually dry season and therefore an unusual occurrence may be inferred from the fact that rain had preceded the discovery but a short time, for water was seen in the surface

cavities of adjacent rocks. We must therefore conclude that it is a permanent character.

The color of the young lamellae is not known. The mycelium binds together a mass of sand at the base of the stem. This adheres to the stem when carefully taken up and gives it the appearance of being bulbous. This most distinct and remarkable species may very appropriately commemorate the name of the illustrious botanist, C. E. Bessey, who with his son, E. A. Bessey, discovered it.

Pileus tenuis, ovatus ovalisve, rare subglobosus, obtusus, glaber, nunquam expansus, isabellinus vel subochraceus, in margine abrupte contractus et stipitem amplexans; lamellae tenues, confertae, ascendentes, adnatae, ferrugineo-brunneae; stipes gracilis, subflexuosus, glaber, levis vel substriatus, pileo in colore similis; sporae ellipsoideae, $14-16 \times 10-12 \mu$.

Pileus 5-12 mm longus, 4-10 mm latus; stipes 2.5-5 cm longus, 1-2 mm crassus.

Hygrophorus obconicus

Pileus fleshy, thick in the center, obconic, convex or nearly plane becoming depressed in the center, involute on the margin, glabrous, pruinose, white or whitish, with the center yellowish, becoming pale alutaceous with age, flesh white; lamellae thick, distant, ventricose, very decurrent, white; stem straight or flexuous, equal or tapering downward, brittle, stuffed, white; spores subglobose, .00016-.00024 of an inch long, .00016-.0002 broad.

Pileus 6-12 lines broad; stem 10-12 lines long, 3-5 lines thick. Cespitose. Among sphagnum in swamps. Stow, Mass. September. S. Davis.

This is allied to *H. pratensis albus* Sacc. from which it may be separated by its habitat, color and smaller spores.

Pileus carneus, centro crassus, convexus vel subplanus, deinde centro depresso, glaber, pruinosis, albus albidusve, disco flavido vel griseo-flavido, in maturitate pallido-alutaceus, carne alba; lamellae crassae, distantes, ventricosae, valde decurrentes, albae; stipes rectus vel flexuosus, aequalis vel deorsum attenuatus, fragilis, farctus, albus; sporae subglobosae, $4-6 \times 4-5 \mu$.

Pileus 1.5-2.5 cm latus; stipes 2-2.5 cm longus, 6-10 mm crassus.

Inocybe intricata

Pileus thin, conic or convex becoming expanded, umbonate, fibrillose, radiately rimose, pale brown or tawny brown, shining, the umbo generally darker, flesh white; lamellae close, adnate or

sinuate adnate, white or whitish becoming tawny; stem fragile, flexuous, pruinose, stuffed or hollow, sometimes slightly bulbous, whitish, brownish below; spores coarsely nodulose, .0004-.0005 of an inch long, .00024-.0003 broad; cystidia .002-.003 of an inch long, .0008-.0012 broad.

Pileus 4-5 lines broad; stem 1.5-2 inches long, :5-1 line thick. Dark vegetable humus under deciduous trees. Stow, Mass. July and August. S. Davis.

The species belongs to the section Rimosi. It is variable. It differs from *I. umboninota* Pk. in its paler color of the pileus, its stuffed or hollow stem and its larger spores. From *I. rimosa* (Bull.) Karst. it is separated by its nodulose spores and from *I. asterospora* Quel. by its smaller size, paler shining pileus and its stuffed or hollow stem with no reddish tint. It is also peculiar in having a slight webby veil when very young.

Pileus tenuis, conicus convexusve, deinde expansus, umbonatus, fibrillosus, radiate rimosus, pallido-brunneus, fulvo-brunneus, nitidus, umbone plerumque nigro-brunneo, carne alba; lamellae confertae, adnatae sinuato-adnataeve, albae albidaeve, deindae fulvae; stipes fragilis, flexuosus, pruinosis, fractus fistulosusve, interdum leviter bulbosus, sursum albidus, deorsum brunnescens; sporae sparsim nodulosae, 10-12 x 6-8 μ , cystidia 55-80 x 20-30 μ .

Pileus 8-10 mm latus; stipes 3-5 cm longus, 1-2 mm crassus.

Panaeolus semilanceatus

Pileus thin, conic-ovate, umbonate, grayish brown; lamellae ascending, black when mature; stem slender, glabrous, hollow, brown; spores ellipsoid, compressed, variable in size, black, .0005-.0007 of an inch long, .0003-.0005 broad.

Pileus 4-6 lines long, 3-4 broad; stem 1.5-2.5 inches long, .5-.75 of an inch thick.

Dawson, British America. September 1905. Communicated by E. B. Sterling.

Similar to *Psilocybe semilanceata* Fr. in size and shape, but differing in color and spore character.

Pileus tenuis, conicus ovatusve, umbonatus, griseo-brunneus; lamellae ascendentes, in maturitate atrae; stipes gracilis, glaber, fistulosus, fuscus; sporae ellipsoideae, compressae, in magnitudine variabiles, atrae, 12-18 x 8-12 μ .

Pileus 8-12 mm longus, 6-8 mm latus; stipes 4-6 cm longus, 1-1.5 mm crassus.

Hendersonia diplodiooides divergens var. nov.

Spores very large, irregular, straight or curved, oblong, subpyriform or elliptic, 1-5-septate, commonly 3-5-septate, .0012-.0016 of an inch long, .0005-.0006 broad.

Dead stems of *Sambucus*. Red Butte Canyon, Utah. July. A. O. Garrett.

Differs from the type chiefly in its spores.

Sporae maximae, irregulares, rectae vel curvæ, oblongæ, subpyriformes, vel ellipsoideæ, 1-5-septatae, plerumque 3-septatae, 30-40 x 12-24 μ .

EDIBLE FUNGI

Tricholoma sordidum (Schum.) Fr.

SORRID TRICHOLOMA

PLATE 115

Pileus thin, campanulate or convex becoming plane or centrally depressed, subumbonate, glabrous, sometimes wavy or irregular on the margin, hygrophanous, dark brown or subviolaceous when moist, pallid or subalutaceous when dry, flesh white, taste sweetish, then disagreeable; lamellæ thin, subdistant, sinuate, adnate or subdecurrent, violaceous when young, then whitish or smoky brownish, sometimes tinged with pink; stem equal or slightly thickened at the base, stuffed or occasionally hollow in large specimens, colored like or a little paler than the pileus, sometimes fibrillose striate; spores pinkish, .0003 of an inch long, .0002 broad.

The sordid tricholoma in this part of our country is most often found in greenhouses. The figures of it in plate 115 were drawn from specimens collected by H. W. Barratt in Poughkeepsie. They were found growing in a greenhouse devoted to the cultivation of violets. Specimens of it were received a little later from B. C. Williams of Newark, Wayne co. These were collected in a greenhouse devoted to the cultivation of carnations. The species is related to the naked tricholoma, *Tricholoma nudum* (Bull.) Fr. with which it was for a time confused, but from which it may be distinguished by its tougher hygrophanous cap. In Europe it is said to grow on manure and in rich cultivated soil in gardens.

The cap is thin except in the center where it sometimes has a prominence called an umbo. It has a moist appearance and a

dark lilac or violaceous color before maturity, but when old it changes color as the moisture escapes and becomes pallid, grayish or reddish brown.

The young gills are also violaceous but with age they assume a pallid or smoky hue sometimes tinged with pink.

The stem is nearly equal in diameter throughout its entire length but sometimes it is a little thickened at the base. It may be solid or stuffed with a pith or in large specimens it may be hollow. It is similar in color to the pileus but may be a little paler. Often several stems are united at the base, and then the caps are frequently so crowded that they become irregular or wavy on the margin and sometimes they may be eccentric. The stems are slightly fibrillose striate and white within. The pinkish tint of the spores and the slightly decurrent lamellae are characters suggestive of the genus *Clitopilus*.

On account of its slight toughness and the somewhat disagreeable flavor of the flesh this species would not be considered a first-class mushroom, but with proper preparation it makes a very good dish and is harmless. The collector of the Poughkeepsie specimens gives the following as his method of cooking this mushroom. Put them in a covered dish with a little water, having previously seasoned them with a little salt and pepper. Put in an oven and after roasting them, not before, add a little butter. He adds, "we roasted some this morning and pronounce them first-rate."

Pholiota durooides Pk.

HARDISH PHOLIOTA

PLATE 116, FIG. 1-7

N. Y. State Mus. Bul. 122, p.148

Pileus thin, convex becoming nearly plane, glabrous or slightly rimose squamose in the center, creamy white or sometimes ochraceous buff either wholly or in the center only, flesh white, taste mild; lamellae thin, close, narrow, adnexed, sometimes broadly sinuate and having a decurrent tooth, whitish becoming brown or rusty brown; stem equal or nearly so, stuffed or hollow, glabrous, whitish, the annulus thick and cottony, often lacerated and evanescent, white; spores broadly elliptic, .00024-.00028 of an inch long, .00016-.0002 broad.

The hardish pholiota is related to the hard pholiota, *Pholiota dura* (Bolt.) Fr. but it may be separated from it by its different

colors, softer substance and specially by its smaller spores. These are more brown than the spores of the early pholiota, *Pholiota praecox* (Pers.) Fr., and this makes it doubtful whether the species would not better be placed in the genus *Stropharia*.

The cap is 1-2 inches broad and convex or nearly flat on the upper surface which is smooth and nearly white or sometimes yellow in the center or wholly ochraceous buff. The gills are rather narrow and closely placed side by side. When young they are whitish but with advancing age they become dark rusty brown. The stem is 1-2 inches long and 2-4 lines thick. It is white and adorned near the top by a thick cottony white collar which is sometimes torn or ragged and sometimes disappears as the plant grows old. It grows in rocky uncultivated places and may be found in August and September. It was discovered in Massachusetts but has been found near Syracuse in this State. Its scarcity detracts somewhat from its importance as an edible species.

Phylloporus rhodoxanthus (Schw.) Bres.

YELLOW RED PHYLLOPORUS

PLATE II6, FIG. 8-II

Pileus fleshy, compact, convex or pulvinate, sometimes becoming plane or depressed in the center when old, minutely flocculose or subtomentose, dry, occasionally rimose, reddish, yellowish red, brownish red or tawny brown, flesh white or whitish; lamellae moderately broad, subdistant, adnate or decurrent, distinct or slightly anastomosing near the stem, golden yellow, the interspaces somewhat venose; stem straight or flexuous, equal or narrowed toward the base, solid or stuffed, reddish or red above and yellow below; spores oblong or subfusiform, .0004-.0005 of an inch long, .00016-.0002 broad.

The yellow red phylloporus is variable in the color of the cap and stem and in the character of the gills. It has been referred by mycologists to various genera and described under various names. *Agaricus rhodoxanthus*, *Agaricus pelletieri*, *Gomphidius rhodoxanthus*, *Clitocybe pelletieri*, *Flammula tammi*, *Flammula paradox*, *Paxillus tammi* and *Paxillus rhodoxanthus* have all been applied to one or another form of this protean species. Because it does not agree well with the characters of any of the genera mentioned a new genus was instituted

which might receive this and kindred species. Its name is *Phylloporus* and indicates the fact that in Europe a form occurs in which the gills are connected by transverse partitions in such a way as to form pores. This form appears to be wanting in this country, but forms sometimes occur here in which the gills are more or less connected near their inner extremity. The color of the gills is a beautiful bright chrome yellow or golden yellow. They are not easily separable from the flesh of the cap. This is the chief objection to placing this species in the genus *Paxillus*.

The stem is usually a little shorter than the horizontal diameter of the cap. It is commonly central but occasionally it is eccentric. It is solid or stuffed and more or less variegated with red and yellow. The cap is 2-4 inches broad, the stem 1.5-3 inches long and 3-5 lines thick.

The mode of growth is either solitary, gregarious or cespitose. It is found in woods and bushy places growing among mosses, grasses or fallen leaves and is generally most plentiful in showery weather in July, August and September. The resemblance of forms having a tawny brown or yellowish brown cap to *Boletus subtomentosus* L. is quite marked and has been noticed by several writers.

Cantharellus minor Pk.

SMALL CHANTARELLE

PLATE 116, FIG. 12-17

Pileus thin, convex or nearly plane, often centrally depressed or umbilicate, glabrous, yellow, flesh whitish or pale yellow; lamellae distant, decurrent, sparingly branched, yellow; stem slender, subflexuous, subequal, smooth, solid when young, then stuffed or hollow, yellow, often with a whitish mycelium at the base; spores .00025-.0003 of an inch long, .00016-.0002 broad.

The small chantarelle is almost exactly like the chantarelle, *Cantharellus cibarius* Fr. in color, but in its much smaller size and more slender appearance, its stem being proportionately longer, it is easily recognized at a glance as a distinct species. But detailed examination sustains the superficial appearance by showing the cap to be very much thinner and often umbilicate or centrally depressed, the gills broader in proportion to the size of the plant and much less branched, the stem slender, elongated, usually flexuous and stuffed or hollow, and the spores smaller. The cap is often wavy or irregular on the margin and

the stem may be hollow in the upper part and solid in the lower. The cap is 6-12 lines broad, the stem 1-1.5 inches long and 1-2 lines thick. It grows in thin woods and in open places and appears in June and July. It is gregarious or subcespitoso and is sometimes associated with the chantarelle craterellus, *Craterellus cantharellus* (Schw.) Fr. Although of excellent flavor its small size detracts from its importance as an edible mushroom, but sometimes in wet showery weather it appears in sufficient abundance to make it available for the table.

NEW YORK SPECIES OF LENTINUS

Lentinus Fr.

Pileus fleshy coriaceous, tough, hard in fleshy species when old, persistent; hymenophorum continuous with the stem or with the base of the sessile pileus; lamellae thin, unequal, serrate or lacerate-dentate on the edge; stem when present, central, eccentric or lateral.

Wood-inhabiting fungi, variable in form, hard or tough in texture and easily recognizable by the uneven or serrate-dentate edge of the lamellae.

KEY TO THE SPECIES

Pileus with a distinct stem.....	1
Pileus sessile or with a very short stem.....	6
1 Pileus squamose or squamułose.....	2
1 Pileus glabrous	5
2 Stem 3 lines thick or more.....	3
2 Stem less than 3 lines thick.....	4
3 Pileus squamose, lamellae sinuate.....	lepidus
3 Pileus squamułose, lamellae not sinuate.....	spretus
4 Margin of the pileus even.....	tigrinus
4 Margin of the pileus sulcate.....	sulcatus
5 Plant cespitose, stem sulcate.....	cochleatus
5 Plant not cespitose, stem not sulcate.....	umbilicatus
6 Mature pileus hairy, sessile.....	ursinus
6 Mature pileus glabrous, very short stemmed.....	7
7 Stem red or chestnut color.....	haematopus
7 Stem whitish, nearly obsolete.....	suavissimus

Lentinus lepidus Fr.

SCALY LENTINUS

Pileus fleshy, compact, tough, hard when dry, convex or nearly plane, sometimes slightly depressed in the center, often irregular, the cuticle cracking and forming brownish spotlike scales, white or

pale ochraceous, flesh white; lamellae subdistant, broad, sinuate, decurrent, transversely lacerate and dentate serrate on the edge, white; stem short, hard, solid, often pointed at the base, more or less adorned with recurved scales sometimes furnished when young with an imperfect evanescent annulus, white or whitish; spores ellipsoidal, .0004-.0005 of an inch long, .0002-.00024 broad.

Pileus 2-4 inches broad; stem 1-2.5 inches long, 3-6 lines thick.

Single or cespitose. Decaying wood of coniferous trees. Often on and injurious to railroad ties, fence posts and bridge timbers. Common. May to October.

The pileus is occasionally umbonate. The scales may be brown or almost black. The stem is sometimes eccentric. It often emerges from cracks in the wood and is then pointed at the base.

Lentinus spretus Pk.

SPURNED LENTINUS

N. Y. State Mus. Bul. 105, p.24.

Pileus thin, tough, convex becoming nearly plane, obtuse or umbonate, rimose squamulose, grayish brown or pale alutaceous, sometimes more highly colored in the center, flesh white; lamellae close, rather narrow, decurrent, whitish, serrate dentate on the edge, sometimes lacerate; stem equal or sometimes narrowed toward the base, sometimes thickened, solid, subsquamose, often eccentric, whitish, often brownish toward the base; spores white, oblong, .0003-.0004 of an inch long, .00016-.0002 broad.

Pileus 2-5 inches broad; stem 1-3 inches long, 3-6 lines thick.

Decaying wood of pine. Warren and Rensselaer counties. July to September.

This species is closely related to *Lentinus lepideus* Fr. from which it may be separated by its more slender habit, thinner pileus, smaller scales, and more decurrent lamellae without a sinus, and specially by its smaller spores. The dimensions ascribed to the spores of *L. lepideus* by European authors vary. It is possible therefore that *L. spretus* may have been confused by them with the preceding species.

Lentinus tigrinus (Bull.) Fr.

SPOTTED LENTINUS

Pileus thin, subcoriaceous, convex or nearly plane, umbilicate, spotted with innate hairy blackish scales, whitish; lamellae narrow, close, unequal, decurrent, toothed on the edge, white; stem slender,

solid, hard, squamulose, whitish, sometimes brownish toward the base; spores ellipsoid, .0002-.0003 of an inch long, .0001-.00016 broad.

Pileus 1-1.5 inches broad; stem 1-1.5 inches long, 1-2 lines thick.

Decaying wood. A small but attractive species.

There is a common form in which the lamellae are obliterated or overrun by a mass of mycelium or compact tomentum. This was at first thought to be a diseased or abnormal state of the species and was characterized as transforming the lamellae to a "woody mass" or "spongy mass." This form was later thought to be a distinct species and was described under the name *Lentodidium squamulosum* Morg. But since the two forms are sometimes found growing together on the same stump or log and as they both produce spores of the same character it seems better to consider them both forms of one species. We may suppose this abnormal form to develop the hyphae of the hymenium in excessive abundance and that these hyphae bear spores directly without the intervention of basidia. The abnormal form might in such a case be considered in the light of a conidial state of the species.

***Lentinus sulcatus* Berk.**

Panus fulvidus Bres.

SULCATE LENTINUS

Pileus fleshy, thin, tough, conic becoming hemispheric or convex, cracking on the surface and forming irregular scales, virgate toward the margin, sulcate on the margin, reddish or tawny, often darker in the center; lamellae subdistant, rounded behind or emarginate, slightly adnexed, obscurely dentate on the edge, white or pallid; stem central, short, solid, sometimes narrowed downward, pruinose or slightly furfuraceous, white or pallid; spores oblong, .0005-.0007 of an inch long, .00024-.0003 broad.

Pileus 8-12 lines broad; stem 6-10 lines long, 1.5-3 lines thick.

Crevices of dry wood or old fence rails. Essex county. June.

A rare species and found but once in our State. In the dried specimens the margin of the pileus is distinctly sulcate and the grooves are paler than the intervening ridges.

Lentinus cochleatus Fr.

SHELL LENTINUS

Pileus thin, tough, flaccid, irregular, often lobed on the margin, plane, centrally depressed or infundibuliform, glabrous, rufescent or brownish flesh color when moist, paler when dry; lamellae rather broad, close, decurrent, serrate on the edge, whitish tinged with flesh color; stem central, eccentric or lateral, usually crowded and united in a tuft, solid, glabrous, sulcate, colored like or paler than the pileus; spores minute, subglobose, .00016-.0002 of an inch in diameter.

Pileus .5-2 inches broad; stem 1.5-3 inches long, 2-4 lines thick.

On and about old stumps or growing from decaying wood buried in the ground. Adirondack region. July and August.

The species is easily recognized by its tufted mode of growth and its grooved stem. The plants sometimes emit an agreeable odor.

Lentinus umbilicatus Pk.

UMBILICATE LENTINUS

N. Y. State Mus. Rep't 28, p.51, pl.1, fig.15-19

Pileus fleshy but thin, tough, glabrous, deeply umbilicate, hygrophanous, brownish tan color when moist, paler when dry; lamellae close, adnate or decurrent, serrate on the edge, whitish; stem short, slender, glabrous, nearly even, tough, stuffed or hollow, central or eccentric, colored like the pileus.

Pileus 6-12 lines broad; stem 8-12 lines long, 1-1.5 lines thick.

Ground and decaying wood. Gregarious. Hamilton and Essex counties. July and August.

This small species resembles *Lentinus cochleatus* Fr. in texture and color, but it is a much smaller plant, gregarious in its mode of growth and without furrows on the stem. It is closely related to *Lentinus omphalodes* Fr. from which it has been separated on account of its hollow stem without elongated furrows or lacunae and its darker color.

Lentinus ursinus Fr.

BEAR LENTINUS

Pileus fleshy, tough, sessile, dimidiate, often imbricated; even or sometimes costate corrugate on the margin, at first whitish and glabrous then reddish brown and hairy or tomentose toward the

base, taste acrid; lamellae broad, lacerate dentate on the edge, whitish; spores minute, globose, uninucleate, rough, hyaline, .00016 of an inch in diameter.

Pileus 2-3 inches broad.

Decaying wood. Rensselaer and Warren counties. August and September.

This species is remarkable for the change that takes place, as it matures, in its color and ornamentation, and for the hot peppery taste of the flesh. Sometimes the pileus is costate corrugate on the margin in our specimens though such a character is not attributed to the European plant, neither is the acrid flavor.

Lentinus haematopus Berk.

RED STEMMED LENTINUS

Pileus $1\frac{1}{4}$ - $1\frac{3}{4}$ inches broad, umbilicate or depressed, ochraceous, quite smooth; lamellae decurrent, margin lacerated; stem 1-2 lines high, blood-red, almost laccate at the base, $\frac{1}{4}$ inch thick.

North America, locality unknown. [Grevillea, 1:33. 1872]

Pileus thin, plane or centrally depressed, lobed on the margin, glabrous, pale yellow or cream color; lamellae decurrent, dentate serrate, white; stem short, firm, eccentric, glabrous, blood-red; spores unknown.

Pileus 1.5-2 inches broad; stem 2-3 lines long, about 2 lines thick.

Prostrate trunk of striped maple, *Acer pennsylvanicum* L. Essex county. Gansevoort, Saratoga co. July.

This rare species has been found but twice in our State, so far as is known. The original description is so brief and unsatisfactory that it has been quoted and a fuller description, derived from our specimens, added. The essential characters of the original description are so peculiar and the agreement of our specimens with them is so close that we do not doubt their specific unity.

Lentinus suavissimus Fr.

SWEET SCENTED LENTINUS

Pileus thin, tough, convex and umbilicate or centrally depressed, glabrous, even or striate on the margin, whitish or yellowish, flesh white, odor agreeable, resembling the odor of mellilot; lamellae denticulate, decurrent, sometimes wavy and anastomosing at the

base, whitish or yellowish; stem very short or obsolete, central, eccentric or almost lateral, white or whitish; spores minute, .0002-.00024 of an inch long, .0001-.00012 broad.

Pileus 6-15 lines broad; stem about 1 line long, 1 line thick. Dead trunks and branches of willow, *Salix discolor* Muhl. Fulton, Hamilton and Essex counties. July and September.

Rare and variable. It has been collected three times in our State, each time on willow. Its odor is strong but agreeable and perceptible at a distance of several feet.

Specimens formerly referred to *Lentinus lecomtei* Fr., *L. strigosus* Schw. and *L. pelliculosus* Schw. are believed to be erroneous determinations. Therefore descriptions of these species are omitted.

NEW YORK SPECIES OF ENTOLOMA

Entoloma Fr.

Pileus subcarneous, margin at first incurved; hymenophorum continuous with the stem; veil not distinct; lamellae sinuate-adnexed or seceding; stem fleshy, fibrous or waxy, soft; spores pink, typically angular.

This genus corresponds to Tricholoma of the white spored series. The species are terrestrial and occur chiefly during showery weather in summer and early autumn. They may be divided into four subgenera or sections.

KEY TO THE SECTIONS.

- | | |
|---|------------|
| Pileus thin, subsilky when dry, hygrophanous..... | Nolanidea |
| Pileus flocculose or squamulose, dry..... | Leptonidea |
| Pileus glabrous, moist or viscid, not hygrophanous..... | I |
| i Pileus conic or subcampanulate..... | Conoidea |
| i Pileus convex or nearly plane..... | Genuina |

Genuina

Pileus glabrous, moist or viscid, not hygrophanous. Large or medium in size with pileus usually convex or becoming so and stem stout.

KEY TO THE SPECIES

- | | |
|--|-----------|
| Pileus even, not umbonate..... | sinutatum |
| Pileus centrally wrinkled, umbonate..... | grande |

Entoloma sinuatum Fr.

SINUATE ENTOLOMA

Pileus fleshy, convex becoming expanded or centrally depressed, glabrous, moist, even, spreading or wavy on the margin, yellowish white, flesh white; lamellae slightly adnexed, very broad, close, pallid becoming pinkish or rufescent; stem stout, equal, firm, solid, fibrillose becoming glabrous, white; spores subglobose, angular, .0003-.0004 of an inch in diameter.

Pileus 2-3 inches broad; stem 3-5 inches long, 5-6 lines thick.

Rare. West Shokan, Ulster co. August. Snyders, Rensselaer co. July.

Entoloma grande Pk.

GRAND ENTOLOMA

N. Y. State Mus. Rep't 50, p.101

Pileus fleshy, thin toward the margin, convex becoming nearly plane, generally umbonate and centrally rugosely wrinkled, moist in wet weather, glabrous, yellowish white becoming brownish or grayish brown, flesh white, odor and flavor farinaceous; lamellae broad, subdistant, slightly adnexed becoming free or nearly so, often wavy or eroded on the edge, whitish becoming pinkish; stem equal, solid, slightly fibrous externally, mealy at the top, white; spores subglobose, angular, .0003-.0004 of an inch in diameter.

Pileus 4-6 inches broad; stem 4-6 inches long, 8-12 lines thick. Woods. Menands, Albany co. August.

The flavor is at first farinaceous and agreeable but it leaves an unpleasant burning sensation in the mouth for a long time. It is therefore probably an unwholesome species and should not be used as food.

Conoidea subg. nov.

Small species with the pileus subsistently conic or campanulate and stem slender, long and hollow. Small slender species growing in damp shaded places, in vegetable mold, among mosses or in bogs and swamps. The lamellae are rather broad, ascending and often wavy or eroded on the edge. The species appear to be peculiar to this country.

KEY TO THE SPECIES

- ' Pileus salmon color *salmoneum*
- Pileus not salmon color.....*I*

- 1 Pileus brown or blackish brown.....peckianum
- 1 Pileus some other color.....2
- 2 Pileus persistently pale yellow, cuspidate.....cuspidatum
- 2 Pileus destitute of these characters.....3
- 3 Pileus yellow or smoky yellow.....luteum
- 3 Pileus pale yellow becoming darker with age.....variabile
- 3 Pileus grayish brownminus

Entoloma salmonicum Pk.

SALMON ENTOLOMA

N. Y. State Mus. Rep't 24, p.65, pl.4, fig.6-9

Pileus thin, conic or campanulate, subacute or with a minute papilla or small cusp at the apex, glabrous, moist, salmon color, the margin sometimes uneven or lobed; lamellae broad, subdistant, ventricose, salmon color; stem slender, equal, glabrous, hollow, colored like the pileus; spores subglobose, angular, .0004-.0005 of an inch in diameter.

Pileus 8-15 lines broad; stem 3-6 inches long, 1-2 lines thick. Gregarious. Damp ground in dense woods, specially under spruce and balsam fir trees or among mosses. Rensselaer county and Adirondack region. July and August.

Entoloma cuspidatum Pk.

CUSPIDATE ENTOLOMA

N. Y. State Mus. Rep't 24, p.64, pl.2, fig.14-18

Pileus thin, conic or campanulate, moist, shining, glabrous, with a distinct cusp at the apex, pale yellow, the thin margin exceeding the lamellae, often irregular or slightly lobed; lamellae ascending, broad, subdistant, narrowed toward the stem, adnexed, often eroded or subdenticulate on the edge, pale yellow becoming flesh color; stem equal, hollow, glabrous, slightly fibrous, colored like the pileus; spores subglobose, angular, .0004-.0005 of an inch in diameter.

Pileus 8-12 lines broad; stem 3-5 inches long, 1-2 lines thick.

Swamps and sphagnum marshes. Rensselaer county and Adirondack region. Also on Fishers island. C. C. Hamner. August and October.

Closely allied to *E. salmonicum* Pk. from which it scarcely differs except in color and in the more fully and commonly developed cusp of the pileus. In both, the moist pileus is sometimes striatulate, the position of the lamellae being faintly shown through

the thin margin of the pileus. In both species the plants usually become darker in drying.

Entoloma peckianum Burt

PECK ENTOLOMA

N. Y. State Mus. Rep't 54, p.146, pl.F, fig.9-16

Pileus thin, conic becoming very convex or subcampanulate, moist, brown or blackish and shining, paler after the escape of the moisture, umbonate, obscurely roughened by the matted ends of minute fibrils; lamellae ascending, subclose, broad, abruptly rounded behind, adnexed, whitish becoming pink; stem slender, equal, hollow, fibrillose striate, pale brown, often with white mycelium at the base, white within; spores angular, uninucleate, .0004-.0005 of an inch long, .0003-.0004 broad.

Pileus 8-15 lines broad; stem 2-4 inches long, 1-2 lines thick.

In sphagnum marshes. Floodwood, Franklin co. August.

In drying the pileus assumes a black color.

Entoloma luteum Pk.

YELLOW ENTOLOMA

N. Y. State Mus. Rep't 54, p.146, pl.F, fig.1-8

Pileus thin, conic or subcampanulate, obtuse or subumbonate, moist, sometimes squamulose at the apex, yellow or smoky yellow, a little paler after the escape of the moisture, sometimes tinged with green; lamellae ascending, moderately close, broad, whitish becoming pale salmon color; stem slender, equal, hollow, slightly fibrillose striate, colored like the pileus, with white mycelium at the base; spores subquadrate, angular, .0004-.0005 of an inch in diameter.

Pileus 6-10 lines broad; stem 3-4 inches long, 1-2 lines thick.

Mossy ground in woods. Floodwood, Franklin co. August.

The squamules of the center of the pileus, when present, are so minute that they may be easily overlooked. To the naked eye the pileus appears to be glabrous.

Entoloma variabile Pk.

VARIABLE ENTOLOMA

N. Y. State Mus. Rep't 54, p.145, pl.F, fig.17-27

Pileus thin, conic, ovate or subcampanulate, umbonate, obtuse or subumbilicate, moist, slightly fibrillose, pale yellow when young,

becoming reddish brown with age, either wholly or in the center only; lamellae ascending, moderately close, broad in front, often eroded on the edge, white or whitish, becoming pale salmon color; stem long, slender, equal, hollow, slightly fibrillose striate, whitish or pallid sometimes becoming reddish brown with age, often with a whitish mycelium at the base; spores subglobose, angular, uninucleate, .0004-.0005 of an inch in diameter.

Pileus 8-15 lines broad; stem 3-5 inches long, 1-2 lines thick.

In sphagnous marshes. Floodwood, Franklin co. August.

Remarkable for the variability in the shape and color of the pileus. Specimens sometimes appear as if they had been sun scorched.

Entoloma minus Pk.

SMALLER ENTOLOMA

N. Y. State Mus. Bul. 116, p.23

Pileus very thin, subconic or hemispheric becoming convex, glabrous, grayish brown, darker in the center; lamellae thin, close, at first ascending, sinuate, adnexed, whitish becoming flesh color; stem slender, glabrous, hollow, white; spores subglobose, angular, .0003-.0004 of an inch in diameter.

Pileus 8-12 lines broad; stem 1-1.5 inches long, about 1 line thick.

Ground in woods. East Schaghticoke, Rensselaer co. August.

A small rare species which departs somewhat from the general character of this subgenus, but agrees better with it than with any other.

Leptonidea

Pileus flocculose or squamulose, dry.

KEY TO THE SPECIES

Pileus umbonate	jubatum
Pileus not umbonate.....	1
1 Pileus white	sericellum
1 Pileus not white.....	2
2 Pileus with violaceous tints.....	cyanescens
2 Pileus not having violaceous tints.....	3
3 Pileus minutely scabrous.....	scabrinellum
3 Pileus squamulose	dysthales
3 Pileus silky, yellowish green.....	flavoviride

Entoloma jubatum Fr.

CRESTED ENTOLOMA

Pileus somewhat fleshy, campanulate becoming expanded, umbo-nate, dry, villose squamulose or fibrillose, grayish brown or mouse color; lamellae close, ventricose, slightly adnexed, easily separating from the stem, smoky brown; stem equal, fibrous, stuffed or hollow, fragile, brownish; spores irregular, subelliptic, .0004-.0005 of an inch long, .00024-.0003 broad.

Pileus 1-2 inches broad; stem 1-2 inches long, 2-3 lines thick.

Ground under white birch trees. West Albany. September. Very rare.

Entoloma sericellum Fr.

SLIGHTLY SILKY ENTOLOMA

Pileus thin, convex becoming plane or centrally depressed, dry, silky, squamulose or nearly glabrous, white or yellowish, the margin at first inflexed and floccose; lamellae broad, subdistant, adnate, easily separating from the stem, flesh color; stem equal, hollow, fibrillose becoming glabrous, somewhat waxy, white; spores irregular, angular, .0003-.0005 of an inch long, .00024-.0003 broad.

Pileus .5-1 inch broad; stem 1-2 inches long, about 1 line thick. Ground. Catskill mountains. July.

A rare species found but once in our limits. It may be distinguished from *Entoloma speculum* Fr., a somewhat similar white species, by its dry silky pileus.

Entoloma cyaneum Pk.

VIOLACEOUS ENTOLOMA

N. Y. State Mus. Rep't 26, p.55

Pileus convex, dry, minutely squamulose, brown or brownish violaceous; lamellae close, whitish becoming tinged with pink; stem equal or slightly thickened downward, hollow, squamulose and violaceous at the top; spores angular, .0003 of an inch long, .00024 broad.

Pileus 1-1.5 inches broad; stem 1.5-2 inches long, 1-1.5 lines thick.

Decaying wood and old mossy logs. Catskill mountains and Worcester, Otsego co. June and July. Rare.

Entoloma scabrinellum Pk.

SLIGHTLY SCABROUS ENTOLOMA

N. Y. State Mus. Rep't 33, p.19

Pileus thin, convex or nearly plane, papillate or with a small umbo, minutely scabrous, dark brown, the thin incurved margin slightly surpassing the lamellae; lamellae broad, close, rounded behind, ventricose, adnexed, floccose on the edge, whitish becoming pink; stem equal, fibrillose, pruinose at the top, paler than the pileus; spores irregular, uninucleate, .0003-.0004 of an inch long, .0002-.0003 broad.

Pileus 6-10 lines broad; stem about 1 inch long and 1 line thick.

Shaded gravelly soil. Wading River, Suffolk co. September.

A rare species, found but once. Its hairy roughness is scarcely visible to the naked eye.

Entoloma flavoviride Pk.

YELLOWISH GREEN ENTOLOMA

N. Y. State Mus. Rep't 41, p.64

Pileus thin, broadly conic becoming convex, sometimes concave by the upcurving of the margin, yellowish green, slightly silky and shining; lamellae broad, subdistant, ventricose, slightly adnexed or free, cinereous becoming pinkish; stem equal, hollow, fibrillose striate, whitish; spores angular, uninucleate, .00045-.0005 of an inch long, .0003-.0004 broad.

Pileus 6-12 lines broad; stem 1-2.5 inches long, 1-2 lines thick.

Low swampy woods. Karner, Albany co. August.

The species is readily recognized by its peculiar yellowish green pileus.

Entoloma dysthales Pk.

STUNTED ENTOLOMA

N. Y. State Mus. Rep't 32, p.28

Pileus thin, submembranaceous, subconic becoming convex or expanded, obtuse, furfuraceous or squamulose, striate, brown becoming paler with age; lamellae broad, subdistant, ventricose, brown or grayish brown, becoming flesh color; stem slender, equal, hollow, squamulose, brownish; spores irregular, oblong-elliptic,

usually uninucleate, .0006-.00065 of an inch long, .0003-.00034 broad.

Pileus 3-6 lines broad; stem 1-1.5 inches long, about 1 line thick.
Damp ground in woods. Catskill mountains. July.

The stunted entoloma has a peculiar starved or deformed appearance which is suggestive of the specific name. To the naked eye the pileus and stem appear to be clothed with minute scales, but under a good lens these are seen to be jointed matted filaments which seem to form a kind of tufted tomentum. In some specimens this tomentum is more dense than in others.

Nolanidea

Pileus thin, hygrophanous, subsilky when dry, often wavy and irregular. The hygrophanous pileus is the principal feature that distinguishes the species of this subgenus from the others.

Entoloma flavifolium Pk.

YELLOW GILLED ENTOLOMA

N. Y. State Mus. Bul. 105, p.21, pl.S, fig.9-15

Pileus thin, firm, broadly convex or nearly plane, glabrous, hygrophanous, watery white and sometimes striatulate on the margin when moist, white when the moisture has disappeared, flesh colored like the surface of the pileus, taste mild or slightly and tardily acrid; lamellae thin, close, rounded behind, adnexed, slightly eroded on the edge, pale yellow becoming pinkish; stem firm, equal, silky fibrillose, stuffed or hollow, whitish, with a white

mealiness at the top; spores subglobose, slightly angular, bright pink, .0003-.0004 of an inch broad, apiculate at one end.

Pileus 1-2 inches broad; stem 1.5-2 inches long, 2-4 lines thick.

Among fallen leaves in dense woods. Port Henry, Essex co. August. Scarce.

The species is well marked by the yellow lamellae. Sometimes the margin of the pileus is wavy or irregular and the center tinged with brown when moist.

Entoloma nidorosum Fr.

STRONG SCENTED ENTOLOMA

Pileus thin, convex becoming nearly plane or centrally depressed, glabrous, hygrophanous, pallid or grayish brown when moist, silky and shining when dry, fragile, odor alkaline; lamellae broad, sub-distant, emarginate, nearly free, sometimes wavy, pallid becoming flesh color; stem equal, glabrous, stuffed, pruinose or mealy at the top, whitish; spores irregular, angular, .0003-.0004 of an inch long, .00024-.0003 broad.

Pileus 1-3 inches broad; stem 2-3 inches long, 2-3 lines thick.

Woods. Shokan, Ulster co. September.

In our specimens the stem is solid and the lamellae are adnate, characters not agreeing well with the description of the species.

Entoloma griseum Pk.

GRAYISH ENTOLOMA

N. Y. State Mus. Bul. 75, p.14

Pileus fleshy, firm, broadly campanulate or convex, obtuse or slightly umboinate, glabrous, often irregular, hygrophanous, grayish brown when moist, paler when dry, flesh whitish, odor and taste farinaceous; lamellae adnexed, emarginate, decurrent with a tooth, about 2 lines broad, pale pink; stem equal or slightly tapering upward, silky-fibrillose, pruinose at the apex, stuffed or hollow, grayish white; spores subglobose, angular, .0003 of an inch in diameter.

Pileus 1-3 inches broad; stem 1-2 inches long, 3-5 lines thick.

Under spruce and balsam fir trees. Lake Pleasant, Hamilton co. August.

This species may be separated from *E. grayanum* Pk. by its darker color, narrower gills and different place of growth.

Entoloma sericeum Fr.

SILKY ENTOLOMA. MEADOW ENTOLOMA

Pileus fleshy but thin, convex becoming nearly plane, sometimes minutely umbilicate, glabrous, hygrophanous, brownish when moist, paler silky and shining when dry, incurved on the margin, odor and taste farinaceous; lamellae rather broad, subdistant, adnexed, grayish becoming salmon color; stem short, equal, hollow, fibrillose, colored like or paler than the pileus; spores subglobose, angular, .0003-.0004 of an inch long, .00024-.0003 broad.

Pileus 1-2 inches broad; stem 1-2 inches long, 1-2 lines thick.

Meadows and pastures. West Albany. June. Very rare. Found but once.

Entoloma grayanum Pk.

GRAY ENTOLOMA

N. Y. State Mus. Rep't. 24, p.64

Pileus fleshy, convex becoming nearly plane, often wavy or irregular on the margin, glabrous, hygrophanous, watery white or yellowish white when moist, shining and whitish when dry; lamellae close, adnexed, whitish becoming pink; stem equal, firm, solid, white; spores subglobose, angular, .0003 of an inch in diameter.

Pileus 1.5-2 inches broad; stem 2-3 inches long, 3-5 lines thick.

Old wood roads and pastures. Rensselaer and Essex counties. August to October. Not common.

Entoloma rhodopolium Fr.

ROSY ENTOLOMA

Pileus thin, fleshy, fragile, subcampanulate, nearly plane or slightly depressed in the center, fibrillose when young, soon glabrous, hygrophanous, brownish and striatulate on the margin when moist, silky, shining and livid isabelline when dry, flesh white; lamellae subdistant, sinuate, adnate, white becoming rosy; stem equal or tapering upward, hollow, pruinose or mealy at the top, white; spores angular, .0003-.0004 of an inch long, .00024-.0003 broad.

Pileus 1.5-3 inches broad; stem 1.5-4 inches long, 2-3 lines thick.

Woods. Albany county and Adirondacks. August and September.

Entoloma rhodopolium umbilicatum Pk. [N. Y. State Mus. Rep't 38, p.109] is not a good entoloma and has been published in the 40th report, page 53 under the name *Clitopilus subvilis* Pk.

Entoloma clypeatum L.

SHIELD ENTOLOMA

Pileus fleshy but thin, fragile, campanulate, then expanded, umboonate or sometimes obtuse, glabrous, hygrophanous, lurid or brown when moist, gray and somewhat shining when dry, sometimes virgate and spotted, flesh white; lamellae broad, ventricose, subdistant, rounded behind, adnexed, seceding, serrulate on the edge, dingy flesh color; stem equal, fragile, fibrillose, stuffed or hollow, slightly pruinose at the top, white or grayish; spores irregular, subangular, .0003-.0004 of an inch in diameter.

Pileus 1.5-3 inches broad; stem 2-3 inches long, 2-4 lines thick.

Grassy places, sometimes among sphagnum. Albany, Rensselaer and Steuben counties. Spring and autumn.

Entoloma strictius irregulare Pk. in the 53d Report of the New York State Museum, page 856, plate D, figures 8-15, appears now to belong to this species rather than to *E. strictius*.

Entoloma strictius Pk.

STRICT ENTOLOMA

N. Y. State Cab. Rep't 23, p.88, pl.2, fig.6-9

Pileus submembranous, broadly convex or expanded, umboonate, glabrous, shining, hygrophanous, grayish brown and generally striatulate on the margin when moist, paler when dry; lamellae broad, rounded behind, adnexed or nearly free, whitish becoming flesh color; stem straight, equal or slightly tapering upward, silky fibrillose or glabrous, hollow, colored like or a little paler than the pileus, often a dense mycelioid tomentum at the base; spores angular, .0004-.0005 of an inch long, .0003-.0004 broad.

Pileus 1-2 inches broad; stem 2-4 inches long, 1-2 lines thick.

Damp places in woods or their borders. June to October.

The regular pileus and usually straight stem give a beautiful and symmetrical appearance to this species.

Entoloma graveolens Pk. [N. Y. State Mus. Rep't 53, p.844 and 54, p.165] has been omitted. It is closely allied to

Tricholoma personatum Fr. and probably will eventually form with it, *Tricholoma nudum* (Bull.) Fr. and *T. sordidum* (Schum.) Fr. a distinct genus.

The following extralimital species are represented in the herbarium: *Entoloma deminutivum* Pk., *E. modestum* Pk., *E. murinum* Pk., *E. nigricans* Pk. and *E. suave* Pk. These are from Massachusetts and it is probable that some of them may yet be found in our State.

N. Y. State Mus. Rep't 49, p.41. 1896. Bot. ed.

Agaricus (Collybia) coloreus Pk.

Buf. Soc. Nat. Sci. Bul. 1, p.46. July 1873

N. Y. State Mus. Rep't 26, p.54-55. 1874

N. Y. State Mus. Rep't 49, p.50-51. 1896. Bot. ed.

Collybia colorea Pk. var. rubescensifolia Pk.

N. Y. State Mus. Rep't 49, p.51. 1896. Bot. ed.

N. Y. State Mus. Rep't 39, p.38. 1886. (As *Agaricus (Tricholoma) rubescensifolius Pk.*)N. Y. State Mus. Rep't 41, p.83. 1888. (As *Collybia rubescensifolia Pk.*)

N. Y. State Mus. Rep't 44, p.64. 1891. Bot. ed. (Note)

Collybia confluens campanulata Pk. var. niveipes Pk.

N. Y. State Mus. Bul. 54, p.963. 1902

*Collybia cremoracea Pk. (Collybia esculentoides Pk.)**Agaricus (Collybia) delicatellus Pk.*

N. Y. State Mus. Rep't 30, p.39. 1878

N. Y. State Mus. Rep't 49, p.46. 1896. Bot. ed.

Agaricus (Collybia) esculentoides Pk.

N. Y. State Mus. Rep't 39, p.39. 1886

N. Y. State Mus. Rep't 49, p.45-46. 1896. Bot. ed.

N. Y. State Mus. Rep't 32, p.26. 1879. (As *Agaricus (Collybia) cremoraceus Pk.*)

N. Y. State Mus. Bul. 2, p.12. 1887

Collybia esculentoides Pk. var. ochroleuca Pk.

N. Y. State Mus. Rep't 49, p.45. 1896. Bot. ed.

N. Y. State Mus. Rep't 46, p.24. 1893. Bot. ed. (As *Collybia ochroleuca Pk.*)

Collybia expallens Pk.

N. Y. State Mus. Rep't 44, p.18. 1891. Bot. ed.

N. Y. State Mus. Rep't 49, p.52-53. 1896. Bot. ed.

Agaricus (Collybia) familia Pk.

N. Y. State Cab. Rep't 23, p.79-80. 1872. Bot. ed.

N. Y. State Mus. Rep't 44, p.35. 1891. Bot. ed. (Note)

N. Y. State Mus. Rep't 49, p.47-48. 1896. Bot. ed.

N. Y. State Mus. Bul. 75, p.28-29, pl.84, fig.1-7. 1904

Collybia fuliginella Pk.

N. Y. State Mus. Rep't 40, p.53. 1887

N. Y. State Mus. Rep't 49, p.36-37. 1896. Bot. ed.

Agaricus (Collybia) fuscolilacinus Pk.

N. Y. State Mus. Rep't 39, p.38-39. 1886

N. Y. State Mus. Rep't 49, p.53. 1896. Bot. ed.

Collybia hirticeps Pk.

Torr. Bot. Club Bul. 34, p.98. Feb. 1907

Agaricus (Collybia) hygrophorooides Pk.

N. Y. State Mus. Rep't 32, p.26-27. 1879

N. Y. State Mus. Bul. 2, p.12, pl.2, fig.23-26. 1887

N. Y. State Mus. Rep't 49, p.51. 1896. Bot. ed.

Collybia lacunosa Pk.

N. Y. State Mus. Rep't 44, p.64. 1891. Bot. ed.

N. Y. State Mus. Bul. 122, p.132. 1908. (Note)

Buf. Soc. Nat. Sci. Bul. 1, p.43. July 1873. (As Agaricus (Tricholoma) lacunosus Pk.)

N. Y. State Mus. Rep't 26, p.51. 1874

Agaricus (Collybia) lentinoides Pk.

N. Y. State Mus. Rep't 32, p.27. 1879

N. Y. State Mus. Rep't 49, p.51-52. 1896. Bot. ed.

Collybia lentinoides Pk. var. flaviceps Pk. var. rufipes Pk.

N. Y. State Mus. Rep't 41, p.83. 1888

Collybia lignarius Pk.

N. Y. State Mus. Rep't 54, p.145. 1901

Collybia luxurians Pk.

Torr. Bot. Club Bul. 24, p.141. Mar. 1897

Collybia microspora Pk.

Torr. Bot. Club Bul. 22, p.486. Dec. 1895

Agaricus (Collybia) myriadophyllus Pk.

Buf. Soc. Nat. Sci. Bul. 1, p.47. July 1873

N. Y. State Mus. Rep't 25, p.75. 1873

N. Y. State Mus. Rep't 49, p.50. 1896. Bot. ed.

EXPLANATION OF PLATES

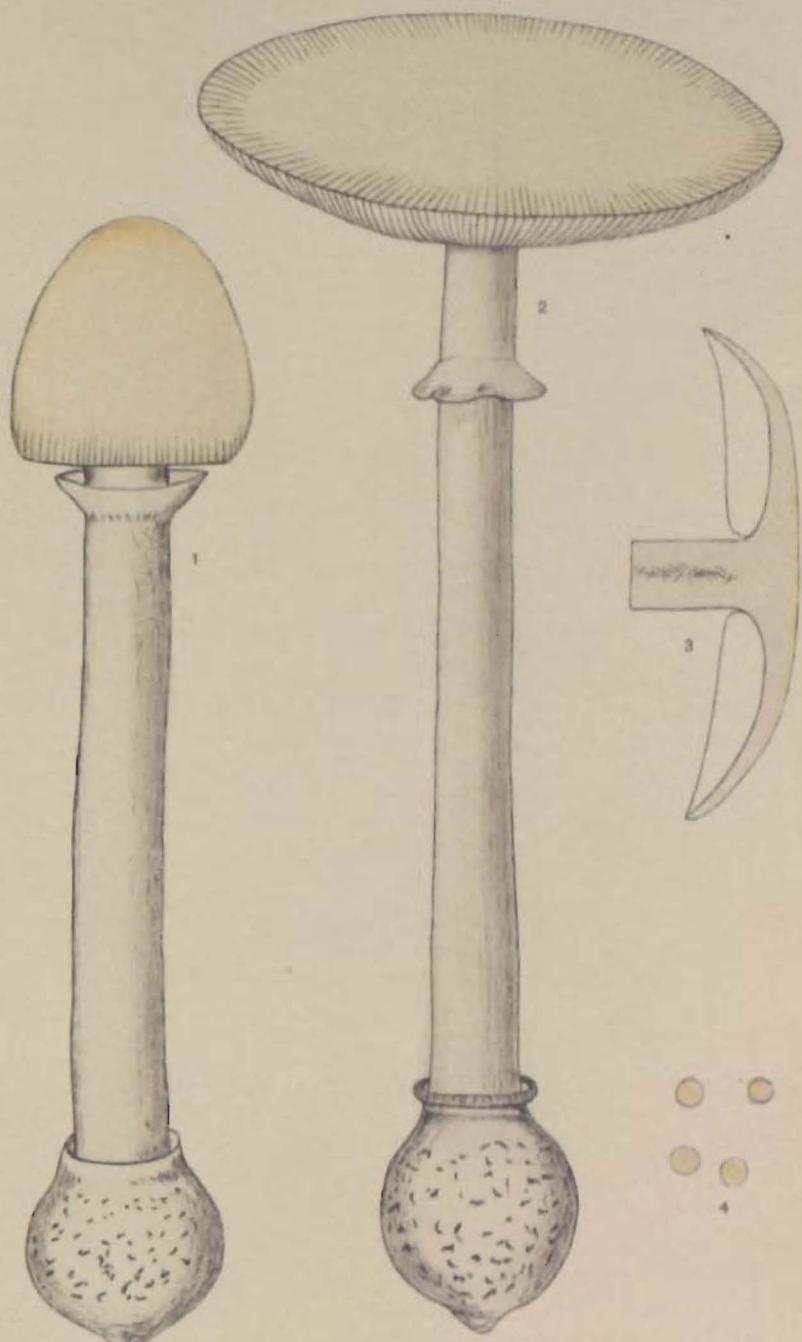

PLATE U

191

Amanita glabriceps Pk.

SMOOTH CAP AMANITA

- 1 Immature plant
- 2 Mature plant
- 3 Vertical section of the upper part of a plant
- 4 Four spores, x 400

AMANITA GLABRICEPS Pk.
SMOOTH CAP AMANITA

PLATE V

193

Hypholoma fragile Pk.

FRAGILE HYPHOLOMA

- 1 Immature plant showing floccose squamules on the cap and an appendiculate margin
- 2 Immature plant showing whitish color of the gills
- 3 Mature plant
- 4 Vertical section of the upper part of an immature plant
- 5 Vertical section of the upper part of a mature plant
- 6 Transverse section of a stem
- 7 Four spores, $\times 400$

Extralimital species

Agaricus approximans Pk.

APPROXIMATE MUSHROOM

- 8 Two immature plants united at the base
- 9 Immature plant
- 10 Mature plant
- 11 Vertical section of the upper part of an immature plant
- 12 Vertical section of the upper part of a mature plant
- 13 Transverse section of a stem
- 14 Four spores, $\times 400$

Galera besseyi Pk.

BESSEY GALERA

- 15 Immature plant
- 16 Mature plant with oval cap
- 17 Mature plant with subglobose cap
- 18 Vertical section of the upper part of a plant
- 19 Transverse section of a stem
- 20 Four spores, $\times 400$

FIG. 1-7.
HYPHOLOMA FRAGILE Pk.
FRAGILE HYPHOLOMA

EXTRA-LIMITAL FUNGI

FIG. 8-14.
AGARICUS APPROXIMANS Pk.
APPROXIMATE MUSHROOM

FIG. 15-20.
GALEREA BESSEYI Pk.
BESSEY GALERA

PLATE 115

195

Tricholoma sordidum (Schum.) Fr.

SORDID TRICHOLOMA

- 1 Cluster of very young plants
- 2 Cluster of three young plants slightly older
- 3 Immature moist plant showing color of young gills
- 4 Mature plant with margin of cap still moist
- 5 Mature plant with cap fully expanded
- 6 Vertical section of the upper part of an immature plant
- 8 Vertical section of the upper part of a mature plant
- 9 Four spores, x 400

TRICHOLOMA SORDIDUM (SCHUM.) FR.
SORDID TRICHOLOMA

PLATE 116

197

Pholiota duroides Pk.

HARDISH PHOLIOTA

- 1 Immature plant
- 2 Mature plant with a broad umbo
- 3 Mature plant with a scaly disk
- 4 Vertical section of the upper part of an immature plant
- 5 Vertical section of the upper part of a mature plant
- 6 Transverse section of a stem
- 7 Four spores, $\times 400$

Phylloporus rhodoxanthus (Schw.) Bres.

YELLOW RED PHYLLOPORUS

- 8 Immature plant
- 9 Mature plant
- 10 Vertical section of the upper part of a plant
- 11 Four spores, $\times 400$

Cantharellus minor Pk.

SMALL CHANTARELLE

- 12 Immature plant
- 13 Mature plant with convex cap
- 14 Mature plant with cap nearly plane
- 15, 16 Vertical sections of the upper part of two plants
- 17 Four spores, $\times 400$

FIG. 1-7.

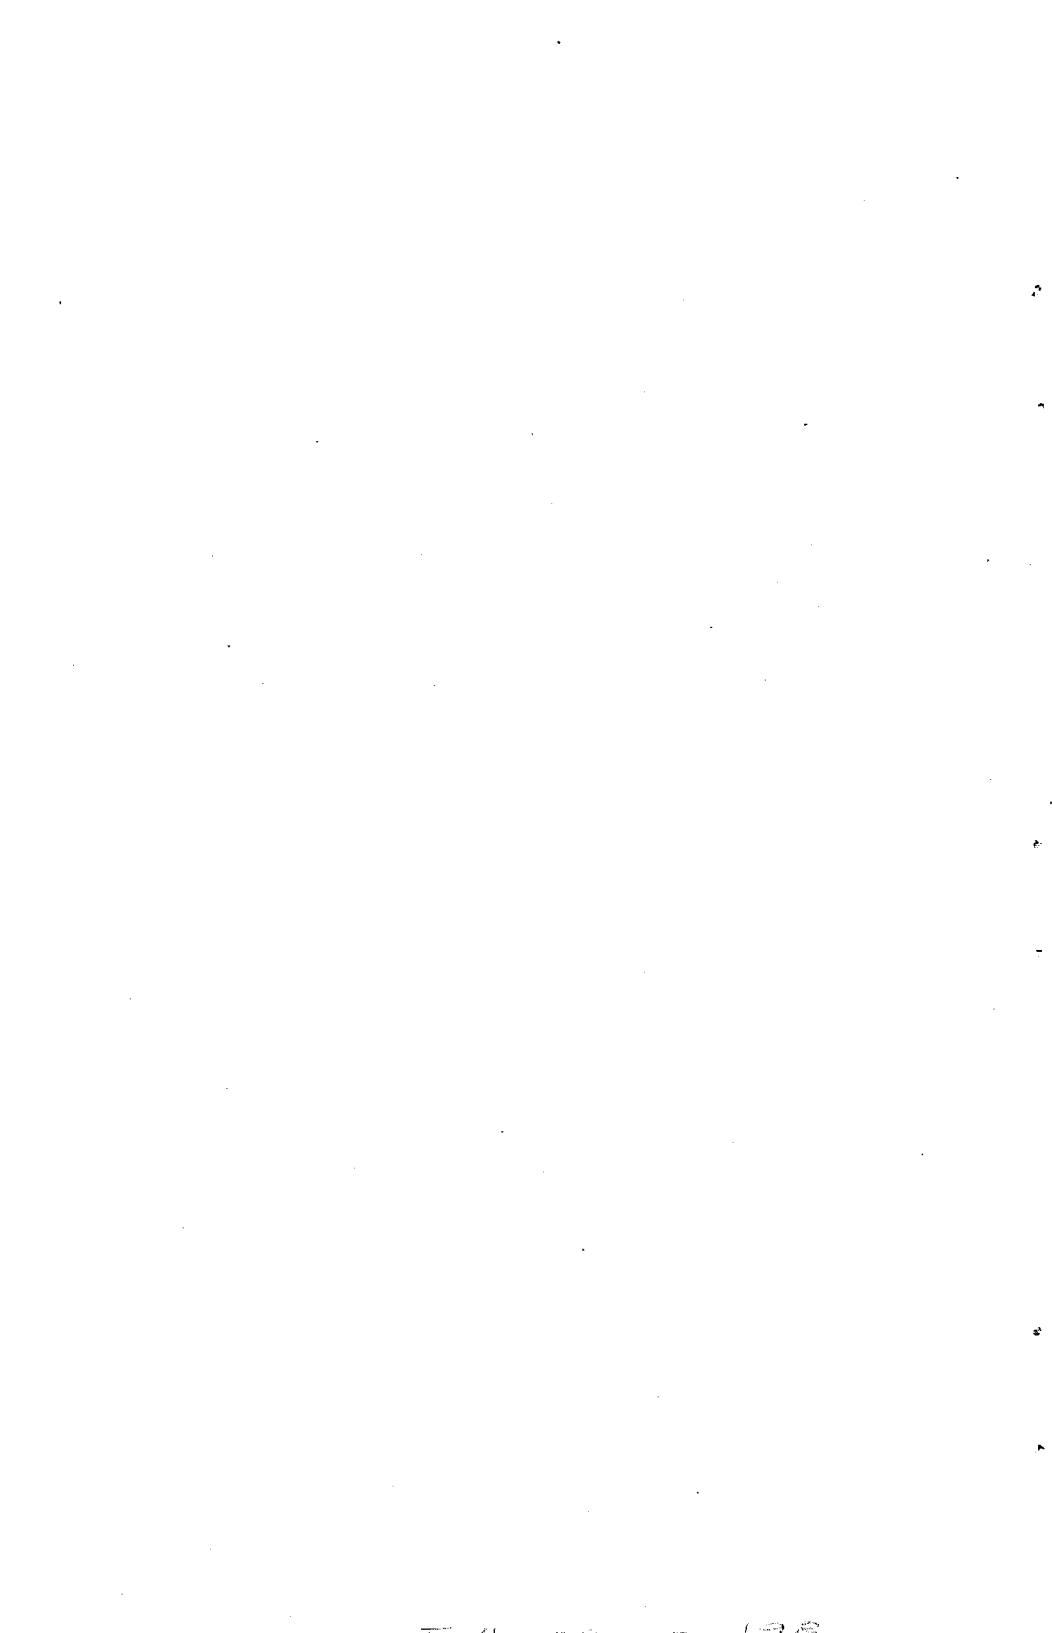

PHOLIOTA DUROIDES Pk.
HARDISH PHOLIOTA

PHYLLOPORUS RHODOXANTHUS (SCHW.) BRES.
YELLOW RED PHYLLOPORUS

FIG. 12-17.

CANTHARELLUS MINOR Pk.
SMALL CHANTARELLE

INDEX

- Aecidium importatum**, 18.
Agaricus applicatus, 25.
 approximans, 33.
 explanation of plate, 194.
 campester, 8.
 pelletieri, 40.
 placomyces, 33.
 rhodoxanthus, 40.
Amanita elongata, 33-34.
 glabriceps, 18-19.
 explanation of plate, 192.
 phalloides, 18.
 striatula, 18.
 porphyria, 19.
Aster vittatus, 19.
- Bear lentinus**, 45-46.
Boletinus glandulosus, 34.
Boletus subtomentosus, 41.
Botrytis cinerea, 21.
 plebeja, 19.
Brachysporium obovatum, 29.
Brassica japonica, 19.
- Calicium albovatrum**, 19.
California pepper grass, 19.
Cantharellus cibarius, 41.
 minor, 41-42.
 explanation of plate, 198.
Castanea dentata, 29.
Celtis crassifolia, 19.
Cephalanthus occidentalis, 30.
Cephalozia lunulæfolia, 19.
Cercospora rudbeckiae, 19-20.
Chantarelle, small, 41-42.
Chantarelle craterellus, 42.
Choriactis, 32.
Clavaria ligula, 35.
 pallescens, 34-35.
Clitocybe clavipes, 20.
 comitialis, 20.
 pelletieri, 40.
Clitopilus, 39.
 subvillus, 57.
- Collybia hirticeps**, 20.
Cololejeunea biddlecomiae, 20.
Commelina communis, 20.
Conoidea, 47, 48.
Craterellus cantharellus, 42.
Craterellus chantarelle, 42.
Crested entoloma, 52.
Cuspidate entoloma, 49-50.
- Dacryomyces corticioides**, 20.
Diaporthe atropuncta, 20-21.
 farinosa, 20.
 parasitica, 24.
Diplodina coronilla, 21.
 robiniae, 21.
- Early pholiota**, 40.
Edible fungi, 6-8, 38-42.
Entoloma, New York species, 47-58.
 crested, 52.
 cuspidate, 49-50.
 grand, 48.
 gray, 56.
 grayish, 55.
 meadow, 56.
 Peck, 50.
 rosy, 56-57.
 salmon, 49.
 shield, 57.
 silky, 56.
 sinuate, 48.
 slightly seabrous, 53.
 slightly silky, 52.
 smaller, 51.
 strict, 57-58.
 strong scented, 55.
 stunted, 53-54.
 variable, 50-51.
 violaceous, 52.
 yellow, 50.
 yellow gilled, 54-55.
 yellowish green, 53.

- Entoloma, 7, 47-58; key to sections, 47; key to species, 47, 48-49, 51, 54.
 clypeatum, 54, 57.
 cuspidatum, 49-50.
 cyanatum, 51, 52.
 deminutivum, 58.
 dysthales, 51, 53-54.
 flavifolium, 54-55.
 flavoviride, 51, 53.
 grande, 47, 48.
 graveolens, 57.
 grayatum, 54, 55, 56.
 griseum, 54, 55.
 jubatum, 51, 52.
 luteum, 49, 50.
 minus, 49, 51.
 modestum, 58.
 murinum, 58.
 nidorosum, 54, 55.
 nigricans, 58.
 peckianum, 49, 50.
 rhodopodium, 54, 56-57.
 umbilicatum, 57.
 salmonicum, 48, 49.
 seabinellum, 51, 53.
 sericellum, 51, 52.
 sericeum, 54, 56.
 sinuatum, 47, 48.
 strictius, 54, 57-58.
 irregulare, 57.
 suave, 58.
 variabile, 49, 50-51.
- Epicoccum neglectum, 30.
Eupatorium sessilifolium, 30.
 Explanation of plates, 191-98.
- Flammula paradoxa*, 40.
 tammi, 40.
- Fungi, edible, 6-8, 38-42; new extrazonal species, 33-42; list of species and varieties, 59-190.
- Fusarium aurantiacum*, 21.
- Galera besseyi*, 35-36.
 explanation of plate, 194.
- Genuina*, 47.
- Geoglossum alveolatum*, 21.
- Gloeosporium medicaginis*, 21.
- Gomphidius rhodoxanthus*, 40.
Gonatobotrys lateritia, 21-22.
Grand entoloma, 48.
Gray entoloma, 56.
Grayish entoloma, 55.
- Hard pholiota**, 39.
Hardish pholiota, 39-40.
- Hendersonia brunaudiana*, 23.
diploidoides divergens, 38.
- Hydrangea arborescens*, 30.
- Hygrophorus obconicus*, 36.
 pratensis albus, 36.
sphaerosporus, 22.
- Hymenula musae*, 22.
- Hypholoma fragile*, 22.
 explanation of plate, 194.
- Hypoderma desmazieri*, 30.
- Inocybe asterospora**, 37.
 intricata, 36-37.
umboninota, 37.
- Key to Lentinus**, 42; *Entoloma*, 47, 48-49, 51, 54.
- Lactarius peckii**, 22.
- Lecanora fuscata*, 22.
- Lentinus*, New York species, 42-47.
 bear, 45-46.
 red stemmed, 46.
 scaly, 42-43.
 shell, 45.
 spotted, 43-44.
 spurned, 43.
 sulcate, 44.
 sweet scented, 46-47.
 umbilicate, 45.
- Lentinus*, 7, 42-47; key to species, 42.
- cochleatus, 42, 45.
haematopus, 42, 46.
lecomtei, 47.
lepidus, 42-43.
omphalodes, 45.
pelliculosus, 47.
spretus, 42, 43.
strigosus, 47.

- Lentinus (*continued*).
 suavissimus, 42, 46-47.
 sulcatus, 42, 44.
 tigrinus, 42, 43-44.
 umbilicatus, 42, 45.
 ursinus, 42, 45-46.
- Lentodium squamulosum, 44.
- Leptonidea, 47, 51.
- Leptosphaeria inquinans, 22-23.
- Leucolejeunea elypeata, 23.
- Lophocolea macounii, 23.
 minor, 23.
- Lycopodium inundatum, 30.
- Massariovalsa sudans, 23.
- Meadow entoloma, 56.
- Melanconis modonia, 23.
- Microsphaera alni, 30.
- Mnium orthorrhynchum, 23.
- Monilia angustior, 23-24.
 peckiana var. angustior, 23-24.
- Myxosporium castaneum, 24.
- Naked tricholoma, 38.
- Nardia crenuliformis, 24.
- Nectria sambuci, 24.
- Neottiella polytrichi, 24.
- Nolanidea, 47, 54.
- Panaeolus semilanceatus, 37.
- Panax quinquefolia, 30-31.
- Panus fulvidus, 44.
- Paxillus rhodoxanthus, 40.
 tammii, 40.
- Peck, C. H., list of species and varieties of fungi described by, 59-190.
- Peck entoloma, 50.
- Pellia endiviaefolia, 24.
- Pepper grass, 19.
- Pholiota, early, 40.
 hard, 39.
 hardish, 39-40.
 Pholiota dura, 39.
 duroides, 39-40.
 explanation of plate, 198.
- praecox, 40.
- Phoma corni, 24.
 lagenariae, 21, 25.
- Phycomyces nitens, 31.
- Phylloporus, yellow red, 40-41.
- Phylloporus rhodoxanthus, 40-41.
 explanation of plate, 198.
- Phyllosticta labruscae, 31.
 orbicula, 25.
- Plants, species added to collection, 5, 9-10; species not before reported, 5-6; means of sending for identification, 6-7; contributors, list of, 10-17; species not before reported, 18-28.
- Plates, explanation of, 191-98.
- Pleurotus applicatus, 25.
 atrocaeruleus griseus, 25.
 atropellitus, 25.
 griseus, 25.
- Polyporus arcularius, 25.
 caesius, 25.
 delectans, 25.
 trabeus, 25.
- Psathyrella graciloides, 31.
- Psilocybe semilanceata, 37.
- Puccinia agrostidis, 26.
 allicheridia, 26.
 campanulac, 26.
 cyani, 26.
 phlei-pratensis, 26.
 suaveolens, 26.
- Pucciniastrum potentillae, 26.
- Ramularia rudbeckiae, 19.
- Red stemmed lentinus, 46.
- Rhinotrichum curtisii, 26.
 ramosissimum, 26.
- Rosy entoloma, 56-57.
- Salmon entoloma, 49.
- Scabrous entoloma, 53.
- Scaly lentinus, 42-43.
- Shell lentinus, 45.
- Shield entoloma, 57.
- Silky entoloma, 52, 56.
- Sinuate entoloma, 48.
- Solanum rostratum, 26.
- Sordid tricholoma, 38-39.
- Sorosporium saponariae, 27.
- Sphenolobus hellerianus, 27.
- Sporodesmium mucosum, 27.
 var. pluriseptatum, 27.
 pluriseptatum, 21, 27.

Spotted lentinus, 43-44.
Spurred lentinus, 43.
Strict entoloma, 57-58.
Strong scented entoloma, 55.
Stunted entoloma, 53-54.
Sulcate lentinus, 44.
Sweet scented lentinus, 46-47.

Tricholoma.
humile, 27.
nudum, 38, 58.
personatum, 58.
schumacheri, 27.
sordidum, 38-39, 58.
 explanation of plate, 196.
subcinereum, 27-28.
subpulverulentum, 27.
Trichothecium candidum, 28.

Umbilicate lentinus, 45.
Urnula craterium, 32.
geaster, 31-32.
Uromyces caricinus, 28.
hyperici, 31.
scirpi, 28.
Variable entoloma, 50-51.
Verpa digitaliformis, 32.
Violaçeous entoloma, 52.
Volutella cucurbitina, 21, 28.
Xyris caroliniana, 30.
Yellow entoloma, 50.
Yellow gilled entoloma, 54-55.
Yellow red phylloporus, 40-41.
Yellowish green entoloma, 53.
